Notes

Before using this information and the product it supports, be sure to read the general information under “Notices” at the end of this information.

Subsequent editions of this PDF will not be delivered in IBM Publications Center. Always download the latest edition from Db2 12 for z/OS Product Documentation.

June 3, 2019 edition

This edition applies to Db2 12 for z/OS (product number 5650-DB2), Db2 12 for z/OS Value Unit Edition (product number 5770-AF3), and to any subsequent releases until otherwise indicated in new editions. Make sure you are using the correct edition for the level of the product.

Specific changes are indicated by a vertical bar to the left of a change. A vertical bar to the left of a figure caption indicates that the figure has changed. Editorial changes that have no technical significance are not noted.

About this information

This book is a reference for Structured Query Language (SQL) for Db2® for z/OS®. Unless otherwise stated, references to SQL in this book imply SQL for Db2 for z/OS, and all objects described in this book are objects of Db2 for z/OS.

The syntax and semantics of most SQL statements are essentially the same in all IBM® relational database products, and the language elements common to the products provide a base for the definition of IBM SQL. Consult IBM DB2 Universal Database™ SQL Reference for Cross-Platform Development if you intend to develop applications that adhere to IBM SQL.

Throughout this information, “Db2” means “Db2 12 for z/OS”. References to other Db2 products use complete names or specific abbreviations.

Important: To find the most up to date content, always use IBM Knowledge Center which is continually updated as soon as changes are ready. PDF manuals are updated only when new editions are published, on an infrequent basis.

How Db2 function levels are documented:

Generally, this information assumes that the highest available function level is activated, and that your applications run with the equivalent application compatibility value. However, changes for function levels are marked in the documentation. For more information, see How Db2 function levels are documented (Db2 for z/OS What’s New?).

Overview of Db2 12 new function availability

The availability of new function depends on the type of enhancement, the activated function level, and the application compatibility levels of applications. In the initial Db2 12 release, most new capabilities are enabled only after the activation of function level 500 or higher.

Virtual storage enhancements

Virtual storage enhancements become available at the activation of the function level that introduces them or higher. Activation of function level 100 introduces all virtual storage enhancements in the initial Db2 12 release. That is, activation of function level 500 introduces no virtual storage enhancements.

Subsystem parameters

New subsystem parameter settings are in effect only when the function level that introduced them or a higher function level is activated. Most subsystem parameter changes in the initial Db2 12 release take effect in function level 500. For a list of these changes, see Subsystem parameter changes in Db2 12 (Db2 for z/OS What’s New?).

Optimization enhancements

Optimization enhancements become available after the activation of the function level that introduces them or higher, and full prepare of the SQL statements. When a full prepare occurs depends on the statement type:

- For static SQL statements, after bind or rebind of the package
• For non-stabilized dynamic SQL statements, immediately, unless the statement is in the dynamic statement cache
• For stabilized dynamic SQL statements, after invalidation, free, or changed application compatibility level

Activation of function level 100 introduces all optimization enhancements in the initial Db2 12 release. That is, function level 500 introduces no optimization enhancements.

**SQL capabilities**
New SQL capabilities become available after the activation of the function level that introduces them or higher, for applications that run at the equivalent application compatibility level or higher. New SQL capabilities in the initial Db2 12 release become available in function level 500 for applications that run at the equivalent application compatibility level or higher. You can continue to run SQL statements compatibly with lower function levels, or previous Db2 releases, including Db2 11 and Db2® 10. For details, see Application compatibility levels in Db2 (Db2 Application programming and SQL).

**Who should read this information**

This information is intended for end users, application programmers, system and database administrators, and for persons involved in error detection and diagnosis.

This information is a reference rather than a tutorial. It assumes that you are already familiar with SQL programming concepts.

When you first use this information, consider reading Chapters 1 and 2 sequentially. These chapters describe the basic concepts of relational databases and SQL, the basic syntax of SQL, and the language elements that are common to many SQL statements. The rest of the chapters and appendixes are designed for the quick location of answers to specific SQL questions. They provide you with query forms, SQL statements, SQL procedure statements, Db2 limits, SQLCA, SQLDA, catalog tables, and SQL reserved words.

**Db2 Utilities Suite for z/OS**

**Important**: In this Db2 12, Db2 Utilities Suite for z/OS is available as an optional product. You must separately order and purchase a license to such utilities, and discussion of those utility functions in this publication is not intended to otherwise imply that you have a license to them.

Db2 12 utilities can use the DFSORT program regardless of whether you purchased a license for DFSORT on your system. For more information, see the following informational APARs:

• II14047
• II14213
• II13495

Db2 utilities can use IBM Db2 Sort for z/OS (5655-W42) as an alternative to DFSORT for utility SORT and MERGE functions. Use of Db2 Sort for z/OS requires the purchase of a Db2 Sort for z/OS license. For more information about Db2 Sort for z/OS, see [Db2 Sort for z/OS](#)

Terminology and citations

When referring to a Db2 product other than Db2 for z/OS, this information uses the product's full name to avoid ambiguity.

About the Db2 brand change: IBM is rebranding DB2 to Db2. As such, there will be changes to all the Db2 offerings. For example, “DB2 for z/OS” is now referred to as “Db2 for z/OS,” beginning with Db2 11. While IBM implements the change across the Db2 family of products, you might see references to the original name “DB2 for z/OS” or “Db2” in different IBM web pages and documents. “Db2 for z/OS” and “Db2 for z/OS” refer to the same product, when the PID, Entitlement Entity, version, modification, and release information match. For more information, see Revised naming for IBM Db2 family products.

The following terms are used as indicated:

Db2 Represents either the Db2 licensed program or a particular Db2 subsystem.

Tivoli® OMEGAMON® XE for Db2 Performance Expert on z/OS Refers to any of the following products:
- IBM Tivoli OMEGAMON XE for Db2 Performance Expert on z/OS
- IBM Db2 Performance Monitor on z/OS
- IBM Db2 Performance Expert for Multiplatforms and Workgroups
- IBM Db2 Buffer Pool Analyzer for z/OS

C, C++, and C language Represent the C or C++ programming language.

CICS® Represents CICS Transaction Server for z/OS.

IMS Represents the IMS Database Manager or IMS Transaction Manager.

MVS™ Represents the MVS element of the z/OS operating system, which is equivalent to the Base Control Program (BCP) component of the z/OS operating system.

RACF® Represents the functions that are provided by the RACF component of the z/OS Security Server.

Accessibility features for Db2 12 for z/OS

Accessibility features help a user who has a physical disability, such as restricted mobility or limited vision, to use information technology products successfully.

Accessibility features

The following list includes the major accessibility features in z/OS products, including Db2 12 for z/OS. These features support:

- Keyboard-only operation.
- Interfaces that are commonly used by screen readers and screen magnifiers.
- Customization of display attributes such as color, contrast, and font size.
Tip: The IBM Knowledge Center (which includes information for Db2 for z/OS) and its related publications are accessibility-enabled for the IBM Home Page Reader. You can operate all features using the keyboard instead of the mouse.

Keyboard navigation

For information about navigating the Db2 for z/OS ISPF panels using TSO/E or ISPF, refer to the z/OS TSO/E Primer, the z/OS TSO/E User’s Guide, and the z/OS ISPF User’s Guide. These guides describe how to navigate each interface, including the use of keyboard shortcuts or function keys (PF keys). Each guide includes the default settings for the PF keys and explains how to modify their functions.

Related accessibility information

IBM and accessibility

See the IBM Accessibility Center at http://www.ibm.com/able for more information about the commitment that IBM has to accessibility.

How to send your comments

Your feedback helps IBM to provide quality information. Please send any comments that you have about this book or other Db2 for z/OS documentation.

Send your comments by email to db2zinfo@us.ibm.com and include the name of the product, the version number of the product, and the number of the book. If you are commenting on specific text, please list the location of the text (for example, a chapter and section title or a help topic title).

How to read syntax diagrams

Certain conventions apply to the syntax diagrams that are used in IBM documentation.

Apply the following rules when reading the syntax diagrams that are used in Db2 for z/OS documentation:

• Read the syntax diagrams from left to right, from top to bottom, following the path of the line.
  The ►► symbol indicates the beginning of a statement.
  The —► symbol indicates that the statement syntax is continued on the next line.
  The —► symbol indicates that a statement is continued from the previous line.
  The —►◄ symbol indicates the end of a statement.
• Required items appear on the horizontal line (the main path).

►►required_item—►

• Optional items appear below the main path.

►►required_item[optional_item]—►

If an optional item appears above the main path, that item has no effect on the execution of the statement and is used only for readability.
• If you can choose from two or more items, they appear vertically, in a stack. If you must choose one of the items, one item of the stack appears on the main path.

• If choosing one of the items is optional, the entire stack appears below the main path.

• If one of the items is the default, it appears above the main path and the remaining choices are shown below.

• An arrow returning to the left, above the main line, indicates an item that can be repeated.

• Sometimes a diagram must be split into fragments. The syntax fragment is shown separately from the main syntax diagram, but the contents of the fragment should be read as if they are on the main path of the diagram.
• With the exception of XPath keywords, keywords appear in uppercase (for example, FROM). Keywords must be spelled exactly as shown. XPath keywords are defined as lowercase names, and must be spelled exactly as shown. Variables appear in all lowercase letters (for example, column-name). They represent user-supplied names or values.
• If punctuation marks, parentheses, arithmetic operators, or other such symbols are shown, you must enter them as part of the syntax.

Conventions for describing mixed data values

When mixed data values are shown in examples, certain conventions are used to represent these values.

At sites using a double-byte character set (DBCS), character strings can include a mixture of single-byte and double-byte characters. When mixed data values are shown in the examples, the conventions shown in the following example apply:

<table>
<thead>
<tr>
<th>Convention</th>
<th>Representation</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>\%</code></td>
<td>&quot;shift-out&quot; control character (X'0E&quot;), used only for EBCDIC data</td>
</tr>
<tr>
<td><code>\_</code></td>
<td>&quot;shift-in&quot; control character (X'0F&quot;), used only for EBCDIC data</td>
</tr>
<tr>
<td><code>sbcstring</code></td>
<td>SBCS string of zero or more single-byte characters</td>
</tr>
<tr>
<td><code>dbcstring</code></td>
<td>DBCS string of zero or more double-byte characters</td>
</tr>
<tr>
<td><code>\'</code></td>
<td>DBCS apostrophe</td>
</tr>
<tr>
<td><code>G</code></td>
<td>DBCS uppercase G</td>
</tr>
</tbody>
</table>

Figure 1. Conventions used when mixed data values are shown in examples

Industry standards for SQL

Db2 12 for z/OS is developed based on specific industry standards for SQL.

Db2 for z/OS conforms to the following IBM and industry standards for SQL:
• ISO/IEC FCD 9075-2:2016, Information technology - Database languages - SQL - Part 2: Foundation (SQL/Foundation)
• ISO/IEC FCD 9075-3:2016, Information technology - Database languages - SQL - Part 3: Call-Level Interface (SQL/CLI)
• ISO/IEC FCD 9075-4:2016, Information technology - Database languages - SQL - Part 4: Persistent Stored Modules (SQL/PSM)
• ISO/IEC FCD 9075-10:2016, Information technology - Database languages - SQL - Part 10: Object Language Bindings (SQL/OLB)
• ISO/IEC FCD 9075-11:2016, Information technology - Database languages - SQL - Part 11: Information and Definition Schemas (SQL/Schemata)
• ISO/IEC FCD 9075-14:2016, Information technology - Database languages - SQL - Part 14: XML-Related Specifications (SQL/XML)
Chapter 1. Db2 for z/OS and SQL concepts

Many structures and processes are associated with a relational database. The structures are the key components of a Db2 database system, and the processes are the interactions that occur when applications access the database system.

In a relational database, data is perceived to exist in one or more tables. Each table contains a specific number of columns and a number of unordered rows. Each column in a table is related in some way to the other columns. Thinking of the data as a collection of tables gives you an easy way to visualize the data that is stored in a Db2 database.

Tables are at the core of a Db2 database. However, a Db2 database involves more than just a collection of tables; a Db2 database also involves other objects, such as views and indexes, and larger data containers, such as table spaces.

With Db2 for z/OS and the other Db2 products, you can define and manipulate your data by using structured query language (SQL). SQL is the standard language for accessing data in relational databases.

Submitting SQL statements to Db2

You can use several different methods to send SQL statements to Db2 in several ways.

You can issue SQL statements from interactively from a keyboard at a terminal or through a terminal emulator.

Another way to issue SQL statements is through application programs. The programs can contain SQL statements that are statically embedded in the application. Alternatively, application programs can create their SQL statements dynamically, for example, in response to information that a user provides by filling in a form.

The method of preparing an SQL statement for execution and the persistence of its operational form distinguish static SQL from dynamic SQL.

Related concepts:

How SQL statements are invoked

Related tasks:

Overview of programming applications that access Db2 for z/OS data (Db2 Application programming and SQL)

Static SQL

The source form of a static SQL statement is embedded within an application program written in a host language such as COBOL. The statement is prepared before the program is executed and the operational form of the statement persists beyond the execution of the program.

Introductory concepts

Static SQL applications (Introduction to Db2 for z/OS)
Static SQL statements in a source program must be processed before the program is compiled. This processing can be accomplished through the Db2 precompiler or the Db2 coprocessor. The Db2 precompiler or the coprocessor checks the syntax of the SQL statements, turns them into host language comments, and generates host language statements to invoke Db2.

The preparation of an SQL application program includes precompilation, the preparation of its static SQL statements, and compilation of the modified source program.

**Related concepts:**
- How SQL statements are invoked

**Related tasks:**
- [Overview of programming applications that access Db2 for z/OS data (Db2 Application programming and SQL)](https://www.ibm.com/docs/en/db2/11.7?topic=sql-reference)

### Embedded dynamic SQL

Programs that contain *embedded dynamic* SQL statements must be precompiled like those that contain static SQL, but unlike static SQL, the dynamic statements are constructed and prepared at run time.

The source form of a dynamic statement is a character string that is passed to Db2 by the program using the static SQL PREPARE or EXECUTE IMMEDIATE statement. A statement that is prepared using the PREPARE statement can be referenced in a DECLARE CURSOR, DESCRIBE, or EXECUTE statement. Whether the operational form of the statement is persistent depends on whether dynamic statement caching is enabled.

SQL statements embedded in a REXX application are dynamic SQL statements. SQL statements submitted to an interactive SQL facility and to the CALL Level Interface (CLI) are also dynamic SQL.

**Related concepts:**
- Embedding a statement in an application program
- Dynamic preparation and execution

**Related tasks:**
- [Including dynamic SQL in your program (Db2 Application programming and SQL)](https://www.ibm.com/docs/en/db2/11.7?topic=sql-reference)

### Deferred embedded SQL

A *deferred embedded* SQL statement is neither fully static nor fully dynamic.

Like a static statement, it is embedded within an application, but like a dynamic statement, it is prepared during the execution of the application. Although prepared at run time, a deferred embedded SQL statement is processed with bind-time rules such that the authorization ID and qualifier determined at bind time for the plan or package owner are used.
Interactive SQL

Interactive SQL refers to SQL statements that you submit to Db2 by using SPUFI (SQL processor using file input), the command line processor, or by using a query tool, such as QMF™ for Workstation.

The easiest and most efficient way to run SQL is to use a query tool. QMF for Workstation is a popular query tool that lets you enter and run your SQL statements easily. This topic acquaints you with using QMF for Workstation to create and run SQL statements. QMF for Workstation simplifies access to Db2 from a workstation. In fact, was QMF for Workstation built for Db2.

Although this topic focuses on QMF for Workstation, other options are available. You can use QMF for WebSphere® to enter and run SQL statements from your web browser or useQMF for TSO/CICS to enter and run SQL statements from TSO or CICS. In addition, you can enter and run SQL statements at a TSO terminal by using the SPUFI (SQL processor using file input) facility. SPUFI prepares and executes these statements dynamically. All of these tools prepare and dynamically execute the SQL statements.

The Db2 Query Management Facility™ (QMF) family of technologies establish pervasive production and sharing of business intelligence for information-oriented tasks in the organization. QMF offers many strengths, including the following:

- Support for functionality in the Db2 database, including long names, Unicode, and SQL enhancements
- Drag-and-drop capability for building OLAP analytics, SQL queries, pivot tables, and other business analysis and reports
- Executive dashboards and data visual solutions that offer visually rich, interactive functionality and interfaces for data analysis
- Support for QMF for WebSphere, a tool that turns any web browser into a zero-maintenance, thin client for visual on demand access to enterprise Db2 data
- Re-engineered cross-platform development environment
- New security model for access control and personalization

The visual solutions previously provided by QMF Vision are now included in the core QMF technology.

In addition to QMF for Workstation, which this topic describes, the QMF family includes the following editions:

- QMF Enterprise Edition provides the entire QMF family of technologies, enabling enterprise-wide business information across user and database operating systems. This edition consists of:
  - QMF for TSO/CICS
  - QMF High Performance Option
  - QMF for Workstation
  - QMF for WebSphere
  - DataQuant for Workstation
  - DataQuant for WebSphere
- QMF Classic Edition supports users who work with traditional mainframe terminals and emulators (including WebSphere Host On Demand) to access Db2 databases. This edition consists of QMF for TSO/CICS.

Related concepts:

[Interactive invocation]
SQL Call Level Interface and Open Database Connectivity

The Db2 Call Level Interface (CLI) is an application programming interface in which functions are provided to application programs to process dynamic SQL statements.

Db2 CLI allows users to access SQL functions directly through a call interface. CLI programs can also be compiled using an Open Database Connectivity (ODBC) Software Developer’s Kit, available from Microsoft or other vendors, enabling access to ODBC data sources. Unlike using embedded SQL, no precompilation is required. Applications developed using this interface can be executed on a variety of databases without being compiled against each of databases. Through the interface, applications use procedure calls at execution time to connect to databases, to issue SQL statements, and to get returned data and status information.

Java database connectivity and embedded SQL for Java

Db2 provides two standards-based Java™ programming APIs: Java Database Connectivity (JDBC) and embedded SQL for Java (SQL/OLB or SQLJ). Both can be used to create Java applications and applets that access Db2.

Static SQL cannot be used by JDBC. SQLJ applications use JDBC as a foundation for such tasks as connecting to databases and handling SQL errors, but can contain embedded static SQL statements in the SQLJ source files. An SQLJ file has to be translated with the SQLJ translator before the resulting Java source code can be compiled.

Use of QMF for Workstation

QMF for Workstation is a tool that helps you build and manage powerful queries without requiring previous experience with SQL.

With the query-related features of Db2 Query Management Facility (QMF) and QMF for Workstation in particular, you can perform the following tasks:

• Build powerful queries without knowing SQL
• Analyze query results online, including OLAP analysis
• Edit query results to update Db2 data
• Format traditional text-based reports and reports with rich formatting
• Display charts and other complex visuals
• Send query results to an application of your choice
• Develop applications using robust API commands

How SQL statements are entered and processed

You can create your SQL statements using QMF for Workstation in several ways:
• Use the Database Explorer window to easily find and run saved queries that everyone at the same database server can share.
• If you know SQL, type the SQL statement directly in the window.
• If you don’t know SQL, use the prompted or diagram interface to build the SQL statement.

The Database Explorer presents the objects that are saved on a server in a tree structure. By expanding and collapsing branches, you can easily locate and use saved queries. You can open the selected query and see the SQL statements or run the query.

If you need to build a new query, you can enter the SQL statements directly in the query window, or you can create the SQL statements using diagrams or prompts. As you build a query by using diagrams or prompts, you can open a view to see the SQL that is being created.

How you can work with query results

When you finish building the query, you can click the Run Query button to execute the SQL statements. After you run the query, QMF for Workstation returns the query results in an interactive window.

The query results are formatted by the comprehensive formatting options of QMF for Workstation. A robust expression language lets you conditionally format query results by retrieved column values. You can add calculated columns to the query results and group data columns on both axes with or without summaries. You can also use extensive drag-and-drop capabilities to easily restructure the appearance of the query results.

In addition to formatting the query results, you can perform the following actions:
• Create traditional text-based reports or state-of-the-art reports with rich formatting.
• Display query results by using charts and other complex visuals.
• Share reports by storing them on the database server.
• Send query results to various applications such as Microsoft Excel or Lotus® 1-2-3.

Db2 database objects overview

In Db2 for z/OS, you use database objects, such as tables, table spaces, indexes, index spaces, keys, views, and databases to organize and access your data.
The brief descriptions here show how the structures fit into an overall view of Db2. The following figure shows how some Db2 structures contain others. To some extent, the notion of “containment” provides a hierarchy of structures.

![Diagram showing hierarchy of Db2 structures]

The Db2 structures from the most to the least inclusive are:

**Databases**
A set of Db2 structures that include a collection of tables, their associated indexes, and the table spaces in which they reside.

**Storage groups**
A set of volumes on disks that hold the data sets in which tables and indexes are stored.
Table spaces

A logical unit of storage in a database. A table space is a page set. The recommended partition-by-growth and partition-by-range table space types always contain data for only a single table. However, the segmented (non-UTS) and simple table space types, which are deprecated, can each contain one or more tables. For more information, see Table space types and characteristics in Db2 for z/OS (Db2 Administration Guide).

Deprecated function: FL504 Non-UTS table spaces for base tables are deprecated. For packages bound with APPLCOMPAT(V12R1M504) or higher, the result of a CREATE TABLESPACE statement is always a partition-by-growth or partition-by-range UTS table space, and a CREATE TABLE statement that specifies a non-UTS table space returns an error. Existing tables in non-UTS table spaces remain supported. However, support is likely to be removed in the future.

Tables

All data in a Db2 database is presented in tables, which are collections of rows all having the same columns. A table that holds persistent user data is a base table. A table that stores data temporarily is a temporary table.

Views

A view is an alternative way of representing data that exists in one or more tables. A view can include all or some of the columns from one or more base tables.

Indexes

An index is an ordered set of pointers to the data in a Db2 table. The index is stored separately from the table. An index is either a simple index or an extended index. An extended index is one of the following objects:

- An expression-based index
- A spatial index
- An XML index

- Storage structures (Introduction to Db2 for z/OS)

Db2 schemas and schema qualifiers

The objects in a relational database are organized into sets called schemas. A schema is a collection of named objects that provides a logical classification of objects in the database. The first part of a schema name is the qualifier.

A schema provides a logical classification of objects in the database. The objects that a schema can contain include tables, indexes, table spaces, distinct types, functions, stored procedures, and triggers. An object is assigned to a schema when it is created.

The schema name of the object determines the schema to which the object belongs. A user object, such as a distinct type, function, procedure, sequence, or trigger should not be created in a system schema, which is any one of a set of schemas that are reserved for use by the Db2 subsystem.

When a table, index, table space, distinct type, function, stored procedure, or trigger is created, it is given a qualified two-part name. The first part is the schema
name (or the qualifier), which is either implicitly or explicitly specified. The default
schema is the authorization ID of the owner of the plan or package. The second
part is the name of the object.

In previous versions, CREATE statements had certain restrictions when the value
of CURRENT SCHEMA was different from CURRENT SQLID value. Although
those restrictions no longer exist, you now must consider how to determine the
qualifier and owner when CURRENT SCHEMA and CURRENT SQLID contain
different values. The rules for how the owner is determined depend on the type of
object being created.

CURRENT SCHEMA and CURRENT SQLID affect only dynamic SQL statements.
Static CREATE statements are not affected by either CURRENT SCHEMA or
CURRENT SQLID.

The following table summarizes the effect of CURRENT SCHEMA in determining
the schema qualifier and owner for these objects:

- Alias
- Auxiliary table
- Created global temporary table
- Table
- View

Table 1. Schema qualifier and owner for objects

<table>
<thead>
<tr>
<th>Specification of name for new object being created</th>
<th>Schema qualifier of new object</th>
<th>Owner of new object</th>
</tr>
</thead>
<tbody>
<tr>
<td>name (no qualifier)</td>
<td>value of CURRENT SCHEMA</td>
<td>value of CURRENT SQLID</td>
</tr>
<tr>
<td>abc.name (single qualifier)</td>
<td>abc</td>
<td>abc</td>
</tr>
<tr>
<td>.....abc.name (multiple qualifiers)</td>
<td>abc</td>
<td>abc</td>
</tr>
</tbody>
</table>

The following table summarizes the effect of CURRENT SCHEMA in determining
the schema qualifier and owner for additional objects:

- User-defined distinct type
- User-defined function
- Procedure
- Sequence
- Trigger

Table 2. Schema qualifier and owner for additional objects

<table>
<thead>
<tr>
<th>Specification of name for new object being created</th>
<th>Schema qualifier of new object</th>
<th>Owner of new object</th>
</tr>
</thead>
<tbody>
<tr>
<td>name (no qualifier)</td>
<td>value of CURRENT SCHEMA</td>
<td>value of CURRENT SQLID</td>
</tr>
<tr>
<td>abc.name (single qualifier)</td>
<td>abc</td>
<td>value of CURRENT SQLID</td>
</tr>
<tr>
<td>.....abc.name (multiple qualifiers)</td>
<td>abc</td>
<td>value of CURRENT SQLID</td>
</tr>
</tbody>
</table>

Reserved schema names
Db2 tables

Tables are logical structures that Db2 maintains. Db2 supports several different types of tables.

Tables are made up of columns and rows. The rows of a relational table have no fixed order. The order of the columns, however, is always the order in which you specified them when you defined the table.

At the intersection of every column and row is a specific data item, which is called a value. A column is a set of values of the same type. A row is a sequence of values such that the nth value is a value of the nth column of the table. Every table must have one or more columns, but the number of rows can be zero.

Db2 accesses data by referring to its content instead of to its location or organization in storage.

Db2 supports several different types of tables:
- Accelerator-only tables
- Archive tables
- Archive-enabled tables
- Auxiliary tables
- Base tables
- Clone tables
- Empty tables
- History tables
- Materialized query tables
- Result tables
- Temporal tables
- Temporary tables
- XML tables

Db2 keys

A key is a column or an ordered collection of columns that is identified in the description of a table, an index, or a referential constraint. Keys are crucial to the table structure in a relational database.

Keys are important in a relational database because they ensure that each record in a table is uniquely identified, they help establish and enforce referential integrity, and they establish relationships between tables. The same column can be part of more than one key.

A composite key is an ordered set of two or more columns of the same table. The ordering of the columns is not constrained by their actual order within the table. The term value, when used with respect to a composite key, denotes a composite value. For example, consider this rule: “The value of the foreign key must be equal to the value of the primary key.” This rule means that each component of the value of the foreign key must be equal to the corresponding component of the value of the primary key.

Db2 supports several types of keys.
Unique keys

A unique constraint is a rule that the values of a key are valid only if they are unique. A key that is constrained to have unique values is a unique key. Db2 uses a unique index to enforce the constraint during the execution of the LOAD utility and whenever you use an INSERT, UPDATE, or MERGE statement to add or modify data. Every unique key is a key of a unique index. You can define a unique key by using the UNIQUE clause of either the CREATE TABLE or the ALTER TABLE statement. A table can have any number of unique keys.

The columns of a unique key cannot contain null values.

Primary keys

A primary key is a special type of unique key and cannot contain null values. For example, the DEPTNO column in the DEPT table is a primary key.

A table can have no more than one primary key. Primary keys are optional and can be defined in CREATE TABLE or ALTER TABLE statements.

The unique index on a primary key is called a primary index. When a primary key is defined in a CREATE TABLE statement or ALTER TABLE statement, Db2 automatically creates the primary index.

If a unique index already exists on the columns of the primary key when it is defined in the ALTER TABLE statement, this unique index is designated as the primary index when Db2 is operating in new-function mode and implicitly created the table space.

Parent keys

A parent key is either a primary key or a unique key in the parent table of a referential constraint. The values of a parent key determine the valid values of the foreign key in the constraint.

Foreign keys

A foreign key is a key that is specified in the definition of a referential constraint in a CREATE or ALTER TABLE statement. A foreign key refers to or is related to a specific parent key.

Unlike other types of keys, a foreign key does not require an index on its underlying column or columns. A table can have zero or more foreign keys. The value of a composite foreign key is null if any component of the value is null.

The following figure shows the relationship between some columns in the DEPT table and the EMP table.
Figure notes: Each table has a primary key:
- DEPTNO in the DEPT table
- EMPNO in the EMP table

Each table has a foreign key that establishes a relationship between the tables:
- The values of the foreign key on the DEPT column of the EMP table match values in the DEPTNO column of the DEPT table.
- The values of the foreign key on the MGRNO column of the DEPT table match values in the EMPNO column of the EMP table when an employee is a manager.

To see a specific relationship between rows, notice how the shaded rows for department C01 and employee number 000030 share common values.

Related concepts:
- Referential constraints (Introduction to Db2 for z/OS)

Constraints
Constraints are rules that control values in columns to prevent duplicate values or set restrictions on data added to a table.

Constraints fall into the following three types:
- Unique constraints
- Referential constraints
- Check constraints

Unique constraints
A unique constraint is a rule that the values of a key are valid only if they are unique in a table.

Unique constraints are optional and can be defined in the CREATE TABLE or ALTER TABLE statements with the PRIMARY KEY clause or the UNIQUE clause. The columns specified in a unique constraint must be defined as NOT NULL. A unique index enforces the uniqueness of the key during changes to the columns of the unique constraint.
A table can have an arbitrary number of unique constraints, with at most one unique constraint defined as a primary key. A table cannot have more than one unique constraint on the same set of columns.

A unique constraint that is referenced by the foreign key of a referential constraint is called the parent key.

**Referential constraints**

Db2 ensures referential integrity between your tables when you define referential constraints.

Referential integrity is the state in which all values of all foreign keys are valid. Referential integrity is based on entity integrity. Entity integrity requires that each entity have a unique key. For example, if every row in a table represents relationships for a unique entity, the table should have one column or a set of columns that provides a unique identifier for the rows of the table. This column (or set of columns) is called the parent key of the table. To ensure that the parent key does not contain duplicate values, a unique index must be defined on the column or columns that constitute the parent key. Defining the parent key is called entity integrity.

A referential constraint is the rule that the nonnull values of a foreign key are valid only if they also appear as values of a parent key. The table that contains the parent key is called the parent table of the referential constraint, and the table that contains the foreign key is a dependent of that table.

The relationship between some rows of the DEPT and EMP tables, shown in the following figure, illustrates referential integrity concepts and terminology. For example, referential integrity ensures that every foreign key value in the DEPT column of the EMP table matches a primary key value in the DEPTNO column of the DEPT table.

![Figure 4. Referential integrity of DEPT and EMP tables](image)

Two parent and dependent relationships exist between the DEPT and EMP tables.
- The foreign key on the DEPT column establishes a parent and dependent relationship. The DEPT column in the EMP table depends on the DEPTNO in
the DEPT table. Through this foreign key relationship, the DEPT table is the parent of the EMP table. You can assign an employee to no department (by specifying a null value), but you cannot assign an employee to a department that does not exist.

- The foreign key on the MGRNO column also establishes a parent and dependent relationship. Because MGRNO depends on EMPNO, EMP is the parent table of the relationship, and DEPT is the dependent table.

You can define a primary key on one or more columns. A primary key that includes two or more columns is called a composite key. A foreign key can also include one or more columns. When a foreign key contains multiple columns, the corresponding primary key must be a composite key. The number of foreign key columns must be the same as the number of columns in the parent key, and the data types of the corresponding columns must be compatible. (The sample project activity table, DSN8C10.PROJACT, is an example of a table with a primary key on multiple columns, PROJNO, ACTNO, and ACSTDATE.)

A table can be a dependent of itself; this is called a self-referencing table. For example, the DEPT table is self-referencing because the value of the administrative department (ADMREDEPT) must be a department ID (DEPTNO). To enforce the self-referencing constraint, Db2 requires that a foreign key be defined.

Similar terminology applies to the rows of a parent-and-child relationship. A row in a dependent table, called a dependent row, refers to a row in a parent table, called a parent row. But a row of a parent table is not always a parent row—perhaps nothing refers to it. Likewise, a row of a dependent table is not always a dependent row—the foreign key can allow null values, which refer to no other rows.

Referential constraints are optional. You define referential constraints by using CREATE TABLE and ALTER TABLE statements.

Db2 enforces referential constraints when the following actions occur:

- An INSERT statement is applied to a dependent table.
- An UPDATE statement is applied to a foreign key of a dependent table or to the parent key of a parent table.
- A MERGE statement that includes an insert operation is applied to a dependent table.
- A MERGE statement that includes an update operation is applied to a foreign key of a dependent table or to the parent key of a parent table.
- A DELETE statement is applied to a parent table. All affected referential constraints and all delete rules of all affected relationships must be satisfied in order for the delete operation to succeed.
- The LOAD utility with the ENFORCE CONSTRAINTS option is run on a dependent table.
- The CHECK DATA utility is run.

Another type of referential constraint is an informational referential constraint. This type of constraint is not enforced by Db2 during normal operations. An application process should verify the data in the referential integrity relationship. An informational referential constraint allows queries to take advantage of materialized query tables.
The order in which referential constraints are enforced is undefined. To ensure that the order does not affect the result of the operation, there are restrictions on the definition of delete rules and on the use of certain statements. The restrictions are specified in the descriptions of the SQL statements CREATE TABLE, ALTER TABLE, INSERT, UPDATE, MERGE, and DELETE.

The rules of referential integrity involve the following concepts and terminology:

**parent key**
A primary key or a unique key of a referential constraint.

**parent table**
A table that is a parent in at least one referential constraint. A table can be defined as a parent in an arbitrary number of referential constraints.

**dependent table**
A table that is a dependent in at least one referential constraint. A table can be defined as a dependent in an arbitrary number of referential constraints. A dependent table can also be a parent table.

**descendent table**
A table that is a dependent of another table or a table that is a dependent of a descendent table.

**referential cycle**
A set of referential constraints in which each associated table is a descendent of itself.

**parent row**
A row that has at least one dependent row.

**dependent row**
A row that has at least one parent row.

**descendent row**
A row that is dependent on another row or a row that is a dependent of a descendent row.

**self-referencing row**
A row that is a parent of itself.

**self-referencing table**
A table that is both parent and dependent in the same referential constraint. The constraint is called a self-referencing constraint.

A temporal referential constraint can be defined for a table that contains a BUSINESS_TIME period. The PERIOD BUSINESS_TIME clause is used in both the FOREIGN KEY clause and the REFERENCES clause to indicate that there must not be a row in the child table for which the period of time represented by the BUSINESS_TIME period value for that row is not contained in the BUSINESS_TIME period of one or more corresponding rows in the parent table. Unlike normal referential constraints, it is not necessary that there be exactly one corresponding row in the parent table where the BUSINESS_TIME period contains the BUSINESS_TIME period of the child row. As long as the BUSINESS_TIME period of a row in the child table is contained in the union of the BUSINESS_TIME periods of two or more contiguous matching rows in the parent table, the temporal referential constraint is satisfied.

Additionally, the following indexes must be defined:

- A unique index on the parent table with the BUSINESS_TIME WITHOUT OVERLAPS clause.
A non-unique index on the child table with the BUSINESS_TIME WITH OVERLAPS clause. Alternatively, the index on the child table, can be defined without the BUSINESS_TIME WITH OVERLAPS clause if the end of the index key includes the end column followed by the begin column of the BUSINESS_TIME period (both in ascending order).

The following rules provide referential integrity:

**insert rule**
A nonnull insert value of the foreign key must match some value of the parent key of the parent table. The value of a composite foreign key is null if any component of the value is null.

**update rule**
A nonnull update value of the foreign key must match some value of the parent key of the parent table. The value of a composite foreign key is treated as null if any component of the value is null.

**delete rule**
Controls what happens when a row of the parent table is deleted. The choices of action, made when the referential constraint is defined, are RESTRICT, NO ACTION, CASCADE, or SET NULL. SET NULL can be specified only if some column of the foreign key allows null values.

More precisely, the delete rule applies when a row of the parent table is the object of a delete or propagated delete operation and that row has dependents in the dependent table of the referential constraint. A propagated delete refers to the situation where dependent rows are deleted when parent rows are deleted. Let P denote the parent table, let D denote the dependent table, and let p denote a parent row that is the object of a delete or propagated delete operation. If the delete rule is:

- **RESTRICT** or NO ACTION, an error occurs and no rows are deleted.
- **CASCADE**, the delete operation is propagated to the dependent rows of p in D.
- **SET NULL**, each nullable column of the foreign key of each dependent row of p in D is set to null.

Each referential constraint in which a table is a parent has its own delete rule, and all applicable delete rules are used to determine the result of a delete operation. Thus, a row cannot be deleted if it has dependents in a referential constraint with a delete rule of RESTRICT or NO ACTION or the deletion cascades to any of its descendents that are dependents in a referential constraint with the delete rule of RESTRICT or NO ACTION.

The deletion of a row from parent table P involves other tables and can affect rows of these tables:

- If D is a dependent of P and the delete rule is RESTRICT or NO ACTION, D is involved in the operation but is not affected by the operation and the deletion from the parent table P does not take place.
- If D is a dependent of P and the delete rule is SET NULL, D is involved in the operation and rows of D might be updated during the operation.
- If D is a dependent of P and the delete rule is CASCADE, D is involved in the operation and rows of D might be deleted during the operation. If rows of D are deleted, the delete operation on P is said to be propagated to D. If D is also a parent table, the actions described in this list apply, in turn, to the dependents of D.
Any table that can be involved in a delete operation on \( P \) is said to be delete-connected to \( P \). Thus, a table is delete-connected to table \( P \) if it is a dependent of \( P \) or a dependent of a table to which delete operations from \( P \) cascade.

**Check constraints**

A check constraint is a rule that specifies the values that are allowed in one or more columns of every row of a base table.

Like referential constraints, check constraints are optional and you define them by using the CREATE TABLE and ALTER TABLE statements. The definition of a check constraint restricts the values that a specific column of a base table can contain.

A table can have any number of check constraints. Db2 enforces a check constraint by applying the restriction to each row that is inserted, loaded, or updated. One restriction is that a column name in a check constraint on a table must identify a column of that table.

**Example:** You can create a check constraint to ensure that all employees earn a salary of $30,000 or more:

```
CHECK (SALARY>= 30000)
```

**Related concepts:**

- Check constraints (Db2 Application programming and SQL)

**Db2 columns**

A column definition has two basic components, the column name and the data type.

A column contains values that have the same data type. If you are familiar with the concepts of records and fields, you can think of a value as a field in a record. A value is the smallest unit of data that you can manipulate with SQL. For example, in the EMP table, the EMPNO column identifies all employees by a unique employee number. The HIREDATE column contains the hire dates for all employees. You cannot overlap columns.

Online schema enhancements provide flexibility that lets you change a column definition. Carefully consider the decisions that you make about column definitions. After you implement the design of your tables, you can change a column definition with minimal disruption of applications.

Throughout the implementation phase of database design, refer to the complete descriptions of SQL statement syntax and usage for each SQL statement that you work with.

**Column names**

Following column naming guidelines that are developed for your organization ensures that you make good choices that are consistent.
Generally, the database administrator (DBA) is involved in determining the names of attributes (or columns) during the physical database design phase. To make the right choices for column names, DBAs follow the guidelines that the data administrators developed.

Sometimes columns need to be added to the database after the design is complete. In this case, Db2 rules for unique column names must be followed. Column names must be unique within a table, but you can use the same column name in different tables. Try to choose a meaningful name to describe the data in a column to make your naming scheme intuitive. The maximum length of a column name is 30 bytes.

**Related concepts:**
- Column names
- Data types

**Related tasks:**
- [Altering the data type of a column (Db2 Administration Guide)]

**Related reference:**
- [Employee table (DSN8C10.EMP) (Introduction to Db2 for z/OS)]

**Data types**

Every column in every Db2 table has a data type. The data type influences the range of values that the column can have and the set of operators and functions that apply to it.

You specify the data type of each column at the time that you create the table. You can also change the data type of a table column. The new data type definition is applied to all data in the associated table when the table is reorganized.

Some data types have parameters that further define the operators and functions that apply to the column. Db2 supports both IBM-supplied data types and user-defined data types. The data types that IBM supplies are sometimes called *built-in data types*.

In Db2 for z/OS, user-defined data types are called *distinct types*.

**How Db2 compares values of different data types**

Db2 compares values of different types and lengths. A comparison occurs when both values are numeric, both values are character strings, or both values are graphic strings. Comparisons can also occur between character and graphic data or between character and datetime data if the character data is a valid character representation of a datetime value. Different types of string or numeric comparisons might have an impact on performance.

**Related concepts:**

- [Data types of columns (Db2 Application programming and SQL)]
- Assignment and comparison
- Casting between data types
- Rules for result data types
- [Distinct types (Introduction to Db2 for z/OS)]
String data types:

Db2 supports several types of string data: character strings, graphic strings, and binary strings.

Character strings contain text and can be either a fixed-length or a varying-length. Graphic strings contain graphic data, which can also be either a fixed-length or a varying-length. Binary strings contain strings of binary bytes and can be either a fixed-length or a varying-length. All of these types of string data can be represented as large objects.

The following table describes the different string data types and indicates the range for the length of each string data type.

**Table 3. String data types**

<table>
<thead>
<tr>
<th>Data type</th>
<th>Denotes a column of...</th>
</tr>
</thead>
<tbody>
<tr>
<td>CHARACTER(n)</td>
<td>Fixed-length character strings with a length of n bytes. n must be greater than 0 and not greater than 255. The default length is 1.</td>
</tr>
<tr>
<td>VARCHAR(n)</td>
<td>Varying-length character strings with a maximum length of n bytes. n must be greater than 0 and less than a number that depends on the page size of the table space. The maximum length is 32704.</td>
</tr>
<tr>
<td>CLOB(n)</td>
<td>Varying-length character strings with a maximum of n characters. n cannot exceed 2,147,483,647. The default length is 1M.</td>
</tr>
<tr>
<td>GRAPHIC(n)</td>
<td>Fixed-length graphic strings that contain n double-byte characters. n must be greater than 0 and less than 128. The default length is 1.</td>
</tr>
<tr>
<td>VARGRAPHIC(n)</td>
<td>Varying-length graphic strings. The maximum length, n, must be greater than 0 and less than a number that depends on the page size of the table space. The maximum length is 16352.</td>
</tr>
<tr>
<td>DBCLOB(n)</td>
<td>Varying-length strings of double-byte characters with a maximum of n double-byte characters. n cannot exceed 1,073,741,824. The default length is 1M.</td>
</tr>
<tr>
<td>BINARY(n)</td>
<td>Fixed-length or varying-length binary strings with a length of n bytes. n must be greater than 0 and not greater than 255. The default length is 1.</td>
</tr>
<tr>
<td>VARBINARY(n)</td>
<td>Varying-length binary strings with a length of n bytes. The length of n must be greater than 0 and less than a number that depends on the page size of the table space. The maximum length is 32704.</td>
</tr>
<tr>
<td>BLOB(n)</td>
<td>Varying-length binary strings with a length of n bytes. n cannot exceed 2,147,483,647. The default length is 1M.</td>
</tr>
</tbody>
</table>

In most cases, the content of the data that a column is to store dictates the data type that you choose.

**Example:** The DEPT table has a column, DEPTNAME. The data type of the DEPTNAME column is VARCHAR(36). Because department names normally vary considerably in length, the choice of a varying-length data type seems appropriate. If you choose a data type of CHAR(36), for example, the result is a lot of wasted, unused space. In this case, Db2 assigns all department names, regardless of length, the same amount of space (36 bytes). A data type of CHAR(6) for the employee number (EMPNO) is a reasonable choice because all values are fixed-length values (6 bytes).

Fixed-length and variable-length character strings
Using VARCHAR saves disk space, but it incurs a 2-byte overhead cost for each value. Using VARCHAR also requires additional processing for varying-length rows. Therefore, using CHAR is preferable to VARCHAR, unless the space that you save by using VARCHAR is significant. The savings are not significant if the maximum column length is small or if the lengths of the values do not have a significant variation.

**Recommendation:** Generally, do not define a column as VARCHAR(n) or CLOB(n) unless n is at least 18 characters.

**String subtypes**

If an application that accesses your table uses a different encoding scheme than your DBMS uses, the following string subtypes can be important:

- **BIT**  Does not represent characters.
- **SBCS** Represents single-byte characters.
- **MIXED** Represents single-byte characters and multibyte characters.

String subtypes apply only to CHAR, VARCHAR, and CLOB data types. However, the BIT string subtype is not allowed for the CLOB data type.

**Graphic and mixed data**

When columns contain double-byte character set (DBCS) characters, you can define them as either graphic data or mixed data.

*Graphic data* can be either GRAPHIC, VARGRAPHIC, or DBCLOB. Using VARGRAPHIC saves disk space, but it incurs a 2-byte overhead cost for each value. Using VARGRAPHIC also requires additional processing for varying-length rows. Therefore, using GRAPHIC data is preferable to using VARGRAPHIC unless the space that you save by using VARGRAPHIC is significant. The savings are not significant if the maximum column length is small or if the lengths of the values do not vary significantly.

**Recommendation:** Generally, do not define a column as VARGRAPHIC(n) unless n is at least 18 double-byte characters (which is a length of 36 bytes).

*Mixed-data* character string columns can contain both single-byte character set (SBCS) and DBCS characters. You can specify the mixed-data character string columns as CHAR, VARCHAR, or CLOB with MIXED DATA.

**Recommendation:** If all of the characters are DBCS characters, use the graphic data types. (Kanji is an example of a language that requires DBCS characters.) For SBCS characters, use mixed data to save 1 byte for every single-byte character in the column.

**Encoding schemes for string data**

For string data, all characters are represented by a common encoding representation (Unicode, ASCII, or EBCDIC). Encoding schemes apply to string data types and to distinct types that are based on string types.

Multinational companies that engage in international trade often store data from more than one country in the same table. Some countries use different coded character set identifiers. Db2 for z/OS supports the Unicode encoding scheme,
which represents many different geographies and languages. If you need to perform character conversion on Unicode data, the conversion is more likely to preserve all of your information.

In some cases, you might need to convert characters to a different encoding representation. The process of conversion is known as character conversion. Most users do not need a knowledge of character conversion. When character conversion does occur, it does so automatically and a successful conversion is invisible to the application and users.

- Department table (DSN8C10.DEPT) (Introduction to Db2 for z/OS)

Numeric data types:

Db2 supports several types of numeric data types, each of which has its own characteristics.

For numeric data, use numeric columns rather than string columns. Numeric columns require less space than string columns, and Db2 verifies that the data has the assigned type.

Example: Assume that Db2 calculates a range between two numbers. If the values have a string data type, Db2 assumes that the values can include all combinations of alphanumeric characters. In contrast, if the values have a numeric data type, Db2 can calculate a range between the two values more efficiently.

The following table describes the numeric data types.

<table>
<thead>
<tr>
<th>Data type</th>
<th>Denotes a column of...</th>
</tr>
</thead>
<tbody>
<tr>
<td>SMALLINT</td>
<td>Small integers. A <em>small integer</em> is binary integer with a precision of 15 bits. The range is -32768 to +32767.</td>
</tr>
<tr>
<td>INTEGER or INT</td>
<td>Large integers. A <em>large integer</em> is binary integer with a precision of 31 bits. The range is -2147483648 to +2147483647.</td>
</tr>
<tr>
<td>BIGINT</td>
<td>Big integers. A <em>big integer</em> is a binary integer with a precision of 63 bits. The range of big integers is -9223372036854775808 to +9223372036854775807.</td>
</tr>
</tbody>
</table>
Table 4. Numeric data types (continued)

<table>
<thead>
<tr>
<th>Data type</th>
<th>Denotes a column of...</th>
</tr>
</thead>
<tbody>
<tr>
<td>DECIMAL or NUMERIC</td>
<td>A decimal number is a packed decimal number with an implicit decimal point. The position of the decimal point is determined by the precision and the scale of the number. The scale, which is the number of digits in the fractional part of the number, cannot be negative or greater than the precision. The maximum precision is 31 digits. All values of a decimal column have the same precision and scale. The range of a decimal variable or the numbers in a decimal column is (-n) to (+n), where (n) is the largest positive number that can be represented with the applicable precision and scale. The maximum range is (1 - 10^{31}) to (10^{31} - 1).</td>
</tr>
<tr>
<td>DECFLOAT</td>
<td>A decimal floating-point value is an IEEE 754r number with a decimal point. The position of the decimal point is stored in each decimal floating-point value. The maximum precision is 34 digits. The range of a decimal floating-point number is either 16 or 34 digits of precision; the exponent range is respectively (10^{-383}) to (10^{-6143}) or (10^{384}) to (10^{6144}).</td>
</tr>
<tr>
<td>REAL</td>
<td>A single-precision floating-point number is a short floating-point number of 32 bits. The range of single-precision floating-point numbers is approximately (-7.2E+75) to (7.2E+75). In this range, the largest negative value is about (-5.4E-79), and the smallest positive value is about (5.4E-079).</td>
</tr>
<tr>
<td>DOUBLE</td>
<td>A double-precision floating-point number is a long floating-point number of 64-bits. The range of double-precision floating-point numbers is approximately (-7.2E+75) to (7.2E+75). In this range, the largest negative value is about (-5.4E-79), and the smallest positive value is about (5.4E-79).</td>
</tr>
</tbody>
</table>

Note: IBM Z and z/Architecture® use the System/390® format and support IEEE floating-point format.

For integer values, use SMALLINT, INTEGER, or BIGINT (depending on the range of the values). Do not use DECIMAL for integer values.

You can define an exact numeric column as an identity column. An identity column has an attribute that enables Db2 to automatically generate a unique numeric value for each row that is inserted into the table. Identity columns are ideally suited to the task of generating unique primary-key values. Applications that use identity columns might be able to avoid concurrency and performance problems that sometimes occur when applications implement their own unique counters.

**Date, time, and timestamp data types:**

Although storing dates and times as numeric values is possible, using datetime data types is recommended. The datetime data types are DATE, TIME, and TIMESTAMP.

The following table describes the data types for dates, times, and timestamps.
Table 5. Date, time, and timestamp data types

<table>
<thead>
<tr>
<th>Data type</th>
<th>Denotes a column of...</th>
</tr>
</thead>
<tbody>
<tr>
<td>DATE</td>
<td>A date is a three-part value representing a year, month, and day in the range of 0001-01-01 to 9999-12-31.</td>
</tr>
<tr>
<td>TIME</td>
<td>A time is a three-part value representing a time of day in hours, minutes, and seconds, in the range of 00.00.00 to 24.00.00.</td>
</tr>
<tr>
<td>TIMESTAMP</td>
<td>A timestamp is a seven-part value representing a date and time by year, month, day, hour, minute, second, and microsecond, in the range of 0001-01-01-00.00.00.000000000 to 9999-12-31-24.00.00.000000000 with nanosecond precision. Timestamps can also hold timezone information.</td>
</tr>
</tbody>
</table>

Db2 stores values of datetime data types in a special internal format. When you load or retrieve data, Db2 can convert it to or from any of the formats in the following table.

Table 6. Date and time format options

<table>

</tr>
</tbody>
</table>

Example 1: The following query displays the dates on which all employees were hired, in IBM USA standard form, regardless of the local default:

```sql
SELECT EMPNO, CHAR(HIREDATE, USA) FROM EMP;
```

When you use datetime data types, you can take advantage of Db2 built-in functions that operate specifically on datetime values, and you can specify calculations for datetime values.

Example 2: Assume that a manufacturing company has an objective to ship all customer orders within five days. You define the SHIPDATE and ORDERDATE columns as DATE data types. The company can use datetime data types and the DAYS built-in function to compare the shipment date to the order date. Here is how the company might code the function to generate a list of orders that have exceeded the five-day shipment objective:

```sql
DAYS(SHIPDATE) - DAYS(ORDERDATE) > 5
```

As a result, programmers do not need to develop, test, and maintain application code to perform complex datetime arithmetic that needs to allow for the number of days in each month.

You can use the following sample user-defined functions (which come with Db2) to modify the way dates and times are displayed.
- **ALTDATE** returns the current date in a user-specified format or converts a user-specified date from one format to another.
- **ALTTIME** returns the current time in a user-specified format or converts a user-specified time from one format to another.

At installation time, you can also supply an exit routine to make conversions to and from any local standard.

When loading date or time values from an outside source, Db2 accepts any of the date and time format options that are listed in this information. Db2 converts valid input values to the internal format. For retrieval, a default format is specified at Db2 installation time. You can subsequently override that default by using a precompiler option for all statements in a program or by using the scalar function CHAR for a particular SQL statement and by specifying the format that you want.

**Related concepts:**

- [Datetime constants](#)

**XML data type:**

The XML data type is used to define columns of a table that store XML values. This pureXML® data type provides the ability to store well-formed XML documents in a database.

All XML data is stored in the database in an internal representation. Character data in this internal representation is in the UTF-8 encoding scheme.

XML values that are stored in an XML column have an internal representation that is not a string and not directly comparable to string values. An XML value can be transformed into a serialized string value that represents the XML document by using the XMLSERIALIZE function or by retrieving the value into an application variable of an XML, string, or binary type. Similarly, a string value that represents an XML document can be transformed to an XML value by using the XMLPARSE function or by storing a value from a string, binary, or XML application data type in an XML column.

The size of an XML value in a Db2 table has no architectural limit. However, serialized XML data that is stored in or retrieved from an XML column is limited to 2 GB.

Validation of an XML document against an XML schema, typically performed during INSERT or UPDATE into an XML column, is supported by the XML schema repository (XSR). If an XML column has an XML type modifier, documents that are inserted into the column or updated in the column are automatically validated against an XML schema.

**Large object data types:**

You can use large object data types to store audio, video, images, and other files that are larger than 32 KB.

The VARCHAR, VARGRAPHIC, and VARBINARY data types have a storage limit of 32 KB. However, applications often need to store large text documents or additional data types such as audio, video, drawings, images, and a combination of text and graphics. For data objects that are larger than 32 KB, you can use the corresponding large object (LOB) data types to store these objects.
Db2 provides three data types to store these data objects as strings of up to 2 GB in size:

**Character large objects (CLOBs)**

Use the CLOB data type to store SBCS or mixed data, such as documents that contain single character set. Use this data type if your data is larger (or might grow larger) than the VARCHAR data type permits.

**Double-byte character large objects (DBCLOBs)**

Use the DBCLOB data type to store large amounts of DBCS data, such as documents that use a DBCS character set.

**Binary large objects (BLOBs)**

Use the BLOB data type to store large amounts of noncharacter data, such as pictures, voice, and mixed media.

If your data does not fit entirely within a data page, you can define one or more columns as LOB columns. An advantage to using LOBs is that you can create user-defined functions that are allowed only on LOB data types.

**Related concepts:**

- [Creation of large objects (Introduction to Db2 for z/OS)](#)
- [Large objects (LOBs)](#)

**ROWID data type:**

You use the ROWID data type to uniquely identify rows in a Db2 subsystem.

Db2 can generate a value for the column when a row is added, depending on the option that you choose (GENERATED ALWAYS or GENERATED BY DEFAULT) when you define the column. You can use a ROWID column in a table for several reasons.

- You can define a ROWID column to include LOB data in a table.
- You can use direct-row access so that Db2 accesses a row directly through the ROWID column. If an application selects a row from a table that contains a ROWID column, the row ID value implicitly contains the location of the row. If you use that row ID value in the search condition of subsequent SELECT statements, Db2 might be able to navigate directly to the row.

**Requirement:** To use direct row access, you must use a retrieved ROWID value before you commit. When your application commits, it releases its claim on the table space. After the commit, if a REORG is run on your table space, the physical location of the rows might change.

- You can define a ROWID column with the IMPLICITLY HIDDEN attribute. Such columns are returned only for SQL statements that explicitly name the column. SQL statements that only imply selection of the column, such as statements that specify SELECT *, do not return the column.

Distinct types:

A distinct type is a user-defined data type that is based on existing built-in Db2 data types.

A distinct type is internally the same as a built-in data type, but Db2 treats them as a separate and incompatible type for semantic purposes.

Defining your own distinct type ensures that only functions that are explicitly defined on a distinct type can be applied to its instances.

Example 1: You might define a US_DOLLAR distinct type that is based on the Db2 DECIMAL data type to identify decimal values that represent United States dollars. The US_DOLLAR distinct type does not automatically acquire the functions and operators of its source type, DECIMAL.

Although you can have different distinct types that are based on the same built-in data types, distinct types have the property of strong typing. With this property, you cannot directly compare instances of a distinct type with anything other than another instance of that same type. Strong typing prevents semantically incorrect operations (such as explicit addition of two different currencies) without first undergoing a conversion process. You define which types of operations can occur for instances of a distinct type.

If your company wants to track sales in many countries, you must convert the currency for each country in which you have sales.

Example 2: You can define a distinct type for each country. For example, to create US_DOLLAR types and CANADIAN_DOLLAR types, you can use the following CREATE DISTINCT TYPE statements:

```
CREATE DISTINCT TYPE US_DOLLAR AS DECIMAL (9,2);
CREATE DISTINCT TYPE CANADIAN_DOLLAR AS DECIMAL (9,2);
```

Example 3: After you define distinct types, you can use them in your CREATE TABLE statements:

```
CREATE TABLE US_SALES
  (PRODUCT_ITEM_NO INTEGER,
   MONTH INTEGER,
   YEAR INTEGER,
   TOTAL_AMOUNT US_DOLLAR);
CREATE TABLE CANADIAN_SALES
  (PRODUCT_ITEM_NO INTEGER,
   MONTH INTEGER,
   YEAR INTEGER,
   TOTAL_AMOUNT CANADIAN_DOLLAR);
```

User-defined functions support the manipulation of distinct types.

Related concepts:
Null values

Some columns cannot have a meaningful value in every row. Db2 uses a special value indicator, the null value, to stand for an unknown or missing value. A null value is a special value that Db2 interprets to mean that no data is present.

If you do not specify otherwise, Db2 allows any column to contain null values. Users can create rows in the table without providing a value for the column.

Using the NOT NULL clause enables you to disallow null values in the column. Primary keys must be defined as NOT NULL.

Example: The table definition for the DEPT table specifies when you can use a null value. Notice that you can use nulls for the MGRNO column only:

```
CREATE TABLE DEPT
    (DEPTNO CHAR(3) NOT NULL,
     DEPTNAME VARCHAR(36) NOT NULL,
     MGRNO CHAR(6),
     ADMRDEPT CHAR(3) NOT NULL,
     PRIMARY KEY (DEPTNO))
IN MYDB.MYTS;
```

Before you decide whether to allow nulls for unknown values in a particular column, you must be aware of how nulls affect results of a query:

- Nulls in application programs
  Nulls do not satisfy any condition in an SQL statement other than the special IS NULL predicate. Db2 sorts null values differently than non-null values. Null values do not behave like other values. For example, if you ask Db2 whether a null value is larger than a given known value, the answer is UNKNOWN. If you then ask Db2 whether a null value is smaller than the same known value, the answer is still UNKNOWN.
  If getting a value of UNKNOWN is unacceptable for a particular column, you could define a default value instead. Programmers are familiar with the way default values behave.

- Nulls in a join operation
  Nulls need special handling in join operations. If you perform a join operation on a column that can contain null values, consider using an outer join.

Related concepts:
- Comparison of null values and default values (Introduction to Db2 for z/OS)
- Nulls

Related information:

Default values
Db2 defines some default values, and you define others (by using the DEFAULT clause in the CREATE TABLE or ALTER TABLE statement).
If a column is defined as NOT NULL WITH DEFAULT or if you do not specify
NOT NULL, Db2 stores a default value for a column whenever an insert or load
does not provide a value for that column. If a column is defined as NOT NULL,
Db2 does not supply a default value.

Db2–defined default values

Db2 generates a default value for ROWID columns. Db2 also determines default
values for columns that users define with NOT NULL WITH DEFAULT, but for
which no specific value is specified, as shown in the following table.

Table 7. Db2-defined default values for data types

<table>
<thead>

<td>ROWID</td>
<td>Db2-generated</td>
</tr>
</tbody>
</table>

User-defined default values

You can specify a particular default value, such as:
DEFAULT 'N/A'

When you choose a default value, you must be able to assign it to the data type of
the column. For example, all string constants are VARCHAR. You can use a
VARCHAR string constant as the default for a CHAR column even though the
type isn't an exact match. However, you could not specify a default value of 'N/A'
for a column with a numeric data type.

In the next example, the columns are defined as CHAR (fixed length). The special
registers (USER and CURRENT SQLID) that are referenced contain varying length
values.

Example: If you want a record of each user who inserts any row of a table, define
the table with two additional columns:

```
PRIMARY_ID CHAR(8) WITH DEFAULT USER,
SQL_ID CHAR(8) WITH DEFAULT CURRENT SQLID,
```

You can then create a view that omits those columns and allows users to update
the view instead of the base table. Db2 then adds, by default, the primary
authorization ID and the SQLID of the process.
When you add columns to an existing table, you must define them as nullable or as not null with default. Assume that you add a column to an existing table and specify not null with default. If Db2 reads from the table before you add data to the column, the column values that you retrieve are the default values. With few exceptions, the default values for retrieval are the same as the default values for insert.

**Default values for ROWID**

Db2 always generates the default values for ROWID columns.

Related concepts:
- [Comparison of null values and default values (Introduction to Db2 for z/OS)](#)
- [Authorization and security mechanisms for data access (Introduction to Db2 for z/OS)](#)

Related reference:
- `ALTER TABLE`
- `CREATE TABLE`

**Comparison of null values and default values**

Using a null value is easier and better than using a default value in some situations.

Suppose that you want to find out the average salary for all employees in a department. The salary column does not always need to contain a meaningful value, so you can choose between the following options:

- Allowing null values for the `SALARY` column
- Using a non-null default value (such as, 0)

By allowing null values, you can formulate the query easily, and Db2 provides the average of all known or recorded salaries. The calculation does not include the rows that contain null values. In the second case, you probably get a misleading answer unless you know the nonnull default value for unknown salaries and formulate your query accordingly.

The following figure shows two scenarios. The table in the figure excludes salary data for employee number 200440, because the company just hired this employee and has not yet determined the salary. The calculation of the average salary for department E21 varies, depending on whether you use null values or nonnull default values.

- The left side of the figure assumes that you use null values. In this case, the calculation of average salary for department E21 includes only the three employees (000320, 000330, and 200340) for whom salary data is available.
- The right side of the figure assumes that you use a nonnull default value of zero (0). In this case, the calculation of average salary for department E21 includes all four employees, although valid salary information is available for only three employees.

As you can see, only the use of a null value results in an accurate average salary for department E21.
Null values are distinct in most situations so that two null values are not equal to each other.

Example: The following example shows how to compare two columns to see if they are equal or if both columns are null:

```
WHERE E1.DEPT IS NOT DISTINCT FROM E2.DEPT
```

Related concepts:

- [Null values (Introduction to Db2 for z/OS)]
- [Default values (Introduction to Db2 for z/OS)]
- [Assignment and comparison]

**Use of check constraints to enforce validity of column values**

You can use check constraints to ensure that only values from the domain for the column or attribute are allowed.

As a result of using check constraints, programmers do not need to develop, test, and maintain application code that performs these checks.

You can choose to define check constraints by using the SQL CREATE TABLE statement or ALTER TABLE statement. For example, you might want to ensure that each value in the SALARY column of the EMP table contains more than a certain minimum amount.

Db2 enforces a check constraint by applying the relevant search condition to each row that is inserted, updated, or loaded. An error occurs if the result of the search condition is false for any row.
Use of check constraints to insert rows into tables:

When you use the INSERT statement or the MERGE statement to add a row to a table, Db2 automatically enforces all check constraints for that table. If the data violates any check constraint that is defined on that table, Db2 does not insert the row.

Example 1: Assume that the NEWEMP table has the following two check constraints:
- Employees cannot receive a commission that is greater than their salary.
- Department numbers must be between '001' to '100,' inclusive.

Consider this INSERT statement, which adds an employee who has a salary of $65,000 and a commission of $600:

```
INSERT INTO NEWEMP
  (EMPNO, FIRSTNAME, LASTNAME, DEPT, JOB, SALARY, COMM)
VALUES ('100125', 'MARY', 'SMITH', '055', 'SLS', 65000.00, 6000.00);
```

The INSERT statement in this example succeeds because it satisfies both constraints.

Example 2: Consider this INSERT statement:

```
INSERT INTO NEWEMP
  (EMPNO, FIRSTNAME, LASTNAME, DEPT, JOB, SALARY, COMM)
VALUES ('120026', 'JOHN', 'SMITH', '055', 'DES', 5000.00, 55000.00);
```

The INSERT statement in this example fails because the $55,000 commission is higher than the $5,000 salary. This INSERT statement violates a check constraint on NEWEMP.

Use of check constraints to update tables:

Db2 automatically enforces all check constraints for a table when you use the UPDATE statement or the MERGE statement to change a row in the table. If the intended update violates any check constraint that is defined on that table, Db2 does not update the row.

Example: Assume that the NEWEMP table has the following two check constraints:
- Employees cannot receive a commission that is greater than their salary.
- Department numbers must be between '001' to '100,' inclusive.

Consider this UPDATE statement:

```
UPDATE NEWEMP
SET DEPT = '011'
WHERE FIRSTNAME = 'MARY' AND LASTNAME= 'SMITH';
```
This update succeeds because it satisfies the constraints that are defined on the NEWEMP table.

**Example:** Consider this UPDATE statement:

```sql
UPDATE NEWEMP
SET DEPT = '166'
WHERE FIRSTNAME = 'MARY' AND LASTNAME= 'SMITH';
```

This update fails because the value of DEPT is '166,' which violates the check constraint on NEWEMP that DEPT values must be between '001' and '100.'

### Db2 indexes

An index is an ordered set of pointers to rows of a table. Db2 can use indexes to improve performance and ensure uniqueness. Understanding the structure of Db2 indexes can help you achieve the best performance for your system.

Conceptually, you can think of an index to the rows of a Db2 table like you think of an index to the pages of a book. Each index is based on the values of data in one or more columns of a table.

The main purpose of an index is to improve performance for access to the data. In most cases, access to data is faster with an index than with a scan of the data. For example, you can create an index on the DEPTNO column of the sample DEPT table so that Db2 can easily locate a specific department and avoid reading through each row of, or scanning, the table.

An index is stored separately from the data in the table. Each index is physically stored in its own index space. When you define an index by using the CREATE INDEX statement, Db2 builds this structure and maintains it automatically. However, you can perform necessary maintenance such as reorganizing it or recovering the index.

Another purpose of an index is to ensure uniqueness. For example, a unique index on the employee table ensures that no two employees have the same employee number.

In most cases, the users of an index are unaware that it is being used because Db2 decides whether to use the index to access the table.

Db2 supports simple indexes and extended indexes. An extended index is one of the following objects:

- An expression-based index
- A spatial index
- An XML index

Be aware that indexes have both benefits and disadvantages. A greater number of indexes can simultaneously improve the access performance of a particular transaction and require additional processing for inserting, updating, and deleting index keys.
A view is an alternative way of representing data that exists in one or more tables. A view can include all or some of the columns from one or more base tables.

**Introductory concepts**

- Creation of views (Introduction to Db2 for z/OS)
- Views on the sample tables (Introduction to Db2 for z/OS)

A view is a named specification of a result table. Conceptually, creating a view is somewhat like using binoculars. You might look through binoculars to see an entire landscape or to look at a specific image within the landscape, such as a tree.

You can create a view that:
- Combines data from different base tables
- Is based on other views or on a combination of views and tables
- Omits certain data, thereby shielding some table data from users

In fact, these are common underlying reasons to use a view. Combining information from base tables and views simplifies retrieving data for a user, and limiting the data that a user can see is useful for security. You can use views for a number of different purposes. A view can:
- Control access to a table
- Make data easier to use
- Simplify authorization by granting access to a view without granting access to the table
- Show only portions of data in the table
- Show summary data for a given table
- Combine two or more tables in meaningful ways
- Show only the selected rows that are pertinent to the process that uses the view

To define a view, you use the CREATE VIEW statement and assign a name (up to 128 characters in length) to the view. Specifying the view in other SQL statements is effectively like running an SQL SELECT statement. At any time, the view consists of the rows that would result from the SELECT statement that it contains. You can think of a view as having columns and rows just like the base table on which the view is defined.

You also can specify a period specification for a view, subject to certain restrictions.

**Examples**

**Example 1**

Example 1: The following figure shows a view of the EMP table that omits sensitive employee information and renames some of the columns.
The EMPINFO view represents a table that includes columns named EMPLOYEE, FIRSTNAME, LASTNAME, TEAM, and JOBTITLE. The data in the view comes from the columns EMPNO, FIRSTNME, LASTNAME, DEPT, and JOB of the EMP table.

Example 2
The following CREATE VIEW statement defines the EMPINFO view that is shown in the preceding figure:

```sql
CREATE VIEW EMPINFO (EMPLOYEE, FIRSTNAME, LASTNAME, TEAM, JOBTITLE)
AS SELECT EMPNO, FIRSTNME, LASTNAME, DEPT, JOB
FROM EMP;
```

When you define a view, Db2 stores the definition of the view in the Db2 catalog. However, Db2 does not store any data for the view itself, because the data exists in the base table or tables.

Example 3
You can narrow the scope of the EMPINFO view by limiting the content to a subset of rows and columns that includes departments A00 and C01 only:

```sql
CREATE VIEW EMPINFO (EMPLOYEE, FIRSTNAME, LASTNAME, TEAM, JOBTITLE)
AS SELECT EMPNO, FIRSTNME, LASTNAME, WORKDEPT, JOB
FROM EMP
WHERE WORKDEPT = 'A00' OR WORKDEPT = 'C01';
```

In general, a view inherits the attributes of the object from which it is derived. Columns that are added to the tables after the view is defined on those tables do not appear in the view.

Restriction: You cannot create an index for a view. In addition, you cannot create any form of a key or a constraint (referential or otherwise) on a view. Such indexes, keys, or constraints must be built on the tables that the view references.

To retrieve or access information from a view, you use views like you use base tables. You can use a SELECT statement to show the information from the view. The SELECT statement can name other views and tables, and it can use the WHERE, GROUP BY, and HAVING clauses. It cannot use the ORDER BY clause or name a host variable.

Whether a view can be used in an insert, update, or delete operation depends on its definition. For example, if a view includes a foreign key of its base table, INSERT and UPDATE operations that use the view are subject to the same
referential constraint as the base table. Likewise, if the base table of a view is a parent table, DELETE operations that use the view are subject to the same rules as DELETE operations on the base table. Read-only views cannot be used for insert, update, and delete operations.

Related information:
- implementing Db2 views (Db2 Administration Guide)
- Employee table (DSN8C10.EMP) (Introduction to Db2 for z/OS)

Aliases

An alias is a substitute for the three-part name of a table or view.

An alias can be defined at a local server and can refer to a table or view that is at the current server or a remote server. The alias name can be used wherever the table name or view name can be used to refer to the table or view in an SQL statement.

Suppose that data is occasionally moved from one Db2 subsystem to another. Ideally, users who query that data are not affected when this activity occurs. They always want to log on to the same system and access the same table or view, regardless of where the data resides. You can achieve this result by using an alias for an object name.

An alias can be a maximum of 128 characters, qualified by an owner ID. You use the CREATE ALIAS and DROP ALIAS statements to manage aliases.

**Note:** Assume that you create an alias as follows:
```
CREATE ALIAS TESTTAB FOR USIBMSTODB22.IDEMP01.EMP;
```

If a user with the ID JONES dynamically creates the alias, JONES owns the alias, and you query the table like this:
```
SELECT SUM(SALARY), SUM(BONUS), SUM(COMM)
  FROM JONES.TESTTAB;
```

The object for which you are defining an alias does not need to exist when you execute the CREATE ALIAS statement. However, the object must exist when a statement that refers to the alias executes.

When you want an application to access a server other than the server that is specified by a location name, you do not need to change the location name. Instead, you can use a location alias to override the location name that an application uses to access a server. As a result, a Db2 for z/OS requester can access multiple Db2 databases that have the same name but different network addresses. Location aliases allow easier migration to a Db2 server and minimize application changes.
After you create an alias, anyone who has authority over the object that the alias is referencing can use that alias. A user does not need a separate privilege to use the alias.

**Related reference:**

---

### Triggers

A *trigger* defines a set of actions that are executed when a delete, insert, or update operation occurs on a specified table or view. When such an operation is executed, the trigger is said to be *activated*.

Db2 supports two types of triggers, basic and advanced:

- **Basic triggers** support a limited set of SQL statements, and require the MODE DB2SQL clause on the CREATE TRIGGER statement. Any trigger created before the activation of function level 500 or higher is a basic trigger. For more information, see [CREATE TRIGGER (basic)](#).

- **Advanced triggers** support a larger set of SQL statements, including SQL PL. A CREATE TRIGGER statement for an advanced trigger must not specify the MODE DB2SQL clause. An application compatibility value of V12R1 is used for advanced triggers. For more information about advanced triggers, see [CREATE TRIGGER (advanced)](#).

You can use triggers along with referential constraints and check constraints to enforce data integrity rules. Triggers are more powerful than constraints because you can use them to do the following things:

- Update other tables
- Automatically generate or transform values for inserted or updated rows
- Invoke functions that perform operations both inside and outside of Db2

For example, assume that you need to prevent an update to a column when a new value exceeds a certain amount. Instead of preventing the update, you can use a trigger. The trigger can substitute a valid value and invoke a procedure that sends a notice to an administrator about the attempted invalid update.

You define triggers with the CREATE TRIGGER statement.

Triggers move the business rule application logic into the database, which results in faster application development and easier maintenance. The business rule is no longer repeated in several applications, and the rule is centralized to the trigger. For example, Db2 can check the validity of the changes that any application makes to a salary column, and you are not required to change application programs when the logic changes.

There are a number of criteria that are defined when creating a trigger, which are used to determine when a trigger should be activated.

- The *subject table* (also known as the triggering table) defines the table or view for which the trigger is defined.

- The *trigger event* defines a specific SQL operation that modifies the subject table. The operation could be a delete, insert, or update.

- The *trigger activation time* defines whether the trigger should be activated before or after the trigger event is performed on the subject table.
The statement that causes a trigger to be activated includes a set of affected rows. These are the rows of the subject table that are being deleted, inserted or updated. The trigger granularity defines whether the actions of the trigger are to be performed once for the statement, or once for each of the rows in the set of affected rows.

The trigger action consists of an optional search condition and a set of SQL statements that are executed whenever the trigger is activated. The SQL statements are only executed if no search condition is specified, or the specified search condition evaluates to true.

The triggered action can refer to the values in the set of affected rows. This is supported through the use of transition variables. Transition variables use the names of the columns in the subject table, qualified by a specified name that identifies whether the reference is to the old value (prior to the update) or the new value (after the update). The new value can also be changed using an assignment in a before update or insert trigger.

Another means of referring to the values in the set of affected rows is by using transition tables. Transition tables also use the names of the columns of the subject table, but have a name specified that allows the complete set of affected rows to be treated as a table. Transition tables can only be used in after triggers, and cannot be modified. Separate transition tables can be defined for old and new values.

Multiple triggers can be specified for a combination of table, event, or activation time. The order in which the triggers are activated is the same as the order in which they were created. Thus, the most recently created trigger is the last trigger that is activated.

The activation of a trigger might cause trigger cascading. This is the result of the activation of one trigger that executes SQL statements that cause the activation of other triggers, or even the same trigger again. The triggered actions might also cause updates as a result of the original modification, which might result in the activation of additional triggers. With trigger cascading, a significant chain of triggers might be activated, causing significant change to the database as a result of a single delete, insert or update statement.

The actions that are performed in the trigger are considered to be part of the operation that caused the trigger to be executed.

- The database manager ensures that the operation and the triggers that are executed as a result of that operation either all complete or are all backed out. Operations that occurred prior to the triggering operation are not affected.
- The database manager effectively checks all constraints (except for a constraint with a RESTRICT delete rule) after the operation and the associated triggers have been executed.

Basic and advanced triggers offer different functionality. See the corresponding syntax diagrams for the CREATE TRIGGER (basic) and CREATE TRIGGER (advanced) SQL statements for more information. The following table identifies some behavioral differences between the two types of triggers.
Table 8. Behavioral differences of basic and advanced triggers

<table>
<thead>
<tr>
<th>Behavior</th>
<th>Basic Trigger</th>
<th>Advanced Trigger</th>
</tr>
</thead>
<tbody>
<tr>
<td>CREATE or ALTER TRIGGER</td>
<td>CREATE or ALTER TRIGGER (basic) statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.</td>
<td>CREATE or ALTER TRIGGER (advanced) statement can be issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.</td>

<td>Changes to transition variables in a procedure are not visible on return to the invoking environment, and changes to transition variables (for an AFTER trigger) are not disallowed.</td>
<td>Changes to transition variables in a procedure are visible on return to the invoking environment, and changes to transition variables (for an AFTER trigger) are disallowed.</td>
</tr>
</tbody>
</table>

Creation of triggers (Introduction to Db2 for z/OS)

User-defined types

A user-defined data type is a data type that is defined to the database using a CREATE statement.

A user-defined data type is a distinct type or an array type.

A distinct type is a user-defined type that shares its internal representation with a built-in data type (its source type), but is considered to be a separate and incompatible data type for most operations. A distinct type is created with an SQL CREATE TYPE (distinct) statement. A distinct type can be used to define a column of a table, or a parameter of a routine.

An array type is a user-defined data type that consists of an ordered set of elements of a single built-in data type. Elements can be accessed and modified by their
index position. An array type is created with an SQL CREATE TYPE (array) statement. An array type can be used as a parameter of an SQL routine, as a variable in an SQL routine, and as a global variable.

Related concepts:
- Array types
- Distinct types

Related reference:
- CREATE TYPE

Routines

A routine is an executable SQL object. The two types of routines are functions and stored procedures.

Functions

A function is a routine that can be invoked from within other SQL statements and that returns a value or a table.

Functions are classified as either SQL functions or external functions. SQL functions are written using SQL statements, which are also known collectively as SQL procedural language. External functions reference a host language program. The host language program can contain SQL, but does not require SQL.

You define functions by using the CREATE FUNCTION statement. You can classify functions as built-in functions, user-defined functions, or cast functions that are generated for distinct types. Functions can also be classified as aggregate, scalar, or table functions, depending on the input data values and result values.

A table function can be used only in the FROM clause of a statement. Table functions return columns of a table and resemble a table that is created through a CREATE TABLE statement. Table functions can be qualified with a schema name.

Related tasks:
- Creating a user-defined function (Db2 Application programming and SQL)

Procedures

A procedure, also known as a stored procedure, is a routine that you can call to perform operations that can include SQL statements.

Procedures are classified as either SQL procedures or external procedures. SQL procedures contain only SQL statements. External procedures reference a host language program that might or might not contain SQL statements.

Db2 for z/OS supports the following types of procedures:

External stored procedures

External stored procedures are procedures that are written in a host language and can contain SQL statements. The source code for an external stored procedure is separate from the definition. You can write an external stored procedure in Assembler, C, C++, COBOL, Java, REXX, or PL/I. All programs must be designed to run using Language Environment®. Your COBOL and C++ stored procedures can contain object-oriented extensions.
External SQL procedures

External SQL procedures are procedures whose body is written in SQL. Db2 supports them by generating an associated C program for each procedure. All SQL procedures that were created prior to Version 9.1 are external SQL procedures. Starting in Version 9.1, you can create an external SQL procedure by specifying FENCED or EXTERNAL in the CREATE PROCEDURE statement.

Native SQL procedures

Native SQL procedures are procedures whose body is written in SQL. For native SQL procedures, Db2 does not generate an associated C program. Starting in Version 9.1, all SQL procedures that are created without the FENCED or EXTERNAL options in the CREATE PROCEDURE statement are native SQL procedures. You can create native SQL procedures in one step. Native SQL statements support more functions and usually provide better performance than external SQL statements.

SQL control statements are supported in SQL procedures. Control statements are SQL statements that allow SQL to be used in a manner similar to writing a program in a structured programming language. SQL control statements provide the capability to control the logic flow, declare and set variables, and handle warnings and exceptions. Some SQL control statements include other nested SQL statements.

SQL procedures provide the same benefits as procedures in a host language. That is, a common piece of code needs to be written and maintained only once and can be called from several programs.

SQL procedures provide additional benefits when they contain SQL statements. In this case, SQL procedures can reduce or eliminate network delays that are associated with communication between the client and server and between each SQL statement. SQL procedures can improve security by providing a user the ability to invoke only a procedure instead of providing them with the ability to execute the SQL that the procedure contains.

You define procedures by using the CREATE PROCEDURE statement.

Sequences

A sequence is a stored object that simply generates a sequence of numbers in a monotonically ascending (or descending) order. A sequence provides a way to have Db2 automatically generate unique integer primary keys and to coordinate keys across multiple rows and tables.
A sequence can be used to exploit parallelization, instead of programmatically generating unique numbers by locking the most recently used value and then incrementing it.

Sequences are ideally suited to the task of generating unique key values. One sequence can be used for many tables, or a separate sequence can be created for each table requiring generated keys. A sequence has the following properties:

- Guaranteed, unique values, assuming that the sequence is not reset and does not allow the values to cycle
- Monotonically increasing or decreasing values within a defined range
- Can increment with a value other than 1 between consecutive values (the default is 1).
- Recoverable. If Db2 should fail, the sequence is reconstructed from the logs so that Db2 guarantees that unique sequence values continue to be generated across a Db2 failure.

Values for a given sequence are automatically generated by Db2. Use of Db2 sequences avoids the performance bottleneck that results when an application implements sequences outside the database. The counter for the sequence is incremented (or decremented) independently of the transaction. In some cases, gaps can be introduced in a sequence. A gap can occur when a given transaction increments a sequence two times. The transaction might see a gap in the two numbers that are generated because there can be other transactions concurrently incrementing the same sequence. A user might not realize that other users are drawing from the same sequence. Furthermore, it is possible that a given sequence can appear to have generated gaps in the numbers, because a transaction that might have generated a sequence number might have rolled back or the Db2 subsystem might have failed. Updating a sequence is not part of a transaction’s unit of recovery.

A sequence is created with a CREATE SEQUENCE statement. A sequence can be referenced using a sequence-reference. A sequence reference can appear most places that an expression can appear. A sequence reference can specify whether the value to be returned is a newly generated value, or the previously generated value.

Although there are similarities, a sequence is different than an identity column. A sequence is an object, whereas an identity column is a part of a table. A sequence can be used with multiple tables, but an identity column is tied to a single table.

**Db2 system objects**

Unlike the Db2 data structures that users create and access, Db2 controls and accesses system objects.

Db2 has a comprehensive infrastructure that enables it to provide data integrity, performance, and the ability to recover user data. In addition, Parallel Sysplex® data sharing uses shared system objects.

Related concepts:

- Db2 database objects overview (Introduction to Db2 for z/OS)
Db2 catalog

Db2 maintains a set of tables that contain information about the data that Db2 controls. These tables are collectively known as the catalog.

The catalog tables contain information about Db2 objects such as tables, views, and indexes. When you create, alter, or drop an object, Db2 inserts, updates, or deletes rows of the catalog that describe the object.

The Db2 catalog consists of tables of data about everything defined to the Db2 system, including table spaces, indexes, tables, copies of table spaces and indexes, and storage groups. The system database DSNDB06 contains the Db2 catalog.

When you create, alter, or drop any structure, Db2 inserts, updates, or deletes rows of the catalog that describe the structure and tell how the structure relates to other structures. For example, SYSIBM.SYSTABLES is one catalog table that records information when a table is created. Db2 inserts a row into SYSIBM.SYSTABLES that includes the table name, its owner, its creator, and the name of its table space and its database.

To understand the role of the catalog, consider what happens when the EMP table is created. Db2 records the following data:

**Table information**
To record the table name and the name of its owner, its creator, its type, the name of its table space, and the name of its database, Db2 inserts a row into the catalog.

**Column information**
To record information about each column of the table, Db2 inserts the name of the table to which the column belongs, its length, its data type, and its sequence number by inserting a row into the catalog for each column of the table.

**Authorization information**
To record that the owner of the table has authorization to create the table, Db2 inserts a row into the catalog.

Tables in the catalog are like any other database tables with respect to retrieval. If you have authorization, you can use SQL statements to look at data in the catalog tables in the same way that you retrieve data from any other table in the Db2 database. Db2 ensures that the catalog contains accurate object descriptions. If you are authorized to access the specific tables or views on the catalog, you can use SELECT on the catalog. You can use INSERT, UPDATE, and DELETE statements on updatable catalog tables, but you cannot use TRUNCATE or MERGE on the catalog.

The communications database (CDB) is part of the Db2 catalog. The CDB consists of a set of tables that establish conversations with remote database management systems (DBMSs). The distributed data facility (DDF) uses the CDB to send and receive distributed data requests.

**Tip:** For best results, check the consistency of the Db2 catalog and directory regularly, even outside of the migration process. For detailed instructions, see [Verify the integrity of Db2 table spaces](#) and [Check for consistency between catalog tables](#).

Db2 catalog tables
Db2 directory

The Db2 directory contains information that Db2 uses during normal operation.

You can use SQL to retrieve data only from the directory tables that are listed in “Db2 directory tables” on page 2827. You can submit queries against the Db2 catalog for Db2 directory objects.

The directory consists of a set of Db2 tables that are stored in table spaces in system database DSNDB01. Each of the table spaces that are listed in the following table is contained in a VSAM linear data set.

Table 9. Directory table spaces

<table>
<thead>
<tr>
<th>Table space name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCT02</td>
<td>Contains the internal form of SQL statements that are contained in an application. If you bound a plan with SQL statements in a prior release, Db2 created a structure in SCT02.</td>
</tr>
<tr>
<td>SPT01 Skeleton package</td>
<td>Contains the internal form of SQL statements that are contained in a package.</td>
</tr>
<tr>
<td>SYSSPUXA</td>
<td>Contains the contents of a package selection.</td>
</tr>
<tr>
<td>SYSSPUXB</td>
<td>Contains the contents of a package explain block.</td>
</tr>
<tr>
<td>SYSLGRNX Log range</td>
<td>Tracks the opening and closing of table spaces, indexes, or partitions. By tracking this information and associating it with relative byte addresses (RBAs) as contained in the Db2 log, Db2 can reduce recovery time by reducing the amount of log that must be scanned for a particular table space, index, or partition.</td>
</tr>
<tr>
<td>SYSUTILX System utilities</td>
<td>Contains a row for every utility job that is running. The row persists until the utility is finished. If the utility terminates without completing, Db2 uses the information in the row when you restart the utility.</td>
</tr>
<tr>
<td>DBD01 Database descriptor (DBD)</td>
<td>Contains internal information, called database descriptors (DBDs), about the databases that exist within the Db2 subsystem. Each database has exactly one corresponding DBD that describes the database, table spaces, tables, table check constraints, indexes, and referential relationships. A DBD also contains other information about accessing tables in the database. Db2 creates and updates DBDs whenever their corresponding databases are created or updated.</td>
</tr>
<tr>
<td>SYSDBDXA</td>
<td>Contains the contents of a DBD section.</td>
</tr>
</tbody>
</table>

Tip: For best results, check the consistency of the Db2 catalog and directory regularly, even outside of the migration process. For detailed instructions, see Verify the integrity of Db2 table spaces and Check for consistency between catalog tables.

Active and archive logs

Db2 records all data changes and other significant events in a log.
If you keep these logs, Db2 can re-create those changes for you in the event of a failure or roll the changes back to a previous point in time.

Db2 writes each log record to a disk data set called the active log. When the active log is full, Db2 copies the contents of the active log to a disk or magnetic tape data set called the archive log.

You can choose either single logging or dual logging.

- A single active log contains up to 93 active log data sets.
- With dual logging, the active log has twice the capacity for active log data sets, because two identical copies of the log records are kept.

Each Db2 subsystem manages multiple active logs and archive logs. The following facts are true about each Db2 active log:

- Each log can be duplexed to ensure high availability.
- Each active log data set is a VSAM linear data set (LDS).
- Db2 supports striped active log data sets.

**Related tasks:**

- Managing the log and the bootstrap data set (Db2 Administration Guide)
- Improving Db2 log performance (Db2 Performance)

**Related information:**

- Reading log records (Db2 Administration Guide)

**Bootstrap data set**

The bootstrap data set (BSDS) is a VSAM key-sequenced data set (KSDS). This KSDS contains information that is critical to Db2, such as the names of the logs. Db2 uses information in the BSDS for system restarts and for any activity that requires reading the log.

Specifically, the BSDS contains:

- An inventory of all active and archive log data sets that are known to Db2. Db2 uses this information to track the active and archive log data sets. Db2 also uses this information to locate log records to satisfy log read requests during normal Db2 system activity and during restart and recovery processing.
- A wrap-around inventory of all recent Db2 checkpoint activity. Db2 uses this information during restart processing.
- The distributed data facility (DDF) communication record, which contains information that is necessary to use Db2 as a distributed server or requester.
- Information about buffer pools.

Because the BSDS is essential to recovery in the event of subsystem failure, during installation Db2 automatically creates two copies of the BSDS and, if space permits, places them on separate volumes.

The BSDS can be duplexed to ensure availability.

For instructions, see Convert BSDS records to the extended 10-byte format: DSNITJJC (Db2 Installation and Migration)

**Related tasks:**

- Managing the log and the bootstrap data set (Db2 Administration Guide)
Buffer pools

Buffer pools are areas of virtual storage that temporarily store pages of table spaces or indexes.

When an application program accesses a row of a table, Db2 places the page that contains that row in a buffer. Access to data in this temporary storage is faster than accessing data on a disk. If the required data is already in a buffer, the application program does not need to wait for it to be retrieved from disk, so the time and cost of retrieving the page is reduced.

Buffer pools require monitoring and tuning. Buffer pool sizes are critical to the performance characteristics of an application or group of applications that access data in those buffer pools.

You can specify default buffer pools for user data and for indexes. A special type of buffer pool that is used only in Parallel Sysplex data sharing is the group buffer pool, which resides in the coupling facility. Group buffer pools reside in a special PR/SM™ LPAR logical partition called a coupling facility, which enables several Db2 subsystems to share information and control the coherency of data.

Buffer pools reside in the DBM1 address space. The maximum size of a buffer pool is 16 TB.

Related concepts:
- The role of buffer pools in caching data (Introduction to Db2 for z/OS)

Related tasks:

- Calculating buffer pool size (Db2 Installation and Migration)
- Enabling automatic buffer pool size management (Db2 Performance)

Data definition control support database

The data definition control support (DDCS) database refers to a user-maintained collection of tables that are used by data definition control support to restrict the submission of specific Db2 DDL (data definition language) statements to selected application identifiers (plans or collections of packages).

This database is automatically created during installation. After this database is created, you must populate the tables to use this facility. The system name for this database is DSNRGFDB.

The resource limit facility

The resource limit facility (sometimes abbreviated RLF) enables you to control the amount of processor resources that are used by SQL statements.

Resource limits apply to the following types of SQL statements:
- SELECT
You can specify resource limits for dynamic SQL statements and static SQL statements. Resource limits apply to SQL statement regardless of whether they are issued locally or remotely. The resource limit facility does not apply to primary or secondary authorization IDs that have installation SYSADM or installation SYSOPR authority.

You can establish a single limit for all users, different limits for individual users, or both. You can choose to have these limits applied before the statement is executed through *predictive governing*, or while a statement is running, through *reactive governing*. You can also use reactive and predictive governing in combination. You define these limits in one or more resource limit tables, named DSNRLSTxx or DSNRLMTxx, depending on the monitoring purpose.

**Related concepts:**
- Resource limit facility controls (Db2 Performance)

**Related tasks:**
- Setting limits for system resource usage by using the resource limit facility (Db2 Performance)

**Related reference:**
- Resource limit facility tables (Db2 Performance)
- START RLIMIT (Db2) (Db2 Commands)

**Work file database**

Use the work file database as storage for processing SQL statements that require working space, such as that required for a sort.

The work file database is used as storage for Db2 work files for processing SQL statements that require working space (such as the space that is required for a sort), and as storage for created global temporary tables and declared global temporary tables.

Db2 creates a work file database and some table spaces in it for you at installation time. You can create additional work file table spaces at any time. You can drop, re-create, and alter the work file database or the table spaces in it, or both, at any time.

In a non-data-sharing environment, the work file database is named DSND807. In a data sharing environment, each Db2 member in the data sharing group has its own work file database.

You can also use the work file database for all temporary tables.
Application processes and transactions

An application process involves running one or more programs. Different application processes might involve running different programs or running the same program at different times. When an application interacts with a Db2 database, a transaction begins.

Many different types of programs access Db2 data: user-written applications, SQL statements that users enter dynamically, and even utilities. The single term that describes any type of access to Db2 data is called an application process. All SQL programs run as part of an application process.

A transaction is a sequence of actions between the application and the database; the sequence begins when data in the database is read or written. A transaction is also known as a unit of work.

Example: Consider what happens when you access funds in a bank account. A banking transaction might involve the transfer of funds from one account to another. During the transaction, an application program first subtracts the funds from the first account, and then it adds the funds to the second account. Following the subtraction step, the data is inconsistent. Consistency is reestablished after the funds are added to the second account.

To ensure data consistency, Db2 uses a variety of techniques that include a commit operation, a rollback operation, and locking.

When the subtraction and addition steps of the banking transaction are complete, the application can use the commit operation to end the transaction, thereby making the changes available to other application processes. The commit operation makes the database changes permanent.

Consider what happens if more than one application process requests access to the same data at the same time. Or, under certain circumstances, an SQL statement might run concurrently with a utility on the same table space. Db2 uses locks to maintain data integrity under these conditions to prevent, for example, two application processes from updating the same row of data simultaneously.

Db2 acquires locks to prevent uncommitted changes that are made by one application process from being perceived by any other. Db2 automatically releases all locks that it has acquired on behalf of an application process when that process ends, but an application process can also explicitly request that locks be released sooner. A commit operation releases locks that an application process has acquired and commits database changes that were made by the same process.

Db2 also provides a way to back out uncommitted changes that an application process makes. A back out might be necessary in the event of a failure on the part of an application process or in a deadlock situation. Deadlock occurs when contention for the use of a resource, such as a table, cannot be resolved. An application process, however, can explicitly request that its database changes be backed out. This operation is called rollback. The interface that an SQL program uses to explicitly specify these commit and rollback operations depends on the environment. For example, in the JDBC environment, applications use commit and rollback methods to commit or roll back transactions.

Related concepts:

- Programming for Db2 for z/OS (Introduction to Db2 for z/OS)
Application processes, concurrency, and recovery

All SQL programs execute as part of an application process. An application process involves the execution of one or more programs, and it is the unit to which Db2 allocates resources and locks.

Different application processes might involve the execution of different programs, or different executions of the same program. The means of initiating and terminating an application process are dependent on the environment.

Locking, commit, and rollback:

More than one application process might request access to the same data at the same time. Furthermore, under certain circumstances, an SQL statement can execute concurrently with a utility on the same table space. Locking is used to maintain data integrity under such conditions, preventing, for example, two application processes from updating the same row of data simultaneously.

Db2 implicitly acquires locks to prevent uncommitted changes made by one application process from being perceived by any other. Db2 will implicitly release all locks it has acquired on behalf of an application process when that process ends, but an application process can also explicitly request that locks be released sooner. A commit operation releases locks acquired by the application process and commits database changes made by the same process.

Db2 provides a way to back out uncommitted changes made by an application process. This might be necessary in the event of a failure on the part of an application process, or in a deadlock situation. An application process, however, can explicitly request that its database changes be backed out. This operation is called rollback.

The interface used by an SQL program to explicitly specify these commit and rollback operations depends on the environment. If the environment can include recoverable resources other than Db2 databases, the SQL COMMIT and ROLLBACK statements cannot be used. Thus, these statements cannot be used in an IMS, CICS, or WebSphere environment.

Unit of work:

A unit of work is a recoverable sequence of operations within an application process. A unit of work is sometimes called a logical unit of work.

At any time, an application process has a single unit of work, but the life of an application process can involve many units of work as a result of commit or full rollback operations.

A unit of work is initiated when an application process is initiated. A unit of work is also initiated when the previous unit of work is ended by something other than the end of the application process. A unit of work is ended by a commit operation, a full rollback operation, or the end of an application process. A commit or rollback operation affects only the database changes made within the unit of work it ends. While these changes remain uncommitted, other application processes are unable to perceive them unless they are running with an isolation level of uncommitted read. The changes can still be backed out. Once committed, these database changes are accessible by other application processes and can no longer be backed out by a rollback. Locks acquired by Db2 on behalf of an application process that protects uncommitted data are held at least until the end of a unit of work.
The initiation and termination of a unit of work define points of consistency within an application process. A point of consistency is a claim by the application that the data is consistent. For example, a banking transaction might involve the transfer of funds from one account to another. Such a transaction would require that these funds be subtracted from the first account, and added to the second. Following the subtraction step, the data is inconsistent. Only after the funds have been added to the second account is consistency reestablished. When both steps are complete, the commit operation can be used to end the unit of work, thereby making the changes available to other application processes. The following figure illustrates this concept.

Figure 7. Unit of work with a commit operation

**Unit of recovery:**

A Db2 unit of recovery is a recoverable sequence of operations executed by Db2 for an application process.

If a unit of work involves changes to other recoverable resources, the unit of work will be supported by other units of recovery. If relational databases are the only recoverable resources used by the application process, then the scope of the unit of work and the unit of recovery are the same and either term can be used.

**Rolling back work:**

Db2 can back out all changes made in a unit of recovery or only selected changes. Only backing out all changes results in a point of consistency.

**Rolling back all changes**

The SQL ROLLBACK statement without the TO SAVEPOINT clause specified causes a full rollback operation. If such a rollback operation is successfully executed, Db2 backs out uncommitted changes to restore the data consistency that existed when the unit of work was initiated.

That is, Db2 undoes the work, as shown in the following figure:
Rolling back selected changes using savepoints

A savepoint represents the state of data at some particular time during a unit of work. An application process can set savepoints within a unit of work, and then as logic dictates, roll back only the changes that were made after a savepoint was set.

For example, part of a reservation transaction might involve booking an airline flight and then a hotel room. If a flight gets reserved but a hotel room cannot be reserved, the application process might want to undo the flight reservation without undoing any database changes made in the transaction prior to making the flight reservation. SQL programs can use the SQL SAVEPOINT statement to set savepoints, the SQL ROLLBACK statement with the TO SAVEPOINT clause to undo changes to a specific savepoint or the last savepoint that was set, and the SQL RELEASE SAVEPOINT statement to delete a savepoint. The following figure illustrates this concept.

Packages and application plans:

A package contains control structures that Db2 uses when it runs SQL statements. An application plan relates an application process to a local instance of Db2 and specifies processing options.

Packages are produced during program preparation. You can think of the control structures as the bound or operational form of SQL statements. All control structures in a package are derived from the SQL statements that are embedded in a single source program.

An application plan contains one or both of the following elements:
A list of package names

Db2 applications require an application plan. Packages make application programs more flexible and easier to maintain.

**Example:** The following figure shows an application plan that contains two packages. Suppose that you decide to change the SELECT statement in package AA to select data from a different table. In this case, you need to bind only package AA again and not package AB.

![Application plan and packages](image)

*Figure 10. Application plan and packages*

In general, you create plans and packages by using the Db2 commands BIND PLAN and BIND PACKAGE.

A **trigger package** is a special type of package that is created when you execute a CREATE TRIGGER statement. A trigger package executes only when the trigger with which it is associated is activated.

Packages for JDBC, SQLJ, and ODBC applications serve different purposes that you can read more about later in this information.

Subsystem parameters

Subsystem parameters are settings that apply to a Db2 for z/OS subsystem. For example, the AUTH subsystem parameter controls whether Db2 checks authorizations. Many users colloquially refer to subsystem parameters as *zparms.*
Generally, system administrators set the value of subsystem parameters when they install or migrate Db2. After installation or migration, a system administrator can change the values of subsystem parameters if needed. However, because these parameters can affect the entire subsystem, system administrators should first carefully evaluate and plan for the impact of any changed values. In some cases, changing the value of a subsystem parameter requires Db2 to be stopped and restarted.

Most subsystem parameters are listed on installation panels. However, some parameters are not. For a list of subsystem parameters, including those parameters that are not on panels, see [Directory of subsystem parameters, panel fields, and application default values (Db2 Installation and Migration)]. This list includes important characteristics of each parameter, including whether changing a parameter requires you to stop and restart Db2.

Subsystem parameter values are contained in a load module that is generated by installation job DSNTIJUZ. The name of this subsystem parameters load module is specified in the PARAMETER MODULE field of installation panel DSNTIPO3. The default name is DSNZPARM. However, to avoid naming conflicts with other members, you should use a different name. Sometimes the naming convention DSNZPxxx is used. In a data sharing environment, each member must have its own subsystem parameter load module.

One way to check the subsystem parameter values is to call stored procedure SYSPROC.ADMIN_INFO_SYSPARM by running sample job DSNTEJ6Z.

Storage structures

In Db2, a storage structure is a set of one or more VSAM data sets that hold Db2 tables or indexes. A storage structure is also called a page set.

The two primary types of storage structures in Db2 for z/OS are table spaces and index spaces.

Related concepts:

Db2 databases

Db2 databases are a set of Db2 structures that include a collection of tables, their associated indexes, and the table spaces in which they reside. You define a database by using the CREATE DATABASE statement.

Whenever a table space is created, it is explicitly or implicitly assigned to an existing database. If you create a table space and do not specify a database name, the table space is created in the default database, DSNDB04. In this case, Db2 implicitly creates a database or uses an existing implicitly created database for the table. All users who have the authority to create table spaces or tables in database DSNDB04 have authority to create tables and table spaces in an implicitly created database. If the table space is implicitly created, and you do not specify the IN clause in the CREATE TABLE statement, Db2 implicitly creates the database to which the table space is assigned.

A single database, for example, can contain all the data that is associated with one application or with a group of related applications. Collecting that data into one database allows you to start or stop access to all the data in one operation. You can also grant authorization for access to all the data as a single unit. Assuming that you are authorized to access data, you can access data that is stored in different databases.

Generally, it is best to minimize the number of table spaces in each database. For the recommended partition-by-range and partition-by-growth table space types, each table space contains only a single table. However, if you do use multi-table segmented (non-UTS) table spaces, which are deprecated, minimize the number of tables in each table space. Too many table spaces and tables in a database can cause decreases in performance and manageability issues. If you reduce the number of table spaces and tables in a database, you improve performance, minimize maintenance, increase concurrency, and decrease log volume.

Deprecated function: [FL 504] Non-UTS table spaces for base tables are deprecated. For packages bound with APPLCOMPAT(V12R1M504) or higher, the result of a CREATE TABLESPACE statement is always a partition-by-growth or partition-by-range UTS table space, and a CREATE TABLE statement that specifies a non-UTS table space returns an error. Existing tables in non-UTS table spaces remain supported. However, support is likely to be removed in the future.

The following figure shows how the main Db2 data structures fit together. Two databases, A and B, are represented as squares. Each database contains a table space and index space. Each index space contains one index. In database B, the table space is partitioned and contains table B1, partitions 1 - 4. The index space contains one partitioning index, parts 1 - 4.
When you migrate Db2 12, Db2 adopts the default database and default storage group that you used in the previous version. You have the same authority for the Db2 12 as you did in the previous version.

**Reasons to define a database**

In Db2 for z/OS, a database is a logical collection of table spaces and index spaces. Consider the following factors when deciding whether to define a new database for a new set of objects:

- You can start and stop an entire database as a unit; you can display the statuses of all its objects by using a single command that names only the database. Therefore, place a set of tables that are used together into the same database. (The same database holds all indexes on those tables.)
- Some operations lock an entire database. For example, some phases of the LOAD utility prevent some SQL statements (CREATE, ALTER, and DROP) from using the same database concurrently. Therefore, placing many unrelated tables in a single database is often inconvenient.
When one user is executing a CREATE, ALTER, or DROP statement for a table, no other user can access the database that contains that table. QMF users, especially, might do a great deal of data definition; the QMF operations SAVE DATA and ERASE data-object are accomplished by creating and dropping Db2 tables. For maximum concurrency, create a separate database for each QMF user.

- The internal database descriptors (DBDs) might become inconveniently large. DBDs grow as new objects are defined, but they do not immediately shrink when objects are dropped; the DBD space for a dropped object is not reclaimed until the MODIFY RECOVERY utility is used to delete records of obsolete copies from SYSIBM.SYSCOPY. DBDs occupy storage and are the objects of occasional input and output operations. Therefore, limiting the size of DBDs is another reason to define new databases.

**Db2 table spaces**

A Db2 table space is a set of volumes on disks that hold the data sets in which tables are actually stored. Every table is stored in table space.

A table space consists of a number of VSAM linear data sets. Table spaces are divided into equal-sized units, called pages. Each page is read from disk to the assigned buffer pool, or written from the buffer pool to disk, in a single operation. The page size is controlled by the buffer pool that you assign to the table space (4 KB, 8 KB, 16 KB, or 32 KB in size) for the data. The default page size is 4 KB.

Data in most table spaces can be compressed, which can allow you to store more data on each data page.

You can let Db2 create and manage the table space for you by issuing a CREATE TABLE statement that does not specify an existing table space. Db2 creates a partition-by-growth or partition-by-range table space. For more information, see [Creation of table spaces (Introduction to Db2 for z/OS)](#).

You can also explicitly define table spaces by issuing CREATE TABLESPACE statements. You specify the database that the table space belongs to, and the storage group that it uses. When you create a table space, certain options that you specify control the type of table space that is created.

**Deprecated function:** [FL 504] Non-UTS table spaces for base tables are deprecated. For packages bound with APPLCOMPAT(V12R1M504) or higher, the result of a CREATE TABLESPACE statement is always a partition-by-growth or partition-by-range UTS table space, and a CREATE TABLE statement that specifies a non-UTS table space returns an error. Existing tables in non-UTS table spaces remain supported. However, support is likely to be removed in the future.

For descriptions of the various table space types, see [Table space types and characteristics in Db2 for z/OS (Db2 Administration Guide)](#).

Segmented non-UTS table spaces, which are deprecated, can contain more than one table. However, with the recommended partition-by-growth and partition-by-range table spaces, each table space contains only a single table.

### Rules for primary and secondary space allocation

You can specify the primary and secondary space allocation or let Db2 choose them. Having Db2 choose the values, especially the secondary space quantity, increases the possibility of reaching the maximum data set size before running out of extents.

In the following rules that describe how allocation works, these terms are used:

**PRIQTY, SECQTY**
- The keywords for CREATE TABLESPACE, ALTER TABLESPACE, CREATE INDEX, and ALTER INDEX.

**specified-priqty**
- The user-specified value for PRIQTY.

**specified-secqty**
- The user-specified value for SECQTY.

**actual-priqty**
- The actual primary space allocation, in kilobytes.

**actual-priqty-cylinders**
- The actual primary space allocation, in cylinders.

**actual-secqty**
- The actual secondary space allocation, in kilobytes.

**actual-secqty-cylinders**
- The actual secondary space allocation, in cylinders.

**calculated-extent-cylinders**
- A value that is calculated by Db2 using a sliding scale. A sliding scale means that the first secondary extent allocations are smaller than later secondary allocations. For example, Figure 12 on page 56 shows the sliding scale of secondary extent allocations that Db2 uses for a 64-GB data set. The size of each secondary extent is larger for each secondary extent that is allocated up to the 127th extent. For the 127th secondary extent and any subsequent extents, the secondary size allocation is 559 cylinders.
Rule 1: (for primary space allocation)
If PRIQTY is specified and specified-priqty is not equal to -1, actual-priqty is at least specified-priqty KB.

Rule 2: (for secondary space allocation)
If SECQTY is not specified, the following formulas determine actual-secqty:
- If the maximum size of a data set in the table space or index is less than 32 GB, the formula is:
  \[
  \text{actual-secqty-cylinders} = \max(0.1 \times \text{actual-priqty-cylinders}, \min(\text{calculated-extent-cylinders}, 127))
  \]
- If the maximum size of a data set in the table space or index is 32 GB or greater, the formula is:
  \[
  \text{actual-secqty-cylinders} = \max(0.1 \times \text{actual-priqty-cylinders}, \min(\text{calculated-extent-cylinders}, 559))
  \]

Rule 3 (for secondary space allocation)
If SECQTY is 0, actual-secqty is 0.

Rule 4 (for secondary space allocation)
This is the only rule that depends on the value of subsystem parameter MGEXTSZ (field OPTIMIZE EXTENT on installation panel DSNTIP7). If MGEXTSZ is YES:
- If SECQTY is specified and specified-secqty is not equal to -1 or 0, the following formulas determine actual-secqty. If the maximum size of a data set in the table space or index is less than 32 GB, the formula is:
  \[
  \text{actual-secqty-cylinders} = \max(\min(\text{calculated-extent-cylinders}, 127), \text{specified-secqty-cylinders})
  \]
  If the maximum size of a data set in the table space or index is 32 GB or greater, the formula is:
actual-secqty-cylinders =
MAX(MIN(calculated-extent-cylinders, 559), specified-secqty-cylinders)

If MGEXTSZ is NO:
• For a table space, if SECQTY is n, the secondary space allocation is at least n kilobytes, with the following exception: If SECQTY is greater than 4194304, n is 4194304 kilobytes.
• For an index, if SECQTY is n, the secondary space allocation is at least n kilobytes, where n is:
  12 If SECQTY and PRIQTY are omitted
  4194304 integer
    If integer is greater than 4194304
    integer
      If integer is not greater than 4194304

Rule 5 (for secondary space allocation):
When a table space requires a new piece, the primary allocation quantity of the new piece is determined as follows: If the value of subsystem parameter MGEXTSZ is NO, the primary quantity from rule 1 is used. Otherwise, the maximum of the following values is used:
•
  – The quantity that is calculated through sliding scale methodology
  – The primary quantity from rule 1
  – The specified SECQTY value

Related information:

Db2 index spaces

An index space is a Db2 storage structure that contains a single index.

When you create an index by using the CREATE INDEX statement, an index space is automatically defined in the same database as the table. You can define a unique name for the index space, or Db2 can derive a unique name for you. Under certain circumstances, Db2 implicitly creates index spaces.

Db2 hash spaces (deprecated)

A hash space is a defined disk space that organizes table data for hash access.

Hash-organized table spaces are deprecated and likely to be unsupported in the future.

Deprecated function:

[FL 504] Hash-organized tables are deprecated. Beginning in Db2 12, packages that are bound with APPLCOMPAT(V12R1M504) or higher cannot create hash-organized tables or alter existing tables to use hash-organization. Existing hash-organized tables remain supported, but they are likely to be unsupported in the future.

When you organize a table for hash access, Db2 requires a defined amount of disk space to contain table data. You can specify the amount of disk space to allocate to the hash space when you create a table or alter an existing table. The hash space on a table must be large enough to contain new rows that are added to the table. If a hash space is full, new rows are relocated to the overflow index, which reduces
the performance of hash access on that table. Hash spaces can contain only a single
table in a partition-by-range or partition-by-growth table space.
Related concepts:

- Hash access paths (deprecated) (Introduction to Db2 for z/OS)

- Monitoring hash access (deprecated) (Db2 Performance)

Db2 storage groups

Db2 storage groups are a set of volumes on disks that hold the data sets in which
tables and indexes are stored.

The description of a storage group names the group and identifies its volumes and
the VSAM (Virtual Storage Access Method) catalog that records the data sets. The
default storage group, SYSDEFLT, is created when you install Db2.

Within the storage group, Db2 does the following actions:

- Allocates storage for table spaces and indexes
- Defines the necessary VSAM data sets
- Extends and deletes VSAM data sets
- Alters VSAM data sets

All volumes of a given storage group must have the same device type. However,
parts of a single database can be stored in different storage groups.

Db2 can manage the auxiliary storage requirements of a database by using Db2
storage groups. Data sets in these Db2 storage groups are called “Db2-managed
data sets.”

These Db2 storage groups are not the same as storage groups that are defined by
the DFSMS storage management subsystem (DFSMSSms).

You have several options for managing Db2 data sets:

- Let Db2 manage the data sets. This option means less work for Db2 database
  administrators.

  After you define a Db2 storage group, Db2 stores information about it in the
  Db2 catalog. (This catalog is not the same as the integrated catalog facility
catalog that describes Db2 VSAM data sets). The catalog table
  SYSIBM.SYSSSTOGROUP has a row for each storage group, and
  SYSIBM.SYSSVOLUMES has a row for each volume. With the proper
  authorization, you can retrieve the catalog information about Db2 storage groups
  by using SQL statements.

  When you create table spaces and indexes, you name the storage group from
  which space is to be allocated. You can also assign an entire database to a
  storage group. Try to assign frequently accessed objects (indexes, for example) to
  fast devices, and assign seldom-used tables to slower devices. This approach to
  choosing storage groups improves performance.

  If you are authorized and do not take specific steps to manage your own
  storage, you can still define tables, indexes, table spaces, and databases. A
  default storage group, SYSDEFLT, is defined when Db2 is installed. Db2 uses
SYSDEFLT to allocate the necessary auxiliary storage. Information about SYSDEFLT, as with any other storage group, is kept in the catalog tables SYSIBM.SYSSTOGROUP and SYSIBM.SYSVOLUMES.

For both user-managed and Db2-managed data sets, you need at least one integrated catalog facility (ICF) catalog; this catalog can be either a user catalog or a master catalog. These catalogs are created with the ICF. You must identify the catalog of the ICF when you create a storage group or when you create a table space that does not use storage groups.

- Let SMS manage some or all the data sets, either when you use Db2 storage groups or when you use data sets that you have defined yourself. This option offers a reduced workload for Db2 database administrators and storage administrators. You can specify SMS classes when you create or alter a storage group.
- Define and manage your own data sets using VSAM Access Method Services. This option gives you the most control over the physical storage of tables and indexes.

**Recommendation:** Use Db2 storage groups and whenever you can, either specifically or by default. Also use SMS managed Db2 storage groups whenever you can.

**Related tasks:**
- [Choosing data page sizes for LOB data (Db2 Performance)](#)

---

**Application processes, concurrency, and recovery**

All SQL programs execute as part of an *application process*. An application process involves the execution of one or more programs, and it is the unit to which Db2 allocates resources and locks.

Different application processes might involve the execution of different programs, or different executions of the same program. The means of initiating and terminating an application process are dependent on the environment.

**Locking, commit, and rollback**

More than one application process might request access to the same data at the same time. Furthermore, under certain circumstances, an SQL statement can execute concurrently with a utility on the same table space. *Locking* is used to maintain data integrity under such conditions, preventing, for example, two application processes from updating the same row of data simultaneously.

Db2 implicitly acquires locks to prevent uncommitted changes made by one application process from being perceived by any other. Db2 will implicitly release all locks it has acquired on behalf of an application process when that process ends, but an application process can also explicitly request that locks be released sooner. A *commit* operation releases locks acquired by the application process and commits database changes made by the same process.

Db2 provides a way to *back out* uncommitted changes made by an application process. This might be necessary in the event of a failure on the part of an application process, or in a *deadlock* situation. An application process, however, can explicitly request that its database changes be backed out. This operation is called *rollback*. 
The interface used by an SQL program to explicitly specify these commit and rollback operations depends on the environment. If the environment can include recoverable resources other than Db2 databases, the SQL COMMIT and ROLLBACK statements cannot be used. Thus, these statements cannot be used in an IMS, CICS, or WebSphere environment.

**Unit of work**

A unit of work is a recoverable sequence of operations within an application process. A unit of work is sometimes called a logical unit of work.

At any time, an application process has a single unit of work, but the life of an application process can involve many units of work as a result of commit or full rollback operations.

A unit of work is initiated when an application process is initiated. A unit of work is also initiated when the previous unit of work is ended by something other than the end of the application process. A unit of work is ended by a commit operation, a full rollback operation, or the end of an application process. A commit or rollback operation affects only the database changes made within the unit of work it ends. While these changes remain uncommitted, other application processes are unable to perceive them unless they are running with an isolation level of uncommitted read. The changes can still be backed out. Once committed, these database changes are accessible by other application processes and can no longer be backed out by a rollback. Locks acquired by Db2 on behalf of an application process that protects uncommitted data are held at least until the end of a unit of work.

The initiation and termination of a unit of work define points of consistency within an application process. A point of consistency is a claim by the application that the data is consistent. For example, a banking transaction might involve the transfer of funds from one account to another. Such a transaction would require that these funds be subtracted from the first account, and added to the second. Following the subtraction step, the data is inconsistent. Only after the funds have been added to the second account is consistency reestablished. When both steps are complete, the commit operation can be used to end the unit of work, thereby making the changes available to other application processes. The following figure illustrates this concept.

![Figure 13. Unit of work with a commit operation](image)

**Unit of recovery**

A Db2 unit of recovery is a recoverable sequence of operations executed by Db2 for an application process.
If a unit of work involves changes to other recoverable resources, the unit of work will be supported by other units of recovery. If relational databases are the only recoverable resources used by the application process, then the scope of the unit of work and the unit of recovery are the same and either term can be used.

**Rolling back work**

Db2 can back out all changes made in a unit of recovery or only selected changes. Only backing out all changes results in a point of consistency.

**Rolling back all changes**

The SQL ROLLBACK statement without the TO SAVEPOINT clause specified causes a full rollback operation. If such a rollback operation is successfully executed, Db2 backs out uncommitted changes to restore the data consistency that existed when the unit of work was initiated.

That is, Db2 undoes the work, as shown in the following figure:

![Figure 14. Rolling back all changes from a unit of work](image1)

**Rolling back selected changes using savepoints**

A *savepoint* represents the state of data at some particular time during a unit of work. An application process can set savepoints within a unit of work, and then as logic dictates, roll back only the changes that were made after a savepoint was set.

For example, part of a reservation transaction might involve booking an airline flight and then a hotel room. If a flight gets reserved but a hotel room cannot be reserved, the application process might want to undo the flight reservation without undoing any database changes made in the transaction prior to making the flight reservation. SQL programs can use the SQL SAVEPOINT statement to set savepoints, the SQL ROLLBACK statement with the TO SAVEPOINT clause to undo changes to a specific savepoint or the last savepoint that was set, and the SQL RELEASE SAVEPOINT statement to delete a savepoint. The following figure illustrates this concept.
A package contains control structures that Db2 uses when it runs SQL statements. An application plan relates an application process to a local instance of Db2 and specifies processing options.

Packages are produced during program preparation. You can think of the control structures as the bound or operational form of SQL statements. All control structures in a package are derived from the SQL statements that are embedded in a single source program.

An application plan contains one or both of the following elements:
- A list of package names

Db2 applications require an application plan. Packages make application programs more flexible and easier to maintain.

Example: The following figure shows an application plan that contains two packages. Suppose that you decide to change the SELECT statement in package AA to select data from a different table. In this case, you need to bind only package AA again and not package AB.
In general, you create plans and packages by using the Db2 commands BIND PLAN and BIND PACKAGE.

A trigger package is a special type of package that is created when you execute a CREATE TRIGGER statement. A trigger package executes only when the trigger with which it is associated is activated.

Packages for JDBC, SQLJ, and ODBC applications serve different purposes that you can read more about later in this information.

Character conversion

A string is a sequence of bytes that can represent characters. Within a string, all the characters are represented by a common encoding representation. In some cases, it might be necessary to convert these characters to a different encoding representation. The process of conversion is known as character conversion.

Character conversion, when required, is automatic, and when successful, it is transparent to the application.

In client/server environments, character conversion can occur when an SQL statement is executed remotely. Consider, for example, the following two cases. In either case, the data could have a different representation at the sending and receiving systems.

- The values of data sent from the requester to the current server
• The values of data sent from the current server to the requester

Conversion can also occur during string operations on the same system, as in the following examples:

• An overriding CCSID is specified.
  For example, an SQL statement with a descriptor, which requires an SQLDA. In the SQLDA, the CCSID is in the SQLNAME field for languages other than REXX, and in the SQLCCSID field for REXX. (For more information, see SQL descriptor area (SQLDA)). A DECLARE VARIABLE statement can also be issued to associate a CCSID with the host variables into which data is retrieved from a table.

• The value of the ENCODING bind option or the APPLICATION ENCODING SCHEMA option of the CREATE PROCEDURE or ALTER PROCEDURE statement for a native SQL procedure (static SQL statements) or the CURRENT APPLICATION ENCODING SCHEME special register (for dynamic SQL) is different than encoding scheme of the data being retrieved.

• A mixed character string is assigned to an SBCS column or host variable.

• An SQL statement refers to data that is defined with different CCSIDs.

The text of an SQL statement is also subject to character conversion because it is a character string.

The following list defines some of the terms used for character conversion.

ASCII  Acronym for American Standard Code for Information Interchange, an encoding scheme used to represent characters. The term ASCII is used throughout this information to refer to IBM-PC Data or ISO 8-bit data.

code page  A set of assignments of characters to code points. For example, in EBCDIC, “A” is assigned code point X’C1’, and “B” is assigned code point X’C2’. In Unicode UTF-8, “A” is assigned code point X’41’, and “B” is assigned code point X’42’. Within a code page, each code point has only one specific meaning.

code point  A unique bit pattern that represents a character. It is a numerical index or position in an encoding table used for encoding characters.

coded character set  A set of unambiguous rules that establishes a character set and the one-to-one relationships between the characters of the set and their coded representations. It is the assignment of each character in a character set to a unique numeric code value.

coded character set identifier (CCSID)  A two-byte, unsigned binary integer that uniquely identifies an encoding scheme and one or more pairs of character sets and code pages.
EBCDIC
Acronym for Extended Binary-Coded Decimal Interchange Code, an encoding scheme used to represent character data, a group of coded character sets that consist of 8 bit coded characters. EBCDIC coded character sets use the first 64 code positions (X’00’ to X’3F’) for control codes. The range X’41’ to X’FE’ is used for single-byte characters. For double-byte characters, the first byte is in the range X’41’ to X’FE’ and the second byte is also in the range X’41’ to X’FE’, while X’4040’ represents a double-byte space.

encoding scheme
A set of rules used to represent character data. All string data stored in a table must use the same encoding scheme and all tables within a table space must use the same encoding scheme, except for global temporary tables, declared temporary tables, and work file table spaces. Db2 supports these encoding schemes:
- ASCII
- EBCDIC
- Unicode

substitution character
A unique character that is substituted during character conversion for any characters in the source encoding representation that do not have a match in the target encoding representation.

Unicode
A universal encoding scheme for written characters and text that enables the exchange of data internationally. It provides a character set standard that can be used all over the world. It provides the ability to encode all characters used for the written languages of the world and treats alphabetic characters, ideographic characters, and symbols equivalently because it specifies a numeric value and a name for each of its characters. It includes punctuation marks, mathematical symbols, technical symbols, geometric shapes, and dingbats. Db2 supports these two encoding forms:
- UTF-8: Unicode Transformation Format, a 8 bit encoding form designed for ease of use with existing ASCII-based systems. UTF-8 can encode any of the Unicode characters. A UTF-8 character is 1,2,3, or 4 bytes in length. A UTF-8 data string can contain any combination of SBCS and MBCS data, including supplementary characters. The CCSID value for data in UTF-8 format is 1208. UTF-8 has multiple code points for spaces, including the '20'X single-byte space that Db2 uses for padding UTF-8 data.
- UTF-16: Unicode Transformation Format, a 16 bit encoding form designed to provide code values for over a million characters and a superset of UCS-2. UTF-16 can encode any of the Unicode characters. In UTF-16 encoding, characters are 2 bytes in length, except for supplementary characters, which take two 2 byte string units per character. The CCSID value for data in UTF-16 format is 1200. UTF-16 has multiple code points for spaces, including the '0020'X single-byte space that Db2 uses for padding UTF-16 data.

Character data (CHAR, VARCHAR, and CLOB) is encoded in Unicode UTF-8. Character strings are also used for mixed data (that is a mixture of single-byte characters and multi-byte characters) and for data that is not associated with any character set (called bit data). Graphic data (GRAPHIC, VARGRAPHIC, and DBCLOB) is encoded in Unicode UTF-16.
characters, see [Character sets and code pages (Introduction to Db2 for z/OS)](#). This table shows how a UTF-8 character can be 1 to 4 bytes in length, a non-supplementary UTF-16 character is 2 bytes in length, and how a supplementary character in either UTF-8 or UTF-16 takes two 2 byte code points.

Character conversion can affect the results of several SQL operations. In this information, the effects are described in:

- Conversion rules for string assignment
- Conversion rules for comparisons
- Character conversion in set operations and concatenations

### Character sets and code pages

Even with the same encoding scheme, different CCSIDs exist, and the same code point can represent a different character in different CCSIDs. Furthermore, a byte in a character string does not necessarily represent a character from a single-byte character set (SBCS).

The following figure shows how a typical character set might map to different code points in two different code pages.

![Character set and code page mappings](image)

**Figure 17. Code page mappings for character set ss1 in ASCII and EBCDIC**

For Unicode, there is only one CCSID for UTF-8 and only one CCSID for UTF-16. The following figure shows how the first 127 single code points for UTF-8 are the same as ASCII with a CCSID of 367. For example, in both UTF-8 and ASCII CCSID 367, an A is X'41' and a 1 is X'31'.
The following figure shows a comparison of how some UTF-16 and UTF-8 code points map to some sample characters. The character for the eighth note musical symbol takes two 2 byte code points because it is a supplementary character.

Coded character sets and CCSIDS

IBM’s character data representation architecture (CDRA) deals with the differences in string representation and encoding. The Coded Character Set Identifier (CCSID) is a key element of this architecture. A CCSID is a 2 byte (unsigned) binary number that uniquely identifies an encoding scheme and one or more pairs of character sets and code pages.

A CCSID is an attribute of strings, just as length is an attribute of strings. All values of the same string column have the same CCSID.

Character conversion is described in terms of CCSIDs of the source and target. With Db2 for z/OS, two methods are used to identify valid source and target combinations and to perform the conversion from one coded character set to another:
- Db2 catalog table SYSIBM.SYSSTRINGS
  Each row in the catalog table describes a conversion from one coded character set to another.
- z/OS support for Unicode
  For more information about the conversion services that are provided, including a complete list of the IBM-supplied conversion tables, see z/OS Support for Unicode: Using Conversion Services.

In some cases, no conversion is necessary even though the strings involved have different CCSIDs.

Different types of conversions might be supported by each database manager. Round-trip conversions attempt to preserve characters in one CCSID that are not defined in the target CCSID so that if the data is subsequently converted back to the original CCSID, the same original characters result. Enforced subset match conversions do not attempt to preserve such characters. Which type of conversion is used for a specific source and target CCSID is product-specific.

For more information on character conversion, see Db2 Installation Guide.

Determining the encoding scheme and CCSID of a string

An encoding scheme and a CCSID are attributes of strings. All values of the same string column have the same encoding scheme and CCSID.

Every string has an encoding scheme and a CCSID that identifies the manner in which the characters in the string are encoded. Strings can be encoded in ASCII, EBCDIC, or Unicode.

The CCSID that is associated with a string value depends on the SQL statement in which the data is referenced and the type of expression. Use the Type 1 rules when the SQL statement meets the following conditions:
- The SQL statement operates with a single set of CCSIDs (SBCS, mixed, and graphic). An SQL statement that does not contain any of the following items operates with a single set of CCSIDs:
  - References to columns from multiple tables or views that are defined with CCSIDs from more than one set of CCSIDs (SBCS, mixed, and graphic)
  - References to an EBCDIC table that contains a Unicode column
  - Graphic hexadecimal (GX) or hexadecimal Unicode (UX) string constants
• References to the XMLCLOB built-in function
• Cast specifications with a CCSID clause
• User-defined table functions

• The SQL statement is not one of the following statements:
  – CALL statement
  – SET assignment statement
  – SET special register
  – VALUES statement
  – VALUES INTO statement

• One of the following built-in functions is not referenced:
  – ASCII_CHR
  – ASCII_STR (or ASCIISTR)
  – CHR
  – DECRYPT_BIT
  – DECRYPT_CHAR
  – DECRYPT_DB
  – EBCDIC_CHR
  – EBCDIC_STR
  – GETVARIABLE
  – NORMALIZE_STRING
  – UNICODE_STR (or UNISTR)
  – XMLSERIALIZE

• The SQL statement does not include a collection-derived table (UNNEST).

Use the Type 2 rules when the statement does not meet the conditions for Type 1 rules.

For those SQL statements and tools that use a SYSDUMMYx table, use the SYSDUMMYx table that has the same encoding scheme as the other objects in your SQL statement, to avoid conversions. A SYSDUMMYx table is available in each encoding scheme. For example, suppose that your SQL statement references a SYSDUMMYx table that is in a different encoding scheme from other objects in the statement. Db2 treats this statement as one that references objects with different CCSIDs (Type 2 rules), and conversion is likely to occur. To avoid this situation, reference the SYSDUMMYx table that has the same encoding scheme as the other objects in your SQL statement. See SYSDUMMYx tables (Introduction to Db2 for z/OS) for more information.

Table 10 describes the rules for determining the CCSID of derived string data when the source data has a string type.

</tr>
</tbody>
</table>

Notes:

1. If the context is within a check constraint or a package for a basic trigger, the CCSID is the appropriate CCSID for Unicode, instead of the application encoding scheme. If the context is within a package for an advanced trigger, the CCSID is determined from the implicitly or explicitly specified APPLICATION ENCODING SCHEME option; otherwise the CCSID is the appropriate CCSID for Unicode instead of the application encoding scheme.

"Determining the encoding scheme and CCSID of a string” on page 68 shows the rules for determining the CCSID of derived string data when the source data has a numeric type.
### Table 11. Rules for determining the CCSID that is associated with string data derived from numeric data

<table>
<thead>
<tr>
<th>Source of the numeric data</th>
<th>Type 1 rules</th>
<th>Type 2 rules</th>
</tr>
</thead>
<tbody>
<tr>
<td>Numeric data</td>
<td>If the statement references a table or view, the encoding scheme of that table or view determines the encoding scheme for the string data that is derived from a numeric value. Otherwise, the default EBCDIC encoding scheme is used for the string data derived from a numeric value. The CCSID is the appropriate character or graphic string CCSID of the application encoding scheme.</td>
<td>The CCSID is the appropriate character or graphic string CCSID of the application encoding scheme.</td>
</tr>
</tbody>
</table>

### Notes:

1. If the context is within a check constraint or a package for a basic trigger, the CCSID is the appropriate CCSID for Unicode, instead of the application encoding scheme. If the context is within a package for an advanced trigger, the CCSID is determined from the implicitly or explicitly specified APPLICATION ENCODING SCHEME option; otherwise the CCSID is the appropriate CCSID for Unicode instead of the application encoding scheme.

The following examples show how these rules are applied.

**Example 1:** Assume that the default encoding scheme for the installation is EBCDIC and that the installation does not support mixed and graphic data. The following statement conforms to the rules for Type 1 in Table 10 on page 69. Therefore, the X’40’ is interpreted as EBCDIC SBCS data because the statement references a table that is in EBCDIC. The CCSID for X’40’ is the default EBCDIC SBCS CCSID for the installation.

```sql
SELECT * FROM EBCDIC_TABLE WHERE COL1 = X'40';
```

the result of the query includes each row that has a value in column COL1 that is equal to a single EBCDIC blank.

**Example 2:** The following statement references data from two different tables that use different encoding schemes. This statement does not conform to the rules for Type 1 statements in Table 10 on page 69. Therefore, the rules for Type 2 statements are used. The CCSID for X’40’ is dependent on the current application encoding scheme. Assuming that the current application encoding scheme is EBCDIC, X’40’ represents a single EBCDIC blank.

```sql
SELECT * FROM EBCDIC_TABLE, UNICODE_TABLE WHERE COL1 = X'40';
```

as with Example 1, the result of the query includes each row that has a value in column COL1 that is equal to a single EBCDIC blank. If the current application encoding scheme were ASCII or Unicode, X’40’ would represent something different and the results of the query would be different.

**Expanding conversions**

An **expanding conversion** occurs when the length of the converted string is greater than that of the source string.

For example, an expanding conversion occurs when an ASCII mixed data string that contains DBCS characters is converted to EBCDIC mixed data. To prevent the loss of data on expanding conversions, use a varying-length string variable with a maximum length that is sufficient to contain the expansion.
Expanding conversions also can occur when string data is converted to or from Unicode. It can also occur between UTF-8 and UTF-16, depending on the data being converted. UTF-8 uses 1, 2, 3, or 4 bytes per character. UTF-16 uses 2 bytes per character, except for supplementary characters, which use two 2 byte code points for each character. If UTF-8 were being converted to UTF-16, a 1 byte character would be expanded to 2 bytes.

**Contracting conversions**

A contracting conversion occurs when the length of the converted string is smaller than that of the source string.

For example, a contracting conversion occurs when an EBCDIC mixed data string that contains DBCS characters is converted to ASCII mixed data due to the removal of shift codes.

Contracting conversions also can occur when string data is converted to or from Unicode data. It can also occur between UTF-8 and UTF-16, depending on the data being converted.

**Distributed data**

The database managers in a distributed relational database communicate and cooperate with each other in a way that allows a Db2 application program to use SQL to access data at any of the interconnected computer systems.

A distributed relational database consists of a set of tables and other objects that are spread across different, but interconnected, computer systems. Each computer system has a relational database manager, such as Db2, that manages the tables in its environment. The database managers communicate and cooperate with each other in a way that allows a Db2 application program to use SQL to access data at any of the computer systems. The Db2 subsystem where the application plan is bound is known as the local Db2 subsystem. Any database server other than the local Db2 subsystem is considered a remote database server, and access to its data is a distributed operation.

Distributed relational databases are built on formal requester-server protocols and functions. An application requester component supports the application end of a connection. It transforms an application's database request into communication protocols that are suitable for use in the distributed database network. These requests are received and processed by an application server component at the database server end of the connection. Working together, the application requester and application server handle the communication and location considerations so that the application is isolated from these considerations and can operate as if it were accessing a local database.

For more information on Distributed Relational Database Architecture™ (DRDA) communication protocols, see Open Group Technical Standard, DRDA Version 3 Vol. 1: Distributed Relational Database Architecture.

Connections

A connection is an association between an application process and a local or remote database server. Connections are managed by applications.

An application process must be connected to the application server facility of a database manager before SQL statements that reference tables or views can be executed. An application can use the CONNECT statement to establish a connection to a database server and make that database server the current server of the application process.

Commit processing: When Db2 for z/OS acts as a requester, it negotiates with the database server during the connection process to determine how to perform commits. If the remote server does not support two-phase commit protocol, Db2 downgrades to perform one-phase commits. Otherwise, Db2 always performs two-phase commits, which allow applications to update one or more databases in a single unit of work and are more reliable than one-phase commits. Two-phase commit is a two-step process:

1. First, all database managers involved in the same unit of work are pooled to determine whether they are ready to commit.
2. Then, if all database managers respond positively, they are directed to execute commit processing. If all database managers do not respond positively, they are directed to execute backout processing.

Db2 can also provide coordination for transactions that include both two-phase commit resources and one-phase commit resources. If an application has multiple connections to several different database servers, and if any of the connections are one-phase commit connections, then only one database that is involved in the transaction can be updated. The connections to all the other databases that are involved in the transaction are read-only.

Supported SQL statements and clauses: For the most part, an application can use the statements and clauses that are supported by the database manager of the current server, even though that application might be running via the application requester of a database manager that does not support some of those statements and clauses. Restrictions to this general rule for Db2 for z/OS are documented in IBM Db2 SQL Reference for Cross-Platform Development.

To execute a static SQL statement that references tables or views, the bound form of the statement is taken from a package that the database manager previously created through a bind operation or when a version of a native SQL procedure was defined.

Distributed unit of work

The distributed unit of work facility provides for the remote preparation and execution of SQL statements.

An application process at computer system A can connect to a database server at computer system B and, within one or more units of work, execute any number of static or dynamic SQL statements that reference objects at B. All objects referenced in a single SQL statement must be managed by the same database server. Any number of database servers can participate in the same unit of work, and any number of connections can exist between an application process and a database server. A commit or rollback operation that does not specify a savepoint ends the unit of work.
Connection management
How connections are managed depends on what states the SQL connection and the application process are in.

At any time:
• An SQL connection is in one of the following states:
  – Current and held
  – Current and release-pending
  – Dormant and held
  – Dormant and release-pending
• An application process is in the connected or unconnected state, and has a set of zero or more SQL connections. Each SQL connection is uniquely identified by the name of the database server at the other end of the connection. Only one SQL connection is active (current) at a time.

Initial state of an application process: An application process is initially in the connected state, and it has exactly one SQL connection. The server of that connection is the local Db2 subsystem.

Initial state of an SQL connection: An SQL connection is initially in the current and held state.

The following figure shows the state transitions:

![State transitions figure]

Figure 20. State transitions for an SQL connection and an application process connection in a distributed unit of work

SQL connection states
If an application process successfully executes a CONNECT statement, the SQL connection states of the connections change.
If an application process successfully executes a CONNECT statement:
• The current connection is placed in the dormant and held state.
• The new connection is placed in the current and held state.
• The location name is added to the set of existing connections.

If the location name is already in the set of existing connections, an error is returned.

An SQL connection in the dormant state is placed in the current state using:
• The SET CONNECTION statement, or
• The CONNECT statement, if the SQLRULES(Db2) bind option is in effect.

When an SQL connection is placed in the current state, the previously-current SQL connection, if any, is placed in the dormant state. No more than one SQL connection in the set of existing connections of an application process can be current at any time. Changing the state of an SQL connection from current to dormant or from dormant to current has no effect on its held or release-pending state.

An SQL connection is placed in the release-pending state by the RELEASE statement. When an application process executes a commit operation, every release-pending connection of the process is ended. Changing the state of an SQL connection from held to release-pending has no effect on its current or dormant state. Thus, an SQL connection in the release-pending state can still be used until the next commit operation. No way exists to change the state of a connection from release-pending to held.

**Application process connection states**
In a distributed unit of work, an application process can be in a connected or unconnected state. Depending on the state, the application process can execute only certain SQL statements successfully.

A connection to a different database server can be established by the explicit or implicit execution of a CONNECT statement. The following rules apply:
• An application process cannot have more than one SQL connection to the same database server at the same time.
• When an application process executes a SET CONNECTION statement, the specified location name must be in the set of existing connections of the application process.
• When an application process executes a CONNECT statement and the SQLRULES(STD) bind option is in effect, the specified location must not be in the set of existing connections of the application process.

**If an application process has a current SQL connection**, the application process is in a connected state. The CURRENT SERVER special register contains the name of the database server of the current SQL connection. The application process can execute SQL statements that refer to objects managed by that server. If the server is a Db2 subsystem, the application process can also execute certain SQL statements that refer to objects managed by a Db2 subsystem with which that server can establish a connection.

An application process in an unconnected state enters a connected state when it successfully executes a CONNECT or SET CONNECTION statement.
If an application process does not have a current SQL connection, the application process is in an unconnected state. The CURRENT SERVER special register contains blanks. The only SQL statements that can be executed successfully are CONNECT, RELEASE, COMMIT, ROLLBACK, and any of the following local SET statements.

- SET CONNECTION
- SET CURRENT APPLICATION ENCODING SCHEME
- SET CURRENT PACKAGE PATH
- SET CURRENT PACKAGESET
- SET host-variable = CURRENT APPLICATION ENCODING SCHEME
- SET host-variable = CURRENT PACKAGESET
- SET host-variable = CURRENT SERVER

Because the application process is in an unconnected state, a COMMIT or ROLLBACK statement is processed by the local Db2 subsystem.

An application process in a connected state enters an unconnected state when its current SQL connection is intentionally ended, or the execution of an SQL statement is unsuccessful because of a failure that causes a rollback operation at the current server and loss of the SQL connection. SQL connections are intentionally ended when an application process successfully executes a commit operation and either of the following are true:

- The SQL connection is in the release-pending state.
- The SQL connection is not in the release-pending state, but it is a remote connection and either of the following are true:
  - The DISCONNECT(AUTOMATIC) bind option is in effect
  - The DISCONNECT(CONDITIONAL) bind option is in effect and an open WITH HOLD cursor is not associated with the connection

An implicit CONNECT to a default Db2 subsystem is executed when an application process executes an SQL statement other than COMMIT, CONNECT TO, CONNECT RESET, SET CONNECTION, RELEASE, or ROLLBACK, and if all of the following conditions apply:

- The CURRENTSERVER bind option was specified when creating the application plan of the application process and the identified server is not the local Db2.
- An explicit CONNECT statement has not already been successfully or unsuccessfully executed by the application process.
- An implicit connection has not already been successfully or unsuccessfully executed by the application process. An implicit connection occurs as the result of execution of an SQL statement that contains a three-part name in a package that is bound with the DBPROTOCOL(DRDA) option.

If the implicit CONNECT fails, the application process is placed in an unconnected state.

When a connection is ended, all resources that were acquired by the application process through the connection and all resources that were used to create and maintain the connection are returned to the connection pool. For example, if application process P placed the connection to application server X in the release-pending state, all cursors of P at X are closed and returned to the connection pool when the connection is ended during the next commit operation.
When a connection is ended as a result of a communications failure, the application process is placed in an unconnected state.

All connections of an application process are ended when the process ends.

**Remote unit of work**

The *remote unit of work facility* also provides for the remote preparation and execution of SQL statements, but in a much more restricted fashion than the distributed unit of work facility.

An application process at computer system A can connect to a database server at computer system B and, within one or more units of work, execute any number of static or dynamic SQL statements that reference objects at B. All objects referenced in a single SQL statement must be managed by the same database server, and all SQL statements in the same unit of work must be executed by the same database server. However, unlike a distributed unit of work, an application process can have only one connection at a time. The process cannot connect to a new server until it executes a commit or rollback operation on the current server to end that unit of work. This restricts the situations in which a CONNECT statement can be executed.

**Connection management**

How connections are managed depends on what states the SQL connection and the application process are in.

An application process is in one of four states at any time:
- Connectable and connected
- Unconnectable and connected
- Connectable and unconnected
- Unconnectable and unconnected

*Initial state of an application process:* An application process is initially in the connectable and connected state. The database server to which the application process is connected is determined by a product-specific option that might involve an implicit CONNECT operation. An implicit connect operation cannot occur if an implicit or explicit connect operation has already successfully or unsuccessfully occurred. Thus, an application process cannot be implicitly connected to a database server more than once. Other rules for implicit connect operations are product-specific.

[Figure 21 on page 79](#) shows the state transitions:
In the following descriptions of application process connections, CONNECT can mean:

- CONNECT TO
- CONNECT RESET
- CONNECT authorization

It cannot mean CONNECT with no operand, which is used to return information about the current server.

Consecutive CONNECT statements can be executed successfully because CONNECT does not remove an application process from the connectable state. A CONNECT statement does not initiate a new unit of work; a unit of work is initiated by the first SQL statement that accesses data. CONNECT cannot execute successfully when it is preceded by any SQL statement other than CONNECT, COMMIT, RELEASE, ROLLBACK, or SET CONNECTION. To avoid an error, execute a commit or rollback operation before a CONNECT statement is executed.

**Connectable and connected state:** In the connectable and connected state, an application process is connected to a database server, and CONNECT statements that target the current server can be executed. An application process re-enters this state when either of the following is true:

- The process completes a rollback or a successful commit from an unconnectable and connected state.
- The process successfully executes a CONNECT statement from a connectable and unconnected state.

**Unconnectable and connected state:** In the unconnectable and connected state, an application process is connected to a database server, and only a CONNECT statement with no operands can be executed. An application process enters this state from a connectable and connected state when it executes any SQL statement other than CONNECT, COMMIT, or ROLLBACK.
Connectable and unconnected state: In the connectable and unconnected state, an application process is not connected to a database server. The only SQL statement that can be executed is CONNECT. An application process enters this state if any of the following is true:

- The process does not successfully execute a CONNECT statement from a connectable and connected state.
- The process executes a COMMIT statement when the SQL connection is in a release-pending state.
- A system failure occurs during a COMMIT or ROLLBACK from an unconnectable and connected state.
- The process executes a ROLLBACK statement from an unconnectable and unconnected state.

Other product-specific reasons can also cause an application process to enter the connectable and unconnected state.

Unconnectable and unconnected state: In the unconnectable and unconnected state, an application process is not connected to a database server and CONNECT statements cannot be executed. The only SQL statement that can be executed is ROLLBACK. An application process enters this state from an unconnectable and connected state as a result of a system failure, except during a COMMIT or ROLLBACK, at the server.
Chapter 2. Language elements

An understanding of the basic syntax of SQL and language elements that are common to many SQL statements can be helpful in using SQL with Db2 for z/OS.

The following topics provide information about these language elements:
- Characters
- Tokens
- Identifiers
- Naming conventions
- SQL path
- “Qualification of unqualified object names” on page 93
- “Authorization IDs, roles, and authorization names” on page 100
- Data types
- Promotion of data types
- “Casting between data types” on page 141
- “Assignment and comparison” on page 151
- “Rules for result data types” on page 174
- Constants
- “Special registers” on page 186
- Column names
- Variables
- “Host structures in PL/I, C, and COBOL” on page 246
- “Host-variable arrays in PL/I, C, C++, and COBOL” on page 247
- Functions
- Expressions
- Predicates
- Search conditions
- Options affecting SQL
- Mappings from SQL to XML

Characters

The basic symbols of keywords and operators in the SQL language are characters that are classified as letters, digits, or special characters.

- A letter is any of the 26 uppercase (A through Z) and 26 lowercase (a through z) letters of the English alphabet.\(^1\)
- A digit is any one of the characters 0 through 9.
- A special character is any character other than a letter or a digit.

\(^1\) Letters also include three code points reserved as alphabetic extenders for national languages (§, #, and @ in the United States). These three code points (X’5B’, X’7B’, and X’7C’) should be avoided because they represent different characters depending on the CCSID.
**Tokens**

The basic syntactical units of the SQL language are called *tokens*. A token consists of one or more characters of which none are blanks, control characters, or characters within a string constant or delimited identifier.

Tokens are classified as *ordinary* or *delimiter* tokens:

- **An ordinary token** is a numeric constant, an ordinary identifier, a host identifier, or a keyword.
  
  Examples:
  
  ```
  1 .1 +2 SELECT E 3
  ```

- **A delimiter token** is a string constant, a delimited identifier, an operator symbol, or any of the special characters shown in the syntax diagrams. A question mark (?) is also a delimiter token when it serves as a parameter marker, as explained in "PREPARE" on page 2196.
  
  Examples:
  
  ```
  , 'string' "fld1" = .
  ```

**Spaces**

A *space* is a sequence of one or more blank characters.

**Control characters**

A *control character* is a special character that is used for string alignment. Treated similar to a space, a control character does not cause a particular action to occur. The following table shows the control characters that Db2 recognizes and their hexadecimal values.

<table>
<thead>
<tr>
<th>Control character</th>
<th>EBCDIC hex value</th>
<th>UTF-8 hex value</th>
<th>UTF-16 hex value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tab</td>
<td>05</td>
<td>09</td>
<td>U+0009</td>
</tr>
<tr>
<td>Form feed</td>
<td>0C</td>
<td>0C</td>
<td>U+000C</td>
</tr>
<tr>
<td>Carriage return</td>
<td>0D</td>
<td>0D</td>
<td>U+000D</td>
</tr>
<tr>
<td>New line</td>
<td>15</td>
<td>C285</td>
<td>U+0085</td>
</tr>
<tr>
<td>Line feed</td>
<td>25</td>
<td>0A</td>
<td>U+000A</td>
</tr>
<tr>
<td>DBCS space</td>
<td>-</td>
<td>-</td>
<td>U+3000</td>
</tr>
</tbody>
</table>

Tokens, other than string constants and certain delimited identifiers, must not include a control character or space. A control character or space can follow a token. A delimiter token, control character, or a space must follow every ordinary token. If the syntax does not allow a delimiter token to follow an ordinary token, a control character or a space must follow that ordinary token.

**Trigraphs**

The left bracket ([) and right bracket (]) characters are used in syntax to refer to an array element. Those characters cannot be specified with some CCSIDs. The following trigraphs can be used as an alternative way to specify left and right brackets:

- The string `??(` can be specified in place of a left bracket ( [ ).
- The string `??)` can be specified in place of a right bracket ( ] ).
Comments

Dynamic SQL statements can include SQL comments. Static SQL statements can include host language comments or SQL comments. Comments can be specified wherever a space can be specified, except within a delimiter token or between the keywords EXEC and SQL. In Java, SQL comments are not allowed within embedded Java expressions. There are two types of SQL comments:

**simple comments**
Simple comments are introduced with two consecutive hyphens (--). Simple comments cannot continue past the end of the line. For additional information, see [SQL comments](#).

**bracketed comments**
Bracketed comments are introduced with /* and end with */. A bracketed comment can continue past the end of the line. For additional information, see [SQL comments](#).

Uppercase and lowercase

A token in an SQL statement can include lowercase letters, but lowercase letters in an ordinary token are folded to uppercase. However, lowercase letters are folded to uppercase in a C or Java program only if the appropriate precompiler option is specified. Delimiter tokens are never folded to uppercase.

**Example:** The following two statements, after folding, are equivalent:

```sql
select *
from DSN8C10.EMP
where lastname = 'Smith';
```

```sql
SELECT * FROM DSN8C10.EMP WHERE LASTNAME = 'Smith';
```

Identifiers

An identifier is a token used to form a name. An identifier in an SQL statement is an SQL identifier or a host identifier.

See [Limits in Db2 for z/OS](#) for the identifier length limits that Db2 imposes.

**SQL identifiers**

SQL identifiers can be *ordinary identifiers* or *delimited identifiers*.

**Ordinary identifiers**

An ordinary identifier is an uppercase letter followed by zero or more characters, each of which is an uppercase letter, a digit, or the underscore character.

An ordinary identifier should not be a reserved word. If a reserved word is used as an identifier in SQL, it must be specified in uppercase and must be a delimited identifier or specified in a host variable. For a list of reserved words, see [Reserved schema names and reserved words](#).

SQL ordinary identifiers can contain DBCS characters unless otherwise specified. However, an SQL ordinary identifier cannot contain a mixture of SBCS and DBCS characters.

The following list shows the rules for forming SQL ordinary identifiers:

- The UTF-8 representation of the name must not exceed 128 bytes.
- Continuation to the next line is not allowed.
If the SQL ordinary identifier contains DBCS characters, the following additional rules apply:

- The identifier, if encoded in EBCDIC, must start with a shift-out (X'0E') and end with a shift-in (X'0F'). There must be an even number of bytes between the shift-out and the shift-in. An odd-numbered byte between those shifts must not be a shift-out. DBCS blanks (X'4040' in EBCDIC) are not acceptable between the shift-out and the shift-in.
- The identifiers are not folded to uppercase or changed in any other way.

Example: The following example is an ordinary identifier:

```
SALARY
```

**Delimited identifiers**

A delimited identifier is a sequence of one or more characters enclosed within escape characters.

The escape character is the quotation mark (""), except for:

- Dynamic SQL when the field SQL STRING DELIMITER on installation panel DSNTIPF is set to the quotation mark (""), and either of these conditions is true:
  - DYNAMICRULES run behavior applies. For a list of the DYNAMICRULES option values that specify run, bind, define, or invoke behavior, see [Authorization IDs and dynamic SQL](#).
  - DYNAMICRULES bind, define, or invoke behavior applies and installation panel field USE FOR DYNAMIC RULES is YES.

In this case, the escape character is the apostrophe (').

However, for COBOL application programs, if DYNAMICRULES run behavior does not apply and installation panel field USE FOR DYNAMICRULES is NO, a COBOL compiler option specifies whether the escape character is the quotation mark or apostrophe.

- Static SQL in COBOL application programs. A COBOL compiler option specifies whether the escape character is the quotation mark (""), or the apostrophe (').

A delimited identifier can be used when the sequence of characters does not qualify as an ordinary identifier. Such a sequence, for example, could be an SQL reserved word, or it could begin with a digit. Two consecutive escape characters are used to represent one escape character within the delimited identifier. A delimited identifier that contains EBCDIC DBCS characters also must contain the necessary shift characters.

Leading and embedded blanks in the sequence are significant. Trailing blanks in the sequence are not significant. The length of a delimited identifier does not include the starting and ending escape characters. Embedded escape characters (that appear as two characters) are counted in the length as a single character.

Example: If the escape character is the quotation mark, the following example is a delimited identifier:

```
"VIEW"
```

**Host identifiers**

A host identifier is a name declared in the host program.

---

2. In CCSID 1026 and CCSID 1155, the code point for the quotation mark can be X'7F' or X'FC'. However, if the beginning delimiter is X'7F', the ending delimiter must also be X'7F'. If the beginning delimiter is X'FC', ending delimiter must also be X'FC'.
The rules for forming a host identifier are the rules of the host language. In non-Java programs, do not use names beginning with 'DB2', 'SQ', 'SQL', 'sql', 'RDI', or 'DSN' because precompilers generate host variable names that begin with these characters. In Java, do not use names beginning with '__sJT__'.

**Restrictions for distributed access**

To use certain identifiers in distributed access, those identifiers need to be restricted to certain characters.

The Db2 internal processing of distributed access must sometimes convert the identifiers for authorization-name, procedure-name, and schema-name between CCSIDs. If there is any possibility that these identifiers will be used in distributed access, restrict the identifiers to characters whose representation in Unicode UTF-8 have code points in the range 0 through 127. You do not need to enter the identifiers in Unicode; this restriction refers to conversion that Db2 performs internally.

---

**Naming conventions**

The rules for forming a name depend on the type of the object designated by the name.

The syntax diagrams use different terms for different types of names. The following list defines these terms.

**accelerator-name**

An unqualified name that identifies an accelerator-only table. An accelerator name is 1 to 8 uppercase characters or digits. The name must be unique within the Db2 subsystem or data sharing group.

**alias-name**

A qualified or unqualified name that designates an alias. A fully qualified alias name is a three-part name. The first part is a location name that designates the DBMS at which the alias is defined. The second part is a schema name. The third part is an SQL identifier. A period must separate each of the parts.

A two-part sequence is implicitly qualified by the location name of the current server. The first part is a schema name. The second part is an SQL identifier. A period must separate the two parts.

A one-part or unqualified alias name is an SQL identifier with two implicit qualifiers. The first implicit qualifier is the location name of the current server. The second is a schema name, which is determined by the rules specified in [Unqualified alias, index, JAR file, sequence, table, trigger, and view names](#). For more information, see [Aliases](#).

**array-type-name**

A qualified or unqualified name that designates an array type.

A qualified array type name is a two-part name. The first part is the schema name of the array type. The second part is an SQL identifier. A period must separate each of the parts.

An unqualified array type name is an SQL identifier with an implicit qualifier. The implicit qualifier is the schema name, which is determined.

---

3. 'SQ' is allowed in C, COBOL, and REXX.
by the context in which the array type appears, as described by the rules in Qualification of unqualified object names.

**authorization-name**

An SQL identifier that designates a set of privileges. It can also designate a user, a group of users, or a role. For a user or a group of users, Db2 does not control this property. For a role, Db2 does control this property. See Authorization IDs, roles, and authorization names for the distinction between an authorization name and an authorization ID.

**aux-table-name**

A qualified or unqualified name that designates an auxiliary table. The rules for the name are the same as the rules for table-name. See table-name.

**bpname**

A name that identifies a buffer pool. The following list shows the names of the different buffer pool sizes.

- **4KB**: BP0, BP1, BP2, ..., BP49
- **8KB**: BP8K0, BP8K1, BP8K2, ..., BP8K9
- **16KB**: BP16K0, BP16K1, BP16K2, ..., BP16K9
- **32KB**: BP32K, BP32K1, BP32K2, ..., BP32K9

**built-in-type**

A qualified or unqualified name that identifies an IBM-supplied data type. A qualified name is SYSIBM followed by a period and the name of the built-in data type. An unqualified name has an implicit qualifier, the schema name, which is determined by the rules in Qualification of unqualified object names.

**catalog-name**

An SQL identifier that designates an integrated catalog facility catalog. The identifier must start with a letter and must not include special characters, or the alphabetic extenders for national languages ($, #, and @ in the United States). These three code points (X'5B', X'7B', and X'7C') should be avoided because they represent different characters depending on the CCSID.

**clone-table-name**

A qualified or unqualified name that designates the name of a clone table. See the definition of table-name for more information about qualification of table names.

**collection-id**

An SQL identifier that identifies a collection of packages, such as a collection ID as a qualifier for a package ID. See Naming conventions.

**column-name**

A qualified or unqualified name that designates a column of a table or view.

A qualified column name is a qualifier followed by a period and an SQL identifier. The qualifier is a table name, a view name, a synonym, an alias, or a correlation name. The unqualified column name is an SQL identifier.

**constraint-name**

An SQL identifier that designates a primary key, check, referential, or unique constraint on a table.

**correlation-name**

An SQL identifier that designates a table, a view, or individual rows of a table or view.
context-name
An unqualified SQL identifier that designates a trusted context.

cursor-name
An SQL identifier that designates an SQL cursor. In SQLJ, cursor-name is a host variable (with no indicator variable) that identifies an instance of an iterator.

database-name
An SQL identifier that designates a database. The identifier must start with a letter and must not include special characters.

descriptor-name
A host identifier that designates an SQL descriptor area (SQLDA). See Host variables for a description of a host identifier. A descriptor name never includes an indicator variable.

distinct-type-name
A qualified or unqualified name that designates a distinct type.
A qualified distinct type name is a two-part name. The first part is the schema name of the distinct type. The second part is an SQL identifier. A period must separate each of the parts.
An unqualified distinct type name is an SQL identifier with an implicit qualifier. The implicit qualifier is the schema name, which is determined by the context in which the distinct type appears as described by the rules in Unqualified type, function, procedure, global variable, and specific names.

descriptor-name
A host identifier that designates an SQL descriptor area (SQLDA). See Host variables for a description of a host identifier. A descriptor name never includes an indicator variable.

distinct-type-name
A qualified or unqualified name that designates a distinct type.
A qualified distinct type name is a two-part name. The first part is the schema name of the distinct type. The second part is an SQL identifier. A period must separate each of the parts.
An unqualified distinct type name is an SQL identifier with an implicit qualifier. The implicit qualifier is the schema name, which is determined by the context in which the distinct type appears as described by the rules in Unqualified type, function, procedure, global variable, and specific names.

external-program-name
A name that specifies the program that runs when the function is invoked or the procedure name is specified in a CALL statement.

function-name
A qualified or unqualified name that designates a user-defined function, a cast function that was generated when a distinct type was created, or a built-in function.
A qualified function name is a two-part name. The first part is the schema name of the function. The second part is an SQL identifier. A period must separate each of the parts.
An unqualified function name is an SQL identifier with an implicit qualifier. The implicit qualifier is the schema name, which is determined by the context in which the unqualified name appears as described by the rules in Unqualified type, function, procedure, global variable, and specific names.

global-variable-name
A qualified or unqualified name that designates a global variable.
A qualified global variable name is a two-part name. The first part is the schema name of the global variable. The second part is an SQL identifier. A period must separate each of the parts.
An unqualified global variable name is an SQL identifier with an implicit qualifier. The implicit qualifier is the schema name, which is determined by the context in which the unqualified name appears as described by the rules in Unqualified type, function, procedure, global variable, and specific names.
**host-label**
A token that designates a label in a host program.

**host-variable**
A sequence of tokens that designates a host variable. A host variable includes at least one host identifier, as explained in [Host variables](#).

**index-name**
A qualified or unqualified name that designates an index.

A qualified index name is an authorization ID or schema name followed by a period and an SQL identifier.

An unqualified index name is an SQL identifier with an implicit qualifier. The implicit qualifier is an authorization ID, which is determined by the context in which the unqualified name appears as described by the rules in [Qualification of unqualified object names](#). For an index on a declared temporary table, the qualifier must be SESSION.

**key-label-name**
An SQL identifier that corresponds to the value of the Integrated Cryptographic Service Facility (ICSF) key label. A keylabel-name can consist of up to 64 characters. The first character must be a letter or national character (#, $, @). It is recommended that the name not include national characters (@ (X'7C'), # (X'7B'), or $ (X'5B')).

**location-name**
An SQL identifier that designates the name of a location. A location name is 1 to 16 bytes, does not include alphabetic extenders (national characters), lowercase letters, or Katakana characters. The characters allowed in the delimited form are the same as those allowed in the ordinary form.

**mask-name**
A qualified or unqualified name that designates a mask.

A qualified mask name is a two-part name. The first part is the schema name. The second part is an SQL identifier. A period must separate each of the parts.

A one-part or unqualified mask name is an SQL identifier with an implicit qualifier. The implicit qualifier is an authorization ID, which is determined by the context in which the unqualified name appears as described by the rules in [Qualification of unqualified object names](#).

**package-name**
A qualified or unqualified name that designates a package. The unqualified form of a package-name is an SQL identifier. A package-name must not be a delimited identifier that includes lowercase letters or special characters. A package-name in an SQL statement must be qualified. In some contexts outside of SQL, a package name can be specified as an unqualified name.

**parameter-name**
An SQL identifier that designates a parameter in an SQL procedure or SQL function.

**permission-name**
A qualified or unqualified name that designates a permission.

A qualified permission name is a two-part name. The first part is the schema name. The second part is an SQL identifier. A period must separate each of the parts.
A one-part or unqualified permission name is an SQL identifier with an implicit qualifier. The implicit qualifier is an authorization ID, which is determined by the context in which the unqualified name appears as described by the rules in Qualification of unqualified object names.

**plan-name**
An SQL identifier that designates an application plan. The identifier must not be a delimited identifier that includes lowercase letters or special characters.

**procedure-name**
A qualified or unqualified name that designates a stored procedure.
A fully qualified procedure name is a three-part name. The first part is a location name that identifies the DBMS at which the procedure is stored. The second part is the schema name of the stored procedure. The third part is an SQL identifier. A period must separate each of the parts in a qualified name.
A two-part procedure name is implicitly qualified with the location name of the current server. The first part is the schema name of the stored procedure. The second part is an SQL identifier. A period must separate the two parts.
A one part, or unqualified, procedure name is an SQL identifier with two implicit qualifiers. The first implicit qualifier is the location name of the current server. The second implicit qualifier is the schema name, which is determined by the context in which the unqualified name appears, as described by the rules in Qualification of unqualified object names.
The SQL identifier in a qualified or unqualified name must not be an asterisk (*).

**profile-name**
An SQL identifier that corresponds to a RACF profile name.

**program-name**
An SQL identifier that designates an exit routine.

**role-name**
An unqualified SQL identifier that designates a role. The identifier cannot begin with the characters SYS and cannot be ACCESSCTRL, DATAACCESS, DBADM, DBCtrl, DBMAINT, NONE, NULL, PACKADM, PUBLIC, SECADM, or SQLADM.

**routine-version-id**
An SQL identifier of up to 64 EBCDIC bytes that designates a version of a routine. The UTF-8 representation of the identifier must not exceed 122 bytes.

**savepoint-name**
An unqualified SQL identifier that designates a savepoint.

**schema-name**
An SQL identifier that provides a logical grouping for SQL objects. A schema-name is used as a qualifier of the name of SQL objects.

**seclabel-name**
An SQL identifier that corresponds to the value of the RACF security label. It is recommended that the name not include national characters (@ (X'7C'), # (X'7B'), or $ (X'5B')). If the table is a Unicode table and the security label
name does include national characters, an error might be issued if substitution occurs when Db2 converts the value from EBCDIC to Unicode.

**sequence-name**

A qualified or unqualified name that designates a sequence.

A qualified sequence name is a two-part name. The first part is the schema name. The second part is an SQL identifier. A period must separate each of the parts.

A one-part or unqualified sequence name is an SQL identifier with an implicit qualifier. The implicit qualifier is an authorization ID, which is determined by the context in which the unqualified name appears as described by the rules in the [Unqualified alias, index, JAR file, sequence, table, trigger, and view names](#).

**server-name**

An SQL identifier that designates an application server. The identifier must start with a letter and must not include lowercase letters or special characters.

**specific-name**

A qualified or unqualified name that designates a unique name for a user-defined function.

A qualified specific name is a two-part name. The first part is the schema name. The second part is an SQL identifier, and it must not be an asterisk (*). A period must separate each of the parts.

An unqualified specific name is an SQL identifier with an implicit qualifier. The implicit qualifier is the schema name, which is determined by the context in which the unqualified name appears as described by the rules in the [Unqualified type, function, procedure, global variable, and specific names](#).

A specific name can be used to identify a function to alter, comment on, drop, grant privileges on, revoke privileges from, or be the source function for another function. A specific name cannot be used to invoke a function. In addition to being used in certain SQL statements, a specific name must be used in Db2 commands to uniquely identify a function.

**SQL-condition-name**

An SQL identifier that designates a condition in an SQL routine or trigger.

**SQL-label**

An SQL identifier that designates a label in an SQL routine or trigger.

**SQL-parameter-name**

A qualified or unqualified name that designates a parameter in an SQL routine body. The unqualified form of an SQL-parameter-name is an SQL identifier. The qualified form is a function-name or procedure-name followed by a period and an SQL identifier.

**SQL-variable-name**

A qualified or unqualified name that designates a variable in an SQL routine or trigger body. The unqualified form of an SQL-variable-name is an SQL identifier. The qualified form is an SQL-label followed by a period (.) and an SQL identifier.

**statement-name**

An SQL identifier that designates a prepared SQL statement.

**stogroup-name**

An SQL identifier that designates a storage group.
**synonym**
An SQL identifier that designates a synonym, a table, or a view. The table or view must exist at the current server. A qualified name is never interpreted as a synonym.

**table-name**
A qualified or unqualified name that designates a table.

A fully qualified table name is a three-part name. The first part is a location name that designates the DBMS at which the table is stored. The second part is a schema name. The third part is an SQL identifier. A period must separate each of the parts.

A two-part table name is implicitly qualified by the location name of the current server. The first part is a schema name. The second part is an SQL identifier. A period must separate the two parts.

A one-part or unqualified table name is an SQL identifier with two implicit qualifiers. The first implicit qualifier is the location name of the current server. The second is a schema name, which is determined by the rules set forth in [Unqualified alias, index, JAR file, sequence, table, trigger, and view names](#). For a declared temporary table, the qualifier (the second part in a three-part name and the first part in a two-part name) must be SESSION.

For complete details on specifying a name when a declared temporary table is defined and then later referring to that declared temporary table in other SQL statements, see [DECLARE GLOBAL TEMPORARY TABLE](#).

**table-space-name**
An SQL identifier that designates a table space of an identified database. The identifier must start with a letter and must not include special characters. If a database is not identified, DSND804 is implicit.

**trigger-name**
A qualified or unqualified name that designates a trigger.

A qualified trigger name is a two-part name. The first part is the schema name of the trigger. The second part is an SQL identifier. A period must separate each of the parts.

An unqualified trigger name is an SQL identifier with an implicit qualifier. The implicit qualifier is the schema name, which is determined by the context in which the unqualified name appears as described by the rules in [Unqualified alias, index, JAR file, sequence, table, trigger, and view names](#).

**trigger-version-id**
An SQL identifier of up to 64 EBCDIC bytes that designates a version of a trigger. The UTF-8 representation of the identifier must not exceed 122 bytes.

**view-name**
A qualified or unqualified name that designates a view.

A fully qualified view name is a three-part name. The first part is a location name that designates the DBMS where the view is defined. The second part is a schema name. The third part is an SQL identifier. A period must separate each of the parts.

A two-part view name is implicitly qualified by the location name of the current server. The first part is a schema name. The second part is an SQL identifier. A period must separate the two parts.
A one-part or unqualified view name is an SQL identifier with two implicit qualifiers. The first implicit qualifier is the location name of the current server. The second is a schema name, which is determined by the context in which the unqualified name appears as described by the rules in Unqualified alias, index, JAR file, sequence, table, trigger, and view names.

**XML-attribute-name**
An identifier that is used as an XML attribute name.

**XML-element-name**
An identifier that is used as an XML element name.

### SQL path

The *SQL path* is an ordered list of schema names. Db2 uses the path to resolve the schema name for certain unqualified object names that appear in any context other than as the main object of an ALTER, CREATE, DROP, COMMENT, GRANT, RENAME, or REVOKE statement.

Db2 uses the path to resolve the schema name for the following object names:
- data types (both built-in types and distinct types)
- functions
- stored procedures
- global variables

Searching through the path from left to right, Db2 implicitly qualifies the object name with the first schema name in the SQL path that contains the same object with the same unqualified name for which the user has appropriate authorization. For functions, Db2 uses a process called function resolution in conjunction with the SQL path to determine which function to choose because several functions with the same name and number of parameters but different parameter data types might be defined in the same schema or other schemas in the SQL path. (For details, see “Function resolution” on page 251.) For procedures, Db2 selects a matching procedure name only if the number of parameters is also the same.

The SQL path does not apply to unqualified procedure names in ASSOCIATE LOCATOR and DESCRIBE PROCEDURE statements. For these statements, an implicit schema name is not generated.

For an example of how Db2 uses the SQL path to resolve the schema name, assume that the SQL path is SMITH, XGRAPHIC, SYSIBM, and that an unqualified distinct type name MYTYPE was specified. Db2 looks for MYTYPE first in schema SMITH, then XGRAPHIC, and then SYSIBM.

The **PATH** option establishes the SQL path that is used to resolve:
- Unqualified data type, global variable, and function names in static SQL statements
- Unqualified procedure names in SQL CALL statements that specify the procedure name as an identifier token (CALL *procedure-name*)

If the **PATH** option was not specified when the plan or package was created or last rebound or when native SQL procedure was defined or last changed, the default value of the SQL path is: SYSIBM, SYSFUN, SYSPROC, *plan or package qualifier*.

The **CURRENT PATH** special register determines the SQL path used to resolve:
• Unqualified data type, global variable, and function names in dynamic SQL statements
• Unqualified procedure names in SQL CALL statements that specify the procedure name in a host variable (CALL host-variable)

Generally, the initial value of the CURRENT PATH special register is one of the following:
• The value of the PATH option
• "SYSIBM", "SYSFUN", "SYSPROC", "SYSIBMADM", value of CURRENT SQLID special register if the PATH option was not specified.

If schema "SYSIBM", "SYSFUN", "SYSPROC", "SYSIBMADM" is not explicitly specified in the SQL path, the schema is implicitly assumed at the front of the path; if all are not specified, they are assumed in the order of "SYSIBM", "SYSFUN", "SYSPROC", "SYSIBMADM".

For example, assume that the SQL path is explicitly specified as SYSIBM, GEORGIA, SMITH. As implicitly assumed schemas, SYSFUN, SYSPROC, and SYSIBMADM are added to the beginning of the explicit path effectively making the path:
SYSFUN, SYSPROC, SYSIBMADM, SYSIBM, GEORGIA, SMITH

For more information about the SQL path for dynamic SQL, see CURRENT PATH and "SET PATH" on page 2325.

Resolution of unqualified object names

Most object names are implicitly or explicitly qualified with a schema name. Synonyms are an exception.

A synonym has a single part name. When Db2 encounters an unqualified name, Db2 must determine which object to process. This process is called name resolution.

When Db2 encounters a single part name in a context where an alias, table, view, or synonym can be specified, Db2 first checks to see if the name refers to a synonym that is defined by the current user.

Qualification of unqualified object names

Unqualified object names, other than synonyms, are implicitly qualified. The rules for qualifying a name differ depending on the type of object that the name identifies.

Unqualified alias, index, JAR file, sequence, table, trigger, and view names

Unqualified alias, index, JAR file, sequence, table, trigger, and view names are implicitly qualified by the default schema.

The default schema is determined as follows:
• For static SQL statements, the default schema is the identifier specified in the QUALIFIER option of the BIND subcommand or the CREATE or ALTER statement for a SQL routine or trigger. If this option is not in effect for the plan, package, or native SQL procedure, the default schema is the authorization ID of the owner of the plan, package, or native SQL procedure.
For dynamic SQL statements, the behavior as specified by the combination of the DYNAMICRULES option and the run time environment determines the default schema. (For a list of these behaviors and the DYNAMICRULES values that determine them, see Table 14 on page 103).

- If DYNAMICRULES run behavior applies, the default schema is the schema in the CURRENT SCHEMA special register. Run behavior is the default.
- If bind behavior applies, the default schema is the identifier that is implicitly or explicitly specified in the QUALIFIER option, as explained for static SQL statements.
- If define behavior applies, the default schema is the owner of the function or stored procedure (the owner is the definer).
- If invoke behavior applies, the default schema is the authorization ID of the invoker of the function or stored procedure.

**Exception**: For bind, define, and invoke behavior, the default schema ofプラン_T, DSN_STMT_TABLE, and DSN_FUNCTION_TABLE (output from the EXPLAIN statement) is always the value in special register CURRENT SQLID.

**Related reference**:

- QUALIFIER bind option (Db2 Commands)
- DYNAMICRULES bind option (Db2 Commands)
- CREATE PROCEDURE (SQL - native)
- ALTER PROCEDURE (SQL - native)
- CREATE TRIGGER (advanced)
- ALTER TRIGGER (advanced)
- CREATE FUNCTION (compiled SQL scalar)
- ALTER FUNCTION (compiled SQL scalar)
- CURRENT SQLID
- EXPLAIN

### Unqualified type, function, procedure, global variable, and specific names

The qualification of unqualified type (built-in type, distinct type, or array type), function, stored procedure, global variable, and specific names depends on the SQL statement in which the unqualified name appears.

- If an unqualified name is the main object of an ALTER, CREATE, COMMENT, DROP, GRANT, or REVOKE statement, the name is implicitly qualified with a schema name as follows:
  - In a static statement, the implicit schema name is the identifier specified in the QUALIFIER option of the BIND subcommand or the CREATE or ALTER statement for a SQL routine or trigger. If this option is not in effect for the package or procedure, the implicit qualifier is the authorization ID of the owner of the package or procedure.
  - In a dynamic statement, the implicit schema name is the schema in the CURRENT SCHEMA special register.
- Otherwise, the implicit schema name for the unqualified name is determined as follows:
For distinct type and array type names, Db2 searches the SQL path and selects the first schema in the path such that the data type exists in the schema and the user has authorization to use the type.

For global variable names, Db2 searches the SQL path and selects the first schema in the path such that the global variable exists in the schema and the user has authorization to use the global variable.

For function names, Db2 uses the SQL path in conjunction with function resolution, as described in “Function resolution” on page 251.

For stored procedure names in CALL statements, Db2 searches the SQL path and selects the first schema in the path such that the schema contains a procedure with the same name and number of parameters and the user has authorization to use the procedure.

For stored procedure names in ASSOCIATE LOCATORS and DESCRIBE PROCEDURE statements, Db2 does not use the SQL path because an implicit schema name is not generated for these statements.

For information about the SQL path, see SQL path.

**Aliases**

An alias is an alternative name for an object such as a table, view, sequence, or another alias. It can be used to reference an object wherever that object can be referenced directly.

The option of referencing an object by an alias is not explicitly shown in the syntax diagrams or mentioned in the description of SQL statements.

Like tables, views, and sequences, an alias can be created, dropped, and associated with a comment. No authority is necessary to use an alias. However, access to the objects that are referred to by the alias still requires the appropriate authorization for the current statement.

An alias is created using the CREATE ALIAS statement.

An alias name designates an alias when it is preceded by the keyword ALIAS, as in CREATE ALIAS, DROP ALIAS, COMMENT ON ALIAS, and LABEL for an ALIAS. In all other contexts, an alias name designates a table, a view, or a sequence. For example, COMMENT ON ALIAS A specifies a comment about the alias A, whereas COMMENT ON TABLE A specifies a comment about the table or view designated by A.

An alias for a table or a view can be defined at a local server to refer to a table or a view that is at the current server or a remote server. An alias name for a table or view can be used wherever the table name or view name can be used to refer to the table or view in an SQL statement. The rules for forming an alias name for a table or view are the same as the rules for forming a table name or a view name. A fully qualified alias name (a three-part name) can refer to an alias at a remote server. However, the table or view identified by the alias at the remote server must exist at the remote server.

An alias for a sequence can be defined at the current server. An alias name for a sequence can be used wherever the sequence name can be used to refer to the sequence in an SQL statement. The rules for forming an alias name for a sequence are the same as the rules for forming a sequence name.
Statements that use three-part names and refer to distributed data result in DRDA access to the remote site. DRDA access for three-part names is used when the package that contains the query to distributed data is bound using the bind option DBPROTOCOL(DRDA), or the value of the DATABASE PROTOCOL field on installation panel DSNTIP5 is DRDA. When an application program uses three-part name aliases for remote table or view objects and DRDA access, the application program must be bound at each location that is specified in the three-part name. Also, each alias must be defined at the local site. An alias at a remote site can refer to another server if a referenced alias eventually refers to a table or view.

The effect of using an alias in an SQL statement is the same as text substitution. For example, if A is an alias for table Q.T, one of the steps involved in the preparation of SELECT * FROM A is the replacement of ‘A’ by ‘Q.T’.

If an alias is defined as a public alias, it can be referenced by its unqualified name without any impact from the current default schema name. It can also be referenced using the schema qualifier SYSPUBLIC.

- CREATE ALIAS

### Synonyms (deprecated)

A synonym is an alternate name for a table or view. A synonym can be used to reference a table or view in cases where an existing table or view can be referenced. However, Db2 no longer supports the creation of new synonyms.

Unsupported function: Beginning in Db2 12, packages bound with APPLCOMPAT(V12R1M504) or higher cannot issue CREATE SYNONYM statements. Although there are some differences, you can use aliases instead. Unlike synonyms, aliases behave the same for all Db2 family products. For more about aliases, see [Aliases (Introduction to Db2 for z/OS)] and CREATE ALIAS.

Existing synonyms remain supported, but support might be removed in the future.

### Differences between synonyms and aliases

The following table summarizes the differences between aliases and synonyms, which are deprecated.

<table>
<thead>
<tr>
<th>Characteristic</th>
<th>Synonyms (deprecated)</th>
<th>Aliases</th>
</tr>
</thead>
<tbody>
<tr>
<td>[FL 504] Can be created in application compatibility V12R1M504 and higher?</td>
<td>No</td>
<td>Yes</td>
</tr>
<tr>
<td>Requires authorization to create?</td>
<td>No</td>
<td>Yes</td>
</tr>
<tr>
<td>Can be defined on objects not at the current server?</td>
<td>No</td>
<td>Yes</td>
</tr>
<tr>
<td>Can be defined on the name of an object that does not yet exist?</td>
<td>No</td>
<td>Yes, but the object must exist when the alias is used</td>
</tr>
</tbody>
</table>

96 SQL Reference
Table 13. Differences between synonyms and aliases (continued)

<table>
<thead>
<tr>
<th>Characteristic</th>
<th>Synonyms (deprecated)</th>
<th>Aliases</th>
</tr>
</thead>
<tbody>
<tr>
<td>Is dropped when referenced objects are dropped?</td>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>Uses a qualified object name for the object?</td>
<td>No, uses a one-part name</td>
<td>Yes</td>
</tr>
<tr>
<td>Can be referenced or used by users other than the object owner?</td>
<td>No</td>
<td>Yes</td>
</tr>
</tbody>
</table>

The option of referencing a table or view by a synonym is not explicitly shown in the syntax diagrams or mentioned in the description of SQL statements. But synonyms can be referred to in an SQL statement.

Like tables and views, a synonym can be dropped, and associated with a comment. No authority is necessary to use a synonym. However, access to the tables and views that are referenced by the synonym still requires the appropriate authorization for the current statement.

A synonym name designates a synonym when it is preceded by the keyword SYNONYM, as in DROP SYNONYM. In all other contexts, a synonym designates a table or a view. In all other contexts, a synonym designates a local table or view and can be used wherever the name of a table or view can be used in an SQL statement.

The effect of using a synonym in an SQL statement is the same as text substitution. For example, if S is a synonym for Q.T, one of the steps involved in the preparation of SELECT * FROM S is the replacement of 'S' by 'Q.T'.

Authorization, privileges, permissions, masks, and object ownership

Users (as identified by an authorization ID) can successfully execute SQL statements only if they have the authority to perform the specified operation. For example, to create a table, a user must be authorized to create tables.

The two forms of authorization are administrative authority and privileges.

Administrative authority

The holder of administrative authority is charged with the task of controlling Db2 and is responsible for the safety and integrity of the data.

Those with SYSADM authority implicitly have all privileges on all objects and control who will have access to Db2 and the extent of this access.

Those with SECADM authority manage security policies by enforcing row and column access control for tables that contain sensitive data. They define row permissions and column masks, which describe how tables that use row or column access controls should be accessed and which determine whether a trigger or a user-defined function is considered secure for those tables.
Privileges

Privileges are those activities that a user is allowed to perform. Authorized users can create objects, have access to objects that they own, and can pass on privileges on the objects that they own to other users by using the GRANT statement. Privileges can be granted to specific users or to PUBLIC. PUBLIC specifies that a privilege is granted to all users (including to future users).

The REVOKE statement can be used to revoke previously granted privileges.

Row permissions and column masks

A row permission is a database object that expresses an access control rule for a row of a specific table. A row permission is in the form of a search condition that describes to which rows users have access. Row permissions are applied after table privileges (like SELECT or INSERT) are checked.

A column mask is a database object that expresses an access control rule for a specific column in a table. A column mask is in the form of a CASE expression that describes to which column values users have access. Column masks are applied after table privileges (like SELECT or INSERT) are checked.

Row permissions and column masks can be created, changed, and dropped only by those with SECADM authority by using the CREATE MASK, CREATE PERMISSION, and DROP statements. The definition of a permission or a mask can reference other objects. Those with SECADM authority do not need additional privileges to reference those objects, such as SELECT privilege to retrieve from a table or EXECUTE privilege to invoke a user-defined function, in the definition of the row permission or column mask. Multiple row permissions and column masks can be created for a table. Only one column mask can be created for each column in a table. A row permission or a column mask can be created before row or column access control is enforced for a table. The definition of the row permission and the column mask is stored in the Db2 catalog. However, the permission and the mask do not take effect until the ALTER TABLE statement with the ACTIVATE ROW ACCESS CONTROL clause is used to enforce row access control or the ACTIVATE COLUMN ACCESS CONTROL clause is used to enforce column access control on the table.

When an ALTER TABLE statement is used to explicitly activate row access control for a table, a default row permission is implicitly created for the table which prevents all access to the table. After row access controls have been activated for a table, if the table is referenced explicitly in a data change statement and if multiple row permissions are defined for the table, a row access control search condition is derived by using the logical OR operator with the search condition of each defined row permission.

When an ALTER TABLE statement is used to explicitly activate column access control for a table, access to the table is not restricted. However, if the table is referenced in a data change statement, all column masks that have been created for the table are applied to mask the column values that are referenced in the output of the queries or to determine the column values that are used in the data change statements.

The authorization ID or role for the statement does not need authority to reference objects that are specified in the definition of the row permission or column mask.
Object ownership

When an object is created, one authorization ID is assigned ownership of the object. Ownership means that the user is authorized to reference the object in any applicable SQL statement. The privileges on the object can be granted by the owner, and cannot be revoked from the owner. Owners of views only receive the level of privileges that they have on the underlying table or view. The owner of the object that is being created is determined as follows:

• If the schema qualifier is not explicitly specified, the owner depends on how the CREATE statement is issued:
  – If the CREATE statement is embedded in a program, the owner of the object that is being created is the authorization ID that serves as the implicit qualifier for unqualified object names. This is the authorization ID that is in the QUALIFIER option when the plan, package, or native SQL procedure (that contains the CREATE statement) is created or last changed. If the QUALIFIER option is not used, the owner of the object is the authorization ID in the OWNER option when the plan, package, or native SQL procedure is created or last changed. If the OWNER option is not used, the owner is the owner of the plan, package, or native SQL procedure. If the plan or package was last bound in a trusted context that is defined with the ROLE AS OBJECT OWNER clause, a role is the owner.
  – If the CREATE statement is dynamically prepared, the owner of the object that is being created is the authorization ID of the process.
  – If the CREATE statement is execute in a trusted context that is defined with the ROLE AS OBJECT OWNER clause, the role of the primary authorization ID is the owner.

• If the schema qualifier is explicitly specified, the owner depends on the type of object that is being created unless the CREATE statement is executed in a trusted context that is defined with the ROLE AS OBJECT OWNER clause. When the CREATE statement is executed in a trusted context that is defined with the ROLE AS OBJECT OWNER clause, the owner of the object is determined as follows:
  – If the CREATE statement is embedded in a program, the role that owns the plan or package is the owner of the object.
  – If the CREATE statement is dynamically prepared, the primary authorization ID is the owner.

If the schema qualifier is explicitly specified, and the CREATE statement is not executed in a trusted context that is defined with the ROLE AS OBJECT OWNER clause, the owner depends on the type of object that is being created:

• For an alias, auxiliary table, created global temporary table, table, or view, the owner of the object that is being created is the same as the explicit schema name.
• For a user-defined distinct type, user-defined function, procedure, sequence, JAR files, or trigger, the owner of the object that is being created is the authorization ID of the process.

The rules that determine ownership of row permissions and column masks are the same as those that determine ownership of objects like user-defined distinct types, user-defined functions, procedures, sequences, JAR files, or trigger.
The owner of a row permission or a column mask does not have implicit owner privileges. Only users with SECADM authority can manage and maintain row permissions and column masks.

Authorization IDs, roles, and authorization names

Processes can successfully execute SQL statements only if they have the necessary authority. A process derives this authority from its authorization IDs. An authorization ID can also designate a user, a group of users, or a role.

An authorization ID is a character string that is associated with a process that is checked to determine the authority to perform a specified operation.

Db2 does not control the association of users to user groups. However, Db2 does control the association between users and roles when a trusted context is defined.

Db2 uses authorization IDs to provide authorization checking of SQL statements.

Whenever a connection is established between Db2 and a process, Db2 obtains an authorization ID and passes it to the authorization connection or sign-on exit routine. The list of one or more authorization IDs that is returned by the exit routine are used as the authorization IDs of the process. If the process is running in a trusted context with a role, the authorization IDs of the process includes this role.

Every process has exactly one primary authorization ID. Any other authorization IDs of a process are secondary authorization IDs. The use of these authorization IDs depends on the type of process (bind process, application process, or process involved in the creation of objects).

Primary authorization ID

An authorization ID that is used to established a connection between Db2 and an application process.

Secondary authorization ID

An authorization ID that is associated with a primary authorization ID.

Secondary authorization IDs includes all the authorization IDs that have been associated with a primary authorization ID by the connection or sign-on authorization exit routine, the CURRENT SQLID (when different from the primary authorization ID), and other authorization IDs like the stored procedure definer and call package owner for stored procedure package checking.

Authorization ID of the process

The user’s primary and secondary authorization IDs. If the process is running in a trusted context with a role, the authorization IDs of the process includes this role.

A role is a database entity that groups together one or more privileges. A role is available only when the process is run in a trusted context. Users are associated with a role in the definition of a trusted context.

A trusted context can have a default role, specific roles for individual users, or no roles at all. A user in a trusted context can have only one active role. This is the role that is specifically defined for the user or the default role of the trusted context. The following restrictions apply to roles:

• A role cannot be a primary authorization ID.
• A role cannot be set by using a SET CURRENT SQLID statement.
• A role can be the schema qualifier of an object. However, when it is used as a
schema qualifier, a role is considered to be a character string and does not add
any implicit schema privileges (ALTERIN, CREATEIN, or DROPIN) to this role.
• A role must already exist for privileges to be granted to it.

The role that is in effect for a user is considered to be one of the secondary
authorization IDs of the user.

Do not confuse an authorization-name that is specified in an SQL statement with an
authorization ID of a process.

Example: Assume that SMITH is your TSO logon, DYNAMICRULES run behavior
is in effect, and you execute the following statements interactively:

```
CREATE TABLE TDEPT LIKE DSN8C10.DEPT;
GRANT SELECT ON TDEPT TO KEENE;
```

Also assume that your site has not replaced the default exit routine for connection
authorization and that you have not executed the SET CURRENT SQLID
statement. Thus, when the GRANT statement is prepared and executed by SPUFI,
the SQL authorization ID is SMITH. KEENE is an authorization name that is
specified in the GRANT statement.

Authorization to execute the GRANT statement is checked against SMITH. The
authorization rule is that the privilege set that is designated by SMITH must
include the SELECT privilege with the GRANT option on SMITH,TDEPT. No
check that involves KEENE is performed. If the GRANT statement specifies a role,
the existence of the role is checked.

Authorization IDs and schema names

An authorization ID that has the same name as the name of a schema implicitly
has certain privileges for that schema.

If an authorization ID is not a role and has the same name as the name of a
schema, that authorization ID implicitly has the following privileges for that
schema:

• CREATEIN privilege
• ALTERIN privilege
• DROPIN privilege

Authorization IDs and statement preparation

The authorization ID that is specified as the owner of the plan or package must be
one of the authorization IDs of the bind process. The owner can be set to any
value if one of the authorization IDs of the bind process has SYSADM or SYSCTRL
authority.

A process that creates a plan or package is called a bind process. The connection
with Db2 is the result of the execution of a BIND or REBIND subcommand. Both
subcommands allow for the specification of the authorization ID of the owner of
the plan or package.

BINDAGENT can specify an owner other than himself (or one of his
representatives), but it has to be someone that granted him BINDAGENT. The
default owner for BIND is the primary authorization ID. The default owner for
REBIND is the previous owner of the plan or package (ownership is unchanged if an owner is not explicitly specified). If the BIND or REBIND is performed in a trusted context that is defined with the ROLE AS OBJECT OWNER clause, the owner of the plan or package is a role. If the OWNER bind option is specified, the role that is specified in it is the owner, otherwise the role that performs the bind or rebinding becomes the owner.

The authorization ID that is used for the authorization checking of embedded SQL statements is that of the owner of the plan or package. If the application is bound in a trusted context using the ROLE AS OBJECT OWNER clause, the authorization ID that is used for authorization checking is the role that owns the plan or package, otherwise the authorization ID is the authorization ID of the owner of the plan or package. If an embedded SQL statement refers to tables or views at a Db2 subsystem other than the one at which the plan or package is bound, the authorization checking is deferred until run time. For more information on this, see “Authorization IDs and remote execution” on page 105.

If VALIDATE(BIND) is specified, the privileges required to use or manipulate objects at the Db2 subsystem at which the plan or package is bound must exist at bind time. If the privileges or the referenced objects do not exist and SQLERROR(NOPACKAGE) is in effect, the bind operation is unsuccessful. If SQLERROR(CONTINUE) is specified, then the bind is successful and any statements in error are flagged. If any statements in error are flagged, an error will occur when you attempt to execute them at run time.

If a plan or package is bound with VALIDATE(RUN), authorization checking is still performed at bind time, but the referenced objects and the privileges required to use these objects need not exist at this time. If any privilege required for a statement does not exist at bind time, an authorization check is performed whenever the statement is first executed within a unit of work, and all privileges required for the statement must exist at that time. If any privilege does not exist, execution of the statement is unsuccessful. When the authorization check is performed at run time, it is performed against the plan or package owner, not the SQL authorization ID. For the effect of this option on cursors, see “DECLARE CURSOR” on page 1955.

Authorization IDs and dynamic SQL

The bind option DYNAMICRULES determines the authorization ID that is used for checking authorization when dynamic SQL statements are processed. The set of values for the authorization ID and other dynamic SQL attributes is called the dynamic SQL statement behavior. The four possible behaviors are run, bind, define, and invoke.
This discussion applies to dynamic SQL statements that refer to objects at the current server. For those that refer to objects elsewhere, see “Authorization IDs and remote execution” on page 105.

In addition to determining the authorization ID, DYNAMICRULES also controls other dynamic SQL attributes such as the implicit qualifier that is used for unqualified alias, index, sequence, table, trigger, and view names; the source for application programming options; and whether certain SQL statements can be invoked dynamically.

As the following table shows, the combination of the value of the DYNAMICRULES option and the run time environment determines which of the four SQL statement behavior is used. DYNAMICRULES(RUN), which implies run behavior, is the default.

<table>
<thead>
<tr>
<th>DYNAMICRULES value</th>
<th>Stand-alone program environment</th>
<th>User-defined function or stored procedure environment</th>
</tr>
</thead>
<tbody>
<tr>
<td>RUN</td>
<td>Run behavior</td>
<td>Run behavior</td>
</tr>
<tr>
<td>BIND</td>
<td>Bind behavior</td>
<td>Bind behavior</td>
</tr>
<tr>
<td>DEFINERUN</td>
<td>Run behavior</td>
<td>Define behavior</td>
</tr>
<tr>
<td>DEFINEBIND</td>
<td>Bind behavior</td>
<td>Define behavior</td>
</tr>
<tr>
<td>INVOKERUN</td>
<td>Run behavior</td>
<td>Invoke behavior</td>
</tr>
<tr>
<td>INVOKEBIND</td>
<td>Bind behavior</td>
<td>Invoke behavior</td>
</tr>
</tbody>
</table>

Note: BIND and RUN values can be specified for packages, plans, and native SQL procedures. The other values can be specified for packages and native SQL procedures but not for plans.

In the following behavior descriptions, a package that *runs under* a user-defined function or stored procedure package is a package whose associated program meets one of the following conditions:

- The program is called by a user-defined function or stored procedure.
- The program is in a series of nested calls that start with a user-defined function or stored procedure.

**Run behavior**

Db2 uses the authorization IDs of the application process and the SQL authorization ID (the value of special register CURRENT SQLID) for authorization checking of dynamic SQL statements. If the process is running in a trusted context with a role associated with the primary authorization ID, the authorization IDs of the application process include this role.

A process that uses a plan and its associated packages is called an *application process*. At any time, the SQL authorization ID is the value of CURRENT SQLID. This SQL special register can be initialized by the connection or sign-on exit routine. If the exit routine does not set a value, the initial value of CURRENT SQLID is the primary authorization ID of the process. You can use the SQL statement SET CURRENT SQLID to change the value of CURRENT SQLID. Unless some authorization ID of
the process has SYSADM authority, the new value must be one of the authorization IDs of the process. Thus, CURRENT SQLID usually contains either the primary authorization ID of the process or one of its secondary authorization IDs. The CURRENT SQLID cannot contain a role.

**Privilege set:** If the dynamically prepared statement is other than an ALTER, CREATE, COMMENT, DROP, GRANT, RENAME, or REVOKE statement, each privilege required for the statement can be a privilege designated by any authorization ID of the process. Therefore, the privilege set is the union of the set of privileges held by each authorization ID of the process. When the process is running in a trusted context with a role, the authorization IDs of the process include this role.

If the dynamic SQL statement is an ALTER, CREATE, COMMENT, DROP, GRANT, RENAME, or REVOKE statement, the only authorization ID that is used for authorization checking is the SQL authorization ID. Therefore, the privilege set is the privileges held by that single authorization ID of the process. If the process is running in a trusted context using the ROLE AS OBJECT OWNER clause for the a CREATE, GRANT, or REVOKE statement, the single authorization ID of the process that is checked is the role that is in effect.

**Implicit qualification:** As explained under "Qualification of unqualified object names" on page 93, when an SQL statement is dynamically prepared, the values of the CURRENT SCHEMA special register is used as the implicit qualifier. For example, it is used as the implicit qualifier for all unqualified tables, aliases, views, indexes, and sequences.

**Bind behavior**

The same rules that are used to determine the authorization ID for static (embedded) statements are used for dynamic statements. Db2 uses the authorization ID of the owner of the package or plan for authorization checking of dynamic SQL statements, as explained in detail under “Authorization IDs and statement preparation” on page 101.

**Privilege set:** The privilege set is the privileges that are held by the owner of the package or plan.

**Implicit qualification:** The identifier specified in the QUALIFIER option of the bind command that is used to bind the SQL statements, or the CREATE PROCEDURE or ALTER PROCEDURE statement that is used to create a version of an SQL procedure is the implicit qualifier for all unqualified tables, views, aliases, indexes, and sequences. If the QUALIFIER option was not used when the plan, package, or native SQL procedure was created or last changed, the implicit qualifier is the owner of the plan, package, or native SQL procedure.

**Define behavior**

Define behavior applies only if the dynamic SQL statement is in a package that is run as a stored procedure or user-defined function (or runs under a stored procedure or user-defined function package), and the package was bound with DYNAMICRULES(DEFINERUN). Db2 uses the authorization ID of the stored procedure or user-defined function owner (the definer) for authorization checking of dynamic SQL statements in the application package.

**Privilege set:** The privilege set is the privileges that are held by the authorization ID of the owner.
**Implicit qualification**: The stored procedure or user-defined function owner is also the implicit qualifier. For example, the owner is the implicit qualifier for unqualified table, view, alias, index, and sequence names.

**Invoke behavior**
Invoke behavior applies only if the dynamic SQL statement is in a package that is run as a stored procedure or user-defined function (or runs under a stored procedure or user-defined function package), and the package was bound with DYNAMICRULES(INVOKEBIND) or DYNAMICRULES(INVOKEBIND). Db2 uses the stored procedure or user-defined function invoker for authorization checking of dynamic SQL statements in the application package. The invoker can also be a role.

**Privilege set**: The privilege set is the privileges that are held by the invoker. However, if the invoker is the primary authorization ID of the process or the CURRENT SQLID value, secondary authorization IDs are also checked. This includes the role of the primary authorization ID, if running in a trusted context with a role. In that case, the privilege set is the union of the set of privileges held by each authorization ID of the process.

**Implicit qualification**: The stored procedure or user-defined function invoker is also the implicit qualifier. For example, it is the implicit qualifier for unqualified table, view, alias, index, and sequence names. The invoker can also be a role.

**Restricted statements when run behavior does not apply**: When bind, define, or invoke behavior is in effect, you cannot use the following dynamic SQL statements: ALTER, CREATE, COMMENT, DROP, GRANT, RENAME, and REVOKE.

**Related reference**:
- [BIND and REBIND options for packages, plans, and services (Db2 Commands)]
- [Privileges required for using dynamic SQL statements (Managing Security)]

**Authorization IDs and remote execution**

The authorization rules for remote execution depend on whether the distributed operation is DRDA access with a Db2 for z/OS server and requester. DRDA access with a server and requester other than Db2 can also affect the authorization rules for remote execution.

**DRDA access with Db2 for z/OS only**
To prepare and execute SQL statements using DRDA access, certain privileges are required by the package owner and additional privileges are required by the user who invokes the application.

Any static statement executed using DRDA access is in a package bound at a server other than the local Db2 subsystem. Before the package can be bound, its owner must have the BINDADD privilege and the CREATE IN privilege for the package's collection. Also required are enough privileges to execute the package's static SQL statements that refer to data on that server. All these privileges are recorded in the Db2 catalog of the server, not in the catalog of the local Db2 subsystem. Such privileges must be granted by GRANT statements executed at the server. This allows the server to control the creation and use of packages that are run from other DBMSs.
A user who invokes an application that has a plan at the local Db2 subsystem
must have the EXECUTE privilege on the plan recorded in the Db2 catalog of the
local subsystem. If that application uses a package that is bound at a Db2 server
other than the local Db2 requester, the EXECUTE privilege on the package must
also be recorded in the Db2 catalog of the server. The ID that must hold the
authorization to run the package at the Db2 server depends on the value of the
PRIVATE_PROTOCOL subsystem parameter at the Db2 server:

- If PRIVATE_PROTOCOL is set to NO, EXECUTE authority on the package must
  be explicitly granted to the primary user ID or an associated secondary ID at the
  Db2 server. If the local requester application invokes a stored procedure that
  resides at the Db2 server, EXECUTE authority on the stored procedure package
  must be explicitly granted at the Db2 server to the owner of the package that
  issues the CALL statement if either of the following is true:
    - The owner of the stored procedure does not have the authority to execute the
      remote stored procedure package.
    - The CALL statement is in the form of CALL: host-variable and neither the
      primary user ID nor an associated secondary ID has the authority to execute
      the remote stored procedure package.

- If PRIVATE_PROTOCOL is not set to NO, EXECUTE authority on the package
  must be explicitly granted to the local requester plan owner at the Db2 server.
  The plan owner needs no other privilege to execute the package. If the local
  requester application invokes a stored procedure that resides at the Db2 server,
  EXECUTE authority on the stored procedure package must be explicitly granted
  at the Db2 server to the Db2 requester plan owner of the application that issues
  the CALL statement if either of the following is true:
    - The owner of the stored procedure does not have the authority to execute the
      remote stored procedure package.
    - The CALL statement is in the form of CALL: host-variable and neither the
      primary user ID nor an associated secondary ID has the authority to execute
      the remote stored procedure package.

EXECUTE authority is also required to use a package for a user-defined function,
trigger, or stored procedure that resides at the Db2 server. However, except as
previously described for a specific stored procedure case, the
PRIVATE_PROTOCOL subsystem parameter is not used to determine the ID that is
required to hold the EXECUTE privilege on that package. The EXECUTE privilege
on that package must be recorded in the Db2 catalog of the server.

Having the appropriate privileges recorded as described above allows the
execution of the static SQL statements in the package, and the execution of
dynamic SQL statements if DYNAMICRULES bind, define, or invoke behavior is in
effect. If DYNAMICRULES run behavior is in effect, the authorization rules for
dynamic SQL statements is different. Authorization for the execution of dynamic
SQL statements must come from the set of authorization IDs that are derived
during connection processing, and, if the process is running in a trusted
connection, the role that is in effect. An application goes through connection
processing when it first connects to a server or when it reuses a CICS or IMS
thread that has a different primary authorization ID.

If an application uses Recoverable Resources Manager Services attachment facility
(RRSAF) and has no plan, authority to execute the package is determined in the
same way as when the requester is not Db2 for z/OS.

DRDA access with a server or requester other than Db2

Related tasks:
- Checking authorization at a Db2 database server (Managing Security)

**DRDA access with a server or requester other than Db2**

Specific privileges are required depending on whether Db2 is the server or the requester involved in DRDA access.

*Db2 for z/OS as the server:* If the requester is not a Db2 for z/OS subsystem, there is no Db2 application plan involved. In this case, the privilege set of the authorization ID, which is determined by the DYNAMICRULES behavior, must have the EXECUTE privilege on the package. Dynamic SQL statements in the package are executed according to the DYNAMICRULES behavior, as described in Authorization IDs and dynamic SQL.

*Db2 for z/OS as the requester:* The authorization rules for remote execution are those of the server.

**Authorization ID translations**

When certain authorization IDs are sent to a remote DBMS, those authorization IDs might undergo translation before being used.

Translation can occur for a primary authorization ID, the authorization ID of the owner of an application plan, or the authorization ID of the owner of a package. For example, a user known as SMITH at the local DBMS could be known, after translation, as JONES at the server. Likewise, a package owner known as GRAY could be known as WINTERS at the server. If so, JONES or WINTERS would be used, instead of SMITH or GRAY, to determine the authorization ID for dynamic SQL statements in the package. If the DYNAMICRULES run behavior applies, JONES, who is executing the dynamic statement at the server, is used. If DYNAMICRULES bind behavior applies, WINTERS, the package owner at the server, is used.

Two sets of communications database (CDB) catalog tables control the translations. One set is at the local Db2, and the other set is at the remote Db2. Translation can take place at either or both sites.

**Related concepts:**
- Communications database for the requester (Managing Security)
- Communications database for the server (Managing Security)

**Other security measures**

Even if Db2 authority requirements are satisfied, other security measures can be in effect when distributed data is accessed.

The fact that Db2 authority requirements are satisfied does not guarantee that a user has access to a given server. Other security measures can also come into play. For example, requests to execute remote SQL statements could be denied based on Resource Access Control Facility (RACF) considerations. Developing such security measures is discussed in *Db2 Administration Guide*.

### Data types

Db2 supports both IBM-supplied data types (built-in data types) and user-defined data types (distinct types).
The smallest unit of data that can be manipulated in SQL is called a \textit{value}. How values are interpreted depends on the data type of their source. The sources of values are:

- Columns
- Constants
- Expressions
- Functions
- Special registers
- Variables (such as host variables, SQL variables, global variables, parameter markers, and parameters of routines)

The following topics describes the built-in data types and distinct types.

\textbf{Figure 22} shows the built-in data types that Db2 supports.

\textbf{Figure 22. Built-in data types supported by Db2}

\textbf{Nulls}

All data types include the null value. Distinct from all nonnull values, the null value is a special value that denotes the absence of a (nonnull) value.

Although all data types include the null value, some sources of values cannot provide the null value. For example, constants, columns that are defined as NOT NULL, and special registers cannot contain null values; the COUNT and COUNT\_BIG functions cannot return a null value; and ROWID columns cannot store a null value although a null value can be returned for a ROWID column as the result of a query.

\textbf{Numbers}

The numeric data types are categorized as exact numerics: binary integer and decimal; decimal floating point; and approximate numerics: floating-point
Binary integer includes small integer, large integer, and big integer. Binary numbers are exact representations of integers. Decimal numbers are exact representations of real numbers. Binary and decimal numbers are considered exact numeric types. Decimal floating point numbers include DECFLOAT(16) and DECFLOAT(34), which are capable of representing either 16 or 34 significant digits. Floating-point includes single precision and double precision. Floating-point numbers are approximations of real numbers and are considered approximate numeric types.

All numbers have a sign, a precision, and a scale. If a column value is zero, the sign is positive. Decimal floating point has distinct values for a number and the same number with various exponents (for example: 0.0, 0.00, 0.0E5, 1.0, 1.00, 1.0000). The precision is the total number of binary or decimal digits excluding the sign. The scale is the total number of binary or decimal digits to the right of the decimal point. If there is no decimal point, the scale is zero.

**Small integer (SMALLINT)**
A small integer is a binary integer with a precision of 15 bits. The range of small integers is -32768 to +32767.

**Large integer (INTEGER)**
A large integer is a binary integer with a precision of 31 bits.

The range of large integers is -2147483648 to +2147483647.

**Big integer (BIGINT)**
A big integer is a binary integer with a precision of 63 bits.

The range of big integers is -9223372036854775808 to +9223372036854775807.

**Single precision floating-point (REAL)**
A single precision floating-point number is a short (32 bits) floating-point number.

The range of single precision floating-point numbers is about -7.2E+75 to 7.2E+75. In this range, the largest negative value is about -5.4E-79, and the smallest positive value is about 5.4E-079.

**Double precision floating-point (DOUBLE or FLOAT)**
A double precision floating-point number is a long (64 bits) floating-point number.

The range of double precision floating-point numbers is about -7.2E+75 to 7.2E+75. In this range, the largest negative value is about -5.4E-79, and the smallest positive value is about 5.4E-079.

**Decimal (DECIMAL or NUMERIC)**
A decimal number is a packed decimal number with an implicit decimal point.

The position of the decimal point is determined by the precision and the scale of the number. The scale, which is the number of digits in the fractional part of the number, cannot be negative or greater than the precision. The maximum precision is 31 digits.

All values of a decimal column have the same precision and scale. The range of a decimal variable or the numbers in a decimal column is -n to +n, where n is the largest positive number that can be represented with the applicable precision and scale. The maximum range is $1 \cdot 10^{31}$ to $10^{31} - 1$. 

Chapter 2. Language elements 109
Decimal floating-point (DECFLOAT)

A decimal floating-point value is an IEEE 754r number with a decimal point. The position of the decimal point is stored in each decimal floating-point value.

The maximum precision is 34 digits.

The range of a decimal floating point number is either 16 or 34 digits of precision, and an exponent range of respectively $10^{-383}$ to $10^{+384}$ or $10^{-6143}$ to $10^{+6144}$.

In addition to the finite numbers, decimal floating point numbers are able to represent one of the following named special values:

- **Infinity** - a value that represents a number whose magnitude is infinitely large.
- **Quiet NaN** - a value that represents undefined results which does not cause an invalid number condition.
- **Signaling NaN** - a value that represents undefined results which will cause an invalid number condition if used in any numerical operation.

When a number has one of these special values, its coefficient and exponent are undefined. The sign of an infinity is significant (that is, it is possible to have both positive and negative infinity). The sign of a NaN has no meaning for arithmetic operations. INF can be used in place of INFINITY.

Numeric host variables

Numeric host variables can be defined in all languages with a few exceptions.

Binary integer variables can be defined in all host languages.

Floating-point variables can be defined in all host languages. All languages, except Java, support System/390 floating-point format. Assembler, C, C++, PL/I, and Java also support IEEE floating-point format. In assembler, C, C++, and PL/I programs, the SQL processing option FLOA T tells Db2 whether floating-point variables contain data in System/390 floating-point format or IEEE floating-point format. The contents of floating-point host variables must match the format that is specified with the FLOA T SQL processing option.

Decimal variables can be defined in all host languages except Fortran.

In COBOL, decimal numbers can be represented in the following formats:

- Packed decimal format, denoted by USAGE PACKED-DECIMAL or COMP-3
- External decimal format, denoted by USAGE DISPLAY with SIGN LEADING SEPARATE
- NATIONAL decimal format denoted by USAGE NATIONAL and SIGN LEADING SEPARATE

Decimal floating-point variables can be defined in Assembler, C, C++, PL/I, and Java.

String representations of numeric values

String representations of numeric values can be used in some contexts. A valid string representation of a numeric value must conform to the rules for numeric constants.

The encoding scheme in use determines what type of strings can be used for string representation of numeric values. For ASCII and EBCDIC, a string representation
of a numeric value must be a character string. For UNICODE, a string representation of a numeric value can be either a character string or a graphic string. Thus, the only time a graphic string can be used for a numeric value is when the encoding scheme is UNICODE.

When a decimal number is cast to a string (for example, using a CAST specification), the implicit decimal point is replaced by the default decimal separator character that is in effect when the statement is prepared.

When a string is cast to a decimal value (for example, using a CAST specification), the default decimal separator character in effect when the statement was prepared is used to interpret the string.

When a floating point or decimal floating-point number is cast to a string (for example, using a CAST specification), or a string is cast to a floating point or decimal floating-point number, the decimal separator character must be a period (.)

For more information, see [Constants](#).

**Subnormal numbers and underflow**

The decimal floating-point data type has a set of non-zero numbers that fall outside the range of normal decimal floating-point values. These numbers are called subnormal.

Non-zero numbers whose adjusted exponents are less than \( E_{\text{min}}^{4} \) are called subnormal numbers. These subnormal numbers are accepted as operands for all operations and can result from any operation. If a result is subnormal before any rounding occurs, the subnormal condition is returned.

For a subnormal result, the minimum values of the exponent becomes \( E_{\text{min}} - \text{(precision-1)} \), called \( E_{\text{tiny}} \), where precision is the working precision. If necessary, the result will be rounded to ensure that the exponent is no smaller than \( E_{\text{tiny}} \). If the result becomes inexact during rounding, an underflow condition is returned. A subnormal result does not always return the underflow condition but will always return the subnormal condition.

When a number underflows to zero during a calculation, its exponent will be \( E_{\text{tiny}} \). The maximum value of the exponent is unaffected.

The maximum value of the exponent for subnormal numbers is the same as the minimum value of the exponent which can arise during operations that do not result in subnormal numbers. This occurs where the length of the coefficient in decimal digits is equal to the precision.

**Character strings**

A character string is a sequence of bytes. The length of the string is the number of bytes in the sequence. If the length is zero, the value is called the empty string. The empty string should not be confused with the null value.

**Default CCSIDs**

The value of the field MIXED DATA (on installation panel DSNTIPF) determines the default CCSIDs for a character string.

The following table shows how the value of the field MIXED DATA (on installation panel DSNTIPF) determines the default CCSIDs for a character string.
### Table 15. Default CCSIDs for character strings

<table>
<thead>
<tr>
<th>Encoding scheme</th>
<th>Value of MIXED DATA field</th>
<th>Default attribute</th>
</tr>
</thead>
<tbody>
<tr>
<td>ASCII or EBCDIC</td>
<td>NO</td>
<td>Character: SBCS</td>
</tr>
<tr>
<td></td>
<td></td>
<td>The value of the ASCII CCSID or EBCDIC CCSID field on installation panel determines the system CCSID for SBCS data.</td>
</tr>
<tr>
<td>ASCII or EBCDIC</td>
<td>YES</td>
<td>Character: MIXED</td>
</tr>
<tr>
<td></td>
<td></td>
<td>The value of the ASCII CCSID or EBCDIC CCSID field on installation panel DSNTIPF determines the system CCSID for SBCS data, MIXED, and graphic data.</td>
</tr>
<tr>
<td>Unicode</td>
<td>Not applicable</td>
<td>Character: MIXED</td>
</tr>
<tr>
<td></td>
<td></td>
<td>The CCSIDs are:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• 367 for SBCS data</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• 1208 for MIXED data</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• 1200 for graphic data</td>
</tr>
</tbody>
</table>

The MIXED DATA field does not apply to Unicode columns in EBCDIC tables. Those columns follow the same rules that are shown for the Unicode encoding scheme in the previous table.

**Related concepts:**
"Unicode column in an EBCDIC table” on page 123

### Fixed-length character strings

When fixed-length character string distinct types, columns, and variables are defined, the length attribute is specified, and all values have the same length. For a fixed-length character string, the length attribute must be between 1 and 255 inclusive.

### Varying-length character strings

The types of varying-length character strings are VARCHAR and character large object (CLOB). A CLOB is a type of LOB. A CLOB column is useful for storing large amounts of character data, such as documents written with a single character set.

When varying-length character strings, distinct types, columns, and variables are defined, the maximum length is specified and this length becomes the length attribute except for C NUL-terminated strings. Actual values might have a smaller value. For varying-length character strings, the length specifies the number of bytes.

For a VARCHAR string, the length attribute must be in the range 1 - 32704. For a VARCHAR column, the maximum for the length attribute is determined by the record size that is associated with the table, as described in Maximum record size the description of the CREATE TABLE statement. For a CLOB string, the length attribute must be in the range 1 - 2147483647 inclusive. For more information about CLOBs, see Large objects (LOBs).

### Character string variables

Character string variables follow specific rules for use in host languages.

- Fixed-length character string variables can be used in all languages except REXX and Java. In C, CHAR string variables are limited to a length of 1.
• Varying-length character string variables can be used in all host languages with the following exceptions:
  – Fortran: varying-length non-LOB character strings cannot be used.
  – Assembler, C, and COBOL: varying-length non-LOB strings are simulated as described in Db2 Application Programming and SQL Guide. In C, NUL-terminated strings can also be used.
  – REXX: CLOBs and DBCLOBs cannot be used.

**Character string encoding schemes**
The method of representing DBCS and MBCS characters within a mixed string differs among the encoding schemes.

Each character string is further defined as one of the following subtypes:

**Bit data**
Data that is not associated with a coded character set and, therefore, is never converted. The CCSID for bit data is X'FFFF' (65535). The bytes do not represent characters.

Bit data is a form of character data. The pad character is a blank for assignments to bit data; the pad character is X'00' for assignments to binary data. It is recommended that binary data be used instead of character for bit data.

If both operands in a predicate are EBCDIC, both operands are padded with X'40'. Otherwise, both operands are padded with X'20'. For example, if both operands are ASCII, or if one operand is ASCII and the other operand is EBCDIC, both are padded with X'20'.

**SBCS data**
Data in which every character is represented by a single byte. Each SBCS string has an associated CCSID. If necessary, an SBCS string is converted before it is used in an operation with a character string that has a different CCSID.

**Mixed data**
Data that can contain a mixture of characters from a single-byte character set (SBCS) and a multiple-byte character set (MBCS). Each mixed string has an associated CCSID. If necessary, a mixed string is converted before an operation with a character string that has a different CCSID. If a mixed data string contains an MBCS character, it cannot be converted to SBCS data.

EBCDIC mixed data can contain shift characters, which are not MBCS data.

When the encoding scheme is Unicode or the Db2 installation is defined to support mixed data, Db2 recognizes MBCS sequences within mixed data string when performing character sensitive operations. These operations include parsing, character conversion, and the pattern matching specified by the LIKE predicate.

Character strings with a CLOB data type can only be SBCS or MIXED. BLOB should be used for binary strings.

The method of representing DBCS and MBCS characters within a mixed string differs among the encoding schemes.
• ASCII reserves a set of code points for SBCS characters and another set as the first half of DBCS characters. When it encounters the first half of a DBCS character, the system reads the next byte in order to obtain the complete character.

• EBCDIC makes use of two special code points:
  – A shift-out character (X'0E') to introduce a string of DBCS characters.
  – A shift-in character (X'0F') to end a string of DBCS characters.

DBCS sequences within mixed data strings are recognized as the string is read from left to right. At any time, the reading of the string is in SBCS mode or DBCS mode. In SBCS mode, which is the initial mode, any byte other than a shift-out is interpreted as an SBCS character. When a shift-out is read, the mode switches to DBCS mode. In DBCS mode, the next byte and every second byte after that byte is interpreted as the first byte of a DBCS character unless it is a shift character. If the byte is a shift-out, an error occurs. If the byte is a shift-in, the mode returns to SBCS mode. An error occurs if the mode is still DBCS mode after processing the last byte of the string. Because of the shift characters, EBCDIC mixed data requires more storage than ASCII mixed data.

• UTF-8 is a varying-length encoding of byte sequences. The high bits indicate the part of the sequence to which a byte belongs. The first byte indicates the number of bytes to follow in a byte sequence.

Examples
The same mixed date character string can be represented as character and hexadecimal data in different encoding schemes.

For the same mixed data character string, the following table shows character and hexadecimal representations of the character string in different encoding schemes. In EBCDIC, the shift-out and shift-in characters are needed to delineate the double-byte characters.

| Table 16. Example of a character string in different encoding schemes |
|---|---|---|
| Data type and encoding scheme | Character representation | Hexadecimal representation (with spaces separating each character) |
| 9 bytes in ASCII | \( \text{\textcopyright}_{\text{gen}} \text{\textcopyright}_{\text{ki}} \) | 8CB3 67 65 6E 8B43 6B 69 |
| 13 bytes in EBCDIC | \( \text{\textcopyright}_{9\text{\textcopyright}_{\text{gen}}} \text{\textcopyright}_{9\text{\textcopyright}_{\text{ki}}} \) | 0E 4695 0F 87 85 95 0E 45B9 0F 92 89 |
| 11 bytes in Unicode UTF-8 | \( \text{\textcopyright}_{\text{gen}} \text{\textcopyright}_{\text{ki}} \) | E58583 67 65 6E 6B097 6B 69 |

Because of the differences of the representation of mixed data strings in ASCII, EBCDIC, and Unicode, mixed data is not transparently portable. To minimize the effects of these differences, use varying-length strings in applications that require mixed data and operate on ASCII, EBCDIC, and Unicode data.

String unit specifications
The ability to specify string units for certain built-in functions and on the CAST specification allows you to process string data in a more "character-based manner" than a "byte-based manner". The string unit determines the length in which the operation is to occur. You can specify CODEUNITS32, CODEUNITS16, or OCTETS as the units for the operation.

CODEUNITS32
Specifies that Unicode UTF-32 is the units for the operation.
CODEUNITS32 is useful when an application wants to process data in a simple fixed-length format and needs the same answer regardless of the storage format of the data (ASCII, EBCDIC, UTF-8, or UTF-16). Although the answers are in terms of CODEUNITS32, the data is not converted to UTF-32 to perform the function.

CODEUNITS16

Specifies that Unicode UTF-16 is the units for the operation. CODEUNITS16 is useful when an application wants to know how many double-byte characters are in a string.

OCTETS

Specifies that bytes are the units for the operation. OCTETS is often used when an application is interested in allocation buffer space or when operations need to use simple byte processing.

Determining the length of a string by counting in string units (CODEUNITS16 or CODEUNITS32) or bytes (OCTETS) can result in different answers. When OCTETS is specified, the length of a string is determined by simply counting the number of bytes in the string. Counting by CODEUNITS16 or CODEUNITS32 gives the same answer unless the data contains supplementary characters. For information about the difference between CODEUNITS16 and CODEUNITS32 when the data contains supplementary characters, see [Difference between CODEUNITS16 and CODEUNITS32](#).

Example: Assume that NAME is a VARCHAR(128) column, encoded in Unicode UTF-8, that contains the value 'Jürgen'. The first two queries, which count the length of the string in CODEUNITS32 and CODEUNITS16, returns the same value, 6. The third query, which counts the length of the string in OCTETS, returns the value 7. These values are the length of the string as expressed in the string units that are specified.

```sql
SELECT CHARACTER_LENGTH(NAME,CODEUNITS32) FROM T1 WHERE NAME = 'Jürgen';
SELECT CHARACTER_LENGTH(NAME,CODEUNITS16) FROM T1 WHERE NAME = 'Jürgen';
SELECT CHARACTER_LENGTH(NAME,OCTETS) FROM T1 WHERE NAME = 'Jürgen';
```

The following table shows the UTF-8, UTF-16, and UTF-32 representations of 'Jürgen'.

<table>
<thead>
<tr>
<th>Format</th>
<th>Representation of the name 'Jürgen'</th>
</tr>
</thead>
<tbody>
<tr>
<td>UTF-8</td>
<td>x'4AC3BC7267656E'</td>
</tr>
<tr>
<td>UTF-16</td>
<td>x'004A00FC007200670065006E'</td>
</tr>
<tr>
<td>UTF-32</td>
<td>x'0000004A000000FC000007200000670000065000006E'</td>
</tr>
</tbody>
</table>

The bold highlighting in the table demonstrates how the representation of the character ü in 'Jürgen' differs between the three string units:

- The UTF-8 representation of the character ü is X'C3BC'. In UTF-8, characters that are not in the Latin-1 subset (essentially a through z, A through Z, and 0 through 9), such as accented characters or Japanese characters, are represented by multiple bytes.
- The UTF-16 representation of the character ü is X'00FC'. In UTF-16, each character is represented in 2 bytes. UTF-16 supplementary characters take two 2-byte code points.

Chapter 2. Language elements 115
• The UTF-32 representation of the character ü is X'000000FC'. In UTF-32, each character is represented in 4 bytes.

Specifying the string units on a built-in function does not affect the data type or the CCSID of the result of the function. If necessary, Db2 converts the data to Unicode for evaluation when CODEUNITS32 or CODEUNITS16 is specified. Db2 always evaluates the data in the encoding scheme of the output data when OCTETS is specified. For more information about the data types and CCSIDs of the results of functions, see the description of each function.

Differences between the way that characters are represented in ASCII, EBCDIC, and Unicode can affect the results of your queries.

Example: Assume that NAME is a VARCHAR(128) column, encoded in EBCDIC (CCSID 37), that contains the value 'Mit freundlichen Grüßen, Jürgen'. The following query returns the string 'Mit freundlichen Grüß':

```
SELECT SUBSTRING(C1,1,21,CODEUNITS16)
FROM T1 WHERE C1 = 'Mit freundlichen Grüßen, Jürgen';
```

The following table shows the result data in more detail:

<table>
<thead>
<tr>
<th>Format</th>
<th>Representation of 'Mit freundlichen Grüß'</th>
</tr>
</thead>
<tbody>
<tr>
<td>EBCDIC</td>
<td>D489A340869985A495849389838859540C799D0C59</td>
</tr>
<tr>
<td>UTF-8</td>
<td>40697420667265756E646C696368656E204720FCDF</td>
</tr>
<tr>
<td>UTF-16</td>
<td>004D00690074002000600075006E0064006C0069006300680</td>
</tr>
<tr>
<td></td>
<td>065006E00200047007200FC00DF</td>
</tr>
</tbody>
</table>

The bold highlighting in the table shows that the representation of the characters ü and ß in UTF-8 and UTF-16 each require two bytes. If OCTETS had been specified on the SUBSTRING function to have the string evaluated in UTF-8 bytes instead of EBCDIC OCTETS or CODEUNITS16, the result would have been 'Mit freundlichen Grü'. The character ß would have been lost.

Difference between CODEUNITS16 and CODEUNITS32:

CODEUNITS16 and CODEUNITS32 return the same answer unless the data contains supplementary characters.

A supplementary character is represented as two UTF-16 code units or one UTF-32 code unit. In UTF-8, a non-supplementary character is represented by 1 to 3 bytes and a supplementary character is represented by 4 bytes. In UTF-16, a non-supplementary character is represented by one CODEUNIT16 code unit or 2 bytes, and a supplementary character is represented by two CODEUNIT16 code units or 4 bytes. In UTF-32, a character is represented by one CODEUNIT32 code unit or 4 bytes. Thus, CODEUNITS16 and CODEUNITS32 return different answers when the data contains supplementary characters.

Example 1: The following table shows the hexadecimal values for the mathematical bold capital A and the Latin capital letter A. The mathematical bold capital A is a supplementary character that is represented by 4 bytes in UTF-8, UTF-16, and UTF-32.
<table>
<thead>
<tr>
<th>Character</th>
<th>UTF-8 representation</th>
<th>UTF-16 representation</th>
<th>UTF-32 representation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Unicode value \u1D400 - 'A'</td>
<td>XF09D9080'</td>
<td>XD835DC00'</td>
<td>X'0001D400'</td>
</tr>
<tr>
<td>MATHEMATICAL BOLD CAPITAL A</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Unicode value \u0041 - 'A'</td>
<td>X'41'</td>
<td>X'0041'</td>
<td>X'00000041'</td>
</tr>
<tr>
<td>LATIN CAPITAL LETTER A</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Assume that C1 is a VARCHAR(128) column, encoded in Unicode UTF-8, and that table T1 contains one row with the value of the mathematical bold capital A (XF09D9080'). The following similar queries return different answers:

-- Query:                        -- Returns the value:
SELECT CHARACTER_LENGTH(C1,CODEUNITS32) FROM T1;  -- 1
SELECT CHARACTER_LENGTH(C1,CODEUNITS16) FROM T1;  -- 2
SELECT CHARACTER_LENGTH(C1,OCTETS) FROM T1;        -- 4

Example 2: Assume that C1 is a VARCHAR(128) column, encoded in Unicode UTF-8, and that table T1 contains one row with the value of the mathematical bold capital A (XF09D9080'). The following similar queries return different answers.

-- Query:                        -- Returns the value:
SELECT HEX(SUBSTRING(C1,1,1,CODEUNITS32)) FROM T1;  -- X'F09D9080'
SELECT HEX(SUBSTRING(C1,1,1,CODEUNITS16)) FROM T1;  -- X'20'
SELECT HEX(SUBSTRING(C1,1,2,CODEUNITS16)) FROM T1;  -- X'F09D9080'
SELECT HEX(SUBSTRING(C1,1,1,OCTETS)) FROM T1;       -- X'20'
SELECT HEX(SUBSTR(C1,1,1)) FROM T1;                 -- X'F0'

The value X'20' is the pad (blank) character.

**Determining the length attribute of the final result:**

When CODEUNITS32, CODEUNITS16, or OCTETS is specified for a function or the CAST specification, the length attribute of the final result string is calculated by applying specific formulas depending on which function is specified.

To determine the final result of a function or the CAST specification, Db2 might need to use an intermediate result string if CODEUNITS32 or CODEUNITS16 is specified, depending on the encoding scheme of the data:

- ASCII and EBCDIC data require the use of a UTF-16 intermediate result string when either CODEUNITS32 or CODEUNITS16 is specified.
- UTF-8 data requires the use of a UTF-16 intermediate result string only when CODEUNITS16 is specified.

Regardless of whether an intermediate string is used, when CODEUNITS32, CODEUNITS16, or OCTETS is specified for a function or the CAST specification, the length attribute of the final result string is calculated by applying the formulas that are described in the following table. The length attributes that are calculated at each step in the formulas are measured in bytes, unless indicated otherwise.
<table>
<thead>
<tr>
<th>Function</th>
<th>Determination of the length attribute of the string</th>
</tr>
</thead>
<tbody>
<tr>
<td>CAST specification</td>
<td>Follow these three steps to determine the length attribute of the final result:</td>
</tr>
<tr>
<td>CHAR</td>
<td>1. <strong>Length of the intermediate string (IML)</strong></td>
</tr>
<tr>
<td></td>
<td>When CODEUNITS32 or CODEUNITS16 is specified:</td>
</tr>
<tr>
<td></td>
<td>• If the source string is not in Unicode CCSID 1200, 1208, or 367, convert the source string to CCSID 1200, using the formulas in Conversion rules for comparisons to determine the result length of the intermediate string (IML).</td>
</tr>
<tr>
<td></td>
<td>• If source string is in Unicode CCSID 1208 or 367, and CODEUNITS16 is specified, convert the source string to CCSID 1200, using the formulas in Conversion rules for comparisons to determine the result length of the intermediate string (IML).</td>
</tr>
<tr>
<td></td>
<td>• Otherwise, the intermediate string is the same as the source string.</td>
</tr>
<tr>
<td>CLOB</td>
<td>When OCTETS is specified:</td>
</tr>
<tr>
<td></td>
<td>• If the CCSID of the source string is different from the CCSID of the result of the function, convert the source string to the CCSID of the result of the function, using the formulas in Conversion rules for comparisons to determine the result length of the intermediate string (IML).</td>
</tr>
<tr>
<td></td>

</tbody>
</table>

**Note:**

1. The final value of the calculation for each length attribute (IML, rl, and the final result of the function) is limited by the maximum length of the function or by the maximum length of the corresponding data type of the result, whichever is applicable. Each length attribute is expressed in terms of bytes.

**Example 1:** Assume that T1 is a table encoded in EBCDIC and C1 is a CHAR(26) column (SBCS data with EBCDIC CCSID 37). The CHAR function is invoked in the following statement:

```
SELECT CHAR(C1,10,CODEUNITS32) as COL1 FROM T1;
```

Db2 uses an intermediate string to evaluate the function and determines the intermediate and final result string lengths using these steps:
1. C1, which is SBCS EBCDIC 37 data, is converted to Unicode 1200 (UTF-16). The result length of the conversion (using the formula from Conversion rules for comparisons \( X \times 2 \)) is 26 * 2. Thus, the length of the intermediate string is 52 bytes (IML = 52).

2. The CHAR function is evaluated against the first 10 UTF-32 characters in this string. The result length attribute is 40 bytes (\( r = 01 \times n \) or 10 * 4) because \( 01 \times n < r_{IML} \) or 40 < 52.

3. The 40 bytes of the string are converted back to SBCS EBCDIC 37. The result length of the conversion (using the formula from Conversion rules for comparisons \( X \times .5 \)) is 40 * .5. Thus, the length of the final result of the functions is 20 bytes.

Example 2: This example is similar to the first example, except that the specified length for the function is 20 instead of 10. Assume that T1 is a table encoded in EBCDIC and C1 is a CHAR(26) column (SBCS data with EBCDIC CCSID 37). The CHAR function is invoked in the following statement:

```
SELECT CHAR(C1,20,CODEUNITS32) as COL1 FROM T1;
```

Db2 uses an intermediate string to evaluate the function and determines the intermediate and final result string lengths using these steps:

1. C1, which is SBCS EBCDIC 37 data, is converted to Unicode 1200 (UTF-16). The result length of the conversion (using the formula from Conversion rules for comparisons \( X \times 2 \)) is 26 * 2. Thus, the length of the intermediate result string is 52 bytes (IML = 52).

2. The CHAR function is evaluated against the first 20 UTF-32 characters in this intermediate string. However, because the estimated number of characters in the intermediate string, as expressed in the specified string units, is only 13 characters (\( r_{IML}/n \) or 52/4), the intermediate string must be padded with 7 padding characters to satisfy the 20 characters that are requested (\( r = 01 - (r_{IML}/n) \) or 20 - 13). In Unicode 1200 (UTF-16), each padding character takes 2 bytes.

The result length attribute is then calculated to be 66 bytes (\( r = \text{MIN}(01 \times n, \text{IML} + (r \times 2)) \) or MIN(20 * 4, 52 + 14)) because \( 01 \times n < r_{IML} \) or 80 < 52 is not true.

3. The 66 bytes of the string are converted back to SBCS EBCDIC 37. The result length of the conversion (using the formula from Conversion rules for comparisons \( X \times .5 \)) is 66 * .5. Thus, the length of the final result of the function is 33 bytes.

**Graphic strings**

A graphic string is a sequence of double-byte characters.

The length of the string is the number of characters in the sequence. Like character strings, graphic strings can be empty. An empty string should not be confused with the null value.

**Related concepts:**

"Unicode column in an EBCDIC table" on page 123

**Fixed-length graphic strings**

When fixed-length graphic string distinct types, columns, and variables are defined, the length attribute is specified and all values have the same length. For a
fixed-length graphic string, the length attribute must be between 1 and 127 inclusive. A fixed-length graphic string column can also be called a GRAPHIC column.

**Varying-length graphic strings**
The types of varying-length graphic strings are VARGRAPHIC and *double-byte character large object* (DBCLOB). DBCLOB is a type of LOB. A DBCLOB column is useful for storing large amounts of double-byte character data, such as documents written with a single double-byte character set.

When varying-length graphic strings, distinct types, columns, and variables are defined, the maximum length is specified and this length becomes the length attribute. Actual values might have a smaller value. For a varying-length graphic string, the length attribute must between 1 and 16352.

For a varying-length graphic string column, the maximum for the length attribute is determined by the record size associated with the table, as described in the description of the CREATE TABLE statement. For a DBCLOB string, the length attribute must be between 1 and 1 073 741 823 inclusive. In UTF-16, although supplementary characters use two 2-byte code points, supplementary characters are still considered double-byte characters. For more information about DBCLOBs, see Large objects (LOBs).

**Graphic string variables**
Graphic string variables must follow certain rules.

Variables with a graphic string type cannot be defined in Fortran. In addition, graphic string variables follow these rules:

- Fixed-length graphic string host variables can be defined in all host languages, except REXX and Java. In C, fixed-length graphic-string variables are limited to a length of 1.
- Varying-length graphic string variables can be defined in all host languages, with the exception of DBCLOBs which cannot be used in REXX.

**Graphic string encoding schemes**
Each graphic string can be further defined as either double-byte data or Unicode data.

**Double-byte data**
Data in which every character is represented by a character from the double-byte character set (DBCS) that does not include shift-out or shift-in characters. Each double-byte graphic string has an associated ASCII or EBCDIC CCSID.

**Unicode data**
Data that contains characters represented by two bytes, except supplementary characters, which take two 2-byte code points per character. Each Unicode graphic string is encoded using UTF-16. The CCSID for UTF-16 is 1200.

**String units in built-in functions**
When working with graphic strings, you can specify the string unit in which the operation is to take place for certain built-in functions and the CAST specification. The string unit determines the length in which the operation is to occur.

For more information about string units, see String unit specifications.
**Unicode column in an EBCDIC table**

A single encoding scheme is used for all character and character string data in a table. An exception is that an EBCDIC table can contain one or more Unicode columns in addition to EBCDIC string columns.

An EBCDIC table can contain:
- A Db2 12 Unicode column for character string data, which is created in Db2 12 or later. The column is encoded in CCSID 1208 (UTF-8) or CCSID 1200 (UTF-16). Db2 12 Unicode columns are subject to fewer restrictions than Db2 11 Unicode columns.
- A Db2 11 Unicode column for character string data, which is created in Db2 Db2 11. The column is encoded in CCSID 1208 (UTF-8).

**Restrictions on a Db2 11 Unicode column in an EBCDIC table**

A Db2 11 Unicode column in an EBCDIC table must satisfy the following criteria:
- The column must not be in the `column-name` list of a `unique-constraint` in a `CREATE TABLE` or `ALTER TABLE` statement.
- The column must not be in the `column-name` list of a `referential-constraint` in a `CREATE TABLE` or `ALTER TABLE` statement.
- The column must not be in the `column-name` list of a `references-clause` in a `CREATE TABLE` or `ALTER TABLE` statement.
- The column must not be in the `column-name` list of an `ORGANIZE BY HASH` clause in a `CREATE TABLE` or `ALTER TABLE` statement.
- The column must not be referenced in the `CHECK(check-condition)` clause in a `CREATE TABLE` or `ALTER TABLE` statement.
- The column must not be referenced in the `CHECK(check-condition)` clause in a `CREATE TABLE` or `ALTER TABLE` statement.
- The column can be the target of an `ALTER COLUMN column-alteration` clause in an `ALTER TABLE` statement only if the column is altered to the same data type, length, and CCSID. This change migrates a Db2 11 Unicode column to a Db2 12 Unicode column.
- In a `default-clause` in a `CREATE TABLE` or `ALTER TABLE` statement, a value cannot follow the `DEFAULT` keyword.
- In a `PARTITION BY RANGE` clause in a `CREATE TABLE` or `ALTER TABLE` statement, `column-name` must not be a Db2 11 Unicode column in an EBCDIC table.
- The column cannot be altered.
- The column must not be referenced in a `join-condition` of a full outer join.
- In a `CREATE TABLE` or `ALTER TABLE` statement, the column definition must not contain a `FIELDPROC` clause.

**Restrictions on an EBCDIC table with Db2 11 Unicode columns**

An EBCDIC table that contains Db2 11 Unicode columns must satisfy the following criteria:
- The table name cannot be the `table-name` value in the `LIKE` clause of a `CREATE TABLE` statement.
• In an *as-result-table* clause in a CREATE TABLE statement, if the *from-clause* in the *fullselect* is an EBCDIC table that contains Db2 11 Unicode columns, the outermost SELECT list of the *fullselect* cannot contain a mixture of EBCDIC and Db2 11 Unicode columns.

• In a *materialized-query-definition* clause in a CREATE TABLE or ALTER TABLE statement, when ENABLE QUERY OPTIMIZATION is in effect, if the *from-clause* in the *fullselect* is an EBCDIC table that contains Db2 11 Unicode columns, the outermost SELECT list of the *fullselect* cannot contain a mixture of EBCDIC and Db2 11 Unicode columns.

• The EDITPROC clause must not be specified in the CREATE TABLE statement.

• The VALIDPROC clause must not be specified in the CREATE TABLE or ALTER TABLE statement.

**Restriction on a created temporary table**

When the LIKE clause is used to create a created temporary table, the table or view on which the created temporary table is based cannot be an EBCDIC table with a Db2 11 Unicode column.

**Restriction on a declared temporary table**

When the LIKE clause is used to create a declared temporary table, the table or view on which the declared temporary table is based cannot be an EBCDIC table with a Db2 11 Unicode column.

**Restrictions on an index that has an index key with Db2 11 Unicode columns**

• A CREATE INDEX statement must not specify DESC, Padded, or RANDOM for a Db2 11 Unicode column in an EBCDIC table.

• An index that is defined on an EBCDIC table and is not an expression-based index must not include Db2 11 Unicode columns and Db2 12 Unicode columns. However, an expression-based index that is defined on an EBCDIC table can include Db2 11 Unicode columns and Db2 12 Unicode columns.

**Restrictions on a table space that contains an EBCDIC table with Db2 11 Unicode columns**

The CCSID of a table space that contains EBCDIC table with Db2 11 Unicode columns cannot be changed.

**How a Db2 11 Unicode column in an EBCDIC table is represented in an SQLDA**

In an SQLVAR of an SQLDA after DESCRIBE or PREPARE INTO, a Db2 11 Unicode column in an EBCDIC table has these characteristics:

• For a column that is defined with CCSID 1208, the SQLTYPE field reflects VARCHAR and the SQLDATA field contains 1208, even though the column might be recorded in the catalog as VARBINARY with CCSID 1208.

• For a column that is defined with CCSID 1200, the SQLTYPE field reflects VARGRAPHIC and the SQLDATA field contains 1200, even though the column might be recorded in the catalog as VARBINARY with CCSID 1200.
Migrating a Db2 11 Unicode column in an EBCDIC table to a Db2 12 Unicode column in an EBCDIC table

Db2 11 Unicode columns in EBCDIC tables can be used with Db2 12, subject to the restrictions that exist in Db2. However, Db2 12 Unicode columns in EBCDIC tables have enhanced support, so you might want to migrate the Db2 11 Unicode columns to Db2 12 Unicode columns.

Procedure

To migrate Db2 11 Unicode columns in EBCDIC tables to Db2 12 Unicode columns:

1. Before or after Db2 12 new function is activated, run job DSNTIJPM. One of the reports that DSNTIJPM produces lists Db2 11 Unicode columns, the EBCDIC tables that contain them, and the indexes that are defined on the Db2 11 Unicode columns.

2. After Db2 12 new function is activated, take one of the following actions:
   - Issue ALTER TABLE ALTER COLUMN to alter the Unicode column.
   - Issue ALTER TABLE DROP COLUMN and ALTER TABLE ADD COLUMN to drop and add the Unicode column.
   - Issue DROP TABLE AND CREATE TABLE to drop and recreate the table with the Unicode column.

3. Repopulate the column or table.

Related tasks:

- Run premigration queries (DSNTIJPM) (Db2 Installation and Migration)

Binary strings

A binary string is a sequence of bytes.

The length of a binary string is the number of bytes in the sequence. Binary strings are not associated with any CCSID. There are three binary string data types: BINARY, VARBINARY (BINARY VARYING) and BLOB (BINARY LARGE OBJECT).

Fixed-length binary strings

The type of fixed-length binary strings is BINARY. When fixed-length binary string distinct types, columns, and variables are defined, the length attribute is specified, and all values have the same length. For a fixed-length binary string, the length attribute must be between 1 and 255 inclusive.

Varying-length binary strings

The types of varying-length binary strings are VARBINARY (BINARY VARYING) and BLOB (BINARY LARGE OBJECT)

When varying-length binary strings, distinct types, columns, and variables are defined, the maximum length is specified and this length becomes the length attribute. Actual length values might have a smaller value than the length attribute value. For varying-length binary strings, the actual length specifies the number of bytes in the string.

For a VARBINARY string, the length attribute must be between 1 and 32704. For a VARBINARY string column, the maximum for the length attribute is determined by the record size that is associated with the table, as described in "Maximum
A binary string column is useful for storing non-character data, such as encoded or compressed data, pictures, voice, and mixed media. Another use is to hold structured data for exploitation by distinct types, user-defined functions, and stored procedures. Note, that although binary strings and FOR BIT DATA character strings might be used for similar purposes, the two data types are not compatible. The BINARY, BLOB, VARBINARY built-in functions and CAST specification can be used to change a FOR BIT DATA character string into a binary string.

Large objects (LOBs)
The term large object (LOB) refers to any of the following data types: CLOB, DBCLOB, or BLOB.

CLOB  A character large object (CLOB) is a varying-length string with a maximum length of 2,147,483,647 bytes (2 gigabytes minus 1 byte). A CLOB is designed to store large SBCS data or mixed data, such as lengthy documents. For example, you can store information such as an employee resume, the script of a play, or the text of a novel in a CLOB. Alternatively, you can store such information in UTF-8 in a mixed CLOB. A CLOB is a varying-length character string.

DBCLOB  A double-byte character large object (DBCLOB) is a varying-length string with a maximum length of 1,073,741,823 double-byte characters. A DBCLOB is designed to store large DBCS data. For example, you could store the information mentioned for CLOB (an employee resume, the script for a play, or the text of a novel) in UTF-16 in a DBCLOB. A DBCLOB is a varying-length graphic string.

BLOB  A binary large object (BLOB) is a varying-length string with a maximum length of 2,147,483,647 bytes (2 gigabytes minus 1 byte). A BLOB is designed to store non-traditional data such as pictures, voice, and mixed media. BLOBs can also store structured data for use by distinct types and user-defined functions. A BLOB is a binary string.

Although BLOB strings and FOR BIT DATA character strings might be used for similar purposes, the two data types are not compatible. The BLOB function can be used to change a FOR BIT DATA character string into a BLOB string.

**Manipulating LOBs using locators**

A LOB locator is a host variable with a value that represents a single LOB value in the database server. LOB locators provide a mechanism for you to easily manipulate very large objects in application programs without having to store the entire LOB value on the client machine where the application program might be running.

Because LOB values can be very large, the transfer of these values from the database server to host variables in client application programs can be time consuming. Also, application programs typically process LOB values a piece at a time, rather than as a whole. For these cases, the application can use a large object locator (LOB locator) to reference the LOB value.

For example, when selecting a LOB value, an application program could handle the value in either of these two ways:

- Select the entire LOB value and place it into an equally large host variable. This method is acceptable if the application program is going to process the entire LOB value at once.
- Select the LOB value into a LOB locator. Then, using the LOB locator, the application program can issue subsequent database operations on the LOB value (such as using it as a parameter to the scalar functions SUBSTR, CONCAT, COALESCE, LENGTH, doing an assignment, searching the LOB value with LIKE or POSSTR, or using it as a parameter to a user-defined function or procedure) by supplying the LOB locator value as input. The resulting output of the LOB locator operation, for example, the amount of data that is assigned to a client host variable, would then typically be a small subset of the input LOB value.
LOB locators can also represent more than just base values; they can also represent
the value associated with a LOB expression. For example, a LOB locator might
represent the value associated with:

```
SUBSTR(lob_value_1 CONCAT lob_value_2 CONCAT lob_value_3, 42, 6000000)
```

For non-locator-based host variables in an application program, when a null value
is selected into that host variable, the indicator variable is set to -1, signifying that
the value is null. For LOB locators, however, the meaning of indicator variables is
slightly different. Because a LOB locator host variable itself can never be null, a
negative indicator variable value indicates that the LOB value represented by the
LOB locator is null. The null information is kept local to the client by virtue of the
indicator variable value (the server does not track null values with valid LOB
locators).

A LOB locator represents a value, not a row or location in the database. Therefore,
after a value is selected into a LOB locator, no action that is subsequently
performed on the original row or table will affect the value that is referenced by
the LOB locator. The value associated with a LOB locator is valid until the
transaction ends, or until the LOB locator is explicitly freed, whichever comes first.

A LOB locator is also not a database type, and it is never stored in the database.
As a result, it cannot participate in views or check constraints. However, values for
the SQLTYPE field of the SQLDA exist for LOB locators so that they can be
described within an SQLDA structure that is used by FETCH, OPEN, CALL and
EXECUTE statements.

For more information about manipulating LOBs with LOB locators, see *Db2
Application Programming and SQL Guide*.

**Datetime values**

Datetime values are neither strings nor numbers. Nevertheless, datetime values can
be used in certain arithmetic and string operations and are compatible with certain
strings.

Moreover, strings can represent datetime values, as discussed in *String
representations of datetime values*.

**Date**

A date is a three-part value (year, month, and day) designating a point in time
using the Gregorian calendar, which is assumed to have been in effect from the
year 1 A.D.

The range of the year part is 0001 to 9999. The range of the month part is 1 to 12.
The range of the day part is 1 to 28, 29, 30, or 31, depending on the month and
year.

The internal representation of a date is a string of 4 bytes. Each byte consists of
two packed decimal digits. The first 2 bytes represent the year, the third byte the
month, and the last byte the day.

The length of a DATE column as described in the catalog is the internal length,
which is 4 bytes. The length of a DATE column as described in the SQLDA is the

---

4 Historical dates do not always follow the Gregorian calendar. Dates between 1582-10-04 and 1582-10-15 are accepted as valid
dates although they never existed in the Gregorian calendar.
A character-string representation must have an actual length that is not greater than 255 bytes and must not be a CLOB or DBCLOB.

**Time**

A time is a three-part value (hour, minute, and second) designating a time of day using a 24-hour clock. The range of the hour part is 0 to 24. The range of the minute and second parts is 0 to 59. If the hour is 24, the minute and second parts are both zero.

The internal representation of a time is a string of 3 bytes. Each byte consists of two packed decimal digits. The first byte represents the hour, the second byte the minute, and the last byte the second.

The length of a TIME column as described in the catalog is the internal length which is 3 bytes. The length of a TIME column as described in the SQLDA is the external length which is 8 bytes unless a time exit routine was specified when the Db2 subsystem was installed. (Writing a time exit routine is described in Db2 Administration Guide.) In that case, the string format of a time can be up to 255 bytes in length. Accordingly, DCLGEN\(^5\) defines fixed-length string variables for TIME columns with a length equal to the value of the field LOCAL TIME LENGTH on installation panel DSNTIP4, or a length of 8 bytes if a value for the field was not specified.

A character-string representation must have an actual length that is not greater than 255 bytes and must not be a CLOB or DBCLOB.

**Timestamp**

A timestamp is a six-part or seven-part value (year, month, day, hour, minute, second, and optional fractional second) with an optional time zone specification, that represents a date and time.

The time portion of a timestamp value can includes a specification of fractional seconds. The number of digits in the fractional seconds portion is specified using an attribute in the range 0 - 12 with a default of 6. The time zone is the difference in hours and minutes between local time and UTC. The range of the hour offset is -12 to 14, and the minute offset is 00 to 59. The optional time zone is specified in the format ±h:tm, with values ranging from -12:59 to +14:00. A timestamp data type is TIMESTAMP WITHOUT TIME ZONE (generically referred to as TIMESTAMP) or TIMESTAMP WITH TIME ZONE.

**TIMESTAMP WITHOUT TIME ZONE**

The internal representation of a timestamp is a string of 7 to 13 bytes, each of which consists of two packed decimal digits. The first 4 bytes represent the date, the next 3 bytes the time, and the remaining bytes the fractional seconds based on the precision of the timestamp.

---

5. DCLGEN is a Db2 DSN subcommand for generating table declarations for designated tables or views. The declarations are stored in z/OS data sets, for later inclusion in Db2 source programs.
The length of a TIMESTAMP WITHOUT TIME ZONE column as described in the catalog is the internal length, which is 7 to 13 bytes.

The length of a TIMESTAMP WITHOUT TIME ZONE column as described in the SQLDA is between 19 and 32 bytes, which corresponds to the length for the character-string representation of the value. For example, a 19 byte character-string representation has no fractional seconds; a 26 byte character-string representation has 6 digits of fractional seconds; and a 29 byte character-string representation has 9 digits of fractional seconds.

A character-string representation must have an actual length that is not greater than 255 bytes and must not be a CLOB or DBCLOB.

**TIMESTAMP WITH TIME ZONE**

The external representation of a TIMESTAMP WITH TIME ZONE value is the local timestamp followed by the time zone offset. For example, New York is 5 hours behind London during standard time, so New York time "8:15" on 2010-02-10 can be represented as '2010-02-10-08.15.00-5:00'. This timestamp with time zone value represents a UTC value '2010-02-10-13.15.00', which is derived by subtracting the time zone offset from local timestamp.

The internal representation of a timestamp is a string of 9 to 15 bytes that contains the UTC timestamp followed by the time zone. Each byte consists of 2 packed decimal digits. The first byte consists of two packed decimal digits representing time zone hour and the first bit is used to represent the sign of the time zone offset. The second byte of time zone, representing the time zone minute, also consists of two packed decimal digits. For example, time zone "-3:30" is represented as X'8330' and time zone "5:30" is represented as X'0530'.

The length of a TIMESTAMP WITH TIME ZONE column as described in the catalog is the internal length, which is between 9 to 15 bytes (a 7 to 13 bytes timestamp followed by 2 bytes time zone).

The length of a TIMESTAMP WITH TIME ZONE column as described in the SQLDA is the external length, which is between 147 and 160 bytes and corresponds to the length for the character-string representation of the value. For example, a 147 byte character representation has no fractional seconds, and a 160 byte character-string representation has 12 digits of fractional seconds, where the time zone component is 7 bytes.

A character-string representation must have an actual length that is not greater than 255 bytes and must not be a CLOB or DBCLOB. DCLGEN therefore defines 147 to 160 byte, varying-length string variables for TIMESTAMP WITH TIME ZONE columns.

**Related concepts:**
- **Datetime constants**
- **Datetime host variables**

**Datetime host variables**

Character-string host variables are normally used to contain date, time, and timestamp values. However, date, time, and timestamp host variables can also be specified in Java as java.sql.Date, java.sql.Time, and java.sql.Timestamp, respectively.

**String representations of datetime values**

Dates, times, and timestamp values can be represented by strings. For many host languages, there are no special SQL constants for datetime values and, except for
Java, no host variables with a data type of date, time, or timestamp. Thus, to be retrieved, a datetime value must be assigned to a string variable.

Values whose data types are DATE, TIME, TIMESTAMP WITHOUT TIME ZONE, or TIMESTAMP WITH TIME ZONE are represented in a form that is transparent to the user of SQL. Dates, times, and timestamps (with or without time zones) can also be represented by strings. These representations directly concern the SQL user because, for many host languages there are no special SQL constants or host variables with a data type for DATE, TIME, TIMESTAMP WITHOUT TIME ZONE, or TIMESTAMP WITH TIME ZONE values (for variables with Java). Thus, to be retrieved, a datetime value must be assigned to a string variable. The format of the resulting string depends on the default date format and the default time format that is in effect when the statement is prepared.

Each datetime value is assigned an encoding scheme. This encoding scheme is used when the datetime value is converted from its internal form to the string representation in the form of the mixed CCSID if the field MIXED DATA is YES on installation panel DSNTIPF. Otherwise the SBCS CCSID of the assigned encoding scheme is used. For Unicode, the mixed CCSID is always used. The following table shows how the encoding scheme is determined:

<table>
<thead>
<tr>
<th>Datetime expression</th>
<th>Result encoding scheme</th>
</tr>
</thead>
<tbody>
<tr>
<td>Columns</td>
<td>The same encoding scheme as the table that contains the column</td>
</tr>
<tr>
<td>Host variables</td>
<td>If the statement references:</td>
</tr>
<tr>
<td></td>
<td>• A single encoding scheme - The same encoding scheme</td>
</tr>
<tr>
<td></td>
<td>• Multiple encoding schemes - The application encoding scheme</td>
</tr>
<tr>
<td>Special registers</td>
<td>If the statement references:</td>
</tr>
<tr>
<td></td>
<td>• A single encoding scheme - The same encoding scheme</td>
</tr>
<tr>
<td></td>
<td>• Multiple encoding schemes - The application encoding scheme</td>
</tr>
<tr>
<td>Expressions</td>
<td>If the statement references:</td>
</tr>
<tr>
<td></td>
<td>• A single encoding scheme - The same encoding scheme</td>
</tr>
<tr>
<td></td>
<td>• Multiple encoding schemes - The application encoding scheme</td>
</tr>
</tbody>
</table>

For ASCII and EBCDIC, a string representation of a datetime value must be a character string. For Unicode, a string representation of a datetime value can be either a character string or a graphic string. Thus, the only time a graphic string can be used for a datetime value is when the encoding scheme is Unicode.

In host languages other than Java, a datetime value must be assigned to a string variable. When a date or time is assigned to a string variable, the string format is determined by a precompiler option or subsystem parameter. When a string representation of a datetime value is used in other operations, it is converted to a datetime value. However, this can be done only if the string representation is recognized by Db2 or an exit provided by the installation and the other operand is
a compatible datetime value. An input string representation of a date or time with LOCAL specified must have an actual length that is not greater than 255 bytes.

Datetime values that are represented by strings can appear in contexts that require values whose data types are DATE, TIME, TIMESTAMP WITHOUT TIME ZONE, or TIMESTAMP WITH TIME ZONE. A string representation of a date, time or timestamp (with or without time zone) can be passed as an argument to the DATE, TIME, TIMESTAMP, or TIMESTAMP_TZ function to obtain a datetime value. A CAST specification can also be used to turn a character representation of a date, time, or timestamp (with or without time zone) into a datetime value.

**Date strings:**
A string representation of a date is a string that starts with a digit and has a length of at least 8 characters. Trailing blanks can be included, leading blanks are not allowed, and leading zeros can be omitted in the month and day portions.

The following table shows the valid string formats for dates. Each format is identified by name and includes an associated abbreviation (for use by the CHAR function) and an example of its use. For an installation-defined date string format, the format and length must have been specified when Db2 was installed. They cannot be listed here.

<table>
<thead>
<tr>
<th>Format name</th>
<th>Abbreviation</th>
<th>Date format</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>International Standards Organization</td>
<td>ISO</td>
<td>yyyy-mm-dd</td>

<td>USA</td>
<td>mm/dd/yyyy</td>
<td>10/12/1987</td>
</tr>
<tr>
<td>IBM European standard</td>
<td>EUR</td>
<td>dd.mm.yyyy</td>
<td>12.10.1987</td>
</tr>
<tr>
<td>Japanese industrial standard Christian era</td>
<td>JIS</td>
<td>yyyy-mm-dd</td>
<td>1987-10-12</td>
</tr>
<tr>
<td>Installation-defined</td>
<td>LOCAL</td>
<td>Any installation-defined form</td>
<td>—</td>
</tr>
</tbody>
</table>

**Time strings:**
A string representation of a time is a string that starts with a digit, and has a length of at least 4 characters. Trailing blanks can be included, leading blanks are not allowed, and leading zeros can be omitted in the hour part of the time; seconds can be omitted entirely. If you choose to omit seconds, an implicit specification of 0 seconds is assumed. Thus 13.30 is equivalent to 13.30.00.

The following table shows the valid string formats for times. Each format is identified by name and includes an associated abbreviation (for use by the CHAR function) and an example of its use. In the case of an installation-defined time string format, the format and length must have been specified when your Db2 subsystem was installed. They cannot be listed here.

<table>
<thead>
<tr>
<th>Format name</th>
<th>Abbreviation</th>
<th>Time format</th>
<th>Example</th>
</tr>
</thead>

<td>LOCAL</td>
<td>Any</td>
<td>—</td>
</tr>
</tbody>
</table>

Note: 1. This is an earlier version of the ISO format. JIS can be used to get the current ISO format.

In the USA format:

- The minutes can be omitted, thereby specifying 00 minutes. For example, 1 PM is equivalent to 1:00 PM.
- The letters A, M, and P can be lowercase.
- A single blank must precede the AM or PM.
- The hour must not be greater than 12 and cannot be 0 except for the special case of 00:00 AM.

Using the ISO format of the 24-hour clock, the correspondence between the USA format and the 24-hour clock is as follows:

- 12:01 AM through 12:59 AM correspond to 00.01.00 through 00.59.00
- 01:00 AM through 11:59 AM correspond to 01.00.00 through 11.59.00
- 12:00 PM (noon) through 11:59 PM correspond to 12.00.00 through 23.59.00
- 12:00 AM (midnight) corresponds to 24.00.00
- 00:00 AM (midnight) corresponds to 00.00.00

Timestamp strings:

A string representation of a timestamp is a character or graphic string that starts with a digit and has a length of at least 16 characters. The character or graphic string must contain a value that conforms to one of the formats listed in [Datetime constants](#), subject to the following rules:

- leading blanks are not allowed
- trailing blanks can be included
- leading zeros can be omitted from the month, day, hour, and time zone hour elements of the timestamp. An implicit specification of 0 is assumed for any digit that is omitted.
- the hour can be 24 if the minutes, seconds, and any fractional seconds are all zeroes.
- leading zeros must be included for the minute, second, and time zone minute elements of the timestamp.
- the number of digits of fractional seconds can vary from 0 to 12. An implicit specification of 0 is assumed if fractional seconds are omitted.
- the separator character that follows the seconds element can be omitted if fractional seconds are not included.
- an optional single blank can be included between the time and the time zone.
- an optional time zone can be included, in one of the following formats:
  - ±th:tm, with values ranging from -24:00 to +24:00. A value of -0:00 is treated the same as a value of +0:00.
– ±th, with values ranging from -24 to +24, and an implicit specification of 00 is assumed for the time zone minute element.
– uppercase Z to specify UTC

If a string representation of a timestamp is implicitly cast to a value with a timestamp data type, the timestamp precision is assumed to be 6, regardless of the number of digits of fractional seconds in the string. Beyond the sixth digit that represents fractional seconds, the digits are truncated and the missing digits are assumed to be zeros. For example, 1990-3-2-8.30.00.10 is equivalent to 1990-03-02-08.30.00.100000. A string representation of a timestamp can be given a different timestamp precision by explicitly casting the value to a timestamp with a specified precision or, in the case of a constant, preceding the string with the TIMESTAMP keyword (for example, TIMESTAMP 2007-03-28-14.50.35.123; has the TIMESTAMP(3) data type).

If a string representation of a timestamp is implicitly cast to a TIMESTAMP WITHOUT TIME ZONE value, the string must not contain a time zone.

SQL statements also support the ODBC or JDBC string representation of a timestamp as an input value only. The ODBC and JDBC string representation of a timestamp has the form yyyy-mm-dd hh:mm:ss.nnnnnn.

**LOCAL date and time exits:** For LOCAL, the date exit for ASCII data is DSNXVDTA, the date exit for EBCDIC is DSNXVDTX, and the date exit for Unicode is DSNXVDTU. For LOCAL, the time exit for ASCII data is DSNXVTMA, the time exit for EBCDIC is DSNXVTMX, and the time exit for Unicode is DSNXVTMU.

**Determination of the implicit time zone**

Db2 uses the IMPLICIT_ZONE parameter of DSNHDECP to implicitly determines the time zone to associate with a value that does not have a time zone on assignment to a TIMESTAMP WITH TIME ZONE column or variable.

The IMPLICIT_ZONE parameter of DSNHDECP is used to support operations that combine TIMESTAMP WITHOUT TIME ZONE values and TIMESTAMP WITH TIME ZONE values and indicates the time zone to associate with TIMESTAMP WITHOUT TIME ZONE values. For example, on assignment of a value that does not have time zone information (the TIMESTAMP WITHOUT TIME ZONE data type, or a string representation of a timestamp without a time zone) to a TIMESTAMP WITH TIME ZONE target such as a column or variable, Db2 implicitly determines the time zone to associate with the value. The implicit time zone is determined as follows:

- If IMPLICIT_ZONE is not specified or is specified as CURRENT, the implicit time zone is the value of the CURRENT TIME ZONE special register.
- If IMPLICIT_ZONE is specified as SESSION, the implicit time zone is the value of the SESSION TIME ZONE special register.
- If IMPLICIT_ZONE is specified as a character string in the format of '±th:tm', the implicit time zone is the time zone value represented by the character string.

**Restrictions on the use of local datetime formats**

Certain restrictions apply on the use of date and time values as input, as output, and for use in binding a package.

The following rules apply to the character-string representation of dates and times:
For input: In distributed operations, Db2 as a server uses its local date or time routine to evaluate host variables and constants. This means that character-string representation of dates and times can be:
  • One of the standard formats
  • A format recognized by the server’s local date/time exit

For output: With DRDA access, Db2 as a server returns date and time host variables in the format defined at the server. To have date and time host variables returned in another format, use `CHAR(date-expression, xxxx)` where `xxxx` is JIS, EUR, USA, ISO, or LOCAL to explicitly specify the specific format.

For BIND PACKAGE COPY: When binding a package using the COPY option, Db2 uses the ISO format for output values unless the SQL statement explicitly specifies a different format. Input values can be specified in the format described previously.

Row ID values

A row ID is a value that uniquely identifies a row in a table. A column or a host variable can have a row ID data type.

A ROWID column enables queries to be written that navigate directly to a row in the table because the column implicitly contains the location of the row. Each value in a ROWID column must be unique. Although the location of the row might change, for example across a table space reorganization, Db2 maintains the internal representation of the row ID value permanently. When a row is inserted into the table, Db2 generates a value for the ROWID column unless one is supplied. If a value is supplied, it must be a valid row ID value that was previously generated by Db2 and the column must be defined as GENERATED BY DEFAULT. Users cannot update the value of a ROWID column.

The internal representation of a row ID value is transparent to the user. The value is never subject to character conversion because it is considered to contain BIT data. The length of a ROWID column as described in the LENGTH column of catalog table SYSCOLUMNS is the internal length, which is 17 bytes. The length as described in the LENGTH2 column of catalog table SYSCOLUMNS is the length of a retrieved ROWID value, which is 40 bytes. The retrieved ROWID value is not permanent. If a commit operation and a REORG on the table space occur after the value is inserted, and before the value is retrieved, the physical location of the row might change.

A ROWID column can be either user-defined or implicitly generated by Db2. You can use the CREATE TABLE statement or the ALTER TABLE statement to define a ROWID column. If you define a LOB column in a table and the table does not have a ROWID column, Db2 implicitly generates a ROWID column. Db2 takes the following actions:
  • Creates the column with a name of `DB2_GENERATED_ROWID_FOR_LOBSnn`. Db2 appends `nn` only if the column name already exists in the table, replacing `nn` with '00' and incrementing by '1' until the name is unique within the row.
  • Defines the column as GENERATED ALWAYS and IMPLICITLY HIDDEN.
  • Appends the column to the end of the row after all the other explicitly defined columns.

An implicitly hidden ROWID column can also be explicitly defined with the IMPLICITLY HIDDEN clause.
If you add a ROWID column to a table that already has an implicitly generated hidden ROWID column, Db2 ensures that the corresponding values in each column are identical. If the ROWID column that you add is defined as GENERATED BY DEFAULT, Db2 changes the attribute of the hidden ROWID column to GENERATED BY DEFAULT.

XML values

An XML value represents well-formed XML in the form of an XML document, XML content, or a sequence of XML nodes.

An XML value that is stored in a table as the value of a column that is defined with the XML data type must be a well-formed XML document. XML values are processed in an internal representation that is not comparable to any string value. The only predicates that can be applied to the XML data type are the XML EXISTS predicate and the NULL predicate.

An XML value can be transformed into a serialized string value that represents the XML document by using the XMLSERIALIZE function. Similarly, a string value that represents an XML document can be transformed to an XML value by using the XMLPARSE function.

The XML data type has a variable length and allows for a wide range of sizes. Although data of this type has no defined maximum length, it does have an effective maximum length limit when treated as a serialized string value that represents XML. The maximum effective length is the same as the Db2 limit for a LOB data value. Db2 treats XML string data in a similar manner as LOB data to accommodate very large XML values. Thus, XML values are constrained by the same maximum length limit as LOB data. Unlike the LOB data type which has a LOB locator type, there is no XML locator type.

Restrictions when using XML values: With a few exceptions, you can use XML values in the same contexts in which you can use other data type. XML values cannot be used in the following contexts:
- SELECT lists that are preceded by the DISTINCT clause
- GROUP BY clauses
- ORDER BY clauses
- A subselect of a fullselect with a set operator that is not UNION ALL
- Basic predicates, quantified predicates, BETWEEN predicates, DISTINCT predicates, IN predicates, or LIKE predicates
- Aggregate functions with the DISTINCT keyword
- Primary, unique, or foreign keys
- CREATE TYPE statements
No host languages have any built-in support for an XML data type.

**User-defined data types**

A *user-defined data type* is a data type that is defined using a `CREATE TYPE` statement.

The following types of user-defined data type are supported:

- Distinct type
- Array type

**Distinct types**

A *distinct type* is a user-defined data type that shares its internal representation with a built-in data type (its *source type*), but is considered to be a separate and incompatible data type for most operations.

For example, the semantics for a picture type, a text type, and an audio type that all use the built-in data type BLOB for their internal representation are quite different. A distinct type is created with the SQL statement `CREATE TYPE`.

For example, the following statement creates a distinct type named AUDIO:

```sql
CREATE TYPE AUDIO AS BLOB (1M);
```

Although AUDIO has the same representation as the built-in data type BLOB, it is a separate data type that is not comparable to a BLOB or to any other data type. This inability to compare AUDIO to other data types allows functions to be created specifically for AUDIO and assures that these functions cannot be applied to other data types.

The name of a distinct type is qualified with a schema name. The implicit schema name for an unqualified name depends on the context in which the distinct type appears. If an unqualified distinct type name is used:

- In a `CREATE TYPE` statement or the object of `DROP`, `COMMENT`, `GRANT`, or `REVOKE` statement, Db2 uses the normal process of qualification by authorization ID to determine the schema name.
- In any other context, Db2 uses the SQL path to determine the schema name. Db2 searches the schemas in the path, in sequence, and selects the first schema in the path such that the distinct type exists in the schema and the user has authorization to use the data type. For a description of the SQL path, see the SQL path.

A distinct type does not automatically acquire the functions and operators of its source type because they might not be meaningful. (For example, it might make sense for a “length” function of the AUDIO type to return the length in seconds rather than in bytes.) Instead, distinct types support *strong typing*. Strong typing ensures that only the functions and operators that are explicitly defined on a distinct type can be applied to that distinct type. However, a function or operator of the source type can be applied to the distinct type by creating an appropriate user-defined function. The user-defined function must be sourced on the existing function that has the source type as a parameter. For example, the following series of SQL statements shows how to create a distinct type named MONEY based on data type DECIMAL(9,2), how to define the + operator for the distinct type, and how the operator might be applied to the distinct type:

```sql
CREATE TYPE MONEY AS DECIMAL(9,2);
CREATE FUNCTION "+"(MONEY,MONEY)
  RETURNS MONEY
```
CREATE TABLE SALARY_TABLE
(SALARY MONEY,
COMMISSION MONEY);
SELECT SALARY + COMMISSION FROM SALARY_TABLE;

A distinct type is subject to the same restrictions as its source type. For example, if a CLOB value is not allowed as input to a function, you cannot specify a distinct type that is based on a CLOB as input.

The comparison operators are automatically generated for distinct types, except those that are based on a CLOB, DBCLOB, or BLOB. In addition, Db2 automatically generates functions for every distinct type that support casting from the source type to the distinct type and from the distinct type to the source type. For example, for the AUDIO type created above, these are generated cast functions:

FUNCTION schema-name.BLOB (schema-name.AUDIO) RETURNS SYSIBM.BLOB (1M)
FUNCTION schema-name.AUDIO (SYSIBM.BLOB (1M)) RETURNS schema-name.AUDIO

Array types
A user-defined array type is a data type that is defined as an array of elements. A user-defined array type can be either an ordinary array or associative array.

A user-defined ordinary array type has a maximum cardinality, which is specified on the CREATE TYPE (array) statement. A user-defined associative array has a maximum cardinality of 2 billion.

Array values:

An array value is a structure that contains an ordered collection of elements.

All elements of an array value must have the same data type. The cardinality of the array is equal to the number of elements in the array.

An array value can be non-empty, empty (cardinality zero), or null. The individual elements in the array can be null or not null. An empty array, an array value of null, and an array for which all elements are the null value are different from each other. An uninitialized array is a null array.

The following example demonstrates the difference between an empty array, a null array, and an array for which individual elements are null.

```
SET PHONELIST = ARRAY[];
   /* Set an entire array to empty */
SET PHONELIST = NULL;
   /* Set an entire array to the NULL value */
SET PHONELIST = ARRAY[NULL];
   /* Set one element of an array to NULL */
SET PHONELIST = ARRAY[NULL, NULL, NULL];
   /* Set three elements of an array to NULL */
```

An ordinary array has a defined upper bound on the number of elements, which is known as the maximum cardinality. Each element in the array is referenced by an associated index value that represents the position of that element in the array. The data type of the index values is INTEGER. If n is the number of elements in an ordinary array, the ordinal position that is associated with each element is an integer value greater than or equal to 1 and less than or equal to n.

Unlike the maximum cardinality of an array in programming languages such as C, the maximum cardinality of an ordinary array in SQL is not related to the physical
representation of the array. The amount of memory that is required to represent the
cardinality of the array, and not to the maximum cardinality of the array type. When an ordinary array is
referenced, all of the values in the array are stored in main memory. Therefore, ordinary arrays that contain a large amount of data consume large amounts of
main memory.

An *associative array* has no predefined upper bound on the number of elements. An
associative array contains an ordered set of zero or more elements, where each
element in the array is ordered by and can be referenced by an associated index
value. The data type of the index values can be an integer or a character string
other than a CLOB, but all index values for the array must have the same data
type. The index values of an associative array are unique, and do not need to be
contiguous.

A *user-defined array type* is a user-defined data type that is defined as an array. A
global variable, an SQL variable or SQL parameter can be defined as a user-defined
array type. Additionally, the result of an invocation of the built-in ARRAY_DELETE
or TRIM_ARRAY functions, or the result of a CAST specification, can be a
user-defined array type. An element of a user-defined array type can be referenced
anywhere that an expression that returns the same data type as an element of that
array can be used.

An *unnamed array type* is an array without an associated user-defined data type.
The result of invocation of the aggregate built-in function ARRAY_AGG or of an
array constructor is an array without an associated user-defined data type. An
element of an array without an associated user-defined array type cannot be
directly referenced.

The value of an array index can be specified by an expression. That expression can
include a reference to a column. If a column is defined with a column mask, the
column mask is applied using the normal rules for applying a column mask.

The value of an index for an array element is never null. If an expression specifies
a value for an index, and the expression evaluates to the null value, the null value
is returned for the array value.

An array value can be specified using one of the following methods:

- A simple reference to a global variable, an SQL variable, or SQL parameter that
  is a user-defined array type.
- Invocation of the ARRAY_AGG function.
- Invocation of the ARRAY_DELETE or TRIM_ARRAY built-in functions.
- Use of an array constructor.
- Invocation of a CAST specification that returns an array value.

An array value cannot be stored in a table or returned to an external application.

Datetime data in the elements of an array is considered to be CCSID UNICODE
(1208).

**Related reference:**

- [ARRAY_AGG](#)
- [TRIM_ARRAY](#)
Promotion of data types

Data types can be classified into groups of related data types. Within such groups, an order of precedence exists in which one data type is considered to precede another data type. This precedence enables Db2 to support the promotion of one data type to another data type that appears later in the precedence order.

For example, Db2 can promote the data type CHAR to VARCHAR and the data type INTEGER to DOUBLE PRECISION; however, Db2 cannot promote a CLOB to a VARCHAR.

Db2 considers the promotion of data types when:
- Performing function resolution (see “Function resolution” on page 251)
- Casting distinct types (see “Casting between data types” on page 141)
- Assigning built-in data types to distinct types (see “Distinct type assignments” on page 161)

For each data type, the following table shows the precedence list (in order) that Db2 uses to determine the data types to which the data type can be promoted. The table indicates that the best choice is the same data type and not promotion to another data type. The table also shows data types that are considered equivalent during the promotion process. For example, CHARACTER and GRAPHIC are considered to be equivalent data types.

Table 22. Precedence of data types

<tr>
<td>A distinct type</td>
<td>The same distinct type</td>
</tr>
</tbody>
</table>

Notes:
1. The data types in lowercase letters represent the following data types:
   - Decimal: DECIMAL(p,s) or NUMERIC(p,s)
   - Real: REAL or FLOAT(n) where n is not greater than 21
   - Double: DOUBLE, DOUBLE PRECISION, FLOAT or FLOAT(n) where n is greater than 21
2. Other synonyms for the listed data types are considered to be the same as the synonym listed.
3. Real and double are checked for function resolution purposes only. Additionally, the number of significant digits (even for DECFLOAT(16)), and the exponent range of DECFLOAT exceeds that of real and double (double has 16 significant digits). Therefore, DECFLOAT values will not be promoted to real or double.

Casting between data types

There are many occasions when a value with a given data type needs to be cast (changed) to a different data type or to the same data type with a different length, precision, or scale.

Data type promotion is one example where the promotion of one data type to another data type requires that the value be cast to the new data type. A data type that can be changed to another data type is castable from the base data type to the target data type.

The casting of one data type to another can occur implicitly or explicitly. The cast functions, CAST specification, or XMLCAST specification can be used to explicitly change a data type, depending on the data types involved. In addition, when a sourced user-defined function is created, the data types of the parameters of the source function must be castable to the data types of the function that is being created.

If truncation occurs when any data type is cast to a character or graphic data type, a warning occurs if any non-blank characters are truncated. The warning also occurs if any characters are truncated when a BLOB operand is cast, or if the time zone characters are truncated when a TIMESTAMP WITH TIME ZONE operand is cast to a string. This truncation behavior is similar to retrieval assignment of character or graphic strings. See "Retrieval assignment" on page 158.

If truncation occurs when casting to a binary string, an error is returned.

For casts that involve a distinct type as either the data type to be cast to or from, Table 23 on page 142 shows the supported casts.
For casting a parameter marker or NULL value to the XML data type, the CAST specification can be used. XML input can also be specified for the CAST specification when the result data type is XML.

Casts that involve an array type as the target and a non-null source value must conform to the following rules:

- If the source value is an array with a user-defined array type:
  - The target array type must be the same user-defined array type.
  - If the target user-defined array type is an ordinary array, the cardinality of the source array value must be less than or equal to the maximum cardinality of the target array type.

- If the source value is an array without an associated user-defined array type:
  - The elements in the source array value must be castable to the data type of the elements of the target array type.
  - The index values for the source array value must be castable to the data type of the index of the target array type.
  - If the target user-defined array type is an ordinary array, the cardinality of the source array value must be less than or equal to the maximum cardinality of the target array type.

<table>
<thead>
<tr>
<th>Table 23. Supported casts when a distinct type is involved</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data type ...</td>
</tr>
<tr>

<tr>
<td>INTEGER</td>
</tr>
<tr>
<td>DOUBLE</td>
</tr>
<tr>
<td>VARCHAR</td>
</tr>
<tr>
<td>VARGRAPHIC</td>
</tr>
<tr>
<td>VARBINARY</td>
</tr>
</tbody>
</table>

When a distinct type is involved in a cast, a cast function that was generated when the distinct type was created is used. How Db2 chooses the function depends on whether function notation or CAST specification syntax is used. (For details, see “Function resolution” on page 251 and “CAST specification” on page 283, respectively.) Function resolution is similar for both. However, in CAST specification, when an unqualified distinct type is specified as the target data type, Db2 first resolves the schema name of the distinct type and then uses that schema name to locate the cast function.

For casts between built-in data types, the following table shows the supported casts.
Table 24. Supported casts between built-in data types

**Note:**

1. Other synonyms for the listed data types are considered to be the same as the synonym listed. Some exceptions exist when the cast involves character string data if the subtype is FOR BIT DATA.

2. The result length for these casts is 3 * LENGTH(graphic string).

3. These data types are castable between each other only if the data is Unicode.

4. The conversion returns a Unicode graphic result. The result value must only be used in a context that supports Unicode data.

Table 25 shows where to find information about the rules that apply when casting to the identified target data types.

When character string values are cast to XML values, the resulting xs:string atomic value cannot contain illegal XML characters. If the input character string is not in Unicode, the input characters are converted to Unicode.

### Casting XML values to non-XML values

An XMLCAST from an XML value to a non-XML value can be described as two casts: an XQuery cast that converts the source XML value to a target XQuery data type that corresponds to the SQL target type, followed by a cast from the corresponding XQuery data type to the actual SQL type. The target XQuery data type is an XML schema data type like xs:decimal or xs:string, as shown in the follow table.

An XMLCAST is supported if the target type has a corresponding XQuery target type that is supported, and if there is a supported XQuery cast from the type of the source value to the corresponding XQuery target type. The target type that is used in the XQuery cast is based on the corresponding XQuery target type and might contain some additional restrictions.

The following table lists the XQuery types that result from such conversion.

The following restrictions are in effect when a value is cast from an XQuery target data type to a target SQL data type:

- If the target type is one of the character or graphic string types, the resulting XML value is converted, if necessary, to the CCSID of the target data type using the rules described in “Conversion rules for string assignment” on page 159, before it is converted to the target type with a limited length. Truncation occurs if the specified length limit is smaller than the length of the resulting string after CCSID conversion. A warning occurs if any non-blank characters are truncated. If the target type is a fixed-length string type (CHAR or GRAPHIC) and the specified length of the target type is greater than the length of the resulting string from CCSID conversion, blanks are padded at the end. This truncation and padding behavior is similar to retrieval assignment of character or graphic strings.

- If the target type is DOUBLE or REAL and the source XML value after the XQuery cast is an xs:double value of INF, -INF, or NaN, an error is returned. If the source value is an xs:double negative zero, the value is converted to positive zero. If the source value is beyond the range of the target data type, an overflow error is returned. If the source value contains more significant digits than the precision of the target data type, the source value is rounded to the precision of the target data type.

- If the target type is DECFLOAT and the source XML value is an xs:double value of INF, -INF, or NaN, the result will be the corresponding special DECFLOAT values INF, -INF, or NaN. If the source value is an xs:double negative zero, the result is negative zero. If the target type is DECFLOAT(16) and the source value is beyond the range of DECFLOAT(16), an overflow error is returned. If the source value has more than 16 significant digits, the value is rounded according to the Rounding mode that is in effect. This rounding behavior is the same as what is used during the cast of DECFLOAT(34) to DECFLOAT(16).

- If the target type is DECIMAL, the resulting xs:decimal value is converted, if necessary, to the precision and scale of the target data type. The necessary number of leading zeros is added or removed. In the fractional part of the number, the necessary number of trailing zeros is added or the necessary
number of digits is eliminated. This truncation behavior is similar to the behavior of the cast from DECIMAL to DECIMAL.

- If the target type is DATE, TIME, or TIMESTAMP WITHOUT TIME ZONE, the resulting XML value is adjusted to UTC time and the time zone component is removed. If the source does not include a time zone and the target data type is TIMESTAMP WITH TIME ZONE, zeroes are used for the time zone component. If the target type is TIME and the resulting XML value contains a seconds component with non-zero digits after the decimal point, those digits are truncated. If the target type is DATE or timestamp, the year part of the resulting xs:date or xs:dateTime value must be in the range of 0001 to 9999. If the target type is timestamp and the precision of the target timestamp is less than 12, the fractional seconds part of the xs:dateTime value will be truncated to the target timestamp precision.

Implicit cast from numeric data to string data

When Db2 implicitly casts a numeric value to a string value, the target type is VARCHAR value which is then compatible with other character string or graphic string data types.

The length attribute and the CCSID attribute of the result of the cast are determined in the same way as the VARCHAR function. When GRAPHIC or VARGRAPHIC data types are involved, the encoding scheme must be UNICODE.

The following table shows the target type and length:

<table>
<thead>
<tr>
<th>Source data type</th>
<th>Target data type</th>
</tr>
</thead>
<tbody>
<tr>
<td>SMALLINT</td>
<td>VARCHAR(6)</td>
</tr>
<tr>
<td>INTEGER</td>
<td>VARCHAR(11)</td>
</tr>
<tr>

<td>VARCHAR(24)</td>
</tr>
<tr>
<td>DOUBLE</td>
<td>VARCHAR(24)</td>
</tr>
<tr>
<td>DECFLOAT</td>
<td>VARCHAR(42)</td>
</tr>
</tbody>
</table>

Implicit conversion from a numeric value to a string value can happen during:

- Assignment (where the source value is a number and the target operand is a character string or graphic string data type).
  
  Among assignment statements, implicit casting is not supported for the SET statements for special registers, the RETURNS clause and RETURN statement for functions, and the SQL control statements: RETURN, SIGNAL, and RESIGNAL.

- Application of concatenation operators (CONCAT and ||)

- Application of set operators.

Implicit conversion is not supported in the following cases:

- One operand of a set operator is a numeric value and the other operand is a string value

- A numeric value is compared to or assigned to a string value that is the result of a fullselect which included a set operator

- Assignment to a global variable that is the target of a SELECT INTO statement
Implicit cast from string data to numeric data

When Db2 implicitly casts a character string or graphic string value to a numeric value, the target type is `DECFLOAT(34)` which is compatible with other numeric data types.

When GRAPHIC or VARGRAPHIC data types are involved, the encoding scheme must be UNICODE. The following table shows the target type and length:

<table>
<thead>
<tr>
<th>Source data type</th>
<th>Target data type</th>
</tr>
</thead>
<tbody>
<tr>
<td>CHAR</td>
<td><code>DECFLOAT(34)</code></td>
</tr>
<tr>
<td>VARCHAR</td>
<td><code>DECFLOAT(34)</code></td>
</tr>
<tr>
<td>GRAPHIC</td>
<td><code>DECFLOAT(34)</code></td>
</tr>
<tr>
<td>VARGRAPHIC</td>
<td><code>DECFLOAT(34)</code></td>
</tr>
<tr>
<td>CHAR FOR BIT DATA</td>
<td>N/A</td>
</tr>
<tr>

<tr>
<td>BLOB</td>
<td>N/A</td>
</tr>
<tr>
<td>CLOB</td>
<td>N/A</td>
</tr>
<tr>
<td>DBCLOB</td>
<td>N/A</td>
</tr>
</tbody>
</table>

Implicit conversion from a string value to a numeric value can happen during:

- Assignment (where the source value is a character string or graphic string and the target operand is a numeric data type).
- Comparisons
  - When a character string or graphic string value is compared with a numeric value, Db2 implicitly converts the string value to `DECFLOAT(34)` and applies numeric comparison rule between the `DECFLOAT(34)` value and the other numeric value.
    - Basic predicates, quantified predicates, and DISTINCT predicates (one operand is numeric value and the other operand is character string or graphic string value)
      Numeric is the dominant data type. The character or graphic string value is cast to `DECFLOAT(34)` value.
    - BETWEEN predicates
      Numeric is the dominant data type. If any of the three operands is a numeric value, Db2 implicitly casts the character or graphic string operands to `DECFLOAT` data type.
    - IN predicates
      Numeric is the dominant data type. If any of the operands is a numeric value, Db2 implicitly casts the character or graphic string operands to `DECFLOAT` data type.
  - `Searched-when-clause` of CASE expression
    Pair-wise comparison is performed. Implicit cast of each pair follows the same rule as for a basic predicate. Implicit string and numeric cast is supported on `searched-when-clause` of CASE expression.
Search conditions in SQL control statements (one operand is numeric value and the other operand is character string or graphic string value)

The search condition can appear in SQL control statements like the CASE statement, the IF statement, the REPEAT statement, and the WHILE statement. For comparisons in the search condition, numeric is the dominant data type. The character string or graphic string value is cast to a DECFLOAT(34) value. Implicit string and numeric cast is supported on the searched-when-clause of the CASE statement.

- Arithmetic operators (unary arithmetic operators + and - and infix arithmetic operators +, -, *, and /)

  If the operand of unary arithmetic operators is of a character string or graphic string data type, that operand is implicitly cast to DECFLOAT(34). For infix arithmetic operators, if one operand is a numeric value or both operands are character or graphic string values, Db2 implicitly casts the character string or graphic string operand to the DECFLOAT data type.

Implicit conversion is not supported in the following cases:

- One operand of a set operator is a string value and the other operand is a numeric value
- A string value is compared to or assigned to a numeric value that is the result of a fullselect which included a set operator
- For FULL OUTER JOIN when the join condition is between string and numeric data types
- Assignment to a global variable that is the target of a SELECT INTO statement

**Assignment and comparison**

The basic operations of SQL are assignment and comparison.

Assignment operations are performed during the execution of statements such as CALL, INSERT, UPDATE, MERGE, FETCH, SELECT INTO, SET host-variable or SET assignment-statement, and VALUES INTO statements. In addition, when a function is invoked or a stored procedure is called, the arguments of the function or stored procedure are assigned. Comparison operations are performed during the execution of statements that include predicates and other language elements such as MAX, MIN, DISTINCT, GROUP BY, and ORDER BY.

The basic rule for both operations is that data types of the operands must be compatible. The compatibility rule also applies to other operations that are described under Rules for result data types.

The following table shows the compatibility of data types for assignments and comparisons.

<table>
<thead>
<tr>
<th>Operand</th>
<th>Binary integer</th>
<th>Decimal number</th>
<th>Floating point</th>
<th>Decimal floating point</th>

</tbody>
</table>
The compatibility rules for user-defined types are as follows:

- A user-defined distinct type value is only comparable to a value that is defined with the same user-defined distinct type. In general, assignments are supported between a distinct type value and its source data type.
- A user-defined array type value is only comparable to a value that is defined with the same user-defined array type.

This means that in general, an ordinary array type is not compatible with an associative array type. The following exceptions apply only to a CALL statement for a remote stored procedure:

- A source value that is an ordinary array with an integer index can be specified for a target that is defined as an associative array, if the definitions of the array elements of the two arrays are compatible. Db2 transforms the ordinary array into an associative array with an integer index, preserving the ordering of the elements in the original ordinary array. However, if the associative array is defined with a VARCHAR index, an SQL error code is returned.
- A source value that is an associative array can be specified for a target defined as an ordinary array. Db2 transforms the associative array into an ordinary array, by assigning the values of the array elements in the associative array in the same order in the target ordinary array, and assigning appropriate index values.

For additional information, see [User-defined type assignments](#).

3. On assignment and comparison from Graphic to Character, the resulting length in bytes is 3 * (LENGTH(graphic-string)), depending on the CCSIDs.

4. Character strings with subtype FOR BIT DATA are not compatible with Graphic Data.

5. All character strings, even those with subtype FOR BIT DATA, are not compatible with binary strings.

6. LOBs are not supported.

7. The compatibility of datetime values is limited to assignment and comparison:

- Datetime values can be assigned to string columns and to string variables that are not LOB values, as explained in [DateTime assignments](#).
- A valid string representation of a date can be assigned to a date column or compared to a date.
- A valid string representation of a time can be assigned to a time column or compared to a time.
- A valid string representation of a timestamp (without or with time zone) can be assigned to a timestamp column (without or with time zone) or compared to a timestamp (without or with time zone).

8. Character and graphic strings, including LOBs, can be assigned to XML columns. For comparison, XML can only be compared using the XML EXISTS and NULL predicates.

Compatibility with a column that has a field procedure is determined by the data type of the column, which applies to the decoded form of its values.

A basic rule for assignment operations is that a null value cannot be assigned to:

- A column that cannot contain null values
- A non-Java host variable that does not have an associated indicator variable

For a host variable that does have an associated indicator variable, a null value is assigned by setting the indicator variable to a negative value. See [Host variables](#) for a discussion of indicator variables.

- A Java host variable that is a primitive type

For a Java host variable that is not a primitive type, the value of that variable is set to a Java null value.
Numeric assignments

The basic rule for numeric assignments is that the whole part of a decimal or integer number cannot be truncated. If necessary, the fractional part of a decimal number is truncated.

Decimal or integer to floating-point

Because floating-point numbers are only approximations of real numbers, the result of assigning a decimal or integer number to a floating-point column or variable might not be identical to the original number.

Floating-point or decimal to integer

When a single precision floating-point number is converted to integer, rounding occurs on the seventh significant digit, zeros are added to the end of the number, if necessary, starting from the seventh significant digit, and the fractional part of the number is eliminated. When a double precision floating-point or decimal number is converted to integer, the fractional part of the number is eliminated.

Example 1: The following example shows single precision floating-point numbers converted to an integer:

<table>
<thead>
<tr>
<th>Floating-point number:</th>
<th>Results when assigned to an integer column or host variable:</th>
</tr>
</thead>
<tbody>
<tr>
<td>2.0000045E6</td>
<td>2000000</td>
</tr>
<tr>
<td>2.00000555E8</td>
<td>200001000</td>
</tr>
</tbody>
</table>

Example 2: The following example shows a double precision floating-point number converted to an integer:

<table>
<thead>
<tr>
<th>Floating-point number:</th>
<th>Results when assigned to an integer column or host variable:</th>
</tr>
</thead>
<tbody>
<tr>
<td>2.0000045E6</td>
<td>2000004</td>
</tr>
<tr>
<td>2.00000555E8</td>
<td>200000555</td>
</tr>
</tbody>
</table>

Example 3: The following example shows a decimal number converted to an integer:

<table>
<thead>
<tr>
<th>Decimal number:</th>
<th>Results when assigned to an integer column or host variable:</th>
</tr>
</thead>
<tbody>
<tr>
<td>2000004.5</td>
<td>2000004</td>
</tr>
<tr>
<td>200000555.0</td>
<td>200000555</td>
</tr>
</tbody>
</table>

Decimal to decimal

When a decimal number is assigned to a decimal column or variable, the number is converted, if necessary, to the precision and the scale of the target.

The necessary number of leading zeros is added or eliminated, and, in the fractional part of the number, the necessary number of trailing zeros is added, or the necessary number of trailing digits is eliminated.

Decimal to DECFLOAT

When a decimal number is assigned to a DECFLOAT column or variable, the number is converted to the precision (16 or 34) of the target. Leading zeros are eliminated.

Depending on the precision and scale of the decimal number, and the precision of the target, the value might be rounded to fit.

For static SQL statements other than CREATE VIEW, the Rounding bind option or the native SQL procedure option determines the rounding mode.
For dynamic SQL statements (and static CREATE VIEW statements), the special
register CURRENT DECIMAL ROUNDING MODE determines the rounding
mode.

**Integer to decimal**
When an integer is assigned to a decimal column or variable, the number is
converted first to a temporary decimal number and then, if necessary, to the
precision and scale of the target.

The precision and scale of the temporary decimal number is 5,0 for a small integer,
11,0 for a large integer, or 19,0 for a big integer.

**Integer to DECIMAL**
When an integer is assigned to a DECIMAL column or variable, the number is
converted first to a temporary decimal number and then to DECIMAL.

The precision and scale of the temporary decimal number is 5,0 for a small integer,
11,0 for a large integer, or 19,0 for a big integer. The decimal number is then
converted to DECIMAL using the rules for Decimal to DECIMAL.

**Floating-point to floating-point**
When a single precision floating-point number is assigned to a double precision
floating-point column or variable, the single precision data is padded with eight
hex zeros. When a double precision floating-point number is assigned to a single
precision floating-point column or variable, the double precision data is converted
and rounded up on the seventh hex digit.

In assembler, C, or C++ applications that are prepared with the FLOAT(IEEE) SQL
processing option, floating-point constants and values in host variables are
assumed to have IEEE floating-point format. All floating-point data is stored in
Db2 in System/390 floating-point format. Therefore, when the FLOAT(IEEE) SQL
processing option is in effect, Db2 performs the following conversions:

- When a number in short or long IEEE floating-point format is assigned to a
  single-precision or double-precision floating-point column, Db2 converts the
  number to System/390 floating-point format.
- When a single-precision or double-precision floating-point column value is
  assigned to a short or long floating-point host variable, Db2 converts the column
  value to IEEE floating-point format.

**Floating-point to decimal**
When a single precision floating-point number is assigned to a decimal column or
variable, the number is first converted to a temporary decimal number.

When a single precision floating-point number is assigned to a decimal column or
variable, the number is first converted to a temporary decimal number of precision
6 by rounding on the seventh decimal digit. Twenty five zeros are then appended
to the number to bring the precision to 31. Because of rounding, a number less
than 0.5×10⁻⁶ is reduced to 0.

When a double precision floating-point number is assigned to a decimal column or
variable, the number is first converted to a temporary decimal number of precision
15, and then, if necessary, truncated to the precision and scale of the target. In this
conversion, zeros are added to the end of the number, if necessary, to bring the
precision to 16. The number is then rounded (using floating-point arithmetic) on
the sixteenth decimal digit to produce a 15-digit number. Because of rounding, a
number less in magnitude than 0.5×10⁻¹⁵ is reduced to 0. If the decimal number
requires more than 15 digits to the left of the decimal point, an error is reported. Otherwise, the scale is given the largest possible value that allows the whole part of the number to be represented without loss of significance.

The following examples show the effect of converting a double precision floating-point number to decimal:

Example 1: The floating-point number, \( .123456789098765 \times 10^{-5} \) in decimal notation is, \( .0000123456789098765 \). Rounding adds 5 in the 16th position, so the number becomes \( .0000123456789148765 \) and truncates the result to \( .00001234567891 \). Zeros are then added to the end of a 31-digit result, and the number becomes \( .0000123456789100000000000000000 \).

Example 2: The floating-point number, \( 1.2339999999999 \times 10^1 \) in decimal notation is, \( 12.3399999999990 \). Rounding adds 5 in the 16th position, so the number becomes \( 12.33999999999905 \) and truncates the result to \( 12.3399999999990 \). Zeros are then added to the end of a 31-digit result and the number becomes \( 12.3399999999990000000000000000000 \).

**Floating point to DECFLOAT**

When a single or double precision floating-point number is assigned to a DECFLOAT column or variable, the number is first converted to a temporary string representation of the floating point number. The string representation of the number is then converted to DECFLOAT.

**DECFLOAT to integer**

When a DECFLOAT is assigned to a binary integer column or variable, the fractional part of the number is lost.

Example 1: The following example shows decimal floating-point numbers converted to an integer:

<table>
<thead>
<tr>
<th>Decimal floating-point number:</th>
<th>Results when assigned to an integer column or host variable:</th>
</tr>
</thead>
<tbody>
<tr>
<td>2.0000045E6</td>
<td>2000004</td>
</tr>
<tr>
<td>2.00000555E6</td>
<td>200000555</td>
</tr>
</tbody>
</table>

**DECFLOAT to decimal**

When a DECFLOAT value is assigned to a decimal column or variable, the DECFLOAT value is converted, if necessary, to the precision and the scale of the target.

During the assignment, the necessary number of leading zeros is added and, in the fractional part of the number, the necessary number of trailing zeros is added, or rounding occurs.

For static SQL statements other than CREATE VIEW, the ROUNDING bind option or the native SQL procedure option determines the rounding mode.

For dynamic SQL statements (and static CREATE VIEW statements), the special register CURRENT DECFLOAT ROUNDING MODE determines the rounding mode.

Example 1: The following example shows decimal floating-point numbers converted to a decimal value:

<table>
<thead>
<tr>
<th>Decimal floating-point number:</th>
<th>Results when assigned to an decimal(15,0) column or host variable:</th>
</tr>
</thead>
<tbody>
<tr>
<td>2.0000045E6</td>
<td>2000005</td>
</tr>
</tbody>
</table>
Decimal floating-point number: Results when assigned to an decimal(15,2) column or host variable:

<table>
<thead>
<tr>
<th>Decimal Value</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>2.0000045E6</td>
<td>2000004.50</td>
</tr>
<tr>
<td>2.00000555E8</td>
<td>200000555.00</td>
</tr>
</tbody>
</table>

**DECFLOAT to floating-point**

Because floating-point numbers are only approximations of real numbers, the result of assigning a DECFLOAT value to a floating-point column or variable might not be identical to the original number.

The DECFLOAT value is first converted to a string representation, and is then converted to floating-point number.

**DECFLOAT(16) to DECFLOAT(34)**

When a DECFLOAT(16) is assigned to a DECFLOAT(34) column or variable, the exponent of the source is converted to the corresponding exponent in the result format, and the coefficient is extended by appending zeros on the left.

**DECFLOAT(34) to DECFLOAT(16)**

When a DECFLOAT(34) is assigned to a DECFLOAT(16) column or variable, the exponent of the source is converted to the corresponding exponent in the result format.

The source coefficient is rounded to the precision of the target.

For static SQL statements, the ROUNDING bind option or the native SQL procedure option determines the rounding mode.

For static SQL statements other than CREATE VIEW, the ROUNDING bind option or the native SQL procedure option determines the rounding mode.

For dynamic SQL statements (and static CREATE VIEW statements), the special register CURRENT DECFLOAT ROUNDDING MODE determines the rounding mode.

**To COBOL integers**

Assignment to COBOL integer variables uses the full size of the integer.

Thus, the value placed in the COBOL data item might be out of the range of values.

COBOL supports some data types with no SQL equivalent (BINARY decimal and DISPLAY decimal data items, for example). In most cases, you can use COBOL statements to convert between the unsupported COBOL data types and the data types that SQL supports.

For Db2 for z/OS, the only BINARY numeric variables allowed as HOST variable are integer binary variables. The only DECIMAL host variables supported by SQL are packed decimal host variables.

**Example 1:** If COL1 contains a value of 12345, the following statements cause the value 12345 to be placed in A, even though A has been defined with only 4 digits:

```
01 A PIC S9999 BINARY.
EXEC SQL SELECT COL1
   INTO :A
   FROM TABLEX
END-EXEC.
```

Example 2: The following COBOL statement results in 2345 being placed in A:

\[ \text{MOVE 12345 TO A}. \]

**String assignments**

There are two types of string assignments; storage assignment and retrieval assignment.

- **Storage assignment** is when a value is assigned to a column or to a transition variable.
- **Retrieval assignment** is when a value is assigned to a variable, except for a transition variable.

The rules differ for storage and retrieval assignment.

**Binary string assignment**

Binary string assignment involves assignment at both the storage and the retrieval of binary strings.

**Storage assignment:**

The length of a string that is assigned to a column or transition variable must not be greater than the length attribute of the column or parameter. If the string is longer than the length attribute of that column or transition variable, an error is returned.

When the string is assigned to a fixed-length binary string column or parameter of a function or procedure, and the length of the string is less than the length attribute of that column or parameter, the string is padded to the right with the necessary number of binary zeros.

**Retrieval assignment:**

The length of a string that is assigned to a variable can be greater than the length attribute of the variable. When a string is assigned to a variable and the string is longer than the length attribute of the variable, the string is truncated on the right by the necessary number of bytes. When this occurs, a warning is returned.

**Character and graphic string assignment**

The rules for storage and retrieval assignment apply when both the source and the target are strings.

When a datetime data type is involved, see “Datetime assignments” on page 159. For the special considerations that apply when a distinct type is involved in an assignment, especially to a variable, see “Distinct type assignments” on page 161.

**Storage assignment:**

The basic rule for character storage assignment is that the length of a string that is assigned to a column or transition variable must not be greater than the length attribute of the column or transition variable.

Trailing blanks are included in the length of the string. When the length of the string is greater than the length attribute of the column or the parameter, the following actions occur:

- If all of the trailing characters that must be truncated to make a string fit the target are blanks and the string is a character or graphic string, the string is truncated and assigned without warning.
Otherwise, the string is not assigned and an error occurs to indicate that at least one of the excess characters is non-blank.

When a string is assigned to a fixed-length column or parameter and the length of the string is less than the length attribute of the target, the string is padded to the right with the necessary number of SBCS or DBCS blanks. The pad character is always a blank even for columns or parameters that are defined with the FOR BIT DATA attribute.

**Retrieval assignment:**

The length of a string that is assigned to a variable can be greater than the length attribute of the variable. When the length of the string is greater than the length of the variable, the string is truncated on the right by the necessary number of SBCS or DBCS characters.

When truncation occurs, a warning is returned (SQLSTATE of '01004'). If the variable is a host variable, the value 'W' is assigned to the SQLWARN1 field of the SQLCA. Furthermore, if an indicator variable is provided and the source of the value is not a LOB, the indicator variable is set to the original length of the string. The truncation result of an improperly formed mixed string is unpredictable.

When a character string is assigned to a fixed-length variable and the length of the string is less than the length attribute of the target, the string is padded to the right with the necessary number of blanks. The pad character is always a blank even for strings defined with the FOR BIT DATA attribute.

When a string of length $n$ is assigned to a varying-length string variable with a maximum length greater than $n$, the characters after the $n$th character of the variable are undefined.

**Assignments involving mixed data strings**

A mixed data string that contains MBCS characters cannot be assigned to an SBCS column, SBCS parameter, or SBCS variable.

The following rules apply when a mixed data string is assigned to a variable and the string is longer than the length attribute of the variable:

- If the string is not well-formed mixed data, it is truncated as if it were BIT or graphic data.
- If the string is well-formed mixed data, it is truncated on the right such that it is well-formed mixed data with a length that is the same as the length attribute of the variable and the number of characters lost is minimal.

**Assignments involving C NUL-terminated strings**

A C NUL-terminated string variable that is referenced in a CONNECT statement does not need to contain a NUL. Otherwise, Db2 enforces the convention that the value of a NUL-terminated string variable, either character or graphic, is NUL-terminated.

An input variable that does not contain a NUL will cause an error. A value that is assigned to an output variable will always be NUL-terminated even if a character must be truncated to make room for the NUL.

When a string of length $n$ is assigned to a C NUL-terminated string variable with a length greater than $n+1$, the rules depend on whether the source string is a value of a fixed-length string or a varying-length string:
If the source is a fixed-length string and the value of field PAD NUL-TERMINATED on installation panel DSNTIP4 is YES, the string is padded on the right with \( x-n-1 \) blanks, where \( x \) is the length of the variable. The padded string is then assigned to the variable and a NUL is appended at the end of the variable. If the value of field PAD NUL-TERMINATED is NO, the string is assigned to the first \( n \) bytes of the variable and a NUL is appended at the end of the variable.

If the source is a varying-length string, the string is assigned to the first \( n \) bytes of the variable and a NUL is appended at the end of the variable.

Conversion rules for string assignment

A character or graphic string that is assigned to a column or variable is first converted, if necessary, to the coded character set of the target. Conversion is necessary only if certain conditions apply.

Conversion is necessary only if all the following are true:

- The CCSIDs of string and target are different.
- Neither CCSID is X'FFFF' (neither the string nor the target is defined as BIT data).
- The string is neither null nor empty.

An error occurs if:

- The SYSTRINGS table is used but contains no information about the pair of CCSIDs and Db2 cannot do the conversion through z/OS support for Unicode.
- A character of the string cannot be converted and the operation is assignment to a column or to a host variable that has no indicator variable. For example, a DBCS character cannot be converted to a variable with an SBCS CCSID.

A warning occurs if:

- A character of the string is converted to a substitution character. A substitution character is the character that is used when a character of the source character set is not part of the target character set. For example, assuming an EBCDIC target character set, if the source character set includes Katakana characters and the target character set does not, a Katakana character is converted to the EBCDIC SUB X'3F'.
- A character of the string cannot be converted and the operation is assignment to a variable that has an indicator variable. For example, a DBCS character cannot be converted if the variable has an SBCS CCSID. In this case, the string is not assigned to the variable and the indicator variable is set to -2.

Datetime assignments

A string value that is assigned to a date, time, or timestamp column, variable, or parameter must be a valid string representation of a date, a time, or a timestamp.

A value that is assigned to a date column, a date variable, or a date parameter must be a date, a valid string representation of a date, or a valid string representation of a timestamp without a time zone. When a string representation of a timestamp without a time zone is assigned to a date target, the Db2 database manager assigns the date portion of the timestamp to the date target, and does not use the time portion of the timestamp.

A date can be assigned only to the following items:

- a date column
- a character-string column
• a character-string variable
• a date variable

A value that is assigned to a time column, a time variable, or a time parameter must be a time, a valid string representation of a time, or a valid string representation of a timestamp without a time zone. When a string representation of a timestamp without a time zone is assigned to a time target, the Db2 database manager assigns the time portion of the timestamp to the time target, truncates any fractions of seconds, and does not use the date portion of the timestamp.

A time can be assigned only to the following items:
• a time column
• a character-string column
• a character-string variable
• a time variable

A value that is assigned to a timestamp column, a timestamp variable, or a timestamp parameter must be a timestamp, a timestamp constant, a valid string representation of a timestamp, or a valid string representation of a date. When a string representation of a date is assigned to a timestamp target, the Db2 database manager inserts zeroes for the time portion of the timestamp target.

A timestamp can be assigned only to the following items:
• a timestamp column
• a character-string or graphic-string column
• a timestamp variable
• a character-string or graphic-string variable

A valid string representation of a datetime value must not be a BLOB, CLOB, or DBCLOB. A datetime value cannot be assigned to a column that has a field procedure. If the timestamp precision of the target is less than the timestamp precision of the assigned value, the extra fractional seconds are truncated.

When a datetime value is assigned to a character-string variable or column, it is converted to its string representation. Leading zeros are not omitted from any part of the date, time, or timestamp. The required length of the target varies depending on the format of the string representation. If the length of the fixed length character-string target is greater than required, it is padded on the right with blanks. If the length of the target is less than required, the result depends on the type of datetime value involved, and the type of the target.

When a datetime value is assigned to a timestamp variable or column, it is converted to the target timestamp data type. If the source data type is not the same as the target data type, the source value is implicitly cast to the target data type. Db2 might implicitly cast data types during assignments that involve a distinct type.
• If the target is not a variable and has a character-string or graphic-string data type (except for BLOB, CLOB, or DBCLOB), truncation is not allowed. The length of the column must be at least the following values:
  – 10 for a DATE
  – 8 for a TIME
  – 19 for a TIMESTAMP WITHOUT TIME ZONE with a precision of 0, 20+p with precision of p
– Sufficient to include the time zone (truncation is not allowed), for a
TIMESTAMP WITH TIME ZONE

• When the target is a character-string or graphic-string variable, the following
rules apply:
  – **For a date:** The length of the variable must not be less than 10.
  – **For a time:** If the USA format is used, the length of the variable must not be
  less than 8. This format does not include seconds.
    If the ISO, EUR, or JIS format is used, the length of the variable must not be
    less than 5. If the length is 5, 6, or 7, the seconds part of the time is omitted
    from the result and SQWARN1 is set to 'W'. In this case, the seconds part of
    the time is assigned to the indicator variable if one is provided, and, if the
    length is 6 or 7, the value is padded with blanks so that it is a valid string
    representation of a time.
  – **For a timestamp:** The length of the variable must not be less than 19. If the
    source is TIMESTAMP WITH TIME ZONE, the length of the variable must be
    sufficient to include the time zone, truncation is not allowed.
    - If the length is between 19 and 31, the timestamp is truncated like a string,
      which causes the omission of one or more digits of the fractional seconds
      part of a timestamp.
    - If the length is 20, the trailing decimal point is excluded so that the value is
      a valid string representation of a timestamp with precision 0.

**Row ID assignments**

A row ID value can be assigned only to a column, parameter, or host variable with
a row ID data type.

For the value of the ROWID column, the column must be defined as GENERATED
BY DEFAULT and the column must have a unique, single-column index. The value
that is specified for the column must be a valid row ID value that was previously
generated by Db2.

**XML assignments**

XML data can be assigned to a column, but when the target is not a column, the
XML data type can only be assigned to another XML data type.

When the target is a column (for example, data change statements), the source can
be the XML data type, or CHAR, VARCHAR, CLOB, GRAPHIC, VARGRAPHIC,
DBCLOB, BINARY, VARBINARY, or BLOB data types. When the source is not
XML data, the source is implicitly parsed as if the XMLPARSE function is invoked
with the STRIP WHITESPACE option. If the source data is graphic data, the
encoding scheme must be Unicode.

All other data types cannot be assigned to a target of the XML data type.

**User-defined type assignments**

User-defined type assignments include distinct type assignments and array
assignments.

**Distinct type assignments**

The rules that apply to the assignments of distinct types to host variables are
different than the rules for all other assignments that involve distinct types.
Assignments to host variables: The assignment of distinct type to a host variable is based on the source data type of the distinct type. Therefore, the value of a distinct type is assignable to a host variable only if the source data type of the distinct type is assignable to the host variable.

Example: Assume that distinct type AGE was created with the following SQL statement:

```
CREATE TYPE AGE AS SMALLINT;
```

When the statement was executed, Db2 also generated these cast functions:

- `AGE (SMALLINT) RETURNS AGE`
- `AGE (INTEGER) RETURNS AGE`
- `SMALLINT (AGE) RETURNS SMALLINT`

Next, assume that column STU_AGE was defined in table STUDENTS with distinct type AGE. Now, consider this valid assignment of a student's age to host variable HV_AGE, which has an INTEGER data type:

```
SELECT STU_AGE INTO :HV_AGE FROM STUDENTS WHERE STU_NUMBER = 200;
```

The distinct type value is assignable to host variable HV_AGE because the source data type of the distinct type (SMALLINT) is assignable to the host variable (INTEGER). If distinct type AGE had been based on a character data type such as CHAR(5), the above assignment would be invalid because a character type cannot be assigned to an integer type.

Assignments other than to host variables: A distinct type can be the source or target of an assignment. Assignment is based on whether the data type of the value to be assigned is castable to the data type of the target. (Casting between data types shows which casts are supported when a distinct type is involved). Therefore, a distinct type value can be assigned to any target other than a host variable when:

- The target of the assignment has the same distinct type, or
- The distinct type is castable to the data type of the target

Any value can be assigned to a distinct type when:

- The value to be assigned has the same distinct type as the target, or
- The data type of the assigned value is castable to the target distinct type

Example: Assume that the source data type for distinct type AGE is SMALLINT:

```
CREATE TYPE AGE AS SMALLINT;
```

Next, assume that two tables TABLE1 and TABLE2 were created with four identical column descriptions:

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>AGECOL</td>
<td>AGE</td>
</tr>
<tr>
<td>SMINTCOL</td>
<td>SMALLINT</td>
</tr>
<tr>
<td>INTCOL</td>
<td>INTEGER</td>
</tr>
<tr>
<td>DECCOL</td>
<td>DEC(6,2)</td>
</tr>
</tbody>
</table>

Using the following SQL statement and substituting various values for X and Y to insert values into various columns of TABLE1 from TABLE2, the following table shows whether the assignments are valid. Db2 uses assignment rules in this INSERT statement to determine if X can be assigned to Y.

```
INSERT INTO TABLE1 (Y) 
SELECT X FROM TABLE2;
```
### Table 32. Assessment of various assignments for example INSERT statement

<table>
<thead>
<tr>
<th>X (column in TABLE2)</th>
<th>Y (column in TABLE1)</th>
<th>Valid</th>
<th>Reason</th>
</tr>
</thead>
<tbody>
<tr>
<td>AGECOL</td>
<td>AGECOL</td>
<td>Yes</td>
<td>Source and target are same distinct type</td>
</tr>
<tr>
<td>SMINTCOL</td>
<td>AGECOL</td>
<td>Yes</td>
<td>SMALLINT can be cast to AGE</td>
</tr>
<tr>
<td>INTCOL</td>
<td>AGECOL</td>
<td>Yes</td>
<td>INTEGER can be cast to AGE (because AGE’s source type is SMALLINT)</td>
</tr>
<tr>
<td>DECCOL</td>
<td>AGECOL</td>
<td>No</td>
<td>DECIMAL cannot be cast to AGE</td>
</tr>
<tr>
<td>AGECOL</td>
<td>SMINTCOL</td>
<td>Yes</td>
<td>AGE can be cast to its source type of SMALLINT</td>
</tr>
<tr>
<td>AGECOL</td>
<td>INTCOL</td>
<td>No</td>
<td>AGE cannot be cast to INTEGER</td>
</tr>
<tr>
<td>AGECOL</td>
<td>DECCOL</td>
<td>No</td>
<td>AGE cannot be cast to DECIMAL</td>
</tr>
</tbody>
</table>

### Array type assignments

An array value can only be assigned to a variable or parameter with a compatible user-defined array type.

The following values can be assigned to an array variable:

- The null value.
- The value of an array with a user-defined array type, where the source and target arrays have the same user-defined array type. The source value can be an array variable, an invocation of the TRIM_ARRAY function, an invocation of the ARRAY_DELETE function, or a CAST specification. The value of an ordinary array variable or parameter can only be assigned to an ordinary array target. The value of an associative array variable or parameter can only be assigned to an associative array target.
- The value of an array without a user-defined array type. The result of an invocation of aggregate built-in function ARRAY_AGG or of an array constructor is an array without an associated user-defined data type.

For an assignment with a FETCH statement, the elements in the source array value must have the same data type as the elements of the user-defined array type of the target array. The index values of the source array value must have the same data type as the index of the user-defined array type of the target array.

For an assignment that is the result of a statement other than FETCH, the source array value is implicitly cast to the target array type.

Assignment of a value to an array element might affect the cardinality of the array, and might result in initializing other new array elements with the null value. Suppose that A is the target array variable, c is the cardinality of array A, idx is an expression that is used as the array index, and SV is the source value. Db2 assigns the values to the elements of the array as follows:

- If array A is the null value, A is set to an empty array.
- If A is an ordinary array:
  - If idx is less than or equal to c, the value in the element of A with array index idx is replaced by the value of SV.
  - If idx greater than c:
    - Each element of A with array index i, for every i that is greater than c and less than idx, is set to the null value.
- The element of A with array index \( idx \) is set to the value of SV.
- The cardinality of A is set to \( idx \).

- If A is an associative array:
  - If \( idx \) matches an existing value of the array index for A, the value of the element with array index \( idx \) is replaced by the value of SV.
  - If \( idx \) does not match an existing value of the array index for A:
    - The element of A with array index \( idx \) is set to the value of SV.
    - The cardinality of A is incremented by 1.

The following values can be assigned to an element of an array variable:
- The null value
- The value of an expression, where the data type of the expression is assignable to the data type of the elements in the target array

### Examples

#### Example: Assigning an array to another array

Suppose that arrays PHONELIST and HOMEPHONELIST are defined with the same user-defined array type named PLIST. PLIST is defined with VARCHAR(12) elements. The following statement assigns the values of the HOMEPHONELIST array to the PHONELIST array:

```sql
SET PHONELIST = HOMEPHONELIST;
```

#### Example: Assigning elements of an array to another array

Suppose that array V is defined with user-defined type MYARRAY. The following statement assigns the values 1, 2, and 3 to array V using an array constructor.

```sql
SET V = ARRAY[1,2,3];
```

This statement is equivalent to the following statement:

```sql
SET V = CAST(ARRAY[1,2,3] AS MYARRAY);
```

#### Example: Assigning values from a column to an array

Suppose that array V is defined with user-defined type MYARRAY. The following statement assigns the values from the column C1 in table T to array V using the ARRAY_AGG function.

```sql
SELECT ARRAY_AGG(C1) INTO V FROM T;
```

This statement is equivalent to the following statement:

```sql
SELECT CAST(ARRAY_AGG(C1) AS MYARRAY) INTO V FROM T;
```

### Assignments to LOB locators

When a LOB locator is used, it can refer only to LOB data. If a LOB locator is used for the first fetch of a cursor, LOB locators must be used for all subsequent fetches.

### Numeric comparisons

Numbers are compared algebraically, that is, with regard to sign. For example, -2 is less than +1. When numbers of different data types are compared, certain rules are in effect as to how the comparison is performed.

If one number is an integer and the other is decimal, the comparison is made with a temporary copy of the integer, which has been converted to decimal.
When decimal numbers with different scales are compared, the comparison is made with a temporary copy of one of the numbers that has been extended with trailing zeros so that its fractional part has the same number of digits as the other number.

If one number is double precision floating-point and the other is integer, decimal, or single precision floating-point, the comparison is made with a temporary copy of the other number which has been converted to double precision floating-point. However, if a single precision floating-point number is compared with a floating-point constant, the comparison is made with a single precision form of the constant.

Two floating-point numbers are equal only if the bit configurations of their normalized forms are identical.

If one number is DECFLOAT and the other number is integer, decimal, single precision floating-point, or double precision floating-point, the comparison is made with a temporary copy of the other number which has been converted to DECFLOAT.

If one number is DECFLOAT(16) and the other number is DECFLOAT(34), the DECFLOAT(16) value is converted to DECFLOAT(34) before the comparison.

Additionally, the DECFLOAT data type supports both positive and negative zero. Positive and negative zero have different binary representations, but the equal (=) predicate will return true for comparisons of positive and negative zero.

The functions, COMPARE_DECFLOAT and TOTALORDER can be used to perform comparisons at a binary level. For example, for a comparison of 2.0<>2.00.

The DECFLOAT data type also supports the specification of negative and positive NaN (quiet and signaling), and negative and positive infinity. From an SQL perspective, infinity = infinity, NaN = NaN, and sNaN = sNaN.

The following rules are the comparison rules for these special values:

- Infinity compares equal only to infinity of the same sign (positive or negative)
- NaN compares equal only to NaN of the same sign (positive or negative)
- sNaN compares equal only to sNaN of the same sign (positive or negative)

The ordering among the different special values is as follows: -NAN < -SNAN < -INFINITY < 0 < INFINITY < SNAN <NAN

String comparisons

String comparisons can occur with binary string, character strings, and graphic strings.

Binary string comparisons

Binary string comparisons are always performed according to the binary values.

Two binary strings are equal only if the lengths of the two strings are identical. If the strings are equal up to the length of the shorter string length, the shorter string is considered less than the longer string even when the remaining bytes in the longer string are hexadecimal zeros. This is illustrated in the following table:
Table 33. Binary string comparison where one operand is longer because of hexadecimal zeros

<table>
<thead>
<tr>
<th>Hexadecimal value of the first operand</th>
<th>relationship</th>
<th>Hexadecimal value of the second operand</th>
</tr>
</thead>
<tbody>
<tr>
<td>X'4100'</td>
<td>&lt;</td>
<td>X'410000'</td>
</tr>
<tr>
<td>X'4100'</td>
<td>&lt;</td>
<td>X'42'</td>
</tr>
<tr>
<td>X'4100'</td>
<td>=</td>
<td>X'4100'</td>
</tr>
<tr>
<td>X'4100'</td>
<td>&gt;</td>
<td>X'41'</td>
</tr>
<tr>
<td>X'4100'</td>
<td>&gt;</td>
<td>X'400000'</td>
</tr>
</tbody>
</table>

Binary strings cannot be compared to character strings (even FOR BIT DATA) unless the character string is cast to a binary string.

Character and graphic string comparisons

Two strings are compared by comparing the corresponding bytes of each string. If the strings do not have the same length, the comparison is made with a temporary copy of the shorter string that has been padded on the right with blanks so that it has the same length as the other string.

Two strings are equal if they are both empty or if all corresponding bytes are equal. An empty string is equal to a blank string. If two strings are not equal, their relationship (that is, which has the greater value) is determined by the comparison of the first pair of unequal bytes from the left end of the strings. This comparison is made according to the collating sequence associated with the encoding scheme of the data. For ASCII data, characters A through Z (both upper and lowercase) have a greater value than characters 0 through 9. For EBCDIC data, characters A through Z (both upper and lowercase) have a lesser value than characters 0 through 9.

Varying-length strings with different lengths are equal if they differ only in the number of trailing blanks. In operations that select one value from a collection of such values, the value selected is arbitrary. The operations that can involve such an arbitrary selection are DISTINCT, MAX, MIN, and references to a grouping column. See the description of GROUP BY for further information about the arbitrary selection involved in references to a grouping column.

Related concepts:

Objects with different CCSIDs in the same SQL statement (Db2 Internationalization Guide)

String comparisons with field procedures:

The rules for string comparisons with field procedures depend on the values being compared.

If a column with a field procedure is compared with the value of a variable or a constant, the variable or constant is encoded by the field procedure before the comparison is made. If the comparison operator is LIKE, the variable or constant is not encoded and the column value is decoded.

If a column with a field procedure is compared with another column, that column must have the same field procedure and both columns must have the same CCSID set. The comparison is performed on the encoded form of the values in the columns. If the encoded values are numeric, their data types must be identical; if they are strings, their data types must be compatible.
If two encoded strings of different lengths are compared, the shorter is temporarily padded with encoded blanks so that it has the same length as the other string.

In a CASE expression, if a column with a field procedure is used as the result-expression in a THEN or ELSE clause, all other columns that are used as result-expressions must have the same field procedure. Otherwise, no column used in a result-expression can name a field procedure.

### Datetime comparisons

A date, time, or timestamp value can be compared with another value of the same data type, a datetime constant of the same data type, or with a string representation of a value of that data type. Additionally, a TIMESTAMP WITHOUT TIME ZONE value can be compared with a TIMESTAMP WITH TIME ZONE value.

All comparisons are chronological, which means the further a point in time is from January 1, 0001, the greater the value of that point in time. The time 24:00:00 compares greater than the time 00:00:00.

Comparisons that involve TIME values and string representations of time values always include seconds. If the string representation omits seconds, zero seconds are implied.

Comparisons that involve timestamp values are evaluated according to the following rules:

- When comparing timestamp values with different precisions, the higher precision is used for the comparison and any missing digits for fractional seconds are assumed to be zero.
- When comparing a TIMESTAMP WITH TIME ZONE value to a TIMESTAMP WITHOUT TIME ZONE value, the TIMESTAMP WITHOUT TIME ZONE value is cast to TIMESTAMP WITH TIME ZONE before the comparison is made.
- When comparing two TIMESTAMP WITH TIME ZONE values, the comparison is made using the UTC representations of the values. Two TIMESTAMP WITH TIME ZONE values are considered equal if they represent the same instance in UTC, regardless of the time zone offsets that are stored in the values. For example, '1999-04-15-08.00.00-08:00' (8:00 a.m. Pacific Standard Time) is the same as '1999-04-15-11.00.00-05:00' (11:00 a.m. Eastern Standard Time).
- When comparing a timestamp value with a string representation of a timestamp, the string representation is first converted to a the data type of the timestamp operand. With the except that the converted value has a precision of 12. If the timestamp operand is TIMESTAMP WITHOUT TIME ZONE, the string must not contain a specification of time zone.
- Timestamp comparisons are chronological without regard to representations that might be considered equivalent. For example, the following predicate is true: `TIMESTAMP('1990-02-23-00.00.00') > '1990-02-22-24.00.00'`

**Example 1:** Table TABLE1 has 2 columns: C1, which is defined as TIMESTAMP WITH TIME ZONE; and C2, which is defined as TIMESTAMP WITHOUT TIME ZONE:

```
CREATE TABLE TABLE1 (C1 TIMESTAMP WITH TIME ZONE, C2 TIMESTAMP);
```

A row is inserted into the table with the following INSERT statement. The input values are provided by character-string representations of a timestamp with a time zone.
INSERT INTO TABLE1 VALUES ( '2007-11-05-08.00.00-08:00', '2007-11-05-08.00.00-08:00' );

Assuming that the implicit time zone is -5:00, the following SELECT statement will not return any rows. The string representation of the TIMESTAMP WITHOUT TIME ZONE value is cast to a TIMESTAMP WITH TIME ZONE value, which results in a timestamp with time zone value of '2007-11-05-08.00.00-05:00' for column C2. The comparison predicate is false because the two values are not equal.
SELECT 1 FROM TABLE1 WHERE C1 = C2;

Example 2: When a TIMESTAMP WITHOUT TIME ZONE value is compared with a string representation of a TIMESTAMP WITHOUT TIME ZONE or a TIMESTAMP WITH TIME ZONE value, the string representation is cast to TIMESTAMP WITHOUT TIME ZONE (regardless of whether the string contains a time zone). The comparison is performed using the two TIMESTAMP WITHOUT TIME ZONE values. Assume that string_hv contains a timestamp with time zone value of '2007-11-05-08.00.00-08:00'. The string value is cast to a TIMESTAMP WITHOUT TIME ZONE value of '2007-11-05-08.00.00', which is compared with the value that is stored in column C2. The following SELECT statement returns a single row because a row exists in the table with a timestamp without time zone value of '2007-11-05-08.00.00'.
SELECT 1 FROM TABLE1 WHERE C2 = :string_hv;

Row ID comparisons
A value with a row ID type can only be compared to another row ID value.

The comparison of the row ID values is based on their internal representations. The maximum number of bytes that are compared is 17 bytes, which is the number of bytes in the internal representation. Therefore, row ID values that differ in bytes beyond the 17th byte are considered to be equal.

XML comparisons
The XML data type cannot be directly compared to any data type, including the XML data type. The method for doing comparison is through the use of the XMLEXISTS predicate.

Conversion rules for comparisons
When two strings are compared, one of the strings is first converted, if necessary, to the coded character set of the other string. Conversion is necessary only if certain rules apply.

Conversion is necessary only if all of the following are true:
• The CCSIDs of the two strings are different.
• Neither CCSID is X'FFFF' (neither string is defined as a binary string).
• The string selected for conversion is neither null nor empty.
• The following conversion tables (Table 35 on page 170 or Table 36 on page 171) indicate when conversion is necessary.

The string selected for conversion depends on the type of the operands. For the purpose of CCSID determination, string expressions in a statement are divided into 6 types, as described in the following table.

<table>
<thead>
<tr>
<th>Table 34. Operand types</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type of operand</td>
</tr>
<tr>
<td>Columns</td>
</tr>
<tr>
<td>Type of operand</td>
</tr>
<tr>
<td>---------------------------------</td>
</tr>
<tr>
<td>String constants</td>
</tr>
<tr>
<td>Special registers</td>
</tr>
<tr>
<td>Host variables</td>
</tr>
<tr>
<td>Global variables</td>
</tr>
<tr>
<td>Derived value based on a column</td>
</tr>
</tbody>
</table>

For example:

- The CCSID of `SUBSTR(column_1, 5, length(column_2))` is the CCSID of `column_1`. Note that the CCSID of `column_2` has no influence on the CCSID of `SUBSTR`.
- The CCSID of `column_1 || 'ABC'` is the CCSID of `column_1`, derived from the rules described in Table 35 on page 170.
- The CCSID of `column_1 || G'42C1'` is the DBCS CCSID from the CCSID set of `column_1`, derived from the rules described in Table 35 on page 170 and Table 36 on page 171.
- The CCSID of `COALESCE(EBCDIC_column_1, ASCII_column_1)` is the UNICODE CCSID, derived from the rules described in Table 35 on page 170.
- The CCSID of `CAST(string_column_1 AS GRAPHIC(10))` is the DBCS CCSID from the CCSID set of `string_column_1`.
- The CCSID of `CAST(EBCDIC_string_column_1 AS VARCHAR(10) CCSID UNICODE)` is the UNICODE CCSID derived from the rules described in Table 35 on page 170.
- The CCSID of `CASE WHEN(1=1) THEN '1' ELSE ASCII_column_1 END` is the CCSID of `ASCII_column_1`, derived from the rules described in Table 35 on page 170.
- The CCSID of `CASE WHEN(1=1) THEN EBCDIC_column_1 ELSE ASCII_column_1 END` is the UNICODE CCSID derived from the rules described in Table 35 on page 170.
- The CCSID of a scalar fullselect (`SELECT column_1 FROM table_1`) is the CCSID of `column_1`.

Chapter 2. Language elements  169
The following table shows which operand supplies the target CCSID set when the comparison is part of an SQL statement involving multiple tables with different CCSID sets.

**Table 35. Operand that supplies the CCSID for character conversion**

<td></td>
</tr>
</tbody>
</table>

Note:
1. If the CCSID sets are different, both operands are converted, if necessary, to Unicode. SBCS and Mixed are converted to UTF-8. DBCS is converted to UTF-16. See the next table to determine which operand supplies the CCSID for character conversion.
2. If the encoding scheme that is in effect for the statement is EBCDIC or ASCII, the host variable is Unicode graphic, and the value of the field MIXED DATA on installation panel DSNTIPF is NO, the column or the derived value that is based on a column supplies the target CCSID set.

The following table shows which operand is selected for conversion when both operands are based on a column or are not based on a column as represented in the previous table.

Table 36. Operand that supplies the CCSID for character conversion when both operands are based or not based on a column

<table>
<thead>
<tr>
<th>First operand</th>
<th>SBCS data</th>
<th>Mixed data</th>
<th>DBCS data</th>
</tr>
</thead>
<tbody>
<tr>
<td>SBCS data</td>
<td>second operand</td>
<td>second operand</td>
<td></td>
</tr>
<tr>
<td>Mixed data</td>
<td>first operand</td>
<td>second operand</td>
<td></td>
</tr>
<tr>
<td>DBCS data</td>
<td>first operand</td>
<td>first operand</td>
<td></td>
</tr>
</tbody>
</table>

Note:
1. For ASCII and EBCDIC data, the conversion depends on the value of the field MIXED DATA on installation panel DSNTIPF at the Db2 that does the comparison. If MIXED DATA = YES, the SBCS operand is converted to MIXED. If MIXED DATA = NO, the MIXED operand is converted to SBCS.

For example, assume a comparison of the form:

```
string-constant-SBCS = derived-value-not-based-on-column-DBCS
```

Assume that the operands have different encoding schemes. First look at Table 35 on page 170. The relevant table entry is in the third row and second column. The value for this entry shows that if the CCSID sets are different, the operands are converted to Unicode. The first operand (string-constant-SBCS) is converted to UTF-8 (Mixed) if it is not already Unicode. In addition, the second operand (derived-value-not-based-on-column-DBCS) is converted to UTF-16 (Unicode DBCS) if necessary. After the operands have been converted to Unicode, Table 36 is used to determine which operand supplies the specific CCSID for the conversion. The relevant table entry is in the second row and third column. It indicates that the second operand (derived-value-not-based-on-column-DBCS) determines the CCSID because DBCS data takes precedence over Mixed data.

An error occurs if a character of the string cannot be converted, the SYSSTRINGS table is used but contains no information about the pair of CCSIDs of the operands being compared, or Db2 cannot do the conversion through z/OS support for Unicode. A warning occurs if a character of the string is converted to a substitution character.
A derived value based on a column is an expression that includes columns that affect the result CCSID of the expression. For example, in the expression COL1||'abc', COL1 determines the result CCSID. Therefore, the expression COL1||'abc' is considered to be a derived value based on a column that continues to give the column precedence in any further comparisons. The expression CASE WHEN COL1 > 1 THEN 'abc' ELSE 'def' END contains a column that does not affect the result CCSID of the expression and is therefore not considered to be a derived value based on a column.

The following table defines which expressions are considered to be a derived value based on a column.

### Table 37. Derived values based on a column

<table>
<thead>
<tr>
<th>Expression</th>
<th>Condition</th>
</tr>
</thead>
<tbody>
<tr>
<td>expression1</td>
<td></td>
</tr>
<tr>
<td>CASE when-clause THEN result-expression ELSE result-expression END</td>
<td>any result-expression is a string-expression that is a column or derived value based on a column</td>
</tr>
<tr>
<td>CAST(expression as data-type)</td>
<td>expression is a string-expression that is a column or a derived value based on a column and data-type is a string data type</td>
</tr>
<tr>
<td>Scalar-fullselect: (SELECT expression FROM table)</td>
<td>expression is a string-expression that is a column or a derived value based on a column and data-type is a string data type</td>
</tr>
</tbody>
</table>

When a statement contains multiple CCSID sets, if the length of one of the strings changes after CCSID conversion, the string becomes a varying-length string. That is, the data type becomes VARCHAR, CLOB, VARGRAPHIC, or DBCLOB. The following table shows the worst case resulting lengths of CCSID conversion, where X is length in bytes.

### Table 38. Worst case result length of CCSID conversion, where X represents LENGTH(string in bytes)

<table>
<thead>
<tr>
<th>From CCSID</th>
<th>To CCSID</th>
<th>EBCDIC</th>

</tr>
</tbody>
</table>

**Note:**
1. Because of the high probability of data loss, IBM does not provide conversion tables for this combination of two CCSIDs and data subtypes.
User-defined type comparisons

User-defined type comparisons include distinct type comparisons and array comparisons.

Distinct type comparisons

A value with a distinct type can only be compared to another value with exactly the same type because distinct types have strong typing, which means that a distinct type is compatible only with its own type.

To compare a distinct type to a value with a different data type, the distinct type value must be cast to the data type of the comparison value or the comparison value must be cast to the distinct type. For example, because constants are built-in data types, a constant can be compared to a distinct type value only if it is first cast to the distinct type or vice versa.

The following table shows examples of valid and invalid comparisons, assuming the following SQL statements were used to define two distinct types AGE_TYPE and CAMP_DATE and table CAMP_ROSTER table.

```sql
CREATE TYPE AGE_TYPE AS INTEGER;
CREATE TYPE CAMP_DATE AS DATE;
CREATE TABLE CAMP_ROSTER
    ( NAME VARCHAR(20),
    ATTENDEE_NUMBER INTEGER NOT NULL,
    AGE AGE_TYPE,
    FIRST_CAMP_DATE CAMP_DATE,
    LAST_CAMP_DATE CAMP_DATE,
    BIRTHDATE DATE);
```

<table>
<thead>
<tr>
<th>SQL statement</th>
<th>Valid</th>
<th>Reason</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Distinct types with distinct types</strong></td>
<td></td>
<td></td>
</tr>
<tr>
<td>SELECT * FROM CAMP_ROSTER WHERE FIRST_CAMP_DATE &lt; LAST_CAMP_DATE;</td>
<td>Yes</td>
<td>Both values are the same distinct type.</td>
</tr>
<tr>
<td><strong>Distinct types with columns of the same source data type</strong></td>
<td></td>
<td></td>
</tr>
<tr>
<td>SELECT * FROM CAMP_ROSTER WHERE AGE &gt; ATTENDEE_NUMBER;</td>
<td>No</td>
<td>A distinct type cannot be compared to integer.</td>
</tr>
<tr>
<td>SELECT * FROM CAMP_ROSTER WHERE INTEGER(AGE) &gt; ATTENDEE_NUMBER;</td>
<td>Yes</td>
<td>The distinct type is cast to an integer, making the comparison of two integers.</td>
</tr>
<tr>
<td>SELECT * FROM CAMP_ROSTER WHERE CAST(AGE AS INTEGER) &gt; ATTENDEE_NUMBER;</td>
<td>Yes</td>
<td>Integer ATTENDEE_NUMBER is cast to the distinct type AGE_TYPE, making both values the same distinct type.</td>
</tr>
<tr>
<td><strong>Distinct types with constants</strong></td>
<td></td>
<td></td>
</tr>
<tr>
<td>SELECT * FROM CAMP_ROSTER WHERE AGE IN (15,16,17);</td>
<td>No</td>
<td>A distinct type cannot be compared to a constant.</td>
</tr>
<tr>
<td>SELECT * FROM CAMP_ROSTER WHERE INTEGER(AGE) IN (15,16,17);</td>
<td>Yes</td>
<td>The distinct type is cast to the data type of constants, making all the values in the comparison integers.</td>
</tr>
<tr>
<td>SELECT * FROM CAMP_ROSTER WHERE AGE IN (AGE_TYPE(15),AGE_TYPE(16),AGE_TYPE(17));</td>
<td>Yes</td>
<td>Constants are cast to distinct type AGE_TYPE, making all the values in the comparison the same distinct type.</td>
</tr>
</tbody>
</table>
Table 39. Examples of valid and invalid comparisons involving distinct types (continued)

<table>
<thead>
<tr>
<th>SQL statement</th>
<th>Valid</th>
<th>Reason</th>
</tr>
</thead>
</table>
| SELECT * FROM CAMP_ROSTER  
  WHERE FIRST_CAMP_DATE > '06/12/99';                                           | No    | A distinct type cannot be compared to a constant.                      |
| SELECT * FROM CAMP_ROSTER  
  WHERE FIRST_CAMP_DATE >  
  CAST('06/12/99' AS CAMP_DATE);                                                  | No    | The string constant '06/12/99', a VARCHAR data type, cannot be cast directly to distinct type CAMP_DATE, which is based on a DATE data type. As illustrated in the next row, the constant must be cast to a DATE data type and then to the distinct type. |
| SELECT * FROM CAMP_ROSTER  
  WHERE FIRST_CAMP_DATE >  
  CAST(DATE('06/12/1999') AS CAMP_DATE);                                          | Yes   | The string constant '06/12/99' is cast to the distinct type CAMP_DATE, making both values the same distinct type. To cast a string constant to a distinct type that is based on a DATE, TIME, or TIMESTAMP data type, the string constant must first be cast to a DATE, TIME, or TIMESTAMP data type. |

Distinct types with host variables

<table>
<thead>
<tr>
<th>SQL statement</th>
<th>Valid</th>
<th>Reason</th>
</tr>
</thead>
</table>
| SELECT * FROM CAMP_ROSTER  
  WHERE AGE BETWEEN :HV_INTEGER AND :HV_INTEGER2;                                 | No    | The host variables have integer data types. A distinct type cannot be compared to an integer. |
| SELECT * FROM CAMP_ROSTER  
  WHERE AGE BETWEEN CAST(:HV_INTEGER AS AGE_TYPE)  
  AND AGE_TYPE(:HV_INTEGER2);                                                        | Yes   | The host variables are cast to distinct type AGE_TYPE, making all the values the same distinct type. |
| SELECT * FROM CAMP_ROSTER  
  WHERE FIRST_CAMP_DATE > :HV_VARCHAR;                                               | No    | The host variable has a VARCHAR data type. A distinct type cannot be compared to a VARCHAR. |
| SELECT * FROM CAMP_ROSTER  
  WHERE FIRST_CAMP_DATE >  
  CAST(DATE(:HV_VARCHAR) AS CAMP_DATE);                                                | Yes   | The host variable is cast to the distinct type CAMP_DATE, making both values the same distinct type. To cast a VARCHAR host variable to a distinct type that is based on a DATE, TIME, or TIMESTAMP data type, the host variable must first be cast to a DATE, TIME, or TIMESTAMP data type. |

Array type comparisons
Comparisons of array values are not supported.

Elements of arrays can be compared based on the comparison rules for the data types of the elements of the arrays.

Rules for result data types
Rules that are applied to the operands of an operation determine the data type of the result. Certain rules apply in certain situations and apply depending on the data type of operands.

The rules apply to:
* Corresponding columns in set operations (UNION, INTERSECT, or EXCEPT)
* Result expressions of a CASE expression
* Arguments of the scalar functions COALESCE, IFNULL, MAX, and MIN
* Expression values of the IN list of an IN predicate
• Expression values for the elements in an array constructor
• Expression values for the arguments for a collection-derived table (UNNEST specification)
• Arguments of a BETWEEN predicate, except if the data types of all operands are numeric
• Arguments for the aggregation group ranges in OLAP specifications

For the result data type of expressions that involve the operators ‘/’, ‘*’, ‘+’ and ‘-’, see “Expressions with arithmetic operators” on page 260.

For the result data type of expressions that involve the CONCAT operator, see “Expressions with the concatenation operator” on page 267.

Evaluation of the operands of an operation determines the data type of the result. If an operation has more than one pair of operands, Db2 determines the result type of the first pair, uses this result type with the next operand to determine the next result type, and so on. The last intermediate result type and the last operand determine the result type of the operation.

With the exception of the COALESCE function, the result of an operation can be null unless the operands do not allow nulls.

If the data type and attributes of any operand column are not the same as those of the result, the operand column values are converted to conform to the data type and attributes of the result. The conversion operation is exactly the same as if the values were assigned to the result. For example:
• If one operand column is CHAR(10), and the other operand column is CHAR(5), the result is CHAR(10), and the values derived from the CHAR(5) column are padded on the right with five blanks.
• If the whole part of a number cannot be preserved then an error is returned.

**Notes:**
1. Precision cannot exceed 31.

---

**Character and graphic string operands**

Character and graphic strings are compatible with other character and graphic strings as long as there is a conversion between their corresponding CCSIDs.

**Table 41. Result data types with string operands**

<table>
<thead>
<tr>
<th>One operand</th>
<th>Other operand</th>

<td>SBCS data</td>
<td>SBCS data</td>
</tr>
</tbody>
</table>

Binary string operands

Binary strings are compatible with other binary strings. Binary strings include BINARY, VARBINARY, and BLOB.

Table 43. Result data types with binary string operands

<table>
<thead>
<tr>
<th>One operand</th>
<th>Other operand</th>
<th>Data type of the result</th>
</tr>
</thead>
<tbody>
<tr>
<td>BINARY(x)</td>
<td>BINARY(y)</td>
<td>BINARY(z) where z = max(x,y)</td>
</tr>
<tr>
<td>VARBINARY(x)</td>
<td>BINARY(y) or VARBINARY(y)</td>
<td>VARBINARY(z) where z = max(x,y)</td>
</tr>
<tr>
<td>BLOB(x)</td>
<td>BINARY(y), VARBINARY(y), or BLOB(y)</td>
<td>BLOB(z) where z = max(x,y)</td>
</tr>
</tbody>
</table>

Datetime operands

A date, time, or timestamp value is compatible with another value of the same type or any string expression that contains a valid string representation of the same type.

A DATE type is compatible with another DATE type or any string expression that contains a valid string representation of a date. A string representation is a value that is a built-in character string data type or graphic string data type. A string representation must not be a CLOB or DBCLOB and must have an actual length that is not greater than 255 bytes. The data type of the result is DATE.

A TIME type is compatible with another TIME type or any string expression that contains a valid string representation of a time. A string representation is a value that is a built-in character string data type or graphic string data type. A string representation must not be a CLOB or DBCLOB and must have an actual length that is not greater than 255 bytes. The data type of the result is TIME.
A timestamp type is compatible with another timestamp type, a timestamp constant, or any string expression that contains a valid string representation of a timestamp. A string representation is a value that is a built-in character string data type or graphic string data type. A string representation must not be a CLOB or DBCLOB and must have an actual length that is not greater than 255 bytes. The data type of the result is a timestamp as determined in the following table.

Table 44. Result data types with datetime operands

<table>
<thead>
<tr>
<th>One operand</th>
<th>Other operand</th>
<th>Data type of the result</th>
</tr>
</thead>
<tbody>
<tr>
<td>TIMESTAMP(x) WITHOUT TIME ZONE</td>
<td>TIMESTAMP(y) WITHOUT TIME ZONE</td>
<td>TIMESTAMP(max(x,y)) WITHOUT TIME ZONE</td>
</tr>
<tr>
<td>TIMESTAMP(x) WITHOUT TIME ZONE</td>
<td>CHAR(y) or VARCHAR(y)</td>
<td>TIMESTAMP(x) WITHOUT TIME ZONE</td>
</tr>
<tr>
<td>TIMESTAMP(x) WITH TIME ZONE</td>
<td>TIMESTAMP(y) WITH TIME ZONE</td>
<td>TIMESTAMP(max(x,y)) WITH TIME ZONE</td>
</tr>
<tr>
<td>TIMESTAMP(x) WITH TIME ZONE</td>
<td>CHAR(y) or VARCHAR(y)</td>
<td>TIMESTAMP(x) WITH TIME ZONE</td>
</tr>
<tr>
<td>TIMESTAMP(x) WITH TIME ZONE</td>
<td>TIMESTAMP(y) WITHOUT TIME ZONE</td>
<td>TIMESTAMP(max(x,y)) WITH TIME ZONE</td>
</tr>
</tbody>
</table>

Note: If one operand is TIMESTAMP(x) WITHOUT TIME ZONE and the other operand is CHAR(y) or VARCHAR(y), the result data type is TIMESTAMP(x) WITHOUT TIME ZONE even if the string representation contains a time zone.

If both operands are in the same encoding scheme, the result is in that encoding scheme. Otherwise the result is in the application encoding scheme.

Row ID operands
A row ID data type is compatible only with itself. The result has a row ID data type.

XML operands
XML data is compatible only with other XML data. The data type of the result is XML.

Other data types can be treated as an XML data type by using the CAST specification or XMLPARSE functions to cast character, graphic, or binary data to XML data.

Distinct type operands
A distinct type is compatible only with itself. The data type of the result is the distinct type.

Constants
A constant (also called a literal) specifies a value. Constants are classified as string constants or numeric constants. Numeric constants are further classified as integer, floating-point, decimal, or decimal floating-point. String constants are classified as character, graphic, or binary.

All constants have the attribute NOT NULL. A negative sign in a numeric constant with a value of zero is ignored, except for a decimal floating-point constant.
Constants have a built-in data type. Therefore, an operation that involves a constant and a distinct type requires that the distinct type be cast to the built-in data type of the constant or the constant be cast to the distinct type. For example, see [Distinct type comparisons](#) which contains an example of casting data types to compare a constant to a distinct type.

**Integer constants**

An *integer constant* specifies an integer as a signed or unsigned number with a maximum of 19 digits that does not include a decimal point.

The data type of an integer constant is large integer if its value is within the range of a large integer. The data type of an integer constant is big integer if its value is outside the range of a large integer, but within the range of a big integer. A constant that is defined outside the range of big integer values is considered a decimal constant.

*Examples:*

|  64  | -15 | +100 | 32767 | 720176 |

In syntax diagrams, the term *integer* is used for a large integer constant that must not include a sign.

**Floating-point constants**

A *floating-point constant* specifies a double-precision floating-point number as two numbers separated by an E.

The first number can include a sign and a decimal point. The second number can include a sign but not a decimal point. The value of the constant is the product of the first number and the power of 10 specified by the second number. It must be within the range of floating-point numbers. The number of characters in the constant must not exceed 30. Excluding leading zeros, the number of digits in the first number must not exceed 17 and the number of digits in the second must not exceed 2.

*Examples: The following floating-point constants represent the numbers '150', '200000', -0.22, and '500':*

|  15E1 |  2.E5 | -2.2E-1 | +5.E+2 |

**Decimal constants**

A *decimal constant* is a signed or unsigned number of no more than 31 digits and either includes a decimal point or is not within the range of binary integers.

The precision is the total number of digits, including those, if any, to the right of the decimal point. The total includes all leading and trailing zeros. The scale is the number of digits to the right of the decimal point, including trailing zeros.

*Examples: The following decimal constants have, respectively, precisions and scales of 5 and 2; 4 and 0; 2 and 0; and 23 and 2:*

|  025.50 |  1000. | -15. | +375893333333333333.33 |
Decimal floating-point constants

A decimal floating-point constant specifies a decimal floating-point number as two numbers separated by an E. The first number can include a sign and a decimal point. The second number can include a sign but not a decimal point.

The value of the constant is the product of the first number and the power of 10 specified by the second number. The value must be within the range of DECFLOAT(34). The number of characters in the constant must not exceed 42. Excluding leading zeros, the number of digits in the first number must not exceed 34 and the number of digits in the second number must not exceed 4.

A constant that is specified as two numbers separated by an E is a decimal-floating point constant only if the value is outside the range of a floating-point constant. A constant that is specified as a number that does not contain an E, and has more than 31 digits, is also a decimal-floating point constant.

In addition to numeric constants, the following special values can be used to specify decimal-floating point special values:

- INF or INFINITY - represents infinity
- NAN - represents quiet not-a-number
- SNAN - represents signaling not-a-number

The special values can be any combination of uppercase or lowercase letters and can be preceded by an operational sign (+ or -).

SNAN results in a warning or exception when it is used in a numerical operation; NAN does not. SNAN can be used in non-numerical operations without causing a warning or exception. For example, SNAN can be used in the VALUES list of an insert operation or as a constant used in a comparison in a predicate.

When the special values are used in a predicate, the following order of precedence applies:

\[-NAN < -SNAN < -INFINITY < -0 < 0 < INFINITY < SNAN < NAN\]

Examples: The following decimal floating-point constants represent the numbers 123456789012345678, sNaN, and negative infinity:

```
SNAN
-INFINITY
```

When one of the special values is used in a context where it could be interpreted as an identifier, such as a column name, cast a string constant that represents the special value to decimal-floating point.

```
CAST ('snan' AS DECFLOAT)
CAST ('INF' AS DECFLOAT)
CAST ('NaN' AS DECFLOAT)
```

Character string constants

A character string constant specifies a varying-length character string. There are two forms of character string constant.

- A sequence of characters that starts and ends with a string delimiter, which is either an apostrophe (’) or a quotation mark (”). For the factors that determine which is applicable, see "Apostrophes and quotation marks as string delimiters" on page 345. This form of string constant specifies the character string contained between the string delimiters. The number of bytes between the delimiters must not be greater than 32704. The limit of 32704 refers to the length (in bytes) of the
UTF-8 representation of the string. If you produced the string in a CCSID other than UTF-8 (for example, an EBCDIC CCSID), the length of the UTF-8 representation might differ from the length of the string’s representation in the source CCSID. Two consecutive string delimiters are used to represent one string delimiter within the character string.

- An X followed by a sequence of characters that starts and ends with a string delimiter. This form of a character string constant is also called a *hexadecimal constant*. The characters between the string delimiters must be an even number of hexadecimal digits. The number of hexadecimal digits must not exceed 32704. A hexadecimal digit is a digit or any of the letters A through F. If the MIXED DATA subsystem parameter is set to YES, hexadecimal digits in a hexadecimal constant must be specified in upper case. Otherwise, an error might be returned when SQL statements are processed. Under the conventions of hexadecimal notation, each pair of hexadecimal digits represents a character. A hexadecimal constant allows you to specify characters that do not have a keyboard representation.

*Examples:*

'12/14/1985'  '32'  'DON’T CHANGE‘  X’FFFF‘  ‘

The right most string in the example (") represents an empty character string constant, which is a string of zero length.

A character string constant is classified as mixed data if it includes a DBCS substring. In all other cases, a character string constant is classified as SBCS data. For information about the CCSID that is assigned to the constant, see Determining the encoding scheme and CCSID of a string (Introduction to Db2 for z/OS). A mixed string constant can be continued from one line to the next only if the break occurs between single byte characters. A Unicode string is always considered mixed regardless of the content of the string.

For Unicode, character constants can be assigned to UTF-8 and UTF-16. The form of the constant does not matter. Typically, character string constants are used only with character strings, but they also can be used with graphic UTF-16 data. However, hexadecimal constants are just character data. Thus, hexadecimal constants being used to insert data into UTF-16 data strings should be in UTF-8 format, not UTF-16 format. For example, if you wanted to insert the number 1 into a UTF-16 column, you would use X’31’, not X’0031’. Even though X’0031’ is a UTF-16 value, Db2 treats it as two separate UTF-8 code points. Thus, X’0031’ would become X’00000031’.

**Binary string constants**

A binary-string constant specifies a varying-length binary string.

A binary-string constant is formed by specifying a BX followed by a sequence of characters that starts and ends with a string delimiter. The characters between the string delimiters must be an even number of hexadecimal digits. The number of hexadecimal digits must not exceed 32704.

A hexadecimal digit is a digit or any of the letters A through F (upper case or lower case). Under the conventions of hexadecimal notation, each pair of hexadecimal digits represents one byte. Note that this representation is similar to the representation of the character-constant that uses the X" form; however binary-string constant and character-string constant are not compatible and the X"
form can not be used to specify a binary-string constant, just as the BX" form cannot be used to specify a character-string constant.

Examples of binary-string constants:
BX'0000'  BX'C141C242'  BX'FF00FF01FF'

**Datetime constants**

A *datetime constant* is a character string constant of a particular format.

Character-string constants are described under “Character string constants” on page 180.

For information about the valid string formats, see “String representations of datetime values” on page 130.

Typically, character-string constants are used to represent constant datetime values in assignments and comparisons. However, the ANSI/ISO SQL standard form of a datetime constant can be used to specifically denote the constant as a datetime constant instead of a character-string constant. The format for the ANSI/ISO SQL standard datetime constants are as follows:

**DATE string-constant**

*string-constant* must contain a value that conforms to one of the valid formats for string representations of dates, subject to the following rules:

- leading blanks are not allowed.
- leading zeros can be omitted from the month and day elements of the date. An implicit specification of 0 is assumed for any digit that is omitted.
- leading zeros must be included for the year element of the date.
- trailing blanks can be included.

The data type of the value is DATE.

**TIME string-constant**

*string-constant* must contain a value that conforms to one of the valid formats for string representations of times, subject to the following rules:

- leading blanks are not allowed.
- leading zeros can be omitted from the hour elements of the time.
- the seconds element of the time can be omitted.
- trailing blanks can be included.
- if the USA format is not used and the minutes and seconds are all zeros, the hour can be 24.
- If the format is USA, the following additional rules apply:
  - the minutes element of the time can be omitted. For example, 1 PM is equivalent to 1:00 PM.
  - the letters A, M, and P can be specified in lowercase.
  - a single blank must precede the AM or PM.
  - the hour must not be greater than 12 and cannot be 0 except when the time is specified as 00:00 AM.

An implicit specification of 0 is assumed for any digit that is omitted.

The correspondence between the USA format and the ISO format (24-hour clock) is as follows:
• 12:01 AM through 12:59 AM correspond to 00.01.00 through 00.59.00
• 01:00 AM through 11:59 AM correspond to 01.00.00 through 11.59.00
• 12:00 PM (noon) through 11:59 PM correspond to 12.00.00 through 23.59.00
• 12:00 AM (midnight) corresponds to 24.00.00
• 00:00 AM (midnight) corresponds to 00.00.00

The data type of the value is TIME.

**TIMESTAMP** *string-constant*

*string-constant* must contain a value that conforms to one of the formats listed in the following tables, subject to the following rules:

• leading blanks are not allowed.
• trailing blanks can be included.
• leading zeros can be omitted from the month, day, hour, and time zone hour elements of the timestamp. An implicit specification of 0 is assumed for any digit that is omitted.
• leading zeros must be included for the minute, second, and time zone minute elements of the timestamp
• the hour can be 24 if the minutes, seconds, and any fractional seconds are all zeroes.
• the separator character that follows the seconds element can be omitted if fractional seconds are not included.
• the number of digits of fractional seconds can vary from 0 to 12. An implicit specification of 0 is assumed if fractional seconds are omitted. The number of digits of fractional seconds determines the precision of the timestamp value.
• an optional single blank can be included between the time and the time zone elements.
• an optional time zone can be included, in one of the following formats:
  – ±th:tm, with values ranging from -24:00 to +24:00. A value of -0:00 is treated the same as +0:00.
  – ±th, with values ranging from -24 to +24 (an implicit specification of 00 is assumed for the time zone minute element)
  – uppercase Z to specify UTC

The data type of the value depends on the content of the string constant (where *p* is the number of digits of fractional seconds in the constant):

• **TIMESTAMP(*p*) WITHOUT TIME ZONE** if the content of the string constant conforms to the rules in the [Table 45](#) table.
• **TIMESTAMP(*p*) WITH TIME ZONE** if the content of the string constant conforms to the rules in the [Table 46 on page 184](#) table.

**Table 45. Formats used to specify a value for a data type of TIMESTAMP WITHOUT TIME ZONE**

<table>
<thead>
<tr>
<th>Description</th>
<th>TIMESTAMP(0) WITHOUT TIME ZONE</th>
<th>TIMESTAMP(<em>p</em>) WITHOUT TIME ZONE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Blank between date and time portions and colons in time portion.</td>
<td>yyyy-mm-dd hh:mm:ss</td>
<td>yyyy-mm-dd hh:mm:ss.nnnnnnnnnn</td>
</tr>
</tbody>
</table>
Table 45. Formats used to specify a value for a data type of `TIMESTAMP WITHOUT TIME ZONE` (continued)

<table>
<thead>
<tr>
<th>Description</th>
<th><code>TIMESTAMP(0) WITHOUT TIME ZONE</code>&lt;sup&gt;1,3&lt;/sup&gt;</th>
<th><code>TIMESTAMP(9) WITHOUT TIME ZONE</code>&lt;sup&gt;2,3&lt;/sup&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>Blank between date and time portions and periods in time portion.</td>
<td>• <code>yyyy-mm-dd hh:mm:ss</code></td>
<td>• <code>yyyy-mm-dd hh:mm:ss.nnnnnnnnnnn</code></td>
</tr>
<tr>
<td>Minus sign between date and time portions and colons in time portion.</td>
<td>• <code>yyyy-mm-dd-hh:mm:ss</code></td>
<td>• <code>yyyy-mm-dd-hh:mm:ss.hh:mm:ss.nnnnnnnnnnn</code></td>
</tr>
<tr>
<td>Minus sign between date and time portions and periods in time portion.</td>
<td>• <code>yyyy-mm-dd-hh:mm:ss</code></td>
<td>• <code>yyyy-mm-dd-hh:mm:ss.nnnnnnnnnnn</code></td>
</tr>
</tbody>
</table>

**Notes:**

1. No fractional seconds; shown with and without optional trailing period after seconds
2. `<p>` is the number of digits of fractional seconds. `nnnnnnnnnnn` can range 1 - 12 instances of `n`
3. As an additional format, the character `T` can be substituted as the separator between the date and time portions of the value.

Table 46. Formats used to specify a value for a data type of `TIMESTAMP WITH TIME ZONE`

<table>
<thead>
<tr>
<th>Description</th>
<th><code>TIMESTAMP(0) WITH TIME ZONE</code>&lt;sup&gt;1,3&lt;/sup&gt;</th>
<th><code>TIMESTAMP(9) WITH TIME ZONE</code>&lt;sup&gt;2,3&lt;/sup&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>Blank between date and time portions and colons in time portion, no space between time and time zone.</td>

<tbody>
<tr>
<td>Blank between date and time portions and periods in time portion.</td>
<td>- <code>yyyy-mm-dd hh:mm:ss±th:tm</code> &lt;br&gt; - <code>yyyy-mm-dd hh:mm:ss±th</code> &lt;br&gt; - <code>yyyy-mm-dd hh:mm.ss±th:tm</code></td>
<td>- <code>yyyy-mm-dd hh:mm.ss.nnnnnnnnnnn ±th:tm</code> &lt;br&gt; - <code>yyyy-mm-dd hh:mm:ss.nnnnnnnnnnn ±th</code></td>
</tr>
</tbody>
</table>

Notes:
1. No fractional seconds; shown with and without optional trailing period after seconds
2. `p` is the number of digits of fractional seconds. `nnnnnnnnnnnn` can range 1 - 12 instances of `n`
3. As an additional format, the character T can be substituted as the separator between the date and time portions of the value.

Graphic string constants

A *graphic string constant* specifies a varying-length graphic string.

In EBCDIC environments, the forms of graphic string constants are shown in the following figure. (Shift-in and shift-out characters for EBCDIC data are discussed in “Character strings” on page 111.)

<table>
<thead>
<tr>
<th>Context</th>
<th>Graphic String Constant</th>

</tbody>
</table>

*Figure 23. Graphic string constants in EBCDIC*

6. The PL/I form of graphic string constants is supported only in static SQL statements.
In SQL statements and in host language statements in a source program, graphic string constants cannot be continued from one line to the next. A graphic string constant must be short enough so that its UTF-8 representation requires no more than 32704 bytes.

Db2 supports two types of hexadecimal graphic string constants.

- **UX'xxxx'** represents a string of graphic Unicode UTF-16 characters, where \( x \) is a hexadecimal digit. The number of digits must be a multiple of 4 and must not exceed 32704. Each group of 4 digits represents a single UTF-16 graphic character. For example, the UX constant for ‘ABC’ is UX’004100420043’.

- **GX'xxxx'** represents a string of graphic characters, where \( x \) is a hexadecimal digit. The number of digits must be a multiple of 4. Each group of 4 digits represents a single double-byte graphic character. The hexadecimal shift-in and shift-out (‘OE’X and ‘OF’X), which apply to EBCDIC only, are not included in the string.

If the MIXED DATA installation option is set to NO, a GX constant cannot be used. Instead, a UX constant should be used. A GX constant cannot be used when the encoding scheme is UNICODE.

For information about the CCSID that is assigned to a graphic string constant, including UX’xxxx’ and GX’xxxx’ string constants, see [Determining the encoding scheme and CCSID of a string (Introduction to Db2 for z/OS)](Introduction-to-Db2-for-z-O5).

### Special registers

A special register is a storage area that is defined for an application process by Db2 and is used to store information that can be referenced in SQL statements. A reference to a special register is a reference to a value provided by the current server. If the value is a string, its CCSID is a default CCSID of the current server.

The special registers can be referenced as follows:
Notes:

1. The SQL standard uses the form with the underline.

2. The ENCRYPTION PASSWORD special register can only be explicitly referenced in the SET ENCRYPTION PASSWORD statement. It is used implicitly by the encryption and decryption functions.
General rules for special registers

Changing register values

A commit operation might cause special registers to be re-initialized. Whether a special register is affected by a commit depends on whether the special register has been explicitly set within the application process. For example, assume that the PATH special register has not been explicitly set with a SET PATH statement in the application process. After a commit, the value of PATH is re-initialized. For information on the initialization of PATH, which can take the current value of CURRENT SQLID into consideration, see [CURRENT SQLID].

A rollback operation has no effect on the values of special registers. Nor does any SQL statement, with the following exceptions:

• SQL SET statements can change the values of the following special registers:
  – CURRENT ACCELERATOR
  – CURRENT APPLICATION COMPATIBILITY
  – CURRENT APPLICATION ENCODING SCHEME
  – CURRENT DEBUG MODE
  – CURRENT DECFLOAT ROUNING MODE
  – CURRENT DEGREE
  – CURRENT EXPLAIN MODE
  – CURRENT GET_ACCEL_ARCHIVE
  – CURRENT LOCALE LC_CTYPE
  – CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION
  – CURRENT OPTIMIZATION HINT
  – CURRENT PACKAGE PATH
  – CURRENT PACKAGESET
  – CURRENT PATH
  – CURRENT PRECISION
  – CURRENT QUERY ACCELERATION
  – CURRENT QUERY ACCELERATION WAITFORDATA
  – CURRENT REFRESH AGE
  – CURRENT ROUTINE VERSION
  – CURRENT RULES
  – CURRENT SCHEMA
  – CURRENT SQLID
  – CURRENT TEMPORAL BUSINESS_TIME
  – CURRENT TEMPORAL SYSTEM_TIME
  – ENCRYPTION PASSWORD
  – SESSION TIME ZONE

• SQL CONNECT statements can change the value of CURRENT SERVER.

7. If the SET CURRENT SQLID statement is executed in a stored procedure or user-defined function package that has a dynamic SQL behavior other than run behavior, the SET CURRENT SQLID statement does not affect the authorization ID that is used for dynamic SQL statements in the package. The dynamic SQL behavior determines the authorization ID. For more information, see [DYNAMICRULES bind option (Db2 Commands)].
Changing register values from IBM Data Server clients and drivers

In addition to using SQL SET statements, you can use the following IBM Data Server client and driver interfaces to change the values of most of the special registers that are listed under “Changing register values” on page 188:

- IBM Data Server Driver for JDBC and SQLJ method `DB2DataSource.setSpecialRegisters`
- For non-Java clients, the `<specialregisters>` subsection in the in `db2dsdriver.cfg` file

Use of these interfaces has the following restrictions:

- You cannot change the values of the following special registers:
  - CURRENT APPLICATION ENCODING SCHEME
  - CURRENT PACKAGESET
- The special register names are allowed to be in mixed case. Extraneous blanks between keywords are removed.
- The special register assigned value is stored as specified. The value must be valid for the special register.
- Special register values cannot be expressions, cannot reference other special registers, and cannot reference global variables.
- For CURRENT REFRESH AGE, the value 99999999999999 is not supported. Use the value ANY instead.
- Db2 treats all special register values that are passed through the client and driver interfaces as literal strings. For example, if a specified special register value is the same as the name of a special register, Db2 stores the special register name, and not the special register value.

Determining register values

You can use various statements to determine the value of a special register. For instance, a SELECT statement, a SET statement, the VALUES statement (if the statement is within a trigger action) will provide the value of a special register. The following examples find the value of the CURRENT PRECISION special register:

```
SELECT CURRENT PRECISION FROM SYSIBM.SYSDUMMY1;
SET :hv = CURRENT PRECISION
VALUES(CURRENT PRECISION)
```

CCSIDS for register values

Special registers that contain character strings have an associated CCSID. The particular CCSID depends on the context in which the special register is referenced. For more information, see Determining the encoding scheme and CCSID of a string (Introduction to Db2 for z/OS).

Datetime special registers

The datetime registers are named CURRENT DATE, CURRENT TIME, and CURRENT TIMESTAMP. Datetime special registers are stored in an internal format. When two or more of these registers are implicitly or explicitly specified in a single SQL statement, they represent the same point in time. A datetime special register is implicitly specified when it is used to provide the default value of a datetime column.
If the SQL statement in which a datetime special register is used is in a user-defined function or stored procedure that is within the scope of a trigger, Db2 uses the timestamp for the triggering SQL statement to determine the special register value.

The values of these special registers are based on:

- The time-of-day clock of the processor for the server executing the SQL statement
- The TIMEZONE parameter for this processor. The TIMEZONE parameter is in SYS1.PARMLIB(CLOCKXX).

To evaluate the references when the statement is being executed, a single reading from the time-of-day clock is incremented by the number of hours, minutes, and seconds specified by the TIMEZONE parameter. The values derived from this are assumed to be the local date, time, or timestamp, where local means local to the Db2 that executes the statement. This assumption is correct if the clock is set to local time and the TIMEZONE parameter is zero or the clock is set to UTC (Coordinated Universal Time) and the TIMEZONE parameter gives the difference from UTC.

Because the datetime special registers and the CURRENT TIMEZONE special register depend on the parameter PARMTZ(SYS1.PARMLIB(CLOCKXX)), their values are affected if the local time at the server is changed by the z/OS system command SET CLOCK. The values of the CURRENT DATE and CURRENT TIMESTAMP special registers might be affected if the local date at the server is changed by the system command SET DATE.

**Where special registers are processed**

In distributed applications, CURRENT APPLICATION ENCODING SCHEME, CURRENT SERVER, and CURRENT PACKAGESET are processed locally. All other special registers are processed at the server.

**Rules for setting special registers in profiles**

In remote applications, a special register can be referenced with a value from the profile attributes table. In addition to general rules, there are rules specific to using special registers set in profiles.

**Changing register values**

A rollback operation has no effect on the values of special registers.

The following special registers can be SET with the SPECIAL_REGISTER keyword in a profile attributes table:

- CURRENT ACCELERATOR
- CURRENT APPLICATION COMPATIBILITY
- CURRENT DEBUG MODE
- CURRENT DECFLOAT ROUNDED MODE
- CURRENT DEGREE
- CURRENT EXPLAIN MODE

---

8. Whether the SET DATE command affects these special registers depends on the system level and the program temporary fix (PTF) level of the system.
Use of this interface has the following restrictions:

- The SET statement must have an equal sign (=) between the special register name and the value that is assigned.
- The maximum length of the SET statement is 1024 bytes.
- The special register names are allowed to be in mixed case. Extraneous blanks between keywords are removed.
- The special register assigned value is stored as specified. The value must be valid for the special register.
- Special register values cannot be expressions, cannot reference other special registers, and cannot reference global variables.
- For CURRENT REFRESH AGE, the value 99999999999999 is not supported. Use the value ANY instead.
- Db2 treats all special register values that are passed through this interface as literal strings. For example, if a specified special register value is the same as the name of a special register, Db2 stores the special register name, and not the special register value.
- The SET statement must be a Unicode string and encoded with the appropriate CCSID for the application.

Special register values that are set through the profile table take precedence over values that are set by the application before the first non-SET SQL statement. For

---

9. If the SET CURRENT SQLID statement is run in a stored procedure or user-defined function package that has a dynamic SQL behavior other than run behavior, the SET CURRENT SQLID statement does not affect the authorization ID that is used for dynamic SQL statements in the package. The dynamic SQL behavior determines the authorization ID. For more information, see DYNAMICRULES bind option (Db2 Commands)
example, values set by a profile override value that are set through a client connection or data source properties when the connection is first established. The special register values persist for the lifetime of the connection unless the application explicitly sets the special register. Special register values that are set explicitly by the application take precedence over values that are set by the profile table facility and values that are set by the client connection and data source properties. System directed connections, such as three-part name references, use the values of the special registers of the requesting Db2 site. For example, if a Java application establishes a connection to Db2 site 1, the special register values are established with the profile tables from site 1. Later, if the application runs an SQL statement with an implicit three-part name connection to Db2 site 2, then the special register values that are established on site 1 are referenced when the SQL statement runs on site 2.

Special register values that are set through the profile table facility observe the existing rules for inheritance within a routine as defined by INHERIT SPECIAL REGISTERS or DEFAULT SPECIAL REGISTERS routine options. After a user-defined function or a stored procedure completes, Db2 restores all special registers to the values they had before invocation.

As with existing special register behavior, commits and rollbacks do not change special register values regardless of how they were established.

- Profiles for monitoring and controlling Db2 for z/OS subsystems (Db2 Performance)

Related reference:
- Profile tables (Db2 Performance)

CURRENT ACCELERATOR

The CURRENT ACCELERATOR special register specifies a particular accelerator or accelerators to which Db2 sends dynamic SQL queries.

The CURRENT ACCELERATOR special register applies only to dynamic SQL queries. For static SQL queries, you can use the ACCELERATOR bind option to specify a particular accelerator.

If you have multiple accelerators on which the same set of Db2 tables are accelerated, by default the workload balancing algorithm (WLB) distributes the queries based on the queue length on each accelerator. When the CURRENT ACCELERATOR special register names a particular eligible accelerator server, Db2 considers sending eligible SQL to that server before it sends it to other accelerator servers. If the accelerator server that is named by the CURRENT ACCELERATOR isn't available, Db2 considers other available accelerator servers.

Specifying a particular target accelerator is useful in the following situations:
- To direct queries to different accelerators based on the priorities of the workload. You can direct higher priority queries to the fastest, highest capacity accelerator, and you can direct lower priority queries to a slower accelerator.
- To avoid increased elapsed times that can occur when queries are sent to a remote accelerator. The WLB algorithm doesn't address the latency that occurs when a query is sent to a remote accelerator. If your environment includes both locally deployed accelerators and remote accelerators (for example, for disaster recovery), you can send higher priority queries to a local accelerator.
The data type is VARCHAR(8).

The initial value of CURRENT ACCELERATOR is determined by one of the following settings:

- If specified for the bind of a package, the ACCELERATOR bind option. This bind option does not have a default value.
- Otherwise, the default setting of CURRENT ACCELERATOR is blank (no preferred accelerator).

Example: The following statement sets the CURRENT ACCELERATOR special register so that ACCEL1 is the preferred accelerator.

```sql
SET CURRENT ACCELERATOR = 'ACCEL1';
```

Related reference:

- "SET CURRENT ACCELERATOR" on page 2290
- ACCELERATOR bind option (Db2 Commands)

CURRENT APPLICATION COMPATIBILITY

CURRENT APPLICATION COMPATIBILITY specifies the application compatibility level support for dynamic SQL statements in packages.

The data type is VARCHAR(10).

Set the value with the SET CURRENT APPLICATION COMPATIBILITY statement.

For packages, the initial value is determined by the value of the APPLCOMPAT bind option. For a user-defined functions or stored procedures, the initial value is inherited according to the rules in Special registers in a user-defined function or a stored procedure. For advanced triggers, the initial value is V12R1.

The following CURRENT APPLICATION COMPATIBILITY values are supported to specify the application compatibility behavior of dynamic SQL statements:

- **function-level**
  - Specifies the application compatibility behavior of the function-level function. The equivalent function level or higher must be activated.
  - The format is \textit{vv}r\textit{mmmm}, where \textit{vv} is the version, \textit{r} is the release, and \textit{mmmm} is the modification level. For example:

```sql
V12R1M504
```
  - Identifies compatibility with the current highest available function level, function level 504.

```sql
V12R1M500
```
  - Identifies compatibility with the function level that enables new function in the initial Db2 12 release, function level 500. V12R1M500 is the same as V12R1.

```sql
V12R1M100
```
  - Identifies compatibility with the function level before you activate new function, after migration to Db2 12, function level 100. V12R1M100 is the same as V11R1.

For a list of supported function-level values, see What's new in Db2 12 function levels (Db2 for z/OS What's New?)
V11R1
Specifies Db2 11 compatibility behavior.

V10R1
Specifies Db2 10 compatibility behavior.

Example: Set the host variable CS to the compatibility level.
EXEC SQL SET :CS = CURRENT APPLICATION COMPATIBILITY;

Related reference:
- BIND and REBIND options for packages, plans, and services (Db2 Commands)
- SET CURRENT APPLICATION COMPATIBILITY
- APPL COMPAT LEVEL field (APPLCOMPAT subsystem parameter) (Db2 Installation and Migration)
- -ACTIVATE (Db2) (Db2 Commands)

CURRENT APPLICATION ENCODING SCHEME

CURRENT APPLICATION ENCODING SCHEME specifies which encoding scheme is to be used for dynamic statements. It allows an application to indicate the encoding scheme that is used to process data. This register is not supported in REXX applications or in stored procedures written in REXX.

The value contained in the special register is a character representation of a CCSID. Although you can use the values ASCII, EBCDIC, or UNICODE to set the special register, what is stored in the special register is a character representation of the numeric CCSID that corresponds to the value used in the SET CURRENT APPLICATION ENCODING SCHEME statement. The value ASCII, EBCDIC, or UNICODE is not stored. The CCSID_ENCODING scalar function can be used to get a value of ASCII, EBCDIC, or UNICODE from a numeric CCSID value.

The data type is CHAR(8). If necessary, the value is padded on the right with blanks so that its length is 8 bytes.

For stored procedures and user-defined functions, the initial value of the CURRENT APPLICATION ENCODING SCHEME special register is determined by the value of the ENCODING bind option for the package that is associated with the procedure or function, or by the APPLICATION ENCODING SCHEME option of the CREATE FUNCTION, ALTER FUNCTION, CREATE PROCEDURE, or ALTER PROCEDURE statement for a compiled SQL function or a native SQL procedure. If the option was not specified, the initial value is the value of the field DEFAULT APPLICATION ENCODING SCHEME field on installation panel DSNTIPF.

For basic triggers, the initial value of the CURRENT APPLICATION ENCODING SCHEME special register is Unicode. For advanced triggers, the initial value of the CURRENT APPLICATION ENCODING SCHEME special register is the value of field DEFAULT APPLICATION ENCODING SCHEME on installation panel DSNTIPF.

Example: The CURRENT APPLICATION ENCODING SCHEME special register can be used like any other special register:
EXEC SQL VALUES (CURRENT APPLICATION ENCODING SCHEME) INTO :HV1;
EXEC SQL INSERT INTO T1 VALUES (CURRENT APPLICATION ENCODING SCHEME);
EXEC SQL SET :HV1 = CURRENT APPLICATION ENCODING SCHEME;
EXEC SQL SELECT C1 FROM T1 WHERE C1 = CURRENT APPLICATION ENCODING SCHEME;

Related reference: 
**SET CURRENT APPLICATION ENCODING SCHEME**

**CURRENT CLIENT_ACCTNG**

CURRENT CLIENT_ACCTNG contains the value of the accounting string from the client information that is specified for the connection.

The data type is VARCHAR(255).

The value of the special register can be changed by using one of the following application programming interfaces (APIs):

- Set Client Information (sqleseti)
- SQLSetConnectAttr (ODBC)
- java.sql.Connection.setClientInfo (JDBC)
- The RRS DSNRLI SIGNON, AUTH SIGNON, CONTEXT SIGNON, or SET_CLIENT_ID function
- The WLM_SET_CLIENT_INFO stored procedure

The value for the accounting string will be obtained first from the accounting string that is set by the SET_CLIENT_ID function, AUTH SIGNON function, or the Set Client Information (sqleseti) API, or alternatively from the accounting token set by RRSAF if accounting string has not been set.

The application compatibility value of the package determines the length and blank padding of the CURRENT_CLIENT_ACCTNG special register returned.

If one of these APIs is not used to set the value of the special register, an empty string is returned when the special register is referenced.

Example: Get the current value of the accounting string for this connection.

```
SET :ACCT_STRING = CURRENT CLIENT_ACCTNG
```

Related concepts:
- RRSAF connection functions (Db2 Application programming and SQL)
- Application compatibility levels in Db2 (Db2 Application programming and SQL)

Related tasks:
- Providing extended client information to the data source with IBM Data Server Driver for JDBC and SQLJ-only methods (Db2 Application Programming for Java)

Related reference:
- WLM_SET_CLIENT_INFO stored procedure
- sqle_client_info data structure

**CURRENT CLIENT_APPLNAME**

CURRENT CLIENT_APPLNAME contains the value of the application name from the client information that is specified for the connection.
The data type is VARCHAR(255).

The default application name varies, depending on the connection:

- If the connection is from a remote application client driver, the default is the application name as supplied by the driver. Default values set by the IBM Data Server Driver for JDBC and SQLJ can be obtained from the DatabaseMetaData.getClientInfoProperties method.

- If the connection is from a remote Db2 12 for z/OS application, the default varies depending on which attachment facility is used:

  **TSO attachment facility**
  
  The default application name is one of the following cases:
  
  - The TSO logon user ID when the application runs in TSO foreground using TSO online applications like SPUFI.
  - The job name when the application runs in TSO background using TSO batch applications like DSNTEP2.

  **RRS attachment facility interface**
  
  The correlation ID that is provided at the call of the RRS DSNRLI SIGNON function.

  **Call attachment facility**
  
  The job name.

  **CICS attachment facility**
  
  The first 8 bytes of the correlation ID. In particular the correlation ID is a 12-byte string for a CICS transaction, where the first 8 bytes are used as the default application name.

  **IMS Attachment facility**
  
  An 8-byte string, the Program Specification Block (PSB) name, or the program name.

The value of the special register can be changed by using one of the following application programming interfaces (APIs):

- SQLE_CLIENT_INFO_APPLNAME (sqleseti)
- SQLSetConnectAttr (ODBC)
- java.sql.Connection.setClientInfo (JDBC)
- The RRS DSNRLI SIGNON, AUTH SIGNON, CONTEXT SIGNON, or SET_CLIENT_ID function
- The WLM_SET_CLIENT_INFO stored procedure

When the client application name is explicitly set, it overwrites the default application name described above and is used as the client application name.

The application compatibility value of the package determines the length and blank padding of the CURRENT CLIENT_APPLNAME special register returned.

If one of these APIs is not used to set the value of the special register, an empty string is returned when the special register is referenced.

*Example:* Select the departments that are allowed to use the application that is being used in this connection.

```sql
SELECT DEPT
FROM DEPT_APPL_MAP
WHERE APPL_NAME = CURRENT CLIENT_APPLNAME
```
CURRENT CLIENT_CORR_TOKEN

CURRENT CLIENT_CORR_TOKEN contains the value of the client correlation token from the client information that is specified for the connection.

The data type is VARCHAR(255).

The value of the special register can be changed by using one of the following application programming interfaces (APIs):

- SQL_CLIENT_INFO_PROGRAMID (sqleseti)
- java.sql.Connection.setClientInfo (JDBC)
- The RRS DSNRLI SIGNON, AUTH SIGNON, CONTEXT SIGNON, or SET_CLIENT_ID function

If one of these APIs is not used to set the value of the special register, the value defaults to the correlation identifier from the client driver such as an application identifier. If a correlation identifier is not provided by the client system, an LUWID (Logical Unit of Work ID) is generated which becomes the correlation token.

Example: Select the departments that are allowed to use the correlation token that is being used in this connection.

```
SELECT DEPT
FROM DEPT_CORR_TOKEN_MAP
WHERE CORR_TOKEN_NAME = CURRENT CLIENT_CORR_TOKEN
```

CURRENT CLIENT_USERID

CURRENT CLIENT_USERID contains the value of the client user ID from the client information that is specified for the connection.
The default client user ID is the primary authorization ID used to establish the connection.

The data type is VARCHAR(255).

The value of the special register can be changed by using one of the following application programming interfaces (APIs):

- SQL_CLIENT_INFO_USERID (sqleseti)
- SQLSetConnectAttr (ODBC)
- java.sql.Connection.setClientInfo (JDBC)
- The RRS DSNRLI SIGNON, AUTH SIGNON, CONTEXT SIGNON, or SET_CLIENT_ID function
- The WLM_SET_CLIENT_INFO stored procedure

When the client user ID is explicitly set, it overwrites the primary authorization id described above and is used as the client user ID.

If the value set by the API exceeds 128 bytes, it is truncated to 128 bytes.

The application compatibility value of the package determines the length and blank padding of the CURRENT CLIENT_USERID special register returned.

**Example**

Find out in which department the current client user ID works.

```sql
SELECT DEPT
FROM DEPT_USERID_MAP
WHERE USER_ID = CURRENT CLIENT_USERID
```

**Related concepts:**

- RRSAF connection functions (Db2 Application programming and SQL)
- Application compatibility levels in Db2 (Db2 Application programming and SQL)

**Related tasks:**

- Providing extended client information to the data source with IBM Data Server Driver for JDBC and SQLJ-only methods (Db2 Application Programming for Java)

**Related reference:**

- WLM_SET_CLIENT_INFO stored procedure
- sqle_client_info data structure
- Client info properties support by the IBM Data Server Driver for JDBC and SQLJ (Db2 Application Programming for Java)

**CURRENT CLIENT_WRKSTNNAME**

CURRENT CLIENT_WRKSTNNAME contains the value of the workstation name from the client information that is specified for the connection.

The data type is VARCHAR(255).

The default workstation name varies, depending on the connection:
• If the connection originates from a Db2 12 for z/OS requester, it is the client host name.
• If the connection is from a remote application client driver, it is the client host name where the request is submitted. Default values that are set by the IBM Data Server Driver for JDBC and SQLJ can be obtained from the DatabaseMetaData.getClientInfoProperties method.
• If the connection is from a remote Db2 12 for z/OS application, the default varies depending on which attachment facility is used:

  **TSO attachment facility**
  The default workstation name is one of the following cases:
  – The default workstation name is 'TSO' when the application runs in TSO foreground with TSO online applications like SPUFI.
  – The default workstation name is 'BATCH' when the application runs in TSO background with TSO batch applications like DSNTEP2.

  **RRS attachment facility interface**
  The default workstation name is 'RRSAF'.

  **Call attachment facility**
  The default workstation name is 'DB2CALL'.

  **CICS attachment facility**
  The default workstation name is the CICS region name.

  **IMS Attachment facility**
  The default workstation name is IMS region ID.

The value of the special register can be changed by using one of the following application programming interfaces (APIs):
• SQL.CLIENT_INFO_WRKSTNNAME (sqleseti)
• SQLSetConnectAttr (ODBC)
• java.sql.Connection.setClientInfo (JDBC)
• The RRS DSNRLI SIGNON, AUTH SIGNON, CONTEXT SIGNON, or SET_CLIENT_ID function
• The WLM_SET_CLIENT_INFO stored procedure

When the client workstation name is explicitly set, it overwrites the default workstation name described above and is used as the client workstation name.

The application compatibility value of the package determines the length and blank padding of the CURRENT CLIENT_WRKSTNNAME special register returned.

If one of these APIs is not used to set the value of the special register, an empty string is returned when the special register is referenced.

*Example:* Get the name of the workstation that is being used in this connection.

```sql
SET :WS_NAME = CURRENT CLIENT_WRKSTNNAME
```

**Related tasks:**

---

Chapter 2. Language elements 199
CURRENT DATE

The CURRENT DATE special register specifies a date that is based on a reading of the time-of-day clock when the SQL statement is executed at the current server.

If this special register is used more than one time within a single SQL statement, or used with CURRENT TIME or CURRENT TIMESTAMP within a single statement, all values are based on a single clock reading.\(^\text{10}\)

The value of CURRENT DATE in a user-defined function or stored procedure is inherited according to the rules in Table 48 on page 225. For other applications, the date is derived by the Db2 that executes the SQL statement that refers to the special register. For a description of how the date is derived, see Datetime special registers.

Specifying CURRENT_DATE is equivalent to specifying CURRENT DATE.

Example: Display the average age of employees.

```
SELECT AVG(YEAR(CURRENT_DATE - BIRTHDATE))
FROM DSNBC10.EMP;
```

CURRENT DEBUG MODE

CURRENT DEBUG MODE specifies the default value for the DEBUG MODE option when advanced triggers and certain routines are created. The DEBUG MODE option specifies whether the trigger or routine should be built with the ability to run in debugging mode.

CURRENT DEBUG MODE specifies the default value for the DEBUG MODE option of the following statements:

- ALTER FUNCTION for a new version of an SQL scalar function
- ALTER PROCEDURE for a new version of a native SQL procedure
- ALTER TRIGGER (advanced) for a new version of a trigger
- CREATE FUNCTION for an SQL scalar function
- CREATE PROCEDURE for a Java procedure
- CREATE PROCEDURE for a native SQL procedure
- CREATE TRIGGER (advanced) for an advanced trigger

The data type is VARCHAR(8). The following values are valid:

- ALLOW — Specifies that the routine or trigger can be run in debugging mode.

\(^\text{10. Except for the case of a non-atomic multiple row INSERT or MERGE statement.}\)
- DISALLOW — Specifies that the routine or trigger cannot be run in debugging mode. A subsequent ALTER statement can change the DEBUG MODE option to allow the routine or trigger to run in debugging mode.

- DISABLE — Specifies that the routine or trigger can never be run in debugging mode. When DISABLE is in effect, the routine or trigger cannot be changed to run in debugging mode. A subsequent ALTER statement cannot change the DEBUG MODE option to allow or disallow the routine or trigger to run in debugging mode.

The value of CURRENT DEBUG MODE in a user-defined function, stored procedure, or trigger is determined according to the rules in Table 48 on page 225. In other contexts the initial value of CURRENT DEBUG MODE is DISALLOW.

You can change the value of the CURRENT DEBUG MODE special register by running the SET CURRENT DEBUG MODE statement.

Example: Set the host variable DEBUG_MODE_OPT to the value of the CURRENT DEBUG MODE special register:

```
VALUES CURRENT DEBUG MODE INTO :DEBUG_MODE_OPT;
```

Related reference: [SET CURRENT DEBUG MODE](#)

### CURRENT DECFLOAT ROUNDDING MODE

CURRENT DECFLOAT ROUNDDING MODE specifies the default rounding mode that is used for DECFLOAT values.

The data type is VARCHAR(128). The following rounding modes are supported:

- ROUND_CEILING — rounds the value towards positive infinity. If all of the discarded digits are zero or if the sign is negative the result is unchanged other than the removal of the discarded digits. Otherwise, the result coefficient is incremented by 1.

- ROUND_DOWN — rounds the value towards 0 (truncation). The discarded digits are ignored.

- ROUND_FLOOR — rounds the value towards negative infinity. If all of the discarded digits are zero or if the sign is positive the result is unchanged other than the removal of discarded digits. Otherwise, the sign is negative and the result coefficient is incremented by 1.

- ROUND_HALF_DOWN — rounds the value to the nearest value; if the values are equidistant, rounds the value towards zero. If the discarded digits represent greater than half (0.5) of the value of a one in the next left position then the result coefficient is incremented by 1. Otherwise the discarded digits are ignored. This rounding mode is not recommended when creating a portable application because it is not supported by the IEEE draft standard for floating-point arithmetic.

- ROUND_HALF_EVEN — rounds the value to the nearest value; if the values are equidistant, rounds the value so that the final digit is even. If the discarded digits represent greater than half (0.5) of the value of one in the next left position then the result coefficient is incremented by 1. If they represent less than half, then the result coefficient is not adjusted (that is, the discarded digits are ignored). Otherwise the result coefficient is unaltered if its rightmost digit is even, or is incremented by 1 if its rightmost digit is odd (to make an even digit).

- ROUND_HALF_UP — rounds the value to the nearest value; if the values are equidistant, rounds the value away from zero. If the discarded digits represent
greater than or equal to half (0.5) of the value of one in the next left position then the result coefficient is incremented by 1. Otherwise the discarded digits are ignored.

- **ROUND_UP** — rounds the value away from 0. If all of the discarded digits are zero the result is unchanged other than the removal of discarded digits. Otherwise, the result coefficient is incremented by 1. This rounding mode is not recommended when creating a portable application because it is not supported by the IEEE draft standard for floating-point arithmetic.

The initial value of CURRENT DECIMAL Rounding Mode is the value of the Rounding bind option or the native SQL procedure option. If the Rounding option is not specified, the initial value is the value of the DEF DECIMAL ROUND MODE field on installation panel DSNTIPF.

The value of CURRENT DECIMAL Rounding Mode in a user-defined function or stored procedure is inherited according to the rules in Table 48 on page 225.

You can change the value of the CURRENT DECIMAL Rounding Mode by executing the statement SET CURRENT DECIMAL Rounding Mode.

*Example:* Set the DECIMAL rounding mode to ROUND_CEILING:

\[
\text{SET CURRENT DECIMAL Rounding Mode} = 'ROUND_CEILING';
\]

*Related reference:* Set CURRENT DECIMAL Rounding Mode

**CURRENT DEGREE**

CURRENT DEGREE specifies the degree of parallelism for the execution of queries that are dynamically prepared by the application process.

The data type of the register is CHAR(3) and the only valid values are 1 (padded on the right with two blanks) and ANY.

If the value of CURRENT DEGREE is 1 when a query is dynamically prepared, the execution of that query will not use parallelism. If the value of CURRENT DEGREE is ANY when a query is dynamically prepared, the execution of that query can involve parallelism.

The initial value of CURRENT DEGREE is determined by the value of field CURRENT DEGREE on installation panel DSNTIPF. The default for the initial value of that field is 1 unless your installation has changed it to be ANY by modifying the value in that field. The initial value of CURRENT DEGREE in a user-defined function or stored procedure is inherited according to the rules in Table 48 on page 225.

You can change the value of the register by executing the statement SET CURRENT DEGREE.

CURRENT DEGREE is a register at the database server. Its value applies to queries that are dynamically prepared at that server and to queries that are dynamically prepared at another Db2 subsystem as a result of the use of a Db2 private connection between that server and that Db2 subsystem.

*Example:* The following statement inhibits parallelism:
SET CURRENT DEGREE = '1';

**Related concepts:**
- [Parallel processing (Db2 Performance)](##)

**Related tasks:**
- [Enabling parallel processing (Db2 Performance)](##)
- [Disabling query parallelism (Db2 Performance)](##)

**Related reference:**
- [SET CURRENT DEGREE](##)
- [CURRENT DEGREE field (CDSSRDEF subsystem parameter) (Db2 Installation and Migration)](##)

### CURRENT EXPLAIN MODE

The CURRENT EXPLAIN MODE special register contains the values that control the EXPLAIN behavior in regards to eligible dynamic SQL statements.

This facility generates and inserts EXPLAIN information into the EXPLAIN tables. Possible values for the CURRENT EXPLAIN MODE special register are YES, NO, and EXPLAIN. The data type is VARCHAR(128).

**NO**
Disable the ability to use EXPLAIN. No EXPLAIN information is kept. NO is the initial value of the EXPLAIN MODE special register.

**YES**
Enables the EXPLAIN facility and causes EXPLAIN information to be inserted into the EXPLAIN tables for eligible dynamic SQL statements after the statement is prepared and executed. All dynamic SQL statements are compiled and executed normally.

**EXPLAIN**
Enables the EXPLAIN facility and causes EXPLAIN information to be captured for any eligible dynamic SQL statement after the statement is prepared. This setting behaves similarly to YES, however, dynamic statements, except for SET statements, are not executed.

For values YES and EXPLAIN, prepared statements are not saved into the dynamic statement cache.

The initial value is NO. The initial value of CURRENT EXPLAIN MODE in a user-defined function or stored procedure is inherited according to the rules in [Special registers in a user-defined function or a stored procedure](##).

The value can be changed using the SET CURRENT EXPLAIN MODE statement.

**Prerequisites for using CURRENT EXPLAIN MODE:**
- Both the PLAN_TABLE and DSN_STATEMENT_CACHE_TABLE exist on the Db2 server and the table names are qualified with the current SQLID that is used when running the application.
- The Dynamic statement cache is enabled.
- The client application contains some explainable statements.

**Required authorization for using CURRENT EXPLAIN MODE:**
If CURRENT EXPLAIN MODE is set to YES or EXPLAIN, the privilege set for the underlying statement must have the necessary authorization to use the EXPLAIN facility.
When the EXPLAIN privilege is in effect and CURRENT EXPLAIN MODE is set to EXPLAIN, any SQLCODE that is returned due to the EXPLAIN privilege override any SQLCODE that is returned due to CURRENT EXPLAIN MODE being set to EXPLAIN.

Considerations when using the CURRENT EXPLAIN MODE special register to explain the acceleration of rowset queries:

A rowset query cannot be passed to an accelerator server for processing in the following cases:

- If the rowset query is run remotely
- If the rowset query is declared WITH RETURN
- If the rowset query is run under an SQL PL routine

When a rowset query is run with the CURRENT EXPLAIN MODE special register set to YES or EXPLAIN, the EXPLAIN output indicates whether the local execution of a rowset cursor can be accelerated, depending on the content of the query. The EXPLAIN output will always indicate that remote rowset queries, rowset queries that are declared WITH RETURN, and rowset queries that run under an SQL PL routine cannot be accelerated.

Related reference:

SET CURRENT EXPLAIN MODE

CURRENT GET_ACCEL_ARCHIVE

The CURRENT GET_ACCEL_ARCHIVE special register specifies whether a dynamic SQL query that references a table that is archived on an accelerator server uses the archived data. The special register does not apply to static SQL queries.

The data type is VARCHAR(255).

Valid values are:

- **NO** Specifies that if a table is archived on an accelerator server, and a query references that table, the query does not use the data that is archived.
- **YES** Specifies that if a table is archived on an accelerator server, and a query references that table, the query uses the data that is archived.

The initial value of CURRENT GET_ACCEL_ARCHIVE is determined by one of the following settings:

- The value of Db2 subsystem parameter GET_ACCEL_ARCHIVE. The default for the initial value of that subsystem parameter is NO unless your installation has changed the value.
- If specified for the bind of a package, the GETACCELARCHIVE bind option. This behavior enables the GETACCELARCHIVE bind option to be used to specify the acceleration archive behavior for dynamic SQL queries and not only static SQL queries. This bind option does not have a default value.

The initial value of CURRENT GET_ACCEL_ARCHIVE in a user-defined function or stored procedure is inherited according to the rules in the Special registers in a user-defined function or a stored procedure.

You can change the value of the register by executing the SET CURRENT GET_ACCEL_ARCHIVE statement.
The precedence order (lowest to highest) for setting the value of the special register is as follows:

- The GET_ACCEL_ARCHIVE subsystem parameter
- The GETACCELARCHIVE bind option, if specified
- An explicit SET CURRENT GET_ACCEL_ARCHIVE statement

**Example:** The following statement sets the CURRENT GET_ACCEL_ARCHIVE special register so that when a table is archived on an accelerator server, the table reference does not include the archived data.

```
SET CURRENT GET_ACCEL_ARCHIVE=NO;
```

**CURRENT LOCALE LC_CTYPE**

CURRENT LOCALE LC_CTYPE specifies the LC_CTYPE locale that will be used to execute SQL statements that use a built-in function that references a locale. Functions LCASE, UCASE, and TRANSLATE (with a single argument) refer to the locale when they are executed.

The data type is CHAR(50). If necessary, the value is padded on the right with blanks so that its length is 50 bytes. The following values are supported:

- **blank** — For a conversion to lowercase, SBCS uppercase characters A-Z are converted to SBCS lowercase characters a-z, and characters with diacritical marks are not converted. If the string contains MIXED or DBCS characters, full-width Latin uppercase characters A-Z are converted to full-width lowercase characters a-z.

  For a conversion to uppercase, SBCS lowercase characters a-z are converted to SBCS uppercase characters A-Z, and characters with diacritical marks are not converted. If the string contains MIXED or DBCS characters, full-width Latin lowercase characters a-z are converted to full-width uppercase characters A-Z.

  For optimal performance, specify a blank string unless your data must be processed by using rules that are defined by a specific locale.

- **UNI** — Case conversions use both the NORMAL and SPECIAL casing capabilities as described in [Select the conversions (z/OS: Unicode Services User’s Guide and Reference)](https://www.ibm.com/support/knowledgecenter/SSDK59_9.1.0/com.ibm.zos.v9r1.sdkinfo/ucaseref.html). UNI cannot be used with EBCDIC data.

- **UNI_SIMPLE** — Case conversions use the NORMAL casing capabilities as described in [Select the conversions (z/OS: Unicode Services User’s Guide and Reference)](https://www.ibm.com/support/knowledgecenter/SSDK59_9.1.0/com.ibm.zos.v9r1.sdkinfo/ucaseref.html). UNI_SIMPLE cannot be used with EBCDIC data.

The initial value of CURRENT LOCALE LC_CTYPE is determined by the value of field LOCALE LC_CTYPE on installation panel DSNTIPF. The default for the initial value of that field is blank unless your installation has changed the value of that field. The initial value of CURRENT LOCALE LC_CTYPE in a user-defined function or stored procedure is inherited according to the rules in [Table 48 on page 225](https://www.ibm.com/support/knowledgecenter/SSDK59_9.1.0/com.ibm.zos.v9r1.sdkinfo/programming/g82164.htm).

You can change the value of the register by executing the statement SET CURRENT LOCALE LC_CTYPE.
Some examples of locales for EBCDIC data include:

Fr_BE
Fr_FR@EURO
En_US
Ja_JP

Example: Save the value of current register CURRENT LOCALE LC_CTYPE in host variable HV1, which is defined as VARCHAR(50).

EXEC SQL VALUES(CURRENT LOCALE LC_CTYPE) INTO :HV1;

Related concepts:

- z/OS Unicode Services User’s Guide and Reference
- SET CURRENT LOCALE LC_CTYPE
- z/OS XL C/C++ Programming Guide

CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION

CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION specifies a value that identifies the types of objects that can be considered to optimize the processing of dynamic SQL queries. This register contains a keyword representing table types.

The data type is VARCHAR(255).

The initial value of CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION is determined by the value of field CURRENT MAINT TYPES on installation panel DSNTIP81. The default for the initial value of that field is SYSTEM unless your installation has changed the value of that field. The initial value of CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION in a user-defined function or stored procedure is inherited according to the rules in Table 48 on page 225.

You can change the value of the register by executing the SET CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION statement. The object types controlled by this special register are never considered by static embedded SQL queries.

Example: Set the CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION special register so that all materialized query tables are considered.

SET CURRENT MAINTAINED TABLE TYPES ALL;

Related reference:

- SET CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION

CURRENT MEMBER

CURRENT MEMBER specifies the member name of a current Db2 data sharing member on which a statement is executing. The value of CURRENT MEMBER is a character string.

The data type is CHAR(8). If necessary, the member name is padded to the right with blanks so that its length is 8 bytes.
The value of a CURRENT MEMBER is a string of blanks when the application process is connected to a Db2 subsystem that is not a member of a data sharing group.

The SQL SET statement cannot change the value of CURRENT MEMBER.

Example: Use one of the following statements to set the host variable MEM to the name of the current Db2 member.

```
EXEC SQL SET :MEM = CURRENT MEMBER;
EXEC VALUES (CURRENT MEMBER) into :MEM;
```

CURRENT OPTIMIZATION HINT

CURRENT OPTIMIZATION HINT specifies the user-defined optimization hint that Db2 should use to generate the access path for dynamic statements.

The data type is VARCHAR(128).

The value of the register identifies the rows in `owner PLAN_TABLE` that Db2 uses to generate the access path. Db2 uses information in the rows in `owner PLAN_TABLE` for which the value of the OPTHINT column matches the value of the CURRENT OPTIMIZATION special register. If the value of the register is an empty string or all blanks, Db2 uses normal optimization and ignores optimization hints. If the value of the register includes any non-blank characters and Db2 was installed without optimization hints enabled (field OPTIMIZATION HINTS on installation panel DSNTIP8), a warning occurs.

The initial value of CURRENT OPTIMIZATION HINT is the value of the OPTHINT bind option or of the native SQL procedure option. The initial value of CURRENT OPTIMIZATION HINT in a user-defined function or stored procedure is inherited according to the rules in Table 48 on page 225. You can change the value of the special register by executing the statement SET CURRENT OPTIMIZATION HINT.

Example: Set the CURRENT OPTIMIZATION HINT special register so that Db2 uses the optimization plan hint that is identified by host variable NOHYB when generating the access path for dynamic statements.

```
SET CURRENT OPTIMIZATION HINT = :NOHYB
```

Related tasks:

- Specifying access paths in a PLAN_TABLE instance (Db2 Performance)
- Preparing to influence access paths (Db2 Performance)

Related reference:

- SET CURRENT OPTIMIZATION HINT

CURRENT PACKAGE PATH

CURRENT PACKAGE PATH specifies a value that identifies the path used to resolve references to packages that are used to execute SQL statements. This special register applies to both static and dynamic statements.

The data type is VARCHAR(4096). The value can be an empty or blank string, or a list of one or more collection IDs, where the collection IDs are enclosed in double quotation marks and separated by commas. Any quotation marks within the string are repeated as they are in any delimited identifier. The delimiters and commas are included in the length of the special register.
The initial value of CURRENT PACKAGE PATH is an empty string. The value is a list of collections only if the application process has explicitly specified a list of collections by means of the SET CURRENT PACKAGE PATH statement.

The initial value of CURRENT PACKAGE PATH in a user-defined function or procedure is inherited according to the rules in Table 48 on page 225.

When CURRENT PACKAGE PATH or CURRENT PACKAGESET is set, Db2 uses the values in these registers to resolve the collection for a package. The value of CURRENT PACKAGE PATH takes priority over CURRENT PACKAGESET. In a distributed environment, the value of CURRENT PACKAGE PATH at the remote server takes precedence of the value of CURRENT PACKAGE PATH at the local server (the requester). For more information on package resolution, see Db2 Application Programming and SQL Guide.

Example: In an application that is using SQLJ packages (in collection SQLJ1 and SQLJ2) and a JDBC package in DB2JAVA, set the CURRENT PACKAGE PATH special register to check SQLJ1 first, followed by SQLJ2, and DB2JAVA:

```
SET CURRENT PACKAGE PATH = SQLJ1, SQLJ2, DB2JAVA;
```

The following statement sets the host variable to the value of the resulting list:

```
SET :HVPKLIST = CURRENT PACKAGE PATH;
```

The value of the host variable would be "SQLJ1", "SQLJ2", "DB2JAVA".

Related reference:

**SET CURRENT PACKAGE PATH**

### CURRENT PACKAGESET

CURRENT PACKAGESET specifies an empty string, a string of blanks, or the collection ID of the package that will be used to execute SQL statements.

The data type is VARCHAR(128).

The initial value of CURRENT PACKAGESET is an empty string. The value is a collection ID only if the application process has explicitly specified a collection ID by means of the SET CURRENT PACKAGESET statement.

The initial value of CURRENT PACKAGESET in a user-defined function or stored procedure is inherited according to the rules in Table 48 on page 225.

Example: Before passing control to another program, identify the collection ID for its package as ALPHA.

```
EXEC SQL SET CURRENT PACKAGESET = 'ALPHA';
```

Related reference:

**SET CURRENT PACKAGESET**

### CURRENT PATH

CURRENT PATH specifies the SQL path used to resolve unqualified data type names and function names in dynamically prepared SQL statements. It is also used to resolve unqualified procedure names that are specified as host variables in SQL CALL statements (CALL host-variable).

The data type is VARCHAR(2048).
The CURRENT PATH special register contains a list of one or more schema names, where each schema name is enclosed in delimiters and separated from the following schema by a comma (any delimiters within the string are repeated as they are in any delimited identifier). The delimiters and commas are included in the 2048 character length.

For information on when the SQL path is used to resolve unqualified names in both dynamic and static SQL statements and the effect of its value, see “SQL path” on page 92.

The initial value of the CURRENT PATH special register is determined from the first of one of the following sets of conditions that is met:

- If the CURRENT PATH special register was assigned a value (by a SET PATH statement) in the scope of the invoking environment, the special register inherits the value from the invoking environment.
- If the connection is trusted, and both the role as object owner and qualifier options in effect, the special register is set to: "SYSIBM", "SYSFUN", "SYSPROC", "SYSIBMADM", "role-name" where role-name is the role that is associated with the user in the trusted context.
- Otherwise, the special register is set to: "SYSIBM", "SYSFUN", "SYSPROC", "SYSIBMADM", "current-sqlid-value".

The initial value of the CURRENT PATH special register in an SQL routine or trigger is determined from the first of one of the following sets of conditions that is met:

- In an SQL routine, the special register inherits the value from the invoking environment, if the special register was assigned a value (by a SET PATH statement) in the scope of the invoking environment.
- In a trigger, the special register inherits the value from the invoking environment, if the special register was assigned a value (by a SET PATH statement) in the scope of the invoking environment.
- In an SQL routine or trigger, the special register is set to the value specified for the SQL PATH routine or trigger option, if specified.
- In an SQL routine or trigger, the special register is set to the value specified for the SQL PATH routine or trigger option, if specified.
- If the connection is trusted, and both the role as object owner and qualifier options in effect, the special register is set to: "SYSIBM", "SYSFUN", "SYSPROC", "SYSIBMADM", "role-name" where role-name is the role that is associated with the user in the trusted context.
- Otherwise, the special register is set to: "SYSIBM", "SYSFUN", "SYSPROC", "SYSIBMADM", "current-sqlid-value".

If the value of the CURRENT SQLID special register changes after the initial value of PATH special register is established, the value of the PATH special register is unaffected when the CURRENT SQLID is updated. However, if a commit later occurs and a SET PATH statement has not been processed, the value of PATH special register is reinitialized taking into consideration the current value of the CURRENT SQLID special register.

You can change the value of the register by executing the statement SET PATH. For portability across the platforms, it is recommended that a SET PATH statement be issued at the beginning of an application.
Example: Set the special register so that schema SMITH is searched before the system schemas:

```
SET PATH = SMITH, SYSTEM PATH;
```

**Related reference:**

[SET PATH](#)

## CURRENT PRECISION

CURRENT PRECISION specifies the rules to be used when both operands in a decimal operation have precisions of 15 or less.

The data type of the register is CHAR(5).

Valid values for the CURRENT PRECISION special register include 'DEC15', 'DEC31', or 'Dpp.s' where 'pp' is either 15 or 31 and 's' is a number between 1 and 9. DEC15 specifies the rules that do not allow a precision greater than 15 digits, and DEC31 specifies the rules that allow a precision of up to 31 digits. The rules for DEC31 are always used if either operand has a precision greater than 15. If the form 'Dpp.s' is used, 'pp' represents the precision that will be used as the rules where DEC15 and DEC31 rules are used, and 's' represents the minimum divide scale to use for division operations. The separator used in the form 'Dpp.s' can be either the '.' or the ',' character, regardless of the setting of the default decimal point.

The initial value of CURRENT PRECISION is determined by the value of field DECIMAL ARITHMETIC on installation panel DSNTIP4. The default for the initial value is DEC15 unless your installation has changed it to be DEC31 by modifying the value in that field. The initial value of CURRENT PRECISION in a user-defined function or stored procedure is inherited according to the rules in Table 48 on page 225.

You can change the value of the register by executing the statement SET CURRENT PRECISION.

CURRENT PRECISION only affects dynamic SQL. When an SQL statement is dynamically prepared and the value of CURRENT PRECISION is DEC15 or D15.s, where 's' is a number between 1 and 9, DEC15 rules will apply. When an SQL statement is dynamically prepared and the value of CURRENT PRECISION is DEC31 or D31.s, where 's' is a number between 1 and 9, DEC31 rules will apply. Preparation of a statement with DEC31 instead of DEC15 is more likely to result in an error, especially for division operations. Specification of CURRENT PRECISION in the form 'Dpp.s' where 'pp' is either 15 or 31 and 's' represents the minimum divide scale, will in some cases make division errors less likely when 'pp' is set to 31. For more information, see “Arithmetic with two decimal operands” on page 261.

Example 1: Set CURRENT PRECISION so that subsequent statements that are prepared use DEC31 rules for decimal arithmetic:

```
SET CURRENT PRECISION = 'DEC31';
```

Example 2: Set CURRENT PRECISION so that subsequent statements that are prepared use DEC31 rules for decimal arithmetic with a minimum divide scale of 3:

```
SET CURRENT PRECISION = 'D31.3';
```

**Related reference:**
CURRENT QUERY ACCELERATION

The CURRENT QUERY ACCELERATION special register specifies a value that identifies when Db2 sends dynamic SQL queries to an accelerator server and what Db2 does if the accelerator server fails. The special register does not apply to static SQL queries.

The data type is VARCHAR(255).

Valid values are:

NONE
   Specifies that no queries are sent to an accelerator server.
ENABLE
   Specifies that queries are accelerated only if Db2 determines that it is advantageous to do so. If an accelerator failure occurs while a query is running or if the accelerator returns an error, Db2 returns a negative SQLCODE to the application.
ENABLE WITH FAILBACK
   Specifies that queries are accelerated only if Db2 determines that it is advantageous to do so. If the accelerator returns an error during the PREPARE or first OPEN for the query, Db2 executes the query without the accelerator. If the accelerator returns an error during a FETCH or a subsequent OPEN, Db2 returns the error to the user and does not execute the query.

**Restriction:** If the query contains a passthrough-only expression, Db2 returns an error and does not accelerate the query, even if a matching user-defined function exists. For more information about passthrough-only expressions, see Accelerating queries with passthrough-only expressions.

ELIGIBLE
   Specifies that queries are accelerated if they are eligible for acceleration. Db2 does not use cost information to determine whether to accelerate the queries. Queries that are not eligible for acceleration are executed by Db2. If an accelerator failure occurs while a query is running or if the accelerator returns an error, Db2 returns a negative SQLCODE to the application.

ALL
   Specifies that queries are accelerated if they are eligible for acceleration. Db2 does not use cost information to determine whether to accelerate the queries. Queries that are not eligible for acceleration are not executed by Db2, and an SQL error is returned. If an accelerator failure occurs while a query is running or if the accelerator returns an error, Db2 returns a negative SQLCODE to the application.

The initial value of CURRENT QUERY ACCELERATION is determined by one of the following settings:

- The value of Db2 subsystem parameter QUERY_ACCELERATION. The default for the initial value of this subsystem parameter is NONE unless your installation has changed the value.
- If specified for the bind of a package, the QUERYACCELERATION bind option. This behavior enables the QUERYACCELERATION bind option to be used to specify the acceleration behavior for dynamic SQL queries and not only static SQL queries. This bind option does not have a default value.
The initial value of CURRENT QUERY ACCELERATION in a user-defined function or stored procedure is inherited according to the rules in Special registers in a user-defined function or a stored procedure.

You can change the value of the register by executing the SET CURRENT QUERY ACCELERATION statement.

The precedence order (lowest to highest) for setting the value of the special register is as follows:

- The QUERY_ACCELERATION subsystem parameter
- The QUERYACCELERATION bind option, if specified
- An explicit SET CURRENT QUERY ACCELERATION statement

Example: The following statement sets the CURRENT QUERY ACCELERATION special register so that no query acceleration occurs.

```
SET CURRENT QUERY ACCELERATION NONE;
```

Related concepts:
- How Db2 determines whether to accelerate eligible queries (Db2 Performance)

Related reference:
- SET CURRENT QUERY ACCELERATION

## CURRENT QUERY ACCELERATION WAITFORDATA

The CURRENT QUERY ACCELERATION WAITFORDATA special register specifies the amount of time, if any, that the accelerator delays a query while the accelerator waits for the replication of committed Db2 data changes that occurred prior to Db2 running the query. This special register does not apply to static SQL queries.

The data type is a DECIMAL(5,1) in the form of \textit{nnnm.m}.

Valid values are a numeric constant in the range of 0.0 - 3600.0 seconds. For example, a value of 20.0 represents 20.0 seconds (or 20000 milliseconds), and a value of 30.5 represents 30.5 seconds (or 30500 milliseconds). The maximum value of 3600.0 means that the query is delayed for 60 minutes.

The default value is 0.0, which means that the query is not delayed and is run immediately on the accelerator. Other WAITFORDATA behavior is not applied to the query.

The wait time value can also be specified as an INTEGER numeric constant value ranging from 0 - 3600 seconds, which Db2 will convert to a DECIMAL (5,1) value.

You can change the value of the special register by executing the SET CURRENT QUERY ACCELERATION WAITFORDATA statement.

The initial value of CURRENT QUERY ACCELERATION WAITFORDATA is determined by the value of the Db2 QUERY_ACCEL_WAITFORDATA subsystem parameter. The default for the initial value of this subsystem parameter is 0.0 unless your installation has changed the value.

For more information about the restrictions, requirements, and behaviors associated with CURRENT QUERY ACCELERATION WAITFORDATA, see SET CURRENT QUERY ACCELERATION WAITFORDATA.
Example: The following statement sets the CURRENT QUERY ACCELERATION WAITFORDATA special register so that the accelerator delays queries for 180 seconds (three minutes) while it waits for committed Db2 data changes to be replicated to the accelerator.

```
SET CURRENT QUERY ACCELERATION WAITFORDATA 180;
```

Related reference:

SET CURRENT QUERY ACCELERATION WAITFORDATA

CURRENT REFRESH AGE

CURRENT REFRESH AGE specifies a timestamp duration value. This duration is the maximum duration since a REFRESH TABLE statement has been processed on a system-maintained REFRESH DEFERRED materialized query table such that the materialized query table can be used to optimize the processing of a query. This special register affects dynamic statement cache matching.

The data type of the register is DECIMAL(20,6). For a description of durations, see “Datetime operands and durations” on page 271.

If CURRENT REFRESH AGE has a value of 99999999999999 (ANY), REFRESH DEFERRED materialized query tables are considered to optimize the processing of a dynamic SQL query. This value represents 9999 years, 99 months, 99 days, 99 hours, and 99 seconds.

The initial value of CURRENT REFRESH AGE is determined by the value of field CURRENT REFRESH AGE on installation panel DSNTIP81. The default for the initial value of that field is 0 unless your installation has changed it to ANY by modifying the value of that field. The initial value of CURRENT REFRESH AGE in a user-defined function or stored procedure is inherited according to the rules in Table 48 on page 225

You can change the value of the register by executing the SET CURRENT REFRESH AGE statement.

Example: The following example retrieves the current value of the CURRENT REFRESH AGE special register into the host variable, CURMAXAGE:

```
EXEC SQL VALUES (CURRENT REFRESH AGE) INTO :CURMAXAGE;
```

The value would be '99999999999999.000000'.

Related reference:

SET CURRENT REFRESH AGE

CURRENT ROUTINE VERSION

CURRENT ROUTINE VERSION specifies the version identifier that is to be used when invoking a native SQL procedure. CURRENT ROUTINE VERSION is used for CALL statements that use a host variable to specify the procedure name.

The data type of CURRENT ROUTINE VERSION is VARCHAR(64).

The initial value of CURRENT ROUTINE VERSION in a user-defined function or stored procedure is inherited according to the rules in Table 48 on page 225.
other contexts the initial value of CURRENT ROUTINE VERSION is an empty string. An empty string indicates that a version identifier is not in effect for the SQL routine. When an SQL routine that does not have a version identifier in effect is invoked, the currently active version (as indicated in the catalog) of that routine is used.

You can change the value of the CURRENT ROUTINE VERSION by executing the statement SET CURRENT ROUTINE VERSION.

Setting the CURRENT ROUTINE VERSION special register to a version identifier might affect native SQL procedures that are invoked until the value of CURRENT ROUTINE VERSION is changed. If a version of an SQL procedure has a version identifier that matches the version identifier in the special register, that version of the SQL procedure is used when the SQL procedure is invoked. If an SQL procedure does not have a version identifier that matches the version identifier in the special register, the currently active version of the SQL procedure (as defined in the catalog) is used when the SQL procedure is invoked.

Example: Set the host variable ROUTINE_VER to the value of the CURRENT ROUTINE VERSION special register:

```
VALUES CURRENT ROUTINE VERSION INTO :ROUTINE_VER;
```

Related reference:

**SET CURRENT ROUTINE VERSION**

**CURRENT RULES**

CURRENT RULES specifies whether certain SQL statements are executed in accordance with Db2 rules or the rules of the SQL standard.

The data type of the register is CHAR(3), and the only valid values are 'DB2' and 'STD'.

CURRENT RULES is a register at the database server. If the server is not the local Db2, the initial value of the register is 'DB2'. Otherwise, the initial value is the same as the value of the SQLRULES bind option. The initial value of CURRENT RULES in a user-defined function or stored procedure is inherited according to the rules in Special registers in a user-defined function or a stored procedure.

You can change the value of the register by executing the statement SET CURRENT RULES.

CURRENT RULES affects the statements listed in the following table. The table summarizes when the statements are affected and shows where to find detailed information. CURRENT RULES also affects whether Db2 issues an existence error (SQLCODE -204) or an authorization error (SQLCODE -551) when an object does not exist. For CURRENT RULES 'STD', Db2 issues an authorization error (SQLCODE -551) when an object does not exist instead of the existence error (SQLCODE -204).
Table 47. Summary of statements affected by CURRENT RULES

<table>
<thead>
<tr>
<th>Statement</th>
<th>What is affected</th>
<th>Details in topic</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALTER TABLE</td>
<td>Enforcement of check constraints added.</td>
<td>ALTER TABLE</td>
</tr>
<tr>

<tr>
<td></td>
<td>BY DEFAULT if the table is explicitly created.</td>
<td></td>
</tr>
<tr>
<td>GRANT</td>
<td>Granting privileges to yourself.</td>
<td>GRANT</td>
</tr>
<tr>
<td>REVOKE</td>
<td>Revoking privileges from authorization IDs.</td>
<td>REVOKE</td>
</tr>
</tbody>
</table>

Example: Set CURRENT RULES so that a later ALTER TABLE statement is executed in accordance with the rules of the SQL standard:

```
SET CURRENT RULES = 'STD';
```

Related reference:

SET CURRENT RULES

CURRENT SCHEMA

The CURRENT SCHEMA special register specifies the schema name used to qualify unqualified database object references in dynamically prepared SQL statements.

The data type is VARCHAR(128).

For information on when the CURRENT SCHEMA is used to resolve unqualified names in dynamic SQL statements and the effect of its value, see “Qualification of unqualified object names” on page 93.

The CURRENT SCHEMA special register contains a value that is a single identifier without delimiters.

The initial value of the special register is the value of CURRENT SQLID at the time the connection is established. If the connection is established as a trusted connection with a role as the object owner and qualifier, the initial value of the special register is the value of the role name that is associated with the user in the trusted context. The initial value of the special register in a user-defined function or procedure is inherited according to the rules in Table 48 on page 225.
The value of the special register can be changed by executing the SET SCHEMA statement. The value of CURRENT SCHEMA is the same as the value of CURRENT SQLID unless a SET SCHEMA statement has been issued specifying a different value. After a SET SCHEMA statement has been issued in an application, the values of CURRENT SCHEMA and CURRENT SQLID are separate. Therefore, if the value of CURRENT SCHEMA needs to be changed, a SET SCHEMA statement must be issued.

Specifying CURRENT_SCHEMA is equivalent to specifying CURRENT SCHEMA.

Example: Set the schema for object qualification to 'D123'.

```
SET SCHEMA = 'D123'
```

**CURRENT SERVER**

CURRENT SERVER specifies the location name of the current server.

The data type is CHAR(16). If necessary, the location name is padded on the right with blanks so that its length is 16 bytes.

The initial value of CURRENT SERVER depends on the CURRENTSERVER bind option. If CURRENTSERVER X is specified on the bind subcommand, the initial value is X. If the option is not specified, the initial value is the location name of the local Db2. The initial value of CURRENT SERVER in a user-defined function or stored procedure is inherited according to the rules in Table 48 on page 225. The value of CURRENT SERVER is changed by the successful execution of a CONNECT statement.

The value of CURRENT SERVER is a string of blanks when either of the following conditions apply:

- The application process is in the unconnected state
- The application process is connected to a local Db2 subsystem that does not have a location name.

Example: Set the host variable CS to the location name of the current server.

```
EXEC SQL SET :CS = CURRENT SERVER;
```

**CURRENT SQLID**

CURRENT SQLID specifies the SQL authorization ID of the process.

The data type is VARCHAR(128).

The SQL authorization ID is:

- The authorization ID used for authorization checking on dynamically prepared CREATE, GRANT, and REVOKE SQL statements.
- The owner of a table space, database, storage group, or synonym created by a dynamically issued CREATE statement.

The initial value of CURRENT SQLID can be provided by the connection or sign-on exit routine. If not, the initial value is the primary authorization ID of the process. The value remains in effect until one of the following events occurs:

- The SQL authorization ID is changed by the execution of a SET CURRENT SQLID statement.
- A SIGNON or re-SIGNON request is received from a CICS transaction subtask or an IMS independent region.
- The Db2 connection is ended.
- When running in a trusted connection, the user is switched.

The initial value of CURRENT SQLID in a user-defined function or stored procedure is inherited according to the rules in Table 48 on page 225.

CURRENT SQLID can only be referred to in an SQL statement that is executed by the current server.

CURRENT SQLID cannot be a role.

Example: Set the SQL authorization ID to 'GROUP34' (one of the authorization IDs of the process).

```
SET CURRENT SQLID = 'GROUP34';
```

### CURRENT TEMPORAL BUSINESS_TIME

The CURRENT TEMPORAL BUSINESS_TIME special register specifies a TIMESTAMP(12) value that is used in the default BUSINESS_TIME period specification for references to application-period temporal tables.

When a query references an application-period temporal table and the value of the CURRENT TEMPORAL BUSINESS_TIME special register is not the null value, the query is affected as follows:

- If the columns of a BUSINESS_TIME period are defined as TIMESTAMP, the following period specification is implicit:
  ```sql
  FOR BUSINESS_TIME AS OF CURRENT TEMPORAL BUSINESS_TIME
  ```
- If the columns of a BUSINESS_TIME period are defined as DATE, the following period specification is implicit:
  ```sql
  FOR BUSINESS_TIME AS OF CAST(CURRENT TEMPORAL BUSINESS_TIME AS DATE)
  ```

The initial value of the special register depends on the context as follows:

- If the special register is in a trigger, the initial value is inherited from the invoking application.
- If the special register is in a user-defined function or procedure that is defined with the INHERIT SPECIAL REGISTERS option, the initial value is inherited from the invoking application.
- If the special register is in a user-defined function or procedure that is defined with the DEFAULT SPECIAL REGISTERS option, the initial value is the null value.
- In other contexts, the initial value of the special register is the null value.

You can change the value of the special register by using the SET CURRENT TEMPORAL BUSINESS_TIME statement. If you change the value within a routine, that new value is not passed back to the invoking application.

### Examples

Example of a query that references an application-period temporal table

Assume the following conditions:

- ATT is an application-period temporal table and POLICY_ID is a column in ATT.
- The value of the BUSTIMESENSITIVE bind option is YES.
- The value of CURRENT TEMPORAL BUSINESS_TIME is not null.
Then, suppose that you issue the following query:

```sql
SELECT * FROM ATT
WHERE POLICY_ID = 123;
```

Db2 generates an implicit BUSINESS_TIME period specification for the query as follows:

```sql
SELECT * FROM ATT
FOR BUSINESS_TIME AS OF CURRENT TEMPORAL BUSINESS_TIME
WHERE POLICY_ID = 123;
```

**Example of a procedure that uses CURRENT TEMPORAL BUSINESS_TIME**

Suppose that procedure MYPROC is defined as follows:

```sql
CREATE PROCEDURE MYPROC(OUT VAR1 VARCHAR(40), OUT VAR2 VARCHAR(40))
BEGIN
  SELECT CURRENT TEMPORAL BUSINESS_TIME INTO VAR1
  FROM SYSIBM.SYSDUMMY1;

  SET CURRENT TEMPORAL BUSINESS_TIME = TIMESTAMP('2011-01-01') + 5 DAYS;

  SELECT CURRENT TEMPORAL BUSINESS_TIME INTO VAR2
  FROM SYSIBM.SYSDUMMY1;
END!
```

Suppose that the application defines string variables VAR1, VAR2, and VAR3 and contains the following SQL statements:

```sql
SET CURRENT TEMPORAL BUSINESS_TIME = TIMESTAMP('2008-01-01') + 5 DAYS;
CALL MYPROC(VAR1, VAR2);
SELECT CURRENT TEMPORAL BUSINESS_TIME INTO VAR3
FROM SYSIBM.SYSDUMMY1;
```

After the execution of the SQL statements, the variables have the following values:

- VAR1 has value '2008-01-06-00.00.00.000000000000', which is the CURRENT TEMPORAL BUSINESS_TIME value that is set before the CALL statement invoked the procedure.
- VAR2 has value '2011-01-06-00.00.00.000000000000', which is the CURRENT TEMPORAL BUSINESS_TIME value that is set during the CALL statement.
- VAR3 has value '2008-01-06-00.00.00.000000000000', which is the CURRENT TEMPORAL BUSINESS_TIME value that is set before the CALL statement. The changes of the register value inside the procedure have no affect on the invoking application.

**Example of a query that references CURRENT TEMPORAL BUSINESS_TIME**

Assume that IN_TRAY is an application-period temporal table that contains users and subject lines for notes in the inbox. The following query returns the user ID and subject line for notes in the IN_TRAY table that were sent on the date that the CURRENT TEMPORAL BUSINESS_TIME special register is set to.

```sql
SELECT SOURCE, SUBJECT
FROM IN_TRAY
WHERE DATE (CURRENT TEMPORAL BUSINESS_TIME) = DATE (RECEIVED)
```

**Related tasks:**

- [Querying temporal tables (Db2 Administration Guide)](URL)

**Related reference:**

- [SQL Reference](URL)
CURRENT TEMPORAL SYSTEM_TIME

The CURRENT TEMPORAL SYSTEM_TIME special register specifies a TIMESTAMP(12) value that is used in the default SYSTEM_TIME period specification for references to system-period temporal tables.

When a query references a system-period temporal table and the value of the CURRENT TEMPORAL SYSTEM_TIME special register is not the null value, the following period specification is implicit:

```sql
FOR SYSTEM_TIME AS OF CURRENT TEMPORAL SYSTEM_TIME
```

The initial value of the special register depends on the context as follows:

- If the special register is in a trigger, the initial value is inherited from the invoking application.
- If the special register is in a user-defined function or procedure that is defined with the INHERIT SPECIAL REGISTERS option, the initial value is inherited from the invoking application.
- If the special register is in a user-defined function or procedure that is defined with the DEFAULT SPECIAL REGISTERS option, the initial value is the null value.
- In other contexts, the initial value of the special register is the null value.

You can change the value of the special register by using the SET CURRENT TEMPORAL SYSTEM_TIME statement. If you change the value within a routine, that new value is not passed back to the invoking application.

When the value of the CURRENT TEMPORAL SYSTEM_TIME special register is not null and the SYSTIMESENSITIVE bind option is set to YES, you cannot explicitly specify FOR SYSTEM_TIME in a select-statement.

Examples

Example of a query that references a system-period temporal table

Assume the following conditions:

- STT is a system-period temporal table, and POLICY_ID is a column of STT.
- The value of the SYSTIMESENSITIVE bind option is YES.
- The value of CURRENT TEMPORAL SYSTEM_TIME is not null.

Then, suppose that you issue the following query:

```sql
SELECT * FROM STT
WHERE POLICY_ID = 123;
```

Db2 generates an implicit SYSTEM_TIME period specification for the query as follows:

```sql
SELECT * FROM STT
FOR SYSTEM_TIME AS OF CURRENT TEMPORAL SYSTEM_TIME
WHERE POLICY_ID = 123;
```
Example of a procedure that uses CURRENT TEMPORAL SYSTEM_TIME

Suppose that procedure MYPROC is defined as follows:

```sql
CREATE PROCEDURE MYPROC(OUT VAR1 VARCHAR(40), OUT VAR2 VARCHAR(40))
BEGIN
    SELECT CURRENT TEMPORAL SYSTEM_TIME INTO VAR1
    FROM SYSIBM.SYSDUMMY1;
    SET CURRENT TEMPORAL SYSTEM_TIME = TIMESTAMP('2011-01-01') + 5 DAYS ;
    SELECT CURRENT TEMPORAL SYSTEM_TIME INTO VAR2
    FROM SYSIBM.SYSDUMMY1;
END!
```

Suppose that the application defines string variables VAR1, VAR2, and VAR3 and contains the following SQL statements:

```sql
SET CURRENT TEMPORAL SYSTEM_TIME = TIMESTAMP('2008-01-01') + 5 DAYS ;
CALL MYPROC(VAR1, VAR2);
SELECT CURRENT TEMPORAL SYSTEM_TIME INTO VAR3
FROM SYSIBM.SYSDUMMY1
```

After the execution of the SQL statements, the variables have the following values:

- VAR1 has value '2008-01-06-00.00.00.000000000000', which is the CURRENT TEMPORAL SYSTEM_TIME value that is set before the CALL statement invoked the procedure.
- VAR2 has value '2011-01-06-00.00.00.000000000000', which is the CURRENT TEMPORAL SYSTEM_TIME value that is set during the CALL statement.
- VAR3 has value '2008-01-06-00.00.00.000000000000', which is the CURRENT TEMPORAL SYSTEM_TIME value that is set before the CALL statement. The changes of the register value inside the procedure have no affect on the invoking application.

Example of a query that references a system-period temporal table

Assume that IN_TRAY is a system-period temporal table that contains users and subject lines for notes in the inbox. The following query returns the user IDs and subject lines based on the state of the messages in IN_TRAY as of the date that is specified by the CURRENT TEMPORAL SYSTEM_TIME special register.

```sql
SELECT SOURCE, SUBJECT
FROM IN_TRAY
```

If the special register is set to a non-null value, the previous statement is equivalent to the following statement:

```sql
SELECT SOURCE, SUBJECT
FROM IN_TRAY
FOR SYSTEM_TIME AS OF CURRENT TEMPORAL SYSTEM_TIME
```

Related tasks:

- Querying temporal tables (Db2 Administration Guide)

Related reference:

- BIND and REBIND options for packages, plans, and services (Db2 Commands)

SET CURRENT TEMPORAL SYSTEM_TIME
Special registers in a user-defined function or a stored procedure

**CURRENT TIME**

The CURRENT TIME special register specifies a time that is based on a reading of the time-of-day clock when the SQL statement is executed at the current server.

If this special register is used more than one time within a single SQL statement, or used with CURRENT DATE or CURRENT TIMESTAMP within a single statement, all values are based on a single clock reading.\(^\text{11}\)

The value of CURRENT TIME in a user-defined function or stored procedure is inherited according to the rules in Table 48 on page 225. For other applications, the time is derived by the Db2 that executes the SQL statement that refers to the special register. For a description of how the date is derived, see Datetime special registers.

Specifying CURRENT TIME is equivalent to specifying CURRENT TIME.

**Example:** Display information about all project activities and include the current date and time in each row of the result.

```
SELECT DSN8C10.PROJACT.*, CURRENT DATE, CURRENT TIME
FROM DSN8C10.PROJACT;
```

**CURRENT TIMESTAMP**

The CURRENT TIMESTAMP special register specifies a timestamp that is based on a reading of the time-of-day clock when the SQL statement is executed at the current server.

If this special register is used more than one time within a single SQL statement, or used with CURRENT DATE or CURRENT TIME within a single statement, all values are based on a single clock reading.\(^\text{12}\)

The value of CURRENT TIMESTAMP in a user-defined function or stored procedure is inherited according to the rules in Table 48 on page 225.

Specifying CURRENT_TIMESTAMP is equivalent to specifying CURRENT TIMESTAMP.

If you want a timestamp with a specified precision, the special register can be referenced as CURRENT TIMESTAMP\((\text{integer})\), where \(\text{integer}\) can range 0 - 12. The default precision is 6. SYSDATE can also be specified as a synonym for CURRENT TIMESTAMP\((0)\).

If you want a timestamp with a time zone, the special register can be referenced as CURRENT TIMESTAMP \((\text{integer})\) WITH TIME ZONE, or CURRENT TIMESTAMP WITH TIME ZONE. SYSTIMESTAMP can be specified as an alternative to CURRENT_TIMESTAMP\((12)\) WITH TIME ZONE. The time zone is determined from the CURRENT TIME ZONE special register.

**Note:** If the CURRENT_TIMESTAMP special register is referenced in a timestamp with time zone context (for example, when compared with a timestamp with time zone)

---

11. Except for the case of a non-atomic multiple row INSERT or MERGE statement.
12. Except for the case of a non-atomic multiple row INSERT or MERGE statement.
zone column) the implicit time zone for the CURRENT TIMESTAMP special register will be based on the implicit time zone system parameter, which could be a different value from the CURRENT TIME ZONE special register. To avoid misinterpretation of the time zone in this case, CURRENT TIMESTAMP WITH TIME ZONE should be used.

Example 1: Display information about the full image copies that were taken in the last week.

```sql
SELECT *
FROM SYSIBM.SYSCOPY
WHERE TIMESTAMP > CURRENT_TIMESTAMP - 7 DAYS;
```

Example 2: Insert a row into the IN_TRAY table. The value of the RECEIVED column should be a timestamp that indicates when the row was inserted. The values for the other three columns come from the host variables SRC (CHAR(8)), SUB (CHAR(64)), and TXT (VARCHAR(200)).

```sql
INSERT INTO IN_TRAY
VALUES (CURRENT_TIMESTAMP, :SRC, :SUB, :TXT)
```

Example 3: Retrieve the value of the CURRENT TIMESTAMP special register with a precision of 8 and include the time zone:

```sql
SELECT CURRENT_TIMESTAMP(8) WITH TIME ZONE
FROM SYSIBM.SYSDUMMY1;
```

**CURRENT TIME ZONE**

The CURRENT TIME ZONE special register specifies a value that contains the difference between UTC and local time as defined by the current server, if the SESSION TIME ZONE special register has not been set.

The local time difference for the current server is set by z/OS, in the CLOCKxx PARMLIB member.

The data type is DECIMAL(6,0).

The difference between UTC and local time at the current server is represented by a time duration. A time duration is a decimal number in which the first two digits are the number of hours, the next two digits are the number of minutes, and the last two digits are the number of seconds. The number of hours is adjusted, if necessary, to fit in the range between -24 and 24 exclusive.

Subtracting CURRENT TIME ZONE from a local time converts that local time to UTC.

CURRENT TIMEZONE can be specified as an alternative to CURRENT TIME ZONE.

Example: Select all the rows of the IN_TRAY table. Assume that the RECEIVED column is defined as TIMESTAMP WITHOUT TIME ZONE. Adjust the timestamp value in the RECEIVED column to UTC by subtracting the value of the CURRENT TIME ZONE special register.

```sql
SELECT RECEIVED - CURRENT_TIME_ZONE, SOURCE, SUBJECT, NOTE_TEXT
FROM IN_TRAY;
```

- CLOCKxx (time of day parameters) (MVS Initialization and Tuning Reference)
ENCRIPTION PASSWORD

The ENCRYPTION PASSWORD special register specifies the encryption password and the password hint (if one exists) that are used by the ENCRYPT_TDES, DECRYPT_BIT, DECRYPT_CHAR, and DECRYPT_DB built-in functions.

DECRYPT_BIT, DECRYPT_CHAR, and DECRYPT_DB

This special register can only be set, by using the SET ENCRYPTION PASSWORD statement, and cannot be referenced directly. The ENCRYPTION PASSWORD special register contains the value of the password that is used by the ENCRYPT_TDES and DECRYPT_BIT, DECRYPT_CHAR, and DECRYPT_DB built-in functions to encrypt and decrypt data when a password is not explicitly specified as a function argument. The ENCRYPTION PASSWORD special register can also contain a password hint which is associated with the values that are encrypted using the encryption password. The password hint is a character string that is used to help in remembering the password. The GETHINT function is used to return the password hint for an encrypted value.

The initial value of the ENCRYPTION PASSWORD special register is the empty string (" ").

The initial value of the ENCRYPTION PASSWORD special register in a user-defined function or procedure is inherited from the invoking application. In other contexts, the initial value of the special register is the empty string.

The password is not related to Db2 authentication and is used only for data encryption.

Related reference: SET ENCRYPTION PASSWORD

SESSION TIME ZONE

The SESSION TIME ZONE special register specifies a value that identifies the time zone of the application process.

The data type is VARCHAR(128).

The time zone value is in the format of ±th:tm. th represents the time zone hour offset. tm represents the time zone minute offset. Valid values for th are between -12 and +14. Valid values for tm are between 0 and 59. SESSION TIMEZONE can be specified as an alternative to SESSION TIME ZONE.

The initial value of the special register in a user-defined function or stored procedure is inherited according to the rules in "Special registers in a user-defined function or a stored procedure" on page 224. In other contexts the initial value of the special register represents the same time zone as the CURRENT TIME ZONE special register.

The value of the special register can be changed by executing the SET SESSION TIME ZONE statement. After a SET SESSION TIME ZONE statement has been processed, the values of the SESSION TIME ZONE and CURRENT TIME ZONE special register might not reflect the same value.

Example: Set the session time zone to `-8:00`:

```
SET SESSION TIME ZONE = '-8:00';
```
Related reference:

**SET SESSION TIME ZONE**

**SESSION_USER**

SESSION_USER specifies the primary authorization ID of the process.

The data type is VARCHAR(128).

If SESSION_USER is referred to in an SQL statement that is executed at a remote Db2 and the primary authorization ID has been translated to a different authorization ID, SESSION_USER specifies the translated authorization ID. For an explanation of authorization ID translation, see *Db2 Administration Guide*. The value of SESSION_USER in a user-defined function or stored procedure is determined according to the rules in Table 48 on page 225.

USER can be specified as a synonym for SESSION_USER.

*Example:* Display information about tables, views, and aliases that are owned by the primary authorization ID of the process.

```sql
SELECT * FROM SYSIBM.SYSTABLES WHERE CREATOR = SESSION_USER;
```

**USER**

USER specifies the primary authorization ID of the process. The data type is VARCHAR(128). SESSION_USER is the preferred spelling.

If USER is referred to in an SQL statement that is executed at a remote Db2 and the primary authorization ID has been translated to a different authorization ID, USER specifies the translated authorization ID. For an explanation of authorization ID translation, see *Db2 Administration Guide*. The value of USER in a user-defined function or stored procedure is determined according to the rules in Table 48 on page 225.

*Example:* Display information about tables, views, and aliases that are owned by the primary authorization ID of the process.

```sql
SELECT * FROM SYSIBM.SYSTABLES WHERE CREATOR = USER;
```

**Special registers in a user-defined function or a stored procedure**

You can use all special registers in a user-defined function or a stored procedure. However, you can modify only some of those special registers.

After a user-defined function or a stored procedure completes, Db2 restores all special registers to the values they had before invocation.

The following table shows information that you need when you use special registers in a user-defined function or stored procedure.
<table>
<thead>
<tr>
<th>Special register</th>
<th>Initial value when INHERIT SPECIAL REGISTERS option is specified</th>
<th>Initial value when DEFAULT SPECIAL REGISTERS option is specified</th>
<th>Routine can use SET statement to modify?</th>

Notes:

1. If the user-defined function or stored procedure is invoked within the scope of a trigger, Db2 uses the timestamp for the triggering SQL statement as the timestamp for all SQL statements in the package.
2. Db2 allows parallelism at only one level of a nested SQL statement. If you set the value of the CURRENT DEGREE special register to ANY, and parallelism is disabled, Db2 ignores the CURRENT DEGREE value.
3. If the routine definition includes a specification for COLLID, Db2 sets CURRENT PACKAGESET to the value of COLLID. If both CURRENT PACKAGE PATH and COLLID are specified, the CURRENT PACKAGE PATH value takes precedence and COLLID is ignored.
4. If the function definition includes a specification for PACKAGE PATH, Db2 sets CURRENT PACKAGE PATH to the value of PACKAGE PATH.
5. Not applicable because no SET statement exists for the special register.
6. If a program within the scope of the invoking program issues a SET statement for the special register before the user-defined function or stored procedure is invoked, the special register inherits the value from the SET statement. Otherwise, the special register contains the value that is set by the bind option for the user-defined function or stored procedure package.
7. If a program within the scope of the invoking program issues a SET CURRENT SQLID statement before the user-defined function or stored procedure is invoked, the special register inherits the value from the SET statement. Otherwise, CURRENT SQLID contains the authorization ID of the application process.
8. If the user-defined function or stored procedure package uses a value other than RUN for the DYNAMICRULES bind option, the SET CURRENT SQLID statement can be executed. However, it does not affect the authorization ID that is used for the dynamic SQL statements in the package. The DYNAMICRULES value determines the authorization ID that is used for dynamic SQL statements.

Column names

The meaning of a column name depends on its context.

A column name can be used to:

• Declare the name of a column, as in a CREATE TABLE statement.
• Specify the name of a column, as in a CREATE FUNCTION statement to name a column of the result table of a table function.
• Identify a column, as in a CREATE INDEX statement.
• Specify values of the column, as in the following contexts:
  – In an aggregate function, a column name specifies all values of the column in the group or intermediate result table to which the function is applied. (Groups and intermediate result tables are explained in Queries) For example, MAX(SALARY) applies the function MAX to all values of the column SALARY in a group.
  – In a GROUP BY or ORDER BY clause, a column name specifies all values in the intermediate result table to which the clause is applied. For example, ORDER BY DEPT orders an intermediate result table by the values of the column DEPT.
  – In an expression, a search condition, or a scalar function, a column name specifies a value for each row or group to which the construct is applied. For example, when the search condition CODE = 20 is applied to some row, the value specified by the column name CODE is the value of the column CODE in that row.
  • Provide a column name for an expression to temporarily rename a column, as in the correlation-clause of a table-reference in a FROM clause or as in the AS clause in the select-clause.

Qualified column names

A qualifier for a column name can be a table name, a view name, an alias name, a synonym, or a correlation name. Whether a column name can be qualified depends, like its meaning, on its context.

• In some forms of the COMMENT and LABEL statements, a column name must be qualified. This is shown in the syntax diagrams.
• Where the column name specifies values of the column, a column name can be qualified at the user's option.
• In the column list of an INSERT statement, a column name can be qualified.
• In the assignment-clause of an UPDATE or a MERGE statement, a column name can be qualified.
• In all other contexts, a column name must not be qualified. This rule will be mentioned in the discussion of each statement to which it applies.

Where a qualifier is optional, it can serve two purposes. See Column name qualifiers to avoid ambiguity for details.

Correlation names

A correlation name can be defined in the FROM clause of a query and after the name of the target table or view in an UPDATE, MERGE, or DELETE statement.

For example, the following clause establishes Z as a correlation name for X.MYTABLE:
FROM X.MYTABLE Z

With Z defined as a correlation name for table X.MYTABLE, only Z should be used to qualify a reference to a column of X.MYTABLE in that SELECT statement.

A correlation name is associated with a table, view, nested table expression or table function only within the context in which it is defined. Hence, the same correlation name can be defined for different purposes in different statements. In a nested table expression or table function, a correlation name is required.

As a qualifier, a correlation name can be used to avoid ambiguity or to establish a correlated reference. It can also be used merely as a shorter name for a table or view. In the example, Z might have been used merely to avoid having to enter X.MYTABLE more than once.

Names that are specified in a FROM clause are either exposed or non-exposed. A correlation name is always an exposed name. A table name or view name is said to be exposed in that FROM clause if a correlation name is not specified. For example, in the following FROM clause, a correlation name is specified for EMPLOYEE, but not for DEPARTMENT; therefore, DEPARTMENT is an exposed name, and EMPLOYEE is not an exposed name:
FROM EMPLOYEE E, DEPARTMENT

The use of a correlation name in the FROM clause also allows the option of specifying a list of column names to be associated with the columns of the result table. As with a correlation name, the listed column names should be the names that are used to reference the columns in that SELECT statement. For example, assume that the name of the first column in the DEPT table is DEPTNO. Given this FROM clause in a SELECT statement:
FROM DEPT D (NUM, NAME, MGR, ANUM, LOC)

You should use D.NUM instead of D.DEPTNO to reference the first column of the table.

If a list of columns is specified, it must consist of as many names as there are columns in the table-reference. Each column must be unique and unqualified.

Column name qualifiers to avoid ambiguity

In the context of a function, a GROUP BY clause, an ORDER BY clause, an expression, or a search condition, a column name refers to values of a column in some table or view in a DELETE, MERGE, or UPDATE statement or table-reference in a FROM clause.

The tables, views, and table-references that might contain the column are called the object tables of the context. Two or more object tables might contain columns with the same name. One reason for qualifying a column name is to designate the object from which the column comes. For information on avoiding ambiguity between SQL parameters and variables and column names, see References to SQL parameters and SQL variables.

13. In the case of a joined-table, each table-reference within the joined-table is an object table.
A nested table expression which is preceded by a TABLE keyword will consider *table-references* that precede it in the FROM clause as object tables. The *table-references* that follow it are not considered as object tables.

**Table designators:** A qualifier that designates a specific object table is called a *table designator*. The clause that identifies the object tables also establishes the table designators for them. For example, the object tables of an expression in a SELECT statement are named in the FROM clause that follows it, as in the following statement:

```
SELECT DISTINCT Z.EMPNO, EMPTIME, PHONENO
FROM DSN8C10.EMP Z, DSN8C10.EMPPROJACT
WHERE WORKDEPT = 'D11'
  AND EMPTIME > 0.5
  AND Z.EMPNO = DSN8C10.EMPPROJACT.EMPNO;
```

Table designators in the FROM clause are established as follows:

- A name that follows a table or view name is both a correlation name and a table designator. Thus, Z is a table designator and qualifies the first column name in the select list.
- An exposed table or view name is a table designator. Thus, the qualified table name, DSN8C10.EMPPROJACT is a table designator and qualifies the second column name in the select list.

Two or more object tables can be instances of the same table. In this case, distinct correlation names must be used to unambiguously designate the particular instance of the table. In the following example, the X and Y in the FROM clause are defined to refer, respectively, to the first and second instances of the DSN8C10.EMP table:

```
SELECT *
FROM DSN8C10.EMP X, DSN8C10.EMP Y;
```

**Avoiding undefined or ambiguous references in Db2 SQL:** When a column name refers to values of a column, the following situations result in errors:

- No object table contains a column with the specified name. The reference is undefined.
- The column name is qualified by a table designator, but the table named does not include a column with the specified name. Again, the reference is undefined.
- The name is unqualified and more than one object table includes a column with that name. The reference is ambiguous.

Avoid ambiguous references by qualifying a column name with a uniquely defined table designator. If the column is contained in several object tables with different names, the table names can be used as designators. Ambiguous references can also be avoided without the use of the table designator by giving unique names to the columns of one of the object tables using the column name list following the correlation name.

Two or more object tables can be instances of the same table. A FROM clause that includes n references to the same table should include at least n - 1 unique correlation names.

For example, in the following FROM clause X and Y are defined to refer, respectively, to the first and second instances of the table EMP.
SELECT X.LASTNAME, Y.LASTNAME
FROM DSN8C10.EMP X, DSN8C10.EMP Y
WHERE Y.JOB = 'MANAGER'
AND X.WORKDEPT = Y.WORKDEPT
AND X.JOB <> 'MANAGER';

When qualifying a column with the exposed table name form of a table designator, either the qualified or unqualified form of the exposed table name can be used. However, the qualifier used and the table used must be the same after fully qualifying the table name or view name and the table designator.

Example 1: If the authorization ID of the statement is CORPDATA, the following statement is valid:

```
SELECT CORPDATA.EMPLOYEE.WORKDEPT
FROM EMPLOYEE;
```

Example 2: If the authorization ID of the statement is REGION, the following statement is invalid because EMPLOYEE represents the table REGION.EMPLOYEE, but the qualifier for WORKDEPT represents a different table, CORPDATA.EMPLOYEE:

```
SELECT CORPDATA.EMPLOYEE.WORKDEPT -- Incorrect
FROM EMPLOYEE;
```

Example 3: If the authorization ID of the statement is REGION, the following statement is invalid because EMPLOYEE in the select list represents the table REGION.EMPLOYEE, but the explicitly qualified table name in the FROM clause represents a different table, CORPDATA.EMPLOYEE:

```
SELECT EMPLOYEE.WORKDEPT -- Incorrect
FROM CORPDATA.EMPLOYEE;
```

Column name qualifiers in correlated references

A reference to a column of a table identified at a higher level is called a correlated reference. Because the same table or view can be identified at many levels, unique correlation names are recommended as table designators. It is good practice to use these unique correlation names to qualify column names.

A subselect is a form of a query that can be used as a component of various SQL statements. A subquery is a form of a fullselect that is enclosed within parenthesis. For example, a subquery can be used in a search condition. A fullselect that is used to retrieve a single value as an expression within a statement is called a scalar fullselect or a scalar subquery. A fullselect that is used in the FROM clause of a query is called a nested table expression.

A subquery can include search conditions of its own, and these search conditions can, in turn, include subqueries. Thus, an SQL statement can contain a hierarchy of subqueries. Those elements of the hierarchy that contain subqueries are said to be at a higher level than the subqueries they contain.

Every element of the hierarchy has a clause that establishes one or more table designators. This is the FROM clause, except in the highest level of a MERGE or UPDATE, where it is the table or view being updated. A search condition of a subquery can reference not only columns of the tables identified by the FROM clause of its own element of the hierarchy, but also columns of tables identified at any level along the path from its own element to the highest level of the hierarchy.
A correlated reference to column C of table T can be of the form C, T.C, or Q.C, if Q is a correlation name defined for T. However, a correlated reference in the form of an unqualified column name is not good practice. The following explanation is based on the assumption that a correlated reference is always in the form of a qualified column name and that the qualifier is a correlation name.

A qualified column name, Q.C, is a correlated reference only if these three conditions are met:
- Q.C is used in a search condition or in a select list of a subquery.
- Q does not name a table used in the FROM clause of that subquery.
- Q does name a table used at some higher level.

Q.C refers to column C of the table or view at the level where Q is used as the table designator of that table or view. Because the same table or view can be identified at many levels, unique correlation names are recommended as table designators. If Q is used to name a table at more than one level, Q.C refers to the lowest level that contains the subquery that includes Q.C.

If a correlation name is defined as the table designator of the table or view, but the table or view name is used as the column qualifier instead of the correlation name, an error is returned.

For example, in the following statement, the correlated reference X.WORKDEPT (in the last line) refers to the value of WORKDEPT in table DSN8C10.EMP at the level of the first FROM clause (which establishes X as a correlation name for DSN8C10.EMP). The statement lists employees who make less than the average salary for their department.

```
SELECT EMPNO, LASTNAME, WORKDEPT
FROM DSN8C10.EMP X
WHERE SALARY < (SELECT AVG(SALARY)
                 FROM DSN8C10.EMP
                 WHERE WORKDEPT = X.WORKDEPT);
```

The following example shows a correlated reference in the select list of the subquery:

```
SELECT T1.KEY1
FROM BP1TBL T1
GROUP BY T1.KEY1
HAVING MAX(T1.KEY1) = (SELECT MIN(T1.KEY1) + MIN(T2.KEY1)
                      FROM BP2TBL T2);
```

Queries

Resolution of column name qualifiers and column names

The rules for resolving column name qualifiers apply to every SQL statement that includes a subselect and are applied before synonyms and aliases are resolved.

Names in a FROM clause are either exposed or non-exposed. A correlation name for a table name, view name, nested table expression, or reference to a table function is always exposed. A table name or a view name that is not followed by a correlation name is also exposed.

Although Db2 for z/OS does not enforce this rule strictly, in IBM SQL and ANSI/ISO SQL, the exposed names in a FROM clause must be unique, and the qualifier of a column name must be an exposed name. Therefore, for good
programming practices, ensure that all exposed names are unique and that all qualified column names are qualified with the appropriate exposed name.

The rules for finding the referent of a column name qualifier are as follows:

1. Let Q be a one-, two-, or three-part name, and let Q.C denote a column name in subselect S. Q must designate a table or view identified in the statement that includes S and that table or view must have a column named C. An additional requirement differs for two cases:
   - If Q.C is not in a search-condition or S is not a subquery, Q must designate a table or view identified in the FROM clause of S. For example, if Q.C is in a SELECT clause, Q refers to a table or view in the following FROM clause.
   - If Q.C is in a search-condition and S is a subquery, Q must designate a table or view identified either in the FROM clause of S or in a FROM clause of a subselect that directly or indirectly includes S. For example, if Q.C is in a WHERE clause and S is the only subquery in the statement, the table or view that Q refers to is either in the FROM clause of S or the FROM clause of the subselect that includes S.

2. The same table or view can be identified more than once in the same statement. The particular occurrence of the table or view that Q refers to is determined by a procedure equivalent to the following steps:
   a. The one- and two-part names in every FROM clause and the one- and two-part qualifiers of column names are expanded into a fully-qualified form.
      For example, if a dynamic SQL statement uses FROM Q and DYNAMICRULES run behavior (RUN) is in effect, Q is expanded to S.A.Q, where S is the value of CURRENT SERVER and A is the value of CURRENT SCHEMA. (If DYNAMICRULES bind behavior is in effect instead, A is the plan or package qualifier as determined during the bind process or the qualifier for the native SQL procedure as determined when the procedure was defined.) This step is later referred to as “name completion”. An error occurs if the first part of every name (the location) is not the same.
   b. Q, now a three-part name, is compared with every name in the FROM clause of S. If Q.C is in a search-condition and S is a subquery, Q is next compared with every name in the FROM clause of the subselect that contains S. If that subselect is a subquery, Q is then compared with every name in the FROM clause of the subselect containing that subquery, and so on. If a FROM clause includes multiple names, the comparisons in that clause are made in order from left to right.
   c. The referent of Q is selected by these rules:
      - If Q matches exactly one name, that name is selected.
      - If Q matches more than one name, but only one exposed name, that exposed name is selected.
      - If Q matches more than one exposed name, the first of those names is selected.
      - If Q matches more than one name, none of which are exposed names, the first of those names is selected.
      If Q does not match any name, or if the table or view designated by Q does not include a column named C, an error occurs.
   d. Otherwise, Q.C is resolved to column C of the occurrence of the table or view identified by the selected name.

3. A warning occurs for any of these cases:
• The selected name is not an exposed name.
• The selected name is an exposed name that has an unexposed duplicate that appears before the selected name in the ordered list of names to which Q is compared.
• The selected name is an exposed name that has an exposed duplicate in the same FROM clause.
• Another name would have been selected had the matching been performed before name completion.

The rules for resolving column name qualifiers apply to every SQL statement that includes a subselect and are applied before synonyms and aliases are resolved. In the case of a searched UPDATE or DELETE statement, or a MERGE statement, the first clause of the statement identifies the table or view to be changed. That clause can include a correlation name and, with regard to name resolution, is equivalent to the first FROM clause of a SELECT statement. For example, a subquery in the search condition of an UPDATE statement can include a correlated reference to a column of the updated rows.

The rules for column names in the ORDER BY clause are the same as other clauses.

Variables

A variable in an SQL statement specifies a value that can be changed when the SQL statement is executed. There are several types of variables used in SQL statements.

global variable
Global variables are either built-in global variables or user-defined global variables. For more information about global variables, see Global variables.

host variable
Host variables are defined by statements of a host language. For more information about how to refer to host variables, see Host variables.

transition variable
Transition variables are defined in a trigger and refer to either the old or new values of columns of the subject table or view of a trigger. For more information about how to refer to transition variables, see CREATE TRIGGER (basic).

SQL variable
SQL variables are defined by an SQL compound statement in an SQL function or SQL procedure. For more information about SQL variables, see References to variables in SQL functions, SQL procedures and triggers.

SQL parameter
SQL parameters are defined in an CREATE FUNCTION (SQL Scalar), CREATE FUNCTION (SQL table), or CREATE PROCEDURE (SQL) statement. For more information about SQL parameters, see “References to variables in SQL functions, SQL procedures and triggers” on page 2372.

parameter marker
Parameter markers are specified in an SQL statement that is dynamically prepared, instead of variables, other than global variables. For more information about parameter markers, see Parameter markers in the PREPARE statement.
Unless otherwise noted, the term variable in syntax diagrams is used to describe where a global variable, host variable, transition variable, SQL variable, SQL parameter, or parameter marker can be used.

Global variables

A global variable is a named memory variable that you access through SQL statements. Global variables let you share relational data between SQL statements without the need for application logic to support this data transfer.

The Db2 database management system supports the following types of global variables:

Built-in global variable

Built-in global variables are provided with the database manager and are used in SQL statements to retrieve scalar values associated with the variables. A built-in global variable is available to any SQL statement that runs on the database manager. Built-in global variables reside in the SYSIBM and SYSIBMADM schemas. As an example, the CLIENT_IPADDR built-in global variable can be referenced in an SQL statement to retrieve the IP address of the current client.

For a list of the built-in global variables and information on these variables, see "Built-in global variables" on page 351.

The READ privilege on a built-in global variable is required for any statement that retrieves the value of that variable. The READ privilege for the built-in global variables is implicitly granted to PUBLIC during installation.

The WRITE privilege on an updatable built-in global variable is required for any statement that assigns a value to that variable. You can control write access to an updatable built-in global variable through the GRANT (variable privileges) and REVOKE (variable privileges) statements.

Examples:

The value of a built-in global variable can be obtained by referencing the variable in the context in which the value is needed.

```
SELECT C1, C2
FROM T1
WHERE C3 = CLIENT_IPADDR
```

To access the global variableCLIENT_HOST, run the following query:

```
SELECT SYSIBM.CLIENT_IPADDR
FROM SYSIBM.SYSDUMMY1
```

The query returns the IP address of the current client.

```
```

To change the value of an updatable built-in global variable, issue the "SET variable" statement:

```
SET SYSIBMADM.GET_ARCHIVE = 'Y'
```

User-defined global variable

A user-defined global variable is available to any active SQL statement that is running on the database manager on which the variable was defined. The value of a user-defined global variable is associated with a specific
session, and contains a value that is unique to that session. User-defined global variables let users extend the functionality of the database management system by adding their own or third-party vendor variable definitions.

A user-defined global variable is created using the CREATE VARIABLE statement, and registered to the database manager in the catalog. A user-defined global variable resides in the schema in which it was created. For more information, see CREATE VARIABLE.

You can control access to a user-defined global variable through the GRANT (variable privileges) and REVOKE (variable privileges) statements. The authorization that is required to use a global variable depends on where it is defined and how it is used.

- The authorization ID of an SQL statement that references a user-defined global variable and retrieves the value must have the READ privilege on the global variable.
- The authorization ID of an SQL statement that references a user-defined global variable and assigns a value to that variable must have the WRITE privilege on the global variable.

The value of a user-defined global variable can be obtained by referencing the variable in the context in which the value is needed. The value of a user-defined global variable can be changed with the following statements:

- EXECUTE
- FETCH
- SET
- SELECT INTO
- VALUES INTO
- CALL, if the variable is an argument to a procedure in which the corresponding parameter is defined as an OUT or INOUT parameter.

A reference, with an unqualified name, that is intended to resolve to a global variable could also resolve to an SQL variable, an SQL parameter, or even a column name, depending on the context of the reference and how the reference is qualified within that context. The implicit schema name for an unqualified variable name depends on the context in which the name appears:

- If an unqualified variable name is used in a CREATE VARIABLE, or the object of a DROP, COMMENT, GRANT, or REVOKE statement, the normal process of qualification by the authorization ID is used to determine the schema name.
- If an unqualified variable name is used in any other context, the SQL path is used to determine the schema name. The database manager searches the schemas in the SQL path in sequence. The schema that is selected is the first schema in the SQL path for which the global variable exists in the schema, and the user has authorization to use the variable. For a description of the SQL path, see SQL path.

**Host variables**

Host variables are defined directly by statements of the host language or indirectly by SQL extensions. A host-variable in an SQL statement must identify a host variable that is described in the program according to the rules for declaring host variables. Host variables cannot be referenced in dynamic SQL statements; parameter markers must be used instead.
A host variable is either of these items that is referred to in an SQL statement:

- A variable in a host language such as a PL/I variable, C variable, Fortran variable, REXX variable, Java variable, COBOL data item, or Assembler language storage area
- A host language construct that was generated by an SQL precompiler from a variable declared using SQL extensions

Host variables are defined directly by statements of the host language or indirectly by SQL extensions as described in Db2 Application Programming and SQL Guide. Host variables cannot be referenced in dynamic SQL statements; parameter markers must be used instead. For more information about parameter markers, see Variables in dynamic SQL.

A host-variable in an SQL statement must identify a host variable that is described in the program according to the rules for declaring host variables.

In PL/I, C, and COBOL, host variables can be referred to in ways that do not apply to Fortran and Assembler language. This is explained in Host structures in PL/I, C, and COBOL. The following applies to all host languages.

The term host-variable, as used in the syntax diagrams, shows a reference to a host variable. In a SET host variable statement and the INTO clause of a FETCH, SELECT INTO, or VALUES INTO statement, a host variable is an output variable to which a value is assigned by Db2. In a CALL statement, a host variable can be an output argument that is assigned a value after execution of the procedure, an input argument that provides an input value for the procedure, or both an input and output argument. In all other contexts, a host variable is an input variable which provides a value to Db2.

Non-Java variable references

The general form of a host variable reference in all languages other than Java is:

```
>>> :host-identifier
          INDICATOR :host-identifier
```

Each host identifier must be declared in the source program, except in a program written in REXX. The first host identifier designates the main variable; the second host identifier designates its indicator variable. The variable designated by the second host identifier must be a small integer. Indicator variables appear in two forms, normal indicator variables and extended indicator variables.

The purposes of normal indicator variable are to:

- Specify a non-null value. A 0 (zero), or positive value of the indicator variable specifies that the associated, first host-identifier provides the value of this host variable reference.
- Specify the null value. A negative value of the indicator variable specifies the null value.

In addition, on output, an indicator variable can indicate the following:
- A numeric conversion error (such as a divide by 0 or overflow) has occurred. A value of -2 for the indicator variable indicates a null result because of either numeric truncation or arithmetic warnings.
- A character could not be converted. A value of -2 for the indicator variable indicates a null result because of character string conversion warnings.
- No value was returned. A value of -3 for the indicator variable indicates a null result because the current row of the cursor is on a hole that is detected during a multiple row FETCH.
- Report the original length of a truncated string, if the string is not a LOB.
- Report the seconds portion of a truncated string, if the time is truncated on assignment to a host variable.

Extended indicator variables are limited to the input of host variables, and can specify the following:
- A non-null value. A 0 (zero), or positive value specifies that the associated, first host-identifier provides the value of this host variable reference.
- The null value. A -1, -2, -3, -4, or -6 value specifies the null value.
- The default value. A -5 value specifies that the target column for this host variable is to be set to its default value.
- An unassigned value. A -7 value specifies that the target column for this host variable is to be treated as if it had not been specified in the statement.

Extended indicator variables are only enabled if requested, and all indicator variables are otherwise normal indicator variables. Extended indicator variables are enabled when EXTENDEDINDICATOR(YES) is used, or when the WITH EXTENDED INDICATORS prepare attribute has been specified for the statement. In comparison to normal indicator variables, extended indicator variables have no additional restrictions for where the values for null and non-null can be used. There are no restrictions against using extended indicator variable values in indicator structures with host structures. There are no restrictions that result from the use of extended indicator variable values with host arrays in multiple-row statements. Restrictions on where the extended indicator variable values of default and unassigned are allowed apply uniformly, no matter how they are represented in the host application. The default and unassigned extended indicator variable values can only appear in limited, specified uses. Output indicator variables are never extended indicator variables.

When extended indicator variables are enabled, there are no restrictions against use of 0 (zero), or positive indicator variable values. However, negative indicator variable values outside the range -1 through -7 must not be specified. When extended indicator variables are enabled, the default and unassigned extended indicator values must not appear in contexts in which they are not supported.

When extended indicator variables are enabled, if the value of an extended indicator variable is greater than or equal to zero, the data type of the input host variable must be compatible with the data type of the target column. If the value of an extended indicator variable is less than zero, Db2 does not test for data type compatibility between the input host variable and the target column.
Java variable references

The general form of a host variable reference in Java is:

```
//: Java-identifier (Java-expression) [INDICATOR :--Java-identifier]
```

Each Java-identifier must be declared in the source program. The variable designated by the second Java-identifier is called an indicator variable and must be a short.

In Java, indicator variables are not always needed. Instead, instances of a Java class can be set to a null value. Variables defined as Java primitive types cannot be set to a null value. When using an extended indicator variable, or when using a Java primitive type in assigning a null value or where the Java primitive type might be assigned null on output, indicator variables must be used.

If IN, OUT, or INOUT is not specified, the default depends on the context in which the variable is used. If the Java variable is used in an INTO clause, OUT is the default. Otherwise, IN is the default.

An SQL statement that refers to host variables must be within the scope of the declaration of those host variables. For host variables referred to in the SELECT statement of a cursor, the OPEN statement, and the DECLARE CURSOR statement have to be in the same scope.

All references to host variables must be preceded by a colon. If an SQL statement references a host variable without a preceding colon, the precompiler issues an error for the missing colon or interprets the host variable as an unqualified column name, which might lead to unintended results. The interpretation of a host variable without a colon as a column name occurs when the host variable is referenced in a context in which a column name can also be referenced.

Variables in dynamic SQL

In dynamic SQL statements, parameter markers are used instead of variables other than global variables. Global variables are the only type of variable that can be specified in a dynamic SQL statement.

A parameter marker is a question mark (?) that represents a position in a dynamic SQL statement where the application will provide a value; that is, where a variable would be found if the statement string were a static SQL statement. The following examples show a static SQL statement that uses variables and a dynamic statement that uses parameter markers:

```
INSERT INTO DEPT VALUES (:HV_DEPTNO, :HV_DEPTNAME, :HV_MGRNO, :HV_ADMRDEPT)
INSERT INTO DEPT VALUES (?, ?, ?, ?)
```

For more information on parameter markers, see Parameter markers under the PREPARE statement.
LOB variables

Regular LOB variables (CLOB, DBCLOB, and BLOB), LOB locator variables and LOB file reference variables can be defined in all host languages with a few exceptions.

- Java supports file reference variables, but not locators for LOBs.

Where LOBs are allowed, the term meta-variable variable in a syntax diagram can refer to a regular variable, a locator variable, or a file reference variable. Because these variables are not native data types in host programming languages, SQL extensions are used, and the precompilers generate the host language constructs that are necessary to represent each variable.

When it is possible to define a variable that is large enough to hold an entire LOB value and the performance benefit of delaying the transfer of data from the server is not required, a LOB locator or LOB file reference is not needed. However, it is often not acceptable to store an entire LOB value in temporary storage due to host language restrictions, storage restrictions, or performance requirements. When storing an entire LOB value at one time is not acceptable, you can use one of the following alternatives:

- Referencing the LOB value using a LOB locator, and accessing portions of the value
- Storing the entire LOB value in a file, and using a LOB file reference to access the data

LOB locator variables

A LOB locator variable is a host variable that contains the locator representing a LOB value on the database server.

See Manipulating LOBs using locators for information about how locators can be used to manipulate LOB values.

A locator variable in an SQL statement must identify a LOB locator variable described in the program according to the rules for declaring locator variables. This is always indirectly through an SQL statement. For example, in C:

```c
static volatile SQL TYPE IS CLOB_LOCATOR *loc1;
```

The term locator-variable, as used in the syntax diagrams, shows a reference to a LOB locator variable. The meta-variable locator-variable can be expanded to include a host-identifier the same as that for host-variable.

Like all other host variables, a LOB locator variable can have an associated indicator variable. Indicator variables for LOB locator variables behave in the same way as indicator variables for other data types. When a null value is returned from the database, the indicator variable is set and the locator host variable is unchanged. This means a locator can never represent a null value. However, when the indicator variable associated with a LOB locator is null, the value of the referenced LOB value is null.

If a locator variable does not currently represent any value, an error occurs when the locator variable is referenced.

When a transaction commits, LOB locators that were acquired by the transaction are released unless a HOLD LOCATOR statement was issued for the LOB locator. When the transaction ends, all LOB locators are released.
It is the application programmer’s responsibility to guarantee that any LOB locator is used only in SQL statements that are executed at the same server that originally generated the LOB locator. For example, assume that a LOB locator is returned from one server and assigned to a LOB locator variable. If that LOB locator variable is subsequently used in an SQL statement that is executed at a different server unpredictable results will occur.

**XML variables**

An XML variable can be defined as a string or file reference variable. Regular XML variables and XML file reference variables can be defined in all host languages with a few exceptions.

- REXX supports file reference variables for XML.
- Java supports XML and file reference variables for XML.

XML variables can be declared as the following variable types:

Where XML variables are allowed, the meta-variable `variable` in a syntax diagram can refer to a regular variable or a file reference variable. Because these variables are not native data types in host programming languages, SQL extensions are used, and the precompilers generate the host language constructs that are necessary to represent each variable.

When it is possible to define a variable that is large enough to hold an entire XML value and the performance benefit of delaying the transfer of data from the server is not required, an XML file reference is not needed. However, it is often not acceptable to store an entire XML value in temporary storage due to host language restrictions, storage restrictions, or performance requirements. When storing an entire XML value at one time is not acceptable, portions of the value can be accessed, or the entire value can be stored in a file. When the entire value is stored in a file, an XML file reference can be used to access the data.

XML host variables can be declared as the following variable types:

- **XML AS CLOB**(n)
  Declares a CLOB variable that contains XML data that is encoded in the CCSID for the variable.

- **XML AS DBCLOB**(n)
  Declares a DBCLOB variable that contains XML data that is encoded in the graphic CCSID for the variable.

- **XML AS BLOB**(n)
  Declares a BLOB variable that contains XML data that is encoded as specified within the data according to the XML 1.0 specification for determining encoding.

- **XML AS CLOB_FILE**
  Declares a CLOB file reference variable that contains XML data that is encoded in the CCSID for the file reference variable.

- **XML AS DBCLOB_FILE**
  Declares a DBCLOB file reference variable that contains XML data that is encoded in the CCSID for the file reference variable.

- **XML AS BLOB_FILE**
  Declares a BLOB file reference variable that contains XML data that is encoded in the CCSID for the file reference variable.
See **LOB or XML file reference variables** for additional information about file reference variables.

Although the application XML variable declaration includes a LOB type specification, the variable declarations all are considered to be the XML data type, not the LOB type that is used in the application declaration. The application might also use non-XML variables in place of XML variables. For example, when a prepared statement is executed, the application might use a character variable to replace an XML parameter marker in the statement.

Although the XML data type is incompatible with all other data types, both XML and non-XML data types can be used for input to and output from XML data. Applications can use either XML variables, character variables, or binary string variables for input and output in SQL statements for XML data.

The following table summarizes the conversions built-in data types (including XML) to and from the supported variable data types within embedded applications. The built-in data types are specified in the rows. A Y indicates that the built-in data type can be assigned to or assigned from the variable type.

**LOB or XML file reference variables**

File reference variables are used for direct file input and output for LOB and XML values (when the XML value is declared using XML AS variable-type), and can be defined in all host languages.

Because these are not native data types, SQL extensions are used and the Db2 precompiler or coprocessor generates the host language constructs necessary to represent each variable. In the case of REXX, LOB values are mapped to strings. See **XML variables** for more information about XML host variables.

A file reference variable represents (rather than contains) the file, just as a LOB locator represents, rather than contains, the LOB data. Database queries, updates, and inserts can use file reference variables to store or to retrieve single column values.
As with all other host variables, file reference variables can have an associated indicator variable. Indicator variables for file reference variables behave in the same way as indicator variables for other data types. When a null value is returned from the database manager, the indicator variable is set, and the variable is unchanged. When the indicator variable that is associated with a file reference variable is null, the value of the referenced LOB or XML object is null. This means that a file reference variable can never point to a null value.

The length attribute of a file reference variable is assumed to be the maximum length of a LOB or XML object.

A file reference variable has the following properties:

**Data type**
BLOB, CLOB, or DBCLOB. This property is specified when the variable is declared using BLOB_FILE, CLOB_FILE, or DBCLOB_FILE.

**Direction**
This must be specified by the application program at run time (it is implicitly specified as part of the File options value). The direction can be either of the following:

- **Input** Input is used as a source of data on an EXECUTE statement, an OPEN statement, an update operation, an insert operation, or a delete operation.

- **Output** Output is used as the target of data. For example, on a FETCH statement or a SELECT INTO statement.

**File name**
This must be specified by the application program at run time. It must be the complete path name of the file. Within an application, a file should only be referenced one time in a file reference variable.

**File name length**
This must be specified by the application program at run time. It is the length of the file name in bytes.

**Data length**
Sets the data length to the length of the new data that is written to the file. The length is in bytes. Data length is unused on input.

**File options**
Options are set by an INTEGER value in a field in the file reference variable structure. One of the following values must be specified in an application for each file reference variable before that file reference variable can be used in the application:

- **SQL_FILE_READ**
  This is a regular file that can be opened, read and closed. (The option is SQL-FILE-READ in COBOL, sql_file_read in FORTRAN, and READ in REXX.) SQL_FILE_READ is an input (from client to server) file option.

- **SQL_FILE_CREATE**
  Create a new file. If the file already exists, an error is returned. (The option is SQL-FILE-CREATE in COBOL, sql_file_create in FORTRAN, and CREATE in REXX.) SQL_FILE_CREATE is an output (from server to client) file option.
**SQL_FILE_OVERWRITE**

If an existing file with the specified name exists, it is overwritten; otherwise a new file is created. (The option is SQL-FILE-OVERWRITE in COBOL, sql_file_overwrite in FORTRAN, and OVERWRITE in REXX.) SQL_FILE_OVERWRITE is an output (from server to client) file option.

**SQL_FILE_APPEND**

If an existing file with the specified name exists, the output is appended to it; otherwise a new file is created. (The option is SQL-FILE-APPEND in COBOL, sql_file_append in FORTRAN, and APPEND in REXX.) SQL_FILE_APPEND is an output (from server to client) file option.

The encoding scheme CCSID of the file name is based on the encoding scheme of the application. The CCSID of the LOB or XML data (the contents of the file) can be set by the application by using a DECLARE host-variable CCSID statement if the CCSID of the LOB or XML data is different from the CCSID of the application. Db2 performs any character conversion that is required prior to insertion of the LOB or XML data into a table or writing of the LOB or XML data to a file.

**Result set locator variables**

A result set locator variable is a variable that contains the locator that identifies a stored procedure result set. A result set locator variable in an SQL statement must identify a result set locator variable described in the program according to the rules for declaring result set locator variables. This is always indirectly through an SQL statement.

For example, in C:

```c
static volatile SQL TYPE IS RESULT_SET_LOCATOR VARYING *loc1;
```

A result set locator variable in an SQL procedure is defined with the RESULT_SET_LOCATOR VARYING clause in a compound statement.

The meta-variable rs-locator-variable, as used in the syntax diagrams, shows a reference to a result set locator variable. A host variable that is a result set locator variable can have an association indicator variable. When the indicator variable that is associated with a result set locator is null, the referenced result set is not defined.

If a result set locator variable does not currently represent any stored procedure result set, an error occurs when the locator variable is referenced.

A commit operation destroys all open cursors that were declared in the stored procedure without the WITH HOLD option and the result set locators that are associated with those cursors. Otherwise, a cursor and its associated result set locator persist past the commit.

An application that is written in a programming language other than Java can access a result set that is returned from a stored procedure. A result set locator is used by the invoking application to access the result set. A result set locator value for a result set can be obtained from an ASSOCIATE LOCATOR statement or with the DESCRIBE PROCEDURE statement. For more information, see "ASSOCIATE LOCATORS" on page 1473 and "DESCRIBE PROCEDURE" on page 2021.
The result set locator value is specified on an ALLOCATE CURSOR statement to define a cursor in the invoking application and to associate it with a stored procedure result set. For more information, see \texttt{ALLOCATE CURSOR}.

A DESCRIBE CURSOR statement can be used in the invoking application to obtain information on the characteristics of the columns of a stored procedure result set. For more information, see \texttt{"DESCRIBE CURSOR" on page 2010}.

The application can then access the rows of the result set using FETCH statements with the allocated cursor.

\section*{Array variables}

An array variable is a variable that is defined as a user-defined array type.

An array variable can be defined in one of the following ways:

\begin{itemize}
  \item An array global variable that is defined using the \texttt{CREATE VARIABLE} statement.
  \item An SQL parameter that is defined using the \texttt{CREATE FUNCTION} (SQL scalar) or \texttt{CREATE PROCEDURE} (SQL native) statement.
  \item An SQL variable that is defined using the \texttt{DECLARE} clause of a compound statement.
\end{itemize}

An array variable (representing an entire array) can be referenced in the following contexts:

\begin{itemize}
  \item An input argument to the \texttt{NULL} predicate.
  \item An input argument to the \texttt{ARRAY_EXISTS} predicate.
  \item An input argument to a built-in array scalar function (\texttt{ARRAY_DELETE}, \texttt{ARRAY_FIRST}, \texttt{ARRAY_LAST}, \texttt{ARRAY_NEXT}, \texttt{ARRAY_PRIOR}, or \texttt{TRIM_ARRAY}).
  \item An argument to \texttt{UNNEST} specification.
  \item The outer SELECT list of a fullselect that does not include a set operator, in the definition of a cursor that is not scrollable. In this case a FETCH statement for the cursor must specify an array variable as the target for the corresponding result column of the fullselect for the array variable.
  \item The outer select list of a SELECT INTO statement, when the target for the corresponding column of the result table of the fullselect is an array variable.
  \item The outer select list of a scalar fullselect, on the right side of a SET \texttt{assignment-statement} statement or an SQL PL \texttt{assignment-statement} statement, when the corresponding target of the assignment is an array variable.
  \item The source value for a VALUES INTO statement, when the target for value is an array variable.
  \item The target of an assignment from a FETCH statement, when the corresponding source data is an array value, and the FETCH statement is issued in an SQL PL context.
  \item The target of a SELECT INTO statement, when source data for the corresponding column of the result table is an array value.
  \item The target of an assignment for a SET \texttt{assignment-statement} statement or an SQL PL \texttt{assignment-statement} statement, when the corresponding source value is an array value.
\end{itemize}
- The target of a VALUES INTO statement, when the source data value is an array value.
- An argument to or from a routine (CALL statement or function invocation).
- The value that is returned in a RETURN statement of an SQL scalar function.
- An ORDER BY or GROUP BY clause of an outer fullselect.
- The source value in a USING clause for an EXECUTE statement or OPEN statement, in an SQL PL context.

An array variable can also be referenced in an array element specification. An element of a user-defined array type can be referenced anywhere that an expression that returns the same data type as an element of that array can be used.

**Restriction:** An array variable or an array element must not be referenced in an SQL statement, other than a CALL statement, after a connection at a remote server has been established. This restriction includes the case of an SQL statement that is executing at a remote server as a result of a three-part name or an alias that resolves to an object at a remote server.

## Host structures in PL/I, C, and COBOL

A *host structure* is a PL/I structure, C structure, or COBOL group that is referred to in an SQL statement.

Host structures are defined by statements of the host language, as explained in [Overview of programming applications that access Db2 for z/OS data](#) (Db2 Application programming and SQL). As used here, the term *host structure* does not include an SQLCA or SQLDA.

In Java and REXX, there is no equivalent to a host structure.

The form of a host structure reference is identical to the form of a host variable reference. The reference :S1:S2 is a host structure reference if S1 names a host structure. If S1 designates a host structure, S2 must be a small integer variable or an array of small integer variables. S1 is the host structure and S2 is its indicator array.

A host structure can be referred to in any context where a list of host variables can be referenced. A host structure reference is equivalent to a reference to each of the host variables contained within the structure in the order which they are defined in the host language structure declaration. The n<sup>th</sup> variable of the indicator array is the indicator variable for the n<sup>th</sup> variable of the host structure.

In PL/I, for example, if V1, V2, and V3 are declared as the variables within the structure S1, the following two statements are equivalent:

```sql
EXEC SQL FETCH CURSOR1 INTO :S1;
EXEC SQL FETCH CURSOR1 INTO :V1, :V2, :V3;
```

If the host structure has m more variables than the indicator array, the last m variables of the host structure do not have indicator variables. If the host structure has m fewer variables than the indicator array, the last m variables of the indicator array are ignored. These rules also apply if a reference to a host structure includes...
an indicator variable or a reference to a host variable includes an indicator array. If an indicator array or variable is not specified, no variable of the host structure has an indicator variable.

In addition to structure references, individual host variables or indicator variables in PL/I, C, and COBOL can be referred to by qualified names. The qualified form is a host identifier followed by a period and another host identifier. The first host identifier must name a structure, and the second host identifier must name a host variable at the next level within that structure.

In PL/I, C, and COBOL, the syntax of host-variable is:

![Diagram of host-variable syntax]

In general, a host-variable in an expression must identify a host variable (not a structure) described in the program according to the rules for declaring host variables. However, there are a few SQL statements that allow a host variable in an expression to identify a structure, as specifically noted in the descriptions of the statements.

The following examples show references to host variables and host structures:

```sql
```

**Host-variable arrays in PL/I, C, C++, and COBOL**

A host-variable array is an array in which each element of the array contains a value for the same column. The first element in the array corresponds to the first value, the second element in the array corresponds to the second value, and so on.

Host-variable arrays can be referenced only in certain contexts: in a FETCH statement for a multiple-row fetch, in an INSERT statement for a multiple-row insert, or in a multiple-row MERGE statement. A host-variable array is designated in syntax diagrams as host-variable-array.

Host-variable arrays are defined by statements of the host language as explained in Db2 Application Programming and SQL Guide.

The form of a host-variable array reference is similar to the form of a host variable reference. The reference :COL1:COL1IND is a host-variable array reference if COL1 designates an array. If COL1 designates an array, COL1IND must be a one-dimensional array of small integer host variables. The dimension of the host-variable array must be less than or equal to the dimension of the indicator array. If an indicator array is not specified, no variable of the main host-variable array has an indicator variable.

In PL/I, C, C++, and COBOL, the syntax of host-variable-array is:
In the following example, `COL1` is the main host-variable array and `COL1IND` is its indicator array. If `COL1` has 10 elements for fetching a single column of data for multiple rows of data, `COL1IND` must also have 10 entries.

EXEC SQL FETCH CURSOR FOR 5 ROWS INTO :COL1 :COL1IND;

**Functions**

A *function* is an operation denoted by a function name followed by zero or more operands that are enclosed in parentheses.

It represents a relationship between a set of input values and a set of result values. The input values to a function are called *arguments*. For example, a function can be passed with two input arguments that have date and time data types and return a value with a timestamp data type as the result.

**Types of functions**

There are several ways to classify functions. One way to classify functions is as built-in functions, user-defined functions, or cast functions that are generated for distinct types.

**Built-in functions**

*Built-in functions* are functions that come with Db2 for z/OS. These functions provide a single-value result.

Built-in functions include operator functions such as `+`, aggregate functions such as AVG, and scalar functions such as SUBSTR. For a list of the built-in aggregate and scalar functions and information on these functions, see [Built-in functions](#).

The built-in functions are in schema SYSIBM.

The RANK, DENSE_RANK, and ROW_NUMBER specifications are sometimes referred to as built-in functions. Refer to [OLAP specification](#) for more information on these specifications.

**User-defined functions**

*User-defined functions* are functions that are created using the `CREATE FUNCTION` statement and registered to the Db2 in the catalog. These functions allow users to extend the function of Db2 by adding their own or third party vendor function definitions.

A user-defined function is an SQL, external, or sourced function. An SQL function is defined to the database using only SQL statements. An *external function* is defined to the database with a reference to an external program that is executed when the function is invoked. A *sourced function* is defined to the database with a reference to a built-in function or another user-defined function. Sourced functions can be used to override built-in aggregate and scalar functions for use on distinct types.
A user-defined function resides in the schema in which it was registered. The schema cannot be SYSIBM.

To help you define and implement user-defined functions, sample user-defined functions are supplied with Db2. You can also use these sample user-defined functions in your application program just as you would any other user-defined function if the appropriate installation job has been run.

Creating a user-defined function (Db2 Application programming and SQL)

Related reference:
CREATE FUNCTION

Generated user-defined functions for distinct types
Generated user-defined functions for distinct types (also called cast functions) are functions that Db2 automatically generates when a distinct type is created using the CREATE TYPE statement.

Cast functions support casting from the distinct type to the source type and from the source type to the distinct type. The ability to cast between the data types is important because a distinct type is compatible only with itself.

The generated cast functions reside in the same schema as the distinct type for which they were created. The schema cannot be SYSIBM.

CREATE TYPE

Additional way to classify functions
Another way to classify functions is as aggregate, scalar, or table functions, depending on the input data values and result values.

- An aggregate function receives a set of values for each argument (such as the values of a column) and returns a single-value result for the set of input values. Aggregate functions are sometimes called column functions. Built-in functions and user-defined sourced functions can be aggregate functions. Aggregate functions cannot be external user-defined function or SQL functions.

- A scalar function receives a single value for each argument and returns a single-value result. Built-in functions and user-defined functions, external, sourced, and SQL, can be scalar functions. The functions that are created for distinct types are also scalar functions.

- A table function returns a table for the set of arguments it receives. Each argument is a single value. A table function can only be referenced in the FROM clause of a subselect. A table function can be defined as an external or SQL function, but a table function cannot be a sourced function.

Table functions can be used to apply SQL language processing power to data that is not stored in the database or to allow access to such data as if it were stored in a table. For example, a table function can read a file or get data from the web and return a result table.

For a list of the aggregate, scalar, and table functions and information on these functions, see Built-in functions.
**Function invocation**

Each reference to a scalar or aggregate function (either built-in or user-defined) conforms to the following syntax:

```
function-name(expr) ALL, DISTINCT
expression TABLE—transition-table-name
```

In the above syntax, `expression` cannot include an aggregate function. See “Expressions” on page 257 for other rules for `expression`.

The **ALL** or **DISTINCT** keyword can only be specified for an aggregate function or a user-defined function that is sourced on an aggregate function.

When a function is invoked within a trigger body, the **TABLE** keyword can be specified to indicate that an argument is a trigger transition table. In this case, the corresponding parameter of the function must have been defined with the **TABLE LIKE** clause.

Table functions can be referenced only in the FROM clause of a subselect. For more information on referencing a table function, see the description of the “from-clause” on page 1077.

An array can only be specified as an argument to a function for a parameter that is defined with an array type. An array element specifies a scalar value, and can therefore be specified as an argument to a function when the data type of the array element is promotable to the data type of the corresponding parameter of the function definition.

When the function is invoked, the value of each of its parameters is assigned using storage assignment, to the corresponding parameter of the function. Control is passed to external functions according to the calling conventions of the host language. When execution of a user-defined aggregate or scalar function is complete, the result of the function is assigned, using storage assignment, to the result data type. For information about assignment rules, see “Assignment and comparison” on page 151.

Additionally, a character FOR BIT DATA argument cannot be passed as input for a parameter that is not defined as character FOR BIT DATA. Likewise, a character argument that is not FOR BIT DATA cannot be passed as input for a parameter defined as character FOR BIT DATA.

For compatibility with other SQL implementations, **UNIQUE** can be specified as a synonym for **DISTINCT** in aggregate functions.
Function resolution

After a function is invoked, Db2 must determine which function to execute. This process is called function resolution and it applies to both built-in and user-defined functions.

A function is invoked by its function name, which is implicitly or explicitly qualified with a schema name, followed by parentheses that enclose the arguments to the function. Within the database, each function is uniquely identified by its function signature, which is its schema name, function name, the number of parameters, and the data types of the parameters. A schema can contain several functions that have the same name but each of which have a different number of parameters or parameters with different data types. Also, a function with the same name, number of parameters, and types of parameters can exist in multiple schemas.

Overloading a function

A function name for which there are multiple function instances with the same number of parameters in the same schema is called an overloaded function.

Overriding a function

Functions can be overridden across the schemas of an SQL path, in which case there is more than one function with the same name and the same number of parameters in different schemas of the SQL path. These functions do not necessarily have different parameter data types.

Function resolution has two steps:
1. Db2 determines the set of candidate functions based on the qualification of the name of the invoked function, the unqualified name of the invoked function, and the number of arguments that are specified.
2. Db2 determines the best fit from the set of candidate functions based on the data types of the arguments of the invoked function as compared with the data types of the parameters of the functions in the set of candidate functions.

Function resolution is similar for functions that are invoked with a qualified or unqualified function name with the exception that for an unqualified name, Db2 needs to search more than one schema.

To improve performance of function resolution and to prevent potential issues as new functions are added, consider invoking user-defined functions by using a fully qualified name, including the schema name.

For a function invocation that passes a transition table, the data type, length, precision, and scale of each column in the transition table must exactly match the data type, length, precision, and scale of each column of the table that is named in the function definition.

The timestamp for the creation of a user-defined function must be older than the timestamp that results from an explicit bind for the plan or package that contains the function invocation. During automatic bind, built-in functions that are introduced in a Db2 release that is later than the Db2 release that is used to explicitly bind the package or plan are not considered for function resolution.
In a CREATE VIEW statement, function resolution occurs at the time the view is created. If another function with the same name is subsequently created, the view is not affected, even if the new function is a better fit than the one that was chosen at the time the view was created.

**Qualified function resolution**

When a function is invoked with a schema name and a function name, Db2 only searches the specified schema to resolve which function to execute.

Db2 selects candidate functions based on the following criteria:

- The name of the function instance must match the name in the function invocation.
- The number of input parameters in the function instance must match the number of arguments in the function invocation.
- The authorization ID of the statement must have the EXECUTE privilege to the function instance.

If no function meets these criteria, an error is returned. If one or more candidate functions are found in the schema, this set of candidate functions is processed for best fit.

For a function invocation that contains untyped parameter markers, the data types of those parameter markers are considered to match or be promotable to the data types of the parameters in the function instance.

**Unqualified function resolution**

When a function is invoked without a qualifier, Db2 searches the list of schemas in the SQL path to resolve which function instance to execute. For each schema in the SQL path, Db2 searches the schema for candidate functions based on the following criteria:

- The name of the function instance must match the name in the function invocation.
- The number of input parameters in the function instance must match the number of function arguments in the function invocation.
- The authorization ID of the statement must have the EXECUTE privilege on the function instance.

If Db2 does not find any candidate functions, an error is returned. If no function meets these criteria, an error is returned. If one or more candidate functions are found in the schema, this set of candidate functions is processed for best fit.

For a function invocation that contains untyped parameter markers, the data types of those parameter markers are considered to match or be promotable to the data types of the parameters in the function instance.

**Determining the best fit**

More than one function with the same name might exist that is a candidate for execution. In that case, Db2 determines which function is the best fit for the invocation by comparing the data types of the parameters of each function in the set of candidate functions to determine which function satisfies the best fit requirements.

Db2 determines the function, or set of functions, that meet the best fit requirements for the invocation by comparing the argument and parameter data types. The data type of the result of the function or the type of function (aggregate, scalar, or table) under consideration does not enter into the determination of best fit.
When determining whether the data types of the parameters are the same as the arguments:

- Synonyms of data types match. For example, DOUBLE and FLOAT are considered to be the same.
- Attributes of a data type (such as length, precision, scale, CCSID) are ignored. Therefore, CHAR(8) and CHAR(35) are considered to be the same, as are DECIMAL(11,2) and DECIMAL(4,3).
- The character and graphic types are considered to be the same. For example, the following data types are considered to be the same type: CHAR and GRAPHIC, VARCHAR and VARGRAPHIC, and CLOB and DBCLOB. CHAR(13) and GRAPHIC(8) are considered to be the same type.
- For this argument, if one function has a data type that fits the function invocation better than the data types in the other functions, that function is the best fit. The precedence list for the promotion of data types in shows the data types that fit each data type, in best-to-worst order.
- If the data types of the first parameter for all the candidate functions fit the function invocation equally well, Db2 repeats this process for the next argument of the function invocation. Db2 continues this process for each argument until a best fit is found.

A subset of the candidate functions is obtained by considering only those functions for which the data type of each input argument of the function invocation matches or is promotable to the data type of the corresponding parameter of the function instance. The precedence list for the promotion of data types in shows the data types that fit (considering promotion) for each data type in best-to-worst order. If this subset is not empty, the best fit is determined using the promotable process on this subset of candidate functions. If this subset is empty, and the original set of candidate functions consisted of a single function, the best fit is determined using the castable process on the original candidate function. Otherwise, an error is returned.

**Promotable process:**

The promotable process determines the best fit for function resolution by considering only whether input arguments in the function invocation match or can be promoted to the data type of the corresponding parameter of the function definition.

For the subset of candidate functions, Db2 compares the parameter lists from left to right, using the following process:

- The data type of the argument in the function invocation is compared to the data type of the corresponding parameter in the definition of each candidate function. (synonyms of data types match and attributes of data type are ignored).
  - Attributes of a data type (such as length, precision, scale, CCSID) are ignored. Therefore, CHAR(8) and CHAR(35) are considered to be the same, as are DECIMAL(11,2) and DECIMAL(4,3).
  - The character and graphic types are considered to be the same. For example, the following data types are considered to be the same type: CHAR and GRAPHIC, VARCHAR and VARGRAPHIC, and CLOB and DBCLOB. CHAR(13) and GRAPHIC(8) are considered to be the same type.
- For this argument, if one candidate function has a data type that fits the function invocation better than the data types in the other candidate functions,
that function is the best fit. The precedence list for the promotion of data types in [Promotion of data types] shows the data types that fit each data type, in best-to-worst order.

• If the data types of the first parameter for more than one candidate functions fits the function invocation equally well, Db2 repeats this process for the next argument of the function invocation. Db2 continues this process for each argument until a best fit is found.

If only one candidate function remains after comparing all the arguments, that function is the best fit. If more than one candidate function remains, all the remaining candidate functions are considered to be equally the best fit. In this case, Db2 selects the function whose schema is first in the SQL path.

If a function is selected, its successful use depends on it being invoked in a context in which the returned result is allowed. For example, if the function returns a table where a table is not allowed, an error is returned.

Function resolution and input argument casting:

In considering the best fit of a candidate function, Db2 determines if the input arguments can be implicitly cast to the data type of the corresponding parameter for function resolution.

The castable process determines the best fit of a function, first considering if the input arguments in the function invocation match or can be promoted to the data type of the corresponding parameter of the function definition, and then if the input arguments can be implicitly cast to the data type of the corresponding parameter for function resolution. For the set of candidate functions, Db2 compares the parameter lists from left to right, using the following process:

• The data type of the argument in the function invocation is compared to the data type of the corresponding parameter in the definition of the candidate function to ensure that each argument can be promoted or cast to the corresponding parameter. If not, an error is returned.

If a function is selected, its successful use depends on it being invoked in a context in which the returned result is allowed. For example, if the function returns a table where a table is not allowed, an error is returned.

Implicit casting for function resolution: Implicit casting for function resolution is not supported for arguments with a user-defined type, binary, ROWID, or XML data type. It is also not supported for built-in or user-defined cast functions. Implicit casting is supported for the following cases:

• A numeric data type can be cast to a value of another numeric data type that is not in the data type promotion list for the source data type. This includes casting a numeric value to a numeric data type that is lower in the promotion list.

• A numeric data type can be cast to a character or graphic string data type, except for a LOB.

• A character or graphic string data type, except for a LOB, can be cast to a numeric data type.

• A character or graphic string data type, except for a LOB, can be cast to a date, time, or timestamp data type.

• A varying length character string data type, except for a LOB, can be cast to a fixed length character data type.
Best-fit consideration:

After determining the function that is the best fit, use of the function still might not be permitted. Each function is defined to return a result with a specific data type. If this result data type is not compatible with the context in which the function is invoked, an error occurs.

For example, assume functions named STEP are defined with different data types:

- `STEP(SMALLINT) returns CHAR(5)`
- `STEP(DOUBLE) returns INTEGER`

Assume also that the function is invoked with the following function reference (where `S` is a SMALLINT column):

```sql
SELECT ... 3+STEP(S) ...
```

Because there is an exact match on argument type, the first STEP is chosen. An error occurs on the statement because the result type is CHAR(5) instead of a numeric type as required for an argument of the addition operator.

In cases where the arguments of the function invocation are not an exact match to the data types of the parameters of the selected function, the arguments are converted to the data type of the parameter at execution using the same rules as assignment to columns. See [Assignment and comparison](#) Problems with conversions can also occur when precision, scale, length, or the encoding scheme differs between the argument and the parameter. Conversion might occur for a character string argument when the corresponding parameter of the function has a different encoding scheme or CCSID. For example, an error occurs on function invocation when mixed data that actually contains DBCS characters is specified as an argument and the corresponding parameter of the function is declared with an SBCS subtype.

Additionally, a character FOR BIT DATA argument cannot be passed as input for a parameter that is not defined as character FOR BIT DATA. Likewise, a character argument that is not FOR BIT DATA cannot be passed as input for a parameter that is defined as character FOR BIT DATA.

An error also occurs in the following examples:

- The function is referenced in a FROM clause, but the function selected by the function resolution step is a scalar or aggregate function.
- The function calls for a scalar or aggregate function, but the function selected by the resolution step is a table function.

SQL path considerations for built-in functions

Function resolution applies to all functions, including built-in functions and other functions provided by Db2. If a function is invoked without its schema name, the SQL path is searched.

With the exception of the Db2 MQSeries® functions, the built-in functions are in schemas SYSIBM or SYSIBMADM.

Additional functions are available in other schemas, but are not considered as built-in functions because they are developed as user-defined functions that have no special processing considerations.
If SYSIBM is not first in the path, it is possible that Db2 will select another function instead of the intended built-in function. If schema "SYSIBM", "SYSFUN", "SYSPROC", "SYSIBMADM" is not explicitly specified in the SQL path, the schema is implicitly assumed at the front of the path. Db2 adds implicitly assumed schemas in the order of "SYSIBM", "SYSFUN", "SYSPROC", "SYSIBMADM".

**Related concepts:**
- SQL path

**Version resolution**

Normally, the currently active version of an SQL function is used for invocation of the function.

However, if the invocation is a recursive invocation that occurs inside the body of the same function, and the currently active version has changed since the original invocation, the active version is not used. The version that is used in the original invocation is used for any recursive invocation until the entire function completes. This preserves the semantics of the version that is used by the original invocation.

The version used in the original invocation is also used when the recursive invocation is indirect. For example, assume that function FN1 invokes function FN2, which in turn invokes FN1 (indirect, recursive invocation). The invocation of function FN1 in function FN2 uses the version of FN1 that is active at the time of the original invocation of function FN1.

Since the currently active version is used at the next invocation (except in recursive invocations), it is possible that two or more versions of the same function can be run by a given thread. For example, an invocation of function FN1 in an application causes the currently active version of FN1 to load and execute. During or after execution of the original invocation of FN1, an ALTER FUNCTION statement that specifies ACTIVE VERSION FN1_V2 is run and changes the active version of the function FN1 to version FN1_V2. Subsequent invocations of function FN1 from the same thread will load and execute the currently active version of the function, FN1_V2.

**Examples of function resolution**

The following examples illustrate function resolution.

*Example 1:* Assume that MYSHEMA contains two functions, both named FUNA, that were registered with these partial CREATE FUNCTION statements.

1. CREATE FUNCTION MYSHEMA.FUNA (VARCHAR(10), INT, DOUBLE) ...
2. CREATE FUNCTION MYSHEMA.FUNA (VARCHAR(10), REAL, DOUBLE) ...

Also assume that a function with three arguments of data types VARCHAR(10), SMALLINT, and DECIMAL is invoked with a qualified name:

   MYSHEMA.FUNA(VARCHARCOL, SMALLINTCOL, DECIMALCOL)

Both MYSHEMA.FUNA functions are candidates for this function invocation because they meet the criteria specified in "function resolution". The data types of the first parameter for the two function instances in the schema, which are both VARCHAR, fit the data type of the first argument of the function invocation, which is VARCHAR, equally well. However, for the second parameter, the data type of the first function (INT) fits the data type of the second argument (SMALLINT) better than the data type of second function (REAL). Therefore, Db2 selects the first MYSHEMA.FUNA function as the function instance to execute.
Example 2: Assume that these functions were registered with these partial CREATE FUNCTION statements:

1. `CREATE FUNCTION SMITH.ADDIT (CHAR(5), INT, DOUBLE) ...`
2. `CREATE FUNCTION SMITH.ADDIT (INT, INT, DOUBLE) ...`
3. `CREATE FUNCTION SMITH.ADDIT (INT, INT, DOUBLE, INT) ...`
4. `CREATE FUNCTION JOHNSON.ADDIT (INT, DOUBLE, DOUBLE) ...`
5. `CREATE FUNCTION JOHNSON.ADDIT (INT, INT, DOUBLE) ...`
6. `CREATE FUNCTION TODD.ADDIT (REAL) ...`
7. `CREATE FUNCTION TAYLOR.SUBIT (INT, INT, DECIMAL) ...`

Also assume that the SQL path at the time an application invokes a function is 'TAYLOR' 'JOHNSON', 'SMITH'. The function is invoked with three data types (INT, INT, DECIMAL) as follows:

```
SELECT ... ADDIT(INTCOL1, INTCOL2, DECIMALCOL) ...
```

Function 5 is chosen as the function instance to execute based on the following evaluation:

- Function 6 is eliminated as a candidate because schema TODD is not in the SQL path.
- Function 7 in schema TAYLOR is eliminated as a candidate because it does not have the correct function name.
- Function 1 in schema SMITH is eliminated as a candidate because the INT data type is not promotable to the CHAR data type of the first parameter of Function 1.
- Function 3 in schema SMITH is eliminated as a candidate because it has the wrong number of parameters.
- Function 2 is a candidate because the data types of its parameters match or are promotable to the data types of the arguments.
- Both Function 4 and 5 in schema JOHNSON are candidates because the data types of their parameters match or are promotable to the data types of the arguments. However, Function 5 is chosen as the better candidate because although the data types of the first parameter of both functions (INT) match the first argument (INT), the data type of the second parameter of Function 5 (INT) is a better match of the second argument (INT) than Function 4 (DOUBLE).
- Of the remaining candidates, Function 2 and 5, Db2 selects Function 5 because schema JOHNSON comes before schema SMITH in the SQL path.

Expressions

An expression specifies a value and can take a number of different forms.

Authorization: The use of some of the expressions, such as a `scalar-fullselect`, `sequence-reference`, `global-variable`, or `function-invocation`, requires having the appropriate authorization. For these objects, the privilege set that is defined below must include the following authorization:

- `cast-specification`. The authorization to reference a user-defined type in a cast specification. For information about authorization considerations, see “CAST specification” on page 283.
- `function-invocation`. Authorization to execute the function. For information about how the particular function is chosen and authorization considerations, see “Function resolution” on page 251.
- `scalar-fullselect`. For information about authorization considerations, see “Authorization” on page 1067.
• *sequence-reference*. The USAGE privilege on the specified sequence, ownership of the sequence, DATAACCESS authority, or SYSADM authority. For example, with a sequence reference, USAGE authorization on the sequence is required.

• *global-variable*. The READ privilege on the specified global variable, ownership of the global variable, DATAACCESS authority, or SYSADM authority.

**Privilege set:** If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the statement is dynamically prepared, the privilege set is the union of the privilege sets that are held by each authorization ID of the process.

The form of an expression is as follows:
operator:

<table>
<thead>
<tr>
<th>Operator Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>(1) function-invocation</td>
<td>Function invocation</td>
</tr>
<tr>

Notes:
1. Must be a scalar function. See “Functions” on page 248 for more information.
2. See “Scalar-fullselect” on page 270 for more information.
3. See Labeled duration for more information.
4. See CASE expressions for more information.
5. See “CAST specification” on page 283 for more information.
6. See “XMLCAST specification” on page 291 for more information.
7. See “Array element specification” on page 292 for more information.
8. See “Array constructor” on page 294 for more information.
9. See “OLAP specification” on page 295.
10. See “ROW CHANGE expression” on page 307.
11. See “Sequence reference” on page 309.
Expressions without operators

If no operators are used, the result of the expression is the specified value.

Examples:

\[
\text{SALARY} : \text{SALARY} \quad \text{MAX(SALARY)}
\]

Expressions with arithmetic operators

If arithmetic operators are used, the result of the expression is a number derived from the application of the operators to the values of the operands.

The result of the expression can be null. If any operand has the null value, the result of the expression is the null value. Arithmetic operators (except unary plus, which is meaningless) must not be applied to strings. For example, USER+2 is invalid. Multiplication and division operators must not be applied to datetime values, which can only be added and subtracted.

The prefix operator + (unary plus) does not change its operand. The prefix operator - (unary minus) reverses the sign of a nonzero, non-decimal floating-point operand. The prefix operator - (unary minus) reverses the sign of all decimal floating-point operands, including zero and special values; that is, signaling and non-signaling NaNs and plus and minus infinity. If the data type of \( A \) is small integer, the data
type of -A is *large integer*. The first character of the token following a prefix
operator must not be a plus or minus sign.

The *infix operators* +, -, *, and / specify addition, subtraction, multiplication, and
division, respectively. The value of the second operand of division must not be
zero.

**Arithmetic with two integer operands**

If both operands of an arithmetic operator are integers, the operation is performed
in binary. The result is a large integer unless either (or both) operand is a big
integer, in which case the result is a big integer.

The result of an integer arithmetic operation (including unary minus) must be
within the range of the result type.

**Arithmetic with an integer and a decimal operand**

If one operand is an integer and the other operand is decimal, the operation is
performed in decimal. The arithmetic operation uses a temporary copy of the
integer that has been converted to a decimal number.

The temporary copy of the integer that has been converted to a decimal number
has a precision $p$ and scale 0. $p$ is 19 for a big integer, 11 for a large integer, and 5
for a small integer. In the case of an integer constant, $p$ depends on the number of
digits in the integer constant. $p$ is 5 for an integer constant consisting of 5 digits or
fewer. Otherwise, $p$ is the same as the number of digits in the integer constant.

**Arithmetic with an integer and a decimal floating-point operand**

If one operand is a small integer, large integer, or big integer and the other is a
decimal floating-point number, the operation is performed in decimal floating
point. The arithmetic operation uses a temporary copy of the integer that has been
converted to a decimal floating-point number.

For small integer or large integer, the temporary copy of the integer is converted to
DECFLOAT(16). For big integer, the temporary copy of the big integer is converted
to DECFLOAT(34). The rules for two decimal floating point operands are then
applied.

**Arithmetic with two decimal operands**

If both operands are decimal, the operation is performed in decimal.

The result of any decimal arithmetic operation is a decimal number with a
precision and scale that depend on two factors:

**The precision and scale of the operands**

In the discussion of operations with two decimal operands, the precision
and scale of the first operand are denoted by $p$ and $s$, that of the second
operand by $p'$ and $s'$. Thus, for a division, the dividend has precision $p$
and scale $s$, and the divisor has precision $p'$ and scale $s'$.

**Whether DEC31 or DEC15 is in effect for the operation**

DEC31 and DEC15 specify the rules to be used when both operands in a
decimal operation have precisions of 15 or less. DEC15 specifies the rules
which do not allow a precision greater than 15 digits, and DEC31 specifies
the rules which allow a precision of up to 31 digits. The rules for DEC31
are always used if either operand has a precision greater than 15.
For static SQL statements, the value of the field DECIMAL ARITHMETIC on installation panel DSNTIP4 or the SQL processing option DEC determines whether DEC15 or DEC31 is used.

For dynamic SQL statements, the value of the field DECIMAL ARITHMETIC on installation panel DSNTIP4, the SQL processing option DEC, or the special register CURRENT PRECISION determines whether DEC15 or DEC31 is used according to these rules:

- Field DECIMAL ARITHMETIC applies if either of these conditions is true:
  - DYNAMICRULES run behavior applies and the application has not set CURRENT PRECISION.
    For a list of the DYNAMICRULES option values that specify run, bind, define, or invoke behavior, see Table 14 on page 103
  - DYNAMICRULES bind, define, or invoke behavior applies; the value of installation panel field USE FOR DYNAMICRULES is YES; and the application has not set CURRENT PRECISION.
- SQL processing option DEC applies if DYNAMICRULES bind, define, or invoke behavior is in effect, the value of installation panel field USE FOR DYNAMICRULES is NO, and the application has not set CURRENT PRECISION.
- Special register CURRENT PRECISION applies if the application sets the register.

The value of DECIMAL ARITHMETIC is the default value for the SQL processing option and the special register. SQL statements executed using SPUFI use the value in DECIMAL ARITHMETIC.

Decimal addition and subtraction:

For decimal operations, the precision and scale of the result depends on the precision and scale of the operands.

If the operation is addition or subtraction and the operands do not have the same scale, the operation is performed with a temporary copy of one of the operands that has been extended with trailing zeros so that its fractional part has the same number of digits as the other operand.

The precision of the result is the minimum of \( n \) and the quantity \( \max(p-s, p'-s') + \max(s, s') + 1 \). The scale is \( \max(s, s') \). \( n \) is 31 if DEC31 is in effect or if the precision of at least one operand is greater than 15. Otherwise, \( n \) is 15.

In COBOL, blanks must precede and follow a minus sign to avoid any ambiguity with COBOL host variable names (which allow the use of a dash).

Decimal multiplication:

For decimal multiplication, the precision and scale of the result depends on the precision and scale of the operands.

For multiplication, the precision of the result is \( \min(n, p+p') \), and the scale is \( \min(n, s+s') \). \( n \) is 31 if DEC31 is in effect or if the precision of at least one operand is greater than 15. Otherwise, \( n \) is 15.

If both operands have a precision greater than 15, the operation is performed using a temporary copy of the operand with the smaller precision. If the operands have
the same precision, the second operand is selected. If more than 15 significant digits are needed for the integral part of the copy, the statement's execution is ended and an error occurs. Otherwise, the copy is converted to a number with precision 15, by truncating the copy on the right. The truncated copy has a scale of \( \max(0, S-(P-15)) \), where \( P \) and \( S \) are the original precision and scale. If, in the process of truncation, one or more nonzero digits are removed, SQLWARN7 in SQLCA is set to W, indicating loss of precision.

When both operands have a precision greater than 15, the foregoing formulas for the precision and scale of the result still apply, with one change: for the operand selected as the copy, use the precision and scale of the truncated copy; that is, use 15 as the precision and \( \max(0, S-(P-15)) \) for the scale.

Let \( n \) denote the value of the operand with the greater precision or the first operand in the case of operands with the same precision. The number of leading zeros in a 31-digit representation of \( n \) must be greater than the precision of the other operand. This is always the case if the precision of the operand is 15 or less. With greater precisions, overflow can occur even if the precision of the result is less than 31. For example, the expression:

\[
10000000000000000000000000. \times 1
\]

will cause overflow because the number of leading zeros in the 31-digit representation of the large number and the precision of the small number are both 5 (see Arithmetic with an integer and a decimal operand).

**Decimal division:**

The rules for a specific decimal division depend on whether the DEC31 option is in effect for the operation, whether \( p \) is greater than 15, and whether \( p' \) is greater than 15.

The following table shows how the precision and scale of the result depend on these factors. In that table, the occurrence of “N/A” in a row implies that the indicated factor is not relevant to the case represented by the row.

<table>
<thead>
<tr>
<th>DEC31</th>
<th>( p )</th>
<th>( p' )</th>
<th>( P )</th>
<th>( S )</th>
</tr>
</thead>
<tbody>
<tr>
<td>Not in effect</td>
<td>( \leq 15 )</td>
<td>( \leq 15 )</td>
<td>15</td>
<td>( 15-(p-s+s') )</td>
</tr>
<tr>
<td>In effect</td>
<td>( \leq 15 )</td>
<td>( \leq 15 )</td>
<td>31</td>
<td>( N-(p-s+s') ), where&lt;br&gt;N is 30-( p' ) if ( p' ) is odd.&lt;br&gt;N is 29-( p' ) if ( p' ) is even.</td>
</tr>
</tbody>
</table>

| N/A          | \( >15 \) | \( \leq 15 \) | 31 | \( N-(p-s+s') \), where<br>N is 30-\( p' \) if \( p' \) is odd.<br>N is 29-\( p' \) if \( p' \) is even. |

Notes on decimal division: If \( p' \) is greater than 15, the division is performed using a temporary copy of the divisor. If more than 15 significant digits are needed for the integral part of the divisor, the statement's execution is ended, and an error occurs. Otherwise, the copy is converted to a number with precision 15, by truncating the copy on the right. The truncated copy has a scale of
\( \max(0, s'-(p'-15)) \), which is the formula for \( x \). If, in the process of truncation, one or more nonzero digits are removed, SQLWARN7 in SQLCA is set to W, indicating loss of precision.

**Minimum divide result scale**

If the calculated value of \( s' \) is negative, an error occurs. If a minimum divide result scale is specified, this error does not occur.

The minimum scale is determined according to the following precedence:

**Static SQL**

1. The precompiler DEC option, if it is set with a non-zero scale.
2. The DECIMAL ARITHMETIC field (DECARTH) on installation panel DSNTIP4, if it is set with a non-zero scale.
3. The MINIMUM DIVIDE SCALE opaque subsystem parameter (MINDVSCLD), if it is set to a value other than NONE.
4. The MINIMUM DIVIDE SCALE field (DECDIV3) on installation panel DSNTIP4, if it is set to YES.

**Dynamic SQL**

1. The CURRENT PRECISION special register, if it is set with a non-zero scale.
2. Either of the following cases:
   - For a package that was bound with DYNAMICRULES RUN or if the USE FOR DYNAMICRULES field (DYNRULS) on installation panel DSNTIP4 is set to YES: The DECIMAL ARITHMETIC field (DECARTH) on installation panel DSNTIP4, if it is set with a non-zero scale.
   - For all other cases: The precompiler DEC option, if it is set with a non-zero scale.
3. The MINIMUM DIVIDE SCALE opaque subsystem parameter (MINDVSCLD), if it is set to value other than NONE.
4. The MINIMUM DIVIDE SCALE field (DECDIV3) on installation panel DSNTIP4, if it is set to YES.

**SQL statements that are executed using SPUFI**

The value in DECIMAL ARITHMETIC (DECARTH).

The default value for both the precompiler DEC option and the CURRENT PRECISION special register is DECIMAL ARITHMETIC.

A minimum divide result scale of 3 can be specified using the MINIMUM DIVIDE SCALE field on the installation panel DSNTIP4. A minimum divide scale result between 1 and 9 can be specified using the DECIMAL ARITHMETIC OPTION of the form 'Dpp.s' where 'pp' is 15 or 31 and represents the precision and 's' represents the minimum divide scale, as a number between 1 and 9. Such a specification overrides the MINIMUM DIVIDE SCALE. When a minimum divide result scale is specified, the formula \( \max(s, s') \), where \( s \) represents the scale derived from the above table and \( s' \) represents the value specified by the minimum divide result scale, is applied and a new scale is derived. The newly derived scale is the scale of the result and overrides any scale derived using the table above.
**Arithmetic with a decimal and a decimal floating-point operand**

If one operand is a decimal and the other is a decimal floating point, the operation is performed in decimal floating point. The arithmetic operation uses a temporary copy of the decimal that has been converted to a decimal floating point based on the precision of the decimal number.

If the decimal number has a precision of less than 17, the decimal number is converted to DECFLOAT(16). Otherwise, the decimal number is converted to DECFLOAT(34). The rules for two decimal floating-point operands are then applied.

**Arithmetic with floating-point operands**

If either operand of an arithmetic operator is floating-point, the operation is performed in floating-point. If necessary, the operands are first converted to double-precision floating-point numbers. Thus, if any element of an expression is a floating-point number, the result of the expression is a double-precision floating-point number.

An operation involving a floating-point number and an integer is performed with a temporary copy of the integer that has been converted to double-precision floating-point. An operation involving a floating-point number and a decimal number is performed with a temporary copy of the decimal number that has been converted to double-precision floating-point. The result of a floating-point operation must be within the range of floating-point numbers.

The order in which floating-point operands (or arguments to functions) are processed can affect the results slightly because floating-point operands are approximate representations of real numbers. Because the order in which operands are processed might be implicitly modified by Db2 (for example, Db2 might decide what degree of parallelism to use and what access plan to use), an application that uses floating-point operands should not depend on the results being precisely the same each time an SQL statement is executed.

**Arithmetic with a floating-point and a decimal floating-point operand**

If one operand is a floating-point number (real or double) and the other is a decimal floating-point number, the operation is performed in decimal floating-point. The arithmetic operation uses a temporary copy of the floating-point number that has been converted to a decimal floating-point number.

**Arithmetic with two decimal floating-point operands**

If both operands are decimal floating point, the operation is performed in decimal floating point. If one operand is DECFLOAT(n) and the other is DECFLOAT(m), the operation is performed in DECFLOAT(max(n,m)).

**General Arithmetic Operation Rules for DECFLOAT:**

Certain general rules apply to all arithmetic operations on the DECFLOAT data type.

The following general rules apply to all arithmetic operations on the DECFLOAT data type:

- Every operation on finite numbers is carried out as though an exact mathematical result is computed, using integer arithmetic on the coefficient where possible.
If the coefficient of the theoretical exact result has no more than the number of digits that reflect its precision (16 or 34), it is used for the result without change (unless there is an underflow or overflow condition). If the coefficient has more than the number of digits that reflect its precision, it is rounded to exactly the number of digits that reflect its precision (16 or 34), and the exponent is increased by the number of digits that are removed.

For static SQL statements other than CREATE VIEW, the ROUNDI NG bind option or the native SQL procedure option determines the rounding mode.

For dynamic SQL statements (and static CREATE VIEW statements), the special register CURRENT DECFLOAT ROUNDING MODE determines the rounding mode.

If the value of the adjusted exponent of the result is less than \( E_{\text{min}} \), an exception condition is returned. In this case, the calculated coefficient and exponent form the result, unless the value of the exponent is less than \( E_{\text{tiny}} \) in which case the exponent is set to \( E_{\text{tiny}} \), the coefficient is rounded (possibly to zero) to match the adjustment of the exponent, and the sign is unchanged. If this rounding gives an inexact result, an underflow exception condition is returned.

If the value of the adjusted exponent of the result is larger than \( E_{\text{max}} \), an overflow exception condition is returned. In this case, the result is as defined as an overflow exception condition and might be infinite. It will have the same sign as the theoretical result.

- Arithmetic that uses the special value infinity follows the usual rules, where negative infinity is less than every finite number and positive infinity is greater than every finite number.

Under these rules, an infinite result is always exact. Certain uses of infinity return an invalid operation condition. The following list is a list of operations that can cause an invalid operation condition and the result of the operation is NaN when one of the operands is infinity but the other operand is not NaN nor sNaN.

- Add \(+\infty\) to \(-\infty\) during an addition or subtraction operation
- Multiply 0 by \(+\infty\) or \(-\infty\)
- Divide either \(+\infty\) or \(-\infty\) by either \(+\infty\) or \(-\infty\)
- The dividend for a MOD function is either \(+\infty\) or \(-\infty\)
- Either argument of the QUANTIZE function is \(+\infty\) or \(-\infty\)
- The second argument of the POWER® function is \(+\infty\) or \(-\infty\)
- Signaling NaNs when used as an operand to an arithmetic operation

The following arithmetic rules apply to arithmetic operations and the NaN value:

- The result of any arithmetic operation which has an operand which is a NaN (a quiet NaN or signaling NaNs) is NaN. The sign of the result is copied from the first operand which is a signaling NaN, or if neither operand is signaling then the sign is copied from the first operand which is a NaN. Whenever a result is a NaN, the sign of the result depends only on the copied operand.
- The sign of the result of a multiplication or division will be negative only if the operands have different signs and neither is a NaN.
- The sign of the result of an addition or subtraction will be negative only if the result is less than zero and neither operand is a NaN, except for the following cases where the result is a negative 0:
  - A result is rounded to zero, and the value, before rounding, had a negative sign
  - Subtract 0 from 0
- Addition of operands with opposite signs (or subtraction of operands with the same sign), the result has a coefficient of 0, and the rounding mode is ROUND_FLOOR
- Multiplication or division and the result has a coefficient of 0 and the signs of the operands are different
- The first argument of the POWER function is -0, and the second argument is a positive odd number
- The argument of the CEIL, FLOOR, or SQRT function is -0
- The first argument of the ROUND or TRUNCATE function is -0

**Examples involving special DECFLOAT values:**

```
INFINITY + 1       = INFINITY
INFINITY + INFINITY = INFINITY
INFINITY + -INFINITY = NAN      -- exception
NAN + 1            = NaN
NAN + INFINITY     = NaN
1 - INFINITY       = -INFINITY
INFINITY - INFINITY = NAN      -- exception
-INFINITY - -INFINITY = NAN    -- exception
-0.0 - 0.0E1       = -0
-1.0 * 0.0E1       = -0
1.0E1 / 0          = INFINITY
-1.0E5 / 0.0        = -INFINITY
1.0E5 / -0         = -INFINITY
INFINITY / -INFINITY = NAN   -- exception
INFINITY / 0        = INFINITY
-INFINITY / 0       = -INFINITY
-INFINITY / -0      = INFINITY
```

**Arithmetic with distinct type operands**

A distinct type cannot be used with arithmetic operators even if its source data type is numeric.

To perform an arithmetic operation, create a function with the arithmetic operator as its source. For example, if there were distinct types INCOME and EXPENSES, both of which had DECIMAL(8,2) data types, the following user-defined function, REVENUE, could be used to subtract one from the other.

```
CREATE FUNCTION REVENUE (INCOME, EXPENSES)
RETURNS DECIMAL(8,2)
SOURCE "-" (DECIMAL, DECIMAL)
```

Alternately, the - (minus) operator could be overloaded using a function to subtract the new data types.

```
CREATE FUNCTION "-" (INCOME, EXPENSES)
RETURNS DECIMAL(8,2) SOURCE "-" (DECIMAL, DECIMAL)
```

Alternatively, the distinct type can be cast to a built-in data type and the result used as an operand of an arithmetic operator.

**Expressions with the concatenation operator**

When two strings operands are concatenated, the result of the expression is a string.

**Introductory concepts**

- String data types (Introduction to Db2 for z/OS)
- Concatenation of strings (Introduction to Db2 for z/OS)
The operands of concatenation must be compatible strings. A binary string cannot be concatenated with a character string, including character strings that are defined as FOR BIT DATA (for more information on the compatibility of data types, see the compatibility matrix in Table 31 on page 151). A distinct type that is based on a string type can be concatenated only if an appropriate user-defined function is created.

Both CONCAT and the vertical bars (||) represent the concatenation operator. Vertical bars (or the characters that must be used in place of vertical bars in some countries) can cause parsing errors in statements passed from one DBMS to another. The problem occurs if the statement undergoes character conversion with certain combinations of source and target CCSIDs. Thus, CONCAT is the preferable concatenation operator.

If either operand can be null, the result can be null, and if either is null, the result is the null value. Otherwise, the result consists of the first operand string followed by the second.

The following table shows how the string operands determine the data type and the length attribute of the result (the order in which the operands are concatenated has no effect on the result).

<table>
<thead>
<tr>
<th>If one operand column is</th>
<th>And the other operand is</th>
<th>The data type of the result column is</th>
</tr>
</thead>
<tbody>
<tr>
<td>CHAR(x)</td>
<td>CHAR(y) with a combined length attribute that is less than 256</td>
<td>CHAR(x+y)</td>
</tr>
<tr>
<td></td>
<td>CHAR(y) with a combined length attribute that is greater than 255</td>
<td>VARCHAR(MIN(x+y,32764))</td>
</tr>
<tr>
<td></td>
<td>VARCHAR(y)</td>
<td>VARCHAR(MIN(x+y,32764))</td>
</tr>
<tr>
<td>VARCHAR(x)</td>
<td>VARCHAR(y)</td>
<td>VARCHAR(MIN(x+y,32764))</td>
</tr>
<tr>
<td>CLOB(x)</td>
<td>CLOB(y)</td>
<td>CLOB(MIN(x+y,2G))</td>
</tr>
<tr>
<td></td>
<td>VARCHAR(y)</td>
<td>VARCHAR(MIN(x+y,2G))</td>
</tr>
<tr>
<td></td>
<td>CLOB(y)</td>

<td>DBCLOB(MIN(x+y,1G))</td>
</tr>
<tr>
<td></td>
<td>DBCLOB(y)</td>
<td>DBCLOB(MIN(x+y,1G))</td>
</tr>
<tr>
<td>GRAPHIC(x)</td>
<td>CHAR(y)</td>
<td>VARGRAPHIC(MIN(x+y,16382))</td>
</tr>
<tr>
<td></td>
<td>VARCHAR(y)</td>
<td>VARGRAPHIC(MIN(x+y,16382))</td>
</tr>
<tr>
<td></td>
<td>VARGRAPHIC(y)</td>
<td>VARGRAPHIC(MIN(x+y,16382))</td>
</tr>
</tbody>
</table>

14. In various EBCDIC code pages, Db2 supports code point combinations X'4F4F', X'BBBB', and X'5A5A' to mean concatenation. X'BBBB' and X'5A5A' are interpreted to mean concatenation only on single byte character set Db2 subsystems. X'BBBB' is a pair of right brackets characters (]) in some EBCDIC code pages and is not used as a concatenation operator when it appears in an array-index expression. Consider using CONCAT as a concatenation operator instead of X'BBBB' because X'BBBB' might be confused with right brackets in an array-index expression.
Table 51. Data type and length of concatenated operands (continued)

<td>BLOB(MIN(x+y, 2G))</td>
</tr>
</tbody>
</table>

Notes:
1.  
   - 2G represents 2,147,483,647 bytes
   - 1G represents 1,073,741,823 double-byte characters
2. Neither CHAR(x) nor CHAR(y) can contain mixed data. If either operand contains mixed data, the result is VARGRAPHIC(MIN(x+y,32764)).
3. If conversion of the first operand is required, x’ = 3x; otherwise, it remains x. If conversion of the second operand is required, y’ = 3y; otherwise, it remains y.
4. Both operands are converted to UTF-16, if necessary (that is, the operand is not already UTF-16), and the results are concatenated.

As the previous table shows, the length of the result is the sum of the lengths of the operands. However, the length of the result is two bytes less if redundant shift code characters are eliminated from the result. Redundant shift code characters exist when both character strings are EBCDIC mixed data, and the first string ends with a “shift-in” character (X’0F’) and the second operand begins with a “shift-out” character (X’0E’). These two shift code characters are removed from the result.

The CCSID of the result is determined by the rules set forth in “Character conversion in set operations and concatenations” on page 1132 Some consequences of those rules are the following:

- If either operand is BIT data, the result is BIT data.
- The conversion that occurs when SBCS data is compared with mixed data depends on the encoding scheme. If the encoding scheme is Unicode, the SBCS
operand is converted to MIXED. Otherwise, the conversion depends on the field MIXED DATA on installation panel DSNTIPF for the Db2 that does the comparison:

- Mixed data if the MIXED DATA option at the server is YES. The result is not necessarily well-formed mixed data.
- SBCS data if the MIXED DATA option at the server is NO. If the mixed data cannot be converted to pure SBCS data, an error occurs.

If an operand is a string from a column with a field procedure, the operation applies to the decoded form of the value. The result does not inherit the field procedure.

One operand of concatenation can be a parameter marker. When one operand is a parameter marker, its data type and length attributes are considered to be the same as those for the operand that is not a parameter marker except for a string data type. Refer to Table 51 on page 268 for the formula used to calculate data type length for untyped parameter markers in the CONCAT operator when another operand is a string data type. The order of concatenation operations must be considered to determine these attributes in the case of nested concatenation.

No operand of concatenation can be a distinct type even if the distinct type is based on a character data type. To concatenate a distinct type, create a user-defined function that is sourced on the CONCAT operator. For example, if distinct types TITLE and TITLE_DESCRIPTION were both based on data type VARCHAR(25), the following user-defined function, named ATTACH, could be used to concatenate the two distinct types:

```sql
CREATE FUNCTION ATTACH (TITLE, TITLE_DESCRIPTION)
RETURNS VARCHAR(50)
SOURCE CONCAT (VARCHAR(), VARCHAR())
```

Alternatively, the concatenation operator could be overloaded by using a user-defined function to add the distinct types:

```sql
CREATE FUNCTION "||" (TITLE, TITLE_DESCRIPTION)
RETURNS VARCHAR(50)
SOURCE CONCAT (VARCHAR(), VARCHAR())
```

Concat

Scalar-fullselect

A scalar-fullselect as supported in an expression is a fullselect, enclosed in parentheses, that returns a single row consisting of a single column value. If the fullselect does not return a row, the result of the expression is the null value. If more than one row is to be returned for a scalar fullselect, an error occurs.

```
(fullselect)
```

If a set operator is not specified in the outermost fullselect and the select list element is an expression that is simply a column name, the result column name is based on the name of the column. Otherwise, the result column is unnamed.

If a column mask is defined to mask the column values in the final result, and if a column mask is applied to the column in the select list of a scalar-fullselect, the
result of the scalar-fullselect must not be derived using set operator EXCEPT or INTERSECT. See Chapter 6, “Queries,” on page 1067 for more information about how column access controls affect a fullselect.

A scalar fullselect cannot be used in the following instances:

- A CHECK constraint in CREATE TABLE and ALTER TABLE statements
- A CREATE VIEW statement where the view definition includes the WITH CHECK option
- A CREATE FUNCTION (SQL) statement (subselect already restricted from the expression in the RETURN clause)
- An argument in a CALL statement for an input parameter
- An argument to an aggregate function, other than the XML-expression argument of the XMLAGG function
- An ORDER BY clause
- A GROUP BY clause
- A join-condition of the ON clause for INNER and OUTER JOINs

If the scalar fullselect is a subselect, it is also referred to as a scalar subselect. See subselect for more information.

The following examples illustrate the use of scalar-fullselect. Assume that four tables (PARTS, PRODUCTS, PARTPRICE, and PARTINVENTORY) contain product data.

Example 1 - scalar-fullselect in a WHERE clause:
Find which products have the prices in the range of at least twice the lowest price of all the products and at most half the price of all the products.

```sql
SELECT PRODUCT, PRICE FROM PRODUCTS A
WHERE
  PRICE BETWEEN 2 * (SELECT MIN(PRICE) FROM PRODUCTS)
  AND .5 * (SELECT MAX(PRICE) FROM PRODUCTS);
```

Example 2 - scalar-fullselect in a SELECT list:
For each part, find its price and its inventory.

```sql
SELECT PART,
  (SELECT PRICE FROM PARTPRICE WHERE PART=A.PART),
  (SELECT ONHAND# FROM INVENTORY WHERE PART=A.PART)
FROM PARTS A;
```

Datetime operands and durations

Datetime values can be incremented, decremented, and subtracted. These operations can involve decimal numbers called durations. A duration is a positive or negative number representing an interval of time.

Labeled durations
The form a labeled duration is as follows:
Notes:

1. Must be a scalar function.

A labeled duration represents a specific unit of time as expressed by
a number (which can be the result of an expression) followed by one of the
seven duration keywords. The number specified is converted as if it were
assigned to a DECIMAL(15,0) number, except for SECONDS, which uses
DECIMAL(27,12) to allow 0 to 12 fractional second digits to be included.

A labeled duration can only be used as an operand of an arithmetic
operator in which the other operand is a value of the data type of date,
time, or timestamp. Thus, the expression HIREDATE + 2 MONTHS + 14
DAYS is valid, whereas the expression HIREDATE + (2 MONTHS + 14
DAYS) is not. In both of these expressions, the labeled durations are 2
MONTHS and 14 DAYS.

Date duration
A date duration represents a number of years, months, and days expressed
as a DECIMAL(8,0) number. To be properly interpreted, the number must
have the format yyyyymmdd, where yyyy represents the number of years, mm
the number of months, and dd the number of days. The result of
subtracting one DATE value from another, as in the expression HIREDATE
- BIRTHDATE, is a date duration.

Time duration
A time duration represents a number of hours, minutes, and seconds
expressed as a DECIMAL(6,0) number. To be properly interpreted, the
number must have the format hhmmss, where hh represents the number of
hours, mm the number of minutes, and ss the number of seconds. The
result of subtracting one TIME value from another is a time duration.

Timestamp duration
A timestamp duration represents a number of years, months, days, hours,
minutes, seconds, and fractional seconds expressed as a DECIMAL(14+s,s)
number, where s is the number of fractional seconds in the range from 0 to
12. To be interpreted properly, the number must have the format
yyyyxxddhhmmss.zzzzzzzzzzzz, where yyyy, xx, dd, hh, mm, ss, and

15. The singular form of these keywords is also acceptable: YEAR, MONTH, DAY, HOUR, MINUTE, SECOND, and MICROSECOND.
zzzzzzzzzzzz represent, respectively, the number of years, months, days, hours, minutes, seconds, and fractional seconds. The result of subtracting one timestamp value from another is a timestamp duration with a scale that matches the maximum timestamp precision of the timestamp operands.

**Time zone specific expressions**

Time zone specific expressions can be used to adjust timestamp values and character-string or graphic-string representations of timestamp values to specific time zones.

The first operand for `time-zone-specific-expression` must be an expression that returns the value of either a built-in timestamp or a built-in character or graphic string data type. If the first operand is a character string or graphic string, it must not be a CLOB or DBCLOB value and its value must be a valid character-string or graphic-string representation of a timestamp. For the valid formats of string representations of datetime values, see “String representations of datetime values” on page 130.

If the first operand of `time-zone-specific-expression` returns a TIMESTAMP WITHOUT TIME ZONE value, the expression is implicitly cast to TIMESTAMP WITH TIME ZONE before being adjusted to the indicated time zone.

**AT LOCAL**

Specifies that the timestamp value is to be adjusted for the local time zone using the SESSION TIME ZONE special register.

**AT TIME ZONE**

Specifies that the timestamp is to be adjusted for the time zone that is represented by the expression.

`expression` is a character or graphic string. It must not be a CLOB or DBCLOB value, and its value must be left justified and be of the form `±th:tm`, where `th`
represents the time zone hour between -12 and +14, and \( tm \) represents the time zone minutes between 0 and 59, with values ranging from -12:59 to +14:00. The value must not be the null value.

The expression returns a \textsc{timestamp with time zone} value in the indicated time zone.

\textbf{Syntax alternatives:} \textsc{timezone} can be specified as an alternative to \textsc{time zone}.

Cast a \textsc{timestamp} for April 12, 2010 to the local time zone. Assume that the \textsc{implicit time zone} system parameter is set to `-8:00'.

\begin{verbatim}
CAST('2010-04-12-10:30:00.0 -5:00' AT LOCAL AS TIMESTAMP)
\end{verbatim}

Returns: \texttt{2010-04-12-07:30:00.000000}.

Insert a \textsc{timestamp} value with a time zone into a table, \texttt{tz}, and retrieve it as a \textsc{timestamp} with the local time zone, with +08:00, and adjusted for UTC. Assume that table \texttt{tz} exists as follows:

\begin{verbatim}
CREATE TABLE tz(tstz TIMESTAMP WITH TIME ZONE);
\end{verbatim}

\begin{verbatim}
INSERT INTO tz(tstz) VALUES(TIMESTAMP '2010-01-01-10.23.51-08:00');
\end{verbatim}

1. Retrieve the value of the \texttt{tstz} column adjusted for the local time:

\begin{verbatim}
SELECT tstz AT LOCAL FROM SYSIBM.SYSDUMMY1;
\end{verbatim}

2. Retrieve the value of the \texttt{tstz} column adjusted for the time zone +08:00:

\begin{verbatim}
SELECT tstz AT TIME ZONE '+08:00' FROM SYSIBM.SYSDUMMY1;
\end{verbatim}

3. Retrieve the value of the \texttt{tstz} column adjusted for UTC:

\begin{verbatim}
SELECT tstz AT TIME ZONE '00:00' FROM SYSIBM.SYSDUMMY1;
\end{verbatim}

\textbf{Datetime arithmetic in SQL}

The only arithmetic operations that can be performed on datetime values are addition and subtraction.

If a datetime value is the operand of addition, the other operand must be a duration. The specific rules governing the use of the addition operator with datetime values follow.

\begin{itemize}
\item If one operand is a date, the other operand must be a date duration or labeled duration of years, months, or days.
\item If one operand is a time, the other operand must be a time duration or a labeled duration of hours, minutes, or seconds.
\item If one operand is a \textsc{timestamp}, the other operand must be a duration. Any type of duration is valid.
\item Neither operand of the addition operator can be a \textsc{parameter marker}. For a discussion of parameter markers, see \texttt{Parameter markers in \textsc{prepare}}.
\end{itemize}

The rules for the use of the subtraction operator on datetime values are not the same as those for addition because a datetime value cannot be subtracted from a duration, and because the operation of subtracting two datetime values is not the same as the operation of subtracting a duration from a datetime value. The specific rules governing the use of the subtraction operator with datetime values follow.
• If the first operand is a date, the second operand must be a date, a date duration, a string representation of a date, or a labeled duration of years, months, or days.

• If the second operand is a date, the first operand must be a date, or a string representation of a date.

• If the first operand is a time, the second operand must be a time, a time duration, a string representation of a time, or a labeled duration of hours, minutes, or seconds.

• If the second operand is a time, the first operand must be a time, or string representation of a time.

• If the first operand is a timestamp, the second operand must be a timestamp, a string representation of a timestamp, or a duration. If the second operand is a string representation of a timestamp, it is implicitly converted to a timestamp with the same precision as the first operand.

• If the second operand is a timestamp, the first operand must be a timestamp or a string representation of a timestamp. If the first operand is a string representation of a timestamp, it is implicitly converted to a timestamp with the same precision as the second operand.

• Neither operand of the subtraction operator can be a parameter marker.

When an operand in a datetime expression is a string, it might undergo character conversion before it is interpreted and converted to a datetime value. When its CCSID is not that of the default for mixed strings, a mixed string is converted to the default mixed data representation. When its CCSID is not that of the default for SBCS strings, an SBCS string is converted to the default SBCS representation.

**Date arithmetic**

Date values can be subtracted, incremented, or decremented.

**Subtracting dates**: The result of subtracting one date (DATE2) from another (DATE1) is a date duration that specifies the number of years, months, and days between the two dates. The data type of the result is DECIMAL(8,0). If DATE1 is greater than or equal to DATE2, DATE2 is subtracted from DATE1. If DATE1 is less than DATE2, however, DATE1 is subtracted from DATE2, and the sign of the result is made negative. The following procedural description clarifies the steps involved in the operation RESULT = DATE1 - DATE2.

<table>
<thead>
<tr>
<th>Date subtraction: result = date1 - date2</th>
</tr>
</thead>
<tbody>
<tr>
<td>• If DAY(DATE2) &lt;= DAY(DATE1) then DAY(RESULT) = DAY(DATE1) - DAY(DATE2)</td>
</tr>
<tr>
<td>• If DAY(DATE2) &gt; DAY(DATE1) then DAY(RESULT) = N + DAY(DATE1) - DAY(DATE2) where N = the last day of MONTH(DATE2). MONTH(DATE2) is then incremented by 1.</td>
</tr>
<tr>
<td>• If MONTH(DATE2) &lt;= MONTH(DATE1) then MONTH(RESULT) = MONTH(DATE1) - MONTH(DATE2)</td>
</tr>
<tr>
<td>• If MONTH(DATE2) &gt; MONTH(DATE1) then MONTH(RESULT) = 12 + MONTH(DATE1) - MONTH(DATE2) and YEAR(DATE2) is incremented by 1.</td>
</tr>
<tr>
<td>• YEAR(RESULT) = YEAR(DATE1) - YEAR(DATE2)</td>
</tr>
</tbody>
</table>

For example, the result of DATE('3/15/2005') - '12/31/2004' is 215 (or, a duration of 0 years, 2 months, and 15 days). In this example, notice that the second operand did not need to be converted to a date. According to one of the rules for subtraction, described under [Datetime arithmetic in SQL](#), the second operand can be a string representation of a date if the first operand is a date.
**Incrementing and decrementing dates:** The result of adding a duration to a date, or of subtracting a duration from a date, is itself a date. (For the purposes of this operation, a month denotes the equivalent of a calendar page. Adding months to a date, then, is like turning the pages of a calendar, starting with the page on which the date appears.) The result must fall between the dates January 1, 0001 and December 31, 9999 inclusive. If a duration of years is added or subtracted, only the year portion of the date is affected. The month is unchanged, as is the day unless the result would be February 29 of a non-leap-year. Here the day portion of the result is set to 28, and the SQLWARN6 field of the SQLCA is set to W, indicating that an end-of-month adjustment was made to correct an invalid date. *Db2 Application Programming and SQL Guide* also describes how SQLWARN6 is set.

Similarly, if a duration of months is added or subtracted, only months and, if necessary, years are affected. The day portion of the date is unchanged unless the result would be invalid (September 31, for example). In this case the day is set to the last day of the month, and the SQLWARN6 field of the SQLCA is set to W to indicate the adjustment.

Adding or subtracting a duration of days will, of course, affect the day portion of the date, and potentially the month and year. Adding or subtracting a duration of days will not cause an end-of-the-month adjustment.

Date durations, whether positive or negative, can also be added to and subtracted from dates. As with labeled durations, the result is a valid date, and SQLWARN6 is set to W to indicate any necessary end-of-month adjustment.

When a positive date duration is added to a date, or a negative date duration is subtracted from a date, the date is incremented by the specified number of years, months, and days, in that order. Thus, DATE1+X, where X is a positive DECIMAL(8,0) number, is equivalent to the expression:

\[
\text{DATE1} + \text{YEAR}(X) \text{ YEARS} + \text{MONTH}(X) \text{ MONTHS} + \text{DAY}(X) \text{ DAYS}
\]

When a positive date duration is subtracted from a date, or a negative date duration is added to a date, the date is decremented by the specified number of days, months, and years, in that order. Thus, DATE1-X, where X is a positive DECIMAL(8,0) number, is equivalent to the expression:

\[
\text{DATE1} - \text{DAY}(X) \text{ DAYS} - \text{MONTH}(X) \text{ MONTHS} - \text{YEAR}(X) \text{ YEARS}
\]

Adding a month to a date gives the same day one month later unless that day does not exist in the later month. In that case, the day in the result is set to the last day of the later month. For example, January 28 plus one month gives February 28; one month added to January 29, 30, or 31 results in either February 28 or, for a leap year, February 29. If one or more months is added to a given date and then the same number of months is subtracted from the result, the final date is not necessarily the same as the original date.

If one or more months are added to a given date and then the same number of months is subtracted from the result, the final date is not necessarily the same as the original date. In addition, logically equivalent expressions might not produce the same result. For example, the following two expressions do not produce the same result:

\[
\begin{align*}
\text{DATE('2005 01 31') + 1 MONTH} & \text{ + 1 MONTH} & \text{ results in 2005-03-28} \\
\text{DATE('2005 01 31') + 2 MONTHS} & \text{ results in 2005-03-31}
\end{align*}
\]

The order in which labeled date durations are added to and subtracted from dates can affect the results. When you add labeled date durations to a date, specify them
in the order of YEARS + MONTHS + DAYS. When you subtract labeled date durations from a date, specify them in the order of DAYS - MONTHS - YEARS. For example, to add one year and one day to a date, specify:

\[ \text{DATE1} + 1 \ \text{YEAR} + 1 \ \text{DAY} \]

To subtract one year, one month, and one day from a date, specify:

\[ \text{DATE1} - 1 \ \text{DAY} - 1 \ \text{MONTH} - 1 \ \text{YEAR} \]

**Time arithmetic**

Times can be subtracted, incremented, or decremented.

*Subtracting times:* The result of subtracting one time \((\text{TIME2})\) from another \((\text{TIME1})\) is a time duration that specifies the number of hours, minutes, and seconds between the two times. The data type of the result is DECIMAL(6,0). If \(\text{TIME1}\) is greater than or equal to \(\text{TIME2}\), \(\text{TIME2}\) is subtracted from \(\text{TIME1}\). If \(\text{TIME1}\) is less than \(\text{TIME2}\), however, \(\text{TIME1}\) is subtracted from \(\text{TIME2}\), and the sign of the result is made negative. The following procedural description clarifies the steps involved in the operation \(\text{RESULT} = \text{TIME1} - \text{TIME2}\).

<table>
<thead>
<tr>
<th>Time subtraction: result = time1 - time2</th>
</tr>
</thead>
<tbody>
<tr>
<td>• If (\text{SECOND(TIME2)} \leq \text{SECOND(TIME1)}) then (\text{SECOND(RESULT)} = \text{SECOND(TIME1)} - \text{SECOND(TIME2)}).</td>
</tr>
<tr>
<td>• If (\text{SECOND(TIME2)} &gt; \text{SECOND(TIME1)}) then (\text{SECOND(RESULT)} = \text{SECOND(TIME1)} - \text{SECOND(TIME2)}) and (\text{MINUTE(TIME2)}) is incremented by 1.</td>
</tr>
<tr>
<td>• If (\text{MINUTE(TIME2)} \leq \text{MINUTE(TIME1)}) then (\text{MINUTE(RESULT)} = \text{MINUTE(TIME1)} - \text{MINUTE(TIME2)}).</td>
</tr>
<tr>
<td>• If (\text{MINUTE(TIME2)} &gt; \text{MINUTE(TIME1)}) then (\text{MINUTE(RESULT)} = \text{MINUTE(TIME1)} - \text{MINUTE(TIME2)}) and (\text{HOUR(TIME2)}) is incremented by 1.</td>
</tr>
<tr>
<td>• (\text{HOUR(RESULT)} = \text{HOUR(TIME1)} - \text{HOUR(TIME2)}).</td>
</tr>
</tbody>
</table>

For example, the result of \(\text{TIME('11:02:26') - '00:32:56'}\) is \('102930'\) (a duration of 10 hours, 29 minutes, and 30 seconds). In this example, notice that the second operand did not need to be converted to a time. According to one of the rules for subtraction, described under [Datetime arithmetic in SQL](#), the second operand can be a string representation of a time if the first operand is a time.

*Incrementing and decrementing times:* The result of adding a duration to a time, or of subtracting a duration from a time, is itself a time. Any overflow or underflow of hours is discarded, thereby ensuring that the result is always a time. If a duration of hours is added or subtracted, only the hours portion of the time is affected. Adding 24 hours to the time \('00:00:00'\) results in the time \('24:00:00'\). However, adding 24 hours to any other time results in the same time; for example, adding 24 hours to the time \('00:00:59'\) results in the time \('00:00:59'\). The minutes and seconds are unchanged.

Similarly, if a duration of minutes is added or subtracted, only minutes and, if necessary, hours are affected. The seconds portion of the time is unchanged.

Adding or subtracting a duration of seconds affects the seconds portion of the time and might affect the minutes and hours.

Time durations, whether positive or negative, can also be added to and subtracted from times. The result is a time that has been incremented or decremented by the specified number of hours, minutes, and seconds, in that order. Thus, \(\text{TIME1} + X\), where \(X\) is a positive DECIMAL(6,0) number, is equivalent to the expression
Timestamp arithmetic

Timestamps can be subtracted, incremented, or decremented.

If any of the operands are TIMESTAMP WITH TIME ZONE, any TIMESTAMP WITHOUT TIME ZONE values are implicitly cast to TIMESTAMP WITH TIME ZONE, and the datetime arithmetic operation is performed in UTC time (ignoring the time zone).

Subtracting timestamps: The result of subtracting one timestamp (TS2) from another (TS1) is a timestamp duration that specifies the number of years, months, days, hours, minutes, seconds, and fractional seconds between the two timestamps.

The data type of the result is DECIMAL(14+s,s), where s is the maximum timestamp precision of TS1 and TS2. If TS1 is greater than or equal to TS2, TS2 is subtracted from TS1. If TS1 is less than TS2. However, TS1 is subtracted from TS2 and the sign of the result is made negative. A subtraction that involves a timestamp with a time zone operand is based on the UTC value of the timestamp with the time zone. The time zone is ignored.

The following procedural description clarifies the steps involved in the operation RESULT = TS1 - TS2.

<table>
<thead>
<tr>
<th>Timestamp subtraction: \textit{result} = \textit{ts1} - \textit{ts2}</th>
</tr>
</thead>
<tbody>
<tr>
<td>• If MICROSECOND(TS2) \leq MICROSECOND(TS1) then MICROSECOND(R\textit{esult}) = MICROSECOND(TS1) - MICROSECOND(TS2).</td>
</tr>
<tr>
<td>• If MICROSECOND(TS2) &gt; MICROSECOND(TS1) then MICROSECOND(R\textit{esult}) = 1000000 + MICROSECOND(TS1) - MICROSECOND(TS2) and SECOND(TS2) is incremented by 1.</td>
</tr>
<tr>
<td>• If SECOND(TS2,s) \leq SECOND(TS1,s) then SECOND(R\textit{esult},s) = SECOND(TS1,s) - SECOND(TS2,s).</td>
</tr>
<tr>
<td>• If SECOND(TS2,s) &gt; SECOND(TS1,s) then SECOND(R\textit{esult},s) = 60 + SECOND(TS1,s) - SECOND(TS2,s).</td>
</tr>
<tr>
<td>MINUTE(TS2) is incremented by 1.</td>
</tr>
<tr>
<td>• If HOUR(TS2) \leq HOUR(TS1) then HOUR(R\textit{esult}) = HOUR(TS1) - HOUR(TS2).</td>
</tr>
<tr>
<td>• If HOUR(TS2) &gt; HOUR(TS1) then HOUR(R\textit{esult}) = 24 + HOUR(TS1) - HOUR(TS2) and DAY(TS2) is incremented by 1.</td>
</tr>
</tbody>
</table>

The minutes part of the timestamps are subtracted as specified in the rules for subtracting times.

The date part of the timestamps is subtracted as specified in the rules for subtracting dates.

Incrementing and decrementing timestamps: The result of adding a duration to a timestamp, or of subtracting a duration from a timestamp, is itself a timestamp.

The precision of the result timestamp matches the precision of the timestamp operand. The date and time arithmetic is performed as previously defined, except that an overflow or underflow of hours is carried into the date part of the result, which must be within the range of valid dates. The time arithmetic portion is similar to time arithmetic, except that it also considers the fractional seconds included in the duration. For example, subtracting a duration, X, from a timestamp, TIMESTAMP1, where X is a DECIMAL(14+s,s) number, is equivalent to the expression:

\[ \text{TIMESTAMP1} - \text{YEAR}(X) \text{ YEARS} - \text{MONTH}(X) \text{ MONTHS} - \text{DAY}(X) \text{ DAYS} - \text{HOUR}(X) \text{ HOURS} - \text{MINUTE}(X) \text{ MINUTES} - \text{SECOND}(X, s) \text{ SECONDS} \]
When subtracting a duration with a non-zero scale or a labeled duration of SECOND or SECONDS with a value that includes fractions of a second, the subtraction is performed as if the timestamp value has up to 12 fractional second digits. The resulting value is assigned to a timestamp value with the timestamp precision of the timestamp operand, which could result in truncation of fractional second digits.

When the result of an operation is midnight, the time portion of the result can be '24.00.00' or '00.00.00'. A comparison of those two values does not result in 'equal'. Microseconds overflow into seconds.

**Precedence of operations**

Expressions within parentheses are evaluated first. When the order of evaluation is not specified by parentheses, prefix operators are applied before multiplication and division, and multiplication, division, and concatenation are applied before addition and subtraction. Operators at the same precedence level are applied from left to right.

*Example 1:* In this example, the first operation is the addition in \( (\text{SALARY} + \text{BONUS}) \) because it is within parenthesis. The second operation is multiplication because it is a higher precedence level than the second addition operator and it is to the left of the division operator. The third operation is division because it is at a higher precedence level than the second addition operator. Finally, the remaining addition is performed.

\[
1.10 \times (\text{SALARY} + \text{BONUS}) + \text{SALARY} / :\text{VAR3}
\]

*Example 2:* In this example, the first operation (CONCAT) combines the character strings in the variables YYYYMM and DD into a string representing a date. The second operation (-) then subtracts that date from the date being processed in DA
tocol. The result is a date duration that indicates the time elapsed between the two dates.

\[
\text{DATECOL} - :\text{YYYYMM CONCAT :DD}
\]

**CASE expressions**

A CASE expression allows an expression to be selected based on the evaluation of one or more conditions.
searched-when-clause:

```plaintext
WHEN search-condition THEN result-expression NULL
```

simple-when-clause:

```plaintext
expression WHEN expression THEN result-expression NULL
```

In general, the value of the `case-expression` is the value of the `result-expression` following the first (leftmost) `when-clause` that evaluates to true. If no case evaluates to true and the ELSE keyword is present, the result is the value of the `result-expression` or NULL. If no case evaluates to true and the ELSE keyword is not present, the result is NULL. When a case evaluates to unknown (because of NULL values), the case is NOT true and hence is treated the same way as a case that evaluates to false.

**searched-when-clause**

Specifies a `search-condition` that is applied to each row or group of table data presented for evaluation, and the result when that condition is true.

Pair-wise comparison is performed. Implicit cast of each pair follows the same rule as for a basic predicate. The `searched-when-clause` performs implicit cast on string and numeric search conditions.

**simple-when-clause**

Specifies that the value of the `expression` prior to the first WHEN keyword is tested for equality with the value of each `expression` that follows the WHEN keyword. It also specifies the result for when that condition is true.

The data type of the `expression` prior to the first WHEN keyword must be compatible with the data types of the `expression` that follows each WHEN keyword. The data type of any of the expressions cannot be a CLOB, DBCLOB or BLOB. In addition, the `expression` prior to the first WHEN keyword cannot include a function that is not deterministic or has an external action.

**result-expression or NULL**

Specifies the value that follows the THEN and ELSE keywords. It specifies the result of a `searched-when-clause` or a `simple-when-clause` that is true, or the result if no case is true. There must be at least one `result-expression` in the CASE expression with a defined data type. NULL cannot be specified for every case.

All `result-expressions` must have compatible data types. The attributes of the result are determined according to the rules that are described in "Rules for result data types" on page 174. When the result is a string, its attributes
include a CCSID. For the rules on how the CCSID is determined, see Determining the encoding scheme and CCSID of a string (Introduction to Db2 for z/OS).

**search-condition**

Specifies a condition that is true, false, or unknown about a row or group of table data. The search-condition can be a predicate, including predicates that contain fullselects (scalar or non-scalar) or row-value expressions.

If search-condition in a searched-when-clause specifies a quantified predicate or an IN predicate that includes a fullselect, the CASE expression cannot be used in the following contexts:

- select lists
- a VALUES clause of an INSERT or MERGE statement
- a SET or assignment clause of an UPDATE, MERGE, or DELETE statement
- the right side of a SET or assignment statement
- the definition of a column mask or a row permission

If search-condition in a searched-when-clause specifies an EXISTS predicate, the CASE expression cannot be used in the following contexts:

- a VALUES clause of an INSERT or MERGE statement
- the right side of a SET or assignment statement

**END**

Ends a case-expression.

If a CASE expression is in a select list that derives the final result table, and if the simple-when-clause or the searched-when-clause references a basic predicate with a fullselect, column masks cannot be applied to the columns in the THEN clauses which derive the result of the CASE expression.

If a CASE expression is in a select list that derives the final result table, and if the simple-when-clause or searched-when-clause references a column for which column access control is activated, the column mask cannot be applied to the column and an error is returned.

If a CASE expression is in a SET clause of an UPDATE, MERGE, or DELETE statement, a VALUES clause of an INSERT or MERGE statement, or the fullselect of an INSERT from a fullselect, and if the simple-when-clause or the searched-when-clause references a column for which column access control is activated, the column access control is ignored for the column.

Two scalar functions, NULLIF and COALESCE, are specialized to handle a subset of the functionality provided by CASE. The following table shows the equivalent expressions using CASE or these functions.

**Table 52. Equivalent case expressions**

<table>
<thead>
<tr>
<th>CASE expression</th>
<th>Equivalent expression</th>
</tr>
</thead>
<tbody>
<tr>
<td>CASE WHEN e1=e2 THEN NULL ELSE e1 END</td>
<td>NULLIF(e1,e2)</td>
</tr>
<tr>
<td>CASE WHEN e1 IS NOT NULL THEN e1 ELSE e2 END</td>
<td>COALESCE(e1,e2)</td>
</tr>
</tbody>
</table>
Table 52. Equivalent case expressions (continued)

<table>
<thead>
<tr>
<th>CASE expression</th>
<th>Equivalent expression</th>
</tr>
</thead>
<tbody>
<tr>
<td>CASE WHEN e1 IS NOT NULL</td>
<td>COALESCE(e1,e2,...,eN)</td>
</tr>
<tr>
<td>THEN e1 ELSE COALESCE(e2,...,eN)</td>
<td>END</td>
</tr>
</tbody>
</table>

Example 1 (simple-when-clause): Assume that in the EMPLOYEE table the first character of a department number represents the division in the organization. Use a CASE expression to list the full name of the division to which each employee belongs.

```sql
SELECT EMPNO, LASTNAME,
    CASE SUBSTR(WORKDEPT,1,1) WHEN 'A' THEN 'Administration'
        WHEN 'B' THEN 'Human Resources'
        WHEN 'C' THEN 'Design'
        WHEN 'D' THEN 'Operations'
    END
FROM EMPLOYEE;
```

Example 2 (searched-when-clause): You can also use a CASE expression to avoid “division by zero” errors. From the EMPLOYEE table, find all employees who earn more than 25 percent of their income from commission, but who are not fully paid on commission:

```sql
SELECT EMPNO, WORKDEPT, SALARY+COMM FROM EMPLOYEE
WHERE (CASE WHEN SALARY=0 THEN 0
            ELSE COMM/(SALARY+COMM)
        END) > 0.25;
```

Example 3 (searched-when-clause): You can use a CASE expression to avoid “division by zero” errors in another way. The following queries show an accumulation or summing operation. In the first query, Db2 performs the division before performing the CASE statement and an error occurs along with the results.

```sql
SELECT REF_ID,PAYMT_PAST_DUE_CT,
    CASE
        WHEN PAYMT_PAST_DUE_CT=0 THEN 0
        WHEN PAYMT_PAST_DUE_CT>0 THEN SUM(BAL_AMT/PAYMT_PAST_DUE_CT)
    END
FROM PAY_TABLE
GROUP BY REF_ID,PAYMT_PAST_DUE_CT;
```

However, if the CASE expression is included in the SUM aggregate function, the CASE expression would prevent the errors. In the following query, the CASE expression screens out the unwanted division because the CASE operation is performed before the division.

```sql
SELECT REF_ID,PAYMT_PAST_DUE_CT,
    SUM(CASE
        WHEN PAYMT_PAST_DUE_CT=0 THEN 0
        WHEN PAYMT_PAST_DUE_CT>0 THEN BAL_AMT/PAYMT_PAST_DUE_CT
    END)
FROM PAY_TABLE
GROUP BY REF_ID,PAYMT_PAST_DUE_CT;
```

Example 4: This example shows how to group the results of a query by a CASE expression without having to re-type the expression. Using the sample employee
table, find the maximum, minimum, and average salary. Instead of finding these values for each department, assume that you want to combine some departments into the same group.

```sql
SELECT CASE_DEPT, MAX(SALARY), MIN(SALARY), AVG(SALARY)
FROM (SELECT SALARY, CASE WHEN WORKDEPT = 'A00' OR WORKDEPT = 'E21'
    THEN 'A00_E21'
    WHEN WORKDEPT = 'D11' OR WORKDEPT = 'E11'
    THEN 'D11_E11'
    ELSE WORKDEPT
    END AS CASE_DEPT
    FROM DSN8C10.EMP) X
GROUP BY CASE_DEPT;
```

**CAST specification**

The CAST specification returns the first operand (the cast operand) converted to the data type that is specified by *data-type*.

```
CAST( expression AS data-type )
```

**data-type:**

```
built-in-type
distinct-type-name
array-type
```
length:

```
integer
  CODEUNITS16
  CODEUNITS32
  OCTETS
```

Notes:

1. OCTETS and CODEUNITS32 must not be specified with GRAPHIC and VARGRAPHIC when the first argument is numeric data.

lob-length:

```
integer
  K
  M
  G
  CODEUNITS16
  CODEUNITS32
  OCTETS
```

If the data type of either operand is a distinct type, the privilege set must implicitly include EXECUTE authority on the generated cast functions for the distinct type. The CAST specification allows the second operand to be cast to a particular encoding scheme or CCSID if the second operand represents character data. The CCSID clause can be specified following CHAR, VARCHAR, CLOB, GRAPHIC, VARGRAPHIC, and DBCLOB data types.

**expression**

Specifies that the cast operand is an expression other than NULL or a parameter marker. The result is the value of the operand value converted to the specified target data type.

The supported casts are shown in Casting between data types. If the cast is not supported, an error is returned.

When any data type is cast to a character for graphic data type, a warning if any non-blank characters are truncated. The warning also occurs if any characters are truncated when a BLOB operand is cast, or if the time zone characters are truncated when a TIMESTAMP WITH TIME ZONE operand is cast to a string.

**NULL**

Specifies that the cast operand is null. The result is a null value with the specified target data type.

**parameter-marker**

A parameter marker, which is normally considered an expression, has a special meaning as a cast operand. When the cast operand is a parameter-marker, the data type that is specified represents the “promise” that the replacement value for the parameter marker will be assignable to the specified data type (using “store assignment” rules). Such a parameter marker is considered a typed
parameter marker. Typed parameter markers are treated like any other typed value for the purpose of function resolution, a DESCRIBE of a select list, or column assignment.

data-type
Specifies the data type of the result. If the data type is not qualified, the SQL path is used to find the appropriate data type. For more information, see "SQL path" on page 92. For a description of data-type, see CREATE TABLE (For portability across operating systems, when specifying a floating-point data type, use REAL or DOUBLE instead of FLOAT.)

- If the cast operand is expression, see "Casting between data types" on page 141 and use any of the target data types that are supported for the data type of the cast operand.
- If the cast operand is NULL, you can use any data type.
- If the cast operand is a parameter-marker:
  - If the target data type is a distinct type, the application that uses the parameter marker uses the base data type of the distinct type.
  - If the target data type is an array type:
    - The elements in the source array value must be castable to the data type of the elements of the target array type. The index values for the source array value must be castable to the data type of the index of the target array type.
    - If the target array type is an ordinary array, the cardinality of the source array value must be less than or equal to the maximum cardinality of the target array type.
  - Otherwise, any data type if valid.

length
Specifies the length of the result.

If data-type is a varying-length character string, length must be between 1 and 32764.

You can specify that the length of the result be evaluated in a specific number of string units: CODEUNITS16, CODEUNITS32, or OCTETS. If expression is a character string that is defined as bit data, CODEUNITS16, or CODEUNITS32 cannot be specified. If expression is a graphic string, OCTETS cannot be specified. If expression is a numeric data value, CODEUNITS32 and OCTETS cannot be specified.

For more information about CODEUNITS16, CODEUNITS32, and OCTETS, see "String unit specifications" on page 114.

lob-length
Specifies the length of the result.

You can specify that the length of the result be evaluated in a specific number of string units: CODEUNITS16, CODEUNITS32, or OCTETS. If expression is a graphic string, OCTETS cannot be specified.

For more information about CODEUNITS16, CODEUNITS32, and OCTETS, see "String unit specifications" on page 114.

CCSID encoding-scheme
Specifies the encoding scheme for the target data type. The specific CCSIDs for SBCS, BIT, and MIXED data are determined by the default CCSIDs for the server for the specified encoding scheme. The valid values are ASCII, EBCDIC, and UNICODE.
**CCSID integer**

Specifies that the target data type be encoded using the CCSID integer. The value must be one of the CCSID values in DECP. If the second operand is CHAR, VARCHAR, or CLOB, the CCSID specified must be either a SBCS, or MIXED CCSID, or 65535 for bit data. If the second operand is GRAPHIC, VARGRAPHIC, or DBCLOB, the CCSID specified must be a DBCS CCSID. See Determining the CCSID of the result if neither CCSID integer nor CCSID encoding-scheme is specified. See Determining the CCSID of the result for special considerations regarding CCSID 367.

**Interaction between length and CCSID clauses:** If both the length and CCSID clauses are specified, the data is first cast to the specified CCSID, and then the length is applied. If either CODEUNITS16 or CODEUNITS32 is specified, the specification of length applies to the units specified. That is, the data is converted to an intermediate form (in Unicode), the length is applied, and the data is converted to the specified CCSID.

**Resolution of cast functions:** Db2 uses the implicit or explicit schema name and the data type name of data-type, and function resolution to determine the specific function to use to convert expression to data-type. See Qualified function resolution for more information.

**Result of the CAST:** When numeric data is cast to character data, the data type of the result is a fixed-length character string, which is similar to the result that the CHAR function would give. (For more information, see “CHAR” on page 424.) When character data is cast to numeric data, the data type of the result depends on the data type of the specified number. For example, character data that is cast to an integer becomes a large integer, which is similar to the result that the INTEGER function would give. (For more information see INTEGER or INT.)

If the data type of the result is character, the subtype of the result is determined as follows:

- If expression is graphic, the subtype of the result is mixed.
- If expression is a datetime data type, the subtype of the result is mixed. The exception is when the default encoding scheme is EBCDIC and there is no mixed or graphic data on the system for EBCDIC.
- If expression is a row ID and data-type is not CLOB, the result is bit data.
- If expression is character, the subtype of the result is the same as expression.
- Otherwise, the subtype depends on the encoding scheme of the result. If the encoding scheme of the result is not Unicode and the field MIXED DATA on installation panel DSNTIPF is NO, the subtype of the result is SBCS. Otherwise, the subtype of the result is mixed.

**Casting constant values to DECFLOAT:** To cast a constant value, where the value is negative zero, or a floating point constant to DECFLOAT, specify the value as a character string constant rather than a numeric constant. For example:

```
DECFLOAT('-01')  -- causes DB2 to retain the negative sign for a value of negative zero
DECFLOAT('1.00E20')  -- causes DB2 to preserve the precision of the floating point constant
```

**Determining the CCSID and encoding scheme of the result:** The CCSID of the result depends on whether the CCSID clause was specified and the context in which the CAST specification was specified.
If the CCSID clause was specified, the CCSID clause is used to determine the
CCSID of the result as follows:

- If the CCSID clause was specified with EBCDIC, ASCII, or UNICODE, the clause
determines the encoding scheme of the result. The CCSID of the result is the
appropriate CCSID (from DECP) for that encoding scheme for the data type of
the result.

- If the CCSID clause was specified with a numeric value representing bit data
(65535), the CCSID of the result depends on the data type of the source. If the
source data is not string data, the CCSID of the result is the appropriate CCSID
for the application encoding scheme. See Note 1 in Determining the encoding
scheme and CCSID of a string (Introduction to Db2 for z/OS). If the source is
string data, the encoding scheme of the result is the same as the encoding
scheme of expression, but the result is considered bit data.

- If the CCSID clause was specified with a numeric value, that number is the
CCSID of the result. The encoding scheme of the result is determined from the
numeric CCSID. In a CAST specification, CCSID 367 refers to ASCII data. For
example, assume that MYDATA is string data to be cast to CHAR(10). The
following CAST specification returns ASCII SBCS data:

```
CAST(MYDATA AS CHAR(10) CCSID 367)
```

To explicitly cast the data to Unicode SBCS, use the following syntax:

```
CAST(MYDATA AS CHAR(10) CCSID UNICODE FOR SBCS DATA)
```

If the CCSID clause was not specified, the CCSID of the result is 65535 if the result
is bit data. Otherwise, if the data type of the result is a character or graphic string
data type, the encoding scheme and CCSID of the result are determined as
follows:

- If the expression and data-type are both character, the encoding scheme of the
result is the same as expression. For example, assume CHAR_COL is a character
column in the following sample:

```
CAST(CHAR_COL AS VARCHAR(25))
```

The result of the CAST is a varying length string with the same encoding
scheme as the input. The CCSID of the result is the appropriate CCSID for the
encoding scheme and subtype of the result.

- If the expression and data-type are both graphic, the encoding scheme and CCSID
of the result is the same as expression.

- If the result is string and the expression is datetime, the result CCSID is the
appropriate CCSID of the expression encoding scheme and the result subtype is
the appropriate subtype of the CCSID.

- If the result is character, the encoding scheme and CCSID of the result depends
on the context in which the CAST specification is specified:

  - If the statement follows the rules that are described for type 1 statements in
Determining the encoding scheme and CCSID of a string (Introduction to Db2
for z/OS), the CCSID is determined as follows:

    - If the statement references a table or view, the encoding scheme of that
      table or view determines the encoding scheme for the result.
    - Otherwise, the default EBCDIC encoding scheme is used for the result.

The CCSID of the result is the appropriate CCSID for the encoding scheme
and subtype of the result.
– Otherwise, the CCSID of the result is the appropriate CCSID for the application encoding scheme and subtype of the result.

• If the result is graphic, the encoding scheme and the CCSID of the result depends on the context in which the CAST specification is specified:

  – If the statement follows the rules that are described for type 1 statements in Determining the encoding scheme and CCSID of a string (Introduction to Db2 for z/OS), the CCSID is determined as follows:

    - If the statement references a table or view, the encoding scheme of that table or view determines the encoding scheme for the result.
    - Otherwise, the default EBCDIC encoding scheme is used for the result.

    The CCSID of the result is the appropriate CCSID for the encoding scheme and data type of the result.

  – Otherwise, the CCSID of the result is the appropriate CCSID for the application encoding scheme of the result.

• Otherwise, the CCSID of the result depends on the context in which the CAST specification was specified.

  – If the statement follows the rules that are described for type 1 in statements in Determining the encoding scheme and CCSID of a string (Introduction to Db2 for z/OS), the CCSID is determined as follows:

    - If the statement references a table or view, the encoding scheme of that table or view determines the encoding scheme for the result.
    - Otherwise, the default EBCDIC encoding scheme is used for the result.

    The CCSID of the result is the appropriate CCSID for the encoding scheme and data type of the result.

Alternative syntax for casting distinct types: There is alternative syntax for casting a distinct type to its base data type and vice versa. Assume that a distinct type D_MONEY was defined with the following statement and column MONEY was defined with that data type.

CREATE TYPE D_MONEY AS DECIMAL(9,2);

DECIMAL(MONEY) is equivalent syntax to CAST(MONEY AS DECIMAL(9,2)). Both forms of the syntax use the cast function that Db2 generated when the distinct type D_MONEY was created to convert the distinct type to its source type of DECIMAL(9,2).

However, it is possible that different cast functions might be chosen for the equivalent syntax forms because of the difference in function resolution, particularly the treatment on unqualified names. Although the process of function resolution is similar for both, in the CAST specification as described above, Db2 uses the schema name of the target data type to locate the function. Therefore, if an unqualified data type name is specified as the target data type, Db2 uses the SQL path to resolve the schema name of the distinct type and then searches for the function in that schema. In function notation, when an unqualified function name is specified, Db2 searches the schemas in the SQL path to find an appropriate function match, as described under "Function resolution" on page 251. For example, assume that you defined the following distinct types, which implicitly gives you both USAGE authority on the distinct types and EXECUTE authority on the cast functions that are generated for them:

CREATE TYPE SCHEMA1.AGE AS DECIMAL(2,0);
one of the generated cast functions is:
FUNCTION SCHEMA1.AGE(SYSIBM.DECIMAL(2,0)) RETURNS SCHEMA1.AGE
CREATE TYPE SCHEMA2.AGE AS INTEGER;
   one of the generated cast functions is:
   FUNCTION SCHEMA2.AGE(SYSIBM.INTEGER) RETURNS SCHEMA2.AGE

If STU_AGE, an INTEGER host variable, is cast to the distinct type with either of the
following statements and the SQL path is SYSIBM, SCHEMA1, SCHEMA2:
Syntax 1: CAST(:STU_AGE AS AGE);
Syntax 2: AGE(:STU_AGE);

different cast functions are chosen. For syntax 1, Db2 first resolves the schema
name of distinct type AGE as SCHEMA1 (the first schema in the path that contains
a distinct type named AGE for which you have EXECUTE authority for the
appropriate generated cast function). Then it looks for a suitable function in that
schema and chooses SCHEMA1.AGE because the data type of STU_AGE, which is
INTEGER, is promotable to the data type of the function argument, which is
DECIMAL(2,0). For syntax 2, Db2 searches all the schemas in the path for an
appropriate function and chooses SCHEMA2.AGE. Db2 selects SCHEMA2.AGE
over SCHEMA1.AGE because the data type of its argument (INTEGER) is an exact
match for STU_AGE (INTEGER) and, therefore, a better match than the argument
for SCHEMA1.AGE, which is DECIMAL(2,0).

Syntax alternatives: TIMEZONE can be specified as an alternative to TIME ZONE.

Example 1: Assume that an application needs only the integer portion of the
SALARY column, which is defined as DECIMAL(9,2) from the EMPLOYEE table.
The following query for the employee number and the integer value of SALARY
could be prepared.
   SELECT EMPNO, CAST(SALARY AS INTEGER) FROM EMPLOYEE;

Example 2: Assume that two distinct types exist in schema SCHEMAX. Distinct
type D_AGE was based on SMALLINT and is the data type for the AGE column in
the PERSONNEL table. Distinct type D_YEAR was based on INTEGER and is the
data type for the RETIRE_YEAR column in the same table. The following UPDATE
statement could be prepared.
   UPDATE PERSONNEL SET RETIRE_YEAR =?
       WHERE AGE = CAST( ? AS SCHEMAX.D_AGE);

The first parameter is an untyped parameter marker that has a data type of
RETIRE_YEAR. However, the application will use an integer for the parameter
marker. The parameter marker does not need to be cast because the SET is an
assignment.

The second parameter marker is a typed parameter marker that is cast to the
distinct type D_AGE. Casting the parameter marker satisfies the requirement that
comparisons must be performed with compatible data types. The application will
use the base data type, SMALLINT, to process the parameter marker.

Example 3: A CAST specification can be used to explicitly specify the data type of a
parameter in a context where a parameter marker must be typed. In the following
example, the CAST specification is used to tell Db2 to assume that the value that
will be provided as input to the TIME function will be CHAR(20). See "PREPARE"
on page 2196 for a list of contexts when invoking functions where parameter
markers can be untyped. For all other contexts when invoking a function, the
CAST specification can be used to explicitly specify the type of a parameter
marker.
   INSERT INTO ADMF001.CASTSQLJ VALUES( TIME(CAST(? AS CHAR(20)) ) )
Example 4: Assume that an application wants to cast an EBCDIC string to Unicode UTF-8. The string contains the value 'Jürgen', which is 6 bytes in ASCII or EBCDIC and is 7 bytes in Unicode UTF-8. In the following query, the CAST specification is invoked with the length clause with CODEUNITS32 specified to ensure that the data is not truncated. (In this case, CODEUNITS16 could also be specified as the string unit.)

```
SELECT CAST('Jürgen' AS VARCHAR(6 CODEUNITS32) CCSID UNICODE)
FROM SYSIBM.SYSDUMMY1;
```

For this query, the data is converted from EBCDIC to Unicode UTF-16, the length clause is applied, and then the UTF-16 result is converted to UTF-8.

Example 5: When a keyword is used for a special value that is expressed as a constant in a context where the keyword could be interpreted as a name, the CAST specification can be used to explicitly cast the special value to decimal-floating point. Assume that MYTAB contains columns named C1 and INFINITY, and that you want to reference the decimal float-point value for infinity in the same SQL statement. Use the CAST specification to explicitly cast INFINITY as a decimal floating-point value to ensure that it is not interpreted as the name of a column, parameter or variable:

```
SELECT INFINITY -- column named INFINITY
FROM MYTAB
WHERE C1 = CAST ('INFINITY' AS DECFLOAT) -- comparison is made with the
-- decimal floating-point
-- infinity value
```

**XMLCAST specification**

The XMLCAST specification returns the first operand (the cast operand) converted to the type specified by data-type.

```
XMLCAST(expression AS data-type)
```

XMLCAST supports casts involving XML values, including conversions between non-XML data types and the XML data type. Either the type of the cast operand or the specified data type must be XML. If both the type of the cast operand and the target data type are XML, XMLCAST acts as a no-op.

**expression**

If the cast operand is an expression, the result is the argument value converted to the specified target data type. The expression or the target data type must be the XML data type. expression cannot be a host variable or parameter marker.

**NULL**

If the cast operand is the NULL keyword, the target data type must be the XML data type. The result is a null XML value.

**parameter-marker**

If the cast operand is a parameter marker, the target data type must be the XML data type. A parameter marker (specified as a question mark character) is normally considered to be an expression, but in this case because it has special
meaning. When the cast operand is a parameter-marker, the data type that is specified represents the "promise" that the replacement value for the parameter marker will be assignable to the specified data type (using assignment rules). Such a parameter marker is considered to be a typed parameter marker, which is treated like any other typed value for the purpose of function resolution, a describe operation on a select list, or column assignment.

data-type
The name of an SQL data type. If the name is not qualified, the SQL path is used to perform data type resolution. data-type must not specify a distinct type. If a data type has associated attributes, such as length or precision and scale, these attributes should be included when specifying a value for data-type. CHAR defaults to a length of 1, and DECIMAL defaults to a precision of 5 and a scale of 0 if not specified. CLOB and DBCLOB default to a length of 1M. When the target data type is XML and the source data type is TIMESTAMP, trailing zeroes in the fractional seconds part of the value are not included in the result. Restrictions on the supported data types are based on the specified cast operand. The default encoding scheme for string data types is Unicode. The encoding scheme can be changed by specifying the CCSID clause.

Table 53. Supported conversions from Non-XML values to XML values

<table>
<thead>
<tr>
<th>Source data type</th>
<th>Target data type: XML</th>
<th>Resulting XML schema type</th>
</tr>
</thead>
<tbody>
<tr>
<td>DATE</td>
<td>Y</td>
<td>xs:date</td>
</tr>
<tr>
<td>TIME</td>
<td>Y</td>
<td>xs:time</td>
</tr>
<tr>
<td>TIMESTAMP(p) WITH TIME</td>
<td>Y</td>
<td>xs:dateTime</td>
</tr>
<tr>
<td>ZONE</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Examples

Example 1: Create a null XML value.
```
XMLCAST(NULL AS XML)
```

Example 2: Convert a value extracted from an XMLQUERY expression into an INTEGER:
```
XMLCAST(XMLQUERY('/PRODUCT/QUANTITY'
     PASSING xmlcol) AS INTEGER)
```

Example 3: Convert a value extracted from an XMLQUERY expression into a varying-length character string:
```
XMLCAST(XMLQUERY('/PRODUCT/NAME'
     PASSING xmlcol) AS VARCHAR(20))
```

Note that in the above two examples, if the XMLQUERY returns a sequence of more than one node, the XMLCAST specification will return an error.

Example 4: Convert a value extracted from an SQL scalar subquery into an XML value:
```
XMLCAST((SELECT quantity FROM product AS p
     WHERE p.id = 1077) AS XML)
```

Array element specification
The array element specification returns the element from an array specified by array-index.
array-expression

Specifies an SQL variable, SQL parameter, or global variable of an array type, or a CAST specification of a parameter marker to an array type.

[array-index]

An expression that specifies the array index of the element that is to be extracted from the array. An array index value for an ordinary array must be castable to INTEGER. The array index value must be between 1 and the cardinality of the array. An array index value for an associative array must be castable to the data type of the index for the array type. The array index value must represent an element that exists in the array. If the index value is a string that is longer than the index data type, the value is truncated, a warning is issued, and processing continues with the truncated value.

array-index must not be:

- An expression that references the CURRENT DATE, CURRENT TIME, or CURRENT TIMESTAMP special register
- A nondeterministic function
- A function that is defined with EXTERNAL ACTION
- A function that is defined with MODIFIES SQL DATA
- A sequence expression

In EBCDIC code pages, X'BBBB' is normally treated as a concatenation operator. Because this sequence of characters is a pair of right brackets characters ([)] in some EBCDIC code pages, it is not treated as a concatenation operator when used inside of an array-index expression.

The data type of the result is the data type that is specified for the array on the CREATE TYPE (array) statement. If array-index is null, or the array is null, the null value is returned.

If the array element is character or graphic data, the CCSID of the result is the CCSID of the array elements of the array type. If the array element is datetime data, the CCSID of the result is 1208.

Examples

Example 1: Suppose that PHONE_NUMBERS is an array variable that is defined as an array type. The array type is defined as an ordinary array of CHAR(10) elements. Also suppose that INT_VAR is an integer variable. The following assignment statements demonstrate how an index for an array element can be specified.

Set the first element of an array to NULL:
SET PHONE_NUMBERS[1] = NULL;

Set the third element to the value ‘4164789683’:
SET PHONE_NUMBERS[3] = '4164789683';
Set an array element to '4164788888', and specify the array index with the variable INT_VAR:

```
SET PHONE_NUMBERS[INT_VAR] = '4164788888';
```

Set an array element to '4164783322', and specify the array index with the expression INT_VAR+5:

```
SET PHONE_NUMBERS[INT_VAR + 5] = '4164783322';
```

**Array constructor**

An array constructor returns an ordinary array. An array constructor is specified by a list of expressions or a fullselect.

![Array Constructor Diagram](image)

**Authorization**

No specific authorizations are required to reference an array constructor within an SQL statement. However, for the statement execution to be successful, all other authorization requirements for the statement must be satisfied.

**fullselect**

A fullselect that returns a single column. The data type of the column must be a data type that can be specified in a CREATE TYPE (array) statement as the data type of an array element. The values that are returned by the fullselect are the elements of the array. The cardinality of the array is equal to the number of rows that are returned by the fullselect. An ORDER BY clause in the fullselect can be used to specify the order among the elements of the array. Otherwise, the order is undefined. The data type of the elements of the resulting array is the same as the data type of the result column of the fullselect.

**element-expression**

An expression that defines the value of an element in the array. The expression must return a value with a data type that can be specified in a CREATE TYPE (array) statement as the data type of an array element. The cardinality of the array is equal to the number of element expressions. The first element expression is assigned to the array element with array index 1. The second element expression is assigned to the array element with array index 2, and so on. All element expressions must have compatible data types. The data type of the elements of the resulting array are determined based on the rules that are described in "Rules for result data types" on page 174.

**NULL**

Specifies the null value.

If no value is specified within the brackets, the result is an empty array.
An array constructor cannot be specified in an inline SQL function, and can only be specified in the following specific contexts:

- As a source value for a SET assignment-statement statement or an SQL PL assignment-statement statement
- As the value that is to be returned in a RETURN statement of a user-defined scalar function

An array constructor cannot be used to construct an associative array. An associative array can be constructed only by assigning values to individual array elements.

**Examples**

*Example 1:* Suppose that the array variable RECENT_CALLS has the array type PHONENUMBERS. Assign an array of fixed numbers to RECENT_CALLS.

```
SET RECENT_CALLS = ARRAY[905553907, 4165554213, 4085553678];
```

*Example 2:* Suppose that the array variable DEPT_PHONES has the array type PHONENUMBERS. Assign array phone numbers that are retrieved from the DEPARTMENT_INFO table to DEPT_PHONES.

```
SET DEPT_PHONES = 
ARRAY[SELECT DECIMAL(AREA_CODE CONCAT '555' CONCAT EXTENSION,16) 
FROM DEPARTMENT_INFO 
WHERE DEPTID = 624];
```

**OLAP specification**

Online analytical processing (OLAP) specifications provide the ability to return ranking, row numbering, and aggregation information as a scalar value in the result of a query. An OLAP specification can be included in an expression, in a select-list, or in the ORDER BY clause of a select-statement. The query result to which the OLAP specifications is applied is the result table of the innermost subselect that includes the OLAP specification.

**OLAP-specification**
lag-function

\[
\text{LAG}(\text{expression}, \text{offset}, \text{default-value} \{'\text{RESPECT NULLS}', '\text{IGNORE NULLS}'\})
\]

lead-function

\[
\text{LEAD}(\text{expression}, \text{offset}, \text{default-value} \{'\text{RESPECT NULLS}', '\text{IGNORE NULLS}'\})
\]

window-partition-clause

\[
\text{PARTITION BY} \text{partitioning-expression}
\]

window-order-clause

\[
\text{ORDER BY} \text{sort-key-expression} \{'\text{ASC NULLS FIRST}', '\text{ASC NULLS LAST}', '\text{DESC NULLS FIRST}', '\text{DESC NULLS LAST}'\}
\]

numbering-specification

\[

group-bound-2

\[ \text{BETWEEN} \text{ group-bound-1 AND group-bound-2} \]
RANK, DENSE_RANK, and ROW_NUMBER are sometimes called window functions.

An OLAP specification is not valid in a WHERE, VALUES, GROUP BY, HAVING, or SET clause. An OLAP specification cannot be used as an argument of an aggregate function.

When invoking an OLAP specification, a window is specified that defines the rows over which the function is applied and in which order.

The result of a RANK, DENSE_RANK, or ROW_NUMBER specification is BIGINT. The result cannot be null.

**CUME_DIST**

Returns a cumulative distribution of a row within an OLAP window, expressed as a value in the range of 0.0 - 1.0. The result is computed by dividing the number of rows preceding or equivalent to the current row in the OLAP window by the number of rows in the OLAP window.

The data type of the result is DECFLOAT(34). The result cannot be NULL.

This function is passthrough-only and cannot run on Db2 for z/OS. Db2 only verifies that the data types of the parameters are valid for the function. The accelerator engine does all other function resolution processing and validation. To invoke this function, you must set the QUERY_ACCELERATION subsystem parameter, CURRENT QUERY ACCELERATION special register, or QUERYACCELERATION bind option to ALL, ENABLE, or ELIGIBLE. The function can be referenced in a view but cannot be specified as a source function for a user-defined function.

**PERCENT_RANK**

Returns a relative percentile rank of a row within an OLAP window, expressed as a value between 0.0 - 1.0. When the number of rows in the OLAP window is greater than 1, the result is computed by dividing the RANK of the current row in the OLAP window minus 1 by the number of rows in the OLAP window minus 1. Otherwise, the result is 0.0.

This function is passthrough-only and cannot run on Db2 for z/OS. Db2 only verifies that the data types of the parameters are valid for the function. The accelerator engine does all other function resolution processing and validation. To invoke this function, you must set the QUERY_ACCELERATION subsystem...
parameter, CURRENT QUERY ACCELERATION special register, or
QUERYACCELERATION bind option to ALL, ENABLE, or ELIGIBLE. The
function can be referenced in a view but cannot be specified as a source
function for a user-defined function.

**RANK** or **DENSE_RANK**
Specifies that the ordinal rank of a row within the specified window is
computed. Rows that are not distinct with respect to the ordering within the
specified window are assigned the same rank. The results of the ranking can
be defined with or without gaps in the numbers that result from duplicate
values.

**RANK**
Specifies that the rank of a row is defined as 1 plus the number of rows
that strictly precede the row. Thus, if two or more rows are not distinct
with respect to the ordering, there will be one or more gaps in the
sequential rank numbering.

**DENSE_RANK**
Specifies that the rank of a row is defined as 1 plus the number of
preceding rows that are distinct with respect to the ordering. Therefore,
there will be no gaps in the sequential rank numbering.

**NTILE**
Returns the quantile rank of a row.

<num-tiles>
An expression that specifies the number of quantiles. The expression must
return a value that is a built-in numeric data type, CHAR, or VARCHAR
data type. In a Unicode database, the expression can also be a GRAPHIC
or VARGRAPHIC data type. CHAR, VARCHAR, GRAPHIC, and
VARGRAPHIC are supported by using implicit casting. If the expression is
not a SMALLINT, INTEGER, or BIGINT, it is cast to BIGINT before the
function is evaluated. The value must be greater than 0. The expression
must be a constant, a variable, or a cast of a constant or variable.

The data type of the result of NTILE is the same data type as the data type of
num-tiles after any implicit casting. If the argument can be null, the result can
be null. If the argument is null, the result is the null value.

The NTILE function computes the quantile rank of a row by dividing the
ordered rows within the OLAP window into num-tiles quantiles and returns a
value between 1 and MIN(n, num-tiles), where n is the number of rows within
the OLAP window. If n is evenly divisible by num-tiles, the rows in the OLAP
window are grouped into num-tiles quantiles, each containing (n / num-tiles)
rows. Otherwise, each of the quantiles 1 through MOD(n, num-tiles) is assigned
(n / num-tiles + 1) rows, and each of the quantiles (MOD(n, num-tiles) + 1)
through num-tiles is assigned (n / num-tiles) rows. The result is the quantile
rank which is associated with the current row.

Equivalent sort keys are not considered when rows are divided into quantiles.
Rows with equivalent sort keys can be assigned to different quantiles based on
the non-deterministic order of these sort keys. Therefore, NTILE is a
non-deterministic function.

This function is passthrough-only and cannot run on Db2 for z/OS. Db2 only
verifies that the data types of the parameters are valid for the function. The
accelerator engine does all other function resolution processing and validation.
To invoke this function, you must set the QUERY_ACCELERATION subsystem
parameter, CURRENT QUERY ACCELERATION special register, or
QUERYACCELERATION bind option to ALL, ENABLE, or ELIGIBLE. The function can be referenced in a view but cannot be specified as a source function for a user-defined function.

LAG

\[ \text{LAG} \] Returns the expression value for the row at offset rows before the current row. The offset must be a positive integer constant. An offset value of 0 indicates the current row. If a window-partition-clause is specified, offset indicates offset rows before the current row and within the current partition. If offset is not specified, the value 1 is used. If default-value (which can be an expression) is specified, it will be returned if the offset goes beyond the scope of the current partition. Otherwise, the null value is returned. If ‘IGNORE NULLS’ is specified, all rows for which the expression value is the null value are not considered in the calculation. If ‘IGNORE NULLS’ is specified and all rows are null, default-value (or the null value if default-value was not specified) is returned.

This function is passthrough-only and cannot run on Db2 for z/OS. Db2 only verifies that the data types of the parameters are valid for the function. The accelerator engine does all other function resolution processing and validation. To invoke this function, you must set the QUERY ACCELERATION subsystem parameter, CURRENT QUERY ACCELERATION special register, or QUERYACCELERATION bind option to ALL, ENABLE, or ELIGIBLE. The function can be referenced in a view but cannot be specified as a source function for a user-defined function.

LEAD

\[ \text{LEAD} \] Returns the expression value for the row at offset rows after the current row. The offset must be a positive integer constant. An offset value of 0 indicates the current row. If a window-partition-clause is specified, offset indicates offset rows after the current row and within the current partition. If offset is not specified, the value 1 is used. If default-value (which can be an expression) is specified, it will be returned if the offset goes beyond the scope of the current partition. Otherwise, the null value is returned. If ‘IGNORE NULLS’ is specified, all rows for which the expression value is the null value are not considered in the calculation. If ‘IGNORE NULLS’ is specified and all rows are null, default-value (or the null value if default-value was not specified) is returned.

This function is passthrough-only and cannot run on Db2 for z/OS. Db2 only verifies that the data types of the parameters are valid for the function. The accelerator engine does all other function resolution processing and validation. To invoke this function, you must set the QUERY ACCELERATION subsystem parameter, CURRENT QUERY ACCELERATION special register, or QUERYACCELERATION bind option to ALL, ENABLE, or ELIGIBLE. The function can be referenced in a view but cannot be specified as a source function for a user-defined function.

ROW_NUMBER

Specifies that a sequential row number is computed for the row that is defined by the ordering, starting with 1 for the first row. If the ORDER BY clause is not specified in the window, the row numbers are assigned to the rows in an arbitrary order, as the rows are returned (not according to any ORDER BY clause in the select-statement).

PARTITION BY (partitioning-expression, ...)

Defines the partition within which the OLAP operation is applied. A partitioning-expression is an expression that is used in defining the partitioning of the result table. Each column name that is referenced in a
partitioning-expression must unambiguously reference a column of the result table of the subselect that contains the OLAP specification. A partitioning-expression cannot include a scalar-fullselect an XMLQUERY or XMLEXISTS expression or any function that is not deterministic or has an external action.

ORDER BY (sort-key-expression,...)
Defines the ordering of rows within a partition that is used to determine the value of the OLAP specification. It does not define the ordering of the result table.

sort-key-expression
Specifies an expression to use in defining the ordering of the rows within a window partition. Each column name that is referenced in a sort-key-expression must unambiguously reference a column of the result table of the subselect, including the OLAP specification. A sort-key-expression cannot include a scalar fullselect, an XMLQUERY or XMLEXISTS expression, or any function that is not deterministic or that has an external action.

ASC
Specifies that the values of sort-key-expression are used in ascending order.

DESC
Specifies that the values of sort-key-expression are used in descending order.

NULLS FIRST
Specifies that the window ordering considers null values before all non-null values in the sort order.

NULLS LAST
Specifies that the window ordering considers null values after all non-null values in the sort order.

FIRST VALUE
Returns the expression value for the first row in an OLAP window. If 'IGNORE NULLS' is specified, all rows for which the expression value is the null value are not considered in the calculation. If 'IGNORE NULLS' is specified and all values in the OLAP window are null, FIRST_VALUE returns the null value.

This function is passthrough-only and cannot run on Db2 for z/OS. Db2 only verifies that the data types of the parameters are valid for the function. The accelerator engine does all other function resolution processing and validation. To invoke this function, you must set the QUERY_ACCELERATION subsystem parameter, CURRENT QUERY ACCELERATION special register, or QUERYACCELERATION bind option to ALL, ENABLE, or ELIGIBLE. The function can be referenced in a view but cannot be specified as a source function for a user-defined function.

LAST VALUE
Returns the expression value for the last row in an OLAP window. If 'IGNORE NULLS' is specified, all rows for which the expression value is the null value are not considered in the calculation. If 'IGNORE NULLS' is specified and all values in the OLAP window are null, LAST_VALUE returns the null value.

This function is passthrough-only and cannot run on Db2 for z/OS. Db2 only verifies that the data types of the parameters are valid for the function. The accelerator engine does all other function resolution processing and validation. To invoke this function, you must set the QUERY_ACCELERATION subsystem parameter...
parameter, CURRENT QUERY ACCELERATION special register, or
QUERYACCELERATION bind option to ALL, ENABLE, or ELIGIBLE. The
function can be referenced in a view but cannot be specified as a source
function for a user-defined function.

**NTH_VALUE**

(FL 504) Returns the expression value for the nth-row row in an OLAP window.

This function is passthrough-only and cannot run on Db2 for z/OS. Db2 only
verifies that the data types of the parameters are valid for the function. The
accelerator engine does all other function resolution processing and validation.
To invoke this function, you must set the QUERY ACCELERATION subsystem
parameter, CURRENT QUERY ACCELERATION special register, or
QUERYACCELERATION bind option to ALL, ENABLE, or ELIGIBLE. The
function can be referenced in a view but cannot be specified as a source
function for a user-defined function.

**expression**

An expression that specifies the current row in an OLAP window. The
expression must return a value that is a built-in data type.

**nth-row**

An expression that specifies which row of the OLAP window to return.
The expression must return a value that is a built-in numeric data type, a
CHAR, or a VARCHAR data type. In a Unicode database, the expression
can also be a GRAPHIC or VARGRAPHIC data type. CHAR, VARCHAR,
GRAPHIC, and VARGRAPHIC are supported using implicit casting. If the
expression is not a SMALLINT, INTEGER, or BIGINT, it is cast to BIGINT
before the function is evaluated. The value must be greater than 0. The
expression must be a constant, a variable, or a cast of a constant or
variable.

Db2 for z/OS does not support the FROM FIRST, FROM LAST, RESPECT
NULLS, and IGNORE NULLS keywords for this function. Omitting these
keywords in Db2 for Linux, UNIX, and Windows results in the default
behavior FROM FIRST RESPECT NULLS.

**RATIO_TO_REPORT**

(FL 504) Returns the ratio of an argument to the sum of the arguments in an
OLAP partition. The division is always performed using DECFLOAT(34). The
result data type is DECFLOAT(34). If the argument can be null, the result can
be null; if the argument is null, the result is the null value.

This function is passthrough-only and cannot run on Db2 for z/OS. Db2 only
verifies that the data types of the parameters are valid for the function. The
accelerator engine does all other function resolution processing and validation.
To invoke this function, you must set the QUERY ACCELERATION subsystem
parameter, CURRENT QUERY ACCELERATION special register, or
QUERYACCELERATION bind option to ALL, ENABLE, or ELIGIBLE. The
function can be referenced in a view but cannot be specified as a source
function for a user-defined function.

**window-aggregation-group-clause**

The aggregation group of a given row is a set of rows that is defined in
relation to the given row (in the ordering of the rows in the partition of the
given row). window-aggregation-group-clause specifies the aggregation group. If
this clause is not specified and a window-order-clause is also not specified, the
aggregation group consists of all rows of the window partition. The
aggregation group of all rows of the window partition can be explicitly specified using the RANGE or ROWS clauses.

If window-order-clause is specified, but window-aggregation-group-clause is not specified, the window aggregation group consists of all rows that precede a given row of the partition of the given row or all rows that are peers of the given row in the window ordering of the window partition that is defined by the window-order-clause

**ROW**
- Specifies that the aggregation group is defined by counting rows.

**RANGE**
- Specifies that the aggregation group is defined by an offset from a sort key.

**group-start**
- Specifies the starting point for the aggregation group. The aggregation group end is the CURRENT ROW. Specifying group-start is equivalent to specifying group-between as BETWEEN group-start AND CURRENT ROW.

**group-between**
- Specifies that the aggregation group start and end based on either ROWS or RANGE.

**group-end**
- Specifies the ending point for the aggregation group. The aggregation group start is the CURRENT ROW. Specifying group-end is equivalent to specifying group-between as BETWEEN CURRENT ROW AND group-end.

**UNBOUNDED PRECEDING**
- Specifies that the entire partition that precedes the current row is included in the aggregation group. This can be specified with either the ROWS or RANGE clauses. Including the entire partition that precedes the current row can also be specified with multiple sort-key-expressions in the window-order-clause.

**UNBOUNDED FOLLOWING**
- Specifies that the entire partition that follows the current row is included in the aggregation group. This can be specified with either the ROWS or RANGE clauses. Including the entire partition that follows the current row can also be specified with multiple sort-key-expressions in the window-order-clause.

**CURRENT ROW**
- Specifies that the aggregation group starts or ends based on the current row. If ROWS is specified, the current row is the aggregation group boundary. If RANGE is specified, the aggregation group boundary includes the set of rows with the values specified for the sort-key-expression as the current row. This clause cannot be specified in group-bound-2 if group-bound-1 specifies unsigned-constant FOLLOWING.

**unsigned-constant PRECEDING**
- Specifies either the range or the number of rows that precede the current row. If ROWS is specified, unsigned-constant must be zero or a positive integer that indicates a number of rows. If RANGE is specified, the data type of unsigned-constant must be comparable to the data type of the sort-key-expression of the window-order-clause. Only one sort-key-expression is allowed, and the data type of sort-key-expression must allow subtraction. This clause cannot be specified in group-bound-2 if group-bound-1 is CURRENT ROW or unsigned-constant FOLLOWING.
**unsigned-constant** **FOLLOWING**

Specifies either the range or the number of rows that follow the current row. If ROWS is specified, **unsigned-constant** must be zero or a positive integer that indicates a number of rows. If RANGE is specified, the data type of **unsigned-constant** must be comparable to the data type of the **sort-key-expression** of the **window-order-clause**. Only one **sort-key-expression** is allowed, and the data type of **sort-key-expression** must allow addition.

**Notes**

**Using a column mask with an OLAP specification:** If a column mask is used to mask the column values in the final result table and an OLAP specification is referenced in the select list that is used to derive the final result table, the column mask cannot be applied to the column that is specified in the **partitioning-expression** or the **sort-key-expression** in the OLAP specification.

**Syntax alternatives and synonyms:** For compatibility, the keywords **DENSERANK** and **ROWNUMBER** can be used as synonyms for **DENSE_RANK** and **ROW_NUMBER** respectively.

**Example 1:** Display the ranking of employees that have a total salary of more than $30,000, in order by last name:

```sql
SELECT EMPNO, LASTNAME, FIRSTNAME, SALARY+BONUS AS TOTAL_SALARY,
    RANK() OVER(ORDER BY SALARY+BONUS DESC) AS RANK_SALARY
FROM EMP WHERE SALARY+BONUS > 30000
ORDER BY LASTNAME;
```

If the result is to be ordered by rank, **ORDER BY LASTNAME** would be replaced with **ORDER BY RANK_SALARY**.

**Example 2:** Rank the departments according to their average total salary:

```sql
SELECT WORKDEPT, AVG(SALARY+BONUS) AS AVG_TOTAL_SALARY,
    RANK() OVER(ORDER BY AVG(SALARY+BONUS) DESC) AS RANK_AVG_SAL
FROM EMP
GROUP BY WORKDEPT
ORDER BY RANK_AVG_SAL;
```

**Example 3:** Rank the departments according to their education level. Having multiple employees with the same rank in the department should not increase the next ranking value:

```sql
SELECT WORKDEPT, EMPNO, LASTNAME, FIRSTNAME, EDLEVEL,
    DENSE_RANK() OVER
        (PARTITION BY WORKDEPT ORDER BY EDLEVEL DESC) AS RANK_EDLEVEL
FROM EMP
ORDER BY WORKDEPT, LASTNAME;
```

**Example 4:** Provide row numbers in the results of a query:

```sql
SELECT ROW_NUMBER() OVER(ORDER BY WORKDEPT, LASTNAME) AS NUMBER,
    LASTNAME, SALARY
FROM EMP
ORDER BY WORKDEPT, LASTNAME;
```

**Example 5:** List the top five wage earners:
SELECT EMPNO, LASTNAME, FIRSTNAME, TOTAL_SALARY, RANK_SALARY
FROM (SELECT EMPNO, LASTNAME, FIRSTNAME, SALARY+BONUS AS TOTAL_SALARY,
    RANK() OVER (ORDER BY SALARY+BONUS DESC) AS RANK_SALARY
    FROM EMP)
AS RANKED_EMPLOYEE
WHERE RANK_SALARY < 6
ORDER BY RANK_SALARY;

A nested table expression is used to first compute the result, including the ranking, before the rank can be used in the WHERE clause. A common table expression could also have been used.

Example 6: The following example is used to calculate the 30 day moving average for the stocks 'ABC' and 'XYZ' during 2005:

CREATE VIEW V1 AS
SELECT SYMBOL, TRADINGDATE,
    AVG(CLOSINGPRICE) OVER (PARTITION BY SYMBOL
        ORDER BY TRADINGDATE
        ROWS BETWEEN 29 PRECEDING AND CURRENT ROW)
    FROM DAILYSTOCKDATA
WHERE SYMBOL IN ('ABC', 'XYZ')
    AND TRADINGDATE BETWEEN DATE('2005-01-01') - 2 MONTHS AND '2005-12-31';

SELECT SYMBOL, TRADINGDATE, MOVINGAVG30DAY
FROM V1
WHERE TRADINGDATE BETWEEN '2005-01-01' AND '2005-12-31'
ORDER BY SYMBOL, TRADINGDATE;

Example 7: Calculate which quartile (4-quantiles) each employee's salary is in.

```sql
SELECT EMPNO, SALARY, NTILE(4) OVER (ORDER BY SALARY) AS QUARTILE
FROM EMPLOYEE
ORDER BY SALARY
```

The result set is:

<table>
<thead>
<tr>
<th>EMPNO</th>
<th>SALARY</th>
<th>QUARTILE</th>
</tr>
</thead>
<tbody>
<tr>
<td>200340</td>
<td>31840.00</td>
<td>1</td>
</tr>
<tr>
<td>000290</td>
<td>35340.00</td>
<td>1</td>
</tr>
<tr>
<td>200330</td>
<td>35370.00</td>
<td>1</td>
</tr>
<tr>
<td>000310</td>
<td>35900.00</td>
<td>1</td>
</tr>
<tr>
<td>200310</td>
<td>35900.00</td>
<td>1</td>
</tr>
<tr>
<td>000280</td>
<td>36250.00</td>
<td>1</td>
</tr>
<tr>
<td>000270</td>
<td>37380.00</td>
<td>1</td>
</tr>
<tr>
<td>000300</td>
<td>37750.00</td>
<td>1</td>
</tr>
<tr>
<td>200240</td>
<td>37760.00</td>
<td>1</td>
</tr>
<tr>
<td>200120</td>
<td>39250.00</td>
<td>1</td>
</tr>
<tr>
<td>000320</td>
<td>39950.00</td>
<td>1</td>
</tr>
<tr>
<td>000230</td>
<td>42180.00</td>
<td>2</td>
</tr>
<tr>
<td>000340</td>
<td>43840.00</td>
<td>2</td>
</tr>
<tr>
<td>000170</td>
<td>44680.00</td>
<td>2</td>
</tr>
<tr>
<td>000330</td>
<td>45370.00</td>
<td>2</td>
</tr>
<tr>
<td>200280</td>
<td>46250.00</td>
<td>2</td>
</tr>
<tr>
<td>200010</td>
<td>46500.00</td>
<td>2</td>
</tr>
<tr>
<td>000260</td>
<td>47250.00</td>
<td>2</td>
</tr>
<tr>
<td>000240</td>
<td>48760.00</td>
<td>2</td>
</tr>
<tr>
<td>000250</td>
<td>49180.00</td>
<td>2</td>
</tr>
<tr>
<td>000120</td>
<td>49250.00</td>
<td>2</td>
</tr>
<tr>
<td>000220</td>
<td>49840.00</td>
<td>2</td>
</tr>
<tr>
<td>000190</td>
<td>50450.00</td>
<td>3</td>
</tr>
<tr>
<td>000180</td>
<td>51340.00</td>
<td>3</td>
</tr>
<tr>
<td>000150</td>
<td>55280.00</td>
<td>3</td>
</tr>
<tr>
<td>000200</td>
<td>57740.00</td>
<td>3</td>
</tr>
<tr>
<td>000160</td>
<td>62250.00</td>
<td>3</td>
</tr>
<tr>
<td>200170</td>
<td>64680.00</td>
<td>3</td>
</tr>
</tbody>
</table>
Example 8: The query in the following example divides the rows into 3 buckets, grouping them by maximum salary. The maximum salary is included to show what values go into each bucket:

```sql
SELECT NTILE(3) OVER (ORDER BY MAX_SALARY) AS Bucket,
MAX_SALARY
FROM GOSALES.GOSALES_DW.EMP_POSITION_DIM;
```

A portion of the output from the query is in the following table:

<table>
<thead>
<tr>
<th>BUCKET</th>
<th>MAX_SALARY</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>0.00</td>
</tr>
<tr>
<td>...</td>
<td>...</td>
</tr>
<tr>
<td>1</td>
<td>35000.00</td>
</tr>
<tr>
<td>2</td>
<td>5000.00</td>
</tr>
<tr>
<td>...</td>
<td>...</td>
</tr>
<tr>
<td>2</td>
<td>12000.00</td>
</tr>
<tr>
<td>3</td>
<td>13000.00</td>
</tr>
<tr>
<td>...</td>
<td>...</td>
</tr>
<tr>
<td>3</td>
<td>301500.00</td>
</tr>
</tbody>
</table>

ROW CHANGE expression

A ROW CHANGE expression returns a token or a timestamp that represents the last change to a row.

**ROW CHANGE expression**

| ROW CHANGE TIMESTAMP FOR table-designator |

**TIMESTAMP**

Specifies that a timestamp is returned that represents the last time when a row was changed. If the row has not been changed, the result is the time that the initial value was inserted.
TOKEN
Specifies that a token that is a BIGINT value is returned that represents a relative point in the modification sequence of a row. If the row has not been changed, the result is a token that represents when the initial value was inserted.

FOR table-designator
Identifies the table in which the expression is referenced. table-designator must uniquely identify a base table, a view, or a nested table expression of a subselect. If table-designator identifies a view or a nested table expression, the ROW CHANGE expression returns the TIMESTAMP or TOKEN of the base table of the view or the nested table expression. The view or nested table expression must contain only one base table in its outer subselect. table-designator must not identify a materialized view, a nested table expression that is materialized, an alias, or a synonym.

The result can be null. The ROW CHANGE TIMESTAMP and ROW CHANGE TOKEN expressions are not deterministic.

Notes
Tables without a row change timestamp column:
For tables without a row change timestamp column, the ROW CHANGE TIMESTAMP expression returns a timestamp value that reflects changes made to the page instead of to the row. This timestamp value indicates that at least one row in the page has changed, but does not indicate which row, or even how many rows, have changed. The ROW CHANGE TIMESTAMP expression might indicate that a row has changed, however, the change might be for other rows in the same page.

In a data sharing environment, the returned timestamp value is based on the LRSN value of the page and reflects the most recent time the page was modified.

In a non-data sharing environment, the returned timestamp value is based on the RBA value of the page. In a non-data sharing environment, changes made to the same page within a half hour of each other might be indistinguishable. For example, issuing the following SELECT statements in a non-data sharing environment will possibly return the same value, even though the row was changed between the two SELECT statements:

```
CREATE TABLE T1 (C1 INTEGER NOT NULL);
INSERT INTO T1 VALUES (1);
SELECT ROW CHANGE TIMESTAMP FOR T1 FROM T1;
UPDATE T1 SET C1 = 2 WHERE C1 = 1;
SELECT ROW CHANGE TIMESTAMP FOR T1 FROM T1;
```

Example 1:
The following example returns all the rows that have been changed in the last day:

```
SELECT * FROM ORDERS
  WHERE ROW CHANGE TIMESTAMP FOR ORDERS >
    CURRENT TIMESTAMP - 24 HOURS;
```

Example 2:
The following example returns a timestamp value that corresponds to the most recent change to each row from the EMP table for those employees in department 20:

```
SELECT ROW CHANGE TIMESTAMP FOR EMP
  FROM EMP WHERE DEPTNO = 20;
```
Example 3:
The following example returns a BIGINT value that corresponds to a relative point in the modification sequence of EMP with employee number '3500':

```
SELECT ROW CHANGE TOKEN FOR EMP
FROM EMP WHERE EMPNO = '3500';
```

**Sequence reference**

A sequence is referenced by using the NEXT VALUE and PREVIOUS VALUE expressions specifying the name of the sequence.

```
sequence-reference
```

**NEXT VALUE FOR** `sequence-name`

A NEXT VALUE expression generates and returns the next value for a specified sequence. A new value is generated for a sequence when a NEXT VALUE expression specifies the name of the sequence. However, if there are multiple instances of a NEXT VALUE expression specifying the same sequence name within a query, the sequence value is incremented only once for each row of the result, and all instances of NEXT VALUE return the same value for a row of the result. The NEXT VALUE expression is a not deterministic with external actions since it causes the sequence value to be incremented.

When the next value for the sequence is generated, if the maximum value for an ascending sequence or the minimum value for a descending sequence of the logical range of the sequence is exceeded and the **NO CYCLE** option is in effect, then an error occurs. To avoid this error, either alter the sequence attributes to extend the range of value or to enable cycles for the sequence or drop and re-create the sequence with a different data type that allows a larger range of values.

The data type and length attributes of the result of a NEXT VALUE expression are the same as for the specified sequence. The result cannot be null.

**PREVIOUS VALUE FOR** `sequence-name`

A PREVIOUS VALUE expression returns the most recently generated value for the specified sequence for a previous statement within the current application process. This value can be repeatedly referenced by using PREVIOUS VALUE expressions to specify the name of the sequence. There can be multiple instances of PREVIOUS VALUE expressions specifying the same sequence name within a single statement and they all return the same value.

A PREVIOUS VALUE expression can be used only if a NEXT VALUE expression specifying the same sequence name has already been referenced in the current application process.

The data type and length attributes of the result of a PREVIOUS VALUE expression are the same as for the specified sequence. The result cannot be null.

`sequence-name`

Identifies the sequence that is to be referenced. The combination of name and...
the implicit or explicit schema name must identify an existing sequence at the current server. *sequence-name* must not be the name of an internal sequence object that is generated by Db2 for an identity column. The contents of the SQL PATH are not used to determine the implicit qualifier of a sequence name.

**Notes**

**Authorization:**

If a sequence is referenced in a statement, the privileges that are held by the authorization ID of the statement must include at least one of the following:

- For the sequence identified in the statement:
  - The USAGE privilege on the sequence
  - Ownership of the sequence
- SYSADM or SYSCTRL authority

**Generating values with NEXT VALUE:**

When a value is generated for a sequence, that value is consumed, and the next time that a value is requested, a new value will be generated. This is true even when the statement containing the NEXT VALUE expression fails or is rolled back.

**Scope of NEXT VALUE and PREVIOUS VALUE:**

The value of PREVIOUS VALUE cannot be directly set and is a result of executing the NEXT VALUE expression for the sequence. The value of PREVIOUS VALUE persists until the next value is generated for the sequence in the current session, the sequence is dropped or altered, or the application session ends.

The value for the sequence cannot persist across a COMMIT or ROLLBACK for a local or remote application if, after the COMMIT or ROLLBACK, the Db2 application thread or server thread is assigned to another user or Db2 connection because of some form of thread reuse, re-signon, or connection pooling is in effect. For example, this can occur for CICS-Db2 applications and for client applications or middleware products that save the state of a session and then restore the state of a session for subsequent processing because they are not able to restore the NEXT or PREVIOUS VALUES for a sequence. In these situations, the availability of the value for a sequence should only be relied on until the end of the transaction. Examples of where this type of situation can occur include applications that do the following:

- issue an EXEC CICS SYNCPOINT command
- use XA protocols
- use connection pooling
- use the connection concentrator
- use Sysplex workload balancing
- connect to a z/OS server that uses DDF inactive threads

When there is a need to preserve the value that is associated with NEXT VALUE or PREVIOUS VALUE expressions across transaction boundaries for local or distributed applications that are subject to thread reuse, re-signon, or connection pooling, take one of the following actions to prevent the local or server thread from re-signon, being reused by a different user, or from being pooled:

- Define at least one cursor as WITH HOLD and leave it as OPEN.
• Specify the bind option KEEP_DYNAMIC(YES).

Use as a unique key value:
The same sequence number can be used as a unique key value in two separate tables by referencing the sequence number with a NEXT VALUE expression for the first row (this generates the sequence value), and a PREVIOUS VALUE expression for the other rows (the instance of PREVIOUS VALUE refers to the sequence value most recently generated in the current session), as shown in the following example:

```
INSERT INTO ORDER (ORDERNO, CUSTNO)
VALUES (NEXT VALUE FOR ORDER_SEQ, 123456);
INSERT INTO LINE_ITEM (ORDERNO, PARTNO, QUANTITY)
VALUES (PREVIOUS VALUE FOR ORDER_SEQ, 987654, 1);
```

Allowed use of NEXT VALUE and PREVIOUS VALUE:
The NEXT VALUE and PREVIOUS VALUE expressions can be specified in the following places:

• Within the select-clause of a SELECT statement or SELECT statement that does not contain a DISTINCT keyword, a GROUP BY clause, an ORDER BY clause, or a set operator.
• Within a VALUES clause of an INSERT statement, including a multiple row INSERT statement with multiple VALUES clauses and the insert operation of a MERGE statement, which can include a NEXT VALUE expression for a particular sequence name for each VALUES clause.
• Within the select-clause of the full select of an INSERT statement.
• Within the SET clause of a searched or positioned UPDATE statement, including the update operation of the MERGE statement, though NEXT VALUE cannot be specified in the select-clause of the full select of an expression in the SET clause.

A PREVIOUS VALUE expression can be specified anywhere with a SET clause of an update operation (the UPDATE or MERGE statement), but a NEXT VALUE expression can be specified only in a SET clause if it is not within the select-clause of the full select of an expression. For instance, the following uses of sequence references are supported:

```
UPDATE T SET C1 = (SELECT PREVIOUS VALUE FOR S1 FROM T);
UPDATE T SET C1 = PREVIOUS VALUE FOR S1;
UPDATE T SET C1 = NEXT VALUE FOR S1;
```

The following uses of sequence references are not supported:

```
UPDATE T SET C1 = (SELECT NEXT VALUE FOR S1 FROM T);
SET :C2 = (SELECT NEXT VALUE FOR S1 FROM T);
```

• In a SET host-variable or assignment-statement, except within the select-clause of the full select of an expression.

The following uses of sequence references are supported:

```
SET ORDERNUM = NEXT VALUE FOR INVOICE;
SET ORDERNUM = PREVIOUS VALUE FOR INVOICE;
```

The following uses of sequence references are not supported:

```
SET X = (SELECT NEXT VALUE FOR S1 FROM T);
SET X = (SELECT PREVIOUS VALUE FOR S1 FROM T);
```

• In a VALUES or VALUES INTO statement though not within the select-clause of the full select of an expression.
• Within the SQL-routine-body of a CREATE or ALTER PROCEDURE statement for a SQL procedure.
Within the \textit{RETURN-statement} of a CREATE FUNCTION statement for an SQL function.

Within the \textit{SQL-trigger-body} of a CREATE TRIGGER statement (PREVIOUS VALUE is not allowed).

\textbf{Use of PREVIOUS VALUE in a nested application:}
PREVIOUS VALUE is defined to have a linear scope within an application session. Therefore, in a nested application on entry to a nested function, procedure, or trigger, the nested application inherits the most recently generated value for a sequence. That is, an invocation of PREVIOUS VALUE in a nested application reflects sequence activity done in the invoking environment prior to entering the nested application. In addition, on return from a function, procedure, or trigger, the invoking application is affected by any sequence activity in the lower level applications. That is, an invocation of PREVIOUS VALUE in the invoking application after returning from the nested application reflects any sequence activity that occurred in the lower level applications.

\textbf{Restrictions on the use of NEXT VALUE and PREVIOUS VALUE:}
Some of the places where the NEXT VALUE and PREVIOUS VALUE expressions cannot be specified include the following:

- Join condition of a full outer join
- DEFAULT value for a column in a CREATE TABLE or ALTER TABLE statement
- Materialized query table definition in a CREATE TABLE or ALTER TABLE statement
- Condition of a CHECK constraint
- Input value specification for LOAD
- CREATE VIEW statement
- The SELECT list of a subselect that contains a NOT ATOMIC data change statement
- ORDER BY clause when used in an OLAP specification

In addition, the NEXT VALUE expression cannot be specified in the following places:

- A CASE expression
- The parameter list of an aggregate function
- A subquery in a context other than those explicitly allowed
- A SELECT statement for which the outer SELECT contains a DISTINCT operator or a GROUP BY clause
- A SELECT statement for which the outer SELECT is combined with another SELECT statement using a set operator
- A join condition of a join
- A nested table expression
- The parameter list of a table function
- A select-clause of the fullselect of an expression in the SET clause of an UPDATE, a DELETE, or a MERGE statement.
- A WHERE clause of the outer-most SELECT statement or a DELETE, an UPDATE, or a MERGE statement
- An ORDER BY clause of the outer-most SELECT statement
- The select list of a fullselect that contains an OFFSET clause
- An IF, WHILE, DO UNTIL, or CASE statement in an SQL routine
Using sequence expressions with a cursor:

Normally, a `SELECT NEXT VALUE FOR ORDER_SEQ FROM T1` would produce a result table containing as many generated values from the sequence ORDER_SEQ as the number of rows retrieved from T1. A reference to a NEXT VALUE expression in the SELECT statement of a cursor refers to a value that is generated for a row of the result table. A sequence value is generated for a NEXT VALUE expression each time a row is retrieved.

If blocking is done at a client in a DRDA environment, sequence values might get generated at the Db2 server before the processing of an application’s FETCH statement. If the client application does not explicitly fetch all the rows that have been retrieved from the database, the application will never see all those values of the sequence that are generated but not fetched (as many values as the rows that are not fetched). These generated but not fetched values might constitute a gap in the sequence. If it is important to prevent such a gap in the sequence, do the following:

- Use NEXT VALUE only where it would function without being controlled by a cursor and where block-fetching by the client will have no effect on it.
- If you must use NEXT VALUE in the SELECT statement of a cursor-definition, weigh the importance of preventing the gap against performance and other implications of taking the following actions:
  - Use FETCH FOR 1 ROW ONLY clause with the SELECT statement.
  - Try preventing block-fetch by other means documented in [Block fetch](Introduction to Db2 for z/OS).

Using the PREVIOUS VALUE expression with a cursor:

A reference to the PREVIOUS VALUE expression in a SELECT statement of a cursor is evaluated at OPEN time. In other words, a reference to the PREVIOUS VALUE expression in the SELECT statement of a cursor refers to the last value generated by this application process for the specified sequence prior to the opening of the cursor and, once evaluated at OPEN time, the value returned by PREVIOUS VALUE within the select statement of the cursor will not change from FETCH to FETCH, even if NEXT VALUE is invoked with the select statement of the cursor. After the cursor is closed, the value of PREVIOUS VALUE will be the last NEXT VALUE that is generated by the application process.

IF PREVIOUS VALUE is used in the SELECT statement of a cursor while the cursor is open, the value of PREVIOUS VALUE would be the last NEXT VALUE that was generated for the sequence before the cursor was opened. After the cursor is closed, the value of PREVIOUS VALUE would be the last NEXT VALUE generated by the application process.

Syntax alternatives and synonyms:

For compatibility, the keywords NEXTVAL and PREVVAL can be used as synonyms for NEXT VALUE and PREVIOUS VALUE respectively.

`sequence-name.NEXTVAL` can be specified in place of `NEXT VALUE FOR sequence-name`, and `sequence-name.CURRVAL` can be specified in place of `PREVIOUS VALUE FOR sequence-name`.

Example

Assume that there is a table called ORDER, and that a sequence called ORDER_SEQ is created as follows:
CREATE SEQUENCE ORDER_SEQ START WITH 1
INCREMENT BY 1
NO MAXVALUE
NO CYCLE
CACHE 24

The following examples illustrate how to generate an ORDER_SEQ sequence number with a NEXT VALUE expression:

```
INSERT INTO ORDER (ORDerno, CUSTNO)
VALUES (NEXT VALUE FOR ORDER_SEQ, 123456);
UPDATE ORDER SET ORDerno = NEXT VALUE FOR ORDER_SEQ
WHERE CUSTNO = 123456;
VALUES NEXT VALUE FOR ORDER_SEQ INTO :HV_SEQ;
```

## Predicates

A *predicate* specifies a condition that is true, false, or unknown about a given row or group.

The types of predicates are:

<table>
<thead>
<tr>
<th>basic predicate</th>
<th>quantified predicate</th>
<th>ARRAY_EXISTS predicate</th>
<th>BETWEEN predicate</th>
<th>DISTINCT predicate</th>
<th>EXISTS predicate</th>
<th>IN predicate</th>
<th>LIKE predicate</th>
<th>NULL predicate</th>
<th>XMLEXISTS predicate</th>
</tr>
</thead>
</table>

The following rules apply to predicates of any type:
- Predicates are evaluated after the expressions that are operands of the predicate.
- All values that are specified in the same predicate must be compatible.
- Except for the EXISTS predicate, a subquery in a predicate must specify a single column unless the operand on the other side of the comparison operator is a fullselect.
- The value of a host variable can be null (that is, the variable can have a negative indicator variable).
- The CCSID conversion of operands of predicates that involve two or more operands is done according to “Conversion rules for comparisons” on page 168.
- Use of an XML value is limited to the NULL or XMLEXISTS predicates.

**Row-value-expression**: The operand of several predicates (basic, quantified, DISTINCT, and IN) can be a row-value-expression.
A row-value-expression returns a single row that consists of one or more column values. The values can be specified as a list of expressions. The number of columns that are returned by the row-value-expression is equal to the number of expressions that are specified in the list.

**Other predicate examples:** In addition to the examples of predicates in the following topics, see information on distinct type comparisons in "Assignment and comparison" on page 151, which contains several examples of predicates that use distinct types "Distinct type comparisons" on page 173, which contains several examples of predicates that use distinct types.

**Related concepts:**
- Predicates and access path selection (Db2 Performance)

**Related tasks:**
- Using predicates efficiently (Db2 Performance)
- Writing efficient SQL queries (Db2 Performance)

**Related reference:**
- where-clause
- having-clause

**Basic predicate**

A basic predicate compares two values or compares a set of values with another set of values.

16. The following forms of the comparison operators are also supported in basic and quantified predicates in code pages where the exclamation point is X'5A': !=, !<, and !>. In addition, the forms ¬=, ¬<, and ¬> are supported as long as the code point used for the logical not symbol is the correct one for the specified code page. These forms of the operators are intended only to support existing SQL statements that use them and are not recommended for use when writing new SQL statements.

A logical not sign (¬) can cause parsing errors in statements passed from one DBMS to another. The problem occurs if the statement undergoes character conversion with certain combinations of source and target CCSIDs. To avoid this problem, substitute an equivalent operator for any operator that includes a not sign. For example, substitute '!=' for '¬=', '<=' for '¬>', and '>=' for '¬<'.

Chapter 2. Language elements 315
When *expression* is a fullselect, the fullselect must return a single result column with a single value, whether null or not null. If the value of either operand is null or the result of the fullselect is empty, the result of the predicate is unknown. Otherwise, the result is either true or false.

When a *row-value-expression* is specified on the left side of the operator, another *row-value-expression*, with an identical number of value expressions, must be specified on the right side. The data types of the corresponding expressions or columns of the *row-value-expressions* must be compatible.

If the comparison operator is <, <=, >, or >=, a *row-value-expression* must not reference a non-deterministic expression, a function with external action, or a scalar fullselect.

The value of each expression on the left side is compared with the value of its corresponding expression on the right side. The result of the predicate depends on the operator, as in the following:

- If the operator is =, the result of the predicate is:
  - True - if all pairs of corresponding value expressions evaluate to true.
  - False - if any one pair of corresponding value expressions evaluates to false.
  - Unknown - if the comparisons is neither true nor false. That is, if at least one comparison of corresponding value expressions is unknown because of a null value and no pair of corresponding value expressions evaluates to false.

- If the operator is <>, the result of the predicate (*Rx1,Rx2,...,Rxn*) <> (*Ry1,Ry2,...,Ryn*) is:
  - True - if, and only if, *Rxi=Ryi* evaluates to false for some value of *i*. That is, there is at least one pair of non-null values, *Rx* and *Ry*, that are not equal to each other.
  - False - if, and only if, *Rxi=Ryi* evaluates to true for every value of *i*. That is, *Rx1,Rx2,...,Rxn*=(*Ry1,Ry2,...,Ryn*) is true.
  - Unknown - if the comparison is neither true nor false. That is, *Rx* or *Ry* is a null value for some value of *i*, and there is no value of *j* such that *Rxj=Ryj* evaluates to false.

- If the operator is <, the result of the predicate is:
- True - if, and only if, the first $N$ pairs of the corresponding value expressions are equal and the next pair has the left value expression less than the right value expression for some value of $N$. That is, $Rx = Ry$ is true for all values of $i < n$ and $Rx_n < Ry_n$ is true for some value of $n$.

- False - if, and only if, all pairs of the corresponding value expressions are equal ($Rx = Ry$ is true) or the first $N$ pairs of the corresponding value expressions are equal and the next pair has the right value expression less than the left value expression for some value of $N$. That is, $Rx = Ry$ is true for all values of $i < n$ and $Rx_n <= Ry_n$ is true for some value of $n$.

- Unknown - if the comparison is neither true nor false.

• If the operator is $<=$, the result of the predicate is:

- True - if, and only if, the first $N$ pairs of the corresponding value expressions are equal and the next pair has the left value expression less than or equal to the right value expression for some value of $N$. That is, $Rx = Ry$ is true for all values of $i < n$ and $Rx_n <= Ry_n$ is true for some value of $n$.

- False - if, and only if, all pairs of the corresponding value expressions are equal ($Rx = Ry$ is true) or the first $N$ pairs of the corresponding value expressions are equal and the next pair has the right value expression less than the left value expression for some value of $N$. That is, $Rx = Ry$ is true for all values of $i < n$ and $Rx_n > Ry_n$ is true for some value of $n$.

- Unknown - if the comparison is neither true nor false.

• If the operator is $>$, the result of the predicate is:

- True - if, and only if, the first $N$ pairs of the corresponding value expressions are equal and the next pair has the left value expression greater than the right value expression for some value of $N$. That is, $Rx = Ry$ is true for all values of $i < n$ and $Rx_n > Ry_n$ is true for some value of $n$.

- False - if, and only if, all pairs of the corresponding value expressions are equal ($Rx = Ry$ is true) or the first $N$ pairs of the corresponding value expressions are equal and the next pair has the right value expression greater than the left value expression for some value of $N$. That is, $Rx = Ry$ is true for all values of $i < n$ and $Rx_n <= Ry_n$ is true for some value of $n$.

- Unknown - if the comparison is neither true nor false.

• If the operator is $=>$, the result of the predicate is:

- True - if, and only if, the first $N$ pairs of the corresponding value expressions are equal and the next pair has the left value expression greater than or equal to the right value expression for some value of $N$. That is, $Rx = Ry$ is true for all values of $i < n$ and $Rx_n >= Ry_n$ is true for some value of $n$.

- False - if, and only if, all pairs of the corresponding value expressions are equal ($Rx = Ry$ is true) or the first $N$ pairs of the corresponding value expressions are equal and the next pair has the right value expression greater than the left value expression for some value of $N$. That is, $Rx = Ry$ is true for all values of $i < n$ and $Rx_n < Ry_n$ is true for some value of $n$.

- Unknown - if the comparison is neither true nor false.

Table 55. For values $x$ and $y$

<table>
<thead>
<tr>
<th>Predicate</th>
<th>Is true if and only if ...</th>
</tr>
</thead>
<tbody>
<tr>
<td>$x = y$</td>
<td>$x$ is equal to $y$</td>
</tr>
<tr>
<td>$x &lt;&gt; y$</td>
<td>$x$ is not equal to $y$</td>
</tr>
<tr>
<td>$x &lt; y$</td>
<td>$x$ is less than $y$</td>
</tr>
<tr>
<td>$x &gt; y$</td>
<td>$x$ is greater than $y$</td>
</tr>
</tbody>
</table>
Table 55. For values x and y (continued)

<table>
<thead>
<tr>
<th>Predicate</th>
<th>Is true if and only if ...</th>
</tr>
</thead>
<tbody>
<tr>
<td>x &lt;= y</td>
<td>x is less than or equal to y</td>
</tr>
<tr>
<td>x &gt;= y</td>
<td>x is greater than or equal to y</td>
</tr>
</tbody>
</table>

Examples for values x and y:

EMPNO = '528671'
SALARY < 20000
PRSTAFF <> :VAR1
SALARY >= (SELECT AVG(SALARY) FROM DSNBC10.EMP)

Example: List the name, first name, and salary of the employee who is responsible for the 'SECRET' project. This employee might appear in either the PROJA1 or PROJA2 tables. A UNION is used in case the employee appears in both tables to eliminate duplicate RESPEMP values.

```
SELECT LASTNAME, FIRSTNAME, SALARY
FROM DSNBC10.EMP X
WHERE EMPNO = (SELECT RESPEMP FROM PROJA1 Y
WHERE MAJPROJ = 'SECRET'
UNION
SELECT RESPEMP FROM PROJA2 Z
WHERE MAJPROJ = 'SECRET');
```

Quantified predicate

A quantified predicate compares a value or values with a collection of values.

```
expression = SOME (fullselect1)
(1)
<> ANY
<= ALL

row-value-expression = SOME (fullselect2)

(1)
<> ANY
<= ALL (fullselect2)
```

Notes:

1 Other comparison operators are also supported.¹⁶

When expression is specified, fullselect1 must return a single result column, and can return any number of values, whether null or not null. The result depends on the operator that is specified:

- When the operator is ALL, the result of the predicate is:
  - True – if the result of the fullselect is empty or if the specified relationship is true for every value returned by the fullselect.
– False – if the specified relationship is false for at least one value returned by the fullselect.
– Unknown – if the specified relationship is not false for any values returned by the fullselect and at least one comparison is unknown because of a null value.

• When the operator is SOME or ANY, the result of the predicate is:
  – True – if the specified relationship is true for at least one value returned by the fullselect.
  – False – if the result of the fullselect is empty or if the specified relationship is false for every value returned by the fullselect.
  – Unknown – if the specified relationship is not true for any of the values returned by the fullselect and at least one comparison is unknown because of a null value.

When row-value-expression is specified, the number of result columns returned by fullselect2 must be the same as the number of value expressions specified by row-value-expression, and fullselect2 can return any number of rows of values. The data types of the corresponding expressions of the row value expressions must be compatible. The value of each expression from row-value-expression is compared with the value of the corresponding result column from fullselect2. The value of the predicate depends on the operator that is specified:

• When the operator is ALL, the result of the predicate is:
  – True – if the result of fullselect2 is empty or if the specified relationship is true for every row returned by fullselect2.
  – False – if the specified relationship is false for at least one row returned by fullselect2.
  – Unknown – if the specified relationship is not false for any row returned by fullselect2 and at least one comparison is unknown because of a null value.

• When the operator is SOME or ANY, the result of the predicate is:
  – True – if the specified relationship is true for at least one row returned by fullselect2.
  – False – if the result of the fullselect is empty or if the specified relationship is false for every row returned by fullselect2.
  – Unknown – if the specified relationship is not true for any of the rows returned by fullselect2 and at least one comparison is unknown because of a null value.

Quantified predicates are equivalent to IN predicates. See Table 61 on page 326 for some examples of equivalent quantified and IN predicates.

Examples: Use the following tables when referring to the following examples. In all examples, “row n of TBLA” refers to the row in TBLA for which COLA has the value n.

Table 56. TBLA

<table>
<thead>
<tr>
<th>COLA</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
</tr>
<tr>
<td>2</td>
</tr>
<tr>
<td>3</td>
</tr>
<tr>
<td>4</td>
</tr>
</tbody>
</table>
**Table 57. TBLB**

<table>
<thead>
<tr>
<th>COLB</th>
<th>COLC</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>2</td>
</tr>
<tr>
<td>3</td>
<td>–</td>
</tr>
</tbody>
</table>

**Table 58. TBLC**

<table>
<thead>
<tr>
<th>COLB</th>
<th>COLC</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>2</td>
</tr>
</tbody>
</table>

**Example 1:** In the following predicate, the fullselect returns the values 2 and 3. The predicate is false for rows 1, 2, and 3 of TBLA, and is true for row 4.

\[
\text{COLA} > \text{ALL}(\text{SELECT COLB FROM TBLB} \\ \text{UNION} \\ \text{SELECT COLB FROM TBLC})
\]

**Example 2:** In the following predicate, the fullselect returns the values 2 and 3. The predicate is false for rows 1 and 2 of TBLA, and is true for rows 3 and 4.

\[
\text{COLA} > \text{ANY}(\text{SELECT COLB FROM TBLB} \\ \text{UNION} \\ \text{SELECT COLB FROM TBLC})
\]

**Example 3:** In the following predicate, the fullselect returns the values 2 and null. The predicate is false for rows 1 and 2 of TBLA, and is unknown for rows 3 and 4. The result is an empty table.

\[
\text{COLA} > \text{ALL}(\text{SELECT COLC FROM TBLB} \\ \text{UNION} \\ \text{SELECT COLC FROM TBLC})
\]

**Example 4:** In the following predicate, the fullselect returns the values 2 and null. The predicate is unknown for rows 1 and 2 of TBLA, and is true for rows 3 and 4.

\[
\text{COLA} > \text{SOME}(\text{SELECT COLC FROM TBLB} \\ \text{UNION} \\ \text{SELECT COLC FROM TBLC})
\]

**Example 5:** In the following predicate, the fullselect returns an empty result column. Hence, the predicate is true for all rows of TBLA.

\[
\text{COLA} < \text{ALL}(\text{SELECT COLB FROM TBLB WHERE COLB}>3 \\ \text{UNION} \\ \text{SELECT COLB FROM TBLC WHERE COLB}>3)
\]

**Example 6:** In the following predicate, the fullselect returns an empty result column. Hence, the predicate is false for all rows of TBLA.

\[
\text{COLA} < \text{ANY}(\text{SELECT COLB FROM TBLB WHERE COLB}>3 \\ \text{UNION} \\ \text{SELECT COLB FROM TBLC WHERE COLB}>3)
\]

If COLA were null in one or more rows of TBLA, the predicate would still be false for all rows of TBLA.

**ARRAY_EXISTS predicate**

The ARRAY_EXISTS predicate tests for the existence of an array element with the specified index in an array.
**ARRAY_EXISTS**

(array-expression, array-index)

---

**array-expression**

Specifies one of the following items:

- An SQL variable, SQL parameter, or global variable of an array type
- A CAST specification of an array or parameter marker to an array type.

**array-index**

Specifies the index for the array element that is to be tested. An array index value for an ordinary array must be castable to INTEGER. An array index value for an associative array must be castable to the data type of the array index.

array-index must not be an expression that references any of the following items:

- The CURRENT DATE, CURRENT TIME, or CURRENT TIMESTAMP special register
- A nondeterministic function
- A function that is defined with EXTERNAL ACTION
- A function that is defined with MODIFIES SQL DATA
- A sequence expression

The result of the ARRAY_EXISTS predicate is:

- True if array-expression includes an array index that is equal to the result of casting array-index to the data type of the array index of array-expression.
- False under either of the following conditions:
  - array-expression does not include an array index that is equal to the result of casting array-index to the data type of the array index of array-expression.
  - Either argument is null.
- Cannot be unknown.

**Example:** Suppose that array variable RECENT_CALLS is defined as an ordinary array of array type PHONENUMBERS. The following IF statement tests whether the recent calls list has reached the 40th saved call. If it has, the local integer variable EIGHTY_PERCENT is set to 1:

```sql
IF (ARRAY_EXISTS(RECENT_CALLS, 40))
    THEN SET EIGHTY_PERCENT = 1;
END IF
```

**Related concepts:**

Array types

---

**BETWEEN predicate**

The BETWEEN predicate determines whether a given value lies between two other given values that are specified in ascending order.
Each of the predicate's two forms has an equivalent search condition, as shown in the following table:

**Table 59. BETWEEN predicate and equivalent search conditions**

<table>
<thead>
<tr>
<th>BETWEEN predicate</th>
<th>Equivalent search condition</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>value1 BETWEEN value2 AND value3</code></td>
<td><code>value1 &gt;= value2 AND value1 &lt;= value3</code></td>
</tr>
<tr>
<td><code>value1 NOT BETWEEN value2 AND value3</code></td>
<td><code>value1 &lt; value2 OR value1 &gt; value3</code></td>
</tr>
</tbody>
</table>

or, equivalently:

`NOT(value1 BETWEEN value2 AND value3)`

**Note:** 1. Might not be equivalent if `value1`, `value2`, or `value3` are columns or derived values based on columns that are not the same CCSID set because the clause is evaluated in Unicode.

Search conditions are discussed in [Search conditions](#).

If the operands include a mixture of datetime values and valid string representations of datetime values, all values are converted to the data type of the datetime operand.

**Example:** Consider the following predicate:

\[
A \text{ BETWEEN } B \text{ AND } C
\]

The following table shows the value of the predicate for various values of `A`, `B`, and `C`.

<table>
<thead>
<tr>
<th>Value of <code>A</code></th>
<th>Value of <code>B</code></th>
<th>Value of <code>C</code></th>
<th>Value of predicate</th>
</tr>
</thead>
<tbody>
<tr>
<td>1, 2, or 3</td>
<td>1</td>
<td>3</td>
<td>true</td>
</tr>
<tr>
<td>0 or 4</td>
<td>1</td>
<td>3</td>
<td>false</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
<td>null</td>
<td>false</td>
</tr>
<tr>
<td>4</td>
<td>null</td>
<td>3</td>
<td>false</td>
</tr>
<tr>
<td>null</td>
<td>any value</td>
<td>any value</td>
<td>unknown</td>
</tr>
<tr>
<td>2</td>
<td>1</td>
<td>null</td>
<td>unknown</td>
</tr>
<tr>
<td>3</td>
<td>null</td>
<td>4</td>
<td>unknown</td>
</tr>
</tbody>
</table>

**DISTINCT predicate**

A distinct predicate compares a value with another value or a set of values with another set of values.
expression and row-value-expression cannot be array expressions.

The number of elements that are returned by the row-value-expression that specified after the distinct operator must match the number of elements that are returned by the row-value-expression that is specified prior to the distinct operator. The data types of the corresponding columns or expressions of the row-value-expressions must be compatible. When the predicate is evaluated, the value of each expression on the left side is compared with the value of its corresponding expression on the right side. The result of the predicate depends on the form of the predicate.

When the predicate is IS DISTINCT, the result of the predicate is true if at least one comparison of a pair of corresponding value expressions evaluates to false. Otherwise, the result of the predicate is false. The result cannot be unknown.

When the predicate IS NOT DISTINCT FROM, the result of the predicate is true if all pairs of corresponding value expressions evaluate to true (null values are considered equal to null values). Otherwise, the predicate is false. The result cannot be unknown.

The DISTINCT predicate cannot be used in the following contexts:
- The ON join-condition of a full outer join
- A check constraint
- A quantified predicate

The following DISTINCT predicates are logically equivalent to the corresponding search conditions:

<table>
<thead>
<tr>
<th>DISTINCT predicate</th>
<th>Search condition</th>
</tr>
</thead>
<tbody>
<tr>
<td>value 1 IS NOT DISTINCT FROM value2</td>
<td>(value1 IS NOT NULL AND value2 IS NOT NULL AND value1 = value 2) OR (value1 IS NULL AND value2 IS NULL)</td>
</tr>
<tr>
<td>value 1 IS DISTINCT FROM value2</td>
<td>NOT (value1 IS NOT DISTINCT FROM value2)</td>
</tr>
</tbody>
</table>

Example 1: Assume that T1 is a single-column table with three rows. Column C1 has the following values: 1, 2, and null. Consider the following query:

```sql
SELECT * FROM T1
WHERE C1 IS DISTINCT FROM :HV;
```

The following table shows the value of the predicate for various values of C1 and the host variable.

<table>
<thead>
<tr>
<th>Value of C1</th>
<th>Value of HV</th>
<th>Result of predicate</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2</td>
<td>True</td>
</tr>
<tr>
<td>Value of C1</td>
<td>Value of HV</td>
<td>Result of predicate</td>
</tr>
<tr>
<td>------------</td>
<td>------------</td>
<td>---------------------</td>
</tr>
<tr>
<td>2</td>
<td>2</td>
<td>False</td>
</tr>
<tr>
<td>null</td>
<td>2</td>
<td>True</td>
</tr>
<tr>
<td>1</td>
<td>null</td>
<td>True</td>
</tr>
<tr>
<td>2</td>
<td>null</td>
<td>True</td>
</tr>
<tr>
<td>null</td>
<td>null</td>
<td>False</td>
</tr>
</tbody>
</table>

Example 2: Assume the same table as in the first example, but now consider the negative form of the predicate in the query:

```sql
SELECT *
FROM T1
WHERE C1 IS NOT DISTINCT FROM :HV;
```

The following table shows the value of the predicate for various values of C1 and the host variable.

<table>
<thead>
<tr>
<th>Value of C1</th>
<th>Value of HV</th>
<th>Result of predicate</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2</td>
<td>False</td>
</tr>
<tr>
<td>2</td>
<td>2</td>
<td>True</td>
</tr>
<tr>
<td>null</td>
<td>2</td>
<td>False</td>
</tr>
<tr>
<td>1</td>
<td>null</td>
<td>False</td>
</tr>
<tr>
<td>2</td>
<td>null</td>
<td>False</td>
</tr>
<tr>
<td>null</td>
<td>null</td>
<td>True</td>
</tr>
</tbody>
</table>

**EXISTS predicate**

The EXISTS predicate tests for the existence of certain rows. The fullselect can specify any number of columns, and can result in true or false.

The result of the EXISTS predicate:

- Is true only if the number of rows that is specified by the fullselect is not zero.
- Is false only if the number of rows specified by the fullselect is zero.
- Cannot be unknown.

The SELECT clause in the fullselect can specify any number of columns because the values returned by the fullselect are ignored. For convenience, use:

```sql
SELECT *
```
Unlike the NULL, LIKE, and IN predicates, the EXISTS predicate has no form that contains the word NOT. To negate an EXISTS predicate, precede it with the logical operator NOT, as follows:

\[
\text{NOT EXISTS (fullselect)}
\]

The result is then false if the EXISTS predicate is true, and true if the predicate is false. Here, NOT is a logical operator and not a part of the predicate. Logical operators are discussed in “Search conditions” on page 339.

**Example 1:** The following query lists the employee number of everyone represented in DSN8C10.EMP who works in a department where at least one employee has a salary less than 20000. Like many EXISTS predicates, the one in this query involves a correlated variable.

```sql
SELECT EMPNO
FROM DSN8C10.EMP
WHERE EXISTS (SELECT * FROM DSN8C10.EMP
  WHERE X.WORKDEPT=WORKDEPT AND SALARY<20000);
```

**Example 2:** List the subscribers (SNO) in the state of California who made at least one call during the first quarter of 2009. Order the results according to SNO. Each MONTH table has columns for SNO, CHARGES, and DATE. The CUST table has columns for SNO and STATE.

```sql
SELECT C.SNO
FROM CUST C
WHERE C.STATE = 'CA'
AND EXISTS (SELECT *
  FROM MONTH1
  WHERE DATE BETWEEN '01/01/2009 AND '01/31/2009'
  AND C.SNO = SNO
UNION ALL
SELECT *
  FROM MONTH2
  WHERE DATE BETWEEN '02/01/2009 AND '02/28/2009'
  AND C.SNO = SNO
UNION ALL
SELECT *
  FROM MONTH3
  WHERE DATE BETWEEN '03/01/2009 AND '03/31/2009'
  AND C.SNO = SNO)
ORDER BY C.SNO;
```

**IN predicate**

The IN predicate compares a value or values with a set of values.
When `expression1` is specified, the IN predicate compares a value with a set of values. When `fullselect1` is specified, the fullselect must return a single result column, and can return any number of values, whether null or not null. The data type of `expression1` and the data type of the result column of `fullselect1` or `expression2` must be compatible. If `expression` is a single host variable, the host variable can identify a structure. Any host variable or structure that is specified must be described in the application program according to the rules for declaring host structures and variables.

When a `row-value-expression` is specified, the IN predicate compares values with a collection of values. The result table of the `fullselect2` must have the same number of columns as the `row-value-expression`. The data type of each expression in `row-value-expression` and the data type of its the corresponding result column of `fullselect2` must be compatible. The value of each expression in `row-value-expression` is compared with the value of its corresponding result column of `fullselect2`. The value of the predicate depends on the operator that is specified:

- When the operator is IN, the result of the predicate is:
  - True if at least one row returned from `fullselect2` is equal to the `row-value-expression`.
  - False if the result of `fullselect2` is empty or if no row returned from `fullselect2` is equal to the `row-value-expression`.
  - Otherwise, unknown (that is, if the comparison of `row-value-expression` to the row returned from `fullselect2` evaluates to unknown because of a null value for at least one row returned from `fullselect2` and no row returned from `fullselect2` is equal to the `row-value-expression`).

- When the operator is NOT IN, the result of the predicate is:
  True if the result of `fullselect2` is empty or if the `row-value-expression` is not equal to any of the rows returned by `fullselect2`.
  False if the `row-value-expression` is equal to at least one row returned by `fullselect2`.
  Otherwise, unknown (that is, if the comparison of `row-value-expression` to the row returned from `fullselect2` evaluates to unknown because of a null value for at least one row returned from `fullselect2` and the comparison of `row-value-expression` to the row returned from `fullselect2` is not true for any row returned by the `fullselect2`).

The IN predicate is equivalent to the quantified predicate as follows:

<table>
<thead>
<tr>
<th>IN predicate</th>
<th>Equivalent quantified predicate</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>expression1</code> IN <code>(expression2)</code></td>
<td><code>expression1 = expression2</code></td>
</tr>
<tr>
<td><code>expression</code> IN <code>(fullselect1)</code></td>
<td><code>expression = ANY (fullselect1)</code></td>
</tr>
<tr>
<td><code>expression</code> NOT IN <code>(fullselect1)</code></td>
<td><code>expression &lt;&gt; ALL (fullselect1)</code></td>
</tr>
</tbody>
</table>

---

326 SQL Reference
Table 61. IN predicate and equivalent quantified predicates (continued)

<table>
<thead>
<tr>
<th>IN predicate</th>
<th>Equivalent quantified predicate</th>
</tr>
</thead>
<tbody>
<tr>
<td>expression1 IN (expressiona,</td>
<td>expression1 IN (SELECT * FROM R)</td>

<td>row-value-expression = ANY (fullselect2)</td>
</tr>
<tr>
<td>row-value-expression NOT IN (fullselect2)</td>
<td>row-value-expression &lt;&gt; ALL (fullselect2)</td>
</tr>
</tbody>
</table>

If the operands of the IN predicate have different data types or attributes, the rules that are used to determine the data type for evaluation of the IN predicate are those for UNION, EXCEPT, and INTERSECT. For a description, see “Rules for result data types” on page 174.

If the operands of the IN predicate are strings with different CCSIDs, the rules used to determine which operands are converted are those for operations that combine strings. See “Character and graphic string comparisons” on page 166.

Example 1: The following predicate is true for any row whose employee is in department D11, B01, or C01.

```sql
WORKDEPT IN ('D11','B01','C01')
```

Example 2: The following predicate is true for any row whose employee works in department E11.

```sql
EMPNO IN (SELECT EMPNO FROM DSNBC10.EMP
WHERE WORKDEPT = 'E11')
```

Example 3: The following predicate is true if the date that a project is estimated to start (PRENDATE) is within the next two years.

```sql
YEAR(PRENDATE) IN (YEAR(CURRENT DATE),
YEAR(CURRENT DATE + 1 YEAR),
YEAR(CURRENT DATE + 2 YEARS))
```

Example 4: The following example obtains the phone number of an employee in DSN8C10.EMP where the employee number (EMPNO) is a value specified within the COBOL structure defined below.

```sql
77 PHNUM PIC X(6).
01 EMPNO-STRUCTURE.
  05 CHAR-ELEMENT-1 PIC X(6) VALUE '000140'.
  05 CHAR-ELEMENT-2 PIC X(6) VALUE '000340'.
  05 CHAR-ELEMENT-3 PIC X(6) VALUE '000220'.
  ... EXEC SQL DECLARE PHCURS CURSOR FOR
```
SELECT PHONENO FROM DSN8C10.EMP
WHERE EMPNO IN
( :EMPNO-STRUCTURE.CHAR-ELEMENT-1,
  :EMPNO-STRUCTURE.CHAR-ELEMENT-2,
  :EMPNO-STRUCTURE.CHAR-ELEMENT-3)
END-EXEC.
EXEC SQL OPEN PHCURS
END-EXEC.
EXEC SQL FETCH PHCURS INTO :PHNUM
END-EXEC.

LIKE predicate
The LIKE predicate searches for strings that have a certain pattern.

match-expression LIKE pattern-expression NOT ESCAPE escape-expression

The match-expression is the string to be tested for conformity to the pattern specified in pattern-expression. Underscore and percent sign characters in the pattern have a special meaning instead of their literal meanings unless escape-expression is specified. For more information, see the description of pattern-expression.

The following rules summarize how a predicate in the form of m LIKE p is evaluated:
• If m or p is null, the result of the predicate is unknown.
• If m and p are both empty, the result of the predicate is true.
• If m is empty and p is not, the result of the predicate is unknown unless p consists of one or more percent signs.
• If m is not empty and p is empty, the result of the predicate is false.
• Otherwise, if m matches the pattern in p, the result of the predicate is true. The description of pattern-expression provides a detailed explanation on how the pattern is matched to evaluate the predicate to true or false.

The way the pattern is matched to evaluate the predicate changes when LIKE blank insignificant behavior is enabled. For more information, see "LIKE blank insignificant behavior subsystem parameter" on page 334.

The values for match-expression, pattern-expression, and escape-expression must all be character or graphic strings or a mixture of both or they must all be binary strings (BLOBs). None of the expressions can yield a distinct type; however, an expression can be a function that casts a distinct type to its source type.

There are slight differences in what expressions are supported for each argument. The description of each argument lists the supported expressions.

match-expression
An expression that specifies the string to be tested for conformity to a certain pattern of characters.

LIKE pattern-expression
An expression that specifies the pattern of characters to be matched.

The expression can be specified by any one of the following:
- A constant
- A special register
- A variable
- A scalar function whose arguments are any of the above (though nested function invocations cannot be used)
- An array element specification
- A CAST specification whose arguments are any of the above
- An expression that concatenates (using CONCAT or ||) any of the above

The expression must also meet these restrictions:
- The maximum length of `pattern-expression` must not be larger than 4000 bytes.
- If a host variable is used in `pattern-expression`, the host variable must be defined in accordance with the rules for declaring string host variables and must not be a structure. For more information about the use of host variables with specific programming languages, see [Host variables (Db2 Application programming and SQL)](https://www.ibm.com/support/knowledgecenter/SSEK75_11.1.0/com.ibm.db2.luw.sql.ref.doc/doc/r000032m.html).
- If `escape-expression` is specified, `pattern-expression` must not contain the escape character that is identified by `escape-expression`, except when immediately followed by the escape character, `%`, or `_`. For example, if `+` is the escape character, any occurrences of `+` other than `++`, `+_*`, or `*_%` in the pattern is an error.

The pattern is used to specify the conformance criteria for values in the `match-expression` where:
- The underscore character (_) represents any single character.
- The percent sign (%) represents a string of zero or more characters.
- Any other character represents a single occurrence of itself.

If the `pattern-expression` must include either the underscore or the percent character, the `escape-expression` is used to specify a character to precede either the underscore or percent character in the pattern. For character strings, the terms `character`, `percent sign`, and `underscore` refer to SBCS characters. For graphic strings, the terms refer to double-byte or UTF-16 characters.

If the pattern is specified in a fixed-length string variable, any trailing blanks are interpreted as part of the pattern. Therefore, it is better to use a varying-length string variable with an actual length that is the same as the length of the pattern. If the host language does not allow varying-length string variables, place the pattern in a fixed-length string variable whose length is the length of the pattern.
A rigorous description of the pattern: This more rigorous description of the pattern ignores the use of the escape-expression.

Let m denote the value of match-expression and let p denote the value of pattern-expression. The string p is interpreted as a sequence of the minimum number of substring specifiers so each character of p is part of exactly one substring specifier. A substring specifier is an underscore, a percent sign, or any non-empty sequence of characters other than an underscore or a percent sign.

The result of the predicate is unknown if m or p is the null value. Otherwise, the result is either true or false. The result is true if m and p are both empty strings or there exists a partitioning of m into substrings such that:

- A substring of m is a sequence of zero or more contiguous characters and each character of m is part of exactly one substring.
- If the nth substring specifier is an underscore, the nth substring of m is any single character.
- If the nth substring specifier is a percent sign, the nth substring of m is any sequence of zero or more characters.
- If the nth substring specifier is neither an underscore nor a percent sign, the nth substring of m is equal to that substring specifier and has the same length as that substring specifier.
- The number of substrings of m is the same as the number of substring specifiers.

It follows that if p is an empty string and m is not an empty string, the result is false. Similarly, if m is an empty string and p is not an empty string consisting of a value other than percentage signs, the result is false.

The predicate m NOT LIKE p is equivalent to the search condition NOT (m LIKE p).

Mixed data patterns: If match-expression represents mixed data, the pattern is assumed to be mixed data. For ASCII and EBCDIC, the special characters in the pattern are interpreted as follows:

- An SBCS underscore refers to one SBCS character.
- A DBCS underscore refers to one MBCS character.
- A percent sign (either SBCS or DBCS) refers to a string of zero or more SBCS or MBCS characters.

For EBCDIC, redundant shift bytes in match-expression or pattern-expression are ignored.

For Unicode, the special characters in the pattern are interpreted as follows:

- An SBCS or DBCS underscore refers to one character (either SBCS or MBCS).
- A percent sign (either SBCS or DBCS) refers to a string of zero or more SBCS or MBCS characters.

When the LIKE predicate is used with Unicode data, the Unicode percent sign and underscore use the code points indicated in the following table:

<table>
<thead>
<tr>
<th>Character</th>
<th>UTF-8</th>
<th>UTF-16</th>
</tr>
</thead>
<tbody>
<tr>
<td>Half-width %</td>
<td>X'25'</td>
<td>X'0025'</td>
</tr>
<tr>
<td>Full-width %</td>
<td>X'EFBC85'</td>
<td>X'FF05'</td>
</tr>
<tr>
<td>Half-width_</td>
<td>X'5F'</td>
<td>X'005F'</td>
</tr>
<tr>
<td>Full-width_</td>
<td>X'EFBCBF'</td>
<td>X'FF3F'</td>
</tr>
</tbody>
</table>

The full-width or half-width % matches zero or more characters. The full-width or half-width_ character matches exactly one character. (For ASCII or EBCDIC...
data, a full-width _ character matches one DBCS character.)

**Binary data patterns**: For columns with binary data, the pattern contains bytes. The special bytes in the pattern are interpreted as follows:
- The code point for an SBCS underscore (X'6D') refers to 1 byte.
- The code point for an SBCS percent (X'6C') refers to any number of bytes.

**Parameter marker**:

When the pattern specified in a LIKE predicate is a parameter marker and a fixed-length character variable is used to replace the parameter marker, specify a value for the variable that is the correct length. If you do not specify the correct length, the select does not return the intended results.

For example, if the variable is defined as CHAR(10) and the value 'WYSE%' is assigned to that variable, the variable is padded with blanks on assignment. The pattern used is 'WYSE%   ', which requests Db2 to search for all values that start with 'WYSE' and end with five blank spaces unless LIKE blank insignificant behavior is in effect. If the search was intended to search only for the values that start with 'WYSE', then assign the value 'WYSE%%%%%' to the variable.

**ESCAPE escape-expression**

An expression that specifies the escape character to be used to modify the special meaning of the underscore (_) and percent (%) characters in pattern-expression. Specifying an expression, which is optional, allows the LIKE predicate to explicitly test that the value contains a '%' or '_' in the character positions that you want. The escape character consists of a single SBCS (1 byte) or DBCS (2 bytes) character. An escape clause is allowed for Unicode mixed (UTF-8) data, but is restricted for ASCII and EBCDIC mixed data.

The expression can be specified by:
- A constant
- A variable
- A scalar function whose arguments are any of the above (though nested function invocations cannot be used)
- A CAST specification whose arguments are any of the above

The following rules also apply to the use of the **ESCAPE** clause and escape-expression:
- The result of escape-expression must be one SBCS or DBCS character or a binary string that contains exactly 1 byte.
- The **ESCAPE** clause cannot be used if match-expression is mixed data.
- If escape-expression is specified by a host variable, the host variable must be defined in accordance with the rules for declaring fixed-length string host variables. If the host variable has a negative indicator variable, the result of the predicate is unknown.
- The pattern must not contain the escape character except when followed by the escape character, '%' or '_'. For example, if '+' is the escape character, any occurrences of '+' other than '++', '+_', or '+%' in the pattern is an error.

The following table shows the effect of successive occurrences of the escape character, which in this case is the plus sign (+).

---

17. If it is NUL-terminated, a C character string variable of length 2 can be specified.
Table 62. Effect of successive occurrences of the escape character

<table>
<thead>
<tr>
<th>When the pattern string is...</th>
<th>The actual pattern is...</th>
</tr>
</thead>
<tbody>
<tr>
<td>+%</td>
<td>A percent sign</td>
</tr>
<tr>
<td>+++%</td>
<td>A plus sign followed by zero or more arbitrary characters</td>
</tr>
<tr>
<td>++++%</td>
<td>A plus sign followed by a percent sign</td>
</tr>
</tbody>
</table>

**Examples**

*Example 1:* The following predicate is true when the string to be tested in NAME has the value SMITH, NESMITH, SMITHSON, or NESMITHY. It is not true when the string has the value SMYTHE:

```
NAME LIKE '%SMITH%'
```

*Example 2:* In the predicate below, a host variable named PATTERN holds the string for the pattern:

```
NAME LIKE :PATTERN ESCAPE '+'
```

Assume that the string in PATTERN has the following value:

```
AB_C_%
```

Observe that in this string, the plus sign preceding the first underscore is an escape character. The predicate is true when the string being tested in NAME has the value AB_CD or AB_CDE. It is false when this string has the value AB, AB_, or AB_C.

*Example 3:* The following two predicates are equivalent; three of the four percent signs in the first predicate are redundant.

```
NAME LIKE 'AB%%%%CD'
NAME LIKE 'AB%CD'
```

*Example 4:* Assume that a distinct type named ZIP_TYPE with a source data type of CHAR(5) exists and an ADDRZIP column with data type ZIP_TYPE exists in some table TABLEY. The following statement selects the row if the zip code (ADDRZIP) begins with '9555'.

```
SELECT * FROM TABLEY
WHERE CHAR(ADDRZIP) LIKE '9555%'
```

*Example 5:* The RESUME column in sample table DSN8C10.EMP_PHOTO_RESUME is defined as a CLOB. The following statement selects the RESUME column when the string JONES appears anywhere in the column.

```
SELECT RESUME FROM DSN8C10.EMP_PHOTO_RESUME
WHERE RESUME LIKE '%JONES%'
```

*Example 6:* In the following table, assume COL1 is a column that contains mixed EBCDIC data. The table shows the results when the predicate in the first column is evaluated using the COL1 value in the second column:
Example 7: In the following table, assume COL1 is a column that contains mixed ASCII data. The table shows the results when the predicate in the first column is evaluated using the COL1 value in the second column:

<table>
<thead>
<tr>
<th>Predicates</th>
<th>COL1 Values</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>WHERE COL1 LIKE 'aaa AB%C';</td>
<td>'aaa ABdZC';</td>
<td>True</td>
</tr>
<tr>
<td>WHERE COL1 LIKE 'aaa AB% C';</td>
<td>'aaa AB dzx C';</td>
<td>True</td>
</tr>
<tr>
<td>WHERE COL1 LIKE 'a% C';</td>
<td>'a C';</td>
<td>True</td>
</tr>
<tr>
<td></td>
<td>'ax C';</td>
<td>True</td>
</tr>
<tr>
<td></td>
<td>'ab DE fg C';</td>
<td>True</td>
</tr>
<tr>
<td>WHERE COL1 LIKE 'a_ C';</td>
<td>'a% C';</td>
<td>True</td>
</tr>
<tr>
<td></td>
<td>'a XC';</td>
<td>False</td>
</tr>
<tr>
<td>WHERE COL1 LIKE 'a_ C';</td>
<td>'a XC';</td>
<td>True</td>
</tr>
<tr>
<td></td>
<td>'ax C';</td>
<td>False</td>
</tr>
<tr>
<td>WHERE COL1 LIKE ''</td>
<td>Empty string</td>
<td>True</td>
</tr>
<tr>
<td>WHERE COL1 LIKE 'ab C_ '</td>
<td>'ab C d';</td>
<td>True</td>
</tr>
<tr>
<td></td>
<td>'ab_ C d';</td>
<td>True</td>
</tr>
</tbody>
</table>

Example 8: In the following table, assume COL1 is a column that contains Unicode data. The table shows the results when the predicate in the first column is evaluated using the COL1 value in the second column:

<table>
<thead>
<tr>
<th>Predicates</th>
<th>COL1 Values</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>WHERE COL1 LIKE 'aaa AB %C'</td>
<td>'aaa ABdZC'</td>
<td>True</td>
</tr>
<tr>
<td>WHERE COL1 LIKE 'aaa AB % C'</td>
<td>'aaa AB dzx C'</td>
<td>True</td>
</tr>
</tbody>
</table>

Table 63. COL1 contain Unicode data
LIKE blank insignificant behavior subsystem parameter

When the LIKE_BLANK_INSIGNIFICANT subsystem parameter is enabled, all of the blanks at the end of a fixed-length string are ignored. This behavior is called LIKE blank insignificant behavior. LIKE blank significant behavior, in which the blanks at the end of fixed-length strings are significant (not ignored), is the default behavior during installation or migration. For variable length strings, blanks are significant.

When you set the LIKE_BLANK_INSIGNIFICANT subsystem parameter, LIKE blank insignificant behavior takes effect the next time an SQL query statement with the LIKE predicate is executed after the statement is bound or prepared. If the statement is not prepared or bound, the LIKE behavior exhibits LIKE blank significant behavior regardless of the subsystem parameter setting.

For the following functions, enabling or disabling LIKE blank insignificant behavior takes effect immediately. This applies to both an explicit LIKE predicate (for example, UNLOAD) and an implicit LIKE predicate (for example, table check constraint).

- INSERT
- UPDATE
- UNLOAD
- REORG
- LOAD
- CHECK DATA

Before the LIKE predicate is applied, any trailing blanks in a CHARACTER or GRAPHIC column are stripped to the last non-blank character. If the column contains all blanks, the blank in character position 1 is not stripped. After stripping occurs, the LIKE predicate is applied against the stripped column data.

Tip: After you enable the LIKE_BLANK_INSIGNIFICANT subsystem parameter, existing rows might not conform to table check constraints that contain a LIKE predicate. Consider running the CHECK DATA utility on all affected tables to find the records that do not conform to the table check constraint.

The following examples, in which b represents a blank character, demonstrate how the LIKE predicate is evaluated when LIKE blank insignificant behavior is enabled.

---

**Table 63. COL1 contain Unicode data (continued)**

<table>
<thead>
<tr>
<th>Predicates</th>
<th>COL1 values</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>WHERE COL1 LIKE '%b'</td>
<td>'aaaABDZC'</td>
<td>True</td>
</tr>
<tr>
<td></td>
<td>'aaaABdzxC'</td>
<td>True</td>
</tr>
<tr>
<td></td>
<td>empty string</td>
<td>True</td>
</tr>
<tr>
<td>WHERE COL1 LIKE 'b%'</td>
<td>'aaaABDZC'</td>
<td>True</td>
</tr>
<tr>
<td></td>
<td>'aaaABdzxC'</td>
<td>True</td>
</tr>
<tr>
<td></td>
<td>empty string</td>
<td>False</td>
</tr>
<tr>
<td>WHERE COL1 LIKE 'b'</td>
<td>'aaaABDZC'</td>
<td>False</td>
</tr>
<tr>
<td></td>
<td>'aaaABdzxC'</td>
<td>False</td>
</tr>
<tr>
<td></td>
<td>empty string</td>
<td>False</td>
</tr>
</tbody>
</table>
SELECT C1
FROM T1
WHERE C1 LIKE 'xyz';

This LIKE predicate will match the following fixed-length strings:

- abcxyz
- abcxyzb
- abcxyzbb
- abcxyzbb..b

While trailing blanks in the column data are insignificant, trailing blanks in the LIKE predicate are significant. The following example, in which b represents a blank character, applies to when the LIKE predicate contains one or more trailing blanks.

SELECT C1
FROM T1
WHERE C1 LIKE 'xyzbb';

This LIKE predicate will not match the following fixed-length strings:

- abcxyz
- abcxyzb
- abcxyzbb
- abcxyzbbb

The following example applies to when the LIKE predicate contains one or more single characters (_) in the last position.

SELECT C1
FROM T1
WHERE C1 LIKE 'xyz_';

This LIKE predicate will not match the following fixed-length strings, because they are all stripped to the 'abcxyz' string:

- abcxyz
- abcxyzb
- abcxyzbb
- abcxyzbb..b

The following example applies to when the LIKE predicate contains more than one single character (_) in the last position.

SELECT C1
FROM T1
WHERE C1 LIKE 'xyz__';

This LIKE predicate will not match the following fixed-length strings:

- abcxyz
- abcxyzb
- abcxyzbb
- abcxyzbb..b

The following example applies to when the LIKE predicate contains more than one single character (_) and a string of zero or more characters (%) are in the last positions.
SELECT C1
FROM T1
WHERE C1 LIKE '%xyz_%';

This LIKE predicate will not match the following fixed-length strings:
- abcxyz
- abcxyzb
- abcxyzbb
- abcxyzbb..b

If the column data contains all blanks, every blank, except the blank in character
position one, is stripped before the LIKE predicate is applied. For example, a
CHAR(6) column contains the following values:

```
bbbbbb
```

The following LIKE predicates will match:
- LIKE 'b'
- LIKE '_'
- LIKE '%'

The following LIKE predicates will not match:
- LIKE 'bbbbbbb'
- LIKE 'bbbb___'
- LIKE '_______'

**NULL predicate**

The NULL predicate tests for null values.

![NULL predicate diagram]

The result of a NULL predicate cannot be unknown. If the value of the expression
is null, the result is true. If the value is not null, the result is false. If NOT is
specified, the result is reversed.

A parameter marker must not be specified for or within the expression.

**Notes**

**Syntax alternatives:**

For compatibility with other SQL dialects, you can use ISNULL as
an alternative syntax for IS NULL and NOTNULL as alternative syntax for
IS NOT NULL.

**Example 1:** The following predicate is true whenever PHONENO has the null
value, and is false otherwise.

```
PHONENO IS NULL
```
Example 2: The following predicate is true whenever the array MYARRAY has the null value, and is false otherwise.

MYARRAY IS NULL

**XMLEXISTS predicate**

The XMLEXISTS predicate tests whether an XQuery expression returns a sequence of one or more items.

```
>> XMLEXISTS xquery-expression-constant
     PASSING BY REF xquery-argument
```

Notes:
1. *xquery-context-item-expression* must not be specified more than one time.

**xquery-argument**

```
>> xquery-context-item-expression
    AS identifier
```

**xquery-expression-constant**

Specifies a character string constant that is interpreted as an XQuery expression using supported XQuery language syntax. For information about the XQuery language syntax, see [Overview of pureXML (Db2 Programming for XML)](https://www.ibm.com/support/knowledgecenter/SS5R02_11.1.0/com.ibm.db2.luw.ur.ref.doc/doc/r_odxmlx.html). *xquery-expression-constant* cannot be an XQuery updating expression. The XQuery expression is evaluated with the arguments specified in *xquery-argument*. *xquery-expression-constant* must not be an empty string or a string of all blanks.

**PASSING**

Specifies input values and the manner in which these values are passed to the XQuery expression specified by *xquery-expression-constant*.

**BY REF**

Specifies that the XML input value arguments are to be passed by reference. When XML values are passed by reference, the XQuery evaluation uses the input node trees, preserving all properties including the original node identities and document order. If two arguments pass the same XML value, node identity comparisons and document ordering comparisons that involve some nodes that are contained between the two input arguments might refer to nodes within the same XML node tree.

This clause has no impact on how non-XML values are passed. The non-XML values create a new copy of the value during the cast to XML.
**xquery-argument**

Specifies an argument to use in the evaluation of the XQuery expression specified by `xquery-expression-constant`. A query argument is an expression that returns a value that is XML, integer, decimal, or a character or graphic string that is not a LOB. `xquery-argument` must not return ROWID, TIMESTAMP, binary string, REAL, DECFLOAT data types, or a character string data type that is bit data, and must not reference a sequence expression or a OLAP-specification.

An argument specifies a value and the manner in which that value is to be passed. How an argument in the PASSING clause is used in the XQuery expression depends on whether the argument is specified as the `xquery-context-item-expression` or an `xquery-variable-expression`. The argument includes an SQL expression that is evaluated before passing the result to the XQuery expression.

- If the resulting value is an XML value, it becomes an `input-xml-value`. It is passed by reference which means that the original values, not copies, are used in the evaluation of the XQuery expression.
- If the resulting value is not an XML value, the result of the expression must be able to be cast to an XML value. The cast value becomes an `input-xml-value`. An empty string is converted to an XML empty string.
- If the resulting value is a null value, it is converted to an XML empty sequence if the argument is `xquery-variable-expression`. If the argument is `xquery-context-expression`, the XMLEXISTS predicates returns unknown.

**xquery-context-item-expression**

`xquery-context-item-expression` specifies the initial context item in the XQuery expression specified by `xquery-expression-constant`. The value of the initial context item is the result of `xquery-context-item-expression` cast to XML. `xquery-context-item-expression` must not be specified more than one time.

`xquery-context-item-expression` must not be a sequence of more than one item. If the result of `xquery-context-item-expression` is an empty string, the XQuery expression is evaluated with the initial context item set to an XML empty string.

If the `xquery-context-item-expression` is not specified or is an empty string, the initial context item in the XQuery expression is undefined, and the XQuery expression must not reference the initial context item. An XQuery variable is not created for the context item expression.

If the `xquery-context-expression` is not specified or the `input-xml-value` that results from the `xquery-context-expression` is an XML empty sequence, the initial context item is undefined. If the XQuery expression refers to the initial context item, it must be specified with a value that is not an XML empty sequence.

**xquery-variable-expression**

`xquery-variable-expression` specifies an argument to the XQuery expression. An XQuery variable is created for each `xquery-variable-expression`, and the XQuery variable is set to the result of `xquery-argument-expression` cast to XML. If the result of `xquery-variable-expression` is an empty string, the XQuery variable is set to an XML empty string. If `xquery-variable-expression` is null, the XQuery variable is set to an XML empty sequence. For example, PASSING T.A + T.B as "sum" creates an XQuery variable named sum. The scope of the XQuery variables created from the PASSING clause is the XQuery expression that is specified by `xquery-expression-constant`. 

338  SQL Reference
AS identifier

Specifies that the value that is generated by xquery-variable-expression will be passed to xquery-expression-constant as an XQuery variable named identifier. The length of the name must not be longer than 128 bytes. The leading dollar sign ($) that precedes variable names in the XQuery language is not included in identifier. The name must be an XML NCName that is not the same as identifier for another xquery-variable-expression in the same PASSING clause.

The result of the predicate is determined as follows:

- The result is unknown if xquery-context-item-expression specified in the PASSING clause is a NULL value
- the result is false if the result of the XQuery expression is an empty sequence
- the result is true in all other cases

If the evaluation of the XQuery expression results in an error, XMLEXISTS returns an error. The XMLEXISTS predicate is not supported in ON clause of outer joins.

Example: Find all the purchase orders that buy a baby monitor. This example finds the product number for baby monitors from the product table and joins the result to the PurchaseOrders table. It then evaluates the XQuery expression //item[@partNum = $n] for each row and returns those rows that contain an item element node with a partNum attribute that is equal to the product number of ‘Baby Monitor’. The context item for the XQuery expression is PO.POrder. An XQuery variable, $n, is created and initialized to the value of S.prodno:

```
SELECT S.prodno, count(*) as result
FROM PurchaseOrders PO, Products S
WHERE XMLEXISTS ('//item[@partNum = $n]' PASSING PO.POrder,
    S.prodno AS "n")
    AND S.prod_name = 'Baby Monitor';
```

The results might be similar to the following:

<table>
<thead>
<tr>
<th>Prodno</th>
<th>result</th>
</tr>
</thead>
<tbody>
<tr>
<td>926-AA</td>
<td>1</td>
</tr>
</tbody>
</table>

Search conditions

A search condition specifies a condition that is true, false, or unknown about a given row or group. When the condition is true, the row or group qualifies for the results. When the condition is false or unknown, the row or group does not qualify.
Selectivity

**SELECTIVITY numeric-constant**

Specifies the expected selectivity percentage for the predicate. You can specify the SELECTIVITY clause only when the predicate contains one of the indexable spatial predicate functions and the predicate is in the form of `spatial-predicate-function operator expression`, where `operator` is either `=` or `<`. The selectivity value must be an integer or decimal constant value in the range from 0 to 1 (inclusive). For example, if you specify 0.01, the spatial predicate function is expected to filter out all but one percent of all the rows in the table. An error is returned if the SELECTIVITY clause is specified for a non-spatial predicate function.

The result of a search condition is derived by application of the specified logical operators (AND, OR, NOT) to the result of each specified predicate. If logical operators are not specified, the result of the search condition is the result of the specified predicate.

AND and OR are defined in the following table, in which P and Q are any predicates:

<table>
<thead>
<tr>
<th>P</th>
<th>Q</th>
<th>P and Q</th>
<th>P or Q</th>
</tr>
</thead>
<tbody>
<tr>
<td>True</td>
<td>True</td>
<td>True</td>
<td>True</td>
</tr>
<tr>
<td>True</td>
<td>False</td>
<td>False</td>
<td>True</td>
</tr>
<tr>
<td>True</td>
<td>Unknown</td>
<td>Unknown</td>
<td>True</td>
</tr>
<tr>
<td>False</td>
<td>True</td>
<td>False</td>
<td>True</td>
</tr>
<tr>
<td>False</td>
<td>False</td>
<td>False</td>
<td>False</td>
</tr>
<tr>
<td>False</td>
<td>Unknown</td>
<td>False</td>
<td>Unknown</td>
</tr>
<tr>
<td>Unknown</td>
<td>True</td>
<td>Unknown</td>
<td>True</td>
</tr>
<tr>
<td>Unknown</td>
<td>False</td>
<td>Unknown</td>
<td>Unknown</td>
</tr>
<tr>
<td>Unknown</td>
<td>Unknown</td>
<td>Unknown</td>
<td>Unknown</td>
</tr>
</tbody>
</table>

NOT(true) is false and NOT(false) is true, but NOT(unknown) is still unknown. The NOT logical operator has no affect on an unknown condition. The result of NOT(unknown) is still unknown.

Search conditions within parentheses are evaluated first. If the order of evaluation is not specified by parentheses, NOT is applied before AND, and AND is applied...
before OR. The order in which operators at the same precedence level are evaluated is undefined to allow for optimization of search conditions.

**Example 1:** In the first of the search conditions below, AND is applied before OR. In the second, OR is applied before AND.

```
SALARY>:SS AND COMM>:CC OR BONUS>:BB
SALARY>:SS AND (COMM>:CC OR BONUS>:BB)
```

**Example 2:** In the first of the search conditions below, NOT is applied before AND. In the second, AND is applied before NOT.

```
NOT SALARY>:SS AND COMM>:CC
NOT (SALARY>:SS AND COMM>:CC)
```

**Example 3:** For the following search condition, AND is applied first. After the application of AND, the OR operators could be applied in either order without changing the result. Db2 can therefore select the order of applying the OR operators.

```
SALARY>:SS AND COMM>:CC OR BONUS>:BB OR SEX=:GG
```

### Options affecting SQL

Certain Db2 precompiler or coprocessor options (referred to as SQL processing options), Db2 subsystem parameters (set through the installation panels), bind options, options for CREATE PROCEDURE and ALTER PROCEDURE statements for native SQL procedures, and special registers affect how SQL statements can be composed or determine how SQL statements are processed.

The following table summarizes the effect of these options and shows where to find more information. (Some of the items are described in detail following the table, while other items are described elsewhere.)

**Table 65. Summary of items affecting composition and processing of SQL statements**

</tbody>
</table>

**Note:** ¹ The entries in this column are fields on installation panels unless otherwise noted.

**Related concepts:**

- [Options for SQL statement processing (Db2 Application programming and SQL)](#)

**SQL processing options for dynamic statements**

Generally, dynamic statements use the application programming defaults specified on installation panel DSNTIPF. However, if the value of installation panel field USE FOR DYNAMICRULES is NO and DYNAMICRULES bind, define, or invoke behavior is in effect, certain SQL processing options are used instead of the application programming defaults.

The following SQL processing options are used instead of the application programming defaults:

- COMMA or PERIOD
- APOST or QUOTE
- APOSTSQL or QUOTESQL
- DEC(15) or DEC(31)

For some languages, the SQL processing option defaults to a value and no alternative is allowed. If the value of installation panel field USE FOR DYNAMICRULES is YES, dynamic statements use the application programming defaults regardless of the value of DYNAMICRULES option.
For additional information on the effect of SQL processing options and application programming defaults on:

- Decimal point representation, see “Decimal point representation.”
- String delimiters, see “Apostrophes and quotation marks as string delimiters” on page 345.
- Decimal arithmetic, see “Arithmetic with two decimal operands” on page 261.

For a list of the DYNAMICRULES option values that specify run, bind, define, or invoke behavior, see Table 14 on page 103.

**DECFLOAT rounding mode**

All views and SQL functions referenced in an SQL statement must either not have rounding mode information stored in the SYSENVIRONMENT catalog, or they must all have the same rounding mode information in the SYSENVIRONMENT catalog.

**Decimal point representation**

Decimal points in SQL statements are represented with either periods or commas.

Two values control the representation:

- The value of field DECIMAL POINT IS on installation panel DSNTIPF, which can be a comma (,) or period (.)
- COMMA or PERIOD, which are mutually exclusive SQL processing options for COBOL

These values apply to SQL statements as follows:

- For a distributed operation, the decimal point is the first of the following values that applies:
  - The decimal point value specified by the requester
  - The value of field DECIMAL POINT IS on panel DSNTIPF at the Db2 where the package is bound

- Otherwise:
  - For static SQL statements:
    - In a COBOL program, the SQL processing option COMMA or PERIOD determines the decimal point representation for every static SQL statement. If neither SQL processing option is specified, the value of DECIMAL POINT IS at precompilation time determines the representation.
    - In non-COBOL programs, the decimal representation for static SQL statements is always the period.
  - For dynamic SQL statements:
    - If DYNAMICRULES run behavior applies, the decimal point is the value of field DECIMAL POINT IS on installation panel DSNTIPF at the local Db2 when the statement is prepared.
      For a list of the DYNAMICRULES option values that specify run, bind, define, or invoke behavior, see Table 14 on page 103
    - If DYNAMICRULES bind, define, or invoke behavior applies, and the value of installation panel field USE FOR DYNAMICRULES is YES, the decimal point is the value of field DECIMAL POINT IS.
      If bind, define, or invoke behavior applies, and field USE FOR DYNAMIC RULES is NO, the SQL processing option determines the decimal point representation. For COBOL programs, which supports SQL processing option COMMA or PERIOD, the decimal point representation is determined as described above for static SQL statements in COBOL.
programs. For programs written in other host languages, the default SQL processing option, which can only be PERIOD, is used.

If the comma is the decimal point, these rules apply:

- In any context, a comma intended as a separator must be followed by a space. Such commas could appear, for example, in a VALUES clause, an IN predicate, or an ORDER BY clause in which numbers are used to identify columns.
- In any context, a comma intended as a decimal point must not be followed by a space.
- If the DECIMAL POINT IS field (and not the SQL processing option) determines the comma as the decimal point, Db2 will recognize either a comma or a period as the decimal point in numbers in dynamic SQL.

Related reference:

- DECIMAL POINT IS field (DECIMAL DECP value) (Db2 Installation and Migration)
- DYNAMICRULES bind option (Db2 Commands)

Apostrophes and quotation marks as string delimiters

SQL processing options and Db2 installation panel fields control the representation of string delimiters in COBOL and SQL statements.

The following SQL processing options control the representation of string delimiters:

- APOST and QUOTE are mutually exclusive SQL processing options for COBOL. Their meanings are exactly what they are for the COBOL compilers:
  - APOST names the apostrophe (') as the string delimiter in COBOL statements.
  - QUOTE names the quotation mark (") as the string delimiter.
  
  Neither option applies to SQL syntax. Do not confuse them with the APOSTSQL and QUOTESQL options.

- APOSTSQL and QUOTESQL are mutually exclusive SQL processing options for COBOL. Their meanings are:
  - APOSTSQL names the apostrophe (') as the string delimiter and the quotation mark (") as the escape character in SQL statements.
  - QUOTESQL names the quotation mark (") as the string delimiter and the apostrophe (') as the escape character in SQL statements.

These values apply to SQL statements as follows:

- For a distributed operation, the string delimiter is the first of the following values that applies:
  - The SQL string delimiter value specified by the requester
  - The value of the field SQL STRING DELIMITER on installation panel DSNTIPF at the Db2 where the package is bound

- Otherwise:
  - For static SQL statements:
    
    In a COBOL program, the SQL processing option APOSTSQL or QUOTESQL determines the string delimiter and escape character. If neither SQL processing option is specified, the value of field SQL STRING DELIMITER on installation panel DSNTIPF determines the string delimiter and escape character.
In a non-COBOL program, the string delimiter is the apostrophe, and the escape character is the quotation mark.

- For dynamic SQL statements:
  - If DYNAMICRULES run behavior applies, the string delimiter and escape character is the value of field SQL STRING DELIMITER on installation panel DSNTIPF at the local Db2 when the statement is prepared.
    For a list of the DYNAMICRULES option values that specify run, bind, define, or invoke behavior, see Table 14 on page 103.
  - If DYNAMICRULES bind, define, or invoke behavior applies and the value of installation panel field USE FOR DYNAMICRULES is YES, the string delimiter and escape character is the value of field SQL STRING DELIMITER.
    If bind, define, or invoke behavior applies and USE FOR DYNAMICRULES is NO, the SQL processing option determines the string delimiter and escape character.
    If neither SQL processing option is specified, the value of field SQL STRING DELIMITER determines them. For programs written in other host languages, the default SQL processing option, which can only be APOSTSQL, determines the string delimiter and escape character.

**Katakana characters for EBCDIC**

Ordinary identifiers with an EBCDIC encoding scheme can contain Katakana characters if the Db2 installation is set to allow it.

The field EBCDIC CCSID on installation panel DSNTIPF determines the system CCSIDs for EBCDIC-encoded data. Ordinary identifiers with an EBCDIC encoding scheme can contain Katakana characters if the field contains the value 5026 or 930. There are no corresponding SQL processing options. EBCDIC CCSID applies equally to static and dynamic statements. For dynamically prepared statements, the applicable value is always the one at the local Db2.

**Mixed data in character strings**

Mixed character data and graphic data are always allowed for Unicode, but for EBCDIC and ASCII, the specific installation of Db2 determines whether mixed data can be used.

The field MIXED DATA on installation panel DSNTIPF can have the value YES or NO for ASCII or EBCDIC character strings. The value YES indicates that character strings can contain a mixture of SBCS and DBCS characters. The value NO indicates that they cannot. Mixed character data and graphic data are always allowed for Unicode; that is the MIXED DATA field does not have an effect on Unicode data.

For static SQL statements, the value of the CCSID SQL processing option or the derived CCSID for the Db2 coprocessor determines whether ASCII or EBCDIC character strings can contain mixed data. If a mixed CCSID is used, mixed strings are allowed. If a single-byte CCSID is used, mixed strings are not allowed.

For dynamic SQL statements, the CCSID that is selected to convert the dynamic statement text to UTF-8 determines whether ASCII or EBCDIC character strings can contain mixed data. The CCSID for a dynamic statement is determined from...
the SQLDA override (if any) for the host variable on the PREPARE statement, the value of the CURRENT ENCODING SCHEME special register, and the ENCODING bind option.

The value of MIXED DATA affects the parsing of SQL character string constants, the execution of the LIKE predicate, and the assignment of character strings to host variables when truncation is needed. It can also affect concatenation, as explained in “Expressions with the concatenation operator” on page 267. A value that applies to a statement executed at the local Db2 also applies to any statement executed at another server. An exception is the LIKE predicate, for which the applicable value of MIXED DATA is always the one at the statement’s server.

The value of MIXED DATA also affects the choice of system CCSIDs for the local Db2 and the choice of data subtypes for character columns. When this value is YES, multiple CCSIDs are available for ASCII and EBCDIC data (SBCS, DBCS, and MIXED). The CCSID specified in the ASCII CCSID or EBCDIC CCSID field is the MIXED CCSID. In this case, Db2 derives the SBCS and MIXED CCSIDs from the DBCS CCSID specified installation panel DSNTIPF. Moreover, a character column can have any one of the allowable data subtypes—BIT, SBCS, or MIXED.

On the other hand, when MIXED DATA is NO, the only ASCII or EBCDIC system CCSIDs are those for SBCS data. Therefore, only BIT and SBCS can be data subtypes for character columns.

**Formatting of datetime strings**

The format for a datetime string that is in effect for a statement that is executed at the local Db2 is not necessarily in effect for a statement that is executed at a different server.

Fields on installation panel DSNTIP4 (DATE FORMAT, TIME FORMAT, LOCAL DATE LENGTH, and LOCAL TIME LENGTH) and SQL processing options affect the formatting of datetime strings.

The formatting of datetime strings is described in “String representations of datetime values” on page 130. Unlike the subsystem parameters and options previously described, a value in effect for a statement executed at the local Db2 is not necessarily in effect for a statement executed at a different server. See “Restrictions on the use of local datetime formats” on page 134 for more information.

**SQL standard language**

Db2 SQL and the SQL standard are not identical. The STDSQL SQL processing option addresses some of the differences.

- STDSQL(NO) indicates that conformance with the SQL standard is not intended. The default is the value of field STD SQL LANGUAGE on installation panel DSNTIP4 (which has a default of NO).
- STDSQL(YES)\(^\text{18}\) indicates that conformance with the SQL standard is intended.

When a program is precompiled with the STDSQL(YES) option, the following rules apply:

---

\(^{18}\) STDSQL(86) is a synonym, but STDSQL(YES) should be used.
Declaring host variables: All host variable declarations except in Java and REXX must lie between pairs of BEGIN DECLARE SECTION and END DECLARE SECTION statements:

```
BEGIN DECLARE SECTION
  -- one or more host variable declarations
END DECLARE SECTION
```

Separate pairs of these statements can bracket separate sets of host variable declarations.

Declarations for SQLCODE and SQLSTATE: The programmer must declare host variables for either SQLCODE or SQLSTATE, or both. SQLCODE should be defined as a fullword integer and SQLSTATE should be defined as a 5-byte character string. SQLCODE and SQLSTATE cannot be part of any structure. The variables must be declared in the DECLARE SECTION of a program; however, SQLCODE can be declared outside of the DECLARE SECTION when no host variable is defined for SQLSTATE. For PL/I, an acceptable declaration can look like this:

```
DECLARE SQLCODE BIN FIXED(31);
DECLARE SQLSTATE CHAR(5);
```

In Fortran programs, the variable SQLCOD should be used for SQLCODE, and either SQLSTATE or SQLSTATA can be used for SQLSTATE.

Definitions for the SQLCA: An SQLCA must not be defined in your program, either by coding its definition manually or by using the INCLUDE SQLCA statement. When STDSQL(YES) is specified, the Db2 precompiler or coprocessor automatically generates an SQLCA that includes the variable name SQLCADE instead of SQLCODE and SQLSTAT instead of SQLSTATE. After each SQL statement executes, Db2 assigns status information to SQLCODE and SQLSTATE, whose declarations are described above, as follows:

- SQLCODE: Db2 assigns the value in SQLCADE to SQLCODE. In Fortran, SQLCAD and SQLCOD are used for SQLCADE and SQLCODE, respectively.
- SQLSTATE: Db2 assigns the value in SQLSTAT to SQLSTATE. (In Fortran, SQLSTT and SQLSTA are used for SQLSTAT and SQLSTATE, respectively.)
- No declaration for either SQLSTATE or SQLCODE: Db2 assigns the value in SQLCADE to SQLCODE.

If the precompiler or coprocessor encounters an INCLUDE SQLCA statement, it ignores the statement and issues a warning message. The precompiler or coprocessor also does not recognize hand-coded definitions, and a hand-coded definition creates a compile-time conflict with the generated definition. A similar conflict arises if definitions of SQLCADE or SQLSTAT, other than the ones generated by the Db2 precompiler or coprocessor, appear in the program.

Positioned updates of columns

Certain SQL processing options affect the use of the FOR UPDATE clause to achieve positioned column updates.

The NOFOR SQL processing option affects the use of the FOR UPDATE clause. The NOFOR option is in effect when either of the following are true:

- The NOFOR option is specified.
- The STDSQL(YES) option is in effect.
Otherwise, the NOFOR option is not in effect. The following table summarizes the differences when the option is in effect and when the option is not in effect:

**Table 66. The NOFOR SQL processing option**

<table>
<thead>
<tr>
<th>When NOFOR is in effect</th>
<th>When NOFOR is not in effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>The use of the FOR UPDATE clause in the SELECT statement of the DECLARE CURSOR statement is optional. This clause restricts updates to the specified columns and causes the acquisition of update locks when the cursor is used to fetch a row. If no columns are specified, positioned updates can be made to any updatable columns in the table or view that is identified in the first FROM clause in the SELECT statement. If the FOR UPDATE clause is not specified, positioned updates can be made to any columns that the program has Db2 authority to update.</td>
<td>The FOR UPDATE clause must be specified.</td>
</tr>
<tr>
<td>DBRMs must be built entirely in virtual storage, which might possibly increase the virtual storage requirements of the Db2 precompiler or coprocessor. However, creating DBRMs entirely in virtual storage might cause concurrency problems with DBRM libraries.</td>
<td>DBRMs can be built incrementally using the Db2 precompiler or coprocessor.</td>
</tr>
</tbody>
</table>

SQL processing options do not affect ODBC behavior.

**Mappings from SQL to XML**

Db2 maps SQL to XML data according to industry standards and performs several different mappings.

To construct XML data from SQL data, the following mappings are performed:
- SQL character sets to XML character sets
- SQL identifiers to XML names
- SQL data values to XML data values

Db2 maps SQL to XML data according to industry standards. For complete information, see *Information technology - Database languages - SQL - Part 14: XML-Related Specifications (SQL/XML) ISO/IEC 9075-14:2003*.

**Mapping SQL character sets to XML character sets**

The character set used for XML data is Unicode UTF-8. SQL character data is converted into Unicode when it is used in XML built-in functions.

**Mapping SQL identifiers to XML names**

Many SQL identifiers that contain certain characters must be escaped when the SQL identifier is converted into an XML name.

Strings that start with 'XML', in any case combination, are reserved for standardization, and characters such as '#', '{', and '}' are not allowed in XML names. Many SQL identifiers containing these characters have to be escaped when converting into XML names.
Full escaping is applied to SQL identifiers that are column names to derive an XML name. The mapping converts a colon (:) to _x003A_, _x to _X005F_x, and other restricted characters to a string of the form _xUUUU_ where xUUUU_ is the Unicode value for the character. An identifier with an initial 'xml' (in any case combination) is escaped by mapping the initial 'x' or 'X' to _x0058_ or _0078_, respectively, while the partially escaped variant does not.

**Mapping SQL data values to XML data values**

SQL data values are mapped to XML values based on SQL data types.

The following data types are not supported and cannot be used as arguments to XML value constructors:
- ROWID
- Character strings that are defined with the FOR BIT DATA attribute
- Binary strings
- A string or a binary string distinct type that is based on a ROWID, FOR BIT DATA character string, or BLOB

For supported data types, the encoding scheme for XML values is Unicode.
Chapter 3. Built-in global variables and session variables

Db2 provides several built-in session variables and built-in global variables.

Built-in session variables contain information about the server and application process. Built-in global variables contain information about the database manager.

Built-in global variables

Db2 provides several built-in global variables.

**CATALOG_LEVEL**

Contains the current catalog level.

This global variable has the following characteristics:

- It is read only, with values maintained by the system.
- The type is VARCHAR(30).
- The schema is SYSIBM.
- The scope of this global variable is session.

The format is `VVvRRMMmm`, where `VV` is the version, `RR` is the release, and `MMmm` is the modification level. For example, `V12R1M504` identifies function level 504. For a list of all available function levels in Db2 12, see [What’s new in Db2 12 function levels (Db2 for z/OS What’s New?)](#)

Values V10R1 and V11R1 are also supported.

**CLIENT_IPADDR**

Contains the value of the client IP address for the connection. For remote client connections, the value is the host IP address of the application that is used to establish the connection. For local host applications, the value is NULL. For remote host applications, the value is the IP address that is associated with the Db2 subsystem used to establish the connection as shown by issuing the `-DISPLAY DDF` command.

This global variable has the following characteristics:

- It is read only, with values maintained by the system.
- The type is CHAR(39).
- The schema is SYSIBM.
- The scope of this global variable is session.

The value is set by Db2 as obtained from the network. If the client did not connect by using the TCP/IP or SSL protocol, the value of the global variable is NULL.

Or IPv4-mapped IPv6 format:

::FFFF:9.30.115.135

Related information:

- `-DISPLAY DDF (Db2) (Db2 Commands)`
- DSNL085I (Db2 Messages)
- DSNL089I (Db2 Messages)
DEFAULT_SQLLEVEL

Contains the value of the default value of the SQLLEVEL SQL processing option (DECPSQLL).

This global variable has the following characteristics:

• It is read only, with values maintained by the system.
• The type is VARCHAR(30)
• The schema is SYSIBM.
• The scope of this global variable is session.

The format is $vvRrMmmm$, where $vv$ is the version, $r$ is the release, and $mmm$ is the modification level. For example, V12R1M504 identifies function level 504. For a list of all available function levels in Db2 12, see What's new in Db2 12 function levels (Db2 for z/OS What's New?).

GET_ARCHIVE

Contains a string value that indicates whether a reference to an archive-enabled table in a table-reference should include rows in the associated archive table.

This global variable is defined with the following characteristics:

• It is updatable, with values maintained by the user.
• The type is CHAR(1).
• The schema is SYSIBMADM.
• The scope of this global variable is session.

The global variable can be set to the following:

Y Specifies that when a table-reference is an archive-enabled table, the table reference includes rows in the associated archive table.

If the SYSIBMADM.GET_ARCHIVE global variable is set to 'Y' and the ARCHIVESENSITIVE bind option is set to 'Y', an archive-enabled table cannot be referenced in an SQL table function or in the definition of a row permission or column mask that is activated by a data change statement or query.

N Specifies that when a table-reference is an archive-enabled table, the table reference does not include rows in the associated archive table. This is the default value.

Related information:

Table-reference Archive-enabled tables and archive tables (Introduction to Db2 for z/OS)

MOVE_TO_ARCHIVE

Contains a string value that indicates whether the deletion of a row of an archive-enabled table should result in storing a copy of the deleted row in the associated archive table.

This global variable has the following characteristics:

• It is updatable, with values maintained by the user.
• The type is CHAR(1).
• The schema is SYSIBMADM.
• The scope of this global variable is session.
The global variable can be set to the following:

**Y** Specifies that a delete of a row in an archive-enabled table will result in storing a copy of the deleted row in the associated archive table. Additionally, when the global variable is set to 'Y', an insert or update operation that specifies the archive-enabled table as the target of the statement will return an error.

**E** Specifies that a delete of a row in an archive-enabled table will result in storing a copy of the deleted row in the associated archive table.

**N** Specifies that a delete of a row in an archive-enabled table will not result in storing a copy of a deleted row in the associated archive table.

The default value is determined from the value of the MOVE_TO_ARCHIVE_DEFAULT subsystem parameter in macro DSN6SPRM.

Related information:

- Archive-enabled tables and archive tables (Introduction to Db2 for z/OS)

**PRODUCTID_EXT**

Contains the extended product identifier of the database manager that invoked the function.

This global variable has the following characteristics:

- It is read only, with values maintained by the system.
- The type is VARCHAR(30).
- The schema is SYSIBM
- The scope of this global variable is session.

The format of extended product identifier values is **ppp**v**v**r**r**m**m**m**, where **ppp** is a 3-letter product code (such as DSN for Db2), **v**v** is the version, **r**r** is the release, and **m**m**m** is the modification level. For example, DSN1201504 represents Db2 12 at the highest released function level.

**REPLICATION_OVERRIDE**

Indicates whether Db2 is to disable recording of temporal history for a system-period temporal table and allow an application to specify values for row-begin, row-end, transaction-start-ID, and generated expression columns. The global variable does not affect new values for row-begin, row-end, transaction-start-ID, and generated expression columns that are not explicitly specified as the target of an assignment clause for a data change statement. Db2 continues to generate values for these columns in other contexts.

**REPLICATION_OVERRIDE** has the following characteristics:

- It is updatable, with values maintained by the user.
- The type is CHAR(1).
- The schema is SYSIBMADM.
- The scope of this global variable is session.
- The default value is 'N'
REPLICATION_OVERRIDE can be set to the following values:

N An application is not allowed to specify values for row-begin, row-end, transaction-start-ID, and generated expression columns. The recording of temporal history for a system-period temporal table is enabled.

N is the default.

Y An application is allowed to specify values for row-begin, row-end, transaction-start-ID, and generated expression columns. The recording of temporal history for a system-period temporal table is disabled.

The REPLICATION_OVERRIDE built-in global variable is not intended for general use. It is intended for use by products that enable Db2 replication. The READ privilege on the variable is granted to PUBLIC. The WRITE privilege on the variable is not granted to PUBLIC.

Setting the SYSIBMADM.REPLICATION_OVERRIDE built-in global variable to 'Y' overrides the following default behaviors:

- Row-begin, row-end, transaction-start-ID, and generated expression columns are normally defined so that Db2 always generates the values. When the override is in effect, and insert or update operation can specify a value for row-begin, row-end, transaction-start-ID, or generated expression columns.
- Update and delete operations for system-period temporal tables normally generate historical rows. When the override is in effect, historical rows are not written to the associated history table for update and delete operations.

```

```
PSPI
```

TEMPORAL_LOGICAL_TRANSACTION_TIME

Specifies the value that is assigned to the row-begin column of a system-period temporal table, or to the end column in a history table during an insert, update, or delete operation.

This global variable has the following characteristics:
- It is updatable, with values maintained by the user or the system.
- The type is TIMESTAMP(12) WITHOUT TIME ZONE.
- The schema is SYSIBM.
- The scope of this global variable is session.

The global variable can be set to the following:

NULL Specifies that temporal logical transactions are not in use. This is the default value. Db2 ensures the uniqueness of the generated values for row-begin columns in system-period temporal tables, and end columns in history tables across transactions, assuming that temporal logical transactions have not been used. If multiple rows are inserted or updated in system-period temporal tables within a single SQL unit of work, the values for the row-begin columns are the same for all of the rows and are unique from the values that are generated for the columns by another transaction. If a conflicting unit of work is updating the same row in the system-period temporal table, and the row to be inserted into the
The associated history table would have an end timestamp value 
greater than the begin timestamp value, an error is returned. If the 
begin timestamp value and end timestamp value for the row in the 
history table are the same, a row is not inserted into the history 
table.

**Non-null value**

Specifies a timestamp value to start a new temporal logical 
transaction. It is recommended that the value be later in time than 
the existing value of the global variable.

While the SYSIBM.TEMPORAL_LOGICAL_TRANSACTION_TIME 
built-in global variable is set to a non-null value, the application 
controls the scope of temporal logical transactions. Db2 does not 
ensure the uniqueness of the generated values for row-begin 
columns in system-period temporal tables, and end columns in 
history tables across transactions.

When the TEMPORAL_LOGICAL_TRANSACTIONS global 
variable is set to 0, within a unit of work, a single assignment of a 
non-null value can be made to the global variable.

The variable must not be assigned a value in the body of a before 
trigger.

The variable must not be assigned a non-null value if values have 
been assigned to row-begin columns or transaction-start-ID 
columns within the same unit of work.

During the execution of a data change operation, the value of the 
TEMPORAL_LOGICAL_TRANSACTION_TIME built-in global 
variable is the value established at the beginning of the data 
change statement.

**TEMPORAL_LOGICAL_TRANSACTIONS**

Specifies whether multiple temporal logical transactions are allowed within 
a single unit of work.

This global variable has the following characteristics:

- It is updatable, with values maintained by the user or the system.
- The type is SMALLINT.
- It is NOT NULL.
- The schema is SYSIBM.
- The scope of this global variable is session.

The global variable can be set to the following:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Disallows multiple temporal logical transactions in a single unit of work. This is the default value.</td>
</tr>
<tr>
<td>1</td>
<td>Allows multiple temporal logical transactions in a single unit of work.</td>
</tr>
</tbody>
</table>

---

**Rules for setting built-in global variables in profiles**

In remote applications, some built-in global variables can be referenced with a 
value from the profile attributes table. When you set built-in global variables 
through the profile attributes table, be aware of the following rules and behavior.
You can set the following built-in global variables by issuing a SET statement with the GLOBAL_VARIABLE keyword in a profile attributes table:

- GET_ARCHIVE
- MOVE_TO_ARCHIVE
- TEMPORAL_LOGICAL_TRANSACTION_TIME
- TEMPORAL_LOGICAL_TRANSITIONS

Adhere to the following rules when using this interface:

- The SET statement must have an equal sign (=) between the global variable name and the value that is assigned.
- The maximum length of the SET statement is 1024 bytes.
- The global variable names can specified be in mixed case. Extraneous blanks between keywords are removed.
- The global variable assigned value is stored as specified. The value must be valid for the global variable.
- Db2 treats all global variable values that are passed through this interface as literal strings. For example, if a specified global variable value is the same as the name of a special register or another global variable, Db2 stores the special register or global variable name, and not the special register or global variable value.
- The SET statement must be a Unicode string and encoded with the appropriate CCSID for the application.

The global variable values persist for the lifetime of the connection unless the application explicitly sets the global variable. Global variable values that are set explicitly by the application take precedence over values that are set by the profile table facility. System directed connections, such as three-part name references, use the values of the global variables of the requesting Db2 site. For example, if a Java application establishes a connection to Db2 site 1, the global variable values are established with the profile tables from site 1. Later, if the application runs an SQL statement with an implicit three-part name connection to Db2 site 2, then the global variable values that are established on site 1 are referenced when the SQL statement runs on site 2.

Commit and rollback operations have no effect on the values of global variables. As with existing global variable behavior, commits and rollbacks do not change global variable values regardless of how they were established.

The authorization that is required to set built-in global variables is the same that is required to insert rows into the DSN_PROFILE_TABLE and DSN_PROFILE_ATTRIBUTES tables.

Built-in session variables

Db2 provides several built-in session variables that contain information about the server and application process. The value of a built-in session variable can be obtained by invoking the GETVARIABLE function with the name of the built-in session variable.

Db2 provides the following built-in session variables:

**SYSIBM.APPLICATION_ENCODING_SCHEME**
Contains a string that corresponds to the value that is specified for the APPLICATION ENCODING field on the DSNTIPF installation panel. The value will be EBCDIC, ASCII, UNICODE, or 1-65533, and this session variable can never be null.

**SYSIBM.COBOL_STRING_DELIMITER**
Contains a string that corresponds to the value that is specified for the STRING DELIMITER field on the DSNTIPF installation panel. The value will be DEFAULT, ',', or '\', and this session variable can never be null.

**SYSIBM.DATA_SHARING_GROUP_NAME**
Contains a string that corresponds to the name of the data sharing group for this Db2 subsystem. If the subsystem is not part of data sharing group, the null value is returned.

**SYSIBM.DATE_FORMAT**
Contains a string that corresponds to the value that is specified for the DATE FORMAT field on the DSNTIP4 installation panel. The value will be ISO, JIS, USA, EUR, or LOCAL, and this session variable can never be null.

**SYSIBM.DATE_LENGTH**
Contains a string that corresponds to the value that is specified for the LOCAL DATE LENGTH field on the DSNTIP4 installation panel. The value will be 10-254, or 0 for no exit, and this session variable can never be null.

**SYSIBM.DECIMAL_ARITHMETIC**
Contains a string that corresponds to the value that is specified for the DECIMAL ARITHMETIC field on the DSNTIP4 installation panel. The value will be DEC15, DEC31, 15, or 31, and this session variable can never be null.

**SYSIBM.DECIMAL_POINT**
Contains a string that corresponds to the value that is specified for the DECIMAL POINT IS field on the DSNTIPF installation panel. The value will be '.' or ',' and this session variable can never be null.

**SYSIBM.DEFAULT_DECFLOAT_ROUND_MODE**
Contains a string that corresponds to the value that is specified for the DECFLOAT Rounding Mode field on the DSNTIPF installation panel. This session variable can never be null.

**SYSIBM.DEFAULT_SSID**
Contains a string that corresponds to the value that is specified for the GROUP ATTACH field on the DSNTIPK installation panel or the SUBSYSTEM NAME field on the DSNTIPM installation panel. This session variable can never be null.

**SYSIBM.DEFAULT_LANGUAGE**
Contains a string that corresponds to the value that is specified for the
LANGUAGE DEFAULT field on the DSNTIPF installation panel. The value will be ASM, C, CPP, IBMCOB, FORTRAN, or PL/I, and this session variable can never be null.

**SYSIBM.DEFAULT_LOCALE LC CTYPE**
Contains a string that corresponds to the value that is specified for the LOCALE LC CTYPE field on the DSNTIPF installation panel. This session variable can never be null.

**SYSIBM.DISTRIBUTED_SQL_STRING_DELIMITER**
Contains a string that corresponds to the value that is specified for the DIST SQL STR DELIMTR field on the DSNTIPF installation panel. The value will be `, or `', and this session variable can never be null.

**SYSIBM.DSNHDECP_NAME**
Contains a string that corresponds to the fully qualified data set name of the data set from which the DSNHDECP or a user-specified application defaults module was loaded. For instance, 'DSN910.SDSNEXIT(DSNHDECP)'. This session variable can never be null.

**SYSIBM.DYNAMIC_RULES**
Contains a string that corresponds to the value that is specified for the USE FOR DYNAMICRULES field on the DSNTIP4 installation panel. The value will be YES or NO, and this session variable can never be null.

**SYSIBM.ENCODING_SCHEME**
Contains a string that corresponds to the value that is specified for the DEF ENCODING SCHEME field on the DSNTIPF installation panel. The value will be EBCDIC, ASCII, or UNICODE, and this session variable can never be null.

**SYSIBM.MIXED_DATA**
Contains a string that corresponds to the value that is specified for the MIXED DATA field on the DSNTIPF installation panel. The value will be YES or NO, and this session variable can never be null.

**SYSIBM.NEWFUN**
Contains a string that represents the default maximum level of the SQL function syntax that is accepted by the Db2 precompiler or the Db2 coprocessor, regardless of the Db2 function level. For more information about the NEWFUN option, see [Descriptions of SQL processing options](#).

**SYSIBM.PACKAGE_NAME**
Contains a string that corresponds to the name of the package that is currently being executed. If a package is not currently being executed, the null value is returned. (This situation can occur when the plan that is being executed bound one or more DBRMs directly).

**SYSIBM.PACKAGE_SCHEMA**
Contains a string that corresponds to the collection id of the package that is currently being executed. If a package is not currently being executed, the null value is returned.

**SYSIBM.PACKAGE_VERSION**
Contains a string that corresponds to the version of the package that is currently being executed. If a package is not currently being executed, the null value is returned.

**SYSIBM.PAD_NUL_TERMINATED**
Contains a string that corresponds to the value that is specified for the
PAD NUL-TERMINATED field on the DSNTIP4 installation panel. The value will be YES or NO, and this session variable can never be null.

**SYSIBM.PLAN_NAME**
Contains a string that corresponds to the name to the plan that is currently being executed. This session variable can never be null.

**SYSIBM.SECLABEL**
Contains a string that corresponds to the RACF SECLABEL value, if any, that has been defined for the current userid. If a value has not been defined, the null value is returned.

**SYSIBM.SQL_STRING_DELIMITER**
Contains a string that corresponds to the value that is specified for the SQL STRING DELIMITER field on the DSNTIPF installation panel. The value will be DEFAULT, ',', or ';', and this session variable can never be null.

**SYSIBM.SSID**
Contains a string that corresponds to the actual Db2 subsystem identifier for this Db2 subsystem. This session variable can never be null.

**SYSIBM.STANDARD_SQL**
Contains a string that corresponds to the value that is specified for the STD SQL LANGUAGE field on the DSNTIP4 installation panel. The value will be YES or NO, and this session variable can never be null.

**SYSIBM.SYSTEM_NAME**
Contains a string that corresponds to the name of the Db2 for z/OS subsystem, as defined in field SUBSYSTEM NAME on installation panel DSNTIPM. This session variable can never be null.

**SYSIBM.SYSTEM_ASCII_CCSID**
Contains a value that represents the ASCII CCSIDs that are in use on this system. The information is returned as a comma-delimited string that corresponds to the ASCII CCSID that was specified on installation panel DSNTIPF. The three values that are returned correspond to the SBCS, MIXED, and graphic CCSID that are in use for ASCII data on this system. A value of 65534 for the MIXED or graphic CCSID indicates that this system does not support storing data in that CCSID. This session variable can never be null.

**SYSIBM.SYSTEM_EBCDIC_CCSID**
Contains a value that represents the EBCDIC CCSIDs that are in use on this system. The information is returned as a comma-delimited string that corresponds to the EBCDIC CCSID that was specified on installation panel DSNTIPF. The three values that are returned correspond to the SBCS, MIXED, and graphic CCSID that are in use for EBCDIC data on this system. A value of 65534 for the MIXED or graphic CCSID indicates that this system does not support storing data in that CCSID. This session variable can never be null.

**SYSIBM.SYSTEM_UNICODE_CCSID**
Contains a value that represents the Unicode CCSIDs that are in use on this system. The information is returned as a comma-delimited string that corresponds to the UNICODE CCSID that was specified on installation panel DSNTIPF. The three values that are returned correspond to the SBCS, MIXED, and graphic CCSID that are in use for Unicode data on this system. This session variable can never be null.

**SYSIBM.TIME_FORMAT**
Contains a string that corresponds to the value that is specified for the
TIME FORMAT field on the DSNTIP4 installation panel. The value will be ISO, JIS, USA, EUR, or LOCAL, and this session variable can never be null.

SYSIBM.TIME_LENGTH
Contains a string that corresponds to the value that is specified for the LOCAL TIME LENGTH field on the DSNTIP4 installation panel. The value will be 8-254 or 0 for no exit, and this session variable can never be null.

SYSIBM.VERSION
Contains a string that represents the version of Db2.

The format of product identifier values is pppvvrnm, where ppp is a 3-letter product code (such as DSN for Db2), vv is the version, rr is the release, and m is the modification level. For example, DSN12015 identifies Db2 12 after the activation of function level 500 or higher. The product code (ppp) is one of the following values:

- **AQT** for IBM Db2 Analytics Accelerator for z/OS
- **ARI** for DB2 Server for VSE & VM
- **DSN** for Db2 for z/OS
- **JCC** for IBM Data Server Driver for JDBC and SQLJ
- **QSQ** for DB2 for i
- **SQL** for Db2 for Linux, UNIX, and Windows

Modification (m) values have the following meanings:

- **0** Function level 100 or 100*.
- **5** Function level 500 or higher.

This session variable can never be null.

For example, the following statement sets the value of host variable hv1 to the name of the plan that is currently being executed:

```sql
SET :hv1 = GETVARIABLE('SYSIBM.PLAN_NAME');
```

For more information about the GETVARIABLE function, see GETVARIABLE.
Chapter 4. Built-in functions

A function is an operation denoted by a function name followed by zero or more input values that are enclosed in parentheses. It represents a relationship between a set of input values and a set of result values. The input values to a function are called arguments.

The types of functions are aggregate, scalar, and table. A built-in function is classified as an aggregate function or a scalar function. A user-defined function can be a column, scalar, or table function.

If a column mask is used to mask the column values in the final result table and a column mask is applied to a column that is an argument for a function, the result of the function might be different because the column mask is applied to the column before the function operation can take place. For example, applying a column mask to column SSN can change the result of the aggregate function, COUNT(DISTINCT SSN).

The DISTINCT operation is performed on the unmasked column values. The keyword DISTINCT is not an argument of the function but rather a specification of an operation that is performed before the function is applied. If DISTINCT is specified, redundant duplicate values are eliminated before column mask is applied. If the column in aggregate function with DISTINCT keyword has column mask definition references columns that are non-grouping column and not the target column of the DISTINCT operation, the result of aggregate function can vary. Db2 does not guarantee the same row is returned from a group of duplicates in each execution, thus, the values in those non-DISTINCT/non-grouping columns in the returned row could be different each time.

OLAP specification and functions

The RANK, DENSE_RANK, and ROW_NUMBER specifications are sometimes referred to as built-in ‘functions’. Refer to OLAP specification for more information on these specifications.

Db2 MQSeries functions

Db2 MQSeries functions integrate MQSeries messaging operations within SQL statements. The functions help you integrate MQSeries messaging with database applications. You can use the functions to access MQSeries messaging from within SQL statements and to combine MQSeries messaging with Db2 database access.

The functions can be scalar or table functions. For more information on using MQSeries functions, see the information on enabling MQSeries functions in Db2 Installation Guide and on programming techniques in Db2 Application Programming and SQL Guide.

Administrative task scheduler functions

The administrative task scheduler table functions provide information and status about the tasks that are scheduled to run using the administrative task scheduler. The administrative task scheduler provides the ability to run stored procedures, JCL jobs, and other administrative tasks according to a time or an event-based schedule. Refer to Db2 Administration Guide for additional information about the administrative task scheduler.
List of supported built-in functions

This section contains an alphabetical list of the built-in functions that Db2 for z/OS supports.

Table 67. Supported built-in functions

<table>
<thead>
<tr>
<th>Function name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ABS</td>
<td>Returns the absolute value of its argument</td>
</tr>
<tr>
<td>ACOS</td>
<td>Returns the arc cosine of an argument as an angle, expressed in radians</td>
</tr>
<tr>
<td>ADD_MONTHS</td>
<td>Returns a date that represents the date argument plus the number of months argument</td>
</tr>
<tr>
<td>ADMIN_TASK_LIST</td>
<td>Returns a table with one row for each of the tasks that are defined in the administrative task scheduler task list</td>
</tr>
<tr>
<td>ADMIN_TASK_OUTPUT</td>
<td>Returns the output parameter values and result sets, if available. If the task that was executed is not a stored procedure or the requested execution status is not available, the function returns an empty table.</td>
</tr>
<tr>
<td>ADMIN_TASK_STATUS</td>
<td>Returns a table with one row for each task in the administrative task scheduler task list that contains the status for the last time the task was run</td>
</tr>
<tr>
<td>ARRAY_AGG</td>
<td>Returns an array in which each value of the input set is assigned to an element of the array.</td>
</tr>
<tr>
<td>ARRAY_DELETE</td>
<td>Deletes elements from an array.</td>
</tr>
<tr>
<td>ARRAY_FIRST</td>
<td>Returns the minimum array index value of an array.</td>
</tr>
<tr>
<td>ARRAY_LAST</td>
<td>Returns the maximum array index value of an array.</td>
</tr>
<tr>
<td>ARRAY_NEXT</td>
<td>Returns the next larger array index value for an array, relative to a specified array index argument.</td>
</tr>
<tr>
<td>ARRAY_PRIOR</td>
<td>Returns the next smaller array index value for an array, relative to a specified array index argument.</td>
</tr>
<tr>
<td>ASCII</td>
<td>Returns the ASCII code value of the leftmost character of the argument as an integer</td>
</tr>
<tr>
<td>ASCII_CHR</td>
<td>Returns the character that corresponds to the ASCII code value that is specified by the argument</td>
</tr>
<tr>
<td>ASCII_STR</td>
<td>Returns an ASCII version of the character or graphic string argument</td>
</tr>
<tr>
<td>ASIN</td>
<td>Returns the arc sine of an argument as an angle, expressed in radians</td>
</tr>
<tr>
<td>ATAN</td>
<td>Returns the arc tangent of an argument as an angle, expressed in radians</td>
</tr>
<tr>
<td>ATANH</td>
<td>Returns the hyperbolic arc tangent of an argument as an angle, expressed in radians</td>
</tr>
<tr>
<td>ATAN2</td>
<td>Returns the arc tangent of x and y coordinates as an angle, expressed in radians</td>
</tr>
<tr>
<td>AVG</td>
<td>Returns the average of a set of numbers</td>
</tr>
<tr>
<td>BLOB</td>
<td>Returns a BLOB representation of its argument</td>
</tr>
<tr>
<td>BIGINT</td>
<td>Returns a big integer representation of its argument</td>
</tr>
<tr>
<td>BITAND, BITANDNOT, BITOR, BITXOR, and BITNOT</td>
<td>Return a corresponding base 10 integer value in a data type that is based on the data type of the input arguments</td>
</tr>
<tr>
<td>BINARY</td>
<td>Returns a fixed-length binary string representation of its argument</td>
</tr>
<tr>
<td>CARDINALITY</td>
<td>Returns a value of that represents the number of elements of an array</td>
</tr>
<tr>
<td>Function name</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------</td>
<td>-------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>CCSID_ENCODING</td>
<td>Returns the encoding scheme of a CCSID with a value of ASCII, EBCDIC, UNICODE, or UNKNOWN</td>
</tr>
<tr>
<td>CEILING</td>
<td>Returns the smallest integer greater than or equal to the argument</td>
</tr>
<tr>
<td>CHAR</td>
<td>Returns a fixed-length character string representation of its argument</td>
</tr>
<tr>
<td>CHARACTER_LENGTH</td>
<td>Returns the length of its argument in the number of string units that are specified</td>
</tr>
<tr>
<td>CLOB</td>
<td>Returns a CLOB representation of its argument</td>
</tr>
<tr>
<td>COALESCE</td>
<td>Returns the first argument in a set of arguments that is not null</td>
</tr>
<tr>
<td>COLLATION_KEY</td>
<td>Returns a string that represents the collation key of the argument in the specified collation</td>
</tr>
<tr>
<td>COMPARE_DECFLOAT</td>
<td>Returns a SMALLINT value that indicates whether two arguments are equal, unordered, or whether one argument is greater than the other</td>
</tr>
<tr>
<td>CONCAT</td>
<td>Returns the concatenation of two strings</td>
</tr>
<tr>
<td>CONTAINS</td>
<td>Returns a result about whether or not a match was found during a search of a text search index</td>
</tr>
<tr>
<td>CORRELATION</td>
<td>Returns the coefficient of the correlation of a set of number pairs</td>
</tr>
<tr>
<td>COS</td>
<td>Returns the cosine of an argument that is expressed as an angle in radians</td>
</tr>
<tr>
<td>COSH</td>
<td>Returns the hyperbolic cosine of an argument that is expressed as an angle in radians</td>
</tr>
<tr>
<td>COUNT</td>
<td>Returns the number of rows or values in a set of rows or values</td>
</tr>
<tr>
<td>COUNT_BIG</td>
<td>Same as COUNT, except the result can be greater than the maximum value of an integer</td>
</tr>
<tr>
<td>COVARIANCE or COVAR</td>
<td>Returns the population covariance of a set of number pairs</td>
</tr>
<tr>
<td>COVAR_SAMP or COVARIANCE_SAMP</td>
<td>Returns unbiased sample covariance (n-1) of a set of number pairs</td>
</tr>
<tr>
<td>CUME_DIST</td>
<td>Returns a cumulative distribution of a row in an OLAP window</td>
</tr>
<tr>
<td>CUME_DIST (aggregate)</td>
<td>Returns the cumulative distribution of a row that is hypothetically inserted into a group of rows</td>
</tr>
<tr>
<td>DATE</td>
<td>Returns a date derived from its argument</td>
</tr>
<tr>
<td>DAY</td>
<td>Returns the day part of its argument</td>
</tr>
<tr>
<td>DAYOFMONTH</td>
<td>Similar to DAY</td>
</tr>
<tr>
<td>DAYOFWEEK</td>
<td>Returns an integer in the range 1 - 7, where 1 represents Sunday</td>
</tr>
<tr>
<td>DAYOFWEEK_ISO</td>
<td>Returns an integer in the range 1 - 7, where 1 represents Monday</td>
</tr>
<tr>
<td>DAYOFYEAR</td>
<td>Returns an integer in the range 1 - 366, where 1 represents January 1</td>
</tr>
<tr>
<td>DAYS</td>
<td>Returns an integer representation of a date</td>
</tr>
<tr>
<td>DBCLOB</td>
<td>Returns a DBCLOB representation of its argument</td>
</tr>
<tr>
<td>DECIMAL or DEC</td>
<td>Returns a decimal representation of its argument</td>
</tr>
<tr>
<td>DECFLOAT</td>
<td>Returns a DECFLOAT representation of its argument</td>
</tr>
<tr>
<td>DECFLOAT_FORMAT</td>
<td>Returns a DECFLOAT(34) value that is based on the interpretation of the input string using the specified format</td>
</tr>
<tr>
<td>DECFLOAT_SORTKEY</td>
<td>Returns a binary value that can be used when sorting DECFLOAT values</td>
</tr>
</tbody>
</table>
### Table 67. Supported built-in functions (continued)

<table>
<thead>
<tr>
<th>Function name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>DECODE</strong></td>
<td>Returns a specified <em>result-expression</em> based on a comparison of input expressions (similar to the CASE expression)</td>
</tr>
<tr>
<td><strong>DECRYPT_BINARY, DECRYPT_BIT, DECRYPT_CHAR, and DECRYPT_DB</strong></td>
<td>Returns the decrypted value of an encrypted argument that was encrypted using the ENCRYPT_TDES function</td>
</tr>
<tr>
<td><strong>DEGREES</strong></td>
<td>Returns the number of degrees for an argument that is expressed in radians</td>
</tr>
<tr>
<td><strong>DIFFERENCE</strong></td>
<td>Returns a value that represents the difference between the sounds of two strings based on applying the SOUNDEX function to the strings</td>
</tr>
<tr>
<td><strong>DIGITS</strong></td>
<td>Returns a character string representation of a number</td>
</tr>
<tr>
<td><strong>DOUBLE_PRECISION</strong> or <strong>DOUBLE</strong></td>
<td>Returns a double precision floating-point representation of its argument</td>
</tr>
<tr>
<td><strong>DSN_XMLVALIDATE</strong></td>
<td>Returns an XML value that is the result of applying XML schema validation to the first argument</td>
</tr>
<tr>
<td><strong>EBCDIC_CHR</strong></td>
<td>Returns the character that corresponds to the EBCDIC code value that is specified by the argument</td>
</tr>
<tr>
<td><strong>EBCDIC_STR</strong></td>
<td>Returns an EBCDIC version of the string argument</td>
</tr>
<tr>
<td><strong>ENCRYPT_TDES</strong></td>
<td>Returns the argument as an encrypted value using the Triple DES encryption algorithm</td>
</tr>
<tr>
<td><strong>EXP</strong></td>
<td>Returns the exponential function of an argument</td>
</tr>
<tr>
<td><strong>EXTRACT</strong></td>
<td>Returns a portion of a date or timestamp based on its arguments</td>
</tr>
<tr>
<td><strong>FIRST_VALUE</strong></td>
<td>Returns the expression value for the first row in an OLAP window</td>
</tr>
<tr>
<td><strong>FLOAT</strong></td>
<td>Same as DOUBLE</td>
</tr>
<tr>
<td><strong>FLOOR</strong></td>
<td>Returns the largest integer that is less than or equal to the argument</td>
</tr>
<tr>
<td><strong>GENERATE_UNIQUE</strong> and <strong>GENERATE_UNIQUE_BINARY</strong></td>
<td>Returns a character string of bit data that is unique compared to any other execution of the function</td>
</tr>
<tr>
<td><strong>GETHINT</strong></td>
<td>Returns the embedded password hint from encrypted data, if one exists</td>
</tr>
<tr>
<td><strong>GETVARIABLE</strong></td>
<td>Returns a varying-length character string representation of the value of a session variable</td>
</tr>
<tr>
<td><strong>GRAPHIC</strong></td>
<td>Returns a fixed-length graphic string representation of its argument</td>
</tr>
<tr>
<td><strong>GROUPING</strong></td>
<td>Returns a value that indicates if a row returned in a GROUP BY result is a row generated by a grouping set that excludes the column represented by its argument</td>
</tr>
<tr>
<td><strong>HEX</strong></td>
<td>Returns a hexadecimal representation of its argument</td>
</tr>
<tr>
<td><strong>HOUR</strong></td>
<td>Returns the hour part of its argument</td>
</tr>
<tr>
<td><strong>IDENTITY_VAL_LOCAL</strong></td>
<td>Returns the most recently assigned value for an identity column</td>
</tr>
<tr>
<td><strong>IFNULL</strong></td>
<td>Returns the first argument in a set of two arguments that is not null</td>
</tr>
<tr>
<td><strong>INSERT</strong></td>
<td>Returns a string that is composed of an argument inserted into another argument at the same position where some number of bytes have been deleted</td>
</tr>
<tr>
<td><strong>INTEGER</strong> or <strong>INT</strong></td>
<td>Returns an integer representation of its argument</td>
</tr>
<tr>
<td><strong>JULIAN_DAY</strong></td>
<td>Returns an integer that represents the number of days from January 1, 4712 B.C.</td>
</tr>
<tr>
<td><strong>LAG</strong></td>
<td>Returns the expression value for the row at offset rows before the current row</td>
</tr>
<tr>
<td>Function name</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>LAST_DAY</td>
<td>Returns a date that represents the last day of the month of the date argument</td>
</tr>
<tr>
<td>LAST_VALUE</td>
<td>Returns the expression value for the last row in an OLAP window</td>
</tr>
<tr>
<td>LOWER</td>
<td>Returns a string with the characters converted to lowercase</td>
</tr>
<tr>
<td>LAST</td>
<td>Returns the expression value for the row at offset rows after the current row</td>
</tr>
<tr>
<td>LEFT</td>
<td>Returns a string that consists of the specified number of leftmost bytes or the specified string units</td>
</tr>
<tr>
<td>LENGTH</td>
<td>Returns the length of its argument</td>
</tr>
<tr>
<td>LOCATE</td>
<td>Returns the starting position of one string within another string</td>
</tr>
<tr>
<td>LOCATE_IN_STRING</td>
<td>Returns the starting position of the first occurrence of one string within another string</td>
</tr>
<tr>
<td>LOG10</td>
<td>Returns the base 10 logarithm of an argument</td>
</tr>
<tr>
<td>LOWER</td>
<td>Returns a string with the characters converted to lowercase</td>
</tr>
<tr>
<td>LPAD</td>
<td>Returns a string that is padded on the left with blanks or a specified string</td>
</tr>
<tr>
<td>TRIM</td>
<td>Returns the characters of a string with the leading blanks or hexadecimal zeros removed</td>
</tr>
<tr>
<td>MAX (aggregate)</td>
<td>Returns the maximum value in a set of column values in a group</td>
</tr>
<tr>
<td>MAX (scalar)</td>
<td>Returns the maximum value in a set of values</td>
</tr>
<tr>
<td>MAX_CARDINALITY</td>
<td>Returns a value of type BIGINT that represents the maximum number of elements that an array can contain. This value is the cardinality that was specified in the CREATE TYPE statement for an ordinary array type.</td>
</tr>
<tr>
<td>MICROSECOND</td>
<td>Returns the microsecond part of its argument</td>
</tr>
<tr>
<td>MIDNIGHT_SECONDS</td>
<td>Returns an integer in the range 0 - 86400 that represents the number of seconds between midnight and the argument</td>
</tr>
<tr>
<td>MIN (aggregate)</td>
<td>Returns the minimum value in a set of values in a group</td>
</tr>
<tr>
<td>MIN (scalar)</td>
<td>Returns the minimum value in a set of values</td>
</tr>
<tr>
<td>MINUTE</td>
<td>Returns the minute part of its argument</td>
</tr>
<tr>
<td>MOD</td>
<td>Returns the remainder of one argument divided by a second argument</td>
</tr>
<tr>
<td>MONTH</td>
<td>Returns the month part of its argument</td>
</tr>
<tr>
<td>MONTHS_BETWEEN</td>
<td>Returns an estimate of the number of months between two arguments</td>
</tr>
<tr>
<td>MQREAD</td>
<td>Returns a message from a specified MQSeries location (return value of VARCHAR) without removing the message from the queue</td>
</tr>
<tr>
<td>MQREADALL</td>
<td>Returns a table containing the messages and message metadata from a specified MQSeries location with a VARCHAR column and without removing the messages from the queue</td>
</tr>
<tr>
<td>MQREADALLCLOB</td>
<td>Returns a table containing the messages and message metadata from a specified MQSeries location with a CLOB column and without removing the messages from the queue</td>
</tr>
<tr>
<td>Function name</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>MQREADCLOB</td>
<td>Returns a message from a specified MQSeries location (return value of CLOB) without removing the message from the queue</td>
</tr>
<tr>
<td>MQRECEIVE</td>
<td>Returns a message from a specified MQSeries location (return value of VARCHAR) with removal of message from the queue</td>
</tr>
<tr>
<td>MQRECEIVEALL</td>
<td>Returns a table containing the messages and message metadata from a specified MQSeries location with a VARCHAR column and with removal of messages from the queue</td>
</tr>
<tr>
<td>MQRECEIVEALLCLOB</td>
<td>Returns a table containing the messages and message metadata from a specified MQSeries location with a CLOB column and with removal of messages from the queue</td>
</tr>
<tr>
<td>MQRECEIVECLOB</td>
<td>Returns a message from a specified MQSeries location (return value of CLOB) with removal of message from the queue</td>
</tr>
<tr>
<td>MQSEND</td>
<td>Sends data to a specified MQSeries location, and returns a varying-length character string that indicates whether the function was successful or unsuccessful</td>
</tr>
<tr>
<td>MULTIPLY_ALT</td>
<td>Returns the product of the two arguments as a decimal value, used when the sum of the argument precisions exceeds 31</td>
</tr>
<tr>
<td>NEXT_DAY</td>
<td>Returns a timestamp that represents the first weekday, specified by the second argument, after the date argument</td>
</tr>
<tr>
<td>NORMALIZE_DECFLOAT</td>
<td>Returns a DECFLOAT value that is the result of normalizing the input argument</td>
</tr>
<tr>
<td>NORMALIZE_STRING</td>
<td>Returns a string value that is the result of normalizing the input Unicode value</td>
</tr>
<tr>
<td>FL 504</td>
<td>NTH_VALUE</td>
</tr>
<tr>
<td>FL 504</td>
<td>NTILE</td>
</tr>
<tr>
<td>NULLIF</td>
<td>Returns NULL if the arguments are equal; else the first argument</td>
</tr>
<tr>
<td>NVL</td>
<td>Returns the first argument that is not null</td>
</tr>
<tr>
<td>OVERLAY</td>
<td>Returns a string that is composed of an argument inserted into another argument at the same position where some number of bytes have been deleted</td>
</tr>
<tr>
<td>PACK</td>
<td>Returns a binary string value that contains a data type array and a packed representation of each non-null argument</td>
</tr>
<tr>
<td>FL 504</td>
<td>PERCENT_RANK</td>
</tr>
<tr>
<td>FL 504</td>
<td>PERCENT_RANK (aggregate)</td>
</tr>
<tr>
<td>POSITION</td>
<td>Returns the position of the first occurrence of an argument within another argument where the position is expressed in terms of the string units that are specified</td>
</tr>
<tr>
<td>POSSTR</td>
<td>Returns the position of the first occurrence of an argument within another argument</td>
</tr>
<tr>
<td>POWER</td>
<td>Returns the value of one argument raised to the power of a second argument</td>
</tr>
<tr>
<td>QUANTIZE</td>
<td>Returns a DECFLOAT value that is equal in value (except for any rounding) and sign to the first argument and which has an exponent set to be equal to the exponent of the second argument</td>
</tr>
<tr>
<td>QUARTER</td>
<td>Returns an integer in the range 1 - 4 that represents the quarter of the year for the date specified in the argument</td>
</tr>
<tr>
<td>Function name</td>
<td>Description</td>
</tr>
<tr>
<td>---------------</td>
<td>-------------</td>
</tr>
<tr>
<td><strong>RADIANS</strong></td>
<td>Returns the number of radians for an argument that is expressed in degrees</td>
</tr>
<tr>
<td><strong>RAISE_ERROR</strong></td>
<td>Raises an error in the SQLCA with the specified SQLSTATE and error description</td>
</tr>
<tr>
<td><strong>RAND</strong></td>
<td>Returns a double precision floating-point random number</td>
</tr>
<tr>
<td><strong>FL 504</strong> RATIO_TO_REPORT</td>
<td>Returns the ratio of an argument to the sum of the arguments in an OLAP partition</td>
</tr>
<tr>
<td><strong>REAL</strong></td>
<td>Returns a single precision floating-point representation of its argument</td>
</tr>
<tr>
<td><strong>FL 504</strong> REGEXP_COUNT</td>
<td>Returns a count of the number of times that a regular expression pattern is matched in a string</td>
</tr>
<tr>
<td><strong>FL 504</strong> REGEXP_INSTR</td>
<td>Returns the starting or ending position of the matched substring, depending on the value of the return_option argument</td>
</tr>
<tr>
<td><strong>FL 504</strong> REGEXP_LIKE</td>
<td>Returns an INTEGER value of 0 or 1 indicating if the regular expression pattern is found in a string</td>
</tr>
<tr>
<td><strong>FL 504</strong> REGEXP_REPLACE</td>
<td>Returns a modified version of the source string where occurrences of the regular expression pattern found in the source string are replaced with the specified replacement string</td>
</tr>
<tr>
<td><strong>FL 504</strong> REGEXP_SUBSTR</td>
<td>Returns one occurrence of a substring of a string that matches the regular expression pattern</td>
</tr>
<tr>
<td><strong>REPEAT</strong></td>
<td>Returns a character string composed of an argument repeated a specified number of times</td>
</tr>
<tr>
<td><strong>REPLACE</strong></td>
<td>Returns a string in which all occurrences of an argument within a second argument are replaced with a third argument</td>
</tr>
<tr>
<td><strong>RID</strong></td>
<td>Returns the RID of a row</td>
</tr>
<tr>
<td><strong>RIGHT</strong></td>
<td>Returns a string that consists of the specified number of rightmost bytes or specified string unit</td>
</tr>
<tr>
<td><strong>ROUND</strong></td>
<td>Returns a number rounded to the specified number of places to the right or left of the decimal place</td>
</tr>
<tr>
<td><strong>ROUND_TIMESTAMP</strong></td>
<td>Returns a timestamp rounded to the unit specified by the timestamp format string</td>
</tr>
<tr>
<td><strong>ROWID</strong></td>
<td>Returns a row ID representation of its argument</td>
</tr>
<tr>
<td><strong>RPAD</strong></td>
<td>Returns a string that is padded on the right with blanks or a specified string</td>
</tr>
<tr>
<td><strong>RTRIM</strong></td>
<td>Returns the characters of an argument with the trailing blanks or hexadecimal zeros removed</td>
</tr>
<tr>
<td><strong>SCORE</strong></td>
<td>Returns a relevance score that measures how well a document matches the query used to search a text search index</td>
</tr>
<tr>
<td><strong>SECOND</strong></td>
<td>Returns the second part of its argument</td>
</tr>
<tr>
<td><strong>SIGN</strong></td>
<td>Returns the sign of an argument</td>
</tr>
<tr>
<td><strong>SIN</strong></td>
<td>Returns the sine of an argument that is expressed as an angle in radians</td>
</tr>
<tr>
<td><strong>SINH</strong></td>
<td>Returns the hyperbolic sine of an argument that is expressed as an angle in radians</td>
</tr>
<tr>
<td><strong>SMALLINT</strong></td>
<td>Returns a small integer representation of its argument</td>
</tr>
<tr>
<td>Function name</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>SOAPHTTPC and SOAPHTTPV</td>
<td>Returns a CLOB or VARCHAR representation of XML data from a request to a web service</td>
</tr>
<tr>
<td>SOAPHTTPNC and SOAPHTTPNV</td>
<td>Returns a complete CLOB or VARCHAR representation of XML data from a complete request to a web service</td>
</tr>
<tr>
<td>SOUNDEX</td>
<td>Returns a value that represents the sound of the words in the argument</td>
</tr>
<tr>
<td>SPACE</td>
<td>Returns a string that consists of the number of blanks the argument specifies</td>
</tr>
<tr>
<td>SQRT</td>
<td>Returns the square root of its argument</td>
</tr>
<tr>
<td>STDDEV_POP or STDDEV</td>
<td>Returns the population standard deviation (division by ( n )) of a set of numbers</td>
</tr>
<tr>
<td>STDDEV_SAMP</td>
<td>Returns the sample standard deviation (division by ( n-1 )) of a set of numbers</td>
</tr>
<tr>
<td>STRIP</td>
<td>Returns the characters of a string with the blanks (or specified character) at the beginning, end, or both beginning and end of the string removed</td>
</tr>
<tr>
<td>SUBSTR</td>
<td>Returns a substring of a string</td>
</tr>
<tr>
<td>SUBSTRING</td>
<td>Returns a substring of a string using the specified string units</td>
</tr>
<tr>
<td>SUM</td>
<td>Returns the sum of a set of numbers</td>
</tr>
<tr>
<td>TAN</td>
<td>Returns the tangent of an argument that is expressed as an angle in radians</td>
</tr>
<tr>
<td>TANH</td>
<td>Returns the hyperbolic tangent of an argument that is expressed as an angle in radians</td>
</tr>
<tr>
<td>TIME</td>
<td>Returns a time derived from its argument</td>
</tr>
<tr>
<td>TIMESTAMP</td>
<td>Returns a timestamp derived from its arguments</td>
</tr>
<tr>
<td>TIMESTAMPADD</td>
<td>Returns a timestamp derived from adding the specified interval to a timestamp</td>
</tr>
<tr>
<td>TIMESTAMP_FORMAT</td>
<td>Returns a timestamp for a character string expression, using a specified format to interpret the string</td>
</tr>
<tr>
<td>TIMESTAMP_ISO</td>
<td>Returns a timestamp derived from its arguments</td>
</tr>
<tr>
<td>TIMESTAMPDIFF</td>
<td>Returns an estimated number of the specified intervals based on the difference between two timestamps</td>
</tr>
<tr>
<td>TIMESTAMP_TZ</td>
<td>Returns a timestamp with a time zone derived from its arguments</td>
</tr>
<tr>
<td>TO_CHAR</td>
<td>Returns a character string representation of a timestamp value that has been formatted using a specified character template</td>
</tr>
<tr>
<td>TO_DATE</td>
<td>Returns a timestamp value that is based on the interpretation of the input string using the specified format</td>
</tr>
<tr>
<td>TO_NUMBER</td>
<td>Returns a DECFLLOAT(34) value that is based on the interpretation of the input string using the specified format</td>
</tr>
<tr>
<td>TOTALORDER</td>
<td>Returns a SMALLINT value that indicates the comparison order of two arguments</td>
</tr>
<tr>
<td>TRANSLATE</td>
<td>Returns a string with one or more characters translated</td>
</tr>
<tr>
<td>TRIM</td>
<td>Removes bytes from the beginning, from the end, or from both the beginning and end of a string expression</td>
</tr>
<tr>
<td>TRIM_ARRAY</td>
<td>Removes elements from the end of an ordinary array</td>
</tr>
<tr>
<td>Function name</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>-------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>TRUNCATE or TRUNC</td>
<td>Returns a number truncated to the specified number of places to the right or left of the decimal point</td>
</tr>
<tr>
<td>TRUNC_TIMESTAMP</td>
<td>Returns a timestamp truncated to the unit specified by the timestamp format string</td>
</tr>
<tr>
<td>UCASE</td>
<td>Returns a string with the characters converted to uppercase</td>
</tr>
<tr>
<td>UNICODE</td>
<td>Returns the Unicode (UTF-16) code value of the leftmost character of the argument as an integer</td>
</tr>
<tr>
<td>UNICODE_STR</td>
<td>Returns a string in Unicode (UTF-8 or UTF-16) that represents a Unicode encoding of the argument</td>
</tr>
<tr>
<td>UNPACK</td>
<td>Returns a row of values that are derived from unpacking the input binary string. It is used to unpack a string that was encoded according to the PACK function</td>
</tr>
<tr>
<td>UPPER</td>
<td>Returns a string with the characters converted to uppercase</td>
</tr>
<tr>
<td>VALUE</td>
<td>Same as COALESCE</td>
</tr>
<tr>
<td>VARBINARY</td>
<td>Returns a varying-length binary string representation of its argument</td>
</tr>
<tr>
<td>VARCHAR</td>
<td>Returns the varying-length character string representation of its argument</td>
</tr>
<tr>
<td>VARCHAR9</td>
<td>Returns the fixed-length character string representation of its argument</td>
</tr>
<tr>
<td>VARCHAR_FORMAT</td>
<td>Returns a varying-length character string representation of a timestamp, with the string in a specified format</td>
</tr>
<tr>
<td>VARGRAPHIC</td>
<td>Returns a varying-length graphic string representation of its argument</td>
</tr>
<tr>
<td>VAR_POP or VARIANCE or VAR</td>
<td>Returns the biased variance (division by ( n )) of a set of numbers</td>
</tr>
<tr>
<td>VAR_SAMP or VARIANCE_SAMP</td>
<td>Returns the sample variance (division by ( n-1 )) of a set of numbers</td>
</tr>
<tr>
<td>VERIFY_GROUP_FOR_USER</td>
<td>Returns a value that indicates whether the primary authorization ID and the group authorization IDs that are associated with the first argument are included in the authorization names that are specified in the list of the second argument.</td>
</tr>
<tr>
<td>VERIFY_ROLE_FOR_USER</td>
<td>Returns a value that indicates whether the roles that are associated with the first argument are included in the role names that are specified in the list of the second argument.</td>
</tr>
<tr>
<td>VERIFY_TRUSTED_CONTEXT_ROLE_FOR_USER</td>
<td>Returns a value that indicates whether the authorization ID that is associated with first argument has acquired a role in a trusted connection and whether that acquired role is included in the role names that are specified in the list of the second argument.</td>
</tr>
<tr>
<td>WEEK</td>
<td>Returns an integer that represents the week of the year with Sunday as the first day of the week</td>
</tr>
<tr>
<td>WEEK_ISO</td>
<td>Returns an integer that represents the week of the year with Monday as first day of a week</td>
</tr>
<tr>
<td>XMLAGG</td>
<td>Returns an XML type that represents a concatenation of XML elements from a collection of XML elements</td>
</tr>
<tr>
<td>XMLATTRIBUTES</td>
<td>Returns an XML sequence that contains an XQuery attribute node for each non-null argument</td>
</tr>
<tr>
<td>XMLCOMMENT</td>
<td>Returns an XML value with a single comment node from a string expression</td>
</tr>
<tr>
<td>Function name</td>
<td>Description</td>
</tr>
<tr>
<td>--------------</td>
<td>-------------</td>
</tr>
<tr>
<td>XMLCONCAT</td>
<td>Returns an XML value that represents a forest of XML elements generated by concatenating a variable number of arguments</td>
</tr>
<tr>
<td>XMLDOCUMENT</td>
<td>Returns an XML value with a single document node and zero or more nodes as its children</td>
</tr>
<tr>
<td>XMLELEMENT</td>
<td>Returns an XML value that represents an XML element</td>
</tr>
<tr>
<td>XMLFOREST</td>
<td>Returns an XML value that represents a forest of XML elements that all share a specific pattern</td>
</tr>
<tr>
<td>XMLOVERRIDE</td>
<td>Returns an XML value that might have been modified by the evaluation of an XQuery updating expression and XQuery variables that are specified as input arguments</td>
</tr>
<tr>
<td>XMLNAMESPACE</td>
<td>Returns the declaration of one or more XML namespaces</td>
</tr>
<tr>
<td>XMLPARSE</td>
<td>Returns an XML value from parsing the argument as an XML document</td>
</tr>
<tr>
<td>XMLPI</td>
<td>Returns an XML value with a single processing instruction node</td>
</tr>
<tr>
<td>XMLQUERY</td>
<td>Returns an XML value from the evaluation of an XPath expression against a set of arguments</td>
</tr>
<tr>
<td>XMLSERIALIZE</td>
<td>Returns an SQL character string or a BLOB value from an XML value</td>
</tr>
<tr>
<td>XMLTABLE</td>
<td>Returns a result table from the evaluation of XQuery expressions, possibly using specified input arguments as XQuery variables</td>
</tr>
<tr>
<td>XMLTEXT</td>
<td>Returns an XML value with a single text node that contains the value of the argument</td>
</tr>
<tr>
<td>XMLXSROBJECTID</td>
<td>Returns the XSR object identifier of the XML schema that is used to validate the XML document specified in the argument</td>
</tr>
<tr>
<td>XSLTRANSFORM</td>
<td>The XSLTRANSFORM function transforms an XML document into a different data format. The output can be any form possible for the XSLT processor, including but not limited to XML, HTML, and plain text. <strong>Note:</strong> This is a Db2-supplied user-defined function.</td>
</tr>
<tr>
<td>YEAR</td>
<td>Returns the year part of its argument</td>
</tr>
</tbody>
</table>

**Notes:**

1. Supported in Db2 for z/OS only for pass-through to IBM Db2 Analytics Accelerator for z/OS.

**Aggregate functions**

An aggregate function receives a set of values for each argument (such as the values of a column) and returns a single-value result for the set of input values. Certain rules apply to all aggregate functions.

The following information applies to all aggregate functions, except for the COUNT(*) and COUNT_BIG(*), variations of the COUNT and COUNT_BIG functions, and the XMLAGG function.

The argument of an aggregate function is a set of values derived from an expression. The expression must not include another aggregate function or a scalar fullselect. The scope of the set is a group or an intermediate result table, as explained in the information on the GROUP BY clause.
If a GROUP BY clause is specified in a query and the intermediate result from the FROM, WHERE, GROUP BY, and HAVING clauses is the empty set, then the aggregate functions are not applied and the result of the query is the empty set.

If the GROUP BY clause is not specified in a query and the intermediate result table of the FROM, WHERE, and HAVING clauses is the empty set, then the aggregate functions are applied to the empty set.

For example, the result of the following SELECT statement is the number of distinct values of JOB for employees in department D11:

```
SELECT COUNT(DISTINCT JOB)
FROM DSN8C10.EMP
WHERE WORKDEPT = 'D11';
```

The keyword DISTINCT is not an argument of the function but rather a specification of an operation that is performed before the function is applied. If DISTINCT is specified, redundant duplicate values are eliminated before column mask is applied. If the column in aggregate function with DISTINCT keyword has column mask definition references columns that are non-grouping column and not the target column of the DISTINCT operation, the result of aggregate function can vary. Db2 does not guarantee the same row is returned from a group of duplicates in each execution, thus, the values in those non-DISTINCT/non-grouping columns in the returned row could be different each time.

DISTINCT must not be specified preceding an XML value.

For compatibility with other SQL implementations, UNIQUE can be specified as a synonym for DISTINCT in aggregate functions.

When interpreting the DISTINCT clause for decimal floating-point values that are numerically equal, the number of significant digits in the value is not considered. For example, the decimal floating-point number 123.00 is not distinct from the decimal floating-point number 123. The representation of the number returned from the query will be any one of the representations encountered (for example, either 123.00 or 123).

An aggregate function can be used in a WHERE clause only if that clause is part of a subquery of a HAVING clause and the column name specified in the expression is a correlated reference to a group. If the expression includes more than one column name, each column name must be a correlated reference to the same group.

The result of the COUNT and COUNT_BIG functions cannot be the null value. As specified in the description of AVG, MAX, MIN, STDDEV, SUM, and VARIANCE, the result is the null value when the function is applied to an empty set. However, the result is also the null value when the function is specified in an outer select list, the argument is given by an arithmetic expression, and any evaluation of the expression causes an arithmetic exception (such as division by zero).

If the argument values of an aggregate function are strings from a column with a field procedure, the function is applied to the encoded form of the values and the result of the function inherits the field procedure.

- group-by-clause
**ARRAY_AGG**

The ARRAY_AGG function returns an array in which each value of the input set is assigned to an element of the array.

**Ordinary array aggregation**

```
ARRAY_AGG(expression) \\
ORDER BY sort-key-expression ASC DESC
```

**Associative array aggregation**

```
ARRAY_AGG(index-expression,expression)
```

The schema is SYSIBM.

**Ordinary array aggregation**

*expression*

Specifies an expression that returns a value with a data type that is valid for an array element. The data type of the expression must be a data type that can be specified in a CREATE TYPE (array) statement.

*ORDER BY*

Specifies the order of the rows from the same grouping set that are processed in the aggregation. If the ORDER BY clause is not specified, or if the ORDER BY clause cannot differentiate the order of the sort key value, the rows in the same grouping set are arbitrarily ordered.

If a SELECT clause includes multiple invocations of the ARRAY_AGG function, all invocations of ARRAY_AGG in the same SELECT clause that explicitly specify an ORDER BY clause must specify the same order, or not specify an order.

*sort-key-expression*

Specifies a sort key value that is either a column name or an expression. *sort-key-expression* must not reference a column for which a column mask is defined.

If the sort key value is a constant, the constant does not refer to the position of the output column, but is simply a constant, which implies that there is no sort key.

*ASC*  Processes the sort key in ascending order. This is the default option.

*DESC*  Processes the sort key in descending order.
### Associative array aggregation

**index-expression**

Specifies an expression for the index of the associative array.

When the ARRAY_AGG function is invoked in a context in which there is a target user-defined array data type in the same statement, or the result of the ARRAY_AGG function is explicitly cast to a user-defined array data type, the data type of `index-expression` must be castable to the index data type of the target associative array data type. Otherwise, the expression must return a value with a data type that is valid for an array element. The data type of the expression must be a data type that can be specified in a CREATE TYPE (Array) statement.

Duplicate `index-expression` values must not exist in the grouping set that is used to produce the associative array.

**expression**

Specifies an expression that returns a value with a data type that is valid for an array element. The data type of the expression must be a data type that can be specified in a CREATE TYPE (array) statement.

The result data type of ARRAY_AGG is an array. The data type of an array element of the result array is the same as the type of `expression`.

The ARRAY_AGG function can be invoked only in the following contexts:

- The SELECT list of a SELECT INTO statement
- The SELECT list of the outermost fullselect in the definition of a cursor that is not scrollable, in an SQL PL context
- The SELECT list of a scalar subquery that provides a source value for a SET assignment-statement or SQL PL assignment-statement
- A RETURN statement in an SQL scalar function

The following restrictions apply to ARRAY_AGG:

- ARRAY_AGG cannot be used as part of an OLAP specification.
- A fullselect that contains an invocation of ARRAY_AGG cannot contain an ORDER BY clause.
- A fullselect that contains an invocation of ARRAY_AGG cannot contain a DISTINCT keyword in its SELECT list.
- The SELECT clause or HAVING clause of the fullselect that contains an invocation of ARRAY_AGG cannot contain a subquery.
- A SELECT clause that includes an invocation of the ARRAY_AGG function that returns an array of LOBs must not also include a GROUP BY clause.
- A SELECT clause that includes an invocation of the ARRAY_AGG function must not also include an invocation of the LISTAGG function or the XMLAGG function.

**Example 1:** Use ARRAY_AGG in an assignment statement to assign the values of the DECIMALARRAY ordinary array to the array INTARRAY.

```
SET INTARRAY = (SELECT ARRAY_AGG(val) FROM UNNEST(DECIMALARRAY) AS T(val));
```

**Example 2:** Use ARRAY_AGG in a SELECT INTO statement to assign the values of the ESALARIES ordinary array to the array ARRAY2.

```
SELECT ARRAY_AGG(T.val) INTO ARRAY2 FROM UNNEST(ESALARIES) AS T(val);
```
**Example 3:** Use `ARRAY_AGG` to aggregate a set of phone numbers into an ordinary array. The array elements are then assigned to ordinary array `NUMBERS` in order by priority, or in arbitrary order.

Suppose that user-defined type `PHONELIST` and table `EMPLOYEE` have the following definitions:

```sql
CREATE TYPE PHONELIST AS DECIMAL(10,0) ARRAY[10];
CREATE TABLE EMPLOYEE (ID INTEGER NOT NULL,
                        PRIORITY INTEGER NOT NULL,
                        PHONENUMBER DECIMAL(10,0),
                        PRIMARY KEY(ID, PRIORITY));
```

The following SQL PL procedure uses a `SELECT INTO` statement that returns a list of contact numbers under which an employee can be reached, ordered by priority.

```sql
CREATE PROCEDURE GETPHONENUMBERS
    (IN EMPID INTEGER,
     OUT NUMBERS PHONELIST)
BEGIN
    SELECT ARRAY_AGG(PHONENUMBER ORDER BY PRIORITY)
    INTO NUMBERS
    FROM EMPLOYEE
    WHERE ID = EMPID;
END
```

The following SQL PL procedure uses `SET assignment-statement` to return the list of contact numbers in an arbitrary order.

```sql
CREATE PROCEDURE GETPHONENUMBERS
    (IN EMPID INTEGER,
     OUT NUMBERS PHONELIST)
BEGIN
    SET NUMBERS =
        (SELECT ARRAY_AGG(PHONENUMBER)
         FROM EMPLOYEE
         WHERE ID = EMPID);
END
```

**Example 4:** Use `ARRAY_AGG` to aggregate a set of phone numbers into an associative array. The array elements are then assigned to associative array `EMPLOYEES`.

Suppose that user-defined type `EMPPHONES` and table `EMPLOYEE` have the following definitions:

```sql
CREATE TYPE EMPPHONES AS DECIMAL(10,0) ARRAY[INTEGER];
CREATE TABLE EMPLOYEE (ID INTEGER NOT NULL,
                        PRIORITY INTEGER NOT NULL,
                        PHONENUMBER DECIMAL(10,0),
                        PRIMARY KEY(ID, PRIORITY));
```

Create a procedure that uses a `SELECT INTO` statement to aggregate priority 1 phone numbers into an associative array that is indexed by IDs from the `EMPLOYEE` table.

```sql
CREATE PROCEDURE GETPHONES
    (OUT EMPLOYEES EMPPHONES)
BEGIN
    SELECT ARRAY_AGG(ID, PHONENUMBER)
    INTO EMPLOYEES
    FROM EMPLOYEE WHERE PRIORITY=1;
END
```
The AVG function returns the average of a set of numbers.

```
AVG(ALL|DISTINCT numeric-expression)
```

The schema is SYSIBM.

The argument values can be of any built-in numeric data type, and their sum must be within the range of the data type of the result.

The arguments can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34).

The data type of the result is determined as follows:
- DECFLOAT(34) if the argument is DECFLOAT(n).
- Large integer if the argument is small integer.
- Double precision floating-point if the argument is single precision floating-point.
- Otherwise, the result is the same as the data type of the argument.

The result can be null.

If the data type of the argument values is decimal with precision p and scale s, the precision (P) and scale (S) of the result depend on p and the decimal precision option:
- If p is greater than 15 or the DEC31 option is in effect, P is 31 and S is \( \max(0, 28-p+s) \).
- Otherwise, P is 15 and S is 15-p+s.

The function is applied to the set of values derived from the argument values by the elimination of null values. If DISTINCT is specified, redundant duplicate values are also eliminated.

If the function is applied to an empty set, the result is the null value. Otherwise, the result is the average value of the set. The order in which the summation part of the operation is performed is undefined but every intermediate result must be within the range of the result data type.

If the type of the result is integer, the fractional part of the average is lost.

Example: Assuming DEC15, set the DECIMAL(15,2) variable AVERAGE to the average salary in department D11 of the employees in the sample table DSN8C10.EMP.

```
EXEC SQL SELECT AVG(SALARY)
   INTO :AVERAGE
   FROM DSN8C10.EMP
   WHERE WORKDEPT = 'D11';
```
The CORRELATION function returns the coefficient of the correlation of a set of number pairs.

\[ \text{CORRELATION}(\text{expression-1}, \text{expression-2}) \]

The schema is SYSIBM.

The argument values must each be the value of any built-in numeric data type.

If an argument is DECFLOAT(n), the result of the function is DECFLOAT(34). Otherwise, the result of the function is double precision floating-point. The result is between -1 and 1. The result can be null.

The function is applied to the set of \((\text{expression-1}, \text{expression-2})\) pairs derived from the argument values by the elimination of all pairs for which either \(\text{expression-1}\) or \(\text{expression-2}\) is null.

If the function is applied to an empty set, or if either STDDEV(\(\text{expression-1}\)) or STDDEV(\(\text{expression-2}\)) is equal to zero, the result is a null value. Otherwise, the result is the correlation coefficient for the value pairs in the set. The result is equivalent to the following expression:

\[
\text{COVARIANCE}(\text{expression-1}, \text{expression-2}) \div (\text{STDDEV}(\text{expression-1}) \times \text{STDDEV}(\text{expression-2}))
\]

The order in which the values are aggregated is undefined, but every intermediate result must be within the range of the result data type.

CORR can be specified as a synonym for CORRELATION.

Example: Using sample table DSN8C10.EMP, set the host variable :corrln (double-precision floating point) to the correlation between the salary and the bonus for those employees in department (WORKDEPT) 'A00'.

\[
\text{SELECT CORRELATION(SALARY, BONUS) INTO :corrln FROM DSN8C10.EMP WHERE WORKDEPT = 'A00'};
\]

:corrln is set to approximately 9.99853953399538E-001.

COUNT

The COUNT function returns the number of rows or values in a set of rows or values.
The schema is SYSIBM.

The argument values can be of any built-in data type other than a BLOB, CLOB, DBCLOB, or XML.

The result is a large integer. The result cannot be null.

The argument of COUNT(*) is a set of rows. The result is the number of rows in the set. Any row that includes only null values is included in the count.

The argument of COUNT(expression) or COUNT(ALL expression) is a set of values. The function is applied to the set of values derived from the argument values by the elimination of null values. The result is the number of nonnull values in the set, including duplicates.

The argument of COUNT(DISTINCT expression) is a set of values. The function is applied to the set of values derived from the argument values by the elimination of null values and redundant duplicate values. The result is the number of different nonnull values in the set.

Example 1: Set the integer host variable FEMALE to the number of females represented in the sample table DSN8C10.EMP.

```
EXEC SQL SELECT COUNT(*)
    INTO :FEMALE
    FROM DSN8C10.EMP
    WHERE SEX = 'F';
```

Example 2: Set the integer host variable FEMALE_IN_DEPT to the number of departments that have at least one female as a member.

```
EXEC SQL SELECT COUNT(DISTINCT WORKDEPT)
    INTO :FEMALE_IN_DEPT
    FROM DSN8C10.EMP
    WHERE SEX = 'F';
```

**COUNT_BIG**

The COUNT_BIG function returns the number of rows or values in a set of rows or values. It is similar to COUNT except that the result can be greater than the maximum value of an integer.
The schema is SYSIBM.

The argument values can be of any built-in data type other than a BLOB, CLOB, DBCLOB, or XML.

The result of the function is a decimal number with precision 31 and scale 0. The result cannot be null.

The argument of COUNT_BIG(*) is a set of rows. The result is the number of rows in the set. A row that includes only null values is included in the count.

The argument of COUNT_BIG(expression) or COUNT_BIG(ALL expression) is a set of values. The function is applied to the set of values derived from the argument values by the elimination of null values. The result is the number of nonnull values in the set, including duplicates.

The argument of COUNT_BIG(DISTINCT expression) is a set of values. The function is applied to the set of values derived from the argument values by the elimination of null and redundant duplicate values. The result is the number of different nonnull values in the set.

Example 1: Set the integer host variable FEMALE to the number of females represented in the sample table DSN8C10.EMP.

```sql
EXEC SQL SELECT COUNT_BIG(*)
    INTO :FEMALE
    FROM DSN8C10.EMP
    WHERE SEX = 'F';
```

Example 2: Set the integer host variable FEMALE_IN_DEPT to the number of departments that have at least one female as a member.

```sql
EXEC SQL SELECT COUNT_BIG(DISTINCT WORKDEPT)
    INTO :FEMALE_IN_DEPT
    FROM DSN8C10.EMP
    WHERE SEX = 'F';
```

Example 3: To create a sourced function that is similar to the built-in COUNT_BIG function, the definition of the sourced function must include the type of the column that can be specified when the new function is invoked. In this example, the CREATE FUNCTION statement creates a sourced function that takes a CHAR column as input and uses COUNT_BIG to perform the counting. The result is returned as a double precision floating-point number. The query shown counts the number of unique departments in the sample employee table.

```sql
CREATE FUNCTION RICK.COUNT(CHAR())
    RETURNS DOUBLE
    SOURCE SYSIBM.COUNT_BIG(CHAR());
SET CURRENT PATH RICK, SYSTEM PATH;
SELECT COUNT(DISTINCT WORKDEPT) FROM DSN8C10.EMP;
```

The empty parenthesis in the parameter list for the new function (RICK.COUNT) means that the input parameter for the new function is the same type as the input parameter for the function named in the SOURCE clause. The empty parenthesis in the parameter list in the SOURCE clause (SYSIBM.COUNT_BIG) means that the length attribute of the CHAR parameter of the COUNT_BIG function is ignored when Db2 locates the COUNT_BIG function.
**COVAR_SAMP or COVARIANCE_SAMP**

The COVAR_SAMP function returns unbiased sample covariance (n-1) of a set of number pairs.

\[
\text{COVAR}_\text{SAMP} (\text{expression-1}, \text{expression-2})
\]

Notes:
1. To conform to the SQL standard, use COVAR_SAMP.

The schema is SYSIBM.

The argument values must each be the value of any built-in numeric data type.

If an argument is DECFLOAT(n), the result of the function is DECFLOAT(34). Otherwise, the result of the function is double precision floating-point. The result can be null.

The function is applied to the set of (expression-1, expression-2) pairs that are derived from the argument values by the elimination of all pairs for which either expression-1 or expression-2 is null.

If the function is applied to an empty set, the result is a null value. Otherwise, the result is the sample covariance of the value pairs in the set. The result is equivalent to the following output:

1. Let samp_avgexp1 be the result of \( \text{SUM} (\text{expression-1})/n - 1 \) and let samp_avgexp2 be the result of \( \text{SUM} (\text{expression-2})/n - 1 \).
2. The result of COVAR_SAMP (expression-1, expression-2) is \( \text{AVG} ((\text{expression-1} - \text{samp_avgexp1}) \times (\text{expression-2} - \text{samp_avgexp2})) \)

The order in which the values are aggregated is undefined, but every intermediate result must be within the range of the result data type.

The following restrictions apply to COVAR_SAMP:
- COVAR_SAMP cannot be used as part of an OLAP specification.

**Example**

Using sample table DSN8C10.EMP, set the host variable COVARNCE (double-precision floating point) to the sample covariance between the salary and the bonus for those employees in department (WORKDEPT) 'A00'.

```
SELECT COVAR_SAMP(SALARY, BONUS)
    INTO :COVARNCE
FROM DSN8C10.EMP
WHERE WORKDEPT = 'A00';
```

The value of COVARNCE is set to 2178750.
CUME_DIST (aggregate)

The CUME_DIST function returns the cumulative distribution of a row that is hypothetically inserted into a group of rows.

This function is passthrough-only and cannot run on Db2 for z/OS. Db2 only verifies that the data types of the parameters are valid for the function. The accelerator engine does all other function resolution processing and validation. To invoke this function, you must set the QUERY_ACCELERATION subsystem parameter, CURRENT QUERY ACCELERATION special register, or QUERYACCELERATION bind option to ALL, ENABLE, or ELIGIBLE. The function can be referenced in a view but cannot be specified as a source function for a user-defined function.

CUME_DIST (expression) WITHIN GROUP (order-by-clause)

order-by-clause:

ORDER BY sort-key asc-option desc-option

asc-option:

ASC
NULLS LAST
NULLS FIRST

desc-option:

DESC
NULLS FIRST
NULLS LAST

The schema is SYSIBM.

expression

An expression that specifies a row that is hypothetically inserted into a group of rows. The expression must return a value that is a built-in data type. The expression must be a constant, a variable, or a cast of a constant or variable.

WITHIN GROUP

Indicates that the aggregation follows the specified ordering within the grouping set.

order-by-clause

ORDER BY

Specifies the order of the rows from the same grouping set that are processed in the aggregation.
sort-key

The sort key can be a column name or a sort-key-expression. If the sort key is a constant, it does not refer to the position of the output column (as in the ordinary ORDER BY clause), but it is a constant, which implies no sort key.

ASC
Uses the values of the sort-key in ascending order.

DESC
Uses the values of the sort-key in descending order.

NULLS FIRST
The ordering considers null values before all non-null values in the sort order.

NULLS LAST
The ordering considers null values after all non-null values in the sort order.

The number of expressions must be the same as the number of sort-key expressions. The data type of each expression and the data type of the corresponding sort-key expression must be compatible.

The data type of the result is DECFLOAT(34). The actual result is greater than 0.0 and less than or equal to 1.0.

Example

Set the host variable CD to the cumulative distribution of a hypothetical new employee’s salary of 47000 within the salaries of the employees in department ‘A00’.

```
SELECT CUME_DIST(47000) WITHIN GROUP (ORDER BY SALARY)
INTO :CD
FROM EMPLOYEE
WHERE WORKDEPT = 'A00'
```

Related concepts:

►► How Db2 determines whether to accelerate eligible queries (Db2 Performance)

GROUPING

When used in conjunction with grouping-sets and super-groups, the GROUPING function returns a value that indicates if a row returned in a GROUP BY result is a row generated by a grouping set that excludes the column represented by expression.

```
GROUPING(expression)
```

The schema is SYSIBM.

expression
An expression that matches a grouping-expression from the GROUP BY clause of the same subselect.
The result of the function is a small integer value. The result is one of the following values:

1  The value of expression in the returned row is a null value, and the row was generated by the super-group. This generated row can be used to provide sub-total values for the GROUP BY expression.

0  The value is other than the previously listed value.

Example

```
SELECT SALES_DATE, SALES_PERSON,
       SUM(SALES) AS UNITS_SOLD,
       GROUPING(SALES_DATE) AS DATE_GROUP,
       GROUPING(SALES_PERSON) AS SALES_GROUP
FROM SALES
GROUP BY CUBE (SALES_DATE, SALES_PERSON)
ORDER BY SALES_DATE, SALES_PERSON;
```

The previous query returns results similar to the following:

<table>
<thead>
<tr>
<th>SALES_DATE</th>
<th>SALES_PERSON</th>
<th>UNITS_SOLD</th>
<th>DATE_GROUP</th>
<th>SALES_GROUP</th>
</tr>
</thead>
<tbody>

<td>1</td>
</tr>
</tbody>
</table>

An application can identify a SALES_DATE sub-total row because the value of DATE_GROUP is 0 and the value of SALES_GROUP is 1. A SALES_PERSON sub-total row can be identified because the value of DATE_GROUP is 1 and the value of SALES_GROUP is 0. A grand total row can be identified by the value 1 for both DATE_GROUP and SALES_GROUP.

- [Examples of grouping sets, rollup, and cube queries](#)

**LISTAGG**

The LISTAGG function aggregates a set of strings into one string by concatenating the strings. Optionally, a separator string can be provided which is inserted between contiguous input strings.

[FL 501]
The schema is SYSIBM.

The LISTAGG function aggregates a set of string values for a group into one string by appending the `string-expression` values based on the order that is specified in the WITHIN GROUP clause.

The function is applied to the set of values that are derived from the first argument by the elimination of null values. If a separator argument is specified that is not the null value, the separator value is inserted between each pair of non-null `string-expression` values.

**string-expression**

An expression that specifies the string values to aggregate. The expression must return a value that is a built-in character string, graphic string, or a binary string data type that is not a LOB. If the value is a CLOB, it is implicitly cast to VARCHAR before the function is evaluated up to a maximum length of 32704. If the value is a DBCLOB, it is implicitly cast to VARGRAPHIC before the function is evaluated up to a maximum length of 16352. If the value is a BLOB, it is implicitly cast to VARBINARY before the function is evaluated up to a maximum length of 32704.

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type.

If `string-expression` is a column encoded by a field procedure, the decoded value is used in the result.

**separator**

A constant expression that defines the string that is to be used between non-null `string-expression` values. The expression must return a value that is a built-in character string, graphic string, or a binary string data type.

LOBs are supported through implicit casting. If the value is a CLOB, it is implicitly cast to VARCHAR before the function is evaluated up to a maximum length of 32704. If the value is a DBCLOB, it is implicitly cast to VARGRAPHIC before the function is evaluated up to a maximum length of 16352. If the value is a BLOB, it is implicitly cast to VARBINARY before the function is evaluated up to a maximum length of 32704.

The separator can be a literal, special register, variable, or an expression that is based on literals, special registers, or variables, provided that the expression does not include a non-deterministic function or a function that takes an external action.
WITHIN GROUP
Indicates that the aggregation follows the specified ordering within the grouping set.

If WITHIN GROUP is not specified, the ordering of strings within the result is not deterministic.

ORDER BY
Specifies the order of the rows from the same grouping set that are processed in the aggregation. If the ORDER BY clause cannot distinguish the order of the column data, the rows in the same grouping set are arbitrarily ordered.

sort-key
The sort key can be a column name or a sort-key-expression. If the sort key is a constant, it does not refer to the position of the output column (as in the ORDER BY clause of a query); It is a constant, which implies no sort key.

If the sort key value is a constant, the constant does not refer to the position of the output column, but is simply a constant, which implies that there is no sort key.

sort-key must not include a scalar fullselect, or any function that is non-deterministic or has an external action. sort-key must not reference a column for which a column mask is defined.

If sort-key is encoded by a field procedure, the encoded value determines the order.

ASC Processes the sort-key in ascending order. This is the default option.

DESC Processes the sort-key in descending order.

The result data type of LISTAGG is based on the data type of string-expression:

- If the data type of string-expression is CHAR(n) or VARCHAR(n), the data type of the result is VARCHAR(MIN(MAX(4000,n), 32704)).
  - If the string-expression and separator are both bit data, the result is bit data. Otherwise, neither string-expression nor separator can be bit data.
  - If string-expression and separator are both SBCS Unicode data, the CCSID of the result is the CCSID for SBCS Unicode data.
  - If string-expression is SBCS Unicode data, and separator is not SBCS Unicode data, the CCSID of the result is the mixed CCSID for Unicode data. Otherwise, the CCSID of the result is the mixed CCSID that corresponds to the CCSID of string-expression. However, if the input is EBCDIC or ASCII and there is no corresponding system CCSID for mixed, the CCSID of the result is the CCSID of string-expression.

- If the data type of string-expression is GRAPHIC(n) or VARGRAPHIC(n), the data type of the result is VARGRAPHIC( MAX(2000,n), 16352). The encoding scheme of the result is the same as string-expression. The CCSID of the result is the same as the CCSID of string-expression. separator cannot be bit data.

- If the data type of string-expression is BINARY(n) or VARBINARY(n), the data type of the result is VARBINARY( MAX(4000,n), 32704).

The result data type can exceed VARCHAR(4000), VARBINARY(4000), or VARGRAPHIC(2000), if a derived size is used to determine the size of the result. The maximum possible value is the maximum for the result data type. The following example yields a return data type of VARCHAR(10000):

LISTAGG(CAST(NAME AS VARCHAR(10000)), ', ')
If the actual length of the aggregated result string exceeds the maximum for the result data type, an error is returned.

The result can be null. If the function is applied to an empty set, or all of the string-expression values in the set are null values, the result is a null value.

The following restrictions apply to LISTAGG:

- LISTAGG cannot be used as part of an OLAP specification.
- If DISTINCT is specified for LISTAGG, ORDER BY must be specified and the first sort-key of the ORDER BY specification must exactly match string-expression.
- A fullselect that contains an invocation of LISTAGG cannot contain an ORDER BY clause.
- A fullselect that contains an invocation of LISTAGG cannot contain a DISTINCT keyword in its SELECT list.
- A SELECT clause that includes an invocation of the LISTAGG function must not also include an invocation of the ARRAY_AGG function or the XMLAGG function.

**Example**

Produce an alphabetical list of comma-separated names, grouped by department, from the sample employee table.

```
SELECT WORKDEPT,
  LISTAGG(LASTNAME, ', ') WITHIN GROUP(ORDER BY LASTNAME)
AS EMPLOYEES
FROM EMP
GROUP BY WORKDEPT;
```

The following result is returned.

```
---------+---------------------------------------------------------
WORKDEPT | EMPLOYEES
---------+---------------------------------------------------------
A00      | HAAS, HEMMINGER, LUCCHESI, O'CONNELL, ORLANDO
B01      | THOMPSON
C01      | KWAN, Natz, NICOLLS, QUINTANA
D11      | ADAMSON, BROWN, JOHN, JONES, LUTZ, PIANKA, SCOUTTEN, STERN, WALKER, YAMAMOTO, YOSHIMURA
D21      | JEFFERSON, JOHNSON, MARINO, MONTEVERDE, PEREZ, PULASKI, SMITH
E01      | GEYER
E11      | HENDERSON, PARKER, SCHNEIDER, SCHWARTZ, SETRIGHT, SMITH, SPRINGER
E21      | ALONZO, GOUNOT, LEE, MEHTA, SPENSER, WONG
```

**Related reference:**

- [Function level 501 (activation enabled by APAR PI70535—May, 2017) (Db2 for z/OS What's New?)](#)
- [Employee table (DSN8C10.EMP) (Introduction to Db2 for z/OS)](#)

**MAX (aggregate)**

The MAX function returns the maximum value in a set of values of a group.
The schema is SYSIBM.

The arguments must be compatible. For more information on compatibility, refer to the compatibility matrix in [Table 31 on page 151]. All arguments except the first argument can be parameter markers.

This function cannot be used as a source function when creating a user-defined function.

**expression**

An expression that returns the value of a built-in data type. Each expression must return a value that is not a CLOB, DBCLOB, BLOB, ROWID, or XML. Character string arguments and binary string arguments cannot have a length attribute greater than 32704, and graphic string arguments cannot have a length attribute greater than 16352.

If there are any mixed character string or graphic string and numeric arguments, the string value is implicitly cast to a DECFLOAT(34) value.

The result of the function is the largest argument value. The data type of the result and its other attributes (for example, the length and CCSID of a string or a datetime value) are the same as the data type and attributes of the argument values. The result can be null.

The function is applied to the set of values derived from the argument values by the elimination of null values.

If the function is applied to an empty set, the result is the null value. Otherwise, the result is the maximum value in the set.

The specification of DISTINCT has no effect on the result and is not advised.

**Example 1:** Set the DECIMAL(8,2) variable MAX_SALARY to the maximum monthly salary of the employees represented in the sample table DSN8C10.EMP.

```
EXEC SQL SELECT MAX(SALARY) / 12
      INTO :MAX_SALARY
      FROM DSN8C10.EMP;
```

**Example 2:** Find the surname that comes last in the collating sequence for the employees represented in the sample table DSN8C10.EMP. Set the VARCHAR(15) variable LAST_NAME to that surname.

```
EXEC SQL SELECT MAX(LASTNAME)
      INTO :LAST_NAME
      FROM DSN8C10.EMP;
```

**MEDIAN**

The MEDIAN function returns the median of a set of numbers.
The schema is SYSIBM.

**numeric-expression**

An expression that returns a built-in numeric data type. *numeric-expression* must not include a scalar fullselect, or invoke a function that is non-deterministic or has an external action.

If the argument is `DECFOAT(n)`, the result of the function is `DECFOAT(34)`. Otherwise, the result of the function is a double precision floating-point number.

The function is applied to the set of values that are derived from the argument values by the elimination of null values.

The result can be null. If *numeric-expression* is null or if the function is applied to the empty set, the result is the null value.

Specifying `MEDIAN(numeric-expression)` is equivalent to specifying `PERCENTILE_CONT(0.5) WITHIN GROUP (ORDER BY numeric-expression)`.

**Example 1:** Calculate the median salary of the employees in department D11 from the EMPLOYEE table.

```sql
SELECT MEDIAN(SALARY)
FROM EMPLOYEE
WHERE WORKDEPT = 'D11';
```

The result is 24680.00. Department D11 has 11 employees. The middle row of a group of 11 values is the sixth row. The result of `MEDIAN` over that group is the value of the sixth row, which is 24680.00.

**Example 2:** Calculate the median salary of the employees in department E21 from the EMPLOYEE table.

```sql
SELECT MEDIAN(SALARY)
FROM EMPLOYEE
WHERE WORKDEPT = 'E21';
```

The result is 24605.00. Department E21 has six employees. Because there are an even number of rows, the `MEDIAN` is computed by interpolating a value between the middle two rows. The middle two rows are the third row with the value 23840.00 and the fourth row with the value 25370.00. `MEDIAN` is computed by averaging those two values, which is 24605.00.

**Note:** Consider the following additional notes:

When EXPLAIN is issued against an SQL statement that references the `MEDIAN` function, but the statement cannot be run on the accelerator server for any reason, the following values are populated in the PLAN_TABLE table:

- For a SELECT statement, column QBLOCK_TYPE would have the value 'PRUNED', and column ACCESSTYPE would have the value ' ' (blank).
- For an INSERT statement with a subselect, the PLAN_TABLE rows for the subselect would have column QBLOCK_TYPE with the value 'NCOSUB', and column ACCESSTYPE with the value ' ' (blank).
Also, when a view is referenced in an SQL statement that uses the MEDIAN function, the tables referred to in the view must be enabled for acceleration. Those tables referred to in the view do not need to be enabled for acceleration when the view is created.

**MIN (aggregate)**

The MIN function returns the minimum value in a set of values of a group.

```
MIN(ALL
DISTINCT
expression)
```

The schema is SYSIBM.

The arguments must be compatible. For more information on compatibility, refer to the compatibility matrix in Table 31 on page 151. All arguments except the first argument can be parameter markers.

This function cannot be used as a source function when creating a user-defined function.

**expression**

An expression that returns the value of a built-in data type. Each expression must return a value that is not a CLOB, DBCLOB, BLOB, ROWID, or XML. Character string arguments and binary string arguments cannot have a length attribute greater than 32704, and graphic string arguments cannot have a length attribute greater than 16352.

If there are any mixed character string or graphic string and numeric arguments, the string value is implicitly cast to a DECFLOAT(34) value.

The result of the function is the smallest argument value. The data type of the result and its other attributes (for example, the length and CCSID of a string or a datetime value) are the same as the data type and attributes of the argument values. The result can be null.

The function is applied to the set of values derived from the argument values by the elimination of null values.

If the function is applied to an empty set, the result is the null value. Otherwise, the result is the minimum value in the set.

The specification of DISTINCT has no effect on the result and is not advised.

**Example 1:** Set the DECIMAL(15,2) variable MIN_SALARY to the minimum monthly salary of the employees represented in the sample table DSN8C10.EMP.

```sql
EXEC SQL SELECT MIN(SALARY) / 12 INTO :MIN_SALARY
    FROM DSN8C10.EMP;
```
Example 2: Find the surname that comes first in the collating sequence for the employees represented in the sample table DSN8C10.EMP. Set the VARCHAR(15) variable LAST_NAME to that surname.

```sql
EXEC SQL SELECT MIN(LASTNAME) INTO :LAST_NAME FROM DSN8C10.EMP;
```

**PERCENTILE_CONT**

The PERCENTILE_CONT function returns a percentile of a set of values. The set of values is treated as a continuous distribution. The calculated percentile is an interpolated value that might not have appeared in the input set.

The schema is SYSIBM.

**percentile-expr**

Specifies the percentile that is to be calculated by the function. `percentile-expr` must return a built-in numeric, character, or graphic string data type that is not a LOB. If the value is not a numeric data type is cast to DECIMAL(34) before the function is evaluated. The value must be between 0 and 1.

**WITHIN GROUP**

Specifies that the percentile is to be calculated over the rows that are identified in the group.

**sort-expression**

Specifies the set of values over which to calculate the percentile and the order of the set. `sort-expression` must return a built-in numeric data type. A string value is implicitly cast to a numeric value. Also, `sort-expression` must not include a scalar fullselect, or any function that is non-deterministic or has an external action.

**ASC**

Specifies that the percentile is calculated using values from `sort-expression` in ascending order.

**DESC**

Specifies that the percentile is calculated using values from `sort-expression` in descending order.

The result is the value at the percentile that is specified by `percentile-expr` over the set of values identified by `sort-expression`.

For PERCENTILE_CONT, the set of values is treated as a continuous distribution. The calculated percentile is a interpolated value that might not have appeared in the input set. If the argument is DECIMAL(n), the result of the function is DECIMAL(34). Otherwise, the result of the function is a double-precision floating point number.

The function is applied to the set of values that are derived from `sort-expression` by the elimination of null values.
The result can be null. If \textit{percentile-expr} is null, or if the function is applied to an empty set, the result is the null value.

The result of using \textit{PERCENTILE\_CONT(0.5) WITHIN GROUP (ORDER BY sort-expression)} is equivalent to \textit{MEDIAN(numeric-expression)}.

\textbf{Example 1:} This example calculates the median salary of the employees in department D11 from the EMP table.

\begin{verbatim}
SELECT PERCENTILE_CONT(0.5) WITHIN GROUP (ORDER BY SALARY)
FROM DSN8C10.EMP
WHERE WORKDEPT = 'D11';
\end{verbatim}

The result is 24,680.00. Department D11 has 11 employees. The middle row of a group of 11 values in the sixth row. Because there are an odd number of rows, the \textit{PERCENTILE\_CONT} function for the percentile 0.5 returns the value of the sixth row, which is 24,680.00.

\textbf{Example 2:} This example calculates the median commission of the employees in department E21 from the EMP table.

\begin{verbatim}
SELECT PERCENTILE_CONT(0.5) WITHIN GROUP (ORDER BY COMM)
FROM DSN8C10.EMP
WHERE WORKDEPT = 'E21';
\end{verbatim}

The result is 1968.50. This example has an even number of rows, so the \textit{PERCENTILE\_CONT} function is computed by interpolating a value between the two middle rows. The two middle rows are row three with a value of 1907.00 and row four with a value of 2030.00. \textit{PERCENTILE\_CONT} is computed by averaging those two values, which is 1968.50.

\textbf{Example 3:} This example calculates the 95th percentile of total salary per department from the EMP table.

\begin{verbatim}
SELECT PERCENTILE_CONT(0.95) WITHIN GROUP (ORDER BY SALARY+BONUS)
FROM DSN8C10.EMP
GROUP BY WORKDEPT;
\end{verbatim}

\section*{PERCENTILE\_DISC}

The \textit{PERCENTILE\_DISC} function returns a percentile of a set of values. Each value in the input set is treated as a discrete value. The calculated percentile is always a value that appeared in the input set.

\begin{verbatim}
PERCENTILE\_DISC(percentile-expr)-WITHIN GROUP-(ORDER BY-sort-expression-ASC-)
\end{verbatim}

The schema is SYSIBM.

\textit{percentile-expr}

\textit{percentile-expr} specifies the percentile that is to be calculated by the function. \textit{percentile-expr} must return a built-in numeric, character, or graphic string data type that is not a LOB. If the value is not a numeric data type is cast to \textit{DEC\_FLOAT(34)} before the function is evaluated. The value must be between 0 and 1.
WITHIN GROUP
  Specifies that the percentile is to be calculated over the rows that are
  identified in the group.

sort-expression
  Specifies the set of values over which to calculate the percentile and the
  order of the set. sort-expression must return a built-in numeric data type.
  Also, sort-expression must not include a scalar fullselect, or any function
  that is non-deterministic or has an external action.

ASC  Specifies that the percentile is calculated using values from sort-expression
       in ascending order.

DESC Specifies that the percentile is calculated using values from sort-expression
       in descending order.

The result is the value at the percentile that is specified by percentile-expr over the
set of values identified by sort-expression.

For PERCENTILE_DISC, each value in the input set is treated as a discrete value.
The calculated percentile is always a value that appeared in the input set. The data
type of the result is the same as the data type of the result of sort-expression.

The function is applied to the set of values that are derived from sort-expression by
the elimination of null values.

The result can be null. If percentile-expr is null, or if the function is applied to an
empty set, the result is the null value.

Example 1: This example calculates the median salary as a discrete value of the
employees in department D11 from the EMP table.
SELECT PERCENTILE_DISC(0.5) WITHIN GROUP (ORDER BY SALARY)
FROM DSN8C10.EMP
WHERE WORKDEPT = 'D11';

The result is 24,680.00. Department D11 has 11 employees. The middle row of a
group of 11 values in the sixth row. Because there are an odd number of rows, the
PERCENTILE_DISC function for the percentile 0.5 returns the value of the sixth
row, which is 24,680.00.

Example 2: This example calculates the median commission as a discrete value of
the employees in department E21 from the EMP table.
SELECT PERCENTILE_DISC(0.5) WITHIN GROUP (ORDER BY COMM)
FROM DSN8C10.EMP
WHERE WORKDEPT = 'E21';

The result is 1907.00. This example has six rows, which is an even number of rows.
The PERCENTILE_DISC function is computed by returning the value of the first of
the two middle rows, which is row three with a value of 1907.00.

Example 3: This example calculates the 95th percentile of total salary per
department from the EMP table.
SELECT PERCENTILE_DISC(0.95) WITHIN GROUP (ORDER BY SALARY+BONUS)
FROM DSN8C10.EMP
GROUP BY WORKDEPT;
PERCENT_RANK (aggregate)

The PERCENT_RANK function returns the relative percentile rank of a row that is hypothetically inserted into a group of rows.

This function is passthrough-only and cannot run on Db2 for z/OS. Db2 only verifies that the data types of the parameters are valid for the function. The accelerator engine does all other function resolution processing and validation. To invoke this function, you must set the QUERY_ACCELERATION subsystem parameter, CURRENT QUERY ACCELERATION special register, or QUERYACCELERATION bind option to ALL, ENABLE, or ELIGIBLE. The function can be referenced in a view but cannot be specified as a source function for a user-defined function.

```
PERCENT_RANK(expression) WITHIN GROUP(order-by-clause)
```

**order-by-clause:**

```
ORDER BY sort-key [asc-option, desc-option]
```

**asc-option:**

```
ASC | NULLS LAST
    | NULLS FIRST
```

**desc-option:**

```
DESC | NULLS FIRST
    | NULLS LAST
```

The schema is SYSIBM.

**expression**

An expression that specifies a row that is hypothetically inserted into a group of rows. The expression must return a value that is a built-in data type. The expression must be a constant, a variable, or a cast of a constant or variable.

**order-by-clause**

```
ORDER BY
```

Specifies the order of the rows from the same grouping set that are processed in the aggregation.

**sort-key**

The sort key can be a column name or a sort-key-expression. If the sort key
is a constant, it does not refer to the position of the output column. A constant implies no sort key, unlike a constant in the ordinary ORDER BY clause.

**ASC**

Uses the values of the sort-key in ascending order.

**DESC**

Uses the values of the sort-key in descending order.

**NULLS FIRST**

The ordering considers null values before all non-null values in the sort order.

**NULLS LAST**

The ordering considers null values after all non-null values in the sort order.

The number of expressions must be the same as the number of sort-key expressions. The data type of each expression and the data type of the corresponding sort-key expression must be compatible.

The data type of the result is DECFLOAT(34). The actual result is greater than 0.0 and less than or equal to 1.0.

**Example**

Set the host variable PR to the relative percentile rank of a hypothetical new employee’s salary of 47000 within the salaries of the employees in department 'A00'.

```sql
SELECT PERCENT_RANK(47000) WITHIN GROUP (ORDER BY SALARY)
  INTO :PR FROM EMPLOYEE WHERE WORKDEPT = 'A00'
```

PR is set to a value of 0.4.

The following result set is shown for reference.

```sql
SELECT SALARY FROM EMPLOYEE WHERE WORKDEPT = 'A00' ORDER BY SALARY
```

<table>
<thead>
<tr>
<th>SALARY</th>
</tr>
</thead>
<tbody>
<tr>
<td>39250.00</td>
</tr>
<tr>
<td>46500.00</td>
</tr>
<tr>
<td>49250.00</td>
</tr>
<tr>
<td>66500.00</td>
</tr>
<tr>
<td>152750.00</td>
</tr>
</tbody>
</table>

5 record(s) selected.

**Related concepts:**

[How Db2 determines whether to accelerate eligible queries (Db2 Performance)](linked)

**STDDEV_POP or STDDEV**

The STDDEV_POP function returns the population standard deviation (division by \( n \)) of a set of numbers.
The schema is SYSIBM.

The formula that is used to calculate the result is logically equivalent to:
\[ \text{STDDEV}_\text{POP} = \sqrt{\text{VAR}_\text{POP}} \]

The argument values must each be the value of any built-in numeric data type, and their sum must be within the range of the data type of the result.

The arguments can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34).

If the argument is DECFLOAT(n), the result of the function is DECFLOAT(34). Otherwise, the result of the function is double precision floating-point. The result can be null.

Before the function is applied to the set of values derived from the argument values, null values are eliminated. If DISTINCT is specified, redundant duplicate values are also eliminated.

If the function is applied to an empty set, the result is the null value. Otherwise, the result is the population standard deviation of the values in the set.

The order in which the values are aggregated is undefined, but every intermediate result must be within the range of the result data type.

Example

Using sample table DSN8C10.EMP, set the host variable DEV, which is defined as double precision floating-point, to the population standard deviation of the salaries for the employees in department 'A00' (WORKDEPT='A00').

```sql
SELECT STDDEV_POP(SALARY)
  INTO :DEV
FROM DSN8C10.EMP
WHERE WORKDEPT = 'A00';
```

The value of DEV is set to an approximate value of 9742.43.

STDDEV_SAMP

The STDDEV_SAMP function returns the sample standard deviation (division by \( n-1 \)) of a set of numbers.
The schema is SYSIBM.

The formula that is used to calculate the result is logically equivalent to:

\[ \text{STDDEV\_SAMP} = \sqrt{\text{VAR\_SAMP}} \]

The argument values must each be the value of any built-in numeric data type, and their sum must be within the range of the data type of the result.

The arguments can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34).

If the argument is DECFLOAT(n), the result of the function is DECFLOAT(34). Otherwise, the result of the function is double precision floating-point. The result can be null.

Before the function is applied to the set of values derived from the argument values, null values are eliminated. If DISTINCT is specified, redundant duplicate values are also eliminated.

If the function is applied to an empty set, the result is the null value. Otherwise, the result is the sample standard deviation of the values in the set.

The order in which the values are aggregated is undefined, but every intermediate result must be within the range of the result data type.

The following restrictions apply to STDDEV\_SAMP:

- STDDEV\_SAMP cannot be used as part of an OLAP specification.

**Example**

Using sample table DSN8C10.EMP, set the host variable DEV, which is defined as double precision floating-point, to the sample standard deviation of the salaries for the employees in department 'A00' (WORKDEPT='A00').

```sql
SELECT STDDEV\_SAMP(SALARY)
  INTO :DEV
FROM DSN8C10.EMP
WHERE WORKDEPT = 'A00';
```

The value of DEV is set to approximately 10892.37.

**SUM**

The SUM function returns the sum of a set of numbers.
The schema is SYSIBM.

The argument values can be of any built-in numeric data type, and their sum must be within the range of the data type of the result.

The arguments can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34).

The data type of the result is determined as follows:
- DECFLOAT(34) if the argument is DECFLOAT(n).
- Large integer if the argument is small integer.
- Double precision floating-point if the argument is single precision floating-point.
- Otherwise, the result is the same as the data type of the argument.

The result can be null.

If the data type of the argument values is decimal, the scale of the result is the same as the scale of the argument values, and the precision of the result depends on the precision of the argument values and the decimal precision option:
- If the precision of the argument values is greater than 15 or the DEC31 option is in effect, the precision of the result is \( \min(31, P+10) \), where \( P \) is the precision of the argument values.
- Otherwise, the precision of the result is 15.

The function is applied to the set of values derived from the argument values by the elimination of null values. If DISTINCT is specified, redundant duplicate values are also eliminated.

If the function is applied to an empty set, the result is the null value. Otherwise, the result is the sum of the values in the set. The order in which the summation is performed is undefined but every intermediate result must be within the range of the result data type.

Example: Set the large integer host variable INCOME to the total income from all sources (salaries, commissions, and bonuses) of the employees represented in the sample table DSN8C10.EMP. If DEC31 is not in effect, the resultant sum is DECIMAL(15,2) because all three columns are DECIMAL(9,2).

```sql
EXEC SQL SELECT SUM(SALARY+COMM+BONUS)
  INTO :INCOME
  FROM DSN8C10.EMP;
```

**VAR_POP or VARIANCE or VAR**

The VAR_POP function returns the biased variance (division by \( n \)) of a set of numbers.
Notes:
1. To conform to the SQL standard, use VAR_POP.

The schema is SYSIBM.

The formula that is used to calculate the result is logically equivalent to:

\[ \text{VAR\_POP} = \frac{\text{SUM}(X^2)}{\text{COUNT}(X)} - \left(\frac{\text{SUM}(X)}{\text{COUNT}(X)}\right)^2 \]

The argument values can be of any built-in numeric type, and their sum must be within the range of the data type of the result. Before the function is applied to the set of values derived from the argument values, null values are eliminated. If DISTINCT is specified, redundant duplicate values are also eliminated.

The arguments can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34).

If the argument is DECFLOAT\(n\), the result of the function is DECFLOAT(34). Otherwise, the result of the function is double precision floating-point.

The result can be null; if any argument is null, the result is the null value.

Otherwise, the result is the population variance of the values in the set.

The order in which the values are added is undefined, but every intermediate result must be within the range of the result data type.

Example

Using sample table DSN8C10.EMP, set host variable VARNCE, which is defined as double precision floating-point, to the population variance of the salaries (SALARY) for those employees in department (WORKDEPT) 'A00'.

```sql
SELECT VAR_POP(SALARY) INTO :VARNCE
FROM DSN8C10.EMP
WHERE WORKDEPT = 'A00';
```

The value of VARNCE is set to 94915000.

**VAR\_SAMP or VARIANCE\_SAMP**

The VAR\_SAMP function returns the sample variance (division by \(n-1\)) of a set of numbers.
(1) VAR_SAMP((numeric-expression) ALL)

(1) VARIANCE_SAMP((numeric-expression) DISTINCT)

Notes:
1. To conform to the SQL standard, use VAR_SAMP

The schema is SYSIBM.

The formula that is used to calculate the result is logically equivalent to:

\[ \text{VAR\_SAMP} = \frac{\left(\sum(X^2) - \frac{\left(\sum(X)^2\right)}{\text{COUNT}(*)}\right)}{\text{COUNT}(*) - 1} \]

The argument values can be of any built-in numeric type, and their sum must be within the range of the data type of the result. Before the function is applied to the set of values derived from the argument values, null values are eliminated. If DISTINCT is specified, redundant duplicate values are also eliminated.

The arguments can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34).

If the argument is DECFLOAT(n), the result of the function is DECFLOAT(34).

Otherwise, the result of the function is double precision floating-point.

The result can be null; if any argument is null, the result is the null value.

Otherwise, the result is the sample variance of the values in the set.

The order in which the values are added is undefined, but every intermediate result must be within the range of the result data type.

The following restrictions apply to VAR_SAMP:
- VAR_SAMP cannot be used as part of an OLAP specification.

Example

Using sample table DSN8C10.EMP, set host variable VARNCE, which is defined as double precision floating-point, to the sample variance of the salaries (SALARY) for those employees in department (WORKDEPT) 'A00'.

```
SELECT VAR_SAMP(SALARY)
INTO :VARNCE_S
FROM DSN8C10.EMP
WHERE WORKDEPT = 'A00';
```

The value of VARNCE is set to 1186437500.

XMLAGG

The XMLAGG function returns an XML sequence that contains an item for each non-null value in a set of XML values.
XMLAGG("XML-expression")

ORDER BY sort-key

sort-key

The schema is SYSIBM.

XML-expression
An expression that returns an XML value.
Unlike the arguments for other aggregate functions, a scalar fullselect is allowed in XML-expression.

ORDER BY
Specifies the order of the rows from the same grouping set that are processed in the aggregation. If the ORDER BY clause is not specified, or if the ORDER BY clause cannot differentiate the order of the sort key value, the rows in the same grouping set are arbitrarily ordered.

sort-key
Specifies a sort key value that is either a column name or an expression. The data type of the column or expression must not be a LOB or an XML value. A character string expression cannot have a length greater than 4000 bytes. If the sort key value is a constant, it does not refer to the position of the output column (as in the ordinary ORDER BY clause), but is simply a constant, which implies no sort key.

The ordering is based on the values of the sort keys, which might or might not be used in XML-expression.

If the sort key value is a character string that uses an encoding scheme other than Unicode, the ordering might be different. For example, a column PROD CODE uses EBCDIC. For two values, ('P001' and 'PA01'), relationship 'P001' > 'PA01' is true in EBCDIC, whereas 'P001' < 'PA01' is true in UTF-8. If the same sort key values are used in XML-expression, use the CAST specification to convert the sort key to Unicode to keep the ordering of XML values consistent with that of the sort key.

The function is applied to the set of values derived from the argument values by the elimination of null values.

The result can be null; if all XML-expression arguments are null. If the function is applied to an empty set, the result is the null value. Otherwise, the result is an XML sequence that contains an item for each value in the set.

The following restrictions apply to XMLAGG:
• XMLAGG cannot be used as part of an OLAP specification.

• A SELECT clause that includes an invocation of the XMLAGG function must not also include an invocation of the ARRAY_AGG function or the LISTAGG function.

Example: Group employees by their department, generate a 'Department' element for each department with its name as the attribute, nest all the 'emp' elements for employees in each department, and order the 'emp' elements by 'lname'.

```sql
SELECT XMLSERIALIZE(XMLDOCUMENT
  ( XMLELEMENT
    ( NAME "Department",
      XMLATTRIBUTES ( e.dept AS "name" ),
      XMLAGG ( XMLELEMENT ( NAME "emp", e.lname)
        ORDER BY e.lname)
    ) ) AS "dept_list"
  AS CLOB(IM))
FROM employees e
GROUP BY dept;
```

The result of the query would look similar to the following result:

```
dept_list
---------------------------------------------
<Department name="Accounting">
  <emp>SMITH</emp>
  <emp>Yates</emp>
</Department>
<Department name="Shipping">
  <emp>Martin</emp>
  <emp>Oppenheimer</emp>
</Department>
------------------------------------------------
```

Scalar functions

A scalar function can be used wherever an expression can be used. The restrictions on the use of aggregate functions do not apply to scalar functions, because a scalar function is applied to single set of parameter values rather than to sets of values. The argument of a scalar function can be a function. However, the restrictions that apply to the use of expressions and aggregate functions also apply when an expression or aggregate function is used within a scalar function. For example, the argument of a scalar function can be a aggregate function only if a aggregate function is allowed in the context in which the scalar function is used.

If the argument of a scalar function is a string from a column with a field procedure, the function applies to the decoded form of the value and the result of the function does not inherit the field procedure.

Example: The following SELECT statement calls for the employee number, last name, and age of each employee in department D11 in the sample table DSN8C10.EMP. To obtain the ages, the scalar function YEAR is applied to the expression:

```sql
CURRENT DATE - BIRTHDATE
```

in each row of DSN8C10.EMP for which the employee represented is in department D11:

```sql
SELECT EMPNO, LASTNAME, YEAR(CURRENT DATE - BIRTHDATE)
FROM DSN8C10.EMP
WHERE WORKDEPT = 'D11';
```
ABS

The ABS function returns the absolute value of a number.

\[ \text{ABS(numeric-expression)} \]

The schema is SYSIBM.

The argument must be an expression that returns a value of any built-in numeric data type.

The arguments can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34).

The result of the function has the same data type and length attribute as the argument.

The result can be null; if the argument is null, the result is the null value.

ABSVAL can be specified as a synonym for ABS. Db2 supports this keyword to provide compatibility with previous releases.

Example: Assume that host variable PROFIT is a large integer with a value of -50000. The following statement returns a large integer with a value of 50000.

\[
\text{SELECT ABS(:PROFIT) FROM SYSIBM.SYSDUMMY1;}
\]

ACOS

The ACOS function returns the arc cosine of the argument as an angle, expressed in radians. The ACOS and COS functions are inverse operations.

\[ \text{ACOS(numeric-expression)} \]

The schema is SYSIBM.

The argument must be an expression that returns the value of any built-in numeric data type except for DECFLOAT. The value must be greater than or equal to -1 and less than or equal to 1. If the argument is not a double precision floating-point number, it is converted to one for processing by the function.

The result of the function is a double precision floating-point number.

The result can be null; if the argument is null, the result is the null value.

Example: Assume that host variable ACOSINE is DECIMAL(10,9) with a value of 0.070737202. The following statement:
SELECT ACOS(:ACOSINE)  
FROM SYSIBM.SYSDUMMY1;

returns a double precision floating-point number with an approximate value of 1.49.

**ADD_MONTHS**

The ADD_MONTHS function returns a date that represents *expression* plus a specified number of months.

```
ADD_MONTHS(expression, numeric-expression)
```

The schema is SYSIBM.

*expression*

An expression that specifies the starting date. *expression* must return a value that is a date, timestamp, or a valid string representation of a date or timestamp. A string representation is a value that is a built-in character string data type or graphic string data type, that is not a LOB, and that has an actual length that is not greater than 255 bytes. A time zone in a string representation of a timestamp is ignored. For the valid formats of string representations of dates and timestamps, see "String representations of datetime values" on page 130.

If *expression* is a TIMESTAMPT WITH TIME ZONE value, *expression* is first cast to a TIMESTAMPT WITHOUT TIME ZONE value with the same precision as *expression*. If *expression* is a string, *expression* is first cast to DATE.

*numeric-expression*

An expression that returns a value of any built-in numeric data type. The integer portion of *numeric-expression* specifies the number of months to add to *expression*. A negative numeric value is allowed.

*numeric-expression* can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34).

If *expression* is a timestamp with a time zone value, or a valid string representation of a timestamp with a time zone value, the result is determined from the UTC representation of the datetime value.

If *expression* is a timestamp value the result is a TIMESTAMPT WITHOUT TIME ZONE with the same precision as *expression*. Otherwise, the result is a DATE value.

The result can be null; if any argument is null, the result is the null value.

If *expression* is the last day of the month or if the resulting month has fewer days than the day component of *expression*, the result is the last day of the resulting month. Otherwise, the result has the same day component as *expression*. Any hours, minutes, seconds, or fractional seconds information included in *expression* is not changed by the function.

The result CCSID is the appropriate CCSID of the argument encoding scheme and the result subtype is the appropriate subtype of the CCSID.
Example 1: Assume today is January 31, 2007. Set the host variable ADD_MONTH with the last day of January plus 1 month.

\[
\text{SET :ADD_MONTH} = \text{ADD_MONTHS(LAST\_DAY(CURRENT\_DATE), 1)};
\]

The host variable ADD_MONTH is set with the value representing the end of February, 2007-02-28.

Example 2: Assume DATE is a host variable with the value July 27, 1965. Set the host variable ADD_MONTH with the value of that day plus 3 months.

\[
\text{SET :ADD_MONTH} = \text{ADD_MONTHS(:DATE, 3)};
\]

The host variable ADD_MONTH is set with the value representing the day plus 3 months, 1965-10-27.

Example 3: It is possible to achieve similar results with the ADD_MONTHS function and date arithmetic. The following examples demonstrate the similarities and contrasts.

\[
\begin{align*}
\text{SET :DATEHV} &= \text{DATE('2008-2-28')} + 4 \text{ MONTHS;} \\
\text{SET :DATEHV} &= \text{ADD\_MONTHS('2008-2-28', 4)};
\end{align*}
\]

In both cases, the host variable DATEHV is set with the value '2008–06–29'.

Now consider the same examples but with the date '2008–2–29' as the argument.

\[
\begin{align*}
\text{SET :DATEHV} &= \text{DATE('2008-2-29')} + 4 \text{ MONTHS;} \\
\text{SET :DATEHV} &= \text{ADD\_MONTHS('2008-2-29', 4)};
\end{align*}
\]

The host variable DATEHV is set with the value '2008–06–29'.

The host variable DATEHV is set with the value '2008–06–30'.

In this case, the ADD_MONTHS function returns the last day of the month, which is June 30, 2008, instead of June 29, 2008. The reason is that February 29 is the last day of the month. So, the ADD_MONTHS function returns the last day of June.

Example 4: Assume TSZ is an SQL variable with the TIMESTAMP WITH TIME ZONE value 2008-02-29.20.00.000000-08.00. Set TIMESZ to the value of that TIMESTAMP WITH TIME ZONE plus 4 months. The string representation of the timestamp is first implicitly cast to TIMESTAMP WITHOUT TIME ZONE for the ADD_MONTHS function. The result of the ADD_MONTHS function does not contain a time zone.

\[
\text{SET TIMESZ:} = \text{ADD\_MONTHS(TIMESTAMP\_TZ(TSZ), 4)};
\]

With the string representation of a timestamp as input, the function returns a DATE value that represents the timestamp plus 4 months: 2008-06-30.

Example 5: Assume TSZ is a host variable with the value 2008-02-29.20.00.000000 -08.00 which is a string representation of a timestamp with a time zone. Set TIMESZ to the value of that timestamp with a time zone plus 4 months.

\[
\text{SET TIMESZ:} = \text{ADD\_MONTHS(:TSZ, 4)};
\]

The host variable TIMESZ is set with the value that represents the timestamp with time zone plus 4 months, 2008-06-30-20.00.00.000000 -8.00.
**ARRAY_DELETE**

The ARRAY_DELETE function deletes elements from an array.

```sql
ARRAY_DELETE(array-expression, array-index1, array-index2)
```

The schema is SYSIBM.

- **array-expression**
  - An SQL variable, SQL parameter, or global variable of an array type, or a CAST specification that specifies an SQL variable, SQL parameter, global variable, or parameter marker as the source value.

- **array-index1**
  - An expression that results in a value that is castable to the data type of the array index. If `array-expression` is an ordinary array, `array-index1` must be the null value.

- **array-index2**
  - An expression that results in a value that is castable to the data type of the array index. If `array-expression` is an ordinary array, `array-index2` must be the null value. If `array-index2` is specified and is a non-null value, `array-index1` must be a non-null value that is less than the value of `array-index2`. If `array-index2` is the null value, ARRAY_DELETE is evaluated as if `array-index2` was not specified.

The result of ARRAY_DELETE has the same data type as `array-expression`.

If `array-index1` and `array-index2` are not specified, or they are the null value, all of the elements of `array-expression` are deleted, and the cardinality of the result array value is 0. If only `array-index1` is specified with a non-null value, the array element at index value `array-index1` is deleted. If `array-index2` is specified with a non-null value, the elements ranging from index value `array-index1` to `array-index2`, inclusive, are deleted.

The result can be null; if the first argument is null, the result is the null value.

The ARRAY_DELETE function can be invoked only in the following contexts:
- A source value for SET assignment-statement, an SQL PL assignment-statement, or a VALUES INTO statement
- The value that is returned in a RETURN statement in an SQL scalar function

**Notes**

**Syntax alternatives:** CAST (SQL-variable AS array-type) can be specified as an alternative to SQL-variable. CAST (SQL-parameter AS array-type) can be specified as an alternative to SQL-parameter.

**Example 1:** Suppose that ordinary array variable RECENT_CALLS has the array type PHONENUMBERS. Use ARRAY_DELETE to delete all the elements from RECENT_CALLS. Assign the result to the RECENT_CALLS array.
SET RECENT_CALLS = ARRAY_DELETE(RECENT_CALLS);

After the SET statement is executed, RECENT_CALLS is an empty array, which has a cardinality of zero.

An equivalent way of setting RECENT_CALLS to an empty array is to use an array constructor:
SET RECENT_CALLS = ARRAY[ ];

Example 2: Suppose that PRODUCTS is defined as an associative array type with VARCHAR values for the array index, and that variables FLOOR_TILES and REMAINING_TILES are defined as arrays of the PRODUCTS array type. Use ARRAY_DELETE to assign the elements from the FLOOR_TILES array variable that do not have an index value between 'PK5100' and 'PS2500', inclusive, to the REMAINING_TILES array variable.
SET REMAINING_TILES = ARRAY_DELETE(FLOOR_TILES, 'PK5100', 'PS2500');

**ARRAY_FIRST**

The ARRAY_FIRST function returns the minimum array index value of an array.

The schema is SYSIBM.

**array-expression**

An SQL variable, SQL parameter, or global variable of an array type, or a CAST specification that specifies an SQL variable, SQL parameter, global variable, or parameter marker as the source value.

The result of ARRAY_FIRST has the same data type as the array index. If **array-expression** is not null, and the array is not empty (the cardinality of the array is greater than 0), the value of the result is the minimum array index value, which is 1 for an ordinary array.

The result can be null; if the argument is null, the result is the null value.

If the array is empty (the cardinality of the array is 0), the result is the null value.

**Notes**

**Syntax alternatives:** CAST (SQL-variable AS array-type) can be specified as an alternative to SQL-variable. CAST (SQL-parameter AS array-type) can be specified as an alternative to SQL-parameter.

Example 1: Suppose that SPECIALNUMBERS is an ordinary array variable, and the elements of the array are integers. Return the first index value in the array variable SPECIALNUMBERS to the SQL variable E_CONSTIDX.
SET E_CONSTIDX = ARRAY_FIRST(SPECIALNUMBERS);

The result is 1.
Example 2: Suppose that PHONELIST is an associative array variable with VARCHAR index values. Values have been assigned to the elements in the array with the following statements:

```sql
SET PHONELIST['Home'] = '4443051234';
SET PHONELIST['Work'] = '4443052345';
SET PHONELIST['Cell'] = '4447893456';
```

The order in which values are assigned to array elements in an associative array does not matter. The elements of an associative array are stored in the array variable in ascending order of the associated array index values. After the values have been assigned to the PHONELIST array variable using the SET assignment-statement statements, the elements in the array variable are ordered as follows:

<table>
<thead>
<tr>
<th>Index value</th>
<th>Element value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cell</td>
<td>4447893456</td>
</tr>
<tr>
<td>Home</td>
<td>4443051234</td>
</tr>
<tr>
<td>Work</td>
<td>4443052345</td>
</tr>
</tbody>
</table>

Assign the value of the first index in the array variable to the character string variable named X.

```sql
SET X = ARRAY_FIRST(PHONELIST);
```

The value of 'Cell' is assigned to X because 'Cell' is the index value of the first element in the array variable.

Assign the value of the array element with index X to the SQL variable NUMBER_TO_CALL.

```sql
SET NUMBER_TO_CALL = PHONELIST[X];
```

The assignment statement assigns the phone number '4447893456' to NUMBER_TO_CALL.

**ARRAY_LAST**

The ARRAY_LAST function returns the maximum array index value of an array.

```
ARRAY_LAST(array-expression)
```

The schema is SYSIBM.

**array-expression**

An SQL variable, SQL parameter, or global variable of an array type, or a CAST specification that specifies an SQL variable, SQL parameter, global variable, or parameter marker as the source value.

The result of ARRAY_LAST has the same data type as the array index, which is INTEGER for an ordinary array. If **array-expression** is not null, and the array is not
empty (the cardinality of the array is greater than 0), the value of the result is the maximum array index value, which is the current cardinality of the array for an ordinary array.

The result can be null; if the argument is null, the result is the null value.

If the array is empty (the cardinality of the array is 0), the result is the null value.

**Notes**

**Syntax alternatives:** CAST (SQL-variable AS array-type) can be specified as an alternative to SQL-variable. CAST (SQL-parameter AS array-type) can be specified as an alternative to SQL-parameter.

**Example 1:** Suppose that SPECIALNUMBERS is an ordinary array variable, and the elements of the array are integers. The cardinality of the array is 10. Return the last index value in the array variable SPECIALNUMBERS to the SQL variable PI_CONSTIDX.

```sql
SET PI_CONSTIDX = ARRAY_LAST(SPECIALNUMBERS);
```

The result is 10.

**Example 2:** Suppose that PHONELIST is an associative array variable with VARCHAR index values. Values have been assigned to the elements in the array with the following statements:

```sql
SET PHONELIST['Home'] = '4443051234';
SET PHONELIST['Work'] = '4443052345';
SET PHONELIST['Cell'] = '4447893456';
```

The order in which values are assigned to array elements in an associative array does not matter. The elements of an associative array are stored in the array variable in ascending order of the associated array index values. After the values have been assigned to the PHONELIST array variable using the SET assignment-statement statements, the elements in the array variable are ordered as follows:

<table>
<thead>
<tr>
<th>Index value</th>
<th>Element value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cell</td>
<td>4447893456</td>
</tr>
<tr>
<td>Home</td>
<td>4443051234</td>
</tr>
<tr>
<td>Work</td>
<td>4443052345</td>
</tr>
</tbody>
</table>

Assign the value of the maximum index in the array variable to the character string variable named X.

```sql
SET X = ARRAY_LAST(PHONELIST);
```

The value of 'Work' is assigned to X because 'Work' is the index value of the last element in the array variable.

Assign the value of the array element with index X to the SQL variable NUMBER_TO_CALL.

```sql
SET NUMBER_TO_CALL = PHONELIST[X];
```

The assignment statement assigns the phone number '4443052345' to NUMBER_TO_CALL.
**ARRAY_NEXT**

The ARRAY_NEXT function returns the next larger array index value for an array, relative to a specified array index argument.

```
ARRAY_NEXT(array-expression, array-index)
```

The schema is SYSIBM.

**array-expression**
- An SQL variable, SQL parameter, or global variable of an array type, or a CAST specification that specifies an SQL variable, SQL parameter, global variable, or parameter marker as the source value.

**array-index**
- An expression that results in a value that is castable to the data type of the array index. Valid values include any valid value for the data type.

**array-index** must not be an expression that references any of the following items:
- The CURRENT DATE, CURRENT TIME, or CURRENT TIMESTAMP special register
- A nondeterministic function
- A function that is defined with EXTERNAL ACTION
- A function that is defined with MODIFIES SQL DATA
- A sequence expression

The result of ARRAY_NEXT is the next larger array index value defined in the array, relative to the specified **array-index** value. If **array-index** is less than the minimum index array value in the array, the result is the first array index value that is defined in the array.

The data type of the result has the same data type as the array index.

The result is null under the following conditions:
- **array-expression** or **array-index** is null
- The array that is represented by **array-expression** is empty (the cardinality of the array is 0)
- The value of **array-index** is greater than or equal to the value of the last index in the array

**Notes**

**Syntax alternatives:** CAST (SQL-variable AS array-type) can be specified as an alternative to SQL-variable. CAST (SQL-parameter AS array-type) can be specified as an alternative to SQL-parameter.

**Example 1:** Suppose that SPECIALNUMBERS is an ordinary array variable, and the elements of the array are integers. The cardinality of SPECIALNUMBERS is 10. Set
the NEXT_CONSTIDX variable to the value of the array index for the
SPECIALNUMBERS array element that follows the array element that is associated
with an array index value of 9.
SET NEXT_CONSTIDX = ARRAY_NEXT(SPECIALNUMBERS,9);

The result is 10.

Example 2: Suppose that PHONELIST is an associative array variable with
VARCHAR index values. Values have been assigned to the elements in the array
with the following statements:
SET PHONELIST['Home'] = '4443051234';
SET PHONELIST['Work'] = '4443052345';
SET PHONELIST['Cell'] = '4447893456';

The order in which values are assigned to array elements in an associative array
does not matter. The elements of an associative array are stored in the array
variable in ascending order of the associated array index values. After the values
have been assigned to the PHONELIST array variable using the SET
assignment-statement statements, the elements in the array variable are ordered as
follows:

<table>
<thead>
<tr>
<th>Index</th>
<th>Element value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cell</td>
<td>4447893456</td>
</tr>
<tr>
<td>Home</td>
<td>4443051234</td>
</tr>
<tr>
<td>Work</td>
<td>4443052345</td>
</tr>
</tbody>
</table>

Assign the array index value that follows an array index value named 'Fax' to the
caracter string variable named X.
SET X = ARRAY_NEXT(PHONELIST,'Fax');

Array index value 'Fax' does not exist, but the string 'Home' follows the string 'Fax'
in sorting order. Therefore, 'Home' is assigned to X.

Assign the value of the array element with index X to the SQL variable
NUMBER_TO_CALL.
SET NUMBER_TO_CALL = PHONELIST[X];

Because the value of X is 'Home', the assignment statement assigns the phone
number '4443051234' to NUMBER_TO_CALL.

**ARRAY_PRIOR**
The ARRAY_PRIOR function returns the next smaller array index value for an
array, relative to a specified array index argument.

►►ARRAY_PRIOR(array-expression,array-index)◄◄

The schema is SYSIBM.
**array-expression**
An SQL variable, SQL parameter, or global variable of an array type, or a CAST specification that specifies an SQL variable, SQL parameter, global variable, or parameter marker as the source value.

**array-index**
An expression that results in a value that is castable to the data type of the array index. Valid values include any valid value for the data type.

array-index must not be an expression that references any of the following items:
- The CURRENT DATE, CURRENT TIME, or CURRENT TIMESTAMP special register
- A nondeterministic function
- A function that is defined with EXTERNAL ACTION
- A function that is defined with MODIFIES SQL DATA
- A sequence expression

The result of ARRAY_PRIOR is the next smaller array index value that is defined in the array, relative to the specified array-index value. If array-index is greater than the maximum index array value in the array, the result is the last array index value that is defined in the array.

The data type of the result has the same data type as the array index.

The result is null under the following conditions:
- array-expression or array-index is null.
- The array that is represented by array-expression is empty (the cardinality of the array is 0).
- The value of array-index is less than or equal to the value of the first index in the array.

**Notes**

**Syntax alternatives:** CAST (SQL-variable AS array-type) can be specified as an alternative to SQL-variable. CAST (SQL-parameter AS array-type) can be specified as an alternative to SQL-parameter.

**Example 1:** Suppose that SPECIALNUMBERS is an ordinary array variable, and the elements of the array are integers. The cardinality of SPECIALNUMBERS is 10. Set the PREV_CONSTIDX variable to the value of the array index for the SPECIALNUMBERS array element that precedes the array element that is associated with an array index value of 2.

SET PREV_CONSTIDX = ARRAY_PRIOR(SPECIALNUMBERS,2);

The result is 1.

**Example 2:** Suppose that PHONELIST is an associative array variable with VARCHAR index values. Values have been assigned to the elements in the array with the following statements:

SET PHONELIST['Home'] = '4443051234';
SET PHONELIST['Work'] = '4443052345';
SET PHONELIST['Cell'] = '4447893456';
The order in which values are assigned to array elements in an associative array does not matter. The elements of an associative array are stored in the array variable in ascending order of the associated array index values. After the values have been assigned to the PHONELIST array variable using the SET assignment-statement statements, the elements in the array variable are ordered as follows:

<table>
<thead>
<tr>
<th>Index value</th>
<th>Element value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cell</td>
<td>4447893456</td>
</tr>
<tr>
<td>Home</td>
<td>4443051234</td>
</tr>
<tr>
<td>Work</td>
<td>4443052345</td>
</tr>
</tbody>
</table>

Assign the array index value that precedes an array index value named 'Fax' to the character string variable named X.

```
SET X = ARRAY_PRIOR(PHONELIST, 'Fax');
```

Array index value 'Fax' does not exist, but the string 'Cell' precedes the string 'Fax' in sorting order. Therefore, 'Cell' is assigned to X.

Assign the array index value that precedes array index value 'Cell' to the character string variable named X.

```
SET X = ARRAY_PRIOR(PHONELIST, 'Cell');
```

The null value is assigned to X, because there is no array element before the array element with the index value 'Cell'.

**ASCII**

The ASCII function returns the leftmost character of the argument as an integer.

```
►►ASCII(string-expression)◄◄
```

The schema is SYSIBM.

The argument can be any built-in character or graphic string data type, except for CLOB or DBCLOB. If the argument is an EBCDIC, Unicode, or graphic string, it is first converted to an SBCS ASCII character string (CCSID 367) before the function is executed.

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type.

The result of the function is a large integer.

The result can be null; if the argument is null, the result is the null value.

**Example:** The following statement returns the ASCII value for the character 'A':

---

19. If the conversion does not exist, the ASCII function will return an error, or a substitution character might be returned.
The host variable, :hv, is set to an integer with the value 65.

ASCII CHR
The ASCII CHR function returns the character that has the ASCII code value that is specified by the argument.

```
ASCII CHR(expression)
```

The schema is SYSIBM.

expression
An expression that returns a built-in data type of BIGINT, INTEGER, or SMALLINT.

expression can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34) which is then assigned to a BIGINT value.

The result of the function is a fixed length character string encoded in the SBCS ASCII CCSID (regardless of the setting of the MIXED option in DSNHDECP). The length of the result is 1. If the value of expression is not in the range of 0 to 255, (0 to 127 if the SBCS ASCII CCSID for this system is CCSID 367) the null value is returned.

The result can be null; if the argument is null, the result is the null value.

CHR can be specified as a synonym for ASCII CHR.

Example: Set :hv with the Euro symbol "€" in CCSID 923:
```
SET :hv = ASCII CHR(164); -- x'4A'
```

Set :hv with the Euro symbol "€" in CCSID 1252:
```
SET :hv = ASCII CHR(128); -- x'80'
```

In both cases, the "€" is assigned to :hv, but because the Euro symbol is located at different code points for the two CCSIDs, the input value is different.

ASCII STR
The ASCII STR function returns an ASCII version of the string in the system ASCII CCSID. The system ASCII CCSID is the SBCS ASCII CCSID on a MIXED=NO system or the MIXED ASCII CCSID on a MIXED=YES system.

```
ASCII STR(string-expression)
```
string-expression
An expression that returns a value of a built-in character or graphic string. A character string must not be bit data. string-expression must be an ASCII, EBCDIC, or Unicode string.

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type.

ASCII_STR returns an ASCII version of the string. Non-ASCII characters are converted to UTF-16 characters and appear in the result in the form \xxxx (or \xxxx\yyyy for surrogate characters), where xxxx and yyyyy represent a UTF-16 code unit.

The length attribute of the result will be \( \text{MIN}(5n, 32764) \). Where \( n \) is the result of applying the formulas in Table 38 on page 172 based on input and output data types.

The result of the function is a varying-length character string in the system ASCII CCSID. If the actual length of the result string exceeds the maximum for the return type, an error occurs.

The result can be null; if the argument is null, the result is the null value.

ASCIISTR can be specified as a synonym for ASCII_STR.

Example: The following example returns the ACSII string equivalent of the Unicode (UTF-8) string, '4869206D616D6520697320D090D0BDD0B4D180D0B5D0B9202020F0908080':

```
SET :HV1 = ASCII_STR(X'4869206D616D6520697320D090D0BDD0B4D180D0B5D0B9202020F0908080');
```

:HV1 is assigned the value 'Hi, my name is \\0410\\043D\\0434\\0440\\0435\\0439 \D800\DC00'. In this example, the UTF-8 characters D090, D0BD, D0B4, D180, D0B5, and D0B9 are converted to \0410\043D\0434\0440\0435\0439 and the non-ASCII character F0908080 is converted to \D800\DC00.

```
SET :HV1 = ASCII_STR('Hi, my name is \u0410\u043D\u0440\u0435\u0439 (Andrei)');
```

:HV1 is assigned the value "Hi, my name is \u0410\u043D\u0440\u0435\u0439 (Andrei)"

ASIN
The ASIN function returns the arc sine of the argument as an angle, expressed in radians. The ASIN and SIN functions are inverse operations.
The argument must be an expression that returns the value of any built-in numeric data type except for DEC_FLOAT. The value must be greater than or equal to -1 and less than or equal to 1. If the argument is not a double precision floating-point number, it is converted to one for processing by the function.

The result of the function is a double precision floating-point number.

The result can be null; if the argument is null, the result is the null value.

The result is greater than or equal to -\(\pi/2\) and less than or equal to \(\pi/2\).

Example: Assume that host variable ASINE is DECIMAL(10,9) with a value of 0.997494987. The following statement:

```
SELECT ASIN(:ASINE)
FROM SYSIBM.SYSDUMMY1;
```

returns a double precision floating-point number with an approximate value of 1.50.

**ATAN**

The ATAN function returns the arc tangent of the argument as an angle, expressed in radians. The ATAN and TAN functions are inverse operations.

```
ATAN(numeric-expression)
```

The schema is SYSIBM.

The argument must be an expression that returns the value of any built-in numeric data type that is not DEC_FLOAT. The value must be greater than or equal to -1 and less than or equal to 1. If the argument is not a double precision floating-point number, it is converted to one for processing by the function.

The result of the function is a double precision floating-point number.

The result can be null; if the argument is null, the result is the null value.

The result is greater than or equal to -\(\pi/2\) and less than or equal to \(\pi/2\).

Example: Assume that host variable ATANGENT is DECIMAL(10,9) with a value of 14.10141995. The following statement returns a double precision floating-point number with an approximate value of 1.50:

```
SELECT ATAN(:ATANGENT)
FROM SYSIBM.SYSDUMMY1;
```

**ATANH**

The ATANH function returns the hyperbolic arc tangent of a number, expressed in radians. The ATANH and TANH functions are inverse operations.
The schema is SYSIBM.

The argument must be an expression that returns the value of any built-in numeric data type that is not DECIMAL. The value must be greater than -1 and less than 1. If the argument is not a double precision floating-point number, it is converted to one for processing by the function.

The result of the function is a double precision floating-point number.

The result can be null; if the argument is null, the result is the null value.

Example: Assume that host variable HATAN is DECIMAL(10,9) with a value of 0.905148254. The following statement returns a double precision floating-point number with an approximate value of 1.50:

```sql
SELECT ATAN(:HATAN)
FROM SYSIBM.SYSDUMMY1;
```

**ATAN2**

The ATAN2 function returns the arc tangent of \( x \) and \( y \) coordinates as an angle, expressed in radians.

The schema is SYSIBM.

The first and second arguments specify the \( x \) and \( y \) coordinates, respectively.

Each argument must be an expression that returns the value of any built-in numeric data type that is not DECIMAL. Both arguments must not be 0. Any argument that is not a double precision floating-point number is converted to one for processing by the function.

The result of the function is a double precision floating-point number.

The result can be null; if any argument is null, the result is the null value.

Example: Assume that host variables HATAN2A and HATAN2B are DOUBLE host variables with values of 1 and 2, respectively. The following statement returns a double precision floating-point number with an approximate value of 1.1071487:

```sql
SELECT ATAN2(:HATAN2A,:HATAN2B)
FROM SYSIBM.SYSDUMMY1;
```

**BIGINT**

The BIGINT function returns a big integer representation of either a number or a character or graphic string representation of a number.
The schema is SYSIBM.

**Numeric to Big Integer**

*numeric-expression*

An expression that returns a value of any built-in numeric data type.

The result is the same number that would occur if the argument were assigned to a big integer column or variable. If the whole part of the argument is not within the range of big integers, an error is returned. The fractional part of the argument is truncated.

**String to Big Integer**

*string-expression*

An expression that returns a value of a character or graphic string (except a CLOB and DBCLOB) with a length attribute that is not greater than 255 bytes.

The string must contain a valid string representation of a number.

The result is the same number that would result from `CAST(string-expression AS BIGINT)`. Leading and trailing blanks are eliminated and the resulting string must conform to the rules for forming an integer constant. If the whole part of the argument is not within the range of big integers, an error is returned.

The result of the function is a big integer.

The result can be null; if the argument is null, the result is the null value.

To increase the portability of applications, use the CAST specification.

*Example 1:* The following function returns the number 12345 (a BIGINT) for the number 12345.6:

```sql
SELECT BIGINT(12345.6)
FROM SYSIBM.SYSDUMMY1;
```

*Example 2:* The following function returns a BIGINT value of 123456789012 for the number 00123456789012.

```sql
SELECT BIGINT('00123456789012')
FROM SYSIBM.SYSDUMMY1;
```

**Related reference:**

CAST specification
**BINAR**

The BINAR function returns a BINAR (fixed-length binary string) representation of a string of any type or of a row ID type.

```sql
BINARY(string-expression [, integer])
```

The schema is SYSIBM.

- **string-expression**
  An expression that returns a value that is a built-in character string, graphic string, binary string, or a row ID type.

- **integer**
  An integer value that specifies the length attribute of the resulting binary string. The value must be an integer between 1 and 255 inclusive.

  If `integer` is not specified:
  - If the `string-expression` is the empty string constant, an error occurs
  - Otherwise, the length attribute of the result is the same as the length attribute of `string-expression`, except when the input is graphic data. In this case, the length attribute of the result is twice the length of `string-expression`.

The result of the function is a fixed-length binary string.

The result can be null; if the first argument is null, the result is the null value.

The actual length is the same as the length attribute of the result. If the length of the `string-expression` is less than the length of the result, the result is padded with hexadecimal zeroes up to the length of the result. If the length of the `string-expression` is greater than the length attribute of the result, truncation is performed. A warning is returned unless the first input argument is a character string and all the truncated characters are blanks, or the first input argument is a graphic string and all the truncated characters are double-byte blanks, or the first input argument is a binary string and all the truncated bytes are hexadecimal zeroes.

Following examples assume EBCDIC encoding of the input string constants.

**Example 1:** The following function returns a fixed-length binary string with a length attribute 1 and a value BX'00'.

```sql
SELECT BINARY('',1)
FROM SYSIBM.SYSDUMMY1;
```

**Example 2:** The following function returns a fixed-length binary string with a length attribute 5 and a value BX'D2C2C800000'

```sql
SELECT BINARY('KBH',5)
FROM SYSIBM.SYSDUMMY1;
```

**Example 3:** The following function returns a fixed-length binary string with a length attribute 3 and a value BX'D2C2C8'
SELECT BINARY('KBH')
FROM SYSIBM.SYSDUMMY1;

*Example 4:* The following function returns a fixed-length binary string with a length attribute 3 and a value BX'D2C2C8'

```
SELECT BINARY('KBH ',3)
FROM SYSIBM.SYSDUMMY1;
```

*Example 5:* The following function returns a fixed-length binary string with a length attribute 3 and a value BX'D2C2C8', a warning is also returned.

```
SELECT BINARY('KBH 93',3)
FROM SYSIBM.SYSDUMMY1;
```

*Example 6:* The following function returns a fixed-length binary string with a length attribute 3 and a value BX'C1C2C3', a warning is also returned.

```
SELECT BINARY(BINARY('ABC',5),3)
FROM SYSIBM.SYSDUMMY1;
```

**BITAND, BITANDNOT, BITOR, BITXOR, and BITNOT**

The bit manipulation functions operate on the *twos complement* representation of the integer value of the input arguments. The functions return the result as a corresponding base 10 integer value in a data type that is based on the data type of the input arguments.

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
<th>The bit in the <em>twos complement</em> representation of the result</th>
</tr>
</thead>
<tbody>
<tr>
<td>BITAND</td>
<td>Performs a bitwise AND operation.</td>
<td>1 - only if the corresponding bits in both arguments are 1.</td>
</tr>
<tr>
<td>BITANDNOT</td>
<td>Clears any bit in the first argument that is in the second argument.</td>
<td>0 - if the corresponding bit in the second argument is 1.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>copied from the corresponding bit in the first argument - if the corresponding bit in the first argument is not 1.</td>
</tr>
<tr>
<td>BITOR</td>
<td>Performs a bitwise OR operation.</td>
<td>1 - unless the corresponding bits in both arguments are 0.</td>
</tr>
<tr>
<td>BITXOR</td>
<td></td>
<td></td>
</tr>
<tr>
<td>BITNOT</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
expression, expression1, or expression2

expression, expression1, or expression2 must be integer values represented by the data types SMALLINT, INTEGER, BIGINT, or DECFLOAT. Arguments that are of type DECIMAL, REAL, or DOUBLE are cast to DECFLOAT. The value is truncated to a whole number.

The bit manipulation functions can operate on up to 16 bits for SMALLINT, 32 bits for INTEGER, 64 bits for BIGINT, and 113 bits for DECFLOAT. The range of supported DECFLOAT values includes integers from \(-2^{122}\) to \(2^{122} - 1\). Special values such as NaN or INFINITY are not supported.

If the two arguments have different data types, the argument that supports fewer bits is cast to a value with the data type of the argument that supports more bits. This cast impacts the bits that are set for negative values. For example, -1 as a SMALLINT value has 16 bits set to 1. When -1 is cast to an INTEGER value, it has 32 bits set to 1.

The result of the functions with two arguments has the data type of the argument that is highest in the data type precedence list for promotion. If either argument is DECFLOAT, the data type of the result is DECFLOAT(34).

The result of the BITNOT function has the same data type as the input argument, except that DECIMAL, REAL, DOUBLE, or DECFLOAT(16) returns DECFLOAT(34).

The result can be null; if any argument is null, the result is the null value.

Due to differences in internal representation between data types and on different hardware platforms, using functions (such as HEX) or host language constructs to view or compare internal representations of BIT function results and arguments is data type-dependent and not portable. The data type- and platform-independent way to view or compare BIT function results and arguments is to use the actual integer values.

The BITXOR function is can be used to toggle bits in a value.

The BITANDNOT function can be used to clear bits.

BITANDNOT(val, pattern) operates more efficiently than BITAND(val, BITNOT(pattern)).

The following examples are based on an ITEM table with a PROPERTIES column of type INTEGER.

**Return all items for which the third property bit is set.**

```
SELECT ITEMID FROM ITEM
WHERE BITAND(PROPERTIES, 4) = 4;
```

---

### Table 68. The bit manipulation functions (continued)

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
<th>The bit in the two's complement representation of the result</th>
</tr>
</thead>
<tbody>
<tr>
<td>BITXOR</td>
<td>Performs a bitwise exclusive OR operation.</td>
<td>1 - unless the corresponding bits in both arguments are the same.</td>
</tr>
<tr>
<td>BITNOT</td>
<td>Performs a bitwise NOT operation.</td>
<td>Opposite of the corresponding bit in the argument.</td>
</tr>
</tbody>
</table>
Return all items for which the fourth or the sixth property bit is set.

```sql
SELECT ITEMID FROM ITEM
WHERE BITAND(PROPERTIES, 40) <> 0;
```

Clear the twelfth property of the item whose ID is 3412.

```sql
UPDATE ITEM
SET PROPERTIES = BITANDNOT(PROPERTIES, 2048)
WHERE ITEMID = 3412;
```

Set the fifth property of the item whose ID is 3412.

```sql
UPDATE ITEM
SET PROPERTIES = BITOR(PROPERTIES, 16)
WHERE ITEMID = 3412;
```

Toggle the eleventh property of the item whose ID is 3412.

```sql
UPDATE ITEM
SET PROPERTIES = BITXOR(PROPERTIES, 1024)
WHERE ITEMID = 3412;
```

Switch all the bits in a 16-bit value that has only the second bit on.

```sql
SELECT BITNOT(CAST(2 AS SMALLINT))
FROM SYSIBM.SYSDUMMY1;
```

This example returns -3 (with a data type of SMALLINT).

---

**BLOB**

The BLOB function returns a BLOB representation of a string of any type or of a row ID type.

```
BLOB(string-expression[, integer])
```

The schema is SYSIBM.

**string-expression**

An expression that returns a value that is a built-in character string, graphic string, binary string, or a row ID type.

**integer**

An integer value that specifies the length attribute of the resulting binary string. The value must be an integer between 1 and the maximum length of a BLOB.

Do not specify `integer` if `string-expression` is a row ID type.

If you do not specify `integer` and `string-expression` is an empty string constant, the length attribute of the result is 1, and the result is an empty string. Otherwise, the length attribute of the result is the same as the length attribute of `string-expression`, except when the input is graphic data. In this case, the length attribute of the result is twice the length of `expression`.

The result of the function is a BLOB.

The result can be null; if the first argument is null, the result is the null value.
The actual length of the result is the minimum of the length attribute of the result and the actual length of string-expression (or twice the length of string-expression when the input is graphic data). If the length of string-expression is greater than the length attribute of the result, truncation is performed. A warning is returned unless the first input argument is a character string and all the truncated characters are blanks, or the first input argument is a graphic string and all the truncated characters are double-byte blanks.

Example 1: The following function returns a BLOB for the string 'This is a BLOB'.

```sql
SELECT BLOB('This is a BLOB')
FROM SYSIBM.SYSDUMMY1;
```

Example 2: The following function returns a BLOB for the large object that is identified by locator myclob_locator.

```sql
SELECT BLOB(:myclob_locator)
FROM SYSIBM.SYSDUMMY1;
```

Example 3: Assume that a table has a BLOB column named TOPOGRAPHIC_MAP and a VARCHAR column named MAP_NAME. Locate any maps that contain the string 'Engles Island' and return a single binary string with the map name concatenated in front of the actual map.

```sql
SELECT BLOB(MAP_NAME || ': ') || TOPOGRAPHIC_MAP
FROM ONTARIO_SERIES_4
WHERE TOPOGRAPHIC_MAP LIKE BLOB('%Engles Island%')
```

**CARDINALITY**

The CARDINALITY function returns a value of type BIGINT that represents the number of elements of an array.

```sql
CARDINALITY(array-expression)
```

The schema is SYSIBM.

**array-expression**

An SQL variable, SQL parameter, or global variable of an array type, or a CAST specification that specifies an SQL variable, SQL parameter, global variable, or parameter marker as the source value.

The result of the CARDINALITY function is as follows:

- For an ordinary array, the result is the highest array index for which the array has an assigned element. Elements that have been assigned the null value are considered to be assigned elements.
- For an associative array, the result is the actual number of unique array index values that are defined in array-expression.
- For an empty array, the result is 0.

The data type of the result is BIGINT.

The result can be null; if array-expression is null, the result is the null value.
Example 1: Suppose that the array RECENT_CALLS is defined and contains a record of recent calls. RECENT_CALLS contains three elements. The following SET statement assigns the number of calls that have been stored in the array so far to SQL variable HOWMANYCALLS:

```sql
SET HOWMANYCALLS = CARDINALITY(RECENT_CALLS);
```

After the statement executes, HOWMANYCALLS contains 3.

Example 2: Suppose that the associative array variable CANADACAPITALS of array type CAPITALSARRAY contains all of the capitals for the 10 provinces and three territories in Canada, as well as the capital of the country, Ottawa. The following SET statement assigns the cardinality of CANADACAPITALS to SQL variable NUMCAPITALS.

```sql
SET NUMCAPITALS = CARDINALITY(CANADACAPITALS);
```

After the statement executes, CANADACAPITALS contains 14.

**CCSID_ENCODING**

The CCSID_ENCODING function returns a string value that indicates the encoding scheme of a CCSID that is specified by the argument.

```
CCSID_ENCODING(expression)
```

The schema is SYSIBM.

*expression*

*expression* must be an expression that returns a value of a built-in numeric, character, or graphic string data type that is not a LOB. A character string must not have a length attribute greater than 255, and a graphic string must not have a length attribute greater than 127. If *expression* is a character or graphic string, the string must contain a valid string representation of a number. Leading and trailing blanks are eliminated and the resulting string must conform to the rules for forming a numeric constant.

The function returns a value of ASCII, EBCDIC, UNICODE, or UNKNOWN depending on the CCSID specified by *expression*.

The result of the function is a fixed-length character string of length 8, which is padded on the right if necessary.

The result can be null; if the argument is null, the result is the null value.

The CCSID of the result is determined from the context in which the function was invoked. For more information, refer to [Determining the encoding scheme and CCSID of a string](Introduction to Db2 for z/OS).

Example 1: The following function returns a CCSID with a value for EBCDIC data.

```sql
SELECT CCSID_ENCODING(37) AS CCSID
FROM SYSIBM.SYSDUMMY1;
```

Example 2: The following function returns a CCSID with a value for ASCII data.
SELECT CCSID_ENCODING(850) AS CCSID
FROM SYSIBM.SYSDUMMY1;

Example 3: The following function returns a CCSID with a value for Unicode data.
SELECT CCSID_ENCODING(1208) AS CCSID
FROM SYSIBM.SYSDUMMY1;

Example 4: The following function returns a CCSID with a value of UNKNOWN.
SELECT CCSID_ENCODING(1) AS CCSID
FROM SYSIBM.SYSDUMMY1;

Example 5: The following function returns a CCSID with a value for EBCDIC data.
The input data is a character string.
SELECT CCSID_ENCODING('37') AS CCSID
FROM SYSIBM.SYSDUMMY1;

CEILING

The CEILING function returns the smallest integer value that is greater than or equal to the argument.

►►CEILING-(numeric-expression)◄◄

The schema is SYSIBM.

The argument must be an expression that returns a value of any built-in numeric data type.

The argument can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECIMAL(34).

The result of the function has the same data type and length attribute as the argument except that the scale is 0 if the argument is DECIMAL. For example, an argument with a data type of DECIMAL(5,5) results in DECIMAL(5,0).

The result can be null; if the argument is null, the result is the null value.

CEIL can be specified as a synonym for CEILING.

Example 1: The following statement shows the use of CEILING on positive and negative values:
SELECT CEILING(3.5), CEILING(3.1), CEILING(-3.1), CEILING(-3.5)
FROM SYSIBM.SYSDUMMY1;

This example returns: 04., 04., -03., -03.

Example 2: Using sample table DSN8C10.EMP, find the highest monthly salary for all the employees. Round the result up to the next integer. The SALARY column has a decimal data type.
SELECT CEILING(MAX(SALARY)/12)
FROM DSN8C10.EMP;
This example returns 04396. because the highest paid employee is Christine Haas who earns $52750.00 per year. Her average monthly salary before applying the CEILING function is 4395.83.

**CHAR**

The CHAR function returns a fixed-length character string representation of the argument.

The syntax of the CHAR function depends on the data type of the input argument. The following types of input arguments are accepted.

**Integer to Character:**

```
CHAR(integer-expression)
```

**Decimal to Character:**

```
CHAR(decimal-expression, decimal-character)
```

**Floating-Point to Character:**

```
CHAR(floating-point-expression)
```

**Decimal floating-point to Character:**

```
CHAR(decimal-floating-point-expression)
```

**Character to Character:**

```
CHAR(character-expression, integer, CODEUNITS16, CODEUNITS32, OCTETS)
```
The schema is SYSIBM.

The CHAR function returns a fixed-length character string representation of one of the following values:

- An integer number if the first argument is a SMALLINT, INTEGER, or BIGINT
- A decimal number if the first argument is a decimal number
- A double-precision floating-point number if the first argument is a DOUBLE or REAL
- A decimal floating-point number if the first argument is a DECFLOAT
- A character string value if the first argument is any type of character string
- A graphic string if the first argument is an EBCDIC or Unicode graphic string
- A datetime value if the first argument is a date, time, or timestamp
- A row ID value if the first argument is a row ID

The result of the function is a fixed-length character string (CHAR).

The result can be null; if the first argument is null, the result is the null value.

**Integer to Character**

*integer-expression*

An expression that returns a value that is a built-in integer data type (SMALLINT, INTEGER, or BIGINT).
The result is the fixed-length character string representation of the argument in the form of an SQL integer constant. The result is the smallest number of characters that can be used to represent the value of the argument, padded with blanks. The result consists of \( n \) characters that are the significant digits that represent the value of the argument with a preceding minus sign if the argument is negative. A positive value starts with a digit and always includes at least one trailing blank. Leading zeroes are not included. The result is left justified:

- If the argument is a small integer, the length of the result is 6. If the number of characters in the result is less than 6, the result is padded on the right with blanks.
- If the argument is a large integer, the length of the result is 11; if the number of characters in the result is less than 11, the result is padded on the right with blanks.
- If the argument is a big integer, the length of the result is 20. If the number of characters in the result is less than 20, the result is padded on the right with blanks.

A positive value always includes one trailing blank.

The CCSID of the result is determined from the application encoding scheme.

### Decimal to Character

**decimal-expression**

An expression that returns a value that is a built-in decimal data type. To specify a different precision and scale for the value of the expression, apply the DECIMAL function before applying the CHAR function.

**decimal-character**

Specifies the single-byte character constant that is used to delimit the decimal digits in the result character string. The character must not be a digit, a plus sign (+), a minus sign (-), or a blank. The default is the period (.) or comma (,). For information on what factors govern the choice, see [Decimal point representation](#).

The result is the fixed-length character string representation of the first argument. The result is the smallest number of characters that can be used to represent the value of the argument, except that trailing zeros are included.

The result includes a decimal character and up to \( p \) digits, where \( p \) is the precision of the `decimal-expression` with the preceding minus sign if the argument is negative. A positive value starts with a digit or the decimal character, and always includes at least one trailing blank. Leading zeros are not returned. If the scale of `decimal-expression` is zero, the decimal character is not returned. If the number of bytes in the result is less than the defined length of the result, the result is padded on the right with blanks.\(^{20}\)

The length of the result is \( 2 + p \), where \( p \) is the precision of the `decimal-expression`.

---

\(^{20}\) If the function is invoked as CHAR and the BIF_COMPATIBILITY subsystem parameter is set to V9_DECIMALVARCHAR, or if the function is invoked as SYSCOMPAT_V9.CHAR, the result is formatted the same as the result of the `CHAR9` function.
The CCSID of the result is determined from the application encoding scheme.

**Floating-Point to Character**

floating-point-expression
An expression that returns a value that is a built-in floating-point data type (DOUBLE or REAL).

The result is the fixed-length character string representation of the argument in the form of an SQL floating-point constant. If the argument is negative, the first character of the result is a minus sign; otherwise, the first character is a digit. If the argument is zero, the result is 0E0.

The length of the result is 24. The result includes the smallest number of characters that can represent the value of the argument such that the mantissa consists of a single digit, other than zero, followed by a period and a sequence of digits.

If the number of characters in the result is less than 24, the result is padded on the right with blanks.

The CCSID of the result is determined from the application encoding scheme.

**Decimal floating-point to Character**

decimal-floating-point-expression
An expression that returns a value that is a built-in decimal floating-point data type (DECFLOAT).

The result is the fixed-length character string representation of the argument in the form of an SQL decimal floating-point constant.

If the result value is Infinity, sNaN, or NaN, the strings 'INFINITY', 'SNAN', and 'NAN', respectively, are returned. The DECFLOAT special value sNaN does not result in an exception when converted to a string.

The length of the result is 42. If the number of characters in the result is less than 42, the result is padded on the right with blanks. Trailing zeros are significant. If the argument is negative, the first character of the result is a minus sign. Otherwise, the first character is a digit, or a letter if the result value is Infinity, sNaN, or NaN.

The CCSID of the result is determined from the application encoding scheme.

**Character to Character**

character-expression
An expression that returns a value of a built-in character string.

integer
The length attribute for the resulting fixed-length character string. The value must be an integer constant between 1 and 255.

If the length is not specified, the length attribute of the result is the minimum of 255 and the length attribute of character-expression. If character-expression is an empty string constant, an error occurs.

If CODEUNITS16 or CODEUNITS32 is specified, see [Determining the length attribute of the final result](#) for information about how to calculate the length attribute of the result string.
**CODEUNITS16, CODEUNITS32, or OCTETS**

Specifies the unit that is used to express `integer`. If `character-expression` is a character string that is defined as bit data, `CODEUNITS16` and `CODEUNITS32` cannot be specified.

**CODEUNITS16**

Specifies that `integer` is expressed in terms of 16-bit UTF-16 code units.

**CODEUNITS32**

Specifies that `integer` is expressed in terms of 32-bit UTF-32 code units.

**OCTETS**

Specifies that `integer` is expressed in terms of bytes.

For more information about `CODEUNITS16`, `CODEUNITS32`, and `OCTETS`, see [String unit specifications](#).

The actual length is the same as the length attribute of the result. If the length of `character-expression` is less than the length attribute of the result, the result is padded with blanks to the length of the result. If the length of `character-expression` is greater than the length attribute of the result, the result is truncated. Unless all of the truncated characters are blanks, a warning is returned.

If `character-expression` is bit data, the result is bit data. Otherwise, the CCSID of the result is the same as the CCSID of `character-expression`.

**Graphic to Character**

```
graphic-expression
```

An expression that returns a value of a built-in graphic string.

```
integer
```

The length attribute for the resulting fixed-length character string. The value must be an integer constant between 1 and 255.

If the length is not specified, the length attribute of the result is the minimum of 255 and the length attribute of `graphic-expression`. The length attribute of `graphic-expression` is `(3 * length(graphic-expression))`. If `graphic-expression` is an empty string constant, an error occurs.

If `CODEUNITS16` or `CODEUNITS32` is specified, see [Determining the length attribute of the final result](#) for information about how to calculate the length attribute of the result string.

**CODEUNITS16 or CODEUNITS32**

Specifies the unit that is used to express `integer`.

**CODEUNITS16**

Specifies that `integer` is expressed in terms of 16-bit UTF-16 code units.

**CODEUNITS32**

Specifies that `integer` is expressed in terms of 32-bit UTF-32 code units.

For more information about `CODEUNITS16` and `CODEUNITS32`, see [String unit specifications](#).
The actual length is the same as the length attribute of the result. If the length of \textit{graphic-expression} is less than the length attribute of the result, the result is padded with blanks to the length of the result. If the length of \textit{graphic-expression} is greater than the length attribute of the result, the result is truncated. Unless all of the truncated characters are blanks, a warning is returned.

The CCSID of the result is the character mixed CCSID that corresponds to the graphic CCSID of \textit{graphic-expression}.

\textbf{Datetime to Character}

\textit{datetime-expression}

An expression that is one of the following built-in data types:

\textbf{date} The result is the character string representation of the date in the format that is specified by the second argument. If the second argument is omitted, the DATE precompiler option, if one is provided, otherwise field DATE FORMAT on installation panel DSNTIP4 specifies the format. If the format is \textit{LOCAL}, field LOCAL DATE LENGTH on installation panel DSNTIP4 specifies the length of the result. Otherwise, the length of the result is 10.

\textit{LOCAL} denotes the local format at the Db2 subsystem that executes the SQL statement. If \textit{LOCAL} is used for the format, a date exit routine must be installed at that Db2 subsystem.

An error occurs if the second argument is specified and is not a valid value.

\textbf{time} The result is the character string representation of the time in the format that is specified by the second argument. If the second argument is omitted, the TIME precompiler option, if one is provided, otherwise field TIME FORMAT on installation panel DSNTIP4 specifies the format. If the format is \textit{LOCAL}, the field LOCAL TIME LENGTH on installation panel DSNTIP4 specifies the length of the result. Otherwise, the length of the result is 8.

\textit{LOCAL} denotes the local format at the Db2 subsystem that executes the SQL statement. If \textit{LOCAL} is used for the format, a time exit routine must be installed at that Db2 subsystem.

An error occurs if the second argument is specified and is not a valid value.

\textbf{timestamp without time zone} The result is the character string representation of the timestamp. If \textit{datetime-expression} is a TIMESTAMP(0) value, the length of the result is 19. If \textit{datetime-expression} is a TIMESTAMP\textit{(integer)} value, the length of the result is \textit{20+integer}. Otherwise, the length of the result is 26. The second argument must not be specified.

\textbf{timestamp with time zone} The result is the character string representation of the timestamp with time zone, formatted as yyyy-mm-dd-hh:mm:ss.mmmnnn±th:tm with the appropriate number of 'n' characters for the precision of the timestamp. If \textit{datetime-expression} is a TIMESTAMP(0) WITH TIME ZONE, the
length of the result is 147. If \textit{datetime-expression} is a \texttt{TIMESTAMP(integer) WITH TIME ZONE}, the length of the result is \texttt{148+integer}. The second argument must not be specified.

The CCSID of the result is determined from the context in which the function is invoked. For more information, see \texttt{Determining the encoding scheme and CCSID of a string (Introduction to Db2 for z/OS)}.

\textbf{ISO, EUR, USA, JIS, or LOCAL}

Specifies the date or time format of the resulting character string. For more information, see \texttt{String representations of datetime values}.

\textbf{Row ID to Character}

\textit{row-ID-expression}

An expression that returns a value that is a built-in row ID data type.

The result is the fixed-length character string representation of the argument. The result is bit data.

The length of the result is 40. If the length of \textit{row-ID-expression} is less than 40, the result is padded on the right with hexadecimal zeros to a length of 40.

\textbf{Recommendation:} To increase the portability of applications, use the CAST specification when the first argument is numeric, or the first argument is a string and the length argument is specified. For more information, see \texttt{CAST specification}.

\textbf{Notes}

\textbf{Syntax alternatives}: \texttt{CHAR9} can be specified as an alternative to \texttt{CHAR}. The result of the function is the same, except when the first argument is decimal data.

\textit{Example 1:} HIREDATE is a DATE column in sample table DSN8C10.EMP. When it represents the date 15 December 1976 (as it does for employee 140), the following example returns the string value \'12/15/1976\' in character string variable \texttt{DATESTRING}:

\begin{verbatim}
EXEC SQL SELECT CHAR(HIREDATE, USA) INTO :DATESTRING FROM DSN8C10.EMP WHERE EMPNO = '000140';
\end{verbatim}

\textit{Example 2:} Host variable \texttt{HOUR} has a data type of \texttt{DECIMAL(6,0)} and contains a value of 50000. Interpreted as a time duration, this value is 5 hours. Assume that \texttt{STARTING} is a TIME column in some table. Then, when \texttt{STARTING} represents 17 hours, 30 minutes, and 12 seconds after midnight, the following example returns the value \texttt{\'10:30 PM\'}:

\begin{verbatim}
CHAR(STARTING+:HOURS, USA)
\end{verbatim}

\textit{Example 3:} Assume that \texttt{RECEIVED} is defined as a \texttt{TIMESTAMP} column in table \texttt{TABLEY}. When the value of the date portion of \texttt{RECEIVED} represents the date 10 March 1997 and the time portion represents 6 hours and 15 seconds after midnight, the following example returns the string value \texttt{\'1997-03-10-06.00.15.000000\'}:

\begin{verbatim}
SELECT CHAR(RECEIVED) FROM TABLEY WHERE INTCOL = 1234;
\end{verbatim}
Example 4: For sample table DSN8C10.EMP, the following SQL statement sets the host variable AVERAGE, which is defined as CHAR(33), to the character string representation of the average employee salary.

```sql
EXEC SQL SELECT CHAR(AVG(SALARY))
INTO :AVERAGE
FROM DSN8C10.EMP;
```

With DEC31, the result of AVG applied to a decimal number is a decimal number with a precision of 31 digits. The only host languages in which such a large decimal variable can be defined are Assembler and C. For host languages that do not support such large decimal numbers, use the method shown in this example.

Example 5: For the rows in sample table DSN8C10.EMP, return the values in column LASTNAME, which is defined as VARCHAR(15), as a fixed-length character string and limit the length of the results to 10 characters.

```sql
SELECT CHAR(LASTNAME,10)
FROM DSN8C10.EMP;
```

For rows that have a LASTNAME with a length greater than 10 characters (excluding trailing blanks), a warning that the value is truncated is returned.

Example 6: FIRSTNAME is a VARCHAR(12) column in a Unicode table T1. One of its values is the 6-character string 'Jürgen'. When FIRSTNAME has the values shown under 'Function', the results are shown under 'Returns':

<table>
<thead>
<tr>
<th>Function</th>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td>CHAR(FIRSTNAME,3,CODEUNITS32) 'Jür'</td>
<td>'x'4AC3BC722020202020202020'</td>
</tr>
<tr>
<td>CHAR(FIRSTNAME,3,CODEUNITS16) 'Jür'</td>
<td>'x'4AC3BC722020202020'</td>
</tr>
<tr>
<td>CHAR(FIRSTNAME,3,OEKTETS) 'Jü'</td>
<td>'x'4AC3BC'</td>
</tr>
</tbody>
</table>

Example 7: For the rows in sample table DSN8C10.EMP, return the values in column EDLEVEL, which is defined as SMALLINT, as a fixed-length character string.

```sql
SELECT CHAR(EDLEVEL)
FROM DSN8C10.EMP;
```

An EDLEVEL of 18 is returned as CHAR(6) value '18    ' (18 followed by four blanks).

Example 8: In sample table DSN8C10.EMP, the SALARY column is defined as DECIMAL(9,2). For those employees who have a salary of 52750.00, return the hire date and the salary, using a comma as the decimal character in the salary (52750.00).

```sql
SELECT HIREDATE, CHAR(SALARY, ',')
FROM DSN8C10.EMP
WHERE SALARY = 52750.00;
```

The salary is returned as the string value '52750,00'.

Example 9: Repeat the scenario in Example 8 except subtract the SALARY column from 60000.00 and return the salary with the default decimal character.

```sql
SELECT HIREDATE, CHAR (60000.00 - SALARY)
FROM DSN8C10.EMP
WHERE SALARY = 52750.00;
```

The salary is returned as the string value '7250.00'.
Example 10: Assume that host variable SEASONS_TICKETS is defined as INTEGER and has a value of 10000. Use the DECIMAL and CHAR functions to change the value into the character string '10000.00'.

```
SELECT CHAR(DECIMAL(:SEASONS_TICKETS,7,2))
FROM SYSIBM.SYSDUMMY1;
```

Example 11: Assume that columns COL1 and COL2 in table T1 are both defined as REAL and that T1 contains a single row with the values 7.1E+1 and 7.2E+2 for the two columns. Add the two columns and represent the result as a character string.

```
SELECT CHAR(COL1 + COL2)
FROM T1;
```

The result is the character value '1.43E2'.

Related concepts:

- Data types (Introduction to Db2 for z/OS)

Related reference:

- "CHAR9"

- BIF COMPATIBILITY field (BIF_COMPATIBILITY subsystem parameter) (Db2 Installation and Migration)

CHAR9

The CHAR9 function returns a fixed-length character string representation of the argument. The CHAR9 function is intended for compatibility with previous releases of Db2 for z/OS that depend on the result format that is returned for decimal input values in Version 9 and earlier.

**Important:** For portable applications that might run on platforms other than Db2 for z/OS, use the CHAR function instead. Other Db2 family products do not support the CHAR9 function.

The first argument can be any one value of the following types:

- Integer number
- Decimal number
- Floating-point number
- Decimal floating-point number
- Character string
- Graphic string
- Datetime value
- Row ID value

If the first argument is a decimal number, the result is formatted as indicated in the following description. However, if the first argument is not a decimal number, the result is identical to the result of the CHAR function.

**Decimal to Character:**

```
| CHAR9(decimal-expression, decimal-character) |
```
Decimal to Character

**decimal-expression**

An expression that returns a value that is a built-in decimal data type. To specify a different precision and scale for the value of the expression, apply the DECIMAL function before applying the CHAR9 function.

**decimal-character**

Specifies the single-byte character constant (CHAR or VARCHAR) that delimits the decimal digits in the result character string. The character must not be a digit, a plus sign (+), a minus sign (-), or a blank. The default is the period (.) or comma (,). For information about the factors that govern the choice, see [Decimal point representation](#).

The result is the fixed-length character string representation of the argument. The result includes a decimal character and up to \( p \) digits, where \( p \) is the precision of the `decimal-expression` with the preceding minus sign if the argument is negative. Leading and trailing zeros are returned, and a leading blank is returned for a positive decimal value. The result includes a decimal character even if the scale of `decimal-expression` is zero. If the number of bytes in the result is less than the defined length of the result, the result is padded on the right with blanks.

The length of the result is 2 \(+p\), where \( p \) is the precision of the `decimal-expression`.

The length attribute of the result is 2+p where \( p \) is the precision of `decimal-expression`.

The actual length of the result is the smallest number of characters that can be used to represent the result, except that trailing zeros are included. If the argument is negative, the result begins with a minus sign. Otherwise, the result begins with a digit. If the scale of `decimal-expression` is zero, the decimal character is not returned.

The CCSID of the result is determined from the context in which the function was invoked. For more information, see [Determining the encoding scheme and CCSID of a string (Introduction to Db2 for z/OS)](#).

### Examples

The following table shows the difference between the results of the CHAR and CHAR9 functions for example decimal number arguments.

<table>
<thead>
<tr>
<th>Decimal argument</th>
<th>CHAR function result</th>
<th>CHAR9 function result</th>
</tr>
</thead>
<tbody>
<tr>
<td>(000.1)</td>
<td>'1'</td>
<td>'000.1'</td>
</tr>
<tr>
<td>(1000)</td>
<td>'1000'</td>
<td>'1000.'</td>
</tr>
<tr>
<td>(1.1)</td>
<td>'1.1'</td>
<td>'1.1'</td>
</tr>
</tbody>
</table>

### Related concepts:
- [Data types (Introduction to Db2 for z/OS)](#)

### Related reference:
- [CHAR](#)
The CHARACTER_LENGTH function returns the length of the first argument in the specified string unit.

**Character string:**

```
CHARACTER_LENGTH(character-expression, CODEUNITS16)
```

CODEUNITS32

OCTETS

**Graphic string:**

```
CHARACTER_LENGTH(graphic-expression, CODEUNITS16)
```

CODEUNITS32

The schema is SYSIBM.

**Character string:**

*character-expression*

An expression that returns a value of a built-in character string. *character-expression* cannot be bit data.

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type.

**CODEUNITS16, CODEUNITS32, or OCTETS**

Specifies the unit that is used to express the length of the result.

**CODEUNITS16**

Specifies that the result is expressed in terms of 16-bit UTF-16 code units.

**CODEUNITS32**

Specifies that the result is expressed in terms of 32-bit UTF-32 code units.

**OCTETS**

Specifies the result is expressed in terms of bytes.

For more information about CODEUNITS16, CODEUNITS32, and OCTETS, see *String unit specifications*.

The result of the function is a large integer.

The result can be null; if the argument is null, the result is the null value.

The result is the length of *character-expression* expressed in the number of string units that were specified. The length of fixed-length strings includes trailing blanks. The length of varying-length strings is the actual length and not the maximum length.

**Graphic string:**
**graphic-expression**
An expression that returns a value of a built-in graphic string.

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type.

**CODEUNITS16 or CODEUNITS32**
Specifies the unit that is used to express the length of the result.

- **CODEUNITS16**
  Specifies that the result is expressed in terms of 16-bit UTF-16 code units.

- **CODEUNITS32**
  Specifies that the result is expressed in terms of 32-bit UTF-32 code units.

For more information about CODEUNITS16 and CODEUNITS32 see [String unit specifications](#).

The result of the function is a large integer.

The result can be null; if the argument is null, the result is the null value.

The result is the length of graphic-expression expressed in the number of string units that were specified. The length of fixed-length strings includes trailing blanks. The length of varying-length strings is the actual length and not the maximum length.

**Example:** Assume that NAME is a VARCHAR(128) column, encoded in Unicode UTF-8, that contains the value 'Jürge'. The following two queries return the value 6:

```sql
SELECT CHARACTER_LENGTH(NAME, CODEUNITS32)
FROM T1 WHERE NAME = 'Jürge';
SELECT CHARACTER_LENGTH(NAME, CODEUNITS16)
FROM T1 WHERE NAME = 'Jürge';
```

The following two queries return the value 7:

```sql
SELECT CHARACTER_LENGTH(NAME, OCTETS)
FROM T1 WHERE NAME = 'Jürge';
SELECT LENGTH(NAME)
FROM T1 WHERE NAME = 'Jürge';
```

**CLOB**

The CLOB function returns a CLOB representation of a string.

**Character to CLOB:**

```
CLOB(character-expression, integer, CODEUNITS16, CODEUNITS32, OCTETS)
```
Graphic to CLOB:

\[
\text{CLOB}(\text{graphic-expression} \rightarrow \text{integer}, \text{CODEUNITS16}, \text{CODEUNITS32})
\]

The schema is SYSIBM.

Character to CLOB

\text{character-expression}

An expression that returns a value of a character string. If \text{character-expression} is bit data, an error occurs.

\text{integer}

An integer constant that specifies the length attribute of the resulting CLOB data type. The value must be between 1 and the maximum length of a CLOB, expressed in the units that are either implicitly or explicitly specified.

If you do not specify \text{integer} and \text{character-expression} is an empty string constant, the length attribute of the result is 1, and the result is an empty string. Otherwise, the length attribute of the result is the same as the length attribute of \text{character-expression}.

If \text{CODEUNITS16} or \text{CODEUNITS32} is specified, see “Determining the length attribute of the final result” on page 117 for information on how to calculate the length attribute of the result string.

\text{CODEUNITS16, CODEUNITS32, or OCTETS}

Specifies the unit that is used to express \text{integer}.

\text{CODEUNITS16}

Specifies that \text{integer} is expressed in terms of 16-bit UTF-16 code units.

\text{CODEUNITS32}

Specifies that \text{integer} is expressed in terms of 32-bit UTF-32 code units.

\text{OCTETS}

Specifies that \text{integer} is expressed in terms of bytes.

For more information about \text{CODEUNITS16}, \text{CODEUNITS32}, and \text{OCTETS}, see \underline{String unit specifications}.

The result of the function is a CLOB.

The result can be null; if the first argument is null, the result is the null value.

The actual length of the result is the minimum of the length attribute of the result and the actual length of \text{character-expression}. If the length of \text{character-expression} is greater than the length specified, the result is truncated. Unless all of the truncated characters are blanks, a warning is returned.

The CCSID of the result is the same as the CCSID of \text{character-expression}.

Graphic to CLOB
**graphic-expression**

An expression that returns a value of a graphic string.

**integer**

An integer constant that specifies the length attribute of the resulting CLOB data type. The value must be between 1 and the maximum length of a CLOB, expressed in the units that are either implicitly or explicitly specified.

If you do not specify `integer` and `graphic-expression` is an empty string constant, the length attribute of the result is 1, and the result is an empty string. Otherwise, the length attribute of the result is \((3 \times \text{length}(\text{graphic-expression}))\).

If `CODEUNITS16` or `CODEUNITS32` is specified, see “Determining the length attribute of the final result” on page 117 for information on how to calculate the length attribute of the result string.

**CODEUNITS16 or CODEUNITS32**

Specifies the unit that is used to express `integer`.

**CODEUNITS16**

Specifies that `integer` is expressed in terms of 16-bit UTF-16 code units.

**CODEUNITS32**

Specifies that `integer` is expressed in terms of 32-bit UTF-32 code units.

For more information about `CODEUNITS16` and `CODEUNITS32`, see [String unit specifications](#).

The result of the function is a CLOB.

The result can be null; if the first argument is null, the result is the null value.

The actual length of the result is the minimum of the length attribute of the result and the actual length of `graphic-expression`. If the length of `graphic-expression` is greater than the length specified, the result is truncated. Unless all of the truncated characters are blanks, a warning is returned.

The CCSID of the result is the character mixed CCSID that corresponds to the graphic CCSID of `graphic-expression`.

**Example 1:** The following function returns a CLOB for the string 'This is a CLOB'.

```sql
SELECT CLOB('This is a CLOB')
FROM SYSIBM.SYSDUMMY1;
```

**Example 2:** `FIRSTNME` is a VARCHAR(12) column in table `T1`. One of its values is the 6-character string 'Jürgen'. When `FIRSTNME` has this value:

<table>
<thead>
<tr>
<th>Function ...</th>
<th>Returns ...</th>
</tr>
</thead>
<tbody>
<tr>
<td>CLOB(FIRSTNME,3,CODEUNITS32)</td>
<td>'Jürgen' -- x'4AC3BC72'</td>
</tr>
<tr>
<td>CLOB(FIRSTNME,3,CODEUNITS16)</td>
<td>'Jürgen' -- x'4AC3BC72'</td>
</tr>
<tr>
<td>CLOB(FIRSTNME,3,OCTETS)</td>
<td>'Jü' -- x'4AC3BC'</td>
</tr>
</tbody>
</table>

**COALESCE**

The COALESCE function returns the value of the first nonnull expression.
The schema is SYSIBM.

The arguments must be compatible. For more information on compatibility, refer to the compatibility matrix in Table 31 on page 151. The arguments can be of either a built-in or user-defined data type.

The COALESCE function cannot be used as a source function when creating a user-defined function.

The arguments are evaluated in the order in which they are specified, and the result of the function is the first argument that is not null. The result can be null only if all arguments can be null. The result is null only if all arguments are null.

The selected argument is converted, if necessary, to the attributes of the result. The attributes of the result are determined using the "Rules for result data types" on page 174. If the COALESCE function has more than two arguments, the rules are applied to the first two arguments to determine a candidate result type. The rules are then applied to that candidate result type and the third argument to determine another candidate result type. This process continues until all arguments are analyzed and the final result type is determined.

If there are any mixed character string or graphic string and numeric arguments, the string value is implicitly cast to a DECFLOAT(34) value.

The COALESCE function can also handle a subset of the functions provided by CASE expressions. The result of using COALESCE(e1,e2) is the same as using the expression:

```
CASE WHEN e1 IS NOT NULL THEN e1 ELSE e2 END
```

VALUE can be specified as a synonym for COALESCE.

**Example 1:** Assume that SCORE1 and SCORE2 are SMALLINT columns in table GRADES, and that nulls are allowed in SCORE1 but not in SCORE2. Select all the rows in GRADES for which SCORE1 + SCORE2 > 100, assuming a value of 0 for SCORE1 when SCORE1 is null.

```
SELECT * FROM GRADES
WHERE COALESCE(SCORE1,0) + SCORE2 > 100;
```

**Example 2:** Assume that a table named DSN8C10.EMP contains a DATE column named HIREDATE, and that nulls are allowed for this column. The following query selects all rows in DSN8C10.EMP for which the date in HIREDATE is either unknown (null) or earlier than 1 January 1960.

```
SELECT * FROM DSN8C10.EMP
WHERE COALESCE(HIREDATE,DATE('1959-12-31')) < '1960-01-01';
```

The predicate could also be coded as COALESCE(HIREDATE,'1959-12-31') because, for comparison purposes, a string representation of a date can be compared to a date.
Example 3: Assume that for the years 1993 and 1994 there is a table that records the sales results of each department. Each table, S1993 and S1994, consists of a DEPTNO column and a SALES column, neither of which can be null. The following query provides the sales information for both years.

```sql
```

The full outer join ensures that the results include all departments, regardless of whether they had sales or existed in both years. The COALESCE function allows the two join columns to be combined into a single column, which enables the results to be ordered.

**COLLATION_KEY**

The COLLATION_KEY function returns a varying-length binary string that represents the collation key of the argument in the specified collation.

```
COLLATION_KEY(string-expression, collation-name)
```

The schema is SYSIBM.

The result of COLLATION_KEY on one string can be compared in binary form with the result of COLLATION_KEY on another string to determine their order within the specified `collation-name`. For the comparison to be meaningful, the results of the COLLATION_KEY must be from the same `collation-name`.

**string-expression**

An expression that returns a character or graphic string that is not a LOB for which the collation key is to be determined. If `string-expression` is a character string, it must not be FOR BIT DATA. If `string-expression` is not in Unicode UTF-16 (CCSID 1200), it is converted to Unicode UTF-16 before the corresponding collation key is obtained. The length of `string-expression` must not exceed 32704 bytes of the UTF-16 representation.

**collation-name**

A string constant or a string host variable that is not a binary string, CLOB, or DBCLOB. `collation-name` specifies the collation to use when determining the collation key. If `collation-name` is not an EBCDIC value, it is converted to EBCDIC. The length of `collation-name` must be between 1 and 255 bytes of the EBCDIC representation. The value of `collation-name` is not case sensitive and must be a left justified, valid "short path" collation setting for the parameter CUNBOPRM_Collation_Keyword in area CUN4BOPR. For detailed information about the "short path" setting in the parameter CUNBOPRM_Collation_Keyword, see z/OS Support for Unicode: Using Conversion Services.

The value of the host variable must not be null. If the host variable has an associated indicator variable, the value of the indicator variable must not indicate a null value. `collation-name` must be left justified within the host.
variable. It must also be padded on the right with blanks if the length is less than that of the host variable and the host variable is a fixed length CHAR or GRAPHIC data type.

collation-name is in the form of CUN4BOPR_Collation_Keyword specification.
You must specify a value that is acceptable for the \texttt{z/OS CUNBOPR_Collation_Keyword parameter}.

The following table lists some supported values:

<table>
<thead>
<tr>
<th>Attribute name</th>
<th>Key</th>
<th>Possible values</th>
</tr>
</thead>
<tbody>
<tr>
<td>Locale</td>
<td>L.R.V</td>
<td>&lt;locale&gt;</td>
</tr>
<tr>
<td>Strength</td>
<td>S</td>
<td>1, 2, 3, 4, I, D</td>
</tr>
<tr>
<td>Case_Level</td>
<td>K</td>
<td>X, O, D</td>
</tr>
<tr>
<td>Case_First</td>
<td>C</td>
<td>X, L, U, D</td>
</tr>
<tr>
<td>Alternate</td>
<td>A</td>
<td>N, S, D</td>
</tr>
<tr>
<td>Variable_Top</td>
<td>T</td>
<td>&lt;hex digits&gt;</td>
</tr>
<tr>
<td>Normalization</td>
<td>N</td>
<td>X, O, D</td>
</tr>
<tr>
<td>French</td>
<td>F</td>
<td>X, O, D</td>
</tr>
<tr>
<td>Hinayana</td>
<td>H</td>
<td>X, O, D</td>
</tr>
</tbody>
</table>

The following table describes the abbreviations for the collation keywords:

<table>
<thead>
<tr>
<th>Abbreviation</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>D</td>
<td>default</td>
</tr>
<tr>
<td>O</td>
<td>on</td>
</tr>
<tr>
<td>X</td>
<td>off</td>
</tr>
<tr>
<td>1</td>
<td>primary</td>
</tr>
<tr>
<td>2</td>
<td>secondary</td>
</tr>
<tr>
<td>3</td>
<td>tertiary</td>
</tr>
<tr>
<td>4</td>
<td>quaternary</td>
</tr>
<tr>
<td>I</td>
<td>identical</td>
</tr>
<tr>
<td>S</td>
<td>shifted</td>
</tr>
<tr>
<td>N</td>
<td>non-ignorable</td>
</tr>
<tr>
<td>L</td>
<td>lower-first</td>
</tr>
<tr>
<td>U</td>
<td>upper-first</td>
</tr>
</tbody>
</table>

The following examples show keywords using the above specifications:

'UCA400R1_AS_LSV_S3_CU'

UCA version 4.0.1; ignore spaces, punctuation and symbols; use Swedish linguistic conventions; use case-first upper; compare case-sensitive.

'UCA400R1_AN_LSV_S3_CL_NO'

UCA version 4.0.1; do not ignore spaces, punctuation and symbols; use Swedish linguistic conventions; use case-first lower (or does not set it to mean the same, since lower is used in most locales as the default); normalization ON; compare case-sensitive.

\textit{integer}

An integer value that specifies the length attribute of the result. If specified, the value must be an integer constant between 1 and 32704.
If the length is not specified, the length attribute of the result is determined as follows:

<table>
<thead>
<tr>
<th>string-expression</th>
<th>Result length attribute</th>
</tr>
</thead>
<tbody>
<tr>
<td>CHAR(n) or VARCHAR(n)</td>
<td>MIN (VARBINARY(12n), 32704)</td>
</tr>
<tr>
<td>GRAPHIC(n) or VARGRAPHIC(n)</td>
<td>MIN (VARBINARY(12n), 32704)</td>
</tr>
</tbody>
</table>

Regardless of whether the length is specified, the length of the collation key must be less than or equal to the length attribute of the result. The actual result length of the collation key is approximately six times of the length of string-expression where the length of string-expression is in Unicode byte representation. For certain collation-name such as UCA410_LKO_RKR (for Korean collation) the default length attribute of the result, 12n, might not be large enough and an error will be returned. To avoid such an error, the length attribute of the result must be explicitly specified to a larger constant. For the proper length attribute of the result, see z/OS Support for Unicode: Using Conversion Services for information about target buffer length considerations for Collation Services.

The result can be null; if the first argument is null, the result is the null value.

The COLLATION_KEY function uses Unicode Collation Services in z/OS to return the collation key. Unicode Collation Services support two collation versions:

- **UCA400R1.** This Collation version support Unicode standard character suite 4.0.0 and use Normalization Service under 4.0.1 Unicode character suite.
- **UCA410.** This Collation version support Unicode standard character suite 4.1.0 and use Normalization Service under 4.1.0 Unicode character suite.

If Unicode Collation Services are not available when the COLLATION_KEY function is run, an error is returned.

**Example 1:** The following query orders the employees by their surnames using the default Unicode Collation Algorithm V4.0.1(UCA), ignoring spaces, punctuation, and symbols, using Swedish linguistic conventions, and not comparing case:

```
SELECT FIRSTNAME, LASTNAME
FROM DSN8C10.EMP
ORDER BY COLLATION_KEY(LASTNAME, 'UCA400R1_AS_LSV_S2');
```

**Example 2:** The following query uses the COLLATION_KEY function on the LASTNAME column and the SALES_PERSON column to obtain the sort keys from the same collation name in order to do a culturally correct comparison. It finds the departments of employees in Quebec:

```
SELECT E.WORKDEPT
FROM EMPLOYEE AS E
INNER JOIN SALES AS S
ON COLLATION_KEY(E.LASTNAME, 'UCA400R1_LFR') =
    COLLATION_KEY(S.SALES_PERSON, 'UCA400R1_LFR')
WHERE S.REGION = 'Quebec';
```

**Example 3:** Create an index EMPLOYEE_NAME_SORT_KEY for table EMPLOYEE based on built-in function COLLATION_KEY with collation name 'UCA410_LDE' tailored for German.

```
CREATE INDEX EMPLOYEE_NAME_SORT_KEY ON EMPLOYEE (COLLATION_KEY(LASTNAME, 'UCA410_LDE', 600),
    COLLATION_KEY(FIRSTNAME, 'UCA410_LDE', 600),
    ID);
```

Description of parameters in area CUN4BOPR (z/OS: Unicode Services User's Guide and Reference)

COMPARE_DECFLOAT

The COMPARE_DECFLOAT function returns a SMALLINT value that indicates whether the two arguments are equal or unordered, or whether one argument is greater than the other.

```
COMPARE_DECFLOAT(decfloat-expression1, decfloat-expression2)
```

The schema is SYSIBM.

- `decfloat-expression1`: An expression that returns a DECFLOAT value.
- `decfloat-expression2`: An expression that returns a DECFLOAT value.

`decfloat-expression1` is compared with `decfloat-expression2` and the result is returned according to the following rules:

- If both arguments are finite, the comparison is algebraic and follows the procedure for DECFLOAT subtraction. If the difference is exactly zero with either sign, the arguments are equal. If a nonzero difference is positive, the first argument is greater than the second argument. If a nonzero difference is negative, the first argument is less than the second.
- Positive zero and negative zero compare as equal.
- Positive infinity compares equal to positive infinity.
- Positive infinity compares greater than any finite number.
- Negative infinity compares equal to negative infinity.
- Negative infinity compares less than any finite number.
- Numeric comparison is exact and the result is determined for finite operands as if range and precision were unlimited. Overflow or underflow cannot occur.
- If either argument is NaN or sNaN (positive or negative), the result is unordered.

Numeric comparison is exact, and the result is determined for finite operands as if the range and precision were unlimited. An overflow or underflow condition cannot occur.

If one argument is DECFLOAT(16) and the other is DECFLOAT(34), the DECFLOAT(16) value is converted to DECFLOAT(34) before the comparison is made.

The arguments can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34).

One of the following values will be the result:

- 0: The arguments are exactly equal
1. `decfloat-expression1` is less than `decfloat-expression2`
2. `decfloat-expression1` is greater than `decfloat-expression2`
3. The arguments are unordered

The result of the function is a SMALLINT value.

The result can be null; if any argument is null, the result is the null value.

**Examples:** The following examples demonstrate the values that will be returned when the function is used:

<table>
<thead>
<tr>
<th>Expression</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>COMPARE_DECFLOAT(DECFLOAT(2.17), DECFLOAT(2.17))</code></td>
<td>0</td>
</tr>
<tr>
<td><code>COMPARE_DECFLOAT(DECFLOAT(2.17), DECFLOAT(2.170))</code></td>
<td>2</td>
</tr>
<tr>
<td><code>COMPARE_DECFLOAT(DECFLOAT(2.170), DECFLOAT(2.17))</code></td>
<td>1</td>
</tr>
<tr>
<td><code>COMPARE_DECFLOAT(DECFLOAT(2.17), DECFLOAT(0.0))</code></td>
<td>2</td>
</tr>
<tr>
<td><code>COMPARE_DECFLOAT(INFINITY, INFINITY)</code></td>
<td>0</td>
</tr>
<tr>
<td><code>COMPARE_DECFLOAT(INFINITY, -INFINITY)</code></td>
<td>2</td>
</tr>
<tr>
<td><code>COMPARE_DECFLOAT(DECFLOAT(-2), INFINITY)</code></td>
<td>1</td>
</tr>
<tr>
<td><code>COMPARE_DECFLOAT(NAN, NAN)</code></td>
<td>3</td>
</tr>
<tr>
<td><code>COMPARE_DECFLOAT(DECFLOAT(-0.1), SNAN)</code></td>
<td>3</td>
</tr>
</tbody>
</table>

**CONCAT**

The CONCAT function combines two compatible string arguments.

The schema is SYSIBM.

The arguments must be compatible strings. For more information on compatibility, refer to the compatibility matrix in [Table 31 on page 151](#).

Either argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type.

The result of the function is a string that consists of the first string followed by the second string.

The result can be null; if any argument is null, the result is the null value.

The CONCAT function is identical to the CONCAT operator. For more information, see “Expressions with the concatenation operator” on page 267.

**Example:** Using sample table DSN8C10.EMP, concatenate column FIRSTNME with column LASTNAME. Both columns are defined as varying-length character strings.

```
SELECT CONCAT(FIRSTNME, LASTNAME)
FROM DSN8C10.EMP;
```

**CONTAINS**

The CONTAINS function searches a text search index using criteria that are specified in a search argument and returns a result about whether or not a match was found.
Requirement: To use the CONTAINS function, Text Search for Db2 for z/OS must be installed and configured. See IBM Text Search for Db2 for z/OS (IBM Text Search for Db2 for z/OS Installation, Administration, and Reference) for more information.

```
> CONTAINS(column-name, search-argument, string-constant)
```

Notes:
1. The SQL statement that invokes the CONTAINS function can be dynamically prepared by using a typed parameter marker for the `search-argument`, as in the following example: `CONTAINS(C1, CAST(?) AS CHAR(10))`.
2. `string-constant` must conform to the rules for the `search-argument-options`.

**search-argument-options:**

```
> QUERYLANGUAGE=value
> RESULTLIMIT=value
> SYNONYM=ON/OFF
```

Notes:
1. The same clause must not be specified more than once.

The schema is SYSIBM.

**column-name**

Specifies a qualified or unqualified name of a column that has a text search index that is to be searched. The column must exist in the table or view that is identified in the FROM clause in the statement and the column of the table, or the column of the underlying base table of the view must have an associated text search index. The underlying expression of the column of a view must be a simple column reference to the column of an underlying table, directly or through another nested view.

**search-argument**

Specifies an expression that returns a value that is a string value (except a LOB) that contains the terms to be searched for and must not be all blanks or the empty string. The actual length of the string must not exceed 4096 Unicode characters. The value is converted to Unicode before it is used to search the text search index. The maximum number of terms per query must not exceed 1024.
**string-constant**  
Identifies a string constant that specifies the search argument options that are in effect for the function.

The options that can be specified as part of the search-argument-options are as follows:

**QUERYLANGUAGE = value**  
Specifies the query language. The value can be any of the supported language codes. If the QUERYLANGUAGE option is not specified, the default is the language value of the text search index that is used when this function is invoked. If the language value of the text search index is AUTO, the default value for QUERYLANGUAGE is en_US.

**RESULTLIMIT = value**  
Specifies the maximum number of results to be returned from the underlying search engine. The value can be an integer value between 1 and 2 147 483 647. If the RESULTLIMIT option is not specified, no result limit is in effect for the query.

This scalar function cannot be called for each row of the result table, depending on the plan that the optimizer chooses. This function can be called once for the query to the underlying search engine, and a result set of all of the primary keys that match are returned from the search engine. This result set is then joined to the table containing the column to identify the result rows. In this case, the RESULTLIMIT value acts like a FETCH FIRST ?? ROWS from the underlying text search engine and can be used as an optimization. If the search engine is called for each row of the result because the optimizer determines that is the best plan, then the RESULTLIMIT option has no effect. Also, the RESULTLIMIT option has no effect when the CONTAINS function is used along with the comparison operators (<, >, <=, and >=) or the equality operator (=) and a value of 0 (zero).

**SYNONYM = OFF or SYNONYM = ON**  
Specifies whether to use a synonym dictionary that is associated with the text search index. Use the Synonym Tool to add a synonym dictionary to the collection. The default is OFF.

**OFF**  
Do not use a synonym dictionary.

**ON**  
Use the synonym dictionary that is associated with the text search index.

The result of the function is a large integer. If the second argument can be null, the result can be null. If the second argument is null, the result is the null value. If the third argument is null, the result is as if the third argument was not specified.

The result is 1 if the document contains a match for the search criteria that are specified in the search argument. Otherwise, the result is 0.

CONTAINS is a non-deterministic function.

**Examples**

**Example 1:** Assume that information about employees' skills are stored in a table named EMP_RESUME. The following statement finds all of the employees who have "COBOL" in their resume. The text search argument is not case-sensitive.
SELECT EMPNO
FROM EMP_RESUME
WHERE RESUME_FORMAT = 'ascii'
    AND CONTAINS(RESUME, 'cobol') = 1

**Example 2:** The search argument does not need to be a string constant. The search argument can be any SQL string expression, including a string contained in a host variable.

The following statement searches for the exact term "ate" in the COMMENT column:

```sql
char search_arg[100]; /* input host variable */
...
EXEC SQL DECLARE C3 CURSOR FOR
    SELECT CUSTKEY
    FROM K55ADMIN.CUSTOMERS
    WHERE CONTAINS(COMMENT, :search_arg)= 1
    ORDER BY CUSTKEY;
strcpy(search_arg, "ate");
EXEC SQL OPEN C3;
...
```

**Example 3:** The following statement finds 10 students at random who wrote online essays that contain the phrase "fossil fuel" in Spanish, which is "combustible fósil." These students will be invited for a radio interview.

Use the synonym dictionary that was created for the associated text search index. Because only 10 students are needed, you can optimize the query by using the RESULTLIMIT option to limit the number of results from the underlying text search server.

```sql
SELECT FIRSTNME, LASTNAME
FROM STUDENT_ESSAYS
WHERE CONTAINS(TERM_PAPER, 'combustible fósil',
    'QUERYLANGUAGE= es_ES RESULTLIMIT = 10 SYNONYM=ON') = 1
```

**COS**

The COS function returns the cosine of the argument, where the argument is an angle, expressed in radians. The COS and ACOS functions are inverse operations.

```
COS(numeric-expression)
```

The schema is SYSIBM.

The argument must be an expression that returns the value of any built-in numeric data type that is not DECFLOAT. If the argument is not a double precision floating-point number, it is converted to one for processing by the function.

The result of the function is a double precision floating-point number.

The result can be null; if the argument is null, the result is the null value.
Example: Assume that host variable COSINE is DECIMAL(2,1) with a value of 1.5. The following statement returns a double precision floating-point number with an approximate value of 0.07:

    SELECT COS(:COSINE)
    FROM SYSIBM.SYSDUMMY1;

**COSH**

The COSH function returns the hyperbolic cosine of the argument, where the argument is an angle, expressed in radians.

    COSH(numeric-expression)

The schema is SYSIBM.

The argument must be an expression that returns the value of any built-in numeric data type that is not DECFLOAT. If the argument is not a double precision floating-point number, it is converted to one for processing by the function.

The result of the function is a double precision floating-point number.

The result can be null; if the argument is null, the result is the null value.

Example: Assume that host variable HCOS is DECIMAL(2,1) with a value of 1.5. The following statement returns a double precision floating-point number with an approximate value of 2.35:

    SELECT COSH(:HCOS)
    FROM SYSIBM.SYSDUMMY1;

**DATE**

The DATE function returns a date that is derived from a value.

    DATE(expression)

The schema is SYSIBM.

The argument must be an expression that returns one of the following built-in data types: a date, a timestamp, a character string, a graphic string, or any numeric data type.

- If expression is a character or graphic string, it must not be a CLOB or DBCLOB, and it must have one of the following values:
  - A valid string representation of a date or timestamp with an actual length that is not greater than 255 bytes. For the valid formats of string representations of dates and timestamps, see "String representations of datetime values" on page 130.
A character or graphic string with an actual length of 7 that represents a valid date in the form yyyy-mm-dd, where yyyy are digits denoting a year and mm are digits between 001 and 366 denoting a day of that year.

- If expression is a number, it must be greater than or equal to one and less than or equal to 3652059.

If expression is not a DATE value, expression is cast as follows:
- If expression is a TIMESTAMP WITH TIME ZONE value, expression is cast to TIMESTAMP WITHOUT TIME ZONE, with the same precision as expression.
- If expression is a string, expression is cast to DATE.

The result of the function is a date.

The result can be null; if the argument is null, the result is the null value.

The other rules depend on the data type of the argument:

- If the argument is a timestamp, the result is the date part of the timestamp.
- If the argument is a date, the result is that date.
- If the argument is a number, the result is the date that is \( n \)-1 days after January 1, 0001, where \( n \) is the integral part of the number.
- If the argument is a string, the result is the date that is represented by the string. If the string contains a time zone, the time zone is ignored. If the CCSID of the string is not the same as the corresponding default CCSID at the server, the string is first converted to that CCSID.

The result CCSID is the appropriate CCSID of the argument encoding scheme and the result subtype is the appropriate subtype of the CCSID.

Example 1: Assume that RECEIVED is a TIMESTAMP column in some table, and that one of its values is equivalent to the timestamp '1988-12-25-17.12.30.000000'. For this value, the following statement returns the internal representation of 25 December 1988.

\[
\text{DATE(RECEIVED)}
\]

Example 2: Assume that DATCOL is a CHAR(7) column in some table, and that one of its values is the character string '1989061'. For this value, the following statement returns the internal representation of 2 March 1989.

\[
\text{DATE(DATCOL)}
\]

Example 3: Db2 recognizes '1989-03-02' as the ISO representation of 2 March 1989. So, the following statement returns the internal representation of 2 March 1989.

\[
\text{DATE('1989-03-02')}
\]

**DAY**

The DAY function returns the day part of a value.
The schema is SYSIBM.

The argument must be an expression that returns one of the following built-in data types: a date, a timestamp, a character string, a graphic string, or any numeric data type.

- If expression is a character or graphic string, it must not be a CLOB or DBCLOB, and its value must be a valid string representation of a date or timestamp with an actual length that is not greater than 255 bytes. For the valid formats of string representations of dates and timestamps, see “String representations of datetime values” on page 130.

- If expression is a number, it must be a date duration or a timestamp duration. For the valid formats of datetime durations, see “Datetime operands” on page 177.

If expression is a timestamp with a time zone value, or a valid string representation of a timestamp with a time zone, the result is determined from the UTC representation of the datetime value.

The result of the function is a large integer.

The result can be null; if the argument is null, the result is the null value.

The other rules for the function depend on the data type of the argument:

- If the argument is a date, timestamp, or string representation of either, the result is the day part of the value, which is an integer between 1 and 31.
- If the argument is a date duration or timestamp duration, the result is the day part of the value, which is an integer between -99 and 99. A nonzero result has the same sign as the argument.
- If the argument contains a time zone, the result is the year part of the value expressed in UTC.

Example 1: Set the INTEGER host variable DAYVAR to the day of the month on which employee 140 in the sample table DSN8C10.EMP was hired.

```
EXEC SQL SELECT DAY(HIREDATE) INTO :DAYVAR FROM DSN8C10.EMP WHERE EMPNO = '000140';
```

Example 2: Assume that DATE1 and DATE2 are DATE columns in the same table. Assume also that for a given row in this table, DATE1 and DATE2 represent the dates 15 January 2000 and 31 December 1999, respectively. Then, for the given row:

```
DAY(DATE1 - DATE2)
```

returns the value 15.

Example 3: The following invocations of the DAY function all return the same result:

```
SELECT DAY('2003-01-02-20.00.00'),
       DAY('2003-01-02-12.00.00-08:00'),
       DAY('2003-01-03-05.00.00+09:00')
FROM SYSIBM.SYSDUMMY1;
```

For each invocation of the DAY function in this SELECT statement, the result is 2.

When the input argument contains a time zone, the result is determined from the UTC representation of the input value. The string representations of a timestamp
with a time zone in the SELECT statement all have the same UTC representation: 2003-01-02-20.00.00. The day portion of the UTC representation is 2.

**DAYOFMONTH**

The DAYOFMONTH function returns the day part of a value. The function is similar to the DAY function, except DAYOFMONTH does not support a date or timestamp duration as an argument.

```
DAYOFMONTH(expression)
```

The schema is SYSIBM.

The argument must be an expression that returns a value of a date, a timestamp, a character string, or a graphic string built-in data type.

If `expression` is a character or graphic string, it must not be a CLOB or DBCLOB, and its value must be a valid string representation of a date or timestamp with an actual length that is not greater than 255 bytes. For the valid formats of string representations of dates and timestamps, see “String representations of datetime values” on page 130.

If `expression` is a timestamp with a time zone value, or a valid string representation of a timestamp with a time zone, the result is determined from the UTC representation of the datetime value.

The result of the function is a large integer between 1 and 31, which represents the day part of the value.

The result can be null; if the argument is null, the result is the null value.

**Example 1:** Set the INTEGER variable DAYVAR to the day of the month on which employee 140 in sample table DSN8C10.EMP was hired.

```sql
SELECT DAYOFMONTH(HIREDATE)
INTO :DAYVAR
FROM DSN8C10.EMP
WHERE EMPNO = '000140';
```

**Example 2:** The following invocations of the DAYOFMONTH function returns the same result:

```sql
SELECT DAYOFMONTH('2003-01-02-20.00.00'),
       DAYOFMONTH('2003-01-02-12.00.00-08:00'),
       DAYOFMONTH('2003-01-03-05.00.00+09:00')
FROM SYSIBM.SYSDUMMY1;
```

For each invocation of the DAYOFMONTH function in this SELECT statement, the result is 2.

When the input argument contains a time zone, the result is determined from the UTC representation of the input value. The string representations of a timestamp with a time zone in the SELECT statement all have the same UTC representation: 2003-01-02-20.00.00. The day portion of the UTC representation is 2.
DAYOFWEEK

The DAYOFWEEK function returns an integer, in the range of 1 to 7, that represents the day of the week, where 1 is Sunday and 7 is Saturday. The DAYOFWEEK function is similar to the DAYOFWEEK_ISO function.

\[ \text{DAYOFWEEK(expression)} \]

The schema is SYSIBM.

The argument must be an expression that returns a value of one of the following built-in data types: a date, a timestamp, a character string, or a graphic string.

If expression is a character or graphic string, it must not be a CLOB or DBCLOB, and its value must be a valid string representation of a date or timestamp with an actual length that is not greater than 255 bytes. For the valid formats of string representations of dates and timestamps, see “String representations of datetime values” on page 130.

If expression is a timestamp with a time zone, or a valid string representation of a timestamp with a time zone, the result is determined from the UTC representation of the datetime value.

The result of the function is a large integer.

The result can be null; if the argument is null, the result is the null value.

Example 1: Using sample table DSN8C10.EMP, set the integer host variable DAY_OF_WEEK to the day of the week that Christine Haas (EMPNO = '000010') was hired (HIREDATE).

```sql
SELECT DAYOFWEEK(HIREDATE)
  INTO :DAY_OF_WEEK
 FROM DSN8C10.EMP
 WHERE EMPNO = '000010';
```

The result is that DAY_OF_WEEK is set to 6, which represents Friday.

Example 2: The following query returns four values: 1, 2, 1, and 2.

```sql
SELECT DAYOFWEEK(CAST('10/11/1998' AS DATE)),
      DAYOFWEEK(TIMESTAMP('10/12/1998', '01.02')),
      DAYOFWEEK(CAST(CAST('10/11/1998' AS DATE) AS CHAR(20))),
      DAYOFWEEK(CAST(TIMESTAMP('10/12/1998', '01.02') AS CHAR(26)))
 FROM SYSIBM.SYSDUMMY1;
```

Example 3: The following invocations of the DAYOFWEEK function returns the same result:

```sql
SELECT DAYOFWEEK('2003-01-02-20.00.00'),
      DAYOFWEEK('2003-01-02-12.00.00-08:00'),
      DAYOFWEEK('2003-01-03-05.00.00+09:00')
 FROM SYSIBM.SYSDUMMY1;
```

For each invocation of the DAYOFWEEK function in this SELECT statement, the result is 5 (Sunday is considered the first day of the week).
When the input argument contains a time zone, the result is determined from the UTC representation of the input value. The string representations of a timestamp with a time zone in the SELECT statement all have the same UTC representation: 2003-01-02-20.00.00.

**DAYOFWEEK_ISO**

The DAYOFWEEK_ISO function returns an integer, in the range of 1 to 7, that represents the day of the week, where 1 is Monday and 7 is Sunday. The DAYOFWEEK_ISO function is similar to the DAYOFWEEK function.

```
DAYOFWEEK_ISO(expression)
```

The schema is SYSIBM.

The argument must be an expression that returns a value of one of the following built-in data types: a date, a timestamp, a character string, or graphic string.

If *expression* is a character or graphic string, it must not be a CLOB or DBCLOB, and its value must be a valid string representation of a date or timestamp with an actual length that is not greater than 255 bytes. For the valid formats of string representations of dates and timestamps, see “String representations of datetime values” on page 130.

If *expression* is a timestamp with a time zone, or a valid string representation of a timestamp with a time zone, the result is determined from the UTC representation of the datetime value.

The result of the function is a large integer.

The result can be null; if the argument is null, the result is the null value.

**Example 1:** Using sample table DSN8C10.EMP, set the integer host variable DAY_OF_WEEK to the day of the week that Christine Haas (EMPNO = '000010') was hired (HIREDATE).

```
SELECT DAYOFWEEK_ISO(HIREDATE)
INTO :DAY_OF_WEEK
FROM DSN8C10.EMP
WHERE EMPNO = '000010';
```

The result is that DAY_OF_WEEK is set to 5, which represents Friday.

**Example 2:** The following query returns four values: 7, 1, 7, and 1.

```
SELECT DAYOFWEEK_ISO(CAST('10/11/1998' AS DATE)),
       DAYOFWEEK_ISO(TIMESTAMP('10/12/1998', '01.02')),
       DAYOFWEEK_ISO(CAST(CAST('10/11/1998' AS DATE) AS CHAR(20))),
       DAYOFWEEK_ISO(CAST(TIMESTAMP('10/12/1998', '01.02') AS CHAR(26)))
FROM SYSIBM.SYSDUMMY1;
```

**Example 3:** The following list shows what is returned by the DAYOFWEEK_ISO function for various dates.
Example 4: The following invocations of the DAYOFWEEK_ISO function returns the same result:

```
SELECT DAYOFWEEK_ISO('2003-01-02-20.00.00'),
       DAYOFWEEK_ISO('2003-01-02-12.00.00-08:00'),
       DAYOFWEEK_ISO('2003-01-03-05.00.00+09:00')
FROM SYSIBM.SYSDUMMY1;
```

For each invocation of the DAYOFWEEK_ISO function in this SELECT statement, the result is 4 (Monday is considered the first day of the week).

When the input argument contains a time zone, the result is determined from the UTC representation of the input value. The string representations of a timestamp with a time zone in the SELECT statement all have the same UTC representation: 2003-01-02-20.00.00.

**DAYOFYEAR**

The DAYOFYEAR function returns an integer, in the range of 1 to 366, that represents the day of the year, where 1 is January 1.

```
<table>
<thead>
<tr>
<th>DATE:</th>
<th>DAYOFWEEK_ISO returns:</th>
</tr>
</thead>
<tbody>
<tr>
<td>2003-12-28</td>
<td>'7'</td>
</tr>
<tr>
<td>2003-12-31</td>
<td>'3'</td>
</tr>
<tr>
<td>2004-01-01</td>
<td>'4'</td>
</tr>
<tr>
<td>2004-01-10</td>
<td>'6'</td>
</tr>
<tr>
<td>2005-01-04</td>
<td>'2'</td>
</tr>
<tr>
<td>2005-12-31</td>
<td>'7'</td>
</tr>
<tr>
<td>2006-01-01</td>
<td>'7'</td>
</tr>
<tr>
<td>2006-01-03</td>
<td>'2'</td>
</tr>
</tbody>
</table>
```

The schema is SYSIBM.

The argument must be an expression that returns a value of one of the following built-in data types: a date, a timestamp, a character string, or a graphic string.

If `expression` is a character or graphic string, it must not be a CLOB or DBCLOB, and its value must be a valid string representation of a date or timestamp with an actual length that is not greater than 255 bytes. For the valid formats of string representations of dates and timestamps, see "String representations of datetime values" on page 130.

If `expression` is a timestamp with a time zone value, or a valid string representation of a timestamp with a time zone, the result is determined from the UTC representation of the datetime value.

The result of the function is a large integer.

The result can be null; if the argument is null, the result is the null value.
Example 1: Using sample table DSN8C10.EMP, set the integer host variable AVG_DAY_OF_YEAR to the average of the day of the year on which employees were hired (HIREDATE):

```sql
SELECT AVG(DAYOFYEAR(HIREDATE))
INTO :AVG_DAY_OF_YEAR
FROM DSN8C10.EMP;
```

The result is that AVG_DAY_OF_YEAR is set to 202.

Example 2: The following invocations of the DAYOFYEAR function returns the same result:

```sql
SELECT DAYOFYEAR('2003-01-02-20.00.00'),
       DAYOFYEAR('2003-01-02-12.00.00-08:00'),
       DAYOFYEAR('2003-01-03-05.00.00+09:00')
FROM SYSIBM.SYSDUMMY1;
```

The results for this SELECT statement are 2, 2, 3.

When the input argument contains a time zone, the result is determined from the UTC representation of the input value. The string representations of a timestamp with a time zone in the SELECT statement all have the same UTC representation: 2003-01-02-20.00.00.

**DAYS**

The DAYS function returns an integer representation of a date.

```
DAYS(expression)
```

The schema is SYSIBM.

The argument must be an expression that returns a value of one of the following built-in data types: a date, a timestamp, a character string, or a graphic string.

If `expression` is a character or graphic string, it must not be a CLOB or DBCLOB, and its value must be a valid string representation of a date or timestamp with an actual length that is not greater than 255 bytes. For the valid formats of string representations of dates and timestamps, see "String representations of datetime values" on page 130.

If `expression` is a timestamp with a time zone value, or a valid string representation of a timestamp with a time zone, the result is determined from the UTC representation of the datetime value.

The result of the function is a large integer.

The result can be null; if the argument is null, the result is the null value.

The result is 1 more than the number of days from January 1, 0001 to `D`, where `D` is the date that would occur if the DATE function were applied to the argument.
Example 1: Set the INTEGER host variable DAYSVAR to the number of days that employee 140 had been with the company on the last day of 1997.

```
EXEC SQL SELECT DAYS('1997-12-31') - DAYS(HIREDATE) + 1
INTO :DAYSVAR
FROM DSN8C10.EMP
WHERE EMPNO = '000140';
```

Example 2: The following invocations of the DAYS function returns the same result:

```
SELECT DAYS('2003-01-02-20.00.00'),
DAYS('2003-01-02-12.00.00-08:00'),
DAYS('2003-01-03-05.00.00+09:00')
FROM SYSIBM.SYSDUMMY1;
```

For each invocation of the DAYS function in this SELECT statement, the result is 731217.

When the input argument contains a time zone, the result is determined from the UTC representation of the input value. The string representations of a timestamp with a time zone in the SELECT statement all have the same UTC representation: 2003-01-02-20.00.00.

**DBCLOB**

The DBCLOB function returns a DBCLOB representation of a character string value (with the single-byte characters converted to double-byte characters) or a graphic string value.

**Character to DBCLOB:**

```
DBCLOB(character-expression, integer)
```

**Graphic to DBCLOB:**

```
DBCLOB(graphic-expression, integer)
```

The schema is SYSIBM.

**Character to DBCLOB**

*character-expression*

An expression that returns a value that is an EBCDIC-encoded or Unicode-encoded character string. It cannot be BIT data. The argument does
The data does not need to be mixed data, but any occurrences of X'0E' and X'0F' in the string must conform to the rules for EBCDIC mixed data. (See “Character strings” on page 111 for these rules.)

**integer**
The length attribute of the resulting DBCLOB. The value of `integer` must be between 1 and the maximum length of a DBCLOB, expressed in the units that are either implicitly or explicitly specified.

If `CODEUNITS16` or `CODEUNITS32` is specified, see “Determining the length attribute of the final result” on page 117 for information about how to calculate the length attribute of the result string. If `CODEUNITS32` is specified, the value of `integer` must be between 1 and the maximum length of a DBCLOB divided by two (to allow for an intermediate result string that is long enough to evaluate the function).

If `integer` is not specified and `character-expression` is an empty string constant, the length attribute of the result is 1, and the result is an empty string. Otherwise, the length attribute of the result is the same as the length attribute of `character-expression`.

**CODEUNITS16 or CODEUNITS32**
Specifies the unit that is used to express `integer`. If `CODEUNITS16` or `CODEUNITS32` is specified, the input is EBCDIC, and there is no system CCSID for EBCDIC GRAPHIC data, an error occurs.

- **CODEUNITS16**
  Specifies that `integer` is expressed in terms of 16-bit UTF-16 code units.

- **CODEUNITS32**
  Specifies that `integer` is expressed in terms of 32-bit UTF-32 code units.

For more information about `CODEUNITS16` and `CODEUNITS32`, see String unit specifications.

The actual length of the result is the minimum of the length attribute of the result and the actual length of `character-expression`. If the length of `character-expression`, as measured in single-byte characters, is greater than the specified length of the result, as measured in double-byte characters, the result is truncated. Unless all the truncated characters are blanks appropriate for `character-expression`, a warning is returned.

The CCSID of the result is the graphic CCSID that corresponds to the character CCSID of `character-expression`.

For EBCDIC input data, each character of `character-expression` determines a character of the result. The argument might need to be converted to the native form of mixed data before the result is derived. Let $M$ denote the system CCSID for mixed data. The argument is not converted if any of the following conditions is true:

- The argument is mixed data and its CCSID is $M$.
- The argument is SBCS data and its CCSID is the same as the system CCSID for SBCS data. In this case, the operation proceeds as if the CCSID of the argument is $M$. 

456 SQL Reference
Otherwise, the argument is a new string $S$ derived by converting the characters to the coded character set identified by $M$. If there is no system CCSID for mixed data, conversion is to the coded character set that the system CCSID for SBCS data identifies.

The result is derived from $S$ using the following steps:
- Each shift character (X'0E' or X'0F') is removed.
- Each double-byte character remains as is.
- Each single-byte character is replaced by a double-byte character.

The replacement for a single-byte character is the equivalent DBCS character if an equivalent exists. Otherwise, the replacement is X'FEFE'. The existence of an equivalent character depends on $M$. If there is no system CCSID for mixed data, the DBCS equivalent of X'xx' for EBCDIC is X'42xx', except for X'40', whose DBCS equivalent is X'4040'.

For Unicode input data, each character of $character-expression$ determines a character of the result. The argument might need to be converted to the native form of mixed data before the result is derived. Let $M$ denote the system CCSID for mixed data. The argument is not converted if any of the following conditions is true:
- The argument is mixed data, and its CCSID is $M$.
- The argument is SBCS data, and its CCSID is the same as the system CCSID for SBCS data. In this case, the operation proceeds as if the CCSID of the argument is $M$.

Otherwise, the argument is a new string $S$ derived by converting the characters to the coded character set identified by $M$.

The result is derived from $S$ using the following steps:
- Each non-supplementary character is replaced by a Unicode double-byte character (a UTF-16 code point). A non-supplementary character in UTF-8 is between 1 and 3 bytes.
- Each supplementary character is replaced by a pair of Unicode double-byte characters (a pair of UTF-16 code points).

The replacement for a single-byte character is the Unicode equivalent character if an equivalent exists. Otherwise, the replacement is X'FFFD'.

**Graphic to DBCLOB**

$graphic-expression$

An expression that returns a value that is an EBCDIC-encoded or Unicode-encoded graphic string.

$integer$

The length attribute for the resulting varying-length graphic string. The value must be an integer between 1 and the maximum length of a DBCLOB, expressed in the units that are either implicitly or explicitly specified.

If CODEUNITS16 or CODEUNITS32 is specified, see "Determining the length attribute of the final result" on page 117 for information about how to calculate the length attribute of the result string.
If integer is not specified and graphic-expression is an empty string constant, the length attribute of the result is 1, and the result is an empty string. Otherwise, the length attribute of the result is the same as the length attribute of graphic-expression.

**CODEUNITS16 or CODEUNITS32**
Specifies the unit that is used to express integer. If CODEUNITS16 or CODEUNITS32 is specified, the input is EBCDIC, and there is no system CCSID for EBCDIC GRAPHIC data, an error occurs.

**CODEUNITS16**
Specifies that integer is expressed in terms of 16-bit UTF-16 code units.

**CODEUNITS32**
Specifies that integer is expressed in terms of 32-bit UTF-32 code units.

For more information about CODEUNITS16 and CODEUNITS32, see String unit specifications.

The actual length of the result is the minimum of the length attribute of the result and the actual length of graphic-expression. If the length of graphic-expression is greater than the length attribute of the result, truncation is performed. Unless all of the truncated characters are double-byte blanks, a warning is returned.

The CCSID of the result is the same as the CCSID of graphic-expression.

The result of the function is a DBCLOB.

The result can be null; if the first argument is null, the result is the null value.

The length attribute and actual length of the result are measured in double-byte characters because the result is a graphic string.

**Example 1:** Assume that the application encoding scheme is Unicode. The following statement returns a graphic (UTF-16) host variable.

```sql
VALUES DBCLOB('123') INTO :GHV1;
```

**Example 2:** FIRSTNAME is a VARCHAR(12) column (Unicode UTF-8 data) in table T1. One of its values is the 6-character string 'Jürgen'. When FIRSTNAME has this value:

```sql
Function ... Returns ...
DBCLOB(FIRSTNAME,3,CODEUNITS32)    'Jür'    -- x'004A00FC0072'
DBCLOB(FIRSTNAME,3,CODEUNITS16)     'Jür'    -- x'004A00FC0072'
```

**DECFLOAT**
The DECFLOAT function returns a decimal floating-point representation of either a number or a character string representation of a number, a decimal number, an integer, a floating-point number, or a decimal floating-point number.
The schema is SYSIBM.

**Numeric to DECFLOAT**

*numeric-expression*

An expression that returns a value of any built-in numeric data type.

34 or 16

Specifies the number of digits of precision for the result. The default is 34.

**String to DECFLOAT**

*string-expression*

An expression that returns a value of a character or graphic string (except a CLOB or DBCLOB) with a length attribute that is not greater than 255 bytes. Leading and trailing blanks are eliminated, and the resulting string is folded to uppercase. The expression must conform to the rules for forming a floating-point, decimal floating-point, integer, or decimal constant.

Use the *string-expression* syntax variation to specify a negative zero as a constant, or to preserve the precision of a floating point constant.

34 or 16

Specifies the number of digits of precision for the result. The default is 34.

The result is the same number that would result from `CAST(string-expression AS DECFLOAT(n))` or `CAST(numeric-expression AS DECFLOAT(n))`. Leading and trailing blanks are removed from the string, and the resulting substring must conform to the rules for forming a string representation of an SQL decimal-floating point constant.

If necessary, the source is rounded to the precision of the target.

For static SQL statements other than CREATE VIEW, the ROUNDDING bind option or the native SQL procedure option determines the rounding mode.

For dynamic SQL statements (and static CREATE VIEW statements), the special register CURRENT DECFLOAT ROUNDING MODE determines the rounding mode.
The result of the function is a DECFLOAT with the implicitly or explicitly specified number of digits of precision.

The result can be null; if the first argument is null, the result is the null value.

**Note:** To increase the portability of applications, use the CAST specification. For more information, see [CAST specification](#).

**Example:** When a keyword is used for a special value that is expressed as a constant in a context where the keyword could be interpreted as a name, the DECFLOAT function can be used to explicitly cast the value to decimal-floating point. Assume that MYTAB contains columns C1 and SNAN, and that you want to reference the decimal floating-point value for infinity in the same SQL statement. Use the DECFLOAT function to explicitly cast SNAN as a decimal floating-point value to ensure that it is not interpreted as the name of a column, parameter or variable:

```sql
SELECT INFINITY -- column named SNAN
FROM MYTAB
WHERE C1 = DECFLOAT ('sNaN') -- comparison is made with the
-- decimal floating-point sNaN value
```

**DECFLOAT_FORMAT**

The DECFLOAT_FORMAT function returns a DECFLOAT(34) value that is based on the interpretation of the input string using the specified format.

```
DECFLOAT_FORMAT(string-expression[,format-string])
```

The schema is SYSIBM.

**string-expression**

An expression that returns a value that is a CHAR and VARCHAR data type. If a supplied argument is a GRAPHIC or VARGRAPHIC data type, it is first converted to VARCHAR before evaluating the function. Leading and trailing blanks are removed from the string. If format-string is not specified, the resulting substring must conform to the rules for forming an SQL integer, decimal, floating-point, or decimal floating-point constant and not be greater than 42 bytes. Otherwise, the resulting substring must contain the components of a number that corresponds to the format specified by format-string.

**format-string**

An expression that returns a value that is a built-in character string data type. If a supplied argument is a graphic string (except DBCLOB), it is first converted to a character string before the function is evaluated. The actual length must not be greater than 254 bytes.

The value is a template for how string-expression is to be interpreted for conversion to a DECFLOAT value. format-string must contain a valid combination of the listed format elements according to the following rules:

- At least one '0' or '9' format element must be specified.
- A sign format element ('S', 'MI', 'PR') can be specified only one time.
- A decimal point format element can be specified only one time.
• Alphabetic format elements must be specified in upper case.
• A prefix format element can only be specified at the beginning of the format string, before any format elements that are not prefix format elements. When multiple prefix format elements are specified they can be specified in any order.
• A suffix format element can only be specified at the end of the format string, after any format elements that are not suffix format elements.
• A comma format element can be the first format element that is not a prefix format element. There can be any number of comma format elements.
• Blanks must not be specified between format elements. Leading and trailing blanks can be specified but are ignored.

Table 71. Format elements for the DECFLOAT_FORMAT function

<table>
<thead>
<tr>
<th>Format element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 or 9</td>
<td>Each 0 or 9 represents a digit.</td>
</tr>
<tr>
<td>$</td>
<td>Prefix</td>
</tr>
<tr>
<td>MI</td>
<td>Suffix</td>
</tr>
<tr>
<td>PR</td>
<td>Suffix</td>
</tr>
<tr>
<td>,</td>
<td></td>
</tr>
<tr>
<td>.</td>
<td></td>
</tr>
</tbody>
</table>

If format-string is not specified, string-expression must conform to the rules for forming an SQL integer, decimal, floating-point, or decimal floating-point constant and have a length not greater than 42 bytes.

The result is a DECFLOAT(34).
The result can be null; if any argument is null, the result is the null value.

**Syntax alternatives:** TO_NUMBER is a synonym for DECFLOAT_FORMAT.

**Table 72. Examples of DECFLOAT_FORMAT**

<table>
<thead>
<tr>
<th>Example</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>DECFLOAT_FORMAT( '123.45' )</td>
<td>123.45</td>
</tr>
<tr>
<td>DECFLOAT_FORMAT( '-123456.78' )</td>
<td>-123456.78</td>
</tr>
<tr>
<td>DECFLOAT_FORMAT( '+123456.78' )</td>
<td>123456.78</td>
</tr>
<tr>
<td>DECFLOAT_FORMAT( '1.23E4' )</td>
<td>12300</td>
</tr>
<tr>
<td>DECFLOAT_FORMAT( '123.4', '9999.99' )</td>
<td>123.40</td>
</tr>
<tr>
<td>DECFLOAT_FORMAT( '001,234', '000,000' )</td>
<td>1234</td>
</tr>
<tr>
<td>DECFLOAT_FORMAT( '1234 ', '9999MI' )</td>
<td>1234</td>
</tr>
<tr>
<td>DECFLOAT_FORMAT( '1234→', '9999MI' )</td>
<td>1234</td>
</tr>
<tr>
<td>DECFLOAT_FORMAT( '+1234', '$9999' )</td>
<td>1234</td>
</tr>
<tr>
<td>DECFLOAT_FORMAT( '-1234', '59999' )</td>
<td>-1234</td>
</tr>
<tr>
<td>DECFLOAT_FORMAT( '1234', '9999PR' )</td>
<td>1234</td>
</tr>
<tr>
<td>DECFLOAT_FORMAT( '&lt;1234&gt;', '9999PR' )</td>
<td>-1234</td>
</tr>
<tr>
<td>DECFLOAT_FORMAT( '$123,456.78', '999,999.99' )</td>
<td>123456.78</td>
</tr>
</tbody>
</table>

**DECFLOAT_SORTKEY**

The DECFLOAT_SORTKEY function returns a binary value that can be used when sorting DECFLOAT values. The sorting occurs in a manner that is consistent with the IEEE 754R specification on total ordering.

The schema is SYSIBM.

*decfloat-expression*

An expression that returns a DECFLOAT value.

*decfloat-expression* can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34).

The result is a fixed length binary string with a length attribute of 9 if *decfloat-expression* is a DECFLOAT(16) value or 17 if *decfloat-expression* is a DECFLOAT(34) value.

The result can be null; if the argument is null, the result is the null value.

*Example:* Assume that the following CREATE TABLE statement is used to create a table with a column that contains DECFLOAT values and the INSERT statements are used to populate the table:
CREATE TABLE T1(D1 DECIMAL(16));
INSERT INTO T1 VALUES (2.100);
INSERT INTO T1 VALUES (2.10);
INSERT INTO T1 VALUES (2.1000);
INSERT INTO T1 VALUES (2.1);

Then the following SELECT statement is used to return the values from D1:
SELECT D1 FROM T1 ORDER BY D1;

The SELECT statement returns the following values, but because all numbers in
the column have the same value, the ORDER BY clause has no effect and the
values are returned in an arbitrary order:
D1
-------
2.1
2.100
2.10
2.100

The following SELECT statement, which includes the DECIMAL_SORTKEY
function in the ORDER BY clause, returns the properly ordered values:
SELECT D1
FROM T1
ORDER BY (DECIMAL_SORTKEY(D1));
D1
-------
2.1000
2.100
2.10
2.1

DECIMAL or DEC
The DECIMAL function returns a decimal representation of either a number or a
character-string or graphic-string representation of a number, an integer, or a
decimal number.

Numeric to Decimal:

```
DECIMAL (numeric-expression precision scale)
```

String to Decimal:

```
DECIMAL (string-expression precision scale decimal-character)
```
The schema is SYSIBM.

**Numeric to decimal**

*numeric-expression*

An expression that returns a value of any built-in numeric data type.

*precision*

An integer constant with a value greater than or equal to 1 and less than or equal to 31.

The default for *precision* depends on the data type of the *numeric-expression*:

- 5 for small integer
- 11 for large integer
- 19 for big integer
- 15 for floating point or decimal
- 31 for decimal floating point

*scale*

An integer constant that is greater than or equal to zero and less than or equal to *precision*. The value specifies the scale of the result. The default value is 0.

The result of the function is the same number that would occur if the argument were assigned to a decimal column or variable with precision *p* and scale *s*, where *p* and *s* are specified by the second and third arguments. An error occurs if the number of significant digits required to represent the whole part of the number is greater than *p*-*s*.

**String to decimal**

*string-expression*

An expression that returns a value of a character or graphic string (except a CLOB or DBCLOB) with a length attribute that is not greater than 255 bytes. The string must contain a valid string representation of a number. Leading and trailing blanks are removed from the string, and the resulting substring must conform to the rules for forming a valid string representation of an SQL integer or decimal constant.

*precision*

An integer constant with a value in the range 1 to 31. The value of this second argument specifies the precision of the result. If not specified, the default is 15.

*scale*

An integer constant that is greater than or equal to zero and less than or equal to *precision*. The value specifies the scale of the result. The default value is 0.

*decimal-character*

A single-byte character constant used to delimit the decimal digits in *string-expression* from the whole part of the number. The character cannot be a digit, plus (+), minus (-), or blank. The default value is period (.) or comma (,); the default value cannot be used in *string-expression* if a different value for *decimal-character* is specified.

Digits are truncated from the end of the decimal number if the number of digits to the right of the decimal separator character is greater than the scale *s*. An error is returned if the number of significant digits to the left of the decimal character (the whole part of the number) in *string-expression* is greater than *p*-*s*. 
The result of the function is a decimal number with precision of \( p \) and scale of \( s \), where \( p \) and \( s \) are the second and third arguments. If the first argument can be null, the result can be null; if the first argument is null, the result is null.

**Note:** To increase the portability of applications when the precision is specified, use the CAST specification. For more information, see CAST specification.

**Example 1:** Represent the average salary of the employees in DSN8C10.EMP as an 8-digit decimal number with two of these digits to the right of the decimal point.

```sql
SELECT DECIMAL(AVG(SALARY),8,2)
FROM DSN8C10.EMP;
```

**Example 2:** Assume that updates to the SALARY column are input as a character string that uses comma as the decimal character. For example, the user inputs 21400,50. The input value is assigned to the host variable NEWSALARY that is defined as CHAR(10), and the host variable is used in the following UPDATE statement:

```sql
UPDATE DSN8C10.EMP
SET SALARY = DECIMAL (:NEWSALARY,9,2,',')
WHERE EMPNO = :EMPID;
```

### DECODE

The DECODE function compares each `expression2` to `expression1`. If `expression1` is equal to `expression2`, or both `expression1` and `expression2` are null, the value of the `result-expression` is returned. If no `expression2` matches `expression1`, the value of `else-expression` is returned. Otherwise a null value is returned.

```sql
DECODE(expression1, expression2, result-expression, else-expression)
```

The schema is SYSIBM.

The DECODE function is similar to the CASE expression, with the exception of how DECODE handles null values:

- A null value in `expression1` will match a corresponding null value in `expression2`.
- If the NULL keyword is used as an argument in the DECODE function, it must be cast to a data type that is appropriate for comparison.

An argument of DECODE must not represent an array value.

The rules for determining the result type of the result of the DECODE function are based on the corresponding CASE expression.

The following table shows equivalent DECODE functions and CASE expressions. Both the DECODE function and the corresponding CASE expression achieve the same result.
Table 73. Equivalent DECODE functions and CASE expressions (each returns the same results)

<table>
<thead>
<tr>
<th>DECODE function</th>

</tbody>
</table>

**DECRYPT_BINARY, DECRYPT_BIT, DECRYPT_CHAR, and DECRYPT_DB**

The decryption functions return a value that is the result of decrypting encrypted data. The decryption functions can decrypt only values that are encrypted by using the ENCRYPT_TDES function.

```sql
DECRYPT_BINARY(encrypted-data, password-string, ccsid-constant)
```

The schema is SYSIBM.

The password used for decryption is either the `password-string` value or the ENCRYPTION PASSWORD value, which is assigned by the SET ENCRYPTION PASSWORD statement.

**encrypted-data**

An expression that returns a complete, encrypted data value of a CHAR FOR BIT DATA, VARCHAR FOR BIT DATA, BINARY, or VARBINARY data type. The data string must have been encrypted using the ENCRYPT_TDES function. The length attribute must be greater than or equal to 0 (zero) and less than or equal to 32672.
**password-string**

An expression that returns a CHAR or VARCHAR value with at least 6 bytes and no more than 127 bytes. This expression must be the same password that was used to encrypt the data or decryption will result in a different value than was originally encrypted. For enhanced security, **password-string** should be specified using a host variable rather than a string constant. If the value of the password argument is null or not provided, the data will be decrypted using the ENCRYPTION PASSWORD value, which must have been assigned by the SET ENCRYPTION PASSWORD statement.

For a static SQL statement, it is recommended that the password be specified with a host variable rather than with a string constant.

**DEFAULT**

The data is decrypted using the ENCRYPTION PASSWORD value, which must have been assigned by the SET ENCRYPTION PASSWORD statement.

**ccsid-constant**

A integer constant that specifies the CCSID in which the data should be returned by the decryption function. If DECRYPT_BIT or DECRYPT_BINARY is specified, **ccsid-constant** must not be specified. The default is

- The ENCODING bind option of the plan or package or the APPLICATION ENCODING SCHEMA option of the CREATE PROCEDURE or ALTER PROCEDURE statement for native SQL procedures that contain the static SQL statements
- The value of the APPLICATION ENCODING special register for dynamic SQL statements

The data type of the result of the function is determined by the function that is specified and the data type of the first argument, as shown in the following table. If the cast from the actual type of the encrypted data to the result of the function is not supported, a warning or error is returned.

*Table 74. Result of the decryption function*

</tr>
</tbody>
</table>

**Note:** ¹ FOR BIT DATA means CHAR or VARCHAR FOR BIT DATA

If *encrypted-data* included a hint, the hint is not returned by the function. The length attribute of the result is the length attribute of *encrypted-data* minus 8 bytes. The actual length of the value that is returned by the function will match the length of the original string that was encrypted. If *encrypted-data* includes bytes beyond the encrypted string, these bytes are not returned by the function.

**Administration of encrypted data:** The decryption functions can only decrypt data that was encrypted using the Triple DES encryption algorithm. Therefore, columns with encrypted data can only be used after replication if they were encrypted using the Triple DES encryption algorithm.

If the data is decrypted using a different CCSID than the originally encrypted value, it is possible that expansion might occur when converting the decrypted value to this CCSID. In such situations, the *encrypted-data* value must first be cast to a VARCHAR string with a larger number of bytes before performing the decryption functions.

The result can be null; if the first argument is null, the result is the null value.
For additional information about using the decryption functions, see “ENCRYPT_TDES” on page 475 and “GETHINT” on page 484.

**Password protection:** To prevent inadvertent access to the encryption password, do not specify *password-string* as a string constant in the source statement. Instead, use the ENCRYPTION PASSWORD special register or specify the password using a host variable.

**Example 1:** Set the ENCRYPTION PASSWORD value to 'Ben123' and use it as the password to insert a decrypted social security number into the table. Decrypt the value of the added social security number, using the ENCRYPTION PASSWORD value.

```sql
SET ENCRYPTION PASSWORD = 'Ben123';
INSERT INTO EMP(SSN) VALUES ENCRYPT_TDES('289-46-8832');
SELECT DECRYPT_CHAR(SSN) FROM EMP;
```

This example returns the value '289-46-8832'.

**Example 2:** Decrypt the social security number that is inserted into the table. Instead of using the ENCRYPTION PASSWORD value, explicitly specify 'Ben123' as the encryption password.

```sql
SELECT DECRYPT_CHAR(SSN, 'Ben123') FROM EMP;
```

This example returns the value '289-46-8832'.

**Example 3:** Insert a decrypted social security number into the table, explicitly specifying 'Ben123' as the password. Decrypt the data and have it converted to CCSID 1208.

```sql
SET ENCRYPTION PASSWORD = 'Ben123';
INSERT INTO EMP(SSN) VALUES ENCRYPT_TDES('289-46-8832');
SELECT DECRYPT_CHAR(SSN) FROM EMP;
```

When a CCSID is specified, it might be necessary to explicitly cast the data to a longer value to ensure that there is room for expansion when the data is decrypted. The following example illustrates the technique:

```sql
SELECT DECRYPT_CHAR(CAST(SSN AS VARCHAR(57)), 'Ben123', 1208)
FROM EMP;
```

In the first case, where the data is not cast to a longer value, the result is a VARCHAR(11) value. In the second case, to allow for expansion, SSN is cast as VARCHAR(57) (11 * 3 + 24). Casting the data to a longer value allows for three times expansion in the normal VARCHAR(11) result. Three times expansion is often associated with a worst case of ASCII or EBCDIC to Unicode UTF-8 conversion. In both cases in this example, the result is the VARCHAR(11) value '289-46-8832'.

**DEGREES**

The DEGREES function returns the number of degrees of the argument, which is an angle, expressed in radians.
The schema is SYSIBM.

The argument must be an expression that returns the value of any built-in numeric data type that is not DECFLOAT. If the argument is not a double precision floating-point number, it is converted to one for processing by the function.

The result of the function is a double precision floating-point number.

The result can be null; if the argument is null, the result is the null value.

Example: Assume that host variable HRAD is a DOUBLE with a value of 3.1415926536. The following statement returns a double precision floating-point number with an approximate value of 180.0.

```
SELECT DEGREES(:HRAD)
FROM SYSIBM.SYSDUMMY1;
```

**DIFFERENCE**

The DIFFERENCE function returns a value, from 0 to 4, that represents the difference between the sounds of two strings, based on applying the SOUNDEX function to the strings. A value of 4 is the best possible sound match.

The schema is SYSIBM.

**expression-1 or expression-2**

Each expression must return a value that is a built-in numeric, character string, or graphic string data type that is not a LOB. A numeric argument is cast to a character string before the function is evaluated. For more information on converting a numeric string to a character string, see "VARCHAR" on page 648.

The data type of the result is INTEGER.

The result can be null; if any argument is null, the result is the null value.

Example 1: Find the DIFFERENCE and SOUNDEX values for 'CONSTRAINT' and 'CONSTANT':

```
SELECT DIFFERENCE('CONSTRAINT', 'CONSTANT'),
       SOUNDEX('CONSTRAINT'),
       SOUNDEX('CONSTANT')
FROM SYSIBM.SYSDUMMY1;
```

This example returns the values 4, C523, and C523. Since the two strings return the same SOUNDEX value, the difference is 4 (the highest value possible).
Example 2: Find the DIFFERENCE and SOUNDEX values for 'CONSTRAINT' and 'CONTRITE':

```
SELECT DIFFERENCE('CONSTRAINT', 'CONTRITE'),
       SOUNDEX('CONSTRAINT'),
       SOUNDEX('CONTRITE')
FROM SYSIBM.SYSDUMMY1;
```

This example returns the values 2, C523, and C536. In this case, the two strings return different SOUNDEX values, and hence, a lower difference value.

**DIGITS**

The DIGITS function returns a character string representation of the absolute value of a number.

```
►►DIGITS(numeric-expression)◄◄
```

The schema is SYSIBM.

The argument must be an expression that returns a value that is a SMALLINT, INTEGER, BIGINT, or DECIMAL built-in numeric data type.

The result of the function is a fixed-length character string representing the absolute value of the argument without regard to its scale. The result does not include a sign or a decimal point. Instead, it consists exclusively of digits, including, if necessary, leading zeros to fill out the string. The length of the string is:

- 5 if the argument is a small integer
- 10 if the argument is a large integer
- 19 if the argument is a big integer
- \( p \) if the argument is a decimal number with a precision of \( p \)

The result can be null; if the argument is null, the result is the null value.

The CCSID of the result is determined from the context in which the function was invoked. For more information, see [Determining the encoding scheme and CCSID of a string (Introduction to Db2 for z/OS)](chapter).  

**Example 1:** Assume that an INTEGER column called INTCOL containing a 10-digit number is in a table called TABLEX. INTCOL has the data type INTEGER instead of CHAR(10) to save space. the following query lists all combinations of the first four digits in column INTCOL.

```
SELECT DISTINCT SUBSTR(DIGITS(INTCOL),1,4)
FROM TABLEX;
```

**Example 2:** Assume that COLUMNX has the data type DECIMAL(6,2), and that one of its values is -6.28. For this value, the following statement returns the value '000628'.

```
DIGITS(COLUMNX)
```
The result is a string of length six (the precision of the column) with leading zeros padding the string out to this length. Neither sign nor decimal point appear in the result.

**DOUBLE PRECISION or DOUBLE**

The DOUBLE PRECISION and DOUBLE functions returns a floating-point representation of either a number or a character-string or graphic-string representation of a number, an integer, a decimal number, or a floating-point number.

**Numeric to Double:**

```
DOUBLE PRECISION (numeric-expression)
```

**String to Double:**

```
DOUBLE PRECISION (string-expression)
```

The schema is SYSIBM.

**Numeric to Double**

*numeric-expression*

An expression that returns a value of any built-in numeric data type.

The result is the same number that would occur if the expression were assigned to a double precision floating-point column or variable.

**String to Double**

*string-expression*

An expression that returns a value of a character or graphic string (except a CLOB or DBCLOB) with a length attribute that is not greater than 255 bytes. The string must contain a valid string representation of a number.

The result is the same number that would result from CAST(*string-expression* AS DOUBLE PRECISION). Leading and trailing blanks are removed from the string, and the resulting substring must conform to the rules for forming a valid string representation of an SQL floating-point, integer, or decimal constant.

The result of the function is a double precision floating-point number.

The result can be null; if the argument is null, the result is the null value.

**Note:** To increase the portability of applications, use the CAST specification. For more information, see [CAST specification](#).
FLOAT can be specified as a synonym for DOUBLE or DOUBLE_PRECISION.

Example: Using sample table DSN8C10.EMP, find the ratio of salary to commission for employees whose commission is not zero. The columns involved in the calculation, SALARY and COMM, have decimal data types. To eliminate the possibility of out-of-range results, apply the DOUBLE function to SALARY so that the division is carried out in floating-point.

```sql
SELECT EMPNO, DOUBLE(SALARY)/COMM
FROM DSN8C10.EMP
WHERE COMM > 0;
```

**DSN_XMLVALIDATE**

The DSN_XMLVALIDATE function returns an XML value that is the result of applying XML schema validation to the first argument of the function. DSN_XMLVALIDATE can validate XML data that has a maximum length of 2 GB - 1 byte.

```
►► DSN_XMLVALIDATE(
  string-expression,
  schema-name-string,
  xml-expression, target-namespace-uri-string, schema-location-string)
◄◄
```

The schema is SYSIBM.

**string-expression**

An expression that returns a built-in character, graphic, or binary string. The value must be a well-formed XML document that conforms to the XML Version 1.0 standard.

**xml-expression**

An expression that returns an XML value in the XML data type. The value must be a well-formed XML document that conforms to XML Version 1.0 standard.

**schema-name-string**

An expression that returns a built-in varying length character string that is not a CLOB. The value specifies the name of the XML schema object that is used for validation. The value must not be an empty string or the null value, and the actual length must be less than or equal to 257. If the XML schema name is qualified, the qualifier must be SYSXSR (SYSXSR is the default qualifier). The value must identify a registered XML schema in the Db2 XML schema repository.

**target-namespace-uri-string**

An expression that returns a built-in varying length character string that is not a CLOB, with a length attribute that is not greater than 1000. The value specifies the target namespace name or universal resource identifier (URI) of the XML schema that is to be used for validation. If the value is an empty string of the null value, no namespace is used to locate the XML schema.

**schema-location-string**

An expression that returns a built-in varying length character string that is not a CLOB, with a length attribute that is not greater than 1000. The value specifies the XML schema location hint URI of the XML schema that is to be used for validation. If the value is an empty string of the null value, no schema location is used to locate the XML schema.
If target-namespace-uri-string and schema-location-string are specified, the combination must identify a registered XML schema in the Db2 XML schema repository, and there must be only one such registered XML schema.

A schema must be registered successfully in the Db2 XML schema repository before it can be used for DSN_XMLVALIDATE. If the validation fails, Db2 returns an error.

The result of the function is an XML value.

The result can be null; if the first argument is null, the result is the null value.

Example 1: The following example shows how the DSN_XMLVALIDATE function validates the XML data that is contained in the value_host_var host variable. The XML schema, SYSXSR.ORDERSCHEMA, was registered prior to this statement:

```sql
INSERT INTO T1(C1) VALUES(
  DSN_XMLVALIDATE(:value_host_var, 'SYSXSR.MYXMLSCHEMA'));
```

Example 2: The following example is similar to the previous example but references the namespace and schema location:

```sql
INSERT INTO T1(C1) VALUES(
  DSN_XMLVALIDATE(:value_host_var,
  'http://www.n1.com',
  'http://www.n1.com/report.xsd'));
```

**EBCDIC_CHR**

The EBCDIC_CHR function returns the character that has the EBCDIC code value that is specified by the argument.

```sql
EBCDIC_CHR(expression)
```

The schema is SYSIBM.

**expression**

An expression that returns a BIGINT, INTEGER, or SMALLINT built-in data type value.

expression can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34) which is then assigned to a BIGINT value.

The result of the function is a CHAR(1) string encoded in the SBCS EBCDIC CCSID (regardless of the setting of the MIXED option in DSNHDECP). If the value of expression is not in the range 0 - 255, the null value is returned.

The result can be null; if the argument is null, the result is the null value.

Example: Set hv with the Euro symbol "€" in CCSID 1140:

```sql
SET :hv = EBCDIC_CHR(159); -- x'9F'
```

Set hv with the Euro symbol "€" in CCSID 1142:

```sql
SET :hv = EBCDIC_CHR(90); -- x'5A'
```
In both cases, the "€" is assigned to $h_v$, but because the Euro symbol is located at different code points for the two CCSIDs, the input value is different.

**EBCDIC_STR**

The EBCDIC_STR function returns a string, in the system EBCDIC CCSID, that is an EBCDIC version of the string.

```
EBCDIC_STR(string-expression)
```

The schema is SYSIBM.

The system EBCDIC CCSID is defined as the SBCS EBCDIC CCSID on a MIXED=NO system or the MIXED EBCDIC CCSID on a MIXED=YES system.

*string-expression*

An expression that returns a value of a built-in character or graphic string. If the string is a character string, it cannot be bit data. *string-expression* must be an ASCII, EBCDIC, or Unicode string. EBCDIC_STR returns an EBCDIC version of the string. Non-EBCDIC characters are converted to the form \xxxx, where xxxx represents a UTF-16 code unit.

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type.

The length attribute of the result is calculated using the formulas in Table 38 on page 172. The length attribute of the result will be $\min \left( (5n), 32764 \right)$. Where $n$ is the result of applying the formulas in Table 38 on page 172 based on input and output data types.

The result of the function is an EBCDIC character string (in the system EBCDIC CCSID). If the actual length of the result string exceeds the maximum for the return type, an error occurs.

The result can be null; if the argument is null, the result is the null value.

*Example:* The following example returns the EBCDIC string equivalent of the text string "Hi my name is Андрей" (Andrei)

```
SET :HV1 = EBCDIC_STR('Hi, my name is Андрей');
```

$HV1$ is assigned the value "Hi, my name is 0410\043D\0434\0435\0439 (Andrei)"

**ENCRYPT_TDES**

The ENCRYPT_TDES function returns a value that is the result of encrypting the first argument by using the Triple DES encryption algorithm. The function can also set the password that is used for encryption.

The encryption password can also be set by using the ENCRYPTION PASSWORD value, which is assigned by using the SET ENCRYPTION PASSWORD statement.
The schema is SYSIBM.

**data-string**

An expression that returns the string value to be encrypted. The string expression must return a built-in string data type that is not a LOB. The length attribute must be greater than or equal to 0 (zero). The length attribute is limited to 32640 if hint-string is specified and 32672 if hint-string is not specified.

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type.

**password-string**

An expression that returns a CHAR or VARCHAR value with at least 6 bytes and no more than 127 bytes.

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type.

The value represents the password that is used to encrypt data-string. If the value of the password argument is null or not specified, the data is encrypted using the ENCRYPTION PASSWORD value, which must have been assigned by the SET ENCRYPTION PASSWORD statement.

**hint-string**

An expression that returns a CHAR or VARCHAR value up to 32 bytes that is to help data owners remember passwords (for example, 'Ocean' as a hint to remember 'Pacific').

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type.

If a hint value is specified, the hint is embedded into the result and can be retrieved using the GETHINT function. If this argument is null or not specified and no hint was specified when the ENCRYPTION PASSWORD was set, no hint is embedded in the result. If password-string is not specified, the hint can be specified using the SET ENCRYPTION PASSWORD statement.

The data type of the result is determined by the first argument as shown in the following table:

<table>
<thead>
<tr>
<th>Data type of the first argument</th>
<th>Data type of the result</th>
</tr>
</thead>
<tbody>
<tr>
<td>BINARY, VARBINARY</td>
<td>VARBINARY</td>
</tr>
<tr>
<td>CHAR, VARCHAR, GRAPHIC, VARGRAPHIC</td>
<td>VARCHAR FOR BIT DATA</td>
</tr>
</tbody>
</table>

The encoding scheme of the result is the same as the encoding scheme of data-string. If the result is character data, the result is bit data.
The length attribute of the result is different depending on whether `hint-string` is specified:

- If `hint-string` is specified, the length attribute of the result is the length attribute of the non-encrypted data + 24 bytes + number of bytes to the next 8 byte boundary + 32 bytes for the hint.
- If `hint-string` is not specified, the length attribute of the result is the length attribute of the non-encrypted data + 24 bytes + the number of bytes to the next 8 byte boundary.

The result can be null; if the first argument is null, the result is the null value.

The encrypted result is longer than the `data-string` value. Therefore, when assigning encrypted values, ensure that the target is declared with a length that can contain the entire encrypted value.

When encrypting data, be aware of the following points:

- **Password protection**: To prevent inadvertent access to the encryption password, do not specify `password-string` as a string constant in the source for a program, procedure, or function. Instead, use the SET ENCRYPTION PASSWORD statement or a variable.
- **Encryption algorithm**: The internal encryption algorithm used is Triple DES cipher block chaining (CBC) with padding. The 128-bit secret key is derived from the password using an MD5 hash.
- **Encryption passwords and data**: It is your responsibility to perform password management. After data is encrypted, only the password that is used to encrypt it can be used to decrypt it. If a different password is used to decrypt the data than was used to encrypt the data, the results of decryption will not match the original string. No error or warning is returned. CHAR variables might be padded with blanks if they are used to set password values. The encrypted result might contain null terminator and other non-printable characters.

- **Table column definitions**: When defining columns and types to contain encrypted data, always calculate the length attribute as follows:
  - For encrypted data with an embedded hint, the column length should be the length attribute of the non-encrypted data + 24 bytes + number of bytes to the next 8 byte boundary + 32 bytes for the hint.
  - For encrypted data without an embedded hint, the column length should be the length attribute of the non-encrypted data + 24 bytes + number of bytes to the next 8 byte boundary.

Here are some sample column length calculations, which assume that a hint is not embedded:

<table>
<thead>
<tr>
<th>Description</th>
<th>Length</th>
</tr>
</thead>
<tbody>
<tr>
<td>Maximum length of non-encrypted data</td>
<td>6 bytes</td>
</tr>
<tr>
<td>24 bytes for encryption key</td>
<td>24 bytes</td>
</tr>
<tr>
<td>Number of bytes to the next 8 byte boundary</td>
<td>2 bytes</td>
</tr>
<tr>
<td>Encrypted data column length</td>
<td>32 bytes</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Description</th>
<th>Length</th>
</tr>
</thead>
<tbody>
<tr>
<td>Maximum length of non-encrypted data</td>
<td>32 bytes</td>
</tr>
<tr>
<td>24 bytes for encryption key</td>
<td>24 bytes</td>
</tr>
<tr>
<td>Number of bytes to the next 8 byte boundary</td>
<td>0 bytes</td>
</tr>
<tr>
<td>Encrypted data column length</td>
<td>56 bytes</td>
</tr>
</tbody>
</table>

- **Administration of encrypted data**: Encrypted data can be decrypted only on servers that support the decryption of data that was encrypted using the Triple
DES encryption algorithm. Hence, replication of columns with encrypted data should only be done to servers that support the decryption functions and the same encryption algorithms.

ENCRYPT can be specified as a synonym for ENCRYPT_TDES. Db2 supports this keyword to provide compatibility with other products in the Db2 family.

Example 1: Encrypt the social security number that is inserted into the table. Set the ENCRYPTION PASSWORD value to 'Ben123' and use it as the password.

```
SET ENCRYPTION PASSWORD = 'Ben123';
INSERT INTO EMP(SSN) VALUES ENCRYPT_TDES ('289-46-8832');
```

Example 2: Encrypt the social security number that is inserted into the table. Explicitly specify 'Ben123' as the encryption password.

```
INSERT INTO EMP(SSN) VALUES ENCRYPT_TDES ('289-46-8832', 'Ben123');
```

Example 3: Encrypt the social security number that is inserted into the table. Specify 'Pacific' as the encryption password, and provide 'Ocean' as a hint to help the user remember the password of 'Pacific'.

```
INSERT INTO EMP(SSN) VALUES ENCRYPT_TDES ('289-46-8832', 'Pacific', 'Ocean');
```

The preceding statement returns a double precision floating-point number with an approximate value of 31.62.

**EXP**

The EXP function returns a value that is the base of the natural logarithm (e), raised to a power that is specified by the argument. The EXP and LN functions are inverse operations.

```
EXP(numeric-expression)
```

The schema is SYSIBM.

The argument must be an expression that returns the value of any built-in numeric data type that is not DECFLOAT. If the argument is not a double precision floating-point number, it is converted to one for processing by the function.

The result of the function is a double precision floating-point number.

The result can be null; if the argument is null, the result is the null value.

Example: Assume that host variable E is DECIMAL(10,9) with a value of 3.453789832. The following statement returns a double precision floating-point number with an approximate value of 31.62.

```
SELECT EXP(:E)
FROM SYSIBM.SYSDUMMY1;
```

**EXTRACT**

The EXTRACT function returns a portion of a date or timestamp, based on its arguments.
The schema is SYSIBM.

The result can be null; if the argument is null, the result is the null value.

**Extract date values**

- **YEAR**
  Specifies that the year portion of `date-expression` or `timestamp-expression` is returned. The result is identical to the YEAR scalar function. For more information, see [YEAR](#).

- **MONTH**
  Specifies that the month portion of `date-expression` or `timestamp-expression` is returned. The result is identical to the MONTH scalar function. For more information, see [MONTH](#).

- **DAY**
  Specifies that the day portion of `date-expression` or `timestamp-expression` is returned. The result is identical to the DAY scalar function. For more information, see [DAY](#).

**date-expression**

- An expression that returns the value of either a built-in date or built-in character string data type.

  If `date-expression` is a character or graphic string, it must not be a CLOB or DBCLOB and its value must be a valid character-string or
graphic-string representation of a date. For the valid formats of string representations of dates, see “String representations of datetime values” on page 130.

timestamp-expression
An expression that returns the value of either a built-in timestamp or built-in character string data type.

If timestamp-expression is a character or graphic string, it must not be a CLOB or DBCLOB and its value must be a valid character-string or graphic-string representation of a timestamp. For the valid formats of string representations of timestamps, see “String representations of datetime values” on page 130.

Extract time values

HOUR
Specifies that the hour portion of time-expression or timestamp-expression is returned. The result is identical to the HOUR scalar function. For more information, see HOUR.

MINUTE
Specifies that the minute portion of time-expression or timestamp-expression is returned. The result is identical to the MINUTE scalar function. For more information, see MINUTE.

SECOND
Specifies that the second portion of time-expression or timestamp-expression is returned. The result is identical to the SECOND scalar function where the precision and scale of the result depend on the type of time-expression or timestamp-expression. For more information, see “SECOND” on page 598.

time-expression
An expression that returns the value of either a built-in time or built-in character string data type.

If time-expression is a character or graphic string, it must not be a CLOB or DBCLOB and its value must be a valid string representation of a time. For the valid formats of string representations of times, see “String representations of datetime values” on page 130.

timestamp-expression
An expression that returns the value of either a built-in timestamp or built-in character string data type.

If timestamp-expression is a character or graphic string, it must not be a CLOB or DBCLOB and its value must be a valid string representation of a timestamp. For the valid formats of string representations of timestamps, see “String representations of datetime values” on page 130.

Extract time zone values

TIMEZONE_HOUR
Specifies that the hour component of the time zone of the timestamp value is returned. TIMEZONE_HOUR can only be specified if the second argument is a timestamp-expression and the timestamp-expression contains a time zone.

TIMEZONE_MINUTE
Specifies that the minute component of the time zone of the timestamp
value is returned. TIMEZONE_MINUTE can only be specified if the second argument is a *timestamp-expression* and the *timestamp-expression* contains a time zone.

The values of **TIMEZONE_HOUR** and **TIMEZONE_MINUTE** shall either both be non-negative or both be non-positive.

If the *timestamp-expression* argument includes a time zone, the result is determined from the UTC representation of the datetime value.

The data type of the result of the function depends on the part of the datetime value that is specified:

- The result is **INTEGER**, if one of the following is specified:
  - YEAR
  - MONTH
  - DAY
  - HOUR
  - MINUTE
  - TIMEZONE_HOUR
  - TIMEZONE_MINUTE
- The result is **DECIMAL(2+p, p)** where \( p \) is the fractional second precision, if SECOND is specified with a TIMESTAMP(\( p \)) value.
- The result is **DECIMAL(8,6)**, if SECOND is specified with a TIME value or a string representation of a TIME or timestamp. The fractional digits contain fractional seconds.

**Example 1:**

Assume that the column PRSTDATE has an internal value that is equivalent to 2010-12-25. The following statement returns the value 12:

```sql
SELECT EXTRACT(MONTH FROM PRSTDATE)
FROM PROJECT;
```

**Example 2:**

Assume that host variable PRSTSZ contains the value 2008-02-29.20.00.000000 -08.30:

```sql
SELECT EXTRACT(HOUR FROM :PRSTSZ) FROM PROJECT;
```

The SELECT statement returns the value 4, which is the hour of the input datetime value expressed in UTC.

To return the same hour value as expressed in the input, cast the value to TIMESTAMP WITHOUT TIME ZONE before using the EXTRACT function:

```sql
SELECT EXTRACT(HOUR FROM CAST (:PRSTSZ AS TIMESTAMP ) ) FROM PROJECT;
```

The SELECT statement returns the value 20, which is the hour as it was originally expressed as a string in the host variable.

```sql
SELECT EXTRACT(TIMEZONE_HOUR FROM :PRSTSZ) FROM PROJECT;
```

This SELECT statement returns the value -8.

```sql
SELECT EXTRACT(TIMEZONE_MINUTE FROM :PRSTSZ) FROM PROJECT;
```

This SELECT statement returns the value -30.
**FLOAT**

The FLOAT function returns a floating-point representation of either a number or a string representation of a number. FLOAT is a synonym for the DOUBLE function.

```sql
FLOAT(numeric-expression)
```

The schema is SYSIBM.

FLOAT is a synonym for the DOUBLE function. See DOUBLE_PRECISION or DOUBLE for details.

**FLOOR**

The FLOOR function returns the largest integer value that is less than or equal to the argument.

```sql
FLOOR(numeric-expression)
```

The schema is SYSIBM.

The argument must be an expression that returns a value of any built-in numeric data type.

The argument can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34).

The result of the function has the same data type and length attribute as the argument. When the argument is DECIMAL, the scale of the result is 0 and not the scale of the input argument. For example, an argument with a date type of DECIMAL(5,5) results in DECIMAL(5,0).

The result can be null; if the argument is null, the result is the null value.

Example 1: Using sample table DSN8C10.EMP, find the highest monthly salary, rounding the result down to the next integer. The SALARY column has a decimal data type.

```sql
SELECT FLOOR(MAX(SALARY)/12)
FROM DSN8C10.EMP;
```

This example returns 04395 because the highest paid employee is Christine Haas who earns $52750.00 per year. Her average monthly salary before applying the FLOOR function is 4395.83.

Example 2: This example demonstrates using FLOOR with both positive and negative numbers.
```
SELECT FLOOR( 3.5),
       FLOOR( 3.1),
       FLOOR(-3.1),
       FLOOR(-3.5)
FROM SYSIBM.SYSDUMMY1;
```

This example returns (leading zeros are shown to demonstrate the precision and scale of the result):
03. 03. -04. -04.

**GENERATE_UNIQUE and GENERATE_UNIQUE_BINARY**

The GENERATE_UNIQUE and GENERATE_UNIQUE_BINARY functions return a value that is unique, compared to any other execution of the same function.

The schema is SYSIBM.

The GENERATE_UNIQUE and GENERATE_UNIQUE_BINARY functions are defined as not deterministic. Although the functions have no arguments, the empty parentheses must be specified when the functions are invoked.

The result of either of the functions is a unique value that includes the internal form of the Universal Time, Coordinated (UTC) and, if in a sysplex environment, the sysplex member where the function was processed.

The data type of the result depends on which function was invoked. GENERATE_UNIQUE returns a bit data character string 13 bytes long (CHAR(13) FOR BIT DATA). GENERATE_UNIQUE_BINARY returns a BINARY(16) value.

The result cannot be null.

The results of these functions can be used to provide unique values in a table. The sequence is based on the time when the function was executed.

These functions differ from using the special register CURRENT TIMESTAMP in that a unique value is generated for each row of a multiple row insert statement, an insert statement with a fullselect, or an insert operation in a MERGE statement.

The timestamp value that is part of the result of either of these functions can be determined using the TIMESTAMP function with the result of GENERATE_UNIQUE or GENERATE_UNIQUE_BINARY as an argument.

**Example:** Create a table that includes a column that is unique for each row. Populate this column using the GENERATE_UNIQUE function. Notice that the UNIQUE_ID column is defined as FOR BIT DATA to identify the column as a bit data character string.

```
CREATE TABLE EMP_UPDATE
    (UNIQUE_ID VARCHAR(13) FOR BIT DATA,
     EMPNO CHAR(6),
```
This table will have a unique identifier for each row if GENERATE_UNIQUE is always used to set the value the UNIQUE_ID column. You can create an insert trigger on the table to ensure that GENERATE_UNIQUE is used to set the value:

```sql
CREATE TRIGGER EMP_UPDATE_UNIQUE
  NO CASCADE BEFORE INSERT ON EMP_UPDATE
  REFERENCING NEW AS NEW_UPD
  FOR EACH ROW MODE DB2SQL
  SET NEW_UPD.UNIQUE_ID = GENERATE_UNIQUE();
```

With this trigger, the previous INSERT statements that were used to populate the table could be issued without specifying a value for the UNIQUE_ID column:

```sql
INSERT INTO EMP_UPDATE VALUES ('000020', 'Update entry 1...');
INSERT INTO EMP_UPDATE VALUES ('000050', 'Update entry 2...');
```

The timestamp (in UTC) for when a row was added to EMP_UPDATE can be returned using:

```sql
SELECT TIMESTAMP(UNIQUE_ID), EMPNO, TEXT FROM EMP_UPDATE;
```

Therefore, the table does not need a timestamp column to record when a row is inserted.

**GETHINT**

The GETHINT function returns a hint for the password if a hint was embedded in the encrypted data. A password hint is a phrase that helps you remember the password with which the data was encrypted. For example, 'Ocean' might be used as a hint to help remember the password 'Pacific'.

```
GETHINT(encrypted-data)
```

The schema is SYSIBM.

*encrypted-data*

An expression that returns a string that contains a complete, encrypted data string. *encrypted-data* must return a value that is a CHAR FOR BIT DATA, VARCHAR FOR BIT DATA, BINARY, or VARBINARY built-in data type. The string must have been encrypted using ENCRYPT_TDES function.

The result of the function is VARCHAR(32). The actual length of the result is the actual length of the hint that was provided when the data was encrypted.

The result can be null; if the argument is null, the result is the null value.

If no hint was specified when the ENCRYPT_TDES function was used to encrypt the data, the result is the null value.
The encoding scheme of the result is the same as the encoding scheme of encrypted-data. If encrypted-data is bit data, the CCSID of the result is the default character CCSID for that encoding scheme. Otherwise, the CCSID of the result is the same as the CCSID of encrypted-data.

For additional information about this function, see "DECRYPT_BINARY, DECRYPT_BIT, DECRYPT_CHAR, and DECRYPT_DB" on page 465 and "ENCRYPT_TDES" on page 475.

Example: This example shows how to embed a hint for the password when encrypting data and how to later use the GETHINT function to retrieve the embedded hint. In this example, the hint 'Ocean' is used to help remember the encryption password 'Pacific'.

```
INSERT INTO EMP (SSN) VALUES ENCRYPT_TDES ('289-46-8832', 'Pacific', 'Ocean');
SELECT GETHINT (SSN) FROM EMP;
```

The value that is returned is 'Ocean'.

### GETVARIABLE

The GETVARIABLE function returns a varying-length character-string representation of the current value of the session variable that is identified by the argument.

```
GETVARIABLE(string-constant[, default-value[, CAST(NULL AS VARCHAR(1))]])
```

The schema is SYSIBM.

**string-constant**

Specifies a string constant that contains the name of the session variable whose value is to be returned. The string constant:

- Must have a length that does not exceed 142 bytes.
- Must contain the fully qualified name of the variable, with no embedded blanks. Delimited identifiers must not be specified.
- Must not contain lowercase letters or characters that cannot be specified in an ordinary identifier.

The schema qualifier for the variable must be:

- SYSIBM for built-in session variables. For a list of the built-in session variables, see “Built-in session variables” on page 357.
- SESSION for user-defined session variables. User-defined session variables are established via the connection or signon exit routines.

**Note:** The GETVARIABLE function can obtain the values of only these session variables. This function cannot obtain the values of built-in global variables or user-defined global variables.

**default-value**

Specifies a string constant that contains the value to be returned if the specified
variable does not exist or is not supported by Db2. default-value must be a string constant that does not exceed 255 bytes.

If default-value is not specified and the specified user-defined session variable does not exist or the built-in session variable is not supported by Db2, an error is returned.

**CAST(NULL AS VARCHAR(1))**

Specifies that a null value is to be returned if the specified variable does not exist or is not supported by Db2.

The data type of the result is VARCHAR(255). The result can be null.

The CCSID of the result is the CCSID for Unicode mixed data.

*Example 1:* Use the GETVARIABLE function to set the value of host variable :hv1 to the name of the plan that is currently being executed. The name of the built-in session variable that contains the name of the plan is SYSIBM.PLAN_NAME.

```
SET :hv1 = GETVARIABLE('SYSIBM.PLAN_NAME');
```

If Db2 does not support the name of the session variable, an error is returned. For example, the following statement returns an error because Db2 does not support a built-in session variable that is named SYSIBM.XYZ.

```
SET :hv1 = GETVARIABLE('SYSIBM.XYZ');
```

*Example 2:* Use the GETVARIABLE function to set the value of host variable :hv2 to the value for the user that is defined in user-defined session variable TEST. If the session variable has not been set or cannot be found, have the function return the value 'TEST FAILED'.

```
SET :hv2 = GETVARIABLE('SESSION.TEST','TEST FAILED');
```

*Example 3:* Use the GETVARIABLE function to set the value of host variable :hv3 to a string representation of the SYSTEM EBCDIC CCSIDs. The name of the built-in session variable that contains the system EBCDIC CCSIDs is SYSIBM.SYSTEM_EBCDIC_CCSID.

```
SET :hv3 = GETVARIABLE('SYSIBM.SYSTEM_EBCDIC_CCSID');
```

Regardless of the setting of the field MIXED DATA on the installation panel (YES or NO), the function returns three comma-delimited values that correspond to the SBCS, MIXED, and GRAPHIC CCSIDs for the encoding scheme.

For example, if the statement were issued on a system with the field MIXED DATA on the installation panel equal to NO and the default system CCSID of 37, this string would be returned:

'37,65534,65534'

If the statement were issued on a system with the field MIXED DATA on the installation panel equal to YES and a default system CCSID of 930 (the mixed CCSID for the system), this string would be returned:

'290,930,300'

**GRAPHIC**

The GRAPHIC function returns a fixed-length graphic-string representation of the type of the first argument.
Integer to Graphic

GRAPHIC(integer-expression)

Decimal to Graphic

GRAPHIC(decimal-expression)

Floating-point to Graphic

GRAPHIC(floating-point-expression)

Decimal floating-point to Graphic

GRAPHIC(decimal-floating-point-expression)

Character to Graphic:

GRAPHIC(character-expression)

Graphic to Graphic:

GRAPHIC(graphic-expression)

The schema is SYSIBM.

The GRAPHIC function returns a graphic-string representation of:

- An integer number if the first argument is a SMALLINT, INTEGER, or BIGINT
- A decimal number if the first argument is a decimal number
- A double-precision floating-point number if the first argument is a DOUBLE or REAL
- A decimal floating-point number if the first argument is DECFLOAT
- A character string if the first argument is any type of character string
- A graphic string if the first argument is an EBCDIC or Unicode graphic string

The result can be null; if the first argument is null, the result is the null value.

The length attribute of the result is measured in double-byte characters because it is a graphic string.

**Integer to Graphic**

\[\text{integer-expression}\]

An expression that returns a value that is an integer data type (either SMALLINT, INTEGER, or BIGINT).

The result is a fixed-length graphic string of the argument in the form of an SQL integer constant. The result is the smallest number of characters that can be used to represent the value of the argument, padded with blanks. The result consists of \(n\) characters that are the significant digits that represent the value of the argument with a preceding minus sign if the argument is negative. A positive value starts with a digit and always includes at least one trailing blank. Leading zeroes are not included. The result is left justified.

- If the argument is a small integer, the length of the result is 6. If the number of characters in the result is less than 6, the result is padded on the right with blanks.
- If the argument is a large integer, the length of the result is 11. If the number of characters in the result is less than 11, the result is padded on the right with blanks.
- If the argument is a big integer, the length of the result is 20. If the number of characters in the result is less than 20, the result is padded on the right with blanks.

The CCSID of the result is 1200 (UTF-16).

**Decimal to Graphic**

\[\text{decimal-expression}\]

An expression that returns a value that is a built-in decimal data type. If a different precision and scale is wanted, the DECIMAL scalar function can be used to make the change. To specify a different precision and scale for the value of the expression, apply the DECIMAL function before applying the GRAPHIC function.

\[\text{decimal-character}\]

Specifies the single-byte character constant that is used to delimit the decimal digits in the result graphic string. The character must not be a digit, a plus sign (+), a minus sign (-), or a blank. The default is the period (.) or comma (,). For information on what factors govern the choice, see Decimal point representation.
The result is a fixed-length graphic string representation of the first argument. The result is the smallest number of characters that can be used to represent the value of the argument, except that trailing zeros are included. The result includes a decimal character and up to $p$ digits, where $p$ is the precision of the \textit{decimal-expression} with a preceding minus sign if the argument is negative. A positive value starts with a digit or the decimal-character, and always includes at least one trailing blank. Leading zeros are not returned. If the scale of \textit{decimal-expression} is zero, the decimal character is not returned. If the number of bytes in the result is less than the defined length of the result, the result is padded on the right with blanks.

The length of the result is $2+p$ where $p$ is the precision of the \textit{decimal-expression}.

The CCSID of the result is 1200 (UTF-16).

**Floating-point to Graphic**

\begin{verbatim}[FL 502]
floating-point-expression
\end{verbatim}

An expression that returns a value that is a floating-point data type (DOUBLE or REAL).

The result is a fixed-length graphic string representation of the argument in the form of an SQL floating-point constant. If the argument is negative, the first character of the result is a minus sign; otherwise, the first character is a digit. If the argument is zero, the result is 0E0.

The length of the result is 24. The result includes the smallest number of characters that can represent the value of the argument such that the mantissa consists of a single digit, other than zero, followed by a period and a sequence of digits. If the number of characters in the result is less than 24, the result is padded on the right with blanks.

The CCSID of the result is 1200 (UTF-16).

**Decimal floating-point to Graphic**

\begin{verbatim}[FL 502]
decimal-floating-point-expression
\end{verbatim}

An expression that returns a value that is a built-in decimal floating-point data type (DECFLOAT).

The result is a fixed-length graphic string representation of the argument in the form of an SQL decimal floating-point constant.

If the result value is Infinity, sNaN, or NaN, the strings 'INFINITY', 'SNAN', and 'NAN', respectively, are returned. The DECFLOAT special value sNaN does not result in an exception when converted to a string.

The length of the result is 42. If the number of characters in the result is less than 42, the result is padded on the right with blanks. Trailing zeros are significant. If the argument is negative, the first character of the result is a minus sign. Otherwise, the first character is a digit, or a letter if the DECFLOAT value is Infinity, sNaN, or NaN.
The CCSID of the result is 1200 (UTF-16).

Character to Graphic

character-expression

An expression that returns a value that is an EBCDIC-encoded or Unicode-encoded character string. It cannot be BIT data. The argument does not need to be mixed data, but any occurrences of X'0E' and X'0F' in the string must conform to the rules for EBCDIC mixed data. (See “Character strings” on page 111 for these rules.)

The value of the expression must not be an empty string if integer is not specified or have the value X'0E0F' if the string is an EBCDIC string.

integer

The length of the resulting fixed-length graphic string in the units that are either implicitly or explicitly specified. The value must be an integer constant between 1 and 127. If the length of character-expression is less than the length specified, the result is padded with double-byte blanks to the length of the result.

If CODEUNITS16 or CODEUNITS32 is specified, see “Determining the length attribute of the final result” on page 117 for information about how to calculate the length attribute of the result string.

If integer is not specified, the length of the result for an EBCDIC string is the minimum of 127 and the length attribute of character-expression, excluding shift characters. For a Unicode (UTF-8) string, the length is data dependent, but does not exceed 127.

CODEUNITS16 or CODEUNITS32

Specifies the unit that is used to express integer. If CODEUNITS16 or CODEUNITS32 is specified, the input is EBCDIC, and there is no system CCSID for EBCDIC GRAPHIC data, an error occurs.

CODEUNITS16

Specifies that integer is expressed in terms of 16-bit UTF-16 code units.

CODEUNITS32

Specifies that integer is expressed in terms of 32-bit UTF-32 code units.

For more information about CODEUNITS16 and CODEUNITS32, see String unit specifications.

The CCSID of the result is the graphic CCSID that corresponds to the character CCSID of character-expression. If the input is EBCDIC and there is no system CCSID for EBCDIC GRAPHIC data, the CCSID of the result is X'FFFFE'.

For EBCDIC data, each character of character-expression determines a character of the result. The argument might need to be converted to the native form of mixed data before the result is derived. Let M be the system CCSID for mixed data. The argument is not converted if any of the following conditions is true:

• The argument is mixed data and its CCSID is M.
• The argument is SBCS data and its CCSID is the same as the system CCSID for SBCS data. In this case, the operation proceeds as if the CCSID of the argument is M.

490  SQL Reference
Otherwise, the argument is a new string $S$ derived by converting the characters to the coded character set identified by $M$. If there is no system CCSID for EBCDIC mixed data, conversion is to the coded character set that the system CCSID for SBCS data identifies.

The result is derived from $S$ using the following steps:
- Each shift character (X'0E' or X'0F') is removed.
- Each double-byte character remains as is.
- Each single-byte character is replaced by a double-byte character.

The replacement for an SBCS character is the equivalent DBCS character if an equivalent exists. Otherwise, the replacement is X'FEFE'. The existence of an equivalent character depends on $M$. If there is no system CCSID for mixed data, the DBCS equivalent of X'xxxx' for EBCDIC is X'42xx', except for X'40', whose DBCS equivalent is X'4040'.

For Unicode data:

Each character of character-expression determines a character of the result. The argument might need to be converted to the native form of mixed data before the result is derived. Let $M$ be the system CCSID for mixed data. The argument is not converted if any of the following conditions is true:
- The argument is mixed data, and its CCSID is $M$.
- The argument is SBCS data, and its CCSID is the same as the system CCSID for SBCS data. In this case, the operation proceeds as if the CCSID of the argument is $M$.

Otherwise, the argument is a new string $S$ derived by converting the characters to the coded character set identified by $M$.

The result is derived from $S$ by using the following steps:
- Each non-supplementary character is replaced by a Unicode double-byte character (a UTF-16 code point). A non-supplementary character in UTF-8 is between 1 and 3 bytes.
- Each supplementary character is replaced by a pair of Unicode double-byte characters (a pair of UTF-16 code points).

The replacement for a single-byte character is the Unicode equivalent character if an equivalent exists. Otherwise, the replacement is X'FEFE'.

**Graphic to Graphic**

graphic-expression
An expression that returns a value that is a graphic string. The graphic string must not be an empty string if integer is not specified.

integer
The length of the resulting fixed-length graphic string in the units that are either implicitly or explicitly specified. The value must be an integer constant between 1 and 127. If the length of graphic-expression is less than the length specified, the result is padded with double-byte blanks to the length of the result.

If CODEUNITS16 or CODEUNITS32 is specified, see “Determining the length attribute of the final result” on page 117 for information about how to calculate the length attribute of the result string.
If `integer` is not specified, the length of the result is the minimum of 127 and the length attribute of `graphic-expression`.

**CODEUNITS16 or CODEUNITS32**

Specifies the unit that is used to express `integer`. If CODEUNITS16 or CODEUNITS32 is specified, the input is EBCDIC, and there is no system CCSID for EBCDIC GRAPHIC data, an error occurs.

**CODEUNITS16**

Specifies that `integer` is expressed in terms of 16-bit UTF-16 code units.

**CODEUNITS32**

Specifies that `integer` is expressed in terms of 32-bit UTF-32 code units.

For more information about CODEUNITS16 and CODEUNITS32, see [String unit specifications](#).

If the length of the `graphic-expression` is greater than the specified length of the result, the result is truncated. Unless all the truncated characters are blanks, a warning is returned.

The CCSID of the result is the same as the CCSID of `graphic-expression`.

### Notes

**Casting numeric data to Unicode**: The result of the GRAPHIC functions is Unicode (UTF-16) when the first argument is numeric data. The GRAPHIC function can only be invoked with numeric data for the first argument if the containing statement:

- references Unicode base tables or views only and the statement is qualified to be a single encoding scheme statement, or
- is considered a multiple encoding scheme statement and the application encoding scheme is Unicode.

### Example 1

Assume that MYCOL is a VARCHAR column in TABLEY. The following function returns the string in MYCOL as a fixed-length graphic string.

```sql
SELECT GRAPHIC(MYCOL)
FROM TABLEY;
```

### Example 2

Assume that an EMPLOYEE_U table exists that is similar to the EMPLOYEE sample table except that it is a Unicode table. The SALARY and COMM columns are defined as DECIMAL with a precision of 9 and a scale of 2. Return the total income for employee Haas as a fixed-length graphic string using the comma decimal character.

```sql
SELECT GRAPHIC(SALARY + COMM, ',')
FROM EMPLOYEE_U
WHERE LASTNAME = 'HAAS'
```

The result is the value G'56970,00'.

### HASH_CRC32, HASH_MD5, HASH_SHA1, and HASH_SHA256

The hashing functions return a fixed-length value that is the result of applying a hashing algorithm to an input argument.
The schema is SYSIBM.

**expression**

An expression that represents the string value that is to be hashed. The expression must return a built-in character string, graphic string, or binary string.

The result is produced by applying the hashing algorithm to expression. The hashing algorithm is determined by the name of the function.

The data type and length attribute of the result depend on which hashing function is used. The following table lists each function and the data type and length of its result.

<table>
<thead>
<tr>
<th>Function</th>
<th>Data type of the result</th>
</tr>
</thead>
<tbody>
<tr>
<td>HASH_CRC32</td>
<td>BINARY(4)</td>
</tr>
<tr>
<td>HASH_MD5</td>
<td>BINARY(16)</td>
</tr>
<tr>
<td>HASH_SHA1</td>
<td>BINARY(20)</td>
</tr>
<tr>
<td>HASH_SHA256</td>
<td>BINARY(32)</td>
</tr>
</tbody>
</table>

The result can be null; if the argument is null, the result is the null value.

**Example 1:** Call the HASH_CRC32 function to use the CRC32 algorithm to generated hashed data.

```sql
SELECT HEX(HASH_CRC32('ABCDEFGHIJKLMNOPQRSTUVWXYZ'))
FROM SYSIBM.SYSDUMMYU;
```

The following value is returned:

X'B4B86309'

**Example 2:** Call the HASH_MD5 function to use the MD5 algorithm to generated hashed data.

```sql
SELECT HEX(HASH_MD5('ABCDEFGHIJKLMNOPQRSTUVWXYZ'))
FROM SYSIBM.SYSDUMMYU;
```

The following value is returned:

X'4338C7BE26A152E54E2EA0C92778160'

**Example 3:** Call the HASH_SHA1 function to use the SHA1 algorithm to generated hashed data.

```sql
SELECT HEX(HASH_SHA1('ABCDEFGHIJKLMNOPQRSTUVWXYZ'))
FROM SYSIBM.SYSDUMMYU;
```

The following value is returned:
Example 4: Call the HASH_SHA256 function to use the SHA256 algorithm to generated hashed data.

```sql
SELECT HEX(HASH_SHA256('ABCDEFGHIJKLMNOPQRSTUVWXYZ'))
FROM SYSIBM.SYSDUMMYU;
```

The following value is returned:

`X'403AC046B04F4A749E9810971083997871F2B6FAF87CECCDE657E93FFCF700F0'`

**HEX**

The HEX function returns a hexadecimal representation of a value.

```
HEX(expression)
```

The schema is SYSIBM.

The argument must an expression that returns a value of any built-in data type that is not XML. A character or binary string must not have a maximum length greater than 16352. A graphic string must not have a maximum length greater than 8176.

The result of the function is a character string.

The result can be null; if the argument is null, the result is the null value.

The result is a string of hexadecimal digits. The first two represent the first byte of the argument, the next two represent the second byte of the argument, and so forth. If the argument is a datetime value, the result is the hexadecimal representation of the internal form of the argument.

If the argument is a fixed-length string and the length of the result is less than 255, the result is a fixed-length string. Otherwise, the result is a varying-length string with a length attribute that depends on the following considerations:

- **If the argument is not a varying-length string**, the length attribute of the result string is the same as the length of the result.

- **If the argument is a varying-length character or binary string**, the length attribute of the result string is twice the length attribute of the argument.

- **If the argument is a varying-length graphic string**, the length attribute of the result string is four times the length attribute of the argument.

If `expression` returns string data, the CCSID of the result is the SBCS CCSID that corresponds to the CCSID of `expression`. Otherwise, the CCSID of the result is determined from the context in which the function was invoked. For more information, see [Determining the encoding scheme and CCSID of a string](Introduction to Db2 for z/OS).

If the argument is a graphic string, the length of the result is four times the maximum length of the argument. Otherwise, the length of the result is twice the (maximum) length of the argument.
Example: Return the hexadecimal representation of START_RBA in the SYSIBM.SYSCOPY catalog table.

```
SELECT HEX(START_RBA) FROM SYSIBM.SYSCOPY;
```

**HOUR**

The HOUR function returns the hour part of a value.

```
HOUR(expression)
```

The schema is SYSIBM.

The argument must be an expression that returns a value of one of the following built-in data types: a time, a timestamp, a character string, a graphic string, or a numeric data type.

- If `expression` is a character or graphic string, it must not be a CLOB or DBCLOB, and its value must be a valid string representation of a time or timestamp with an actual length of not greater than 255 bytes. For the valid formats of string representations of times and timestamps, see "String representations of datetime values" on page 130.
- If `expression` is a number, it must be a time or timestamp duration. For the valid formats of time and timestamp durations, see "Datetime operands" on page 177.

If `expression` is a timestamp with a time zone, or a valid string representation of a timestamp with a time zone, the result is determined from the UTC representation of the datetime value.

The result of the function is a large integer.

The result can be null; if the argument is null, the result is the null value.

The other rules depend on the data type of the argument:

- **If the argument is a time, timestamp, or string representation of either**, the result is the hour part of the value, which is an integer between 1 and 24.
- **If the argument is a time duration or timestamp duration**, the result is the hour part of the value, which is an integer between -99 and +99. A nonzero result has the same sign as the argument.
- **If the argument contains a time zone**, the result is the year part of the value expressed in UTC.

**Example 1:** Assume that a table named CLASSES contains a row for each scheduled class. Also assume that the class starting times are in a TIME column named STARTTM. Select those rows in CLASSES that represent classes that start after the noon hour.

```
SELECT *
FROM CLASSES
WHERE HOUR(STARTTM) > 12;
```

**Example 2:** The following invocations of the HOUR function returns the same result:
SELECT HOUR('2003-01-02-20.00.00'), HOUR('2003-01-02-12.00.00-08:00'), HOUR('2003-01-03-05.00.00+09:00') FROM SYSIBM.SYSDUMMY1;

For each invocation of the HOUR function in this SELECT statement, the result is 20.

When the input argument contains a time zone, the result is determined from the UTC representation of the input value. The string representations of a timestamp with a time zone in the SELECT statement all have the same UTC representation: 2003-01-02-20.00.00.

**IDENTITY_VAL_LOCAL**

The IDENTITY_VAL_LOCAL function returns the most recently assigned value for an identity column.

The schema is SYSIBM.

The IDENTITY_VAL_LOCAL function is not deterministic. Although the function has no input parameters, the empty parentheses must be specified when the function is invoked.

The result is DECIMAL(31,0), regardless of the actual data type of the identity column to which the result value corresponds.

A **qualifying data change statement** refers to an insert operation (specified in either an INSERT statement or a MERGE statement).

The value that is returned is the value that was assigned to the identity column of the table identified in the most recent qualifying data change statement or LOAD utility operation for a table with an identity column. The insert operation has to be issued at the same level; that is, the value has to be available locally within the level at which it was assigned until replaced by the next assigned value. A new level is initiated when a trigger, function, or stored procedure is invoked. A trigger condition is at the same level as the associated triggered action.

The assigned value can be a value supplied by the user (if the identity column is defined as GENERATED BY DEFAULT) or an identity value that was generated by Db2.

**Note:** Use a SELECT FROM data change statement to obtain the assigned value for an identity column. See [data-change-table-reference](#) for more information.

The result can be null. The result is null in the following situations:

---

21. Being not deterministic affects what optimization (such as view processing and parallel processing) can be done when this function is used and in what contexts the function can be invoked. For example, the RAND function is another built-in scalar function that is not deterministic. Using functions that are not deterministic within a predicate can cause unpredictable results.
- When a qualifying data change statement has not been issued for a table containing an identity column at the current processing level
- When a COMMIT or ROLLBACK of a unit of work occurred since the most recent qualifying data change statement that assigned a value

The result of the function is not affected by a ROLLBACK TO SAVEPOINT statement.

**Invoking the function within a qualifying data change statement:** Expressions in a qualifying data change statement are evaluated before values are assigned to the target columns of the qualifying data change statement. Thus, when you invoke IDENTITY_VAL_LOCAL in a qualifying data change statement, the value that is used is the most recently assigned value for an identity column from a previous qualifying data change statement. The function returns the null value if no such qualifying data change statement had been executed within the same level as the invocation of the IDENTITY_VAL_LOCAL function. Each qualifying data change statement that involves an IDENTITY column causes the identity value to be copied into connection-specific storage in Db2. Thus, the most recent identity value is used for a connection, regardless of what is happening with other concurrent user connections.

**Invoking the function following a failed insert operation:** The function returns an unpredictable result when it is invoked after the unsuccessful execution of a qualifying data change statement for a table with an identity column. The value might be the value that would have been returned from the function had it been invoked before the failed qualifying data change statement or the value that would have been assigned had the qualifying data change statement succeeded. The actual value returned depends on the point of failure and is therefore unpredictable.

**Invoking the function within the SELECT statement of a cursor:** Because the results of the IDENTITY_VAL_LOCAL function are not deterministic, the result of an invocation of the IDENTITY_VAL_LOCAL function from within the SELECT statement of a cursor can vary for each FETCH statement.

**Invoking the function within the trigger condition of an insert trigger:** The result of invoking the IDENTITY_VAL_LOCAL function from within the condition of an insert trigger is the null value.

**Invoking the function within a triggered action of an insert trigger:** Multiple before or after insert triggers can exist for a table. In such cases, each trigger is processed separately, and identity values generated by SQL statements issued within a triggered action are not available to other triggered actions using the IDENTITY_VAL_LOCAL function. This is the case even though the multiple triggered actions are conceptually defined at the same level.

Do not use the IDENTITY_VAL_LOCAL function in the triggered action of a before insert trigger. The result of invoking the IDENTITY_VAL_LOCAL function from within the triggered action of a before insert trigger is the null value.

The value for the identity column of the table for which the trigger is defined cannot be obtained by invoking the IDENTITY_VAL_LOCAL function within the triggered action of a before insert trigger. However, the value for the identity column can be obtained in the triggered action by referencing the trigger transition variable for the identity column.
The result of invoking the IDENTITY_VAL_LOCAL function in the triggered action of an after insert trigger is the value assigned to an identity column of the table identified in the most recent qualifying data change statement. That statement is the one invoked in the same triggered action that had a qualifying data change statement for a table containing an identity column. If a qualifying data change statement for a table containing an identity column was not executed within the same triggered action before invoking the IDENTITY_VAL_LOCAL function, then the function returns a null value.

**Invoking the function following an insert operation with triggered actions:** The result of invoking the function after an insert that activates triggers is the value actually assigned to the identity column (that is, the value that would be returned on a subsequent SELECT statement). This value is not necessarily the value provided in the qualifying data change statement or a value generated by Db2. The assigned value could be a value that was specified in a SET transition variable statement within the triggered action of a before insert trigger for a trigger transition variable associated with the identity column.

**Scope of IDENTITY_VAL_LOCAL:** The IDENTITY_VAL_LOCAL value persists until the next insert in the current session into a table that has an identity column defined on it, or the application session ends. The value is unaffected by COMMIT or ROLLBACK statements for local applications. The IDENTITY_VAL_LOCAL value cannot be directly set and is a result of inserting a row into a table. Client applications or middleware products that save the state of a session and then restore the state of a session for subsequent processing are not able to restore the IDENTITY_VAL_LOCAL value. In these situations, the availability of the IDENTITY_VAL_LOCAL value should only be relied on until the end of the transaction. Examples of where this type of situation can occur include applications that do the following actions:

- use XA protocols
- use connection pooling
- use the connection concentrator
- use Sysplex workload balancing
- connect to a z/OS server that uses DDF inactive threads

When there is a need to preserve the value associated with IDENTITY_VAL_LOCAL across transaction boundaries for distributed applications, define the cursors as WITH HOLD, or specify the bind option KEEPDYNAMIC(YES) to prevent the server thread from being pooled.

**Example 1:** Set the variable IVAR to the value assigned to the identity column in the EMPLOYEE table. The value returned from the function in the VALUES statement should be 1.

```
CREATE TABLE EMPLOYEE
(EMPNO INTEGER GENERATED ALWAYS AS IDENTITY,
 NAME CHAR(30),
 SALARY DECIMAL(5,2),
 DEPTNO SMALLINT);
INSERT INTO EMPLOYEE
(NAME, SALARY, DEPTNO)
VALUES ('Rupert', 989.99, 50);
VALUES IDENTITY_VAL_LOCAL() INTO :IVAR;
```

**Example 2:** Assume two tables, T1 and T2, have an identity column named C1. Db2 generates values 1, 2, 3, . . . for the C1 column in table T1, and values 10, 11, 12, . . . for the C1 column in table T2.
CREATE TABLE T1 (C1 SMALLINT GENERATED ALWAYS AS IDENTITY,
  C2 SMALLINT);
CREATE TABLE T2 (C1 DECIMAL(15,0) GENERATED BY DEFAULT AS IDENTITY
  (START WITH 10),
  C2 SMALLINT);
INSERT INTO T1 (C2) VALUES (5);
INSERT INTO T1 (C2) VALUES (5);
SELECT * FROM T1;
  C1  C2
  1   5
  2   5
VALUES IDENTITY_VAL_LOCAL() INTO :IVAR;

At this point, the IDENTITY_VAL_LOCAL function would return a value of 2 in
IVAR. The following INSERT statement inserts a single row into T2 where column
C2 gets a value of 2 from the IDENTITY_VAL_LOCAL function

  INSERT INTO T2 (C2) VALUES (IDENTITY_VAL_LOCAL());
SE
SELECT * FROM T2
  WHERE C1 = DECIMAL(IDENTITY_VAL_LOCAL(),15,0);
  C1  C2
  ---------------  ---
  10   2

Invoking the IDENTITY_VAL_LOCAL function after this insert would result in a
value of 10, which is the value generated by Db2 for column C1 of T2. Assume
another single row is inserted into T2. For the following INSERT statement, Db2
assigns a value of 13 to identity column C1 and gives C2 a value of 10 from
IDENTITY_VAL_LOCAL. Thus, C2 is given the last identity value that was
inserted into T2.

  INSERT INTO T2 (C2, C1) VALUES (IDENTITY_VAL_LOCAL(), 13);

Example 3: The IDENTITY_VAL_LOCAL function can also be invoked in an
INSERT statement that both invokes the IDENTITY_VAL_LOCAL function and
causes a new value for an identity column to be assigned. The next value to be
returned is thus established when the IDENTITY_VAL_LOCAL function is invoked
after the INSERT statement completes. For example, consider the following table
definition:

  CREATE TABLE T1 (C1 SMALLINT GENERATED BY DEFAULT AS IDENTITY,
  C2 SMALLINT);

For the following INSERT statement, specify a value of 25 for the C2 column, and
Db2 generates a value of 1 for C1, the identity column. This establishes 1 as the
value that will be returned on the next invocation of the IDENTITY_VAL_LOCAL
function.

  INSERT INTO T1 (C2) VALUES (25);

In the following INSERT statement, the IDENTITY_VAL_LOCAL function is
invoked to provide a value for the C2 column. A value of 1 (the identity value
assigned to the C1 column of the first row) is assigned to the C2 column, and Db2
generates a value of 2 for C1, the identity column. This establishes 2 as the value
that will be returned on the next invocation of the IDENTITY_VAL_LOCAL
function.

  INSERT INTO T1 (C2) VALUES (IDENTITY_VAL_LOCAL());

In the following INSERT statement, the IDENTITY_VAL_LOCAL function is again
invoked to provide a value for the C2 column, and the user provides a value of 11
for C1, the identity column. A value of 2 (the identity value assigned to the C1 column of the second row) is assigned to the C2 column. The assignment of 11 to C1 establishes 11 as the value that will be returned on the next invocation of the IDENTIFY_VAL_LOCAL function.

```
INSERT INTO T1 (C2, C1) VALUES (IDENTITY_VAL_LOCAL(), 11);
```

After the 3 INSERT statements have been processed, table T1 contains the following actions:

```
SELECT * FROM T1;
C1  C2
---  ---
1  25
2  1
11 2
```

The contents of T1 illustrate that the expressions in the VALUES clause are evaluated before the assignments for the columns of the INSERT statement. Thus, an invocation of an IDENTIFY_VAL_LOCAL function invoked from a VALUES clause of an INSERT statement uses the most recently assigned value for an identity column in a previous INSERT statement.

**IFNULL**

The IFNULL function returns the first nonnull expression.

```
IFNULL(expression, expression)
```

The schema is SYSIBM.

IFNULL is identical to the COALESCE scalar function except that IFNULL is limited to two arguments instead of multiple arguments. For a description, see [COALESCE](#).

Example: For all the rows in sample table DSN8C10.EMP, select the employee number and salary. If the salary is missing (is null), have the value 0 returned.

```
SELECT EMPNO, IFNULL(SALARY, 0)
FROM DSN8C10.EMP;
```

**INSERT**

The INSERT function returns a string where, beginning at start in source-string, length characters have been deleted and insert-string has been inserted.

```
INSERT(source-string, start, length, insert-string)
```

SQL Reference
The schema is SYSIBM.

The INSERT function returns a string where length characters have been deleted from source-string, beginning at start, and where insert-string has been inserted into source-string, beginning at start.

source-string
An expression that specifies the source string. The expression must return a value that is a built-in character string, graphic string, or binary string data type that is not a LOB. The actual length of the string must be greater than or equal to 1 and less than or equal to 32704 bytes.

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type.

start
An expression that returns an integer. The integer specifies the starting point within the source string where the deletion of bytes and the insertion of another string is to begin. The value of the integer must be in the range of 1 to the length of source-string plus one. If OCTETS is specified and the result is graphic data, the value must be an odd value between 1 and twice the length of source-string plus one.

The argument can also be a character string or graphic string data type. The string argument is implicitly cast to a DECFLOAT(34) data type which is then assigned to an INTEGER.

length
An expression that specifies the length of the string to replace in source-string starting at start. length must be an expression that returns a value of the built-in INTEGER data type. length is expressed in the string unit specified, and the value must be in the range of 0 to the length of source-string. If OCTETS is specified and the result is graphic data, length must be even and be between 0 and twice the length of source-string. Not specifying length is equivalent to specifying a value of 1, except when OCTETS is specified and the result is graphic data, in which case, not specifying length is equivalent to specifying a value of 2.

The argument can also be a character string or graphic string data type. The string argument is implicitly cast to a DECFLOAT(34) data type which is then assigned to an INTEGER.

insert-string
An expression that specifies the string to be inserted into the source string, starting at the position identified by start. The expression must return a value that is a built-in character string, graphic string, or binary string data type that is not a LOB.

source-string and insert-string must have compatible data types.

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type.

CODEUNITS16, CODEUNITS32, or OCTETS
Specifies the units that are used to express start and length. If source-string is a character string that is defined as bit data, CODEUNITS16 and CODEUNITS32 cannot be specified. If source-string is a graphic string, OCTETS cannot be specified. If source-string is a binary string, CODEUNITS16, CODEUNITS32, and OCTETS cannot be specified.
If a string unit is not explicitly specified, the data type of the result determines the unit that is used:

- If the result is a graphic string, a string unit is two bytes. For ASCII and EBCDIC data, this corresponds to a double byte character. For Unicode, this corresponds to a UTF-16 code point.
- Otherwise, a string unit is a byte.

**CODEUNITS16**

Specifies that `start` and `length` are expressed in terms of 16-bit UTF-16 code units.

**CODEUNITS32**

Specifies that `start` and `length` are expressed in terms of 32-bit UTF-32 code units.

**OCTETS**

Specifies that `start` and `length` are expressed in terms of bytes.

For more information about CODEUNITS16, CODEUNITS32, and OCTETS, see String unit specifications.

If `source-string` and `insert-string` have different CCSID sets, `insert-string` (the string to be inserted) is converted to the CCSID of `source-string` (the source string).

The encoding scheme of the result is the same as `source-string`. The data type of the result of the function depends on the data type of `source-string` and `insert-string`:

- **VARCHAR** if `source-string` is a character string. The CCSID of the result depends on the arguments:
  - If either `source-string` or `insert-string` is character bit data, the result is bit data.
  - If `source-string` is SBCS Unicode data and `insert-string` is not SBCS Unicode data, the CCSID of the result is the mixed CCSID for Unicode data.
  - If both `source-string` and `insert-string` are SBCS Unicode data, the CCSID of the result is the CCSID for SBCS Unicode data.
  - Otherwise, the CCSID of the result is the mixed CCSID that corresponds to the CCSID of `source-string`. However, if the input is EBCDIC or ASCII and there is no corresponding system CCSID for mixed, the CCSID of the result is the CCSID of `source-string`.
- **VARGRAPHIC** if `source-string` is a graphic. The CCSID of the result is the same as the CCSID of `source-string`.
- **VARBINARY** if `source-string` and `insert-string` are both binary strings.

The length attribute of the result depends on the arguments:

- If `start` and `length` are constants, the length attribute of the result is:
  \[ L1 - \min((L1 - V2 + 1), V3) + L4 \]

  where:
  - \( L1 \) is the length attribute of `source-string`
  - \( V2 \) is the value of `start`
  - \( V3 \) is the value of `length`
  - \( L4 \) is the length attribute of `insert-string`

- Otherwise, the length attribute of the result is the length attribute of `source-string` plus the length attribute of `insert-string`. In this case, the length attribute of `source-string` plus the length attribute of `insert-string` must not exceed 32704 for a VARCHAR result or 16352 for a VARGRAPHIC result.
If CODEUNITS16 or CODEUNITS32 is specified, the insert operation is performed on a Unicode version of the data. If needed, the data is converted to an intermediate form in order to evaluate the function. If an intermediate form is used, the actual length of the result depends on the original data (source-string and insert-string), and the representation of that data in Unicode. See “Determining the length attribute of the final result” on page 117 for more information on how to calculate the length attribute of the result string.

If CODEUNITS16 or CODEUNITS32 are not specified, the actual length of the result is:

\[ A1 - \min((A1 - V2 + 1), V3) + A4 \]

where:
- \( A1 \) is the actual length of source-string
- \( V2 \) is the value of start
- \( V3 \) is the value of length
- \( A4 \) is the actual length of insert-string

If the actual length of the result string exceeds the maximum for the return data type, an error occurs.

The result can be null; if any argument is null, the result is the null value.

**Example 1:** The following example shows how the string 'INSERTING' can be changed into other strings. The use of the CHAR function limits the length of the resulting string to 10 bytes.

```sql
SELECT CHAR(INSERT('INSERTING',4,2,'IS'),10),
       CHAR(INSERT('INSERTING',4,0,'IS'),10),
       CHAR(INSERT('INSERTING',4,2,''),10)
FROM SYSIBM.SYSDUMMY1;
```

This example returns 'INSISTING', 'INSISER'TIN', and 'INSTING'.

**Example 2:** The previous example demonstrated how to insert text into the middle of some text. This example shows how to insert text before some text by using 1 as the starting point (start).

```sql
SELECT CHAR(INSERT('INSERTING',1,0,'XX'),10),
       CHAR(INSERT('INSERTING',1,1,'XX'),10),
       CHAR(INSERT('INSERTING',1,2,'XX'),10),
       CHAR(INSERT('INSERTING',1,3,'XX'),10)
FROM SYSIBM.SYSDUMMY1;
```

This example returns 'XXINSERTIN', 'XXNSERTING', 'XXERTING ', and 'XXERTING '.

**Example 3:** The following example shows how to insert text after some text. Add 'XX' at the end of string 'ABCABC'. Because the source string is 6 characters long, set the starting position to 7 (one plus the length of the source string).

```sql
SELECT CHAR(INSERT('ABCABC',7,0,'XX'),10)
FROM SYSIBM.SYSDUMMY1;
```

This example returns 'ABCABCXX'.

**Example 4:** The following example shows how the string 'Hegelstraße' can be changed to 'Hegelstrasse'.

```sql
SELECT VARCHAR(INSERT('Hegelstraße',10,1,'ss'),15)
FROM SYSIBM.SYSDUMMY1;
```
This example returns 'Hegelstrasse'.

**INTEGER or INT**

The INTEGER function returns an integer representation of either a number or a character string or graphic string representation of an integer.

**Numeric to Integer:**

```
INTEGER(numeric-expression)
```

**String to Integer:**

```
INTEGER(string-expression)
```

The schema is SYSIBM.

**Numeric to Integer**

`numeric-expression`

An expression that returns a value of any built-in numeric data type.

The result is the same number that would occur if the argument were assigned to a large integer column or variable. If the whole part of the argument is not within the range of large integers, an error occurs. The fractional part of the argument is truncated.

**String to Integer**

`string-expression`

An expression that returns a value of a character or graphic string (except a CLOB or DBCLOB) with a length attribute that is not greater than 255 bytes. The string must contain a valid string representation of a number.

The result is the same number that would result from `CAST(string-expression AS INTEGER)`. Leading and trailing blanks are eliminated and the resulting string must conform to the rules for forming an integer constant. If the whole part of the argument is not within the range of large integers, an error is returned.

The result of the function is a large integer.

The result can be null; if the argument is null, the result is the null value.

**Recommendation:** To increase the portability of applications, use the CAST specification. For more information, see “CAST specification” on page 283.

**Example 1:** Using sample table DSN8C10.EMP, find the average salary of the employees in department A00, rounding the result to the nearest dollar.
SELECT INTEGER(AVG(SALARY)+.5)
FROM DSN8C10.EMP
WHERE WORKDEPT = 'A00';

Example 2: Using sample table DSN8C10.EMP, select the EMPNO column, which is defined as CHAR(6), in integer form.

SELECT INTEGER(EMPNO)
FROM DSN8C10.EMP;

**JULIAN_DAY**

The JULIAN_DAY function returns an integer value that represents a number of days from January 1, 4713 B.C. (the start of the Julian date calendar) to the date that is specified in the argument.

```sql
JULIAN_DAY(expression)
```

The schema is SYSIBM.

The argument must be an expression that returns one of the following data types: a date, a timestamp, or a valid string representation of a date or timestamp. An argument with a character string data type must not be a CLOB. An argument with a graphic string data type must not be a DBCLOB. A string argument must have an actual length that is not greater than 255 bytes. For the valid formats of string representations of dates and timestamps, see “String representations of datetime values” on page 130.

If expression is a timestamp with a time zone, or a valid string representation of a timestamp with a time zone, the result is determined from the UTC representation of the datetime value.

The result of the function is a large integer.

The result can be null; if the argument is null, the result is the null value.

Example 1: Using sample table DSN8C10.EMP, set the integer host variable JDAY to the Julian day of the day that Christine Haas (EMPNO = '000010') was employed (HIREDATE = '1965-01-01').

```sql
SELECT JULIAN_DAY(HIREDATE)
INTO :JDAY
FROM DSN8C10.EMP
WHERE EMPNO = '000010';
```

The result is that JDAY is set to 2438762.

Example 2: Set integer host variable JDAY to the Julian day for January 1, 1998.

```sql
SELECT JULIAN_DAY('1998-01-01')
INTO :JDAY
FROM SYSIBM.SYSDUMMY1;
```

The result is that JDAY is set to 2450815.
Example 3: The following invocations of the JULIAN_DAY function returns the same result:

```
SELECT JULIAN_DAY('2003-01-02-20.00.00'),
       JULIAN_DAY('2003-01-02-12.00.00-08:00'),
       JULIAN_DAY('2003-03-03-05.00.00+09:00')
FROM SYSIBM.SYSDUMMY1;
```

For each invocation of the JULIAN_DAY function in this SELECT statement, the result is 2452642.

When the input argument contains a time zone, the result is determined from the UTC representation of the input value. The string representations of a timestamp with a time zone in the SELECT statement all have the same UTC representation: 2003-01-02-20.00.00.

LAST_DAY

The LAST_DAY scalar function returns a date that represents the last day of the month of the date argument.

```
►►LAST_DAY(expression)◄◄
```

The schema is SYSIBM.

eexpression

An expression that specifies the starting date. The expression must returns a value of one of the following data types:
- a date
- a timestamp
- a valid string representation of a date or timestamp

An argument with a character string data type must not be a CLOB. An argument with a graphic string data type must not be a DBCLOB. A string argument must have an actual length that is not greater than 255 bytes. A time zone in a string representation of a timestamp is ignored. For the valid formats of string representations of dates and timestamps, see "String representations of datetime values" on page 130.

If eexpression is a TIMEST IMP WITH TIME ZONE value, expression is first cast to a TIMESTAMP WITHOUT TIME ZONE value with the same precision as expression.

The result of the function has the same data type as expression, unless expression is a string, in which case the result data type is DATE.

The result CCSID is the appropriate CCSID of the argument encoding scheme and the result subtype is the appropriate subtype of the CCSID.

The result can be null; if the argument is null, the result is the null value.

Any hours, minutes, seconds, or fractional seconds information that is included in expression is not changed by the function.
Example 1: Set the host variable `END_OF_MONTH` with the last day of the current month.

```sql
SET :END_OF_MONTH = LAST_DAY(CURRENT_DATE);
```

The host variable `END_OF_MONTH` is set with the value representing the end of the current month. If the current day is 2000-02-10, `END_OF_MONTH` is set to 2000-02-29.

Example 2: Set the host variable `END_OF_MONTH` with the last day of the month in EUR format for the given date.

```sql
SET :END_OF_MONTH = CHAR(LAST_DAY('1965-07-07'), EUR);
```

The host variable `END_OF_MONTH` is set with the value '31.07.1965'.

Example 3: Assume that host variable `PRSTSZ` contains '2008-02-29.20.00.000000-08.30'. The `TIMESTAMP` with time zone value is implicitly cast to `TIMESTAMP WITHOUT TIME ZONE` before the `LAST_DAY` function is evaluated.

```sql
SELECT LAST_DAY(:PRSTSZ) FROM PROJECT;
```

The `LAST_DAY` function returns the value '31' (month in UTC is March).

Example 4: Assume `PRSTSZ` is a host variable with the string value '2008-04-15.20.00.000000-08.30'. The string value, which is a string representation of a `TIMESTAMP` with a time zone, is implicitly cast to a `DATE` before the `LAST_DAY` function is evaluated. The `LAST_DAY` function returns the last day of the month as a `DATE` value.

```sql
SELECT LAST_DAY(:PRSTSZ) FROM PROJECT;
```

The `LAST_DAY` function returns the value '2008-04-30', the last day of the month of April, as a `DATE` value.

Example 5: Assuming that the default date format is ISO, the following select statement returns '2000–04–30', which is the last day of April in 2000:

```sql
SELECT LAST_DAY('2000-04-24') FROM SYSIBM.SYSDUMMY1;
```

**LCASE**

The `LCASE` function returns a string in which all the characters are converted to lowercase characters.

```sql
LCASE(string-expression [, locale-name-string [, integer]])
```

The schema is `SYSIBM`.

The `LCASE` function is identical to the `LOWER` function. For more information, see "LOWER" on page 518.
**LEFT**

The LEFT function returns a string that consists of the specified number of leftmost bytes of the specified string units.

**Character string:**

```
LEFT(character-expression,length)
```

The schema is SYSIBM.

The LEFT function returns the leftmost string of `character-expression`, `graphic-expression`, or `binary-expression` consisting of length of the string units that are specified implicitly or explicitly.

**Character string:**

*character-expression*

An expression that specifies the string from which the result is derived. The string must be a character string. A substring of `character-expression` is zero or more contiguous code points of `character-expression`.

The string can contain mixed data. Depending on the units that are specified to evaluate the function, the result is not necessarily a properly formed mixed data character string.

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type.

*length*

An expression that specifies the length of the result. The value must be an integer between 0 and `n`, where `n` is the length attribute of `character-expression`, expressed in the units that are either implicitly or explicitly specified.
The argument can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34) which is then assigned to an INTEGER value.

If CODEUNITS16 or CODEUNITS32 is specified, see “Determining the length attribute of the final result” on page 117 for information about how to calculate the length attribute of the result string.

**CODEUNITS16, CODEUNITS32, or OCTETS**

Specifies the unit that is used to express length. If character-expression is defined as bit data, CODEUNITS16 and CODEUNITS32 cannot be specified.

**CODEUNITS16**

Specifies that length is expressed in terms of 16-bit UTF-16 code units.

**CODEUNITS32**

Specifies that length is expressed in terms of 32-bit UTF-32 code units.

**OCTETS**

Specifies that length is expressed in terms of bytes.

For more information about CODEUNITS16, CODEUNITS32, and OCTETS, see String unit specifications.

**Graphic string:**

**graphic-expression**

An expression that specifies the string from which the result is derived. The string must be a graphic string. A substring of graphic-expression is zero or more contiguous code points of graphic-expression. A partial surrogate character in the expression is replaced with a blank.

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type.

**length**

An expression that specifies the length of the result. The value must be an integer between 0 and \( n \), where \( n \) is the length attribute of graphic-expression, expressed in the units that are either implicitly or explicitly specified.

The argument can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34) which is then assigned to an INTEGER value.

If CODEUNITS16 or CODEUNITS32 is specified, see “Determining the length attribute of the final result” on page 117 for information about how to calculate the length attribute of the result string.

**CODEUNITS16 or CODEUNITS32**

Specifies the unit that is used to express length.

**CODEUNITS16**

Specifies that length is expressed in terms of 16-bit UTF-16 code units.

**CODEUNITS32**

Specifies that length is expressed in terms of 32-bit UTF-32 code units.

For more information about CODEUNITS16 and CODEUNITS32, see String unit specifications.

**Binary string:**
binary-expression

An expression that specifies the string from which the result is derived. The string must be a binary string. A substring of binary-expression is zero or more contiguous code points of binary-expression.

length

An expression that specifies the length of the result. The value must be an integer between 0 and n, where n is the length attribute of binary-expression, expressed in the units that are either implicitly or explicitly specified.

The character-expression, graphic-expression, or binary-expression is effectively padded on the right with the necessary number of padding characters so that the specified substring of the expression always exists. The encoding scheme of the data determines the padding character:

- For ASCII SBCS data or ASCII mixed data, the padding character is X'20'.
- For ASCII DBCS data, the padding character depends on the CCSID; for example, for Japanese (CCSID 301) the padding character is X'8140', while for simplified Chinese it is X'A1A1'.
- For EBCDIC SBCS data or EBCDIC mixed data, the padding character is X'40'.
- For EBCDIC DBCS data, the padding character is X'4040'.
- For Unicode SBCS data or UTF-8 (Unicode mixed data), the padding character is X'20'.
- For UTF-16 (Unicode DBCS) data, the padding character is X'0020'.
- For binary data, the padding character is X'00'.

The result of the function is a varying-length string with a length attribute that is the same as the length attribute of the first expression and a data type that depends on the data type of the expression:

- VARCHAR if character-expression is CHAR or VARCHAR
- CLOB if character-expression is CLOB
- VARGRAPHIC if graphic-expression is GRAPHIC or VARGRAPHIC
- DBCLOB if graphic-expression is DBCLOB
- VARBINARY if binary-expression is BINARY or VARBINARY
- BLOB if binary-expression is BLOB

The actual length of the result is determined from length.

The result can be null; if any argument is null, the result is the null value.

The CCSID of the result is the same as that of the first expression.

Example 1: Assume that host variable ALPHA has a value of 'ABCDEF'. The following statement returns 'ABC', which are the three leftmost characters in ALPHA:

```
SELECT LEFT(:ALPHA,3)
FROM SYSIBM.SYSDUMMY1;
```

Example 2: Assume that host variable NAME, which is defined as VARCHAR(50), has a value of 'KATIE AUSTIN' and the integer host variable FIRSTNAME_LEN has a value of 5. The following statement returns the value 'KATIE':

```
SELECT LEFT(:NAME, :FIRSTNAME_LEN)
FROM SYSIBM.SYSDUMMY1;
```

Example 3: The following statement returns a zero length string.
SELECT LEFT('ABCABC',0) 
FROM SYSIBM.SYSDUMMY1;

Example 4: The FIRSTNAME column in sample EMP table is defined as VARCHAR(12). Find the first name for an employee whose last name is 'BROWN' and return the first name in a 10-byte string.

SELECT LEFT(FIRSTNAME,10) 
FROM DSN8C10.EMP 
WHERE LASTNAME='BROWN';

This function returns a VARCHAR(10) string that has the value of 'DAVID' followed by 5 blank characters.

Example 5: FIRSTNAME is a VARCHAR(12) column in table T1. One of its values is the 6-character string 'Jürgen'. When FIRSTNAME has this value:

<table>
<thead>
<tr>
<th>Function</th>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td>LEFT(FIRSTNAME,2,CODEUNITS32)</td>
<td>'Jü' -- x'4AC3BC'</td>
</tr>
<tr>
<td>LEFT(FIRSTNAME,2,CODEUNITS16)</td>
<td>'Jü' -- x'4AC3BC'</td>
</tr>
<tr>
<td>LEFT(FIRSTNAME,2,OCTETS)</td>
<td>'J' -- x'4A20' A truncated string</td>
</tr>
</tbody>
</table>

Example 6: In the following example, the last invocation of the LEFT function returns a partial surrogate character:

<table>
<thead>
<tr>
<th>Function</th>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td>LEFT('Jürgen',2,CODEUNITS32)</td>
<td>'Jü' -- x'4AC3BC'</td>
</tr>
<tr>
<td>LEFT('Jürgen',2,CODEUNITS16)</td>
<td>'Jü' -- x'4AC3BC'</td>
</tr>
<tr>
<td>LEFT('Jürgen',2,OCTETS)</td>
<td>'J' -- x'4A20' A truncated string</td>
</tr>
<tr>
<td>HEX(LEFT('Jürgen',2))</td>
<td>x'4AC3' -- The letter 'J' and a partial character</td>
</tr>
</tbody>
</table>

LENGTH

The LENGTH function returns the length of a value.

The schema is SYSIBM.

The argument must be an expression that returns a value of any built-in data type that is not XML.

The result of the function is a large integer.

The result can be null; if the argument is null, the result is the null value.

The result is the length of the argument. The length does not include the null indicator byte of column arguments that allow null values. The length of strings includes blanks. The length of a varying-length string is the actual length, not the maximum length.

The length of a graphic string is the number of double-byte characters. Unicode UTF-16 data is treated as graphic data; a UTF-16 supplementary character takes two DBCS characters to represent and as such is counted as two DBCS characters.

The length of all other values is the number of bytes used to represent the value:
• 2 for small integer
• 4 for large integer
• 8 for big integer
• The integer part of \((p/2)+1\) for decimal numbers with precision \(p\)
• 16 for DECFLOAT(34)
• 8 for DECFLOAT(16)
• 4 for single precision floating-point
• 8 for double precision floating-point
• The length of the string for strings
• 4 for DATE
• 3 for TIME
• 10 for TIMESTAMP
• 12 for TIMESTAMP WITH TIME ZONE
• \(7+((p+1)/2)\) for TIMESTAMP\((p)\)
• \(9+((p+1)/2)\) for TIMESTAMP\((p)\) WITH TIME ZONE
• The length of the row ID

Example 1: Assume that FIRSTNME is a VARCHAR(12) column that contains 'ETHEL' for employee 280. The following query returns the value 5:
```sql
SELECT LENGTH(FIRSTNME)
FROM DSN8C10.EMP
WHERE EMPNO = '000280';
```

Example 2: Assume that HIREDATE is a column of data type DATE. Then, regardless of value the following statement returns the value 4:
```sql
LENGTH(HIREDATE)
```

And the following function returns the value 10:
```sql
LENGTH(CHAR(HIREDATE, EUR))
```

**LN**

The LN function returns the natural logarithm of the argument. The LN and EXP functions are inverse operations.

```
LN(numeric-expression)
```

The schema is SYSIBM.

The argument must be an expression that returns the value of any built-in numeric data type that is not DECFLOAT. If the argument is not a double precision floating-point number, it is converted to one for processing by the function.

The result of the function is a double precision floating-point number.

The result can be null; if the argument is null, the result is the null value.

LOG is a synonym for LN.
Example: Assume that host variable NATLOG is DECIMAL(4,2) with a value of 31.62. The following statement returns a double precision floating-point number with an approximate value of 3.45:

```sql
SELECT LN(:NATLOG)
FROM SYSIBM.SYSDUMMY1;
```

**LOCATE**

The LOCATE function returns the position at which the first occurrence of an argument starts within another argument.

```
LOCATE(search-string, source-string start)
```

The schema is SYSIBM.

The LOCATE function returns the starting position of `search-string` within `source-string`. If `search-string` is not found and neither argument is null, the result is zero. If `search-string` is found, the result is a number from 1 to the actual length of `source-string`. If `search-string` has a length of zero, the result returned by the function is 1. If the optional `start` is specified, it indicates the character position in `source-string` at which the search is to begin. An optional string unit can be specified to indicate in what units the start and result of the function are expressed.

**search-string**

An expression that specifies the string that is to be searched for. `search-string` must return a value that is a built-in character string data type, graphic string data type, or binary string data type with an actual length that is no greater than 4000 bytes.

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type.

**source-string**

An expression that specifies the source string in which the search is to take place. `source-string` must return a value that is a built-in character string data type, graphic string data type, or binary string data type.

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type.

**start**

An expression that specifies the position within `search-string` where the search is to start. `start` is expressed in the specified string unit and must return an integer value that is greater than or equal to zero.

The argument can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34) which is then assigned to an INTEGER value.
If `start` is specified, the LOCATE function is similar to the following POSITION function, where `string-units` is CODEUNITS16, CODEUNITS32, or OCTETS:

```
POSITION(search-string,
    SUBSTRING(source-string, start, string-units)) + start - 1
```

If `start` is not specified, the search begins at the first position of `source-string` and the LOCATE function is similar to the following POSITION function, where `string-units` is CODEUNITS16, CODEUNITS32, or OCTETS:

```
POSITION(search-string, source-string, string-units)
```

### CODEUNITS16, CODEUNITS32, or OCTETS

Specifies the string unit that is used to express `start` and the result. If `source-string` is a character string that is defined as bit data, CODEUNITS16 and CODEUNITS32 cannot be specified. If `source-string` is a graphic string, OCTETS cannot be specified. If `source-string` is a binary string, CODEUNITS16, CODEUNITS32, and OCTETS cannot be specified.

**CODEUNITS16**

Specifies that `start` and the result are expressed in terms of 16-bit UTF-16 code units.

**CODEUNITS32**

Specifies that `start` and the result are expressed in terms of 32-bit UTF-32 code units.

**OCTETS**

Specifies that `start` and the result are expressed in terms of bytes.

If a string unit is not explicitly specified, the data type of the result determines the string unit that is used. If the result is graphic data, `start` and the returned position are expressed in two-byte units; otherwise, they are expressed in bytes.

For more information about CODEUNITS16, CODEUNITS32, and OCTETS, see "String unit specifications" on page 114.

The first and second arguments must have compatible string types. For more information on compatibility, see "Conversion rules for comparisons" on page 168.

The result of the function is a large integer.

The result can be null; if any argument is null, the result is the null value.

For more information about LOCATE, see the description of "POSITION" on page 557.

**Example 1:** Find the location of the first occurrence of the character 'N' in the string 'DINING'.

```
SELECT LOCATE('N', 'DINING')
FROM SYSIBM.SYSDUMMY1;
```

The result is the value 3.

**Example 2:** For all the rows in the table named IN_TRAY, select the RECEIVED column, the SUBJECT column, and the starting position of the string 'GOOD' within the NOTE_TEXT column.

```
SELECT RECEIVED, SUBJECT, LOCATE('GOOD', NOTE_TEXT)
FROM IN_TRAY
WHERE LOCATE('GOOD', NOTE_TEXT) <> 0;
```
Example 3: Locate the character 'ß' in the string 'Jürgen lives on Hegelstraße', and set the host variable LOCATION with the position, as measured in CODEUNITS32 units, within the string.

```
SET :LOCATION = LOCATE('ß','Jürgen lives on Hegelstraße',1,CODEUNITS32);
```

The value of host variable LOCATION is set to 26.

Example 4: Locate the character 'ß' in the string 'Jürgen lives on Hegelstraße', and set the host variable LOCATION with the position, as measured in CODEUNITS16 units, within the string.

```
SET :LOCATION = LOCATE('ß','Jürgen lives on Hegelstraße',1,CODEUNITS16);
```

The value of host variable LOCATION is set to 26.

Example 5: Locate the character 'ß' in the string 'Jürgen lives on Hegelstraße', and set the host variable LOCATION with the position, as measured in OCTETS, within the string.

```
SET :LOCATION = LOCATE('ß','Jürgen lives on Hegelstraße',1,OCTETS);
```

The value of host variable LOCATION is set to 27.

- "LOCATE_IN_STRING"
- "POSITION" on page 557
- "POSSTR" on page 559

**LOCATE_IN_STRING**

The LOCATE_IN_STRING function returns the position at which an argument starts within a specified string.

```
LOCATE_IN_STRING(source-string, search-string [start, instance], CODEUNITS16/32/OCTETS)
```

The schema is SYSIBM.

The LOCATE_IN_STRING function returns the starting position of a string (called the search-string) within another string (called the source-string). If the search-string is not found and neither argument is null, the result is zero. If the search-string is found, the result is a number from 1 to the actual length of the source-string.

If the optional start is specified, an optional instance number can also be specified. The instance argument is used to determine the specific occurrence of search-string within source-string. Each unique instance can include any of the characters in a previous instance, but not all characters in a previous instance. An optional string unit can be specified to indicate in what units the start and result of the function are expressed.

If the search-string has a length of zero, the result returned by the function is 1. If the source-string has a length of zero, the result returned by the function is 0. If
neither condition exists, and if the value of search-string is equal to an identical
length of a substring of contiguous positions within the value of source-string, the
result returned by the function is the starting position of that substring within the
source-string value; otherwise, the result returned by the function is 0.

**source-string**

An expression that specifies the source string in which the search is to take
place. source-string must return a value that is a built-in character string data
type, graphic string data type, or binary string data type.

The argument can also be a numeric data type. The numeric argument is
implicitly cast to a VARCHAR data type.

**search-string**

An expression that specifies the string that is the object of the search.
search-string must return a value that is a built-in character string data type,
graphic string data type, or binary string data type with an actual length that
is no greater than 4000 bytes.

The argument can also be a numeric data type. The numeric argument is
implicitly cast to a VARCHAR data type.

**start**

An expression that specifies the position within source-string at which the
search is to start. The expression must return a value that is a built-in
INTEGER or SMALLINT data type.

The argument can also be a character string or graphic string data type. The
string input is implicitly cast to a numeric value of DECFLOAT(34) which is
then assigned to an INTEGER value.

If the value of the integer is greater than zero, the search begins at start and
continues for each position to the end of the string. If the value of the integer
is less than zero, the search begins at the LENGTH(source-string) + start + 1 and
continues for each position to the beginning of the string.

If start is not specified, the default is 1. If the value of the integer is zero, an
error is returned.

**instance**

An expression that specifies which instance of search-string to search for within
source-string. The expression must return a value that is a built-in INTEGER or
SMALLINT data type. If instance is not specified, the default is 1. The value of
the integer must be greater than or equal to one.

**CODEUNITS16, CODEUNITS32, or OCTETS**

Specifies the string unit that is used to express start and the result. If
source-string is a character string that is defined as bit data, CODEUNITS16 and
CODEUNITS32 cannot be specified. If source-string is a graphic string, OCTETS
cannot be specified. If source-string is a binary string, CODEUNITS16,
CODEUNITS32, and OCTETS cannot be specified.

**CODEUNITS16**

Specifies that start and the result are expressed in terms of 16-bit UTF-16
code units.

**CODEUNITS32**

Specifies that start and the result are expressed in terms of 32-bit UTF-32
code units.

**OCTETS**

Specifies that start and the result are expressed in terms of bytes.
If a string unit is not explicitly specified, the data type of the result determines the string unit that is used. If the result is graphic data, start and the returned position are expressed in two-byte units; otherwise, they are expressed in bytes.

For more information about CODEUNITS16, CODEUNITS32, and OCTETS, see “String unit specifications” on page 114.

The first and second arguments must have compatible string types. For more information on compatibility, see “Conversion rules for comparisons” on page 168.

At each search position, a match is found when the substring at that position and LENGTH(search-string) - 1 values to the right of the search position in source-string, is equal to search-string.

The result of the function is a large integer. The result is the starting position of the instance of search-string within source-string. The value is relative to the beginning of the string (regardless of the specification of start).

The result can be null; if any argument is null, the result is the null value.

INSTR can be used as a synonym for LOCATE_IN_STRING.

Example 1: Find the position of an occurrence of the character 'N' in the string 'WINNING' by searching from the start of the string as measured in bytes, within the string.

```sql
SELECT LOCATE_IN_STRING('WINNING', 'N', 1, 3, OCTETS),
       LOCATE_IN_STRING('WINNING', 'N', 3, 2, OCTETS),
       LOCATE_IN_STRING('WINNING', 'N', 3, 3, OCTETS),
       LOCATE_IN_STRING('WINNING', 'N', -1, 3, OCTETS),
       LOCATE_IN_STRING('WINNING', 'N', -3, 2, OCTETS),
       LOCATE_IN_STRING('WINNING', 'N', -3, 3, OCTETS)
FROM SYSIBM.SYSDUMMY1;
```

Returns the values:

```
6 4 6 3 3 0
```

Related reference:

“LOCATE” on page 513
“POSITION” on page 557
“POSSTR” on page 559

**LOG10**

The LOG10 function returns the common logarithm (base 10) of a number.

```
LOG10(numeric-expression)
```

The schema is SYSIBM.

The argument is an expression that returns the value of any built-in numeric data type that is not DECFLOAT. If the argument is not a double precision floating-point number, it is converted to one for processing by the function.
The result of the function is a double precision floating-point number.

The result can be null; if the argument is null, the result is the null value.

Example: Assume that host variable HLOG is an INTEGER with a value of 100. The following statement returns a double precision floating-point number with an approximate value of 2:

```
SELECT LOG10(:HLOG)
FROM SYSIBM.SYSDUMMY1;
```

**LOWER**

The LOWER function returns a string in which all the characters are converted to lowercase characters.

```
LOWER(string-expression [, locale-name-string [, integer]]
```

The schema is SYSIBM.

**string-expression**

An expression that specifies the string to be converted. *string-expression* must return a value that is a built-in character or graphic string. A character string argument must not be a CLOB, and a graphic string argument must not be a DBCLOB. If *string-expression* is an EBCDIC graphic string, a blank string must not be specified for *locale-name-string*. If *string-expression* is bit data, *locale-name-string* must not be specified.

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type.

**locale-name-string**

A string constant or a string host variable other than a CLOB or DBCLOB that specifies a valid locale name. If *locale-name-string* is not in EBCDIC, it is converted to EBCDIC. The length of *locale-name-string* must be between 1 and 255 bytes of the EBCDIC representation. The value of *locale-name-string* is not case sensitive and must be a valid locale. For information on locales and their naming conventions, see z/OS C/C++ Programming Guide. Some examples of locales include:

- Fr_BE
- Fr_FR@EURO
- En_US
- Ja_JP

The conversion process is determined by the value that is specified for the locale name, as follows:

- blank — SBCS uppercase characters A-Z are converted to SBCS lowercase characters a-z, and characters with diacritical marks are not converted. If the string contains MIXED or DBCS characters, full-width Latin uppercase characters A-Z are converted to full-width lowercase characters a-z. For optimal performance, specify a blank string unless your data must be processed by using the rules that are defined by a specific locale.
• UNI — The conversion uses both the NORMAL and SPECIAL casing capabilities as described in "Select the conversions (z/OS: Unicode Services User’s Guide and Reference)." You must not specify UNI when string-expression is EBCDIC data.

• UNI_SIMPLE — Case conversions use the NORMAL casing capabilities as described in "Select the conversions (z/OS: Unicode Services User’s Guide and Reference)." UNI_SIMPLE cannot be used with EBCDIC data.

• locale name — The locale defines the rules for conversion to lowercase characters.

The value of the host variable must not be null. If the host variable has an associated indicator variable, the value of the indicator variable must not indicate a null value. The locale name must be:

• left justified within the host variable

• padded on the right with blanks if its length is less than that of the host variable and the host variable is in fixed length character or graphic data type

If locale-name-string is not specified, the locale is determined by special register CURRENT LOCALE LC_CTYPE. For information about the special register, see CURRENT LOCALE LC_CTYPE. However, if an index references the LOWER function, the local is determined as follows (in order) to determine if the index can be used:

• At prepare time — using the value in the CURRENT LOCALE LC_CTYPE special register

• At bind time — using the value in the LOCALE LC_CTYPE field on installation panel DSNTIPF

If the index is chosen in the access path, the locale in the CURRENT LOCALE LC_CTYPE special register must remain the same at run time, and prepare or bind time. To avoid this dependency, do not omit locale-name-string.

If the LOWER function is referenced in an expression-based index, locale-name-string must be specified. See the examples section for an example of how the index can be used in a query.

integer

An integer value that specifies the length attribute of the result. If specified, integer must be an integer constant between 1 and 32704 bytes in the representation of the encoding scheme of string-expression.

If integer is not specified, the length attribute of the result is the same as the length of string-expression.

For Unicode data, usage of the LOWER function can result in expansion if certain characters are processed. For example, LOWER (‘Ì’) —UX’00CC’— will result in UX’006903070300’ (if the LT_LT locale is in effect at the time). You should ensure that the result length is large enough to contain the result of the expression.

The result can be null; if the argument is null, the result is the null value.

LCASE is a synonym for LOWER.

Example 1: Return the characters in the value of host variable NAME in lowercase. NAME has a data type of VARCHAR(30) and a value of 'Christine Smith'. Assume that the locale in effect is blank.
SELECT LCASE(:NAME)
FROM SYSIBM.SYSDUMMY1;

The result is the value 'christine smith'.

Example 2: Return the lowercase of 'ï'. Assume that the locale in effect is LT_LT.
SELECT LOWER('ï')
FROM SYSIBM.SYSDUMMYU;

This would result in an error because of the expansion that occurs when certain
Unicode characters are processed. To avoid the error, you would need to use the
following statement instead:
SELECT LOWER(VARCHAR('ï', 3))
FROM SYSIBM.SYSDUMMYU;

The result of the preceding statement is the value UX'006903070300'.

Example 3: Create an index EMPLOYEE_NAME_LOWER for table EMPLOYEE
based on built-in function LOWER with locale name 'LT_LT'.

CREATE INDEX EMPLOYEE_NAME_LOWER
ON EMPLOYEE (LOWER(LASTNAME, 'LT_LT', 60),
LOWER(FIRSTNAME, 'LT_LT', 60),
ID);

Example 4: Create an index LNAME for table T1 based on the LOWER function
with the default local value, '. Then specify the same expression in a query.

CREATE INDEX LNAME
ON T1 (LOWER(LASTNAME, ' '));

SELECT LOWER(LASTNAME, ' ')
FROM T1
WHERE LOWER(LASTNAME, ' ') = 'smith';

Example 5: Create an index LNAME that is based on the LOWER function with a
locale name 'FR_CA' for the table T1. Then specify the same expression in a query
except locale-name-string is omitted.

CREATE INDEX LNAME
ON T1 (LOWER(LASTNAME, 'FR_CA'));

If the query is a dynamic statement and the CURRENT LOCALE LC_CTYPE
special register contains 'FR_CA':

SELECT LASTNAME
FROM T1
WHERE LOWER(LASTNAME)= 'smith';

At prepare time, locale 'FR_CA' in CURRENT LOCALE LC_CTYPE is used for
LOWER(LASTNAME) in the predicate to determine whether index LNAME can be
used for index access. If index LNAME is used in access path selection, at run
time, the locale in CURRENT LOCALE LC_CTYPE must remain the same.

If the query is a static statement and locale 'FR_CA' has been set on the LOCALE
LC_CTYPE field of installation panel DSNTIPF:

SELECT LASTNAME
FROM T1
WHERE LOWER(LASTNAME)= 'smith';

At bind time, local 'FR_CA' in the LOCALE LC_CTYPE file of installation panel
DSNTIPF is used for LOWER(LASTNAME) in the predicate to determine whether
index LNAME is used for index access. If index LNAME is chosen in access path selection, the locale in the CURRENT LOCALE LC_CTYPE special register must contain ‘FR_CA’.

Related concepts:

Related reference:

LPAD

The LPAD function returns a string that is composed of string-expression that is padded on the left, with pad or blanks. The LPAD function treats leading or trailing blanks in string-expression as significant.

```
LPAD(string-expression, integer [, pad])
```

Padding occurs only if the actual length of string-expression is less than integer, and if pad is not an empty string.

The schema is SYSIBM.

**string-expression**

An expression that specifies the source string. The expression must return a value that is a built-in string data type that is not a LOB.

**integer**

An integer constant that specifies the length of the result. The value must be zero or a positive integer that is less than or equal to \( n \), where \( n \) is 32704 if string-expression is a character or binary string, or where \( n \) is 16352 if string-expression is a graphic string.

**pad**

An expression that specifies the string with which to pad. The expression must return a value that is a built-in string data type that is not a LOB. If pad is not specified, the pad character is determined as follows:

- SBCS blank character if string-expression is a character string.
- DBCS blank character if string-expression is a graphic string.
- Hexadecimal zero (X’00’), if string-expression is a binary string.

The result of the function is a varying length string that has the same CCSID of string-expression. string-expression and pad must have compatible data types. If the string expressions have different CCSID sets, then pad is converted to the CCSID set of string-expression. If either string-expression or pad is FOR BIT DATA, no character conversion occurs.

The length attribute of the result depends on integer. If integer is greater than 0, the length attribute of the result is integer. If integer is 0, the length attribute of the result is 1.
The actual length of the result is determined from `integer`. If `integer` is 0, the actual length is 0, and the result is the empty result string. If `integer` is less than the actual length of `string-expression`, the actual length is `integer` and the result is truncated.

The result can be null; if any argument is null, the result is the null value.

**Example 1:** Assume that `NAME` is a `VARCHAR(15)` column that contains the values 'Chris', 'Meg', and 'Jeff'. The following query will pad a value on the left with periods.

```sql
SELECT LPAD(NAME, 15, '.') AS NAME
FROM T1;
```

The results are similar to the following output:

```
NAME
----------
............Chris
.............Meg
.............Jeff
```

**Example 2:** Similar to Example 1, the following query will only pad each value to a length of 5:

```sql
SELECT LPAD(NAME, 5, '.') AS NAME
FROM T1;
```

The results are similar to the following output:

```
NAME
----------
Chris
..Meg
.Jeff
```

**Example 3:** Assume that `NAME` is a `CHAR(15)` column containing the values 'Chris', 'Meg', and 'Jeff'. 'Note that the LPAD function does not pad because `NAME` is a fixed length character field and is blank padded already. However, since the length of the result is 5, the columns are truncated:

```sql
SELECT LPAD(NAME, 5, '.') AS NAME
FROM T1;
```

The results are similar to the following output:

```
NAME
----------
Chris
Meg
Jeff
```

**Example 4:** Assume that `NAME` is a `VARCHAR(15)` column containing the values 'Chris', 'Meg', and 'Jeff'. Note that in some cases, a partial instance of the pad specification is returned.

```sql
SELECT LPAD(NAME, 15, '123') AS NAME
FROM T1;
```

The results are similar to the following output:
The LTRIM function removes bytes from the beginning of a string expression based on the content of a trim expression.

\[ \text{LTRIM}( \text{string-expression}, \text{trim-expression} ) \]

The schema is SYSIBM.

The LTRIM function removes all of the characters that are contained in \text{trim-expression} from the beginning of \text{string-expression}. The search is done by comparing the binary representation of each character (which consists of one or more bytes) in \text{trim-expression} to the bytes at the beginning of \text{string-expression}. If the \text{string-expression} is defined as FOR BIT DATA, the search is done by comparing each byte in \text{trim-expression} to the byte at the beginning of \text{string-expression}.

\text{string-expression}

An expression that specifies the source string. The argument must be an expression that returns a value that is a built-in string data type that is not a LOB, or a numeric data type. If the value is not a string data type, it is implicitly cast to VARCHAR before the function is evaluated. If \text{string-expression} is not FOR BIT DATA, \text{trim-expression} must not be FOR BIT DATA.

\text{trim-expression}

An expression that specifies the characters to remove from the beginning of \text{string-expression}. The expression must return a value that is a built-in string data type that is not a LOB, or a numeric data type. If the value is not a string data type, it is implicitly cast to VARCHAR before the function is evaluated.

The default for \text{trim-expression} depends on the data type of \text{string-expression}:

- A DBCS blank if \text{string-expression} is a DBCS graphic string. For ASCII, the CCSID determines the hex value that represents a DBCS blank. For example, for Japanese (CCSID 301), X'8140' represents a DBCS blank, while for Simplified Chinese, X'A1A1' represents a DBCS blank. For EBCDIC, X'4040' represents a DBCS blank.
- A UTF-16 or UCS-2 blank (X'0020') if \text{string-expression} is a Unicode graphic string.
- A value of X'00' if \text{string-expression} is a binary string.
- Otherwise, a single byte blank. For EBCDIC, X'40' represents a blank. If not EBCDIC, X'20' represents a blank.

\text{string-expression} and \text{trim-expression} must have compatible data types. If \text{string-expression} and \text{trim-expression} have different CCSID sets, \text{trim-expression} is converted to the CCSID of \text{string-expression}.
The result of the function depends on the data type of string-expression:

- VARCHAR if string-expression is a character string. If string-expression is defined as FOR BIT DATA the result is FOR BIT DATA.
- VARGRAPHIC if string-expression is a graphic string.
- VARBINARY if string-expression is a binary string.

The length attribute of the result is the same as the length attribute of string-expression.

The actual length of the result for a character or binary string is the length of string-expression minus the number of bytes that are removed. The actual length of the result for a graphic string is the length (in the number of double byte characters) of string-expression minus the number of double byte characters removed. If all of the characters bytes are removed, the result is an empty string (the length is zero).

The result can be null; if the argument is null, the result is the null value.

The CCSID of the result is the same as that of string-expression.

Example: Use the LTRIM function to remove individual numbers in the second argument from the beginning (left side) of the first argument:

```sql
SELECT LTRIM ('123DEFG123', '321'),
       LTRIM ('12DEFG123', '321'),
       LTRIM ('123123222XYZ22', '123'),
       LTRIM ('12321', '213'),
       LTRIM ('XYX123', '321')
FROM SYSIBM.SYSDUMMY1
```

The result is 'DEFG123', 'DEFG123', 'XYZ22', '' (an empty string - all characters removed), and 'XYX123' (no characters removed).

The LTRIM function does not remove instances of '1', '2', and '3' on the right side of the string, following characters that are not '1', '2', or '3'.

Example: Use the LTRIM function to remove individual special characters in the second argument from the beginning (left side) of the first argument:

```sql
SELECT LTRIM ('[[ -78]]', '- []')
FROM SYSIBM.SYSDUMMY1
```

The result is '78]]'.

Example: Use the LTRIM function to remove dollar signs and periods in the second argument from the beginning (left side) of the first argument:

```sql
SELECT LTRIM ('...$V..$.AR', '$.')
FROM SYSIBM.SYSDUMMY1
```

The result is 'V..$AR'.

Example: Use the LTRIM function to trim full multi-byte X'D090' characters:
Assume that these strings are encoded in UTF-8.

```sql
SELECT LTRIM (X'D090D091D092', X'D090')
FROM SYSIBM.SYSDUMMY1
```

The result is X'D091D092'.

Note that the function does not remove individual bytes x'D0' and x'90'.
MAX (scalar)

The MAX scalar function returns the maximum value in a set of values.

```
MAX(expression, expression)
```

The schema is SYSIBM.

The arguments must be compatible. For more information on compatibility, refer to the compatibility matrix in Table 31 on page 151. All but the first argument can be parameter markers. There must be two or more arguments.

Each argument must be an expression that returns a value of any built-in data type other than a CLOB, DBCLOB, BLOB, ROWID, or XML.

Character string arguments and binary string arguments cannot have a length attribute greater than 32704, and graphic string arguments cannot have a length attribute greater than 16352.

The arguments are evaluated in the order in which they are specified. The result of the function is the maximum argument value.

The result can be null; if any argument is null, the result is the null value.

The selected argument is converted, if necessary, to the attributes of the result. The attributes of the result are determined using the "Rules for result data types" on page 174. If the MAX function has more than two arguments, the rules are applied to the first two arguments to determine a candidate result type. The rules are then applied to that candidate result type and the third argument to determine another candidate result type. This process continues until all arguments are analyzed and the final result type and CCSID is determined.

GREATES can be specified as a synonym for MAX.

Example 1: Assume the host variable M1 is a DECIMAL(2,1) host variable with a value of 5.5, host variable M2 is a DECIMAL(3,1) host variable with a value of 4.5, and host variable M3 is a DECIMAL(3,2) host variable with a value of 6.25. The following function returns the value 6.25.

```
MAX(:M1,:M2,:M3)
```

Example 2: Assume the host variable M1 is a CHAR(2) host variable with a value of 'AA', host variable M2 is a CHAR(3) host variable with a value of 'AA ', and host variable M3 is a CHAR(4) host variable with a value of 'AA A'. The following function returns the value 'AA A'.

```
MAX(:M1,:M2,:M3)
```
MAX_CARDINALITY

The MAX_CARDINALITY function returns a value of type BIGINT that represents the maximum number of elements that an array can contain. This value is the cardinality that was specified in the CREATE TYPE statement for an ordinary array type.

```
MAX_CARDINALITY(array-expression)
```

The schema is SYSIBM.

`array-expression`

An SQL variable, SQL parameter, or global variable of an array type, or a CAST specification that specifies an SQL variable, SQL parameter, global variable, or parameter marker as the source value.

The result of the MAX_CARDINALITY function is as follows:
- For an ordinary array, the result is the maximum number of elements that an array can contain.
- For an associative array, the result is the null value.

The data type of the result is BIGINT.

If the argument is an associative array, the result can be null and the result is the null value. Otherwise, the result cannot be null.

**Examples**

**Example 1:** Suppose that array type PHONENUMBERS and array variable RECENT_CALLS are defined as follows:

```
CREATE TYPE PHONENUMBERS AS DECIMAL(10,0) ARRAY[50];
CREATE VARIABLE RECENT_CALLS PHONENUMBERS;
```

The following statement sets LIST_SIZE to the maximum cardinality with which RECENT_CALLS was defined.

```
SET LIST_SIZE = MAX_CARDINALITY(RECENT_CALLS);
```

After the statement executes, LIST_SIZE contains 50.

MICROSECOND

The MICROSECOND function returns the microsecond part of a value.

```
MICROSECOND(expression)
```

The schema is SYSIBM.
The argument must be an expression that returns a value of one of the following built-in data types: a timestamp, a character string, a graphic string, or a numeric data type.

- If *expression* is a character or graphic string, it must not be a CLOB or DBCLOB, and its value must be a valid string representation of a timestamp with an actual length of not greater than 255 bytes. For the valid formats of string representations of times and timestamps, see "String representations of datetime values" on page 130.

- If *expression* is a number, it must be a timestamp duration. For the valid formats of timestamp durations, see "Datetime operands".

If *expression* is a timestamp with a time zone, or a valid string representation of a timestamp with a time zone, the result is determined from the UTC representation of the datetime value.

The result of the function is a large integer.

The result can be null; if the argument is null, the result is the null value.

The other rules depend on the data type of the argument:

- **If the argument is a timestamp or string representation of a timestamp**, the result is the microsecond part of the value, which is an integer between 0 and 999999. If the precision of the timestamp exceeds 6, the value is truncated.

- **If the argument is a duration**, the result is the microsecond part of the value, which is an integer between -999999 and 999999. A nonzero result has the same sign as the argument.

**Example 1**: Assume that table TABLEX contains a TIMESTAMP column named TSTMPCOL and a SMALLINT column named INTCOL. Select the microseconds part of the TSTMPCOL column of the rows where the INTCOL value is 1234:

```sql
SELECT MICROSECOND(TSTMPCOL) FROM TABLEX
WHERE INTCOL = 1234;
```

**Example 2**: The following invocations of the MICROSECOND function returns the same result:

```sql
SELECT MICROSECOND('2003-01-02-20.00.00.123456'),
       MICROSECOND('2003-01-02-12.00.00.123456-08:00'),
       MICROSECOND('2003-01-03-05.00.00.123456+09:00')
FROM SYSIBM.SYSDUMMY1;
```

For each invocation of the MICROSECOND function in this SELECT statement, the result is 123456.

When the input argument contains a time zone, the result is determined from the UTC representation of the input value. The string representations of a timestamp with a time zone in the SELECT statement all have the same UTC representation: 2003-01-02-20.00.00.123456.

**MIDNIGHT.SECONDS**

The MIDNIGHT.SECONDS function returns an integer, in the range 0 - 86400, that represents the number of seconds between midnight and the time that is specified in the argument.
The schema is SYSIBM.

The argument must be an expression that returns a value of one of the following built-in data types: a time, a timestamp, a character string, or a graphic string. If expression is a character or graphic string, it must not be a CLOB or DBCLOB, and its value must be a valid string representation of a time or timestamp with an actual length of not greater than 255 bytes. For the valid formats of string representations of times and timestamps, see "String representations of datetime values" on page 130. If expression is a timestamp with a time zone, or a valid string representation of a timestamp with a time zone, the result is determined from the UTC representation of the datetime value.

The result of the function is a large integer.

The result can be null; if the argument is null, the result is the null value.

Example 1: Find the number of seconds between midnight and 00:01:00, and midnight and 13:10:10. Assume that host variable XTIME1 has a value of '00:01:00', and that XTIME2 has a value of '13:10:10'.

```sql
SELECT MIDNIGHT_SECONDS(:XTIME1), MIDNIGHT_SECONDS(:XTIME2)
FROM SYSIBM.SYSDUMMY1;
```

This example returns 60 and 47410. Because there are 60 seconds in a minute and 3600 seconds in an hour, 00:01:00 is 60 seconds after midnight ((60 * 1) + 0), and 13:10:10 is 47410 seconds ((3600 * 13) + (60 * 10) + 10).

Example 2: Find the number of seconds between midnight and 24:00:00 of a specified day, and between midnight and 00:00:00 of the following day.

```sql
SELECT MIDNIGHT_SECONDS('2019-05-20-24:00:00'), MIDNIGHT_SECONDS('2019-05-21-00:00:00')
FROM SYSIBM.SYSDUMMY1;
```

This example returns 86400 and 0. Although the two MIDNIGHT_SECONDS arguments represent the same point in time, different values are returned.

Example 3: The following invocations of the MIDNIGHT_SECONDS function return the same result:

```sql
SELECT MIDNIGHT_SECONDS('2003-01-02-20.10.05.123456'),
        MIDNIGHT_SECONDS('2003-01-02-12.10.05.123456-08:00'),
        MIDNIGHT_SECONDS('2003-01-03-05.10.05.123456+09:00')
FROM SYSIBM.SYSDUMMY1;
```

For each invocation of the MIDNIGHT_SECONDS function in this SELECT statement, the result is 72605.

When the input argument contains a time zone, the result is determined from the UTC representation of the input value. The string representations of a timestamp with a time zone in the SELECT statement all have the same UTC representation: 2003-01-02-20.10.05.123456.
**MIN (scalar)**

The MIN scalar function returns the minimum value in a set of values.

```
MIN(expression, expression)
```

The schema is SYSIBM.

The arguments must be compatible. For more information on compatibility, refer to the compatibility matrix in Table 31 on page 151. All but the first argument can be parameter markers. There must be two or more arguments.

Each argument must be an expression that returns a value of any built-in data type other than a CLOB, DBCLOB, BLOB, ROWID, or XML.

Character string arguments and binary string arguments cannot have a length attribute greater than 32704, and graphic string arguments cannot have a length attribute greater than 16352.

The arguments are evaluated in the order in which they are specified. The result of the function is the minimum argument value.

The result can be null; if any argument is null, the result is the null value.

The selected argument is converted, if necessary, to the attributes of the result. The attributes of the result are determined using the "Rules for result data types" on page 174. If the MIN function has more than two arguments, the rules are applied to the first two arguments to determine a candidate result type. The rules are then applied to that candidate result type and the third argument to determine another candidate result type. This process continues until all arguments are analyzed and the final result type and CCSID is determined.

LEAST can be specified as a synonym for MIN.

*Example 1:* Assume the host variable M1 is a DECIMAL(2,1) host variable with a value of 5.5, host variable M2 is a DECIMAL(3,1) host variable with a value of 4.5, and host variable M3 is a DECIMAL(3,2) host variable with a value of 6.25. The following function returns the value 4.5.

```
MIN(:M1, :M2, :M3)
```

*Example 2:* Assume the host variable M1 is a CHAR(2) host variable with a value of 'AA', host variable M2 is a CHAR(3) host variable with a value of 'AAA', and host variable M3 is a CHAR(4) host variable with a value of 'AAAA'. The following function returns the value 'AA'.

```
MIN(:M1, :M2, :M3)
```
MINUTE

The MINUTE function returns the minute part of a value.

\[ \text{MINUTE} \text{(expression)} \]

The schema is SYSIBM.

The argument must be an expression that returns a value of one of the following built-in data types: a time, a timestamp, a character string, a graphic string, or a numeric data type.

- If \( \text{expression} \) is a character or graphic string, it must not be a CLOB or DBCLOB, and its value must be a valid string representation of a time or timestamp with an actual length of not greater than 255 bytes. For the valid formats of string representations of times and timestamps, see "String representations of datetime values" on page 130.
- If \( \text{expression} \) is a number, it must be a time or timestamp duration. For the valid formats of time and timestamp durations, see "Datetime operands" on page 177.

If \( \text{expression} \) is a timestamp with a time zone, or a valid string representation of a timestamp with a time zone, the result is determined from the UTC representation of the datetime value.

The result of the function is a large integer.

The result can be null; if the argument is null, the result is the null value.

The other rules depend on the data type of the argument:

- If the argument is a time, timestamp, or string representation of either, the result is the minute part of the value, which is an integer between 0 and 59.
- If the argument is a time duration or timestamp duration, the result is the minute part of the value, which is an integer between -99 and 99. A nonzero result has the same sign as the argument.
- If the argument contains a time zone, the result is the year part of the value expressed in UTC.

Example 1: Assume that a table named CLASSES contains one row for each scheduled class. Assume also that the class starting times are in the TIME column named STARTTM. Using these assumptions, select those rows in CLASSES that represent classes that start on the hour.

```sql
SELECT * FROM CLASSES
WHERE MINUTE(STARTTM) = 0;
```

Example 2: The following invocations of the MINUTE function returns the same result:

```sql
SELECT MINUTE('2003-01-02-20.10.05.123456'),
      MINUTE('2003-01-02-12.10.05.123456-08:00'),
      MINUTE('2003-01-03-05.10.05.123456+09:00')
FROM SYSIBM.SYSDUMMY1;
```
For each invocation of the MINUTE function in this SELECT statement, the result is 2.

When the input argument contains a time zone, the result is determined from the UTC representation of the input value. The string representations of a timestamp with a time zone in the SELECT statement all have the same UTC representation: 2003-01-02-20.10.05.123456. The minute portion of the UTC representation is 10.

**MOD**

The MOD function divides the first argument by the second argument and returns the remainder.

\[
\text{MOD}(\text{numeric-expression-1, numeric-expression-2})
\]

The schema is SYSIBM.

The formula used to calculate the remainder is:

\[
\text{MOD}(x,y) = x - \text{FLOOR}(x/y) \times y
\]

Where \(x/y\) is the truncated integer result of the division. The result is negative only if the first argument is negative.

Each argument must be an expression that returns a value of any built-in numeric data type.

The arguments can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECIMAL(34).

The result can be null; if any argument is null, the result is the null value.

The attributes of the result are based on the arguments as follows:

- If both arguments are large or small integers, the data type of the result is large integer.
- If both arguments are integers and at least one argument is a big integer, the data type of the result is big integer.
- If one argument is an integer and the other is a decimal, the data type of the result is decimal with the same precision and scale as the decimal argument.
- If both arguments are decimal, the data type of the result is decimal. The precision of the result is \(\min(p-s,p'-s') + \max(s,s')\), and the scale of the result is \(\max(s,s')\), where the symbols \(p\) and \(s\) denote the precision and scale of the first argument, and the symbols \(p'\) and \(s'\) denote the precision and scale of the second argument.
- If one argument is a floating-point number, and the other is not a DECIMAL, or both argument is a floating-point number, the data type of the result is double precision floating-point.

The operation is performed in floating-point. If necessary, the operands are first converted to double precision floating-point numbers. For example, an operation that involves a floating-point number and either an integer or a decimal number is performed with a temporary copy of the integer or decimal number that has
been converted to double precision floating-point. The result of a floating-point operation must be within the range of floating-point numbers.

- If either argument is a DECFLOAT, the data type of the result is DECFLOAT(34).
- If either argument is a special decimal floating point value, the general rules for arithmetic operations apply. See "General Arithmetic Operation Rules for DECFLOAT" on page 265 for more information.
- If one argument is a DECFLOAT and the second argument is zero, the result is NaN and an invalid operation condition is returned.

**Example:** Assume that $M1$ and $M2$ are two host variables. Find the remainder of dividing $M1$ by $M2$.

```sql
SELECT MOD(:M1,:M2)
FROM SYSIBM.SYSDUMMY1;
```

The following table shows the result for this function for various values of $M1$ and $M2$.

<table>
<thead>
<tr>
<th>$M1$ data type</th>
<th>$M1$ value</th>
<th>$M2$ data type</th>
<th>$M2$ value</th>
<th>Result of MOD (:M1,:M2)</th>
</tr>
</thead>
<tbody>

<td>DECFLOAT</td>
<td>-INFINITY</td>
<td>-0</td>
</tr>
</tbody>
</table>

### MONTH

The MONTH function returns the month part of a value.

```
MONTH(expression)
```

The schema is SYSIBM.

The argument must be an expression that returns one of the following built-in data types: a date, a timestamp, a character string, a graphic string, or a numeric data type.

- If `expression` is a character or graphic string, it must not be a CLOB or DBCLOB, and its value must be a valid string representation of a date or timestamp with an actual length of not greater than 255 bytes. For the valid formats of string representations of dates and timestamps, see "String representations of datetime values" on page 130.

- If `expression` is a number, it must be a date or timestamp duration. For the valid formats of date and timestamp durations, see "Datetime operands" on page 177.
If `expression` is a timestamp with a time zone, or a valid string representation of a timestamp with a time zone, the result is determined from the UTC representation of the datetime value.

The result of the function is a large integer.

The result can be null; if the argument is null, the result is the null value.

The other rules depend on the data type of the argument:

If the argument is a date, timestamp, or string representation of either, the result is the month part of the value, which is an integer between 1 and 12.

If the argument is a date duration or timestamp duration, the result is the month part of the value, which is an integer between -99 and 99. A nonzero result has the same sign as the argument.

If the argument contains a time zone, the result is the year part of the value expressed in UTC.

**Example 1**: Select all rows in the sample table DSN8C10.EMP for employees who were born in May:

```sql
SELECT * FROM DSN8C10.EMP
WHERE MONTH(BIRTHDATE) = 5;
```

**Example 2**: The following invocations of the MONTH function returns the same result:

```sql
SELECT MONTH('2003-01-02-20.10.05.123456'),
    MONTH('2003-01-02-12.10.05.123456-08:00'),
    MONTH('2003-01-03-05.10.05.123456+09:00')
FROM SYSIBM.SYSDUMMY1;
```

For each invocation of the MONTH function in this SELECT statement, the result is 1.

When the input argument contains a time zone, the result is determined from the UTC representation of the input value. The string representations of a timestamp with a time zone in the SELECT statement all have the same UTC representation: 2003-01-02-20.10.05.123456. The month portion of the UTC representation is 1.

**MONTHS_BETWEEN**

The MONTHS_BETWEEN function returns an estimate of the number of months between two arguments.

```sql
MONTHS_BETWEEN(expression1, expression2)
```

The schema is SYSIBM.

`expression1` or `expression2`

Expressions that return a value of any of the following built-in data types: a date, a timestamp, a character string, or a graphic string. If either expression is a character or graphic string, it must not be a CLOB or DBCLOB, and its value must be a valid string representation of a date or timestamp with an actual length that is not greater than 255 bytes. A time zone in a string representation
of a timestamp is ignored. For the valid formats of string representations of
dates and timestamps, see “String representations of datetime values” on page

If \textit{expression1} is a \textsc{timestamp} \textsc{with time zone} value, \textit{expression1} is first cast to
\textsc{timestamp} \textsc{without time zone} with the same precision as \textit{expression1}. If
\textit{expression2} is a \textsc{timestamp} \textsc{with time zone} value, \textit{expression2} is first cast to
\textsc{timestamp} \textsc{without time zone} with the same precision as \textit{expression2}.

If \textit{expression1} represents a date that is later than \textit{expression2}, the result is positive. If
\textit{expression1} represents a date that is earlier than \textit{expression2}, the result is negative.

- If \textit{expression1} and \textit{expression2} represent dates or timestamps with the same day of
the month, or both arguments represent the last day of their respective months,
the result is a the whole number difference based on the year and month values,
ignoring any time portions of timestamp arguments.

- Otherwise, the whole number part of the result is the difference based on the
year and month values. The fractional part of the result is calculated from the
remainder based on an assumption that every month has 31 days. If either
argument represents a timestamp, the arguments are effectively processed as
timestamps with maximum precision, and the time portions of these values are
also considered when determining the result.

The result of the function is a \textsc{decimal}(31,15).

The result can be null; if any argument is null, the result is the null value.

\textit{Examples 1}: The following example calculates the months between two dates:

\begin{verbatim}
SELECT MONTHS_BETWEEN ('2008-01-17', '2008-02-17')
  AS MONTHS_BETWEEN
FROM SYSIBM.SYSDUMMY1;
\end{verbatim}

The results of this statement are similar to the following results:

\begin{verbatim}
MONTHS_BETWEEN
------------------------
-1.000000000000000
\end{verbatim}

\textit{Examples 2}: The following example calculates the months between two dates:

\begin{verbatim}
SELECT MONTHS_BETWEEN ('2008-02-20', '2008-01-17')
  AS MONTHS_BETWEEN
FROM SYSIBM.SYSDUMMY1;
\end{verbatim}

The results of this statement are similar to the following results:

\begin{verbatim}
MONTHS_BETWEEN
------------------------
1.096774193548387
\end{verbatim}

\textit{Example 3}: Calculate the number of months that project AD3100 will take. Assume
that the start date is 1982-01-01 and the end date is 1983-02-01:

\begin{verbatim}
SELECT MONTHS_BETWEEN (PRENDATE, PRSDATE)
  FROM PROJECT
WHERE PROJNO='AD3100';
\end{verbatim}

The result is 13.000000000000000.
Example 4: The following table illustrates the use of the MONTHS_BETWEEN function in certain situations:

<table>
<thead>
<tr>
<th>Value for expression1</th>
<th>Value for expression2</th>
<th>Value returned by MONTHS_BETWEEN (expression1,expression2)</th>
<th>Value returned by ROUND (MONTHS_BETWEEN (expression1,expression2))*31,2</th>
</tr>
</thead>
<tbody>
<tr>
<td>2005-02-02</td>
<td>2005-01-01</td>
<td>1.032258064516129</td>
<td>32.00</td>
</tr>
<tr>
<td>2007-11-01-09.00.00.000000</td>
<td>2007-12-07-14.30.12.12345</td>
<td>-1.200945386592741</td>
<td>-37.23</td>
</tr>
<tr>
<td>2007-03-15</td>
<td>2007-02-20</td>
<td>0.8387096774193540</td>
<td>26.000101</td>
</tr>
<tr>
<td>2008-02-29</td>
<td>2008-02-28-12.00.00</td>
<td>0.16129032258064</td>
<td>0.50</td>
</tr>
<tr>
<td>2008-03-29</td>
<td>2008-02-29</td>
<td>1.00000000000000000000</td>
<td>31.00</td>
</tr>
<tr>
<td>2008-03-30</td>
<td>2008-02-29</td>
<td>1.032258064516129</td>
<td>32.00</td>
</tr>
<tr>
<td>2008-03-31</td>
<td>2008-02-29</td>
<td>1.00000000000000000000</td>
<td>31.000101</td>
</tr>
</tbody>
</table>

Notes:
1. The time difference is ignored because the day of the month is the same for both values.
2. The result is not 23 because, even though February has 28 days, the assumption is that all months have 31 days.
3. The result is not 33 because both dates are the last day of their respective month, and so the result is only based on the year and month portions.

**MQREAD**

The MQREAD function returns a message from a specified MQSeries location without removing the message from the queue.

```sql
MQREAD( receive-service, service-policy )
```

The schema is DB2MQ.

The MQREAD function returns a message from the MQSeries location that is specified by `receive-service`, using the quality-of-service policy that is defined in `service-policy`. Performing this operation does not remove the message from the queue that is associated with `receive-service`, but instead returns the message at the beginning of the queue.

**receive-service**

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be an empty string or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression must refer to a service point that is defined in the DB2MQ.MQSERVICE table. A service point is a logical end-point from which a message is sent or received. A service point definition includes the name of the MQSeries queue manager and the name of the queue. See *MQSeries Application Messaging Interface* for more details.

If `receive-service` is not specified or is the null value, DB2.DEFAULT.POLICY is used.
**service-policy**

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be an empty string or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression must refer to a service policy that is defined in the DB2MQ.MQPOLICY table. A service policy specifies a set of quality-of-service options that are to be applied to this messaging operation. These options include message priority and message persistence. See *MQSeries Application Messaging Interface* for more details.

If `service-policy` is not specified or is the null value, DB2.DEFAULT.POLICY is used.

The result of the function is a varying-length string with a length attribute of 4000. The result can be null. If no messages are available to be returned, the result is the null value.

The CCSID of the result is the system CCSID that was in effect at the time that the MQSeries function was installed into Db2.

*Example 1:* Retrieve the message at the beginning of the queue that is specified by the default service (Db2.DEFAULT.SERVICE), using the default policy (Db2.DEFAULT.POLICY).

```sql
SELECT MQREAD()
FROM SYSIBM.SYSDUMMY1;
```

The message at the beginning of the queue specified by the default server and using the default policy is returned as VARCHAR(4000).

*Example 2:* Read the message from the beginning of the queue specified by the service MYSERVICE, using the default policy (Db2.DEFAULT.POLICY).

```sql
SELECT MQREAD('MYSERVICE')
FROM SYSIBM.SYSDUMMY1;
```

The message at the beginning of the queue specified by MYSERVICE and using Db2.DEFAULT.POLICY is returned as VARCHAR(4000).

*Example 3:* Read the message from the beginning of the queue specified by the service MYSERVICE, using the policy MYPOLICY.

```sql
SELECT MQREAD('MYSERVICE','MYPOLICY')
FROM SYSIBM.SYSDUMMY1;
```

The message at the beginning of the queue specified by MYSERVICE and using the policy MYPOLICY is returned as VARCHAR(4000).

**MQREADCLOB**

The MQREADCLOB function returns a message from a specified MQSeries location without removing the message from the queue.
The schema is DB2MQ.

The MQREADCLOB function returns a message from the MQSeries location that is specified by receive-service, using the quality-of-service policy that is defined in service-policy. Performing this operation does not remove the message from the queue that is associated with receive-service, but instead returns the message at the beginning of the queue.

**receive-service**

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be an empty string or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression must refer to a service point that is defined in the DB2MQ.MQSERVICE table. A service point is a logical end-point from which a message is sent or received. A service point definition includes the name of the MQSeries queue manager and the name of the queue. See MQSeries Application Messaging Interface for more details.

If receive-service is not specified or is the null value, DB2.DEFAULT.POLICY is used.

**service-policy**

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be an empty string or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression must refer to a service policy that is defined in the DB2MQ.MQPOLICY table. A service policy specifies a set of quality-of-service options that are to be applied to this messaging operation. These options include message priority and message persistence. See MQSeries Application Messaging Interface for more details.

If service-policy is not specified or is the null value, DB2.DEFAULT.POLICY is used.

The result of the function is a CLOB with a length attribute of 1 MB. The result can be null. If no messages are available to be returned, the result is the null value.

The CCSID of the result is the system CCSID that was in effect at the time that the MQSeries function was installed into Db2.

**Example 1:** Read the message from the beginning of the queue specified by the default service (Db2.DEFAULT.SERVICE), using the default policy (Db2.DEFAULT.POLICY).

```
SELECT MQREADCLOB()
FROM SYSTBM.SYSDUMMY1;
```

The message at the beginning of the queue specified by the default service and using the default policy is returned as a CLOB.
Example 2: Read the message from the beginning of the queue specified by the service MYSERVICE, using the default policy (Db2.DEFAULTPOLICY).

```
SELECT MQREADCLOB('MYSERVICE')
FROM SYSIBM.SYSDUMMY1;
```

The message at the beginning of the queue specified by MYSERVICE and using the default policy is returned as a CLOB.

Example 3: Read the message from the beginning of the queue specified by the service MYSERVICE, using the policy MYPOLICY:

```
SELECT MQREADCLOB('MYSERVICE', 'MYPOLICY')
FROM SYSIBM.SYSDUMMY1;
```

The message at the beginning of the queue specified by MYSERVICE and using the policy MYPOLICY is returned as a CLOB.

**MQRECEIVE**

The MQRECEIVE function returns a message from a specified MQSeries location and removes the message from the queue.

```
MQRECEIVE( receive-service, service-policy, correl-id )
```

The schema is DB2MQ.

The MQRECEIVE function returns a message from the MQSeries location specified by *receive-service*, using the quality-of-service policy defined in *service-policy*. Performing this operation removes the message from the queue that is associated with *receive-service*.

**receive-service**

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be an empty string or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression must refer to a service point that is defined in the DB2MQ.MQSERVICE table. A service point is a logical end-point from which a message is sent or received. A service point definition includes the name of the MQSeries queue manager and the name of the queue. See *MQSeries Application Messaging Interface* for more details.

If *receive-service* is not specified or is the null value, Db2.DEFAULTPOLICY is used.

**service-policy**

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be an empty string or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression must refer to a service policy that is defined in the DB2MQ.MQPOLICY table. A
service policy specifies a set of quality-of-service options that are to be applied to this messaging operation. These options include message priority and message persistence. See *MQSeries Application Messaging Interface* for more details.

If *service-policy* is not specified or is the null value, *DB2.DEFAULT.POLICY* is used.

**correl-id**

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The expression must have an actual length that is no greater than 24 bytes. The value of the expression specifies the correlation identifier that is associated with this message. A correlation identifier is often specified in request-and-reply scenarios to associate requests with replies. Only those messages with a matching correlation identifier are returned.

A fixed length string with trailing blanks is considered a valid value. However, when the *correl-id* is specified on another request such as MQSEND, the *correl-id* must be specified the same to be recognized as a match. For example, specifying a value of 'test' for *correl-id* for this function does not match a *correl-id* value of 'test ' (with trailing blanks) specified earlier on an MQSEND request.

If *correl-id* is not specified, is an empty string, or is the null value, a correlation identifier is not used, and the message at the beginning of the queue is returned.

The result of the function is a varying-length string of length attribute of 4000. The result can be null. The result is null if no messages are available to return.

The CCSID of the result is the system CCSID that was in effect at the time that the MQSeries function was installed into Db2.

**Example 1:** Retrieve the message from beginning of the queue specified by the default service (Db2.DEFAULSERVICE), using the default policy (Db2.DEFAULTPOLICY).

```sql
SELECT MQRECEIVE()
FROM SYSIBM.SYSDUMMY1;
```

The message at the beginning of the queue is returned as VARCHAR(4000) and is deleted from the queue. The queue is specified by the default service and using the default policy.

**Example 2:** Retrieve the first message from the beginning of the queue specified by the service MYSERVICE, using the default policy, Db2.DEFAULTPOLICY.

```sql
SELECT MQRECEIVE('MYSERVICE')
FROM SYSIBM.SYSDUMMY1;
```

The message at the beginning of the queue is returned as VARCHAR(4000) and is deleted from the queue. The queue is specified by the service MYSERVICE using the default policy, Db2.DEFAULTPOLICY.

**Example 3:** Retrieve the message from the beginning of the queue specified by the service MYSERVICE, using the policy MYPOLICY.

```sql
SELECT MQRECEIVE('MYSERVICE','MYPOLICY')
FROM SYSIBM.SYSDUMMY1;
```
The message at the beginning of the queue is returned as VARCHAR(4000) and the message is deleted from the queue. The queue is specified by the service MYSERVICE using the policy MYPOLICY.

Example 4: Retrieve the first message with a correlation identifier that matches '1234' from the beginning of the queue specified by the service MYSERVICE, using the policy MYPOLICY.

```sql
SELECT MQRECEIVE('MYSERVICE','MYPOLICY','1234')
FROM SYSIBM.SYSDUMMY1;
```

The first message with CORRELID of '1234' from the beginning of the queue is returned as VARCHAR(4000) and is deleted from the queue. The queue is specified by MYSERVICE and using MYPOLICY.

**MQRECEIVECLOB**

The MQRECEIVECLOB function returns a message from a specified MQSeries location and removes the message from the queue.

![Diagram of MQRECEIVECLOB function]

The schema is DB2MQ.

The MQRECEIVECLOB function returns a message from the MQSeries location that is specified by `receive-service`, using the quality-of-service policy that is defined in `service-policy`. Performing this operation removes the message from the queue that is associated with `receive-service`.

**receive-service**

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be an empty string or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression must refer to a service point that is defined in the DB2MQ.MQSERVICE table. A service point is a logical end-point from which a message is sent or received. A service point definition includes the name of the MQSeries queue manager and the name of the queue. See MQSeries Application Messaging Interface for more details.

If `receive-service` is not specified or is the null value, DB2.DEFAULT.POLICY is used.

**service-policy**

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be an empty string or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression must refer to a service policy that is defined in the DB2MQ.MQPOLICY table. A service policy specifies a set of quality-of-service options that are to be applied...
to this messaging operation. These options include message priority and message persistence. See MQSeries Application Messaging Interface for more details.

If service-policy is not specified or is the null value, DB2.DEFAULT.POLICY is used.

correl-id
An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The expression must have an actual length that is no greater than 24 bytes. The value of the expression specifies the correlation identifier that is associated with this message. A correlation identifier is often specified in request-and-reply scenarios to associate requests with replies. Only those messages with a matching correlation identifier are returned.

A fixed length string with trailing blanks is considered a valid value. However, when the correl-id is specified on another request such as MQSEND, the correl-id must be specified the same to be recognized as a match. For example, specifying a value of 'test' for correl-id for this function does not match a correl-id value of 'test ' (with trailing blanks) specified earlier on an MQSEND request.

If correl-id is not specified, is an empty string, or is the null value, a correlation identifier is not used, and the message at the beginning of the queue is returned.

The result of the function is a CLOB with a length attribute of 1 MB. The result can be null. If no messages are available to be returned, the result is the null value.

The CCSID of the result is the system CCSID that was in effect at the time that the MQSeries function was installed into Db2.

Example 1: Retrieve the message from the beginning of the queue specified by the default service (Db2.DEFAULT.SERVICE), using the default policy (Db2.DEFAULT.POLICY).

```sql
SELECT MQRERECEIVECLOB()
FROM SYSIBM.SYSDUMMY1;
```

The message at the beginning of the queue is returned as a CLOB and is deleted from the queue. The queue is specified by the default service and using the default policy.

Example 2: Retrieve the message from the beginning of the queue specified by the service MYSERVICE, using the policy (Db2.DEFAULT.POLICY).

```sql
SELECT MQRERECEIVECLOB('MYSERVICE')
FROM SYSIBM.SYSDUMMY1;
```

The message at the beginning of the queue is returned as a CLOB and is deleted from the queue. The queue is specified by MYSERVICE and using the default policy.

Example 3: Retrieve the message from the beginning of the queue specified by the service MYSERVICE, using the policy MYPOLICY.

```sql
SELECT MQRERECEIVECLOB('MYSERVICE','MYPOLICY')
FROM SYSIBM.SYSDUMMY1;
```
The message at the beginning of the queue is returned as a CLOB and is deleted from the queue. The queue is specified by MYSERVICE and using the policy MYPOLICY.

Example 4: Retrieve the first message from the beginning of the queue with a correlation identifier that matches '1234' from the queue specified by the service MYSERVICE, using the policy MYPOLICY.

```
SELECT MQRECEIVECLOB('MYSERVICE','MYPOLICY','1234')
FROM SYSIBM.SYSDUMMY1;
```

The first message at the beginning of the queue with a correlation identifier with '1234' is returned as a CLOB and is deleted from the queue. The queue is specified by MYSERVICE and using the policy MYPOLICY.

**MQSEND**

The MQSEND function sends data to a specified MQSeries location.

```
MQSEND(send-service, msg-data, service-policy, correl-id)
```

**Notes:**

1. `correl-id` cannot be specified unless a send service and a service policy are also specified.

The schema is DB2MQ.

The MQSEND function sends the data that is contained in `msg-data` to the MQSeries location that is specified by `send-service`, using the quality-of-service policy that is defined in `service-policy`.

**send-service**

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be an empty string or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression must refer to a service point that is defined in the DB2MQ.MQSERVICE table. A service point is a logical end-point from which a message is sent or received. A service point definition includes the name of the MQSeries queue manager and the name of the queue. See *MQSeries Application Messaging Interface* for more details.

If `send-service` is not specified or is the null value, Db2.DEFAULTSERVICE is used.

**service-policy**

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be an empty string or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression must refer to a service policy that is defined in the DB2MQ.MQPOLICY table. A service policy specifies a set of quality-of-service options that are to be applied.
to this messaging operation. These options include message priority and message persistence. See MQSeries Application Messaging Interface for more details.

If service-policy is not specified or is the null value, DB2.DEFAULT_POLICY is used.

**msg-data**
An expression that returns a value that is a built-in character string data type. If the expression is a CLOB, the value must not be longer than 1 MB. Otherwise, the value must not be longer than 4000 bytes. The value of the expression is the message data that is to be sent via MQSeries. A null value, an empty string, and a fixed length string with trailing blanks are all considered valid values.

**correl-id**
An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The expression must have an actual length that is no greater than 24 bytes. The value of the expression specifies the correlation identifier that is associated with this message. A correlation identifier is often specified in request-and-reply scenarios to associate requests with replies. correl-id must not be specified unless send-service and service-policy are also specified.

A fixed length string with trailing blanks is considered a valid value. However, when the correl-id is specified on another request such as MQRECEIVE, the correl-id must be specified the same to be recognized as a match. For example, specifying a value of ‘test’ for correl-id on MQSEND does not match a correl-id value of ‘test ’ (with trailing blanks) specified subsequently on an MQRECEIVE request.

If correl-id is not specified, is an empty string, or is the null value, a correlation identifier is not sent.

The returned value is a varying-length character string with the value ‘1’ if function execution was successful, or an error message if function execution was unsuccessful.

The CCSID of the result is the system CCSID that was in effect at the time that the MQSeries function was installed into Db2.

**Notes**

The application needs to check the SQLCODE after issuing the MQSEND function. If the SQLCODE is not 0, the application needs to retrieve and handle the returned error message.

**Examples**

*Example 1:* Send the string "Testing msg" to the default service (Db2.DEFAULTSERVICE), using the default policy (Db2.DEFAULTPOLICY) and no correlation identifier.

```
SELECT MQSEND('Testing msg')
FROM SYSIBM.SYSDUMMY1;
```

The message is sent to the default service, using the default policy.

*Example 2:* Send the message 'Testing 345' to the service MYSERVICE, using the policy MYPOLICY, with no correlation identifier.
SELECT MQSEND('MYSERVICE', 'MYPOLICY', 'Testing 345')
FROM SYSIBM.SYSDUMMY1;

The message 'Testing 345' is sent to the MYSERVICE service, using the policy MYPOLICY.

Example 3: Send the message 'Testing 123' to the service MYSERVICE, using the policy MYPOLICY and the correlation identifier 'TEST3':
SELECT MQSEND('MYSERVICE', 'MYPOLICY', 'Testing 123', 'TEST3')
FROM SYSIBM.SYSDUMMY1;

The message 'Testing 123' is sent to the service MYSERVICE, using the policy MYPOLICY and the correlation identifier 'TEST3'.

Example 4: Send the message 'Testing 901' to the service "MYSERVICE", using the default policy (Db2.DEFAULTPOLICY), and no correlation identifier.
SELECT MQSEND('MYSERVICE', 'Testing 901')
FROM SYSIBM.SYSDUMMY1;

The message 'Testing 901' is sent to the service MYSERVICE, using the default policy (Db2.DEFAULTPOLICY).

MULTIPLY_ALT

The MULTIPLY_ALT scalar function returns the product of the two arguments. This function is an alternative to the multiplication operator and is especially useful when the sum of the precisions of the arguments exceeds 31.

```
MULTIPLY_ALT(exact-numeric-expression-1, exact-numeric-expression-2)
```

The schema is SYSIBM.

Each argument must be an expression that returns the value of one of the following built-in numeric data types: DECIMAL, BIGINT, INTEGER, or SMALLINT.

The result of the function is a DECIMAL. The precision and scale of the result are determined as follows, using the symbols \(p\) and \(s\) to denote the precision and scale of the first argument, and the symbols \(p'\) and \(s'\) to denote the precision and scale of the second argument.

- The precision is \(\text{MIN}(31, p+p')\)
- The scale is:
  - 0 if the scale of both arguments is 0
  - \(\text{MIN}(31, s+s')\) if \(p+p'\) is less than or equal to 31
  - \(\text{MAX}(\text{MIN}(3, s+s'), 31-(p-s+p'-s')\) if \(p+p'\) is greater than 31.

The result can be null; if any argument is null, the result is the null value.

The MULTIPLY_ALT function is a better choice than the multiplication operator when performing decimal arithmetic where you want a scale of at least 3 and the sum of the precisions exceeds 31. In these cases, the internal computation is

544 SQL Reference
performed so that overflows are avoided and then assigned to the result type value using truncation for any loss of scale in the final result. Note that the possibility of overflow of the final result is still possible when the scale is 3.

The following table compares the result data types from the MULTIPLY_ALT function with the result data type of the multiplication operator when decimal data is used:

<table>
<thead>
<tr>
<th>Type of Argument1</th>
<th>Type of Argument2</th>
<th>Result using MULTIPLY_ALT</th>
<th>Result using multiplication operator</th>
</tr>
</thead>
<tbody>
<tr>
<td>DECIMAL(31,3)</td>
<td>DECIMAL(15,8)</td>
<td>DECIMAL(31,3)</td>
<td>DECIMAL(31,11)</td>
</tr>
<tr>
<td>DECIMAL(26,23)</td>
<td>DECIMAL(10,1)</td>
<td>DECIMAL(31,19)</td>
<td>DECIMAL(31,24)</td>
</tr>
<tr>
<td>DECIMAL(18,17)</td>
<td>DECIMAL(20,19)</td>
<td>DECIMAL(31,29)</td>
<td>DECIMAL(31,31)</td>
</tr>
<tr>
<td>DECIMAL(16,3)</td>
<td>DECIMAL(17,8)</td>
<td>DECIMAL(31,9)</td>
<td>DECIMAL(31,11)</td>
</tr>
<tr>
<td>DECIMAL(26,5)</td>
<td>DECIMAL(11,0)</td>
<td>DECIMAL(31,3)</td>
<td>DECIMAL(31,5)</td>
</tr>
<tr>
<td>DECIMAL(21,1)</td>
<td>DECIMAL(15,1)</td>
<td>DECIMAL(31,2)</td>
<td>DECIMAL(31,2)</td>
</tr>
</tbody>
</table>

**NEXT_DAY**

The NEXT_DAY function returns a datetime value that represents the first weekday, named by string-expression, that is later than the date in expression.

The schema is SYSIBM.

If expression is a timestamp or valid string representation of a timestamp, the timestamp value has the same hours, minutes, seconds, and partial seconds as expression. If expression is a date, or a valid string representation of a date, then the hours, minutes, seconds, and partial seconds value of the result is 0.

**expression**

An expression that returns one of the following built-in data types: a date, a timestamp, a character string, or a graphic string. If expression is a character or graphic string, it must not be a CLOB or DBCLOB, and its value must be a valid string representation of a date or timestamp with an actual length of not greater than 255 bytes. A time zone in a string representation of a timestamp is ignored. For the valid formats of string representations of dates and timestamps, see "String representations of datetime values" on page 130.

If expression does not have data type TIMESTAMP WITHOUT TIME ZONE, expression is cast as follows:

- If expression is a TIMESTAMP WITH TIME ZONE value, expression is cast to TIMESTAMP WITHOUT TIME ZONE, with the same precision as expression.
- Otherwise, expression is cast to TIMESTAMP(6) WITHOUT TIME ZONE.

**string-expression**

An expression that returns a built-in character or graphic string data type that is not a LOB. For portability across the platforms, the value should compare
equal to the full name of a day of the week or should compare equal to the abbreviation of a day of the week. For example:

<table>
<thead>
<tr>
<th>Day of week</th>
<th>Abbreviation</th>
</tr>
</thead>
<tbody>
<tr>
<td>MONDAY</td>
<td>MON</td>
</tr>
<tr>
<td>TUESDAY</td>
<td>TUE</td>
</tr>
<tr>
<td>WEDNESDAY</td>
<td>WED</td>
</tr>
<tr>
<td>THURSDAY</td>
<td>THU</td>
</tr>
<tr>
<td>FRIDAY</td>
<td>FRI</td>
</tr>
<tr>
<td>SATURDAY</td>
<td>SAT</td>
</tr>
<tr>
<td>SUNDAY</td>
<td>SUN</td>
</tr>
</tbody>
</table>

The minimum length of the input value is the length of the abbreviation. Leading blanks must not be specified in `string-expression`. Trailing blanks are trimmed from `string-expression`. The resulting value is folded to uppercase. Any characters other than blank that immediately follow a valid abbreviation are ignored.

If `expression` is a timestamp, the result is a `TIMESTAMP WITHOUT TIME ZONE` value with the same precision as `expression`. If `expression` is `DATE`, the result is a `DATE` value. Otherwise, the result is a `TIMESTAMP(6) WITHOUT TIME ZONE` value.

Any hours, minutes, seconds, or fractional seconds information that is included in `expression` is not changed by the function. If `expression` is a string that represents a date, the time information in the resulting timestamp value is all set to zero.

The result can be null; if any argument is null, the result is the null value.

The result CCSID is the appropriate CCSID of the argument encoding scheme and the result subtype is the appropriate subtype of the CCSID.

**Example 1:** Set the host variable `NEXTDAY` with a timestamp for the date of the Tuesday that follows April 24, 2007.

```sql
SET :NEXTDAY = NEXT_DAY(TIMESTAMP '2007-04-24-00.00.00.000000', 'TUESDAY');
```

The host variable `NEXTDAY` is set with the value of '2007-05-01-00.00.00.000000', since April, 24, 200 is itself a Tuesday'.

**Example 2:** Set the host variable `vNEXTDAY` with the date of the first Monday in May, 2007. Assume the host variable `vDAYOFWEEK` = 'MON':

```sql
SET :vNEXTDAY = NEXT_DAY(LAST_DAY(CURRENT_DATE), :vDAYOFWEEK);
```

The host variable `vNEXTDAY` is set with the value of '2007-05-07', assuming that the value of the `CURRENT_DATE` special register is '2007-04-24'.

**NORMALIZE_DECFLOAT**

The `NORMALIZE_DECFLOAT` function returns a `DECFLOAT` value that is the result of the argument, set to its simplest form. That is, a non-zero number that has any trailing zeros in the coefficient has those zeros removed by dividing the coefficient by the appropriate power of ten and adjusting the exponent accordingly. A zero has its exponent set to 0.
The schema is SYSIBM.

decfloat-expression
The argument must be an expression that returns a DECFLOAT value.
decfloat-expression can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34).

If the argument is a special decimal floating point value then the general rules for arithmetic operations apply. See “General Arithmetic Operation Rules for DECFLOAT” on page 265 for more information.

The result of the function is a DECFLOAT(16) value if the data type of decfloat-expression is DECFLOAT(16). Otherwise, the result of the function is a DECFLOAT(34) value.

The result can be null; if the argument is null, the result is the null value.

Examples: The following examples show the result of using the NORMALIZE_DECFLOAT function on various DECFLOAT values:

<table>
<thead>
<tr>
<th>Expression</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>NORMALIZE_DECFLOAT(DECFLOAT(2.1))</td>
<td>2.1</td>
</tr>
<tr>
<td>NORMALIZE_DECFLOAT(DECFLOAT(-2.0))</td>
<td>-2</td>
</tr>
<tr>
<td>NORMALIZE_DECFLOAT(DECFLOAT(1.2))</td>
<td>1.2</td>
</tr>
<tr>
<td>NORMALIZE_DECFLOAT(DECFLOAT(-1.2))</td>
<td>-1.2E+2</td>
</tr>
<tr>
<td>NORMALIZE_DECFLOAT(DECFLOAT(1.2E+2))</td>
<td>1.2E+2</td>
</tr>
<tr>
<td>NORMALIZE_DECFLOAT(DECFLOAT(0.0))</td>
<td>0</td>
</tr>
<tr>
<td>NORMALIZE_DECFLOAT(NAN)</td>
<td>-NAN</td>
</tr>
<tr>
<td>NORMALIZE_DECFLOAT(-INFINITY)</td>
<td>-INFINITY</td>
</tr>
</tbody>
</table>

NORMALIZE_STRING
The NORMALIZE_STRING function takes a Unicode string argument and returns a normalized string that can be used for comparison.

The NORMALIZE_STRING function can convert two strings that look the same (such as Å, which can be encoded in UTF-16 as X'00C5' and as X'0041030a') but might not be encoded using the same Unicode code point, to a normalized form that can be compared.
string data type that is either Unicode UTF-8 or Unicode UTF-16, and is not a LOB. The CAST specification can be used to convert ASCII or EBCDIC data to Unicode for use with this function.

**NFC, NFD, NFKC, or NFKD**

Specifies the normalized form:
- **NFC**  Canonical Decomposition followed by Canonical Composition
- **NFD**  Canonical Decomposition
- **NFKC** Compatibility Decomposition followed by Canonical Composition
- **NFKD** Compatibility Decomposition

**integer**

The length attribute, in bytes if the string is a character string, or in double byte code points if the string is a graphic string, for the resulting variable length string. The value must be an integer between 1 and 32704 if the source string is character, or 16352 if the source string is graphic.

The result of the function is a varying length string with a data type that depends on the data type of `unicode-string`:
- **VARCHAR** if `unicode-string` is CHAR or VARCHAR
- **VARGRAPHIC** if `unicode-string` is GRAPHIC or VARGRAPHIC

The CCSID of the result is the same as the CCSID of `unicode-string`.

The length attribute of the result depends on whether `integer` is specified. If `integer` is specified, the length attribute of the result is `integer` bytes or double byte code points. If `integer` is not specified, the length attribute of the result is \( \min(3 \times n, 32704) \) for character strings, or \( \min(3 \times n, 16352) \) for graphic strings, where \( n \) is the length attribute of the source.

The result can be null; if the first argument is null, the result is the null value.

**Example 1:** In the following example, "ábc" is normalized to normalization form NFC:

```sql
SET :hv1 = NORMALIZE_STRING('ábc',NFC) -- x'0061030100620063'
```

`hv1` is set to 'ábc' -- X'006100620063'. Using normalization form NFC, the two code-point sequence X'00610301', which represents the character 'á', is normalized to X'00E1' which is also the pre-composed equivalent of X'00610301'.

**Example 2:** In the following example, "ábc" is normalized to normalization form NFD.

```sql
SET :hv1 = NORMALIZE_STRING('ábc',NFD) -- x'00E100620063'
```

`hv1` is set to 'ábc' -- X'0061030100620063'. Using normalization form NFD, the code point X'00E1' is decomposed into the two code-point sequence X'00610301', which consists of the Latin lower case letter A and the combining acute accent character.

**NULLIF**

The NULLIF function returns the null value if the two arguments are equal; otherwise, it returns the value of the first argument.
The schema is SYSIBM.

The two arguments must be compatible. The arguments can be of either a built-in or user-defined distinct type. Neither argument can be a BLOB, CLOB, DBCLOB, or XML. Character-string and graphic-string arguments are compatible with datetime values. For more information on compatibility, refer to the compatibility matrix in Table 31 on page 151.

If there are any mixed character string or graphic string and numeric arguments, the string value is implicitly cast to a DECFLOAT(34) value.

The attributes of the result are the attributes of the first argument.

The result of using NULLIF(e1,e2) is the same as using the CASE expression:

```sql
CASE WHEN e1=e2 THEN NULL ELSE e1 END
```

When e1=e2 evaluates to unknown because one or both arguments is null, CASE expressions consider the evaluation not true. In this case, NULLIF returns the value of the first argument.

**Example:** Assume that host variables PROFIT, CASH, and LOSSES have decimal data types with the values of 4500.00, 500.00, and 5000.00 respectively. The following function returns a null value:

```sql
NULLIF (:PROFIT + :CASH , :LOSSES)
```

**NVL**

The NVL function returns the first argument that is not null.

The schema is SYSIBM.

The NVL function is a synonym for the COALESCE function.

**OVERLAY**

The OVERLAY function returns a string that is composed of one argument that is inserted into another argument at the same position where some number of bytes have been deleted.
The schema is SYSIBM.

The OVERLAY function returns a string where a substring of length, beginning at start has been deleted from source-string, and where insert-string has been inserted into source-string beginning at start. If the value of start plus length is greater than the length of source-string, the substring that is deleted is from start to the end of source-string.

If the length of the result string exceeds the maximum for the return type, an error is returned.

The OVERLAY function is identical to the INSERT function, except that the length argument is optional.

source-string
An expression that specifies the source string. The expression must return a value that is a built-in character string, graphic string, or binary string data type that is not a LOB.

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type. The actual length of the string must be greater than or equal to 1 byte and less than or equal to 32704 bytes.

insert-string
An expression that specifies the string that is inserted into source-string, starting at the position that is identified by start. insert-string must return a value that is a built-in character string, graphic string, or binary string data type that is not a LOB. source-string and insert-string must have compatible data types.

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type.

start
An expression that returns an integer. The integer specifies the starting point within the source string where the deletion of bytes and the insertion of another string is to begin. The value of the integer must be in the range of 1 to the length of source-string plus one. If OCTETS is specified and the result is graphic data, the value must be an odd value between 1 and twice the length of source-string plus one.

The argument can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34) which is then assigned to an INTEGER value.

length
An expression that specifies the length of the string to replace in source-string starting at start. length must be an expression that returns a value of the built-in INTEGER data type. length is expressed in the string unit specified, and the value must be in the range of 0 to the length of source-string. If OCTETS is specified and the result is graphic data, length must be even and be between 0 and twice the length of source-string. Not specifying length is
equivalent to specifying a value of 1, except when OCTETS is specified and the result is graphic data, in which case, not specifying length is equivalent to specifying a value of 2.

The argument can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34) which is then assigned to an INTEGER value.

**CODEUNITS16, CODEUNITS32, or OCTETS**

Specifies the units that are used to express start and length in the result. If source-string is a character string that is defined as bit data, CODEUNITS16 and CODEUNITS32 cannot be specified. If source-string is a graphic string, OCTETS cannot be specified. If source-string is a binary string, CODEUNITS16, CODEUNITS32, and OCTETS cannot be specified.

If a string unit is not explicitly specified, the data type of the result determines the unit that is used. If the result is a graphic string, a string unit is two bytes. For ASCII and EBCDIC data, this corresponds to a double byte character. For Unicode, this corresponds to a UTF-16 code point. Otherwise, a string unit is a byte.

**CODEUNITS16**

Specifies that start and length are expressed in terms of 16-bit UTF-16 code units.

**CODEUNITS32**

Specifies that start and length are expressed in terms of 32-bit UTF-32 code units.

**OCTETS**

Specifies that start and length are expressed in terms of bytes.

For more information about CODEUNITS16, CODEUNITS32, and OCTETS, see [String unit specifications](#).

length must be an even number if source-string is graphic data and OCTETS is specified.

If source-string and insert-string have different CCSID sets, insert-string (the string to be inserted) is converted to the CCSID of source-string (the source string).

The encoding scheme of the result is the same as source-string. The data type of the result of the function depends on the data type of source-string and insert-string:

- **VARCHAR** if source-string is a character string. The CCSID of the result depends on the arguments:
  - If either source-string or insert-string is character bit data, the result is bit data.
  - If both source-string and insert-string are SBCS:
    - If both source-string and insert-string are SBCS Unicode data, the CCSID of the result is the CCSID for SBCS Unicode data.
    - If source-string is SBCS Unicode data and insert-string is not SBCS Unicode data, the CCSID of the result is the mixed CCSID for Unicode data.
    - Otherwise, the CCSID of the result is the same as the CCSID of source-string.
  - Otherwise, the CCSID of the result is the mixed CCSID that corresponds to the CCSID of source-string. However, if the input is EBCDIC or ASCII and there is no corresponding system CCSID for mixed, the CCSID of the result is the CCSID of source-string.

- **VARGRAPHIC** if source-string is a graphic. The CCSID of the result is the same as the CCSID of source-string.
• VARBINARY if source-string and insert-string are both binary strings.

The length attribute of the result depends on the arguments:

• If start and length are constants, the length attribute of the result is:

\[ L1 - \min((L1 - V2 + 1), V3) + L4 \]

where:

- \( L1 \) is the length attribute of source-string
- \( V2 \) is the value of start
- \( V3 \) is the value of length
- \( L4 \) is the length attribute of insert-string

• Otherwise, the length attribute of the result is the length attribute of source-string plus the length attribute of insert-string. In this case, the length attribute of source-string plus the length attribute of insert-string must not exceed 32704 for a VARCHAR result or 16352 for a VARGRAPHIC result.

If CODEUNITS16 or CODEUNITS32 is specified, the insert operation is performed on a Unicode version of the data. If needed, the data is converted to an intermediate form in order to evaluate the function. If an intermediate form is used, the actual length of the result depends on the original data (source-string and insert-string), and the representation of that data in Unicode. See "Determining the length attribute of the final result" on page 117 for more information on how to calculate the length attribute of the result string.

If CODEUNITS16 or CODEUNITS32 are not specified, the actual length of the result is:

\[ A1 - \min((A1 - V2 + 1), V3) + A4 \]

where:

- \( A1 \) is the actual length of source-string
- \( V2 \) is the value of start
- \( V3 \) is the value of length
- \( A4 \) is the actual length of insert-string

If the actual length of the result string exceeds the maximum for the return data type, an error occurs.

The result can be null; if any argument is null, the result is the null value.

Example 1: The following example shows how the string 'INSERTING' can be changed into other strings. The use of the CHAR function limits the length of the resulting string to 10 bytes.

```sql
SELECT CHAR(OVERLAY('INSERTING', 'IS', 4, 2, OCTETS), 10),
       CHAR(OVERLAY('INSERTING', 'IS', 4, 0, OCTETS), 10),
       CHAR(OVERLAY('INSERTING', '', 4, 2, OCTETS), 10)
FROM SYSIBM.SYSDUMMY1;
```

This example returns 'INSISTING', 'INSISERTIN', and 'INSTING'.

Example 2: Use the OVERLAY function to insert the character 'C' into the Unicode string '&N~AB', where '&' is the character for the musical symbol, G CLEF, and '~' is the character for combining tilde. The following table shows the Unicode string in different Unicode encoding forms:
Assume the host variable $UTF8\_VAR$ contains the UTF-8 representation of '\&N~AB', and $UTF16\_VAR$ contains the UTF-16 representation of '\&N~AB'. Then
the following SELECT statement is run:

```sql
SELECT OVERLAY (:UTF8\_VAR, 'C', 1, CODEUNITS16),
       OVERLAY (:UTF8\_VAR, 'C', 1, CODEUNITS32),
       OVERLAY (:UTF8\_VAR, 'C', 1, OCTETS)
FROM SYSIBM.SYSDUMMY1;
```

This statement returns the following values:

\[ C \&N\_A \]
\[ CN\_A \]
\[ CN?\_A \]

-- ? is the invalid UTF-8 sequence X'9D849E'

Assume that the previous SELECT statement was not run, but the following SELECT statement is run:

```sql
SELECT OVERLAY (:UTF8\_VAR, 'C', 5, CODEUNITS16),
       OVERLAY (:UTF8\_VAR, 'C', 5, CODEUNITS32),
       OVERLAY (:UTF8\_VAR, 'C', 5, OCTETS)
FROM SYSIBM.SYSDUMMY1;
```

This statement returns the values:

\[ \&N\_C \]
\[ \&N\_A \]
\[ \&C\_A \]

Assume that the previous SELECT statement was not run, but the following SELECT statement is run:

```sql
SELECT OVERLAY (:UTF16\_VAR, 'C', 1, CODEUNITS16),
       OVERLAY (:UTF16\_VAR, 'C', 1, CODEUNITS32)
FROM SYSIBM.SYSDUMMY1;
```

This statement returns the values:

\[ C?\_N\_A \]
\[ CN\_A \]

Assume that the previous SELECT statement was not run, but the following SELECT statement is run:

```sql
SELECT OVERLAY (:UTF16\_VAR, 'C', 5, CODEUNITS16),
       OVERLAY (:UTF16\_VAR, 'C', 5, CODEUNITS32)
FROM SYSIBM.SYSDUMMY1;
```

This statement returns the values:

\[ \&N\_C \]
\[ \&N\_A \]

**PACK**

The PACK function returns a binary string value that contains a data type array and a packed representation of each non-null *expression* argument.
The schema is SYSIBM.

**CCSID 1208**

Specifies that CCSID 1208 is used to encode character string values.

**CCSID DEFAULT**

Specifies that character strings are to be packed in their original encoding, as-is, without CCSID conversion.

**expression**

An expression that returns a value to be encoded in the result string. The expression must be a built-in data type that is not DECFLOAT, GRAPHIC, VARGRAPHIC, ROWID, a LOB, XML, or a character string defined as FOR BIT DATA.

The result of the PACK function is a binary string that is constructed from the following items:

- A flag byte that is reserved for future use
- A 2-byte integer value that indicates the number of arguments encoded in the resulting string
- The data type array that contains an element with data type information for each of the encoded arguments
- The encoded values for the expression arguments in the order as specified in the function invocation.

The resulting binary string is formatted as follows:

<table>
<thead>
<tr>
<th>2-byte length</th>
<th>Flag byte</th>
<th>Number of items</th>
<th>Data type array</th>
<th>Encoded data values</th>
</tr>
</thead>
<tbody>
<tr>
<td>VARBINARY</td>
<td></td>
<td></td>
<td>VARBINARY data</td>
<td></td>
</tr>
<tr>
<td>length</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The data type array includes an element for each expression argument in the same order as specified in the function invocation. Each array element contains a 2-byte SQLTYPE value that indicates the data type of the corresponding expression. When the SQLTYPE value is an odd number, the corresponding expression represents a null value and the value is not encoded in the resulting string. When the SQLTYPE value is an even number, the resulting string contains an encoded representation of the value depending on the data type. The following table describes the data types:

*Table 78. Data types for the expression of the PACK function*

<table>
<thead>
<tr>
<th>Data type of expression</th>
<th>Description of the encoded representation of the value in the resulting string</th>
</tr>
</thead>
<tbody>
<tr>
<td>SMALLINT, INTEGER, or BIGINT</td>
<td>The value of expression as a 16-bit signed binary integer, 32-bit signed binary integer, or 64-bit signed binary integer depending on the data type</td>
</tr>
</tbody>
</table>
Table 78. Data types for the expression of the PACK function (continued)

<table>
<thead>
<tr>
<th>Data type of expression</th>
<th>Description of the encoded representation of the value in the resulting string</th>
</tr>
</thead>
<tbody>
<tr>
<td>decimal((p,s))(^1)</td>
<td>A sequence of 1-byte precision (p), 1-byte scale (s), and ((p+2)/2) bytes of the signed packed-decimal number</td>
</tr>
<tr>
<td>real(^2) or double(^2)</td>
<td>The value of (expression) as a 64-bit IEEE floating-point format</td>
</tr>
<tr>
<td>CHAR or VARCHAR</td>
<td>A sequence of the 2-byte CCSID of the string encoding, followed by the 2-byte length of the string and then the argument data in the specified CCSID encoding</td>
</tr>
<tr>
<td>BINARY or VARBINARY</td>
<td>A sequence of: 2-byte length of the string, followed by the argument data</td>
</tr>
<tr>
<td>DATE</td>
<td>A 4-byte unsigned packed-decimal number representation of the date in the form of YYYYMMDD</td>
</tr>
<tr>
<td>TIME</td>
<td>A 3-byte unsigned packed-decimal number representation of the time in the form of HHMMSS</td>
</tr>
<tr>
<td>TIMESTAMP((p)) WITHOUT TIME ZONE</td>
<td>A sequence of a 2-byte unsigned binary integer value of the precision (p), followed by (7+(p+1)/2) bytes of an unsigned packed-decimal number representation of the timestamp in the form of YYYYMMDDHHMMSSNN, where NN is zero to six bytes of the fractional seconds, depending on the precision (p)</td>
</tr>
<tr>
<td>TIMESTAMP((p)) WITH TIME ZONE</td>
<td>A sequence of a 2-byte unsigned binary integer value of the precision (p), followed by (7+(p+1)/2) bytes of an unsigned packed-decimal number representation of the timestamp in the form of YYYYMMDDHHMMSSNN, where NN is zero to six bytes of the fractional seconds, depending on the precision (p), and then followed by 2 bytes of an unsigned packed-decimal number representation of the time zone (with high order bit set for negative time zone value)</td>
</tr>
</tbody>
</table>

**Note:** The data types in lower case are defined as follows:
1. decimal = DECIMAL\((p,s)\) or NUMERIC\((p,s)\)
2. real = REAL or FLOAT\((n)\) where \(n\) is the specification for a single precision floating point
3. double = DOUBLE, DOUBLE PRECISION, FLOAT or FLOAT\((n)\) where \(n\) is the specification for a double precision floating point

The synonyms for the data types, in either long or short form, are considered the same as those that are listed.

All numeric data is represented in big endian format.

The result of the function is VARBINARY. The length attribute of the result is MIN (32704, the length of the header + length of data type array + SUM(maximum lengths of encoded expression values)). The result cannot be null.

**Example 1:** The following statement shows that the VARCHAR, DATE, and DOUBLE values are packed into a binary string, and the string is then returned to the application:

```
SELECT PACK(CCSID 1208, 'Alina', DATE '1977-08-01', DOUBLE 0.5) FROM SYSIBM.SYSDUMMYU;
```

The statement returns a VARBINARY string with the following content (The result is displayed in hexadecimal format and includes space separators for readability. The actual result is not in hexadecimal format and does not include any space separators):
The character string ‘Alina’ is in UTF-8 (CCSID 1208) format regardless of the string's original encoding because of the CCSID 1208 specification in the PACK invocation.

The resulting string is VARBINARY(30). The length attribute of 30 is determined by the following elements:
1 (flag byte)
+2 (size of number of items)
+2*3 (2-byte data type times number of items)
+2 (CCSID) + 2 (length) + 5 (VARCHAR(5) data length)
+4 (DATE data length)
+8 (DOUBLE length)

The actual length of the result is also 30.

Example 2: The following statement shows that when NULL values are packed into a binary string, they do not occupy any space in the encoded values portion of the result:

```
SELECT PACK(CCSID DEFAULT, '', CAST(NULL AS TIME),
            CAST('Bridget' AS VARCHAR(20) CCSID EBCDIC))
FROM SYSIBM.SYSDUMMYU;
```

The statement returns a VARBINARY string with the following content. (The result is displayed in hexadecimal format and includes space separators for readability. The actual result is not in hexadecimal format and does not include any space separators.)
00 0003 01C4 01B5 01C4 04B80000 00250007C2D9C9C4C7C5E3

The character string '' (empty string) is packed in its original CCSID 1208 format, and 'Bridget' is packed in its original CCSID 37 format, because of the CCSID DEFAULT specification in the PACK invocation.

The resulting string is VARBINARY(40). The length attribute of 40 is determined by the following elements:
1 (flag byte)
+2 (size of number of items)
+2*3 (2-byte data type times number of items)
+2 (CCSID) + 2 (length) + 0 (empty string data length)
+3 (TIME data length)
+2 (CCSID) + 2 (length) + 20 (VARCHAR(20) max length)

The actual length of the resulting string is 24, which is determined by the following elements:
1 (flag byte)
+2 (size of number of items)
+2*3 (2-byte data type times number of items)
+2 (CCSID) + 2 (length) + 0 (empty string data length)
+0 (NULL)
+2 (CCSID) + 2 (length) + 7 (VARCHAR(20) actual length)

SQLTYPE and SQLLEN
UNPACK

POSITION

The POSITION function returns the position of the first occurrence of an argument within another argument, where the position is expressed in terms of the string units that are specified.

\[ \text{POSITION} (\text{search-string}, \text{source-string}, \text{CODEUNITS}16) \]

The schema is SYSIBM.

If search-string is not found and neither argument is null, the result is 0. If search-string is found, the result is a number from 1 to the actual length of source-string, expressed in the units that are explicitly specified.

search-string

An expression that specifies the string for which to search. search-string must return a value that is any built-in string data type with an actual length that is no greater than 4000 bytes.

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type. The expression can be specified by any of the following items:

- A constant
- A special register
- A variable
- A scalar function whose arguments are any of the above (although nested function invocations cannot be used)
- An array element specification
- An expression that concatenates (using CONCAT or ||) any of the above
- A CAST specification whose arguments are any of the above
- A column name

These rules are similar to those that are described for pattern-expression for the LIKE predicate.

source-string

An expression that specifies the source string in which the search is to take place. source-string must return a value that is any built-in string data type.

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type. The expression can be specified by any of the following items:

- A constant
- A special register
- A variable
- A scalar function whose arguments are any of the above (though nested function invocations cannot be used)
- A column name
• An array element specification
• A CAST specification whose arguments are any of the above
• An expression that concatenates (using CONCAT or ||) any of the above

**CODEUNITS16, CODEUNITS32, or OCTETS**

Specifies the string unit that is used to express the result. If _source-string_ is a character string that is defined as bit data, CODEUNITS16, or CODEUNITS32 cannot be specified. If _source-string_ is a graphic string, OCTETS cannot be specified.

**CODEUNITS16**

Specifies that the result is expressed in terms of 16-bit UTF-16 code units.

**CODEUNITS32**

Specifies that the result is expressed in terms of 32-bit UTF-32 code units.

**OCTETS**

Specifies that the result is expressed in terms of bytes.

For more information about CODEUNITS16, CODEUNITS32, and OCTETS, see [String unit specifications](#).

The first and second arguments must have compatible string types. For more information on compatibility, see “Conversion rules for operations that combine strings”.

If the search string and source string have different CCSID sets, then the _search-string_ is converted to the CCSID set of the source string. If either CODEUNITS16 or CODEUNITS32 is specified, the function might be evaluated on a temporary copy of the data in Unicode.

The strings can contain mixed data. If OCTETS is specified:

• For ASCII data, if the search string or source string contains mixed data, the search string is found only if the same combination of single-byte and double-byte characters are found in the source string in exactly the same positions.

• For EBCDIC data, if the search string or source string contains mixed data, the search string is found only if any shift-in or shift-out characters are found in the source string in exactly the same positions, ignoring any redundant shift characters.

• For UTF-8 data, if the search string or source string contains mixed data, the search string is found only if the same combination of single-byte and multi-byte characters are found in the source string in exactly the same position.

The result of the function is a large integer. The POSITION function accepts mixed data strings.

The result can be null; if any argument is null, the result is the null value.

When the POSITION function is invoked with OCTETS, the function operates on a strict byte-count basis without regard to single-byte or double-byte characters.

If the CCSID of the search string is different than the CCSID of the source string, it is converted to the CCSID of the source string.

The value of the result is determined by applying these rules in the order in which they appear:
- If search-string has a length of zero, the result is 1.
- If source-string has a length of zero, the result is 0.
- If the value of search-string is equal to an identical length of substring of contiguous positions within the value of source-string, the result is the starting position of the first such substring within the source string value.
- Otherwise, the result is 0. This includes the case where search-string is longer than source-string.

Example 1: Select the RECEIVED column, the SUBJECT column, and the starting position of the string 'GOOD BEER' within the NOTE_TEXT column for all rows in the IN_TRAY table that contain that string.

```sql
SELECT RECEIVED, SUBJECT, POSITION('GOOD BEER', NOTE_TEXT, OCTETS)
FROM IN_TRAY
WHERE POSITION('GOOD BEER', NOTE_TEXT, OCTETS) <> 0;
```

Example 2: Find the position of the character 'ß' in the string 'Jürgen lives on Hegelstraße', and set the host variable LOCATION with the position, as measured in CODEUNITS32 units, within the string.

```sql
SET :LOCATION = POSITION('ß','Jürgen lives on Hegelstraße',CODEUNITS32);
```

The value of host variable LOCATION is set to 27.

Example 3: Find the position of the character 'ß' in the string 'Jürgen lives on Hegelstraße', and set the host variable LOCATION with the position, as measured in OCTETS, within the string.

```sql
SET :LOCATION = POSITION('ß','Jürgen lives on Hegelstraße',OCTETS);
```

The value of host variable LOCATION is set to 28.

**Related reference:**
- "LOCATE" on page 513
- "LOCATE_IN_STRING" on page 515
- "POSSTR"

POSSTR

The POSSTR function returns the position of the first occurrence of an argument within another argument.

```sql
POSSTR(source-string,search-string)
```

The schema is SYSIBM.

If search-string is not found and neither argument is null, the result is 0. If search-string is found, the result is a number from 1 to the actual length of source-string.

**source-string**

An expression that specifies the source string in which the search is to take place. source-string must return a value that is a built-in character string data type, graphic string data type, or binary string data type.
The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type.

**search-string**
An expression that specifies the string for which to search. search-string must return a value that is a built-in character string data type, graphic string data type, or binary string data type with an actual length that is no greater than 4000 bytes.

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type.

The first and second arguments must have compatible string types. For more information on compatibility, see “Conversion rules for comparisons” on page 168.

If the search-string and source-string have different CCSID sets, then the search-string is converted to the CCSID set of the source-string.

Both search-string and source-string have zero or more contiguous positions. For character strings and binary strings, a position is a byte. For graphic strings, a position is a DBCS character. Graphic Unicode data is treated as UTF-16 data; a UTF-16 supplementary character takes two DBCS characters to represent and as such is counted as two DBCS characters.

The strings can contain mixed data.
- For ASCII data, if search-string or source-string contains mixed data, search-string is found only if the same combination of single-byte and double-byte characters are found in source-string in exactly the same positions.
- For EBCDIC data, if search-string or source-string contains mixed data, search-string is found only if any shift-in or shift-out characters are found in source-string in exactly the same positions, ignoring any redundant shift characters.
- For UTF-8 data, if search-string or source-string contains mixed data, search-string is found only if the same combination of single-byte and multi-byte characters are found in source-string in exactly the same position.

POSSTR operates on a strict byte-count basis without regard to single-byte or double-byte characters. It is recommended that if either the search-string or source-string contains mixed data, POSITION should be used instead of POSSTR. The POSITION function operates on a character basis. In an EBCDIC encoding scheme, any shift-in and shift-out characters are not required to be in exactly the same position and their only significance is to indicate which characters are SBCS and which characters are DBCS.

The result of the function is a large integer. The value of the result is determined by applying these rules in the order in which they appear:
- If the length of search-string is zero, the result is 1.
- If the length of source-string is zero, the result is 0.
- If the value of search-string is equal to an identical length substring of contiguous positions from the value of source-string, the result is the starting position of the first such substring within the value of source-string.
- If none of the above conditions are met, the result is 0.

The result can be null; if any argument is null, the result is the null value.
Example: Select the RECEIVED column, the SUBJECT column, and the starting position of the string 'GOOD BEER' within the NOTE_TEXT column for all rows in the IN_TRAY table that contain that string.

```
SELECT RECEIVED, SUBJECT, POSSTR(NOTE_TEXT, 'GOOD BEER')
FROM IN_TRAY
WHERE POSSTR(NOTE_TEXT, 'GOOD BEER') <> 0;
```

Related reference:
- "LOCATE" on page 513
- "LOCATE_IN_STRING" on page 515
- "POSITION" on page 557

**POWER**

The POWER function returns the value of the first argument to the power of the second argument.

```
POWER(numeric-expression-1, numeric-expression-2)
```

The schema is SYSIBM.

Each argument must be an expression that returns the value of any built-in numeric data type. If either argument includes a DECIMAL or REAL data type, but not a DECFLOAT data type, the arguments are converted to a double precision floating-point number for processing by the function. If either argument includes a DECFLOAT data type, the arguments are converted to DECFLOAT for processing by the function.

The result of the function depends on the data type of the arguments:
- If both arguments are SMALLINT or INTEGER, the result is INTEGER.
- If either argument is a DECFLOAT, the data type of the result is DECFLOAT(34).
  - If either argument is a DECFLOAT and one of the following statements is true, the result is NaN and an invalid operation condition:
    - both arguments are zero
    - the second argument has a non-zero fractional part
    - the second argument has more than 9 digits
    - the second argument is Infinite
  - Otherwise, the result is DOUBLE.

The result can be null; if any argument is null, the result is the null value.

**Example 1:** Assume that host variable HPOWER is INTEGER with a value of 3. The following statement returns the value 8.

```
SELECT POWER(2,:HPOWER)
FROM SYSIBM.SYSDUMMY1;
```

**Example 2:** The following statement returns the value 1.

```
SELECT POWER(0,0)
FROM SYSIBM.SYSDUMMY1;
```
The QUANTIZE function returns a DECIMAL value that is equal in value (except for any rounding) and sign to the first argument and that has an exponent that is set to equal the exponent of the second argument.

**QUANTIZE(expression-1,expression-2)**

The schema is SYSIBM.

The number of digits that is returned (16 or 34) is the same as the number of digits in *expression-1*.

*expression-1*

The argument must be an expression that returns a value of any built-in numeric data type. If the argument is not a DECIMAL value, it is converted to DECIMAL(34) for processing.

The argument can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECIMAL(34).

*expression-2*

The argument must be an expression that returns a value of any built-in numeric data type. If the argument is not a DECIMAL value, it is converted to DECIMAL(34) for processing. *expression-2* is an expression that is used as an example pattern that will be used to rescale *expression-1*. The sign and coefficient of the second argument are ignored.

The argument can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECIMAL(34).

If one argument (after conversion) is DECIMAL(16) and the other is DECIMAL(34), the DECIMAL(16) argument is converted to DECIMAL(34) before the function is processed.

The coefficient of the result is derived from that of *expression-1*. It is rounded, if necessary (if the exponent is being increased), multiplied by a power of ten (if the exponent is being decreased), or remains unchanged (if the exponent is already equal to that of *expression-2*).

For static SQL statements other than CREATE VIEW, the Rounding bind option or the native SQL procedure option determines the rounding mode.

For dynamic SQL statements (and static CREATE VIEW statements), the special register CURRENT DECIMAL ROUNDING MODE determines the rounding mode.

Unlike other arithmetic operations on the DECIMAL data type, if the length of the coefficient after the quantize operation is greater than the precision specified by *expression-2*, a warning occurs. This ensures that, unless there is an error condition, the exponent of the result of QUANTIZE is always equal to that of *expression-2*.

Furthermore:

- If either argument is NaN, NaN is returned.
• If either argument is sNaN, NaN is returned and an exception occurs
• If both arguments are infinity (positive or negative), infinity (positive or negative) is returned.
• If one argument is infinity (positive or negative) and the other argument is not infinity (positive or negative), NaN is returned and an exception occurs.

The result of the function is a DECFLOAT(16) value if both arguments are DECFLOAT(16). Otherwise, the result of the function is a DECFLOAT(34) value.

The result can be null; if any argument is null, the result is the null value.

Examples: The following examples illustrate the value that is returned for the QUANTIZE function given the input DECFLOAT values:

- QUANTIZE(2.17, DECFLOAT(0.001)) = 2.170
- QUANTIZE(2.17, DECFLOAT(0.01)) = 2.17
- QUANTIZE(2.17, DECFLOAT(0.1)) = 2.2
- QUANTIZE(2.17, DECFLOAT('1E+0')) = 2
- QUANTIZE(2.17, DECFLOAT('1E+1')) = 0E+1
- QUANTIZE(2, DECFLOAT(INFINITY)) = NAN -- exception
- QUANTIZE(-0.1, DECFLOAT(1)) = 0
- QUANTIZE(0, DECFLOAT('1E+5')) = 0E+5
- QUANTIZE(217, DECFLOAT('1E-1')) = 217.0
- QUANTIZE(217, DECFLOAT('1E+0')) = 217
- QUANTIZE(217, DECFLOAT('1E+1')) = 2.2E+2
- QUANTIZE(217, DECFLOAT('1E+2')) = 2E+2

QUARTER

The QUARTER function returns an integer between 1 and 4 that represents the quarter of the year in which the date resides. For example, any dates in January, February, or March return the integer 1.

\[ \text{QUARTER(expression)} \]

The schema is SYSIBM.

The argument must be an expression that returns one of the following built-in data types: a date, a timestamp, a character string, or a graphic string. If expression is a character or graphic string data type, it must not be a CLOB or DBCLOB, and its value must be a valid string representation of a date or timestamp with an actual length of not greater than 255 bytes. For the valid formats of string representations of dates and timestamps, see "String representations of datetime values" on page 130.

If expression is a timestamp with a time zone, or a valid string representation of a timestamp with a time zone, the result is determined from the UTC representation of the datetime value.

The result of the function is a large integer.

The result can be null; if the argument is null, the result is the null value.
Example 1: The following function returns 3 because August is in the third quarter of the year.

```sql
SELECT QUARTER('2008-08-25')
FROM SYSIBM.SYSDUMMY1
```

Example 2: Using sample table DSN8C10.PROJ, set the integer host variable QUART to the quarter of the year in which activity number 70 for project 'AD3111' occurred. Activity completion dates are recorded in column ACENDATE.

```sql
SELECT QUARTER(ACENDATE)
INTO :QUART
FROM DSNBC10.PROJ
WHERE PROJNO = 'AD3111' AND ACTNO = 70;
```

QUART is set to 4.

Example 3: The following invocations of the QUARTER function returns the same result:

```sql
SELECT QUARTER('2003-01-02-20.10.05.123456'),
       QUARTER('2003-01-02-12.10.05.123456-08:00'),
       QUARTER('2003-01-03-05.10.05.123456+09:00')
FROM SYSIBM.SYSDUMMY1;
```

For each invocation of the QUARTER function in this SELECT statement, the result is 1.

When the input argument contains a time zone, the result is determined from the UTC representation of the input value. The string representations of a timestamp with a time zone in the SELECT statement all have the same UTC representation: 2003-01-02-20.10.05.123456. The month portion of the UTC representation is 1 for January, which is in the first quarter.

RADIANS

The RADIANS function returns the number of radians for an argument that is expressed in degrees.

```sql
RADIANS(numeric-expression)
```

The schema is SYSIBM.

The argument must be an expression that returns the value of any built-in numeric data type that is not DECFLOAT. If the argument is not a double precision floating-point number, it is converted to one for processing by the function.

The result of the function is a double precision floating-point number.

The result can be null; if the argument is null, the result is the null value.

Example: Assume that host variable HDEG is an INTEGER with a value of 180. The following statement returns a double precision floating-point number with an approximate value of 3.1415926536.
SELECT RADIANS(:HDEG)
FROM SYSIBM.SYSDUMMY1;

RAISE_ERROR

The RAISE_ERROR function causes the statement that invokes the function to return an error with the specified SQLSTATE (along with SQLCODE -438) and error condition. The RAISE_ERROR function always returns the null value with an undefined data type.

RAISE_ERROR(sqlstate, diagnostic-string)

The schema is SYSIBM.

sqlstate

An expression that returns a character string (CHAR or VARCHAR) of exactly 5 characters.

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR(5) data type. The sqlstate value must follow these rules for application-defined SQLSTATEs:

- Each character must be from the set of digits ('0' through '9') or non-accented upper case letters ('A' through 'Z').
- The SQLSTATE class (first two characters) cannot be '00', '01', or '02' because these are not error classes.
- If the SQLSTATE class (first two characters) starts with the character '0' through '6' or 'A' through 'H', the subclass (last three characters) must start with a letter in the range 'I' through 'Z'.
- If the SQLSTATE class (first two characters) starts with the character '7', '8', '9', or 'I' through 'Z', the subclass (last three characters) can be any of '0' through '9' or 'A' through 'Z'.

diagnostic-string

An expression that returns a character string with a data type of CHAR or VARCHAR and a length of up to 70 bytes. The string contains EBCDIC data that describes the error condition. If the string is longer than 70 bytes, it is truncated.

Since the data type of the result of RAISE_ERROR is undefined, it can only be used in a SET host-variable or SQL procedure language assignment-statement. To use this function in another context, such as alone in a select list, you must use a cast specification to give a data type to the null value that is returned. The RAISE_ERROR function is most useful with CASE expressions.

Example: For each employee in sample table DSN8C10.EMP, list the employee number and education level. List the education level as 'Post Graduate', 'Graduate' and 'Diploma' instead of the integer that it is stored as in the table. If an education level is greater than '20', raise an error ('70001') with a description.

```sql
SELECT EMPNO,
    CASE WHEN EDLEVEL < 16 THEN 'Diploma'
         WHEN EDLEVEL < 18 THEN 'Graduate'
         WHEN EDLEVEL < 21 THEN 'Post Graduate'
```
ELSE RAISE_ERROR('70001',
'EDUCLVL has a value greater than 20')
END
FROM DSNBC10.EMP;

RAND

The RAND function returns a random floating-point value between 0 and 1. An argument can be specified as an optional seed value.

```
RAND(numeric-expression)
```

The schema is SYSIBM.

**numeric-expression**

If *numeric-expression* is specified, it is used as the seed value. The argument must be an expression that returns a value of a built-in integer data type (SMALLINT or INTEGER). The value must be between 0 and 2,147,483,646.

The argument can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECIMAL(34) and then assigned to an INTEGER value.

The result of the function is a double precision floating-point number.

The result can be null; if the argument is null, the result is the null value.

A specific seed value, other than zero, will produce the same sequence of random numbers for a specific instance of a RAND function in a query each time the query is executed. The seed value is used only for the first invocation of an instance of the RAND function within a statement. RAND(0) is processed the same as RAND().

The RAND function is not deterministic.

*Example:* Assume that host variable HRAND is an INTEGER with a value of 100. The following statement returns a random floating-point number between 0 and 1, such as the approximate value 0.0121398:

```
SELECT RAND(:HRAND)
FROM SYSIBM.SYSDUMMY1;
```

To generate values in a numeric interval other than 0 to 1, multiply the RAND function by the size of the interval that you want. For example, to get a random number between 0 and 10, such as the approximate value 5.8731398, multiply the function by 10:

```
SELECT (RAND(:HRAND) * 10)
FROM SYSIBM.SYSDUMMY1;
```

REAL

The REAL function returns a single-precision floating-point representation of either a number or a string representation of a number.
**Numeric to Real:**

\[ \text{REAL(numeric-expression)} \]

**String to Real:**

\[ \text{REAL(string-expression)} \]

The schema is SYSIBM.

**Numeric to Real**

*numeric-expression*

An expression that returns a value of any built-in numeric data type.

The result is the same number that would occur if the argument were assigned to a single precision floating-point column or variable. If the numeric value of the argument is not within the range of single precision floating-point, an error occurs.

**String to Real**

*string-expression*

An expression that returns a value of a character or graphic string (except a CLOB or DBCLOB) with a length attribute that is not greater than 255 bytes. The string must contain a valid string representation of a number.

The result is the same number that would result from \( \text{CAST(string-expression AS REAL)} \). Leading and trailing blanks are eliminated and the resulting string must conform to the rules for forming an SQL floating-point, integer, or decimal constant.

The result of the function is a single precision floating-point number.

The result can be null; if the argument is null, the result is the null value.

**Recommendation:** To increase the portability of applications, use the \text{CAST} specification. For more information, see “CAST specification” on page 283.

**Example:** Using sample table DSN8C10.EMP, find the ratio of salary to commission for employees whose commission is not zero. The columns involved, SALARY and COMM, have decimal data types. To express the result in single precision floating-point, apply REAL to SALARY so that the division is carried out in floating-point (actually double precision) and then apply REAL to the complete expression so that the results are returned in single precision floating-point.

```sql
SELECT EMPNO, REAL(REAL(SALARY)/COMM) FROM DSN8C10.EMP WHERE COMM > 0;
```
REGEXP_COUNT

The REGEXP_COUNT scalar function returns a count of the number of times that a regular expression pattern is matched in a string.

This function is passthrough-only and cannot run on Db2 for z/OS. Db2 only verifies that the data types of the parameters are valid for the function. The accelerator engine does all other function resolution processing and validation. To invoke this function, you must set the QUERY_ACCELERATION subsystem parameter, CURRENT QUERY ACCELERATION special register, or QUERYACCELERATION bind option to ALL, ENABLE, or ELIGIBLE. The function can be referenced in a view but cannot be specified as a source function for a user-defined function.

\[
\text{REGEXP_COUNT} \left( \text{source-string}, \text{pattern-expression} \right)
\]

The schema is SYSIBM.

source-string
An expression that specifies the string in which the search is to take place. This expression must return a built-in character string, graphic string, numeric value, Boolean value, or datetime value. A numeric, Boolean, or datetime value is implicitly cast to VARCHAR before the function is evaluated. A character string cannot specify the FOR BIT DATA attribute.

pattern-expression
An expression that specifies the regular expression string that is the pattern for the search. This expression must return a built-in character string, graphic string, numeric value, Boolean value, or datetime value. A numeric, Boolean, or datetime value is implicitly cast to VARCHAR before the function is evaluated. A character string cannot specify the FOR BIT DATA attribute.

start
An expression that specifies the position within source-string at which the search is to start. The expression must return a built-in character string, graphic string, Boolean, or numeric value. If the value is not of type INTEGER, it is implicitly cast to INTEGER before the function is evaluated. The value of the integer must be greater than or equal to 1. If OCTETS is specified and the source string is graphic data, the value of the integer must be odd. The default start value is 1. See parameter description for CODEUNITS16, CODEUNITS32, or OCTETS for the string unit that applies to the start position.

flags
An expression that specifies flags that controls aspects of the pattern matching. The expression must return a built-in character string that does not specify the FOR BIT DATA attribute. The string can include one or more valid flag values and the combination of flag values must be valid. An empty string is the same as the value 'c'. The default flag value is 'c'. 
Table 79. Supported flag values

<table>
<thead>
<tr>
<th>Flag value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>c</td>
<td>Specifies that matching is case-sensitive. This flag is the default value if ‘c’ or ‘i’ is not specified. This value must not be specified with a value of ‘i’.</td>
</tr>
<tr>
<td>i</td>
<td>Specifies that matching is case insensitive. This value must not be specified with a value of ‘c’.</td>
</tr>
<tr>
<td>m</td>
<td>Specifies that the input data can contain more than one line. By default, the ‘^’ in a pattern matches only the start of the input string; the ‘$’ in a pattern matches only the end of the input string. If this flag is set, ”^” and ”$” also matches at the start and end of each line within the input string.</td>
</tr>
<tr>
<td>n</td>
<td>Specifies that the ‘.’ character in a pattern matches a line terminator in the input string. By default, the ‘.’ character in a pattern does not match a line terminator. A carriage-return and line-feed pair in the input string behaves as a single-line terminator and matches a single “.” in a pattern.</td>
</tr>
<tr>
<td>s</td>
<td>Specifies that the ‘.’ character in a pattern matches a line terminator in the input string. This value is a synonym for the ‘n’ value.</td>
</tr>
<tr>
<td>x</td>
<td>Specifies that white space characters in a pattern are ignored, unless escaped.</td>
</tr>
</tbody>
</table>

**CODEUNITS16, CODEUNITS32, or OCTETS**

Specifies the string unit of the start value:

- CODEUNITS16 specifies that the start value is expressed in 16-bit UTF-16 code units.
- CODEUNITS32 specifies that the start value is expressed in 32-bit UTF-32 code units. This is the default.
- OCTETS specifies that the start value is expressed in bytes.

If the string unit is specified as CODEUNITS16 or OCTETS, and if the string unit of the source string is CODEUNITS32, an error is returned.

For more information, see [String unit specifications](#).

**Result**

The result of the function is an INTEGER that represents the number of occurrences of the pattern expression within the source string. If the pattern expression is not found and no argument is null, the result is 0.

If any argument of the REGEXP_COUNT function can be null, the result can be null. If any argument is null, the result is the null value.

**Notes**

- The regular expression processing is done by using the International Components for Unicode (ICU) regular expression interface.
- Considerations for non-Unicode databases:
  - A regular expression pattern supports only halfwidth control characters; use a character string data type for the pattern expression argument. A character string data type can be used for the pattern expression argument even when a graphic string data type is used for the source string argument.
  - The source string argument must be a graphic string data type if the pattern expression argument is a graphic string data type.
Example

Count the number of times "Steven" or "Stephen" occurs in the string "Steven Jones and Stephen Smith are the best players".

```sql
SELECT REGEXP_COUNT('Steven Jones and Stephen Smith are the best players', 'Ste(v|ph)en')
FROM sysibm.sysdummy1
```

The result is 2.

**REGEXP_INSTR**

The REGEXP_INSTR scalar function returns the starting or ending position of the matched substring, depending on the value of the `return_option` argument.

> This function is passthrough-only and cannot run on Db2 for z/OS. Db2 only verifies that the data types of the parameters are valid for the function. The accelerator engine does all other function resolution processing and validation. To invoke this function, you must set the QUERY_ACCELERATION subsystem parameter, CURRENT QUERY ACCELERATION special register, or QUERYACCELERATION bind option to ALL, ENABLE, or ELIGIBLE. The function can be referenced in a view but cannot be specified as a source function for a user-defined function.

```sql
REGEXP_INSTR(source-string, pattern-expression, start, occurrence, return_option, flags, group)
```

The schema is SYSIBM.

**source-string**

An expression that specifies the string in which the search is to take place. This expression must return a built-in character string, graphic string, numeric value, Boolean value, or datetime value. A numeric, Boolean, or datetime value is implicitly cast to VARCHAR before the function is evaluated. A character string cannot specify the FOR BIT DATA attribute.

**pattern-expression**

An expression that specifies the regular expression string that is the pattern for the search. This expression must return a built-in character string, graphic string, numeric value, Boolean value, or datetime value. A numeric, Boolean, or datetime value is implicitly cast to VARCHAR before the function is evaluated. A character string cannot specify the FOR BIT DATA attribute.

**start**

An expression that specifies the position within `source-string` at which the search is to start. The expression must return a built-in character string,
graphic string, Boolean, or numeric value. If the value is not of type INTEGER, it is implicitly cast to INTEGER before the function is evaluated. The value of the integer must be greater than or equal to 1. If OCTETS is specified and the source string is graphic data, the value of the integer must be odd. The default start value is 1. See parameter description for CODEUNITS16, CODEUNITS32, or OCTETS for the string unit that applies to the start position.

**occurrence**
An expression that specifies which occurrence of the pattern expression within the source string to search for. The expression must return a built-in character string, graphic string, Boolean, or numeric value. If the value is not of type INTEGER, it is implicitly cast to INTEGER before the function is evaluated. This value must be greater than or equal to 1. The default occurrence value is 1, which indicates that only the first occurrence of the pattern expression is considered.

**return-option**
An expression that specifies what is returned relative to the occurrence. The expression must return a built-in character string, graphic string, Boolean, or numeric value. If the value is not of type INTEGER, it is implicitly cast to INTEGER before the function is evaluated. This value must be 0 or 1:
- A value of 0 returns the position of the first string unit of the occurrence.
- A value of 1 returns the position of the string unit that follows the occurrence.

The default return option value is 0.

**flags**
An expression that specifies flags that controls aspects of the pattern matching. The expression must return a built-in character string that does not specify the FOR BIT DATA attribute. The string can include one or more valid flag values and the combination of flag values must be valid. An empty string is the same as the value 'c'. The default flag value is 'c'.

<table>
<thead>
<tr>
<th>Flag value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>c</td>
<td>Specifies that matching is case-sensitive. This flag is the default value if 'c' or 'i' is not specified. This value must not be specified with a value of 'i'.</td>
</tr>
<tr>
<td>i</td>
<td>Specifies that matching is case insensitive. This value must not be specified with a value of 'c'.</td>
</tr>
<tr>
<td>m</td>
<td>Specifies that the input data can contain more than one line. By default, the '^' in a pattern matches only the start of the input string; the '$' in a pattern matches only the end of the input string. If this flag is set, &quot;^&quot; and &quot;$&quot; also matches at the start and end of each line within the input string.</td>
</tr>
<tr>
<td>n</td>
<td>Specifies that the '.' character in a pattern matches a line terminator in the input string. By default, the '.' character in a pattern does not match a line terminator. A carriage-return and line-feed pair in the input string behaves as a single-line terminator and matches a single &quot;.&quot; in a pattern.</td>
</tr>
<tr>
<td>s</td>
<td>Specifies that the '.' character in a pattern matches a line terminator in the input string. This value is a synonym for the 'n' value.</td>
</tr>
<tr>
<td>x</td>
<td>Specifies that white space characters in a pattern are ignored, unless escaped.</td>
</tr>
</tbody>
</table>

**group**
An expression that specifies which capture group of the pattern expression is used to determine the position within source string to return. The expression...
must return a built-in character string, graphic string, Boolean, or numeric value. If the value is not of type INTEGER, it is implicitly cast to INTEGER before the function is evaluated. This value must be greater than or equal to 0 and must not be greater than the number of capture groups in the pattern expression. The default group value is 0, which indicates that the position is based on the string that matches the entire pattern.

**CODEUNITS16, CODEUNITS32, or OCTETS**

Specifies the string unit of both the start value and the result:

- CODEUNITS16 specifies that the start value and result are expressed in 16-bit UTF-16 code units.
- CODEUNITS32 specifies that the start value and result are expressed in 32-bit UTF-32 code units. This is the default.
- OCTETS specifies that the start value and result are expressed in bytes.

If the string unit is specified as CODEUNITS16 or OCTETS, and the string unit of the source string is CODEUNITS32, an error is returned.

For more information, see [String unit specifications](#).

**Result**

The result of the function is a large integer. If the pattern expression is found, the result is a number from 1 to n, where n is the actual length of the source string plus 1. The result value represents the position expressed in the string units used to process the function. If the pattern expression is not found and no argument is null, the result is 0.

If any argument of the REGEXP_INSTR function can be null, the result can be null. If any argument is null, the result is the null value.

**Notes**

- The regular expression processing is done by using the International Components for Unicode (ICU) regular expression interface.
- Considerations for non-Unicode databases:
  - A regular expression pattern supports only halfwidth control characters; use a character string data type for the pattern expression argument. A character string data type can be used for the pattern expression argument even when a graphic string data type is used for the source string argument.
  - The source string argument must be a graphic string data type if the pattern expression argument is a graphic string data type.

**Examples**

1. Find the first occurrence of a 'o' that has a character that is preceding it.

   ```sql
   SELECT REGEXP_INSTR('hello to you', '.o', 1, 1)
   FROM sysibm.sysdummy1
   ```

   The result is 4, which is the position of the second 'l' character.

2. Find the second occurrence of a 'o' that has a character that is preceding it.

   ```sql
   SELECT REGEXP_INSTR('hello to you', '.o', 1, 2)
   FROM sysibm.sysdummy1
   ```

   The result is 7, which is the position of the character 't'.

3. Find the position after the third occurrence of the first capture group of the regular expression '(o)' using case insensitive matching.
SELECT REGEXP_INSTR('hello TO you', '(o)', 1,3,1,'i',1)
FROM sysibm.sysdummy1

The result is 12, which is the position of the character 'u' at the end of the string.

**REGEXP_LIKE**

The REGEXP_LIKE scalar function returns an INTEGER value of 0 or 1 indicating if the regular expression pattern is found in a string.

This function is passthrough-only and cannot run on Db2 for z/OS. Db2 only verifies that the data types of the parameters are valid for the function. The accelerator engine does all other function resolution processing and validation. To invoke this function, you must set the QUERY_ACCELERATION subsystem parameter, CURRENT QUERY_ACCELERATION special register, or QUERYACCELERATION bind option to ALL, ENABLE, or ELIGIBLE. The function can be referenced in a view but cannot be specified as a source function for a user-defined function.

Db2 for z/OS casts the result of this function to an INTEGER (1 = 'true', 0 = 'false'). Db2 for z/OS currently does not support Boolean functions or data types.

```
REGEXP_LIKE(source-string, pattern-expression, start, flags, CODEUNITS32, CODEUNITS16, OCTETS
```

The schema is SYSIBM.

**source-string**

An expression that specifies the string in which the search is to take place. This expression must return a built-in character string, graphic string, numeric value, Boolean value, or datetime value. A numeric, Boolean, or datetime value is implicitly cast to VARCHAR before the function is evaluated. A character string cannot specify the FOR BIT DATA attribute.

**pattern-expression**

An expression that specifies the regular expression string that is the pattern for the search. This expression must return a built-in character string, graphic string, numeric value, Boolean value, or datetime value. A numeric, Boolean, or datetime value is implicitly cast to VARCHAR before the function is evaluated. A character string cannot specify the FOR BIT DATA attribute.

**start**

An expression that specifies the position within source-string at which the search is to start. The expression must return a built-in character string, graphic string, Boolean, or numeric value. If the value is not of type INTEGER, it is implicitly cast to INTEGER before the function is evaluated. The value of the integer must be greater than or equal to 1. If OCTETS is specified and the source string is graphic data, the value of the integer must be odd. The default start value is 1. See parameter description for CODEUNITS16, CODEUNITS32, or OCTETS for the string unit that applies to the start position.
flags

An expression that specifies flags that controls aspects of the pattern matching. The expression must return a built-in character string that does not specify the FOR BIT DATA attribute. The string can include one or more valid flag values and the combination of flag values must be valid. An empty string is the same as the value 'c'. The default flag value is 'c'.

Table 81. Supported flag values

<table>
<thead>
<tr>
<th>Flag value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>c</td>
<td>Specifies that matching is case-sensitive. This flag is the default value if 'c' or 'i' is not specified. This value must not be specified with a value of 'i'.</td>
</tr>
<tr>
<td>i</td>
<td>Specifies that matching is case insensitive. This value must not be specified with a value of 'c'.</td>
</tr>
<tr>
<td>m</td>
<td>Specifies that the input data can contain more than one line. By default, the '^' in a pattern matches only the start of the input string; the '$' in a pattern matches only the end of the input string. If this flag is set, &quot;^&quot; and &quot;$&quot; also matches at the start and end of each line within the input string.</td>
</tr>
<tr>
<td>n</td>
<td>Specifies that the '.' character in a pattern matches a line terminator in the input string. By default, the '.' character in a pattern does not match a line terminator. A carriage-return and line-feed pair in the input string behaves as a single-line terminator and matches a single &quot;.&quot; in a pattern.</td>
</tr>
<tr>
<td>s</td>
<td>Specifies that the '.' character in a pattern matches a line terminator in the input string. This value is a synonym for the 'n' value.</td>
</tr>
<tr>
<td>x</td>
<td>Specifies that white space characters in a pattern are ignored, unless escaped.</td>
</tr>
</tbody>
</table>

CODEUNITS16, CODEUNITS32, or OCTETS

 Specifies the string unit of the start value:

- CODEUNITS16 specifies that the start value is expressed in 16-bit UTF-16 code units.
- CODEUNITS32 specifies that the start value is expressed in 32-bit UTF-32 code units. This is the default.
- OCTETS specifies that the start value is expressed in bytes.

If the string unit is specified as CODEUNITS16 or OCTETS, and if the string unit of the source string is CODEUNITS32, an error is returned.

For more information, see [String unit specifications](#).

Result

The result of the function is an INTEGER value of 0 or 1. If the pattern expression is found, the result is true. If the pattern expression is not found, the result is false. If the value of any of the arguments is null, the result is unknown.

Examples

1. Select the employee number where the last name is spelled LUCHESSI, LUCHESSI, or LUCHESI from the EMPLOYEE table without considering upper or lower case letters.

   ```sql
   SELECT EMPNO FROM EMPLOYEE
   WHERE REGEXP_LIKE(LASTNAME,'luc+?hes+?i','i') = 1
   ```

   The result is 1 row with EMPNO value '000110'.
2. Select any invalid product identifier values from the PRODUCT table. The expected format is 'nnn-nnn-nn' where 'n' is a digit 0 - 9.

```sql
SELECT PID FROM PRODUCT
WHERE NOT REGEXP_LIKE(pid, '[0-9]{3}-[0-9]{3}-[0-9]{2}') = 1
```

The result is 0 rows because all the product identifiers match the pattern.

**REGEXP_REPLACE**

The REGEXP_REPLACE scalar function returns a modified version of the source string where occurrences of the regular expression pattern found in the source string are replaced with the specified replacement string.

```sql
REGEXP_REPLACE(source-string, pattern-expression, replacement-string, start, occurrence, flags)
```

The schema is SYSIBM.

- **source-string**
  An expression that specifies the string in which the search is to take place. This expression must return a built-in character string, graphic string, numeric value, Boolean value, or datetime value. A numeric, Boolean, or datetime value is implicitly cast to VARCHAR before the function is evaluated. A character string cannot specify the FOR BIT DATA attribute.

- **pattern-expression**
  An expression that specifies the regular expression string that is the pattern for the search. This expression must return a built-in character string, graphic string, numeric value, Boolean value, or datetime value. A numeric, Boolean, or datetime value is implicitly cast to VARCHAR before the function is evaluated. A character string cannot specify the FOR BIT DATA attribute.

- **replacement-string**
  An expression that specifies the replacement string for matching substrings. The expression must return a value that is a built-in character string, graphic string, numeric value, Boolean value, or datetime value. A numeric, Boolean, or...
A datetime value is implicitly cast to VARCHAR before the function is evaluated.

A character string cannot specify the FOR BIT DATA attribute. The default replacement string is the empty string.

The content of the replacement string can include references to capture group text from the search to use in the replacement text. These references are of the form '$n' or '\n', where n is the number of the capture group and 0 represents the entire string that matches the pattern. The value for n must be in the range 0-9 and not greater than the number of capture groups in the pattern. For example, either '$2' or '\2' can be used to refer to the content found in the source string for the second capture group that is specified in the pattern expression. If the pattern expression must include a literal reference to a '$' or \ character, that character must be preceded with an '/' character as an escape character ('\$' or '\\').

**start**

An expression that specifies the position within source-string at which the search is to start. The expression must return a built-in character string, graphic string, Boolean, or numeric value. If the value is not of type INTEGER, it is implicitly cast to INTEGER before the function is evaluated. The value of the integer must be greater than or equal to 1. If OCTETS is specified and the source string is graphic data, the value of the integer must be odd. The default start value is 1. See parameter description for CODEUNITS16, CODEUNITS32, or OCTETS for the string unit that applies to the start position.

**occurrence**

An expression that specifies which occurrence of the pattern expression within the source string is to be searched for and replaced. The expression must return a built-in character string, graphic string, Boolean, or numeric value. If the value is not of type INTEGER, it is implicitly cast to INTEGER before the function is evaluated. The occurrence value must be greater than or equal to 0. The default occurrence value is 0, which indicates that all occurrences of the pattern expression in the source string are replaced.

**flags**

An expression that specifies flags that controls aspects of the pattern matching. The expression must return a built-in character string that does not specify the FOR BIT DATA attribute. The string can include one or more valid flag values and the combination of flag values must be valid. An empty string is the same as the value 'c'. The default flag value is 'c'.

**Table 82. Supported flag values**

<table>
<thead>
<tr>
<th>Flag value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>c</td>
<td>Specifies that matching is case-sensitive. This flag is the default value if 'c' or 'i' is not specified. This value must not be specified with a value of 'i'.</td>
</tr>
<tr>
<td>i</td>
<td>Specifies that matching is case insensitive. This value must not be specified with a value of 'c'.</td>
</tr>
<tr>
<td>m</td>
<td>Specifies that the input data can contain more than one line. By default, the '^' in a pattern matches only the start of the input string; the '$' in a pattern matches only the end of the input string. If this flag is set, &quot;^&quot; and &quot;$&quot; also matches at the start and end of each line within the input string.</td>
</tr>
<tr>
<td>n</td>
<td>Specifies that the '.' character in a pattern matches a line terminator in the input string. By default, the '.' character in a pattern does not match a line terminator. A carriage-return and line-feed pair in the input string behaves as a single-line terminator and matches a single &quot;\n&quot; in a pattern.</td>
</tr>
</tbody>
</table>
Table 82. Supported flag values (continued)

<table>
<thead>
<tr>
<th>Flag value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>s</td>
<td>Specifies that the . character in a pattern matches a line terminator in the input string. This value is a synonym for the ‘n’ value.</td>
</tr>
<tr>
<td>x</td>
<td>Specifies that white space characters in a pattern are ignored, unless escaped.</td>
</tr>
</tbody>
</table>

**CODEUNITS16, CODEUNITS32, or OCTETS**

Specifies the string unit of the start value:

- CODEUNITS16 specifies that the start value is expressed in 16-bit UTF-16 code units.
- CODEUNITS32 specifies that the start value is expressed in 32-bit UTF-32 code units. This is the default.
- OCTETS specifies that the start value is expressed in bytes.

If the string unit is specified as CODEUNITS16 or OCTETS, and if the string unit of the source string is CODEUNITS32, an error is returned.

For more information, see [String unit specifications](#).

**Result**

The result of the function is a string. If there are no occurrences of the pattern to be replaced and no argument is null, the original string is returned. The data type of the string is the same data type as the source string, except for CHAR, which becomes VARCHAR, and VARGRAPHIC, which becomes GRAPHIC.

The length attribute of the result data type is determined based on the length attributes of the source string and the replacement string by using the following calculation:

\[
\text{MIN}(\text{MaxTypeLen}, \ LAS + (\LAS + 1) \times \LAR)
\]

where MaxTypeLen represents the maximum length attribute for the data type of the result, LAS represents the length attribute for the data type of the source string, and LAR represents the length attribute for the data type of the replacement string. If the replacement string is not specified, the value for LAR is 0. If the actual length of the result string exceeds the maximum for the return data type, an error is returned.

If the replacement string is specified, the result buffer length is 32672 bytes. If the replacement string is not specified, the result buffer length is the same as the length of the source string except for the following data types:

Table 83. Data types with different result buffer lengths

<table>
<thead>
<tr>
<th>Data Type</th>
<th>Length (in bytes)</th>
</tr>
</thead>
<tbody>
<tr>
<td>numerical</td>
<td>42</td>
</tr>
<tr>
<td>date</td>
<td>10</td>
</tr>
<tr>
<td>time</td>
<td>8</td>
</tr>
<tr>
<td>timestamp</td>
<td>32</td>
</tr>
</tbody>
</table>

If any argument of the REGEXP_REPLACE function can be null, the result can be null. If any argument is null, the result is the null value.
Notes

- The regular expression processing is done by using the International Components for Unicode (ICU) regular expression interface.
- Considerations for non-Unicode databases:
  - A regular expression pattern supports only halfwidth control characters; use a character string data type for the pattern expression argument. A character string data type can be used for the pattern expression argument even when a graphic string data type is used for the source string argument.
  - The source string argument must be a graphic string data type if the pattern expression argument is a graphic string data type.
  - The source string and replacement string arguments must both be character string data types or both be graphic string data types.

Example

Replace the second occurrence of the pattern 'R.d' with 'Orange' using a case sensitive search.

```sql
SELECT REGEXP_REPLACE('Red Yellow RED Blue Red Green Blue', 'R.d','Orange',1,2,'c')
FROM sysibm.sysdummy1
```

The result is 'Red Yellow RED Blue Orange Green Blue'.

REGEXP_SUBSTR

The REGEXP_SUBSTR scalar function returns one occurrence of a substring of a string that matches the regular expression pattern.

This function is pass-through-only and cannot run on Db2 for z/OS. Db2 only verifies that the data types of the parameters are valid for the function. The accelerator engine does all other function resolution processing and validation. To invoke this function, you must set the QUERY_ACCELERATION subsystem parameter, CURRENT QUERY ACCELERATION special register, or QUERYACCELERATION bind option to ALL, ENABLE, or ELIGIBLE. The function can be referenced in a view but cannot be specified as a source function for a user-defined function.

```sql
REGEXP_SUBSTR(source-string, pattern-expression, start, occurrence, flags, group, CODEUNITS32, CODEUNITS16, OCTETS)
```

The schema is SYSIBM.

source-string

An expression that specifies the string in which the search is to take place. This expression must return a built-in character string, graphic string, numeric value, Boolean value, or datetime value. A numeric, Boolean, or datetime value is implicitly cast to VARCHAR before the function is evaluated. A character string cannot specify the FOR BIT DATA attribute.
pattern-expression
An expression that specifies the regular expression string that is the pattern for
the search. This expression must return a built-in character string, graphic
string, numeric value, Boolean value, or datetime value. A numeric, Boolean, or
datetime value is implicitly cast to VARCHAR before the function is evaluated.
A character string cannot specify the FOR BIT DATA attribute.

start
An expression that specifies the position within source-string at which the
search is to start. The expression must return a built-in character string,
graphic string, Boolean, or numeric value. If the value is not of type INTEGER,
it is implicitly cast to INTEGER before the function is evaluated. The value of
the integer must be greater than or equal to 1. If OCTETS is specified and the
source string is graphic data, the value of the integer must be odd. The default
start value is 1. See parameter description for CODEUNITS16, CODEUNITS32,
or OCTETS for the string unit that applies to the start position.

occurrence
An expression that specifies which occurrence of the pattern expression within
source-string to search for. The expression must return a built-in character
string, graphic string, Boolean, or numeric value. If the value is not of type
INTEGER, it is implicitly cast to INTEGER before the function is evaluated.
The occurrence value must be greater than or equal 1. The default occurrence
value is 1, which indicates that only the first occurrence of the pattern
expression is considered.

flags
An expression that specifies flags that controls aspects of the pattern matching.
The expression must return a built-in character string that does not specify the
FOR BIT DATA attribute. The string can include one or more valid flag values
and the combination of flag values must be valid. An empty string is the same
as the value 'c'. The default flag value is 'c'.

Table 84. Supported flag values

<table>
<thead>
<tr>
<th>Flag value</th>
<th>Description</th>
</tr>
</thead>
</table>
| c          | Specifies that matching is case-sensitive. This flag is the default value if 'c' or 'i'
             | is not specified. This value must not be specified with a value of 'i'. |
| i          | Specifies that matching is case insensitive. This value must not be specified with
             | a value of 'c'. |
| m          | Specifies that the input data can contain more than one line. By default, the '
             | ^' in a pattern matches only the start of the input string; the '$' in a pattern
             | matches only the end of the input string. If this flag is set, "^" and "$" also
             | matches at the start and end of each line within the input string. |
| n          | Specifies that the '.' character in a pattern matches a line terminator in the input
             | string. By default, the '.' character in a pattern does not match a line terminator.
             | A carriage-return and line-feed pair in the input string behaves as a single-line
             | terminator and matches a single "." in a pattern. |
| s          | Specifies that the '.' character in a pattern matches a line terminator in the input
             | string. This value is a synonym for the 'n' value. |
| x          | Specifies that white space characters in a pattern are ignored, unless escaped. |

group
An expression that specifies which capture group of the pattern expression
within source string to return. The expression must return a built-in character,
binary, or graphic string, or a Boolean value. If the value is not of type
INTEGER, it is implicitly cast to INTEGER before the function is evaluated.
The group value must be greater than or equal to 0 and must not be greater
than the number of capture groups in the pattern expression. The default
group value is 0, which indicates that the string that matches the entire pattern
is to be returned.

**CODEUNITS16, CODEUNITS32, or OCTETS**
Specifies the string unit of the start value:
- CODEUNITS16 specifies that the start value is expressed in 16-bit UTF-16
code units.
- CODEUNITS32 specifies that the start value is expressed in 32-bit UTF-32
code units. This is the default.
- OCTETS specifies that the start value is expressed in bytes.

If the string unit is specified as CODEUNITS16 or OCTETS, and if the string
unit of the source string is CODEUNITS32, an error is returned.

For more information, see [String unit specifications](#).

**Result**

The result of the function is a string. The data type of the string is the same data
type as the source string, except for CHAR, which becomes VARCHAR; and
GRAPHIC, which becomes and VARGRAPHIC. The length attribute of the result
data type is same as the length attribute of the source string. The actual length of
the result is the length of the occurrence in the string that matches the pattern
expression. If the pattern expression is not found, the result is the null value.

The result buffer length is the same as the length of the source string except for the
following data types:

<table>
<thead>
<tr>
<th>Data Type</th>
<th>Length (in bytes)</th>
</tr>
</thead>
<tbody>
<tr>
<td>numerical</td>
<td>42</td>
</tr>
<tr>
<td>date</td>
<td>10</td>
</tr>
<tr>
<td>time</td>
<td>8</td>
</tr>
<tr>
<td>timestamp</td>
<td>32</td>
</tr>
</tbody>
</table>

The result of the REGEXP_SUBSTR function can be null. If any argument is null,
the result is the null value.

**Notes**
- The regular expression processing is done by using the International
  Components for Unicode (ICU) regular expression interface.
- Considerations for non-Unicode databases:
  - A regular expression pattern supports only halfwidth control characters; use a
    character string data type for the pattern expression argument. A character
    string data type can be used for the pattern expression argument even when a
    graphic string data type is used for the source string argument.
  - The source string argument must be a graphic string data type if the pattern
    expression argument is a graphic string data type.
Examples

1. Return the string which matches any character preceding a 'o'.

   ```sql
   SELECT REGEXP_SUBSTR('hello to you', '.o', 1, 1)
   FROM sysibm.sysdummy1
   ```

   The result is 'lo'.

2. Return the second string occurrence which matches any character preceding a 'o'.

   ```sql
   SELECT REGEXP_SUBSTR('hello to you', '.o', 1, 2)
   FROM sysibm.sysdummy1
   ```

   The result is 'to'.

3. Return the third string occurrence which matches any character preceding a 'o'.

   ```sql
   SELECT REGEXP_SUBSTR('hello to you', '.o', 1, 3)
   FROM sysibm.sysdummy1
   ```

   The result is 'yo'.

**REPEAT**

The REPEAT function returns a character string that is composed of an argument that is repeated a specified number of times.

```sql
REPEAT(expression, integer)
```

The schema is SYSIBM.

**expression**

An expression that specifies the string to be repeated. The expression must return a value that is a built-in character string, graphic string, or binary string data type that is not a LOB.

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type. The actual length of the string must be greater or equal to 1 and less than or equal to 32704 bytes.

**integer**

`integer` must be a positive large integer value that specifies the number of times to repeat the string.

The argument can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34) which is then assigned to an INTEGER value.

The result can be null; if any argument is null, the result is the null value.

The encoding scheme of the result is the same as `expression`. The data type of the result of the function depends on the data type of `expression`:
- VARBINARY if `expression` is a binary string
- VARCHAR if `expression` is a character string
- VARGRAPHIC if `expression` is graphic string

The CCSID of the result is the same as the CCSID of `expression`.
If integer is a constant, the length attribute of the result is the length attribute of expression times integer. Otherwise, the length attribute depends on the data type of the result:
- 4000 for VARBINARY and VARCHAR
- 2000 for VARGRAPHIC

The actual length of the result is the actual length of expression times integer. If the actual length of the result string exceeds the maximum for the return type, an error occurs.

Example 1: Repeat 'abc' two times to create 'abcabc'.

```sql
SELECT REPEAT('abc',2)
FROM SYSIBM.SYSDUMMY1;
```

Example 2: List the phrase 'REPEAT THIS' five times. Use the CHAR function to limit the output to 60 bytes.

```sql
SELECT CHAR(REPEAT('REPEAT THIS',5), 60)
FROM SYSIBM.SYSDUMMY1;
```

This example results in 'REPEAT THISREPEAT THISREPEAT THISREPEAT THISREPEAT THIS'.

Example 3: For the following query, the LENGTH function returns a value of 0 because the result of repeating a string zero times is an empty string, which is a zero-length string.

```sql
SELECT LENGTH(REPEAT('REPEAT THIS',0))
FROM SYSIBM.SYSDUMMY1;
```

Example 4: For the following query, the LENGTH function returns a value of 0 because the result of repeating an empty string any number of times is an empty string, which is a zero-length string.

```sql
SELECT LENGTH(REPEAT('', 5))
FROM SYSIBM.SYSDUMMY1;
```

**REPLACE**

The REPLACE function replaces all occurrences of search-string in source-string with replace-string. If search-string is not found in source-string, source-string is returned unchanged.

```sql
REPLACE(source-string, search-string, replace-string)
```

The schema is SYSIBM.

**source-string**

An expression that specifies the source string. The expression must return a value that is a built-in character string, graphic string, or binary string data type that is not a LOB and it cannot be an empty string.

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type.
**search-string**
An expression that specifies the string to be removed from the source string. The expression must return a value that is a built-in character string, graphic string, or binary string data type that is not a LOB; the value cannot be an empty string.

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type.

**replace-string**
An expression that specifies the replacement string. The expression must return a value that is a built-in character string, graphic string, or binary string data type that is not a LOB.

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type. If replace-string is not specified or is an empty string, nothing replaces the string that is removed from the source string.

The actual length of each string must be 32764 bytes or less for character and binary strings or 16382 or less for graphic strings.

All three arguments must have compatible data types. If the expressions have different CCSID sets, then the expressions are converted to the CCSID set of source-string.

The data type of the result of the function depends on the data type of source-string, search-string, and replace-string:

- VARCHAR if source-string is a character string. The encoding scheme of the result is the same as source-string. The CCSID of the result depends on the arguments:
  - If source-string, search-string, or replace-string is bit data, the result is bit data.
  - If source-string, search-string, and replace-string are all SBCS Unicode data, the CCSID of the result is the CCSID for SBCS Unicode data.
  - If source-string is SBCS Unicode data, and search-string or replace-string is not SBCS Unicode data, the CCSID of the result is the mixed CCSID for Unicode data.
  - Otherwise, the CCSID of the result is the mixed CCSID that corresponds to the CCSID of source-string. However, if the input is EBCDIC or ASCII and there is no corresponding system CCSID for mixed, the CCSID of the result is the CCSID of source-string.

- VARGRAPHIC if source-string is a graphic. The encoding scheme of the result is the same as source-string. The CCSID of the result is the same as the CCSID of source-string.

- VARBINARY if source-string, search-string, and replace-string are binary strings.

The length attribute of the result depends on the arguments:

- If the length attribute of replace-string is less than or equal to the length attribute of search-string, the length attribute of the result is the length attribute of source-string.

- If the length attribute of replace-string is greater than the length attribute of search-string, the length attribute of the result is determined as follows depending on the data type of the result:
  - For VARCHAR or VARBINARY:
- If $L_1 \leq 4000$, the length attribute of the result is $\min(4000, (L_3 \times (L_1 / L_2)) + \text{MOD}(L_1, L_2))$
- Otherwise, the length attribute of the result is $\min(32764, (L_3 \times (L_1 / L_2)) + \text{MOD}(L_1, L_2))$

- For VARGRAPHIC:
  - If $L_1 \leq 2000$, the length attribute of the result is $\min(2000, (L_3 \times (L_1 / L_2)) + \text{MOD}(L_1, L_2))$
  - Otherwise, the length attribute of the result is $\min(16382, (L_3 \times (L_1 / L_2)) + \text{MOD}(L_1, L_2))$

where:
- $L_1$ is the length attribute of source-string
- $L_2$ is the length attribute of search-string if the search string is a string constant. Otherwise, $L_2$ is 1.
- $L_3$ is the length attribute of replace-string

If the result is a character string or binary string, the length attribute of the result must not exceed 32764. If the result is a graphic string, the length attribute of the result must not exceed 16382.

The actual length of the result is the actual length of source-string plus the number of occurrences of search-string that exist in source-string multiplied by the actual length of replace-string minus the actual length of search-string. If the actual length of the result string exceeds the maximum for the return data type, an error occurs.

The result can be null; if any argument is null, the result is the null value.

Example 1: Replace all occurrences of the character 'N' in the string 'DINING' with 'VID'. Use the CHAR function to limit the output to 10 bytes.

```sql
SELECT CHAR(REPLACE('DINING', 'N', 'VID'), 10)
FROM SYSIBM.SYSDUMMY1;
```

The result is the string 'DIVIDIVIDG'.

Example 2: Replace string 'ABC' in the string 'ABCXYZ' with nothing, which is the same as removing 'ABC' from the string.

```sql
SELECT REPLACE('ABCXYZ', 'ABC', '')
FROM SYSIBM.SYSDUMMY1;
```

The result is the string 'XYZ'.

Example 3: Replace string 'ABC' in the string 'ABCCABCC' with 'AB'. This example illustrates that the result can still contain the string that is to be replaced (in this case, 'ABC') because all occurrences of the string to be replaced are identified prior to any replacement.

```sql
SELECT REPLACE('ABCCABCC', 'ABC', 'AB')
FROM SYSIBM.SYSDUMMY1;
```

The result is the string 'ABCABC'.

Related concepts:
- Character strings
- Binary strings
- Graphic strings
The RID function returns the record ID (RID) of a row. The RID is used to uniquely identify a row.

The schema is SYSIBM.

The function might return a different value when it is invoked multiple times for a row. For example, after the REORG utility is run, the RID function might return a different value for a row than would have been returned prior to the REORG utility being run. The RID function is not deterministic.

**table-designator**

*table-designator* must uniquely identify a base table, a view, or a nested table expression of a subselect in which the function is referenced.

If *table-designator* specifies a view or a nested table expression, the RID function returns the RID of the base table of the view or nested table expression. The specified view or nested table expression must contain only one base table in its outer subselect.

*table-designator* must not specify a table function, a collection-derived table, a materialized view, a nested table expression that is materialized, an alias, or a synonym.

The result of the function is BIGINT. The result can be null.

**Considerations for RID values:** Db2 might reuse RID numbers when a REORG operation is performed. If the RID function is used to obtain a value for a row and an application depends on that value remaining the same as long as the row exists, consider the following alternatives:

- Add a ROWID column to the table to provide a value that can be associated with each row, rather than invoking the RID function to generate a value for a row.
- Define a primary key for the table, using the columns of the primary key to ensure uniqueness, rather than invoking the RID function to generate a value for a row.

**Example 1:** Return the RID and last name of employees who are in department '20':

```sql
SELECT RID(EMP), LASTNAME
FROM EMP
WHERE DEPTNO = '20';
```

**Example 2:** Set the host variable *HV_EMP_RID* as the value of the RID for the employee with the employee number of '3500':

```sql
SELECT RID(EMP) INTO :HV_EMP_RID
FROM EMP
WHERE EMPNO = '3500';
```
RIGHT

The RIGHT function returns a string that consists of the specified number of rightmost bytes or specified string unit from a string.

\[
\text{RIGHT}(\text{string-expression}, \text{integer}) \begin{cases} \text{CODEUNITS16} \\ \text{CODEUNITS32} \\ \text{OCTETS} \end{cases}
\]

The schema is SYSIBM.

\textit{string-expression}

An expression that specifies the string from which the result is derived. The string must be any built-in string data type. A substring of \textit{string-expression} is zero or more contiguous code points of \textit{string-expression}. A partial surrogate character in the expression is replaced with a blank.

The string can contain mixed data. Depending on the units that are specified to evaluate the function, the result is not necessarily a properly formed mixed data character string.

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type.

\textit{integer}

An expression that specifies the length of the result. The value must be an integer between 0 and \(n\), where \(n\) is the length attribute of \textit{string-expression}, expressed in the units that are either implicitly or explicitly specified.

The argument can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of \text{DECFLOAT}(34) which is then assigned to an \text{INTEGER} value.

If \text{CODEUNITS16} or \text{CODEUNITS32} is specified, see "Determining the length attribute of the final result" on page 117 for information about how to calculate the length attribute of the result string.

\text{CODEUNITS16}, \text{CODEUNITS32}, \text{or OCTETS}

Specifies the unit that is used to express \textit{integer}. If \textit{string-expression} is a character string that is defined as bit data, \text{CODEUNITS16} and \text{CODEUNITS32} cannot be specified. If \textit{string-expression} is a graphic string, OCTETS cannot be specified. If \textit{string-expression} is a binary string, \text{CODEUNITS16}, \text{CODEUNITS32}, and OCTETS cannot be specified.

\text{CODEUNITS16}

Specifies that \textit{integer} is expressed in terms of 16-bit UTF-16 code units.

\text{CODEUNITS32}

Specifies that \textit{integer} is expressed in terms of 32-bit UTF-32 code units.

\text{OCTETS}

Specifies that \textit{integer} is expressed in terms of bytes.

For more information about \text{CODEUNITS16}, \text{CODEUNITS32}, and OCTETS, see \text{String unit specifications}.
The string-expression is effectively padded on the right with the necessary number of padding characters so that the specified substring of string-expression always exists. The encoding scheme of the data determines the padding character:

- For ASCII SBCS data or ASCII mixed data, the padding character is X'20'.
- For ASCII DBCS data, the padding character depends on the CCSID; for example, for Japanese (CCSID 301) the padding character is X'8140', while for simplified Chinese it is X'A1A1'.
- For EBCDIC SBCS data or EBCDIC mixed data, the padding character is X'40'.
- For EBCDIC DBCS data, the padding character is X'4040'.
- For Unicode SBCS data or UTF-8 data (Unicode mixed data), the padding character is X'20'.
- For UTF-16 data (Unicode DBCS data), the padding character is X'0020'.
- For binary data, the padding character is X'00'.

The result of the function is a varying-length string with a length attribute that is the same as the length attribute of string-expression and a data type that depends on the data type of string-expression:

- VARBINARY if string-expression is BINARY or VARBINARY
- VARCHAR if string-expression is CHAR or VARCHAR
- CLOB if string-expression is CLOB
- VARGRAPHIC if string-expression is GRAPHIC or VARGRAPHIC
- DBCLOB if string-expression is DBCLOB
- BLOB if string-expression is BLOB

The actual length of the result is determined from integer.

The result can be null; if any argument is null, the result is the null value.

The CCSID of the result is the same as that of string-expression.

**Example 1:** Assume that host variable ALPHA has a value of 'ABCDEF'. The following statement returns the value 'DEF', which are the three rightmost characters in ALPHA.

```
SELECT RIGHT(ALPHA,3)
FROM SYSIBM.SYSDUMMY1;
```

**Example 2:** The following statement returns a zero length string.

```
SELECT RIGHT('ABCABC',0)
FROM SYSIBM.SYSDUMMY1;
```

**Example 3:** FIRSTNME is a VARCHAR(12) column in table T1. When FIRSTNME has the 6-character string 'Jürgen' as a value:

```
Function ... | Returns ...
------------|----------
RIGHT(FIRSTNME,5,CODEUNITS32) | 'ürgen' -- x'C3BC7267656E'
RIGHT(FIRSTNME,5,CODEUNITS16) | 'ürgen' -- x'C3BC7267656E'
RIGHT(FIRSTNME,5,OCTETS) | 'rgen' -- x'207267656E' A truncated string
```

**Example 4:** In the following example, the last invocation of the RIGHT function returns a partial surrogate character:

```
Function ... | Returns ...
------------|----------
RIGHT('Jürgen',5,CODEUNITS32) | 'ürgen' -- x'C3BC7267656E'
RIGHT('Jürgen',5,CODEUNITS16) | 'ürgen' -- x'C3BC7267656E'
RIGHT('Jürgen',5,OCTETS) | 'rgen' -- x'207267656E' A truncated string
HEX(RIGHT('Jürgen',5)) | x'BC7267656E' -- A partial character followed by 'rgen'
```
ROUND

The ROUND function returns a number that is rounded to the specified number of places to the right or left of the decimal place.

\[ \text{ROUND}(\text{numeric-expression-1}, \text{numeric-expression-2}) \]

The schema is SYSIBM.

**numeric-expression-1**

An expression that returns a value of any built-in numeric data type.

If `expression-1` is a decimal floating-point data type, the DECFLOAT ROUNDMODE will not be used. The rounding behavior of ROUND corresponds to a value of ROUND_HALF_UP. If you want a different rounding behavior, use the QUANTIZE function.

The argument can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34).

**numeric-expression-2**

An expression that returns a value that is a built-in numeric, character string or graphic string data type. If the value is not of type INTEGER, it is implicitly cast to INTEGER before evaluating the function.

The absolute value of integer specifies the number of places to the right of the decimal point for the result if `numeric-expression-2` is not negative. If `numeric-expression-2` is negative, `numeric-expression-1` is rounded to the sum of the absolute value of `numeric-expression-2` + 1 number of places to the left of the decimal point.

If the absolute value of `numeric-expression-2` is larger than the number of digits to the left of the decimal point, the result is 0. (For example, ROUND(748.58, -4) returns 0.)

If `numeric-expression-1` is positive, a digit value of 5 is rounded to the next higher positive number. If `numeric-expression-1` is negative, a digit value of 5 is rounded to the next lower negative number.

The result of the function has the same data type and length attribute as the first argument except that the precision is increased by one if the argument is DECIMAL and the precision is less than 31. For example, an argument with a data type of DECIMAL(5,2) results in DECIMAL(6,2). An argument with a data type of DECIMAL(31,2) results in DECIMAL(31,2).

The result can be null; if any argument is null, the result is the null value.

**Example 1**: Calculate the number '873.726' rounded to '2', '1', '0', '-1', and '-2' decimal places respectively.

```
SELECT ROUND(873.726, 2),
       ROUND(873.726, 1),
       ROUND(873.726, 0),
       ROUND(873.726, -1),
```

588 SQL Reference
The ROUND function returns the values '0873.730', '0873.700', '0874.000', '0870.000', '0900.000', '1000.000', and '0000.000'.

Example 2: To demonstrate how numbers are rounded in positive and negative values, calculate the numbers '3.5', '3.1', '-3.1', '-3.5' rounded to '0' decimal places.

```sql
SELECT ROUND(3.5,0),
       ROUND(3.1,0),
       ROUND(-3.1,0),
       ROUND(-3.5,0)
FROM SYSIBM.SYSDUMMY1;
```

This example returns the values '04.0', '03.0', '-03.0', and '-04.0'. (Notice that in the positive value '3.5' is rounded up to the next higher number while in the negative value '-3.5' is rounded down to the next lower negative number.)

### ROUND_TIMESTAMP

The ROUND_TIMESTAMP scalar function returns a timestamp that is rounded to the unit that is specified by the timestamp format string.

```
ROUND_TIMESTAMP(expression, 'DD')
```

The schema is SYSIBM.

**expression**

An expression that returns a value of any of the following built-in data types: a timestamp, a character string, or a graphic string. If `expression` is a character or graphic string, it must not be a CLOB or DBCLOB, and its value must be a valid string representation of a timestamp with an actual length that is not greater than 255 bytes. A time zone in a string representation of a timestamp is ignored. For the valid formats of string representations of dates and timestamps, see "String representations of datetime values" on page 130.

**format-string**

An expression that returns a built-in character string or graphic string data type, with a length that is not greater than 255 bytes. `format-string` contains a template of how the timestamp represented by `expression` should be rounded. For example, if `format-string` is 'DD', the timestamp that is represented by `expression` is rounded to the nearest day. `format-string` must be a valid template for a timestamp, and not include leading or trailing blanks.

Allowable values for `format-string` are listed in the following table.
<table>

| SS24         |                              | Result: 2000-05-17-23.58.46.000000        | Result: 2000-05-17-23.58.45.000000 |

If expression does not have data type TIMESTAMP WITHOUT TIME ZONE, expression is cast as follows:

- If expression is a TIMESTAMP WITH TIME ZONE value, expression is cast to TIMESTAMP WITHOUT TIME ZONE, with the same precision as expression.
- Otherwise, expression is cast to TIMESTAMPT(6) WITHOUT TIME ZONE.

The result of the function has the same data type as the data type to which expression is cast.

The result can be null; if any argument is null, the result is the null value.

The result CCSID is the appropriate CCSID of the argument encoding scheme and the result subtype is the appropriate subtype of the CCSID.

Example 1: Set the host variable RND_TMSTMP with the input timestamp rounded to the nearest year value.

```sql
SET :RND_TMSTMP = ROUND_TIMESTAMP(TIMESTAMP_FORMAT('2000-08-14 17:30:00', 'YYYY-MM-DD HH24:MI:SS'), 'YEAR');
```

The value set is '2001-01-01-00.00.00.000000'.

Example 2: Assume PRSTSZ is an SQL variable with the TIMESTAMP WITH TIME ZONE value '2008-04-15.20.00.000000-08:30'. The input value is first cast to TIMESTAMP WITHOUT TIME ZONE (as '2008-04-15.20.00.000000') for the ROUND_TIMESTAMP function.

```sql
SELECT ROUND_TIMESTAMP(PRSTSZ) FROM PROJECT;
```

The ROUND_TIMESTAMP function returns a TIMESTAMP WITHOUT TIME ZONE value of '2008-04-16.00.00.000000'.
**ROWID**

The ROWID function returns a row ID representation of its argument.

```sql
ROWID(expression)
```

The schema is SYSIBM.

The argument must be an expression that returns a value of a built-in character string data type, other than a CLOB, with a maximum length that is no greater than 255 bytes. Although the character string can contain any value, it is recommended that the character string contain a ROWID value that was previously generated by Db2 to ensure a valid ROWID value is returned. For example, the function can be used to convert a ROWID value that was cast to a CHAR value back to a ROWID value.

If the actual length of `expression` is less than 40, the result is not padded. If the actual length of `expression` is greater than 40, the result is truncated. If non-blank characters are truncated, a warning is returned.

The result of the function is a row ID value.

The length attribute of the result is 40. The actual length of the result is the length of `expression`.

The result can be null; if the argument is null, the result is the null value.

A null ROWID value cannot be used as the value for a row ID column in the database.

Assume that table EMPLOYEE contains a row ID column, 'EMP_ROWID'. Also assume that the table contains a row that is identified by a ROWID value that is equivalent to `X'F0DF230E3C0D80D81C201AA0A28010000000000203'`. Using direct row access, select the employee number for that row.

```sql
SELECT EMPNO
FROM EMPLOYEE
WHERE EMP_ROWID=ROWID('X'F0DF230E3C0D80D81C201AA0A28010000000000203');
```

**Related information:**

**RPAD**

The RPAD function returns a string that is padded on the right with blanks or a specified string.

```sql
RPAD(string-expression, integer, pad)
```
The schema is SYSIBM.

The RPAD function returns a string composed of string-expression padded on the right, with pad or blanks. The RPAD function treats leading or trailing blanks in string-expression as significant. Padding will only occur if the actual length of string-expression is less than integer, and pad is not an empty string.

string-expression
An expression that specifies the source string. The expression must return a value that is a built-in string data type that is not a LOB.

integer
An integer constant that specifies the length of the result. The value must be zero or a positive integer that is less than or equal to n, where n is 32704 if string-expression is a character or binary string, or where n is 16352 if string-expression is a graphic string.

pad
An expression that specifies the string with which to pad. The expression must return a value that is a built-in string data type that is not a LOB. If pad is not specified, the pad character is determined as follows:
- SBCS blank character if string-expression is a character string.
- DBCS blank character if string-expression is a graphic string.
- Hexadecimal zero (X'00'), if string-expression is a binary string.

The result of the function is a varying length string that has the same CCSID of string-expression. string-expression and pad must have compatible data types. If the string expressions have different CCSID sets, then pad is converted to the CCSID set of string-expression. If either string-expression or pad is FOR BIT DATA, no character conversion occurs. The actual length of the result is determined from integer.

The length attribute of the result depends on integer. If integer is greater than 0, the length attribute of the result is integer. If integer is 0, the length attribute of the result is 1.

The actual length of the result is determined from integer. If integer is 0, the actual length is 0, and the result is the empty string. If integer is less than the actual length of string-expression, the actual length is integer and the result is truncated.

The result can be null; if any argument is null, the result is the null value.

Example 1: Assume that NAME is a VARCHAR(15) column that contains the values 'Chris', 'Meg', and 'Jeff'. The following query will completely pad out a value on the right with periods.

```
SELECT RPAD(NAME,15,'.') AS NAME
FROM T1;
```

The results are similar to the following output:

```
NAME
------------------
Chris............
Meg..............
Jeff..............
```
Example 2: Similar to Example 1, the following query will completely pad out a value on the right with pad (note that in some cases there is a partial instance of the padding specification):

```sql
SELECT RPAD(NAME,15,'123') AS NAME
FROM T1;
```

The results are similar to the following output:

<table>
<thead>
<tr>
<th>NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>Chris1231231231</td>
</tr>
<tr>
<td>Meg123123123123</td>
</tr>
<tr>
<td>Jeff12312312312</td>
</tr>
</tbody>
</table>

Example 3: Similarly, the following query will only pad each value to a length of 5:

```sql
SELECT RPAD(NAME,5,'.') AS NAME
FROM T1;
```

The results are similar to the following output:

<table>
<thead>
<tr>
<th>NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>Chris</td>
</tr>
<tr>
<td>Meg..</td>
</tr>
<tr>
<td>Jeff.</td>
</tr>
</tbody>
</table>

Example 4: Assume that NAME is a CHAR(15) column that contains the values 'Chris', 'Meg', and 'Jeff'. Note that the result of RTRIM in the following example is a varying length string with the blanks removed:

```sql
SELECT RPAD(RTRIM(NAME),15,'.') AS NAME
FROM T1;
```

The results are similar to the following output:

<table>
<thead>
<tr>
<th>NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>Chris........</td>
</tr>
<tr>
<td>Meg...........</td>
</tr>
<tr>
<td>Jeff...........</td>
</tr>
</tbody>
</table>

**RTRIM**

The RTRIM function removes bytes from the end of a string expression based on the content of a trim expression.

```
RTRIM(—string-expression—,—trim-expression—)
```

The schema is SYSIBM.

The RTRIM function removes all of the characters contained in trim-expression from the end of string-expression. The search is done by comparing the binary representation of each character (which consists of one or more bytes) in trim-expression to the bytes at the end of string-expression. If string-expression is
defined as FOR BIT DATA, the search is done by comparing each byte in
trim-expression to the byte at the end of string-expression.

string-expression
An expression that specifies the source string. The argument must be an
expression that returns a value that is a built-in string data type that is not a
LOB, or a numeric data type. If the value is not a string data type, it is
implicitly cast to VARCHAR before the function is evaluated. If
string-expression is not FOR BIT DATA, trim-expression must not be FOR BIT
DATA.

trim-expression
An expression that specifies the characters to remove from the end of
string-expression. The expression must return a value that is a built-in string
data type that is not a LOB, or a numeric data type. If the value is not a string
data type, it is implicitly cast to VARCHAR before the function is evaluated.

The default for trim-expression depends on the data type of string-expression:

- A DBCS blank if string-expression is a DBCS graphic string. For ASCII, the
  CCSID determines the hex value that represents a DBCS blank. For example,
  for Japanese (CCSID 301), X'8140' represents a DBCS blank, while for
  Simplified Chinese, X'A1A1' represents a DBCS blank. For EBCDIC, X'4040'
  represents a DBCS blank.
- A UTF-16 or UCS-2 blank (X'0020') if string-expression is a Unicode graphic
  string.
- A value of X'00' if string-expression is a binary string.
- Otherwise, a single byte blank. For EBCDIC, X'40' represents a blank. When
  not EBCDIC, X'20' represents a blank.

string-expression and trim-expression must have compatible data types. If
string-expression and trim-expression have different CCSID sets, trim-expression is
converted to the CCSID of string-expression.

The result of the function depends on the data type of string-expression.

- VARCHAR if string-expression is a character string. If string-expression is defined
  as FOR BIT DATA, the result is FOR BIT DATA.
- VARGRAPHIC if string-expression is a graphic string.
- VARBINARY if string-expression is a binary string.

The length attribute of the result is the same as the length attribute of
string-expression.

The actual length of the result for a character or binary string is the length of
string-expression minus the number of bytes removed. The actual length of the
result for a graphic string is the length (in number of double byte characters) of
string-expression minus the number of double byte characters removed. If all of the
characters are removed, the result is an empty string (the length is zero).

The result can be null; if the argument is null, the result is the null value.

The CCSID of the result is the same as that of string-expression.
Example: Use the RTRIM function to remove individual numbers in the second argument from the end (right side) of the first argument:

```sql
SELECT RTRIM ('123DEFG123', '321'),
       RTRIM ('12322XYZ1232222', '123'),
       RTRIM ('12321', '213'),
       RTRIM ('123XYX', '321')
FROM SYSIBM.SYSDUMMY1
```

The result is '123DEFG', '12322XYZ', " (empty string - all characters removed), and '123XYX' (no characters removed).

The RTRIM function does not remove instances of '1', '2', and '3' on the left side of the string, before characters that are not '1', '2', or '3'.

Example: Use the RTRIM function to remove individual characters in the second argument from the end (right side) of the first argument:

```sql
SELECT RTRIM ('((-78.0))', '-0.()')
FROM SYSIBM.SYSDUMMY1
```

The result is '((-78).'.

Example: Use the RTRIM function to remove dollar signs and periods in the second argument from the end (right side) of the first argument:

```sql
SELECT RTRIM ('...$VAR$...', '$.')
FROM SYSIBM.SYSDUMMY1
```

The result is '...$VAR'.

**SCORE**

The SCORE function searches a text search index using criteria that are specified in a search argument and returns a relevance score that measures how well a document matches the query.

**Requirement:** To use the SCORE function, Text Search for Db2 for z/OS must be installed and configured. See IBM Text Search for Db2 for z/OS (IBM Text Search for Db2 for z/OS Installation, Administration, and Reference) for more information.

```
SCORE(---column-name---,---search-argument--- ,---string-constant---) (1)
```

**Notes:**

1. *string-constant* must conform to the rules for the *search-argument-options.*
The schema is SYSIBM.

**column-name**
Specifies a qualified or unqualified name of a column that has a text search index that is to be searched. The column must exist in the table or view that is identified in the FROM clause in the statement and the column of the table, or the column of the underlying base table of the view must have an associated text search index. The underlying expression of the column of a view must be a simple column reference to the column of an underlying table, either directly or through another nested view.

**search-argument**
Specifies an expression that returns a value that is a string value (except a LOB) that contains the terms to be searched for and must not be all blanks or the empty string. The actual length of the string must not exceed 4096 Unicode characters. The value is converted to Unicode before it is used to search the text search index. The maximum number of terms per query must not exceed 1024.

**string-constant**
Identifies a string constant that specifies the search argument options that are in effect for the function.

The options that can be specified as part of the *search-argument-options* are as follows:

**QUERYLANGUAGE = value**
Specifies the query language. The value can be any of the supported language codes. If the QUERYLANGUAGE option is not specified, the default is the language value of the text search index that is used when this function is invoked. If the language value of the text search index is AUTO, the default value for QUERYLANGUAGE is en_US.

**RESULTLIMIT = value**
Specifies the maximum number of results that are to be returned from the underlying search engine. The value can be an integer value between 1 and 2,147,483,647. If the RESULTLIMIT option is not specified, no result limit is in effect for the query.

This scalar function cannot be called for each row of the result table, depending on the plan that the optimizer chooses. This function can be called once for the query to the underlying search engine, and a result set of all of the primary keys that match are returned from the search engine. This result set is then joined to the table containing the column
to identify the result rows. In this case, the RESULTLIMIT value acts like a FETCH FIRST ?? ROWS from the underlying text search engine and can be used as an optimization. If the search engine is called for each row of the result because the optimizer determines that is the best plan, then the RESULTLIMIT option has no effect.

**SYNONYM = OFF or SYNONYM = ON**

Specifies whether to use a synonym dictionary that is associated with the text search index. Use the Synonym Tool to add a synonym dictionary to the collection. The default is OFF.

- **OFF**: Do not use a synonym dictionary.
- **ON**: Use the synonym dictionary that is associated with the text search index.

The result of the function is a double-precision floating-point number. If the second argument can be null, the result can be null. If the second argument is null, the result is the null value. If the third argument is null, the result is as if the third argument was not specified.

The result is greater than 0 but less than 1 if the column contains a match for the search criteria that the search argument specifies. The better a document matches the query, the more relevant the score and the larger the result value. If the column does not contain a match, the result is 0.

**SCORE** is a non-deterministic function.

**Example**

Assume that information about employees’ skills are stored in a table named EMP_RESUME. The following statement generates a list of employees in the order of how well their resumes matches the query "programmer AND (java OR cobol)", along with a relevance value that is normalized between 0 (zero) and 100.

```sql
SELECT EMPNO,
       INTEGER(SCORE(RESUME, 'programmer AND (java OR cobol)') * 100) AS RELEVANCE
FROM EMP_RESUME
WHERE RESUME_FORMAT = 'ascii'
  AND CONTAINS(RESUME, 'programmer AND (java OR cobol)') = 1
ORDER BY RELEVANCE DESC
```

Db2 first evaluates the CONTAINS predicate in the WHERE clause, and therefore, does not evaluate the SCORE function in the SELECT list for every row of the table. In this case, the arguments for SCORE and CONTAINS must be identical.

**SECOND**

The SECOND function returns the seconds part of a value with optional fractional seconds.

```
SECOND(expression[, integer-constant])
```

The schema is SYSIBM.
expression

expression must be an expression that returns a value of one of the following built-in data types: a time, a timestamp, a character string, a graphic string, or a numeric data type.

- If expression is a character or graphic string, it must not be a CLOB or DBCLOB, and its value must be a valid string representation of a time or timestamp with an actual length that is not greater than 255 bytes. For the valid formats of string representations of times and timestamps, see “String representations of datetime values” on page 130.
- If expression is a number, it must be a time or timestamp duration. For the valid formats of time and timestamp durations, see “Datetime operands” on page 177.

integer-constant

integer-constant must be an integer constant that represents the scale for the fractional seconds portion of expression. The value must be in the range 0 through 12. If integer-constant is not specified, the result does not include fractional seconds.

If expression is a timestamp with a time zone, or a valid string representation of a timestamp with a time zone, the result is determined from the UTC representation of the datetime value.

The result of the function with a single argument is a large integer. The result of the function with two arguments is DECIMAL(2+s,s) where s is the value of integer-constant.

The result can be null; if the first argument is null, the result is the null value.

The other rules depend on the data type of the argument:

If the argument is a time, timestamp, or string representation of a time or a timestamp:

The result is the seconds part of the value (0 to 59) and any fractional seconds that are included in the value. If the second argument is specified, the result includes integer-constant digits of the fractional seconds part of the value where applicable. If there are no fractional seconds in the value, zeros are returned.

If the argument is a time duration or timestamp duration:

The result is the seconds part of the value (-99 to 99) and any fractional seconds that are included in the value. If the second argument is specified, the result includes integer-constant digits of the fractional seconds part of the value where applicable. If there are no fractional seconds in the value, zeros are returned. A nonzero result has the same sign as the expression.

Example 1: Assume that the variable TIME_DUR is declared in a PL/I program as DECIMAL(6,0) and can therefore be interpreted as a time duration. When TIME_DUR has the value 153045, the following function returns the value 45.

SECOND(:TIME_DUR)

Example 2: Assume that RECEIVED is a TIMESTAMP column and that one of its values is the internal equivalent of '1988-12-25-17.12.30.000000'. The following function returns the value 30.

SECOND(RECEIVED)
**Example 3:** The following invocations of the SECOND function returns the same result:

```sql
SELECT SECOND('2003-01-02-20.10.05.123456'),
       SECOND('2003-01-02-12.10.05.123456-08:00'),
       SECOND('2003-01-03-05.10.05.123456+09:00')
FROM SYSIBM.SYSDUMMY1;
```

For each invocation of the SECOND function in this SELECT statement, the result is 5.

When the input argument contains a time zone, the result is determined from the UTC representation of the input value. The string representations of a timestamp with a time zone in the SELECT statement all have the same UTC representation: 2003-01-02-20.10.05.123456. The second portion of the UTC representation is 5.

**Example 4:** Return the seconds with fractional seconds from a current timestamp with milliseconds.

```sql
SELECT SECOND(CURRENT_TIMESTAMP(3),3)
FROM SYSIBM.SYSDUMMY1;
```

The SELECT statement returns a DECIMAL(5,3) value that is based on the current timestamp and could be something like 54.321.

**SIGN**

The SIGN function returns an indicator of the sign of the argument.

```sql
SIGN(numeric-expression)
```

The schema is SYSIBM.

The returned value is one of the following values:

- 1 if the argument is less than zero
- 0 if the argument is DECFLOAT negative zero
- 0 if the argument is zero
- 1 if the argument is greater than zero

The argument must be an expression that returns a value of any built-in numeric data type, except DECIMAL(31,31).

The argument can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34).

The result has the same data type and length attribute as the argument, except that precision is increased by one if the argument is DECIMAL and the scale of the argument is equal to its precision. For example, an argument with a data type of DECIMAL(5,5) will result in DECIMAL(6,5).

The result can be null; if the argument is null, the result is the null value.

**Example:** Assume that host variable PROFIT is a large integer with a value of 50000.
SELECT SIGN(:PROFIT)
    FROM SYSIBM.SYSDUMMY1;

This example returns the value 1.

**SIN**

The SIN function returns the sine of the argument, where the argument is an angle, expressed in radians.

\[
\text{SIN(numeric-expression)}
\]

The schema is SYSIBM.

The SIN and ASIN functions are inverse operations.

The argument must be an expression that returns the value of any built-in numeric data type that is not DECFLOAT. If the argument is not a double precision floating-point number, it is converted to one for processing by the function.

The result of the function is a double precision floating-point number.

The result can be null; if the argument is null, the result is the null value.

*Example:* Assume that host variable SINE is DECIMAL(2,1) with a value of 1.5. The following statement returns a double precision floating-point number with an approximate value of 0.99.

```
SELECT SIN(:SINE)
    FROM SYSIBM.SYSDUMMY1;
```

**SINH**

The SINH function returns the hyperbolic sine of the argument, where the argument is an angle, expressed in radians.

\[
\text{SINH(numeric-expression)}
\]

The schema is SYSIBM.

The argument must be an expression that returns the value of any built-in numeric data type that is not DECFLOAT. If the argument is not a double precision floating-point number, it is converted to one for processing by the function.

The result of the function is a double precision floating-point number.

The result can be null; if the argument is null, the result is the null value.
Example: Assume that host variable HSINE is DECIMAL(2,1) with a value of 1.5. The following statement returns a double precision floating-point number with an approximate value of 2.12.

```
SELECT SINH(:HSINE)
FROM SYSIBM.SYSDUMMY1;
```

**SMALLINT**

The SMALLINT function returns a small integer representation either of a number or of a string representation of a number.

**Numeric to Smallint:**

```
SMALLINT(numeric-expression)
```

**String to Smallint:**

```
SMALLINT(string-expression)
```

The schema is SYSIBM.

**Numeric to Smallint**

`numeric-expression`

An expression that returns a value of any built-in numeric data type.

The result is the same number that would occur if the argument were assigned to a small integer column or variable. If the whole part of the argument is not within the range of small integers, an error occurs. If present, the decimal part of the argument is truncated.

**String to Smallint**

`string-expression`

An expression that returns a value of character or graphic string (except a CLOB or DBCLOB) with a length attribute that is not greater than 255 bytes for a character string or 127 for a graphic string. The string must contain a valid string representation of a number.

The result is the same number that would result from `CAST(string-expression AS SMALLINT)`. Leading and trailing blanks are eliminated and the resulting string must conform to the rules for forming an SQL integer constant.

The result of the function is a small integer.

The result can be null; if the argument is null, the result is the null value.

**Recommendation:** To increase the portability of applications, use the CAST specification. For more information, see “CAST specification” on page 283.
Example: Using sample table DSN8C10.EMP, find the average education level (EDLEVEL) of the employees in department 'A00'. Round the result to the nearest full education level.

```sql
SELECT SMALLINT(AVG(EDLEVEL)+.5) FROM DSN8C10.EMP WHERE DEPT = 'A00';
```

Assuming that the five employees in the department have education levels of '19', '18', '14', '18', and '14', the result is '17'.

**SOUNDEX**

The SOUNDEX function returns a 4-character code that represents the sound of the words in the argument. The result can be compared to the results of the SOUNDEX function of other strings.

```
SOUNDEX(expression)
```

The schema is SYSIBM.

**expression**

An expression that must return a value of any built-in numeric, character, or graphic string data type that is not a LOB. A numeric, mixed character, or graphic string value is cast to a Unicode SBCS character string before the function is evaluated. For more information about converting numeric data to a character string, see VARCHAR. For more information about converting mixed or graphic strings to Unicode SBCS, see “CAST specification” on page 283.

The data type of the result is CHAR(4).

The result can be null; if the argument is null, the result is the null value.

The CCSID of the result is the Unicode SBCS CCSID.

The SOUNDEX function is useful for finding strings for which the sound is known but the precise spelling is not. It makes assumptions about the way that letters and combinations of letters sound that can help to search for words with similar sounds. The comparison of words can be done directly or by passing the strings as arguments to the DIFFERENCE function. For more information, see “DIFFERENCE” on page 470.

**Example 1:** Use the SOUNDEX function to find a row where the sound of the LASTNAME value closely matches the phonetic spelling of 'Loucesy':

```sql
SELECT EMPNO, LASTNAME FROM DSN910.EMPLOYEE WHERE SOUNDEX(LASTNAME) = SOUNDEX('Loucesy');
```

This example returns the following row:

000110 LUCCHESI;
SOAPHTTPC and SOAPHTTPPV

The SOAPHTTPC function returns a CLOB representation of XML data that results from a SOAP request to the web service that is specified by the first argument. The SOAPHTTPPV function returns a VARCHAR representation of XML data that results from a SOAP request to the web service that is specified by the first argument.

The schema is DB2XML.

These functions are deprecated and might not be available in future releases of Db2.

**endpoint_url**

An expression that returns a value of a built-in character string or graphic string data type that is not a LOB. The value specifies the URL of the web service endpoint for which Db2 is acting as a client.

**soap_action**

An expression that returns a value of a built-in character string or graphic string data type that is not a LOB. The value specifies a SOAP action URI reference. If it is required for the web service that is specified in **endpoint_url**, the required value is defined in the WSDL of that web service.

**soap_body**

An expression that returns a value of a built-in character string data type that is defined as VARCHAR(3072) or CLOB(1M). The value specifies the name of an operation with the requested namespace URI, an encoding style, and input arguments. **soap_body** can include well-formed XML content for the SOAP body. The specific operations and arguments for a web service are defined in the WSDL of the specified web service.

If the arguments can be null, the result can be null; if all of the arguments are null, the result is the null value.

The result can be null; if all of the arguments are null, the result is the null value.

**Example 1:** The following SQL statement retrieves information (as VARCHAR data) about a web service:

```sql
SELECT DB2XML.SOAPHTTPPV('http://www.myserver.com/services/db2sample/ivt.dadx/SOAP',
   'http://tempuri.org/db2sample/ivt.dadx',
   '<testInstallation xmlns="http://tempuri.org/db2sample/ivt.dadx"/>
')
FROM SYSIBM.SYSDUMMY1
```

**Example 2:** The following SQL statement inserts the results (as CLOB data) from a request to a web service into a table:

```sql
INSERT INTO EMPLOYEE(XMLCOL)
VALUES (DB2XML.SOAPHTTPC('http://www.myserver.com/services/db2sample/list.dadx/SOAP',
```
The SOAPHTTPNC and SOAPHTTPNV functions allow you to specify a complete SOAP message as input and to return complete SOAP messages from the specified web service. The returned SOAP messages are CLOB or VARCHAR representations of the returned XML data.

**SOAPHTTPNC and SOAPHTTPNV**

The schema is DB2XML.

*endpoint_url*

Specifies the URL of the web service for which Db2 is acting as a client. *endpoint_url* is defined as a VARCHAR(4096) value. The URL is in the following format:

```
proto://[user[:password]@]hostname[:port]/[path]
```

Where *proto* can be http or https.

*soap_action*

Specifies a SOAP action URI reference. *soap_action* is defined as a VARCHAR(4096) value. Depending on the web server, *soap_action* might be required. If it is required for the web service that is specified in *endpoint_url*, the required value is defined in the WSDL of that web service.

*soap_input*

Specifies an XML document that contains the complete SOAP message. *soap_input* can contain optional SOAP headers and must contain a SOAP body that specifies the operation name and parameters to the web service. *soap_input* should be well-formed XML that is defined as VARCHAR(32672) or CLOB(1M).

**Example 1:** The following SQL statement retrieves information (as VARCHAR data) about a web service:

```sql
SELECT DB2XML.SOAPHTTPNV('http://rpc.geocoder.us/service/soap/', 'http://rpc.geocoder.us/Geo/Coder/US#geocode_address', ' <?xml version="1.0" encoding="UTF-8"?>
xmlns:xsd="http://www.w3.org/2001/XMLSchema"
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
<SOAP-ENV:Body>
<ns0:geocode_address xmlns:ns0="http://rpc.geocoder.us/Geo/Coder/US/">
<address xsi:type="xsd:string">555 Bailey Avenue, San Jose, CA,95141</address>
```

Chapter 4. Built-in functions 605
Example 2: The following SQL statement inserts the results (as CLOB data) from a request to a web service into a table:

```sql
INSERT INTO EMPLOYEE(XMLCOL)
VALUES (DB2XML.SOAPHTTPNC('http://www.myserver.com/services/db2sample/list.dadx/SOAP',
'http://tempuri.org/db2sample/list.dadx',
'<?xml version="1.0" encoding="UTF-8" ?>',
xmlns:xsd="http://www.w3.org/2001/XMLSchema"
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
<SOAP-ENV:Body>
<listDepartments xmlns="http://tempuri.org/db2sample/list.dadx">
<deptNo>A00</deptNo>
</listDepartments>
</SOAP-ENV:Body>
</SOAP-ENV:Envelope>'))
```

**SPACE**

The SPACE function returns a character string that consists of the number of SBCS blanks that the argument specifies.

```sql
SPACE(numeric-expression)
```

The schema is SYSIBM.

**numeric-expression**

An expression that returns the value of any built-in integer data type. The expression specifies the number of SBCS blanks for the result, and it must be between 0 and 32764.

The argument can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34) which is then assigned to a BIGINT value.

The result of the function is a varying-length character string (VARCHAR) that contains SBCS data.

If `numeric-expression` is a constant, the length attribute of the result is the constant. Otherwise, the length attribute of the result is 4000. The actual length of the result is the value of `numeric-expression`. The actual length of the result must not be greater than the length attribute of the result.

The result can be null; if the argument is null, the result is the null value.

**Example:** The following statement returns a character string that consists of 5 blanks followed by a zero-length string.

```sql
SELECT SPACE(5), SPACE(0)
FROM SYSIBM.SYSDUMMY1;
```
Related concepts:

- Character string encoding schemes
- Varying-length character strings

**SQRT**

The SQRT function returns the square root of the argument.

\[ \text{SQRT}(\text{numeric-expression}) \]

The schema is SYSIBM.

The argument must be an expression that returns the value of any built-in numeric data type. If the argument is DECFLOAT, the operation is performed in DECFLOAT. Otherwise, the argument is converted to a double precision floating-point number for processing by the functions.

The argument can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34).

If the argument is DECFLOAT\( (n) \), the result is DECFLOAT\( (n) \). Otherwise, the result of the function is a double precision floating-point number. If the argument is a special decimal floating point value, the general rules for arithmetic operations apply. See "General Arithmetic Operation Rules for DECFLOAT" on page 265 for more information.

The result can be null; if the argument is null, the result is the null value.

**Example:** Assume that host variable SQUARE is defined as DECIMAL(2,1) and has a value of 9.0. Find the square root of SQUARE.

```sql
SELECT SQRT(:SQUARE)
FROM SYSIBM.SYSDUMMY1;
```

This example returns a double precision floating-point number with an approximate value of 3.

**STRIP**

The STRIP function removes blanks or another specified character from the end, the beginning, or both ends of a string expression.
The schema is SYSIBM.

The STRIP function is similar to the TRIM scalar function.

**Related reference:**

[TRIM](#)

**SUBSTR**

The SUBSTR function returns a substring of a string.

The schema is SYSIBM.

**string-expression**

An expression that specifies the string from which the result is derived. The string must be a character, graphic, or binary string. If `string-expression` is a character string, the result of the function is a character string. If it is a graphic string, the result of the function is a graphic string. If it is a binary string, the result of the function is a binary string.

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type.

A substring of `string-expression` is zero or more contiguous characters of `string-expression`. If `string-expression` is a graphic string, a character is a DBCS character. If `string-expression` is a character string or a binary string, a character is a byte. The SUBSTR function accepts mixed data strings. However, because SUBSTR operates on a strict byte-count basis, the result will not necessarily be a properly formed mixed data string.

**start**

An expression that specifies the position within `string-expression` to be the first character of the result. The value of the large integer must be between 1 and the length attribute of `string-expression`. (The length attribute of a varying-length string is its maximum length.) A value of 1 indicates that the first character of the substring is the first character of `string-expression`.

The argument can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34) which is then assigned to an INTEGER value.
**length**

An expression that specifies the length of the resulting substring. If specified, **length** must be an expression that returns a value that is a built-in large integer data type.

The argument can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34) which is then assigned to an INTEGER value. The value must be greater than or equal to 0 and less than or equal to \( n \), where \( n \) is the length attribute of \( \text{string-expression} \) - \( \text{start} \) + 1. The specified length must not, however, be the large integer constant 0.

If **length** is explicitly specified, **string-expression** is effectively padded on the right with the necessary number of characters so that the specified substring of **string-expression** always exists. Hexadecimal zeros are used as the padding character when **string-expression** is binary data. Otherwise, a blank is used as the padding character.

If **string-expression** is a fixed-length string, omission of **length** is an implicit specification of \( \text{LENGTH(} \text{string-expression} \text{)} - \text{start} + 1 \), which is the number of characters (or bytes) from the character (or byte) specified by start to the last character (or byte) of **string-expression**. If **string-expression** is a varying-length string, omission of **length** is an implicit specification of the greater of zero or \( \text{LENGTH(} \text{string-expression} \text{)} - \text{start} + 1 \). If the resulting length is zero, the result is an empty string.

If **length** is explicitly specified by a large integer constant that is 255 or less, and **string-expression** is not a LOB, the result is a fixed-length string with a length attribute of **length**. If **length** is not explicitly specified, but **string-expression** is a fixed-length string and \( \text{start} \) is an integer constant, the result is a fixed-length string with a length attribute equal to \( \text{LENGTH(} \text{string-expression} \text{)} - \text{start} + 1 \). In all other cases, the result is a varying-length string. If **length** is explicitly specified by a large integer constant, the length attribute of the result is **length**; otherwise, the length attribute of the result is the same as the length attribute of **string-expression**.

The result can be null; if any argument is null, the result is the null value.

The CCSID of the result is the CCSID of **string-expression**.

**Example 1:** **FIRSTNME** is a VARCHAR(12) column in sample table DSN8C10.EMP. When **FIRSTNME** has the value 'MAUDE':

<table>
<thead>
<tr>
<th>Function</th>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td>SUBSTR(FIRSTNME,2,3)</td>
<td>'AUD'</td>
</tr>
<tr>
<td>SUBSTR(FIRSTNME,2)</td>
<td>'AUNE'</td>
</tr>
<tr>
<td>SUBSTR(FIRSTNME,2,6)</td>
<td>'AUNE' followed by two blanks</td>
</tr>
<tr>
<td>SUBSTR(FIRSTNME,6)</td>
<td>a zero-length string</td>
</tr>
<tr>
<td>SUBSTR(FIRSTNME,6,4)</td>
<td>four blanks</td>
</tr>
</tbody>
</table>

**Example 2:** Sample table DSN8C10.PROJ contains column PROJNAME, which is defined as VARCHAR(24). Select all rows from that table for which the string in PROJNAME begins with 'W L PROGRAM'.

```
SELECT * FROM DSN8C10.PROJ
WHERE SUBSTR(PROJNAME,1,12) = 'W L PROGRAM ';
```

Assume that the table has only the rows that were supplied by Db2. Then the predicate is true for just one row, for which PROJNAME has the value 'W L
PROGRAM DESIGN. The predicate is not true for the row in which PROJNAME has the value 'W L PROGRAMMING' because, in the predicate's string constant, 'PROGRAM' is followed by a blank.

Example 3: Assume that a LOB locator named my_loc represents a LOB value that has a length of 1 gigabyte. Assign the first 50 bytes of the LOB value to host variable PORTION.

```
SET :PORTION = SUBSTR(:my_loc,1,50);
```

Example 4: Assume that host variable RESUME has a CLOB data type and holds an employee's resume. This example shows some of the statements that find the section of department information in the resume and assign it to host variable DeptBuf. First, the POSSTR function is used to find the beginning and ending location of the department information. Within the resume, the department information starts with the string 'Department Information Section' and ends immediately before the string 'Education Section'. Then, using these beginning and ending positions, the SUBSTR function assigns the information to the host variable.

```
SET :DInfoBegPos = POSSTR(:RESUME, 'Department Information Section');
SET :DInfoEnPos = POSSTR(:RESUME, 'Education Section');
SET :DeptBuf = SUBSTR(:RESUME, :DInfoBegPos, :DInfoEnPos - :DInfoBegPos);
```

**SUBSTRING**

The SUBSTRING function returns a substring of a string.

**Character:**

```
SUBSTRING(character-expression, start, length)
```

**Graphic:**

```
SUBSTRING(graphic-expression, start, length)
```

**Binary:**

```
SUBSTRING(binary-expression, start, length)
```

The schema is SYSIBM.
character-expression
An expression that specifies the string from which the result is derived. The
string must be a built-in character string.

The argument can also be a numeric data type. The numeric argument is
implicitly cast to a VARCHAR data type. The result of the function is a
character string.

A substring of character-expression is zero or more contiguous units of
character-expression. If CODEUNITS32 is specified, a unit is a Unicode UTF-32
character. If CODEUNITS16 is specified, a unit is a Unicode UTF-16 character.
If OCTETS is specified, a unit is a byte.

start
An expression that specifies the position within the character-expression that is
to be the first string unit of the result. start is expressed in the specified string
unit, and must return an integer value.

The argument can also be another numeric value, a character string, or a
graphic string data type. The input is implicitly cast to a numeric value of
DECFLOAT(34) which is then assigned to an INTEGER value. The value of start
can be positive, negative, or zero. A value of 1 indicates that the first string
unit of the result is the first string unit of character-expression.

length
An expression that specifies the maximum length of the resulting substring.

If character-expression is a fixed-length string, omission of length is an implicit
specification of CHARACTER_LENGTH(character-expression) - start + 1, which
is the number of string units (CODEUNITS16, CODEUNITS32, or OCTETS)
from start to the last position of character-expression.

If character-expression is a varying length string, omission of length is an implicit
specification of zero or CHARACTER_LENGTH(character-expression) - start + 1,
whichever is greater. If the resulting length is zero, the result is an empty
string.

If specified, length must be an expression that returns a value of an integer
data type.

The argument can also be another numeric value, a character string, or a
graphic string data type. The input is implicitly cast to a numeric value of
DECFLOAT(34) which is then assigned to an INTEGER value.

The value must be greater than or equal to 0. If a value greater than n is
specified, where n is the length attribute of character-expression - start + 1,
then n is used as the length of the resulting substring. The value is expressed
in the units that are explicitly specified.

For more information, see Rigorous description of the actual length and result

CODEUNITS16, CODEUNITS32, or OCTETS
Specifies the string unit that is used to express start and length. If character-expression is a character string that is defined as bit data,
CODEUNITS16 and CODEUNITS32 cannot be specified.

CODEUNITS16
Specifies that start and length are expressed in terms of 16-bit UTF-16 code
units.

CODEUNITS32
Specifies that start and length are expressed in terms of 32-bit UTF-32 code
units.
OCTETS

Specifies that \textit{start} and \textit{length} are expressed in terms of bytes.

For more information about CODEUNITS16, CODEUNITS32, and OCTETS, see \cite{String unit specifications} on page 114.

Graphic

\textit{graphic-expression}

An expression that specifies the string from which the result is derived. The string must be a built-in graphic string. The result of the function is a graphic string. A partial surrogate character in the expression is replaced with a blank.

A substring of \textit{graphic-expression} is zero or more contiguous units of \textit{graphic-expression}. If CODEUNITS32 is specified, a unit is a Unicode UTF-32 character. If CODEUNITS16 is specified, a unit is a Unicode UTF-16 character.

\textit{start}

An expression that specifies the position within the \textit{graphic-expression} that is to be the first string unit of the result. \textit{start} is expressed in the specified string unit, and must return an integer value. The value of \textit{start} can be positive, negative, or zero. A value of 1 indicates that the first string unit of the result is the first string unit of \textit{graphic-expression}.

The argument can also be another numeric value, a character string, or a graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34) which is then assigned to an INTEGER value.

\textit{length}

An expression that specifies the maximum length of the resulting substring.

If \textit{graphic-expression} is a fixed-length string, omission of \textit{length} is an implicit specification of \texttt{CHARACTER\_LENGTH(\textit{graphic-expression}) - start +1}, which is the number of units (CODEUNITS16, CODEUNITS32) either explicitly or implicitly specified, from the start position to the last position of \textit{graphic-expression}. If \textit{graphic-expression} is a varying length string, omission of \textit{length} is an implicit specification of zero or \texttt{CHARACTER\_LENGTH(\textit{graphic-expression}) - start +1}, which is the number of units (CODEUNITS16, CODEUNITS32) either explicitly or implicitly specified, whichever is greater. If the resulting length is zero, the result is an empty string.

If specified, \textit{length} must be an expression that returns a value of an integer data type.

The argument can also be another numeric value, a character string, or a graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34) which is then assigned to an INTEGER value.

The value must be greater than or equal to 0. If a value greater than \texttt{n} is specified, where \texttt{n} is the length attribute of \textit{graphic-expression} - \textit{start} + 1, then \texttt{n} is used as the length of the resulting substring. The value is expressed in the units that are explicitly specified.

For more information, see Rigorous description of the actual length and result

\texttt{CODEUNITS16 or CODEUNITS32}

Specifies the string unit that is used to express \textit{start} and \textit{length}.

\texttt{CODEUNITS16}

Specifies that \textit{start} and \textit{length} are expressed in terms of 16-bit UTF-16 code units.
CODEUNITS32

Specifies that start and length are expressed in terms of 32-bit UTF-32 code units.

For more information about CODEUNITS16 and CODEUNITS32, see “String unit specifications” on page 114.

Binary

binary-expression
An expression that specifies the string from which the result is derived. The string must be a built-in binary string. The result of the function is a binary string.

A substring of binary-expression is zero or more contiguous units of binary-expression.

start
An expression that specifies the position within binary-expression to be the first byte of the result. It must be an integer value. start can be negative or zero. (The length attribute of a varying-length string is its maximum length.) A value of 1 indicates that the first byte of the substring is the byte unit of binary-expression.

length
An expression that specifies the length of the resulting substring.

If binary-expression is a fixed-length string, omission of length is an implicit specification of LENGTH(binary-expression) - start + 1 from the start position to the last position of binary-expression. If binary-expression is a varying length string, omission of length is an implicit specification of zero or CHARACTER_LENGTH(binary-expression) - start + 1, whichever is greater. If the resulting length is zero, the result is an empty string.

If specified, length must be a value of an integer data type. The value must be greater than or equal to 0. If a value greater than n is specified, where n is the length attribute of binary-expression - start+ 1, then n is used as the length of the resulting substring.

For more information, see Rigorous description of the actual length and result.
Rigorous description of the actual length and result

In this description, the term *character* means the “unit specified by string units” or “bytes” if the input is binary.

Let $C$ be the value of the first argument, let $LC$ be the length in characters of $C$, and let $S$ be the value of the *start*.

- If *length* is specified, let $L$ be the value of *length* and let $E = S + L$. Otherwise, let $E$ be the larger of $LC + 1$ and $S$.
- If either $C$, $S$, or $L$ is the null value, the result of the function is the null value.
- If $E$ is less than $S$, an exception condition is raised: data exception — substring error.
- Otherwise:
  - If $S$ is greater than $LC$ or if $E$ is less than 1 (one), the result of the function is a zero-length string.
  - Otherwise:
    - Let $S1$ be the larger of $S$ and 1 (one). Let $E1$ be the smaller of $E$ and $LC+1$. Let $L1$ be $E1 - S1$.
    - The result of the function is a character string that contains the $L1$ characters of $C$ starting at character number $S1$ in the same order that the characters appear in $C$.

The data type of the result depends on the data type of the first argument, as shown in the following table.

*Table 87. Data type of the result of SUBSTRING*

<table>
<thead>
<tr>
<th>Data type of the first argument</th>
<th>Data type of the result</th>
</tr>
</thead>
<tbody>
<tr>
<td>CHAR or VARCHAR</td>
<td>VARCHAR</td>
</tr>
<tr>
<td>CLOB</td>
<td>CLOB</td>
</tr>
<tr>
<td>GRAPHIC or VARGRAPHIC</td>
<td>VARGRAPHIC</td>
</tr>
<tr>
<td>DBCLOB</td>
<td>DBCLOB</td>
</tr>
<tr>
<td>BINARY or VARBINARY</td>
<td>VARBINARY</td>
</tr>
<tr>
<td>BLOB</td>
<td>BLOB</td>
</tr>
</tbody>
</table>

The length attribute of the result is equal to the length attribute of the first argument. If CODEUNITS16 or CODEUNITS32 is specified, see “Determining the length attribute of the final result” on page 117 for information about how to calculate the length attribute of the result string.

The result can be null; if any argument is null, the result is the null value.

If the first argument is character or graphic data, the CCSID of the result is the same as that of the first argument.

*Example 1:* $C1$ is a VARCHAR(12) column in table T1. One of its values is the string 'ABCDEFG'. When $C1$ has the value 'ABCDEFG':

<table>
<thead>
<tr>
<th>Function</th>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td>SUBSTRING($C1$, -2, 2, OCTETS)</td>
<td>-- a zero-length string</td>
</tr>
<tr>
<td>SUBSTRING($C1$, -2, 4, OCTETS)</td>
<td>'A'</td>
</tr>
<tr>
<td>SUBSTRING($C1$, -2, 4, OCTETS)</td>
<td>'ABCDEFG'</td>
</tr>
<tr>
<td>SUBSTRING($C1$, 0, 1, OCTETS)</td>
<td>-- a zero-length string</td>
</tr>
</tbody>
</table>
Example 2: FIRSTNAME is a VARCHAR(12) column in table T1. One of its values is the 6-character string 'Jürgen'. When FIRSTNAME has the value 'Jürgen':

<table>
<thead>
<tr>
<th>Function:</th>
<th>Returns:</th>
</tr>
</thead>
<tbody>
<tr>
<td>SUBSTRING(FIRSTNAME,1,2,CODEUNITS32)</td>
<td>'Jü' -- x'4AC3BC'</td>
</tr>
<tr>
<td>SUBSTRING(FIRSTNAME,1,2,CODEUNITS16)</td>
<td>'Jü' -- x'4AC3BC'</td>
</tr>
<tr>
<td>SUBSTRING(FIRSTNAME,1,2,0CTETS)</td>
<td>'J' -- x'4A20' (a truncated string)</td>
</tr>
<tr>
<td>SUBSTRING(FIRSTNAME,8,CODEUNITS16)</td>
<td>-- a zero-length string</td>
</tr>
<tr>
<td>SUBSTRING(FIRSTNAME,8,4,0CTETS)</td>
<td>-- a zero-length string</td>
</tr>
</tbody>
</table>

**TAN**

The TAN function returns the tangent of the argument, where the argument is an angle, expressed in radians.

\[ \text{TAN(numeric-expression)} \]

The schema is SYSIBM.

The TAN and ATAN functions are inverse operations.

The argument must be an expression that returns the value of any built-in numeric data type that is not DECFLOAT. If the argument is not a double precision floating-point number, it is converted to one for processing by the function.

The result of the function is a double precision floating-point number.

The result can be null; if the argument is null, the result is the null value.

*Example:* Assume that host variable TANGENT is DECIMAL(2,1) with a value of 1.5. The following statement returns a double precision floating-point number with an approximate value of 14.10.

```sql
SELECT TAN(:TANGENT)
FROM SYSIBM.SYSDUMMY1;
```

**TANH**

The TANH function returns the hyperbolic tangent of the argument, where the argument is an angle, expressed in radians.

\[ \text{TANH(numeric-expression)} \]

The schema is SYSIBM.

The TANH and ATANH functions are inverse operations.
The argument must be an expression that returns the value of any built-in numeric data type that is not DECFLOAT. If the argument is not a double precision floating-point number, it is converted to one for processing by the function.

The result of the function is a double precision floating-point number.

The result can be null; if the argument is null, the result is the null value.

Example: Assume that host variable HTANGENT is DECIMAL(2,1) with a value of 1.5. The following statement returns a double precision floating-point number with an approximate value of 0.90.

```
SELECT TANH(:HTANGENT)
FROM SYSIBM.SYSDUMMY1;
```

TIME

The TIME function returns a time that is derived from a value.

The schema is SYSIBM.

The argument must be an expression that returns a value of one of the following built-in data types: a time, a timestamp, a character string, or a graphic string. If expression is a character or graphic string, it must not be a CLOB or DBCLOB, and its value must be a valid string representation of a time or timestamp with an actual length of not greater than 255 bytes. A time zone in a string representation of a timestamp is ignored. For the valid formats of string representations of times and timestamps, see “String representations of datetime values” on page 130.

If expression is a TIMESTAMP WITH TIME ZONE value, expression is first cast to TIMESTAMP WITHOUT TIME ZONE, with the same precision as expression.

If expression is not a TIME value, expression is cast as follows:
• If expression is a TIMESTAMP WITH TIME ZONE value, expression is cast to TIMESTAMP WITHOUT TIME ZONE, with the same precision as expression.
• If expression is a string, expression is cast to TIME.

The result of the function is a time.

The result can be null; if the argument is null, the result is the null value.

The other rules depend on the data type of the argument:
If the argument is a time the result is that time.
If the argument is a timestamp the result is the time part of the timestamp.
If the argument is a string the result is the time or time part of the timestamp represented by the string. If the CCSID of the string is not the same as the corresponding default CCSID at the server, the string is first converted to that CCSID.
The result CCSID is the appropriate CCSID of the argument encoding scheme and the result subtype is the appropriate subtype of the CCSID.

Example: Assume that a table named CLASSES contains one row for each scheduled class. Assume also that the class starting times are in the TIME column named STARTTM. Using these assumptions, select those rows in CLASSES that represent classes that start at 1:30 P.M.

```sql
SELECT *
FROM CLASSES
WHERE TIME(STARTTM) = '13:30:00';
```

TIMESTAMP

The TIMESTAMP function returns a TIMESTAMP WITHOUT TIME ZONE value from its argument or arguments.

See TIMESTAMP_TZ for a similar function.

The schema is SYSIBM.

The rules for the arguments depend on whether the second argument is specified.

• If only one argument is specified:

  The argument must be an expression that returns a value of one of the following built-in data types: a date, a timestamp, a character string, a graphic string, or a binary string. If `expression-1` is a character or graphic string, it must not be a CLOB or DBCLOB and it must have one of the following values:
  - A valid string representation of a date or timestamp with an actual length that is not greater than 255 bytes. A time zone in a string representation of a timestamp is ignored. For the valid formats of string representations of timestamps, see String representations of datetime values.
  - A character string or graphic string with an actual length of 8 that is assumed to be an IBM Z Store Clock value.
  - A character string with an actual length of 13 that is assumed to be a result from the GENERATE_UNIQUE function.
  - A character string or graphic string with an actual length of 14 that represents a valid date and time in the form `yyyyxxddhhmmss`, where `yyyy` is the year, `xx` is the month, `dd` is the day, `hh` is the hour, `mm` is the minute, and `ss` is the seconds.\(^{22}\)

If `expression-1` is a binary string, it must not be a BLOB and its value must be one of the following:
  - A binary string with an actual length of 8 bytes that is assumed to be an IBM Z Store Clock value.

---

\(^{22}\) A character or graphic string with an actual length of 14 that represents a valid date and time (as allowed for the TIMESTAMP function) is also allowed as input to other scalar functions that accept a timestamp as an input argument.
- A binary string with an actual length of 16 bytes that is assumed to be a IBM Z Store Clock extended value.
- A binary string with an actual length of 13 bytes that is assumed to be a result from the GENERATE_UNIQUE function.

- **If both arguments are specified:**
  - If the data type of the second argument is not an integer:
    The first argument must be an expression that returns a value of one of the following built-in data types: a date, a character string, or a graphic string. The second argument must be an expression that returns a value of one of the following built-in data types: a time, a character string, or a graphic string. A character string or graphic string must be a valid string representation of a time.
    If expression-1 is a character string or graphic string, it must not be a CLOB or DBCLOB, and its value must be a valid string representation of a date with an actual length that is not greater than 255 bytes. If expression-2 is a character string or graphic string, it must not be a CLOB or DBCLOB, and its value must be a valid string representation of a time with an actual length that is not greater than 255 bytes. For the valid formats of string representations of dates and times, see [String representations of datetime values](#).
  - If the data type of the second argument is integer:
    The first argument must be an expression that returns a value of one of the following built-in data types: a timestamp, a date, a character string, or a graphic string. The second argument must be an integer constant in the range 0 to 12 that represents the timestamp precision.
    If expression-1 is a character string or graphic string, it must not be a CLOB or DBCLOB, and its value must be a valid string representation of a timestamp or a date with an actual length that is not greater than 255 bytes.
    If expression-1 is a binary string, it must not be a BLOB, and its value must conform to the rules for when only one argument is specified. The second argument must be an integer constant in the range 0 to 12 that represents the timestamp precision.

The result of the function is a TIMESTAMP WITHOUT TIME ZONE value.

The timestamp precision and other rules depend on whether the second argument is specified:

- **If both arguments are specified and the second argument is not an integer:**
  The result is a TIMESTAMP(6) WITHOUT TIME ZONE value with the date that is specified by the first argument and the time that is specified by the second argument. The fractional seconds part of the timestamp is zero.

- **If both arguments are specified and the second argument is an integer:**
  The result is a TIMESTAMP WITHOUT TIME ZONE value with the precision that is specified in the second argument.

- **If only one argument is specified and it is a TIMESTAMP (p) WITHOUT TIME ZONE:**
  The result is that TIMESTAMP (p) WITHOUT TIME ZONE value.

- **If only one argument is specified and it is a TIMESTAMP(p) WITH TIME ZONE:**
  The result is the argument value, cast to TIMESTAMP(p) WITHOUT TIME ZONE. The value is the local timestamp, not UTC.
If only one argument is specified and it is a date:
The result is that date with an assumed time of midnight that is cast to
TIMESTAMP(0) WITHOUT TIME ZONE.

If only one argument is specified and it is a character or graphic string:
The result is the TIMESTAMP(6) WITHOUT TIME ZONE value that is
represented by that string extended with any missing time information. If
the argument is a string of length 14, the TIMESTAMP has a fractional
seconds part of zero. The string value must not contain a specification of
time zone.

If only one argument is specified and it is a binary string:
The result is the TIMESTAMP(6) WITHOUT TIME ZONE value that is
represented by that string. If the year value in the resulting timestamp is
greater than 9999 an error is returned (SQLSTATE 22007, SQLCODE -180).

If the arguments include only date information, the time information in the result
value is all zeros.

The result can be null; if any argument is null, the result is the null value.

If an argument is a string with a CCSID that is not the same as the corresponding
default CCSID at the server, the string is first converted to that CCSID.

The result CCSID is the appropriate CCSID of the argument encoding scheme and
the result subtype is the appropriate subtype of the CCSID. If both arguments are
specified and their encoding schemes are different, the result CCSID is the
appropriate CCSID of the application encoding scheme.

Notes
Specifying an LRSN as an argument:
When a 6-byte LRSN is used as the argument to the TIMESTAMP function,
it must be left justified and padded on the right to a total length of 8 bytes.
When a 10-byte LRSN is used, it must be left justified and padded on the
right to a total length of 16 bytes.

Syntax alternatives:
If only one argument is specified, the CAST specification should be used
for maximal portability. For more information, see CAST specification.

Examples
Example: TIMESTAMP with a DATE column and a TIME column as arguments
Assume that table TABLEX contains a DATE column named DATECOL
and a TIME column named TIMECOL. For some row in the table, assume
that DATECOL represents 25 December 2008 and TIMECOL represents 17
hours, 12 minutes, and 30 seconds after midnight. The following function
returns the value '2008-12-25-17.12.30.000000'.
TIMESTAMP(DATECOL, TIMECOL)

Example: TIMESTAMP with a timestamp with time zone argument
Assume that host variable PRSTSZ contains '2008-02-29.20.00.000000 -08.30.'
The following statement returns the value '2008-02-29.20.00.000000':
SELECT TIMESTAMP(:PRSTSZ)
FROM PROJECT;

Example: TIMESTAMP with a timestamp and an integer as arguments
The following invocation of the TIMESTAMP function converts a
timestamp string with 7 digits of fractional seconds to a TIMESTAMP(9) WITHOUT TIME ZONE value and returns a value of '2007-09-24-15.53.37.216247400':
TIMESTAMP('2007-09-24-15.53.37.2162474',9);

**TIMESTAMPADD**

The TIMESTAMPADD function returns the result of adding the specified number of the designated interval to the timestamp value.

```
TIMESTAMPADD(interval, number, expression)
```

The schema is SYSIBM.

**interval**

An expression that returns a value of a built-in SMALLINT or INTEGER data type. The following values are valid values for **interval**:

<table>
<thead>
<tr>
<th>Valid values for interval</th>
<th>equivalent intervals</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Microseconds</td>
</tr>
<tr>
<td>2</td>
<td>Seconds</td>
</tr>
<tr>
<td>4</td>
<td>Minutes</td>
</tr>
<tr>
<td>8</td>
<td>Hours</td>
</tr>
<tr>
<td>16</td>
<td>Days</td>
</tr>
<tr>
<td>32</td>
<td>Weeks</td>
</tr>
<tr>
<td>64</td>
<td>Months</td>
</tr>
<tr>
<td>128</td>
<td>Quarters</td>
</tr>
<tr>
<td>256</td>
<td>Years</td>
</tr>
</tbody>
</table>

**number**

An expression that returns a value of a built-in SMALLINT or INTEGER data type.

**expression**

An expression that returns a value of a built-in TIMESTAMP WITHOUT TIME ZONE data type.

The result of the function is the same timestamp data type with the same timestamp precision as **expression**.

The result can be null; if any argument is null, the result is the null value.

The result is determined using the normal rules for datetime arithmetic. See "Datetime arithmetic in SQL" on page 274. When the interval to add is expressed as weeks, the result is calculated as if number x 7 days had been specified. When the interval to add is expressed as quarters, the result is calculated as if number x 3 months had been specified.
Example 1: The following example will add 40 years to the specified timestamp. An interval of 256 designates years, while 40 specifies the number of intervals to add. The following statement returns the value '2005-07-27-15.30.00.000000'.

```
SELECT TIMESTAMPADD(256,40,TIMESTAMP('1965-07-27-15.30.00'))
FROM SYSIBM.SYSDUMMY1;
```

Example 2: The following example will add 18 months to the specified timestamp. An interval of 64 designates months, while 18 specifies the number of intervals to add. The following statement returns the value '2008-07-20-08.08.00.000000'.

```
SELECT TIMESTAMPADD(64,18,TIMESTAMP('2007-01-20-08.08.00'))
FROM SYSIBM.SYSDUMMY1;
```

Example 3: The following example will subtract 16 quarters (4 years) from the specified timestamp. An interval of 128 designates quarters, while -16 specifies the number of intervals to add (the '-' adds a negative amount). The following statement returns the value '2003-09-28-05.30.00.000000'.

```
SELECT TIMESTAMPADD(128,-16,TIMESTAMP('2007-09-28-05.30.00'))
FROM SYSIBM.SYSDUMMY1;
```

Example 4: The following example will add 18 weeks to the specified timestamp. An interval of 32 designates weeks, while 18 specifies the number of intervals to add. The following statement returns the value '2007-05-27-08.08.00.000000'.

```
SELECT TIMESTAMPADD(32,18,TIMESTAMP('2007-01-20-08.08.00'))
FROM SYSIBM.SYSDUMMY1;
```

TIMESTAMPDIFF

The TIMESTAMPDIFF function returns an estimated number of intervals of the type that is defined by the first argument, based on the difference between two timestamps.

```
TIMESTAMPDIFF(numeric-expression,string-expression)
```

The schema is SYSIBM.

numeric-expression

An expression that returns a value that is a built-in SMALLINT or INTEGER data type. The value specifies the interval that is used to determine the difference between two timestamps. The following table lists the valid values for numeric-expression:

<table>
<thead>
<tr>
<th>Valid values for numeric-expression</th>
<th>equivalent intervals</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Microseconds</td>
</tr>
<tr>
<td>2</td>
<td>Seconds</td>
</tr>
<tr>
<td>4</td>
<td>Minutes</td>
</tr>
<tr>
<td>8</td>
<td>Hours</td>
</tr>
<tr>
<td>16</td>
<td>Days</td>
</tr>
<tr>
<td>32</td>
<td>Weeks</td>
</tr>
</tbody>
</table>
Table 89. Valid values for numeric-expression and equivalent intervals that are used to determine the difference between two timestamps (continued)

<table>
<thead>
<tr>
<th>Valid values for numeric-expression</th>
<th>equivalent intervals</th>
</tr>
</thead>
<tbody>
<tr>
<td>64</td>
<td>Months</td>
</tr>
<tr>
<td>128</td>
<td>Quarters</td>
</tr>
<tr>
<td>256</td>
<td>Years</td>
</tr>
</tbody>
</table>

string-expression

An expression that returns a value of a built-in character string or a graphic string data type that is not a LOB. The value is expected to be the result of subtracting two timestamps and converting the result to a character string of length 22. The string value must not have more than 6 digits to the right of a decimal point. If the supplied argument is a graphic string, it is first converted to a character string before the function is executed.

The following table describes the elements of string-expression:

Table 90. TIMESTAMPDIFF String Elements

<table>
<thead>
<tr>
<th>String elements</th>
<th>Valid values</th>
<th>Character position from the decimal point (negative is left)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Years</td>
<td>1-9998 or blank</td>
<td>-14 to -11</td>
</tr>
<tr>
<td>Months</td>
<td>0-11 or blank</td>
<td>-10 to -9</td>
</tr>
<tr>
<td>Days</td>
<td>0-30 or blank</td>
<td>-8 to -7</td>
</tr>
<tr>
<td>Hours</td>
<td>0-24 or blank</td>
<td>-6 to -5</td>
</tr>
<tr>
<td>Minutes</td>
<td>0-59 or blank</td>
<td>-4 to -3</td>
</tr>
<tr>
<td>Seconds</td>
<td>0-59</td>
<td>-2 to -1</td>
</tr>
<tr>
<td>Decimal separator</td>
<td>period</td>
<td>0</td>
</tr>
<tr>
<td>Microsecond</td>
<td>0000000-999999</td>
<td>1 to 6</td>
</tr>
</tbody>
</table>

The result of the function is an integer with the same sign as the second argument.

The result can be null; if any argument is null, the result is the null value.

The returned value is determined for each interval as indicated by the following table:

Table 91. TIMESTAMPDIFF Computations

<table>
<thead>
<tr>
<th>Result interval</th>
<th>Computation using duration elements</th>
</tr>
</thead>
<tbody>
<tr>
<td>Years</td>
<td>years</td>
</tr>
<tr>
<td>Quarters</td>
<td>integer value of (months+(years*12))/3</td>
</tr>
<tr>
<td>Months</td>
<td>months + (years*12)</td>
</tr>
<tr>
<td>Weeks</td>
<td>integer value of ((days+(months<em>30))/7)+(years</em>52)</td>
</tr>
<tr>
<td>Days</td>
<td>days + (months<em>30)+(years</em>365)</td>
</tr>
<tr>
<td>Hours</td>
<td>hours+ ((days + (months<em>30)+(years</em>365)))*24</td>
</tr>
<tr>
<td>Minutes (the absolute value of the duration must not exceed 40850913020759.9999999)</td>
<td>minutes + (hours+((days+(months<em>30)+(years</em>365))*24))*60</td>
</tr>
<tr>
<td>Seconds (the absolute value of the duration must be less than 680105031408.000000)</td>
<td>seconds + (minutes+hours+((days+(months<em>30)+(years</em>365))*24))*60 *60</td>
</tr>
</tbody>
</table>
Table 91. TIMESTAMPDIFF Computations (continued)

<table>
<thead>
<tr>
<th>Result interval</th>
<th>Computation using duration elements</th>
</tr>
</thead>
<tbody>
<tr>
<td>Microseconds (the absolute value of the duration must be less than 3547.483648)</td>
<td>micros + (seconds+(minutes*60))*1000000</td>
</tr>
</tbody>
</table>

The following assumptions are used in estimating a difference:

- One year has 365 days
- One year has 52 weeks
- One year has 12 months
- One month has 30 days
- One day has 24 hours
- One hour has 60 minutes
- One minute has 60 seconds

The use of these assumptions imply that some result values are an estimate of the interval. Consider the following examples:

- Difference of 1 month where the month has less than 30 days.
  
  \[
  \text{TIMESTAMPDIFF}(16, \text{CHAR(TIMESTAMP('1997-03-01-00.00.00') - TIMESTAMP('1997-02-01-00.00.00'))})
  \]
  
The result of the timestamp arithmetic is a duration of 00000100000000.000000, or 1 month. When the TIMESTAMPDIFF function is invoked with 16 for the interval argument (days), the assumption of 30 days in a month is applied and the result is 30.

- Difference of 1 day less than 1 month where the month has less than 30 days.
  
  \[
  \text{TIMESTAMPDIFF}(16, \text{CHAR(TIMESTAMP('1997-03-01-00.00.00') - TIMESTAMP('1997-02-02-00.00.00'))})
  \]
  
The result of the timestamp arithmetic is a duration of 00000027000000.000000, or 27 days. When the TIMESTAMPDIFF function is invoked with 16 for the interval argument (days), the result is 27.

- Difference of 1 day less than 1 month where the month has 31 days.
  
  \[
  \text{TIMESTAMPDIFF}(64, \text{CHAR(TIMESTAMP('1997-09-01-00.00.00') - TIMESTAMP('1997-08-02-00.00.00'))})
  \]
  
The result of the timestamp arithmetic is a duration of 00000030000000.000000, or 30 days. When the TIMESTAMPDIFF function is invoked with 64 for the interval argument (months), the result is 0. The days portion of the duration is 30, but it is ignored because the interval specified months.

Example: The following statement estimates the age of employees in months and returns that value as AGE_IN_MONTHS:

\[
\text{SELECT TIMESTAMPDIFF}(64, \text{CAST(CURRENT_TIMESTAMP-CAST(BIRTHDATE AS TIMESTAMP) AS CHAR(22))})
\text{ AS AGE_IN_MONTHS FROM EMPLOYEE;}
\]

**TIMESTAMP_FORMAT**

The TIMESTAMP_FORMAT function returns a TIMESTAMP WITHOUT TIME ZONE value that is based on the interpretation of the input string using the specified format.
The schema is SYSIBM.

**string-expression**

An expression that returns a value of any built-in character or graphic string data type, other than a CLOB or DBCLOB, with an actual length that is not greater than 255 bytes. The *string-expression* must contain the components of a timestamp that correspond to the format that is specified in *format-string*, except for hour, minute, second, or fractional seconds.

**format-string**

An expression that returns a value that is a built-in character or graphic string data type, other than a CLOB or DBCLOB. The actual length must not be greater than 255 bytes. The value is a template for how *string-expression* is interpreted and then converted to a timestamp value.

A valid *format-string* must contain at least one format element, must not contain multiple specifications for any component of a timestamp, and can contain any combination of the format elements, unless otherwise noted in the following table. For example, *format-string* cannot contain both `YY` and `YYYY`, because both are used to interpret the year component of a *string-expression*. Two format elements can be separated by one or more of the following separator characters:

- minus sign (-)
- period (
- forward slash (/)
- comma (,)
- apostrophe (‘)
- semicolon (;)
- colon (:)
- blank ( )

Separator characters can also be specified at the start or end of *format-string*. These separator characters can be used in any combination in the format string, for example 'YYYY/MM-DD HH:MM.SS'. Separator character that is specified in a *string-expression* are used to separate components and are not required to match the separator character that is specified in the *format-string*.

<table>
<thead>
<tr>
<th>Format element</th>
<th>Related component of a timestamp</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AM or PM ¹</td>

<td>DDD</td>
<td>month, day</td>
<td>Day of the year (001-366).</td>
</tr>
<tr>
<td>FF or FFn</td>
<td>fractional seconds</td>
<td>Fractional seconds (0.000000-999999999999). The number n is used to specify the number of digits that is expected in the string-expression. Valid values for n are 1-12 with no leading zeros. Specifying FF is equivalent to specifying FF6. When the component in string-expression that corresponds to the FF format element is followed by a separator character or is the last component, the number of digits for the fractional seconds can be less than what is specified by the format element. In this case, zero digits are padded onto the right of the number of specified digits.</td>
</tr>
<tr>
<td>HH</td>
<td>hour</td>
<td>HH behaves the same as HH12.</td>
</tr>
<tr>
<td>HH12</td>
<td>hour</td>
<td>Hour of the day (01-12) in 12-hour format. AM is the default meridian indicator.</td>
</tr>
<tr>
<td>HH24</td>
<td>hour</td>
<td>Hour of the day (00-24) in 24-hour format.</td>
</tr>
<tr>
<td>J</td>
<td>year, month, and day</td>
<td>Julian day, the number of days since January 1, 4713 BC. (0000000-9999999)</td>
</tr>
<tr>
<td>MI</td>
<td>minute</td>
<td>Minute (00-59).</td>
</tr>
<tr>
<td>MM</td>
<td>month</td>
<td>Month (01-12).</td>
</tr>
<tr>
<td>MONTH, Month, or month 1, 2</td>
<td>month</td>
<td>Name of the month in English.</td>
</tr>
<tr>
<td>MON, Mon, or mon 1, 2</td>
<td>month</td>
<td>Abbreviated name of the month in English.</td>
</tr>
<tr>
<td>NNNNNNN</td>
<td>microseconds</td>
<td>Microseconds, in the same format as FF6. (000000-9999999).</td>
</tr>
<tr>
<td>RR</td>
<td>year</td>
<td>Last two digits of the adjusted year (00-99).</td>
</tr>
<tr>
<td>RRRR</td>
<td>year</td>
<td>RRRR behaves the same as YYYY.</td>
</tr>
<tr>
<td>SS</td>
<td>seconds</td>
<td>Seconds (00-59).</td>

</tbody>
</table>
Table 92. Format elements for the `TIMESTAMP_FORMAT` function (continued)

<table>
<thead>
<tr>
<th>Format element</th>
<th>Related component of a timestamp</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SSSSS</td>
<td>hours, minutes, and seconds</td>
<td>Seconds since the previous midnight (00000 - 86400).</td>
</tr>
<tr>
<td>Y</td>
<td>year</td>
<td>Last digit of the year (0-9). First three digits of the current year are used to determine the full 4-digit year.</td>
</tr>
<tr>
<td>YY</td>
<td>year</td>
<td>Last two digits of the year (00-99). First two digits of the current year are used to determine the full 4-digit year.</td>
</tr>
<tr>
<td>YYY</td>
<td>year</td>
<td>Last three digits of the year (000-999). First digit of the current year is used to determine the full 4-digit year.</td>
</tr>
<tr>
<td>YYYY</td>
<td>year</td>
<td>4-digit year (0000-9999).</td>
</tr>
</tbody>
</table>

Notes:
1. This format element is case sensitive.
2. Only these exact spellings and case combinations can be used. If this format element is specified in an invalid case combination an error is returned.
3. The D format element does not contribute to any components of the resulting timestamp. However, a specified value for this format element must be correct for the combination of the day component of the resulting timestamp. For example, a value of '5' for `string-expression` is valid for a format string value of 'D'. However, value of '9' for `string-expression` would result in an error for the same format-string.

The RR format element can be used to change how a specification for a year is to be interpreted by adjusting the value to produce a 4-digit value depending on the last two digits of the current year according to the following table:

Table 93. Correspondence of adjusted year value and timestamp component

<table>
<thead>
<tr>
<th>Digits of the current year</th>
<th>Two-digit year in <code>string-expression</code></th>
<th>First two digits of the year component of timestamp</th>
</tr>
</thead>
<tbody>
<tr>
<td>00-50</td>
<td>00-49</td>
<td>First two digits of the current year</td>
</tr>
<tr>
<td>51-99</td>
<td>00-49</td>
<td>First two digits of the current year + 1</td>
</tr>
<tr>
<td>00-50</td>
<td>50-99</td>
<td>First two digits of the current year -1</td>
</tr>
<tr>
<td>51-99</td>
<td>50-99</td>
<td>First two digits of the current year</td>
</tr>
</tbody>
</table>

For example, if the current year is 2007, '86' with format 'RR' means 1986, but if the current year is 2052, it means 2086.

The following defaults are used when a `format-string` does not include a format element for one of the following components of a timestamp:
<table>
<thead>
<tr>
<th>Timestamp component</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>year</td>
<td>current year, as 4 digits</td>
</tr>
<tr>
<td>month</td>
<td>current month, as 2 digits</td>
</tr>
<tr>
<td>day</td>
<td>01 (first day of the month)</td>
</tr>
<tr>
<td>hour</td>
<td>00</td>
</tr>
<tr>
<td>minute</td>
<td>00</td>
</tr>
<tr>
<td>second</td>
<td>00</td>
</tr>
<tr>
<td>fractional seconds</td>
<td>a number of zeros to match the timestamp precision of the result</td>
</tr>
</tbody>
</table>

If *string-expression* does not include a value that corresponds to an hour, minute, second, or fractional seconds format element that is specified in the *format-string*, the same defaults are used.

Leading zeros can be specified for any component of the timestamp value (that is, month, day, hour, minutes, seconds) that does not have the maximum number of significant digits for the corresponding format element in the *format-string*.

A substring of the *string-expression* that represents a component of a timestamp (such as year, month, day, hour, minutes, seconds) can include fewer than the maximum number of digits for that component of the timestamp that is indicated by the corresponding format element. Any missing digits default to zero. For example, with a format-string of 'YYYY-MM-DD HH24:MI:SS', an input value of '999-3-9 5:7:2' produces the same result as '0999-03-09 05:07:02'.

**precision-constant**

An integer constant that specifies the timestamp precision of the result. The value must be in the range 0 to 12. If *precision-constant* is not specified, the timestamp precision defaults to 6.

The result of the function is a TIMESTAMP with a precision that is based on *precision-constant*.

If either of the first two arguments can be null, the result can be null; if either of the first two arguments is null, the result is the null value.

The result CCSID is the appropriate CCSID of the encoding scheme of the first argument and the result subtype is the appropriate subtype of the CCSID.

**Notes**

**Julian and Gregorian calendar:**

The transition from the Julian calendar to the Gregorian calendar on 15 October 1582 is taken into account by this function.

**Determinism:**

TIMESTAMP_FORMAT is a deterministic function. However, the following invocations of the function depend on the value of the special register CURRENT_TIMESTAMP.

- *format-string* is not a constant
- *format-string* is a constant and includes format elements that are locale sensitive
• *format-string* is a constant and does not include a format element that fully defines the year (that is, J or YYYY). In this case the current year is used.

• *format-string* is a constant and does not include a format element that fully defines the month (for example, J, MM, MONTH, or MON). In this case the current month is used.

These invocations, which depend on the value of a special register, cannot be used wherever special registers cannot be used.

**Using the ’D’, ’Y’, and ’y’ format elements:**
Db2 for z/OS does not support the ’DY’, ’dy’, and ’Dy’ format elements that are supported by other platforms. If ’DY’ or ’Dy’ is specified in the format string, it is interpreted as the ’D’ format element followed by the ’Y’ or ’y’ format element. This behavior might change in a future release. To ensure that a ’D’ followed by ’Y’ or ’y’ is interpreted as two separate format elements, include a separator character after the ’D’ format element.

**Syntax alternatives:**
*TO_DATE* can be specified as a synonym for *TIMESTAMP_FORMAT*.

**Example 1:**
Insert a row into the IN_TRAY table with a receiving timestamp that is equal to one second before the beginning of the year 2000 (December 31, 1999 at 23:59:59).

```sql
INSERT INTO IN_TRAY (RECEIVED)
```

**Example 2:**
An application receives strings of date information into a variable called *INDATEVAR*. This value is not strictly formatted and might include two or four digits for years, and one or two digits for months and days. Date components might be separated with minus sign (-) or forward-slash (/) characters and are expected to be in day, month, and year order. Time information consists of hours (in 24-hour format) and minutes, and is usually separated by a colon. Sample values include ’15/12/98 13:48’ and ’9-3-2004 8:02’. Insert such values into the IN_TRAY table.

```sql
INSERT INTO IN_TRAY (RECEIVED)
VALUES (TIMESTAMP_FORMAT(:INDATEVAR, 'DD/MM/YYYY HH24:MI'))
```

The use of ’RRRR’ in the format allows for 2-digit and 4-digit year values and assigns the missing first two digits based on the current year. If ’YYYY’ is used, input values with a 2-digit year will have leading zeros. The forward-slash separator also allows the minus sign character. Assuming a current year of 2007, resulting timestamp values from the sample values are as follows:

'9-3-2004 8:02' --> 2004-03-09-08.02.00.000000

**TIMESTAMP_ISO**
The TIMESTAMP_ISO function returns a timestamp value that is based on a date, a time, or a timestamp argument.
The schema is SYSIBM.

If the argument is a date, TIMESTAMP_ISO inserts a value of zero for the time and the partial seconds parts of the timestamp. If the argument is a time, TIMESTAMP_ISO inserts the value of CURRENT DATE for the date part of the timestamp and a value of zero for the partial seconds part of the timestamp.

expression

An expression that returns a value of one of the following built-in data types:

- a TIMESTAMP WITHOUT TIME ZONE
- a date
- a time
- a character string
- or a graphic string

If expression is a character or graphic string, it must not be a CLOB or DBCLOB and its value must be a valid string representation of a date, a time, or a timestamp. For the valid formats of string representations of dates, times, and timestamps, see "String representations of datetime values" on page 130.

If expression is a timestamp, the result of the function is the same timestamp data type with the same precision as expression. Otherwise, the result of the function is a TIMESTAMP (6) WITHOUT TIME ZONE.

The result can be null; if the argument is null, the result is the null value.

Recommendation: Use the CAST specification for maximum portability. For more information, see "CAST specification" on page 283.

Example: Assume the following date value '1965-07-27'. The following statement returns the value '1965-07-27-00.00.00.000000'.

```
SELECT TIMESTAMP_ISO( DATE( '1965-07-27' ) )
FROM SYSIBM.SYSDUMMY1
```

**TIMESTAMP_TZ**

The TIMESTAMP_TZ function returns a TIMESTAMP WITH TIME ZONE value from the input arguments.

The schema is SYSIBM.

expression-1

An expression that returns a value of one of the following built-in data types:

- a timestamp without time zone
- a timestamp with time zone
- a character string
- a graphic string

If expression-1 is a character string or a graphic string, it must conform to the following rules:
- It must not be a CLOB or DBCLOB
- Its value must be a valid string representation of a timestamp without a time zone or a timestamp with a time zone value
- It must have an actual length that is not greater than 255 bytes

For the valid formats of string representations of datetime values, see "String representations of datetime values" on page 130.

If expression-2 is specified, expression-1 must be a timestamp without a time zone, or a string representation of a timestamp without a time zone.

expression-2
An expression that returns a character string or a graphic string.

If expression-2 is a character string or graphic string, it must not be a CLOB or DBCLOB, and its value must be a valid string representation of a time zone in the format of '\±th:tm' with values ranging from -24:00 to +24:00, where \(th\) represents time zone hour and \(tm\) represents time zone minute.

The result of the function is equivalent to invoking the CAST specification, as indicated in the following table:

<table>
<thead>
<tr>
<th>TIMESTAMP_TZ function syntax</th>
<th>Equivalent CAST specification syntax</th>
</tr>
</thead>
<tbody>
<tr>
<td>TIMESTAMP_TZ(timestamp_wo_tz)</td>
<td>CAST(timestamp_wo_tz AS TIMESTAMP WITH TIME ZONE)</td>
</tr>
<tr>
<td>TIMESTAMP_TZ(timestamp_wo_tz, n)</td>
<td>CAST(timestamp_wo_tz AS TIMESTAMP(n) WITH TIME ZONE)</td>
</tr>
<tr>
<td>TIMESTAMP_TZ(timestamp_wo_tz, timezone)</td>
<td>CAST(CONCAT(VARCHAR(timestamp_wo_tz, timezone) AS TIMESTAMP WITH TIME ZONE)</td>
</tr>
<tr>
<td>TIMESTAMP_TZ(timestamp_wo_tz, timezone, n)</td>
<td>CAST(CONCAT(VARCHAR(timestamp_wo_tz, timezone) AS TIMESTAMP(n) WITH TIME ZONE)</td>
</tr>
<tr>
<td>TIMESTAMP_TZ(timestamp_w_tz)</td>
<td>CAST(timestamp_w_tz AS TIMESTAMP WITH TIME ZONE)</td>
</tr>
<tr>
<td>TIMESTAMP_TZ(timestamp_w_tz, n)</td>
<td>CAST(timestamp_w_tz AS TIMESTAMP(n) WITH TIME ZONE)</td>
</tr>
<tr>
<td>TIMESTAMP_TZ(timestamp_w_tz, timezone)</td>
<td>N/A</td>
</tr>
<tr>
<td>TIMESTAMP_TZ(timestamp_w_tz, timezone, n)</td>
<td>N/A</td>
</tr>
</tbody>
</table>

timestamp_wo_tz
A timestamp without time zone value.

timestamp_w_tz
A timestamp with time zone value.

timezone
A time zone value.

n
The precision value.
When a string representation of a timestamp is a single-byte character set (SBCS) with a CCSID that is not the same as the default CCSID for SBCS data, that value is converted to the default CCSID for SBCS data before it is interpreted and converted to a timestamp value.

**Syntax alternatives:**

- If only one argument is specified, the CAST specification should be used to ensure maximal portability. For more information, see “CAST specification” on page 283.
- FROM_TZ can be specified as a synonym for TIMESTAMP_TZ when TIMESTAMP_TZ specifies both expression-1 and expression-2.

**Example 1:** Assume that TIMES is a host variable with the value 2008-02-29-20.00.00.000000 and that TZ is a host variable with the value -3:00.

Convert the value of TIMES and TZ to a timestamp with time zone.

```sql
SET :TIMESZ = TIMESTAMP_TZ(:TIMES, :TZ);
```

The host variable TIMESZ is set with the value that represents the timestamp with time zone as 2008-02-29-20.00.00.000000 -03:00.

**TO_CHAR**

The TO_CHAR function returns a character string representation of a timestamp value that has been formatted using a specified character template.

The schema is SYSIBM.

The TO_CHAR scalar function is a synonym for the VARCHAR_FORMAT scalar function.

**Related reference:**

VARCHAR_FORMAT

---

**Character to VARCHAR**

```
TO_CHAR((character-expression))
```

**Timestamp to VARCHAR**

```
TO_CHAR((timestamp-expression), format-string)
```

**Decimal floating-point to VARCHAR**

```
TO_CHAR((decimal-floating-point-expression), format-string)
```
TO_DATE

The TO_DATE function returns a timestamp value that is based on the interpretation of the input string using the specified format.

```
TO_DATE((string-expression), format-string [, precision-constant])
```

The schema is SYSIBM.

The TO_DATE scalar function is a synonym for the TIMESTAMP_FORMAT scalar function. Refer to the description of the TIMESTAMP_FORMAT function for information about how to use the TO_DATE function.

TO_NUMBER

The TO_NUMBER function returns a DECFLOAT(34) value that is based on the interpretation of the input string using the specified format.

```
TO_NUMBER(string-expression [, format-string])
```

The schema is SYSIBM.

The TO_NUMBER scalar function is a synonym for the DECFLOAT_FORMAT scalar function.

TOTALORDER

The TOTALORDER function returns an ordering for DECFLOAT values. The TOTALORDER function returns a small integer value that indicates how `expression1` compares with `expression2`.

```
TOTALORDER(expression1, expression2)
```

The schema is SYSIBM.

`expression1`

An expression that returns a built-in DECFLOAT value.

The argument can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34).
expression2
An expression that returns a built-in DECFLOAT value.

The argument can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34).

Numeric comparison is exact, and the result is determined for finite operands as if range and precision are unlimited. An overflow or underflow conditions cannot occur.

If one value is DECFLOAT(16) and the other is DECFLOAT(34), the DECFLOAT(16) value is converted to DECFLOAT(34) before the comparison is made.

TOTALORDER determines ordering based on the total order predicate rules of IEEE 754R, with the following result:
-1 if the first argument is lower in order compared to the second.
0 if both arguments have the same order.
1 if the first argument is higher in order compared to the second.

The ordering of the special values and finite numbers is as follows:
-NAN<-SNAN<-INFINITY<-0.10<-0.100<-0<0.100<0.10<INFINITY<SNAN<NAN

The result of the function is a SMALLINT value.

The result can be null; if any argument is null, the result is the null value.

Examples: The following examples show the use of the TOTALORDER function to compare decimal floating point values:

<table>
<thead>
<tr>
<th>Expression</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>TOTALORDER(-INFINITY, -INFINITY)</td>
<td>0</td>
</tr>
<tr>
<td>TOTALORDER(DECFLOAT(-1.0), DECFLOAT(-1.0))</td>
<td>0</td>
</tr>
<tr>
<td>TOTALORDER(DECFLOAT(-1.0), DECFLOAT(-1.00))</td>
<td>-1</td>
</tr>
<tr>
<td>TOTALORDER(DECFLOAT(-1.0), DECFLOAT(-0.5))</td>
<td>-1</td>
</tr>
<tr>
<td>TOTALORDER(DECFLOAT(-1.0), DECFLOAT(0.5))</td>
<td>-1</td>
</tr>
<tr>
<td>TOTALORDER(DECFLOAT(-1.0), INFINITY)</td>
<td>-1</td>
</tr>
<tr>
<td>TOTALORDER(DECFLOAT(-1.0), SNAN)</td>
<td>-1</td>
</tr>
<tr>
<td>TOTALORDER(DECFLOAT(-1.0), NAN)</td>
<td>-1</td>
</tr>
<tr>
<td>TOTALORDER(NAN, DECFLOAT(-1.0))</td>
<td>1</td>
</tr>
<tr>
<td>TOTALORDER(-NAN, -NAN)</td>
<td>0</td>
</tr>
<tr>
<td>TOTALORDER(-SNAN, -SNAN)</td>
<td>0</td>
</tr>
<tr>
<td>TOTALORDER(NAN, NAN)</td>
<td>0</td>
</tr>
<tr>
<td>TOTALORDER(SNAN, SNAN)</td>
<td>0</td>
</tr>
</tbody>
</table>

TRANSLATE
The TRANSLATE function returns a value in which one or more characters of the first argument might have been converted to other characters.
The schema is SYSIBM.

**string-expression**

An expression that specifies the string to be converted. `string-expression` must return a value that is a built-in character or graphic string data type that is not a LOB. If `string-expression` is an EBCDIC or ASCII graphic string and `string-expression` is the only argument that is specified, the locale name that is specified by the CURRENT LOCALE LC_CTYPE special register must be a non-blank string.

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type.

**to-string**

An expression that specifies the characters to which certain characters in `string-expression` are to be converted. This string is sometimes called the output translation table. `to-string` must return a value that is a built-in character or graphic string data type that is not a LOB.

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type.

If the length of `to-string` is less than the length of `from-string`, `to-string` is padded to the length of `from-string` with the `pad` or a blank. If the length of `to-string` is greater than `from-string`, the extra characters in `to-string` are ignored without warning.

**from-string**

An expression that specifies the characters that if found in `string-expression` are to be converted. This string is sometimes called the input translation table. When a character in `from-string` is found, the character in `string-expression` is converted to the character in `to-string` that is in the corresponding position of the character in `from-string`.

`from-string` must return a value that is a built-in character or graphic string data type that is not a LOB.

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type.

If `from-string` contains duplicate characters, the first occurrence of the character is used, and no warning is issued. The default value for `from-string` is a string that starts with the character X'00' and ends with the character X'FF' (decimal 255).

**pad**

An expression that specifies the character with which to pad `to-string` if its length is less than `from-string`. `pad` is an expression that must return a value that is a built-in character or graphic string data type that is not a LOB and has a length of 1. A length of 1 is one single byte for character strings and one double byte string for graphic strings. The default is a blank that is appropriate for `string-expression`.

If `string-expression` is the only argument that is specified, the string is converted to uppercase based on the locale name that is specified by the CURRENT LOCALE LC_CTYPE special register, as follows:

- blank — SBCS lowercase characters a-z are converted to SBCS uppercase characters A-Z, and characters with diacritical marks are not converted. If the string contains MIXED or DBCS characters, full-width lowercase characters a-z are converted to full-width Latin uppercase characters A-Z. For optimal
performance, specify a blank string unless your data must be processed by using rules that are defined by a specific locale.

- **UNI_SIMPLE** — Case conversions use the NORMAL casing capabilities as described in [Select the conversions (z/OS: Unicode Services User’s Guide and Reference)](https://www.ibm.com/support/docview/techdocs/ibm_zosmf_110?rs=717&context=10231&mic=1028&locale=en_US&cc=us&lang=en&partnumber=081-6564-05) UNI_SIMPLE cannot be used with EBCDIC data.

- **UNI** — The conversion uses both the NORMAL and SPECIAL casing capabilities as described in [Select the conversions (z/OS: Unicode Services User’s Guide and Reference)](https://www.ibm.com/support/docview/techdocs/ibm_zosmf_110?rs=717&context=10231&mic=1028&locale=en_US&cc=us&lang=en&partnumber=081-6564-05). You must not specify UNI when `string-expression` is EBCDIC data.

- **locale name** — The locale defines the rules for conversion to uppercase characters.

For Unicode data, usage of the TRANSLATE function (the TRANSLATE function with one argument is equivalent to the UPPER function) can result in expansion if certain characters are processed. You should ensure that the result string is large enough to contain the result of the expression.

If more than one argument is specified, the result string is built character-by-character from `string-expression` with each character in `from-string` being converted to the corresponding character in `to-string`. For each character in `string-expression`, the `from-string` is searched for the same character. If the character is found to be the `n`th character in `from-string`, the resulting string will contain the `n`th character from `to-string`. If `to-string` is less than `n` characters long, the resulting string will contain the `pad`. If the character is not found in `from-string`, it is moved to the result string without being converted.

The string can contain mixed data. If only one argument is specified, the UPPER function is performed on the argument, and the rules for operating on mixed data in the UPPER function are observed. Full-width Latin lowercase a-z are converted to full-width Latin uppercase letters A-Z. Otherwise, the function operates on a strict byte-count basis, and the result is not necessarily a properly formed mixed data character string.

The encoding scheme of the result is the same as `string-expression`. The data type of the result of the function depends on the data type of `string-expression`, `to-string`, `from-string`, and `pad`:

- **VARCHAR** if `string-expression` is a character string. The CCSID of the result depends on the arguments:
  - If `string-expression`, `to-string`, `from-string`, or `pad` is bit data, the result is bit data.
  - If `string-expression`, `to-string`, `from-string`, and `pad` are all SBCS:
    - If `string-expression`, `to-string`, `from-string`, and `pad` are all SBCS Unicode data, the CCSID of the result is the CCSID for SBCS Unicode data.
    - If `string-expression` is SBCS Unicode data, and `to-string`, `from-string`, or `pad` are not SBCS Unicode data, the CCSID of the result is the mixed CCSID for Unicode data.
    - Otherwise, the CCSID of the result is the same as the CCSID of `string-expression`.
  - Otherwise, the CCSID of the result is the mixed CCSID that corresponds to the CCSID of `string-expression`. However, if the input is EBCDIC or ASCII and there is no corresponding system CCSID for mixed, the CCSID of the result is the CCSID of `string-expression`.
- **VARGRAPHIC** if `string-expression` is a graphic. The CCSID of the result is the same as the CCSID of `source-string`.
The result can be null; if the first argument is null, the result is the null value.

**Example 1:** Return the string 'abcdef' in uppercase characters. Assume that the locale in effect is blank.

```sql
SELECT TRANSLATE ('abcdef')
FROM SYSIBM.SYSDUMMY1
```

The result is the value 'ABCDEF'.

**Example 2:** Assume that host variable `SITE` has a data type of VARCHAR(30) and contains 'Hanauma Bay'.

```sql
SELECT TRANSLATE (:SITE)
FROM SYSIBM.SYSDUMMY1
```

Returns the value 'HANAUMA BAY'. The result is all uppercase characters because only one argument is specified.

```sql
SELECT TRANSLATE (:SITE, 'j', 'B')
FROM SYSIBM.SYSDUMMY1
```

Returns the value 'Hanauma jay'.

```sql
SELECT TRANSLATE (:SITE, 'ei', 'aa')
FROM SYSIBM.SYSDUMMY1
```

Returns the value 'Heneume Bey'.

```sql
SELECT TRANSLATE (:SITE, 'bA', 'Bay', '%')
FROM SYSIBM.SYSDUMMY1
```

Returns the value 'HAnAumA bA%'.

```sql
SELECT TRANSLATE (:SITE, 'r', 'Bu')
FROM SYSIBM.SYSDUMMY1
```

Returns the value 'Hana ma ray'.

**Example 3:** Assume that host variable `SITE` has a data type of VARCHAR(30) and contains 'Pivabiska Lake Place'.

```sql
SELECT TRANSLATE (:SITE, '$$', 'Ll')
FROM SYSIBM.SYSDUMMY1
```

Returns the value 'Pivabiska $ake P$ace'.

```sql
SELECT TRANSLATE (:SITE, 'pLA', 'Place', '.')
FROM SYSIBM.SYSDUMMY1
```

Returns the value 'pivAbiskA LAk. pLA..'.

**Related concepts:**

- [z/OS Unicode Services User’s Guide and Reference](#)

**TRIM**

The TRIM function removes bytes from the beginning, from the end, or from both the beginning and end of a string expression.
The schema is SYSIBM.

The first argument, if specified, indicates whether characters are removed from the end or the beginning of the string. If the first argument is not specified, the characters are removed from both the end and the beginning of the string.

**trim-constant**

Specifies a constant that indicates the binary, SBCS, or DBCS character that is to be removed. If **string-expression** is a character string, **trim-constant** must be an SBCS or DBCS single-character (2 bytes) constant. If **string-expression** is a binary string, **trim-constant** must be a single-byte binary string constant. If **string-expression** is a DBCS graphic or DBCS-only string, **trim-constant** must be a graphic constant that consists of a single DBCS character.

The default for **trim-constant** depends on the data type of **string-expression**:

- A DBCS blank if **string-expression** is a DBCS graphic string. For ASCII, the CCSID determines the hex value that represents a DBCS blank. For example, for Japanese (CCSID 301), X'8140' represents a DBCS blank, while for Simplified Chinese, X'A1A1' represents a DBCS blank. For EBCDIC, X'4040' represents a DBCS blank.
- A UTF-16 or UCS-2 blank (X'0020') if **string-expression** is a Unicode graphic string.
- A value of X'00' if **string-expression** is a binary string.
- Otherwise, a single byte blank. For EBCDIC, X'40' represents a blank. When not EBCDIC, X'20' represents a blank.

**string-expression**

An expression that returns a value that is a built-in character string data type, graphic data type, binary string data type, or numeric data type. **string-expression** must not be a LOB. If **string-expression** is numeric, it is cast to a character string before the function is evaluated. For more information about converting numeric to a character string, see [VARCHAR](#).

**string-expression** and **trim-expression** must have compatible data types.

The data type of the result depends on the data type of **string-expression**:

- If **string-expression** is a character string data type, the result is VARCHAR. If **string-expression** is defined as FOR BIT DATA the result is FOR BIT DATA.
- If **string-expression** is a graphic string data type, the result is VARGRAPHIC.
- If **string-expression** is a binary string data type, the result is VARBINARY.
The length attribute of the result is the same as the length attribute of string-expression. The actual length of the result is the length of string-expression minus the number of characters removed. If all of the characters are removed, the result is an empty string.

If string-expression can be null, the result can be null; if string-expression is null, the result is the null value.

The CCSID of the result is the same as that of string-expression.

Example: Assume the host variable HELLO of type CHAR(9) has a value of 'Hello'.

```sql
SELECT TRIM(:HELLO), TRIM(TRAILING FROM :HELLO)
FROM SYSIBM.SYSDUMMY1
```

Results in 'Hello' and 'Hello' respectively.

Example: Assume the host variable BALANCE of type CHAR(9) has a value of '000345.50'.

```sql
SELECT TRIM(L '0' FROM :BALANCE)
FROM SYSIBM.SYSDUMMY1
```

Results in '345.50'

Related reference:

**STRIP**

**TRIM_ARRAY**

The TRIM_ARRAY function deletes elements from the end of an ordinary array.

```sql
TRIM_ARRAY(array-expression, numeric-expression)
```

The schema is SYSIBM.

**array-expression**

An SQL variable, SQL parameter, or global variable of an ordinary array type, or a CAST specification of a parameter marker to an array type. An associative array type cannot be specified.

**numeric-expression**

Specifies the number of elements that are trimmed from the end of the array. numeric-expression can be any numeric data type with a value that can be cast to INTEGER. The value of numeric-expression must be greater than or equal to 0 and less than or equal to the cardinality of array-expression.

TRIM_ARRAY returns a value with the same array type as array-expression, with the cardinality reduced by the value of INTEGER(numeric-expression).

The result can be null; if any argument is null, the result is the null value.

The TRIM_ARRAY function can be invoked only in the following contexts:
- A source value for SET assignment-statement or SQL PL assignment-statement, or a VALUES INTO statement
- The value that is returned in a RETURN statement in an SQL scalar function

Notes

Syntax alternatives: CAST (SQL-variable AS array-type) can be specified as an alternative to SQL-variable. CAST (SQL-parameter AS array-type) can be specified as an alternative to SQL-parameter.

Example 1: Suppose that PHONENUMBERS is a user-defined array type that is defined as an ordinary array. RECENT_CALLS is an array variable of the PHONENUMBERS type. The following statement removes the last element from the array variable RECENT_CALLS.

SET RECENT_CALLS = TRIM_ARRAY(RECENT_CALLS,1);

Example 2: Suppose that INTARRAY is a user-defined array type that is defined as an ordinary array with integer elements. SPECIALNUMBERS and LOWPRIMES are array variables of the INTARRAY type. The SPECIALNUMBERS array contains the values of all the prime numbers less than 1000, which is 168 values. The following statement assigns the 10 smallest prime numbers in the SPECIALNUMBERS array to the first 10 elements of the LOWPRIMES array.

SET LOWPRIMES = TRIM_ARRAY(SPECIALNUMBERS,CARDINALITY(SPECIALNUMBERS)-10);

TRUNCATE or TRUNC

The TRUNCATE function returns the first argument, truncated as specified. Truncation is to the number of places to the right or left of the decimal point this is specified by the second argument.

The schema is SYSIBM.

numeric-expression-1

An expression that returns a value of any built-in numeric data type.

If expression-1 is a decimal floating-point data type, the DECFLOAT ROUNDING MODE will not be used. The rounding behavior of TRUNCATE corresponds to a value of ROUND_DOWN. If you want a different rounding behavior, use the QUANTIZE function.

The argument can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34).

numeric-expression-2

An expression that returns a value that is a built-in SMALLINT or INTEGER data type. The absolute value of the integer specifies the number of places to truncate. The value of numeric-expression-2 determines whether truncation is to the right or left of the decimal point.
If numeric-expression-2 is not negative, numeric-expression-1 is truncated to the absolute value of numeric-expression-2 places to the right of the decimal point.

If numeric-expression-2 is negative, numeric-expression-1 is truncated to 1 + (the absolute value of numeric-expression-2) places to the left of the decimal point. If 1 + (the absolute value of numeric-expression-2) is greater than or equal to the number of digits to the left of the decimal point, the result is 0. For example, TRUNCATE(748.58,-4) returns 0.

The argument can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34), which is then assigned to an INTEGER value.

The result of the function has the same data type and length attribute as the first argument.

The result can be null; if any argument is null, the result is the null value.

Example 1: Using sample employee table DSN8C10.EMP, calculate the average monthly salary for the highest paid employee. Truncate the result to two places to the right of the decimal point.

```
SELECT TRUNCATE(MAX(SALARY/12),2) FROM DSN8C10.EMP;
```

Because the highest paid employee in the sample employee table earns $52750.00 per year, the example returns the value 4395.83.

Example 2: Return the number 873.726 truncated to 2, 1, 0, -1, -2, -3, and -4 decimal places respectively.

```
SELECT TRUNC(873.726,2), TRUNC(873.726,1), TRUNC(873.726,0), TRUNC(873.726,-1), TRUNC(873.726,-2), TRUNC(873.726,-3), TRUNC(873.726,-4) FROM TABLEX WHERE INTCOL = 1234;
```

This example returns the values 873.720, 873.700, 873.000, 870.000, 800.000, 0000.000, and 0000.000.

Example 3: Calculate both positive and negative numbers.

```
SELECT TRUNCATE( 3.5, 0), TRUNCATE( 3.1, 0), TRUNCATE(-3.1, 0), TRUNCATE(-3.5, 0) FROM TABLEX;
```

This example returns: the values 3.0, 3.0, -3.0, -3.0.

### TRUNC_TIMESTAMP

The TRUNC_TIMESTAMP function returns a TIMESTAMP WITHOUT TIME ZONE value that is the expression, truncated to the unit that is specified by the format-string.
The schema is SYSIBM.

**expression**
An expression that returns a value of any of the following built-in data types: a
timestamp, a character string, or a graphic string. If expression is a character or
graphic string, it must not be a CLOB or DBCLOB, and its value must be a
valid string representation of a timestamp with an actual length that is not
greater than 255 bytes. A time zone in a string representation of a timestamp is
ignored. For the valid formats of string representations of dates and
timestamps, see "String representations of datetime values" on page 130.

**format-string**
An expression that returns a built-in character string or graphic string data
type, with a length that is not greater than 255 bytes. *format-string* contains a
template of how the timestamp represented by *expression* should be trun-
cated. For example, if *format-string* is 'DD', the timestamp that is repre-
sented by *expression* is truncated to the near-
est day.

*format-string* must be a valid template
for a timestamp, and not include leading or trailing blanks. Allowable values
for *format-string* are listed in the following table.

<table>

<td>Result: 2000-05-17-23.58.45.000000</td>
</tr>
</tbody>
</table>

If expression is not a TIMESTAMP WITH TIME ZONE value, expression is cast as follows:

- If expression is a TIMESTAMP WITH TIME ZONE value, expression is cast to TIMESTAMP WITHOUT TIME ZONE, with the same precision as expression.
- Otherwise, expression is cast to TIMESTAMP(6) WITHOUT TIME ZONE.
The result of the function is a timestamp.

The result can be null; if any argument is null, the result is the null value.

The result CCSID is the appropriate CCSID of the argument encoding scheme and the result subtype is the appropriate subtype of the CCSID.

Example: Set the host variable TRNK_TMSTMP with the specified date rounded to the nearest year value.

```
SET :TRNK_TMSTMP = TRUNC_TIMESTAMP('2008-03-14-17.30.00', 'YEAR');
```

The host variable TRNK_TMSTMP is set with the value '2008-01-01-00.00.00.000000'.

**UCASE**

The UCASE function returns a string in which all the characters have been converted to uppercase characters, based on the CCSID of the argument. The UCASE function is identical to the UPPER function.

```
UCASE(string-expression[,locale-name-string[,integer]])
```

The schema is SYSIBM.

For more information, see "UPPER" on page 645.

**UNICODE**

The UNICODE function returns the Unicode UTF-16 code value of the leftmost character of the argument as an integer.

```
UNICODE(string-expression)
```

The schema is SYSIBM.

*string-expression* can be of any built-in string data type that is not a LOB.

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type.

If the argument is ASCII, EBCDIC, or Unicode UTF-8, it is first converted to a Unicode UTF-16 string (CCSID 1200) before the function is executed.

The result of the function is an INTEGER.

The result can be null; if the argument is null, the result is the null value.
Example: The following example returns the Unicode value of the character '峰' as an integer and assigns the value to the host variable `hv`.

Set :hv = UNICODE('峰'); `hv` is set to an integer with a value '23792'.

**UNICODE_STR**

The UNICODE_STR function returns a string in Unicode UTF-8 or UTF-16, depending on the specified option. The string represents a Unicode encoding of the input string.

```
UNICODE_STR(string-expression [UTF8] [UTF16])
```

The schema is SYSIBM.

*string-expression*

An expression that returns a value of a built-in character or graphic string. A character string must not be bit data. Values that are preceded by a backslash (\) are treated as Unicode UTF-16 characters (for example '\0041' is the Unicode UTF-16 representation for 'A'). A double backslash (\\') indicates a backslash in the string. A partial surrogate character in the expression is replaced with a blank.

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type.

*UTF8 or UTF16*

Specifies the Unicode encoding of the result. If UTF8 is specified, the result is returned as a Unicode UTF-8 character string. If UTF16 is specified, the result is returned as a Unicode UTF-16 graphic string. UTF8 is the default.

The result of the function depends on the second argument:
- VARCHAR if **UTF8** is specified
- VARGRAPHIC if **UTF16** is specified

The length attribute of the result is depends on the second argument (**UTF8** or **UTF16**). The length attribute of the result is calculated using the formulas in Table 38 on page 172. If the result is a character string, the length attribute of the result is MAX(n, 32704). If the result is a graphic string, the length attribute of the result is MAX(n, 16352). Where n is the result of applying the formulas in Table 38 on page 172 based on input and output data types.

If the actual length of the result string exceeds the maximum for the return type, an error occurs.

The result can be null; if the argument is null, the result is the null value.
UNISTR can be specified as a synonym for UNICODE_STR.

Example: The following example sets the host variable \(HV1\) to a VARCHAR value that represents the Unicode UTF-8 string that corresponds to the argument:

\[
\text{SET :HV1 = UNICODE_STR('Hi, my name is \5CF0');}
\]

\(HV1\) is assigned a Unicode UTF-8 string with the following value ‘Hi, my name is 峰’.

**UPPER**

The UPPER function returns a string in which all the characters have been converted to uppercase characters.

\[
\text{UPPER(string-expression [,locale-name-string [,integer]])}
\]

The schema is SYSIBM.

*string-expression*

An expression that specifies the string to be converted. *string-expression* must return a value that is a built-in character or graphic string. A character string argument must not be a CLOB, and a graphic string argument must not be a DBCLOB. If *string-expression* is an EBCDIC graphic string, a blank string must not be specified for *locale-name-string*. If *string-expression* is bit data, *locale-name-string* must not be specified.

*locale-name-string*

A string constant or a string host variable other than a CLOB or DBCLOB that specifies a valid locale name. If *locale-name-string* is not in EBCDIC, it is converted to EBCDIC. The length of *locale-name-string* must be between 1 and 255 bytes of the EBCDIC representation. The value of *locale-name-string* is not case sensitive and must be a valid locale. For information on locales and their naming conventions, see *z/OS C/C++ Programming Guide*. Some examples of locales include:

- Fr_BE
- Fr_FR@EURO
- En_US
- Ja_JP

The conversion process is determined by the value that is specified for the locale name, as follows:

- blank — SBCS lowercase characters a-z are converted to SBCS uppercase characters A-Z, and characters with diacritical marks are not converted. If the string contains MIXED or DBCS characters, full-width lowercase characters a-z are converted to full-width Latin uppercase characters A-Z. For optimal performance, specify a blank string unless your data must be processed by using the rules that are defined by a specific locale.
- UNI_SIMPLE — Case conversions use the NORMAL casing capabilities as described in *Select the conversions (z/OS: Unicode Services User’s Guide and Reference)*. UNI_SIMPLE cannot be used with EBCDIC data.
• UNI — The conversion uses both the NORMAL and SPECIAL casing capabilities as described in the z/OS Unicode Services User’s Guide and Reference. You must not specify UNI when string-expression is EBCDIC data.

• locale name — The locale defines the rules for conversion to uppercase characters.

The value of the host variable must not be null. If the host variable has an associated indicator variable, the value of the indicator variable must not indicate a null value. The locale name must be:

• left justified within the host variable

• padded on the right with blanks if its length is less than that of the host variable and the host variable is in fixed length CHAR or GRAPHIC data type

If locale-name-string is not specified, the locale is determined by special register CURRENT LOCALE LC_CTYPE. For information about the special register, see “CURRENT LOCALE LC_CTYPE” on page 205.

If the UPPER function is referenced in an expression-based index, locale-name-string must be specified

integer

An integer value that specifies the length attribute of the result. If specified, integer must be an integer constant between 1 and 32704 bytes in the representation of the encoding scheme of string-expression.

If integer is not specified, the length attribute of the result is the same as the length of string-expression.

For Unicode data, usage of the UPPER function can result in expansion if certain characters are processed. For example, UPPER(UX’FB03’) will result in UX’004600460049’. You should ensure that the result string is large enough to contain the result of the expression.

The result can be null; if the argument is null, the result is the null value.

Example 1: Return the string 'abcdef' in uppercase characters. Assume that the locale in effect is blank.

SELECT UPPER('abcdef')
FROM SYSIBM.SYSDUMMY1

The result is the value 'ABCDEF'.

Example 2: Return the string 'ffi' in the uppercase characters ('FFI'). Assume that the locale in effect is "UNI".

SELECT UPPER(UX'FB03')
FROM SYSIBM.SYSDUMMYU;

This would result in an error because of the expansion that occurs when certain Unicode characters are processed. To avoid the error, you would need to use the following statement instead:

SELECT UPPER(CAST(UX'FB03' AS VARCHAR(3))
FROM SYSIBM.SYSDUMMYU;

The result of the preceding statement is the value 'FFI'.
Example 3: Create an index EMPLOYEE_NAME_UPPER for table EMPLOYEE based on built-in function UPPER with locale name 'Fr_FR@EURO'.

```sql
CREATE INDEX EMPLOYEE_NAME_UPPER
ON EMPLOYEE (UPPER(LASTNAME, 'Fr_FR@EURO', 60),
               UPPER(FIRSTNAME, 'Fr_FR@EURO', 60),
               ID);
```

The result is the value 'ABCDEF'.

Related concepts:
- [z/OS Unicode Services User’s Guide and Reference](#)

Related reference:
- [z/OS XL C/C++ Programming Guide](#)

**VALUE**

The VALUE function returns the value of the first non-null expression.

```
VALUE(expression, expression)
```

The schema is SYSIBM.

**Syntax alternatives:** The VALUE function can be specified in place of the COALESCE function. COALESCE should be used for conformance to SQL 2003 Core. For more information, see [COALESCE](#).

**VARBINARY**

The VARBINARY function returns a VARBINARY (varying-length binary string) representation of a string of any type.

```
VARBINARY(string-expression, integer)
```

The schema is SYSIBM.

**string-expression**

An expression that returns a value that is a built-in character string, graphic string, binary string, or a row ID type.

**integer**

An integer value that specifies the length attribute of the resulting binary string. The value must be an integer between 1 and 32704 inclusive. If integer is not specified:
- If the `string-expression` is the empty string constant, the length attribute of the result is 1.
• Otherwise, the length attribute of the result is the same as the length attribute of the string-expression, unless the string-expression is a graphic string. In this case, the length attribute of the result is twice the length attribute of the string-expression.

The result of the function is a varying-length binary string.

The result can be null; if the first argument is null, the result is the null value.

The actual length of the result is the minimum of the length attribute of the result and the actual length of the string-expression (or twice the length of the string-expression if string-expression returns a graphic string). If the length of the string-expression is greater than the length attribute of the result, truncation is performed, and a warning is returned unless the string-expression is a character string and all the truncated characters are blanks, or the string-expression is a graphic string and all the truncated characters are double-byte blanks.

Example 1: The following function returns a varying-length binary string with a length attribute 1, actual length 0, and a value of empty string:

```
SELECT VARBINARY("")
FROM SYSIBM.SYSDUMMY1;
```

Example 2: The following function returns a varying-length binary string with a length attribute 5, actual length 3, and a value BX'D2C2C8':

```
SELECT VARBINARY('KBH',5)
FROM SYSIBM.SYSDUMMY1;
```

Example 3: The following function returns a varying-length binary string with a length attribute 3, actual length 3, and a value BX'D2C2C8':

```
SELECT VARBINARY('KBH ',3)
FROM SYSIBM.SYSDUMMY1;
```

Example 4: The following function returns a varying-length binary string with a length attribute 3, actual length 3, and a value BX'D2C2C8', a warning is also returned.

```
SELECT VARBINARY('KBH-93',3)
FROM SYSIBM.SYSDUMMY1;
```

Example 5: The following function returns a varying-length binary string with a length attribute 3, actual length 3, and a value BX'C1C2C3', a warning is also returned.

```
SELECT VARBINARY(BINARY('ABC',5),3)
FROM SYSIBM.SYSDUMMY1;
```

VARCHAR

The VARCHAR function returns a varying-length character string representation of the value specified by the first argument.

The syntax of the VARCHAR function depends on the data type of the input argument. The following types of input arguments are accepted.
Integer to Varchar:

\[ \text{VARCHAR}(\text{integer-expression}) \]

Decimal to Varchar:

\[ \text{VARCHAR}(\text{decimal-expression}, \text{decimal-character}) \]

Floating-point to Varchar:

\[ \text{VARCHAR}(\text{floating-point-expression}) \]

Decimal floating point to Varchar:

\[ \text{VARCHAR}(\text{decimal-float-expression}) \]

Character to Varchar:

\[ \text{VARCHAR}(\text{character-expression}, \text{integer}, \text{CODEUNITS16}, \text{CODEUNITS32}, \text{OCTETS}) \]

Graphic to Varchar:

\[ \text{VARCHAR}(\text{graphic-expression}, \text{integer}, \text{CODEUNITS16}, \text{CODEUNITS32}) \]
The schema is SYSIBM.

The VARCHAR function returns a varying-length character string representation of one of the following values:

- An integer number if the first argument is a SMALLINT, INTEGER, or BIGINT
- A decimal number if the first argument is a decimal number
- A double-precision floating-point number if the first argument is a DOUBLE or REAL
- A decimal floating-point number if the first argument is a DECFLOAT
- A character string value if the first argument is any type of character string
- A graphic string if the first argument is an EBCDIC or Unicode graphic string
- A datetime value if the first argument is a date, time, or timestamp
- A row ID value if the first argument is a row ID

The result of the function is a varying-length character string (VARCHAR).

The result can be null; if the first argument is null, the result is the null value.

**Integer to Varchar**

```
Integer-expression
```

An expression that returns a value that is a built-in integer data type (SMALLINT, INTEGER, BIGINT).

The result is a varying-length character string representation of the argument in the form of an SQL integer constant. The actual length of the result is the smallest number of characters that can be used to represent the value of the argument. The result consists of n characters that are the significant digits that represent the value of the argument with a preceding minus sign if the argument is negative. A positive value starts with a digit. Leading zeroes are not included.

- If the argument is a small integer, the length attribute of the result is 6.
- If the argument is a large integer, the length attribute of the result is 11.
- If the argument is a big integer, the length attribute of the result is 20.

The CCSID of the result is determined from the application encoding scheme.

**Decimal to Varchar**

```
Decimal-expression
```

An expression that returns a value that is a decimal number (DECIMAL).

The result is a varying-length character string representation of the argument in the form of an SQL decimal number constant. The actual length of the result is the smallest number of characters that can be used to represent the value of the argument. The result consists of n characters that are the significant digits that represent the value of the argument with a preceding minus sign if the argument is negative. A positive value starts with a digit. Leading zeroes are not included.

- If the argument is a small decimal, the length attribute of the result is 11.
- If the argument is a large decimal, the length attribute of the result is 23.
- If the argument is a big decimal, the length attribute of the result is 38.

The CCSID of the result is determined from the application encoding scheme.
**decimal-expression**
An expression that returns a value that is a built-in decimal data type. To specify a different precision and scale for the expression’s value, apply the DECIMAL function to the expression before applying the VARCHAR function.

**decimal-character**
Specifies the single-byte character constant that is used to delimit the decimal digits in the result character string. The character must not be a digit, a plus sign (+), a minus sign (-), or a blank. The default is the period (.) or comma (,). For information on what factors govern the choice, see [Decimal point representation](#).

The result is a varying-length character string representation of the first argument. The actual length of the result is the smallest number of characters that can be used to represent the result, except that trailing zeros are included. The result includes a decimal character and up to $p$ digits where $p$ is the precision of `decimal-expression` with a preceding minus sign if the argument is negative. A positive value starts with a digit or the `decimal-character`. Leading zeros are not returned. If the scale of decimal expression is zero, the decimal character is not returned.

The length attribute of the result is $2+p$ where $p$ is the precision of `decimal-expression`.

The CCSID of the result is determined from the application encoding scheme.

**Floating-point to Varchar**

**floating-point-expression**
An expression that returns a value that is a built-in floating-point data type.

The result is a varying-length character string representation of the argument in the form of an SQL floating-point constant. If the argument is negative, the first character of the result is a minus sign; otherwise, the first character is a digit. If the argument is zero, the result is 0E0.

The length attribute of the result is 24. The actual length of the result is the smallest number of characters that can represent the value of the argument such that the mantissa consists of a single digit other than zero followed by a period and a sequence of digits.

The CCSID of the result is determined from the application encoding scheme.

**Decimal floating-point to Varchar**

**decimal-floating-point-expression**
An expression that returns a value that is the built-in DECFLOAT data type.

The result is the varying-length character string representation of the argument in the form of an SQL decimal floating-point constant.

---

23. If the BIF_COMPATIBILITY system parameter is set to V9_DECIMALVARCHAR, or if the SYSCOMPAT_V9.VARCHAR function is used, the format of the result matches the result of the VARCHAR function with decimal input.
If the result value is one of the special values Infinity, sNaN, or NaN, the strings 'INFINITY', 'SNAN', or 'NAN', respectively, are returned. The DECFLOAT special value sNaN does not result in an exception when it is converted to a string.

The length attribute of the result is 42. The actual length of the result is the smallest number of characters that represents the value of the argument, including the sign, digits, and period. Trailing zeros are significant. If the argument is negative, the first character of the result is a minus sign. Otherwise, the first character is a digit, or a letter if the result value is Infinity, sNaN, or NaN.

The CCSID of the result is determined from the application encoding scheme.

**Character to Varchar**

*character-expression*

An expression that returns a value that is a built-in character data type.

*integer*

Specifies the length attribute for the resulting varying-length character string. The value must be between 1 and 32764, expressed in the units that are either implicitly or explicitly specified. If the length is not specified, the length of the result is the same as the length of *character-expression*.

If CODEUNITS16, CODEUNITS32, or OCTETS is specified, see [Determining the length attribute of the final result](#) for information about how to calculate the length attribute of the result string.

If a length attribute is not specified and if the *character-expression* is an empty string constant, the length attribute of the result is 1 and the result is an empty string. Otherwise, the length attribute of the result is the same as the length attribute of the first argument.

**CODEUNITS16, CODEUNITS32, or OCTETS**

Specifies the unit that is used to express *integer*. If *character-expression* is a character string that is defined as bit data, CODEUNITS16 and CODEUNITS32 cannot be specified.

**CODEUNITS16**

Specifies that *integer* is expressed in terms of 16-bit UTF-16 code units.

**CODEUNITS32**

Specifies that *integer* is expressed in terms of 32-bit UTF-32 code units.

**OCTETS**

Specifies that *integer* is expressed in terms of bytes.

For more information about CODEUNITS16, CODEUNITS32, and OCTETS, see [String unit specifications](#).

The actual length of the result is the minimum of the length attribute of the result and the actual length of *character-expression*. If the length of *character-expression* is greater than the length attribute of the result, the result is truncated. Unless all the truncated characters are blanks appropriate for *character-expression*, a warning is returned.
If \textit{character-expression} is bit data, the result is bit data. Otherwise, the CCSID of the result is the same as the CCSID of \textit{character-expression}.

\textbf{Graphic to Varchar}

\textit{graphic-expression}

An expression that returns a value that is a built-in graphic data type.

\textit{integer}

The length attribute for the resulting varying-length graphic string. The value must be between 1 and 32704, expressed in the units that are either implicitly or explicitly specified.

If \textsc{CODEUNITS16} or \textsc{CODEUNITS32} is specified, see \textit{Determining the length attribute of the final result} for information about how to calculate the length attribute of the result string.

If a length attribute is not specified, the length attribute of the result is determined as follows (where \textsc{n} is the length attribute of the first argument):

\begin{itemize}
  \item If the \textit{graphic-expression} is the empty graphic string constant, the length attribute of the result is 1.
  \item If the result is SBCS data, the result length is \textsc{n}.
  \item If the result is mixed data, the result length is \textit{3*(length(graphic-expression)).}
\end{itemize}

\textbf{CODEUNITS16 or CODEUNITS32}

Specifies the unit that is used to express \textit{integer}.

\textbf{CODEUNITS16}

Specifies that \textit{integer} is expressed in terms of 16-bit UTF-16 code units.

\textbf{CODEUNITS32}

Specifies that \textit{integer} is expressed in terms of 32-bit UTF-32 code units.

For more information about \textsc{CODEUNITS16} or \textsc{CODEUNITS32}, see \textit{String unit specifications}.

The actual length of the result is the minimum of the length attribute of the result and the actual length of \textit{graphic-expression}. If the length of the graphic expression is greater than the length attribute of the result, the result is truncated. Unless all the truncated characters were blanks appropriate for \textit{graphic-expression}, a warning is returned.

The CCSID of the result is the character mixed CCSID that corresponds to the graphic CCSID of \textit{graphic-expression}.

\textbf{Datetime to Varchar}

\textit{datetime-expression}

An expression whose value has one of the following three built-in data types:

\textbf{date}

The result is a varying-length character string representation of the date in the format that is specified by the \textsc{DATE precompiler option}, if one is provided, or else field \textsc{DATE FORMAT} on installation panel \textsc{DSNTIP4} specifies the format. If the format is to be \textsc{LOCAL}, field \textsc{LOCAL DATE LENGTH} on
installation panel DSNTIP4 specifies the length of the result. Otherwise, the length attribute and actual length of the result is 10.

LOCAL denotes the local format at the Db2 that executes the SQL statement. If LOCAL is used for the format, a time exit routine must be installed at that Db2.

An error occurs if the second argument is specified and is not a valid value.

time  The result is a varying-length character string representation of the time in the format specified by the TIME precompiler option, if one is provided, or else field TIME FORMAT on installation panel DSNTIP4 specifies the format. If the format is to be LOCAL, the field LOCAL TIME LENGTH on installation panel DSNTIP4 specifies the length of the result. Otherwise, the length attribute and actual length of the result is 8.

LOCAL denotes the local format at the Db2 that executes the SQL statement. If LOCAL is used for the format, a time exit routine must be installed at that Db2.

An error occurs if the second argument is specified and is not a valid value.

timestamp  The result is the character string representation of the timestamp with time zone. The second argument must not be specified.

• If datetime-expression is a TIMESTAMP (0) WITHOUT TIME ZONE, the length of the result is 19.
• If datetime-expression is a TIMESTAMP (p) WITHOUT TIME ZONE, the length of the result is 20+p where p is the timestamp precision. The second argument must not be specified.
• If datetime-expression is a TIMESTAMP (0) WITH TIME ZONE, the length of the result is 25.
• If datetime-expression is a TIMESTAMP (p) WITH TIME ZONE, the length of the result is 26 +p where p is the timestamp precision. The second argument must not be specified.

The CCSID of the result is determined from the context in which the function was invoked. For more information, see Determining the encoding scheme and CCSID of a string (Introduction to Db2 for Z/OS).

Row ID to Varchar

row-ID-expression  An expression that returns a value that is a built-in row ID data type.

The result is a varying-length character string representation (VARCHAR) of the argument. It is bit data.

The length attribute of the result is 40. The actual length of the result is the length of row-ID-expression.
Notes

Syntax alternatives: VARCHAR9 can be specified as an alternative to VARCHAR. The result of the function is the same, except when the first argument is decimal data.

Examples

Example 1: Assume that host variable JOB_DESC is defined as VARCHAR(8). Using sample table DSN8C10.EMP, set JOB_DESC to the varying-length string equivalent of the job description (column JOB defined as CHAR(8)) for the employee with the last name of 'QUINTANA'.

```sql
SELECT VARCHAR(JOB)
INTO :JOB_DESC
FROM DSN8C10.EMP
WHERE LASTNAME = 'QUINTANA';
```

Example 2: FIRSTNME is a VARGRAPHIC(6) column in a Unicode table T1. One of its values is the string 'Jürgen' (X'004A00FC007200670055006E'). When FIRSTNME has this value:

<table>
<thead>
<tr>
<th>Function</th>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td>VARCHAR(FIRSTNME,3,CODEUNITS32)</td>
<td>'Jür' -- x'4AC3BC72'</td>
</tr>
<tr>
<td>VARCHAR(FIRSTNME,3,CODEUNITS16)</td>
<td>'Jür' -- x'4AC3BC72'</td>
</tr>
<tr>
<td>VARCHAR(FIRSTNME,3,OCTETS)</td>
<td>'Jü' -- x'4AC38C'</td>
</tr>
</tbody>
</table>

Related concepts:

Related reference:

- "VARCHAR9"
- [BIF COMPATIBILITY field (BIF_COMPATIBILITY subsystem parameter) (Db2 Installation and Migration)](Db2 Installation and Migration)

VARCHAR9

The VARCHAR9 function returns a fixed-length character string representation of the argument. The VARCHAR9 function is intended for compatibility with previous releases of Db2 for z/OS that depend on the result format that is returned for decimal input values in Version 9 and earlier.

**Important**: For portable applications that might run on platforms other than Db2 for z/OS, use the VARCHAR function instead. Other Db2 family products do not support the VARCHAR9 function.

The first argument can be any value of the of the following types:

- Integer number
- Decimal number
- Floating-point number
- Character string
- Graphic string
- Datetime value
- Row ID value
If the first argument is a decimal number, the result is formatted as indicated in the following description. However, if the first argument is not a decimal number, the result is identical to the result of the VARCHAR function.

**Decimal to Varchar:**

\[-\text{VARCHAR9}(\text{decimal-expression},\text{-decimal-character})\]

Decimal to Varchar

*decimal-expression*

An expression that returns a value that is a built-in decimal data type. To specify a different precision and scale for the expression's value, apply the DECIMAL function to the expression before applying the VARCHAR9 function.

*decimal-character*

Specifies the single-byte character constant (CHAR or VARCHAR) that is used to delimit the decimal digits in the result character string. The character must not be a digit, a plus sign (+), a minus sign (-), or a blank. The default is the period (.) or comma (,). For information about the factors that govern the choice, see [Decimal point representation](#).

The result is a varying-length character string representation of the argument. The result includes a decimal character and up to \( p \) digits where \( p \) is the precision of *decimal-expression* with a preceding minus sign if the argument is negative. Leading and trailing zeros are returned. The result includes a decimal character even if the scale of *decimal-expression* is zero.

The CCSID of the result is determined from the context in which the function was invoked. For more information, see [Determining the encoding scheme and CCSID of a string (Introduction to Db2 for z/OS)](#).

**Examples**

The following table shows the difference between the results of the VARCHAR and VARCHAR9 functions for example decimal number arguments.

<table>
<thead>
<tr>
<th>Decimal Argument</th>
<th>VARCHAR Function Result</th>
<th>VARCHAR9 Function Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>(000.1)</td>
<td>'1.1'</td>
<td>'0.1'</td>
</tr>
<tr>
<td>(1000.)</td>
<td>'1000'</td>
<td>'1000.'</td>
</tr>
<tr>
<td>(1.1)</td>
<td>'1.1'</td>
<td>'1.1'</td>
</tr>
</tbody>
</table>

**Related concepts:**

- Data types (Introduction to Db2 for z/OS)

**Related reference:**

- VARCHAR
- BIF COMPATIBILITY field (BIF_COMPATIBILITY subsystem parameter) (Db2 Installation and Migration)
**VARCHAR_BIT_FORMAT**

The VARCHAR_BIT_FORMAT function returns a bit data string representation of a character string that has been formatted using a format-string.

\[ \text{VARCHAR_BIT_FORMAT}(\text{expression}, \text{format-string}) \]

**expression**

An expression that returns a value of any built-in numeric, character-string, or graphic-string data type that is not a LOB. A numeric or graphic argument is cast to a VARCHAR data type before evaluating the function. **expression** must not return bit data.

All leading and trailing blanks are removed from **expression** before evaluating the function.

If a format-string is specified, the length of **expression** must be equal to the length of the **format-string** and the value of **expression** must conform to the template specified by the **format-string**. If a **format-string** is not specified, the value of **expression** (after removing leading and trailing blanks) should be an even number of characters from the ranges '0' to '9', 'a' to 'f', and 'A' to 'F'. If the length is an odd number of characters, the string is padded on the right with one '0' character.

**format-string**

An expression that returns a built-in character string or graphic string data type. **format-string** contains a template for how the value for **expression** is to be interpreted. **format-string** must not return bit data.

The valid format strings are: '
\'xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx\'

and '
\'XXXXXXXX-XXXX-XXXX-XXXX-XXXXXXXXXXXX\', where each 'x' or 'X' corresponds to one hexadecimal digit in the result. If 'X' is specified, the corresponding hexadecimal digit must not be a lower case character. If 'x' is specified, the corresponding hexadecimal digit must not be an upper case character.

The result is a varying-length bit data string. The length attribute of the result is half the length attribute of **expression**. If a **format-string** is not specified, the actual length is half the actual length of **expression** (after leading and trailing blanks have been removed and padding to an even number of characters). If a **format-string** is specified, the actual length is half the actual length of the **format-string** (after removing the non-digit separator characters). If any of the arguments can be null, the result can be null; if any of the arguments is null, the result is the null value.

**Examples**

**Represent a Universal Unique Identifier in its binary form**

```sql
SELECT VARCHAR_BIT_FORMAT ('d83d6360-1818-11db-9804-b622a1ef5492',
'xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx')
FROM SYSIBM.SYSDUMMY1
```

Result returned: X'D83D6360181811DB9804B622A1EF5492'

**Represent a Universal Unique Identifier in its binary form:**

```sql
SELECT VARCHAR_BIT_FORMAT ('D83D6360-1818-11DB-9804-B622A1EF5492',
'XXXXXXXX-XXXX-XXXX-XXXX-XXXXXXXXXXXX')
FROM SYSIBM.SYSDUMMY1
```

Result returned: X'D83D6360181811DB9804B622A1EF5492'
Represent a string of hexadecimal characters in binary form:

```
SELECT VARCHAR_BIT_FORMAT ('ef01abC9') FROM SYSIBM.SYSDUMMY1
```

Result returned: X'EF01ABC9'

**VARCHAR_FORMAT**

The VARCHAR_FORMAT function returns a character string representation of the first argument in the format indicated by format-string.

**Character to VARCHAR**

```
VARCHAR_FORMAT(character-expression)
```

**Timestamp to VARCHAR**

```
VARCHAR_FORMAT(timestamp-expression, format-string)
```

**Numeric to VARCHAR**

```
VARCHAR_FORMAT(numeric-expression, format-string)
```

The schema is SYSIBM.

**Character to VARCHAR**

*character-expression*

An expression that returns a value that must be a built-in CHAR or VARCHAR data type. If a supplied argument is a GRAPHIC or VARGRAPHIC data type, it is first converted to VARCHAR before evaluating the function.

The length attribute of the result and the action length are determined as follows:

- If *string-expression* is an empty string constant, the length attribute of the result is 1.
- Otherwise, the length attribute of the result is that same as the length attribute of *string-expression*.
- The actual length of the result is the minimum of the length attribute of the result and the actual length of *string-expression*.

The value of the result is the same as the value of *character-expression*.

If *character-expression* returns graphic data, the CCSID of the result is the character mixed CCSID that corresponds to the graphic argument. If *character-expression*
returns bit data, the result is bit data. Otherwise, the CCSID of the result is the same as the CCSID of character-expression.

**Timestamp to VARCHAR**

*timestamp-expression*

An expression that returns a value that must be a DATE or TIMESTAMP, or a valid character string or graphic string representation of a date or timestamp that is not a CLOB or DBCLOB. If the argument is a graphic string representation of a data or timestamp, it is first converted to a character string before evaluating the function.

If *timestamp-expression* is a DATE or a valid string representation of a date, it is first converted to a TIMESTAMP(0) value, assuming a time of exactly midnight (00:00:00). If the HH12 format element is specified and the time component of the first argument is 24:00:00, the input timestamp value is adjusted to 00:00:00 and the date is incremented by one day.

For the valid formats of string representations of datetime values, see [String representations of datetime values](#).

*format-string*

An expression that returns a built-in character string or graphic string data type that is not a LOB and has a length attribute that is not greater than 255 bytes. If the value is not a CHAR or VARCHAR data type, it is implicitly cast to VARCHAR before the function is evaluated. If the expression returns timestamp data type, the resulting substring must conform to the rules for formatting a timestamp. If the expression returns timestamp with a time zone, the resulting substring must conform to the rules for formatting a timestamp with time zone.

The value is a template for how *timestamp-expression* is to be formatted.

A valid *format-string* can contain a combination of the format elements listed below. Two format elements can be separated by one or more of the following separator characters.

- minus sign (-)
- period (.)
- forward slash (/)
- comma (,)
- apostrophe (’)
- semicolon (;)
- colon (:
- blank ( )

Separator characters can also be specified at the start or end of *format-string*. *format-string* can also be an empty string, a string of blanks, or a string of separator characters.

The following table lists the valid format elements that *format-string* can contain.
<table>
<thead>
<tr>
<th>Format element</th>
<th>Description (assuming the default is to return leading zeros)</th>
</tr>
</thead>
<tbody>
<tr>
<td>AM or PM (^1)</td>
<td>Meridian indicator (morning or evening) without periods. This format element uses the exact strings “AM” or “PM”.</td>
</tr>
<tr>
<td>A.M. or P.M. (^1)</td>
<td>Meridian indicator (morning or evening) with periods. This format element uses the exact strings “A.M.” or “P.M.”.</td>
</tr>
<tr>
<td>CC</td>
<td>Century (00-99). If the last two digits of the four digit year are zero, the result is the first two digits of the year. Otherwise, the result is the first two digits of the year plus one.</td>
</tr>
<tr>
<td>D (^1)</td>
<td>Day of the week (1-7). 1 is Sunday and 7 is Saturday.</td>
</tr>
<tr>
<td>DD</td>
<td>Day of the month (01-31).</td>
</tr>
<tr>
<td>DDD</td>
<td>Day of the year (001-366).</td>
</tr>
<tr>
<td>FF or FF(n)</td>
<td>Fractional seconds (0-999999). The number (n) is used to specify the number of digits to include in the returned value. Valid values for (n) are 1-12 (FF1-FF12) with no leading zeros. Specifying FF is equivalent to specifying FF6. If the timestamp precision of (timestamp-expression) is less than what is specified by the format, zero digits are padded onto the right of the specified digits.</td>
</tr>
<tr>
<td>HH</td>
<td>Hour of the day (01-12).</td>
</tr>
<tr>
<td>HH12</td>
<td>Hour of the day (01-12).</td>
</tr>
<tr>
<td>HH24</td>
<td>Hour of the day (00-24).</td>
</tr>
<tr>
<td>ID</td>
<td>ISO day of the week (1-7). 1 is Monday and 7 is Sunday.</td>
</tr>
<tr>
<td>IW</td>
<td>ISO week of the year (01-53). The week starts on Monday and includes 7 days. Week 1 is the first week of the year to contain a Thursday, which is equivalent to the first week of the year to contain January 4.</td>
</tr>
<tr>
<td>I</td>
<td>ISO year (0-9). The last digit of the year based on the ISO week that is returned.</td>
</tr>
<tr>
<td>IY</td>
<td>ISO year (00-99). The last two digits of the year based on the ISO week that is returned.</td>
</tr>
<tr>
<td>IYY</td>
<td>ISO year (000-999). The last three digits of the year based on the ISO week that is returned.</td>
</tr>
</tbody>
</table>
Table 97. Valid format elements of format-string (continued)

<table>
<thead>
<tr>
<th>Format element</th>
<th>Description (assuming the default is to return leading zeros)</th>
</tr>
</thead>
<tbody>
<tr>
<td>IYYY</td>
<td>ISO year (0000-9999). The last four digits of the year based on the ISO week that is returned.</td>
</tr>
<tr>
<td>J</td>
<td>Julian date (0000000-9999999).</td>
</tr>
<tr>
<td>MI</td>
<td>Minute (00-59).</td>
</tr>
<tr>
<td>MM</td>
<td>Month (01-12). January is 01.</td>
</tr>
<tr>
<td>MONTH, Month, or month ¹, ²</td>
<td>Name of the month in uppercase, sentence case, or lowercase format in English.</td>
</tr>
<tr>
<td>MON, Mon, or mon ¹, ²</td>
<td>Three-character abbreviated name of the month in uppercase, sentence case, or lowercase format in English.</td>
</tr>
<tr>
<td>NNNNNNNN</td>
<td>Microseconds (000000-999999). This format is equivalent to specifying FF6.</td>
</tr>
<tr>
<td>Q</td>
<td>Quarter (1-4). January through March is 1.</td>
</tr>
<tr>
<td>RR</td>
<td>Last two digits of the year (00-99). RR behaves the same as YY.</td>
</tr>
<tr>
<td>RRRR</td>
<td>Year (0000-9999). RRRR behaves the same as YYYY.</td>
</tr>
<tr>
<td>SS</td>
<td>Seconds (00-59).</td>
</tr>
<tr>
<td>SSSSSS</td>
<td>Seconds since the previous midnight (00000-86400).</td>
</tr>
<tr>
<td>TZH</td>
<td>Time zone hour. (-24 to +24, This range accommodates daylight saving time changes.)</td>
</tr>
<tr>
<td>TZM</td>
<td>Time zone minute (00-59).</td>
</tr>
<tr>
<td>W</td>
<td>Week of the month (1-5). Week 1 starts on the first day of the month and ends on the seventh day.</td>
</tr>
<tr>
<td>WW</td>
<td>Week of the year (01-53). Week 1 begins on January 1 and ends on January 7.</td>
</tr>
<tr>
<td>Y</td>
<td>Last digit of the year (0-9).</td>
</tr>
<tr>
<td>YY</td>
<td>Last two digits of the year (00-99).</td>
</tr>
<tr>
<td>YYYY</td>
<td>Last three digits of the year (000-999). Year (0000-9999).</td>
</tr>
</tbody>
</table>

Notes:
1. This format element is case sensitive. In cases where the format elements are ambiguous, the case insensitive format elements will be considered first.
2. Only these exact spellings and case combinations can be used. If this format element is specified in an invalid case combination an error is returned.

If timestamp-expression is a TIMESTAMP WITHOUT TIME ZONE value, format-string must not contain TZH or TZM.
The result is a representation of timestamp-expression in the format specified by format-string. format-string is interpreted as a series of format elements that can be separated by one or more separator characters. A string of characters in format-string is interpreted as the longest matching format element in the previous table. If two format elements that contain the same characters are not separated by a separator character, the specification is interpreted, starting from the left, as the longest matching element in the table, and continues until matches are found for the remainder of the format string. For example, 'YYYYYDD' is interpreted as the format elements, 'YYYY', 'YY', and 'DD'.

If the first argument is timestamp with time zone, or the second argument is a constant that contains a format element for a time zone, the resulting string contains a timestamp with time zone. Otherwise, the resulting string does not contain a time zone.

The result is the varying-length character string that contains timestamp-expression in the format that is specified by format-string. If format-string is a constant, The length attribute of the result is the maximum of 255 and the length attribute of format-string. Otherwise, the length attribute is 255. The format-string determines the actual length of the result. The actual length must not be greater than the length attribute of the result.

The result can be null; if any argument is null, the result is the null value.

The CCSID of the result is determined from the context in which the function is invoked. For more information, see Determining the encoding scheme and CCSID of a string (Introduction to Db2 for z/OS)

**Decimal floating-point to VARCHAR**

**numeric-expression**

An expression that returns a value of any built-in numeric data type. If the argument is not a decimal floating-point value, it is converted to DECFLOAT(34) for processing.

**format-string**

An expression that must return a value that is a built-in CHAR, VARCHAR, or numeric data type. If the value is not a CHAR or VARCHAR data type, it is implicitly cast to VARCHAR before evaluating the function. If the supplied argument is a GRAPHIC or VARGRAPHIC data type, it is first converted to VARCHAR before evaluating the function. The actual length must not be greater than 254 bytes.

The value is a template for how numeric-expression is to be formatted. A format-string must contain a valid combination of the listed format elements according to the following rules:

- A sign format element ('S', 'MI', 'PR') can be specified only one time.
- A decimal point format element can be specified only one time.
- Alphabetic format elements must be specified in upper case.
- A prefix format element can only be specified at the beginning of the format string, before any format elements that are not prefix format elements. When multiple prefix format elements are specified they can be specified in any order.
- A suffix format element can only be specified at the end of the format string, after any format elements that are not suffix format elements. When multiple suffix format elements are specified they can be specified in any order.
• A comma format element must not be the first format element that is not a prefix format element. There can be any number of comma format elements.

• Blanks must not be specified between format elements. Leading and trailing blanks can be specified but are ignored when formatting the result.

Table 98. Format elements for the VARCHAR_FORMAT (numeric to VARCHAR) function

<table>
<thead>
<tr>
<th>Format element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Each 0 represents a significant digit. Leading zeros in a number are formatted as zeros.</td>
</tr>
<tr>
<td>9</td>
<td>Each 9 represents a significant digit that can be included at the specified location. Leading zeros in a number are formatted as blanks. Only group separators that have at least one digit to the left of the separator are generated.</td>
</tr>
<tr>
<td>S</td>
<td>Prefix If numeric-expression is a negative number, a leading minus sign (−) is included. If numeric-expression is a positive number, a leading plus sign (+) is included in the result.</td>
</tr>
<tr>
<td>$</td>
<td>Prefix A leading dollar sign ($) is included in the result.</td>
</tr>
<tr>
<td>MI</td>
<td>Suffix If numeric-expression is a negative number, a trailing minus sign (−) is included in the result. If numeric-expression is a positive number, a trailing blank is included in the result.</td>
</tr>
<tr>
<td>PR</td>
<td>Suffix If numeric-expression is a negative number, a leading less than character (&lt;) and a trailing greater than character (&gt;) are included in the result. If numeric-expression is a positive number, a leading blank and a trailing blank are included in the result.</td>
</tr>
<tr>
<td>, (comma)</td>
<td>Each comma represents a group separator that is included at the specified location in the result provided there would be a character to the left of it that is not a prefix character. This comma is used as a group separator.</td>
</tr>
<tr>
<td>. (period/decimal point)</td>
<td>A period represents the decimal point that is included at the specified location in the result. This period is used as a decimal point.</td>
</tr>
</tbody>
</table>

If format-string is not specified, the function is equivalent to VARCHAR(numeric-expression).

The result is a representation of the numeric-expression value (which might be rounded) in the format that is specified by format-string. Prior to being formatted,
the value of numeric-expression is rounded by using the ROUND function, if the number of digits to the right of the decimal point is greater than the number of digit format elements ('0' or '9') to the right of the decimal point in format-string.

format-string is applied according to the following rules:

- The result does not include any digit characters to the left of the decimal point if all of the following conditions are true:
  - \(-1 < \text{rounded-input-value} < 1\)
  - format-string does not include a '0' format element to the left of the decimal point
  - format-string includes at least one digit format element ('0' or '9') to the right of the decimal point
- The result includes a single 0 character immediately before the implicit or explicit decimal point if all of the following conditions are true:
  - The value of rounded-input-value is 0 or -0
  - format-string includes only the '9' digit format elements to the left of the implicit or explicit decimal point
  - format-string does not include any digit format elements to the right of the decimal point
- If format-string includes both '0' and '9' format elements to the left of the decimal point, the position of the first digit format element from the left side of the format string determines the presence of leading blanks or zeroes. All '9' format elements specified after the leftmost '0' format element to the left of the implicit or explicit decimal point are treated the same as if a '0' format element had been specified. For example, the format-string value '99099' is the same as the value '99000'.
- If the number of digits to the right of the decimal point in rounded-input-value is less than the number of digit format elements to the right of the decimal point in format-string, the result includes the number of digit characters to the right of the decimal point that corresponds to the number of digit format elements to the right of the decimal point in format-string, padded to the right with zeroes.
- If the number of digits to the left of the decimal point in rounded-input-value is greater than the number of digit format elements to the left of the decimal point in format-string, the result is a string of number sign (#) characters that matches the length that format-string produces in the result for valid values.
- If the value of rounded-input-value represents any of the positive or negative special values, Infinity, sNaN, or NaN, the string 'INFINITY', 'SNaN', 'NAN', '-INFINITY', '-sNaN', or '-Nan' is returned without using the format that is specified by format-string. The decimal floating-point special value sNaN does not result in an exception when converted to a string.
- If format-string does not include any of the sign format elements 'S', 'MI', or 'PR', and the value of rounded-input-value is negative, a minus sign (−) is included in the result. Otherwise, a blank is included in the resulting string. The minus sign or blank immediately precedes the first digit of the result to the left of the decimal point, or the decimal point if there are no digits to the left of the decimal point.

The result is a varying-length character string representation of rounded-input-value. If a single argument is specified the length attribute is 42. Otherwise the length attribute is 254. The actual length of the result is determined by format-string, if specified. Otherwise, the actual length of the result is the smallest number of characters that can represent the value of rounded-input-value. If the resulting string exceeds the length attribute of the result, the result will be truncated.
The CCSID of the result is determined from the context in which the function is invoked. For more information, see Determining the encoding scheme and CCSID of a string (Introduction to Db2 for z/OS).

Notes

Julian and Gregorian calendar:
For timestamp to a varying length character string, the transition from the Julian calendar to the Gregorian calendar on 15 October 1582 is taken into account by this function.

Determinism:
VARCHAR_FORMAT is a deterministic function.

Using the 'D', 'Y', and 'y' format elements:
Db2 for z/OS does not support the 'DY', 'dy', and 'Dy' format elements that are supported by other platforms. If 'DY' or 'Dy' is specified in the format string, it is interpreted as the 'D' format element followed by the 'Y' or 'y' format element. This behavior might change in a future release. To ensure that a 'D' followed by 'Y' or 'y' is interpreted as two separate format elements, include a separator character after the 'D' format element.

Syntax alternatives:
TO_CHAR can be specified as a synonym for VARCHAR_FORMAT.

Example: Timestamp to VARCHAR
Set the character variable TVAR to a string representation of the timestamp value of RECEIVED from CORPDATA.IN_TRAY, formatted as 'YYYY-MM-DD HH24:MI:SS'.

```
SELECT VARCHAR_FORMAT(RECEIVED,'YYYY-MM-DD HH24:MI:SS') INTO :TVAR
FROM CORPDATA.IN_TRAY;
```

Assuming that the value in the RECEIVED column is 'January 1, 2000 at 10am', the following string is returned:

'2000-01-01 10:00:00'

Assuming that the value in the RECEIVED column is now one second before the beginning of the year 2000 ('December 31, 1999 at 23:59:59pm', the following string is returned:

'1999-12-31 23:59:59'

The result would be different if HH12 had been specified instead of HH24 in the format string:

'1999-12-31 11:59:59'

Example: Timestamp to VARCHAR
Assume that the variable TMSTAMP is defined as a TIMESTAMP and has the following value: 2007-03-09-14.07.38.123456. The following examples show several invocations of the function and the resulting string values. The result data type in each case is VARCHAR(255).

<table>
<thead>
<tr>
<th>Function invocation</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>VARCHAR_FORMAT(TMSTAMP,'YYYYMMDDHHMISSFF3')</td>
<td>20070309020738123</td>
</tr>
<tr>
<td>VARCHAR_FORMAT(TMSTAMP,'YYYYMMDDHH24MISS')</td>
<td>20070309140738</td>
</tr>
<tr>
<td>VARCHAR_FORMAT(TMSTAMP,'YYYYMMDDHHMMI')</td>
<td>2007030920207</td>
</tr>
<tr>
<td>VARCHAR_FORMAT(TMSTAMP,'DD/MM/YY')</td>
<td>09/03/07</td>
</tr>
<tr>
<td>VARCHAR_FORMAT(TMSTAMP,'DD-YY')</td>
<td>09-03-2007</td>
</tr>
<tr>
<td>VARCHAR_FORMAT(TMSTAMP,'YY-MM-YY')</td>
<td>2454169</td>
</tr>
<tr>
<td>VARCHAR_FORMAT(TMSTAMP,'J')</td>
<td>1</td>
</tr>
</tbody>
</table>
Example: Timestamp to VARCHAR

Assume that the variable \textit{DTE} is defined as a \texttt{DATE} and has the value of '2007-03-09'. The following examples show several invocations of the function and the resulting string values. The result data type in each case is VARCHAR(255):

<table>
<thead>
<tr>
<th>Function invocation</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{VARCHAR_FORMAT(DTE,'YYYYMMDD')}</td>
<td>20070309</td>
</tr>
<tr>
<td>\texttt{VARCHAR_FORMAT(DTE,'YYYYMMDDHH24MISS')}</td>
<td>20070309000000</td>
</tr>
</tbody>
</table>

Assuming that today is May 26, 2008, the function returns:

26-MAY-2007

If the format string is 'YYYY-MON-YYYY', the result would be:

2007-MAY-2008

Example: Timestamp to VARCHAR

Format the hour of the specified string representation of a timestamp using a 12 hour clock and a 24 hour clock:

\begin{verbatim}
SELECT
  VARCHAR\_FORMAT(TIMESTAMP('1979-04-07-14.00.00.000000'), 'HH'),
  VARCHAR\_FORMAT(TIMESTAMP('1979-04-07-14.00.00.000000'), 'HH12'),
  VARCHAR\_FORMAT(TIMESTAMP('1979-04-07-14.00.00.000000'), 'HH24'),
  VARCHAR\_FORMAT(TIMESTAMP('2000-01-01-00.00.00.000000'), 'HH'),
  VARCHAR\_FORMAT(TIMESTAMP('2000-01-01-00.00.00.000000'), 'HH12'),
  VARCHAR\_FORMAT(TIMESTAMP('2000-01-01-00.00.00.000000'), 'HH24'),
  VARCHAR\_FORMAT(TIMESTAMP('2000-01-01-12.00.00.000000'), 'HH'),
  VARCHAR\_FORMAT(TIMESTAMP('2000-01-01-12.00.00.000000'), 'HH12'),
  VARCHAR\_FORMAT(TIMESTAMP('2000-01-01-24.00.00.000000'), 'HH'),
  VARCHAR\_FORMAT(TIMESTAMP('2000-01-01-24.00.00.000000'), 'HH12'),
  VARCHAR\_FORMAT(TIMESTAMP('2000-01-01-24.00.00.000000'), 'HH24')
FROM SYSIBM.SYSDUMMY1;
\end{verbatim}

The previous SELECT statement returns the following values:

'02' '02' '14' '12' '12' '12' '12' '00' '12' '24'

Note that the values '00' and '24' on a 24 hour scale both map to a value of '12' on a 12 hour scale.

Example: Timestamp with time zone to VARCHAR

Assume that column \textit{PRSTSZ} contains a timestamp with time zone value of '2008-02-29.20.00.000000 -08:00'. The following statement returns the value '2008-02-29 20:00:00.000000 -08:00'.

\begin{verbatim}
SELECT VARCHAR\_FORMAT(PRSTSZ, 'YYYY-MM-DD HH24:MI:SS.NNNNNN TZH:TZM'))
FROM PROJECT;
\end{verbatim}

Example: decimal floating-point to VARCHAR

Assume that the variables \textit{POSNUM} and \textit{NEGNUM} are defined as \texttt{DECFLLOAT}(34) and have the following values: '1234.56' and '-1234.56', respectively. The following examples show several invocations of the function and the resulting string values. The result data type in each case is VARCHAR(254).
### VARGRAPHIC

The VARGRAPHIC function returns a varying-length graphic string representation of the first argument.

**Integer to Vargraphic**

\[ \text{FL 502} \]

\[ \text{---VARGRAPHIC(integer-expression)} \]

**Decimal to Vargraphic**

\[ \text{FL 502} \]

\[ \text{---VARGRAPHIC(decimal-expression)} \]

**Floating-point to Vargraphic**

\[ \text{FL 502} \]

\[ \text{---VARGRAPHIC(floating-point-expression)} \]
Decimal floating-point to Vargraphic

\[
\text{VARGRAPHIC}(\text{decimal-floating-point-expression})
\]

Character to Vargraphic:

\[
\text{VARGRAPHIC}(\text{character-expression}, \text{integer}, \text{CODEUNITS16}, \text{CODEUNITS32})
\]

Graphic to Vargraphic:

\[
\text{VARGRAPHIC}(\text{graphic-expression}, \text{integer}, \text{CODEUNITS16}, \text{CODEUNITS32})
\]

The schema is SYSIBM.

The GRAPHIC function returns a varying length-graphic-string representation of:

- An integer number if the first argument is a SMALLINT, INTEGER, or BIGINT
- A decimal number if the first argument is a decimal number
- A double-precision floating-point number if the first argument is a DOUBLE or REAL
- A decimal floating-point number if the first argument is DECFLOAT
- A character string if the first argument is any type of character string
- A graphic string if the first argument is an EBCDIC or Unicode graphic string

The result can be null; if the first argument is null, the result is the null value.

The length attribute and actual length of the result are measured in double-byte characters because the result is a graphic string.

**Integer to Vargraphic**

\[
\text{integer-expression}
\]

An expression that returns a value that is an integer data type (either SMALLINT, INTEGER, or BIGINT).

The result is a varying-length graphic string of the argument in the form of an SQL integer constant. The actual length of the result is the smallest number of
characters that can be used to represent the value of the argument. The result
consists of n characters that are the significant digits that represent the value of the
argument with a preceding minus sign if the argument is negative. A positive
value starts with a digit. Leading zeroes are not included.

- If the argument is a small integer, the length attribute of the result is 6.
- If the argument is a large integer, the length attribute of the result is 11.
- If the argument is a big integer, the length attribute of the result is 20.

The CCSID of the result is 1200 (UTF-16).

**Decimal to Vargraphic**

```
[FL 502]
```

*decimal-expression*

An expression that returns a value that is a built-in decimal data type. If a
different precision and scale is wanted, the DECIMAL scalar function can
be used to make the change. To specify a different precision and scale for
the value of the expression, apply the DECIMAL function before applying
the VARGRAPHIC function.

*decimal-character*

Specifies the single-byte character constant that is used to delimit the
decimal digits in the result graphic string. The character must not be a
digit, a plus sign (+), a minus sign (-), or a blank. The default is the period
(,) or comma (.). For information on what factors govern the choice, see
Decimal point representation.

The result is a varying-length graphic string representation of the first argument.
The actual length of the result is the smallest number of characters that can be
used to represent the result, except that trailing zeros are included. The result
includes a decimal character and up to p digits, where p is the precision of the
*decimal-expression* with a preceding minus sign if the argument is negative. A
positive value starts with a digit or the decimal-character, and always includes at
least one trailing blank. Leading zeros are not returned. If the scale of
*decimal-expression* is zero, the decimal character is not returned. If the number of
bytes in the result is less than the defined length of the result, the result is padded
on the right with blanks.

The length of the result is 2+p where p is the precision of the *decimal-expression*.

The CCSID of the result is 1200 (UTF-16).

**Floating-point to Vargraphic**

```
[FL 502]
```

*floating-point-expression*

An expression that returns a value that is a floating-point data type
(DOUBLE or REAL).

The result is a varying-length graphic string representation of the argument in the
form of an SQL floating-point constant. If the argument is negative, the first
character of the result is a minus sign; otherwise, the first character is a digit. If the
argument is zero, the result is 0E0.
The length of the result is 24. The actual length of the result includes the smallest number of characters that can represent the value of the argument such that the mantissa consists of a single digit, other than zero, followed by a period and a sequence of digits. If the number of characters in the result is less than 24, the result is padded on the right with blanks.

The CCSID of the result is 1200 (UTF-16).

**Decimal floating-point to Vargraphic**

**decimal-floating-point expression**

An expression that returns a value that is a built-in decimal floating-point data type (DECFLOAT).

The result is a varying-length graphic string representation of the argument in the form of an SQL decimal floating-point constant.

If the result value is Infinity, sNaN, or NaN, the strings 'INFINITY', 'SNAN', and 'NAN', respectively, are returned. The DECFLOAT special value sNaN does not result in an exception when converted to a string.

The length of the result is 42. The actual length of the result is the smallest number of characters that represents the value of the argument, including the sign, digits, and the period. Trailing zeros are significant. If the argument is negative, the first character of the result is a minus sign. Otherwise, the first character is a digit, or a letter if the DECFLOAT value is Infinity, sNaN, or NaN.

The CCSID of the result is 1200 (UTF-16).

**Character to Vargraphic**

**character-expression**

An expression that returns a value of a built-in character string data type that contains an EBCDIC-encoded or Unicode-encoded character string value. It cannot be BIT data. The argument does not need to be mixed data, but any occurrences of 'X'0E' and 'X'0F' in the string must conform to the rules for EBCDIC mixed data. (See “Character strings” on page 111 for these rules.)

**integer**

The length attribute of the resulting varying-length graphic string. The value must be an integer constant between 1 and 16352.

If CODEUNITS16 or CODEUNITS32 is specified, see “Determining the length attribute of the final result” on page 117 for information about how to calculate the length attribute of the result string.

If integer is not specified and if the character-expression is an empty string constant or has a value X'0EOF', the length attribute of the result is 1 and the result is an empty string. Otherwise, the length attribute of the result is the same as the length attribute of the first argument.

CODEUNITS16 or CODEUNITS32

Specifies the unit that is used to express integer. If CODEUNITS16 or CODEUNITS32 is specified, the input is EBCDIC, and there is no corresponding CCSID for EBCDIC GRAPHIC data, an error occurs.
CODEUNITS16
Specifies that integer is expressed in terms of 16-bit UTF-16 code units.

CODEUNITS32
Specifies that integer is expressed in terms of 32-bit UTF-32 code units.

For more information about CODEUNITS16 and CODEUNITS32, see String unit specifications.

The actual length of the result is the minimum of the length attribute of the result and the actual length of character-expression. If the length of character-expression, as measured in single-byte characters, is greater than the specified length of the result, as measured in double-byte characters, the result is truncated. Unless all the truncated characters are blanks appropriate for character-expression, a warning is returned.

The CCSID of the result is the graphic CCSID that corresponds to the character CCSID of character-expression. If the input is EBCDIC and there is no system CCSID for EBCDIC GRAPHIC data, the CCSID of the result is X'FFFFE'.

For EBCDIC input data:

Each character of character-expression determines a character of the result. The argument might need to be converted to the native form of mixed data before the result is derived. Let M denote the system CCSID for mixed data. The argument is not converted if any of the following conditions is true:

• The argument is mixed data and its CCSID is M.
• The argument is SBCS data and its CCSID is the same as the system CCSID for SBCS data. In this case, the operation proceeds as if the CCSID of the argument is M.

Otherwise, the argument is a new string S derived by converting the characters to the coded character set identified by M. If there is no system CCSID for mixed data, conversion is to the coded character set that the system CCSID for SBCS data identifies.

The result is derived from S using the following steps:

• Each shift character (X'0E' or X'0F') is removed.
• Each double-byte character remains as is.
• Each single-byte character is replaced by a double-byte character.

The replacement for a single-byte character is the equivalent DBCS character if an equivalent exists. Otherwise, the replacement is X'FEFE'. The existence of an equivalent character depends on M. If there is no system CCSID for mixed data, the DBCS equivalent of X'xx' for EBCDIC is X'42xx', except for X'40', whose DBCS equivalent is X'4040'.

For Unicode input data:

Each character of character-expression determines a character of the result. The argument might need to be converted to the native form of mixed data before the result is derived. Let M denote the system CCSID for mixed data. The argument is not converted if any of the following conditions is true:

• The argument is mixed data, and its CCSID is M.
• The argument is SBCS data, and its CCSID is the same as the system CCSID for SBCS data. In this case, the operation proceeds as if the CCSID of the argument is M.

Otherwise, the argument is a new string S derived by converting the characters to the coded character set identified by M.

The result is derived from S using the following steps:
• Each non-supplementary character is replaced by a Unicode double-byte character (a UTF-16 code point). A non-supplementary character in UTF-8 is between 1 and 3 bytes.
• Each supplementary character is replaced by a pair of Unicode double-byte characters (a pair of UTF-16 code points).

The replacement for a single-byte character is the Unicode equivalent character if an equivalent exists. Otherwise, the replacement is X'FFFD'.

**Graphic to Vargraphic**

graphic-expression

An expression that returns a value of a built-in graphic string data type that contains an EBCDIC-encoded or Unicode-encoded graphic string value.

integer

The length attribute for the resulting varying-length graphic string. The value must be an integer constant between 1 and 16352.

If CODEUNITS16 or CODEUNITS32 is specified, see “Determining the length attribute of the final result” on page 117 for information about how to calculate the length attribute of the result string.

If integer is not specified and if the graphic-expression is an empty string constant, the length attribute of the result is 1 and the result is an empty string. Otherwise, the length attribute of the result is the same as the length attribute of the first argument.

**CODEUNITS16 or CODEUNITS32**

Specifies the unit that is used to express integer. If CODEUNITS16 or CODEUNITS32 is specified, the input is EBCDIC, and there is no corresponding CCSID for EBCDIC GRAPHIC data, an error occurs.

**CODEUNITS16**

Specifies that integer is expressed in terms of 16-bit UTF-16 code units.

**CODEUNITS32**

Specifies that integer is expressed in terms of 32-bit UTF-32 code units.

For more information about CODEUNITS16 and CODEUNITS32, see String unit specifications.

The actual length of the result depends on the number of characters in graphic-expression. If the length of graphic-expression is greater than the length specified, the result is truncated. Unless all of the truncated characters are double-byte blanks, a warning is returned.

The CCSID of the result is the same as the CCSID of graphic-expression.
Notes

Casting numeric data to Unicode: The result of the VARGRAPHIC functions is Unicode (UTF-16) when the first argument is numeric data. The VARGRAPHIC function can only be invoked with numeric data for the first argument if the containing statement:

- references Unicode base tables or views only and the statement is qualified to be a single encoding scheme statement, or
- is considered a multiple encoding scheme statement and the application encoding scheme is Unicode.

Example 1

Assume that an EMPLOYEE_U table exists that is similar to the EMPLOYEE sample table except that it is a Unicode table. The EDLEVEL column is defined as SMALLINT. Assume that employee Christine Haas was in school for 18 years. The following statement returns the EDLEVEL column value as a varying-length graphic string.

```
SELECT VARGRAPHIC(EDLEVEL)
FROM EMPLOYEE_U
WHERE LASTNAME = 'HAAS'
```

The result value is G'18'.

Example 2

Assume that an EMPLOYEE_U table exists that is similar to the EMPLOYEE sample table except that it is a Unicode table. The SALARY and COMM columns are defined as DECIMAL with a precision of 9 and a scale of 2. Assume that employee Christine Haas has a salary of $52750.00 and a commission of $4220.00. Return the total of the salary and commission for employee Christine Haas as a varying-length graphic string using the comma decimal character.

```
SELECT VARGRAPHIC(SALARY + COMM, ',')
FROM EMPLOYEE_U
WHERE LASTNAME = 'HAAS'
```

The result value is G'56970,00'.

**VERIFY_GROUP_FOR_USER**

The VERIFY_GROUP_FOR_USER function returns a value that indicates whether the primary authorization ID and the secondary authorization IDs that are associated with the first argument are in the authorization names that are specified in the list of the second argument.

```
VERIFY_GROUP_FOR_USER(SESSION_USER, group-name-expression)
```

The schema is SYSIBM.
SESSION_USER or USER

Specifies the value of the SESSION_USER (or USER) special register.

group-name-expression

An expression that specifies an authorization name. The existence of the
authorization name at the current server is not verified. group-name-expression
must return a built-in character string data type or graphic string data type
that is not a LOB. The string must have a length that does not exceed the
maximum length of an SQL identifier. The content of the string is not folded to
uppercase and is not left justified.

The result of the function is a large integer. The result cannot be null.

The result is 1 if the primary or secondary authorization IDs that are associated
with the user that is identified by the SESSION_USER (or USER) special register is
in the list that is specified by group-name-expression. Otherwise, the result is 0.

The VERIFY_GROUP_FOR_USER function is deterministic within a connection. It
is not deterministic across connections. The function can be referenced in a
CREATE MASK or a CREATE PERMISSION statement and is considered for table
expressions or the merging of views.

Example: In the following example, the EMPLOYEE table has column access control
enabled. If the connection is established outside a trusted context and Mary, who
has a secondary authorization ID of “MGR”, queries the social security number of
Tom from the EMPLOYEE table, the social security number is returned. When
Mary is no longer a manager, the same query displays the last four digits of Tom's
social security number.

Assume that a user who has SECADM authority has created the following column
mask:

```
CREATE MASK SSN_MASK ON EMPLOYEE
    FOR COLUMN SSN
    RETURN
    CASE WHEN VERIFY_GROUP_FOR_USER(SESSION_USER, 'MGR') = 1
        THEN SSN
    ELSE 'XXX-XX-' || SUBSTR(SSN, 8, 4)
    END
    ENABLE;
```

An ALTER TABLE statement is then issued to activate the column mask on the
EMPLOYEE table:

```
ALTER TABLE EMPLOYEE
    ACTIVATE COLUMN ACCESS CONTROL;
```

Mary connects to Db2, issues the following query, then disconnects from Db2:

```
SELECT SSN
    FROM EMPLOYEE
    WHERE NAME = 'Tom';
```

Mary receives Tom's social security number.

When Mary is no longer a manager, the secondary authorization ID, MGR is
removed for her authorization ID. The next time Mary connects to Db2 and issues
the following command, only the last four digits of Tom’s social security number are displayed because of the column mask SSN_MASK:

```
SELECT SSN
FROM EMPLOYEE
WHERE NAME = 'Tom';
```

**VERIFY_ROLE_FOR_USER**

The VERIFY_ROLE_FOR_USER function returns a value that indicates whether the roles that are associated with the authorization ID that is specified in the first argument are included in the role names that are specified in the list of the second argument.

If the only way to acquire a role is under a trusted connection that is associated with a trusted context, the VERIFY_ROLE_FOR_USER function is equivalent to the VERIFY_TRUSTEDCONTEXT_ROLE_FOR_USER function.

The schema is SYSIBM.

**SESSION_USER or USER**

Specifies the value of the SESSION_USER (or USER) special register.

**role-name-expression**

An expression that specifies a role name. The existence of the role name at the current server is not verified. role-name-expression must return a built-in character string data type or graphic string data type that is not a LOB. The string must have a length that does not exceed the maximum length of an SQL identifier. The content of the string is not folded to uppercase and is not left justified.

The result of the function is a large integer. The result cannot be null.

The result is 1 if any of the roles that are associated with the user that is identified by the SESSION_USER (or USER) special register is in the list of roles specified by role-name-expression. Otherwise, the result is 0.

The VERIFY_ROLE_FOR_USER function is deterministic within a trusted connection. It is not deterministic across trusted connections. The function can be referenced in a CREATE MASK or a CREATE PERMISSION statement and is considered for table expressions or the merging of views.

**Example 1:** Assume that the following statements have been issued to create specific roles and the trusted context CTX1:

```
CREATE ROLE EMPLOYEE;
COMMIT;

CREATE ROLE MGR;
COMMIT;
```
CREATE ROLE PAYROLL;
COMMIT;

CREATE TRUSTED CONTEXT CTX1
BASED UPON CONNECTION USING SYSTEM AUTHID ADMF001
ATTRIBUTES (ADDRESS '9.30.131.203', ENCRYPTION 'LOW')
DEFAULT ROLE EMPLOYEE
ENABLE
WITH USE FOR SAM, JOE ROLE MGR WITH AUTHENTICATION;
COMMIT;

Joe, who is a manager, issues the following dynamic query through the trusted connection CTX1 to view the salaries of the employees in the DSN8910.EMP table that are in his department:

SELECT SALARY FROM DSN8910.EMP
WHERE VERIFY_ROLE_FOR_USER(SESSION_USER, 'MGR', 'PAYROLL') = 1
AND WORKDEPT = ?;

Example 2: For the following example, suppose that a user with SECADM authority needs to control access for specific users who execute a statement that is accessing a table:

Is the current user, B, using role X to run a statement owned by user C
SESSION_USER = B AND
VERIFY_ROLE_FOR_USER(SESSION_USER, 'X')

Is the current user, B, using role X to run a statement owned by role D
SESSION_USER = B AND
VERIFY_ROLE_FOR_USER(SESSION_USER, 'X')

Is the current user, B, using role B to execute a dynamic statement
SESSION_USER = B AND
VERIFY_ROLE_FOR_USER(SESSION_USER, 'B')

VERIFY_TRUSTED_CONTEXT_ROLE_FOR_USER
The VERIFY_TRUSTED_CONTEXT_ROLE_FOR_USER function returns a value that indicates whether the authorization ID that is associated with first argument has acquired a role in a trusted connection and whether that acquired role is included in the role names that are specified in the list of the second argument.

The schema is SYSIBM.

SESSION_USER or USER
Specifies the value of the SESSION_USER (or USER) special register.

role-name-expression
An expression that specifies a role name. The existence of the role name at the current server is not verified. role-name-expression must return a built-in character string data type or graphic string data type that is not a LOB. The
The VERIFY_TRUSTED_CONTEXT_ROLE_FOR_USER function is deterministic within a trusted connection. It is not deterministic across trusted connections. The function can be referenced in a CREATE MASK or a CREATE PERMISSION statement and is considered for table expressions or the merging of views.

Example 1: Assume that the following statements have been issued to create specific roles and the trusted context CTX1:

```sql
CREATE ROLE EMPLOYEE;
COMMIT;

CREATE ROLE MGR;
COMMIT;

CREATE ROLE PAYROLL;
COMMIT;

CREATE TRUSTED CONTEXT CTX1
BASED UPON CONNECTION USING SYSTEM AUTHID ADMF001
ATTRIBUTES (ADDRESS '9.30.131.203', ENCRYPTION 'LOW')
DEFAULT ROLE EMPLOYEE
ENABLE
WITH USE FOR SAM, JOE ROLE MGR WITH AUTHENTICATION;
COMMIT;
```

Joe, who is a manager, issues the following dynamic query through the trusted connection CTX1 to view the salaries of the employees in the DSN8910.EMP table that are in his department:

```sql
SELECT SALARY FROM DSN8910.EMP
WHERE VERIFY_TRUSTED_CONTEXT_ROLE_FOR_USER(SESSION_USER, 'MGR', 'PAYROLL')= 1
AND WORKDEPT = ?;
```

Example 2: For the following example, suppose that a user with SECADM authority needs to control access for specific users who execute a statement that is accessing a table:

Is the current user, B, using role X to run a statement owned by user C

```sql
SESSION_USER = B AND
VERIFY_TRUSTED_CONTEXT_ROLE_FOR_USER(SESSION_USER, 'X')
```

Is the current user, B, using role X to run a statement owned by role D

```sql
SESSION_USER = B AND
VERIFY_TRUSTED_CONTEXT_ROLE_FOR_USER(SESSION_USER, 'X')
```

Is the current user, B, using role B to execute a dynamic statement

```sql
SESSION_USER = B AND
VERIFY_TRUSTED_CONTEXT_ROLE_FOR_USER(SESSION_USER, 'B')
```
**WEEK**

The WEEK function returns an integer in the range of 1 to 54 that represents the week of the year. The week starts with Sunday, and January 1 is always in the first week.

The schema is SYSIBM.

The argument must be an expression that returns a value of one of the following built-in data types: a date, a timestamp, a character string, or a graphic string. If expression is a character or graphic string, it must not be a CLOB or DBCLOB, and its value must be a valid string representation of a date or timestamp with an actual length that is not greater than 255 bytes. For the valid formats of string representations of dates and timestamps, see "String representations of datetime values" on page 130.

If expression is a timestamp with a time zone, or a valid string representation of a timestamp with a time zone, the result is determined from the UTC representation of the datetime value.

The result of the function is a large integer.

The result can be null; if the argument is null, the result is the null value.

**Example 1:** Using sample table DSN8C10.PROJ, set the integer host variable WEEK to the week of the year that project 'AD2100' ended.

```sql
SELECT WEEK(PREDATE) INTO :WEEK
FROM DSN8C10.PROJ
WHERE PROJNO = 'AD2100';
```

The result is that WEEK is set 6.

**Example 2:** The following invocations of the WEEK function returns the same result:

```sql
SELECT WEEK('1993-08-10-20.00.00'),
       WEEK('1993-08-10-20.00.00-08:00'),
       WEEK('1993-08-10-20.00.00+09:00')
FROM SYSIBM.SYSDUMMY1;
```

For each invocation of the WEEK function in this SELECT statement, the result is 33.

When the input argument contains a time zone, the result is determined from the UTC representation of the input value. The string representations of a timestamp with a time zone in the SELECT statement all have the same UTC representation: '1993-08-10-20.00.00'.
WEEK_ISO

The WEEK_ISO function returns an integer in the range of 1 to 53 that represents the week of the year. The week starts with Monday and includes seven days. Week 1 is the first week of the year that contains a Thursday, which is equivalent to the first week that contains January 4.

\[ \text{WEEK_ISO(expression)} \]

With the WEEK_ISO function, the first one, two, or three days in January might be included in the last week of the previous year. Likewise, the last one, two, or three days in December might be included in the first week of the next year.

The schema is SYSIBM.

The argument must be a date, a timestamp, or a valid string representation of a date or timestamp. A string representation must not be a CLOB or DBCLOB value and must have an actual length that is not greater than 255 bytes. For the valid formats of string representations of dates and timestamps, see "String representations of datetime values" on page 130.

If \( \text{expression} \) is a timestamp with a time zone, or a valid string representation of a timestamp with a time zone, the result is determined from the UTC representation of the datetime value.

The result of the function is a large integer.

The result can be null; if the argument is null, the result is the null value.

Example 1: Using sample table DSN8C10.PROJ, set the integer host variable WEEK_ISO to the week of the year that project 'AD2100' ended.

```sql
SELECT WEEK_ISO(PRENDATE) INTO :WEEKISO FROM DSN8C10.PROJ WHERE PROJNO = 'AD2100';
```
SELECT WEEK_ISO('1993-08-10-20.00.00'),
    WEEK_ISO('1993-08-10-20.00.00-08:00'),
    WEEK_ISO('1993-08-10-20.00.00+09:00')
FROM SYSIBM.SYSDUMMY1;

For each invocation of the WEEK_ISO function in this SELECT statement, the result is 32.

When the input argument contains a time zone, the result is determined from the UTC representation of the input value. The string representations of a timestamp with a time zone in the SELECT statement all have the same UTC representation: '1993-08-10-20.00.00'.

**WRAP**

The WRAP built-in function encodes a readable data definition statement into an obfuscated data definition statement. The procedural logic and embedded SQL statements in an *obfuscated data definition statement* are scrambled in such a way that any intellectual property in the logic cannot be easily extracted.

►►WRAP—(*object-definition-string—*)◄◄

The schemas is SYSIBM.

The WRAP function is not deterministic.

**object-definition-string**

A string of any built-in character type that contains any of the following data definition statements:

- CREATE FUNCTION (compiled SQL scalar)
- CREATE FUNCTION (inlined SQL scalar)
- CREATE PROCEDURE (SQL - native)
- CREATE PROCEDURE (SQL table)
- CREATE TRIGGER (basic)
- CREATE TRIGGER (advanced)

**object-definition-string** must not be bit data, and it cannot contain the VERSION keyword.

The result is a string of type CLOB(2M) that contains an encoded version of the input statement. The result cannot be null. The encoded statement consists of the following parts:

- The original statement up to and including the routine signature or trigger name.
- The WRAPPED keyword.
- The product identifier of the database manager that invoked the function. The format of product identifier values is *pppvvrm*, where *ppp* is a 3-letter product code (such as DSN for Db2), *vv* is the version, *rr* is the release, and *m* is the modification level. For example, DSN12015 identifies Db2 12 after the activation of function level 500 or higher.
- The encoded remainder of the data definition statement, in the form of a string of letters (a-z and A-Z), digits (0-9), underscores, and colons. It is converted to Unicode UTF-8 before it is encoded. An error is issued if **object-definition-string**
cannot be converted or if the intermediate string exceeds the maximum length for SQL statements. A warning occurs if a character is converted to the substitution character.

The encoded data definition statement can be up to one-third longer than the plain text form of the statement. If the result exceeds the maximum length for SQL statements, an error is issued.

**Important:** The encoding of the statement is meant to obfuscate the content and is not considered a form of strong encryption.

### Examples

#### Example 1

The following example, produces an obfuscated version of a function that computes a yearly salary from an hourly wage given a 40 hour work week.

```sql
SELECT WRAP('CREATE FUNCTION salary(wage DEC_FLOAT)
RETURNS DEC_FLOAT
RETURN wage * 40 * 52')
FROM SYSIBM.SYSDUMMY1
```

The result is similar to the following form:

```sql
CREATE FUNCTION salary(wage DEC_FLOAT) WRAPPED DSN12015
ab1GwmdiwntyTmdutMjQmTntaUmCmZwUnmWntnWmZaWeWmXmtaUmdaWmdaWmdaWmZG1mIaG
icaGy31TyStm_q6be3sdxjtC8ymVGlpmXnuL81kmNuRhhz6qYJ2YyidXGaa
```

#### Example 2

The following statement produced an obfuscated version of a trigger that sets a complex default value.

```sql
SELECT WRAP('CREATE OR REPLACE TRIGGER trig1
BEFORE INSERT ON emp
REFERENCING NEW AS n FOR EACH ROW
WHEN (n.bonus IS NULL)
SET n.bonus = n.salary * .04')
FROM SYSIBM.SYSDUMMY1
```

The result is similar to the following form:

```sql
CREATE TRIGGER trig1 WRAPPED DSN12015
ab1GwmdiwntyTmdutMjQmTntaUmCmZwUnmWntnWmZaWeWmXmtaUmdaWmdaWmdaWmZG1mIaG
icaGy31TyStm_q6be3sdxjtC8ymVGlpmXnuL81kmNuRhhz6qYJ2YyidXGaa
```

### XMLATTRIBUTES

The XMLATTRIBUTES function constructs XML attributes from the arguments. This function can be used as an argument only for the XMLELEMENT function.
The schema is SYSIBM.

The result is an XML sequence that contains an XQuery attribute node for each non-null attribute-value-expression argument.

**attribute-value-expression**
An expression that returns a value for the attribute. The data type of attribute-value-expression must not be ROWID, a LOB, a distinct type that is based on a ROWID or a LOB, or XML.

The result of attribute-value-expression is mapped to an XML value according to the rules for mapping an SQL value to an XML value. If the expression is not a simple column reference, an attribute name must be specified.

**AS attribute-name**
Specifies an attribute name. The name is an SQL identifier that must be in the form of an XML qualified name, or QName. If attribute-name is a qualified name, the namespace prefix must be declared within the scope of the qualified name.

attribute-name cannot be 'xmlns' or prefixed with 'xmlns:'. A namespace is declared using the function XMLNAMESPACES. The attribute names for an element must be unique for the XML element to be well-formed.

If attribute-name is not specified, the expression for attribute-value must be a column name. The attribute name will be created from the column name using the fully escaped mapping from a column name to an XML attribute name.

The result of the function is an XML value. The result can be null; if all attribute-value-expression arguments are null, the result is the null value.

**XMLCOMMENT**
The XMLCOMMENT function returns an XML value with a single comment node from a string expression. The content of the comment node is the value of the input string expression, mapped to Unicode (UTF-8).

**string-expression**
An expression that returns a value of a built-in character or graphic string that is not a LOB and is not bit data. The result of string-expression is converted to UTF-8 and then parsed to check for conformance to the content of XML comment as specified by the following rules:
- ‘–’ (double-hyphen) must not occur in the string expression
• The string expression must not end with a hyphen (’-’)
• Each character of the string can be any Unicode character, excluding the surrogate blocks, X'FFE', and X'FFFF'

If string-expression does not conform to the previous rules, an error is returned.

The result of the function is an XML value that is an XML sequence that contains one XML comment node.

The result can be null; if the argument is null, the result is the null value.

Example: Generate an XML comment:

```sql
SELECT XMLCOMMENT('This is an XML comment')
FROM SYSIBM.SYSDUMMY1;
```

The result of the query would look similar to the following result:

```
<!--This is an XML comment-->
```

**XMLCONCAT**

The XMLCONCAT function returns an XML sequence that contains the concatenation of a variable number of XML input arguments.

```
XMLCONCAT(XML-expression)
```

The schema is SYSIBM.

**XML-expression**

An expression that returns an XML value.

The data type of the result is XML. The result of the function is an XML sequence that contains the concatenation of the non-null input XML values. Null values in the input are ignored. The result can be null; if the result of every input value is null, the result is the null value.

Example: Concatenate first name and last name elements by using ‘first’ and ‘last’ element names for each employee.

```sql
SELECT XMLSERIALIZE( XMLCONCAT
    ( XMLELEMENT ( NAME "first", e.fname),
     XMLELEMENT ( NAME "last", e.lname)
    ) ) AS "result"
FROM employees e;
```

The result of the query would look similar to the following result:

```
result
-----------------------------
<first>John</first><last>Smith</last>
<first>Mary</first><last>Smith</last>
```
The XMLDOCUMENT function returns an XML value with a single document node and zero or more nodes as its children. The content of the generated XML document node is specified by a list of expressions.

The schema is SYSIBM.

XML-expression
An expression that returns an XML value. A sequence item in the XML value must not be an attribute node. If XML-expression returns a null value, it is ignored for further processing. However, if all XML-expression values are null, the result of the function is the null value.

The result of the function is an XML value.

The result can be null; if all of the arguments are null, the result is the null value.

The resulting XML value is built from the list of XML-expression arguments. The children of the resulting document node are constructed as follows:

1. All of the non-null XML values that are returned by XML-expression are concatenated together. The result is a sequence of nodes or atomic values, which is referred to in the following steps as the input sequence. Any document node in the input sequence is replaced by copies of its children.
2. For each node in the input sequence, a new deep copy of the node is constructed. A deep copy of a node is a copy of the whole subtree that is rooted at that node, including the node itself and its descendants and attributes. Each copied node has a new node identity. Copied element nodes are given the type annotation 'xdt:untyped', and copied attribute nodes are given the type annotation 'xdt:untypedAtomic'. For each adjacent sequence of one or more atomic values that is returned in the input sequence, a new text node is constructed that contains the result of casting each atomic value to a string, with a single blank character inserted between adjacent values. The resulting sequence of nodes is called the content sequence. Adjacent text nodes in the content sequence are merged into a single text node by concatenating the contents of the text nodes with no intervening blanks. After concatenation, any text node that contains a zero-length string is deleted from the content sequence.
3. The nodes in the content sequence become the children of the new document node.

Example 1: Insert a constructed document into an XML column:

```sql
INSERT INTO T1 VALUES(123,
  (SELECT XMLDOCUMENT(XMLELEMENT(NAME "Emp",
    e.fname || ' ' || e.lname),
    XMLCOMMENT('This is just a simple example'))
FROM EMPLOYEE e
WHERE e.empid = 123));
```
XMLELEMENT

The XMLELEMENT function returns an XML value that is an XML element node.

The schema is SYSIBM.

**NAME**  **element-name**

Specifies the name of an XML element. **element-name** is an SQL identifier that must be in the form of an XML qualified name, or QName. If the name is qualified, the namespace prefix must be declared within the scope.

**xmlns:namespaces-declaration**

Specifies the XML namespace declarations that are the result of the XMLNAMESPACES function. The namespaces that are declared are in the scope of the XMLELEMENT function. The namespaces apply to any nested XML functions within the XMLELEMENT function, regardless of whether or not they appear inside another subselect. See “XMLNAMESPACES” on page 695 for more information on declaring XML namespaces.

If xmlns:namespaces-declaration is not specified, namespace declarations are not associated with the constructed XML element node.

**xmlns:attributes-function**

Specifies the attributes for the XML element. The attributes are the result of the XMLATTRIBUTES function. See “XMLATTRIBUTES” on page 681 for more information on constructing attributes.

**Notes:**

1. The OPTION clause can only be specified if at least one xmlns:attributes-function or element-content-expression is specified.
2. If element-content-expression is not specified, EMPTY ON NULL and NULL ON NULL must not be specified.
3. The same clause must not be specified more than one time.
If `xmlattributes-function` is not specified, attributes are not explicitly part of the constructed XML element node.

**element-content-expression**

The content of the generated XML element node is specified by an expression or a list of expressions. Each `element-content-expression` must return a value of any built-in data type or distinct type. The expression is used to construct the namespace declarations, attributes, and content of the constructed element node.

If `element-content-expression` is not specified, an empty string is used as the content for the element and `NULL ON NULL` or `EMPTY ON NULL` must not be specified.

**OPTION**

Specifies additional options for constructing the XML element. This clause has no impact on nested invocations of the `XMLELEMENT` function invocations that are specified in `element-content-expression`.

**EMPTY ON NULL or NULL ON NULL**

Specifies if a null value or an empty element is returned when the values of each `element-content-expression` is a null value. This option only affects null handling of element contents, not attribute values. The option is not inherited by a nested invocation of `XMLELEMENT` function within an `element-content-expression`.

**EMPTY ON NULL**

If the value of each `element-content-expression` is null, an empty element is returned.

`EMPTY ON NULL` is the default.

**NULL ON NULL**

If the value of each `element-content-expression` is null, a null value is returned.

**XMLBINARY USING BASE64 or XMLBINARY USING HEX**

Specifies the assumed encoding of binary input data, character string data with the `FOR BIT DATA` attribute, `ROWID`, or a distinct type that is based on one of these types. The encoding applies to element content or attribute values.

**XMLBINARY USING BASE64**

Specifies that the assumed encoding is base64 characters, as defined for XML schema type `xs:base64Binary`. The base64 encoding uses a 65-character subset of US-ASCII (10 digits, 26 lowercase characters, 26 uppercase characters, '+' and '/') to represent every 6 bits of the binary or bit data by one printable character in the subset. These characters are selected so that they are universally representable. Using this method, the size of the encoded data is 33 percent larger than the original binary or bit data.

`XMLBINARY USING BASE64` is the default.

**XMLBINARY USING HEX**

Specifies that the assumed encoding is hexadecimal characters as defined for XML schema type `xs:hexBinary` encoding. The hex encoding represents each byte (8 bits) with two hexadecimal characters. Using this method, the encoded data is twice the size of the original binary or bit data.
This function takes an element name, an optional collection of namespace declarations, an optional collection of attributes, and zero or more optional arguments that make up the content of the XML element. The result is an XML sequence that contains an XML element node or the null value. If the results of all element-content-expression arguments are empty strings, the result is an XML sequence that contains an empty element.

The result of the function is an XML value. The result can be null; if all element-content-expression arguments are null and the NULL ON NULL option is in effect, the result is the null value.

**Constructing an element node:** The resulting element node is constructed as follows:

1. **xmlnamespace-declaration** adds a set of in-scope namespaces for the constructed element. Each in-scope namespace associates a namespace prefix (or the default namespace) with a namespace URI. The in-scope namespaces define the set of namespace prefixes that are available for interpreting QNames within the scope of the element.
2. If the **xmlattributes-function** is specified, it is evaluated and the result is a sequence of attribute nodes.
3. Each element-content-expression is evaluated and the result is converted into a sequence of nodes as follows:
   - If the result type is not XML, it is converted to an XML text node that contains the result of the element-content-expression this is mapped to XML.
   - If the result type is XML, the result is a sequence of items. Some of the items in that sequence might be document nodes. Each document node in the sequence is replaced by the sequence of its top-level children. Then for each node in the resulting sequence, a new deep copy of the node is constructed, including its children and attributes. Each copied node has a new node identity. Copied element nodes are given the type annotation xdt:untyped, and copied attribute nodes are given the type annotation xdt:untypedAtomic. For each adjacent sequence of one or more atomic values that are returned in the sequence, a new text node is constructed that contains the result of casting each atomic value to a string, with a single blank character inserted between adjacent values. If any of these atomic values cannot be cast into a string, an error is returned.
4. The result sequence of xmlattributes-function and the resulting sequences of all element-content-expression clauses are concatenated into one sequence which is called the content sequence. Any sequence of adjacent text nodes in the content sequence is merged into a single text node by concatenating their contents, with no intervening blanks. After concatenation, any text node that is a zero-length string is deleted from the content sequence.
5. If the content sequence contains an attribute node that follows a node that is not an attribute node, an error is returned. Attribute nodes that occur in the content sequence become attributes of the new element node. If two or more of these attribute nodes have the same name, an error is returned. A namespace declaration is created that corresponds to any namespace that is used in the names of the attribute nodes if the namespace URI is not in the in-scope namespaces of the constructed element.
6. Element, text, comment, and processing instruction nodes in the content sequence become the children of the constructed element node.
7. The constructed element node is given a type annotation of xdt:untyped, and each of its attributes is given a type annotation of xdt:untypedAtomic. The node name of the constructed element node is the XML element name that is specified after the NAME keyword.

**Rules for using namespaces within XML_ELEMENT:** The following rules describe scoping of namespaces:

- The namespaces that are declared in the XMLNAMESPACES function are the in-scope namespaces of the element node that are constructed by the XML_ELEMENT function. If the element node is serialized, each of its in-scope namespaces will be serialized as a namespace attribute unless it is an in-scope namespace of the parent of the element node and the parent element is also serialized.

- The scope of these namespaces is the lexical scope of the XML_ELEMENT function, including the element name, the attribute names that are specified in the XMLATTRIBUTES function, and all `element-content-expressions`. These are used to resolve the QNames in the scope.

- If an XMLQUERY or XML_EXISTS function is in an `element-content-expression`, the namespaces become the *statically known namespaces* of the XQuery expression of the XMLQUERY or XML_EXISTS function. Statically known namespaces are used to resolve the QNames that are in the XQuery expression. If the XQuery prolog declares a namespace that has the same prefix within the scope of the XQuery expression, the namespace that is declared in the prolog will override the namespaces that are declared in the XMLNAMESPACES function.

- If an attribute of the constructed element comes from `element-content-expression`, its namespace might not already be declared as an in-scope namespace of the constructed element. In this case, a new namespace is created for it. If the prefix of the attribute name is already bound to a different URI by a in-scope namespace, Db2 generates a different prefix to be used in the attribute name. A namespace is created for this generated prefix. The name of the generated prefix follows the following pattern: db2ns-xx, where xx is a pair of characters chosen from the set [A-Z,a-z,0-9].

**Example 1:** The following statement uses the XML_ELEMENT function to create an XML element that contains an employees name. The statement also stores the employee number as an attribute named serial. If there is a null value in the referenced column, the function returns the null value:

```sql
SELECT e.empno, e.firstname, e.lastname, XML_ELEMENT ( NAME "foo:Emp", XMLNAMESPACES('http://www.foo.com' AS "foo"), XMLATTRIBUTES(e.empno as "serial"), e.firstname, e.lastname OPTION NULL ON NULL ) AS "Result"
FROM EMP e
WHERE e.edlevel = 12;
```

The result of the query would look similar to the following result:

<table>
<thead>
<tr>
<th>EMPNO</th>
<th>FIRSTNAME</th>
<th>LASTNAME</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>B0002 (null)</td>
<td>(null)</td>
<td>(null)</td>
<td>(null)</td>
</tr>
</tbody>
</table>

688 SQL Reference
Example 2: The following example is similar to Example 1, however, when a null value is in one of the referenced columns, an empty element is returned:

```sql
SELECT e.empno, e.firstname, e.lastname,
    XMLELEMENT (NAME "foo:Emp",
        XMLNAMESPACES('http://www.foo.com' AS "foo"),
        XMLATTRIBUTES(e.empno as "serial"),
        e.firstname,
        e.lastname
    OPTION EMPTY ON NULL) AS "Result"
FROM EMP e
WHERE e.edlevel = 12;
```

The result of the query would look similar to the following result:

<table>
<thead>
<tr>
<th>EMPNO</th>
<th>FIRSTNME</th>
<th>LASTNAME</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>A0001</td>
<td>John</td>
<td>Parker</td>
<td></td>
</tr>
<tr>
<td>B0001</td>
<td>(null)</td>
<td>Smith</td>
<td></td>
</tr>
<tr>
<td>B0002</td>
<td>(null)</td>
<td>(null)</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>&lt;foo:Emp xmlns:foo=&quot;<a href="http://www.foo.com">http://www.foo.com</a>&quot; serial=&quot;B0002&quot;/&gt;</td>

</tr>
</tbody>
</table>

**XMLFOREST**

The XMLFOREST function returns an XML value that is a sequence of XML element nodes.

```
XMLFOREST (xmlnamespace-function, element-content-expression AS element-name)
```

Notes:

1. The OPTION clause can only be specified if at least one `xmlattributes-function` or `element-content-expression` is specified.
2. The same clause must not be specified more than one time.
The schema is SYSIBM.

`xmlnamespace-function`
Specifies the XML namespace declarations that are the result of the XMLNAMESPACES function. The namespaces that are declared are in the scope of the XMLFOREST function. The namespaces apply to any nested XML functions within the XMLFOREST function, regardless of whether or not those functions appear inside another subselect. See `XMLNAMESPACES` for more information on declaring XML namespaces.

If `xmlnamespace-function` is not specified, namespace declarations are not associated with the constructed sequence of XML element nodes.

`element-content-expression`
Specifies an expression that returns a value that is used for the content of a generated XML element. The result of the expression is mapped to an XML value according to the mapping rules from an SQL value to an XML value. If the expression is not a simple column reference, `element-name` must be specified.

AS `element-name`
Specifies an identifier that is used for the XML element name.

An XML element name must be an XML QName. If the name is qualified, the namespace prefix must be declared within the scope.

If `element-name` is not specified, `element-content-expression` must be a column name. The element name is created from the column name using the fully escaped mapping from a column name to a QName.

`OPTION`
Specifies options for the result for NULL values, binary data, and bit data. The options will not be inherited by the XMLELEMENT or XMLFOREST functions that appear in `element-content-expression`.

`EMPTY ON NULL` or `NULL ON NULL`
Specifies if a null value or an empty element is returned when the values of each `element-content-expression` is a null value. `EMPTY ON NULL` and `NULL ON NULL` only affect null handling of the `element-content-expression` arguments, not the handling of values from an `xmlattributes-function` argument.

`EMPTY ON NULL`
If the value of each `element-content-expression` is null, an empty element is returned.

`EMPTY ON NULL` is the default.

`NULL ON NULL`
If the value of each `element-content-expression` is null, a null value is returned.

`XMLBINARY USING BASE64` or `XMLBINARY USING HEX`
Specifies the assumed encoding of binary input data, character string data with the FOR BIT DATA attribute, ROWID, or a distinct type that is based on one of these types. The encoding applies to element content or attribute values.

`XMLBINARY USING BASE64`
Specifies that the assumed encoding is base64 characters, as defined for XML schema type xs:base64Binary encoding. The base64 encoding uses a 65-character subset of US-ASCII (10 digits, 26 lowercase characters,
26 uppercase characters, ‘+’ and ‘/’) to represent every 6 bits of the binary or bit data by one printable character in the subset. These characters are selected so that they are universally representable. Using this method, the size of the encoded data is 33 percent larger than the original binary or bit data.

XMLBINARY USING BASE64 is the default.

XMLBINARY USING HEX
Specifies that the assumed encoding is hexadecimal characters, as defined for XML schema type xs:hexBinary encoding. The hex encoding represents each byte (8 bits) with two hexadecimal characters. Using this method, the encoded data is twice the size of the original binary or bit data.

The XMLFOREST function can be expressed using the XMLCONCAT and XMLELEMENT functions.

This function takes an optional set of namespace declarations and one or more arguments that make up the name and element content for one or more element nodes. The result is an XML sequence containing a sequence of element nodes or the null value.

The result of the function is an XML value. The result can be null; if all the element-content-expression arguments are null and the NULL ON NULL option is in effect, the result is the null value.

Example: Generate an "Emp" element for each employee. Use employee name as its attribute and two subelements generated from columns HIRE and DEPT by using XMLFOREST as its content. The element names for the two subelements are "HIRE" and "department".

```sql
SELECT e.id, XMLSERIALIZE ( XMLELEMENT ( NAME "Emp", 
    XMLATTRIBUTES ( e.fname || ' ' || e.lname 
        AS "name" ),
    XMLFOREST ( e.hire,
        e.dept AS "department" )
    ) AS "result"
FROM employees e;
```

The result of the query would be similar to the following result:

```
<table>
<thead>
<tr>
<th>ID</th>
<th>result</th>
</tr>
</thead>
<tbody>
<tr>
<td>1001</td>
<td>&lt;Emp name=&quot;John Smith&quot;&gt;</td>
</tr>
<tr>
<td></td>
<td>&lt;HIRE&gt;2000-05-24&lt;/HIRE&gt;</td>
</tr>
<tr>
<td></td>
<td>&lt;department&gt;Accounting&lt;/department&gt;</td>
</tr>
<tr>
<td>1001</td>
<td>&lt;/Emp&gt;</td>
</tr>
<tr>
<td>1001</td>
<td>&lt;Emp name=&quot;Mary Martin&quot;&gt;</td>
</tr>
<tr>
<td></td>
<td>&lt;HIRE&gt;1996-02-01&lt;/HIRE&gt;</td>
</tr>
<tr>
<td></td>
<td>&lt;department&gt;Shipping&lt;/department&gt;</td>
</tr>
<tr>
<td>1001</td>
<td>&lt;/Emp&gt;</td>
</tr>
</tbody>
</table>
```

XMLMODIFY
The XMLMODIFY function returns an XML value that might have been modified by the evaluation of an XQuery updating expression and XQuery variables that are specified as input arguments.
The schema is SYSIBM.

**xquery-update-constant**

Specifies an SQL character string constant that is interpreted as an XQuery updating expression that uses supported XQuery language syntax.  
*xquery-update-constant* must be one of the following items:

- An insert expression.
- A delete expression.
- A replace expression.
- A FLWOR expression that contains an updating expression in its return clause.
- A conditional expression that contains an updating expression in its then or else clause.
- A sequence expression that contains two or more updating expressions, separate by commas. All operands are either updating expressions or an empty sequence.

*xquery-update-constant* must not be an empty string or a string of all blanks.

**xquery-variable-expression**

*xquery-variable-expression* specifies an SQL expression whose value is available to the XQuery expression that is specified by *xquery-update-constant* during execution.

The data type of *xquery-variable-expression* can be XML, integer, decimal, or a character or graphic string that is not a LOB.  *xquery-variable-expression* must not return a ROWID, TIMESTAMP, binary string, REAL, DECIMAL data types, or a character string that is bit data, and *xquery-variable-expression* must not reference a sequence expression. If the result value is of type XML, it is passed by reference, which means that the original values, not copies, are used in the evaluation of the XQuery expression. A null XML value is converted to an XML empty sequence. If the resulting value is not of type XML, the result of the expression must be castable to an XML value. A null value is converted to an XML empty sequence. The non-XML values creates a new copy of the value during the cast to XML.

An XQuery variable is created for each *xquery-variable-expression* this is specified, and the XQuery variable is set to a value that is equal to the *input-xml-value*.

**AS identifier**

Specifies that the value that is generated by *xquery-variable-expression* is passed to *xquery-update-constant* as an XQuery variable named *identifier*. The length of the name must not be longer than 128 bytes. If the length of the name is longer than 128 bytes, an error is returned. The leading dollar sign ($) that precedes variable names in the XQuery language is not included in *identifier*. The name must be an XML 1.0 NCName that is not the same as the identifier for another *xquery-variable-expression* in the same PASSING clause. If the identifier is not an XML 1.0 NCName an error is returned. If more than one *xquery-variable*
expression have the same name, an error is returned. If the result of an
xquery-variable expression is null, an empty sequence is assigned to the
corresponding XQuery variable.

The XMLMODIFY function can only be used in an SQL UPDATE statement or
within the update clause of an SQL MERGE statement. The XMLMODIFY function
must be the topmost expression on the right hand side of the SET assignment
clause of the update.

In an XMLMODIFY invocation, updating expressions cannot modify new nodes
that are added by other updating expressions. For example, if an updating
expression adds a new element node, another updating expression cannot change
the newly created node.

For an XMLMODIFY invocation, the Db2 database manager applies updating
expressions in the following order:
1. The following operations, in a non-deterministic order:
   • Insert operations that do not use ordering keywords, such as before, after, as
     first, or as last
   • Replace operations in which the keyword value of is specified, and the target
     node is an attribute node, text node, comment node, or processing instruction
     node
2. Insert operations that use ordering keywords such as before, after, as first, or as
   last
3. Replace operations in which the keyword value of is not specified
4. Replace operations in which the keyword value of is specified, and the target
   node is an element node
5. All delete operations

The target-xml-column is the XML column in the SET assignment clause that is to be
updated by the value that is returned by the XMLMODIFY function. The initial
context item in the XQuery updating expression is the value of the
target-xml-column that is passed by reference. Only the value of the
target-xml-column can be modified by the XQuery updating expression. In other
words, the target expression nodes in the XQuery updating expression must be a
node in the value of target-xml-column. The target-xml-column must be an XML
column that is defined in the XML versioning format.

The value of target-xml-column that is modified by the XQuery updating expression
is returned by the function. If the value of target-xml-column is null, the function
returns null. Otherwise, the result of the XMLMODIFY function must be a
well-formed XML document. If the XQuery updating expressions makes no
modifications to the value of target-xml-column, the unmodified XML value is
returned by the function. The XMLMODIFY function preserves the original node
identities and the document order of target-xml-column. Although XMLMODIFY
modifies target-xml-column by reference, for each row that is updated by the SQL
UPDATE statement, any reference to target-xml-column in the SQL UPDATE
statement is the value of the target-xml-column before the row is updated.

Example 1: The following is an example of an XMLMODIFY function with an
XQuery insert expression. Assume that a table contains a column named PO that
contains an XML document, 'purchaseOrders':
UPDATE purchaseOrders
SET PO = XMLMODIFY('declare namespace ipo = "http://www.example.com/IPO";
declare namespace pyd = "http://www.examplepayment.com";
insert node $payment/@pyd:paidDate
as first into /ipo:purchaseOrder/billTo',
XMLPARSE(DOCUMENT
'<payment xmlns:pyd="http://www.examplepayment.com" pyd:paidDate="2000-01-07">278.94
</payment>') AS "payment")

The result of the purchaseOrders XML document in the PO column is as follows:

```xml
<ipo:purchaseOrder
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xmlns:ipo="http://www.example.com/IPO"
  xmlns:pyd="http://www.examplepayment.com"
  orderDate="1999-12-01" pyd:paidDate="2000-01-07">
  <shipTo exportCode="1" xsi:type="ipo:UKAddress">
    <name>Helen Zoe</name>
    <street>47 Eden Street</street>
    <city>Cambridge</city>
    <postcode>CB1 1JR</postcode>
  </shipTo>
  <items>
    <item partNum="872-AA">
      <productName>Lawnmower</productName>
      <quantity>1</quantity>
      <USPrice>149.99</USPrice>
      <shipDate>2011-05-20</shipDate>
    </item>
    <item partNum="945-ZG">
      <productName>Sapphire Bracelet</productName>
      <quantity>2</quantity>
      <USPrice>178.99</USPrice>
      <comment>Not shipped</comment>
    </item>
  </items>
</ipo:purchaseOrder>
```

**Example 2:** Assume that table PURCHASEORDER contains a column named PORDER that contains the following XML document:

```xml
<ipo:purchaseOrder
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xmlns:ipo="http://www.example.com/IPO"
  xmlns:pyd="http://www.examplepayment.com"
  orderDate="1999-12-01" pyd:paidDate="2000-01-07">
  <shipTo exportCode="1" xsi:type="ipo:UKAddress">
    <name>Helen Zoe</name>
    <street>47 Eden Street</street>
    <city>Cambridge</city>
    <postcode>CB1 1JR</postcode>
  </shipTo>
  <items>
    <item partNum="872-AA">
      <productName>Lawnmower</productName>
      <quantity>1</quantity>
      <USPrice>149.99</USPrice>
      <shipDate>2011-05-20</shipDate>
    </item>
    <item partNum="945-ZG">
      <productName>Sapphire Bracelet</productName>
      <quantity>2</quantity>
      <USPrice>178.99</USPrice>
      <comment>Not shipped</comment>
    </item>
  </items>
</ipo:purchaseOrder>
```

The following is an example of an XMLMODIFY function with an XQuery replace expression and an XQuery delete expression.

```
UPDATE PURCHASEORDER
SET PORDER = XMLMODIFY('declare namespace ipo = "http://www.example.com/IPO";
```
replace value of node /ipo:purchaseOrder/items/item[@partNum="872-AA"]/quantity
with xs:integer(2),
delete node /ipo:purchaseOrder/items/item[@partNum="945-ZG"]');

After the UPDATE statement executes, the result is as follows:

```xml
<ipo:purchaseOrder
 xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
 xmlns:ipo="http://www.example.com/IPO"
 xmlns:pyd="http://www.examplepayment.com"
 orderDate="1999-12-01" pyd:paidDate="2000-01-07">
  <shipTo exportCode="1" xsi:type="ipo:UKAddress">
    <name>Helen Zoe</name>
    <street>47 Eden Street</street>
    <city>Cambridge</city>
    <postcode>CB1 1JR</postcode>
  </shipTo>
  <items>
    <item partNum="872-AA">
      <productName>Lawnmower</productName>
      <quantity>2</quantity>
      <USPrice>149.99</USPrice>
      <shipDate>2011-05-20</shipDate>
    </item>
  </items>
</ipo:purchaseOrder>
```

### XMLNAMESPACES

The XMLNAMESPACES function constructs namespace declarations from the arguments. This function can be used as an argument only for specific functions, such as the XMLELEMENT function and the XMLFOREST function.

```
XMLNAMESPACES(namespace-uri AS namespace-prefix)
```

Notes:

1. The DEFAULT or NO DEFAULT clause can only be specified one time.

The schema is SYSIBM.

The result is one or more XML namespace declarations containing in-scope namespaces for each non-null input value.

*namespace-uri*

Specifies an SQL character string constant that contains the namespace name or a universal resource identifier (URI). The character string constant must not be an empty string if it is used with `namespace-prefix`. `namespace-uri` cannot be `http://www.w3.org/XML/1998/namespace` or `http://www.w3.org/2000/xmlns/`. 
AS namespace-prefix
   Specifies a namespace prefix. The prefix is an SQL identifier that must be in the form of an XML NCName. The prefix must not be "xml" or "xmlns". The prefix must be unique within the list of namespace declarations.

   The following namespace prefixes are pre-defined in SQL/XML: "xml", "xs", "xsd", "xsi", and "sqlxml". Their bindings are:
   • xmlns:xml = "http://www.w3.org/XML/1998/namespace"
   • xmlns:xs = "http://www.w3.org/2001/XMLSchema"
   • xmlns:xsd = "http://www.w3.org/2001/XMLSchema"
   • xmlns:xsi = "http://www.w3.org/2001/XMLSchema-instance"

DEFAULT namespace-uri or NO DEFAULT
   Specifies whether a default namespace is to be used within the scope of this namespace declaration.

   The scope of this namespace declaration is the specified XML element and all XML expressions that are contained in the specified XML element.

   DEFAULT namespace-uri
   Specifies the default namespace to use within the scope of this namespace declaration. The namespace-uri applies for unqualified names in the scope unless it is overridden in a nested scope by another DEFAULT declaration or by a NO DEFAULT declaration.

   namespace-uri specifies an SQL character string constant that contains a namespace name or universal resource identifier (URI). The character string constant can be an empty string in the context of the DEFAULT clause.

   NO DEFAULT
   Specifies that no default namespace is to be used within the scope of this namespace declaration. There is no default namespace in the scope unless the NO DEFAULT clause is overridden in a nested scope by a DEFAULT declaration.

The result of the function is an XML value that is an XML sequence that contains an XML namespace declaration for each specified namespace. The result cannot be null.

Example 1: Generate an "employee" element for each employee. The employee element is associated with XML namespace "urn:bo", which is bound to prefix "bo". The element contains attributes for names and a hiredate subelement.

SELECT e.empno, XMLSERIALIZE(XMLELEMENT(NAME "bo:employee",
   XMLNAMESPACES('urn:bo' as "bo"),
   XMLATTRIBUTES(e.lastname, e.firstname),
   XMLELEMENT(NAME "bo:hiredate", e.hiredate)) AS CLOB(50))
FROM employee e where e.edlevel = 12;

The result of the query would be similar to the following result:

00029 <bo:employee xmlns:bo="urn:bo" LASTNAME="PARKER" FIRSTNAME="JOHN">
<bo:hiredate>198-5-3</bo:hiredate>
</bo:employee>

00031 <bo:employee xmlns:bo="urn:bo" LASTNAME="SETRIGHT" FIRSTNAME="MAUDE">
<bo:hiredate>1964-9-12</bo:hiredate>
</bo:employee>
Example 2: Generate two elements for each employee using XMLFOREST. The first "lastname" element is associated with the default namespace "http://hr.org", and the second "job" element is associated with XML namespace "http://fed.gov", which is bound to prefix "d".

```sql
SELECT empno, XMLSERIALIZE(XMLFOREST(
    XMLNAMESPACES(DEFAULT 'http://hr.org', 'http://fed.gov' AS "d"),
    lastname, job AS "d:job") AS CLOB(50))
FROM employee WHERE edlevel = 12;
```

The result of the query would be similar to the following result:

```
00029 <LASTNAME xmlns="http://hr.org" xmlns:d="http://fed.gov">PARKER</LASTNAME>
00031 <LASTNAME xmlns="http://hr.org" xmlns:d="http://fed.gov">SETRIGHT</LASTNAME>
```

### XMLPARSE

The XMLPARSE function parses the argument as an XML document and returns an XML value.

```
XMLPARSE (DOCUMENT string-expression
           XML-host-variable
           PRESERVE WHITESPACE)
```

The schema is SYSIBM.

**DOCUMENT**

Specifies that the character string expression to be parsed must evaluate to a well-formed XML document that conforms to XML 1.0.

**string-expression**

An expression that returns a character, graphic, or binary string.

**string-expression** must evaluate to a character string that conforms to the definition of a well-formed XML document as defined in XML 1.0.

**XML-host-variable**

An XML host variable that contains a well-formed XML document as defined in XML 1.0. **XML-host-variable** must not be binary XML data.

**STRIP WHITESPACE** or **PRESERVE WHITESPACE**

Specifies whether whitespace is to be removed or preserved. Any DTD attributes for xml:space have no impact on whitespace handling.

**STRIP WHITESPACE**

Specifies that whitespace (space that is between element nodes without any non-whitespace text nodes) will be stripped unless the nearest containing element has a value of 'preserve' for the xml:space attribute.

**STRIP WHITESPACE** is the default.
**PRESERVE WHITESPACE**

Specifies that all whitespace is preserved, even when the nearest containing element has a value of 'default' for the xml:space attribute.

The result of the function is XML. If `string-expression` can be null, the result can be null; if `string-expression` is null, the result is the null value.

**Direct use of XMLPARSE with character string input:** Applications should avoid direct use of the XMLPARSE function with character string input and should send strings that contain XML documents directly by using host variables to maintain the match between the external encoding and the encoding in the XML declaration. If XMLPARSE must be used in this situation, a BLOB type should be specified as the argument to avoid code page conversion.

*Example 1:* The following example inserts an XML document into the EMP table and preserves the whitespace in the original XML document. Assume that `hv` contains the value, ‘<a xml:space='preserve'> <b> <c>c</c>b </b> </a>’:

```sql
INSERT INTO EMP (id, xvalue) VALUES(1001, 
XMLPARSE(DOCUMENT :hv
  PRESERVE WHITESPACE));
```

XMLPARSE will treat the value in `hv` for the insert statement as equivalent to the following value:

```
<a xml:space='preserve'> <b> <c>c</c>b </b> </a>
```

*Example 2:* The following example inserts an XML document into the EMP table and strips the whitespace in the original XML document. Assume that `hv` contains the value, ‘<a xml:space='preserve'> <b xml:space='default'> <c>c</c>b </b> </a>’:

```sql
INSERT INTO EMP (id, xvalue) VALUES(1001, 
XMLPARSE(DOCUMENT :hv
  STRIP WHITESPACE));
```

XMLPARSE will treat the value in `hv` for the insert statement as equivalent to the following value:

```
<a xml:space='preserve'>
<b xml:space='default'><c>c</c>b </b>
</a>
```

**XMLPI**

The XMLPI function returns an XML value with a single processing instruction node.

```sql
XMLPI(NAME pi-name, string-expression)
```

The schema is SYSIBM.
**NAME pi-name**

Specifies the name of a processing instruction. The name is an SQL identifier that must be in the form of an XML NCName. The name must not contain "xml" in any case combination.

**string-expression**

An expression that returns a value of a built-in character or graphic string that is not a LOB and is not bit data. The resulting string will be converted to UTF-8 and parsed to check for conformance to the content of XML processing instruction as specified by the following rules:

- The string must not contain the substring '?>' as this terminates a processing instruction.
- Each character can be any Unicode character, excluding the surrogate blocks, X'FFFE', and X'FFFF'.

If the resulting string does not conform to the preceding rules, an error is returned. The resulting string becomes the contents of the constructed processing instruction node. If `string-expression` is not specified or is an empty string, the contents of the process instruction node are empty.

The result of the function is an XML value. The result can be null; if the `string-expression` argument is null, the result is the null value.

**Example:** Generate an XML processing instruction node:

```sql
SELECT XMLPI(NAME "Instruction", 'Push the red button')
FROM SYSIBM.SYSDUMMY1;
```

The result looks similar to the following results:

```xml
<?Instruction Push the red button?>
```

**XMLQUERY**

The XMLQUERY function returns an XML value from the evaluation of an XQuery expression, by using specified input arguments, a context item, and XQuery variables.

**Notes:**

1. `xquery-context-item-expression` must not be specified more than one time.
**xquery-expression-constant**

Specifies an SQL character string constant that is interpreted as an XQuery expression using supported XQuery language syntax. For information about the supported XQuery expressions, see XQuery prologs and expressions (Db2 Programming for XML). Xquery-expression-constant cannot be an XQuery updating expression. The XQuery expression is evaluated with the arguments specified in xquery-argument, and returns an output sequence that is also returned as the result of the XMLQUERY function. Xquery-expression-constant must not be an empty string or a string of all blanks.

**PASSING**

Specifies input values and the manner in which these values are passed to the XQuery expression that is specified by xquery-expression-constant.

**BY REF**

Specifies that the XML input value arguments are to be passed by reference. When XML values are passed by reference, the XQuery evaluation uses the input node trees which preserves all properties, including the original node identities and document order. If two arguments pass the same XML value, node identity comparisons and document ordering comparisons involving some nodes that are contained between the two input arguments might refer to nodes that are within the same XML node tree.

BY REF has no impact on how non-XML values are passed. The non-XML values create a new copy of the value during the cast to XML.

**xquery-argument**

Specifies an argument that is passed to the XQuery expression that is specified by xquery-expression-constant. A query argument is an expression that returns a value that is XML, integer, decimal, or a character or graphic string that is not a LOB. Xquery-argument must not return ROWID, TIMESTAMP, binary string, REAL, DECFLOAT data types, or a character string data type that is bit data, and must not reference a sequence expression.

Xquery-argument specifies both a value and the manner in which that value is to be passed. How an argument in the PASSING clause is used in the XQuery expression depends on whether the argument is specified as xquery-context-item-expression or xquery-variable-expression. Xquery-argument includes an SQL expression that is evaluated before passing the result to the XQuery expression.

- If the resulting value is of type XML, it becomes an input-xml-value. It is passed by reference, which means that the original values, not copies, are used in the evaluation of the XQuery expression. A null XML value is converted to an XML empty sequence.
- If the resulting value is not of type XML, the result of the expression must be able to be cast to an XML value. A null value is converted to an XML empty sequence. The converted value becomes an input-xml-value.
When `xquery-expression-constant` is evaluated, an XQuery variable receives a value that is equal to `input-xml-value` and a name as specified by the AS clause.

**xquery-context-item-expression**

`xquery-context-item-expression` specifies the initial context item in the XQuery expression specified by `xquery-expression-constant`. The value of the initial context item is the result of `xquery-context-item-expression` cast to XML. `xquery-context-item-expression` must not be specified more than one time.

`xquery-context-item-expression` must not be a sequence of more than one item. If `input-xml-value` is an empty XML string, the XQuery expression is evaluated with the initial context item set to an empty XML string. If the value of `input-xml-value` is null, the function returns a null value.

If the `xquery-context-item-expression` is not specified or is an empty sequence, the initial context item in the XQuery expression is undefined and the XQuery expression must not reference the initial context item.

An XQuery variable is not created for the context item expression.

**xquery-variable-expression**

`xquery-variable-expression` specifies an SQL expression whose value is available to the XQuery expression that is specified by `xquery-expression-constant` during execution. The sequence cannot contain a sequence reference.

An XQuery variable is created for each `xquery-variable-expression`, and the XQuery variable is set to a value equal to `input-xml-value`. For example, `PASSING T.A + T.B AS "sum"` creates an XQuery variable named sum. The scope of the XQuery variables that are created from the PASSING clause is the XQuery expression that is specified by `xquery-expression-constant`.

**AS identifier**

Specifies that the value that is generated by `xquery-variable-expression` is passed to `xquery-expression-constant` as an XQuery variable named `identifier`. The length of the name must not be longer than 128 bytes. The leading dollar sign ($) that precedes variable names in the XQuery language is not included in `identifier`. The name must be an XML 1.0 NCName that is not the same as the identifier for another `xquery-variable-expression` in the same PASSING clause.

**RETURNING SEQUENCE**

Specifies that the XQuery expression returns a sequence.

**BY REF**

Specifies that the result of the XQuery expression is returned by reference. If this value contains nodes, any expression that is using the return value of the XQuery expression will receive node references directly, preserving all node properties including the original node identities and document order.

**EMPTY ON EMPTY**

Specifies that an empty sequence that results from processing the XQuery expression is returned as an empty sequence.

The result of the function is an XML value, and the result can be null. For example, if `xquery-context-item-expression` is specified and if its value is null, the result of the function is the null value.

If the evaluation of the XQuery expression results in an error, the XMLQUERY function returns the XQuery error.
**Implicit casting of a non XML value to an XML value:** If the result of `xquery-argument` is not an XML type, the value is cast to XML as follows. The SQL data type of the expression is mapped to a corresponding XML Schema data type according to the following table:

<table>
<thead>
<tr>
<th>SQL data type</th>
<th>XML schema data type</th>
</tr>
</thead>
<tbody>
<tr>
<td>CHAR, VARCHAR</td>
<td>xs:string</td>
</tr>
<tr>
<td>GRAPHIC, VARGRAPHIC</td>
<td>xs:string</td>
</tr>
<tr>
<td>SMALLINT</td>
<td>xs:integer</td>
</tr>
<tr>
<td>INTEGER</td>
<td>xs:integer</td>
</tr>
<tr>
<td>BIGINT</td>
<td>xs:integer</td>
</tr>
<tr>
<td>DECIMAL</td>
<td>xs:decimal</td>
</tr>
<tr>
<td>DOUBLE</td>
<td>xs:double</td>
</tr>
<tr>
<td>FLOAT</td>
<td>xs:double</td>
</tr>
</tbody>
</table>

Let \( V \) be the value of the expression. An atomic value of the corresponding XML schema data type is constructed such that the result of `cast (V as varchar)` is a lexical representation of the constructed atomic value. For example, an SQL VARCHAR value '123' is converted to an atomic value '123' of xs:string type. An SQL integer '12' is converted to an atomic value '12' of xs:integer. An SQL decimal value '1.20' is converted to an atomic value '1.2' of xs:decimal.

**Example 1:** The following example returns an XML value from evaluation of the specified XQuery expression:

```sql
SELECT XMLQUERY('//*[productName=$n]
    PASSING PO.POrder,
    :hv AS "n") AS "Result"
FROM PurchaseOrders PO;
```

Assume that the value of the host variable `hv` is 'Baby Monitor', the result is similar to the following results:

```
Result
<item partNum="926-AA"><productName>Baby Monitor</productName><quantity>1</quantity><USPrice>39.98</USPrice><shipDate>1999-05-21</shipDate></item>
```

**XMLSERIALIZE**

The XMLSERIALIZE function returns a serialized XML value of the specified data type that is generated from the first argument.
XMLSERIALIZE

CONTENT

XML-expression

AS

data-type

(1)

VERSION '1.0'

EXCLUDING XMLDECLARATION

INCLUDING XMLDECLARATION

Notes:
1 The same clause must not be specified more than one time.

**data-type**

The schema is SYSIBM.

**CONTENT**

Specifies that any XML value can be specified and the result of the serialization is based on this input value.

**XML-expression**

An expression that returns an XML value that is not an attribute node. The atomic values in the input sequence must be able to be cast to xs:string. **XML-expression** is the input to the serialization process.

**AS data type**

Specifies the data type of the result. The implicit or explicit length attribute for the specified result data type must be sufficient to contain the serialized output.

The CCSID of a resulting character or graphic string is determined by the data type of the result:

- If the result is a CLOB, the CCSID for mixed Unicode data (1208).
- If the result is a DBCLOB, the CCSID for graphic Unicode data (1200).

**VERSION '1.0'**

Specifies the XML version of the serialized value. The only version that is supported is '1.0', which must be specified as a string constant.

**EXCLUDING XMLDECLARATION or INCLUDING XMLDECLARATION**

Specifies whether an XML declaration is included in the result.

**EXCLUDING XMLDECLARATION**

Specifies that an XML declaration is not included in the result.
EXCLUDING XMLDECLARATION is the default.

INCLUDING XMLDECLARATION
Specifications that an XML declaration is included in the result. The XML declaration contains values for XML serialization version 1.0 and an encoding specification of UTF-8. An XML sequence is effectively converted to have a single document node by applying the XMLDOCUMENT function to XML-expression prior to serializing the resulting XML nodes.

The data type and length attribute of the result are determined from the specified data-type. The result can be null; if the XML-expression argument is null, the result is the null value.

**Serializing a sequence**: The value of the input argument to XMLSERIALIZE is a sequence. Before a sequence is serialized, it is normalized. The purpose of sequence normalization is to create a sequence that can be serialized as a well-formed XML document or external general parsed entity, that also reflects the content of the input sequence to the extent possible. If the input sequence is an XML empty string, the result of serialization is an empty string. Otherwise, the result is constructed as follows:

- For each item in the sequence, if the item is atomic, the lexical representation of the item is obtained by casting it to an xs:string.
- Each subsequence of adjacent strings in the sequence is merged into a single string with the values of the adjacent strings separated by a single space.
- For each item in the sequence, if the item is a string, a text node is created with a value that is equal to the string.
- For each node in the sequence, if the node is a document node, it is replaced by its children.
- Each node must not be an attribute node.
- Each subsequence of adjacent text nodes in the sequence are merged into a single text node that with the values of the adjacent text nodes concatenated in order without a space between each node. Any text nodes of zero length are dropped.
- A document node is created and the sequence of nodes that was generated is copied as the children of the new document node.

Let S be any sequence, the normalization described in the preceding list is equivalent to XMLDOCUMENT(S). Therefore, the following two expressions produce the same result:

- XMLSERIALIZE(S AS CLOB)
- XMLSERIALIZE(XMLDOCUMENT(S) AS CLOB)

Each instance of the following characters that appear in the content of a text node or in the value of an attribute node is mapped as follows during serialization:

<table>
<thead>
<tr>
<th>Character in content of text node</th>
<th>during serialization, the character is mapped to</th>
</tr>
</thead>
<tbody>
<tr>
<td>' &amp;' (X'26')</td>
<td>'&amp;'</td>
</tr>
<tr>
<td>' &lt;' (X'3C')</td>
<td>'&lt;'</td>
</tr>
<tr>
<td>' &gt;' (X'3E')</td>
<td>'&gt;'</td>
</tr>
<tr>
<td>carriage return (X'0D')</td>
<td>''</td>
</tr>
<tr>
<td>quote (X'22')</td>
<td>' &quot;'</td>
</tr>
</tbody>
</table>
Syntax alternatives: XML2CLOB(\textit{XML-expression}) can be specified as an alternative to XMLSERIALIZE(\textit{XML-expression} \textit{AS CLOB}(\textit{1G})). XML2CLOB is supported only for compatibility with previous releases of Db2.

Example 1: Serialize into CLOB of UTF-8, the XML value that is returned by the XMLELEMENT function, which is a simple XML element with "Emp" as the element name, and an employee name as the element content:

\begin{verbatim}
SELECT e.id, XMLSERIALIZE(XMLELEMENT (NAME "Emp",
   e.fname || ' ' || e.lname)
   AS CLOB(100)) AS "result"
FROM employees e;
\end{verbatim}

The result looks similar to the following results:

\begin{tabular}{lc}
  ID & result \\
  1001 & <Emp>John Smith</Emp> \\
  1206 & <Emp>Mary Martin</Emp>
\end{tabular}

Example 2: Serialize into a string of BLOB type, the XML value that is returned by the XMLELEMENT function:

\begin{verbatim}
SELECT XMLSERIALIZE(XMLELEMENT(NAME "emp",
   e.fname || ' ' || e.lname))
   AS BLOB(1K) VERSION '1.0' AS result
FROM employee e WHERE e.id = '1001';
\end{verbatim}

The result looks similar to the following results:

\textit{result}

\begin{verbatim}
<emp>John Smith</emp>
\end{verbatim}

\section*{XMLTEXT}

The XMLTEXT function returns an XML value with a single text node that contains the value of the argument.

\begin{verbatim}
XMLTEXT((---string-expression---))
\end{verbatim}

The schema is SYSIBM.

\textit{string-expression}

An expression that returns a value of a built-in character or graphic string that is not bit data. Any character in the resulting string must be a valid XML 1.0 character when it is converted to UTF-8.

If \textit{string-expression} is an empty string, an empty text node is returned.
The result of the function is an XML value.

The result can be null; if the argument is null, the result is the null value.

**Example 1:** The following example returns an XML value with a single text node that contains the specified value:

```sql
SELECT XMLTEXT('The stock symbol for Johnson & Johnson is JNJ.') AS "Result"
FROM SYSIBM.SYSDUMMY1;
```

The result looks similar to the following results:

```
Result
-----------------------------------
The stock symbol for Johnson & Johnson is JNJ.
```

**Example 2:** The XMLTEXT function enables the XMLELEMENT function to construct mixed content, as in the following example:

```sql
SELECT XMLELEMENT(NAME "para",
    XMLELEMENT(NAME "emphasis",
        emphtext))
FROM T;
```

Suppose that the content of the table T is as the following example:

<table>
<thead>
<tr>
<th>seqno</th>
<th>plaintext</th>
<th>emphtext</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>This query shows how to construct mixed content</td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>using XMLAGG and XMLTEXT. Without XMLTEXT</td>
<td>mixed content</td>
</tr>
<tr>
<td>3</td>
<td>XMLAGG cannot group text nodes with other nodes, therefore, cannot generate mixed content</td>
<td>mixed content</td>
</tr>
</tbody>
</table>

The result looks like the following result:

```
result
-----------------------------------
<para>This query shows how to construct <emphasis>mixed content</emphasis>
using XMLAGG and XMLTEXT. Without <emphasis>XMLTEXT</emphasis>, XMLAGG cannot group text nodes with other nodes, therefore, cannot generate <emphasis>mixed content</emphasis>.</para>
```

**XMLXSROBJECTID**

The XMLXSROBJECTID function returns the XSR object identifier of the XML schema that is used to validate the XML document specified in the argument.

```sql
XMLXSROBJECTID(xml-value-expression)
```

The schema is SYSIBM.

**xml-value-expression**

An expression that results in a value with a data type of XML. The resulting XML value must be an XML sequence with a single item that is an XML document or the null value.
The XSR object identifier is returned as a BIGINT value and provides the key to a single row in the SYSIBM.XSROBJECTS table.

The result can be null; if the argument is null, the result is the null value.

If xml-value-expression does not specify a validated XML document, the function returns 0.

Note: The XML schema that corresponds to an XSR object ID returned by the function might no longer exist, because an XML schema can be dropped without affecting XML values that were validated using that XML schema. Therefore, queries that use the XSR object ID to fetch further XML schema information from the SYSIBM.XSROBJECTS table might return an empty result set.

Example 1: Use the XMLXSROBJECTID function in conjunction with the DSN_XMLVALIDATE function to find all XML documents that are not validated in a table and validate them:

```
UPDATE orders
SET content = dsn_xmlvalidate(content, 'SYSXSR.PO1')
WHERE XMLXSROBJECTID(content) = 0;
```

Example 2: Use the XMLXSROBJECTID function to find the names and target namespaces of the XML schemas that are used to validate the XML documents in a table:

```
SELECT DISTINCT s.XSROBJECTNAME, s.targetNamespace
FROM orders o, XSROBJECTS s
WHERE XMLXSROBJECTID(content) = s.XSROBJECTID;
```

XSLTRANSFORM

The XSLTRANSFORM function transforms an XML document into a different data format. The output can be any form possible for the XSLT processor, including but not limited to XML, HTML, and plain text.

```
XSLTRANSFORM(xml-document,xsl-stylesheet,xsl-parameters)
```

The schema is SYSFUN.

xml-document

An expression that returns a well-formed XML document with a data type of CHAR, VARCHAR, or CLOB(2 MB). The input expression can contain XMLSERIALIZE to serialize an XML data type into a CLOB. The xml-document is transformed with the XSL style sheet that is specified in xsl-stylesheet. The XML document must at minimum be single-rooted and well-formed.

xsl-stylesheet

An expression that returns a well-formed XML document with a data type of CHAR, VARCHAR, or CLOB(256 KB). The input expression can contain XMLSERIALIZE to serialize an XML data type into a CLOB. The document is an XSL style sheet that conforms to the W3C XSLT Version 1.0 Recommendation. This style sheet is applied to transform the value that is specified in xml-document.

xsl-parameters

An expression that returns a well-formed XML document or empty string with
a data type of CHAR, VARCHAR, or CLOB(64 KB). The input expression can contain XMLSERIALIZE to serialize an XML data type into a CLOB. The xsl-parameters provides parameter values to the XSL style sheet specified in xsl-stylesheet. The value of the parameter can be specified as an attribute, or as a text node. If both are specified, the value in the attribute is used. The xsl-stylesheet document must have matching param name attribute values. The syntax of the parameter document is as follows:

```xml
<params xmlns="http://www.ibm.com/XSLTransformParameters">
  <param name="...">
    value="..."/>
  <param name="...">enter value here</param>
  ...
</params>
```

**Important:** If xsl-parameters are not needed, you still must supply an empty string or the function result is null.

The result of the function is of type CLOB(2 MB).

This user-defined function requires IBM SDK for z/OS, Java Technology Edition Version 6.

This user-defined function uses the XSLT support that is provided by the W3C XSL Transformations V1.0 Recommendation.

**Tip:** To create your own variation of XSLTRANSFORM, start with the CREATE FUNCTION shown in sample member DSNTESR. Change the function name and size of the definition of the input parameters for your environment.

**Example 1:** This example illustrates how to use XSLT as a formatting engine in a C program.

```sql
EXEC SQL BEGIN DECLARE SECTION;
SQL TYPE IS CLOB(2M) xmldoc;
SQL TYPE IS CLOB(256K) stylesheet;
SQL TYPE IS CLOB(64K) xslparms;
SQL TYPE IS CLOB(2M) result;
EXEC SQL END DECLARE SECTION;

EXEC SQL SET :xmldoc = CLOB('"<?xml version="1.0"?>
  <hi>Hello</hi>"
);

EXEC SQL SET :stylesheet = CLOB('"<?xml version="1.0"?>
  <xsl:stylesheet xmlns:xsl="http://www.w3.org/1999/XSL/Transform" version="1.0">
    <xsl:output indent="yes"/>
    <xsl:param name="parm" select="'World'"/>
    <xsl:template match="hi">
      <out>
        <xsl:value-of select="."/>
        <xsl:text>, </xsl:text>
        <xsl:value-of select="$parm"/>
        <xsl:text>!!!</xsl:text>
      </out>
    </xsl:template>
  </xsl:stylesheet>"
);

EXEC SQL SET :xslparms = CLOB(
  '"<params xmlns="http://www.ibm.com/XSLTransformParameters">
    <param name="parm">Silicon Valley</param>
  </params>"');
```
EXEC SQL
SELECT SYSFUN.XSLTRANSFORM(:xmldoc, :stylesheet :xslparms)
    INTO :result FROM SYSIBM.SYSDUMMY1;

The XML document is transformed by the XSL style sheet. The result of the transformation is:

```xml
<?xml version="1.0" encoding="UTF-8"?>
<out>Hello, Silicon Valley!!!</out>
```

YEAR

The YEAR function returns the year part of a value that is a character or graphic string. The value must be a valid string representation of a date or timestamp.

```sql
YEAR(expression)
```

The schema is SYSIBM.

The argument must be an expression that returns one of the following built-in data types: a date, a timestamp, a character string, a graphic string, or a numeric data type.

- If `expression` is a character or graphic string, it must not be a CLOB or DBCLOB, and its value must be a valid string representation of a date or timestamp with an actual length of not greater than 255 bytes. For the valid formats of string representations of dates and timestamps, see "String representations of datetime values" on page 130.
- If `expression` is a number, it must be a date or timestamp duration. For the valid formats of date and timestamp durations, see "Datetime operands" on page 177.

If `expression` is a timestamp with a time zone, or a valid string representation of a timestamp with a time zone, the result is determined from the UTC representation of the datetime value.

The result of the function is a large integer.

The result can be null; if the argument is null, the result is the null value.

The other rules depend on the data type of the argument specified:
If the argument is a date, a timestamp, or a string representation of either, the result is the year part of the value, which is an integer between 1 and 9999.

If the argument is a date duration or a timestamp duration, the result is the year part of the value, which is an integer between -9999 and 9999. A nonzero result has the same sign as the argument.

If the argument contains a time zone, the result is the year part of the value expressed in UTC.

Example 1: From the table DSN8C10.EMP, select all rows for employees who were born in 1941.

```sql
SELECT *
FROM DSN8C10.EMP
WHERE YEAR(BIRTHDATE) = 1941;
```

Example 2: The following invocations of the YEAR function returns the same result:

```sql
SELECT YEAR('1993-08-10-20.00.00'),
       YEAR('1993-08-10-20.00.00-08:00'),
       YEAR('1993-08-10-20.00.00+09:00')
FROM SYSIBM.SYSDUMMY1;
```

For each invocation of the YEAR function in this SELECT statement, the result is 1993.

When the input argument contains a time zone, the result is determined from the UTC representation of the input value. The string representations of a timestamp with a time zone in the SELECT statement all have the same UTC representation: '1993-08-10-20.00.00'.

### Table functions

A table function can be used only in the FROM clause of a statement. Table functions return columns of a table and resemble a table created through a CREATE TABLE statement. Table functions can be qualified with a schema name.

**ADMIN_TASK_LIST**

The ADMIN_TASK_LIST function returns a table with one row for each of the tasks that are defined in the administrative task scheduler task list.

**Authorization**

The user who calls this function must have MONITOR1 privilege.

```sql
ADMIN_TASK_LIST()
```

The schema is DSNADM.

The result of the function is a table with the format shown in the following table. All the columns are nullable except TASK_NAME.
Table 100. Format of the resulting table for ADMIN_TASK_LIST

<table>
<thead>
<tr>
<th>Column name</th>
<th>Data type</th>
<th>Contains</th>
</tr>
</thead>
<tbody>
<tr>
<td>BEGIN_TIMESTAMP</td>
<td>TIMESTAMP</td>
<td>Contains the timestamp of when the task can first run.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>When the task begins to run depends on what values this and other columns contain:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• If BEGIN_TIMESTAMP contains a non-null value:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- If POINT_IN_TIME and TRIGGER_TASK_NAME contain null values,</td>
</tr>
<tr>
<td></td>
<td></td>
<td>the task begins to run at the timestamp in BEGIN_TIMESTAMP</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- If POINT_IN_TIME contains a non-null value, the task begins to run at the next point in time that is defined at or after the timestamp in BEGIN_TIMESTAMP</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- If TRIGGER_TASK_NAME is a non-null value, the task begins to run at the next time that the task identified in TRIGGER_TASK_NAME completes or after the timestamp in BEGIN_TIMESTAMP</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• If BEGIN_TIMESTAMP contains a null value:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- If POINT_IN_TIME and TRIGGER_TASK_NAME contain null values,</td>
</tr>
<tr>
<td></td>
<td></td>
<td>the task begins to run immediately</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- If POINT_IN_TIME contains a non-null value, the task begins to run at the next point in time that is defined</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- If TRIGGER_TASK_NAME is a non-null value, the task begins to run at the next time that the task identified in TRIGGER_TASK_NAME completes</td>
</tr>
<tr>
<td>END_TIMESTAMP</td>
<td>TIMESTAMP</td>
<td>Contains the timestamp of when the task is last able to run. If this column is NULL, there are no restrictions as to when the task must not run.</td>
</tr>
<tr>
<td>MAX_INVOCATIONS</td>
<td>INTEGER</td>
<td>Contains the maximum number of times the task can run. The maximum number applies to all types of schedules: triggered by events, scheduled by time interval, or by point in time. If this column is null, the task has no limit on the number of times it can be run.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>If both END_TIMESTAMP and MAX_INVOCATIONS contain values, the value in END_TIMESTAMP takes precedence over the value for MAX_INVOCATIONS. That is, if the value in END_TIMESTAMP is reached, even though the number of times the task has run has not reached the value for MAX_INVOCATIONS, the task will not run again</td>
</tr>
<tr>
<td>INTERVAL</td>
<td>INTEGER</td>
<td>Contains an integer that indicates the duration between the start of one instance of a task and the start of the next instance of the same task. If the value of this column is NULL, the task is not scheduled to run at a regular interval.</td>
</tr>
</tbody>
</table>
Table 100. Format of the resulting table for ADMIN_TASK_LIST  (continued)

<table>
<thead>
<tr>
<th>Column name</th>
<th>Data type</th>
<th>Contains</th>
</tr>
</thead>
<tbody>
<tr>
<td>POINT_IN_TIME</td>
<td>VARCHAR(400)</td>
<td>Contains one or more points in time (in UNIX cron format) for which the task is scheduled to run. If the value of this column is NULL, the task is not scheduled to run at a specific point in time. The format contains the following pieces of information separated by blanks: given hour, given minute, given day of the week, given day of the month, given month of the year.</td>
</tr>
<tr>
<td>TRIGGER_TASK_NAME</td>
<td>VARCHAR(128)</td>
<td>Contains the task name of the task that, when its execution is complete, will trigger the running of the task that is described in the row. Task name DB2STOP is reserved for Db2 stop events and task name DB2START is reserved for Db2 start events. Those events are handled by the administrative task scheduler that is associated with the Db2 subsystem that is starting or stopping. If the value of this column is NULL, the task that is described in this row will not be triggered to run by another task.</td>
</tr>
<tr>
<td>TRIGGER_TASK_COND</td>
<td>CHAR(2)</td>
<td>Contains the type of comparison that is to be made to the return code after the running of task that is indicated in TRIGGER_TASK_NAME. The following values are possible: GT Greater than GE Greater than or equal to EQ Equal to LT Less than LE Less than or equal to NE Not equal to If this column contains NULL, the task is triggered to run without consideration of the return code of the task that is indicated in TRIGGER_TASK_NAME.</td>
</tr>
</tbody>
</table>
Table 100. Format of the resulting table for ADMIN_TASK_LIST (continued)

<table>
<thead>
<tr>
<th>Column name</th>
<th>Data type</th>
<th>Contains</th>
</tr>
</thead>
<tbody>
<tr>
<td>TRIGGER_TASK_CODE</td>
<td>INTEGER</td>
<td>Contains the return code from running the task indicated in TRIGGER_TASK_NAME. If the running of this task is triggered by a stored procedure, TRIGGER_TASK_CODE contains the SQLCODE that must be returned by the stored procedure in order for this task to run. If the running of this task is triggered by a JCL job, TRIGGER_TASK_CODE contains the MAXRC that must be returned by the job in order for this task to run. ADMIN_TASK_STATUS returns the SQLCODE or MAXRC value in the SQLCODE or MAXRC column. If TRIGGER_TASK_COND is NULL, this column will also be NULL.</td>
</tr>
<tr>
<td>DB2_SSID</td>
<td>VARCHAR(4)</td>
<td>Contains the Db2 subsystem ID of the Db2 subsystem that is associated with the administrative task scheduler that should run this task. The value in this column is used in a data sharing environment where, for example different Db2 members have different configurations and running the task relies on a certain environment. A value in DB2_SSID will prevent an administrative scheduler of other members to run this task, so that the task can only be run as long as the administrative task scheduler of the subsystem indicated in DB2_SSID is running. For a task that is being triggered by a Db2 start or Db2 stop event as indicated in the TRIGGER_TASK_NAME column, a value in DB2_SSID will allow the task to be run only when the indicated subsystem is starting or stopping. If no value is indicated in DB2_SSID, each subsystem that starts or stops will trigger a the task to be run locally, provided that the triggered task is run serially. If this column is NULL, any administrative scheduler can run this task.</td>
</tr>
<tr>
<td>PROCEDURE_SCHEMA</td>
<td>VARCHAR(128)</td>
<td>Contains the schema of the Db2 stored procedure that this task will run. If the value of this column is null, Db2 uses a default schema.</td>
</tr>
<tr>
<td>PROCEDURE_NAME</td>
<td>VARCHAR(128)</td>
<td>Contains the name of the Db2 stored procedure that this task will run. If the value of this column is NULL, no stored procedure will be called when this task is run.</td>
</tr>
</tbody>
</table>
Table 100. Format of the resulting table for ADMIN_TASK_LIST (continued)

<table>
<thead>
<tr>
<th>Column name</th>
<th>Data type</th>
<th>Contains</th>
</tr>
</thead>
<tbody>
<tr>
<td>PROCEDURE_INPUT</td>
<td>VARCHAR(4096)</td>
<td>Contains a statement that returns one row of data. The returned value will be used as the input parameter of the stored procedure that this task will run. If this column contains the null value, no parameters are passed to the stored procedure when this task is run.</td>
</tr>
<tr>
<td>JCL_LIBRARY</td>
<td>VARCHAR(44)</td>
<td>Contains the name of the data set that contains the JCL job that is run when this task is run. If the value of this column is the null value, no JCL job will be run when this task is run.</td>
</tr>
<tr>
<td>JCL_MEMBER</td>
<td>VARCHAR(8)</td>
<td>Contains the name of the library member that contains the JCL job that is run when this task is run. If the value of this column is the null value, the data set that is specified in JCL_LIBRARY is sequential and contains the JCL job that is run when this task is run.</td>
</tr>
</tbody>
</table>
| JOB_WAIT             | VARCHAR(8)   | Contains one of the following values, which indicates whether the JCL job can be run synchronously. If the value in the column is not null, this column contains one of the following values:  
|                      |             | NO  Runs asynchronously                                                   |
|                      |             | YES Runs synchronously                                                      |
|                      |             | PURGE Runs synchronously and then the job status in z/OS is purged          |
| TASK_NAME            | VARCHAR(128) | Contains the unique name that is assigned to this task.                        |
| DESCRIPTION          | VARCHAR(128) | Contains a description of the task if one exists.                                 |
| USERID               | VARCHAR(128) | Contains the authorization ID of the user under which the task will be invoked. If this column is NULL, the task is invoked by the default authorization ID that is associated with the administrative task scheduler. |
| CREATOR              | VARCHAR(128) | Contains the authorization ID that added the task to the administrative task scheduler task list. |
| LAST_MODIFIED        | TIMESTAMP   | Timestamp of when the task was added or last modified.                         |

Example 1: Retrieve information about all of the tasks that are defined in the administrative task scheduler task list:

```
SELECT * 
FROM TABLE (DSNADM.ADMIN_TASK_LIST()) AS T;
```

**ADMIN_TASK_OUTPUT**

For an execution of a stored procedure, the ADMIN_TASK_OUTPUT function returns the output parameter values and result sets, if available. If the task that was executed is not a stored procedure or the requested execution status is not available, the function returns an empty table.
**Authorization**

The user who calls this function must have MONITOR1 privilege.

```
►►ADMIN_TASK_OUTPUT(task-name, num-invocations)◄◄
```

The schema is DSNADM.

**Important:** The ADMIN_TASK_OUTPUT function returns as many output parameter values and result sets as possible. However, this information is not always available. The administrative task scheduler cannot store output that exceeds 32,180 bytes in length. Therefore, some output parameters and result set values might be null if the values are too long to be stored by the administrative task scheduler. Also, if the result sets are too large to be stored, only some of the most recent rows of each result set might be available (for example, the first rows missing).

`task-name`  
Specifies the unique name of the task whose execution output you want returned. This is an input parameter of type VARCHAR(128).

`num-invocations`  
Specifies the execution number of the task whose output you want returned. This value must be a valid value in the NUM_INVOCATIONS column of the returned table of DSNADM.ADMIN_TASK_STATUS(NULL) for the specified task. This is an input parameter of type INTEGER.

The result of the function is a table with the format shown in the following table. This function might return an empty table for the output of a stored procedure for the following reasons:

- The stored procedure does not have output parameters or result sets.
- The output of the stored procedure was not stored at execution time, because the SYSIBM.ADMIN_TASKS_HIST table was not available.
- The `num-invocations` parameter is not valid.
- The output for the task that is specified by the `num-invocations` parameter is no longer stored, because the task is older than the value that is specified for the MAXHIST parameter of the administrative task scheduler. (The MAXHIST parameter specifies the maximum number of execution statuses to keep for each task.)

ADMIN_TASK_STATUS

The ADMIN_TASK_STATUS function returns a table with one row for each task that is defined in the administrative task scheduler task list. Each row indicates the status of the task for the last time it was run.

Optionally, if you specify the max-history parameter, the function returns a row of data for each execution of a task (up to the max-history value). For tasks that have not been executed, this function returns a row of data with a NULL status.

Authorization

The user who calls this function must have MONITOR1 privilege.

```
 ADMIN_TASK_STATUS(max-history)
```

The schema is DSNADM.
max-history

Specifies the maximum number of execution statuses per task to be returned. The most recent execution statuses are returned.

If the parameter is set to NULL, all available task execution statuses are returned. If the parameter is set to 1, only the status for the last time the task was run is returned, which is the same result as not specifying this option. This is an input parameter of type INTEGER.

The result of the function is a table with the format shown in the following table.

<table>
<thead>
<tr>
<th>Column name</th>
<th>Data type</th>
<th>Contains</th>
</tr>
</thead>
<tbody>
<tr>
<td>TASK_NAME</td>
<td>VARCHAR(128)</td>
<td>Contains the name of the task that has run, is running, or has been bypassed.</td>
</tr>
<tr>
<td>STATUS</td>
<td>VARCHAR(10)</td>
<td>Contains one of the following values that indicates task status:</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>RUNNING</strong></td>
</tr>
<tr>
<td></td>
<td></td>
<td>The task is currently running.</td>

- [Listing multiple execution statuses of scheduled tasks (Db2 Administration Guide)]

MQREADALL

The MQREADALL function returns a table that contains the messages and message metadata from a specified MQSeries location without removing the messages from the queue.

```sql
MQREADALL( (1) )
```

Notes:
1. The comma is required before `num-rows` when any of the preceding arguments to the function are specified.

The schema is DB2MQ.
The MQREADALL function returns a table containing the messages and message meta-data from the MQSeries location that is specified by `receive-service`, using the quality-of-service policy that is defined in `service-policy`. Performing this operation does not remove the messages from the queue that is associated with `receive-service`.

**receive-service**

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be an empty string or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression must refer to a service point that is defined in the DB2MQ.MQSERVICE table. A service point is a logical end-point from which a message is sent or received. A service point definition includes the name of the MQSeries queue manager and the name of the queue. See MQSeries Application Messaging Interface for more details.

If `receive-service` is not specified or is the null value, DB2.DEFAULT.POLICY is used.

**service-policy**

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be an empty string or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression must refer to a service policy that is defined in the DB2MQ.MQPOLICY table. A service policy specifies a set of quality-of-service options that are to be applied to this messaging operation. These options include message priority and message persistence. See MQSeries Application Messaging Interface for more details.

If `service-policy` is not specified or is the null value, DB2.DEFAULT.POLICY is used.

**num-rows**

An expression that returns a value that is a SMALLINT or INTEGER data type whose value is a positive integer or zero. The value of the expression specifies the maximum number of messages to return.

If `num-rows` is not specified or if the value of the expression is zero, all available messages are returned.

The result of the function is a table with the format shown in the following table. All the columns are nullable.

<table>
<thead>
<tr>
<th>Column name</th>
<th>Data type</th>
<th>Contains</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSG</td>
<td>VARCHAR(4000)</td>
<td>The contents of the MQSeries message</td>
</tr>
<tr>
<td>CORRELID</td>
<td>VARCHAR(24)</td>
<td>The correlation ID that is used to relate messages</td>
</tr>
<tr>
<td>TOPIC</td>
<td>VARCHAR(40)</td>
<td>The topic that the message was published with, if available</td>
</tr>
<tr>
<td>QNAME</td>
<td>VARCHAR(48)</td>
<td>The name of the queue from which the message was received</td>
</tr>
<tr>
<td>MSGID</td>
<td>CHAR(24)</td>
<td>The unique, MQSeries-assigned identifier for the message</td>
</tr>
<tr>
<td>MSGFORMAT</td>
<td>VARCHAR(8)</td>
<td>The format of the message, as defined by MQSeries</td>
</tr>
</tbody>
</table>
Example 1: Read all the messages from the queue specified by the default service (Db2.DEFUALT.SERVICE), using the default policy (Db2.DEFUALT.POLICY).

```
SELECT *
FROM SYSIBM.SYSDUMMY1 (MQREADALL()) AS T;
```

The messages and all the metadata are returned as a table.

Example 2: Read all the messages from the beginning of the queue specified by the service MYSERVICE, using the default policy (Db2.DEFUALT.POLICY).

```
SELECT T.MSG, T.CORRELID
FROM SYSIBM.SYSDUMMY1 (MQREADALL('MYSERVICE')) AS T;
```

Only the MSG and CORRELID columns are returned.

Example 3: Read all the messages from the queue specified by the default service (Db2.DEFUALT.SERVICE), using the default policy (Db2.DEFUALT.POLICY). Only messages with a CORRELID of '1234' are returned.

```
SELECT *
FROM SYSIBM.SYSDUMMY1 (MQREADALL(10)) AS T
WHERE T.CORRELID = '1234';
```

All columns are returned.

Example 4: Retrieve the first 10 messages from the beginning of the queue specified by the default service (Db2.DEFUALT.SERVICE), using the default policy (Db2.DEFUALT.POLICY).

```
SELECT *
FROM SYSIBM.SYSDUMMY1 (MQREADALL(10)) AS T;
```

The first 10 messages and all the columns are returned as a table.

### MQREADALLCLOB

The MQREADALLCLOB function returns a table that contains the messages and message metadata from a specified MQSeries location without removing the messages from the queue.

```
MQREADALLCLOB()
```

Num-rows, service-policy

**(1)**

**Notes:**

1. The comma is required before `num-rows` when any of the preceding arguments to the function are specified.

The schema is DB2MQ.

The MQREADALLCLOB function returns a table containing the messages and message meta-data from the MQSeries location that is specified by `receive-service`,...
using the quality-of-service policy that is defined in `service-policy`. Performing this operation does not remove the messages from the queue that is associated with `receive-service`.

`receive-service`
An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be an empty string or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression must refer to a service point that is defined in the DB2MQ.MQSERVICE table. A service point is a logical end-point from which a message is sent or received. A service point definition includes the name of the MQSeries queue manager and the name of the queue. See *MQSeries Application Messaging Interface* for more details.

If `receive-service` is not specified or is the null value, `DB2.DEFAULT.POLICY` is used.

`service-policy`
An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be an empty string or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression must refer to a service policy that is defined in the DB2MQ.MQPOLICY table. A service policy specifies a set of quality-of-service options that are to be applied to this messaging operation. These options include message priority and message persistence. See *MQSeries Application Messaging Interface* for more details.

If `service-policy` is not specified or is the null value, `DB2.DEFAULT.POLICY` is used.

`num-rows`
An expression that returns a value that is a SMALLINT or INTEGER data type whose value is a positive integer or zero. The value of the expression specifies the maximum number of messages to return.

If `num-rows` is not specified or if the value of the expression is zero, all available messages are returned.

The result of the function is a table with the format shown in the following table. All the columns in the table are nullable.

<table>
<thead>
<tr>
<th>Column name</th>
<th>Data type</th>
<th>Contains</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSG</td>
<td>CLOB(1M)</td>
<td>The contents of the MQSeries message</td>
</tr>
<tr>
<td>CORRELID</td>
<td>VARCHAR(24)</td>
<td>The correlation ID that is used to relate messages</td>
</tr>
<tr>
<td>TOPIC</td>
<td>VARCHAR(40)</td>
<td>The topic that the message was published with, if available</td>
</tr>
<tr>
<td>QNAME</td>
<td>VARCHAR(48)</td>
<td>The name of the queue from which the message was received</td>
</tr>
<tr>
<td>MSGID</td>
<td>CHAR(24)</td>
<td>The unique, MQSeries-assigned identifier for the message</td>
</tr>
<tr>
<td>MSGFORMAT</td>
<td>VARCHAR(8)</td>
<td>The format of the message, as defined by MQSeries</td>
</tr>
</tbody>
</table>

The CCSID of the result is the system CCSID that was in effect at the time that the MQSeries function was installed into Db2.
**Example 1:** Read all the messages from the queue specified by the default service (Db2.DEFAUL.T.SERVICE), using the default policy (Db2.DEFAUL.T.POLICY).

```
SELECT *
FROM SYSIBM.SYSDUMMY1 (MQREADALLCLOB()) AS T;
```

The messages and all the metadata are returned as a table.

**Example 2:** Read all the messages from the queue specified by the service MYSERVICE, using the default policy (Db2.DEFAUL.T.POLICY).

```
SELECT T.MSG, T.CORRELID
FROM SYSIBM.SYSDUMMY1 (MQREADALLCLOB('MYSERVICE')) AS T;
```

Only the MSG and CORRELID columns are returned as a table.

**Example 3:** Read all the messages from the queue specified by the service MYSERVICE, using the default policy (Db2.DEFAUL.T.POLICY), with a correlation identifier of '1234'.

```
SELECT *
FROM SYSIBM.SYSDUMMY1 (MQREADALLCLOB('MYSERVICE')) AS T
WHERE T.CORRELID = '1234';
```

All columns are returned.

**Example 4:** Read the first 10 messages from the queue specified by the default service (Db2.DEFAUL.T.SERVICE), using the default policy (Db2.DEFAUL.T.POLICY).

```
SELECT *
FROM SYSIBM.SYSDUMMY1 (MQREADALLCLOB('10')) AS T;
```

All columns are returned.

**MQRECEIVEALL**

The MQRECEIVEALL function returns a table that contains the messages and message metadata from a specified MQSeries location and removes the messages from the queue.

```
MQRECEIVEALL(
receive-service,
/service-policy,
correl-id
num-rows)
```

**Notes:**
1. The comma is required before `num-rows` when any of the preceding arguments to the function are specified.

The schema is DB2MQ.
The MQRECEIVEALL function returns a table containing the messages and message meta-data from the MQSeries location that is specified by receive-service, using the quality-of-service policy that is defined in service-policy. Performing this operation removes the messages from the queue that is associated with receive-service.

receive-service
An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be an empty string or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression must refer to a service point that is defined in the DB2MQ.MQSERVICE table. A service point is a logical end-point from which a message is sent or received. A service point definition includes the name of the MQSeries queue manager and the name of the queue. See MQSeries Application Messaging Interface for more details.

If receive-service is not specified or is the null value, DB2.DEFAULT.POLICY is used.

service-policy
An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be an empty string or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression must refer to a service policy that is defined in the DB2MQ.MQPOLICY table. A service policy specifies a set of quality-of-service options that are to be applied to this messaging operation. These options include message priority and message persistence. See MQSeries Application Messaging Interface for more details.

If service-policy is not specified or is the null value, DB2.DEFAULT.POLICY is used.

correl-id
An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The expression must have an actual length that is no greater than 24 bytes. The value of the expression specifies the correlation identifier that is associated with this message. A correlation identifier is often specified in request-and-reply scenarios to associate requests with replies. Only those messages with a matching correlation identifier are returned.

A fixed length string with trailing blanks is considered a valid value. However, when the correl-id is specified on another request such as MQSEND, the correl-id must be specified the same to be recognized as a match. For example, specifying a value of 'test' for correl-id for this function does not match a correl-id value of 'test  ' (with trailing blanks) specified earlier on an MQSEND request.

If correl-id is not specified, is an empty string, or is the null value, a correlation identifier is not used, and the message at the beginning of the queue is returned.

num-rows
An expression that returns a value that is a SMALLINT or INTEGER data type whose value is a positive integer or zero. The value of the expression specifies the maximum number of messages to return.

If num-rows is not specified or if the value of the expression is zero, all available messages are returned.
The result of the function is a table with the format shown in the following table. All of the columns are nullable.

**Table 105. Format of resulting table for MQRECEIVEALL**

<table>
<thead>
<tr>
<th>Column name</th>
<th>Data type</th>
<th>Contains</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSG</td>
<td>VARCHAR(4000)</td>
<td>The contents of the MQSeries message</td>
</tr>
<tr>
<td>CORRELID</td>
<td>VARCHAR(24)</td>
<td>The correlation ID that is used to relate messages</td>
</tr>
<tr>
<td>TOPIC</td>
<td>VARCHAR(40)</td>
<td>The topic that the message was published with, if available</td>
</tr>
<tr>
<td>QNAME</td>
<td>VARCHAR(48)</td>
<td>The name of the queue from which the message was received</td>
</tr>
<tr>
<td>MSGID</td>
<td>CHAR(24)</td>
<td>The unique, MQSeries-assigned identifier for the message</td>
</tr>
<tr>
<td>MSGFORMAT</td>
<td>VARCHAR(8)</td>
<td>The format of the message, as defined by MQSeries</td>
</tr>
</tbody>
</table>

The CCSID of the result is the system CCSID that was in effect at the time that the MQSeries function was installed into Db2.

**Example 1:** Retrieve all the messages from the queue specified by the default service (Db2.DEFAULT.SERVICE), using the default policy (Db2.DEFAULT.POLICY).

```sql
SELECT *
FROM SYSIBM.SYSDUMMY1 (MQRECEIVEALL()) AS T;
```

The messages and all the metadata are returned as a table and the messages are removed from the queue.

**Example 2:** Retrieve all the messages from the queue specified by the service MYSERVICE, using the default policy (Db2.DEFAULT.POLICY).

```sql
SELECT T.MSG, T.CORRELID
FROM SYSIBM.SYSDUMMY1 (MQRECEIVEALL('MYSERVICE')) AS T;
```

Only the MSG and CORRELID columns are returned. The messages are removed from the queue.

**Example 3:** Retrieve all the messages from the beginning of the queue specified by the service MYSERVICE, using the policy MYPOLICY, with a correlation identifier of '1234'.

```sql
SELECT T.MSG, T.CORRELID
FROM SYSIBM.SYSDUMMY1 (MQRECEIVEALL('MYSERVICE','MYPOLICY','1234')) AS T;
```

Only the MSG and CORRELID columns are returned. The messages are removed from the queue.

**Example 4:** Retrieve the first 10 messages from the beginning of the queue specified by the default service (Db2.DEFAULT.SERVICE), using the default policy (Db2.DEFAULT.POLICY).

```sql
SELECT *
FROM SYSIBM.SYSDUMMY1 (MQRECEIVEALL(10)) AS T;
```

All columns are returned. The messages are removed from the queue.
The MQRECEIVEALLCLOB function returns a table that contains the messages and message metadata from a specified MQSeries location and removes the messages from the queue.

```
MQRECEIVEALLCLOB(
  receive-service,
  service-policy,
  correl-id
)
```

Notes:
1. The comma is required before `num-rows` when any of the preceding arguments to the function are specified.

The schema is DB2MQ.

The MQRECEIVEALLCLOB function returns a table containing the messages and message metadata from the MQSeries location that is specified by `receive-service`, using the quality-of-service policy that is defined in `service-policy`. Performing this operation removes the messages from the queue that is associated with `receive-service`.

**receive-service**
An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be an empty string or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression must refer to a service point that is defined in the DB2MQ.MQSERVICE table. A service point is a logical end-point from which a message is sent or received. A service point definition includes the name of the MQSeries queue manager and the name of the queue. See *MQSeries Application Messaging Interface* for more details.

If `receive-service` is not specified or is the null value, `DB2.DEFAULT.POLICY` is used.

**service-policy**
An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be an empty string or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression must refer to a service policy that is defined in the DB2MQ.MQPOLICY table. A service policy specifies a set of quality-of-service options that are to be applied to this messaging operation. These options include message priority and message persistence. See *MQSeries Application Messaging Interface* for more details.

If `service-policy` is not specified or is the null value, `DB2.DEFAULT.POLICY` is used.
**correl-id**

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The expression must have an actual length that is no greater than 24 bytes. The value of the expression specifies the correlation identifier that is associated with this message. A correlation identifier is often specified in request-and-reply scenarios to associate requests with replies. Only those messages with a matching correlation identifier are returned.

A fixed length string with trailing blanks is considered a valid value. However, when the `correl-id` is specified on another request such as MQSEND, the `correl-id` must be specified the same to be recognized as a match. For example, specifying a value of 'test' for `correl-id` for this function does not match a `correl-id` value of 'test ' (with trailing blanks) specified earlier on an MQSEND request.

If `correl-id` is not specified, is an empty string, or is the null value, a correlation identifier is not used, and the message at the beginning of the queue is returned.

**num-rows**

An expression that returns a value that is a SMALLINT or INTEGER data type whose value is a positive integer or zero. The value of the expression specifies the maximum number of messages to return.

If `num-rows` is not specified or if the value of the expression is zero, all available messages are returned.

The result of the function is a table with the format shown in the following table. All of the columns are nullable.

<table>
<thead>
<tr>
<th>Column name</th>
<th>Data type</th>
<th>Contains</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSG</td>
<td>CLOB(1M)</td>
<td>The contents of the MQSeries message</td>
</tr>
<tr>
<td>CORRELID</td>
<td>VARCHAR(24)</td>
<td>The correlation ID that is used to relate messages</td>
</tr>
<tr>
<td>TOPIC</td>
<td>VARCHAR(40)</td>
<td>The topic that the message was published with, if available</td>
</tr>
<tr>
<td>QNAME</td>
<td>VARCHAR(48)</td>
<td>The name of the queue from which the message was received</td>
</tr>
<tr>
<td>MSGID</td>
<td>CHAR(24)</td>
<td>The unique, MQSeries-assigned identifier for the message</td>
</tr>
<tr>
<td>MSGFORMAT</td>
<td>VARCHAR(8)</td>
<td>The format of the message, as defined by MQSeries</td>
</tr>
</tbody>
</table>

The CCSID of the result is the system CCSID that was in effect at the time that the MQSeries function was installed into Db2.

**Example 1:** Retrieve all the messages from the queue specified by the default service (Db2.DEFAULT.SERVICE), using the default policy (Db2.DEFAULT.POLICY).

```sql
SELECT *
FROM SYIBM.SYSDUMMY1 (MQRECEIVEALLCLOB()) AS T;
```

The messages and all the metadata are returned as a table, and the messages are removed.
Example 2: Retrieve all the messages from the beginning of the queue specified by the service MYSERVICE, using the policy (Db2.DEFAULT.POLICY).

```sql
SELECT T.MSG, T.CORRELID
FROM SYSIBM.SYSDUMMY1 (MQRECEIVEALLCLOB('MYSERVICE')) AS T;
```

Only the MSG and CORRELID columns are returned as a table, and the messages removed from the queue.

Example 3: Retrieve all the messages from the queue specified by the service MYSERVICE, using the policy "MYPOLICY", with a correlation identifier of '1234'.

```sql
SELECT *
FROM SYSIBM.SYSDUMMY1 (MQRECEIVEALLCLOB('MYSERVICE', 'MYPOLICY', '1234')) AS T;
```

All columns are returned, and the messages removed from the queue.

Example 4: Retrieve the first 10 messages from the beginning of the queue specified by the default service (Db2.DEFAULT.SERVICE), using the default policy (Db2.DEFAULT.POLICY).

```sql
SELECT *
FROM SYSIBM.SYSDUMMY1 (MQRECEIVEALLCLOB(10)) AS T;
```

All columns are returned, and the messages removed from the queue.

**XMLTABLE**

The XMLTABLE function returns a result table from the evaluation of XQuery expressions, possibly by using specified input arguments as XQuery variables. Each item in the result sequence of the row XQuery expression represents one row of the result table.

```sql
XMLTABLE(xmlnamespaces-declaration, row-xquery-expression-constant, BY REF (1) PASSING row-xquery-argument, COLUMNS xml-table-regular-column-definition (2) xml-table-ordinality-column-definition)
```

**Notes:**

1. *xquery-context-item-expression* must not be specified more than one time.
2. The xml-table-ordinality-column-definition clause must not be specified more than one time.
row-xquery-argument

```plaintext
xquery-context-item-expression
  xquery-variable-expression AS identifier
```

xml-table-regular-column-definition

```plaintext
column-name data-type
default-clause
PATH column-xquery-expression-constant
```

Notes:
1. Neither the default-clause or the PATH clause can be specified more than one time.

xml-table-ordinality-column-definition

```plaintext
column-name FOR ORDINALITY
```

The schema is SYSIBM.

The function name cannot be specified as a qualified name.

xmlnamespaces-declaration

Specifies one or more XML namespace declarations, using the XMLNAMESPACES function, that become part of the static context of the row-xquery-expression-constant and the column-xquery-expression-constant. The set of statically known namespaces for XQuery expressions which are arguments of XMLTABLE is the combination of the pre-established set of statically known namespaces and the namespace declarations specified in this clause. The XQuery prolog within an XQuery expression can override these namespaces.

If xmlnamespaces-declaration is not specified, only the pre-established set of statically known namespaces apply to the XQuery expressions.

row-xquery-expression-constant

Specifies an SQL character string constant that is interpreted as an XQuery expression using supported XQuery language syntax. row-xquery-expression-constant cannot be an XQuery updating expression. This expression determines the number of rows in the result table. The expression is evaluated using the optional set of input XML values that is specified in row-xquery-argument, and returns an output XQuery sequence where one row is generated for each item in the sequence. If the sequence is empty, the result of XMLTABLE is an empty table. row-xquery-expression-constant must not contain an empty string or a string of all blanks.
PASSING
Specifies input values and the manner in which these values are passed to row-xquery-expression-constant.

BY REF
Specifies that any XML input arguments are, by default, passed by reference. When XML values are passed by reference, the XQuery evaluation uses the input node trees, if any exist, directly from the specified input expressions and preserves all properties, including the original node identities and document order.

This clause has no impact on how non-XML values are passed. The non-XML values create a new copy of the value during the cast to XML.

row-xquery-argument
Specifies an argument that is to be passed to the XQuery expression specified by row-xquery-expression-constant. row-xquery-argument is an SQL expression that returns a value that is not a ROWID, LOB, DATE, TIME, TIMESTAMP, BINARY, VARBINARY, REAL, DECFLOAT, or character string with FOR BIT DATA attribute.

How row-xquery-argument is used in the XQuery expression depends on whether the argument is specified as an xquery-context-item-expression or an xquery-variable-expression.

If the data type of row-xquery-argument is not XML, the result of the expression for the argument is implicitly cast to XML. A null value is converted to an XML empty sequence if the argument is xquery-variable-expression.

row-xquery-argument must not contain NEXT VALUE or PREVIOUS VALUE expressions or OLAP specifications.

xquery-context-item-expression
An expression that returns a value that is XML, integer, decimal, or a character or graphic string that is not a LOB. xquery-context-item-expression must not be a character string that is bit data.

xquery-context-item-expression specifies the initial context item for the row-xquery-expression. The value of the initial context item is the result of xquery-context-item-expression cast to XML. xquery-context-item-expression must not be specified more than one time.

xquery-variable-expression
Specifies an SQL expression whose value is available to the XQuery expression specified by row-xquery-expression-constant during execution. The expression must returns a value that is XML, integer, decimal, or a character or graphic string that is not a LOB.

xquery-variable-expression specifies an argument that will be passed to row-xquery-expression-constant as an XQuery variable. If xquery-variable-expression is a null value, the XQuery variable is set to an XML empty sequence. The scope of the XQuery variables that are created from the PASSING clause is the XQuery expression specified by row-xquery-expression-constant.

AS identifier
Specifies that the value generated by xquery-variable-expression will be passed to row-xquery-expression-constant as an XQuery variable. The variable name will be identifier. The leading dollar sign ($) that precedes variable names in the XQuery language is not included in
identifier. The identifier must not be greater than 128 bytes in length. Two arguments within the same PASSING clause cannot use the same identifier.

**COLUMNS**

Specifies the output columns of the result table including the column name, data type, and how the column value is computed for each row. If this clause is not specified, a single unnamed column of data type XML is returned, with the value based on the sequence item from evaluating the XQuery expression in the row-xquery-expression-constant (equivalent to specifying PATH '.'). To reference the result column, a column-name must be specified in the correlation-clause following the function.

**xml-table-regular-column-definition**

Specifies one output column of the result table including the column name, data type, and an XQuery expression to extract the value from the sequence item for the row.

- **column-name**
  Specifies the name of the column in the result table. The name cannot be qualified and the same name cannot be used for more than one column of the table.

- **data-type**
  Specifies the data type of the column. See CREATE TABLE for the syntax and a description of types available. A data-type can be used in XMLTABLE if there is a supported XMLCAST from the XML data type to the specified data-type.

- **default-clause**
  Specifies a default value for the column. See CREATE TABLE for the syntax and a description of the default-clause. For XMLTABLE result columns, the default is applied when the processing of the XQuery expression contained in column-xquery-expression-constant returns an empty sequence. This default value will not be inherited by declared global temporary tables even when the INCLUDING COLUMN DEFaulTS clause is specified in the definition of the declared global temporary table.

**PATH column-xquery-expression-constant**

Specifies an SQL character string constant that is interpreted as an XQuery expression using supported XQuery language syntax. The column-xquery-expression-constant specifies an XQuery expression that determines the column value with respect to an item that is the result of evaluating the XQuery expression in row-xquery-expression-constant. Given an item from the result of processing the row-xquery-expression-constant as the externally provided context item, the column-xquery-expression-constant is evaluated and returns an output sequence. The column value is determined based on this output sequence as follows.

- If the output sequence contains zero items, the default-clause provides the value of the column.
- If an empty sequence is returned and no default-clause was specified, a null value is assigned to the column.
- If a non-empty sequence is returned, the value is cast to the data-type specified for the column using the XMLCAST expression. An error could be returned from processing this XMLCAST.
The value for column-xquery-expression-constant must not be an empty string or a string of all blanks. If this clause is not specified, the default XQuery expression is simply the column-name.

xml-table-ordinality-column-definition
Specifies the ordinality column of the result table.

column-name
Specifies the name of the column in the result table. The name cannot be qualified and the same name cannot be used for more than one column of the table.

FOR ORDINALITY
Specifies that column-name is the ordinality column of the result table. The data type of this column is BIGINT. The value of this column in the result table is the sequential number of the item for the row in the resulting sequence from evaluating the XQuery expression in row-xquery-expression-constant.

The result of the function is a table. The encoding scheme of the table is Unicode. If the evaluation of any of the XQuery expressions results in an error, the XMLTABLE function returns the XQuery error.

Example: List as a table result the purchase order items for orders with a status of 'NEW':

```
FROM PURCHASEORDER P,
XMLTABLE(XMLNAMESPACES('http://podemo.org' AS "pod"),
'/$po/PurchaseOrder/itemlist/item' PASSING P.PORDER as "po"
COLUMNS "PO ID" INTEGER PATH '.../POid',
"Part #" CHAR(6) PATH 'product/pid',
"Product Name" CHAR(50) PATH 'product/pod:name',
"Quantity" INTEGER PATH 'quantity',
"Price" DECIMAL(9,2) PATH 'product/pod:price',
"Order Date" TIMESTAMP PATH '.../dateTime'
) AS U
WHERE P.STATUS = 'NEW'
```

Row functions

A row function can be used only in contexts that are specifically described for the function.

UNPACK

The UNPACK function returns a row of values that are derived from unpacking the input binary string. It is used to unpack a string that was encoded according to the PACK function.

```
UNPACK(expression)
```

The schema is SYSIBM.
An expression that returns the string value to be unpacked. The expression must be a binary string that is not a BLOB and that is not null. The format of the binary string must match the one that is produced by the PACK function.

The UNPACK function can only be specified in the SELECT list and the SET clause of the UPDATE statement.

The result of the function is a row of fields corresponding to the data elements that were encoded in the input packed string. The result is not null.

**Example 1:** Assume that a user-defined function named myUDF returns a VARBINARY result. The body of the function includes the following invocation of the PACK function to pack some data into a binary string:

```sql
SET :udf_result = PACK(CCSID 1208, 'Alina', DATE('1977-08-01'), DOUBLE(0.5));
```

The following SELECT statement unpacks the result of the myUDF function and returns a row of individual column values:

```sql
SELECT UNPACK(myUDF(C1)).* AS (Name VARCHAR(40) CCSID UNICODE, DOB DATE, Score DOUBLE)
FROM T1;
```

The use of ".*" indicates that the result of the UNPACK function should be flattened into a list of result column values. When the UNPACK function is used in a select clause, an AS clause is specified to provide the names and data types for the resulting values.

**Example 2:** Assume that a user-defined function UDF_SCORE returns a VARBINARY result. The PACK function is invoked to return a binary string in which the column values of table T1 are encoded and packed. The UNPACK function returns the individual data values for a row with column names ID, SCORE, and CONF:

```sql
  UNPACK( UDF_SCORE( PACK(CCSID 1208, T1.C1, T1.C2, T1.C3)) ).* AS (ID INT, SCORE DOUBLE, CONF DOUBLE)
FROM T1;
```

**Example 3:** Assume that a user-defined function named myUDF returns a VARBINARY result. The body of the function includes the following invocation of the PACK function to pack some data into a binary string. The character data that is packed includes EBCDIC and Unicode data. The CCSID DEFAULT clause causes the data to be packed with its original encoding.

```sql
SET :udf_result = PACK(CCSID DEFAULT, CAST('Privet' AS VARCHAR(10) CCSID UNICODE),
  CAST(NULL AS TIME), CAST('Bridget' AS VARCHAR(20) CCSID EBCDIC));
```

The following SELECT statement unpacks the result of the myUDF function and returns a row of individual column values. The CCSID clauses ensure that the data is unpacked in the same encoding scheme as it was before it was packed.

```sql
SELECT UNPACK(myUDF(C1)).* AS (MSG VARCHAR(10) CCSID UNICODE, DOB DATE, NAME VARCHAR(20) CCSID EBCDIC)
FROM T1;
```

PACK
Chapter 5. Procedures that are supplied with Db2

A procedure is an application program that can be started through the SQL CALL statement. The procedure is specified by a procedure name, which may be followed by arguments that are enclosed within parentheses. This information contains syntax diagrams, semantic descriptions, rules, and examples of the use of the system supplied procedures.

Important: Do not create additional versions of Db2-supplied procedures by specifying the VERSION keyword. Only versions that are supplied with Db2 are supported. Additional versions of such routines cause the installation and configuration of Db2-supplied routines to fail.

Related concepts:
- Procedures (Introduction to Db2 for z/OS)
- Migration step 23: Configure Db2 for running stored procedures and user-defined functions (optional) (Db2 Installation and Migration)
- Common SQL API stored procedures (Db2 Administration Guide)

Related tasks:
- Migration step 24: Set up Db2-supplied routines (Db2 Installation and Migration)
- Installing Db2-supplied routines during installation (Db2 Installation and Migration)
- Implementing Db2 stored procedures (Db2 Administration Guide)

Related reference:
- CALL statement
- Installation information for procedures and functions that are supplied with Db2 (Db2 Installation and Migration)

ADMIN_COMMAND_DB2 stored procedure

The SYSPROC.ADMIN_COMMAND_DB2 stored procedure executes one or more Db2 commands on a connected Db2 subsystem, or on a Db2 data sharing group member. This stored procedure also returns the command output messages.

GUPI

Environment

ADMIN_COMMAND_DB2 must run in a WLM-established stored procedure address space.

Authorization

To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges on each package that the stored procedure uses:
- The EXECUTE privilege on the package for DSNADMCD
- Ownership of the package
- PACKADM authority for the package collection
- SYSADM authority

To execute the Db2 command, you must use a privilege set that includes the authorization to execute the Db2 command. For more information, see “Privileges and authorization IDs for commands” in [Commands in Db2 (Db2 Commands)]

**Syntax**

The following syntax diagram shows the SQL CALL statement for invoking this stored procedure:

```
CALL SYSPROC.ADMIN_COMMAND_DB2(
    db2-command,
    command-length,
    processing-type,
    db2-member,
    commands-executed,
    IFI-return-code,
    IFI-reason-code,
    excess-bytes,
    group-IFI-reason-code,
    group-excess-bytes,
    return-code,
    message)
```

**Option descriptions**

**db2-command**

Specifies any Db2 command, such as `DISPLAY THREAD(*)`, or multiple Db2 commands. With multiple Db2 commands, use a null value (CHAR string of ‘\0’) to delimit the commands. The Db2 command is executed using the authorization ID of the user who invoked the stored procedure.

If you specify `processing-type`, you must specify the command name in full, such as “-DISPLAY THREAD”. You cannot abbreviate Db2 commands, such as “-DIS THD”.

This is an input parameter of type VARCHAR(32704) and cannot be null.

**command-length**

Specifies the length of the Db2 command or commands. When multiple Db2 commands are specified in `db2-command`, `command-length` is the sum of all of those commands, including the ‘\0’ command delimiters.

This is an input parameter of type INTEGER and cannot be null.

**processing-type**

Identifies the action that you want ADMIN_COMMAND_DB2 to complete. You can request ADMIN_COMMAND_DB2 to parse the output messages of a command and provide the formatted result in a global temporary table, or you can request for a command to run synchronously.

If you specify `processing-type`, you must specify `db2-command` as a full command name, such as “-DISPLAY THREAD”. You cannot abbreviate Db2 commands, such as “-DIS THD”.

To request output message parsing, specify one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PARSE</td>
<td>Parse output messages and return formatted result in a global temporary table.</td>
</tr>
<tr>
<td>Synchronous</td>
<td>Run command synchronously.</td>
</tr>
</tbody>
</table>

**Note:** If you specify any of the following values, ADMIN_COMMAND_DB2 returns the parsed output message in a second result, as described in the
Output section. Otherwise, if you specify any value that does not appear in the list below, ADMIN_COMMAND_DB2 returns the complete unparsed command output message, and only one result set is returned.

BP Parse “-DISPLAY BUFFERPOOL” command output messages.

DB Parse “-DISPLAY DATABASE” command output messages and return database information.

TS Parse “-DISPLAY DATABASE(...) SPACENAM(...)” command output messages and return table spaces information.

IX Parse “-DISPLAY DATABASE(...) SPACENAM(...)” command output messages and return index spaces information.

THD Parse “-DISPLAY THREAD” command output messages.

UT Parse “-DISPLAY UTILITY” command output messages.

GRP Parse “-DISPLAY GROUP” command output messages.

DDF Parse “-DISPLAY DDF” command output messages.

LS Parse “-DISPLAY DATABASE(...) SPACENAM(...)” command output messages and return information for LOB table spaces.

XS Parse “-DISPLAY DATABASE(...) SPACENAM(...)” command output messages and return information for XML table spaces.

UN Parse “-DISPLAY DATABASE(...) SPACENAM(...)” command output messages and return information for table spaces when the type is unknown.

To request for a command to run synchronously, specify:

SYC Issue the command synchronously.

Only the following commands can be processed synchronously. For all other commands, SYC is ignored.

- ALTER BUFFERPOOL
- SET LOG
- SET SYSPARM
- STOP DATABASE

This is an input parameter of type VARCHAR(3).

db2-member
Specifies the name of a single data sharing group member on which an IFI request is to be executed.

This is an input parameter of type VARCHAR(8).

commands-executed
Provides the number of commands that were executed.

This is an output parameter of type INTEGER.

IFI-return-code
Provides the IFI return code.

This is an output parameter of type INTEGER.

IFI-reason-code
Provides the IFI reason code.

This is an output parameter of type INTEGER.
**excess-bytes**
Indicates the number of bytes that did not fit in the return area
This is an output parameter of type INTEGER.

**group-IFI-reason-code**
Provides the reason code for the situation in which an IFI call requests data from members of a data sharing group, and not all the data is returned from group members.
This is an output parameter of type INTEGER.

**group-excess-bytes**
Indicates the total length of data that was returned from other data sharing group members and did not fit in the return area
This is an output parameter of type INTEGER.

**return-code**
Provides the return code from the stored procedure. Possible values are:
0 The stored procedure did not encounter an SQL error during processing. Check the IFI-return-code value to determine whether the Db2 command issued using the instrumentation facility interface (IFI) was successful or not.
12 The stored procedure encountered an SQL error during processing. The message output parameter contains messages describing the SQL error.
This is an output parameter of type INTEGER.

**message**
Contains messages describing the SQL error encountered by the stored procedure. If no SQL error occurred, then no message is returned.
The first messages in this area are generated by the stored procedure. Messages that are generated by Db2 might follow the first messages.
This is an output parameter of type VARCHAR(1331).

**Example**
The following C language sample shows how to invoke ADMIN_COMMAND_DB2:
```c
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

/*********************** DB2 SQL Communication Area ***********************
EXEC SQL INCLUDE SQLCA;

int main(int argc, char *argv[])
{ /* Argument count and list */

return(retcd);
Output

This stored procedure returns the following output parameters, which are described in "Option descriptions" on page 736:

- commands-executed
- IFI-return-code
- IFI-reason-code
- excess-bytes
- group-IFI-reason-code
- group-excess-bytes
- return-code
- message

In addition to the preceding output, the stored procedure returns two result sets.

The first result set is returned in the created global temporary table SYSIBM.DB2_CMD_OUTPUT and contains the Db2 command output messages that were not parsed.

The following table shows the format of the first result set:

<table>
<thead>
<tr>
<th>Column name</th>
<th>Data type</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>ROWNUM</td>
<td>INTEGER</td>
<td>Sequence number of the table row, from 1 to n</td>
</tr>
<tr>
<td>TEXT</td>
<td>CHAR(80)</td>
<td>Db2 command output message line</td>
</tr>
</tbody>
</table>

The format of the second result set varies, depending on the Db2 command issued and the processing-type value.

- Result set row for second ADMIN_COMMAND_DB2 result set (processing-type = "BP")
- Result set row for second ADMIN_COMMAND_DB2 result set (processing-type = "THD")
- Result set row for second ADMIN_COMMAND_DB2 result set (processing-type = "UT")
- Result set row for second ADMIN_COMMAND_DB2 result set (processing-type = "DB” or “TS” or “IX”)
- Result set row for second ADMIN_COMMAND_DB2 result set (processing-type = "GRP")
- Result set row for second ADMIN_COMMAND_DB2 result set (processing-type = "DDF")

The following table shows the format of the result set returned in the created global temporary table SYSIBM.BUFFERPOOL_STATUS when processing-type = "BP":

**ADMIN_COMMAND_DSN stored procedure**

The SYSPROC.ADMIN_COMMAND_DSN stored procedure executes a BIND, REBIND, or FREE DSN subcommand and returns the output from the DSN subcommand execution.

**Environment**

ADMIN_COMMAND_DSN runs in a WLM-established stored procedures address space. TCB=1 is also required.

**Authorization**

To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges:

- The EXECUTE privilege on the ADMIN_COMMAND_DSN stored procedure
- Ownership of the stored procedure
- SYSADM authority

To execute the DSN subcommand, you must use a privilege set that includes the authorization to execute the DSN subcommand.

**Syntax**

The following syntax diagram shows the SQL CALL statement for invoking this stored procedure:

```
CALL SYSPROC.ADMIN_COMMAND_DSN(—DSN-subcommand,—message—)
```

**Option descriptions**

**DSN-subcommand**

Specifies the DSN subcommand to be executed. If the DSN subcommand passed to the stored procedure is not BIND, REBIND, or FREE, an error message is returned. The DSN subcommand is performed using the authorization ID of the user who invoked the stored procedure.

ADMIN_COMMAND_DSN does not support three-part names if a wildcard character is specified in the package name.

This parameter is case sensitive. You must specify `DSN-subcommand` in uppercase characters.

This is an input parameter of type VARCHAR(32704) and cannot be null.

**message**

Contains messages if an error occurs during stored procedure execution.

The stored procedure might not return a result set if `message` is not blank. Even if `message` is not blank, the stored procedure might return a result set if the error described in `message` occurred after the stored procedure executed at least
one DSN subcommand, and the stored procedure can successfully insert the
DSN subcommand output message in the result set and open the result set
cursor.

A blank message does not mean that the DSN subcommand completed
successfully. The calling application must read the result set to determine if the
DSN subcommand was successful or not.

This is an output parameter of type VARCHAR(1331).

Example

The following C language sample shows how to invoke
ADMIN_COMMAND_DSN:

```c
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

/********************
  DB2 SQL Communication Area ********************/
EXEC SQL INCLUDE SQLCA;

int main(int argc, char *argv[]) /* Argument count and list */
{

/********************
  DB2 Host Variables ********************/
EXEC SQL BEGIN DECLARE SECTION;

char subcmd[32705]; /* BIND, REBIND or FREE DSN */
char errmsg[1332]; /* subcommand */

EXEC SQL END DECLARE SECTION;

/********************
  Set input parameter to execute a REBIND PLAN DSN subcommand
  which indicates that result sets were returned
/********************
strcpy(subcmd, "REBIND PLAN (DSNACCOB) FLAG(W)");

EXEC SQL CALL SYSPROC.ADMIN_COMMAND_DSN (:subcmd, :errmsg);

if (SQLCODE == +446) /* Result sets were returned */
{
    /* Establish a link between the result set and its locator */
    EXEC SQL ASSOCIATE LOCATORS (:rs_loc1)
        WITH PROCEDURE SYSPROC.ADMIN_COMMAND_DSN;

    /* Associate a cursor with the result set */
    EXEC SQL ALLOCATE C1 CURSOR FOR RESULT SET :rs_loc1;

    /* Perform fetches using C1 to retrieve all rows from the */
    /* result set */
```
EXEC SQL FETCH C1 INTO :rownum, :text;
while(SQLCODE==0)
{
   EXEC SQL FETCH C1 INTO :rownum, :text;
}
EXEC SQL CLOSE C1;
}
return;
}

Output

This stored procedure returns an error message, message, if an error occurs.

The stored procedure returns one result set that contains the DSN subcommand output messages.

The following table shows the format of the result set returned in the created global temporary table SYSIBM.DSN_SUBCMD_OUTPUT:

<table>
<thead>
<tr>
<th>Column name</th>
<th>Data type</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>ROWNUM</td>
<td>INTEGER</td>
<td>Sequence number of the table row, from 1 to n</td>
</tr>
<tr>
<td>TEXT</td>
<td>VARCHAR(255)</td>
<td>DSN subcommand output message line</td>
</tr>
</tbody>
</table>

- [About Db2 and related commands (Db2 Commands)]

**ADMIN_COMMAND_MVS stored procedure**

The SYSPROC.ADMIN_COMMAND_MVS stored procedure issues the QUERY COPYPOOL, LIST COPYPOOL, Db2 START, Db2 STOP, DUMP, or DISPLAY WLM command.

Environment

The load module for the ADMIN_COMMAND_MVS stored procedure, DSNADMCM, must reside in an APF-authorized library. The ADMIN_COMMAND_MVS stored procedure runs in a WLM-established stored procedures address space, and all of the libraries that are specified in the STEPLIB DD statement must be APF-authorized.
Authorization

To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges:

- The EXECUTE privilege on the stored procedure
- Ownership of the stored procedure
- SYSADM authority

ADMIN_COMMAND_MVS uses an extended MCS console to issue the requested command.

The caller of ADMIN_COMMAND_MVS must have READ access to the MVS.MCSOPER.* or MVS.MCSOPER.xxxxxxxxx (where xxxxxxxxx is the name of the extended console) resource profile of the RACF OPERCMDS class. By default, unless overwritten by CONSNAME which is specified in the subparameters input parameter of ADMIN_COMMAND_MVS, the name of the extended MCS console is DSNADMCM. If MVS.MCSOPER.xxxxxxxxx exists, the ADMIN_COMMAND_MVS caller must have READ access to this profile. Otherwise, the caller must have READ access to MVS.MCSOPER.*.

In the OPERPARM segment of the extended MCS console's user profile (defined in a security product, such as RACF), specify the following console attributes:

- STORAGE= 512 or higher
- AUTH= ALL
- UD= NO
- HC= NO
- INTIDS= NO
- UNKNIDS= NO

You must also set the ROUTCODE, LEVEL, and MSCOPE console attributes. The attributes that you specify depend on the type of command:

**START DB2, STOP DB2, DISPLAY WLM, LIST COPYPOOL, or QUERY COPYPOOL commands**

Specify:

- ROUTCODE=NONE
- LEVEL=NB
- MSCOPE=* 

**DUMP command**

Specify:

- ROUTCODE=ALL
- LEVEL=NB
- MSCOPE=* 

**STOP DB2 command when Db2 is already stopping**

Specify:

- ROUTCODE=ALL
- LEVEL=NB
- MSCOPE=*ALL
Important: Specify ROUTCODE=ALL and MSCOPE=*ALL only when you anticipate that Db2 is already stopping when the STOP DB2 command is issued by ADMIN_COMMAND_MVS, and plan to increase the STORAGE value in these cases.

If the OPERPARM segment of the extended MCS console’s user profile is not defined, default values are applied for all console attributes, except for the following attributes:

- STORAGE=512
- AUTH=ALL
- LEVEL=NB
- MSCOPE=*  

For more information about controlling attributes for users of extended MCS consoles, see Defining console attributes for extended MCS consoles (z/OS MVS Planning: Operations)

The extended MCS console must be authorized to execute the requested command.

Syntax

The following syntax diagram shows the SQL CALL statement for invoking this stored procedure:

```
CALL ADMIN_COMMAND_MVS(
  type, command_prefix, remote_system, jobname, command, parameters, subparameters, wait_timeout, return-code, command_completion_code, message);
```

Option descriptions

**type**

Specifies the type of command to be issued.

Valid values are:

- HSM
- DB2
- DUMP
- WLM

This parameter is an input parameter of type VARCHAR(24) and cannot be null.

**command_prefix**

Specifies the command prefix that identifies which Db2 subsystem to direct the command to.

This parameter is an input parameter of type VARCHAR(8).
You cannot specify null for this parameter if the type parameter is set to Db2.

remote_system

 specifies the z/OS system to which the Db2 command is to be routed.

This parameter is an input parameter of type VARCHAR(8).

You cannot specify null for this parameter if both of the following conditions apply:

- Db2 is the type parameter
- The Db2 command will be routed to a z/OS system that is different from the system where the stored procedure is executing

jobname

 specifies the name of the batch job or started task to be modified.

This parameter is an input parameter of type VARCHAR(8).

You cannot specify null for this parameter if HSM is the type parameter.

command

 specifies the command to be executed.

Valid values depend on the value of the type parameter.

- When the type parameter is set to Db2, valid values are:
  - START
  - STOP
- When the type parameter is set to DUMP, the valid value is DUMP.
- When the type parameter is set to HSM, valid values are:
  - QUERY COPYPOOL
  - LIST COPYPOOL
- When the type parameter is set to WLM, the valid value is DISPLAY.

This parameter is an input parameter of type VARCHAR(126) and cannot be null.

parameters

 specifies the parameters of the command, or the program parameters that will be passed to the started task.

Valid values depend on the value of the command parameter.

This parameter is an input parameter of type VARCHAR(124).

You cannot specify null for this parameter if the type parameter is set to HSM, DUMP, or WLM.

subparameters

 specifies the sub-parameters of the command. The following keyword-value pairs are supported:

CONSNAMES=console-name

The name of the console that the stored procedure activates. If not specified, the default is DSNADMCM. The specified console must not already be active.

IRLMPROC=procedure-name

The procedure name of the connected IRLM. The stored procedure performs the following actions if IRLMPPROC is specified:
• If Db2 is already stopping when the stored procedure issues the STOP DB2 command, it starts monitoring IRLM termination after the DSN9022I message is received.

• If Db2 is not stopped or is not already stopping when the stored procedure issues the STOP DB2 command, it starts monitoring IRLM termination after message DSN3100I is received.

Monitoring occurs within the specified wait-timeout period and ends when the IRLM address space terminates or the wait timeout period expires. The stored procedure reports Db2 normal termination only after it determines that IRLM address space is terminated.

The IRLM procedure name is 1 - 8 characters. The first character must be a letter A - Z, #, $, or @; the remaining characters can be A through Z, 0 - 9, or #, $, or @.

This keyword-value pair can only be specified when the type parameter is Db2, the command parameter is STOP, and the SSNM keyword is not specified.

SSNM=subsystem-name
The Db2 subsystem name. The stored procedure performs the following actions:
• If Db2 is already stopping when the stored procedure issues the STOP DB2 command, it starts monitoring ssnmMSTR termination after the DSN9022I message is received.

• If Db2 is not stopped or is not already stopping when the stored procedure issues the STOP DB2 command, the keyword is ignored and no monitoring of ssnmMSTR termination occurs.

Monitoring occurs within the specified wait-timeout period and ends when the ssnmMSTR address space terminates or the wait timeout period expires. The stored procedure reports Db2 normal termination only after it determines that the ssnmMSTR address space is terminated.

The subsystem name is 1 - 4 characters. The first character must be a letter A - Z, #, $, or @; the remaining characters can be A through Z, 0 - 9, or #, $, or @.

This keyword-value pair can be specified only when the the type parameter is Db2, the command parameter is STOP, and the IRLMPROC keyword is not specified.

LIST_CP_KEYWORDS=DUMPVOLS
This keyword-value pair can be specified only when the type parameter is HSM and the command parameter is LIST COPYPOOL.

QUERY_CP_BACKUP=number-of-versions
The number of copy pool backup versions. This key-value pair can be specified only when the command parameter is set to QUERY COPYPOOL.

Alternatively, if no key-value pairs specified for subparameters, the following values are supported:
• DUMPVOLS, when the command parameter is LIST COPYPOOL.

• The number of copy pool backup versions, when command parameter is QUERY COPYPOOL.

This parameter is an input parameter of type VARCHAR(124).
You cannot specify null for this parameter if both of the following conditions apply:
- The type parameter is set to HSM
- The command parameter is set to QUERY COPYPOOL

`wait_timeout`

Specifies the amount of time (in seconds) that this procedure waits for the command to complete and for the message to be routed to the console. If the console is already active, the wait time includes the time that the procedure waits for the console to become available. If stopping Db2 and the IRLM or ssnmMSTR address space termination is being monitored, the wait time includes the time the procedure monitors the status of these address spaces.

For Db2 START and Db2 STOP, valid values are 1-900, and the default wait time is 180 seconds. Otherwise, valid values are 1-120, and the default wait time is 5 seconds.

This parameter is an input parameter of type INTEGER.

`return_code`

Provides the return code from the stored procedure.

Possible values are:

- **0**: The stored procedure did not encounter any errors during processing. However, this return code does not indicate that the command executed successfully. The `command_completion_code` output parameter indicates whether the command executed successfully or not.

- **4**: The stored procedure issued the command but was unable to determine the command execution status based on the command messages that were retrieved within the prescribed wait time. For example, the wait time might have expired.

  When `return_code` is 4, the `command_completion_code` parameter is set to 8 or 16.

  All command messages that were retrieved within the prescribed wait time are returned in the result set.

- **8**: The stored procedure issued the command but was unable to determine the command execution status because it was unable to retrieve all the command messages that were queued to the extended MCS console. When `return_code` is 8, the `command_completion_code` parameter is set to 8 or 16. All the command messages that were retrieved so far are returned in the result set. For STOP DB2, the latest IRLM or Db2 MSTR address space status information (from the 'D A' output) is also returned in the result set if IRLM or MSTR termination monitoring was performed successfully. For STOP DB2, the latest IRLM or Db2 MSTR address space status information (from the 'D A' output) is also returned in the result set if IRLM or MSTR termination monitoring was performed successfully.

- **12**: The stored procedure encountered an error during processing. The `message` output parameter contains messages that describe the error.

This parameter is an output parameter of type INTEGER.

`command_completion_code`

Indicates the completion status of the command.
Possible values are:

0

One of the following conditions applies:

- The command completed successfully.
- If the command parameter is QUERY COPYPOOL, there is no FlashCopy® process that is active in the background.

For details about command_completion_code 0, see Table 115.

4

One of the following conditions applies:

- The command was not processed. For example, Db2 was already stopped when STOP DB2 was requested.
- If the command parameter is QUERY COPYPOOL, one or more FlashCopy processes are active in the background.

For details about command_completion_code 4, see Table 116 on page 758.

8

The command started but the completion status is unknown. For details about command_completion_code 8, see Table 117 on page 758.

12

The command completed abnormally. For details about command_completion_code 12, see Table 118 on page 760.

16

The command output does not satisfy the conditions that are listed for command_completion_code 0, 4, 8, or 12.

This parameter is an output parameter of type INTEGER.

The following tables describe the messages that ADMIN_COMMAND_MVS looks for when assigning a specific value to command_completion_code.

Table 115. Description of command_completion_code 0

<table>
<thead>

### Table 115. Description of command_completion_code 0 (continued)

<table>
<thead>
<tr>
<th>Command</th>
<th>Command completion code description</th>
<th>Messages received</th>
</tr>
</thead>
</table>
| STOP DB2 | STOP DB2 completed successfully. | • DSN3100I cmd_prefix  
• Message 'irlm_procname NOT FOUND' was found in the 'D A, irlm_procname' command output when the stored procedure checked the IRLM address space status. |

### Table 116. Description of command_completion_code 4

<table>
<thead>
<tr>
<th>Command</th>
<th>Command completion code description</th>
<th>Messages received</th>
</tr>
</thead>
<tbody>
<tr>
<td>QUERY COPYPOOL</td>
<td>One or more FlashCopy processes are active in the background.</td>
<td>One or more ARC1820I messages and zero or more ARC1821I messages were received. The number of copy pool backup versions (as specified in the subparameters input parameter) and the number of copy pool versions that are in active and not in active FlashCopy relationships is the same.</td>
</tr>
<tr>
<td>START DB2</td>
<td>Db2 is already active when the command was issued.</td>
<td>Message DSNY003I cmd_prefix was received.</td>
</tr>
</tbody>
</table>
| STOP DB2 | One of the following scenarios applies:  
• Db2 was already stopped when the command was issued.  
• Db2 was in the process of stopping when the command was issued, and it stopped successfully. | Db2 was already stopped:  
• DSN3106I cmd_prefix  
Db2 was in the process of stopping:  
• DSNY004I cmd_prefix and DSN9022I cmd_prefix, where DSN9022I cmd_prefix indicates that Db2 STOP completed normally, and either message 'ssnmMSTR NOT FOUND' was found in the 'D A, ssnmMSTR' command output when the stored procedure checked the ssnmMSTR address space status, or message 'irlm_procname NOT FOUND' was found in the 'D A, irlm_procname' command output when the stored procedure checked the IRLM address space status. |

### Table 117. Description of command_completion_code 8

<table>
<thead>
<tr>
<th>Command</th>
<th>Command completion code description</th>
<th>Messages received</th>
<th>Expected completion messages not received</th>
</tr>
</thead>
</table>
| DUMP | The dump was captured but not written. | Message IEA794I was received. | One of the following messages was not received:  
• IEA911E  
• IEA611I |
| LIST COPYPOOL | The listing from LIST COPYPOOL is truncated. | Message COPYPOOL=xx...xxx was received, where xx...xx is the name of the copy pool that is specified in the parameters input parameter. | Message ARC0140I was not received. |
| QUERY COPYPOOL | One or more FlashCopy processes are active or not active in the background. | One or more ARC1820I or ARC1821I messages was received. | The total number of ARC1820I and ARC1821I messages is not equal to the total number of copy pool backup versions that is specified in the subparameters input parameter. |
Table 117. Description of command_completion_code 8 (continued)

<table>
<thead>
<tr>
<th>Command</th>
<th>Command completion code description</th>
<th>Messages received</th>
<th>Expected completion messages not received</th>
</tr>
</thead>
</table>
| START DB2 | Db2 is in the process of starting, but the completion status of START DB2 is unknown. | Message DSNY024I cmd_prefix was received. | One of the following messages was not received:  
  • DSN9023I cmd_prefix  
  • DSNV086E cmd_prefix  
  • DSN3104I cmd_prefix  
  • DSN9022I cmd_prefix, which indicates that Db2 START completed normally  
  • DSN3100I cmd_prefix |
| STOP DB2  | Db2 is in the process of stopping, but the completion status of STOP DB2 is unknown. | One of the following messages was received:  
  • DSNY002I cmd_prefix  
  • DSNY004I cmd_prefix | DSNY002I cmd_prefix received:  
  • None of the following messages were received:  
    – DSN3100I cmd_prefix  
    – DSN3107I cmd_prefix  
    – DSN9023I cmd_prefix  
    – Or, message DSN3100I cmd_prefix was received but message 'irlm_procname NOT FOUND' was not found in the 'D A, irlm_procname' command output when the stored procedure checked the IRLM address space status.  
  • DSNY004I cmd_prefix received:  
    • None of the following messages were received:  
      – DSN9022I cmd_prefix, which indicates that Db2 STOP completed normally  
      – DSN9023I cmd_prefix  
    • Or, message DSN9022I cmd_prefix was received but either message 'irlm_procname NOT FOUND' was not found in the 'D A, irlm_procname' command output when the stored procedure checked the IRLM address space status, or message 'ssnmMSTR NOT FOUND' was not found in the 'D A, ssnmMSTR' command output when the stored procedure checked the ssnmMSTR address space status. |

<tr>
<td></td>
<td></td>
<td>• DSN9023I cmd_prefix</td>
</tr>
</tbody>
</table>

**message**

Contains messages that describe the error that was encountered by the stored procedure.

This parameter is an output parameter of type VARCHAR(1331).

**Example**

The following C language example shows how to invoke ADMIN_COMMAND_MVS.

```c
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

/****************************************************************************
** DB2 SQL Communication Area ***********************************************/
EXEC SQL INCLUDE SQLCA;
int main( int argc, char *argv[] ) /* Argument count and list */
{
  EXEC SQL BEGIN DECLARE SECTION;
  /* SYSPROC.ADMIN_COMMAND_MVS parameters */
  EXEC SQL BEGIN DECLARE SECTION;
  /* SYSPROC.ADMIN_COMMAND_MVS parameters */
  char ptype[25]; /* Command type */
  char pcpprefix[9]; /* DB2 subsystem command prefix */
  char prmtsys[9]; /* Remote system */
  char pjobnm[9]; /* Started task job name */
  char pcmd[127]; /* Command to be executed */
  char pparms[125]; /* Command parameters */
  char psparms[125]; /* Command subparameters */
  long int pwait; /* Command completion wait time */
  long int prc; /* Return code */
  long int pccc; /* Command completion code */
  char pmsg[1332]; /* Error message */
```
short int ind_ptype;    /* Indicator variable */
short int ind_pcprefix; /* Indicator variable */
short int ind_prmtsy;   /* Indicator variable */
short int ind_pjobnm;   /* Indicator variable */
short int ind_pcmd;     /* Indicator variable */

/*********************************************/

if (SQLCODE == +446) /* Result sets were returned */ {
  EXEC SQL ASSOCIATE LOCATORS (:rs_loc1)
    WITH PROCEDURE SYSPROC.ADMIN_COMMAND_MVS;
  EXEC SQL ALLOCATE C1 CURSOR FOR RESULT SET :rs_loc1;
  /* Perform fetches using C1 to retrieve all rows from the */
  /* result set */
  EXEC SQL FETCH C1 INTO :rownum, :text;
    while(SQLCODE==0) 
  
}
EXEC SQL FETCH C1 INTO :rownum, :text;
} 
} 
return;
}

Output

This stored procedure returns the following output parameters, which are described in "Option descriptions" on page 753:

- return-code
- command_completion_code
- message

In addition to the preceding output, the stored procedure returns one result set that contains the command messages. For STOP DB2, the latest IRLM or Db2 ssnmMSTR address space status information (from the 'D A' output) is also returned in the result set if IRLM or MSTR termination monitoring was performed successfully.

For Db2 START, Db2 STOP, and DUMP commands, both solicited messages (which are command responses) and unsolicited messages (which are other system messages) are retrieved and returned. Otherwise, only solicited messages are returned.

The following table shows the format of the result set that is returned in the created global temporary table SYSIBM.MVS_CMD_OUTPUT:

<table>
<thead>
<tr>
<th>Column name</th>
<th>Data type</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>ROWNUM</td>
<td>INTEGER</td>
<td>Sequence number of the table row (1...n)</td>
</tr>
<tr>
<td></td>
<td>NOT NULL</td>
<td></td>
</tr>
<tr>
<td>TEXT</td>
<td>VARCHAR(2000)</td>
<td>A command message line</td>
</tr>
<tr>
<td></td>
<td>NOT NULL</td>
<td></td>
</tr>
</tbody>
</table>

ADMIN_COMMAND_UNIX stored procedure

The SYSPROC.ADMIN_COMMAND_UNIX stored procedure executes a z/OS UNIX System Services command and returns the output.

Environment

ADMIN_COMMAND_UNIX runs in a WLM-established stored procedure address space.

The load module for ADMIN_COMMAND_UNIX, DSNADMCU, must be program controlled if the BPX.DAEMON.HFSCTL FACILITY class profile has not been set.
up. For information on how to define DSNADMCU to program control, see installation job DSNTIJRA.

**Authorization**

To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges on each package that the stored procedure uses:

- The EXECUTE privilege on the package for DSNADMCU
- Ownership of the package
- PACKADM authority for the package collection
- SYSADM authority

The user specified in the user-ID input parameter of the SQL CALL statement must have the appropriate authority to execute the z/OS UNIX System Services command.

**Syntax**

The following syntax diagram shows the SQL CALL statement for invoking this stored procedure:

```sql
CALL SYSPROC.ADMIN_COMMAND_UNIX(
  user-ID
, password
, USS-command,
output-layout
, return-code, message)
```

**Option descriptions**

**user-ID**

Specifies the user ID under which the z/OS UNIX System Services command is issued.

If user-ID is NULL, password must also be NULL. If the user-ID and password values are NULL, the login process uses the primary authorization ID of the process.

You can specify NULL for this parameter in the following circumstances:

- The operating system is any supported level, and the authorization ID that is associated with the stored procedure address space has daemon authority.
- The operating system is z/OS Version 1 Release 13 or later, and the authorization ID that is associated with the stored procedure address space does not have daemon authority but is authorized to the BPX.SRV.userid SURROGAT class profile, where 'userid' is the authorization ID of the stored procedure. In this case, you must install APAR OA36062. For more information about how the RACF security administrator can authorize the authorization ID that is associated with the stored procedure address space to a SURROGAT class profile, see [Defining servers to process users without passwords or password phrases](#).
Daemon authority is given to any superuser that is permitted to the BPX.DAEMON FACILITY class profile. If the BPX.DAEMON FACILITY class profile is not defined, all superusers have daemon authority.

This is an input parameter of type VARCHAR(128).

**password**

Specifies the password associated with the input parameter user-ID.

The value of password is passed to the stored procedure as part of payload, and is not encrypted. It is not stored in dynamic cache when parameter markers are used.

If password is NULL, user-ID must also be NULL. If the user-ID and password values are NULL, the login process uses the primary authorization ID of the process.

You can specify NULL for this parameter in the following circumstances:

- The operating system is any supported level, and the authorization ID that is associated with the stored procedure address space has daemon authority.
- The operating system is z/OS Version 1 Release 13 or later, and the authorization ID that is associated with the stored procedure address space does not have daemon authority but is authorized to the BPX.SRV.userid SURROGAT class profile, where ‘userid’ is the authorization ID of the stored procedure. In this case, you must install APAR OA36062.

This is an input parameter of type VARCHAR(24).

**USS-command**

Specifies the z/OS UNIX System Services command to be executed.

This is an input parameter of type VARCHAR(32704) and cannot be null.

**output-layout**

Specifies how the output from the z/OS UNIX System Services command is returned and the default home directory of the specified user-ID.

The output from the z/OS UNIX System Services command is a multi-line message. Possible values are:

<table>
<thead>
<tr>
<th>OUTMODE</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>LINE</td>
<td>Each line is returned as a row in the result set.</td>
</tr>
<tr>
<td>BLK</td>
<td>The lines are blocked into 32677 blocks and each block is returned as a row in the result set.</td>
</tr>
</tbody>
</table>

You specify the default home directory for user-ID as follows:

**DEFAULT_HOME_DIR=home_directory**

If the home directory of the specified user-ID does not exist, or user-ID does not have a home directory, the SYSPROC.ADMIN_COMMAND_UNIX stored procedure runs the command under the default home directory that you specify.

The maximum length of home_directory is 1007.

If you need to specify both OUTMODE and DEFAULT_HOME_DIR, consider the following examples:

```
OUTMODE=LINE,DEFAULT_HOME_DIR=/tmp
DEFAULT_HOME_DIR=/tmp,OUTMODE=LINE
```
If a null or empty string is provided, the default option OUTMODE=BLK is used.

This is an input parameter of type VARCHAR(1024).

**return-code**

Provides the return code from the stored procedure. Possible values are:

0  The call completed successfully.
4  The stored procedure used the default home directory.
12 The call did not complete successfully. The message output parameter contains messages describing the error.

This is an output parameter of type INTEGER.

**message**

Contains messages describing the error encountered by the stored procedure. If no error occurred, then no message is returned.

The first messages in this area are generated by the stored procedure. Messages that are generated by Db2 might follow the first messages.

This is an output parameter of type VARCHAR(1331).

**Example**

The following C language sample shows how to invoke ADMIN_COMMAND_UNIX:

```c
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

/********************
DB2 SQL Communication Area ******************/
EXEC SQL INCLUDE SQLCA;

int main(int argc, char *argv[])
{
/******************** DB2 Host Variables ******************/
EXEC SQL BEGIN DECLARE SECTION;

/* SYSPROC.ADMIN_COMMAND_UNIX parameters */
char userid[129]; /* User ID */
short int ind_userid; /* Indicator variable */
char password[25]; /* Password */
short int ind_password; /* Indicator variable */
char command[32705]; /* USS command */
short int ind_command; /* Indicator variable */
char layout[1025]; /* Command output layout */
short int ind_layout; /* Indicator variable */
long int retcd; /* Return code */
short int ind_retcd; /* Indicator variable */

   while(SQLCODE==0)
   {
      EXEC SQL FETCH C1 INTO :rownum, :text;
   }

   EXEC SQL CLOSE C1;
}

return(retcd);

Output

This stored procedure returns the following output parameters, which are described in “Option descriptions” on page 763:

- return-code
- message

In addition to the preceding output, the stored procedure returns one result set that contains the z/OS UNIX System Services command output messages.

The following table shows the format of the result set returned in the created global temporary table SYSIBM.USS_CMD_OUTPUT:
Table 120. Result set row for ADMIN_COMMAND_UNIX result set

<table>
<thead>
<tr>
<th>Column name</th>
<th>Data type</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>ROWNUM</td>

</tr>
<tr>
<td>TEXT</td>
<td>VARCHAR(32677)</td>
<td>A block of text or a line from the output messages of a z/OS UNIX System Services command</td>
</tr>
</tbody>
</table>

**ADMIN_DS_BROWSE stored procedure**

The SYSPROC.ADMIN_DS_BROWSE stored procedure returns either text or binary records from certain data sets or their members. You can browse a physical sequential (PS) data set, a generation data set, a partitioned data set (PDS) member, or a partitioned data set extended (PDSE) member. This stored procedure supports only data sets with LRECL=80 and RECFM=FB.

**Environment**

The load module for ADMIN_DS_BROWSE, DSNADMDB, must reside in an APF-authorized library. ADMIN_DS_BROWSE runs in a WLM-established stored procedures address space, and all libraries in this WLM procedure STEPLIB DD concatenation must be APF-authorized.

**Authorization**

To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges on each package that the stored procedure uses:

- The EXECUTE privilege on the package for DSNADMDB
- Ownership of the package
- PACKADM authority for the package collection
- SYSADM authority

The ADMIN_DS_BROWSE caller also needs authorization from an external security system, such as RACF, in order to browse or view an z/OS data set resource.

**Syntax**

The following syntax diagram shows the SQL CALL statement for invoking this stored procedure:
CALL SYSPROC.ADMIN_DS_BROWSE(
  data-type, data-set-name, member-name, dump-option,
  return-code, message)

Option descriptions

data-type
   Specifies the type of data to be browsed and how the data set will be allocated. Possible values are:
   1  Text data with exclusive access
   2  Binary data with exclusive access
   3  Text data with shared access. This value is valid only if browsing a library member.
   4  Binary data with shared access. This value is valid only if browsing a library member.

   This is an input parameter of type INTEGER and cannot be null.

data-set-name
   Specifies the name of the data set, or of the library that contains the member to be browsed. Possible values are:
   
   PS data set name
      If reading from a PS data set, the data-set-name contains the name of the PS data set.
   
   PDS or PDSE name
      If reading from a member that belongs to this PDS or PDSE, the data-set-name contains the name of the PDS or PDSE.
   
   GDS name
      If reading from a generation data set, the data-set-name contains the name of the generation data set, such as USERGDG.FILE.G0001V00.

   This is an input parameter of type CHAR(44) and cannot be null.

member-name
   Specifies the name of the PDS or PDSE member, if reading from a PDS or PDSE member. Otherwise, a blank character.

   This is an input parameter of type CHAR(8) and cannot be null.

dump-option
   Specifies whether to use the Db2 standard dump facility to dump the information necessary for problem diagnosis when an SQL error occurred or when a call to the IBM routine IEFDB476 to get messages about an unsuccessful SVC 99 call failed.

   Possible values are:
      Y  Generate a dump.
      N  Do not generate a dump.

   This is an input parameter of type CHAR(1) and cannot be null.

return-code
   Provides the return code from the stored procedure. Possible values are:
0  The call completed successfully.
12  The call did not complete successfully. The message output parameter contains messages describing the error.

This is an output parameter of type INTEGER.

message
Contains messages describing the error encountered by the stored procedure. If no error occurred, then no message is returned.

The first messages in this area are generated by the stored procedure. Messages that are generated by Db2 or by z/OS might follow the first messages.

This is an output parameter of type VARCHAR(1331).

Example

The following C language sample shows how to invoke ADMIN_DS_BROWSE:

```c
#include <stdio.h>
#include <stdlib.h>
#include <string>

/**************** DB2 SQL Communication Area ****************/
EXEC SQL INCLUDE SQLCA;

int main( int argc, char *argv[] ) /* Argument count and list */
{
    /* DB2 Host Variables */
    EXEC SQL BEGIN DECLARE SECTION;

    /* SYSPROC.ADMIN_DS_BROWSE parameters */
    long int datatype; /* Data type */
    char dsname[45]; /* Data set name */
    char mbrname[9]; /* Library member name */
    char dumpopt[2]; /* Dump option */
    long int retcd; /* Return code */
    char errmsg[1332]; /* Error message */

    /* Result set locators */
    volatile SQL TYPE IS RESULT_SET_LOCATOR *rs_loc1;

    /* Result set row */
    long int rownum; /* Sequence number of the */
    /* table row */
    char text_rec[81]; /* A data set record */

    EXEC SQL END DECLARE SECTION;

    /* Assign values to input parameters to browse a library member */
    datatype = 1;
    strcpy(dsname, "USER.DATASET.PDS");
    strcpy(mbrname, "MEMBER0A");
    strcpy(dumpopt, "N");

    /* Call stored procedure SYSPROC.ADMIN_DS_BROWSE */
    EXEC SQL CALL SYSPROC.ADMIN_DS_BROWSE
    (:datatype, :dsname, :mbrname, :dumpopt,
     :retcd, :errmsg);

    /* Retrieve result set when the SQLCODE from the call is +446, */
    /* which indicates that result sets were returned */
```
if (SQLCODE == +466) /* Result sets were returned */
{
    /* Establish a link between the result set and its locator */
    EXEC SQL ASSOCIATE LOCATORS (:rs_loc1)
        WITH PROCEDURE SYSPROC.ADMIN_DS_BROWSE;

    /* Associate a cursor with the result set */
    EXEC SQL ALLOCATE C1 CURSOR FOR RESULT SET :rs_loc1;

    /* Perform fetches using C1 to retrieve all rows from the result set */
    EXEC SQL FETCH C1 INTO :rownum, :text_rec;
    while(SQLCODE==0)
    {
        EXEC SQL FETCH C1 INTO :rownum, :text_rec;
    }
    EXEC SQL CLOSE C1;

    return(retcd);
}

Output

This stored procedure returns the following output parameters, which are described in "Option descriptions" on page 768:

* return-code
* message

In addition to the preceding output, the stored procedure returns one result set that contains the text or binary records read.

The following table shows the format of the result set returned in the created global temporary table SYSIBM.TEXT_REC_OUTPUT containing text records read:

<table>
<thead>
<tr>
<th>Column name</th>
<th>Data type</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>ROWNUM</td>
<td>INTEGER</td>
<td>Sequence number of the table row, from 1 to n.</td>
</tr>
<tr>
<td>TEXT_REC</td>
<td>VARCHAR(80)</td>
<td>Record read (text format).</td>
</tr>
</tbody>
</table>

The following table shows the format of the result set returned in the created global temporary table SYSIBM.BIN_REC_OUTPUT containing binary records read:

<table>
<thead>
<tr>
<th>Column name</th>
<th>Data type</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>ROWNUM</td>
<td>INTEGER</td>
<td>Sequence number of the table row, from 1 to n.</td>
</tr>
<tr>
<td>BINARY_REC</td>
<td>VARCHAR(80) FOR BIT DATA</td>
<td>Record read (binary format).</td>
</tr>
</tbody>
</table>
**ADMIN_DS_DELETE stored procedure**

The SYSPROC.ADMIN_DS_DELETE stored procedure deletes certain data sets or their members. You can delete a physical sequential (PS) data set, a partitioned data set (PDS), a partitioned data set extended (PDSE), a generation data set (GDS), or a member of a PDS or PDSE.

**Environment**

The load module for ADMIN_DS_DELETE, DSNADMDD, must reside in an APF-authorized library. ADMIN_DS_DELETE runs in a WLM-established stored procedures address space, and all libraries in this WLM procedure STEPLIB DD concatenation must be APF-authorized.

**Authorization**

To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges:

- The EXECUTE privilege on the ADMIN_DS_DELETE stored procedure
- Ownership of the stored procedure
- SYSADM authority

The ADMIN_DS_DELETE caller also needs authorization from an external security system, such as RACF, in order to delete an z/OS data set resource.

**Syntax**

The following syntax diagram shows the SQL CALL statement for invoking this stored procedure:

```sql
CALL SYSPROC.ADMIN_DS_DELETE( data-set-type, data-set-name, parent-data-set-name, dump-option, return-code, message )
```

**Option descriptions**

- **data-set-type**
  Specifies the type of data set to delete. Possible values are:
  - 1 Partitioned data set (PDS)
  - 2 Partitioned data set extended (PDSE)
  - 3 Member of a PDS or PDSE
  - 4 Physical sequential data set (PS)
  - 6 Generation data set (GDS)

  This is an input parameter of type INTEGER and cannot be null.
**data-set-name**

Specifies the name of the data set, library member, or GDS absolute generation number to be deleted. Possible values are:

**PS, PDS, or PDSE name**

If `data-set-type` is 1, 2, or 4, the `data-set-name` contains the name of the PS, PDS, or PDSE to be deleted.

**PDS or PDSE member name**

If `data-set-type` is 3, the `data-set-name` contains the name of the PDS or PDSE member to be deleted.

**absolute generation number**

If `data-set-type` is 6, the `data-set-name` contains the absolute generation number of the GDS to be deleted, such as G0001V00.

This is an input parameter of type CHAR(44) and cannot be null.

**parent-data-set-name**

Specifies the name of the library that contains the member to be deleted, or of the GDG that contains the GDS to be delete. Otherwise blank. Possible values are:

**blank**

If `data-set-type` is 1, 2, or 4, the `parent-data-set-name` is left blank.

**PDS or PDSE name**

If `data-set-type` is 3, the `parent-data-set-name` contains the name of the PDS or PDSE whose member is to be deleted.

**GDG name**

If `data-set-type` is 6, the `parent-data-set-name` contains the name of the GDG that the GDS to be deleted belongs to.

This is an input parameter of type CHAR(44) and cannot be null.

**dump-option**

Specifies whether to use the Db2 standard dump facility to dump the information necessary for problem diagnosis when a call to the IBM routine IEFDB476 to get messages about an unsuccessful SVC 99 call failed.

Possible values are:

**Y**

Generate a dump.

**N**

Do not generate a dump.

This is an input parameter of type CHAR(1) and cannot be null.

**return-code**

Provides the return code from the stored procedure. Possible values are:

**0**

Data set, PDS member, PDSE member, or GDS was deleted successfully.

**12**

The call did not complete successfully. The `message` output parameter contains messages describing the error.

This is an output parameter of type INTEGER.

**message**

Contains messages describing the error encountered by the stored procedure. If no error occurred, then no message is returned.

The first messages in this area are generated by the stored procedure. Messages that are generated by z/OS might follow the first messages.
This is an output parameter of type VARCHAR(1331).

Example

The following C language sample shows how to invoke ADMIN_DS_DELETE:

```c
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

/*****************
DB2 SQL Communication Area **************/
EXEC SQL INCLUDE SQLCA;

int main( int argc, char *argv[] ) /* Argument count and list */ {
    /*************** DB2 Host Variables ******************/
    EXEC SQL BEGIN DECLARE SECTION;
    /* SYSPROC.ADMIN_DS_DELETE parameters */
    long int dstype; /* Data set type */
    char dsname[45]; /* Data set name, */
    /* member name, or */
    /* generation # (G0001V00) */
    char parentds[45]; /* PDS, PDSE, GDG or blank */
    char dumpopt[2]; /* Dump option */
    long int retcd; /* Return code */
    char errmsg[1332]; /* Error message */
    EXEC SQL END DECLARE SECTION;

    /* Assign values to input parameters to delete a data set */
    dstype = 4;
    strcpy(dsname, "USER.DATASET.PDS");
    strcpy(parentds, " ");
    strcpy(dumpopt, "N");

    /* Call stored procedure SYSPROC.ADMIN_DS_DELETE */
    EXEC SQL CALL SYSPROC.ADMIN_DS_DELETE
        (:dstype, :dsname, :parentds, :dumpopt,
        :retcd, :errmsg);

    return(retcd);
}

Output

This stored procedure returns the following output parameters, which are described in “Option descriptions” on page 771:

- return-code
- message
Environment

The load module for ADMIN_DS_LIST, DSNADMDL, must reside in an APF-authorized library. ADMIN_DS_LIST runs in a WLM-established stored procedures address space, and all libraries in this WLM procedure STEPLIB DD concatenation must be APF-authorized.

Authorization

To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges on each package that the stored procedure uses:

- The EXECUTE privilege on the package for DSNADMDL
- Ownership of the package
- PACKADM authority for the package collection
- SYSADM authority

The ADMIN_DS_LIST caller also needs authorization from an external security system, such as RACF, in order to perform the requested operation on an z/OS data set resource.

Syntax

The following syntax diagram shows the SQL CALL statement for invoking this stored procedure:

```
CALL SYSPROC.ADMIN_DS_LIST(
  data-set-name,
  list-members,
  list-generations,
  max-results,
  dump-option,
  return-code,
  message
)
```

Option descriptions

data-set-name

Specifies the data set name. You can use masking characters, except for when you list members of a PDS/PDSE (list-members = 'Y') or the generation data sets of a GDG (list-generations = 'Y'). For example: USER.* or USER.A*CD. In addition, the specified data set name cannot start with a masking character.

If no masking characters are used, only one data set will be listed.

This is an input parameter of type CHAR(44) and cannot be null.

list-members

Specifies whether to list PDS or PDSE members. Possible values are:

Y List members. Only set to Y when data-set-name is a fully qualified PDS or PDSE.

N Do not list members.

This is an input parameter of type CHAR(1) and cannot be null.
**list-generations**
Specifies whether to list generation data sets. Possible values are:

- **Y**: List generation data sets. Only set to Y when `data-set-name` is a fully qualified GDG.
- **N**: Do not list generation data sets.

This is an input parameter of type CHAR(1) and cannot be null.

**max-results**
Specifies the maximum number of result set rows. This option is applicable only when both list-members and list-generations are 'N'.

This is an input parameter of type INTEGER and cannot be null.

**dump-option**
Specifies whether to use the Db2 standard dump facility to dump the information necessary for problem diagnosis when any of the following errors occur:

- SQL error.
- A call to the IBM routine IEFDB476 to get messages about an unsuccessful SVC 99 call failed.
- Load Catalog Search Interface module error.

Possible values are:

- **Y**: Generate a dump.
- **N**: Do not generate a dump.

This is an input parameter of type CHAR(1) and cannot be null.

**return-code**
Provides the return code from the stored procedure. Possible values are:

- **0**: The call completed successfully.
- **4**: Processing completed, but some data sets received catalog management errors. Data set information is returned for the data sets that did not receive catalog management errors. Error information is returned for the data sets that received catalog management errors.
- **12**: The call did not complete successfully. The `message` output parameter contains messages describing the error.

This is an output parameter of type INTEGER.

**message**
Contains messages describing the error encountered by the stored procedure. If no error occurred, then no message is returned.

The first messages in this area are generated by the stored procedure. Messages that are generated by Db2 or by z/OS might follow the first messages.

This is an output parameter of type VARCHAR(1331).

**Example**
The following C language sample shows how to invoke `ADMIN_DS_LIST`:
```c
#pragma csect(CODE,"SAMDLPGM")
#pragma csect(STATIC,"PGMDLSAM")
#pragma runopts(plist(os))
#include <stdio.h>
```

Chapter 5. Procedures that are supplied with Db2 775
/* Include standard libraries */
#include <stdlib.h>
#include <string.h>

}

EXEC SQL CLOSE C1;

return(retcd);

Output

This stored procedure returns the following output parameters, which are described in “Option descriptions” on page 774:

* return-code
* message

In addition to the preceding output, the stored procedure returns one result set that contains the list of data sets, GDGs, PDS or PDSE members, or generation data sets that were requested.

The following table shows the format of the result set:

Table 123. Result set row for ADMIN_DS_LIST result set

<tr>
<td>ERRMSG</td>
<td>VARCHAR(256)</td>
<td>An error message that explains the first data set-related failure that was encountered by the stored procedure while gathering the attributes of a data set. Some possible error messages are DSNA661I, DSNA662I, and DSNA635I. If an error did not occur while gathering data set attributes, this column is blank.</td>
</tr>
</tbody>
</table>

When a data set spans more than one volume, one row is returned for each volume that contains a piece of the data set. The VOLUME, EXTENTS_IN_USE, DASD_USAGE, HARBA, and HURBA columns reflect information for the specified volume.

If a data set entry error is encountered, the ADMIN_DS_LIST stored procedure returns the data set that caused the error in the result set, along with data sets that did not have errors. In the result set, the attribute columns for the data set that caused the error are set to specific values, as shown in the following table.

Table 124. Values of data set attributes when an error is encountered

ADMIN_DS_RENAME stored procedure

The SYSPROC.ADMIN_DS_RENAME stored procedure renames a physical
sequential (PS) data set, a partitioned data set (PDS), a partitioned data set
extended (PDSE), or a member of a PDS or PDSE.

Environment

The load module for ADMIN_DS_RENAME, DSNADMDR, must reside in an
APF-authorized library. ADMIN_DS_RENAME runs in a WLM-established stored
procedures address space, and all libraries in this WLM procedure STEPLIB DD
concatenation must be APF-authorized.

Authorization

To execute the CALL statement, the owner of the package or plan that contains the
CALL statement must have one or more of the following privileges:
• The EXECUTE privilege on the ADMIN_DS_RENAME stored procedure
• Ownership of the stored procedure
• SYSADM authority

The ADMIN_DS_RENAME caller also needs authorization from an external
security system, such as RACF, in order to rename an z/OS data set resource.

Syntax

The following syntax diagram shows the SQL CALL statement for invoking this
stored procedure:

```sql
CALL SYSPROC.ADMIN_DS_RENAME(data-set-type, data-set-name, parent-data-set-name,
new-data-set-name, dump-option, return-code, message)
```

Option descriptions

`data-set-type`

Specifies the type of data set to rename. Possible values are:

1 Partitioned data set (PDS)
2 Partitioned data set extended (PDSE)
3 Member of a PDS or PDSE
4 Physical sequential data set (PS)

This is an input parameter of type INTEGER and cannot be null.
**data-set-name**
 Specifies the data set or member to be renamed. Possible values are:

**PS, PDS, or PDSE name**
 If `data-set-type` is 1, 2, or 4, the `data-set-name` contains the name of the PS, PDS, or PDSE to be renamed.

**PDS or PDSE member name**
 If `data-set-type` is 3, the `data-set-name` contains the name of the PDS or PDSE member to be renamed.

This is an input parameter of type `CHAR(44)` and cannot be null.

**parent-data-set-name**
 Specifies the name of the PDS or PDSE, if renaming a PDS or PDSE member. Otherwise, a blank character. Possible values are:

**blank**
 If `data-set-type` is 1, 2, or 4, the `parent-data-set-name` is left blank.

**PDS or PDSE name**
 If `data-set-type` is 3, the `parent-data-set-name` contains the name of the PDS or PDSE whose member is to be renamed.

This is an input parameter of type `CHAR(44)` and cannot be null.

**new-data-set-name**
 Specifies the new data set or member name. Possible values are:

**new data set name**
 If `data-set-type` is 1, 2, or 4, the `new-data-set-name` contains the new data set name.

**new member name**
 If `data-set-type` is 3, the `new-data-set-name` contains the new member name.

This is an input parameter of type `CHAR(44)` and cannot be null.

**dump-option**
 Specifies whether to use the Db2 standard dump facility to dump the information necessary for problem diagnosis when any of the following errors occurred:

- A call to the IBM routine IEFDB476 to get messages about an unsuccessful SVC 99 call failed.
- Load IDCAMS program error.

Possible values are:

**Y**
 Generate a dump.

**N**
 Do not generate a dump.

This is an input parameter of type `CHAR(1)` and cannot be null.

**return-code**
 Provides the return code from the stored procedure. Possible values are:

**0**
 The data set, PDS member, or PDSE member was renamed successfully.

**12**
 The call did not complete successfully. The `message` output parameter contains messages describing the error.

This is an output parameter of type `INTEGER`.

---

Chapter 5. Procedures that are supplied with Db2 781
message
Contains messages based on return-code and data-set-type combinations.

<table>
<thead>
<tr>
<th>return-code</th>
<th>data-set-type</th>
<th>Content</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1, 2, or 4</td>
<td>Contains IDCAMS messages.</td>
</tr>
<tr>
<td>0</td>
<td>3</td>
<td>No message is returned.</td>
</tr>
<tr>
<td>Not 0</td>
<td>not applicable</td>
<td>Contains messages describing the error encountered by the stored procedure. The first messages are generated by the stored procedure and messages that are generated by z/OS might follow these first messages. The first messages can also be generated by z/OS.</td>
</tr>
</tbody>
</table>

This is an output parameter of type VARCHAR(1331).

Example

The following C language sample shows how to invoke ADMIN_DS_RENAME:

```c
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

/******************
* DB2 SQL Communication Area ******************/
EXEC SQL INCLUDE SQLCA;

int main(int argc, char *argv[]) /* Argument count and list */ {
    /*************
* DB2 Host Variables *************/
EXEC SQL BEGIN DECLARE SECTION;

/* SYSPROC.ADMIN_DS_RENAME parameters */
long int dstype; /* Data set type */
char dsname[45]; /* Data set or member name */
char parentds[45]; /* Parent data set (PDS or PDSE) name or blank */
char newdsname[45]; /* New data set or member name*/
char dumpopt[2]; /* Dump option */
long int retcd; /* Return code */
char errmsg[1332]; /* Error message */
EXEC SQL END DECLARE SECTION;

/*************************************/
/* Assign values to input parameters to rename a library member */
/*************************************/
dstype = 3;
strcpy(dsname, "MEMBER01");
strcpy(parentds, "USER.DATASET.PDS");
strcpy(newdsname, "MEMBER0A");
strcpy(dumpopt, "N");

/*************************************/
/* Call stored procedure SYSPROC.ADMIN_DS_RENAME */
/*************************************/
EXEC SQL CALL SYSPROC.ADMIN_DS_RENAME
    (:dstype, :dsname, :parentds, :newdsname,
```
dumpopt, :retcd, :errmsg)

    return(retcd);
}

Output

This stored procedure returns the following output parameters, which are described in "Option descriptions" on page 780:

- return-code
- message

ADMIN_DS_SEARCH stored procedure

The SYSPROC.ADMIN_DS_SEARCH stored procedure determines if certain data sets are cataloged, or if a library member of a cataloged data set exists. You can search for a physical sequential (PS) data set, a partitioned data set (PDS), a partitioned data set extended (PDSE), a generation data group (GDG), a generation data set (GDS), or the library member of a cataloged PDS or PDSE.

Environment

The load module for ADMIN_DS_SEARCH, DSNADMDE, must reside in an APF-authorized library. ADMIN_DS_SEARCH runs in a WLM-established stored procedures address space, and all libraries in this WLM procedure STEPLIB DD concatenation must be APF-authorized.

Authorization

To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges:

- The EXECUTE privilege on the ADMIN_DS_SEARCH stored procedure
- Ownership of the stored procedure
- SYSADM authority

The ADMIN_DS_SEARCH caller also needs authorization from an external security system, such as RACF, in order to perform the requested operation on an z/OS data set resource.

Syntax

The following syntax diagram shows the SQL CALL statement for invoking this stored procedure:
CALL SYSPROC.ADMIN_DS_SEARCH(—data-set-name,—member-name,—dump-option,—data-set-exists,—return-code,—message—)

Option descriptions

data-set-name
  Specifies the name of a PS data set, PDS, PDSE, GDG or GDS.
  This is an input parameter of type CHAR(44) and cannot be null.

member-name
  Specifies the name of a PDS or PDSE member. Set this parameter to a blank
  character if you only want to check the existence of the PDS or PDSE.
  This is an input parameter of type CHAR(8) and cannot be null.

dump-option
  Specifies whether to use the Db2 standard dump facility to dump the
  information necessary for problem diagnosis when any of the following errors
  occurred:
  • A call to the IBM routine IEFDB476 to get messages about an unsuccessful
    SVC 99 call failed.
  • Load IDCAMS program error.
  Possible values are:
  Y    Generate a dump.
  N    Do not generate a dump.
  This is an input parameter of type CHAR(1) and cannot be null.

data-set-exists
  Indicates whether a data set or library member exists or not. Possible values
  are:
  -1    Call did not complete successfully. Unable to determine if data set or
        member exists.
  0     Data set or member was found
  1     Data set not found
  2     PDS or PDSE member not found
  This is an output parameter of type INTEGER.

return-code
  Provides the return code from the stored procedure. Possible values are:
  0     The call completed successfully.
  12    The call did not complete successfully. The message output parameter
        contains messages describing the error.
  This is an output parameter of type INTEGER.

message
  Contains IDCAMS messages if return-code is 0. Otherwise, contains messages
  describing the error encountered by the stored procedure. The first messages
  are generated by the stored procedure and messages that are generated by
  z/OS might follow these first messages.
This is an output parameter of type VARCHAR(1331).

Example

The following C language sample shows how to invoke ADMIN_DS_SEARCH:

```c
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

/****************************************************************************
**  DB2 SQL Communication Area  ***************
EXEC SQL INCLUDE SQLCA;

int main(int argc, char *argv[]) /* Argument count and list */
{
    /***********  DB2 Host Variables ***************
EXEC SQL BEGIN DECLARE SECTION;

/*  SYSPROC.ADMIN_DS_SEARCH parameters  */
char  dsname[45];  /* Data set name or GDG  */
char  mbrname[9];  /* Library member name  */
char  dumpopt[2];  /* Dump option  */
long  int  exist;  /* Data set or library member  */
       /* existence indicator  */
long  int  retcd;  /* Return code  */
char  errmsg[1332];  /* Error message  */
EXEC SQL END DECLARE SECTION;

/****************************************************************************
/*  Assign values to input parameters to determine whether a  */
/*  library member exists or not  */
/****************************************************************************
strcpy(dsname, "USER.DATASET.PDS");
strcpy(mbrname, "MEMBER0A");
strcpy(dumpopt, "N");

/****************************************************************************
/*  Call stored procedure SYSPROC.ADMIN_DS_SEARCH  */
/****************************************************************************
EXEC SQL CALL SYSPROC.ADMIN_DS_SEARCH
   (:dsname, :mbrname, :dumpopt,
     :exist, :retcd, :errmsg);

    return(retcd);
}

Output

This stored procedure returns the following output parameters, which are
described in "Option descriptions" on page 784:

- data-set-exists
- return-code
- message
ADMIN_DS_WRITE stored procedure

The SYSPROC.ADMIN_DS_WRITE stored procedure writes either text or binary records that are passed in a global temporary table to data sets or their members. You can write to a physical sequential (FS) data set, a partitioned data set (PDS) member, a partitioned data set extended (PDSE) member, or a generation data set (GDS).

This stored procedure can either append or replace an existing PS data set, PDS or PDSE member, or GDS. Also, this stored procedure can create a new PS data set, PDS or PDSE data set or member, or a new GDS for an existing generation data group (GDG) as needed. This stored procedure supports only data sets with LRECL=80 and RECFM=FB.

Environment

The load module for ADMIN_DS_WRITE, DSNADMDW, must reside in an APF-authorized library. ADMIN_DS_WRITE runs in a WLM-established stored procedures address space, and all libraries in this WLM procedure STEPLIB DD concatenation must be APF-authorized.

Authorization

To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges on each package that the stored procedure uses:

- The EXECUTE privilege on the package for DSNADMDW
- Ownership of the package
- PACKADM authority for the package collection
- SYSADM authority

The ADMIN_DS_WRITE caller also needs authorization from an external security system, such as RACF, in order to write to an z/OS data set resource.

Syntax

The following syntax diagram shows the SQL CALL statement for invoking this stored procedure:

```
CALL SYSPROC.ADMIN_DS_WRITE(data-type, data-set-name, member-name, processing-option, dump-option, return-code, message)
```

Option descriptions

This stored procedure takes the following input options:
**data-type**
Specifies the type of data to be saved. Possible values are:

1 Text data
2 Binary data

This is an input parameter of type INTEGER and cannot be null.

**data-set-name**
Specifies the name of the data set, GDG that contains the GDS, or library that contains the member, to be written to. Possible values are:

PS data set name
Name of the PS data set, if writing to a PS data set.

GDG name
Name of the GDG, if writing to a GDS within this GDG.

PDS or PDSE name
Name of the PDS or PDSE, if writing to a member that belongs to this library.

This is an input parameter of type CHAR(44) and cannot be null.

**member-name**
Specifies the relative generation number of the GDS, if writing to a GDS, or the name of the PDS or PDSE member, if writing to a PDS or PDSE member. Otherwise, a blank character. Possible values are:

GDS relative generation number
Relative generation number of a GDS, if writing to a GDS. For example: -1, 0, +1

PDS or PDSE member name
Name of the PDS or PDSE member, if writing to a library member.

blank
In all other cases, blank.

This is an input parameter of type CHAR(8) and cannot be null.

**processing-option**
Specifies the type of operation. Possible values are:

R Replace
A Append
NM New member
ND New PS, PDS, PDSE, or GDS data set

This is an input parameter of type CHAR(2) and cannot be null.

**dump-option**
Specifies whether to use the Db2 standard dump facility to dump the information necessary for problem diagnosis when an SQL error has occurred or when a call to the IBM routine IEFDB476 to get messages about an unsuccessful SVC 99 call failed.

Possible values are:

Y Generate a dump.
N Do not generate a dump.

This is an input parameter of type CHAR(1) and cannot be null.
return-code
Provides the return code from the stored procedure. Possible values are:

0 The call completed successfully.
12 The call did not complete successfully. The message output parameter contains messages describing the error.

This is an output parameter of type INTEGER.

message
Contains messages describing the error encountered by the stored procedure. If no error occurred, then no message is returned.

The first messages in this area are generated by the stored procedure. Messages that are generated by Db2 or by z/OS might follow the first messages.

This is an output parameter of type VARCHAR(1331).

Additional input
In addition to the input parameters, the stored procedure reads records to be written to a file from a created global temporary table. If the data to be written is text data, then the stored procedure reads records from SYSIBM.TEXT_REC_INPUT. If the data is binary data, then the stored procedure reads records from the created global temporary table SYSIBM.BIN_REC_INPUT.

The following table shows the format of the created global temporary table SYSIBM.TEXT_REC_INPUT containing text records to be saved:

<table>
<thead>
<tr>
<th>Column name</th>
<th>Data type</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>ROWNUM</td>
<td>INTEGER</td>
<td>Sequence number of the table row, from 1 to n.</td>
</tr>
<tr>
<td>TEXT_REC</td>
<td>CHAR(80)</td>
<td>Text record to be saved.</td>
</tr>
</tbody>
</table>

The following table shows the format of the created global temporary table SYSIBM.BIN_REC_INPUT containing binary records to be saved:

<table>
<thead>
<tr>
<th>Column name</th>
<th>Data type</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>ROWNUM</td>
<td>INTEGER</td>
<td>Sequence number of the table row, from 1 to n.</td>
</tr>
<tr>
<td>BINARY_REC</td>
<td>VARCHAR(80) FOR BIT DATA</td>
<td>Binary record to be saved.</td>
</tr>
</tbody>
</table>

Example
The following C language sample shows how to invoke ADMIN_DS_WRITE:

```c
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

/********************** DB2 SQL Communication Area **********************/
EXEC SQL INCLUDE SQLCA;

int main( int argc, char *argv[] ) /* Argument count and list */
```
EXEC SQL BEGIN DECLARE SECTION;

/* SYSPROC.ADMIN_DS_WRITE parameters */
long int datatype;  /* Data type */
char dsnname[45];  /* Data set name or GDG */
char mbrname[9];  /* Library member name, */
                 /* generation # (-1, 0, +1), */
                 /* or blank */
char procopt[3];  /* Processing option */
char dumpopt[2];  /* Dump option */
long int retcd;  /* Return code */
char errmsg[1332];  /* Error message */

EXEC SQL END DECLARE SECTION;

CREATE the records to be saved

DATATYPE = 1;
strcpy(dsname, "USER.DATASET.PDS");
strcpy(mbrname, "MEMBER01");
strcpy(procopt, "ND");
strcpy(dumpopt, "N");

EXEC SQL DELETE FROM SYSIBM.TEXT_REC_INPUT;

EXEC SQL INSERT INTO SYSIBM.TEXT_REC_INPUT
VALUES (:rownum, :textrec);

}
EXEC SQL CALL SYSPROC.ADMIN_DS_WRITE
   (:datatype, :dsname, :mbrname, :procopt,
   :dumpopt, :retcd, :errmsg );

return(retcd);
}

Output

This stored procedure returns the following output parameters, which are described in "Option descriptions" on page 786:

- return-code
- message

ADMIN_EXPLAIN_MAINT stored procedure

You can use the ADMIN_EXPLAIN_MAINT stored procedure to create EXPLAIN tables, upgrade the tables to the format for the current Db2 version, and complete other administrative tasks.

For more detailed information about administrative tasks that you can complete for EXPLAIN tables by using the ADMIN_EXPLAIN_MAINT stored procedure, see the description of the action input parameter.

Important: The ADMIN_EXPLAIN_MAINT stored procedure does not convert EXPLAIN tables that are encoded in EBCDIC to Unicode. However, it does upgrade the format of such tables to the format for the current Db2 version. Starting in DB2 10, SQLCODE -878 is issued for EXPLAIN tables that are encoded in CCSIDs other than Unicode.

Environment

The ADMIN_EXPLAIN_MAINT stored procedure must run in a WLM-established stored procedure address space.

Authorization

To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges on each package that the stored procedure uses:

- EXECUTE privilege on the stored procedure package
- Ownership of the package
- PACKADM authority for the package collection
- SYSADM authority
The stored procedure executes the SET CURRENT SQLID statement to change the value of CURRENT SQLID to the value that is specified by the authid input parameter. The value of CURRENT SQLID is the authorization ID for dynamic SQL statements.

Syntax

The following syntax diagram shows the SQL CALL statement for invoking this stored procedure:

```sql
CALL ADMIN_EXPLAIN_MAINT(
  mode, action,
  manage-alias, table-set, authid,
  schema-name, schema-alias, database-name,
  stogroup-database, stogroup-index,
  4k-bufferpool, 8k-bufferpool,
  16k-bufferpool, 32k-bufferpool, index-bufferpool,
  bp-4kb-lob, bp-8kb-lob, bp-16kb-lob, bp-32kb-lob,
  return-code, message
)
```

Option descriptions

**mode** Specifies the processing mode. This input parameter accepts the following values:

- **RUN** Alter and create EXPLAIN tables for the specified SCHEMA.
- **PREVIEW** No changes are processed.

The data type of this input parameter is VARCHAR(8). If this option is not specified, the default value is RUN.

**action** Specifies the action that is completed for the EXPLAIN tables in the specified schema. This input parameter accepts the following values:

- **STANDARDIZE** Upgrade all existing EXPLAIN tables to the format for the current Db2 version.
- **STANDARDIZE_AND_CREATE** Upgrade all existing EXPLAIN tables to the format for the current Db2 version, and create any missing tables of those that are specified by the table-set input parameter.
CREATE
Create a new set of EXPLAIN tables in the specified schema. Only tables that are specified by the table-set input parameter are created.

CREATE_ALIAS
Create a new set of aliases only. The new aliases are qualified by the value that is specified for the schema-alias input parameter.

DROP
Drop all existing EXPLAIN tables and the associated table space.

DROP_AND_CREATE
Drop all existing EXPLAIN tables, and the associated table spaces, and create a replacement set of the tables that are specified by the table-set input parameter.

The data type of this input parameter is VARCHAR(30). If this option is not specified, the default value is STANDARDIZE.

manage-alias
Specifies whether to create aliases for EXPLAIN tables. This input parameter accepts the following values:

YES The stored procedure creates aliases so that all EXPLAIN tables in the specified schema have aliases that correspond to the existing PLAN_TABLE aliases.

NO Aliases are not created.

The data type of this input parameter is VARCHAR(3). If this option is not specified, the default value is NO.

table-set
Specifies the list of EXPLAIN tables to be created.

If the action value is CREATE, the tables that are specified must not already exist. This input parameter accepts the following values:

'table-name-1, table-name-2, ..., table-name-n'
Specifies an explicit list of tables to create.

ALL All EXPLAIN tables that are created by the DSNTESC and DSNTESH sample jobs.

ACCEL
The following tables only:

• PLAN_TABLE
• DSN_STATEMNT_TABLE
• DSN_STATEMENT_CACHE_TABLE
• DSN_QUERYINFO_TABLE

DIAGNOSTICS
The following tables only:

• PLAN_TABLE
• DSN_STATEMNT_TABLE
• DSN_DETTCOST_TABLE
• DSN_PREDICAT_TABLE
• DSN_FILTER_TABLE
• DSN_COLDIST_TABLE
• DSN_KEYTGTIDIST_TABLE
• DSN_QUERYINFO_TABLE

ALL_EXCEPT(table-name-1, table-name-2, ..., table-name-n)

All tables that are created by the DSNTESC and DSNTESH sample jobs except for the tables that are specified in the list.

This value is applicable only if action is one of the following values:
• STANDARDIZE_AND_CREATE
• CREATE
• DROP_AND_CREATE

The data type of this input parameter is VARCHAR(1000). If this option is not specified, the following EXPLAIN tables are created by default:
• PLAN_TABLE
• DSN_STATEMNT_TABLE
• DSN_STATEMENT_CACHE_TABLE

authid

The CURRENT SQLID setting. If this option is not specified, the value of the CURRENT SQLID special register is used. The data type of this required input parameter is VARCHAR(128).

schema-name

Specifies the schema name that qualifies the EXPLAIN tables. If this option is not specified, the value of the CURRENT SCHEMA special register is used. The data type of this required input parameter is VARCHAR(128).

schema-alias

Specifies the schema name that qualifies aliases that are created when the action value is CREATE_ALIAS. The data type of this input parameter is VARCHAR(128). This input parameter is required when the action value is CREATE_ALIAS.

database-name

Specifies the database that contains the new EXPLAIN tables. The stored procedure creates the database if it does not exist. The data type of this input parameter is VARCHAR(8). If this option is not specified, the stored procedure omits the database and table space names in the CREATE TABLE statements for the EXPLAIN tables.

stogroup-database

Specifies the storage group for the database that contains the new EXPLAIN tables. The data type of this input parameter is VARCHAR(128). If this option is not specified, the stored procedure omits the STOGROUP keyword from the CREATE DATABASE statement, if the database does not already exist.

stogroup-index

Specifies the storage group for the indexes for the new EXPLAIN tables. The data type of this input parameter is VARCHAR(128). If this option is not specified, the stored procedure omits the USING STOGROUP keyword from the CREATE INDEX statement.

4k-bufferpool

Specifies the name of the 4-KB page buffer pool that is assigned to new table spaces. The data type of this input parameter is VARCHAR(8). If this option is not specified, the stored procedure omits the table space name in the CREATE TABLE statements for the EXPLAIN tables.

8k-bufferpool

Specifies the name of the 8 KB page buffer pool that is assigned to new
table spaces. The data type of this input parameter is VARCHAR(8). If this option is not specified, the stored procedure omits the table space name in the CREATE TABLE statements for the EXPLAIN tables.

16k-bufferpool
Specifies the name of the 16 KB page buffer pool that is assigned to new table spaces. The data type of this input parameter is VARCHAR(8). If this option is not specified, the stored procedure omits the table space name in the CREATE TABLE statements for the EXPLAIN tables.

32k-bufferpool
Specifies the name of the 32 KB page buffer pool that is assigned to new table spaces. The data type of this input parameter is VARCHAR(8). If this option is not specified, the stored procedure omits the table space name in the CREATE TABLE statements for the EXPLAIN tables.

index-bufferpool
Specifies the name of the buffer pool for the indexes for the new EXPLAIN tables. The data type of this input parameter is VARCHAR(8). If this option is not specified, the stored procedure omits the BUFFERPOOL keyword from the CREATE INDEX statement.

bp-4kb-lob
Specifies the name of the 4-KB page buffer pool that is assigned to new LOB tables spaces for the new auxiliary tables of the new EXPLAIN tables. The data type of this input parameter is VARCHAR(8). If this option is not specified, the stored procedure omits the BUFFERPOOL keyword from the CREATE LOB TABLESPACE statement.

bp-8kb-lob
Specifies the name of the 8-KB page buffer pool that is assigned to new LOB tables spaces for the new auxiliary tables of the new EXPLAIN tables. The data type of this input parameter is VARCHAR(8). If this option is not specified, the stored procedure omits the BUFFERPOOL keyword from the CREATE LOB TABLESPACE statement.

bp-16kb-lob
Specifies the name of the 16-KB page buffer pool that is assigned to new LOB tables spaces for the new auxiliary tables of the new EXPLAIN tables. The data type of this input parameter is VARCHAR(8). If this option is not specified, the stored procedure omits the BUFFERPOOL keyword from the CREATE LOB TABLESPACE statement.

bp-32kb-lob
Specifies the name of the 32-KB page buffer pool that is assigned to new LOB tables spaces for the new auxiliary tables of the new EXPLAIN tables. The data type of this input parameter is VARCHAR(8). If this option is not specified, the stored procedure omits the BUFFERPOOL keyword from the CREATE LOB TABLESPACE statement.

return-code
An output parameter that contains the return code from the stored procedure. It contains one of the following values:

0    The call completed successfully.
4    One or more existing EXPLAIN tables are not in Unicode. The table formats are updated to the format for the current Db2 version. However, the tables are not converted to Unicode.
8    The format of one or more existing EXPLAIN tables that were
The following C language sample shows how to invoke the ADMIN_EXPLAIN_MAINT stored procedure:

```c
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

EXEC SQL INCLUDE SQLCA;
int main( int argc, char *argv[] ) /* Argument count and list */
{

        :reason;
    }
}
return;

Output

The ADMIN_EXPLAIN_MAINT stored procedure creates as many as three result sets that are returned in the following global temporary tables:

SYSIBM.EXPLAIN_MAINT_SUMMARY

The summary of the actions completed by the stored procedure if the value of the mode input parameter is RUN. If the value of the mode input parameter is PREVIEW, this result set summarizes the actions, but the actions are not completed. The values of the various type_CREATED, type_ALTERED, type_DROPPED columns summarize the numbers of corresponding statements for each action in the SQL column of SYSIBM.EXPLAIN_MAINT_SQL result set.

Table 127. Format of the SYSIBM.EXPLAIN_MAINT_SUMMARY result set

<table>
<thead>
<tr>
<th>Column name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DB_CREATED</td>
<td>INTEGER NOT NULL</td>
<td>The number of databases that are created.</td>
</tr>
<tr>
<td>TS_CREATED</td>
<td>INTEGER NOT NULL</td>
<td>The number of tables pages that are created.</td>
</tr>
<tr>
<td>TB_CREATED</td>
<td>INTEGER NOT NULL</td>
<td>The number of EXPLAIN tables that are created.</td>
</tr>
<tr>
<td>AUX_CREATED</td>
<td>INTEGER NOT NULL</td>
<td>The number of auxiliary tables that are created.</td>
</tr>
<tr>
<td>IX_CREATED</td>
<td>INTEGER NOT NULL</td>
<td>The number of indexes that are created.</td>
</tr>
<tr>
<td>ALIAS_CREATED</td>
<td>INTEGER NOT NULL</td>
<td>The number of aliases that are created.</td>
</tr>
<tr>
<td>TB_EXAMINED</td>
<td>INTEGER NOT NULL</td>
<td>The number of EXPLAIN tables that were examined for formats older than the format for the current Db2 version.</td>
</tr>
<tr>
<td>TB_ALTERED</td>
<td>INTEGER NOT NULL</td>
<td>The number of tables that are altered to use the format for the current Db2 version.</td>
</tr>
</tbody>
</table>
Table 127. Format of the SYSIBM.EXPLAIN_MAINT_SUMMARY result set (continued)

<table>
<thead>
<tr>
<th>Column name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TS_DROPPED</td>
<td>INTEGER NOT NULL</td>
<td>The number of table spaces that were dropped.</td>
</tr>
<tr>
<td>TB_DROPPED</td>
<td>INTEGER NOT NULL</td>
<td>The number of EXPLAIN tables that are dropped.</td>
</tr>
<tr>
<td>TB_UNEXPECTED_FORMAT</td>
<td>INTEGER NOT NULL</td>
<td>The number of EXPLAIN tables that do not match any known valid format.</td>
</tr>
<tr>
<td>TB_NOT_STANDARDIZED</td>
<td>INTEGER NOT NULL</td>
<td>The number of EXPLAIN tables that cannot be converted to the format for the current Db2 version.</td>
</tr>
<tr>
<td>TB_NOT_UNICODE</td>
<td>INTEGER NOT NULL</td>
<td>The number of existing EXPLAIN tables that are encoded in a CCSID other than Unicode. Such tables are upgraded to the format for the current Db2 version, but the CCSID is not changed to Unicode.</td>
</tr>
</tbody>
</table>

SYSIBM.EXPLAIN_MAINT_SQL

A list of the SQL statements that the stored procedure issues if the value of the mode input parameter is RUN. If the value of the mode input parameter is PREVIEW, this result set summarizes the actions, but the statements are not issued.

Table 128. Format of the SYSIBM.EXPLAIN_MAINT_SQL result set

<table>
<thead>
<tr>
<th>Column name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ROWNUM</td>
<td>INTEGER NOT NULL</td>
<td>The sequence number of the table row, 1 - n.</td>
</tr>
<tr>
<td>SQL</td>
<td>VARCHAR(16000) NOT NULL</td>
<td>The text of an SQL statement that is issued by the stored procedure to create, alter, or drop EXPLAIN tables and related objects.</td>
</tr>
</tbody>
</table>

Table space names: Table spaces that the ADMIN_EXPLAIN_MAINT stored procedure creates for EXPLAIN tables and related auxiliary tables have names that are based on a four-letter abbreviation of the name of the associated table, followed by a four-digit number that ensures the uniqueness name. The four-letter abbreviations do not follow a consistent pattern in relation to the various table names. For example, PLANnnnn is used for PLAN_TABLE, STMNTnnnn is for DSN_STATEMNT_TABLE, and SFEDnnnn is used for DSN_STAT_FEEDBACK table.

You can find the names of the table spaces that the stored procedure creates in the SYSIBM.EXPLAIN_MAINT_SQL result set.

SYSIBM.EXPLAIN_MAINT_TB_NOT_UPGRADED

This result set is returned only when the value of the action input parameter is STANDARDIZE or STANDARDIZE_AND_CREATE and at
least one of the following conditions is true. The result set contains one row for each of the following occurrences:

- The table is created with a CSSID other than Unicode. Such tables might be upgraded to the format for the current Db2 version. However, the CCSID is not changed to Unicode.
- The format of the EXPLAIN table does not match any known format. Such tables are not upgraded.
- ALTER TABLE statements cannot complete changes that are required to upgrade a table to the format for the current Db2 version. Such tables are not upgraded.

<table>
<thead>
<tr>
<th>Column name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ROWNUM</td>
<td>INTEGER NOT NULL</td>
<td>The sequence number of the table row, 1 - n.</td>
</tr>
<tr>
<td>SCHEMA</td>
<td>VARCHAR(128) NOT NULL</td>
<td>The schema of an EXPLAIN table that cannot be converted to the format for the current version of Db2.</td>
</tr>
<tr>
<td>TBNAME</td>
<td>VARCHAR(128) NOT NULL</td>
<td>The name of an EXPLAIN table that cannot be converted to the format for the current version of Db2.</td>
</tr>
<tr>
<td>REASON</td>
<td>VARCHAR(1000) NOT NULL</td>
<td>A description of the reason why the table cannot be converted to the format for the current version of Db2.</td>
</tr>
</tbody>
</table>

**ADMIN_INFO_HOST stored procedure**

The SYSPROC.ADMIN_INFO_HOST stored procedure returns the host name of a connected Db2 subsystem or the host name of every member of a data sharing group.

**Environment**

---

GUPI
ADMIN_INFO_HOST runs in a WLM-established stored procedures address space.

**Authorization**

To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges on each package that the stored procedure uses:

- The EXECUTE privilege on the package for DSNADMIH
- Ownership of the package
- PACKADM authority for the package collection
- SYSADM authority

The ADMIN_INFO_HOST stored procedure internally calls the ADMIN_COMMAND_DB2 stored procedure to execute the following Db2 commands:

- `DISPLAY DDF`
- `DISPLAY GROUP`

The owner of the package or plan that contains the CALL ADMIN_INFO_HOST statement must also have the authorization required to execute the stored procedure ADMIN_COMMAND_DB2 and the specified Db2 commands.

**Syntax**

The following syntax diagram shows the SQL CALL statement for invoking this stored procedure:

```sql
CALL SYSPROC.ADMIN_INFO_HOST(processing-option, db2-member, return-code, message)
```

**Option descriptions**

**processing-option**

Specifies processing option. Possible values are:

1. Return the host name of the connected Db2 subsystem or the host name of a specified Db2 data sharing group member.

   For a data sharing group member, you must specify `db2-member`.

2. Return the host name of every Db2 member of the same data sharing group.

   This is an input parameter of type INTEGER and cannot be null.

**DB2-member**

Specifies the Db2 data sharing group member name.

This parameter must be null if `processing-option` is 2.

This is an input parameter of type CHAR(8).
**return-code**

Provides the return code from the stored procedure. Possible values are:

0  The call completed successfully.
4  Unable to list the host name of the connected Db2 subsystem or of every Db2 member of the same data sharing group due to one of the following reasons:
   • The IPADDR field returned when the -DISPLAY DDF command is executed on the connected Db2 subsystem or Db2 member contains the value -NONE
   • One of the Db2 members is down
12  The call did not complete successfully. The message output parameter contains messages describing the error.

This is an output parameter of type INTEGER.

**message**

Contains messages describing the error encountered by the stored procedure. If no error occurred, then no message is returned.

The first messages in this area are generated by the stored procedure. Messages that are generated by Db2 might follow the first messages.

This is an output parameter of type VARCHAR(1331).

**Example**

The following C language sample shows how to invoke ADMIN_INFO_HOST:

```c
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

/******************
/* DB2 SQL Communication Area */
EXEC SQL INCLUDE SQLCA;

int main(int argc, char *argv[]) /* Argument count and list */
{
    /* DB2 Host Variables */
    EXEC SQL BEGIN DECLARE SECTION;
    
    /* SYSPROC.ADMIN_INFO_HOST parameters */
    long int procopt; /* Processing option */
    short int ind_procopt; /* Indicator variable */
    char db2mbr[9]; /* Data sharing group member */
    short int ind_db2mbr; /* Indicator variable */
    long int retcd; /* Return code */
    short int ind_retcd; /* Indicator variable */
    char errmsg[1332]; /* Error message */
    short int ind_errmsg; /* Indicator variable */

    /* Result set locators */
    volatile SQL TYPE IS RESULT_SET_LOCATOR *rs_loc1;

    /* Result set row */
    long int rownum; /* Sequence number of the */
    /* table row */
    char db2member[9]; /* Db2 data sharing group */
    char hostname[256]; /* Host name of the connected */
    /* Db2 subsystem or Db2 */
    
    802 SQL Reference
```
EXEC SQL END DECLARE SECTION;

/******************************************************************************
/* Assign values to input parameters to find the host name of the connected DB2 subsystem */
/* Set the indicator variables to 0 for non-null input parameters */
/* Set the indicator variables to -1 for null input parameters */
*******************************************************************************/

procopt = 1;
ind_procopt = 0;
ind_db2mbr = -1;

/******************************************************************************/
/* Call stored procedure SYSPROC.ADMIN_INFO_HOST */
*******************************************************************************/

EXEC SQL CALL SYSPROC.ADMIN_INFO_HOST
    (:procopt :ind_procopt,
     :db2mbr  :ind_db2mbr,
     :retcd   :ind_retcd,
     :errmsg  :ind_errmsg);

/******************************************************************************/
/* Retrieve result set when the SQLCODE from the call is +446, which indicates that result sets were returned */
*******************************************************************************/

if (SQLCODE == +446)
    /* Result sets were returned */
    {
    /* Establish a link between the result set and its locator */
    EXEC SQL ASSOCIATE LOCATORS (:rs_loc1)
        WITH PROCEDURE SYSPROC.ADMIN_INFO_HOST;

    /* Associate a cursor with the result set */
    EXEC SQL ALLOCATE C1 CURSOR FOR RESULT SET :rs_loc1;

    /* Use C1 to fetch the only row from the result set */
    EXEC SQL FETCH C1 INTO :rownum, :db2mbr, :hostname;

    EXEC SQL CLOSE C1;
    }

return(retcd);

Output

This stored procedure returns the following output parameters, which are described in "Option descriptions" on page 801:

- return-code
- message

In addition to the preceding output, the stored procedure returns one result set that contains the host names.

The following table shows the format of the result set returned in the created global temporary table SYSIBM.SYSTEM_HOSTNAME:

<table>
<thead>
<tr>
<th>Column name</th>
<th>Data type</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>ROWNUM</td>
<td>INTEGER</td>
<td>Sequence number of the table row, from 1 to n.</td>
</tr>
<tr>
<td>DB2_MEMBER</td>
<td>CHAR(8)</td>
<td>Db2 data sharing group member name.</td>
</tr>
</tbody>
</table>

ADMIN_INFO_SMS stored procedure

The ADMIN_INFO_SMS stored procedure returns space information about copy pools and their storage groups and volumes.

Environment

The load module for this stored procedure, DSNADMIV, must reside in an APF-authorized library. ADMIN_INFO_SMS runs in a WLM-established stored procedures address space. All libraries in this WLM procedure STEPLIB DD concatenation must be APF-authorized.

Authorization

To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges on each package that the stored procedure uses:
- The EXECUTE privilege on the package for DSNADMIV
- Ownership of the package
- PACKADM authority for the package collection
- SYSADM authority

Syntax

The following syntax diagram shows the SQL CALL statement for invoking this stored procedure:
Option descriptions

return-code
Provides the return code from the stored procedure. The following values are possible:

0  The stored procedure completed successfully.
4  The stored procedure could not return the volume space statistics for all of the requested objects. The message output parameter contains messages that describe the warnings.

This return code is issued when one or more objects that are returned in the result set contains one of the following messages in the ERRMSG column:
- OBJECT NOT FOUND: Indicates that the copy pool, storage group, or volume that is specified in the input table is not found, as reported by the SMS construct access services.
- NO VOLUMES ASSOCIATED WITH STORAGE GROUP: Indicates that the storage group that is specified in the input table does not have any volumes, as reported by the SMS construct access services.
- NO STORAGE GROUPS ASSOCIATED WITH COPY POOL: Indicates that the copy pool that is specified in the input table does not have any storage groups, as reported by the SMS construct access services.
- DSNA661I DSNADMIV THE MACRO LSPACE FAILED WITH RETURN CODE=mn

12  The call did not complete successfully. The message output parameter contains messages that describe a parameter error, an SQL error, or an internal error that was encountered by the stored procedure.

This is an output parameter of type INTEGER.

message
Contains messages that describe a parameter error, an SQL error, or an internal error that was encountered by the stored procedure. If an error did not occur, a message is not returned.

This is an output parameter of type VARCHAR(1331).

Input

This stored procedure reads from the created global temporary table SYSIBM.SMS_OBJECTS to determine which objects' space statistics to return.

The following table shows the format of the SYSIBM.SMS_OBJECTS input table.

Table 131. Input row for the ADMIN_INFO_SMS stored procedure

<table>
<thead>
<tr>
<th>Column name</th>
<th>Data type</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>OBJECTID</td>
<td>INTEGER, NOT NULL</td>
<td>A unique positive identifier for the object that a set of volume space statistics is associated with.</td>
</tr>
</tbody>
</table>
Table 131. Input row for the ADMIN_INFO_SMS stored procedure (continued)

<table>
<thead>
<tr>
<th>Column name</th>
<th>Data type</th>
<th>Contents</th>

</tr>
<tr>
<td></td>
<td></td>
<td>• Volume name, if OBJECTTYPE is 'V'. Returns the volume space statistics for</td>
</tr>
<tr>
<td></td>
<td></td>
<td>this volume.</td>
</tr>
</tbody>
</table>

Output

This stored procedure returns the following output parameters, which are described in "Option descriptions" on page 805:
• return-code
• message

In addition to the preceding output, the stored procedure returns one result set that contains the volume space statistics.

The following table shows the format of the result set that is returned in the created global temporary table SYSIBM.SMS_INFO. The result set rows are returned in ascending order by ROWNUM and OBJECTID.

Table 132. Result set row for ADMIN_INFO_SMS result set

ADMIN_INFO_SSID stored procedure

The SYSPROC.ADMIN_INFO_SSID stored procedure returns the name of the connected Db2 subsystem.

Environment

ADMIN_INFO_SSID must run in a WLM-established stored procedure address space.

Authorization

To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges:

• The EXECUTE privilege on the ADMIN_INFO_SSID stored procedure
• Ownership of the stored procedure
• SYSADM authority
Syntax

The following syntax diagram shows the SQL CALL statement for invoking this stored procedure:

```
CALL-SYSPROC.ADMIN_INFO_SSID(--subsystem-ID--,--return-code--,--message--)  
```

Option descriptions

`subsystem-ID`

Identifies the subsystem ID of the connected Db2 subsystem.

This is an output parameter of type VARCHAR(4).

`return-code`

Provides the return code from the stored procedure. Possible values are:

- 0   The call completed successfully.
- 12  The call did not complete successfully. The `message` output parameter contains messages describing the error.

This is an output parameter of type INTEGER.

`message`

Contains messages describing the error encountered by the stored procedure. If no error occurred, no message is returned.

This is an output parameter of type VARCHAR(1331).

Example

The following C language sample shows how to invoke ADMIN_INFO_SSID:

```c
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

/**************************
DB2 SQL Communication Area **************************/
EXEC SQL INCLUDE SQLCA;

int main( int argc, char *argv[] ) /* Argument count and list */
{
    /************************** DB2 Host Variables **************************/
    EXEC SQL BEGIN DECLARE SECTION;

    /* SYSPROC.ADMIN_INFO_SSID PARAMETERS */
    char ssid[5];  /* DB2 subsystem identifier */
    long int retcd; /* Return code */
    char errmsg[1332]; /* Error message */
    EXEC SQL END DECLARE SECTION;

    /************************** Call stored procedure SYSPROC.ADMIN_INFO_SSID **************************/
    EXEC SQL CALL SYSPROC.ADMIN_INFO_SSID
        (:ssid, :retcd, :errmsg);

    return(retcd);
}
```

Chapter 5. Procedures that are supplied with Db2  809
Output

The output of this stored procedure includes the following output parameters, which are described in "Option descriptions" on page 809:

- subsystem-ID
- return-code
- message

ADMIN_INFO_SQL stored procedure

The ADMIN_INFO_SQL stored procedure captures statistics about a Db2 subsystem, its objects, and applications and returns the results in a data set or as a result set. The result, often called “service SQL”, is a standard diagnostic documentation format that helps IBM Support re-create and troubleshoot problems, such as a poorly performing SQL query.

The output from ADMIN_INFO_SQL is intended primarily for the use of IBM Support. The format and content of the output might change at any time.

For information about submitting the service SQL data to IBM Support, see Contacting IBM Support about Db2 problems.

Environment

ADMIN_INFO_SQL must run in a WLM-established stored procedures address space, where NUMTCB is a value between 40 and 60.

If you collect information by using PLAN_TABLE, ensure that the DSN_VIEWREF_TABLE table exists before you capture EXPLAIN information. Especially if the query contains a view, the availability of DSN_VIEWREF_TABLE helps to narrow the view so that it is specific to the query, rather than collecting all of the view dependencies. DSN_VIEWREF_TABLE must have the same qualifier as the PLAN_TABLE. This qualifier is the table-creator value, which is the first input parameter.

Authorization

To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges:

- The EXECUTE privilege on the ADMIN_INFO_SQL stored procedure
- Ownership of the stored procedure
- SYSADM authority

Optionally, you need authority to create data sets, or access existing data sets, if the information is collected into a data set.
Syntax

The following syntax diagram shows the SQL CALL statement for invoking this stored procedure:

```
CALL SYSPROC.ADMIN_INFO_SQL(—table-creator,—table-name,—catalog-creator,—plan-info,—
collect-ddl,—collect-stats,—collect-column-stats,—edit-ddl,—edit-version-mode,—
partition-rotation,—output-method,—output-info,—pmr-info,—return-code,—message—)
```

Option descriptions

table-creator

Specifies the explicit qualifier for the object, the list of tables, or the plan table (PLAN_TABLE).

This is an input parameter of type VARCHAR(128) and cannot be null.

table-name

Specifies the name of a single user object, a list of objects, or the plan table (PLAN_TABLE).

Valid options are an object name, LIST_TABLE-table, or PLAN_TABLE. The table portion of the LIST_TABLE-table option is the name of a Db2 table that contains two columns, CREATOR and TABLE. These two columns drive the program to collect information. The PLAN_TABLE option uses the CREATOR and TNAME columns of the PLAN_TABLE to collect information. This option depends on the plan_info parameter to qualify tables as input. The reference point to the plan table must point to a base table only.

When you specify PLAN_TABLE, ensure that the DSN_VIEWREF_TABLE table exists before you execute EXPLAIN. The availability of DSN_VIEWREF_TABLE minimizes the size of the DDL information. DSN_VIEWREF_TABLE must have the same qualifier as the plan table. This qualifier is the table-creator value, which is the first input parameter.

The input for a single user object or a list of objects must be one of the following types of objects:
• Base table
• View
• Alias
• Clone table
• Created temporary table
• History table
• Materialized query table
• Implicitly created table for an XML column

The input parameter table-creator must be the qualifier for these tables.

This is an input parameter of type VARCHAR(128).

catalog-creator

Specifies the catalog to use for collection. The default catalog is SYSIBM. To use the default catalog, you can specify DEFAULT or SYSIBM.
This is an input parameter of type VARCHAR(128) and cannot be null.

**plan-info**

Specifies the programs and query numbers from PLAN_TABLE for the tables to be collected.

If you are collecting information from a single table that is not PLAN_TABLE, or a list of tables, specify NONE.

This is an input parameter of type VARCHAR(150) and cannot be null.

**collect-ddl**

Specifies whether to collect DDL information. Valid values are Y, N, 0 (zero), 1, 2, 3, or 4.

This is an input parameter of type CHAR(1) and cannot be null.

When the input table is not PLAN_TABLE, possible values are:

- **N** Do not return the data definition language statements that created the objects.
- **Y** Return the data definition language statements that created:
  - The input objects
  - Foreign keys that reference the input objects
  - Views on the input objects
- **0** Return the data definition language statements that created:
  - The input objects. Statements that create views on the input objects or foreign keys that reference the input objects are not collected.
- **1** Return the data definition language statements that created:
  - The input objects
  - Views on the input objects
- **2** Return the data definition language statements that created:
  - The input objects
  - Foreign keys that reference the input objects
- **3** Return the data definition language statements that created:
  - The input objects
  - Foreign keys that reference the input objects
  - Views on the input objects
  - Other objects that depend on the input objects, such as materialized query tables

This option can result in a large amount of data. Do not specify this option for problem analysis except at the direction of IBM Support.

- **4** Return the same data definition language statements that are returned when option Y is specified.

When the input table is PLAN_TABLE, possible values are:

- **N** Do not return the data definition language statements that created the objects.
- **Y** Return the data definition language statements that created:
  - The objects that are identified by plan-info
  - Foreign keys that reference the objects that are identified by plan-info
• If DSN_VIEWREF_TABLE exists and is populated, views or materialized query tables that are used to process the queries that are identified by plan-info.

• If DSN_VIEWREF_TABLE does not exist, views on objects that are identified by plan-info.

0 Return the data definition language statements that created:
• The objects that are identified by plan-info only. Statements that create views on the objects or foreign keys that reference the objects that are identified by plan-info are not collected.

1 Return the data definition language statements that created:
• The objects that are identified by plan-info

• If DSN_VIEWREF_TABLE exists and is populated, views or materialized query tables that are used to process the queries that are identified by plan-info.

• If DSN_VIEWREF_TABLE does not exist, views on objects that are identified by plan-info.

2 Return the data definition language statements that created:
• Foreign keys that reference the objects that are identified by plan-info

3 Return the data definition language statements that created:
• The objects that are identified by plan-info

• Foreign keys that reference the objects that are identified by plan-info

• Views on objects that are identified by plan-info

• Other objects that depend on the objects that are identified by plan-info, such as materialized query tables

This option can result in a large amount of data. Do no specify this option for problem analysis by IBM Support unless they direct you to do so.

4 Return the data definition language statements that created:
• The objects that are identified by plan-info

• Foreign keys that reference the objects that are identified by plan-info

• Views on objects that are identified by plan-info

This option does not use information from DSN_VIEWREF_TABLE.

**collect-stats**
Specifies whether to collect statistics information. Valid values are Y for yes, or N for no.

This is an input parameter of type CHAR(1) and cannot be null.

**collect-column-stats**
Specifies whether to collect column-level statistics information. Valid values are Y for yes, or N for no.

To collect column statistics, the collect-stats parameter must be set to Y.

This is an input parameter of type CHAR(1) and cannot be null.

**edit-ddl**
Specifies whether to edit the DDL output. Valid values are Y for yes, or N for no.

If edited, the DDL output contains changes, such as the STOGROUP set to SYSDEFLT, PRIQTY and SECQTY set to minimum values, and FOREIGNKEY
definitions commented out. Sometimes IBM Support needs DDL output that is not edited. However, if the data to populate the DDL-defined tables will not be sent with the problem report, specify Y for this parameter.

This is an input parameter of type CHAR(1) and cannot be null.

**edit-version-mode**

Specifies that the output should be formatted for a different version and mode of Db2 for z/OS than the version and mode that is currently running when collecting information. You must specify the version number and the mode, or you can specify NONE so that the output is not converted to another format.

Valid values for mode are C for conversion mode and N for new-function mode. For example, if your Db2 subsystem is running in DB2 10 conversion mode, and you want to generate the output for DB2 9 new-function mode, specify 9-N.

This is an input parameter of type CHAR(4) and cannot be null.

**partition-rotation**

Specifies whether you want to verify the number of partition rotations that are required to balance the table. Valid values are Y for yes, or N for no.

This is an input parameter of type CHAR(1) and cannot be null.

**output-method**

Specifies the data set attributes that you want the output to include.

This is an input parameter of type CHAR(1) and cannot be null.

Possible values for **output-method** are:

- **Q** Returns dynamically created data sets with size parameters.
- **N** Returns the result data sets in an already existing data set in the WLM environment.
- **D** Returns dynamically created data sets on a volume that you specify.
- **R** Returns a result set in a predetermined format.

Output data sets and result sets contain the following information:

- **DDL** The creation statements for databases, table spaces, tables, and indexes.
- **SQL** INSERT statements for PLAN_TABLE, DSN_PROFILE_TABLE, DSN_PROFILE_ATTRIBUTES, and SYSACCELERATORS if the tables exist.
- **STATS** Statistical information related to the tables.
- **COLST** Statistical information related to the columns.
- **EXPL** The output begins with a first-pass analysis report, which contains the following information, if it is available:
  - A report on missing EXPLAIN tables
  - A report on statistics that are recommended but were not collected
  - Results of a preliminary analysis of the EXPLAIN data

The following information is also returned:
...Visual output of the following tables, if they exist: PLAN_TABLE, DSN_PREDICAT_TABLE, DSN_DET COST_TABLE, DSN_PROFILE_TABLE, DSN_PROFILE_ATTRIBUTES, and SYSACCELERATORS...

...Information about the objects, messages, and input parameters. The output also contains the following reports which describe object structures in relation the query:

- A table report contains information about the table space, table, and index key columns, organized by table space. It includes information about multi-column and index key cardinality.
- An index report that maps index details to predicates.

**PARM** Subsystem parameter, service, module, and relational data system (RDS) MEPL information.

**output-info**

Specifies the output information. The values that you specify depend on the value of the **output-method** parameter.

This is an input parameter of type VARCHAR(1024) and cannot be null.

Based on the value of **output-method**, you must format the input for **output-info** as follows:

**output-method = Q**

This output method has the following format:

*qualifier-primary(value or DEFLT)-secondary(value or DEFLT)*

You specify a 29-character qualifier, including periods. You also can specify a primary and secondary track value. The default value is 200 for primary and 200 for secondary.

The result data set is created on temporary storage as a data set with one of the following types:

- .DDL
- .SQL
- .STATS
- .COLST
- .EXPL
- .PARM

The file might be deleted in a short period of time, depending on the configuration of your z/OS system. Because the data set is created as a new one, existing data sets with the same name are deleted.

The DEFAULT value creates a data set name with the following format:

`PMxxxxx.Dxxxxxx.Txxxxxx.Vx.Type`

For example, for PMR 12345, the ADMIN_INFO_SQL stored procedure generates the following files:

output-method = N
For established data sets in the WLM environment, you must specify the DD name in the following format:

```
DDL_DDname-SQL_DDname-Stats_DDname-Colst_DDname-Expl_DDname-
Parm_DDname
```

The WLM administrator must create these data sets with DD names in the WLM startup procedure and supply those names to the person calling the stored procedure. These data sets can be generational. You must create the data sets as new ones rather than appending existing data sets. The ADMIN_INFO_SQL stored procedure opens the data set at initialization and closes the file when complete.

output-method = D
You specify the volume where you want the data sets created and the names and sizes of the data sets. This output method has the following format but in one continuous line with no spaces:

```
DDL;DSname(DEFAULT);volser;alcunit(TRK or CYL);primary;secondary-
SQL;DSname(DEFAULT);volser;alcunit(TRK or CYL);primary;secondary-
STATS;DSname(DEFAULT);volser;alcunit(TRK or CYL);primary;secondary-
COLST;DSname(DEFAULT);volser;alcunit(TRK or CYL);primary;secondary-
EXPL;DSname(DEFAULT);volser;alcunit(TRK or CYL);primary;secondary-
PARM;DSname(DEFAULT);volser;alcunit(TRK or CYL);primary;secondary
```

The DEFAULT value creates the data set name with the same format and types as for output method Q. The data set name must contain the type identifier (for example, .DDL, .SQL, .STATS, etc.). As a result, the data sets can be listed in any order.

These data sets are created with the option disp=(NEW,CATLG,KEEP). Therefore, if a data set with the same name already exists, the ADMIN_INFO_SQL stored procedure generates an error.

output-method = R
You must specify NONE. This output method returns a result set in the following format:

```
EXEC SQL CREATE GLOBAL TEMPORARY TABLE SYSIBM.SERVICE_SQL_OUTPUT
  (TID INTEGER NOT NULL, SEQNO INTEGER NOT NULL,
  TEXT VARCHAR(4096) NOT NULL);
```

Where TEXT is the information in the result set, such as DDL statements, statistical information, and service and module information. SEQNO is the sequence number in the table, and TID is the table number. For example:

### Table 133. Table numbers for result set information

<table>
<thead>
<tr>
<th>Table number (TID)</th>
<th>Result set information</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>DDL</td>
</tr>
<tr>
<td>2</td>
<td>SQL</td>
</tr>
<tr>
<td>3</td>
<td>STATS</td>
</tr>
<tr>
<td>4</td>
<td>COLST</td>
</tr>
<tr>
<td>5</td>
<td>EXPL</td>
</tr>
<tr>
<td>6</td>
<td>PARM</td>
</tr>
</tbody>
</table>
The following table shows the format of the result set that is returned in the created global temporary table SYSIBM.SERVICE_SQL_OUTPUT:

<table>
<thead>
<tr>
<th>Column name</th>
<th>Data type</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>TID</td>
<td>INTEGER NOT NULL</td>
<td>The table number.</td>
</tr>
<tr>
<td>SEQNO</td>
<td>INTEGER NOT NULL</td>
<td>The sequence number in the table.</td>
</tr>
<tr>
<td>TEXT</td>
<td>VARCHAR(4096)</td>
<td>The information in the result set, such as DDL statements, statistical information, and service and module information.</td>
</tr>
</tbody>
</table>

The following DECLARE statement shows the data that is returned for the result set and the order that the data is returned in:

```sql
EXEC SQL DECLARE DATA_CSR CURSOR WITH RETURN WITH HOLD FOR
SELECT TID, SEQNO, TEXT FROM SYSIBM.SERVICE_SQL_OUTPUT
ORDER BY TID, SEQNO;
```

**pmr-info**

Specifies the PMR number, branch code, and country code in the following format: `xxxxx.xxx.xxx`.

This is an input parameter of type VARCHAR(13) and cannot be null.

**return-code**

Provides the return code from the stored procedure. Possible values are:

- **0** The call completed successfully.
- **4** Warning. The `message` output parameter contains messages describing the warning.
- **12** The call did not complete successfully. The `message` output parameter contains messages describing the error.

This is an output parameter of type INTEGER.

**message**

Contains messages describing the error or warning encountered by the stored procedure. If no error occurred, the message states "DSNADMSS completed successfully."

The first messages in this area are generated by the stored procedure. Messages that are generated by Db2 might follow the first messages.

This is an output parameter of type VARCHAR(1331).

**Examples**

You can invoke the call for the ADMIN_INFO_SQL stored procedure from a Db2 command line processor, if you have access to a z/OS server. You also can call this stored procedure by using Java JDBC applications and by using the C language.

In addition, you can use DSNADMSB, an IBM-supplied program, to call the ADMIN_INFO_SQL stored procedure. The result set is returned in a data set or as part of the job stream.
Example 1: The following example calls the ADMIN_INFO_SQL stored procedure to collect information from the PLAN_TABLE for program APROGRAM and query numbers between 1 and 12345.

```sql
CALL SYSPROC.ADMIN_INFO_SQL('sysadm','PLAN_TABLE','DEFAULT', 'APROGRAM=1-12345','Y','Y','N','Y','NONE','N','D','DDL;DEFAULT;EDSDMP;TRK;200;200-SQL;DEFAULT;EDSDMP;TRK;200;200-STATS;DEFAULT;EDSDMP;TRK;200;200-COLST;DEFAULT;EDSDMP;TRK;200;200-EXPL;DEFAULT;EDSDMP;TRK;200;200-PARM;DEFAULT;EDSDMP;TRK;200;200-12345.000.000','?',?)
```

The output is created in data sets on volume EDSDMP with 200 primary tracks and 200 secondary tracks. These data sets have the following naming convention, where ‘x’ is the creation date and ‘y’ is the creation time:

Example 2: The following example of the ADMIN_INFO_SQL stored procedure uses the list table TL1 to collect data from all of the base tables whose names are specified by rows in TL1. The following SQL statements show how to create and populate the list table:

```sql
DROP TABLE TL1;
DROP DATABASE DL1;
COMMIT;
CREATE DATABASE DL1;
CREATE TABLESPACE TSL1 IN DL1;
CREATE TABLE TL1 (CREATOR VARCHAR(128), TABLE VARCHAR(128)) IN DL1.TSL1;
COMMIT;
INSERT INTO TL1 VALUES ('SYSADM','T1');
INSERT INTO TL1 VALUES ('SYSADM','T2');
INSERT INTO TL1 VALUES ('SYSADM','T3');
COMMIT;
```

The following CALL statement for the ADMIN_INFO_SQL stored procedure returns a single result set in the job stream. The list table name must be preceded by 'LIST_TABLE-'.

```sql
CALL SYSPROC.ADMIN_INFO_SQL('SYSADM','LIST_TABLE-TL1','DEFAULT','NONE','Y','Y','N','Y','NONE','N','R','NONE','12345.000.000','?','?');
```

Even though the column name is TABLE in the list table, the input for a list of objects can be any of the following types of objects:

- Base table
- View
- Alias
- Clone table
- Created temporary table
- History table
- Materialized query table
- Implicitly created table for an XML column

Example 3: You also can call this stored procedure by using Java JDBC applications or by using the C language. The following examples call the ADMIN_INFO_SQL
stored procedure to collect information from the PLAN_TABLE for program APROGRAM and query numbers between 1 and 12345, and return a result set.

**Java JDBC code snippet example:**

```java
try {
    cstmt = conn.prepareCall("CALL SYSPROC.ADMIN_INFO_SQL(?,?,?,?,?,?,?,
    ?,?,?,?,?,?,?)");
    // Create a CallableStatement object
    cstmt.setString(1, "sysadm");
    cstmt.setString(2, "PLAN_TABLE");
    cstmt.setString(3, "DEFAULT");
    cstmt.setString(4, "APROGRAM-1-12345");
    cstmt.setString(5, "Y");
    cstmt.setString(6, "Y");
    cstmt.setString(7, "Y");
    cstmt.setString(8, "N");
    cstmt.setString(9, "NONE");
    cstmt.setString(10, "N");
    cstmt.setString(11, "R");
    cstmt.setString(12, "NONE");
    cstmt.setString(13, "12345.000.000");
    // Set input parameters (DB2 command)
    cstmt.registerOutParameter(14, Types.INTEGER);
    cstmt.registerOutParameter(15, Types.VARCHAR);
    // Register output parameters
    boolean resultsAvailable = cstmt.execute();
    rc = cstmt.getInt(14);  // Get the output parameter values
    errbuff = cstmt.getString(15);
    while (resultsAvailable) {
        ResultSet rs = cstmt.getResultSet();
        while (rs.next()) {
            String s = rs.getString(3);
            System.out.println(s);
        }
        rs.close();
        resultsAvailable = cstmt.getMoreResults();
    }
}
```

**C language code snippet example:**

```c
EXEC SQL CALL SYSPROC.ADMIN_INFO_SQL ('sysadm', 'PLAN_TABLE'
    , 'DEFAULT', 'APROGRAM-1-12345', 'Y', 'Y', 'N', 'Y', '9-R', 'N', 'R',
    'NONE', '12345.000.000', :out1,:out2);
printf("%d CALL SQLCODE\n", SQLCODE);
printf("%d CALL RC\n", out1);
printf("%s CALL DETAILS\n", out2);
if(SQLCODE==+466) {
    EXEC SQL ASSOCIATE LOCATORS (:loc1) WITH
        PROCEDURE SYSPROC.ADMIN_INFO_SQL;
    printf("%d ASSOC SQLCODE\n", SQLCODE);
}
EXEC SQL ALLOCATE C1 CURSOR FOR RESULT SET :loc1;
printf("%d ALLOC SQLCODE\n", SQLCODE);
while(SQLCODE==0) {
    DATA.LNG = 0;
    SEQNO = 0;
}
```

Chapter 5. Procedures that are supplied with Db2
