ind3 = -1;

EXEC SQL FETCH C1 INTO :TID, :SEQNO, :DATA;
memcpy(output, DATA.THEDATA, DATA.LNG);
output??(DATA.LNG??) = '\0';
printf("\%s\n", output);
}
}
printf("\%d FETCH SQLCODE\n", SQLCODE);

Output

This stored procedure returns the following output parameters, which are described in "Option descriptions" on page 81:

- return-code
- message

In addition, this stored procedure returns output in data sets or a result set. You must ensure that enough space is available for the output. The ADMIN_INFO_SQL stored procedure might generate large amounts of data. Two to three megabytes of space is the average, but larger workloads might generate up to 20 megabytes of data. To conserve space, set the collect-column-stats option to N.

ADMIN_INFO_SYSLOG stored procedure

The ADMIN_INFO_SYSLOG stored procedure returns system log entries. You can specify filters, such as search string, system name, begin date and time, end date and time, and maximum number of entries, to limit the number of system log entries that are returned.

Note: This stored procedure is supported for z/OS Version 1 Release 12 and later.

Environment

ADMIN_INFO_SYSLOG runs in a WLM-established stored procedures address space, where TCB=1 is required.
**Authorization**

To use ADMIN_INFO_SYSLOG, you need to be licensed to use the SDSF utility. The ADMIN_INFO_SYSLOG stored procedure uses the SDSF ISFEXEC host command to issue the SDSF command MAS, and the SDSF ISFLOG host command to access the SYSLOG. These commands are issued under the security context of the user who is calling ADMIN_INFO_SYSLOG. SDSF determines the user command authority in the same way that it does when the user issues the SDSF commands MAS and LOG in an interactive mode. For more information about granting access to SDSF commands, see *z/OS SDSF Operation and Customization*.

**Syntax**

The following syntax diagram shows the SQL CALL statement for invoking this stored procedure:

```
CALL SYSPROC.ADMIN_INFO_SYSLOG(
  search-filter,
  system-name,
  start-date, start-time,
  end-date, end-time,
  max-entries,
  message)
```

**Option descriptions**

*search-filter*

Specifies a logical expression that is used to filter the SYSLOG records. If this parameter is set to NULL or is empty, filtering is not done.

A logical expression is composed of one or more operands, separated by operators. For example:

```plaintext
operand operator operand operator operand ... operator operand
```

where:

- operator is one of the following logical operators:
  - AND
  - and
  - OR
  - or

- operand is a string of characters, or a string of characters enclosed in quotation marks.

The operand is used unchanged to search and locate a system log record. Therefore, characters such as '*', '%', and '?' are not handled as masking characters.

If an operand is enclosed in quotations marks and you want to include quotation marks in the operand, use two sets of quotation marks. If an operand includes one or more blanks or the logical operators (AND, and, OR, or), enclose the string of characters in quotations marks.

For a multi-line message, each operand in the *search-filter* parameter is checked against each line of the multi-line message. A match is found if the operand is in at least one line of the multi-line message. If the operand is split over several lines, a match is not found. If the whole message satisfies the *search-filter*, the whole message is returned.
JES3 DLOG does not have a column that indicates whether a line is a continuation of a previous line. For a multi-line message, the filter is applied separately on each line in the message, and only matching lines (not the whole message) are returned.

This is an input parameter of type VARCHAR(1300).

**system-name**
Specifies the system in the sysplex where the system log entries will be processed or searched. Specify NULL if you are retrieving SYSLOG records for the z/OS subsystem where the stored procedure is running. Specify "*" (an asterisk) if you want all of the systems in a sysplex to be processed. The following restrictions apply:

- If the stored procedure is running in a JES2 system, specifying "*" causes the stored procedure to process only the logical SYSLOG of every active JES2 system in the sysplex.
- If the stored procedure is running in a JES3 system, specifying "*" causes the stored procedure to process the logical SYSLOG of every active JES3 system in the sysplex. All DLOG entries in the global SYSLOG that are within the specified time interval, which can contain messages from every JES2 and JES3 system in the sysplex, will also be returned.

This is an input parameter of type VARCHAR(8).

**start-date**
Specifies the starting date for system log records to be processed. If this parameter is set to NULL, the default is the current date.

This is an input parameter of type DATE.

**start-time**
Specifies the starting time for system log records to be processed. If this parameter is set to NULL, the default time is 00:00:00.

This is an input parameter of type TIME.

**end-date**
Specifies the ending date for system log records to be processed. If this parameter is set to NULL, the default is the current date.

This is an input parameter of type DATE.

**end-time**
Specifies the ending time for system log records to be processed. If this parameter is set to NULL, the default time is 23:59:59.

This is an input parameter of type TIME.

Together, **start-date**, **start-time**, **end-date**, and **end-time** define the date and time range for the SYSLOG records. The starting date and time must be less than the ending date and time. SDSF positions the SYSLOG as close as possible to the requested record. However, due to the precision that is used for timestamps and the time that the record is actually written to SYSLOG, the time parameters might be several lines away from the record that you want. SYSLOG records from before a specified time interval might be returned, while SYSLOG records that are closer to a specified ending date and time might not be returned.

**max-entries**
Specifies a limit for the number of SYSLOG records to be processed for each system. If this parameter is set to NULL, the default is 500. Valid values are 1 to 99999999 and -1 to -99999999.
If max-entries is a positive number, the stored procedure processes only the oldest max-entries records for a specified time interval. If the limit for records occurs in the middle of a message, the message will be truncated if returned by the stored procedure.

If max-entries is a negative number, the stored procedure processes only the most current max-entries records for the specified time interval. If the limit for records occurs in the middle of a message, the message will be truncated if returned by the stored procedure.

**Note:** If you specified the search-filter parameter, the value specified for max-entries is not the maximum number of result set rows to be returned for a system. The number of rows that are returned in a result set for a system is always less than or equal to max-entries.

This is an input parameter of type INTEGER.

**message**

Contains messages that describe errors that occurred during stored procedure processing. The first messages are generated by the stored procedure. Messages that are generated by ISFEXEC or ISFLOG might follow the stored procedure messages.

If the stored procedure completed successfully, no message is returned.

This is an output parameter of type VARCHAR(1331).

**Output**

This stored procedure returns the following output parameters, which are described in [“Option descriptions” on page 821](#):

* message

In addition to the preceding output, the stored procedure returns one result set that contains the system log records that you requested.

The following table shows the format of the result set that is returned in the created global temporary table SYSIBM.SYSLOG:

**Table 135. Result set row for ADMIN_INFO_SYSLOG result set**

<table>
<thead>
<tr>
<th>Column name</th>
<th>Data type</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>ROWNUM</td>
<td>INTEGER</td>
<td>Sequence number of the table row, from 1 to n.</td>
</tr>
<tr>
<td>TEXT</td>
<td>VARCHAR(130)</td>
<td>A system log entry. For multi-line messages, a row is returned for each line in the message.</td>
</tr>
</tbody>
</table>

The result set rows are returned in ascending order by ROWNUM. The system log records that are returned are grouped by system. Within each system, the system log records are returned in the same order as they appear in the SDSF system log.
ADMIN_INFO_SYSPARM stored procedure

The SYSPROC.ADMIN_INFO_SYSPARM stored procedure returns the system parameters, application defaults module, and IRLM parameters of a connected Db2 subsystem, or member of its data sharing group.

Environment

ADMIN_INFO_SYSPARM runs in a WLM-established stored procedures address space, where NUMTCB=1 is required.

Authorization

To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges on each package that the stored procedure uses:

- The EXECUTE privilege on the package for DSNADMIZ
- Ownership of the package
- PACKADM authority for the package collection
- SYSADM authority

The user who calls this stored procedure must have MONITOR1 privilege.

Syntax

The following syntax diagram shows the SQL CALL statement for invoking this stored procedure:

```
CALL SYSPROC.ADMIN_INFO_SYSPARM (db2-member, return-code, message)
```

Option descriptions

**db2-member**

Specifies the name of the Db2 data sharing group member that you want to get the system parameters, DSNHDECP or a user-specified application defaults module, and IRLM parameters from.

Specify NULL for this parameter if you are retrieving the system parameters, DSNHDECP values, and IRLM parameters from the connected Db2 subsystem.

This is an input parameter of type VARCHAR(8).

**return-code**

Provides the return code from the stored procedure. The following values are possible:

- 0  The call completed successfully.
- 12 The call did not complete successfully. The message output parameter
contains messages that describe the IFI error or SQL error that is encountered by the stored procedure.

This is an output parameter of type INTEGER.

**message**

Contains messages that describe the IFI error or SQL error that was encountered by the stored procedure. If an error did not occur, a message is not returned.

This is an output parameter of type VARCHAR(1331).

**Example**

The following C language sample shows how to invoke ADMIN_INFO_SYSPARM:

```c
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

/********************** DB2 SQL Communication Area **********************/
EXEC SQL INCLUDE SQLCA;

int main(int argc, char *argv[]) /* Argument count and list */ {
  /************ DB2 Host Variables *************/
  EXEC SQL BEGIN DECLARE SECTION;
  /* SYSPROC.ADMIN_INFO_SYSPARM parameters */
  char db2_member[9]; /* Data sharing group member */
  short int ind_db2_member; /* Indicator variable */
  long int retcd; /* Return code */
  short int ind_retcd; /* Indicator variable */
  char errmsg[1332]; /* Error message */
  short int ind_errmsg; /* Indicator variable */
  /* Result set locators */
  volatile SQL TYPE IS RESULT_SET_LOCATOR *rs_loc1;
  /* Result set row */
  long int rownum; /* Sequence number of the */
  /* table row (1,...,n) */
  char macro[9]; /* Macro that contains the */
  /* system parameter, or */
  /* DSNHDECP parameter, or the */
  /* name of the IRLM procedure */
  /* that z/OS invokes if IRLM */
  /* is automatically started */
  /* by DB2 */
  char parameter[41]; /* Name of the system */
  /* parameter, DSNHDECP */
  /* parameter, or IRLM */
  /* parameter */
  char install_panel[9]; /* Name of the installation */
  /* panel where the parameter */
  /* value can be changed when */
  /* installing or migrating DB2*/
  short int ind_install_panel; /* Indicator variable */
  char install_field[41]; /* Name of the parameter on */
  /* the installation panel */
  short int ind_install_field; /* Indicator variable */
  char install_location[13]; /* Location of the parameter */
  /* on the installation panel */
  short int ind_install_location; /* Indicator variable */
  char value[2049]; /* Value of the parameter */
  char additional_info[201]; /* Reserved for future use */
  short int ind_additional_info; /* Indicator variable */

  EXEC SQL END DECLARE SECTION;
```
ind_db2_member = -1;
EXEC SQL CALL SYSPROC.ADMIN_INFO_SYSPARM
  (:db2_member :ind_db2_member,
   :retcd :ind_retcd,
   :errmsg :ind_errmsg);
if (SQLCODE == +466)
  /* Result sets were returned */
  { /* Establish a link between the result set and its locator */
    EXEC SQL ASSOCIATE LOCATORS (:rs_loc1)
      WITH PROCEDURE SYSPROC.ADMIN_INFO_SYSPARM;
    /* Associate a cursor with the result set */
    EXEC SQL ALLOCATE C1 CURSOR FOR RESULT SET :rs_loc1;
    /* Perform fetches using C1 to retrieve all rows from the */
    /* result set */
    EXEC SQL FETCH C1
      INTO :rownum, :macro, :parameter,
         :install_panel :ind_install_panel,
         :install_field :ind_install_field,
         :install_location :ind_install_location,
         :value,
         :additional_info :ind_additional_info;
    while(SQLCODE==0)
      { EXEC SQL FETCH C1
        INTO :rownum, :macro, :parameter,
           :install_panel :ind_install_panel,
           :install_field :ind_install_field,
           :install_location :ind_install_location,
           :value,
           :additional_info :ind_additional_info;
      }
    EXEC SQL CLOSE C1;
  }
return(retcd);

Output

This stored procedure returns the following output parameters, which are described in "Option descriptions" on page 824:

- return-code
- message

In addition to the preceding output, the stored procedure returns one result set that contains the parameter settings.

The following table shows the format of the result set that is returned in the created global temporary table SYSIBM.DB2_SYSPARM:
### ADMIN_INFO_SYSPARM result set

<table>
<thead>
<tr>
<th>Column name</th>
<th>Data type</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>ROWNUM</td>
<td>INTEGER</td>
<td>Sequence number of the table row, from 1 to n.</td>
</tr>
<tr>

<td>VARCHAR(2048)</td>
<td>The value of the parameter.</td>
</tr>
<tr>
<td>ADDITIONAL_INFO</td>
<td>VARCHAR(200)</td>
<td>Specifies whether a parameter can be updated online. If the value is null, the stored procedure could not retrieve the information for the parameter.</td>
</tr>
</tbody>
</table>

**ADMIN_JOB_CANCEL stored procedure**

The SYSPROC.ADMIN_JOB_CANCEL stored procedure purges or cancels a job.

**Environment**

The load module for ADMIN_JOB_CANCEL, DSNADMJP, must reside in an APF-authorized library. ADMIN_JOB_CANCEL runs in a WLM-established stored procedure address space, and all libraries in this WLM procedure STEPLIB DD concatenation must be APF-authorized.

The load module for ADMIN_JOB_CANCEL, DSNADMJP, must be program controlled if the BPX.DAEMON.HFSCTL FACILITY class profile has not been set up. For information on how to define DSNADMJP to program control, see installation job DSNTIJRA.
Authorization

To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges:

- The EXECUTE privilege on the ADMIN_JOB_CANCEL stored procedure
- Ownership of the stored procedure
- SYSADM authority

The user specified in the user-ID input parameter of the SQL CALL statement also needs authorization from an external security system, such as RACF, in order to perform the requested operation.

Syntax

The following syntax diagram shows the SQL CALL statement for invoking this stored procedure:

```sql
CALL SYSPROC.ADMIN_JOB_CANCEL (user-ID, password, processing-option, job-ID, return-code, message)
```

Option descriptions

**user-ID**

Specifies the user ID under which the job is canceled or purged.

If user-ID is NULL, password must also be NULL. If the user-ID and password values are NULL, the login process uses the primary authorization ID of the process.

You can specify NULL for this parameter in the following circumstances:

- The operating system is any supported level, and the authorization ID that is associated with the stored procedure address space has daemon authority.
- The operating system is z/OS Version 1 Release 13 or later, and the authorization ID that is associated with the stored procedure address space does not have daemon authority but is authorized to the BPX.SRV.userid SURROGAT class profile, where ‘userid’ is the authorization ID of the stored procedure. In this case, you must install APAR OA36062. For more information about how the RACF security administrator can authorize the authorization ID that is associated with the stored procedure address space to a SURROGAT class profile, see [Defining servers to process users without passwords or password phrases](#).

Daemon authority is given to any superuser that is permitted to the BPX.DAEMON FACILITY class profile. If the BPX.DAEMON FACILITY class profile is not defined, all superusers have daemon authority.

This is an input parameter of type VARCHAR(128).

**password**

Specifies the password associated with the input parameter user-ID.
The value of `password` is passed to the stored procedure as part of payload, and is not encrypted. It is not stored in dynamic cache when parameter markers are used.

If `password` is NULL, `user-ID` must also be NULL. If the `user-ID` and `password` values are NULL, the login process uses the primary authorization ID of the process.

You can specify NULL for this parameter in the following circumstances:

- The operating system is any supported level, and the authorization ID that is associated with the stored procedure address space has daemon authority.
- The operating system is z/OS Version 1 Release 13 or later, and the authorization ID that is associated with the stored procedure address space does not have daemon authority but is authorized to the BPX.SRV.userid SURROGAT class profile, where 'userid' is the authorization ID of the stored procedure. In this case, you must install APAR OA36062.

This is an input parameter of type VARCHAR(24).

**processing-option**

Identifies the type of command to invoke. Possible values are:

- `1` Cancel a job.
- `2` Purge a job.

This is an input parameter of type INTEGER and cannot be null.

**job-ID**

Specifies the job ID of the job to be canceled or purged. Acceptable formats are:

- `Jnmmmmmm`  
- `JOBnmmmm`

where `n` is a digit between 0 and 9. For example: JOB01035

Both `Jnmmmmmm` and `JOBnmmmm` must be exactly 8 characters in length.

This is an input parameter of type CHAR(8) and cannot be null.

**return-code**

Provides the return code from the stored procedure. Possible values are:

- `0` The call completed successfully.
- `12` The call did not complete successfully. The `message` output parameter contains messages describing the error.

This is an output parameter of type INTEGER.

**message**

Contains messages describing the error encountered by the stored procedure. If no error occurred, then no message is returned.

The first messages in this area are generated by the stored procedure. Messages that are generated by z/OS might follow the first messages.

This is an output parameter of type VARCHAR(1331).

**Example**

The following C language sample shows how to invoke ADMIN_JOB_CANCEL:

```c
#include <stdio.h>
#include <stdlib.h>
#include <string.h>
```
EXEC SQL INCLUDE SQLCA;

int main( int argc, char *argv[] ) /* Argument count and list */ {
  /* SYSPROC.ADMIN_JOB_CANCEL parameters */
  char userid[129]; /* User ID */
  short int ind_userid; /* Indicator variable */
  char password[25]; /* Password */
  short int ind_password; /* Indicator variable */
  long int procopt; /* Processing option */
  short int ind_procopt; /* Indicator variable */
  char jobid[9]; /* Job ID */
  short int ind_jobid; /* Indicator variable */
  long int retcd; /* Return code */
  short int ind_retcd; /* Indicator variable */
  char errmsg[1332]; /* Error message */
  short int ind_errmsg; /* Indicator variable */
  EXEC SQL END DECLARE SECTION;

  /* Assign values to input parameters to purge a job */
  /* Set the indicator variables to 0 for non-null input parameters */
  strcpy(userid, "USRT001");
  ind_userid = 0;
  strcpy(password, "N1CETEST");
  ind_password = 0;
  procopt = 2;
  ind_procopt = 0;
  strcpy(jobid, "JOB00105");
  ind_jobid = 0;

  /* Call stored procedure SYSPROC.ADMIN_JOB_CANCEL */
  EXEC SQL CALL SYSPROC.ADMIN_JOB_CANCEL
    (:userid :ind_userid,
     :password :ind_password,
     :procopt :ind_procopt,
     :jobid :ind_jobid,
     :retcd :ind_retcd,
     :errmsg :ind_errmsg);

  return(retcd);
}

Output

This stored procedure returns the following output parameters, which are described in "Option descriptions" on page 828:

- return-code
- message
ADMIN_JOB_FETCH stored procedure

The SYSPROC.ADMIN_JOB_FETCH stored procedure retrieves SYSOUT from JES spool and returns the SYSOUT.

Environment

The load module for ADMIN_JOB_FETCH, DSNADMJF, must reside in an APF-authorized library. ADMIN_JOB_FETCH runs in a WLM-established stored procedure address space, and all libraries in this WLM procedure STEPLIB DD concatenation must be APF-authorized.

The load module for ADMIN_JOB_FETCH, DSNADMJF, must be program controlled if the BPX.DAEMON.HFSCTL FACILITY class profile has not been set up. For information on how to define DSNADMJF to program control, see installation job DSNTIJRA.

Authorization

To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges on each package that the stored procedure uses:

- The EXECUTE privilege on the package for DSNADMJF
- Ownership of the package
- PACKADM authority for the package collection
- SYSADM authority

Syntax

The following syntax diagram shows the SQL CALL statement for invoking this stored procedure:

```sql
CALL SYSPROC.ADMIN_JOB_FETCH(
  user-ID, password, job-ID, return-code,
  message)
```

Option descriptions

**user-ID**

Specifies the user ID under which SYSOUT is retrieved.

If `user-ID` is NULL, `password` must also be NULL. If the `user-ID` and `password` values are NULL, the login process uses the primary authorization ID of the process.

You can specify NULL for this parameter in the following circumstances:

- The operating system is any supported level, and the authorization ID that is associated with the stored procedure address space has daemon authority.
• The operating system is z/OS Version 1 Release 13 or later, and the authorization ID that is associated with the stored procedure address space does not have daemon authority but is authorized to the BPX.SRV.userid SURROGAT class profile, where 'userid' is the authorization ID of the stored procedure. In this case, you must install APAR OA36062. For more information about how the RACF security administrator can authorize the authorization ID that is associated with the stored procedure address space to a SURROGAT class profile, see [Defining servers to process users without passwords or password phrases](#).

Daemon authority is given to any superuser that is permitted to the BPX.DAEMON FACILITY class profile. If the BPX.DAEMON FACILITY class profile is not defined, all superusers have daemon authority.

This is an input parameter of type VARCHAR(128).

**password**

Specifies the password associated with the input parameter `user-ID`.

The value of `password` is passed to the stored procedure as part of payload, and is not encrypted. It is not stored in dynamic cache when parameter markers are used.

If `password` is NULL, `user-ID` must also be NULL. If the `user-ID` and `password` values are NULL, the login process uses the primary authorization ID of the process.

You can specify NULL for this parameter in the following circumstances:

• The operating system is any supported level, and the authorization ID that is associated with the stored procedure address space has daemon authority.

• The operating system is z/OS Version 1 Release 13 or later, and the authorization ID that is associated with the stored procedure address space does not have daemon authority but is authorized to the BPX.SRV.userid SURROGAT class profile, where 'userid' is the authorization ID of the stored procedure. In this case, you must install APAR OA36062.

This is an input parameter of type VARCHAR(24).

**job-ID**

Specifies the JES2 or JES3 job ID whose SYSOUT data sets are to be retrieved.

This is an input parameter of type CHAR(8) and cannot be null.

**return-code**

Provides the return code from the stored procedure. Possible values are:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>The call completed successfully.</td>
</tr>
<tr>
<td>12</td>
<td>The call did not complete successfully. The <code>message</code> output parameter contains messages describing the error.</td>
</tr>
</tbody>
</table>

This is an output parameter of type INTEGER.

**message**

Contains messages describing the error encountered by the stored procedure. If no error occurred, then no message is returned.

The first messages in this area are generated by the stored procedure. Messages that are generated by Db2 might follow the first messages.

This is an output parameter of type VARCHAR(1331).
Example

The following C language sample shows how to invoke ADMIN_JOB_FETCH:

```c
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

/********************
* DB2 SQL Communication Area *******************/
EXEC SQL INCLUDE SQLCA;

int main(int argc, char *argv[]) { /* Argument count and list */
    /******************
* DB2 Host Variables *****************************/
EXEC SQL BEGIN DECLARE SECTION;

    /* SYSPROC.ADMIN_JOB_FETCH parameters */
    char userid[129]; /* User ID */
    short int ind_userid; /* Indicator variable */
    char password[25]; /* Password */
    short int ind_password; /* Indicator variable */
    char jobid[9]; /* Job ID */
    short int ind_jobid; /* Indicator variable */
    long int retcd; /* Return code */
    short int ind_retcd; /* Indicator variable */
    char errmsg[1332]; /* Error message */
    short int ind_errmsg; /* Indicator variable */

    /* Result set locators */
    volatile SQL TYPE IS RESULT_SET_LOCATOR *rs_loc1;

    /* Result set row */
    long int rownum; /* Sequence number of the */
    /* table row */
    char text[4097]; /* A row in SYSOUT data set */

EXEC SQL END DECLARE SECTION;

/********************
* Assign values to input parameters to fetch the SYSOUT of a job */
* Set the indicator variables to 0 for non-null input parameters */
EXEC SQL CALL SYSPROC.ADMIN_JOB_FETCH (:userid :ind_userid,
:password :ind_password,
:jobid :ind_jobid,
:retcd :ind_retcd,
:errmsg :ind_errmsg);

/********************
* Retrieve result set when the SQLCODE from the call is +466, *
* which indicates that result sets were returned *
EXEC SQL ASSOCIATE LOCATORS (:rs_loc1) WITH PROCEDURE SYSPROC.ADMIN_JOB_FETCH;
```
/* Associate a cursor with the result set */
EXEC SQL ALLOCATE C1 CURSOR FOR RESULT SET :rs_loc1;

/* Perform fetches using C1 to retrieve all rows from the result set */
EXEC SQL FETCH C1 INTO :rownum, :text;
while(SQLCODE==0)
{
  EXEC SQL FETCH C1 INTO :rownum, :text;
}
EXEC SQL CLOSE C1;
}

return(retcd);
}

Output

This stored procedure returns the following output parameters, which are described in "Option descriptions" on page 831:

- return-code
- message

In addition to the preceding output, the stored procedure returns one result set that contains the data from the JES-managed SYSOUT data set that belong to the job ID specified in the input parameter job-ID.

The following table shows the format of the result set returned in the created global temporary table SYSIBM.JES_SYSOUT:

<table>
<thead>
<tr>
<th>Column name</th>
<th>Data type</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>ROWNUM</td>
<td>INTEGER</td>
<td>Sequence number of the table row</td>
</tr>
<tr>
<td>TEXT</td>
<td>VARCHAR(4096)</td>
<td>A record in the SYSOUT data set</td>
</tr>
</tbody>
</table>

ADMIN_JOB_QUERY stored procedure

The SYSPROC.ADMIN_JOB_QUERY stored procedure displays the status and completion information about a job.

Environment

The load module for ADMIN_JOB_QUERY, DSNADMJQ, must reside in an APF-authorized library. ADMIN_JOB_QUERY runs in a WLM-established stored procedure address space, and all libraries in this WLM procedure STEPLIB DD concatenation must be APF-authorized.
The load module for ADMIN_JOB_QUERY, DSNADMJQ, must be program controlled if the BPX.DAEMON.HFSCTL FACILITY class profile has not been set up. For information on how to define DSNADMJQ to program control, see installation job DSNTIJRA.

Authorization

To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges:

- The EXECUTE privilege on the ADMIN_JOB_QUERY stored procedure
- Ownership of the stored procedure
- SYSADM authority

Syntax

The following syntax diagram shows the SQL CALL statement for invoking this stored procedure:

```
CALL SYSPROC.ADMIN_JOB_QUERY((user-ID, NULL, password, NULL, job-ID, status, max-RC,
 completion-type, system-abend-code, user-abend-code, return-code, message))
```

Option descriptions

**user-ID**

Specifies the user ID under which the job is queried.

If **user-ID** is NULL, **password** must also be NULL. If the **user-ID** and **password** values are NULL, the login process uses the primary authorization ID of the process.

You can specify NULL for this parameter in the following circumstances:

- The operating system is any supported level, and the authorization ID that is associated with the stored procedure address space has daemon authority.
- The operating system is z/OS Version 1 Release 13 or later, and the authorization ID that is associated with the stored procedure address space does not have daemon authority but is authorized to the BPX.SRV.userid SURROGAT class profile, where 'userid' is the authorization ID of the stored procedure. In this case, you must install APAR OA36062. For more information about how the RACF security administrator can authorize the authorization ID that is associated with the stored procedure address space to a SURROGAT class profile, see [Defining servers to process users without passwords or password phrases](#).

Daemon authority is given to any superuser that is permitted to the BPX.DAEMON FACILITY class profile. If the BPX.DAEMON FACILITY class profile is not defined, all superusers have daemon authority.

This is an input parameter of type VARCHAR(128).

**password**

Specifies the password associated with the input parameter **user-ID**.
The value of password is passed to the stored procedure as part of payload, and is not encrypted. It is not stored in dynamic cache when parameter markers are used.

If password is NULL, user-ID must also be NULL. If the user-ID and password values are NULL, the login process uses the primary authorization ID of the process.

You can specify NULL for this parameter in the following circumstances:
- The operating system is any supported level, and the authorization ID that is associated with the stored procedure address space has daemon authority.
- The operating system is z/OS Version 1 Release 13 or later, and the authorization ID that is associated with the stored procedure address space does not have daemon authority but is authorized to the BPX.SRV.userid SURROGAT class profile, where ‘userid’ is the authorization ID of the stored procedure. In this case, you must install APAR OA36062.

This is an input parameter of type VARCHAR(24).

**job-ID**
Speifies the job ID of the job being queried. Acceptable formats are:
- Jnnnnnnn
- JOBnnnnnn

where n is a digit between 0 and 9. For example: JOB01035

Both Jnnnnnnn and JOBnnnnnn must be exactly 8 characters in length.

This is an input parameter of type CHAR(8) and cannot be null.

**status**
Identifies the current status of the job. Possible values are:

1. Job received, but not yet run (INPUT).
2. Job running (ACTIVE).
3. Job finished and has output to be printed or retrieved (OUTPUT).
4. Job not found.
5. Job in an unknown phase.

This is an output parameter of type INTEGER.

**max-RC**
Provides the job completion code.

This parameter is always null if querying in a JES3 z/OS Version 1.7 or earlier system. For JES3, this feature is only supported for z/OS Version 1.8 or higher.

This is an output parameter of type INTEGER.

**completion-type**
Identifies the job's completion type. Possible values are:

0. No completion information is available.
1. Job ended normally.
2. Job ended by completion code.
3. Job had a JCL error.
4. Job was canceled.
5. Job terminated abnormally.
Converter terminated abnormally while processing the job.

Job failed security checks.

Job failed in end-of-memory.

This parameter is always null if querying in a JES3 z/OS Version 1.7 or earlier system. For JES3, this feature is only supported for z/OS Version 1.8 or higher.

The completion-type information is the last six bits in the field STTRMXRC of the IAZSSST mapping macro. This information is returned via SSI 80. For additional information, see the discussion of the SSST macro in z/OS MVS Data Areas.

This is an output parameter of type INTEGER.

**system-abend-code**

Returns the system abend code if an abnormal termination occurs.

This parameter is always null if querying in a JES3 z/OS Version 1.7 or earlier system. For JES3, this feature is only supported for z/OS Version 1.8 or higher.

This is an output parameter of type INTEGER.

**user-abend-code**

Returns the user abend code if an abnormal termination occurs.

This parameter is always null if querying in a JES3 z/OS Version 1.7 or earlier system. For JES3, this feature is only supported for z/OS Version 1.8 or higher.

This is an output parameter of type INTEGER.

**return-code**

Provides the return code from the stored procedure. Possible values are:

0  The call completed successfully.
4  The job was not found, or the job status is unknown.
12 The call did not complete successfully. The message output parameter contains messages describing the error.

This is an output parameter of type INTEGER.

**message**

Contains messages describing the error encountered by the stored procedure. If no error occurred, then no message is returned.

This is an output parameter of type VARCHAR(1331).

**Example**

The following C language sample shows how to invoke ADMIN_JOB_QUERY:

```c
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

/******************** DB2 SQL Communication Area *******************/
EXEC SQL INCLUDE SQLCA;

int main(int argc, char *argv[]) /* Argument count and list */ {
    /* DB2 Host Variables */
    EXEC SQL BEGIN DECLARE SECTION;

    /* SYSPROC.ADMIN_JOB_QUERY parameters */
    char userid[129]; /* User ID */
```

Chapter 5. Procedures that are supplied with Db2
short int  ind_userid; /* Indicator variable */
char       password[25]; /* Password */
short int  ind_password; /* Indicator variable */
char       jobid[9]; /* Job ID */
short int  ind_jobid; /* Indicator variable */
long int   stat; /* Job status */
short int  ind_stat; /* Indicator variable */
long int   maxrc; /* Job maxcc */
short int  ind_maxrc; /* Indicator variable */
long int   comptype; /* Job completion type */
short int  ind_comptype; /* Indicator variable */
long int   sabndcd; /* System abend code */
short int  ind_sabndcd; /* Indicator variable */
long int   uabndcd; /* User abend code */
short int  ind_uabndcd; /* Indicator variable */
long int   retcd; /* Return code */
short int  ind_retcd; /* Indicator variable */
char       errmsg[1332]; /* Error message */
short int  ind_errmsg; /* Indicator variable */
EXEC SQL END DECLARE SECTION;

/*******************************************************************/
/* Assign values to input parameters to query the status and */
/* completion code of a job */
/* Set the indicator variables to 0 for non-null input parameters */
/*******************************************************************/
strcpy(userid, "USRT001");
ind_userid = 0;
strcpy(password, "N1CETEST");
ind_password = 0;
strcpy(jobid, "JOB00111");
ind_jobid = 0;

/*******************************************************************/
/* Call stored procedure SYSPROC.ADMIN_JOB_QUERY */
/*******************************************************************/
EXEC SQL CALL SYSPROC.ADMIN_JOB_QUERY
  (:userid :ind_userid,
    :password :ind_password,
    :jobid :ind_jobid,
    :stat :ind_stat,
    :maxrc :ind_maxrc,
    :comptype :ind_comptype,
    :sabndcd :ind_sabndcd,
    :uabndcd :ind_uabndcd,
    :retcd :ind_retcd,
    :errmsg :ind_errmsg);

return(retcd);
} }

Output

This stored procedure returns the following output parameters, which are described in “Option descriptions“ on page 835:

- status
- max-RC
- completion-type
- system-abend-code
- user-abend-code
- return-code
- message
ADMIN_JOB_SUBMIT stored procedure

The SYSPROC.ADMIN_JOB_SUBMIT stored procedure submits a job to a JES2 or JES3 system.

Environment

ADMIN_JOB_SUBMIT runs in a WLM-established stored procedure address space.

The load module for ADMIN_JOB_SUBMIT, DSNADMJS, must be program controlled if the BPX.DAEMON.HFSCTL FACILITY class profile has not been set up. For information on how to define DSNADMJS to program control, see installation job DSNTIJRA.

Authorization

To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges on each package that the stored procedure uses:

• The EXECUTE privilege on the package for DSNADMJS
• Ownership of the package
• PACKADM authority for the package collection
• SYSADM authority

Syntax

The following syntax diagram shows the SQL CALL statement for invoking this stored procedure:

```
CALL SYSPROC.ADMIN_JOB_SUBMIT (user-ID, password, job-ID, return-code, message)
```

Option descriptions

**user-ID**

Specifies the user ID under which the job is submitted.

If user-ID is NULL, password must also be NULL. If the user-ID and password values are NULL, the login process uses the primary authorization ID of the process.

You can specify NULL for this parameter in the following circumstances:

• The operating system is any supported level, and the authorization ID that is associated with the stored procedure address space has daemon authority.
• The operating system is z/OS Version 1 Release 13 or later, and the 
authorization ID that is associated with the stored procedure address space
does not have daemon authority but is authorized to the BPX.SRV.userid
SURROGAT class profile, where 'userid' is the authorization ID of the stored
procedure. In this case, you must install APAR OA36062. For more
information about how the RACF security administrator can authorize the
authorization ID that is associated with the stored procedure address space
to a SURROGAT class profile, see [Defining servers to process users without
passwords or password phrases](#). 

Daemon authority is given to any superuser that is permitted to the
BPX.DAEMON FACILITY class profile. If the BPX.DAEMON FACILITY class
profile is not defined, all superusers have daemon authority.

This is an input parameter of type VARCHAR(128).

**password**

Specifies the password associated with the input parameter *user-ID*.

The value of *password* is passed to the stored procedure as part of payload and
is not encrypted. It is not stored in dynamic cache when parameter markers
are used.

If *password* is NULL, *user-ID* must also be NULL. If the *user-ID* and *password*
values are NULL, the login process uses the primary authorization ID of the
process.

You can specify NULL for this parameter in the following circumstances:

• The operating system is any supported level, and the authorization ID that
is associated with the stored procedure address space has daemon authority.

• The operating system is z/OS Version 1 Release 13 or later, and the
authorization ID that is associated with the stored procedure address space
does not have daemon authority but is authorized to the BPX.SRV.userid
SURROGAT class profile, where 'userid' is the authorization ID of the stored
procedure. In this case, you must install APAR OA36062.

This is an input parameter of type VARCHAR(24).

**job-ID**

Identifies the JES2 or JES3 job ID of the submitted job.

This is an output parameter of type CHAR(8).

**return-code**

Provides the return code from the stored procedure. Possible values are:

0       The call completed successfully.

12      The call did not complete successfully. The *message* output parameter
contains messages describing the error.

This is an output parameter of type INTEGER.

**message**

Contains messages describing the error encountered by the stored procedure. If
no error occurred, then no message is returned.

The first messages in this area are generated by the stored procedure. Messages
that are generated by Db2 might follow the first messages.

This is an output parameter of type VARCHAR(1331).
**Additional input**

In addition to the input parameters, the stored procedure submits the job's JCL from the created global temporary table SYSIBM.JOB_JCL for execution.

The following table shows the format of the created global temporary table SYSIBM.JOB_JCL:

<table>
<thead>
<tr>
<th>Column name</th>
<th>Data type</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>ROWNUM</td>
<td>INTEGER</td>
<td>Sequence number of the table row, from 1 to n</td>
</tr>
<tr>
<td>STMT</td>
<td>VARCHAR(80)</td>
<td>A JCL statement</td>
</tr>
</tbody>
</table>

**Example**

The following C language sample shows how to invoke ADMIN_JOB_SUBMIT:

```c
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

/********************
* DB2 SQL Communication Area *************/
EXEC SQL INCLUDE SQLCA;

int main(int argc, char *argv[]) { /* Argument count and list */
  EXEC SQL BEGIN DECLARE SECTION;

  /* SYSPROC.ADMIN_JOB_SUBMIT parameters */
  char userid[129]; /* User ID */
  short int ind_userid; /* Indicator variable */
  char password[25]; /* Password */
  short int ind_password; /* Indicator variable */
  char jobid[9]; /* Job ID */
  short int ind_jobid; /* Indicator variable */
  long int retcd; /* Return code */
  short int ind_retcd; /* Indicator variable */
  char errmsg[1332]; /* Error message */
  short int ind_errmsg; /* Indicator variable */

  /* Temporary table SYSIBM.JOB_JCL columns */
  long int rownum; /* Sequence number of the */
  /* table row */
  char stmt[81]; /* JCL statement */

  EXEC SQL END DECLARE SECTION;

  /******************************************************************************/
  /* Create the JCL job to be submitted for execution */
  /******************************************************************************/
  char jclstmt[12][50] = { "//IEBCOPY JOB ,CLASS=K,MSGCLASS=H,MSGLEVEL=(1,1)"
                              "//STEP010 EXEC PGM=IEBCOPY"
                              "//SYSPRINT DD SYSOUT="
                              "//SYSUT3 DD SPACE=(TRK,(1,1)),UNIT=SYSDA"
                              "//SYSUT4 DD SPACE=(TRK,(1,1)),UNIT=SYSDA"
                              "/*",
                              "//DDI1 DD DSN=USER.DEV.LOADLIB1,DISP=SHR"
                              "//DDO1 DD DSN=USER.DEV.LOADLIB2,DISP=SHR"
                              "//SYSIN *
                              "COPY OUTDD=DDO1,INDD=DDI1",
                              "/*"),
```

Chapter 5. Procedures that are supplied with Db2  841
"*/
}
int i = 0;  /* loop counter  */

/**************************************************************
/* Assign values to input parameters */
/* Set the indicator variables to 0 for non-null input parameters */
/**************************************************************
strcpy(userid, "USRT001");
ind_userid = 0;
strcpy(password, "NICTEST");
ind_password = 0;

/**************************************************************
/* Clear temporary table SYSIBM.JOB_JCL */
/**************************************************************
EXEC SQL DELETE FROM SYSIBM.JOB_JCL;

/**************************************************************
/* Insert the JCL job into the temporary table SYSIBM.JOB_JCL */
/**************************************************************
for (i = 0; i < 12; i++)
{
    rownum = i+1;
    strcpy(stmt, jclstmt[i]);
    EXEC SQL INSERT INTO SYSIBM.JOB_JCL
    (ROWNUM, STMT)
    VALUES (:rownum, :stmt);
}

/**************************************************************
/* Call stored procedure SYSPROC.ADMIN_JOB_SUBMIT */
/**************************************************************
EXEC SQL CALL SYSPROC.ADMIN_JOB_SUBMIT
    (:userid  :ind_userid,
     :password  :ind_password,
     :jobid  :ind_jobid,
     :retcd  :ind_retcd,
     :errmsg  :ind_errmsg);

return(retcd);
}

Output

This stored procedure returns the following output parameters, which are described in "Option descriptions" on page 839:

- job-ID
- return-code
- message

ADMIN_TASK_ADD stored procedure

The SYSPROC.ADMIN_TASK_ADD stored procedure adds a task to the task list of the administrative task scheduler.
**Environment**

ADMIN_TASK_ADD runs in a WLM-established stored procedure address space and uses the Resource Recovery Services attachment facility to connect to Db2.

**Authorization**

Anyone who can execute this Db2 stored procedure is allowed to add a task.

The user who calls this stored procedure must have MONITOR1 privilege.

**Syntax**

The following syntax diagram shows the SQL CALL statement for invoking this stored procedure:

```
CALL SYSPROC.ADMIN_TASK_ADD(
  user-ID, password, begin-timestamp, NULL,
  NULL, NULL, end-timestamp, max-invocations,

**begin-timestamp**

Specifies when a task can first begin execution. When task execution begins depends on how this and other parameters are set:

**Non-null value for begin-timestamp**

At **begin-timestamp**

The task execution begins at **begin-timestamp** if **point-in-time** and **trigger-task-name** are NULL.

Next point in time defined at or after **begin-timestamp**

The task execution begins at the next point in time defined at or after **begin-timestamp** if **point-in-time** is non-null.

When **trigger-task-name completes at or after begin-timestamp**

The task execution begins the next time that **trigger-task-name** completes at or after **begin-timestamp**.

**Null value for begin-timestamp**

Immediately

The task execution begins immediately if **point-in-time** and **trigger-task-name** are NULL.

Next point in time defined

The task execution begins at the next point in time defined if **point-in-time** is non-null.

When **trigger-task-name completes**

The task execution begins the next time that **trigger-task-name** completes.

The value of this parameter cannot be in the past, and it cannot be later than **end-timestamp**.

This is an input parameter of type TIMESTAMP.

**end-timestamp**

Specifies when a task can last begin execution. If this parameter is set to NULL, then the task can continue to execute as scheduled indefinitely.

The value of this parameter cannot be in the past, and it cannot be earlier than **begin-timestamp**.

This is an input parameter of type TIMESTAMP.

**max-invocations**

Specifies the maximum number of executions allowed for a task. This value applies to all schedules: triggered by events, recurring by time interval, and recurring by points in time. If this parameter is set to NULL, then there is no limit to the number of times this task can execute.

For tasks that execute only one time, **max-invocations** must be set to 1 and **interval**, **point-in-time** and **trigger-task-name** must be NULL.

If both **end-timestamp** and **max-invocations** are specified, the first limit reached takes precedence. That is, if **end-timestamp** is reached, even though the number of task executions so far has not reached **max-invocations**, the task will not be executed again. If **max-invocations** have occurred, the task will not be executed again even if **end-timestamp** is not reached.

This is an input parameter of type INTEGER.

**interval**

Defines a duration in minutes between two executions of a repetitive regular
task. The first execution occurs at `begin-timestamp`. If this parameter is set to NULL, the task is not regularly executed. If this parameter contains a non-null value, the parameters `point-in-time` and `trigger-task-name` must be set to NULL.

This is an input parameter of type INTEGER.

**point-in-time**
Defines one or more points in time when a task is executed. If this parameter is set to NULL, the task is not scheduled at fixed points in time. If this parameter contains a non-null value, the parameters `interval` and `trigger-task-name` must be set to NULL.

The `point-in-time` string uses the UNIX cron format. The format contains the following pieces of information separated by blanks: given minute or minutes, given hour or hours, given day or days of the month, given month or months of the year, and given day or days of the week. For each part, you can specify one or several values, ranges, and so forth.

This is an input parameter of type VARCHAR(400).

**trigger-task-name**
Specifies the name of the task which, when its execution is complete, will trigger the execution of this task.

Task names of DB2START and DB2STOP are reserved for Db2 stop and start events respectively. Those events are handled by the scheduler associated with the Db2 subsystem that is starting or stopping.

If this parameter is set to NULL, the execution of this task will not be triggered by another task. If this parameter contains a non-null value, the parameters `interval` and `point-in-time` must be set to NULL.

This is an input parameter of type VARCHAR(128).

**trigger-task-cond**
Specifies the type of comparison to be made to the return code after the execution of task `trigger-task-name`. Possible values are:

- GT  Greater than
- GE  Greater than or equal to
- EQ  Equal to
- LT  Less than
- LE  Less than or equal to
- NE  Not equal to

If this parameter is set to NULL, the task execution is triggered without considering the return code of task `trigger-task-name`. This parameter must be set to NULL if `trigger-task-name` is set to NULL or is either DB2START or DB2STOP.

This is an input parameter of type CHAR(2).

**trigger-task-code**
Specifies the return code from executing `trigger-task-name`.

If the execution of this task is triggered by a stored procedure, `trigger-task-code` contains the SQLCODE that must be returned by the triggering stored procedure in order for this task to execute.
If the execution of this task is triggered by a JCL job, \textit{trigger-task-code} contains the MAXRC that must be returned by the triggering job in order for this task to execute.

To find out what the MAXRC or SQLCODE of a task is after execution, invoke the user-defined function DSNADM. \texttt{ADMIN_TASK_STATUS} returns these information in the columns MAXRC and SQLCODE.

The following restrictions apply to the value of \textit{trigger-task-code}:
\begin{itemize}
  \item If \textit{trigger-task-cond} is null, then \textit{trigger-task-code} must also be null.
  \item If \textit{trigger-task-cond} is non-null, then \textit{trigger-task-code} must also be non-null.
\end{itemize}

If \textit{trigger-task-cond} and \textit{trigger-task-code} are not null, they are used to test the return code from executing \textit{trigger-task-name} to determine whether to execute this task or not.

For example, if \textit{trigger-task-cond} is set to "GE" and \textit{trigger-task-code} is set to "8", then this task will execute if and only if the previous execution of \textit{trigger-task-name} returned a MAXRC (for a JCL job) or an SQLCODE (for a stored procedure) greater than or equal to 8.

This is an input parameter of type INTEGER.

\textit{db2-ssid}

Specifies the Db2 subsystem ID whose associated scheduler should execute the task.

This parameter is used in a data sharing environment where, for example different Db2 members have different configurations and executing the task relies on a certain environment. However, specifying a value in \textit{db2-ssid} will prevent schedulers of other members to execute the task, so that the task can only be executed as long as the scheduler of \textit{db2-ssid} is running.

For a task being triggered by a Db2 start or Db2 stop event in \textit{trigger-task-name}, specifying a value in \textit{db2-ssid} will let the task be executed only when the named subsystem is starting and stopping. If no value is given, each member that starts or stops will trigger a local execution of the task, provided that the executions are serialized.

If this parameter is set to NULL, any scheduler can execute the task.

This is an input parameter of type VARCHAR(4).

\textit{procedure-schema}

Specifies the schema of the Db2 stored procedure this task will execute. If this parameter is set to NULL, Db2 uses a default schema. This parameter must be set to NULL if \textit{procedure-name} is set to NULL.

This is an input parameter of type VARCHAR(128).

\textit{procedure-name}

Specifies the name of the Db2 stored procedure this task will execute. If this parameter is set to NULL, no stored procedure will be called. In this case, a JCL job must be specified.

This is an input parameter of type VARCHAR(128).

\textit{procedure-input}

Specifies the input parameters of the Db2 stored procedure this task will execute. This parameter must contain a Db2 SELECT statement that returns one row of data. The returned values will be passed as parameter to the stored procedure.
If this parameter is set to NULL, no parameters are passed to the stored procedure. This parameter must be set to NULL when *procedure-name* is set to NULL.

This is an input parameter of type VARCHAR(4096).

**JCL-library**

Specifies the name of the data set where the JCL job to be executed is saved.

If this parameter is set to NULL, no JCL job will be executed. In this case, a stored procedure must be specified.

This is an input parameter of type VARCHAR(44).

**JCL-member**

Specifies the name of the library member where JCL job to be executed is saved.

If this parameter is set to NULL, the data set specified in *JCL-library* must be sequential and contain the JCL job to be executed. This parameter must be set to NULL if *JCL-library* is set to NULL.

This is an input parameter of type VARCHAR(8).

**job-wait**

Specifies whether the job can be executed synchronously or not. This parameter can only be set to NULL if *JCL-library* is set to NULL. Otherwise, it must be one of the following values:

- NO    Asynchronous execution
- YES   Synchronous execution
- PURGE Synchronous execution after which the job status in z/OS is purged

This is an input parameter of type VARCHAR(8).

**task-name**

Specifies a unique name assigned to the task.

A unique task name is returned when the task is created with a NULL *task-name* value. This name is of the format “TASK_ID_xxxx” where xxxx is 0001 for the first task named, 0002 for the second task, and so forth.

The following task names are reserved and cannot be given as the value of *task-name*:
- Names starting with “TASK_ID_”
- DB2START
- DB2STOP

This is an input-output parameter of type VARCHAR(128).

**description**

Specifies a description assigned to the task.

This is an input parameter of type VARCHAR(128).

**return-code**

Provides the return code from the stored procedure. Possible values are:

- 0    The call completed successfully.
- 12   The call did not complete successfully. The *message* output parameter contains messages describing the error.
message

Contains messages describing the error encountered by the stored procedure. The first messages in this area, if any, are generated by the stored procedure. Messages that are generated by Db2 might follow the first messages.

This is an output parameter of type VARCHAR(1331).

Example

The following Java sample shows how to invoke ADMIN_TASK_ADD:

```java
import java.sql.CallableStatement;
import java.sql.Connection;
import java.sql.DriverManager;
import java.sql.Statement;
import java.sql.Timestamp;
import java.sql.Types;

Connection con = DriverManager.getConnection("jdbc:db2://myserver:myport/mydatabase", "myuser", "mypassword");
// provide the authid
callStmt.setString(1, "myexecuser");
// provide the password
callStmt.setString(2, "myexecpwd");
// set the start time to now
callStmt.setNull(3, Types.TIMESTAMP);
// no end time
callStmt.setNull(4, Types.TIMESTAMP);
// set the max invocation
callStmt.setInt(5, 1);
// This is a non recurrent task
callStmt.setNull(6, Types.INTEGER);
callStmt.setNull(7, Types.VARCHAR);
callStmt.setNull(8, Types.VARCHAR);
callStmt.setNull(9, Types.CHAR);
callStmt.setNull(10, Types.INTEGER);
callStmt.setNull(11, Types.VARCHAR);
// provide the stored procedure schema
callStmt.setString(12, "MYSCHEMA");
// provide the name of the stored procedure to be executed
callStmt.setString(13, "MYPROC");
// provide the stored procedure input parameter
callStmt.setString(14, "SELECT 1 FROM SYSDUMMY1");
// This is not a JCL job
callStmt.setNull(15, Types.VARCHAR);
callStmt.setNull(16, Types.VARCHAR);
callStmt.setNull(17, Types.VARCHAR);
// add a new task with task name mytask
callStmt.setString(18, "mytask");
callStmt.registerOutParameter(18, Types.VARCHAR);
// provide the task description
callStmt.setString(19, "MY DESCRIPTION");
// register output parameters for error management
callStmt.registerOutParameter(20, Types.INTEGER);
callStmt.registerOutParameter(21, Types.VARCHAR);
// execute the statement
callStmt.execute();
// manage the return code
if (callStmt.getInt(20) == 0)
{
    System.out.println("\nSuccessfully added task " + callStmt.getString(18));
}
```
else
{
    System.out.print("\nError code and message are: "+callStmt.getInt(20)+"/"+callStmt.getString(21));
}

Output

The output of this stored procedure is the task name, task-name and the following output parameters, which are described in "Option descriptions" on page 843:

- return-code
- message

Related tasks:

[Adding a task (Db2 Administration Guide)]

**ADMIN_TASK_CANCEL** stored procedure

The ADMIN_TASK_CANCEL stored procedure attempts to stop the execution of a task that is currently running.

For a task that is running, the stored procedure cancels the Db2 thread or the JES job that the task runs in, and issues a return code of 0 (zero). If the task is not running or if cancellation of the task cannot be initiated, the stored procedure issues a return code of 12.

Not all tasks can be canceled as requested. Only the administrative task scheduler that currently executes the task can cancel a JCL task or a stored procedure task. Call the ADMIN_TASK_CANCEL stored procedure on the Db2 subsystem that is specified in the DB2_SSID column of the task status.

**Environment**

ADMIN_TASK_CANCEL runs in a WLM-established stored procedure address space and uses the Resource Recovery Services attachment facility to connect to Db2.

**Authorization**

To call this stored procedure, you must have MONITOR1 privilege.

Anyone with SYSOPR, SYSCtrl, or SYSADM authority can call this stored procedure on any task. Anyone who has EXECUTE authority on this stored procedure can call it on tasks that they added. If you try to cancel the execution of a task that was added by a different user, an error is returned in the output.

The task is canceled under the authorization context of the user that currently calls the ADMIN_TASK_CANCEL stored procedure, as defined in CURRENT SQLID. To cancel a stored procedure task, you must have authority to call the Db2 command CANCEL THREAD. To cancel a JCL task, you must have UPDATE authority in RACF.
on the resource MVS.CANCELJOB.jobname.

**Syntax**

The following syntax diagram shows the SQL CALL statement for invoking this stored procedure:

```sql
CALL ADMIN_TASK_CANCEL(task-name, return-code, message)
```

**Option descriptions**

**task-name**

Specifies the unique name of the task whose execution you want to cancel. This is an input parameter of type VARCHAR(128).

**return-code**

Provides the return code from the stored procedure. Possible values are:

- **0**: The call completed successfully.
- **12**: The call did not complete successfully. The `message` output parameter contains messages describing the error.

This is an output parameter of type INTEGER.

**message**

Contains messages describing the error encountered by the stored procedure. The first messages in this area, if any, are generated by the stored procedure. Messages that are generated by Db2 might follow the stored procedure messages.

This is an output parameter of type VARCHAR(1331).

**Output**

This stored procedure has the following output parameters, which are described in Option descriptions:

- **return-code**
- **message**

**Related tasks:**

- [Stopping the execution of a task (Db2 Administration Guide)](#)

**ADMIN_TASK_REMOVE stored procedure**

The `SYSPROC.ADMIN_TASK_REMOVE` stored procedure removes a task from the task list of the administrative task scheduler.

If the task is running, the task continues to execute until completion and is not removed from the task list. If other tasks depend on the execution of the task that is to be removed, the task is not removed from the task list of the administrative task scheduler.
Environment

See the recommended environment in installation job DSNTIJRA.

Authorization

Users with SYSOPR, SYSCTRL, or SYSADM authority can remove any task. Other users who have EXECUTE authority on this stored procedure can remove tasks that they added. Attempting to remove a task that was added by a different user returns an error in the output.

The user who calls this stored procedure must have MONITOR1 privilege.

Syntax

The following syntax diagram shows the SQL CALL statement for invoking this stored procedure:

```
CALL SYSPROC.ADMIN_TASK_REMOVE(task-name, return-code, message)
```

Option descriptions

task-name

Specifies the name of the task to be removed from the task list of the administrative task scheduler.

This is an input parameter of type VARCHAR(128) and cannot be null.

return-code

Provides the return code from the stored procedure. Possible values are:

0 The call completed successfully.

12 The call did not complete successfully. The message output parameter contains messages describing the error.

This is an output parameter of type INTEGER.

message

Contains messages describing the error encountered by the stored procedure. The first messages in this area, if any, are generated by the stored procedure. Messages that are generated by Db2 might follow the stored procedure messages.

This is an output parameter of type VARCHAR(1331).

Example

The following Java sample shows how to invoke ADMIN_TASK_REMOVE:

```java
import java.sql.CallableStatement;
import java.sql.Connection;
import java.sql.DriverManager;
import java.sql.Statement;
```
import java.sql.Timestamp;
import java.sql.Types;

Connection con = 
    DriverManager.getConnection("jdbc:db2://myserver:myport/mydatabase",
    "myuser", "mypassword");
CallableStatement callStmt =
    con.prepareCall("CALL SYSPROC.ADMIN_TASK_REMOVE(?,:,?)");
// provide the id of the task to be removed
callStmt.setString(1, "mytask");
// register output parameters for error management
callStmt.registerOutParameter(2, Types.INTEGER);
callStmt.registerOutParameter(3, Types.VARCHAR);
// execute the statement callStmt.execute();
// manage the return code
if (callStmt.getInt(2) == 0)
{
    System.out.print("\nSuccessfully removed task "+callStmt.getString(1));
}
else
{
    System.out.print("\nError code and message are: "+callStmt.getInt(2)+"/"+callStmt.getString(3));
}

Output

The output of this stored procedure includes the following output parameters, which are described in “Option descriptions” on page 851:

- return-code
- message

** ADMIN_TASK_UPDATE stored procedure **

The ADMIN_TASK_UPDATE stored procedure updates the schedule of a task that is in the task list for the administrative task scheduler. If the task that you want to update is running, the changes go into effect after the current execution finishes.

You must specify all of the parameters for the task that you want to modify the schedule for, even if those parameters have not changed since you created the task by using the ADMIN_TASK_ADD stored procedure.
Environment

ADMIN_TASK_UPDATE runs in a WLM-established stored procedure address space and uses the Resource Recovery Services attachment facility to connect to Db2.

Authorization

To call this stored procedure, you must have MONITOR1 privilege.

Anyone with SYSOPR, SYSCTRL, or SYSADM authority can update any task. Anyone who has EXECUTE authority on this stored procedure can update tasks that they added. If you try to update a task that was added by a different user, an error is returned in the output.

Syntax

The following syntax diagram shows the SQL CALL statement for invoking this stored procedure:

```
CALL ADMIN_TASK_UPDATE(task-name, description, begin_timestamp, end_timestamp, max_invocations, interval, point-in-time, trigger-task-name, trigger-task-cond, trigger-task-code, db2-ssid, return-code, message)
```

Option descriptions

task-name

Specifies the unique name of the task that is to be updated in the task list of the administrative task scheduler. This is an input parameter of type VARCHAR(128).

description

Specifies a description that is assigned to the task. This is an input parameter of type VARCHAR(128).

begin-timestamp

An input argument of type TIMESTAMP that specifies the earliest time a task can begin execution. The value of this argument cannot be in the past, and it cannot be later than end_timestamp.

When the execution of a task begins depends on how this parameter and other parameters are defined:

Non-null value for begin-timestamp

At begin-timestamp

The task execution begins at begin-timestamp if point-in-time and trigger-task-name are NULL.

Interval in minutes after the last execution of this task

The task execution begins at begin-timestamp.

Next point in time defined at or after begin-timestamp

The task execution begins at the next point in time that is defined at or after begin-timestamp if point-in-time is non-null.
When *trigger-task-name* completes after *begin-timestamp*

The task execution begins the next time that *trigger-task-name* completes or after *begin-timestamp*.

**Null value for *begin-timestamp***

**Immediately**

The task execution begins immediately if *point-in-time* and *trigger-task-name* are NULL.

**Interval in minutes after the last execution of this task**

The task execution begins at *begin-timestamp*.

**Next point in time defined**

The task execution begins at the next point in time that is defined if *point-in-time* is non-null.

When *trigger-task-name* completes

The task execution begins the next time that *trigger-task-name* completes.

**end-timestamp**

An input argument of type TIMESTAMP that specifies the latest time that a task can begin execution. The value of this argument cannot be in the past, and it cannot be earlier than *begin_timestamp*. If the argument is NULL, the task can continue to execute as scheduled indefinitely.

An executing task will not be interrupted at its *end_timestamp* value.

**max-invocations**

Specifies the maximum number of executions that are allowed for the modified task. This value applies to all scheduled executions, whether they be triggered by events, recurring by time interval, or recurring by points in time. This value includes the previous executions of the modified task.

If *max-invocations* is smaller than, or equal to the number of times that the task has already been executed, the task will not be executed again. To modify the task to run again, you must specify *max-invocations* as NULL, or as a value that is greater than the current number of times that the task has already been executed. In addition, if *max-invocations*, *interval*, *point-in-time*, and *trigger-task-name* are NULL, the task executes only one more time.

If this parameter is set to NULL, there is no limit to the number of times this task can execute. If both *end-timestamp* and *max-invocations* are specified, the first limit that is reached takes precedence. For example, if the value for *end-timestamp* is reached, the task will not be executed again, even if the number of task executions has not reached the value of *max-invocations*. Likewise, if the value for *max-invocations* is reached, the task will not be executed again, even if the value for *end-timestamp* is not reached.

This is an input parameter of type INTEGER.

**interval**

Defines a time duration between two executions of a repetitive regular task. The first execution occurs at *begin-timestamp*.

If this parameter is set to NULL, the task is not regularly executed. If this parameter contains a non-null value, you must set the *point-in-time* and *trigger-task-name* parameters to NULL.

This is an input parameter of type INTEGER.
**point-in-time**

Specifies one or more points in time when a task is executed. If this parameter is set to NULL, the task is not scheduled at fixed points in time. If this parameter contains a non-null value, the parameters `interval` and `trigger-task-name` must be set to NULL.

The `point-in-time` string uses the UNIX cron format. This format contains the following pieces of information separated by blank spaces:

- Given minute or minutes
- Given hour or hours
- Given day or days of the month
- Given month or months of the year
- Given day or days of the week

For each part, you can specify one or several values and ranges.

This is an input parameter of type VARCHAR(400).

**trigger-task-name**

Specifies the name of the task that, upon completion, will trigger the execution of this task. The task names DB2START and DB2STOP are reserved for Db2 startup and shutdown events. Those events are handled by the scheduler that is associated with the Db2 subsystem that is starting or stopping.

If this parameter is set to NULL, the execution of this task will not be triggered by another task. If this parameter contains a non-null value, the parameters `interval` and `point-in-time` must be NULL.

This is an input parameter of type VARCHAR(128).

**trigger-task-cond**

Specifies the type of comparison to be made to the return code after the execution of task `trigger-task-name`. Possible values are:

- GT: Greater than
- GE: Greater than or equal to
- EQ: Equal to
- LT: Less than
- LE: Less than or equal to
- NE: Not equal to

If this parameter is set to NULL, the task execution is triggered without considering the return code of task `trigger-task-name`. This parameter must be set to NULL if `trigger-task-name` is set to NULL or is either DB2START or DB2STOP.

This is an input parameter of type CHAR(2).

**trigger-task-code**

Specifies the return code from executing the task `trigger-task-name`.

If the execution of this task is triggered by a stored procedure, `trigger-task-code` contains the SQLCODE that must be returned by the triggering stored procedure in order for this task to execute.

If the execution of this task is triggered by a JCL job, `trigger-task-code` contains the MAXRC that must be returned by the triggering job in order for this task to execute.
To find out what the MAXRC or SQLCODE of a task is after execution, invoking the user-defined function DSNADM. ADMIN_TASK_STATUS returns this information in the columns MAXRC and SQLCODE.

The following restrictions apply to the value of trigger-task-code:

- If trigger-task-cond is NULL, then trigger-task-code must also be NULL.
- If trigger-task-cond is non-null, then trigger-task-code must also be non-null.

If trigger-task-cond and trigger-task-code are not set to NULL, they are used to test the return code from executing trigger-task-name to determine whether to execute this task. For example, if trigger-task-cond is set to "GE", and trigger-task-code is set to "8", then this task will execute only if the previous execution of trigger-task-name returned a MAXRC (for a JCL job) or an SQLCODE (for a stored procedure) that is greater than or equal to 8.

This is an input parameter of type INTEGER.

db2-ssid

Specifies the Db2 subsystem ID whose associated scheduler should execute the task.

This parameter is used in a data sharing environment, where different Db2 members have different configurations and executing the task relies on a certain environment. However, specifying a value in db2-ssid will prevent the administrative task schedulers of other members from executing the task. Therefore, the task can be executed only if the administrative task scheduler of db2-ssid is running.

For a task that is being triggered by a Db2 start or Db2 stop event in trigger-task-name, specifying a value in db2-ssid causes the task to be executed only when the named Db2 subsystem is starting or stopping. If no value is given, each member that starts or stops will trigger a local execution of the task, if the executions are serialized.

If this parameter is set to NULL, any administrative task scheduler can execute the task.

This is an input parameter of type VARCHAR(4).

return-code

Provides the return code from the stored procedure. Possible values are:

- 0: The call completed successfully.
- 12: The call did not complete successfully. The message output parameter contains messages describing the error.

This is an output parameter of type INTEGER.

message

Contains messages describing the error encountered by the stored procedure. The first messages in this area, if any, are generated by the stored procedure. Messages that are generated by Db2 might follow the stored procedure messages.

This is an output parameter of type VARCHAR(1331).

Output

This stored procedure has the following output parameters, which are described in "Option descriptions" on page 853:

- return-code
ADMIN_UPDATE_SYSPARM stored procedure

The SYSPROC.ADMIN_UPDATE_SYSPARM stored procedure changes the value of one or more subsystem parameters which are located in one of these macros: DSN6SPRM, DSN6ARVP, DSN6LOGP, DSN6SYSP, DSN6FAC, and DSN6GRP.

ADMIN_UPDATE_SYSPARM builds a subsystem parameters load module and, if requested by the user, loads it into storage by issuing the Db2 command SET SYSPARM with the LOAD option. If all of the parameters that are modified cannot be updated online, SET SYSPARM LOAD is not run.

Environment

ADMIN_UPDATE_SYSPARM must run in a WLM-established stored procedure address space. At least one library in this WLM procedure STEPLIB DD concatenation must not be APF-authorized. TCB=1 is also required. By default, the SQL procedure processor (DSNTPSMP) and ADMIN_UPDATE_SYSPARM share the WLM environment.

Authorization

To issue the CALL statement, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges:

• The EXECUTE privilege on the ADMIN_UPDATE_SYSPARM stored procedure
• Ownership of the stored procedure
• SYSADM authority

The ADMIN_UPDATE_SYSPARM stored procedure internally calls the following stored procedures:

• ADMIN_COMMAND_DB2, to issue the Db2 DISPLAY GROUP and SET SYSPARM commands
• ADMIN_INFO_SYSPARM, to obtain the current subsystem parameters settings

The owner of the package or plan that contains the CALL ADMIN_UPDATE_SYSPARM statement must also have the following authority and privilege:

• Authorization to run these stored procedures and issue the specified Db2 commands
• MONITOR1 privilege

The ADMIN_UPDATE_SYSPARM caller also needs authorization from an external security system, such as RACF, to complete the following tasks:
• Browse the data set that is pointed to by the ZPMDFLTS DD statement in the WLM startup procedure
• Update the library where the sample JCL that assembles and link-edits the new subsystem parameters load module will be saved
• Update the load module library where the new subsystem parameters load module will be saved

**Syntax**

The following syntax diagram shows the SQL CALL statement for running this stored procedure:

```sql
CALL SYSPROC.ADMIN_UPDATE_SYSPARM(
    db2_member, NULL,
    parameter_module, NULL,
    module_library, NULL,
    source_library, NULL,
    load, NULL,
    return-code)
```

**Option descriptions**

**db2_member**

Specifies the name of a single data sharing group member on which the SET SYSPARM command with the LOAD option is to be run.

If this parameter is null, the SET SYSPARM command is run on the connected Db2 subsystem.

This is an input parameter of type VARCHAR(8).

In a data-sharing environment, some additional requirements apply. For example, if ADMIN_UPDATE_SYSPARM is run on member A to update a subsystem parameter setting on member B, the WLM environment for ADMIN_UPDATE_SYSPARM needs to be able to access the following resources:

• The library that is used to store the new subsystem parameters load module for member B
• The library that is used to store the sample JCL that assembles and link-edits the new subsystem parameters load module for member B.

**parameter_module**

Specifies the name of the subsystem parameters load module that has the new values assembled and linked into it.

If this parameter is null, the default is the last named subsystem parameters load module that was loaded into storage.

This is an input parameter of type VARCHAR(8).

**module_library**

Specifies the name of the library where the stored procedure saves the new subsystem parameters load module. If the `load` parameter is set to `Y`, this module library is also used to load the subsystem parameters load module.

If this parameter is null, the default is the SDSNEXIT_NAME library that is specified in the data set that is pointed to by the ZPMDFLTS DD statement in the WLM startup procedure.
This is an input parameter of type VARCHAR(44).

**source_library**
Specifies the name of the library where the stored procedure saves a sample JCL that assembles and link-edits the new subsystem parameters load module offline. This JCL contains the updated subsystem parameters.

This parameter must specify a partitioned data set (PDS) or a partitioned data set extended (PDSE) with record format (RECFM) F or FB and record length (LRECL) 80.

If this parameter is null, the default is the SRCLIB_NAME library that is specified in the data set that is pointed to by the ZPMDFLTS DD statement in the WLM startup procedure.

The name of the library member where the sample JCL is saved is the same as the library member name of the new subsystem parameters load module. This JCL is not used by ADMIN_UPDATE_SYSPARM to assemble and link-edit the subsystem parameters load module. This JCL is generated and saved so that it can be referenced for any subsequent subsystem parameter modification by the Db2 system programmer.

This is an input parameter of type VARCHAR(44).

**load**
Specifies whether to issue SET SYSPARM with the LOAD option to load the new subsystem parameters load module into storage. Possible values are:

- **Y** Issue SET SYSPARM with the LOAD option.
- **N** Do not issue SET SYSPARM with the LOAD option.

If this parameter is null, the default is 'N'.

If at least one modified subsystem parameter cannot be changed online or if SET SYSPARM synchronous support is not available (PM40501 is not installed), SET SYSPARM with the LOAD option is not issued even if load is set to 'Y'. Instead, a value of 4 is returned in the output parameter return-code.

This is an input parameter of type CHAR(1).

**return-code**
Provides the return code from the stored procedure. Possible values are:

- **0** The call completed successfully.
  
  Message DSNA658I is written to the JES SYSLOG, but not to the JES job log of ssnmMSTR.
  
  The following information is returned in the result table of the stored procedure:
  
  • Message DSNA658I
  • Assembler listing
  • Link-edit listing
  • SET SYSPARM command with LOAD option messages (if applicable)

- **4** The stored procedure modified the value of at least one Db2 subsystem parameter. However, the stored procedure did not complete a required or requested action after the subsystem parameter values were changed.
The SET SYSPARM command with the LOAD option was not issued because of one of the following reasons:
- At least one modified subsystem parameter cannot be changed online.
- Synchronous processing of the SET SYSPARM command is not supported.
- The stored procedure encountered an error while it was writing a DSNA658I message to the JES SYSLOG.

For more information, see message DSNA666I.

- The cleanup processing that occurs when the stored procedure completes successfully did not complete successfully because of one of the following reasons:
  - The backup of the library member that the stored procedure replaced with the new JCL that assembles and link-edits the new subsystem parameters load module was not deleted.
  - The backup of the library member that the stored procedure replaced with the new subsystem parameters load module was not deleted.

For more information, see message DSNA658I.

Message DSNA658I is written to the JES SYSLOG (if applicable), but not to the JES job log of ssnmMSTR.

The following information is returned in the result table of the stored procedure:
- Message DSNA658I
- Message DSNA666I or DSNA658I (depending on which reason caused return_code to be set to 4)
- Assembler listing
- Link-edit listing
- SET SYSPARM command with LOAD option messages (if applicable)

The call did not complete successfully.

Message DSNA669I is returned in the result set.

Objects that were replaced by the stored procedure are restored. For more information, see "Backup copies" on page 862.

If the new subsystem parameters load module was loaded into storage, the stored procedure will reload the subsystem parameters load module that was loaded previously.

The call did not complete successfully because of a REXX programming violation.

Message DSNA669I is displayed in the WLM job log.

The call did not complete successfully because of one of the following global temporary table failures:
The created global temporary table SYSIBM.UPDSYPARM_MSG does not exist.

The user does not have authority to use the created global temporary table SYSIBM.UPDSYPARM_MSG.

Message DSNA669I is displayed in the WLM job.

The call did not complete successfully because of one of the following DSNREXX failures:

- The DSNREXX package was not found.
- Db2 cannot access a DSNREXX environment. Db2 REXX Language Support is not available.

Message DSNA669I is displayed in the WLM job log.

There was an error that occurred while the result set was being returned.

The result set is written to the WLM job log. However, the assembler listing and the link-edit listing are not written to the WLM job log unless the call did not complete successfully because the assembly failed or the link-edit failed. If the assembly failed, the assembler listing is written to the WLM job log. If the link-edit failed, the link-edit listing is written to the WLM job log.

This is an output parameter of type INTEGER.

**ADMIN_UPDATE_SYSPARM input row**

In addition to the input parameters, the stored procedure reads from the created global temporary table SYSIBM.SYSPARM_SETTINGS to retrieve the subsystem parameters to be modified. The following table shows the format of the created global temporary table SYSIBM.SYSPARM_SETTINGS:

<table>
<thead>
<tr>
<th>Column name</th>
<th>Data type</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>ROWNUM</td>
<td>INTEGER</td>
<td>A unique positive identifier for each row.</td>
</tr>
<tr>
<td></td>
<td>NOT NULL</td>
<td>When you insert multiple rows, increment ROWNUM by 1, starting at 0 for every insert.</td>
</tr>
<tr>
<td>MACRO</td>
<td>VARCHAR(8)</td>
<td>Macro that contains the Db2 subsystem parameter to be modified.</td>
</tr>
<tr>
<td></td>
<td>NOT NULL</td>
<td>Valid values are: DSN6SPRM, DSN6ARVP, DSN6LOGP, DSN6SYSIP, DSN6FAC, and DSN6GRP.</td>
</tr>
<tr>
<td>PARAMETER</td>
<td>VARCHAR(40)</td>
<td>Name of the Db2 subsystem parameter to be modified.</td>
</tr>
<tr>
<td></td>
<td>NOT NULL</td>
<td></td>
</tr>
<tr>
<td>NEW_VALUE</td>
<td>VARCHAR(2048)</td>
<td>New value of the Db2 subsystem parameter to be modified. This parameter is not validated by the stored procedure.</td>
</tr>
<tr>
<td></td>
<td>NOT NULL</td>
<td></td>
</tr>
</tbody>
</table>
Backup copies

In the subsystem parameters load module library, if a member exists with the same name as the name of the new subsystem parameters load module, the stored procedure creates a backup copy of this member before it is replaced with the new subsystem parameters load module. Similarly, in the JCL source library, if a member exists with the same name as the name of the sample JCL that assembles and link-edits the new subsystem parameters load module, the stored procedure creates a backup copy of this member before it is replaced with the sample JCL. The backup copy is created in the same library where the member it replaced resides, and its name has the following format: ssnnhhmm, where:

ssnm The ssid of the Db2 subsystem where the subsystem parameter changes are implemented.

hh The hour the stored procedure started execution (00-23).

mm The minute the stored procedure started execution (00-59).

When the stored procedure completes successfully, the backup copies are deleted.

When the stored procedure does not complete successfully, the stored procedure restores the replaced members to their state before the stored procedure was run by using their respective backup copies. If the stored procedure is unable to restore a member from the backup, the user must complete this task.

If a member exists with the same name as the backup copy the stored procedure is creating, the stored procedure terminates processing.

Example

The following C language example shows how to invoke ADMIN_UPDATE_SYSPARM.

```c
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

/*******************
* DB2 SQL Communication Area *******************/
EXEC SQL INCLUDE SQLCA;
int main( int argc, char *argv[] ) /* Argument count and list */ {

/*******************
* DB2 Host Variables *******************/
EXEC SQL BEGIN DECLARE SECTION;
/* SYSPROC.ADMIN_UPDATE_SYSPARM parameters */
char pmember[9]; /* Data sharing group member */
char pmodname[9]; /* Subsystem parameters load */
char pmodlib[45]; /* Subsystem parameters load */
char psrclib[45]; /* Subsystem parameters load */
char pload[2]; /* Sample JCL library */
char pload[2]; /* Sample JCL library */
char pload[2]; /* Sample JCL library */
char pload[2]; /* Sample JCL library */
short int ind_pmember; /* Indicator variable */
short int ind_pmodname; /* Indicator variable */
short int ind_pmodlib; /* Indicator variable */
short int ind_pscrlib; /* Indicator variable */
short int ind_pload; /* Indicator variable */
short int ind_pretcd; /* Indicator variable */
/* Temporary table SYSIBM.SYSPARM_SETTINGS columns */
long int zrownum; /* Sequence number of the */
char zmacro[9]; /* Macro containing the */
```
/* subsystem parameter to be */
char zparam[41]; /* Name of the subsystem */
char znew_value[2049]; /* New value of the subsystem */

/* Result set locators */
volatile SQL TYPE IS RESULT_SET_LOCATOR *rs_loc1;

EXEC SQL END DECLARE SECTION;

/*******************************************************************/
/* Clear temporary table SYSIBM.SYSPARM_SETTINGS */
EXEC SQL DELETE FROM SYSIBM.SYSPARM_SETTINGS;

/*******************************************************************/
/* Clear temporary table SYSIBM.UPDSYSPARM_MSG */
EXEC SQL DELETE FROM SYSIBM.UPDSYSPARM_MSG;

/*******************************************************************/
/* Insert the subsystem parameters to be modified into the */
/* created global temporary table SYSIBM.SYSPARM_SETTINGS */

zrownum = 1;
strcpy(zmacro, "DSN6FAC");
strcpy(zparam, "IDTHTOIN");
strcpy(znew_value, "600");
EXEC SQL INSERT INTO SYSIBM.SYSPARM_SETTINGS
 ( ROWNUM, MACRO, PARAMETER, NEW_VALUE)
VALUES (:zrownum, :zmacro, :zparam, :znew_value);

/*******************************************************************/
/* Set procedure input parameters */
ind_pmember = -1;
ind_pmodname = -1;
ind_pmodlib = -1;
ind_psrlib = -1;
ind_pload = -1;
ind_pretcd = -1;

/*******************************************************************/
/* Call stored procedure SYSPROC.ADMIN_UPDATE_SYSPARM */
EXEC SQL CALL SYSPROC.ADMIN_UPDATE_SYSPARM
 ( :pmember :ind_pmember,
 :pmodname :ind_pmodname,
 :pmodlib :ind_pmodlib,
 :psrlib :ind_psrlib,
 :pload :ind_pload,
 :pretcd :ind_pretcd);

/*******************************************************************/
/* Retrieve result set when the SQLCODE from the call is +466, */
/* which indicates that result sets were returned */
if (SQLCODE == +466) /* Result sets were returned */
{
    /* Establish a link between the result set and its locator */
    EXEC SQL ASSOCIATE LOCATORS (:rs_loc1)
    WITH PROCEDURE SYSPROC.ADMIN_UPDATE_SYSPARM;
    /* Associate a cursor with the result set */
    EXEC SQL ALLOCATE C1 CURSOR FOR RESULT SET :rs_loc1;
    /* Perform fetches using C1 to retrieve all rows from the */
    /* result set */
EXEC SQL FETCH C1 INTO :rownum, :type, :text;
while(SQLCODE==0)
{
    EXEC SQL FETCH C1 INTO :rownum, :type, :text;
}
EXEC SQL CLOSE C1;
}
return;
}

Output

This stored procedure returns the **return-code** output parameter, which is described in "Option descriptions" on page 858.

In addition to the preceding output, the stored procedure returns one result set that contains successful, warning, or error messages that are generated by the stored procedure. The stored procedure also returns (if applicable) the assembler and link-edit listings, IEBCOPY listing, and output from the **SET SYSPARM** with **LOAD** option command.

The following table shows the format of the result set that is returned in the created global temporary table **SYSIBM.UPDSYSPARM_MSG**:

<table>
<thead>
<tr>
<th>Column name</th>
<th>Data type</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>ROWNUM</td>
<td>INTEGER</td>
<td>Sequence number of the table row, from 1 to n.</td>
</tr>
<tr>
<td></td>
<td>NOT NULL</td>
<td></td>
</tr>
<tr>
<td>TYPE</td>
<td>VARCHAR(12)</td>
<td>Type of information that is found in the corresponding TEXT column. Possible values are:</td>
</tr>
<tr>
<td></td>
<td>NOT NULL</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• DSNADMUZ - TEXT is a message that is internally generated by the stored procedure, such as DSNA658I, DSNA666I, DSNA669I, or DSNA685I.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• ASSEMBLE - TEXT is a line from the assembler listing.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• LINK - TEXT is a line from the link-edit listing.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• LOAD - TEXT is a line from the message that is returned by <strong>SET SYSPARM</strong> with the <strong>LOAD</strong> option command when this command was issued to load the new subsystem parameters load module into storage.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• IEBCOPY1 - TEXT is a line from the <strong>IEBCOPY</strong> listing which was generated when <strong>IEBCOPY</strong> was issued to back up the subsystem parameters load module that was being replaced.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• IEBCOPY2 - TEXT is a line from the <strong>IEBCOPY</strong> listing which was generated when <strong>IEBCOPY</strong> was issued to restore the subsystem parameters load module which the stored procedure replaced with the new subsystem parameters load module.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• LOAD2 - TEXT is a line from the message that is returned by <strong>SET SYSPARM</strong> with the <strong>LOAD</strong> option command when this command was issued during restore processing to load the current subsystem parameters load module into storage.</td>
</tr>
</tbody>
</table>
Table 140. Result set row for the ADMIN_UPDATE_SYSPARM result set (continued)

<table>
<thead>
<tr>
<th>Column name</th>
<th>Data type</th>
<th>Contents</th>
</tr>
</thead>
</table>
| TEXT        | VARCHAR(1331) | • A successful, warning, or error message that is generated by the stored procedure. If the message is longer than 1331 characters, the message continues in the next result set row.  
• Assembler listing  
• Link-edit listing  
• Output from SET SYSPARM with the LOAD option command  
• IEBCOPY listing |
| NOT NULL    |           |          |

ADMIN_UTL_EXECUTE stored procedure

ADMIN_UTL_EXECUTE is a stored procedure that solves alerts stored in the SYSIBM.SYSAUTOMONALERTS catalog table within the maintenance windows defined by the SYSIBM.SYSAUTOTIMEWINDOWS catalog table. It is required for the use of autonomic statistics.

The ADMIN_UTL_EXECUTE stored procedure performs the following tasks:
• Determines the order for resolving alerts.
• Within the maintenance windows that are defined in the SYSIBM.SYSAUTOTIMEWINDOWS catalog table, calls the ADMIN_UTL_SCHEDULE stored procedure to resolve alerts by executing the RUNSTATS utility. For each alert, the options for RUNSTATS are provided in the SYSIBM.SYSAUTOMONALERTS table.
• Updates the status and output of resolved alerts in the SYSIBM.SYSAUTOMONALERTS table.
• If the administrative task scheduler is used, reschedules its own execution for the next maintenance window when unsolved alerts remain.

Environment

The ADMIN_UTL_EXECUTE stored procedure runs in a WLM-established stored procedure address space and uses the Resource Recovery Services attachment facility to connect to Db2. The ADMIN_UTL_EXECUTE stored procedures calls ADMIN_UTL_SCHEDULE stored procedures to execute a RUNSTATS operations. The ADMIN_UTL_EXECUTE stored procedure is required and must be installed and executable.

It calls the DSNADM.ADMIN_TASK_LIST and the SYSPROC.ADMIN_TASK_UPDATE routines.
Authorization required

To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have DBADM or higher authority.

Syntax

```
CALL SYSPROC.ADMIN_UTL_EXECUTE(
    execute-options,
    history-entry-id,
    return-code,
    message)
```

Option descriptions

The ADMIN_UTL_EXECUTE stored procedure has the following options:

`execute-options`

A string representation of the configuration parameters for the ADMIN_UTL_EXECUTE stored procedure, consisting of "NAME=VALUE" pairs separated by commas. Optional parameters include:

- **STAND-ALONE**
  - **NO**  
    The ADMIN_UTL_EXECUTE stored procedure interacts with the administrative task scheduler to its own next execution. NO is the default value.
  - **YES**  
    The ADMIN_UTL_EXECUTE stored procedure does not interact with the administrative task scheduler.

`execute-options` is an input parameter of type VARCHAR(30000).

`history-entry-id`

Provides a unique identifier that can be used to read the execution log written in the SYSIBM.SYSAUTORUNS_HIST table when the SYSPROC.ADMIN_UTL_EXECUTE stored procedure executes. This is an output parameter of type BIGINT.

`return-code`

Provides the return code from the stored procedure. Possible values are:

- **0**  
  The call completed successfully.
- **4**  
  The call completed successfully. The message output parameter contains a warning message.
- **12**  
  The call did not complete successfully. The message output parameter contains messages describing the error.

The `return-code` parameter is an output parameter of type INTEGER.

`message`

Contains messages describing the error encountered by the stored procedure.

The `message` parameter is an output parameter of type VARCHAR(1331)
Example

The following example shows a Java call to the ADMIN_UTL_EXECUTE stored procedure:

```java
long taskid = 7;
CallableStatement callStmt = con.prepareCall("CALL SYSPROC.ADMIN_UTL_EXECUTE(? , ? , ? , ?)");
callStmt.setString(1, "");
callStmt.registerOutParameter(2, Types.BIGINT);
callStmt.registerOutParameter(3, Types.INTEGER);
callStmt.registerOutParameter(4, Types.LONGVARCHAR);
callStmt.execute();
if (callStmt.getInt(3) > 0 )
{
    System.err.println("Error: " + callStmt.getString(4));
}
```

External input

The ADMIN_UTL_EXECUTE stored procedure reads additional input from the SYSIBM.SYSAUTOALERTS and SYSIBM.SYSAUTOTIMEWINDOWS catalog tables.

Output

The ADMIN_UTL_EXECUTE stored procedure returns the following output parameters:

- **history-entry-id**
- **return-code**
- **message**

The ADMIN_UTL_EXECUTE stored procedure also updates the following catalog tables:

- In the SYSIBM.SYSAUTOALERTS catalog table, the following columns are updated for each alert that is solved:
  - STARTTS
  - ENDTTS
  - STATUS
  - RETURN_CODE
  - MESSAGE
  - OUTPUT
- In the SYSIBM.SYSAUTORUNS_HIST stored procedure, one row of data is added to log the activity.

Related tasks:

- Automating statistics maintenance (Db2 Performance)
- Specifying time windows for collecting autonomic statistics (Db2 Performance)

SYSAUTOALERTS catalog table
ADMIN_UTL_MONITOR stored procedure

SYSPROC.ADMIN_UTL_MONITOR is an autonomic stored procedure that provides functions that enable analysis of database statistics. These functions include alerts for out-of-date, missing, or conflicting statistics, summary reports and detailed table-level reports that describe generated RUNSTATS statements. It is required for the use of autonomic statistics.

The ADMIN_UTL_MONITOR stored procedure enables for the analysis of database statistics, by providing the following functions:

- Issuing RUNSTATS alerts for out-of-date statistics. Counters in the SYSIBM.SYSTABLESPACESTATS table are used to identify out of date statistics. Cloned table spaces, work file table spaces, and directory table spaces are excluded from AUTOSTATS processing.
- Issuing RUNSTATS alerts for missing and conflicting database statistics, including statistics for columns, column groups, and indexes.
- Generating a summary report for the number of tables analyzed and the number of RUNSTATS alerts that were generated.
- Generating detailed table-level reports for RUNSTATS commands, including explanations.
- Scheduling execution of the ADMIN_UTL_EXECUTE stored procedure in the administrative task scheduler to resolve alerts.

Environment

The ADMIN_UTL_MONITOR stored procedure runs in a WLM-established address space and uses the Resource Recovery Services attachment facility to connect to Db2. The ADMIN_UTL_MONITOR stored procedure is required and must be installed and executable.

If the stand-alone option is set to NO, the ADMIN_UTL_MONITOR stored procedure must be defined as a trusted context in RACF and must run in a specific trusted WLM environment to get a RACF PassTicket for the user that called the stored procedure. The ADMIN_UTL_MONITOR stored procedure calls the following interface routines:

- SYSPROC.ADMIN_TASK_ADD
- SYSPROC.ADMIN_TASK_REMOVE
- SYSPROC.ADMIN_TASK_UPDATE
- DSNADM.ADMIN_TASK_LIST
- DSNADM.ADMIN_TASK_STATUS

Authorization required

To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have DBADM or higher authority.

Syntax

The following syntax diagram shows the SQL CALL statement for invoking the ADMIN_UTL_MONITOR stored procedure:
**Option descriptions**

The ADMIN_UTIL_MONITOR stored procedure has the following options:

**monitor-options**

A string representation of the configuration parameters for the ADMIN_UTIL_MONITOR stored procedure, consisting of "NAME = VALUE" pairs separated by commas. Values, including blanks, equal sign, and comma must be surrounded by single or double quotation marks. For example:

- restrict-ts='partition=1' is valid.
- restrict-ts="partition=1" is valid.
- restrict-ts=partition=1 is not valid.

Any value that contains single or double quotation marks must be surrounded by the opposite kind of quotation marks. For example: restrict-ts="DBNAME='DSNDB06'" is valid because the single quotation marks used in the value are surrounded by double quotation marks.

The following optional parameters are available:

- The following parameters specify general monitoring options:
  - **restrict-ts**
    - Indicates which table spaces require checking. Allowed values are strings that contain valid contents for a WHERE clause on the SYSIBM.SYSTABLESPACESTATS catalog table. For example:
      
      DBNAME LIKE 'MYDB%'
      
      If no restriction is specified, all table spaces are checked.
  - **stand-alone**
    - Whether alerts trigger the ADMIN_UTL_EXECUTE stored procedure:
      - NO: Alerts are written and the ADMIN_UTL_EXECUTE stored procedure is called to resolve the alerts. NO is the default value.
      - YES: Alerts are written but no call is issued to the ADMIN_UTL_EXECUTE stored procedure.
  - **statistics-scope**
    - Specifies the scope of the statistics for the ADMIN_UTIL_MONITOR stored procedure to check:
      - **BASIC**
        - Out-of-date statistics are checked, such as whether RUNSTATS has been run since the last LOAD or REORG operation or whether the number and percentage of changes in a table space are greater than a defined threshold. BASIC is the default value.
      - **PROFILE**
        - Out-of-date statistics and the completeness of statistics are checked, including whether all statistics in the table profile have been collected.
PROFILE-CONSISTENCY
Out-of-date statistics, the completeness of statistics, and the
consistency of statistics are checked.

- The following optional parameters specify a threshold and settings for the
  use of table-sampling by RUNSTATS.

  **sampling-rate**
  Indicates the percentage of rows that RUNSTATS samples when
collecting statistics on non-indexed columns. You can specify any value
from 1 through 100. When sampling-rate is not specified, AUTO is used.
When a sampling-rate is not specified, the TABLESAMPLE SYSTEM
AUTO option is used for RUNSTATS alerts on single-table table spaces
and the SAMPLE 25 option is used for RUNSTATS alerts on multi-table
table spaces.

  **sampling-threshold**
  Indicates a threshold for the absolute number of rows in a table. When
the threshold is exceeded, a sampling option is recorded in the
RUNSTATS alert, and that option is used later when RUNSTATS
executes to resolve the alert. You can specify a positive integer. A value
of 500,000 is used when sampling-threshold is not specified. The
specified sampling-rate is used for all tables when you specify
sampling-threshold=0.

- The following optional parameters specify thresholds for out-of-date
statistics. A RUNSTATS alert might be written when a threshold is exceeded.

### Table 141. Parameters for out-of-date statistics

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Allowed values</th>
<th>Default value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>num-changes</strong></td>
<td>Absolute number of inserted, updated, or deleted rows in a table space. A RUNSTATS alert is written when the thresholds for both num-changes and pct-changes are exceeded.</td>
<td>Positive integers, in the range 0 to 2,147,483,647</td>
<td>0</td>
</tr>
<tr>
<td><strong>num-mass-deletes</strong></td>
<td>Absolute number of massive delete operations. A RUNSTATS alert is written when the num-mass deletes threshold is exceeded.</td>
<td>Positive integers, in the range 0 to 2,147,483,647</td>
<td>0</td>
</tr>
<tr>
<td><strong>pct-changes</strong></td>
<td>Percentage of inserted, updated, or deleted rows in a table space. A RUNSTATS alert is written when the thresholds for both num-changes and pct-changes are exceeded.</td>
<td>A real number float value greater than 0.0 and less than or equal to 100.0</td>
<td>20.0</td>
</tr>
</tbody>
</table>

- The following parameters specify thresholds for inconsistent statistics. The
  thresholds apply only when the value of profile-consistency is specified
for **statistics-scope**. A RUNSTATS alert is written when a threshold is
exceeded. Each threshold is a percentage difference when related statistics
are compared, as described in the following table.
<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Allowed values</th>
<th>Default value</th>
</tr>
</thead>
<tbody>
<tr>
<td>colgroup-card-greater-than-superset-colgroup-card</td>

<td>0.1</td>
</tr>
<tr>
<td>tabcard-less-than-index-keycard</td>
<td>The cardinality of a table is smaller than the cardinality of an index for this table.</td>
<td>A real number between 0.0 and 100.0 inclusive</td>
<td>0.1</td>
</tr>
<tr>
<td>tabcard-not-equal-unique-index-fullkeycard</td>
<td>The cardinality of a table is different from the cardinality of a unique index on that table.</td>
<td>A real number between 0.0 and 100.0 inclusive</td>
<td>0.1</td>
</tr>
</tbody>
</table>

monitor-options is an input parameter of type VARCHAR(30000).
history-entry-id

Returns a unique identifier that can be used to read the execution log in the SYSIBM.SYSAUTORUNS_HIST table and the alerts in the SYSIBM.SYSAUTOALERTS table when the SYSPROC.ADMIN_UTL_MONITOR stored procedure executes. This is an output parameter of type BIGINT.

return-code

Provides the return code from the stored procedure. Possible values are:

0  The call completed successfully.
4  The call completed successfully. The message output parameter contains a warning message.
12 The call did not complete successfully. The message output parameter contains messages describing the error.

The return-code parameter is an output parameter of type INTEGER.

message

Contains messages describing the error encountered by the stored procedure.

The message parameter is an output parameter of type VARCHAR(1331)

Example

The following example shows a Java call to the ADMIN_UTL_MONITOR stored procedure:

```java
CallableStatement callStmt = con.prepareCall("CALL SYSPROC.ADMIN_UTL_MONITOR(? , ?, ?, ?)");
callStmt.setString(1, "");
callStmt.registerOutParameter(2, Types.INTEGER);
callStmt.registerOutParameter(3, Types.INTEGER);
callStmt.registerOutParameter(4, Types.LONGVARCHAR);
callStmt.execute();
if ( callStmt.getInt(3) > 0 )
{
    System.err.println("Error: " + callStmt.getString(4));
}
```

External input

The ADMIN_UTL_MONITOR stored procedure reads additional input from the following catalog tables:

- SYSIBM.SYSTABLESPACESTATS
- SYSIBM.SYSTABLESPACE
- SYSIBM.SYSTABLES
- SYSIBM.SYSCOLUMNS
- SYSIBM.SYSCOLDIST
- SYSIBM.SYSINDEXES
- SYSIBM.SYSKEYS
- SYSIBM.SYSTABLES_PROFILES

Output

The ADMIN_UTL_MONITOR stored procedure returns the following output parameters:

- history-entry-id
The ADMIN_UTL_MONITOR stored procedure also inserts rows of data into the following catalog tables:

- In the SYSIBM.SYSAUTOALERTS catalog table, a row of data is inserted for each RUNSTATS alert issued, with values for following columns:
  - HISTORY_ENTRY_ID
  - ACTION
  - TARGET_QUALIFIER
  - TARGET_OBJECT
  - TARGET_PARTITION
  - OPTIONS
  - DURATION
  - STATUS

- In the SYSIBM.SYSTABLES_PROFILES catalog table, a row of data is inserted for each monitored table that doesn’t have a profile yet, with values in the following columns:
  - SCHEMA
  - TBNAME
  - PROFILE_TYPE
  - PROFILE_MODE
  - PROFILE_TEXT
  - PROFILE_UPDATE
  - PROFILE_USED

- In the SYSIBM.SYSAUTORUNS_HIST stored procedure, one row of data is added to log the activity.

---

**ADMIN_UTL_MODIFY stored procedure**

ADMIN_UTL_MODIFY is an autonomic stored procedure that maintains the SYSIBM.SYSAUTORUNS_HIST and SYSIBM.SYSAUTOALERTS catalog tables.

The ADMIN_UTL_MODIFY stored procedure removes all entries in the SYSIBM.SYSAUTORUNS_HIST table that are older than a configurable threshold and removes all entries in the SYSIBM.SYSAUTOALERTS table that are older than the configured threshold and are in COMPLETE state.
Environment

The ADMIN_UTIL_MODIFY stored procedure runs in a WLM-established address space and uses the Resource Recovery Services attachment facility to connect to Db2. The ADMIN_UTIL_MODIFY stored procedure is required and must be installed and executable.

Authorization required

To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have DBADM or higher authority.

Syntax

```
CALL ADMIN_UTIL_MODIFY(
   modify-options, history-entry-id, return-code, message
)
```

Option descriptions

The ADMIN_UTIL_MODIFY stored procedure has the following options:

modify-options
A string representation of the configuration parameters for the ADMIN_UTIL_MODIFY stored procedure, consisting of "NAME = VALUE" pairs separated by commas. Optional parameters include:

HISTORY-DAYS
Number of days after that entries in the SYSIBM.SYSAUTORUNS_HIST table and completed alerts in SYSIBM.SYSAUTOALERTS table are deleted. The value be a positive number of days.

modify-options is an input parameter of type VARCHAR(30000)

history-entry-id
Returns a unique identifier that can be used to read the execution log in the SYSIBM.SYSAUTORUNS_HIST table when the SYSPROC.ADMIN_UTIL_MODIFY stored procedure executes. This is an output parameter of type BIGINT.

return-code
Provides the return code from the stored procedure. Possible values are:

0  The call completed successfully.
4  The call completed successfully. The message output parameter contains a warning message.
12 The call did not complete successfully. The message output parameter contains messages describing the error.

The return-code parameter is an output parameter of type INTEGER.

message
Contains messages describing the error encountered by the stored procedure.

The message parameter is an output parameter of type VARCHAR(1331)
Example

The following example shows a Java call to the ADMIN_UTL MODIFY stored procedure:

```java
String options = "history-days=90";
CallableStatement callStmt = con.prepareCall("CALL SYSPROC.ADMIN_UTL_MODIFY(?,
?, ?, ?)");
callStmt.setString(1, options);
callStmt.registerOutParameter(2, Types.INTEGER);
callStmt.registerOutParameter(3, Types.INTEGER);
callStmt.registerOutParameter(4, Types.LONGVARCHAR);
callStmt.execute();
if (callStmt.getInt(3) > 0)
{
    System.err.println("Error: " + callStmt.getString(4));
}
```

External input

The AUTO_UTL MODIFY stored procedure reads additional input from the SYSIBM.SYSAUTORUNS_HIST and SYSIBM.SYSAUTOALERTS catalog tables.

Output

The ADMIN_UTL_MONITOR stored procedure returns the following output parameters:

- `history-entry-id`
- `return-code`
- `message`

The ADMIN_UTL MODIFY stored procedure also deletes rows from the SYSIBM.SYSAUTORUNS_HIST and SYSIBM.SYSAUTOALERTS tables and inserts a single row in to the SYSIBM.SYSAUTORUNS_HIST table to log its activity.

Related tasks:

- [Automating statistics maintenance (Db2 Performance)](#)
- [Scheduling log and alert history cleanup for autonomic statistics (Db2 Performance)](#)

**ADMIN_UTL_SCHEDULE stored procedure**

The SYSPROC.ADMIN_UTL_SCHEDULE stored procedure executes utilities in parallel.

Environment

ADMIN_UTL_SCHEDULE runs in a WLM-established stored procedures address space.
Authorization

To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges on each package that the stored procedure uses:

- The EXECUTE privilege on the package for DSNADMUM
- Ownership of the package
- PACKADM authority for the package collection
- SYSADM authority

The ADMIN_UTL_SCHEDULE stored procedure internally calls the following stored procedures:

- ADMIN_COMMAND_DB2, to execute the Db2 DISPLAY UTILITY command
- ADMIN_INFO_SSID, to obtain the subsystem ID of the connected Db2 subsystem
- ADMIN_UTL_SORT, to sort objects into parallel execution units
- DSNUTILU, to run the requested utilities

The owner of the package or plan that contains the CALL ADMIN_UTL_SCHEDULE statement must also have the authorization required to execute these stored procedures and run the requested utilities.

Syntax

The following syntax diagram shows the SQL CALL statement for invoking this stored procedure:

```
CALL SYSPROC.ADMIN_UTL_SCHEDULE(
  max-parallel, optimize-workload, NULL
  stop-condition, utility-ID-stem, shutdown-duration, number-of-objects, NULL
  utilities-run, highest-return-code, parallel-tasks, return-code, message)
```

Option descriptions

**max-parallel**

Specifies the maximum number of parallel threads that may be started. The actual number may be lower than the requested number based on the optimizing sort result. Possible values are 1 to 99.

This is an input parameter of type SMALLINT and cannot be null.

**optimize-workload**

Specifies whether the parallel utility executions should be sorted to achieve shortest overall execution time. Possible values are:

- **NO** or null
  The workload is not to be sorted.

- **YES**
  The workload is to be sorted.

This is an input parameter of type VARCHAR(8). The default value is NO.
stop-condition
Specifies the utility execution condition after which ADMIN_UTL_SCHEDULE will not continue starting new utility executions in parallel, but will wait until all currently running utilities have completed and will then return to the caller. Possible values are:

AUTHORIZ or null
No new utility executions will be started after one of the currently running utilities has encountered a return code from DSNUTILU of 12 or higher.

WARNING
No new utility executions will be started after one of the currently running utilities has encountered a return code from DSNUTILU of 4 or higher.

ERROR
No new utility executions will be started after one of the currently running utilities has encountered a return code from DSNUTILU of 8 or higher.

This is an input parameter of type VARCHAR(8). The default value is AUTHORIZ.

utility-ID-stem
Specifies the first part of the utility ID of a utility execution in a parallel thread. The complete utility ID is dynamically created in the form utility-ID-stem followed by TT followed by NNNNNN, where:

TT The zero-padded number of the subtask executing the utility
NNNNNN A consecutive number of utilities executed in a subtask.

For example, utilityidstem02000005 is the fifth utility execution that has been processed by the second subtask.

This is an input parameter of type VARCHAR(8) and cannot be null.

shutdown-duration
Specifies the elapsed time in seconds that ADMIN_UTL_SCHEDULE will allow utility executions before a shutdown is initiated. When a shutdown is initiated, current utility executions can run to completion, and no new utility will be started. Possible values are:

null A shutdown will not be performed.
1 to 999999999999 A shutdown will be performed after this many seconds.

This is an input parameter of type FLOAT(8). The default value is null.

number-of-objects
As an input parameter, this specifies the number of utility executions and their sorting objects that were passed in the SYSIBM.UTILITY_OBJECTS table. Possible values are 1 to 999999.

As an output parameter, this specifies the number of objects that were passed in SYSIBM.UTILITY_OBJECTS table that are found in the Db2 catalog.

This is an input and output parameter of type INTEGER and cannot be null.

utilities-run
Indicates the number of actual utility executions.
This is an output parameter of type INTEGER.

**highest-return-code**
Indicates the highest return code from DSNUTILU for all utility executions.

This is an output parameter of type INTEGER.

**parallel-tasks**
Indicates the actual number of parallel tasks that were started to execute the utility in parallel.

This is an output parameter of type SMALLINT.

**return-code**
Provides the return code from the stored procedure. Possible values are:

0  All parallel utility executions ran successfully.
4  The statistics for one or more sorting objects have not been gathered in the catalog.
12 An ADMIN_UTL_SCHEDULE error occurred or all the objects passed in the SYSIBM.UTILITY_OBJECTS table are not found in the Db2 catalog. The *message* parameter contains details.

This is an output parameter of type INTEGER.

**message**
Contains messages describing the error encountered by the stored procedure. If no error occurred, then no message is returned.

The first messages in this area are generated by the stored procedure. Messages that are generated by Db2 might follow the first messages.

This is an output parameter of type VARCHAR(1331).

### Additional input

In addition to the input parameters, the stored procedure reads from the created global temporary tables SYSIBM.UTILITY_OBJECTS and SYSIBM.UTILITY_STMT.

The stored procedure reads objects for utility execution from SYSIBM.UTILITY_OBJECTS. The following table shows the format of the created global temporary table SYSIBM.UTILITY_OBJECTS:

<table>
<thead>
<tr>
<th>Column name</th>
<th>Data type</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>OBJECTID</td>
<td>INTEGER</td>
<td>A unique positive identifier for the object the utility execution is associated with. When you insert multiple rows, increment OBJECTID by 1, starting at 0 for every insert.</td>
</tr>
<tr>
<td>STMTID</td>
<td>INTEGER</td>
<td>A statement row in SYSIBM.UTILITY_STMT</td>
</tr>
<tr>
<td>Column name</td>
<td>Data type</td>
<td>Contents</td>

</tbody>
</table>

The stored procedure reads the corresponding utility statements from SYSIBM.UTILITY_STMT. The following table shows the format of the created global temporary table SYSIBM.UTILITY_STMT:

Table 144. Format of the utility statements

<table>
<thead>
<tr>
<th>Column name</th>
<th>Data type</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>STMTID</td>
<td>INTEGER</td>
<td>A unique positive identifier for a single utility execution statement</td>
</tr>
</tbody>
</table>
### Table 144. Format of the utility statements (continued)

<table>
<thead>
<tr>
<th>Column name</th>
<th>Data type</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>STMTSEQ</td>
<td>INTEGER</td>
<td>If a utility statement exceeds 4000 characters, it can be split up and inserted into SYSIBM.UTILITY_STMT with the sequence starting at 0, and then being incremented with every insert. During the actual execution, the statement pieces are concatenated without any separation characters or blanks in between.</td>
</tr>
<tr>
<td>UTSTMT</td>
<td>VARCHAR(4000)</td>
<td>A utility statement or part of a utility statement. A placeholder &amp;OBJECT. can be used to be replaced by the object name passed in SYSIBM.UTILITY_OBJECTS. A placeholder &amp;THDINDEX. can be used to be replaced by the current thread index (01-99) of the utility being executed. You can use this when running REORG with SHRLEVEL CHANGE in parallel, so that you can specify a different mapping table for each thread of the utility execution.</td>
</tr>
</tbody>
</table>

### Example

The following C language sample shows how to invoke ADMIN_UTIL_SCHEDULE:

```c
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

/******************

return(retcd);
}
```

**Output**

This stored procedure returns the following output parameters, which are described in "Option descriptions" on page 877:

- number-of-objects
- utilities-run
- highest-return-code
- parallel-tasks
- return-code
- message
In addition to the preceding output, the stored procedure returns two results sets.

The first result set is returned in the created global temporary table SYSIBMUTILITY_SYSPRINT and contains the output from the individual utility executions. The following table shows the format of the created global temporary table SYSIBM.UTILITY_SYSPRINT:

### Table 145. Result set row for first ADMIN_UTL_SCHEDULE result set

<table>
<thead>
<tr>
<th>Column name</th>
<th>Data type</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>OBJECTID</td>
<td>INTEGER</td>
<td>A unique positive identifier for the object the utility execution is associated with</td>
</tr>
<tr>
<td>TEXTSEQ</td>
<td>INTEGER</td>
<td>Sequence number of utility execution output statements for the object whose unique identifier is specified in the OBJECTID column</td>
</tr>
<tr>
<td>TEXT</td>
<td>VARCHAR(254)</td>
<td>A utility execution output statement</td>
</tr>
</tbody>
</table>

The second result set is returned in the created global temporary table SYSIBM.UTILITY_RETCODE and contains the return code for each of the individual DSNUTILU executions. The following table shows the format of the output created global temporary table SYSIBM.UTILITY_RETCODE:

### Table 146. Result set row for second ADMIN_UTL_SCHEDULE result set

<table>
<thead>
<tr>
<th>Column name</th>
<th>Data type</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>OBJECTID</td>
<td>INTEGER</td>
<td>A unique positive identifier for the object the utility execution is associated with</td>
</tr>
<tr>
<td>RETCODE</td>
<td>INTEGER</td>
<td>Return code from DSNUTILU for this utility execution</td>
</tr>
</tbody>
</table>

**DSNUTILU stored procedure**

### ADMIN_UTL_SORT stored procedure

The SYSPROC.ADMIN_UTL_SORT stored procedure sorts objects for parallel utility execution using JCL or the ADMIN_UTL_SCHEDULE stored procedure.

#### Environment

ADMIN_UTL_SORT runs in a WLM-established stored procedures address space.
Authorization
To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges on each package that the stored procedure uses:
- The EXECUTE privilege on the package for DSNADMUS
- Ownership of the package
- PACKADM authority for the package collection
- SYSADM authority

The owner of the package or plan that contains the CALL statement must also have SELECT authority on the following catalog tables:
- SYSIBM.SYSTABLEPART
- SYSIBM.SYSINDEXPART
- SYSIBM.SYSINDEXES
- SYSIBM.SYSTABLES

Syntax
The following syntax diagram shows the SQL CALL statement for invoking this stored procedure:

```
CALL SYSPROC.ADMIN_UTL_SORT(max-parallel, max-per-job, optimize-workload, null, batch-execution, number-of-objects, parallel-units, max-objects, max-sequences, return-code, message)
```

Option descriptions

max-parallel
Specifies the maximum number of parallel units. The actual number may be lower than the requested number based on the optimizing sort result. Possible values are: 1 to 99.

This is an input parameter of type SMALLINT and cannot be null.

max-per-job
Specifies the maximum number of steps per job for batch execution. Possible values are:

1 to 255
Steps per job for batch execution

null Online execution

This is an input parameter of type SMALLINT. This parameter cannot be null if batch-execution is YES.

optimize-workload
Specifies whether the parallel units should be sorted to achieve shortest overall execution time. Possible values are:
NO or null
  The workload is not to be sorted.

YES  The workload is to be sorted.

This is an input parameter of type VARCHAR(8). The default value is NO.

*batch-execution*
Indicates whether the objects should be sorted for online or batch (JCL) execution.

NO or null
  The workload is for online execution.

YES  The workload is for batch execution.

This is an input parameter of type VARCHAR(8). The default value is NO.

*number-of-objects*
As an input parameter, this specifies the number of objects that were passed in SYSIBM.UTILITY_SORT_OBJ. Possible values are: 1 to 999999.

As an output parameter, this specifies the number of objects that were passed in SYSIBM.UTILITY_SORT_OBJ table that are found in the Db2 catalog.

This is an input and output parameter of type INTEGER and cannot be null.

*parallel-units*
Indicates the number of recommended parallel units.

This is an output parameter of type SMALLINT.

*max-objects*
Indicates the maximum number of objects in any parallel unit.

This is an output parameter of type INTEGER.

*max-sequences*
Indicates the number of jobs in any parallel unit.

This is an output parameter of type INTEGER.

*return-code*
Provides the return code from the stored procedure. Possible values are:

0    Sort ran successfully.

4    The statistics for one or more sorting objects have not been gathered in the catalog or the object no longer exists.

12   An ADMIN_UTL_SORT error occurred. The message parameter will contain details.

This is an output parameter of type INTEGER.

*message*
Contains messages describing the error encountered by the stored procedure. If no error occurred, then no message is returned.

The first messages in this area are generated by the stored procedure. Messages that are generated by Db2 might follow the first messages.

This is an output parameter of type VARCHAR(1331).
Additional input

In addition to the input parameters, this stored procedure reads the objects for sorting and the corresponding utility names from the created global temporary table SYSIBM.UTILITY_SORT_OBJ.

The following table shows the format of the created global temporary table SYSIBM.UTILITY_SORT_OBJ:

Table 147. Input for the ADMIN_UTL_SORT stored procedure

<table>
<thead>
<tr>
<th>Column name</th>
<th>Data type</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>OBJECTID</td>
<td>INTEGER</td>
<td>A unique positive identifier for the object the utility execution is associated with. When you insert multiple rows, increment OBJECTID by 1, starting at 0 for every insert.</td>
</tr>
</tbody>
</table>
| TYPE        | VARCHAR(10) | Object type:  
• TABLESPACE  
• INDEXSPACE  
• TABLE  
• INDEX  
• STOGROUP |
| QUALIFIER   | VARCHAR(128)| Qualifier (database or creator) of the object in NAME, empty or null for STOGROUP. If the qualifier is not provided and the type of the object is TABLESPACE or INDEXSPACE, then the default database is DSNDB04. If the object is of the type TABLE or INDEX, the schema is the current SQL authorization ID. If the object no longer exists, it will be ignored. |
| NAME        | VARCHAR(128) | Unqualified name of the object. NAME cannot be null. |
| PART        | SMALLINT    | Partition number of the object for which the utility will be invoked. Null or 0 if the object is not partitioned. |
Table 147. Input for the ADMIN_UTL_SORT stored procedure (continued)

<table>
<thead>
<tr>
<th>Column name</th>
<th>Data type</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>UTILITY_NAME</td>
<td>VARCHAR(20)</td>
<td>Utility name. UTILITY_NAME cannot be null.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>Recommendation:</strong> Sort objects for the same utility.</td>
</tr>
</tbody>
</table>

Possible values are:
- CHECK DATA
- CHECK INDEX
- CHECK LOB
- COPY
- COPYTOCOPY
- DIAGNOSE
- LOAD
- MERGECOPY
- MODIFY RECOVERY
- MODIFY STATISTICS
- QUIESCE
- REBUILD INDEX
- RECOVER
- REORG INDEX
- REORG LOB
- REORG TABLESPACE
- REPAIR
- REPORT RECOVERY
- REPORT TABLESPACESET
- RUNSTATS INDEX
- RUNSTATS TABLESPACE
- STOSPACE
- UNLOAD

Example

The following C language sample shows how to invoke ADMIN_UTL_SORT:

```c
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

/**************** DB2 SQL Communication Area ****************/
EXEC SQL INCLUDE SQLCA;

int main(int argc, char *argv[]) /* Argument count and list */ {
    /*************** DB2 Host Variables *************** /
    EXEC SQL BEGIN DECLARE SECTION;
    
    /* SYSPROC.ADMIN_UTL_SORT parameters */
    short int maxparallel; /* Max parallel */
    short int ind_maxparallel; /* Indicator variable */
    short int maxperjob; /* Max per job */
    short int ind_maxperjob; /* Indicator variable */
    char optimizeworkload[9]; /* Optimize workload */
    short int ind_optimizeworkload; /* Indicator variable */
    char batchexecution[9]; /* Batch execution */
    short int ind_batchexecution; /* Indicator variable */
    long int numberofobjects; /* Number of objects */
    short int ind_numberofobjects; /* Indicator variable */
    short int parallelunits; /* Parallel units */
    short int ind_parallelunits; /* Indicator variable */
```
long int maxobjects; // Maximum objects per parallel unit
short int ind_maxobjects; // Indicator variable
long int maxseqs; // Maximum jobs per unit
short int ind_maxseqs; // Indicator variable
long int retcd; // Return code
short int ind_retcd; // Indicator variable
char errmsg[1332]; // Error message
short int ind_errmsg; // Indicator variable

/* Temporary table SYSIBM.UTILITY_SORT_OBJ columns */
long int objectid; // Object id
char type[11]; // Object type (e.g. "INDEX")
char qualifier[129]; // Object qualifier
short int ind_qualifier; // Object qualifier ind.
char name[129]; // Object name (qual. or unq.)
short int part; // Optional partition
short int ind_part; // Partition indicator var
char utname[21]; // Utility name
char exclusive[2]; // Exclusive execution flag

EXEC SQL END DECLARE SECTION;

long int objid_array[4] = {0, 1, 2, 3};
char type_array[4][11] = "TABLESPACE", "TABLESPACE",
"TABLESPACE", "TABLESPACE"; // Object id
char qualifier[129]; // Object type (e.g. "INDEX")
char name[129]; // Object qualifier
short int part; // Optional partition
short int ind_part; // Partition indicator var
char utname[21]; // Utility name
char exclusive[2]; // Exclusive execution flag

maxparallel = 2;
ind_maxparallel = 0;
ind_maxperjob = -1;
strcpy(optimizeworkload, "YES");
ind_optimizeworkload = 0;
strcpy(batchexecution, "NO");
ind_batchexecution = 0;
numberofobjects = 4;
ind_numberofobjects = 0;

/* Clear temporary table SYSIBM.UTILITY_SORT_OBJ */
EXEC SQL DELETE FROM SYSIBMUTILITY_SORT_OBJ;

EXEC SQL DELETE FROM SYSIBM.UTILITY_SORT_OBJ;

/* Insert the objects into the temporary table */
/* SYSIBM.UTILITY_SORT_OBJ */

for (i = 0; i < 4; i++)
{
    objectid = objid_array[i];
    strcpy(type, type_array[i]);
    strcpy(qualifier, qual_array[i]);
    strcpy(name, name_array[i]);
    part = part_array[i];
    strcpy(utname, utname_array[i]);
    EXEC SQL INSERT INTO SYSIBM.UTILITY_SORT_OBJ
    (OBJECTID, TYPE, QUALIFIER, NAME, PART, UTILITY_NAME)
    VALUES (:objectid, :type, :qualifier, :name, :part, :utname);
};

EXEC SQL CALL SYSPROC.ADMIN_UTL_SORT

EXEC SQL CALL SYSPROC.ADMIN_UTL_SORT

/* Retrieve result set when the SQLCODE from the call is +446, */
/* which indicates that result sets were returned */
/* which indicates that result sets were returned */

if (SQLCODE == +466) /* Result sets were returned */
{
    /* Establish a link between the result set and its locator */
    EXEC SQL ASSOCIATE LOCATORS (:rs_loc1)
        WITH PROCEDURE SYSPROC.ADMIN_UTL_SORT;

    /* Associate a cursor with the result set */
    EXEC SQL ALLOCATE C1 CURSOR FOR RESULT SET :rs_loc1;

    /* Perform fetches using C1 to retrieve all rows from the */
    /* result set */
    EXEC SQL FETCH C1 INTO :resobjectid, :unit,
        :unitseq, :unitseqpos, :exclusive;
    while(SQLCODE==0)
    {
        EXEC SQL FETCH C1 INTO :resobjectid, :unit,
            :unitseq, :unitseqpos, :exclusive;
    }

    EXEC SQL CLOSE C1;
}
return(retcd);
Output

This stored procedure returns the following output parameters, which are described in “Option descriptions” on page 887:

- number-of-objects
- parallel-units
- max-objects
- max-sequences
- return-code
- message

In addition to the preceding output, the stored procedure returns one result set that contains the objects sorted into parallel execution units.

The following table shows the format of the result set returned in the created global temporary table SYSIBM.UTILITY_SORT_OUT:

Table 148. Result set row for ADMIN_UTL_SORT result set

<table>
<thead>
<tr>
<th>Column name</th>
<th>Data type</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>OBJECTID</td>
<td>INTEGER</td>
<td>A unique positive identifier for the object</td>

<td>Requires execution with nothing running in parallel</td>
</tr>
</tbody>
</table>

**CREATE_WRAPPED stored procedure**

The CREATE_WRAPPED procedure encodes a readable data definition statement into an obfuscated data definition statement and then deploys the object in the database. The procedural logic and embedded SQL statements in an obfuscated data definition statement are scrambled in such a way that any intellectual property in the logic cannot be easily extracted.

```sql
CALL CREATE_WRAPPED (object-definition-string)
```

The schema is SYSIBMADM.

**object-definition-string**

A string of any built-in character type that contains any of the following data definition statements:

- CREATE FUNCTION (compiled SQL scalar)
- CREATE FUNCTION (inlined SQL scalar)
- CREATE PROCEDURE (SQL - native)
• CREATE PROCEDURE (SQL table)
• CREATE TRIGGER (basic)
• CREATE TRIGGER (advanced)

Object-definition-string must not be bit data, and it cannot contain the VERSION keyword.

The procedure encodes the input into an obfuscated data definition statement string and then dynamically executes that data definition statement. The encoded statement consists of the following parts:

• The original statement up to and including the routine signature or trigger name.
• The WRAPPED keyword.
• The product identifier of the database manager that invoked the function. The format of product identifier values is pppvvrrm, where ppp is a 3-letter product code (such as DSN for Db2), vv is the version, rr is the release, and m is the modification level. For example, DSN12015 identifies Db2 12 after the activation of function level 500 or higher.
• The encoded remainder of the data definition statement, in the form of a string of letters (a-z and A-Z), digits (0-9), underscores, and colons. It is converted to Unicode UTF-8 before it is encoded. An error is issued if object-definition-string cannot be converted or if the intermediate string exceeds the maximum length for SQL statements. A warning occurs if a character is converted to the substitution character.

The encoded data definition statement can be up to one-third longer than the plain text form of the statement. If the result exceeds the maximum length for SQL statements, an error is issued.

Examples

Example 1
The following procedure call produces an obfuscated version of a function that computes a yearly salary from an hourly wage given a 40 hour work week.

CALL CREATE_WRAPPED('CREATE FUNCTION salary(wage DECFLOAT) RETURNS DECFLOAT
RETURN wage * 40 * 52');
SELECT TEXT FROM SYSIBM.SYSROUTINES
WHERE NAME = 'SALARY' AND SCHEMA = CURRENT SCHEMA;

The result is similar to the following form:

CREATE FUNCTION salary(wage DECFLOAT) WRAPPED DSN12015
ab1GmtdiWmyTmduTmqTmtaUmCmZqUmdd1x3idawmdaWmZG1mIa6
icagY3Tytmc_qGbe3sOdxjtc8yMpxnul81kmNuRhhZ6yYJDGaa

Example 2
The following procedure call produces an obfuscated version of a trigger that sets a complex default value.

CALL CREATE_WRAPPED('CREATE OR REPLACE TRIGGER trig1 BEFORE INSERT ON emp
REFERENCING NEW AS n FOR EACH ROW
WHEN (n.bonus IS NULL)
SET n.bonus = n.salary * .04')
SELECT STATEMENT FROM SYSIBM.SYSTRIGGERS
WHERE NAME = 'TRIG1' AND SCHEMA = CURRENT SCHEMA;

The result is similar to the following form:

**DSNACCOX stored procedure**

The Db2 real-time statistics stored procedure (DSNACCOX) is a sample stored procedure that makes recommendations to help you maintain your Db2 databases.

You can call the DSNACCOX stored procedure to accomplish the following actions:

- Get recommendations for when to reorganize, image copy, or update statistics for table spaces or index spaces
- Identify when a data set has exceeded a specified threshold for the number of extents that it occupies.
- Identify whether objects are in restricted states

DSNACCOX uses data from catalog tables, including real-time statistics tables, to make its recommendations. DSNACCOX provides its recommendations in a result set.

DSNACCOX uses the set of criteria that are shown in “DSNACCOX formulas for recommending actions” on page 909 to evaluate table spaces and index spaces. By default, DSNACCOX evaluates all table spaces and index spaces in the subsystem that have entries in the real-time statistics tables. However, you can override this default through input parameters.

**About DSNACCOX recommendations**

- You can improve the quality of DSNACCOX recommendations, especially for frequently changed objects, by externalizing in-memory statistics to the real-time statistics tables immediately before calling the stored procedure.

**Related information:**

- Updating real-time statistics immediately (Db2 Performance)
- When Db2 externalizes real-time statistics (Db2 Performance)
- ACCESS DATABASE (Db2) (Db2 Commands)
• DSNACCOX makes recommendations based on general formulas that require input from the user about the maintenance policies for a subsystem. These recommendations might not be accurate for every installation.

• If the real-time statistics tables contain information for only a small percentage of your Db2 subsystem, the recommendations that DSNACCOX makes might not be accurate for the entire subsystem.

• Before you perform any action that DSNACCOX recommends, ensure that the object for which DSNACCOX makes the recommendation is available, and that the recommended action can be performed on that object. For example, REORG might be recommended for an object, but the object might be stopped.

Environment

DSNACCOX must run in a WLM-established stored procedure address space. The DSNWLM_GENERAL core WLM environment is a suitable environment for this stored procedure.

DSNACCOX is installed and configured by installation job DSNTIJRT, which binds the package for DSNACCOX with isolation UR to avoid lock contention.

Authorization required

To execute the CALL DSNACCOX statement, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges on each package that the stored procedure uses:

• The EXECUTE privilege on the package for DSNACCOX
• Ownership of the package
• PACKADM authority for the package collection
• SYSADM authority

The owner of the package or plan that contains the CALL statement must also have:

• SELECT authority on catalog tables
• The DISPLAY system privilege

Syntax diagram

The following syntax diagram shows the CALL statement for invoking DSNACCOX. Because the linkage convention for DSNACCOX is GENERAL WITH NULLS, if you pass parameters in host variables, you need to include a null indicator with every host variable. Null indicators for input host variables must be initialized before you execute the CALL statement.

Related information:

- Indicator variables, arrays, and structures (Db2 Application programming and SQL)
- Linkage conventions for external stored procedures (Db2 Application programming and SQL)
Option descriptions

In the following option descriptions, the default value for an input parameter is the value that DSNACCOX uses if you specify a null value.

**QueryType**

Specifies the types of actions that DSNACCOX recommends. This field contains one or more of the following values. Each value is enclosed in single quotation marks and separated from other values by a space.
ALL  Makes recommendations for all of the following actions.
COPY  Makes a recommendation on whether run an image copy.
RUNSTATS  Makes a recommendation on whether to run RUNSTATS.
REORG  Makes a recommendation on whether to run REORG. Choosing this value causes DSNACCOX to process the EXTENTS value also.
EXTENTS  Indicates when data sets have exceeded a user-specified extents limit.
RESTRICT  Indicates which objects are in a restricted state.

DSNACCOX recommends REORG on the table space when one of the following conditions is true, and REORG (or ALL) is also specified for the value of QUERYTYPE:
- The table space is in REORG-pending status.
- The table space is in advisory REORG-pending status as the result of an ALTER TABLE statement.

DSNACCOX recommends REORG on the index when on the following conditions is true and REORG (or ALL) is also specified for the value of QUERYTYPE::
- The index is in REORG-pending status.
- The index is in advisory REORG-pending as the result of an ALTER TABLE statement.

DSNACCOX recommends FULL COPY on the table space when on the following conditions is true and COPY (or ALL) is also specified for the value of QUERYTYPE::
- The table space is in COPY-pending status.
- The table space is in informational COPY-pending status.

DSNACCOX recommends FULL COPY on the index when on the following conditions is true and COPY (or ALL) is also specified for the value of QUERYTYPE: and SYSINDEX.COPY='Y':
- The index is in COPY-pending status.
- The index is in informational COPY-pending status.

QueryType is an input parameter of type VARCHAR(40). The default value is ALL.

ObjectType
Specifies the types of objects for which DSNACCOX recommends actions:

ALL  Table spaces and index spaces.
TS   Table spaces only.
IX   Index spaces only.

ObjectType is an input parameter of type VARCHAR(3). The default value is ALL.

ICType
Specifies the types of image copies for which DSNACCOX is to make recommendations:
F Full image copy.
I Incremental image copy. This value is valid for table spaces only.
B Full image copy or incremental image copy.

ICType is an input parameter of type VARCHAR(1). The default is B.

CatlgSchema
Specifies the qualifier for Db2 catalog table names. CatlgSchema is an input parameter of type VARCHAR(128). The default value is SYSIBM.

LocalSchema
Specifies the qualifier for the names of local tables that DSNACCOX references. LocalSchema is an input parameter of type VARCHAR(128). The default value is DSNACC.

ChkLvl
Specifies the types of checking that DSNACCOX performs, and indicates whether to include objects that fail those checks in the DSNACCOX recommendations result set. This value is the sum of any combination of the following values:

0 DSNACCOX performs none of the following actions.
1 Exclude rows from the DSNACCOX recommendations result set for RUNSTATS on:
   • Index spaces that are related to tables that are defined as VOLATILE.
   • Table spaces for which all of the tables are defined as VOLATILE.

2 Choosing this value causes DSNACCOX to over-ride the default SSDMultiplier when making a REORG recommendation for a table space or table space partition. The default value is 2 times RRTUnclustInsPct. If CHKLVL 2 is specified RRTUnclustInsPct * 5 is used.

4 Check whether rows that are in the DSNACCOX recommendations result set refer to objects that are in the exception table. For recommendations result set rows that have corresponding exception table rows, copy the contents of the QUERYTYPE column of the exception table to the INEXCEPTTABLE column of the recommendations result set.

8 Check for objects that have restricted states. The value of the QueryType option must be ALL or contain RESTRICTED when this value is specified. The OBJECTSTATUS column of the result set indicates the restricted state of the object. A row is added to the result set for each object that has a restricted state.

16 Reserved for future use.

32 Exclude rows from the DSNACCOX recommendations result set for index spaces for which the related table spaces have been recommended for REORG or RUNSTATS.

64 For index spaces that are listed in the DSNACCOX recommendations result set, check whether the related table spaces are listed in the exception table. For recommendations result set rows that have corresponding exception table rows, copy the contents of the QUERYTYPE column of the exception table to the INEXCEPTTABLE column of the recommendations result set. Selecting CHKLVL64 also activates CHKLVLs 32 and 4.
ChkLvl is an input parameter of type INTEGER. The default is 5 (values 1+4).

Criteria
Narrows the set of objects for which DSNACCOX makes recommendations. This value is the search condition of an SQL WHERE clause. Criteria is an input parameter of type VARCHAR(4096). The default is that DSNACCOX makes recommendations for all table spaces and index spaces in the subsystem. The search condition can use any column in the result set and wildcards are allowed.

DSNACCOX can optimize the retrieval of recommendations if the criteria references only the following columns in the real-time statistics tables:

• DBNAME
• NAME
• PARTITION
• DBID
• PSID

SpecialParm
SpecialParm is an input of type CHAR(160), broken into 4 byte sections to accommodate new options. An empty 4 bytes of EBCDIC blanks indicates that the default is used for the option. An EBCDIC character string of ‘-1’, indicates that this option is not used.

RRIEmptyLimit
Is the ratio of pseudo-empty pages to the total number of leaf pages. Specifies a criterion for recommending that the REORG utility is to be run on an index space. If the following value is greater than RRIEmptyLimit, DSNACCOX recommends running REORG: The number of pseudo-empty leaf pages that were created since the last CREATE, REORG, REBUILD INDEX, or LOAD REPLACE, divided by the total number of leaf pages in the index space or partition, expressed as a percentage.

RRIEmptyLimit is an input parameter of type CHAR 4. The default value is ’10’. A plus sign (+) preceding the value indicates that the DSNACCOX stored procedure returns the value in the result set. A negative value turns off this criterion.

The ratio of pseudo-empty pages to the total number of leaf pages is returned in column RRIEMPTYLIMIT of the result set.

RRTHashOvrFlwRatio
The ratio of hash access overflow index entries to the total number of rows. Specifies a criterion for recommending that the REORG utility is to be run on a table space. If the following condition is true, DSNACCOX recommends running REORG: The hash access overflow index is being used for access, and the ratio of hash access overflow index entries divided by the total number of rows (expressed as a percentage) is greater than RRTHashOvrFlwRatio.

RRTHashOvrFlwRatio is an input parameter of type CHAR 4. The default value is ’15’. A plus sign (+) preceding or after the value or by itself indicates that the DSNACCOX stored procedure returns the calculated ratio value in the result set. The value of the ObjectType parameter must be ALL, or contain both TS and IX, for this criterion to be used. A negative value turns off this criterion.

The ratio of Hash Access overflow index entries to the total number of rows is returned in the RRTHASHOVRFLOWRAT column of the result set.
**CRUpdatedPagesPct**

Is the ratio of the total number of distinct updated pages to the total number of preformatted pages. Specifies, when combined with *CRUpdatedPagesAbs*, a criterion for recommending a full image copy on a table space or index space. If both of the following conditions are true for a table space, DSNACCOX recommends an image copy:

- The total number of distinct updated pages, divided by the total number of preformatted pages (expressed as a percentage) is greater than *CRUpdatedPagesPct*.
- The total number of distinct updates pages is greater than *CRUpdatedPagesABS*.

If all of the following conditions are true for an index space, DSNACCOX recommends an image copy:

- The total number of distinct updated pages, divided by the total number of preformatted pages (expressed as a percentage) is greater than *CRUpdatedPagesPct*.
- The total number of distinct updates pages is greater than *CRUpdatedPagesABS*.
- The number of active pages in the index space or partition is greater than *CRIndexSize*.

*CRUpdatedPagesPct* is an input parameter of type DOUBLE. The default is **20.0**. A negative value turns off both this criterion and *CRUpdatedPagesAbs*.

**CRUpdatedPagesABS**

Is the total number of distinct updated pages. Specifies, when combined with *CRUpdatedPagesPct*, a criterion for recommending a full image copy on a table space or index space. If both of the following conditions are true for a table space, DSNACCOX recommends an image copy:

- The total number of distinct updated pages, divided by the total number of preformatted pages (expressed as a percentage) is greater than *CRUpdatedPagesPct*.
- The total number of distinct updates pages is greater than *CRUpdatedPagesABS*.
- The number of active pages in the index space or partition is greater than *CRIndexSize*.

If all of the following conditions are true for an index space, DSNACCOX recommends an image copy:

- The total number of distinct updated pages, divided by the total number of preformatted pages (expressed as a percentage) is greater than *CRUpdatedPagesPct*.
- The total number of distinct updates pages is greater than *CRUpdatedPagesAbs*.
- The number of active pages in the index space or partition is greater than *CRIndexSize*.

*CRUpdatedPagesABS* is an input parameter of type INTEGER. The default value is **0**.

**CRChangesPct**

Is the ratio of the total number of insert, update, and delete operations to the total number of rows. Specifies a criterion for recommending a full image copy on a table space or index space. If the following condition is true for a table space, DSNACCOX recommends an image copy:
The total number of insert, update, and delete operations since the last image copy, divided by the total number of rows or LOBs in a table space or partition (expressed as a percentage) is greater than CRChangesPct.

If both of the following conditions are true for an index table space, DSNACCOX recommends an image copy:

- The total number of insert and delete operations since the last image copy, divided by the total number of entries in the index space or partition (expressed as a percentage) is greater than CRChangesPct.
- The number of active pages in the index space or partition is greater than CRIndexSize.

CRChangesPct is an input parameter of type DOUBLE. The default is 10.0. A negative value turns off this criterion.

CRDaySncLastCopy
Is the number of days since the last image copy. Specifies a criterion for recommending a full image copy on a table space or index space. If the number of days since the last image copy is greater than this value, DSNACCOX recommends an image copy.

CRDaySncLastCopy is an input parameter of type INTEGER. The default is 7. A negative value turns off this criterion.

ICRUpdatedPagesPct
Is the ratio of the total number of distinct updated pages to the total number of preformatted pages. Specifies a criterion for recommending an incremental image copy on a table space. If both of the following conditions are true, DSNACCOX recommends an incremental image copy:

- The number of distinct pages that were updated since the last image copy, divided by the total number of active pages in the table space or partition (expressed as a percentage) is greater than ICRUpdatedPagesPct.
- The number of distinct pages that were updated since last image copy is greater than ICRUpdatedPagesAbs.

ICRUpdatedPagesPct is an input parameter of type DOUBLE. The default value is 1.0. A negative value turns off this criterion and ICRUpdatedPagesAbs.

ICRUpdatedPagesAbs
Is the total number of distinct updated pages. Specifies, when combined with ICRUpdatedPagesPct, a criterion for recommending an incremental image copy on a table space. If both of the following conditions are true, DSNACCOX recommends an incremental image copy:

- The number of distinct pages that were updated since the last image copy, divided by the total number of active pages in the table space or partition (expressed as a percentage) is greater than ICRUpdatedPagesPct.
- The number of distinct pages that were updated since last image copy is greater than ICRUpdatedPagesAbs.

ICRUpdatedPagesAbs is an input parameter of type INTEGER. The default is 0.

ICRChangesPct
Is the ratio of the total number of insert, update, or delete operations to the total number of rows. Specifies a criterion for recommending an incremental image copy on a table space. If the following condition is true, DSNACCOX recommends an incremental image copy:

The ratio of the number of insert, update, or delete operations since the last image copy, to the total number of rows or LOBs in a table space or partition (expressed as a percentage) is greater than ICRChangesPct.
ICRChangesPct is an input parameter of type DOUBLE. The default is 1.0. A negative value turns off this criterion.

CRIndexSize
Is the minimum index size. Specifies the minimum index size before checking the CRUpdatedPagesPct or CRChangesPct criteria for recommending a full image copy on an index space.

CRIndexSize is an input parameter of type INTEGER. The default is 50. A negative value turns off this criterion and ICRChangesPct.

RRTInsertsPct
Is the ratio of total number of insert operations to the total number of rows. Specifies, when combined with RRTInsertsAbs, a criterion for recommending that the REORG utility is to be run on a table space. If both of the following condition are true, DSNACCOX recommends running REORG:

- The sum of insert, update, and delete operations since the last REORG, divided by the total number of rows or LOBs in the table space or partition (expressed as a percentage) is greater than RRTInsertsPct
- The sum of insert operations since the last REORG is greater than RRTInsertsAbs.

RRTInsertsPct is an input parameter of type DOUBLE. The default value is -1. A negative value turns off this criterion and RRTInsertsAbs.

RRTInsertsAbs
Is the total number of insert operations. Specifies, when combined with RRTInsertsPct, a criterion for recommending that the REORG utility is to be run on a table space. If both of the following condition are true, DSNACCOX recommends running REORG:

- The sum of insert operations since the last REORG, divided by the total number of rows or in the table space or partition (expressed as a percentage) is greater than RRTInsertsPct
- The sum of insert operations since the last REORG is greater than RRTInsertsAbs.

RRTInsertsAbs is an input parameter of type INTEGER. The default value is 0.

RRTDeletesPct
Is the ratio of the total number of delete operations to the total number of rows. Specifies, when combined with RRTDeletesAbs, a criterion for recommending that the REORG utility is to be run on a table space. If both of the following condition are true, DSNACCOX recommends running REORG:

- The sum of delete operations since the last REORG, divided by the total number of rows or in the table space or partition (expressed as a percentage) is greater than RRTDeletesPct
- The sum of delete operations since the last REORG is greater than RRTDeletesAbs.

RRTDeletesPct is an input parameter of type DOUBLE. The default value is 25.0. A negative value turns off this criterion and RRTDeletesAbs.

RRTDeletesAbs
Is the total number of delete operations. Specifies, when combined with RRTDeletesPct, a criterion for recommending that the REORG utility is to be run on a table space. If both of the following condition are true, DSNACCOX recommends running REORG:
• The sum of delete operations since the last REORG, divided by the total number of rows or in the table space or partition (expressed as a percentage) is greater than $RRTDeletesPct$.

• The sum of delete operations since the last REORG is greater than $RRTDeletesAbs$.

$RRTDeletesAbs$ is an input parameter of type INTEGER. The default value is 0.

$RRTUnclustInsPct$
Is the ratio of the total number of unclustered insert operations to the total number of rows. Specifies a criterion for recommending that the REORG utility is to be run on a table space. If the following condition is true, DSNACCOX recommends running REORG:

The number of unclustered insert operations, divided by the total number of rows or LOBs in the table space or partition (expressed as a percentage) is greater than $RRTUnclustInsPct$.

$RRTUnclustInsPct$ is an input parameter of type DOUBLE. The default is 10.0. A negative value will turn off this criterion.

$RRTDisorgLOBPct$
Is the ratio of the number of imperfectly chunked LOBs to the total number of rows. Specifies a criterion for recommending that the REORG utility is to be run on a table space. If the following condition is true, DSNACCOX recommends running REORG:

The number of imperfectly chunked LOBs, divided by the total number of rows or LOBs in the table space or partition (expressed as a percentage) is greater than $RRTDisorgLOBPct$.

$RRTDisorgLOBPct$ is an input parameter of type DOUBLE. The default is 50.0. A negative value will turn off this criterion.

$RRTDataSpaceRat$
Is the ratio of the space allocated to the actual space used. Specifies a criterion for recommending that the REORG utility is to be run on table space for space reclamation. If the following condition is true, DSNACCOX recommends running REORG:

The object is not using hash organization.

The SPACE allocated is greater than $RRTDataSpaceRat$ multiplied by the actual space used. ($SPACE > RRTDataSpaceRat \times (DATASIZE/1024)$)

$RRTDataSpaceRat$ is an input parameter of type DOUBLE. The default value is -1. A negative value turns off this criterion.

$RRTMassDelLimit$
Is the sum of the number of mass deletes. Specifies a criterion for recommending that the REORG utility is to be run on a table space. If one of the following values is greater than $RRTMassDelLimit$, DSNACCOX recommends running REORG:

• The sum of mass deletes from a segmented or LOB table space since the last REORG or LOAD REPLACE

• The number of dropped tables from a nonsegmented table space since the last REORG or LOAD REPLACE

$RRTMassDelLimit$ is an input parameter of type INTEGER. The default is 0.

$RRTIndRefLimit$
Is the ratio of the total number of overflow records that were created to the total number of rows. Specifies a criterion for recommending that the REORG
utility is to be run on a table space. If the following value is greater than
\textit{RRTIndRefLimit}, DSNACCOX recommends running REORG:

The total number of overflow records that were created since the last
REORG or LOAD REPLACE, divided by the total number of rows or LOBs
in the table space or partition (expressed as a percentage)

\textit{RRTIndRefLimit} is an input parameter of type DOUBLE. The default is \textbf{5.0} in
data sharing environment and \textbf{10.0} in a non-data sharing environment.

\textbf{\textit{RRI InsertsPct}}

Is the ratio of the total number of index entries that were inserted to the total
number of index entries. Specifies a criterion for recommending that the
REORG utility is to be run on an index space. If the both of the following
conditions are true, DSNACCOX recommends running REORG:

\begin{itemize}
  \item The sum of the number of index entries that were inserted since the last
        REORG, divided by the total number of index entries in the index space or
        partition (expressed as a percentage) is greater than \textit{RRI InsertsPct}.
  \item The sum of the number of index entries that were inserted since the last
        REORG is greater than \textit{RRI InsertsAbs}.
\end{itemize}

\textit{RRI InsertsPct} is an input parameter of type DOUBLE. The default is \textbf{-1}. A
negative value turns off this criterion and \textit{RRI InsertsAbs}.

\textbf{\textit{RRI InsertsAbs}}

Is the sum of the number of index entries that were inserted. Specifies a
criterion for recommending that the REORG utility is to be run on an index
space. If both of the following conditions are true, DSNACCOX recommends
running REORG:

\begin{itemize}
  \item The sum of the number of index entries that were inserted since the last
        REORG, divided by the total number of index entries in the index space or
        partition (expressed as a percentage) is greater than \textit{RRI InsertsPct}.
  \item The sum of the number of index entries that were inserted since the last
        REORG is greater than \textit{RRI InsertsAbs}.
\end{itemize}

\textit{RRI InsertsAbs} is an input parameter of type INTEGER. The default is \textbf{0}. A
negative value turns off this criterion.

\textbf{\textit{RRID DeletesPct}}

Is the ratio of the sum of the number of index entries that were deleted to the
total number of index entries. Specifies a criterion for recommending that the
REORG utility is to be run on an index space. If the following value is greater than
\textit{RRID DeletesPct}, DSNACCOX recommends running REORG:

\begin{itemize}
  \item The sum of the number of index entries that were deleted since the last
        REORG, divided by the total number of index entries in the index space or
        partition (expressed as a percentage) is greater than \textit{RRID DeletesPct}.
  \item The sum of the number of index entries that were deleted since the last
        REORG is greater than \textit{RRID DeletesAbs}.
\end{itemize}

\textit{RRID DeletesPct} is an input parameter of type DOUBLE. The default is \textbf{30.0}. A
negative value turns off this criterion.

\textbf{\textit{RRID DeletesAbs}}

Is the sum of the number of index entries that were deleted. Specifies a
criterion for recommending that the REORG utility is to be run on an index
space. If the following value is greater than \textit{RRID DeletesPct}, DSNACCOX
recommends running REORG:
The sum of the number of index entries that were deleted since the last REORG, divided by the total number of index entries in the index space or partition (expressed as a percentage) is greater than RRIDeletesPct.

The sum of the number of index entries that were deleted since the last REORG is greater than RRIDeletesAbs.

RRIDeletesAbs is an input parameter of type INTEGER. The default is 0. A negative value turns off this criterion.

RRIAppendInsertPct
Is the ratio of the number of index entries that were inserted with a key value greater than the maximum key value in the index space or partition to the number of index entries. Specifies a criterion for recommending that the REORG utility is to be run on an index space. If the following value is greater than RRIAppendInsertPct, DSNACCOX recommends running REORG:

The number of index entries that were inserted since the last REORG, REBUILD INDEX, or LOAD REPLACE with a key value greater than the maximum key value in the index space or partition, divided by the number of index entries in the index space or partition (expressed as a percentage)

RRIAppendInsertPct is an input parameter of type DOUBLE. The default is 20.0. A negative value turns off this criterion.

RRIPseudoDeletePct
Is the ratio of the number of index entries that were pseudo-deleted to the number of index entries. Specifies a criterion for recommending that the REORG utility is to be run on an index space. If the following value is greater than RRIPseudoDeletePct, DSNACCOX recommends running REORG:

The number of index entries that were pseudo-deleted since the last REORG, REBUILD INDEX, or LOAD REPLACE, divided by the number of index entries in the index space or partition (expressed as a percentage)

RRIPseudoDeletePct is an input parameter of type DOUBLE. The default is -1. A negative value turns off this criterion.

RRIMassDelLimit
Is the sum of the number of mass deletes of index entries. Specifies a criterion for recommending that the REORG utility is to be run on an index space. If the number of mass deletes from an index space or partition since the last REORG, REBUILD, or LOAD REPLACE is greater than this value, DSNACCOX recommends running REORG.

RRIMassDelLimit is an input parameter of type INTEGER. The default is 0. A negative value turns off this criterion.

RRILeafLimit
Is the ratio of the number of index page splits in which the higher part of the split page was far from the location of the original page to the total number of active pages. Specifies a criterion for recommending that the REORG utility is to be run on an index space. If the following value is greater than RRILeafLimit, DSNACCOX recommends running REORG:

The number of index page splits that occurred since the last REORG, REBUILD INDEX, or LOAD REPLACE in which the higher part of the split page was far from the location of the original page, divided by the total number of active pages in the index space or partition (expressed as a percentage)

RRILeafLimit is an input parameter of type DOUBLE. The default is 10.0. A negative value turns off this criterion.
RRINumLevelsLimit
Is the number of levels in the index tree that were added or removed. Specifies a criterion for recommending that the REORG utility is to be run on an index space. If the following value is greater than RRINumLevelsLimit, DSNACCOX recommends running REORG:

The number of levels in the index tree that were added or removed since the last REORG, REBUILD INDEX, or LOAD REPLACE

RRINumLevelsLimit is an input parameter of type INTEGER. The default is 0. A negative value turns off this criterion.

SRTInsDelUpdPct
Is the ratio of the total number of insert, update, or delete operations to the total number of rows. Specifies, when combined with SRTInsDelUpdAbs, a criterion for recommending that the RUNSTATS utility is to be run on a table space. If both of the following conditions are true, DSNACCOX recommends running RUNSTATS:

• The number of insert, update, or delete operations since the last RUNSTATS on a table space or partition, divided by the total number of rows or LOBs in table space or partition (expressed as a percentage) is greater than SRTInsDelUpdPct.
• The sum of the number of inserted and deleted index entries since the last RUNSTATS on an index space or partition is greater than SRTInsDelUpdAbs.

SRTInsDelUpdPct is an input parameter of type DOUBLE. The default is 20.0. A negative value turns off this criterion.

SRTInsDelUpdAbs
Is the number of insert, update, and delete operations. Specifies, when combined with SRTInsDelUpdPct, a criterion for recommending that the RUNSTATS utility is to be run on a table space. If both of the following conditions are true, DSNACCOX recommends running RUNSTATS:

• The number of insert, update, and delete operations since the last RUNSTATS on a table space or partition, divided by the total number of rows or LOBs in table space or partition (expressed as a percentage) is greater than SRTInsDelUpdPct.
• The sum of the number of inserted and deleted index entries since the last RUNSTATS on an index space or partition is greater than SRTInsDelUpdAbs.

SRTInsDelUpdAbs is an input parameter of type INTEGER. The default is 0.

SRTMassDelLimit
Is the sum of the number of mass deletes. Specifies a criterion for recommending that the RUNSTATS utility is to be run on a table space. If the following condition is true, DSNACCOX recommends running RUNSTATS:

• The number of mass deletes from a table space or partition since the last REORG or LOAD REPLACE is greater than SRTMassDelLimit.

SRTMassDelLimit is an input parameter of type INTEGER. The default is 0. A negative value turns off this criterion.

SRIInsDelPct
Is the ratio of the total number of inserted and deleted index entries to the total number of index entries. Specifies, when combined with SRIInsDelAbs, a criterion for recommending that the RUNSTATS utility is to be run on an index space. If both of the following conditions are true, DSNACCOX recommends running RUNSTATS:
- The number of inserted and deleted index entries since the last RUNSTATS on an index space or partition, divided by the total number of index entries in the index space or partition (expressed as a percentage) is greater than $SRIInsDelPct$

- The sum of the number of inserted and deleted index entries since the last RUNSTATS on an index space or partition is greater than $SRIInsDelAbs$

$SRIInsDelPct$ is an input parameter of type DOUBLE. The default is 20.0. A negative value turns off this criterion.

$SRIInsDelAbs$

Is the total number of inserted and deleted index entries. Specifies, when combined with $SRIInsDelPct$, a criterion for recommending that the RUNSTATS utility is to be run on an index space. If the following condition is true, DSNACCOX recommends running RUNSTATS:

- The number of inserted and deleted index entries since the last RUNSTATS on an index space or partition, divided by the total number of index entries in the index space or partition (expressed as a percentage) is greater than $SRIInsDelPct$

- The sum of the number of inserted and deleted index entries since the last RUNSTATS on an index space or partition is greater than $SRIInsDelAbs$.

$SRIInsDelAbs$ is an input parameter of type INTEGER. The default is 0. A negative value turns off this criterion.

$SRIMassDelLimit$

Is the sum of the number of mass deletes. Specifies a criterion for recommending that the RUNSTATS utility is to be run on an index space. If the number of mass deletes from an index space or partition since the last REORG, REBUILD INDEX, or LOAD REPLACE is greater than this value, DSNACCOX recommends running RUNSTATS.

$SRIMassDelLimit$ is an input parameter of type INTEGER. The default value is 0. A negative value turns off this criterion.

$ExtentLimit$

Is the number of physical extents. Specifies a criterion for recommending that the REORG utility is to be run on a table space or index space. Also specifies that DSNACCOX is to warn the user that the table space or index space has used too many extents. DSNACCOX recommends running REORG, and altering data set allocations if the following condition is true:

- The number of physical extents in the index space, table space, or partition is greater than $ExtentLimit$.

$ExtentLimit$ is an input parameter of type INTEGER. The default value is 254. A negative value turns off this criterion.

$LastStatement$

When DSNACCOX returns a severe error (return code 12), this field contains the SQL statement that was executing when the error occurred. $LastStatement$ is an output parameter of type VARCHAR(8012).

$ReturnCode$

The return code from DSNACCOX execution. Possible values are:

<table>
<thead>
<tr>
<th>Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>DSNACCOX executed successfully.</td>
</tr>
<tr>
<td>4</td>
<td>DSNACCOX completed with a warning. The $ErrorMsg$ parameter contains the input parameters that might be incompatible.</td>
</tr>
<tr>
<td>8</td>
<td>DSNACCOX terminated with errors. The $ErrorMsg$ parameter contains a message that describes the error.</td>
</tr>
</tbody>
</table>
12 DSNACCOX terminated with severe errors. The ErrorMsg parameter contains a message that describes the error. The LastStatement parameter contains the SQL statement that was executing when the error occurred.

14 DSNACCOX terminated because the real-time statistics table were not yet migrated to the catalog.

15 DSNACCOX terminated because it encountered a problem with one of the declared temporary tables that it defines and uses.

16 DSNACCOX terminated because it could not define a declared temporary table.

NULL DSNACCOX terminated but could not set a return code.

ReturnCode is an output parameter of type INTEGER.

ErrorMsg
Contains information about DSNACCOX execution when DSNACCOX terminates with a non-zero value for ReturnCode.

IFCAREtCode
Contains the return code from an IFI COMMAND call. DSNACCOX issues commands through the IFI interface to determine the status of objects. IFCAREtCode is an output parameter of type INTEGER.

IFCAResCode
Contains the reason code from an IFI COMMAND call. IFCAResCode is an output parameter of type INTEGER.

XsBytes
Contains the number of bytes of information that did not fit in the IFI return area after an IFI COMMAND call. XsBytes is an output parameter of type INTEGER.

DSNACCOX formulas for recommending actions

The following formulas specify the criteria that DSNACCOX uses for its recommendations and warnings. The variables in italics are DSNACCOX input parameters. The capitalized variables are columns of the SYSIBM.SYSTABLESPACESTATS or SYSIBM.SYINDEXSPACESTATS catalog tables.

The following figure shows the formula that DSNACCOX uses to recommend a full image copy on a table space.
The following figure shows the formula that DSNACCOX uses to recommend a full image copy on a table space.

$((\text{QueryType} = '\text{COPY}') \text{ OR } \text{QueryType} = '\text{ALL}') \text{ AND } \text{ObjectType} = '\text{IX}' \text{ OR } \text{ObjectType} = '\text{ALL}') \text{ AND }$  
$\text{SYSINDEXES.COPY} = 'Y') \text{ AND } \text{COPYLASTTIME IS NULL OR REORGLASTTIME} = \text{COPYLASTTIME OR LOADRLASTTIME} = \text{COPYLASTTIME OR REBUILDLASTTIME} = \text{COPYLASTTIME OR (CURRENT DATE}-\text{COPYLASTTIME)} > \text{CRDaySncLastCopy OR (ACTIVE} = \text{CRUpdatedPagesPct}) \text{ AND } (\text{COPYUPDATING} > \text{CRUpdatedPagesAbs}) \text{ OR (COPYCHANGES} > \text{TOTALROWS} > \text{ICRChangesPct}) \text{ OR ((QueryType} = '\text{RESTRICT'}) \text{ OR QueryType} = '\text{ALL'}) \text{ OR } \text{QueryType} = '\text{COPY}' \text{ AND (ObjectType} = '\text{IX}' \text{ OR ObjectType} = '\text{ALL'}) \text{ AND (Object is not in Persistent Read Only (PRO) status) AND (ICType} = 'F') \text{ OR ICType} = 'B') \text{ AND } (ICType} = 'I') \text{ AND } \text{COPYLASTTIME IS NOT NULL)} \text{ AND LOADRLASTTIME} = \text{COPYLASTTIME OR REORGLASTTIME} = \text{COPYLASTTIME OR ((COPYUPDATING} > \text{ICRUpdatedPagesPct}) \text{ AND (COPYUPDATING} > \text{ICRUpdatedPagesAbs}) \text{ OR (COPYCHANGES} > \text{TOTALROWS} > \text{ICRChangesPct})}$

Figure 25. DSNACCOX formula for recommending a full image copy on an index space

The following figure shows the full image copy on an index space.

$((\text{QueryType} = '\text{COPY}') \text{ OR } \text{QueryType} = '\text{ALL}') \text{ AND } \text{ObjectType} = '\text{TS}' \text{ OR } \text{ObjectType} = '\text{ALL}') \text{ AND Object is not in Persistent Read Only (PRO) status) AND (ICType} = 'F') \text{ OR ICType} = 'B') \text{ AND } (ICType} = 'I') \text{ AND (COPYLASTTIME IS NOT NULL)} \text{ AND LOADRLASTTIME} = \text{COPYLASTTIME OR REORGLASTTIME} = \text{COPYLASTTIME OR ((COPYUPDATING} > \text{ICRUpdatedPagesPct}) \text{ AND (COPYUPDATING} > \text{ICRUpdatedPagesAbs}) \text{ OR (COPYCHANGES} > \text{TOTALROWS} > \text{ICRChangesPct})}$

Figure 26. DSNACCOX formula for recommending an incremental image copy on a table space

The following figure shows the formula that DSNACCOX uses to recommend an incremental image copy on a table space.
The following figure shows the formula that DSNACCOX uses to recommend a REORG on a table space. If the table space is a LOB table space, and CHKLVL=1, the formula does not include EXTENTS>ExtentLimit.

\[
\begin{align*}
\text{((QueryType='REORG' OR QueryType='ALL') AND} \\
\text{(ObjectType='TS' OR ObjectType='ALL')) AND} \\
\text{(Object is not in Persistent Read Only (PRO) status) AND} \\
\text{(REORGLASTTIME IS NULL AND LOADRLASTTIME IS NULL) OR} \\
\text{(NACTIVE IS NULL OR NACTIVE > 5) AND} \\
\text{((REORGINSERTS*100)/TOTALROWS>RRTInsertsPct) AND} \\
\text{REORGINSERTS>RRTInsertsAbs) OR} \\
\text{((REORGDELETE*100)/TOTALROWS>RRTDeletesPct) AND} \\
\text{REORGDELETE>RRTDeletesAbs) OR} \\
\text{(REORGCLUSTERSENS > 0 AND (REORGUNCLUSTINS*100)/TOTALROWS>RRTUnclustInsPct) OR} \\
\text{(REORGDISORGLOB*100)/TOTALROWS>RRTDisorgLOBPct OR} \\
\text{(SPACE*1024)/DATASIZE>RRTDataSpaceRat OR} \\
\text{((REORGNEARINDREF+REORGFARINDREF)*100)/TOTALROWS>RRTIndRefLimit OR} \\
\text{REORGMASSDELETE>RRTMassDelLimit OR} \\
\text{EXTENTS>ExtentLimit)) OR} \\
\text{(QueryType='REORG' OR QueryType='ALL') AND} \\
\text{ObjectType='ALL' AND} \\
\text{overflow index for hash access is used) and} \\
\text{(overflow index TOTALENTRY x 100) / TOTALROWS > RRTHashOvrFlwRatio)) OR} \\
\text{((QueryType='RESTRICT' OR QueryType='ALL' OR QueryType='REORG') AND} \\
\text{(ObjectType='TS' OR ObjectType='ALL') AND} \\
\text{The table space is in advisory or informational reorg pending status)}
\end{align*}
\]

Notes:
1. If RRTInsertsPct defaults to -1, DSNACCOX does no checking for RRTInsertsPct or RRTInsertsAbs. If you want to use this criterion, you need to pass the RRTInsertsPct parameter to DSNACCOX.
2. Both IX and TS must be selected, thus Object=ALL must be specified to use this criterion. If only TS or IX is specified, and the value of the special parameter contains a plus sign (+) to indicate that the RRTHASHOVRFLOWWRAT column is to be included in the result set, an error message is issued. Otherwise, this criterion does not apply when only TS or IX is specified.
3. The overflow index is used when SYSINDEXES.HASH = 'Y' AND SYSINDEXSPACESTATS.REORGINDEXACCESS > 0.

Figure 27. DSNACCOX formula for recommending a REORG on a table space

The following figure shows the formula that DSNACCOX uses to recommend a REORG on an index space.
The following figure shows the formula that DSNACCOX uses to recommend RUNSTATS on a table space.

```
((QueryType='REORG' OR QueryType='ALL') AND
 (ObjectType='IX' OR ObjectType='ALL') AND
 (REORGLASTTIME IS NULL AND REBUILDLASTTIME IS NULL) OR
 (NACTIVE IS NULL OR NACTIVE > 5) AND
 (((REORGINSETS>100)/TOTALENTRIES>RRIInsertsPct) AND
  REORGINSETS>RRIInsertsAbs) OR
 (((REORGDELETEx100)/TOTALENTRIES>RRIDeletesPct) AND
  REORGDELETE>RRIDeletesAbs) OR
 (REORGPSUDELETEx100)/TOTALENTRIES>RRIAppendInsertPct OR
 (REORGMASSDELETEx100)/TOTALENTRIES>RRIMassDeleteLimit OR
 (REORGLEAFFARx100)/NACTIVE>RRILeafLimit OR
 REORGNUMLEVELS>RRINumLevelsLimit OR
 (NPGAGES>5 AND
  (NPGAGES>100)/NLEAF=RRIEmptyLimit) OR
  EXTENTS>ExtentLimit)) OR
 ((QueryType='REORG' OR QueryType='ALL') AND
 (ObjectType='IX' OR ObjectType='ALL') AND
 An index is in advisory-REBUILD-pending stats (ARBDP))
```

Notes:

1. If RRIInsertsPct defaults to -1, DSNACCOX does no checking for RRIInsertsPct or RRIInsertsAbs. If you want to use this criterion, you need to pass the RRIInsertsPct parameter to DSNACCOX.
2. If RRIPseudoDeletePct defaults to -1, DSNACCOX does no checking for this criterion. If you want to use this criterion, you need to pass the RRIPseudoDeletePct parameter to DSNACCOX.

---

The following figure shows the formula that DSNACCOX uses to recommend RUNSTATS on a table space.

```
((QueryType='RUNSTATS' OR QueryType='ALL') AND
 (ObjectType='TS' OR ObjectType='ALL') AND
 Table Space is not cloned) AND
 (STATSLASTTIME IS NULL OR
  STATSLASTTIME<LOADRLASTTIME OR
  STATSLASTTIME<REORGLASTTIME OR
  STATSLASTTIME= latest PROFILE_UPDATE for the table space) OR
 ((STATSINSERTS+STATSDELETES+STATSUPDATES)x100)/TOTALROWS>SRTInsDelUpdPct AND
 ((STATSINSERTS+STATSDELETES+STATSUPDATES)>SRTInsDelUpdAbs) OR
 (STATSMASDELETES>SRTMassDeleteLimit))
```

---

Notes:

1. PROFILE_UPDATE is a table-level timestamp column in the SYSIBM.SYSTABLES_PROFILES catalog table. It is updated by RUNSTATS SET or UPDATE. The PROFILE_UPDATE value is not returned as a column in the DSNACCOX result set.

The following figure shows the formula that DSNACCOX uses to recommend RUNSTATS on an index space.
Using an exception table

An exception table is an optional, user-created Db2 table that you can use to place information in the INEXCEPTTABLE column of the recommendations result set. You can put any information in the INEXCEPTTABLE column, but the most common use of this column is to filter the recommendations result set. Each row in the exception table represents an object for which you want to provide information for the recommendations result set.

To create the exception table, issue a CREATE TABLE statement similar to the following one. You can include other columns in the exception table, but you must include at least the columns that are shown. It is best to create a primary key on the exception table to prevent the duplication of rows in the exception table.

```
CREATE TABLE DSNACC.EXCEPT_TBL
(DBNAME CHAR(8) NOT NULL,
 NAME CHAR(8) NOT NULL,
 QUERYTYPE CHAR(40),
 PRIMARY KEY (DBNAME,NAME))
CCSID EBCDIC;
```

The exception table columns have the following meanings:

**DBNAME**
- The database name for an object in the exception table.

**NAME**
- The table space name or index space name for an object in the exception table.

**QUERYTYPE**
- The information that you want to place in the INEXCEPTTABLE column of the recommendations result set.

If you put a null value in this column, DSNACCOX puts the value YES in the INEXCEPTTABLE column of the recommendations result set row for the object that matches the DBNAME and NAME values.

If you plan to put many rows in the exception table, create a nonunique index on DBNAME, NAME, and QUERYTYPE.

After you create the exception table, insert a row for each object for which you want to include information in the INEXCEPTTABLE column.

**Example:** Suppose that you want the INEXCEPTTABLE column to contain the string 'IRRELEVANT' for table space STAFF in database DSNDB04. You also want the INEXCEPTTABLE column to contain 'CURRENT' for table space DSN8S12D in database DSN8D12A. Execute these INSERT statements:

```sql
((QueryType='RUNSTATS' OR QueryType='ALL') AND
 (ObjectType='IX' OR ObjectType='ALL'))
Table Space for the index is not cloned ) AND
(STATSLASTTIME IS NULL OR
 STATSLASTTIME<LOADRLASTTIME OR
 STATSLASTTIME<REORGLASTTIME OR
 (((STATSINSERTS+STATSDELETES)*100)/TOTALENTRIES>SRIInsDelPct AND
 (STATSINSERTS+STATSDELETES)>SRIInsDelAbs) OR
 STATSMASSDELETE>SRIInsDelAbs)))
```
To use the contents of INEXCEPTTABLE for filtering, include a condition that involves the INEXCEPTTABLE column in the search condition that you specify in your Criteria input parameter.

**Example:** Suppose that you want to include all rows for database DSNDB04 in the recommendations result set, except for those rows that contain the string 'IRRELEVANT' in the INEXCEPTTABLE column. You might include the following search condition in your Criteria input parameter:

```sql
DBNAME='DSNDB04' AND INEXCEPTTABLE<> 'IRRELEVANT'
```

**Example**

The following figure is a COBOL example that shows variable declarations and an SQL CALL for obtaining recommendations for objects in databases DSN8D12A and DSN8D12L. This example also outlines the steps that you need to perform to retrieve the two result sets that DSNACCOX returns. These result sets are described in "DSNACCOX output" on page 918.

**DSNACCOX output**

If DSNACCOX executes successfully, in addition to the output parameters described in "Option descriptions" on page 897, DSNACCOX returns two result sets.

The first result set contains the results from IFI COMMAND calls that DSNACCOX makes. The following table shows the format of the first result set.

<table>
<thead>
<tr>
<th>Column name</th>
<th>Data type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>RS_SEQUENCE</td>
<td>INTEGER</td>
<td>Sequence number of the output line</td>
</tr>
<tr>
<td>RS_DATA</td>
<td>CHAR(80)</td>
<td>A line of command output</td>
</tr>
</tbody>
</table>

The second result set contains rows for table spaces, index spaces, or partitions, if both of the following conditions are true for the object:

- If the *Criteria* input parameter contains a search condition, and the search condition is true for the table space, index space, or partition.
- DSNACCOX recommends at least one action for the table space, index space, or partition.

The second result set contains one row for each nonpartitioned table space or nonpartitioning index space. For partitioned table spaces or partitioning indexes, the result set contains one row for each partition.

The following table shows the columns of a result set row.

<table>
<thead>
<tr>
<th>Column name</th>
<th>Data type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DBNAME</td>
<td>VARCHAR(24) NOT NULL</td>
<td>Name of the database that contains the object.</td>
</tr>
</tbody>
</table>
Table 150. Result set row for second DSNACCOX result set (continued)

<table>
<thead>
<tr>
<th>Column name</th>
<th>Data type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NAME</td>
<td>VARCHAR(128) NOT NULL</td>
<td>Table space name, index name, or index space name. Index space name is used if the row is added as a result of checking a restricted state and the index name is not available at the time.</td>
</tr>
<tr>
<td>PARTITION</td>
<td>INTEGER NOT NULL</td>
<td>Data set number or partition number.</td>
</tr>
<tr>
<td>INSTANCE</td>
<td>SMALLINT NOT NULL</td>
<td>Indicates whether the object is associated with a data set instance.</td>
</tr>
<tr>
<td>CLONE</td>
<td>CHAR(1)</td>
<td>‘Y’ or ‘N’, ‘Y’ indicates a cloned object.</td>
</tr>
<tr>
<td>OBJECTTYPE</td>
<td>CHAR(2) NOT NULL</td>
<td>Db2 object type:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• ‘TS’ for a table space</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• ‘IX’ for an index space</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• ‘LS’ for an LOB table space</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• ‘XS’ for an XML table space</td>
</tr>
<tr>
<td>INDEXSPACE</td>
<td>VARCHAR(24)</td>
<td>Index space name.</td>
</tr>
<tr>
<td>CREATOR</td>
<td>VARCHAR(128)</td>
<td>Index creator name.</td>
</tr>
<tr>
<td>OBJECTSTATUS</td>
<td>CHAR(40)</td>
<td>Status of the object:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• ORPHANED, if the object is an index space with no corresponding table space, or if the object does not exist</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• If the object is in a restricted state, one of the following values:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– TS=restricted-state, if OBJECTTYPE is TS</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– IX=restricted-state, if OBJECTTYPE is IX</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– LS=restricted-state, if OBJECTTYPE is LS</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– LX=restricted-state, if OBJECTTYPE is XS</td>
</tr>
<tr>
<td></td>
<td></td>
<td>restricted-state is one of the status codes that appear in the output of the DISPLAY DATABASE command.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>Related information:</strong></td>
</tr>
<tr>
<td></td>
<td></td>
<td>[DSNT362I (Db2 Messages)]</td>
</tr>
<tr>
<td></td>

<td>[DISPLAY DATABASE (Db2) (Db2 Commands)]</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• A, if the object is in an advisory state.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• L, if the object is a logical partition, but not in an advisory state.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• AL, if the object is a logical partition and in an advisory state.</td>
</tr>
<tr>
<td>IMAGECOPY</td>
<td>CHAR(4)</td>
<td>COPY recommendation:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• If the object is a table space, one of the following values:</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>FULL</strong> Full image copy is recommended</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>INC</strong> Incremental image copy is recommended</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>NO</strong> Image copy is not recommended.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• If the object is an index, whether image copy is recommended: YES or NO</td>
</tr>
</tbody>
</table>
Table 150. Result set row for second DSNACCOX result set (continued)

<table>
<thead>
<tr>
<th>Column name</th>
<th>Data type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>RUNSTATS</td>
<td>CHAR(3)</td>
<td>RUNSTATS recommendation: YES, NO, or Y**. Y** indicates that the table space contains volatile and non-volatile tables.</td>
</tr>
<tr>
<td>EXTENTS</td>
<td>CHAR(3)</td>
<td>Indicates whether the data sets for the object have exceeded <code>ExtentLimit</code>: YES or NO.</td>
</tr>
<tr>
<td>REORG</td>
<td>CHAR(3)</td>
<td>REORG recommendation: YES or NO.</td>
</tr>
<tr>
<td>INEXCEPTTABLE</td>
<td>CHAR(40)</td>
<td>A string that contains one of the following values:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Text that you specify in the <code>QUERYTYPE</code> column of the exception table.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• YES, if you put a row in the exception table for the object that this result set row represents, but you specify NULL in the <code>QUERYTYPE</code> column.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• NO, if the exception table exists but does not have a row for the object that this result set row represents.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Null, if the exception table does not exist, or if the <code>ChkLvl</code> input parameter does not include the value 4.</td>
</tr>
<tr>
<td>ASSOCIATEDTS</td>
<td>VARCHAR(128)</td>
<td>If <code>OBJECTTYPE</code> is IX this value is the name of the table space that is associated with the index space. Otherwise null.</td>
</tr>

DSNACICS stored procedure

The CICS transaction invocation stored procedure (DSNACICS) invokes CICS server programs.

DSNACICS gives workstation applications a way to invoke CICS server programs while using TCP/IP as their communication protocol. The workstation applications use TCP/IP and Db2 Connect to connect to a Db2 for z/OS subsystem, and then call DSNACICS to invoke the CICS server programs.

The DSNACICS input parameters require knowledge of various CICS resource definitions with which the workstation programmer might not be familiar. For this reason, DSNACICS invokes the DSNACICX user exit routine. The system programmer can write a version of DSNACICX that checks and overrides the parameters that the DSNACICS caller passes. If no user version of DSNACICX is provided, DSNACICS invokes the default version of DSNACICX, which does not modify any parameters.

Environment

DSNACICS runs in a WLM-established stored procedure address space and uses the Resource Recovery Services attachment facility to connect to Db2.

If you use CICS Transaction Server for OS/390® Version 1 Release 3 or later, you can register your CICS system as a resource manager with recoverable resource management services (RRMS). When you do that, changes to Db2 databases that are made by the program that calls DSNACICS and the CICS server program that DSNACICS invokes are in the same two-phase commit scope. This means that when the calling program performs an SQL COMMIT or ROLLBACK, Db2 and RRS inform CICS about the COMMIT or ROLLBACK.

If the CICS server program that DSNACICS invokes accesses Db2 resources, the server program runs under a separate unit of work from the original unit of work that calls the stored procedure. This means that the CICS server program might deadlock with locks that the client program acquires.

Authorization

To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges:

- The EXECUTE privilege on stored procedure DSNACICS
- Ownership of the stored procedure
- SYSADM authority

The CICS server program that DSNACICS calls runs under the same user ID as DSNACICS. That user ID depends on the SECURITY parameter that you specify when you define DSNACICS.

The DSNACICS caller also needs authorization from an external security system, such as RACF, to use CICS resources.
Syntax

The following syntax diagram shows the SQL CALL statement for invoking this stored procedure.

Because the linkage convention for DSNACICS is GENERAL WITH NULLS, if you pass parameters in host variables, you need to include a null indicator with every host variable. Null indicators for input host variables must be initialized before you execute the CALL statement.

```
CALL DSNACICS(
  parm-level, pgm-name, CICS-applid,
  CICS-level, connect-type, netname,
  mirror-trans, COMMAREA, COMMAREA-total-len,
  sync-opts, return-code, msg-area)
```

Option descriptions

**parm-level**

Specifies the level of the parameter list that is supplied to the stored procedure. This is an input parameter of type INTEGER. The value must be 1.

**pgm-name**

Specifies the name of the CICS program that DSNACICS invokes. This is the name of the program that the CICS mirror transaction calls, not the CICS transaction name.

This is an input parameter of type CHAR(8).

**CICS-applid**

Specifies the applid of the CICS system to which DSNACICS connects.

This is an input parameter of type CHAR(8).

**CICS-level**

Specifies the level of the target CICS subsystem:

2. The CICS subsystem is CICS Transaction Server for OS/390 Version 1 Release 3 or later.

This is an input parameter of type INTEGER.

**connect-type**

Specifies whether the CICS connection is generic or specific. Possible values are GENERIC or SPECIFIC.

This is an input parameter of type CHAR(8).

**netname**

If the value of `connection-type` is SPECIFIC, specifies the name of the specific connection that is to be used. This value is ignored if the value of `connection-type` is GENERIC.
This is an input parameter of type CHAR(8).

**mirror-trans**

Specifies the name of the CICS mirror transaction to invoke. This mirror transaction calls the CICS server program that is specified in the pgm-name parameter. mirror-trans must be defined to the CICS server region, and the CICS resource definition for mirror-trans must specify DFHMIRS as the program that is associated with the transaction.

If this parameter contains blanks, DSNACICS passes a mirror transaction parameter value of null to the CICS EXCI interface. This allows an installation to override the transaction name in various CICS user-replaceable modules. If a CICS user exit routine does not specify a value for the mirror transaction name, CICS invokes CICS-supplied default mirror transaction CSMI.

This is an input parameter of type CHAR(4).

**COMMAREA**

Specifies the communication area (COMMAREA) that is used to pass data between the DSNACICS caller and the CICS server program that DSNACICS calls.

This is an input/output parameter of type VARCHAR(32704). In the length field of this parameter, specify the number of bytes that DSNACICS sends to the CICS server program.

**commarea-total-len**

Specifies the total length of the COMMAREA that the server program needs.

This is an input parameter of type INTEGER. This length must be greater than or equal to the value that you specify in the length field of the COMMAREA parameter and less than or equal to 32704. When the CICS server program completes, DSNACICS passes the server program’s entire COMMAREA, which is commarea-total-len bytes in length, to the stored procedure caller.

**sync-optx**

Specifies whether the calling program controls resource recovery, using two-phase commit protocols that are supported by RRS. Possible values are:

1. The client program controls commit processing. The CICS server region does not perform a syncpoint when the server program returns control to CICS. Also, the server program cannot take any explicit syncpoints. Doing so causes the server program to abnormally terminate.

2. The target CICS server region takes a syncpoint on successful completion of the server program. If this value is specified, the server program can take explicit syncpoints.

When CICS has been set up to be an RRS resource manager, the client application can control commit processing using SQL COMMIT requests. Db2 for z/OS ensures that CICS is notified to commit any resources that the CICS server program modifies during two-phase commit processing.

When CICS has not been set up to be an RRS resource manager, CICS forces syncpoint processing of all CICS resources at completion of the CICS server program. This commit processing is not coordinated with the commit processing of the client program.

This option is ignored when CICS-level is 1. This is an input parameter of type INTEGER.

**return-code**

Return code from the stored procedure. Possible values are:
The call completed successfully.

The request to run the CICS server program failed. The msg-area parameter contains messages that describe the error.

This is an output parameter of type INTEGER.

**msg-area**

Contains messages if an error occurs during stored procedure execution. The first messages in this area are generated by the stored procedure. Messages that are generated by CICS or the DSNACICX user exit routine might follow the first messages. The messages appear as a series of concatenated, viewable text strings.

This is an output parameter of type VARCHAR(500).

**User exit routine**

DSNACICS always calls user exit routine DSNACICX. You can use DSNACICX to change the values of DSNACICS input parameters before you pass those parameters to CICS. If you do not supply your own version of DSNACICX, DSNACICS calls the default DSNACICX, which modifies no values and does an immediate return to DSNACICS. The source code for the default version of DSNACICX is in member DSNASCIX in data set prefix:SDSNSAMP. The source code for a sample version of DSNACICX that is written in COBOL is in member DSNASCIO in data set prefix:SDSNSAMP.

**Example**

The following PL/I example shows the variable declarations and SQL CALL statement for invoking the CICS transaction that is associated with program CICSPGM1.

```pli

:SYNC_OPTS :IND_SYNC_OPTS,
:RET_CODE :IND_RETCODE,
:MSG_AREA :IND_MSG_AREA);
Output

DSNACICS places the return code from DSNACICS execution in the return-code parameter. If the value of the return code is non-zero, DSNACICS puts its own error messages and any error messages that are generated by CICS and the DSNACICX user exit routine in the msg-area parameter.

The COMMAREA parameter contains the COMMAREA for the CICS server program that DSNACICS calls. The COMMAREA parameter has a VARCHAR type. Therefore, if the server program puts data other than character data in the COMMAREA, that data can become corrupted by code page translation as it is passed to the caller. To avoid code page translation, you can change the COMMAREA parameter in the CREATE PROCEDURE statement for DSNACICS to VARCHAR(32704) FOR BIT DATA. However, if you do so, the client program might need to do code page translation on any character data in the COMMAREA to make it readable.

Restrictions

Because DSNACICS uses the distributed program link (DPL) function to invoke CICS server programs, server programs that you invoke through DSNACICS can contain only the CICS API commands that the DPL function supports.

Debugging

If you receive errors when you call DSNACICS, ask your system administrator to add a DSNDUMP DD statement in the startup procedure for the address space in which DSNACICS runs. The DSNDUMP DD statement causes Db2 to generate an SVC dump whenever DSNACICS issues an error message.

[CICSPlex SM API commands (CICS Transaction Server for z/OS)]

DSNAIMS stored procedure

DSNAIMS is a stored procedure that allows Db2 applications to invoke IMS transactions and commands easily, without maintaining their own connections to IMS.

DSNAIMS uses the IMS Open Transaction Manager Access (OTMA) API to connect to IMS and to execute the transactions.

Environment

DSNAIMS runs in a WLM-established stored procedures address space. DSNAIMS requires Db2 with RRSAF enabled and IMS version 7 or later with OTMA Callable Interface enabled.

To use a two-phase commit process, you must have IMS Version 8 with UQ70789 or later.
Authorization

To set up and run DSNAIMS, you must be authorized to perform the following steps:

1. Use the job DSNTIJIM to issue the CREATE PROCEDURE statement for DSNAIMS and to grant the execution of DSNAIMS to PUBLIC. DSNTIJIM is provided in the SDNSAMP data set. You need to customize DSNTIJIM to fit the parameters of your system.

2. Ensure that the OTMA Callable Interface is initialized.

Syntax

The following syntax diagram shows the SQL CALL statement for invoking this stored procedure:

```
CALL SYSPROC.DSNAIMS(dsnaims-function, dsnaims-2pc, xcf-group-name, xcf-ims-name, racf-userid, racf-groupid, imslterm, imsmodname, imstran-name, otma-tpipe-name, user-data-in, user-data-out, status-message, return-code)
```

Option descriptions

**dsnaims-function**

A string that indicates whether the transaction is send-only, receive-only, or send-and-receive. Possible values are:

**SENDRECV**

Sends and receives IMS data. SENDRECV invokes an IMS transaction or command and returns the result to the caller. The transaction can be an IMS full function or a fast path transaction. SENDRECV does not support multiple iterations of a conversational transaction.

**SEND**

Sends IMS data. SEND invokes an IMS transaction or command but does not receive IMS data. If result data exists, it can be retrieved with the RECEIVE function. A send-only transaction cannot be an IMS fast path transaction or a conversational transaction.

**RECEIVE**

Receives IMS data. The data can be the result of a transaction or a command that is initiated by the SEND function, or it can be an unsolicited output message from an IMS application. The RECEIVE function does not initiate an IMS transaction or command.

**dsnaims-2pc**

Specifies whether to use a two-phase commit process to perform the transaction syncpoint service. Possible values are Y or N. For N, commits and rollbacks that are issued by the IMS transaction do not affect commit and rollback processing in the DB2 application that invokes DSNAIMS.
Furthermore, IMS resources are not affected by commits and rollbacks that are issued by the calling Db2 application. If you specify Y, you must also specify SENDRECV. To use a two-phase commit process, you must set the IMS control region parameter (RRS) to Y.

This parameter is optional. The default is N.

**xcf-group-name**

Specifies the XCF group name that the IMS OTMA joins. You can obtain this name by viewing the GRNAME parameter in IMS PROCLIB member DFSPBxxx or by using the IMS command /DISPLAY OTMA.

**xcf-ims-name**

Specifies the XCF member name that IMS uses for the XCF group. If IMS is not using the XRF or RSR feature, you can obtain the XCF member name from the OTMANM parameter in IMS PROCLIB member DFSPBxxx. If IMS is using the XRF or RSR feature, you can obtain the XCF member name from the USERVAR parameter in IMS PROCLIB member DFSPBxxx.

**racf-userid**

Specifies the RACF user ID that is used for IMS to perform the transaction or command authorization checking. This parameter is required if DSNAIMS is running APF-authorized. If DSNAIMS is running unauthorized, this parameter is ignored, and the EXTERNAL SECURITY setting for the DSNAIMS stored procedure definition determines the user ID that is used by IMS.

**racf-groupid**

Specifies the RACF group ID that is used for IMS to perform the transaction or command authorization checking. This field is used for stored procedures that are APF-authorized. It is ignored for other stored procedures.

**ims-lterm**

Specifies an IMS LTERM name that is used to override the LTERM name in the I/O program communication block of the IMS application program.

This field is used as an input and an output field:

- For SENDRECV, the value is sent to IMS on input and can be updated by IMS on output.
- For SEND, the parameter is IN only.
- For RECEIVE, the parameter is OUT only.

An empty or NULL value tells IMS to ignore the parameter.

**ims-modname**

Specifies the formatting map name that is used by the server to map output data streams, such as 3270 streams. Although this invocation does not have IMS MFS support, the input MODNAME can be used as the map name to define the output data stream. This name is an 8-byte message output descriptor name that is placed in the I/O program communication block.

When the message is inserted, IMS places this name in the message prefix with the map name in the program communication block of the IMS application program.

For SENDRECV, the value is sent to IMS on input, and can be updated on output. For SEND, the parameter is IN only. For RECEIVE it is OUT only. IMS ignores the parameter when it is an empty or NULL value.

**ims-tran-name**

Specifies the name of an IMS transaction or command that is sent to IMS. If the IMS command is longer than eight characters, specify the first eight characters (including the "/" of the command). Specify the remaining
characters of the command in the **ims-tran-name** parameter. If you use an empty or NULL value, you must specify the full transaction name or command in the **ims-data-in** parameter.

**ims-data-in**
Specifies the data that is sent to IMS. This parameter is required in each of the following cases:

- Input data is required for IMS.
- No transaction name or command is passed in **ims-tran-name**.
- The command is longer than eight characters.

This parameter is ignored for RECEIVE functions.

**ims-data-out**
Data that is returned after successful completion of the transaction. This parameter is required for SENDRECV and RECEIVE functions. The parameter is ignored for SEND functions.

The length of **ims-data-out** is 32000 bytes. If the data that is returned from IMS is greater than the length of **ims-data-out**, the data is truncated.

**otma-tpipe-name**
Specifies an 8-byte user-defined communication session name that IMS uses for the input and output data for the transaction or the command in a SEND or a RECEIVE function. If the **otma_tpipe_name** parameter is used for a SEND function to generate an IMS output message, the same **otma_pipe_name** must be used to retrieve output data for the subsequent RECEIVE function.

**otma-dru-name**
Specifies the name of an IMS user-defined exit routine, OTMA destination resolution user exit routine, if it is used. This IMS exit routine can format part of the output prefix and can determine the output destination for an IMS ALT_PCB output. If an empty or null value is passed, IMS ignores this parameter.

**user-data-in**
This optional parameter contains any data that is to be included in the IMS message prefix, so that the data can be accessed by IMS OTMA user exit routines (DFSYIOE0 and DFSYDRU0) and so that it can be tracked by IMS log records. IMS applications that run in dependent regions do not access this data. The specified user data is not included in the output message prefix. You can use this parameter to store input and output correlator tokens or other information. This parameter is ignored for RECEIVE functions.

**user-data-out**
On output, this field contains the **user-data-in** in the IMS output prefix. IMS user exit routines (DFSYIOE0 and DFSYDRU0) can also create **user-data-out** for SENDRECV and RECEIVE functions. The parameter is not updated for SEND functions.

The length of **user-data-out** is 1022 bytes. If the data that is returned from IMS is greater than the length of **user-data-out**, the data is truncated.

**status-message**
Indicates any error message that is returned from the transaction or command, OTMA, RRS, or DSNAIMS.

**return-code**
Indicates the return code that is returned for the transaction or command, OTMA, RRS, or DSNAIMS.
Examples

The following examples show how to call DSNAIMS.

Example 1: Sample parameters for executing an IMS command:
```sql
CALL SYSPROC.DSNAIMS("SENDRECV", "N", "IMS7GRP", "IMS7MEM", 
  "IMSCNLM", 
  "/LOG Hello World.", ims_data_out, 
  user_out, error_message, rc)
```

Example 2: Sample parameters for executing an IMS IVTNO transaction:
```sql
CALL SYSPROC.DSNAIMS("SENDRECV", "N", "IMS7GRP", "IMS7MEM", 
  "IMSCNLM", 
  "IVTNO DISPLAY LAST1 ", ims_data_out 
  "", user_out, error_message, rc)
```

Example 3: Sample parameters for a send-only IMS transaction:
```sql
CALL SYSPROC.DSNAIMS("SEND", "N", "IMS7GRP", "IMS7MEM", 
  "IMSCNLM", 
  "IVTNO DISPLAY LAST1 ", ims_data_out, 
  "DSNAPIPE", "", user_out, error_message, rc)
```

Example 4: Sample parameters for a receive-only IMS transaction:
```sql
CALL SYSPROC.DSNAIMS("RECEIVE", "N", "IMS7GRP", "IMS7MEM", 
  "IMSCNLM", 
  "IVTNO DISPLAY LAST1 ", ims_data_out, 
  "DSNAPIPE", "", user_out, error_message, rc)
```

Connecting to multiple IMS subsystems with DSNAIMS

By default, DSNAIMS connects to only one IMS subsystem at a time. The first request to DSNAIMS determines to which IMS subsystem the stored procedure connects. DSNAIMS attempts to reconnect to IMS only in the following cases:

- IMS is restarted and the saved connection is no longer valid.
- WLM loads another DSNAIMS task.

To connect to multiple IMS subsystems simultaneously, perform the following steps:

1. Make a copy of the Db2-supplied job DSNTIJIM and customize it to your environment, as follows:
   - Specify a separate WLM application environment name for each copy of the DSNTIJIM job that connects to a separate IMS subsystem.
   - Change the procedure name from SYSPROC.DSNAIMS to another name, such as DSNAIMSB.

   Do not change the EXTERNAL NAME option. Leave it as DSNAIMS.

2. Run the new job to create a second instance of the stored procedure.

3. To ensure that you connect to the intended IMS target, consistently use the XFC group and member names that you associate with each stored procedure instance. For example:
```sql
CALL SYSPROC.DSNAIMS("SENDRECV", "N", "IMS7GRP", "IMS7MEM", ...) 
CALL SYSPROC.DSNAIMSB("SENDRECV", "N", "IMS8GRP", "IMS8MEM", ...)
```
DSNAIMS2 stored procedure

DSNAIMS2 is a stored procedure that allows Db2 applications to invoke IMS transactions and commands easily, without maintaining their own connections to IMS. DSNAIMS2 includes multi-segment input support for IMS transactions.

DSNAIMS2 uses the IMS Open Transaction Manager Access (OTMA) API to connect to IMS and execute the transactions.

When you define the DSNAIMS2 stored procedure to your Db2 subsystem, you can use the name DSNAIMS in your application if you prefer. Customize DSNTIJI2 to define the stored procedure to your Db2 subsystem as DSNAIMS; however, the EXTERNAL NAME option must still be DSNAIMS2.

Environment

DSNAIMS2 runs in a WLM-established stored procedures address space. DSNAIMS2 requires Db2 with RRSAF enabled and IMS version 7 or later with OTMA Callable Interface enabled.

To use a two-phase commit process, you must have IMS Version 8 with UQ70789 or later.

Authorization

To set up and run DSNAIMS2, you must be authorized to perform the following steps:

1. Use the job DSNTIJI2 to issue the CREATE PROCEDURE statement for DSNAIMS2 and to grant the execution of DSNAIMS2 to PUBLIC. DSNTIJI2 is provided in the SDSNSAMP data set. You need to customize DSNTIJI2 to fit the parameters of your system.

2. Ensure that OTMA C/I is initialized.

Syntax

The following syntax diagram shows the SQL CALL statement for invoking this stored procedure:

Option descriptions

dsnaims-function

A string that indicates whether the transaction is send-only, receive-only, or send-and-receive. Possible values are:

SENDRECV
Sends and receives IMS data. SENDRECV invokes an IMS transaction or command and returns the result to the caller. The transaction can be an IMS full function or a fast path. SENDRECV does not support multiple iterations of a conversational transaction.

SEND
Sends IMS data. SEND invokes an IMS transaction or command, but does not receive IMS data. If result data exists, it can be retrieved with the RECEIVE function. A send-only transaction cannot be an IMS fast path transaction or a conversations transaction.

RECEIVE
Receives IMS data. The data can be the result of a transaction or command initiated by the SEND function or an unsolicited output message from an IMS application. The RECEIVE function does not initiate an IMS transaction or command.

dsnaims-2pc

Specifies whether to use a two-phase commit process to perform the transaction syncpoint service. Possible values are Y or N. For N, commits and rollbacks that are issued by the IMS transaction do not affect commit and rollback processing in the Db2 application that invokes DSNAIMS2. Furthermore, IMS resources are not affected by commits and rollbacks that are issued by the calling Db2 application. If you specify Y, you must also specify SENDRECV. To use a two-phase commit process, you must set the IMS control region parameter (RRS) to Y.

This parameter is optional. The default is N.

xcf-group-name

Specifies the XCF group name that the IMS OTMA joins. You can obtain this name by viewing the GRNAME parameter in IMS PROCLIB member DFSPBxxx or by using the IMS command /DISPLAY OTMA.

xcf-ims-name

Specifies the XCF member name that IMS uses for the XCF group. If IMS is not using the XRF or RSR feature, you can obtain the XCF member name from the OTMANM parameter in IMS PROCLIB member DFSPBxxx. If IMS is using the
XRF or RSR feature, you can obtain the XCF member name from the USERVAR parameter in IMS PROCLIB member DFSPBxxx.

**racf-userid**
Specifies the RACF user ID that is used for IMS to perform the transaction or command authorization checking. This parameter is required if DSNAIMS2 is running APF-authorized. If DSNAIMS2 is running unauthorized, this parameter is ignored and the EXTERNAL SECURITY setting for the DSNAIMS2 stored procedure definition determines the user ID that is used by IMS.

**racf-groupid**
Specifies the RACF group ID that is used for IMS to perform the transaction or command authorization checking. This field is used for stored procedures that are APF-authorized. It is ignored for other stored procedures.

**ims-lterm**
Specifies an IMS LTERM name that is used to override the LTERM name in the I/O program communication block of the IMS application program.
This field is used as an input and an output field:
- For SENDRECV, the value is sent to IMS on input and can be updated by IMS on output.
- For SEND, the parameter is IN only.
- For RECEIVE, the parameter is OUT only.
An empty or NULL value tells IMS to ignore the parameter.

**ims-modname**
Specifies the formatting map name that is used by the server to map output data streams, such as 3270 streams. Although this invocation does not have IMS MFS support, the input MODNAME can be used as the map name to define the output data stream. This name is an 8-byte message output descriptor name that is placed in the I/O program communication block.
When the message is inserted, IMS places this name in the message prefix with the map name in the program communication block of the IMS application program.
For SENDRECV, the value is sent to IMS on input, and can be updated on output. For SEND, the parameter is IN only. For RECEIVE it is OUT only. IMS ignores the parameter when it is an empty or NULL value.

**ims-tran-name**
Specifies the name of an IMS transaction or command that is sent to IMS. If the IMS command is longer than eight characters, specify the first eight characters (including the "/" of the command). Specify the remaining characters of the command in the *ims-tran-name* parameter. If you use an empty or NULL value, you must specify the full transaction name or command in the *ims-data-in* parameter.

**ims-data-in**
Specifies the data that is sent to IMS. This parameter is required in each of the following cases:
- Input data is required for IMS
- No transaction name or command is passed in *ims-tran-name*
- The command is longer than eight characters
This parameter is ignored when for RECEIVE functions.
**ims-data-out**
Data returned after successful completion of the transaction. This parameter is required for SENDRECV and RECEIVE functions. The parameter is ignored for SEND functions.

The length of *ims-data-out* is 32,000 bytes. If the data that is returned from IMS is greater than the length of *ims-data-out*, the data will be truncated.

**otma-tpipe-name**
Specifies an 8-byte user-defined communication session name that IMS uses for the input and output data for the transaction or the command in a SEND or a RECEIVE function. If the *otma_tpipe_name* parameter is used for a SEND function to generate an IMS output message, the same *otma_pipe_name* must be used to retrieve output data for the subsequent RECEIVE function.

**otma-dru-name**
Specifies the name of an IMS user-defined exit routine, OTMA destination resolution user exit routine, if it is used. This IMS exit routine can format part of the output prefix and can determine the output destination for an IMS ALT_PCB output. If an empty or null value is passed, IMS ignores this parameter.

**user-data-in**
This optional parameter contains any data that is to be included in the IMS message prefix, so that the data can be accessed by IMS OTMA user exit routines (DFSYIOE0 and DFSYDRU0) and can be tracked by IMS log records. IMS applications that run in dependent regions do not access this data. The specified user data is not included in the output message prefix. You can use this parameter to store input and output correlator tokens or other information. This parameter is ignored for RECEIVE functions.

**user-data-out**
On output, this field contains the *user-data-in* in the IMS output prefix. IMS user exit routines (DFSYIOE0 and DFSYDRU0) can also create *user-data-out* for SENDRECV and RECEIVE functions. The parameter is not updated for SEND functions.

The length of *user-data-out* is 1,022 bytes. If the data that is returned from IMS is greater than the length of *user-data-out*, the data will be truncated.

**status-message**
Indicates any error message that is returned from the transaction or command, OTMA, RRS, or DSNAIMS2.

**otma-data-inseg**
Specifies the number of segments followed by the lengths of the segments to be sent to IMS. All values should be separated by semicolons. This field is required to send multi-segment input to IMS. For single-segment transactions and commands, set the field to NULL, "0" or "0;".

**return-code**
Indicates the return code that is returned for the transaction or command, OTMA, RRS, or DSNAIMS2.

**Examples**

The following examples show how to call DSNAIMS2.

**Example 1:** Sample parameters for executing a multi-segment IMS transaction:
Example 2: Sample parameters for executing a single-segment IMS IVTNO transaction:

```sql
CALL SYSPROC.DSNAIMS2("SEND", "N", "IMS7GRP", "IMS7TMEM", "IMSCLNM", ":", ":", ":", ":", ":", ":", "PART 1ST SEGMENT FROM CI 2ND SEGMENT FROM CI ", ims_data_out, ":", ":", ":", user_out, error_message, "2;25;20", rc)
```

Connecting to multiple IMS subsystems with DSNAIMS2

By default DSNAIMS2 connects to only one IMS subsystem at a time. The first request to DSNAIMS2 determines to which IMS subsystem the stored procedure connects. DSNAIMS2 attempts to reconnect to IMS only in the following cases:

- IMS is restarted and the saved connection is no longer valid
- WLM loads another DSNAIMS2 task

To connect to multiple IMS subsystems simultaneously, perform the following steps:

1. Make a copy of the Db2-supplied job DSNTIJI2 and customize it to your environment.
2. Change the procedure name from SYSPROC.DSNAIMS2 to another name, such as DSNAIMS2B.
3. Do not change the EXTERNAL NAME option. Leave it as DSNAIMS2.
4. Change the name of the stored procedure in the grant statement in job DSNTIJI2.
5. Run the new job to create a second instance of the stored procedure.
6. To ensure that you connect to the intended IMS target, consistently use the XFC group and member names that you associate with each stored procedure instance. For example:

```sql
CALL SYSPROC.DSNAIMS2("SENDRECV", "N", "IMS7GRP", "IMS7TMEM", ...)  
CALL SYSPROC.DSNAIMS2B("SENDRECV", "N", "IMS8GRP", "IMS8TMEM", ...)
```

**DSNLEUSR stored procedure**

The DSNLEUSR stored procedure is a sample stored procedure. Use this stored procedure to store encrypted values in the translated authorization ID (NEWAUTHID) and password fields of the SYSIBM.USERNAMES table.
You provide all the values for a SYSIBM.USERNAMES row as input to DSNLEUSR. DSNLEUSR encrypts the translated authorization ID and password values before it inserts the row into SYSIBM.USERNAMES.

Environment

DSNLEUSR has the following requirements:

- DSNLEUSR runs in a WLM-established stored procedure address space.
- z/OS Integrated Cryptographic Service Facility (ICSF) must be installed, configured, and active. The services that ICSF calls that are used by this stored procedure are CSNBCKM and CSNBENC.

Authorization

To execute the CALL DSNLEUSR statement, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges:

- The EXECUTE privilege on the package for DSNLEUSR
- Ownership of the package
- PACKADM authority for the package collection
- SYSADM authority

The owner of the package or plan that contains the CALL statement must also have INSERT authority on SYSIBM.USERNAMES.

Syntax

The following syntax diagram shows the SQL CALL statement for invoking this stored procedure:

```
CALL DSNLEUSR(                                                 
  Type, AuthID=NULL, LinkName=NULL, NewAuthID=NULL, Password=NULL, 
  ReturnCode, MsgArea)                                            
```

Option descriptions

Type

- Specifies the value that is to be inserted into the TYPE column of SYSIBM.USERNAMES.
- This is an input parameter of type CHAR(1).

AuthID

- Specifies the value that is to be inserted into the AUTHID column of SYSIBM.USERNAMES.
- This is an input parameter of type VARCHAR(128). If you specify a null value, DSNLEUSR does not insert a value for AuthID.

LinkName

- Specifies the value that is to be inserted into the LINKNAME column of SYSIBM.USERNAMES.
This is an input parameter of type CHAR(8). Although the LINKNAME field of SYSIBM.USERNAMES is VARCHAR(24), this value is restricted to a maximum of 8 bytes.

If you specify a null value, DSNLEUSR does not insert a value for LinkName.

**NewAuthID**

Specifies the value that is to be inserted into the NEWAUTHID column of SYSIBM.USERNAMES.

This is an input parameter of type VARCHAR(54). The NEWAUTHID field is type VARCHAR(54) to allow for expansion during encryption.

If you specify a null value, DSNLEUSR does not insert a value for NewAuthID.

**Password**

Specifies the value that is to be inserted into the PASSWORD column of SYSIBM.USERNAMES.

If the input value to Password represents a password, the password value is restricted to 100 or fewer bytes. This applies even if the PASSWORD column of SYSIBM.USERNAMES is VARCHAR(255).

If you specify a null value, DSNLEUSR does not insert a value for Password.

**ReturnCode**

The return code from DSNLEUSR execution. Possible values are:

0  DSNLEUSR executed successfully.
8  The request to encrypt the translated authorization ID or password failed. **MsgArea** contains the following fields:
   • An unformatted SQLCA that describes the error.
   • A string that contains a DSNL045I message with the ICSF return code, the ICSF reason code, and the ICSF function that failed. The string immediately follows the SQLCA field and does not begin with a length field.
12  The insert operation for the SYSIBM.USERNAMES row failed. **MsgArea** contains an SQLCA that describes the error.
16  DSNLEUSR terminated because the Db2 subsystem is not in new-function mode. **MsgArea** contains an SQLCA that describes the error.

This is an output parameter of type INTEGER.

**MsgArea**

Contains information about DSNLEUSR execution. The information that is returned is described in the ReturnCode description.

This is an output parameter of type VARCHAR(500).

**Example**

The following COBOL example shows variable declarations and an SQL CALL for inserting a row into SYSIBM.USERNAMES with an encrypted translated authorization ID and an encrypted password.

        :RETURNCODE :RETURNCODE-IND,
        :MSGAREA  :MSGAREA-IND)
END-EXEC.

Output

If DSNLEUSR executes successfully, it inserts a row into SYSIBM.USERNAMES with encrypted values for the NEWAUTHID and PASSWORD columns and returns 0 for the ReturnCode parameter value. If DSNLEUSR does not execute successfully, it returns a non-zero value for the ReturnCode value and additional diagnostic information for the MsgArea parameter value.

DSNUTILS stored procedure (deprecated)

The DSNUTILS stored procedure enables you to use the SQL CALL statement to execute Db2 utilities from a Db2 application program that specifies EBCDIC input.

**Important:** The DSNUTILS stored procedure is deprecated and replaced by DSNUTIL or DSNUTILV. It is best to convert existing callers of SYSIBM.SYSUTILS to use the SYSIBM.SYSUTILU or SYSIBM.SYSUTILV stored procedures instead.

When called, DSNUTILS performs the following actions:
- Dynamically allocates the specified data sets
- Creates the utility input (SYSIN) stream
- Invokes Db2 utilities (program DSNUTILB)
- Deletes all the rows that are currently in the created temporary table (SYSIBM.SYSPRINT)
- Captures the utility output stream (SYSPRINT) into a created temporary table (SYSIBM.SYSPRINT)
- Declares a cursor to select from SYSPRINT:
  ```sql
  DECLARE SYSPRINT CURSOR WITH RETURN FOR
  SELECT SEQNO, TEXT FROM SYSPRINT
  ORDER BY SEQNO;
  ```
- Opens the SYSPRINT cursor and returns.

The calling program then fetches from the returned result set to obtain the captured utility output.

**Environment for DSNUTILS**

DSNUTILS must run in a WLM environment. The DSNWLM_UTILS environment is created for Db2 utilities stored procedures only. Stored procedures require special data set allocations.

The WLM core environment DSNWLM_UTILS. DSNWLM_UTILS is intended for the following Db2 utilities stored procedures only:
- DSNUTIL
- DSNUTILU
- DSNUTILS (deprecated)

If you plan to run other applications in this environment other than DSNUTILS or DSNUTILU, add the procedure and add the DCB information for SYSIN. For example:

```
//SYSIN DD UNIT=SYSDA,SPACE=(4000,(20,20),,,ROUND),
// DCB=(RECFM=V,LRECL=32708)
```
Table 151. DSNWLM_UTILS environment

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NUMTCB</td>
<td>1</td>
</tr>
<tr>
<td>APF authorized</td>
<td>Yes</td>
</tr>
</tbody>
</table>

**Special DDs**

These DDs are required:
- SYSIN Allocates a work file for temporarily storing utility input statements.
- SYSPRINT Allocates a work file for temporarily storing utility output messages.
- RNPRIN01 Allocates a data set for messages from the sort program. Required only if you plan to invoke RUNSTATS and collect distribution statistics.
- UTPRINT Allocates a data set for messages from the sort program.
- DSSPRINT Allocates a data set for messages when making concurrent copies.

Example:
```
//UTPRINT DD SYSOUT=*  
//RNPRIN01 DD SYSOUT=*  
//DSSPRINT DD SYSOUT=*  
//SYSIN DD UNIT=SYSDA,SPACE=(4000,(20,20),,,ROUND)  
//SYSPRINT DD UNIT=SYSDA,SPACE=(4000,(20,20),,,ROUND)  
```

**Other considerations**

The STEPLIB needs to include DSN=prefix.SDSNEXIT or other library where the authorization exit modules (DSN3@ATH and DSN3@SGN) reside.

Installation job DSNTIJMV creates an address space proc called DSNWLMU for DSNWLM_UTILS. When the installation CLIST is customized, the name and library name of this proc are changed according to the Db2 subsystem name you specified on panel DSNTIPM in the field SUBSYSTEM NAME. For example, if you specified a subsystem name of VA1A then this proc will be named VA1AWLMU.

**Authorization required for DSNUTILS**

To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges on each package that the stored procedure uses:
- The EXECUTE privilege on the package for DSNUTILS
- Ownership of the package
- PACKADM authority for the package collection
- SYSADM authority

Then, to execute the utility, you must use a privilege set that includes the authorization to run the specified utility.

**Control statement for DSNUTILS**

DSNUTILS dynamically allocates the specified data sets. Any utility that requires a sort must include the SORTDEVT keyword in the utility control statement, and optionally, the SORTNUM keyword.

If the DSNUTILS stored procedure invokes a new utility, refer to Table 152 on page 947 for information about the default data dispositions that are specified for
If the DSNUTILS stored procedure restarts a current utility, refer to Table 153 for information about the default data dispositions that are specified for dynamically-allocated data sets on RESTART. This table lists the DD name that is used to identify the data set and the default dispositions for the data set by utility.

**DSNUTILS stored procedure syntax diagram**

The following syntax diagram shows the SQL CALL statement for invoking utilities as a stored procedure. Because the linkage convention for DSNUTILS is GENERAL, you cannot pass null values for input parameters. For character parameters that you are not using, specify an empty string ("").

```
CALL DSNUTILS(--utility-id, restart, utstmt, retcode--, --utility-name----------------------------------)
```

**DSNUTILS option descriptions**

**utility-id**

Specifies a unique identifier for this utility within Db2.

This is an input parameter of type VARCHAR(16) in EBCDIC.
**restart**

Specifies whether Db2 is to restart a current utility, and, if so, at what point the utility is to be restarted.

*restart* is an input parameter of type VARCHAR(8) in Unicode UTF-8, which must be translatable to allowable EBCDIC characters. Specify one of the following values for this parameter:

- **NO** or **null**
  - Indicates that the utility job is new, not a restart. No other utility with the same utility identifier (UID) can exist.
  - The default is **null**.

- **CURRENT**
  - Restarts the utility at the last commit point.

- **PHASE**
  - Restarts the utility at the beginning of the currently stopped phase. Use the DISPLAY UTILITY to determine the currently stopped phase.

- **PREVIEW**
  - Executes in PREVIEW mode the utility control statements that follow. While in PREVIEW mode, Db2 parses all utility control statements for syntax errors, but normal utility execution does not take place. If the syntax is valid, Db2 expands all LISTDEF lists and TEMPLATE data set name expressions that appear in SYSIN and prints the results to the SYSPRINT data set. Db2 evaluates and expands all LISTDEF definitions into an actual list of table spaces or index spaces. Db2 also evaluates TEMPLATE data set name expressions into actual data set names through variable substitution. Db2 also expands lists from the SYSLISTD DD and TEMPLATE data set name expressions from the SYSTEMPL DD that is referenced by a utility invocation.

  Absence of the PREVIEW keyword turns off preview processing with one exception. The absence of this keyword does not override the PREVIEW JCL parameter which, if specified, remains in effect for the entire job step.

  This option is identical to the PREVIEW JCL parameter.

**utstmt**

Specifies the utility control statements.

This is an input parameter of type VARCHAR(32704) in EBCDIC.

**retcode**

Specifies the utility highest return code.

This is an output parameter of type INTEGER.

**utility-name**

Specifies the utility that you want to invoke.

This is an input parameter of type VARCHAR(20) in EBCDIC.

Because DSNUTILS allows only a single utility here, dynamic support of data set allocation is limited. Specify only a single utility that requires data set allocation in the **utstmt** parameter.

Select the utility name from the following list:

- ANY
- CHECK DATA
- CHECK INDEX
CHECK LOB
COPY
COPYTOCOPY
DIAGNOSE
LOAD
MERGECOPY
MODIFY RECOVERY
MODIFY STATISTICS
QUIESCE
REBUILD INDEX
RECOVER
REORG INDEX
REORG LOB
REORG TABLESPACE
REPAIR
REPORT RECOVERY
REPORT TABLESPACESET
RUNSTATS INDEX
RUNSTATS TABLESPACE
STOSPACE
UNLOAD

1. Use ANY to indicate that TEMPLATE dynamic allocation is to be used. This value suppresses the dynamic allocation that is normally performed by DSNUTILS.

**Recommendation:** Invoke DSNUTILS with a *utility-name* of ANY and omit all of the xxxdsn, xxxdevt, and xxxspace parameters. Use TEMPLATE statements to allocate the data sets.

When you use TEMPLATE, utilities attempt to close and deallocate data sets when the utilities complete. However, under some circumstances, utilities cannot deallocate data sets. Under those circumstances, take one of the following sets of actions:

- **If you want to terminate a utility after a failure:**
  1. Use the TERM UTIL command to terminate the failing utility.
  2. Refresh the WLM environment in one of the following ways:
     - Submit the VARY command:
       ```sql
       VARY WLM,APPLENV=xxx,REFRESH
       ```
     - Call the WLM_REFRESH stored procedure.

   When you terminate the utility, Db2 deletes the data sets that are needed by the utility.

- **If you want to restart a utility after a failure:**
  1. Specify DISP (NEW,CATLG,CATLG) in your template for data sets that are needed by the utility.
  2. When the utility fails, refresh the WLM environment, but do not terminate the utility.

   You need to delete the allocated data sets manually after the utility completes.
**recdsn**

Specifies the cataloged data set name that is required by LOAD for input, or by REORG TABLESPACE as the unload data set. **recdsn** is required for LOAD. It is also required for REORG TABLESPACE unless you also specified NOSYSREC or SHRLEVEL CHANGE. If you specify **recdsn**, the data set is allocated to the SYSPRC DD name.

This is an input parameter of type VARCHAR(54) in EBCDIC.

If you specified the INDDN parameter for LOAD, the specified ddname value **must** be SYSREC.

If you specify the UNLDDN parameter for REORG TABLESPACE, the specified ddname value **must** be SYSREC.

**recdevt**

Specifies a unit address, a generic device type, or a user-assigned group name for a device on which the **recdsn** data set resides.

This is an input parameter of type CHAR(8) in EBCDIC.

**recspace**

Specifies the number of cylinders to use as the primary space allocation for the **recdsn** data set. The secondary space allocation is 10% of the primary space allocation.

This is an input parameter of type SMALLINT.

**discdsn**

Specifies the cataloged data set name that is used by LOAD as a discard data set to hold records not loaded, and by REORG TABLESPACE as a discard data set to hold records that are not reloaded. If you specify **discdsn**, the data set is allocated to the SYSDISC DD name.

This is an input parameter of type VARCHAR(54) in EBCDIC.

If you specify the DISCARDDN parameter for LOAD or REORG TABLESPACE, the specified ddname value **must** be SYSDISC.

**discdevt**

Specifies a unit address, a generic device type, or a user-assigned group name for a device on which the **discdsn** data set resides.

This is an input parameter of type CHAR(8) in EBCDIC.

**discspace**

Specifies the number of cylinders to use as the primary space allocation for the **discdsn** data set. The secondary space allocation is 10% of the primary space allocation.

This is an input parameter of type SMALLINT.

**pnchdsn**

Specifies the cataloged data set name that REORG TABLESPACE UNLOAD EXTERNAL or REORG TABLESPACE DISCARD uses to hold the generated LOAD utility control statements. If you specify a value for **pnchdsn**, the data set is allocated to the SYSPUNCH DD name.

This is an input parameter of type VARCHAR(54) in EBCDIC.

If you specify the PUNCHDDN parameter for REORG TABLESPACE, the specified ddname value **must** be SYSPUNCH.
**pnchdevt**

Specifies a unit address, a generic device type, or a user-assigned group name for a device on which the *pnchdsn* data set resides.

This is an input parameter of type CHAR(8) in EBCDIC.

**pnchspace**

Specifies the number of cylinders to use as the primary space allocation for the *pnchdsn* data set. The secondary space allocation is 10% of the primary space allocation.

This is an input parameter of type SMALLINT.

**copydsn1**

Specifies the name of the required target (output) data set, which is needed when you specify the COPY, COPYTOCOPY, or MERGECOPY utilities. It is optional for LOAD and REORG TABLESPACE. If you specify *copydsn1*, the data set is allocated to the SYSCOPY DD name.

This is an input parameter of type VARCHAR(54) in EBCDIC.

If you specify the COPYDDN parameter for COPY, COPYTOCOPY, MERGECOPY, LOAD, or REORG TABLESPACE, the specified *ddname1* value must be SYSCOPY.

**copydevt1**

Specifies a unit address, a generic device type, or a user-assigned group name for a device on which the *copydsn1* data set resides.

This is an input parameter of type CHAR(8) in EBCDIC.

**copyspace1**

Specifies the number of cylinders to use as the primary space allocation for the *copydsn1* data set. The secondary space allocation is 10% of the primary space allocation.

This is an input parameter of type SMALLINT.

**copydsn2**

Specifies the name of the cataloged data set that is used as a target (output) data set for the backup copy. It is optional for COPY, COPYTOCOPY, MERGECOPY, LOAD, and REORG TABLESPACE. If you specify *copydsn2*, the data set is allocated to the SYSCOPY2 DD name.

This is an input parameter of type VARCHAR(54) in EBCDIC.

If you specify the COPYDDN parameter for COPY, COPYTOCOPY, MERGECOPY, LOAD, or REORG TABLESPACE, the specified *ddname2* value must be SYSCOPY2.

**copydevt2**

Specifies a unit address, a generic device type, or a user-assigned group name for a device on which the *copydsn2* data set resides.

This is an input parameter of type CHAR(8) in EBCDIC.

**copyspace2**

Specifies the number of cylinders to use as the primary space allocation for the *copydsn2* data set. The secondary space allocation is 10% of the primary space allocation.

This is an input parameter of type SMALLINT.

**rcpydsn1**

Specifies the name of the cataloged data set that is required as a target (output)
data set for the remote site primary copy. It is optional for COPY, COPYTOCOPY, LOAD, and REORG TABLESPACE. If you specify rcpydsn1, the data set is allocated to the SYSRCPY1 DD name.

This is an input parameter of type VARCHAR(54) in EBCDIC.

If you specified the RECOVERYDDN parameter for COPY, COPYTOCOPY, MERGECOPY, LOAD, or REORG TABLESPACE, the specified ddname value must be SYSRCPY1.

rcpydevt1
Specifies a unit address, a generic device type, or a user-assigned group name for a device on which the rcpydsn1 data set resides.

This is an input parameter of type CHAR(8) in EBCDIC.

rcpyspace1
Specifies the number of cylinders to use as the primary space allocation for the rcpydsn1 data set. The secondary space allocation is 10% of the primary space allocation.

This is an input parameter of type SMALLINT.

rcpydsn2
Specifies the name of the cataloged data set that is required as a target (output) data set for the remote site backup copy. It is optional for COPY, COPYTOCOPY, LOAD, and REORG TABLESPACE. If you specify rcpydsn2, the data set is allocated to the SYSRCPY2 DD name.

This is an input parameter of type VARCHAR(54) in EBCDIC.

If you specify the RECOVERYDDN parameter for COPY, COPYTOCOPY, MERGECOPY, LOAD, or REORG TABLESPACE, the specified ddname2 value must be SYSRCPY2.

rcpydevt2
Specifies a unit address, a generic device type, or a user-assigned group name for a device on which the rcpydsn2 data set resides.

This is an input parameter of type CHAR(8) in EBCDIC.

rcpyspace2
Specifies the number of cylinders to use as the primary space allocation for the rcpydsn2 data set. The secondary space allocation is 10% of the primary space allocation.

This is an input parameter of type SMALLINT.

workdsn1
Specifies the name of the cataloged data set that is required as a work data set for sort input and output. It is required for CHECK DATA, CHECK INDEX and REORG INDEX. It is also required for LOAD and REORG TABLESPACE unless you also specify the SORTKEYS keyword. It is optional for REBUILD INDEX. If you specify workdsn1, the data set is allocated to the SYSUT1 DD name.

This is an input parameter of type VARCHAR(54) in EBCDIC.

If you specify the WORKDDN parameter for CHECK DATA, CHECK INDEX, LOAD, REORG INDEX, REORG TABLESPACE, or REBUILD INDEX, the specified ddname value must be SYSUT1.
**workdevt1**
Specifies a unit address, a generic device type, or a user-assigned group name for a device on which the workdsn1 data set resides.

This is an input parameter of type CHAR(8) in EBCDIC.

**workspace1**
Specifies the number of cylinders to use as the primary space allocation for the workdsn1 data set. The secondary space allocation is 10% of the primary space allocation.

This is an input parameter of type SMALLINT.

**workdsn2**
Specifies the name of the cataloged data set that is required as a work data set for sort input and output. It is required for CHECK DATA. It is also required if you use REORG INDEX to reorganize non-unique type 1 indexes. It is required for LOAD or REORG TABLESPACE unless you also specify the SORTKEYS keyword. If you specify workdsn2, the data set is allocated to the SORTOUT DD name.

This is an input parameter of type VARCHAR(54) in EBCDIC.

If you specify the WORKDDN parameter for CHECK DATA, LOAD, REORG INDEX, or REORG TABLESPACE, the specified ddname value must be SORTOUT.

**workdevt2**
Specifies a unit address, a generic device type, or a user-assigned group name for a device on which the workdsn2 data set resides.

This is an input parameter of type CHAR(8) in EBCDIC.

**workspace2**
Specifies the number of cylinders to use as the primary space allocation for the workdsn2 data set. The secondary space allocation is 10% of the primary space allocation.

This is an input parameter of type SMALLINT.

**mapdsn**
Specifies the name of the cataloged data set that is required as a work data set for error processing during LOAD with ENFORCE CONSTRAINTS. It is optional for LOAD. If you specify mapdsn, the data set is allocated to the SYSMAP DD name.

This is an input parameter of type VARCHAR(54) in EBCDIC.

If you specify the MAPDDN parameter for LOAD, the specified ddname value must be SYSMAP.

**mapdevt**
Specifies a unit address, a generic device type, or a user-assigned group name for a device on which the mapdsn data set resides.

This is an input parameter of type CHAR(8).

**mapsparse**
Specifies the number of cylinders to use as the primary space allocation for the mapdsn data set. The secondary space allocation is 10% of the primary space allocation.

This is an input parameter of type SMALLINT.
errdsn
Specifications the name of the cataloged data set that is required as a work data set for error processing. It is required for CHECK DATA, and it is optional for LOAD. If you specify errdsn, the data set is allocated to the SYSERR DD name.

This is an input parameter of type VARCHAR(54) in EBCDIC.

If you specify the ERRDDN parameter for CHECK DATA or LOAD, the specified ddname value must be SYSERR.

errdevt
Specifies a unit address, a generic device type, or a user-assigned group name for a device on which the errdsn data set resides.

This is an input parameter of type CHAR(8) in EBCDIC.

errspace
Specifies the number of cylinders to use as the primary space allocation for the errdsn data set. The secondary space allocation is 10% of the primary space allocation.

This is an input parameter of type SMALLINT.

filtrdsn
Specifies the name of the cataloged data set that is required as a work data set for error processing. It is optional for COPY CONCURRENT. If you specify filtrdsn, the data set is allocated to the FILTER DD name.

This is an input parameter of type VARCHAR(54) in EBCDIC.

If you specify the FILTERDDN parameter for COPY, the specified ddname value must be FILTER.

filtrdevt
Specifies a unit address, a generic device type, or a user-assigned group name for a device on which the filtrdsn data set resides.

This is an input parameter of type CHAR(8) in EBCDIC.

filtrspace
Specifies the number of cylinders to use as the primary space allocation for the filtrdsn data set. The secondary space allocation is 10% of the primary space allocation.

This is an input parameter of type SMALLINT.

Modifying the WLM-established address space for DSNUTILS

Add DSSPRINT, SYSIN, and SYSPRINT to the JCL procedure for starting the WLM-established address space in which DSNUTILS runs.

Requirement: You must allocate SYSIN and SYSPRINT in the procedure to temporarily store utility input statements and utility output messages. If you plan to invoke RUNSTATS and collect distribution statistics, you also need to allocate RNPRIN01.

Use JCL similar to the following sample PROC:

```sql
/**********************************************************
/* JCL FOR RUNNING THE WLM-ESTABLISHED STORED PROCEDURES
/* ADDRESS SPACE
/* RGN -- THE MVS REGION SIZE FOR THE ADDRESS SPACE.
/* DB2SSN -- THE DB2 SUBSYSTEM NAME.
/* APPLENV -- THE MVS WLM APPLICATION ENVIRONMENT
**********************************************************/
```
Sample program for calling DSNUTILS

Three example programs calling DSNUTILS are shipped in SDSNSAMP.

- **DSNTEJ6U**: A DSNUTILS caller that uses PL/I. Job DSNTEJ6U compiles, link-edits, binds, and runs sample PL/I program DSN8EPU, which invokes the DSNUTILS stored procedure to execute an utility.
- **DSNTEJ6V**: A DSNUTILS caller that uses C++. Job DSNTEJ6V compiles, link-edits, binds, and runs sample C++ program DSN8EE1, which invokes the DSNUTILS stored procedure to execute an utility.
- **DSNTEJ80**: A DSNUTILS caller that uses C and ODBC. You can use this sample to compile, pre-link, link-edit, and execute the sample application DSN8OIVP, which you can use to verify that your Db2 ODBC installation is correct.

**DSNUTILS output**

Db2 creates the result set according to the DECLARE statement that is shown under Example of declaring a cursor to select from SYSPRINT.

Output from a successful execution of the DSNTEJ6U sample job or an equivalent job lists the specified parameters followed by the messages that are generated by the Db2 DIAGNOSE DISPLAY MEPL utility.

If DSNUTILB abends, the abend codes are returned as DSNUTILS return codes.

**Related reference**:

**Related information**:

- DFSORT Application Programming Guide

**DSNUTILU stored procedure**

Use the DSNUTILU stored procedure to run Db2 utilities from a Db2 application program.

Alternatively, you can use the DSNUTILV stored procedure, which also statements that are larger than 32 KB. For more information about the DSNUTILV stored procedure, see DSNUTILV stored procedure.

When called, DSNUTILU performs the following actions:
- Translates the values that are specified for the `utility-id` and `restart` parameters to EBCDIC
- Creates the utility input stream (SYSIN) for utility control statements that are encoded in Unicode
- Invokes Db2 utilities by using DSNUTILB
- Deletes all the rows that are currently in the created temporary table (SYSIBM.SYSPRINT)
- Captures the utility output stream (SYSPRINT) into a created temporary table (SYSIBM.SYSPRINT)
- Declares a cursor to select from SYSPRINT:
  ```sql
  DECLARE SYSPRINT CURSOR WITH RETURN FOR
  SELECT SEQNO, TEXT FROM SYSPRINT
  ORDER BY SEQNO;
  ```
- Opens the SYSPRINT cursor

The calling program then fetches rows from the returned result set to obtain the captured utility output.

The character set of the resulting utility SYPRINT output that is placed in the SYSIBM.SYSPRINT table is determined by the BIND PACKAGE statement for the DSNUTILU stored procedure. If the bind option ENCODING(EBCDIC) is specified, the SYSPRINT contents are in EBCDIC. If the bind option ENCODING(UNICODE) is specified, the SYSPRINT contents are in Unicode. The default installation job, DSNTIJRT, contains ENCODING(EBCDIC).

**Environment for DSNUTILU**

DSNUTILU must run in a WLM environment.

The WLM core environment DSNWLM_UTILS. DSNWLM_UTILS is intended for the following Db2 utilities stored procedures only:
- DSNUTILV
- DSNUTILU
- DSNUTILS (deprecated)

If you plan to run other applications in this environment, add the procedure and add the DCB information for SYSIN, as shown in the following example:
```
//SYSIN DD UNIT=SYSDA,SPACE=(4000,(20,20),,,ROUND),
// DCB=(RECFM=V,LRECL=32708)
```

**Related information:**

[Core WLM environments for Db2-supplied routines (Db2 Installation and Migration)]

**The WLM-established address space for DSNUTILU**

The JCL procedure for starting the WLM-established address space in which DSNUTILU runs requires DD statements for DSSPRINT, SYSIN, and SYSPRINT. The SYSIN and SYSPRINT DD statements must allocate workfiles that DSNUTILU can use to temporarily store utility input statements and utility output messages. If you plan to run RUNSTATS and collect distribution statistics, you also need to allocate a DD statement for RNPRIN01.
Db2 provides an address space procedure for DSNWLM_UTILS, which is the core WLM environment for DSNUTILU. That address space procedure is called DSNWLMU. For detailed information about DSNWLMU, see Core WLM environments for Db2-supplied routines (Db2 Installation and Migration).

Authorization required for DSNUTILU

To call the DSNUTILU stored procedure, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges on each package that the stored procedure uses:

- The EXECUTE privilege on the package for DSNUTILU
- Ownership of the package
- PACKADM authority for the package collection
- SYSADM authority

Then, to execute the utility, you must use a privilege set that includes the authorization to run the specified utility.

Utility control statements that are passed to DSNUTILU

Input data sets for the utility control statements can begin with the following Unicode characters:

- A Unicode UTF-8 blank (X'20')
- A Unicode UTF-8 dash (X'2D')
- Uppercase Unicode UTF-8 "A" through "Z" (X'41' through X'5A')

Any utility that requires a sort must include the SORTDEVT keyword in the utility control statement. Use of the SORTNUM keyword is optional.

Also, DSNUTILU does not dynamically allocate data sets. Use the TEMPLATE utility control statement to dynamically allocate data sets.

DSNUTILU stored procedure syntax diagram

The following syntax diagram shows the SQL CALL statement for invoking utilities as a stored procedure.

```
CALL DSNUTILU(utility-id, restart, utstmt, retcode)
```

DSNUTILU option descriptions

utility-id

Specifies a unique identifier for this utility within Db2.

utility-id is an input parameter of type VARCHAR(16) in Unicode UTF-8, which must be translatable to the following allowable EBCDIC characters:
• A - Z (uppercase and lowercase)
• 0 - 9
• #, $, @, ©, ¢, !, ^, or period (.)

restart
Specifies whether Db2 is to restart a current utility, and, if so, at what point the
utility is to be restarted.

restart is an input parameter of type VARCHAR(8) in Unicode UTF-8, which
must be translatable to allowable EBCDIC characters. Specify one of the
following values for this parameter:

NO or null
Indicates that the utility job is new and is not a restarted job. No other
utility with the same utility identifier (UID) can exist.

The default is null.

CURRENT
Restarts the utility at the last commit point.

PHASE
Restarts the utility at the beginning of the currently stopped phase. Use the
DISPLAY UTILITY command to determine the currently stopped phase.

PREVIEW
Executes the utility control statements that follow in preview mode.

In preview mode, Db2 parses all utility control statements for syntax
errors, but normal utility execution does not occur. If the syntax is valid,
Db2 expands all LISTDEF lists and TEMPLATE data set name expressions
that are included in SYSIN and prints the results to the SYSPRINT data set.
Db2 evaluates and expands all LISTDEF statements into a list of table
spaces or index spaces. Db2 also evaluates TEMPLATE data set name
expressions into data set names through variable substitution. Db2 also
expands lists and data set name expressions from any LISTDEF libraries
and TEMPLATE libraries that are referenced by a utility invocation.

If the PREVIEW keyword is omitted, preview processing is turned off with
one exception. The absence of this keyword does not override the
PREVIEW JCL parameter, which, if specified, remains in effect for the
entire job step.

This option is identical to the PREVIEW JCL parameter.

Related information:
- Restarting an online utility (Db2 Utilities)
- DISPLAY UTILITY (Db2) (Db2 Commands)
- Executing statements in preview mode (Db2 Utilities)

utstmt
Specifies the utility control statements.

utstmt is an input parameter of type VARCHAR(32704) in Unicode UTF-8. If
the utility statement is not in Unicode UTF-8, Db2 converts it to UTF-8.
Therefore, if you pass a utility control statement in another format, consider
the Possible consequences of character conversion (Db2 Internationalization
Guide).

retcode
Specifies the utility highest return code.

Chapter 5. Procedures that are supplied with Db2 959
recode is an output parameter of type INTEGER.

**Terminating or restarting a utility with DSNUTILU**

If you do not want to restart a utility after a failure, take the following actions:

1. Use the TERM UTIL command to terminate the failing utility.
   
   When you terminate the utility, Db2 deletes the data sets that are needed by the utility.

2. Refresh the WLM environment in one of the following ways:
   
   - Submit the VARY command:
     
     VARY WLM,APPLENV=xxx,REFRESH
   
   - Call the WLM_REFRESH stored procedure.

If you want to restart a utility after a failure, take the following actions:

1. When you run the utility, use a TEMPLATE utility control statement, and specify DISP (NEW,CATLG,CATLG) in your template for data sets that are needed by the utility.

2. When the utility fails, refresh the WLM environment, but do not terminate the utility.

3. After the utility completes, delete the allocated data sets manually.

**Related information:**

- [WLM_REFRESH stored procedure](#)

**Sample program for calling DSNUTILU**

The following sample program calls DSNUTILU and is included in SDSNSAMP:

**Job DSNTEJ6R** compiles, link-edits, binds, and runs sample C-language caller program DSN8ED8, which invokes the DSNUTILU stored procedure to execute a utility. DSN8ED8 can pass either a utility statement or the name of a data set that contains the utility statement.

**Related information:**

- [Job DSNTEJ6R (Db2 Installation and Migration)](#)

**DSNUTILU output**

Db2 creates the result set according to the DECLARE statement shown in [Example of declaring a cursor to select from SYSPRINT](#)

Output from a successful execution of the DSNTEJ6R sample job or an equivalent job lists the specified parameters, followed by the messages that are generated by the Db2 DIAGNOSE DISPLAY MEPL utility.

**Related information:**

- [DIAGNOSE (Db2 Utilities)](#)
DSNUTILV stored procedure

Use the DSNUTILV stored procedure to run Db2 utilities from a Db2 application program. It can run utility statements as large as 2 GB.

The DSNUTILV stored procedure

When called, DSNUTILV performs the following actions:

- Translates the values that are specified for the utility-id and restart parameters to EBCDIC
- Creates the utility input stream (SYSIN) for utility control statements that are encoded in Unicode
- Invokes Db2 utilities by using DSNUTILB
- Deletes all the rows that are currently in the created temporary table (SYSIBM.SYSPRINT)
- Captures the utility output stream (SYSPRINT) into a created temporary table (SYSIBM.SYSPRINT)
- Declares a cursor to select from SYSPRINT:
  
  DECLARE SYSPRINT CURSOR WITH RETURN FOR
  SELECT SEQNO, TEXT FROM SYSPRINT
  ORDER BY SEQNO;

- Opens the SYSPRINT cursor

The calling program then fetches rows from the returned result set to obtain the captured utility output.

The character set of the resulting utility SYSPRINT output that is placed in the SYSIBM.SYSPRINT table is determined by the BIND PACKAGE statement for the DSNUTILV stored procedure. If the bind option ENCODING(EBCDIC) is specified, the SYSPRINT contents are in EBCDIC. If the bind option ENCODING(UNICODE) is specified, the SYSPRINT contents are in Unicode. The default installation job, DSNTIJRT, contains ENCODING(EBCDIC).

Environment for DSNUTILV

DSNUTILV must run in a WLM environment. The WLM core environment DSNWLM_UTILS. DSNWLM_UTILS is intended for the following Db2 utilities stored procedures only:

- DSNUTILV
- DSNUTILU
- DSNUTILS (deprecated)

If you plan to run other applications in this environment, add the procedure and add the DCB information for SYSIN, as shown in the following example:

```
//SYSIN DD UNIT=SYSDA,SPACE=(4000,(20,20),,,ROUND),
//
// DCB=(RECFM=V,LRECL=32708)
```

Related information:

Core WLM environments for Db2-supplied routines (Db2 Installation and Migration)
The WLM-established address space for DSNUTILV

The JCL procedure for starting the WLM-established address space in which DSNUTILV runs requires DD statements for DSSPRINT, SYSIN, and SYSPRINT. The SYSIN and SYSPRINT DD statements must allocate workfiles that DSNUTILV can use to temporarily store utility input statements and utility output messages. If you plan to run RUNSTATS and collect distribution statistics, you also need to allocate a DD statement for RNPRIN01.

Db2 provides an address space procedure for DSNWLM_UTILS, which is the core WLM environment for DSNUTILV. That address space procedure is called DSNWLMU. For detailed information about DSNWLMU, see Core WLM environments for Db2-supplied routines (Db2 Installation and Migration).

Authorization required for DSNUTILV

To call the DSNUTILV stored procedure, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges on each package that the stored procedure uses:

• The EXECUTE privilege on the package for DSNUTILV
• Ownership of the package
• PACKADM authority for the package collection
• DATAACCESS authority
• SYSADM authority

Then, to execute the utility, you must use a privilege set that includes the authorization to run the specified utility.

Utility control statements that are passed to DSNUTILV

Input data sets for the utility control statements can begin with the following Unicode characters:

• A Unicode UTF-8 blank (X'20')
• A Unicode UTF-8 dash (X'2D')
• Uppercase Unicode UTF-8 "A" through "Z" (X'41' through X'5A')

Any utility that requires a sort must include the SORTDEVT keyword in the utility control statement. Use of the SORTNUM keyword is optional.

Also, DSNUTILV does not dynamically allocate data sets. Use the TEMPLATE utility control statement to dynamically allocate data sets.

DSNUTILV stored procedure syntax diagram

The following syntax diagram shows the SQL CALL statement for invoking utilities as a stored procedure.
DSNUTILV option descriptions

utility-id
  Specifies a unique identifier for this utility within Db2.
  
  utility-id is an input parameter of type VARCHAR(16) in Unicode UTF-8, which
  must be translatable to the following allowable EBCDIC characters:
  • A - Z (uppercase and lowercase)
  • 0 - 9
  • #, $, @, ¢, !, ^, or period (.)

restart
  Specifies whether Db2 is to restart a current utility, and, if so, at what point the
  utility is to be restarted.
  
  restart is an input parameter of type VARCHAR(8) in Unicode UTF-8, which
  must be translatable to allowable EBCDIC characters. Specify one of the
  following values for this parameter:
  • NO or null
    Indicates that the utility job is new and is not a restarted job. No other
    utility with the same utility identifier (UID) can exist.
    The default is null.
  • CURRENT
    Restarts the utility at the last commit point.
  • PHASE
    Restarts the utility at the beginning of the currently stopped phase. Use the
    DISPLAY UTILITY command to determine the currently stopped phase.
  • PREVIEW
    Executes the utility control statements that follow in preview mode.
    In preview mode, Db2 parses all utility control statements for syntax
    errors, but normal utility execution does not occur. If the syntax is valid,
    Db2 expands all LISTDEF lists and TEMPLATE data set name expressions
    that are included in SYSIN and prints the results to the SYSPRINT data set.
    Db2 evaluates and expands all LISTDEF statements into a list of table
    spaces or index spaces. Db2 also evaluates TEMPLATE data set name
    expressions into data set names through variable substitution. Db2 also
    expands lists and data set name expressions from any LISTDEF libraries
    and TEMPLATE libraries that are referenced by a utility invocation.
    
    If the PREVIEW keyword is omitted, preview processing is turned off with
    one exception. The absence of this keyword does not override the
    PREVIEW JCL parameter, which, if specified, remains in effect for the
    entire job step.
    
    This option is identical to the PREVIEW JCL parameter.

Related information:

- Restoring an online utility (Db2 Utilities)
- DISPLAY UTILITY (Db2) (Db2 Commands)
- Executing statements in preview mode (Db2 Utilities)
**utstmt**

Specifies the utility control statements.

**utstmt** is an input parameter of type CLOB(2G) in Unicode UTF-8. If the utility statement is not in Unicode UTF-8, Db2 converts it to UTF-8. Therefore, if you pass a utility control statement in another format, consider the possible consequences of character conversion (Db2 Internationalization Guide).

You can specify a CLOB file reference variable for this parameter. However, the referenced data set must be in variable record format. For example, suppose that you want DSNUTILV to use LOAD utility statements that were generated by the UNLOAD utility. You can pass these statements to DSNUTILV by using a file reference variable. However, you must first convert the data set that contains these statements to variable record format. (By default, UNLOAD creates these data sets in fixed record format.) Then, make any other necessary changes, such as adding templates for the LOAD data sets.

**Restriction:** Any keywords, names, or constants in the utility control statement cannot be larger than 32,704 bytes.

Because conversion between UNICODE and EBCDIC is not always exact, some constants (such as table names, index names, column names, and constant values) can be incorrectly converted. In such cases, use hexadecimal constants. For example, use X'31' instead of the UNICODE value of character '1'.

**Related information:**
- TEMPLATE (Db2 Utilities)
- LOAD statements that are generated by UNLOAD (Db2 Utilities)

**retnode**

Specifies the utility highest return code.

**retnode** is an output parameter of type INTEGER.

**Terminating or restarting a utility with DSNUTILV**

If you do not want to restart a utility after a failure, take the following actions:

1. Use the TERM UTIL command to terminate the failing utility.
   - When you terminate the utility, Db2 deletes the data sets that are needed by the utility.
2. Refresh the WLM environment in one of the following ways:
   - Submit the VARY command:
     ```sql
     VARY WLM,APPLENV=xxx,REFRESH
     ```
   - Call the WLM_REFRESH stored procedure.

If you want to restart a utility after a failure, take the following actions:

1. When you run the utility, use a TEMPLATE utility control statement, and specify DISP (NEW,CATLG,CATLG) in your template for data sets that are needed by the utility.
2. When the utility fails, refresh the WLM environment, but do not terminate the utility.
3. After the utility completes, delete the allocated data sets manually.

**Related information:**
- WLM_REFRESH stored procedure
Sample program for calling DSNUTILV

The following sample program calls DSNUTILV and is included in SDSNSAMP:

Job DSNTEJ6X compiles, link-edits, binds, and runs sample C-language caller program DSN8EDA, which invokes the DSNUTILV stored procedure to execute a utility. DSN8EDA can pass either a utility statement or the name of a data set that contains the utility statement.

Related information:
- Job DSNTEJ6R (Db2 Installation and Migration)

DSNUTILV output

Db2 creates the result set according to the DECLARE statement shown in Example of declaring a cursor to select from SYSPRINT.

Output from a successful execution of the DSNTEJ6R sample job or an equivalent job lists the specified parameters, followed by the messages that are generated by the Db2 DIAGNOSE DISPLAY MEPL utility.

Related information:
- DIAGNOSE (Db2 Utilities)

DSN_WLM_APPLENV stored procedure

This procedure provides a convenient way to define, install, and activate a new WLM application environment for Db2. You can also use it to remove WLM application environments.

Environment

DSN_WLM_APPLENV runs in a WLM-established stored procedures address space.

Authorization

To execute the CALL DSN_WLM_APPLENV statement, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges on each package that the stored procedure uses:
- The EXECUTE privilege on the DSN_WLM_APPLENV stored procedure
- Ownership of the stored procedure
- SYSADM authority

If the RACF facility class is active and a profile has been defined for the MVSADMIN.WLM.POLICY facility class, then the caller of the stored procedure needs the following access:
- ACCESS(READ) for action WLINFO:
  PERMIT MVSADMIN.WLM.POLICY CLASS(FACILITY) ID(user) ACCESS(READ)
- ACCESS(UPDATE) for action ADD, ADD_ACTIVATE, ACTIVATE:
  PERMIT MVSADMIN.WLM.POLICY CLASS(FACILITY) ID(user) ACCESS(UPDATE)
Syntax

CALL DSN_WLM_APPLENV(action, policyid, wlmoptions, return-code, message)

Procedure parameters

ACTION
An input parameter of type VARCHAR(20) that identifies the type of action to be performed. This is a required parameter and supports the following values:

ACTIVATE
The stored procedure activates a WLM service policy.

ADD
The stored procedure installs a new WLM application environment to an existing WLM service definition without activating a service policy. The new WLM application environment becomes available only on the next activation of a WLM policy.

ADD_ACTIVATE
The stored procedure installs a new WLM application environment to an existing WLM service definition and automatically activates a WLM service policy to enable the new WLM application environment.

REMOVE
The stored procedure installs a WLM application environment from an existing WLM service definition, and installs the modified service definition without activating it.

REMOVE_ACTIVATE
The stored procedure removes a WLM application environment from an existing WLM service definition, installs the modified service definition, and activate it.

REMOVE_IF_EXISTS
The same as REMOVE, except that if the WLM application environment to be removed does not exist, the return code is 4 (warning), instead of 8 (error).

REMOVEIfExists_ACTIVATE
The same as REMOVE_ACTIVATE, except that if the WLM application environment to be removed does not exist, the return code is 4 (warning), instead of 8 (error).

WLMINFO
The stored procedure queries the existing WLM service definition and returns basic information. Examples of the information returned include:

• The service definition name
• The timestamp in the local time the service definition was installed
• The user ID of the service administrator that installed the service definition
• The name of the system on which the service definition was installed from
• The number of application environment currently defined
If the any action other than ACTIVATE or WLMINFO is specified, the WLMOPTIONS input parameter is also required.

**POLICYID**

An input parameter of type VARCHAR(8) that identifies the WLM service policy to be activated. It can be 1-8 characters long or the word ACTIVE. If the policy specified is ACTIVE, the active service policy is used. This parameter is required if any of the following actions is specified:

- ACTIVATE
- ADD_ACTIVATE
- REMOVE_ACTIVATE
- REMIFEXISTS_ACTIVATE

Otherwise, it is ignored and can be set to NULL or an empty string.

**WLMOPTIONS**

An input parameter of type VARCHAR(4000).

This parameter with the WLMNAME parameter is required if any of the following actions is specified, and other WLM parameters are not valid:

- ADD
- ADD_ACTIVATE
- REMOVE
- REMOVE_ACTIVATE
- REMOVE_I
- REMIFEXISTS_ACTIVATE

The following WLM options are supported. Separate multiple options by one or more spaces.

**WLMNAME(name)**

WLMNAME is the defined name for an application environment. It can be 1-32 characters long. It cannot begin with the letters SYS. This is a required option.

**DESCRIPTION(description)**

DESCRIPTION is a 32-character area describing the application environment. This option is not required and can be set to an empty value. For example,

DESCRIPTION()

**PROCNAME(procedure-name)**

PROCNAME defines the JCL procedure that WLM uses to start server address spaces for the application environment. It can be 1-8 characters long. This is a required option.

**STARTPARM(start-up-parameters)**

STARTPARM contains the parameters that WLM uses to start the JCL procedure. The parameters can be up to 115 characters. If the parameters include the subsystem name, the symbol &IWMSSNM can be used to cause WLM to substitute the subsystem name instead of typing the subsystem name directly. This option is useful because multiple instances of the subsystem with different names can use the application environment. For example:

STARTPARM(DB2SSN=&IWMSSNM,APPLENV=WLMENV1,NUMTCB=1)

This option is not required and can be set to an empty value.
**WLMOPT (WLM_MANAGED|SINGLE_SERVER)**

WLMOPT tells WLM to limit the number of server address spaces. For example, if a server address space requires exclusive use of a resource, only a single address space can exist. For Db2 routines, you can set a limit of 1 address space per system if required by the routine. Note that if there are multiple Db2 subsystems on a given system, WLM creates 1 server for each Db2 subsystem that calls the routines. A limit of 1 address space per sysplex does not apply to Db2 routines.

This option is not required and can be set to an empty value. The default is WLM_MANAGED.

**Examples**

**Example: Returning the basic information of the WLM service definition:**

```
CALL SYSPROC.DSN_WLM_APPLENV('WLMINFO', NULL, NULL, ?, ?)
```

Here is an example of the output:

```
RETURN_CODE: 0
MESSAGE: DSNT051I DSNTWLMS ACTIVE WLM SERVICE DEFINITION

SERVICE DEFINITION NAME       WLMSAMPL
INSTALLED ON                   2010-01-25-07.11.57.764052
INSTALLED BY                  SYSADM
INSTALLED FROM                LABEC130
NUMBER OF APPL ENVIRONMENT    12

DSN023I DSNTWLMS DISPLAY WLM INFORMATION SUCCESSFUL
```

**Example: Identifying the action and WLM options:**

```
CALL SYSPROC.DSN_WLM_APPLENV('ADD_ACTIVATE',
   'ACTIVE',
   'WLMNAME(DSNWLM_SAMPLE)
   DESCRIPTION(DB2 SAMPLE WLM ENVIRONMENT)
   PROCNAME(DSNWLM)
   STARTPARM(DB2SSN=&IWMSSNM,APPLENV='DSNWLM_SAMPLE')
   WLMOPT(WLM_MANAGED)', ?, ?)
```

Here is an example of the output:

```
RETURN_CODE: 0
MESSAGE: DSNT023I DSNTWLMS ADD WLM APPLICATION ENVIRONMENT DSNWLM_SAMPLE SUCCESSFUL

APPLICATION ENVIRONMENT NAME : DSNWLM_SAMPLE
DESCRIPTION                  : DB2 SAMPLE WLM ENVIRONMENT

```

**DSN8.CREATE_DGTT stored procedure**

The DSN8.CREATE_DGTT sample procedure creates a declared temporary table named SESSION.DBMS_BUFFER.

SESSION.DBMS_BUFFER is used by the sample trace procedures.
Environment

The CREATE_DGTT stored procedure must be called from within a native SQL routine.

Authorization

To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges:

- The EXECUTE privilege on the DSN8.CREATE_DGTT stored procedure
- Ownership of the stored procedure
- SYSADM authority

Syntax

```
CALL DSN8.CREATE_DGTT
```

Notes

Creation of this procedure:
Sample job DSNTEJTR creates this procedure.

Examples

Example: Create the SESSION.DBMS_BUFFER declared temporary table.
```
CALL DSN8.CREATE_DGTT;
```

DSN8.DISABLE stored procedure

The DISABLE sample procedure disables the message buffer into which trace messages for native SQL routines are written.

Environment

The DISABLE stored procedure must be called from within a native SQL routine.

Authorization

To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges:

- The EXECUTE privilege on the DSN8.DISABLE stored procedure
- Ownership of the stored procedure
- SYSADM authority

Syntax

```
CALL DSN8.DISABLE
```
**Notes**

Creation of this procedure:

Sample job DSNTEJTR creates this procedure.

**Examples**

Example: Disable the message buffer for the current debug session.

```sql
CALL DSN8.DISABLE;
```

---

**DSN8.ENABLE stored procedure**

The ENABLE sample procedure enables the message buffer into which trace messages for native SQL routines are written.

**Environment**

The ENABLE stored procedure must be called from within a native SQL routine.

**Authorization**

To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges:

- The EXECUTE privilege on the DSN8.ENABLE stored procedure
- Ownership of the stored procedure
- SYSADM authority

**Syntax**

```sql
CALL DSN8.ENABLE(---buffer-size---)
```

**Option descriptions**

**buffer-size**

This value is not used by DSN8.ENABLE.

This is an input argument of type INTEGER.

**Notes**

Creation of this procedure:

Sample job DSNTEJTR creates this procedure.

**Examples**

Example: Enable the message buffer for the current debug session.

```sql
CALL DSN8.ENABLE(17000);
```

Example: Enable the message buffer for the current debug session, without specifying the `buffer-size` parameter.

```sql
CALL DSN8.ENABLE(CAST(NULL AS INTEGER));
```
**DSN8.GET_LINE stored procedure**

The GET_LINE sample procedure returns a single line from the message buffer, up to, but not including the end-of-line character sequence.

**Environment**

The GET_LINE stored procedure must be called from within a native SQL routine.

**Authorization**

To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges:
- The EXECUTE privilege on the DSN8.GET_LINE stored procedure
- Ownership of the stored procedure
- SYSADM authority

**Syntax**

```
CALL DSN8.GET_LINE(line, status)
```

**Option descriptions**

- **line**
  - A line from the message buffer. The CCSID of the result is 1200.
  - This is an output argument of type VARGRAPHIC(16334).

- **status**
  - Indicates whether a line was returned from the message buffer. Possible values are:
    - 0 : A line was returned.
    - 1 : There was no line available to returned.
  - This is an output argument of type INTEGER.

**Notes**

**Creation of this procedure:**
- Sample job DSNTEJTR creates this procedure.

**Putting end-of-line character sequences in the message buffer:**
- You can put end-of-line character sequences in the message buffer in one of the following ways:
  - Use the PUT_LINE procedure to put each line in the message buffer with an end-of-line character sequence.
  - After a series of calls to the PUT procedure, call the NEW_LINE procedure.

**Examples**

**Example:** Retrieve a line from the message buffer into SQL variable LINE. Retrieve the status of the request into SQL variable STATUS.
CALL DSN8.GET_LINE(LINE,STATUS);

**DSN8.GET_LINES stored procedure**

The GET_LINES sample procedure returns one or more lines from the message buffer, and stores the text in an array.

Each line of text in the message buffer, up to, but not including the end-of-line character, is stored in an element of the target array.

**Environment**

The GET_LINES stored procedure must be called from within a native SQL routine.

**Authorization**

To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges:

- The EXECUTE privilege on the DSN8.GET_LINES stored procedure
- Ownership of the stored procedure
- SYSADM authority

**Syntax**

```
CALL DSN8.GET_LINES(lines, numlines)
```

**Option descriptions**

**lines**

Lines of text from the message buffer. The CCSID of the result is 1200.

This is an output argument of user-defined type DSN8.GRPHICARR. DSN8.GRPHICARR is defined as:

```
VARGRAPHIC(16334) ARRAY[2147483647]
```

**numlines**

When numlines is used as an input argument, it specifies the number of lines to retrieve from the message buffer.

When numlines is used as an output argument, it specifies the number of lines that were retrieved from the message buffer. When the output value of numlines is less than the input value of numlines, the number of lines remaining in the message buffer is less than the requested number of lines.

If the input value of numlines is 0 or NULL, NULL is returned for lines, and 0 is returned for numlines.

This is an input and output argument of type INTEGER.

**Notes**

**Creation of this procedure:**

Sample job DSNTEJTR creates this procedure.
Examples

Example: Retrieve five lines from the message buffer into SQL variable LINES. Use SQL variable NUMLINES to specify that you want five lines, and to determine the number of lines that you receive.

```
CALL DSN8.GET_LINES(LINES,NUMLINES);
```

DSN8.NEW_LINE stored procedure

The NEW_LINE sample procedure writes an end-of-line character sequence to the message buffer.

Each line of text in the message buffer, up to, but not including the end-of-line character, is stored in an element of the target array.

Environment

The NEW_LINE stored procedure must be called from within a native SQL routine.

Authorization

To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges:

- The EXECUTE privilege on the DSN8.NEW_LINE stored procedure
- Ownership of the stored procedure
- SYSADM authority

Syntax

```
CALL DSN8.NEW_LINE
```

Notes

Creation of this procedure:

Sample job DSNTEJTR creates this procedure.

Examples

Example: Write an end-of-line character sequence to the message buffer.

```
CALL DSN8.NEW_LINE;
```

DSN8.PUT stored procedure

The PUT sample procedure writes a line to the message buffer, without an end-of-line character sequence at the end.

Environment

The PUT stored procedure must be called from within a native SQL routine.
Authorization

To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges:

- The EXECUTE privilege on the DSN8.PUT stored procedure
- Ownership of the stored procedure
- SYSADM authority

Syntax

```
CALL DSN8.PUT((item))
```

Option descriptions

`item`

Specifies the line to write to the message buffer. If `item` is an empty string or NULL, the message buffer is unmodified.

This is an output argument of type VARGRAPHIC(16334).

Notes

Creation of this procedure:
Sample job DSNTEJTR creates this procedure.

Adding an end-of-line character sequence to the end of the message buffer:
When you use the DSN8.PUT procedure to write a string to the message buffer, you can use the NEW_LINE procedure to add the end-of-line character sequence to the end of the message buffer.

Examples

Example: Write the string 'Hello' to the message buffer, without an end-of-line character sequence at the end.
```
CALL DSN8.PUT('Hello');
```

Related reference:
- DSN8.NEW_LINE stored procedure

DSN8.PUT_LINE stored procedure

The PUT_LINE sample procedure writes a line, including the end-of-line character sequence, to the message buffer.

Environment

The PUT_LINE stored procedure must be called from within a native SQL routine.

Authorization

To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges:

- The EXECUTE privilege on the DSN8.PUT_LINE stored procedure
Ownership of the stored procedure
SYSDAM authority

Syntax

►►CALL DSN8.PUT_LINE(—item—)◄◄

Option descriptions

item
Specifies the line to write to the message buffer. If item is an empty string or NULL, a null character is put in the message buffer.
This is an output argument of type VARGRAPHIC(16334).

Notes

Creation of this procedure:
Sample job DSNTEJTR creates this procedure.

Examples

Example: Write the string 'Hello' to the message buffer, with an end-of-line sequence at the end.
CALL DSN8.PUT_LINE('Hello');

Objects that are used by the sample trace stored procedures

The sample trace stored procedures use a global variable, an user-defined array type, and a declared temporary table.

Sample job DSNTEJTR creates those objects.

Global variable DSN8.DBMS_ENABLE

The DSN8.DBMS_ENABLE global variable is used to test if the trace is enabled.

Example: Test whether the trace is enabled before attempting to write to the trace buffer.
IF DSN8.DBMS_ENABLE = 'Y' THEN CALL DSN8.PUT_LINE (LINE);
END IF;

Array type DSN8.GRPHICARR

The user-defined array type DSN8.GRPHICARR is used for the first parameter to the DSN8.GET_LINES procedure. An array variable that is declared with the DSN8.GRPHICARR type is used to hold lines that are retrieved from the message buffer.

DSN8.GRPHICARR is defined as:
VARGRAPHIC(16334) ARRAY[2147483647]
Example: Declare SQL variable LINES to hold lines that are retrieved from the message buffer.

```
DECLARE LINES DSN8.GRPHICARR;
```

Declared temporary table SESSION.DBMS_BUFFER

The SESSION.DBMS_BUFFER declared temporary table contains the message buffer.

GET_CONFIG stored procedure

The GET_CONFIG stored procedure retrieves data server configuration information.

This data server configuration information includes:
- Data sharing group information
- Db2 subsystem status information
- Db2 subsystem parameters, DSNHDECP or a user-specified application defaults module, and the IRLM parameters that are found in IFCID 106 section 5
- Db2 distributed access information
- Active log data set information
- The time of the last restart of Db2
- Resource limit facility information
- Connected Db2 subsystems information

Environment

The GET_CONFIG stored procedure runs in a WLM-established stored procedures address space.

Authorization

To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have EXECUTE privilege on the GET_CONFIG stored procedure.

Syntax

```
CALL GET_CONFIG (major_version, minor_version, requested_locale, xml_input, xml_filter, xml_output, xml_message)
```

The schema is SYSPROC.
Option descriptions

major_version
An input and output parameter of type INTEGER that indicates the major document version. On input, this parameter indicates the major document version that you support for the XML documents that are passed as parameters in the stored procedure (xml_input, xml_output, and xml_message). The stored procedure processes all XML documents in the specified version, or returns an error (-20457) if the version is invalid.

On output, this parameter specifies the highest major document version that is supported by the procedure. To determine the highest supported document version, specify NULL for this input parameter and all other required parameters. Currently, the highest major document version that is supported is 2. Major document version 1 is also supported.

If the XML document in the xml_input parameter specifies the Document Type Major Version key, the value for that key must be equal to the value provided in the major_version parameter, or an error (+20458) is raised.

This parameter is used in conjunction with the minor_version parameter. Therefore, you must specify both parameters together. For example, you must specify both as either NULL, or non-NULL.

minor_version
An input and output parameter of type INTEGER that indicates the minor document version. On input, this parameter specifies the minor document version that you support for the XML documents that are passed as parameters for this stored procedure (xml_input, xml_output, and xml_message). The stored procedure processes all XML documents in the specified version, or returns an error (-20457) if the version is invalid.

On output, this parameter indicates the highest minor document version that is supported for the highest supported major version. To determine the highest supported document version, specify NULL for this input parameter and all other required parameters. Currently, the highest and only minor document version that is supported is 0 (zero).

If the XML document in the xml_input parameter specifies the Document Type Minor Version key, the value for that key must be equal to the value provided in the minor_version parameter, or an error (+20458) is raised.

This parameter is used in conjunction with the major_version parameter. Therefore, you must specify both parameters together. For example, you must specify both as either NULL, or non-NULL.

requested_locale
An input parameter of type VARCHAR(33) that specifies a locale. If the specified language is supported on the server, translated content is returned in the xml_output and xml_message parameters. Otherwise, content is returned in the default language. Only the language and possibly the territory information is used from the locale. The locale is not used to format numbers or influence the document encoding. For example, key names are not translated. The only translated portion of XML output and XML message documents are Display Name, Display Unit, and Hint. The value might be globalized where applicable. You should always compare the requested language to the language that is used in the XML output document (see the Document Locale entry in the XML output document).

Currently, the supported values for requested_locale are en_US and NULL. If you specify a null value, the result is the same as specifying en_US.
**xml_input**

An input parameter of type BLOB(2G) that specifies an XML input document of type Data Server Configuration Input in UTF-8 that contains input values for the stored procedure.

To pass an XML input document to the stored procedure, you must specify the `major_version` parameter as 2 and the `minor_version` parameter as 0 (zero).

For a non-data sharing system, a sample of a Version 2.0 XML input document is as follows:

```xml
<plist version="1.0">
  <?xml version="1.0" encoding="UTF-8" ?>
  <dict>
    <key>Document Type Name</key>
    <string>Data Server Configuration Input</string>
    <key>Document Type Major Version</key>
    <integer>2</integer>
    <key>Document Type Minor Version</key>
    <integer>0</integer>
    <key>Document Locale</key>
    <string>en_US</string>
    <key>Complete</key><false/>
    <key>Optional Parameters</key>
    <dict>
      <key>Include</key>
      <dict>
        <key>Value</key>
        <array>
          <string>DB2 Subsystem Status Information</string>
          <string>DB2 Subsystem Parameters</string>
          <string>DB2 Distributed Access Information</string>
          <string>Active Log Data Set Information</string>
          <string>Time of Last DB2 Restart</string>
          <string>Resource Limit Facility Information</string>
          <string>Connected DB2 Subsystem</string>
        </array>
      </dict>
    </dict>
  </dict>
</plist>
```

For a data sharing system, a sample of a Version 2.0 XML input document is as follows:

```xml
<plist version="1.0">
  <?xml version="1.0" encoding="UTF-8" ?>
  <dict>
    <key>Document Type Name</key>
    <string>Data Server Configuration Input</string>
    <key>Document Type Major Version</key>
    <integer>2</integer>
    <key>Document Type Minor Version</key>
    <integer>0</integer>
    <key>Document Locale</key>
    <string>en_US</string>
    <key>Complete</key><false/>
    <key>Optional Parameters</key>
    <dict>
      <key>Include</key>
      <dict>
        <key>Value</key>
        <array>
          <string>Common Data Sharing Group Information</string>
          <string>DB2 Subsystem Status Information</string>
          <string>DB2 Subsystem Parameters</string>
          <string>DB2 Distributed Access Information</string>
          <string>Active Log Data Set Information</string>
        </array>
      </dict>
    </dict>
  </dict>
</plist>
```
When passing an XML input document to the stored procedure, you must specify the Document Type Name key. In a non-data sharing system, you must specify the Include parameter. In a data sharing system, you must specify at least one of the following parameters:

- Include
- DB2 Data Sharing Group Members

If no XML input document is passed to the stored procedure, and you specified the major_version parameter as 2 and the minor_version parameter as 0 (zero), the stored procedure returns the following parameters for a non-data sharing system in a Version 2.0 XML output document by default:

- DB2 Subsystem Status Information
- DB2 Subsystem Parameters
- DB2 Distributed Access Information
- Active Log Data Set Information
- Time of Last DB2 Restart
- Resource Limit Facility Information
- Connected DB2 Subsystem

For a data sharing system, the same information is returned for each member of a data sharing group, plus the Common Data Sharing Group Information parameter.

If you passed a Version 2.0 XML input document to the stored procedure, the stored procedure returns the information in a Version 2.0 XML output document. The information returned is dependent on what you specified in the Include array and in the DB2 Data Sharing Group Members array (if applicable). For a non-data sharing system, the items that are specified in the Include array are returned. For a data sharing system, the following information is returned:

- The items that are specified in the Include array for each Db2 member that is specified in the DB2 Data Sharing Group Members array, if both the Include parameter and the DB2 Data Sharing Group Members parameter are specified.
- The items that are specified in the Include array for every Db2 member in the data sharing group, if only the Include parameter is specified.
- The Common Data Sharing Group Information and the following items for each member that is specified in the DB2 Data Sharing Group Members array, if only the DB2 Data Sharing Group Members parameter is specified:
  - DB2 Subsystem Status Information
  - DB2 Subsystem Parameters

Chapter 5. Procedures that are supplied with Db2 979
Note: If the Common Data Sharing Group Information item is specified in the Include array, this information is returned only once for the data sharing group. This information is not returned repeatedly for every Db2 member that is processed.

Complete mode: For an example of a Version 2.0 XML input document that is returned by the xml_output parameter when the stored procedure is running in Complete mode in a non-data sharing system, see Example 4 in the Examples section. For an example of a Version 2.0 XML input document that is returned by the xml_output parameter when the stored procedure is running in Complete mode in a data sharing system with two Db2 members, DB2A and DB2B, see Example 5.

XML Filter
An input parameter of type BLOB(4K) in UTF-8 that specifies a valid XPath query string. Use a filter when you want to retrieve a single value from an XML output document. For more information, see XPath expressions for filtering output (Db2 Administration Guide).

The following example selects the value for the Data Server Product Version from the XML output document:
`/plist/dict/key[.='Data Server Product Version']/following-sibling::string[1]`

If the key is not followed by the specified sibling, an error is returned.

XML Output
An output parameter of type BLOB(2G) that returns a complete XML output document of type Data Server Configuration Output in UTF-8. If a filter is specified, this parameter returns a string value. If the stored procedure is unable to return a complete output document (for example, if a processing error occurs that results in an SQL warning or error), this parameter is set to NULL.

The xml_output parameter can return either a Version 1.0 or Version 2.0 XML output document depending on the major_version and minor_version parameters that you specify. For information about the content of a Version 2.0 XML output document, see the option description for the xml_input parameter.

For a sample Version 1.0 XML output document, see Example 1 in the Examples section.

For a sample Version 2.0 XML output document in a non-data sharing system, see Example 6.

For a sample Version 2.0 XML output document in a data sharing system, see Example 7.

XML Message
An output parameter of type BLOB(64K) that returns a complete XML output document of type Data Server Message in UTF-8 that provides detailed information about an SQL warning condition. This document is returned when a call to the stored procedure results in an SQL warning, and the warning message indicates that additional information is returned in the XML message.
The XML output document. If the warning message does not indicate that additional information is returned, then this parameter is set to NULL.

The `xml_message` parameter can return either a Version 1.0 or Version 2.0 XML message document depending on the `major_version` and `minor_version` parameters that you specify.

For an example of an XML message document, see `Example 2`.

If the GET_CONFIG stored procedure is processing more than one Db2 member in a data sharing system and an error is encountered when processing one of the Db2 members, the stored procedure specifies the name of the Db2 member that is causing the error as the value of the `DB2 Object` key in the XML message document. The value of the `Short Message Text` key applies to the Db2 member that is specified.

The following example shows a fragment of a Version 2.0 XML message document with the `DB2 Object` key specified:

```xml
<key>Short Message Text</key>
<dict>
  <key>Display Name</key>
  <string>Short Message Text</string>
  <key>Value</key>
  <string>DSNA6xx1 DSNAADMGC .....</string>
  <key>DB2 Object</key>
  <string>DB2B</string>
  <key>Hint</key>
  <string />
</dict>
```

**Examples**

**Example 1:** The following example shows a fragment of a Version 1.0 XML output document for the GET_CONFIG stored procedure for a data sharing member. For a non-data sharing member, the following entries in the `DB2 Distributed Access Information` item are not included: `Resynchronization Domain`, `Alias List`, `Member IPv4 Address`, `Member IPv6 Address`, and `Location Server List`.

The two major sections that the XML output document always contains are `Common Data Sharing Group Information` and `DB2 Subsystem Specific Information`. In this example, the ellipsis (....) represent a dictionary entry that is comprised of `Display Name`, `Value`, and `Hint`, such as:

```xml
<dict>
  <key>Display Name</key>
  <string>DDF Status</string>
  <key>Value</key>
  <string>STARTD</string>
  <key>Hint</key>
  <string />
</dict>
```

<?xml version="1.0" encoding="UTF-8"?>

Chapter 5. Procedures that are supplied with Db2  985
Example 2: The following example shows a sample XML message document for the GET_CONFIG stored procedure. Similar to an XML output document, the details about an SQL warning condition are encapsulated in a dictionary entry, which is comprised of Display Name, Value, and Hint.

```xml
<xml version="1.0" encoding="UTF-8" ?>
<plist version="1.0">
  <dict>
    <key>Data Server Message</key>
    <string>DSNA630I DSNADMGC A PARAMETER FORMAT OR CONTENT ERROR WAS FOUND.
    The XML input document must be empty or NULL.</string>
  </dict>
</plist>
```

Example 3: This example shows a simple and static Java program that calls the GET_CONFIG stored procedure with an XPath that queries the value of the data server's IP address. The XPath is statically created as a string object by the program, and then converted to a BLOB to serve as input for the xml_filter parameter. After the stored procedure is called, the xml_output parameter contains only a single string and no XML document. This output is materialized as a file called xml_output.xml that is in the same directory where the GetConfDriver class resides.
import java.io.*;
import java.sql.*;
public class GetConfDriver {
    public static void main (String[] args) {
        Connection con = null;
        CallableStatement cstmt = null;
        String driver = "com.ibm.db2.jcc.DB2Driver";
        String url = "jdbc:db2:"
        String userid = null;
        String password = null;

        // Parse arguments
        if (args.length != 3) {
            System.err.println("Usage: GetConfDriver <alias or //server/database> <userid> <password>");
            System.err.println("where <alias or //server/database> is DB2 subsystem alias or //server/database for type 4 connectivity");
            System.err.println("<userid> is user ID to connect as");
            System.err.println("<password> is password to connect with");
            return;
        }        url += args[0];
        userid = args[1];
        password = args[2];

        try {
            byte[] xml_input;
            String str_xmlfilter = new String("/plist/dict/key[.='DB2 Subsystem Specific Information']/following-sibling::dict[1]/key[.='V91A']/following-sibling::dict[1]/key[.='DB2 Distributed Access Information']/following-sibling::dict[1]/key[.='IP Address']/following-sibling::dict[1]/key[.='Value']/following-sibling::string[1]");

            // Convert XML_FILTER to byte array to pass as BLOB
            byte[] xml_filter = str_xmlfilter.getBytes("UTF-8");
        }
    }
}
// Connect to database
con = DriverManager.getConnection(url, userid, password);
con.setAutoCommit(false);

cstmt = con.prepareCall("CALL SYS_PROC.GET_CONFIG(?,?,?,?,?,?,?)");

// Major / Minor Version / Requested Locale
cstmt.setInt(1, 1);
cstmt.setInt(2, 0);
cstmt.setString(3, "en_US");
// No Input document
// OutputParms
cstmt.registerOutParameter(1, Types.INTEGER);
cstmt.registerOutParameter(2, Types.INTEGER);
cstmt.registerOutParameter(6, Types.BLOB);
cstmt.registerOutParameter(7, Types.BLOB);
cstmt.execute();
con.commit();

SQLWarning cstmt_warning = cstmt.getWarnings();
if (cstmt_warning != null) {
    System.out.println("SQL Warning: " + cstmt_warning.getMessage());
} else {
    System.out.println("SQL Warning: None\n");
}

System.out.println("Major Version returned " + cstmt.getInt(1));
System.out.println("Minor Version returned " + cstmt.getInt(2));

/* get output BLOBs */
Blob b_out = cstmt.getBlob(6);
if(b_out != null)
{
    int out_length = (int)b_out.length();
    byte[] bxml_output = new byte[out_length];

    /* open an inputStream on BLOB data */
    InputStream instr_out = b_out.getBinaryStream();

    /* copy from inputStream into byte array */
    int out_len = instr_out.read(bxml_output, 0, out_length);

    /* write byte array into FileOutputStream */
    FileOutputStream fxml_out = new FileOutputStream("xml_output.xml");

    /* write byte array content into FileOutputStream */
    fxml_out.write(bxml_output, 0, out_length);

    //Close streams
    instr_out.close();
    fxml_out.close();
}

Blob b_msg = cstmt.getBlob(7);
if(b_msg != null)
{
    int msg_length = (int)b_msg.length();
    byte[] bxml_message = new byte[msg_length];

    /* open an inputStream on BLOB data */
InputStream instr_msg = b_msg.getBinaryStream();

/* copy from inputStream into byte array */
int msg_len = instr_msg.read(bxml_message, 0, msg_length);

/* write byte array content into FileOutputStream */
FileOutputStream fxml_msg = new FileOutputStream(new File("xml_message.xml"));
fxml_msg.write(bxml_message, 0, msg_length);
//Close streams
instr_msg.close();
fxml_msg.close();
}

} catch (SQLException sqle) {
    System.out.println("Error during CALL "
        + " SQLSTATE = " + sqle.getSQLState() 
        + " SQLCODE = " + sqle.getErrorCode() 
        + " : " + sqle.getMessage());
}

} catch (Exception e) {
    System.out.println("Internal Error " + e.toString());
}
finally {
    if(cstmt != null)
        try { cstmt.close(); } catch (SQLException sqle) {
            sqle.printStackTrace();
        }
    if(con != null)
        try { con.close(); } catch (SQLException sqle) {
            sqle.printStackTrace();
        }
}

Example 4: The following example shows a Version 2.0 XML input document that is returned by the xml_output parameter when the stored procedure is running in Complete mode in a non-data sharing system:

```xml
<plist version="1.0">
    <dict>
        <key>Document Type Name</key>
        <string>Data Server Configuration Input</string>
        <key>Document Type Major Version</key>
        <integer>2</integer>
        <key>Document Type Minor Version</key>
        <integer>0</integer>
        <key>Document Locale</key>
        <string>en_US</string>
        <key>Optional Parameters</key>
        <dict>
            <key>Display Name</key>
            <string>Optional Parameters</string>
            <key>Include</key>
            <dict>
                <key>Display Name</key>
                <string>Include</string>
                <key>Value</key>
                <array>
                    <string>DB2 Subsystem Status Information</string>
                    <string>DB2 Subsystem Parameters</string>
                    <string>DB2 Distributed Access Information</string>
                    <string>Active Log Data Set Information</string>
                    <string>Time of Last DB2 Restart</string>
                    <string>Resource Limit Facility Information</string>
                </array>
```
Example 5: The following example shows a Version 2.0 XML input document that is returned by the `xml_output` parameter when the stored procedure is running in Complete mode in a data sharing system with two Db2 members, DB2A and DB2B:

```xml
<plist version="1.0">
  <?xml version="1.0" encoding="UTF-8" ?>
  <dict>
    <key>Document Type Name</key>
    <string>Data Server Configuration Input</string>
    <key>Document Type Major Version</key>
    <integer>2</integer>
    <key>Document Type Minor Version</key>
    <integer>0</integer>
    <key>Document Locale</key>
    <string>en_US</string>
    <key>Optional Parameters</key>
    <dict>
      <key>Display Name</key>
      <string>Optional Parameters</string>
      <key>Include</key>
      <dict>
        <key>Display Name</key>
        <string>Include</string>
        <key>Value</key>
        <array>
          <string>Common Data Sharing Group Information</string>
          <string>DB2 Subsystem Status Information</string>
          <string>DB2 Subsystem Parameters</string>
          <string>DB2 Distributed Access Information</string>
          <string>Active Log Data Set Information</string>
          <string>Time of Last DB2 Restart</string>
          <string>Resource Limit Facility Information</string>
          <string>Connected DB2 Subsystem</string>
        </array>
        <key>Hint</key><string />
      </dict>
    </dict>
    <key>DB2 Data Sharing Group Members</key>
    <dict>
      <key>Display Name</key>
      <string>DB2 Data Sharing Group Members</string>
      <key>Value</key>
      <array>
        <string>DB2A</string>
        <string>DB2B</string>
      </array>
      <key>Hint</key><string />
    </dict>
  </dict>
</plist>
```

Example 6: This example shows a fragment of a Version 2.0 XML output document for the `GET_CONFIG` stored procedure in a non-data sharing system. An XML input document is not passed to the stored procedure. The ellipsis (…) represent a
dictionary entry that is comprised of **Display Name**, **Value**, and **Hint**, as in the following example, or an entry that is the same as the corresponding entry in a Version 1.0 XML output document:

```xml
<dict>
  <key>Display Name</key>
  <string>DDF Status</string>
  <key>Value</key>
  <string>STARTD</string>
  <key>Hint</key>
  <string />  
</dict>
```

```xml
<?xml version="1.0" encoding="UTF-8" ?>
.plist version="1.0">
  <dict>
    <key>Document Type Name</key>
    <string>Data Server Configuration Output</string>
    <key>Document Type Major Version</key>

        </dict>
      </dict>
    </dict>
  </dict>
</plist>
```
Example 7: This example shows a fragment of a Version 2.0 XML output document for the GET_CONFIG stored procedure in a data sharing system with two Db2 members, DB2A and DB2B. An XML input document is not passed to the stored procedure. The ellipsis (....) represent a dictionary entry that is comprised of Display Name, Value, and Hint, as in the following example, or an entry that is the same as the corresponding entry in a Version 1.0 XML output document:

```xml
<dict>
  <key>Display Name</key>
  <string>DDF Status</string>
  <key>Value</key>
  <string>STARTD</string>
  <key>Hint</key>
  <string /></dict>
```
<key>Data Server Product Version</key>  
<string>9.1.5</string>

- [Common SQL API stored procedures (Db2 Administration Guide)]

**GET_MESSAGE stored procedure**

The GET_MESSAGE stored procedure returns the short message text for an SQLCODE.

**Authorization**

To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have EXECUTE privilege on the GET_MESSAGE stored procedure.
Syntax

The following syntax diagram shows the SQL CALL statement for invoking this stored procedure:

```
CALL GET_MESSAGE(
    major_version, minor_version, NULL
    requested_locale, xml_input, xml_filter, xml_output, xml_message)
```

The schema is SYSPROC.

Option descriptions

`major_version`

An input and output parameter of type INTEGER that indicates the major document version. On input, this parameter indicates the major document version that you support for the XML documents that are passed as parameters in the stored procedure (xml_input, xml_output, and xml_message). The stored procedure processes all XML documents in the specified version, or returns an error (-20457) if the version is invalid.

On output, this parameter specifies the highest major document version that is supported by the stored procedure. To determine the highest supported document version, specify NULL for this input parameter and all other required parameters. Currently, the highest and only major document version that is supported is 1.

If the XML document in the xml_input parameter specifies the Document Type Major Version key, the value for that key must be equal to the value provided in the major_version parameter, or an error (+20458) is raised.

This parameter is used in conjunction with the `minor_version` parameter. Therefore, you must specify both parameters together. For example, you must specify both as either NULL, or non-NULL.

`minor_version`

An input and output parameter of type INTEGER that indicates the minor document version. On input, this parameter specifies the minor document version that you support for the XML documents that are passed as parameters for this stored procedure (xml_input, xml_output, and xml_message). The stored procedure processes all XML documents in the specified version, or returns an error (-20457) if the version is invalid.

On output, this parameter indicates the highest minor document version that is supported for the highest supported major version. To determine the highest supported document version, specify NULL for this input parameter and all other required parameters. Currently, the highest and only minor document version that is supported is 0 (zero).

If the XML document in the xml_input parameter specifies the Document Type Minor Version key, the value for that key must be equal to the value provided in the minor_version parameter, or an error (+20458) is raised.
This parameter is used in conjunction with the major_version parameter. Therefore, you must specify both parameters together. For example, you must specify both as either NULL, or non-NULL.

requested_locale
An input parameter of type VARCHAR(33) that specifies a locale. If the specified language is supported on the server, translated content is returned in the xml_output and xml_message parameters. Otherwise, content is returned in the default language. Only the language and possibly the territory information is used from the locale. The locale is not used to format numbers or influence the document encoding. For example, key names are not translated. The only translated portion of the XML output and XML message documents are Display Name, Display Unit, and Hint. The value might be globalized where applicable. You should always compare the requested language to the language that is used in the XML output document (see the Document Locale entry in the XML output document).

Currently, the supported values for requested_locale are en_US and NULL. If you specify a null value, the result is the same as specifying en_US.

xml_input
An input parameter of type BLOB(2G) that specifies an XML input document of type Data Server Message Input in UTF-8 that contains input values for the stored procedure.

For this stored procedure, the general structure of an XML input document is as follows:

```xml
<?xml version="1.0" encoding="UTF-8"?>
<plist version="1.0">
 <dict>
   <key>Document Type Name</key><string>Data Server Message Input</string>
   <key>Document Type Major Version</key><integer>1</integer>
   <key>Document Type Minor Version</key><integer>0</integer>
   <key>Document Locale</key><string>en_US</string>
   <key>Complete</key><false/>
   <key>Required Parameters</key>
   <dict>
     <key>SQLCODE</key>
     <dict>
       <key>Value</key><integer>sqlcode</integer>
     </dict>
   </dict>
   <key>Optional Parameters</key>
   <dict>
     <key>Message Tokens</key>
     <dict>
       <key>Value</key>
       <array>
         <string>token1 in SQLCA</string>
         <string>token2 in SQLCA</string>
       </array>
     </dict>
   </dict>
 </dict>
</plist>
```

For an example of an XML input document that will not run in Complete mode, see Example 2 in the Examples section.

**Complete mode:** For an example of an XML input document that is returned by the xml_output parameter when the stored procedure is running in Complete mode, see Example 1 in the Examples section.
xml_filter
An input parameter of type BLOB(4K) in UTF-8 that specifies a valid XPath query string. Use a filter when you want to retrieve a single value from an XML output document. For more information, see "XPath expressions for filtering output (Db2 Administration Guide)."

The following example selects the value for the short message text from the XML output document:

```
/plist/dict/key[.='Short Message Text']/following-sibling::dict[1]/key[.='Value']/following-sibling::string[1]
```

If the key is not followed by the specified sibling, an error is returned.

xml_output
An output parameter of type BLOB(2G) that returns a complete XML output document of type Data Server Message Output in UTF-8. If a filter is specified, this parameter returns a string value. If the stored procedure is unable to return a complete output document (for example, if a processing error occurs that results in an SQL warning or error), this parameter is set to NULL.

For an example of an XML output document, see Example 3.

xml_message
An output parameter of type BLOB(64K) that returns a complete XML output document of type Data Server Message in UTF-8 that provides detailed information about an SQL warning condition. This document is returned when a call to the procedure results in an SQL warning, and the warning message indicates that additional information is returned in the XML message output document. If the warning message does not indicate that additional information is returned, then this parameter is set to NULL.

For an example of an XML message document, see Example 4.

Example

Example 1: The following example shows an XML input document that is returned by the xml_output parameter when the stored procedure is running in Complete mode.

```
<xml version="1.0" encoding="UTF-8" ?>
<plist version="1.0">
<dict>
  <key>Document Type Name</key>
  <string>Data Server Message Input</string>
  <key>Document Type Major Version</key>
  <integer>1</integer>
  <key>Document Type Minor Version</key>
  <integer>0</integer>
  <key>Document Locale</key>
  <string>en_US</string>
  <key>Required Parameters</key>
  <dict>
    <key>Display Name</key>
    <string>Required Parameters</string>
    <key>SQLCODE</key>
    <dict>
      <key>Display Name</key>
      <string>SQLCODE</string>
      <key>Value</key>
      <integer />
    </dict>
    <key>Hint</key>
    <string />
  </dict>
</dict>
```
<key>Hint</key>
<string />
</dict>
</plist>

Example 2: The following example shows a complete sample of an XML input document for the GET_MESSAGE stored procedure.

```xml
<?xml version="1.0" encoding="UTF-8"?>
<plist version="1.0">
<dict>
<key>Document Type Name</key>
<string>Data Server Message Input</string>
<key>Document Type Major Version</key><integer>1</integer>
<key>Document Type Minor Version</key><integer>0</integer>
<key>Document Locale</key><string>en_US</string>
<key>Required Parameters</key>
<dict>
<key>SQLCODE</key>
<dict>
<key>Value</key><integer>-104</integer>
</dict>
</dict>
<key>Optional Parameters</key>
<dict>
<key>Message Tokens</key>
<dict>
<key>Value</key>
<array>
<string>X</string>
<string>(. LIKE AS</string>
</array>
</dict>
</dict>
</dict>
</plist>
```

Example 3: The following example shows a complete sample of an XML output document for the GET_MESSAGE stored procedure. The short message text for an SQLCODE will be encapsulated in a dictionary entry, which is comprised of Display Name, Value, and Hint.

```xml
<?xml version="1.0" encoding="UTF-8"?>
<plist version="1.0">
<dict>
<key>Document Type Name</key>
<string>Data Server Message Output</string>
<key>Document Type Major Version</key><integer>1</integer>
```
Example 4: The following example shows a sample XML message document for the GET_MESSAGE stored procedure. Similar to an XML output document, the details about an SQL warning condition will be encapsulated in a dictionary entry, which is comprised of Display Name, Value, and Hint.

```xml
<?xml version="1.0" encoding="UTF-8" ?>
<plist version="1.0">
  <dict>
    <key>Document Type Name</key><string>Data Server Message</string>
    <key>Document Type Major Version</key><integer>1</integer>
    <key>Document Type Minor Version</key><integer>0</integer>
    <key>Data Server Product Name</key><string>DSN</string>
    <key>Data Server Product Version</key><string>9.1.5</string>
    <key>Data Server Major Version</key><integer>9</integer>
    <key>Data Server Minor Version</key><integer>1</integer>
    <key>Data Server Platform</key><string>z/OS</string>
    <key>Document Locale</key><string>en_US</string>
    <key>Short Message Text</key>
      <dict>
        <key>Display Name</key><string>Short Message Text</string>
        <key>Value</key>
          <string>DSNA630I DSNADMGM  A PARAMETER FORMAT OR CONTENT ERROR WAS FOUND. The value for key 'Document Type Minor Version' is '2'. It does not match the value '0', which was specified for parameter 2 of the stored procedure. Both values must be equal.</string>
        <key>Hint</key><string />
      </dict>
  </dict>
</plist>
```

Example 5: This example shows a simple and static Java program that calls the GET_MESSAGE stored procedure with an XML input document and an XPath that queries the short message text of an SQLCODE.

The XML input document is initially saved as a file called xml_input.xml that is in the same directory where the GetMessageDriver class resides. This sample program uses the following xml_input.xml file:

```xml
<?xml version="1.0" encoding="UTF-8" ?>
<plist version="1.0">
  <dict>
    <key>Document Type Name</key><string>Data Server Message Input</string>
    <key>Document Type Major Version</key><integer>1</integer>
    <key>Document Type Minor Version</key><integer>0</integer>
    <key>Data Server Locale</key><string>en_US</string>
  </dict>
</plist>
```
The XPath is statically created as a string object by the program and then converted to a BLOB to serve as input for the xml_filter parameter. After the stored procedure is called, the xml_output parameter contains only a single string and no XML document. This output is materialized as a file called xml_output.xml that is in the same directory where the GetMessageDriver class resides.

Sample invocation of the GET_MESSAGE stored procedure with a valid XML input document and a valid XPath:

```java
public class GetSystemDriver {

    public static void main(String[] args) {
        Connection con = null;
        CallableStatement cstmt = null;
        String driver = "com.ibm.db2.jcc.DB2Driver";
        String url = "jdbc:db2:"
        String userid = null;
        String password = null;

        try {
            Class.forName(driver);
            con = DriverManager.getConnection(url, userid, password);
            cstmt = con.prepareCall("CALL DB2PROCS.GET_MESSAGE(?, ?, ?, ?)"sv);
            cstmt.setXML(1, new String("xml"sv)
            cstmt.setXML(2, new String("xml"sv)
            cstmt.setString(3, "userid"sv)
            cstmt.setString(4, "password"sv)
            cstmt.executeUpdate();

            String xmlOutput = cstmt.getString("xml_output"sv);
            System.out.println("XML Output: "sv + xmlOutput);
        }
        catch (SQLException e) {
            e.printStackTrace();
        }
    }
}
```
String password = null;

// Parse arguments
if (args.length != 3) {
    System.err.println("Usage: GetSystemDriver <alias or //server/database> <userid> <password>");
    System.err.println("Where <alias or //server/database> is DB2 subsystem alias or //server/database for type 4 connectivity");
    System.err.println("<userid> is user ID to connect as");
    System.err.println("<password> is password to connect with");
    return;
}
url += args[0];
userid = args[1];
password = args[2];

try {
    String str_xmlfilter = new String("/plist/dict/key[.=‘Operating System Information’]/following-sibling::dict[1]" +
        "/key[.=‘Name and Release’]/following-sibling::dict[1]" +
        "/key[.=‘Value’]/following-sibling::string[1]");

    // Convert XML_FILTER to byte array to pass as BLOB
    byte[] xml_filter = str_xmlfilter.getBytes("UTF-8");

    // Read XML_INPUT from file
    File fptr = new File("xml_input.xml");
    int file_length = (int)fptr.length();
    byte[] xml_input = new byte[file_length];
    FileInputStream instream = new FileInputStream(fptr);
    int tot_bytes = instream.read(xml_input, 0, xml_input.length);
    if (tot_bytes == -1) {
        System.out.println("Error during file read");
        return;
    }
    instream.close();

    // Load the DB2 Universal JDBC Driver
    Class.forName(driver);

    // Connect to database
    con = DriverManager.getConnection(url, userid, password);
    con.setAutoCommit(false);
    cstmt = con.prepareCall("CALL SYSPROC.GET_SYSTEM_INFO(?,?,?,?,?,?,?)");

    // Major / Minor Version / Requested Locale
    cstmt.setInt(1, 1);
    cstmt.setInt(2, 1);
    cstmt.setString(3, "en_US");

    // Input documents
    cstmt.setObject(4, xml_input, Types.BLOB);
    cstmt.setObject(5, xml_filter, Types.BLOB);

    // OutputParms
    cstmt.registerOutParameter(1, Types.INTEGER);
    cstmt.registerOutParameter(2, Types.INTEGER);
    cstmt.registerOutParameter(6, Types.BLOB);
    cstmt.registerOutParameter(7, Types.BLOB);

    cstmt.execute();
con.commit();

SQLWarning ctstmt_warning = cstmt.getWarnings();
if (ctstmt_warning != null) {
    System.out.println("SQL Warning: " + ctstmt_warning.getMessage());
} else {
    System.out.println("SQL Warning: None\n");
}

System.out.println("Major Version returned " + cstmt.getInt(1));

        try { con.close(); } catch (SQLException sqle)
            { sqle.printStackTrace(); }
}

Related concepts:

GET_SYSTEM_INFO stored procedure

The GET_SYSTEM_INFO stored procedure returns system information about the data server.

This system information includes:
- Operating system information
- Product information
- Db2 MEPL
- SYMMD APPL status
- Workload Manager (WLM) classification rules that apply to Db2 Workload for subsystem types Db2 and DDF

Environment

The load module for the GET_SYSTEM_INFO stored procedure, DSNADMGS, must reside in an APF-authorized library. The GET_SYSTEM_INFO stored procedure runs in a WLM-established stored procedures address space, and all of the libraries that are specified in the STEPLIB DD statement must be APF-authorized. TCB=1 is also required.

Authorization

To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have EXECUTE privilege on the GET_SYSTEM_INFO stored procedure.

In addition, because the GET_SYSTEM_INFO stored procedure queries the SMPCSI data set for the status of the SYMMDs, the authorization ID that is associated with the stored procedure address space where the GET_SYSTEM_INFO stored procedure is running must have at least RACF read authority to the SMPCSI data set.
## Syntax

```sql
CALL GET_SYSTEM_INFO(
  major_version
  minor_version
  requested_locale
  xml_input
  xml_filter
  xml_output
  xml_message
)
```

The schema is SYSPROC.

### Option descriptions

#### `major_version`

An input and output parameter of type INTEGER that indicates the major document version. On input, this parameter indicates the major document version that you support for the XML documents passed as parameters in the stored procedure (`xml_input`, `xml_output`, and `xml_message`). The stored procedure processes all XML documents in the specified version, or returns an error (-20457) if the version is invalid.

On output, this parameter specifies the highest major document version that is supported by the stored procedure. To determine the highest supported document version, specify NULL for this input parameter and all other required parameters. Currently, the highest and the only major document version that is supported is 1.

If the XML document in the `xml_input` parameter specifies a **Document Type Major Version** key, the value for that key must be equal to the value that is provided in the `major_version` parameter, or an error (+20458) is raised.

This parameter is used in conjunction with the `minor_version` parameter. Therefore, you must specify both parameters together. For example, you must specify both as either NULL, or non-NULL.

#### `minor_version`

An input and output parameter of type INTEGER that indicates the minor document version. On input, this parameter specifies the minor document version that you support for the XML documents passed as parameters for this stored procedure (`xml_input`, `xml_output`, and `xml_message`). The stored procedure processes all XML documents in the specified version, or returns an error (-20457) if the version is invalid.

On output, this parameter indicates the highest minor document version that is supported for the highest supported major version. To determine the highest supported document version, specify NULL for this input parameter and all other required parameters. The highest minor document version that is supported is 1. Minor document version 0 (zero) is also supported.

If the XML document in the `xml_input` parameter specifies a **Document Type Minor Version** key, the value for that key must be equal to the value that is provided in the `minor_version` parameter, or an error (+20458) is raised.

This parameter is used in conjunction with the `major_version` parameter. Therefore, you must specify both parameters together. For example, you must specify both as either NULL, or non-NULL.

#### `requested_locale`

An input parameter of type VARCHAR(33) that specifies a locale. If the
specified language is supported on the server, translated content is returned in the xml_output and xml_message parameters. Otherwise, content is returned in the default language. Only the language and possibly the territory information is used from the locale. The locale is not used to format numbers or influence the document encoding. For example, key names are not translated. The only translated portion of the XML output and XML message documents are Display Name, Display Unit, and Hint. The value might be globalized where applicable. You should always compare the requested language to the language that is used in the XML output document (see the Document Locale entry in the XML output document).

Currently, the supported values for requested_locale are en_US and NULL. If you specify a null value, the result is the same as specifying en_US.

xml_input
An input parameter of type BLOB(2G) that specifies an XML input document of type Data Server System Input in UTF-8 that contains input values for the stored procedure.

This XML input document is optional. If the XML input document is not passed to the stored procedure, the stored procedure returns the following information by default:

- Operating system information
- Product information
- Db2 MEPL
- Workload Manager (WLM) classification rules for Db2 Workload

This stored procedure supports two types of XML input documents, Version 1.0 or Version 1.1.

For Version 1.0, the general structure of an XML input document is as follows:

```xml
<?xml version="1.0" encoding="UTF-8"?>
<plist version="1.0">
  <dict>
    <key>Document Type Name</key><string>Data Server System Input</string>
    <key>Document Type Major Version</key><integer>1</integer>
    <key>Document Type Minor Version</key><integer>0</integer>
    <key>Document Locale</key><string>en_US</string>
    <key>Complete</key><false/>
    <key>Optional Parameters</key>
    <dict>
      <key>SMPCSI Data Set</key>
      <dict>
        <key>Value</key><string>SMPCSI data set name</string>
      </dict>
      <key>SYSMOD</key>
      <dict>
        <key>Value</key><array>
          <string>SYSMOD number</string>
          <string>SYSMOD number</string>
        </array>
      </dict>
    </dict>
  </dict>
</plist>
```

For Version 1.1, the general structure of an XML input document is as follows:

```xml
<?xml version="1.0" encoding="UTF-8"?>
<plist version="1.0">
  <dict>
    <key>Document Type Name</key><string>Data Server System Input</string>
  </dict>
</plist>
```
Version 1.0: When a Version 1.0 XML input document is passed to the stored procedure, the stored procedure returns the following information in a Version 1.0 XML output document:

- Operating system information
- Product information
- Db2 MEPL
- SYSMOD status (APPLY status for the SYSMODs that are listed in the XML input document)
- Workload Manager (WLM) classification rules for Db2 Workload

To use Version 1.0 of the XML input document you must specify the major_version parameter as 1 and the minor_version parameter as 0 (zero). You must also specify the Document Type Name key, the SMPCSI data set, and the list of SYSMODs.

For an example of a Version 1.0 XML input document for the GET_SYSTEM_INFO stored procedure, see Example 3 in the Examples section.

Version 1.1: A Version 1.1 XML input document supports the Include parameter, in addition to the SMPCSI Data Set and SYSMOD parameters that are supported by a Version 1.0 XML input document.

You can use the Version 1.1 XML input document in the following ways:

- To specify which items to include in the XML output document by specifying these items in the Include array
- To specify the SMPCSI data set and list of SYSMODs so that the stored procedure returns their APPLY status
To use Version 1.1 of the XML input document, you must specify the *major_version* parameter as 1 and the *minor_version* parameter as 1. You must also specify the Document Type Name key, and at least one of the following parameters:

- **Include**
- **SMPCSI Data Set** and **SYSMOD**

If you pass a Version 1.1 XML input document to the stored procedure and specify the **Include**, **SMPCSI Data Set**, and **SYSMOD** parameters, the stored procedure will return the items that you specified in the **Include** array, and the SYSMOD status of the SYSMODs that you specified in the **SYSMOD** array.

If you pass a Version 1.1 XML input document to the stored procedure and specify the **Include** parameter only, the stored procedure will return only the items that you specified in the **Include** array.

If you pass a Version 1.1 XML input document to the stored procedure and specify only the **SMPCSI Data Set** and **SYSMOD** parameters, the stored procedure returns the following information in a Version 1.1 XML output document:

- Operating system information
- Product information
- Db2 MEPL
- SYSMOD status (APPLY status for the SYSMODs that are listed in the XML input document)
- Workload Manager (WLM) classification rules for Db2 Workload

For an example of a complete Version 1.1 XML input document for the **GET_SYSTEM_INFO** stored procedure, see [Example 4](#).

**Complete mode:** For examples of Version 1.0 and Version 1.1 XML input documents that are returned by the **xml_output** parameter when the stored procedure is running in Complete mode, see [Example 1](#) and [Example 2](#) respectively.

**xml_filter**

An input parameter of type BLOB(4K) in UTF-8 that specifies a valid XPath query string. Use a filter when you want to retrieve a single value from an XML output document. For more information, see [XPath expressions for filtering output (Db2 Administration Guide)](#).

The following example selects the value for the Data Server Product Version from the XML output document:

```
/plist/dict/key[.='Data Server Product Version']/following-sibling::string[1]
```

If the key is not followed by the specified sibling, an error is returned.

**xml_output**

An output parameter of type BLOB(2G) that returns a complete XML output document of type Data Server System Output in UTF-8. If a filter is specified, this parameter returns a string value. If the stored procedure is unable to return a complete output document (for example, if a processing error occurs that results in an SQL warning or error), this parameter is set to NULL.

The **xml_output** parameter can return either a Version 1.0 or Version 1.1 XML output document depending on the *major_version* and *minor_version* parameters that you specify. For more information about the content differences between the Version 1.0 and Version 1.1 XML output documents, see the option description for the **xml_input** parameter.
A complete XML output document provides the following system information:

- Operating system information
- Product information
- Db2 MEPL
- The APPLY status of SYSMODs
- Workload Manager (WLM) classification rules for Db2 Workload for subsystem types Db2 and DDF

For an example of an XML output document, see Example 5.

**xml_message**

An output parameter of type BLOB(64K) that returns a complete XML output document of type Data Server Message in UTF-8 that provides detailed information about a SQL warning condition. This document is returned when a call to the stored procedure results in a SQL warning, and the warning message indicates that additional information is returned in the XML message output document. If the warning message does not indicate that additional information is returned, then this parameter is set to NULL.

The xml_message parameter can return either a Version 1.0 or Version 1.1 XML message document, depending on the major_version and minor_version parameters that you specify. The format of a Version 1.0 or Version 1.1 XML message document is similar. For an example of an XML message document, see Example 6.

**Examples**

**Example 1:** The following example shows a Version 1.0 XML input document that is returned by the xml_output parameter when the stored procedure is running in Complete mode.

```xml
<?xml version="1.0" encoding="UTF-8" ?>
<plist version="1.0">
<dict>
  <key>Document Type Name</key><string>Data Server System Input</string>
  <key>Document Type Major Version</key><integer>1</integer>
  <key>Document Type Minor Version</key><integer>0</integer>
  <key>Document Locale</key><string>en_US</string>
  <key>Optional Parameters</key>
  <dict>
    <key>Display Name</key><string>Optional Parameters</string>
    <key>SMPCSI Data Set</key>
    <dict>
      <key>Display Name</key><string>SMPCSI Data Set</string>
      <key>Value</key><string />
      <key>Hint</key><string />
    </dict>
  </dict>
  <key>SYSMOD</key>
  <dict>
    <key>Display Name</key><string>SYSMOD</string>
    <key>Value</key><string />
    <array>
      <string />
    </array>
    <key>Hint</key><string />
  </dict>
  <key>Hint</key><string />
</dict>
</plist>
```
Example 2: The following example shows a Version 1.1 XML input document that is returned by the xml_output parameter when the stored procedure is running in Complete mode.

```xml
<?xml version="1.0" encoding="UTF-8" ?>
<plist version="1.0">
  <dict>
    <key>Document Type Name</key><string>Data Server System Input</string>
    <key>Document Type Major Version</key><integer>1</integer>
    <key>Document Type Minor Version</key><integer>1</integer>
    <key>Document Locale</key><string>en_US</string>
    <key>Optional Parameters</key>
      <dict>
        <key>Display Name</key><string>Optional Parameters</string>
        <key>Value</key>
          <array>
            <string>Operating System Information</string>
            <string>Product Information</string>
            <string>DB2 MEPL</string>
            <string>Workload Manager (WLM) Classification Rules for DB2 Workload</string>
          </array>
        <key>Hint</key><string />
      </dict>
      <key>SMPCSI Data Set</key>
        <dict>
          <key>Display Name</key><string>SMPCSI Data Set</string>
          <key>Hint</key><string />
        </dict>
      <key>SYSMOD</key>
        <dict>
          <key>Display Name</key><string>SYSMOD</string>
          <key>Value</key>
            <array>
              <string>1010</string>
            </array>
          <key>Hint</key><string />
        </dict>
    <key>Hint</key><string />
  </dict>
</plist>
```

Example 3: The following example shows a complete sample of a Version 1.0 XML input document for the GET_SYSTEM_INFO stored procedure.

```xml
<?xml version="1.0" encoding="UTF-8" ?>
<plist version="1.0">
  <dict>
    <key>Document Type Name</key><string>Data Server System Input</string>
    <key>Document Type Major Version</key><integer>1</integer>
    <key>Document Type Minor Version</key><integer>0</integer>
    <key>Document Locale</key><string>en_US</string>
    <key>Optional Parameters</key>
      <dict>
        <key>SMPCSI Data Set</key>
          <dict>
            <key>Value</key><string>IXM180.GLOBAL.CSI</string>
          </dict>
        <key>SYSMOD</key>
          <dict>
            <key>Value</key>
```

1010  SQL Reference
You must specify the SMPCSI data set and one or more SYSMODs. SYSMOD status information will be returned for only the SYSMODs that are listed in the Optional Parameters section, provided that the SMPCSI data set that you specify is valid.

Example 4: The following example shows a complete sample of a Version 1.1 XML input document for the GET_SYSTEM_INFO stored procedure.

```xml
<?xml version="1.0" encoding="UTF-8"?>
<plist version="1.0">
  <dict>
    <key>Document Type Name</key><string>Data Server System Input</string>
    <key>Document Type Major Version</key><integer>1</integer>
    <key>Document Type Minor Version</key><integer>1</integer>
    <key>Document Locale</key><string>en_US</string>
    <key>Optional Parameters</key>
    <dict>
      <key>Include</key>
      <dict>
        <key>Value</key><array>
          <string>Operating System Information</string>
          <string>Product Information</string>
          <string>DB2 MEPL</string>
          <string>Workload Manager (WLM) Classification Rules for DB2 Workload</string>
        </array>
      </dict>
      <key>SMPCSI Data Set</key>
      <dict>
        <key>Value</key><string>IXM180.GLOBAL.CSI</string>
      </dict>
      <key>SYSMOD</key>
      <dict>
        <key>Value</key><array>
          <string>UK24596</string>
          <string>UK24709</string>
        </array>
      </dict>
    </dict>
  </dict>
</plist>
```

Example 5: The following example shows a fragment of an XML output document for the GET_SYSTEM_INFO stored procedure. In this example, the ellipsis (...) represent a dictionary entry that is comprised of Display Name, Value, and Hint, such as:

```xml
<dict>
  <key>Display Name</key><string>Name</string>
  <key>Value</key><string>JES2</string>
  <key>Hint</key><string />
</dict>
```
<key>Display Name</key><string>Product Information</string>
<key>Primary Job Entry Subsystem</key>

        </dict>
    </dict>
  <key>Hint</key><string />
</dict>
</plist>

Example 6: The following example shows a sample XML message document for the GET_SYSTEM_INFO stored procedure. Similar to an XML output document, the details about an SQL warning condition will be encapsulated in a dictionary entry, which is comprised of Display Name, Value, and Hint.

<?xml version="1.0" encoding="UTF-8" ?>
<plist version="1.0">
  <key>Document Type Name</key><string>Data Server Message</string>
  <key>Document Type Major Version</key><integer>1</integer>
  <key>Document Type Minor Version</key><integer>1</integer>
Example 7: This example shows a simple and static Java program that calls the GET_SYSTEM_INFO stored procedure with an XML input document and an XPath that queries the value of the operating system name and release.

The XML input document is initially saved as a file called xml_input.xml that is in the same directory where the GetSystemDriver class resides. This sample program uses the following xml_input.xml file:

```xml
<?xml version="1.0" encoding="UTF-8" ?>
<plist version="1.0">
  <dict>
    <key>Document Type Name</key>
    <string>Data Server System Input</string>
    <key>Document Type Major Version</key>
    <integer>1</integer>
    <key>Document Type Minor Version</key>
    <integer>1</integer>
    <key>Document Locale</key>
    <string>en_US</string>
    <key>Optional Parameters</key>
    <dict>
      <key>Include</key>
      <dict>
        <key>Value</key>
        <array>
          <string>Operating System Information</string>
        </array>
      </dict>
    </dict>
  </dict>
</plist>
```

The XPath is statically created as a string object by the program and then converted to a BLOB to serve as input for the xml_filter parameter. After the stored procedure is called, the xml_output parameter contains only a single string and no XML document. This output is materialized as a file called xml_output.xml that is in the same directory where the GetSystemDriver class resides.

Sample invocation of the GET_SYSTEM_INFO stored procedure with a valid XML input document and a valid XPath:

```sql
//************************************************************
// Licensed Materials - Property of IBM
// 5635-DB2
```
import java.io.*;
import java.sql.*;

public class GetSystemDriver {

    public static void main(String[] args) {
        Connection con = null;
        CallableStatement cstmt = null;
        String driver = "com.ibm.db2.jcc.DB2Driver";
        String url = "jdbc:db2:"
        String userid = null;
        String password = null;

        // Parse arguments
        if (args.length != 3) {
            System.err.println("Usage: GetSystemDriver <alias or //server/database> <userid> <password>");
            System.err.println("where <alias or //server/database> is DB2 subsystem alias or //server/database for type 4 connectivity");
            System.err.println("<userid> is user ID to connect as");
            System.err.println("<password> is password to connect with");
            return;
        }
        url += args[0];
        userid = args[1];
        password = args[2];

        try {
            String str_xmlfilter = new String("/plist/dict/key[.='Operating System Information']/following-sibling::
dict[1]" +
            "/key[.='Name and Release']/following-sibling::dict[1]" +
            "/key[.='Value']/following-sibling::string[1]");

            // Convert XML_FILTER to byte array to pass as BLOB
            byte[] xml_filter = str_xmlfilter.getBytes("UTF-8");

            // Read XML_INPUT from file
            File fptr = new File("xml_input.xml");
            int file_length = (int)fptr.length();
            byte[] xml_input = new byte[file_length];

            FileInputStream instream = new FileInputStream(fptr);
            int tot_bytes = instream.read(xml_input, 0, xml_input.length);
if (tot_bytes == -1) {
    System.out.println("Error during file read");
    return;
}
instream.close();

// Load the DB2 Universal JDBC Driver
Class.forName(driver);

// Connect to database
con = DriverManager.getConnection(url, userid, password);
con.setAutoCommit(false);

cstmt = con.prepareCall("CALL SYSPROC.GET_SYSTEM_INFO(?,?,?,?,?,?,?)");

// Major / Minor Version / Requested Locale
    cstmt.setInt(1, 1);
    cstmt.setInt(2, 1);
    cstmt.setString(3, "en_US");

// Input documents
    cstmt.setObject(4, xml_input, Types.BLOB);
    cstmt.setObject(5, xml_filter, Types.BLOB);

// OutputParms
    cstmt.registerOutParameter(1, Types.INTEGER);
    cstmt.registerOutParameter(2, Types.INTEGER);
    cstmt.registerOutParameter(6, Types.BLOB);
    cstmt.registerOutParameter(7, Types.BLOB);

cstmt.execute();
con.commit();

SQLWarning ctstmt_warning = cstmt.getWarnings();
if (ctstmt_warning != null) {
    System.out.println("SQL Warning: " + ctstmt_warning.getMessage());
}
else {
    System.out.println("SQL Warning: None\n");
}

System.out.println("Major Version returned " + cstmt.getInt(1) );
System.out.println("Minor Version returned " + cstmt.getInt(2) );

// Get output BLOBs
Blob b_out = cstmt.getBlob(6);

if(b_out != null)
{
    int out_length = (int)b_out.length();
    byte[] bxml_output = new byte[out_length];

    // Open an inputstream on BLOB data
    InputStream instr_out = b_out.getBinaryStream();

    // Copy from inputstream into byte array
    int out_len = instr_out.read(bxml_output, 0, out_length);

    // Write byte array content into FileOutputStream
    FileOutputStream fxml_out = new FileOutputStream("xml_output.xml");
    fxml_out.write(bxml_output, 0, out_length);

    //Close streams
    instr_out.close();
    fxml_out.close();
}
Blob b_msg = cstmt.getBlob(7);

if(b_msg != null)
{
    int msg_length = (int)b_msg.length();
    byte[] bxml_message = new byte[msg_length];

    // Open an inputstream on BLOB data
    InputStream instr_msg = b_msg.getBinaryStream();

    // Copy from inputstream into byte array
    int msg_len = instr_msg.read(bxml_message, 0, msg_length);

    // Write byte array content into FileOutputStream
    FileOutputStream fxml_msg = new FileOutputStream(new File("xml_message.xml"));
    fxml_msg.write(bxml_message, 0, msg_length);

    // Close streams
    instr_msg.close();
    fxml_msg.close();
}

} catch (SQLException sqle) {
    System.out.println("Error during CALL "
            + " SQLSTATE = " + sqle.getSQLState()
            + " SQLCODE = " + sqle.getErrorCode()
            + " : " + sqle.getMessage());
}

catch (Exception e) {
    System.out.println("Internal Error " + e.toString());
}

finally
{
    if(cstmt != null) try { cstmt.close(); } catch (SQLException sqle) {
        sqle.printStackTrace(); }
    if(con != null) try { con.close(); } catch (SQLException sqle) {
        sqle.printStackTrace(); }
}

**SET_MAINT_MODE_RECORD_NO_TEMPORALHISTORY stored procedure**

The SYSPROC.SET_MAINT_MODE_RECORD_NO_TEMPORALHISTORY stored procedure indicates that Db2 is to disable recording of temporal history for a system-period temporal table and allow an application to specify values for row-begin, row-end, and transaction-start-ID columns on subsequent operations.
Db2 continues to generate new values for row-begin, row-end, and transaction-start-ID columns that are not explicitly specified as the target of an assignment clause for a data change statement.

This procedure is not intended for general use. It is intended to be used by products that enable Db2 replication.

**Note:** The SYSPROC.SET_MAINT_MODE_RECORD_NO_TEMPORALHISTORY stored procedure is deprecated at V12R1M503. The procedure will continue to work if you run with APPLCOMPAT set to V12R1M502 or lower, as long as V12R1M502 is supported. The functionality provided by the procedure has been subsumed by the new SYSIBMADM.REPLICATION_OVERRIDEBuilt-in global variable.

### Environment

SET_MAINT_MODE_RECORD_NO_TEMPORALHISTORY must run in a WLM-established stored procedure address space.

### Authorization

To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges:

- The EXECUTE privilege on the
  SYSPROC.SET_MAINT_MODE_RECORD_NO_TEMPORALHISTORY stored procedure
- Ownership of the stored procedure
- SYSADM authority

### Syntax

The following syntax diagram shows the SQL CALL statement for invoking this stored procedure:

```sql
CALL SYSPROC.SET_MAINT_MODE_RECORD_NO_TEMPORALHISTORY();
```

### Description

The procedure has no parameters.

The result of the procedure is that recording of temporal history for a system-period temporal table is disabled, and an application is allowed to specify values for row-begin, row-end, and transaction-start-ID columns.
SET_PLAN_HINT stored procedure

The SET_PLAN_HINT stored procedure validates, deploys, modifies, or deletes catalog tables rows that influence access path selection for SQL statements.

The actions that are taken when you call the SET_PLAN_HINT stored procedure depend on a mode value and the type of hint that you specify. You can specify the following modes: CREATE, DELETE, MODIFY or VALIDATE.

Environment

The SET_PLAN_HINT stored procedure runs in a WLM-established stored procedures address space.

The following staging tables, and related objects, which are created by job DSNTIJRT, must exist for use by the SET_PLAN_HINT stored procedure:
- DSN8BQRY.PLAN_TABLE
- DSN8BQRY.DSN_USER_QUERY_TABLE
- DSN8BQRY.DSN_PREDICAT_TABLE
- DSN8BQRY.DSN_PREDICATE_SELECTIVITY

Authorization

To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have EXECUTE privilege on the SET_PLAN_HINT stored procedure.

Syntax

```
CALL SET_PLAN_HINT(
  major_version, minor_version,
  requested_locale,
  xml_input, xml_filter, xml_output, xml_message)
```

The schema is SYSPROC.

Option descriptions

**major_version**

An input and output parameter of type INTEGER that indicates the major document version. On input, this parameter indicates the major document version that you support for the XML documents that are passed as parameters in the stored procedure (xml_input, xml_output, and xml_message). The stored procedure processes all XML documents in the specified version, or returns an error (-20457) if the version is invalid.

On output, this parameter specifies the highest major document version that is supported by the procedure. To determine the highest supported document version, specify NULL for this input parameter and all other required parameters. The only supported value is 1.
If the XML document in the xml_input parameter specifies the Document Type Major Version key, the value for that key must be equal to the value provided in the major_version parameter, or an error (+20458) is raised.

This parameter is used in conjunction with the minor_version parameter. Therefore, you must specify both parameters together. For example, you must specify both as either NULL, or non-NULL.

minor_version
An input and output parameter of type INTEGER that indicates the minor document version. On input, this parameter specifies the minor document version that you support for the XML documents that are passed as parameters for this stored procedure (xml_input, xml_output, and xml_message). The stored procedure processes all XML documents in the specified version, or returns an error (-20457) if the version is invalid.

On output, this parameter indicates the highest minor document version that is supported for the highest supported major version. To determine the highest supported document version, specify NULL for this input parameter and all other required parameters. The only minor document version that is supported is 0 (zero).

If the XML document in the xml_input parameter specifies the Document Type Minor Version key, the value for that key must be equal to the value provided in the minor_version parameter, or an error (+20458) is raised.

This parameter is used in conjunction with the major_version parameter. Therefore, you must specify both parameters together. For example, you must specify both as either NULL, or non-NULL.

requested_locale
An input parameter of type VARCHAR(33) that specifies a locale. If the specified language is supported on the server, translated content is returned in the xml_output and xml_message parameters. Otherwise, content is returned in the default language. Only the language and possibly the territory information is used from the locale. The locale is not used to format numbers or influence the document encoding. For example, key names are not translated. The only translated portion of XML output and XML message documents are Display Name, Display Unit, and Hint. The value might be globalized where applicable. You should always compare the requested language to the language that is used in the XML output document (see the Document Locale entry in the XML output document).

Currently, the supported values for requested_locale are en_US and NULL. If you specify a null value, the result is the same as specifying en_US.

xml_input
An input parameter of type BLOB(2G) that specifies an XML input document of type Data Server Hint Management Input in UTF-8 that represents the hint customization. The SET_PLAN_HINT stored procedure does not support Complete mode.

The input document has the following format.

<?xml version="1.0" encoding="UTF-8"?>
<plist version="1.0">
<dict>
  <key>Document Type Name</key><string>Data Server Hint Management Input</string>
  <key>Document Type Major Version</key><integer>1</integer>
  <key>Document Type Minor Version</key><integer>0</integer>
  <key>HINT_CUSTOMIZATION</key>
</dict>
In the preceding example, *hint-customization* is an XML fragment that describes the customized hint to be generated, validated, or deleted. The following example shows the overview of the format of the hint customization dictionary:

```
<key>HINT_CUSTOMIZATION</key>
<dict>
  <key>DeploymentParameters</key>
  <dict>
  </dict>
  <key>StatementList</key>
  <array>
    <dict>
      <key>DeploymentParameters</key>
      <dict>
      </dict>
      <key>SQLStatement</key>
      <dict>
      </dict>
      <key>ExistingAccessPlanIdentifier</key>
      <dict>
      </dict>
      <key>StatementLevelRules</key>
      <dict>
      </dict>
      <key>PlanLevelRules</key>
      <dict>
      </dict>
      <key>TableAccessRules</key>
      <array></array>
      <key>JoinSequenceRules</key>
      <array></array>
    </dict>
    <key>PredicateSelectivityInstances</key>
    <array>
      <key>ExistingPredicateSelectivityIdentifier</key>
    </array>
  </array>
</dict>
```

*hint-customization* is a dictionary that contains the following keys:

**DeploymentParameters**

The type of hint, the action for the stored procedure, and the deployment parameters for the hint.

Deployment parameters can also be specified at the statement level, within the "StatementList" on page 1032 array. Statement-level deployment parameters override the global deployment parameters for a particular statement.

The DeploymentParameters dictionary can contain the following keys:

**MODE**

The MODE value is required. It specifies the hint processing mode and controls the actions taken by the SET_PLAN_HINT stored procedure:
**CREATE** Generates a hint in the deployment table. The following table describes the specific actions and required input parameters for different types of hints:

<table>
<thead>
<tr>
<th>Hint type</th>
<th>Action</th>
<th>Required Input Parameters</th>
</tr>
</thead>
</table>
| PLAN_TABLE access path hints | 1. A check is completed to ensure that the deployment PLAN_TABLE does not contain an existing hint that has matching values for the following parameters that are specified in the DeploymentParameters dictionary:  
  - QUERYNO  
  - APPLNAME  
  - PROGNAME  
  - COLLID  
  - VERSION  
  - OPTHINT  
  - BIND_TIME  
  2. An existing access path is copied from the source PLAN_TABLE to the deployment PLAN_TABLE, and the information specified in the DeploymentParameters, TableAccessRules, and JoinSequenceRules dictionaries are applied to the copied plan.  
  - The existing access path is identified by the parameters specified in the ExistingAccessPathIdentifier dictionary.  
  - The source PLAN_TABLE is `schema-name`.PLAN_TABLE, where `schema-name` is the PLAN_SCHEMA value that is specified in the ExistingAccessPlanIdentifier dictionary.  
  - The deployment PLAN_TABLE is the `schema-name`.PLAN_TABLE, where `schema-name` is the PLAN_SCHEMA value that is specified in the DeploymentParameters dictionary.                                                                 | - DeploymentParameters

    - COLLID  
    - VERSION |
| | 2. If incompatible catalog table rows are not found, the following input tables are populated with values from the DeploymentParameters and PredicateSelectivityInstances dictionaries, and the SYSIBM.SYSQUERYPREDICATE catalog table:  
  • DSN8QRY.DSN_USER_QUERY_TABLE  
  • DSN8QRY.DSN_PREDICATE_SELECTIVITY  
  • DSN8QRY.DSN_PREDICATE_TABLE | | |
| | If compatible rows that have the same scope are found, the values of these rows are also copied to the input tables. |
| | 3. The following BIND QUERY command is issued to create temporary rows in the catalog tables:  
  BIND QUERY  
  EXPLAININPUTSCHEMA('DSN8QRY') | • SQLStatement:  
  - SQLTEXT |
| | 4. EXPLAIN information is captured for the resulting access path. The copied access path and the EXPLAIN output are kept or deleted based on the SQLCODE value that is returned for the EXPLAIN operation.  
  If the SQLCODE +000 is returned by the explain operation, the value of the PLAN_TABLE.HINT_USED column is checked. If the value is 'SYSQUERYSEL n', the EXPLAIN records are kept.  
  The generated EXPLAIN records are identified by the QUERYSNO and EXPLAIN_TIME values that are specified by in the ExistingPredicateSelectivityIdentifier dictionary. | • PredicateSelectivityInstances:  
  - QBLOCKNO  
  - Predicates:  
    - PREDNO  
    - SelectivityInstances:  
      • INSTANCE  
      • SELECTIVITY (required only if SELECTIVITY_ACTION is 'UPDATE')  
      • WEIGHT (required only if SELECTIVITY_ACTION is 'UPDATE') |
| | 5. A FREE QUERY command is issued to remove the selectivity overrides from the catalog tables. |

Notes:

1. In VALIDATE processing for static statements and dynamic statements that are bound with the DYNAMICRULES(BIND) option, the COLLID, PROGNAME, and VERSION values for the package that contains the SET_PLAN_HINT stored procedure are used for the BIND QUERY operation. Therefore, the SQL processing options of DSNADM.DSNADMHS are used. Differences between the SQL processing options
of the specified package and DSNADMHS might cause the BIND QUERY command to fail. When that happens, the validate operation fails. Option differences that might cause such failures include decimal point representation and others.

Related information:

Options affecting SQL
Decimal point representation

Notes:

1. If the SET_PLAN_HINT stored procedure is called to create, modify, or delete statement-level optimization parameters (HINT_TYPE=INSTANCE-LEVEL and INSTANCE_LEVEL_HINT_TYPE=OPTIMIZATION-PARAMETERS), any existing predicate selectivity overrides for the same statement are removed.

**HINT_TYPE**
The type of access path hint:

**TRADITIONAL**
PLAN_TABLE access path hints. This value is used by default.

**INSTANCE-LEVEL**
Statement-level hints, including:

- Access paths.
- Optimization parameters.
- Predicate selectivity overrides.

**HINT_SCOPE**
The scope of the statement-level hint:

**SYSTEM-LEVEL**
The hint applies at the system level. This value is used by default.

**PACKAGE-LEVEL**
The hint applies at the package level.

**INSTANCE_LEVEL_HINT_TYPE**
The action specified by statement-level rows:

**ACCESS-PATH**
Statement-level access paths. This value is used by default.

**OPTIMIZATION-PARAMETERS**
Statement-level optimization parameters.

**SELECTIVITY-OVERRIDE**
Statement-level predicate selectivity overrides.

Keys that correspond to the following PLAN_TABLE columns:

- **OPTHINT**
- **PROGNAME**
- **APPLNAME**
- **VERSION**
- **COLLID**
For the meanings and accepted values for these keys, see: PLAN_TABLE (Db2 Performance)

PLAN_SCHEMA
The schema of the deployment PLAN_TABLE.

The following example shows the format of the DeploymentParameters dictionary for a PLAN_TABLE access path hint:

```xml
<key>DeploymentParameters</key>
<dict>
  <key>MODE</key>
  <string>CREATE</string>
  <key>HINT_TYPE</key>
  <string>TRADITIONAL</string>
  <key>HINT_SCOPE</key>
  <string>PACKAGE-LEVEL</string>
  <key>APPLNAME</key>
  <string></string>
  <key>PROGNAME</key>
  <string>DSNTIAD</string>
  <key>COLLID</key>
  <string>DSNTIAB1</string>
  <key>VERSION</key>
  <string></string>
  <key>QUERYNO</key>
  <string>200</string>
  <key>PLAN_SCHEMA</key>
  <string>ADMF002</string>
  <key>OPTHINT</key>
  <string>HINT001</string>
</dict>
```

The following example shows the format of the DeploymentParameters dictionary for a statement-level predicate selectivity override:

```xml
<key>DeploymentParameters</key>
<dict>
  <key>MODE</key>
  <string>CREATE</string>
  <key>HINT_TYPE</key>
  <string>INSTANCE-LEVEL</string>
  <key>INSTANCE_LEVEL_HINT_TYPE</key>
  <string>SELECTIVITY-OVERRIDE</string>
  <key>HINT_SCOPE</key>
  <string>PACKAGE-LEVEL</string>
  <key>PROGNAME</key>
  <string>DSNTIAD</string>
  <key>COLLID</key>
  <string>DSNTIAB1</string>
  <key>VERSION</key>
  <string></string>
</dict>
```

StatementList
A list of SQL statements and the hint definition that is associated with each. Only one SQL statement is supported. Additional SQL statements are ignored. The following example shows the format of the StatementList array:

```xml
<key>StatementList</key>
<array>
  <dict>
```

1032 SQL Reference
DeploymentParameters
Deployment parameters can be specified globally, or specified at the statement level. Statement-level deployment parameters override the global parameters for a particular statement. For a description of the DeploymentParameter dictionary, see "DeploymentParameters" on page 1022.

SQLStatement
The statement text and the default schema for resolving unqualified table names in the statement.

The SQLStatement dictionary can contain the following keys:

SQLText
The text of the SQL statement.

SCHEMA
The default schema for resolving unqualified table names in the statement.

The following example shows the format of the SQLStatement dictionary:

```
<key>SQLStatement</key>
<dict>
  <key>SCHEMA</key>
  <string>USER001</string>
  <key>SQLText</key>
  <string>
    SELECT s_name,
    count(*) as numwait
    FROM supplier,
    lineitem l1,
    order,
    nation
    WHERE s_suppkey = l1.l_suppkey
    AND o_orderkey = l1.l_orderkey
    AND o_orderstatus = 'F'
  </string>
</dict>
```
AND l1.l_receiptdate > l1.l_commitdate
AND EXISTS(
    SELECT *
    FROM lineitem l2
    WHERE l2.l_orderkey = l1.l_orderkey
    AND l2.l_suppkey <> l1.l_suppkey
)
AND NOT EXISTS ( 
    SELECT *
    FROM lineitem l3
    WHERE l3.l_orderkey = l1.l_orderkey
    AND l3.l_suppkey <> l1.l_suppkey
    AND l3.l_receiptdate > l3.l_commitdate
)
AND s_nationkey = n_nationkey
AND n_name = 'USA'
GROUP BY s_name
ORDER BY numwait desc, s_name
</string>
</dict>

**ExistingAccessPlanIdentifier**

A list of parameters that identify an access path in a PLAN_TABLE. ExistingAccessPlanIdentifier applies only for hints that specify access paths.

The ExistingAccessPlanIdentifier dictionary can contain the following keys:

**Keys that correspond to the following PLAN_TABLE columns**

- OPTHINT
- PROGNAME
- APPLNAME
- VERSION
- COLLID
- QUERYNO
- BIND_TIME

For the meanings and accepted values for these keys, see: [PLAN_TABLE (Db2 Performance)](#).

**PLAN_SCHEMA**

The schema of the PLAN_TABLE that contains the original access path.

The following example shows the format of the ExistingAccessPlanIdentifier dictionary:

```
<key>ExistingAccessPlanIdentifier</key>
<dict>
<key>APPLNAME</key>
<string></string>
<key>PROGNAME</key>
<string>DSNADMXX</string>
<key>COLLID</key>
<string>DSNADM</string>
<key>VERSION</key>
<string>*</string>
<key>QUERYNO</key>
<string>200</string>
<key>PLAN_SCHEMA</key>
<string>ADMF002</string>
<key>OPTHINT</key>
```
<string>HINT001</string>
<key>BIND_TIME</key>
<string>2012-11-05-07.10.41.700000</string>
</dict>

StatementLevelRules
A list of parameters that identify optimization parameter hint properties. StatementLevelRules applies only to hints for optimization parameters.

The StatementLevelRules dictionary can contain the following keys:

Keys that correspond to the following DSN_USERQUERY_TABLE columns:

- **REOPT**
- **STARJOIN**
- **MAX_PAR_DEGREE**
- **DEGREE** (for the DEF_CURR_DEGREE column)
- **SJTABLES**

For meanings and accepted values for these keys, see the column descriptions in DSN_USERQUERY_TABLE (Db2 Performance).

The following example shows the format of the StatementLevelRules dictionary:

<key>StatementLevelRules</key>
<dict>
  <key>REOPT</key>
  <dict>
    <key>VALUE</key>
    <string>1</string>
  </dict>
  <key>STARJOIN</key>
  <dict>
    <key>VALUE</key>
    <string>N</string>
  </dict>
  <key>MAX_PAR_DEGREE</key>
  <dict>
    <key>VALUE</key>
    <string>2</string>
  </dict>
  <key>DEGREE</key>
  <dict>
    <key>VALUE</key>
    <string>ONE</string>
  </dict>
  <key>SJTABLES</key>
  <dict>
    <key>VALUE</key>
    <string>2</string>
  </dict>
</dict>

PlanLevelRules
A list of parameters that describe the customized access path that is specified by the hint, including separate arrays for table access and join sequence information. PlanLevelRules applies only to hints that specify access paths. The following example shows the format of this PlanLevelRules dictionary:  

Chapter 5. Procedures that are supplied with Db2
TableAccessRules
A list of rules that are related to table access and that describe data access methods, such as table space scans and index scans, for example.

Each table access rule is represented by a TableReferenceIdentifier and its corresponding Settings.

TableReferenceIdentifier
A list of properties that identify the table reference. The properties correspond to PLAN_TABLE columns:

- QBLOCKNO
- TABNO
- TABLE_CREATOR (for the CREATOR column)
- TABLE_NAME (for the TNAME column)
- CORRELATION_NAME

For the meanings and accepted values for these properties, see: PLAN_TABLE (Db2 Performance)

Settings
A list of access properties. The properties correspond to PLAN_TABLE columns:

- ACCESS_TYPE (for the ACCESSTYPE column)
- ACCESS_CREATOR (for the ACCESCREATOR column)
- ACCESS_NAME (for the ACCESSNAME column)
- PREFETCH
- PAGE_RANGE
- SORTN_JOIN
- SORTC_JOIN
- PARALLELISM_MODE
- ACCESS_DEGREE
- JOIN_DEGREE
- ACCESS_PGROUP_ID
- JOIN_PGROUP_ID
- PRIMARY_ACCESSSTYPE
- METHOD

For the meanings and accepted values for these properties, see: PLAN_TABLE (Db2 Performance)

The following example shows the format of this TableAccessRules array:

<key>TableAccessRules</key>
<array>
 <dict>
  <key>TableReferenceIdentifier</key>
  <array>
  <key>JoinSequenceRules</key>
  <array>
</array>
JoinSequenceRules
A list of join sequence customization rules. Each join sequence rule is represented by the Settings and Roots (root nodes) for the join sequence. The join sequence rules correspond to the join sequence and join methods, such as merge join and hybrid join, for example.

Settings
A property for the join sequence rule that correspond to the PLAN_TABLE column of the same name: QBLOCKNO

Roots
A list of root nodes in the join sequence, where each root node is identified by the node type. Depending on the node type, a TABLE_REFERENCE_NODE holds the properties to identify the table reference, while an OPERATOR_NODE holds the properties of the operator.

TYPE
The node type:
• TABLE_REFERENCE_NODE
• OPERATOR_NODE

TableReferenceIdentifier
A list of properties to identify the table reference if node type is TABLE_REFERENCE_NODE. These properties correspond to PLAN_TABLE columns:
• QBLOCKNO
• TABNO
• TABLE_CREATOR (for the CREATOR column)
• TABLE_NAME (for the TNAME column)
• CORRELATION_NAME

For the meanings and accepted values for these properties, see: [PLAN_TABLE (Db2 Performance)]

Settings
A list of properties of this operator if node type is OPERATOR_NODE. These properties correspond to PLAN_TABLE columns:
• JOIN_METHOD (for the METHOD column)
• SORTN_JOIN
- SORTC_JOIN
- JOIN_DEGREE
- JOIN_PGROUP_ID

For the meanings and accepted values for these properties, see: PLAN_TABLE (Db2 Performance)

Left
A description of a left-side child node. The data structure is similar to the root node.

Right
A description of a right-side child node. The data structure is similar to the root node.

The following example shows the format of this JoinSequence array:

```xml
<key>JoinSequenceRules</key>
<array>
  <dict>
    <key>Settings</key>
    <array>
      <dict>
        <key>NAME</key>
        <string>QBLOCKNO</string>
        <key>VALUE</key>
        <string>1</string>
      </dict>
    </array>
    <key>Roots</key>
    <array>
      <dict>
        <key>TYPE</key>
        <string>OPERATOR_NODE</string>
        <key>Settings</key>
        <array>
          <dict>
            <key>NAME</key>
            <string>JOIN_METHOD</string>
            <key>VALUE</key>
            <string>NLJOIN</string>
          </dict>
        </array>
        <key>Left</key>
        <dict>
          <key>TYPE</key>
          <string>OPERATOR_NODE</string>
          <key>Settings</key>
          <array>
            <dict>
              <key>NAME</key>
              <string>JOIN_METHOD</string>
              <key>VALUE</key>
              <string>SMJOIN</string>
            </dict>
          </array>
        </key>
      </dict>
    </array>
  </dict>
</array>
```
Chapter 5. Procedures that are supplied with Db2
PredicateSelectivityInstances
A list of predicates and their selectivity instances. 
PredicateSelectivityInstances applies only to hints that specify selectivity overrides.

QBLOCKNO
The identifier of the query block that contains the predicate.

Predicates

SELECTIVITY_ACTION
The processing mode for the selectivity instance. One of the following values:

- UPDATE (valid when MODE is CREATE, MODIFY, or VALIDATE.) This is the default value.
- DELETE (valid when MODE is MODIFY, or VALIDATE for an existing hint.)

INSTANCE
The identifier of the selectivity instance. A positive integer greater than or equal to 1.

SELECTIVITY
Percentage of rows in the table that satisfy the predicate as a value 0 - 1. This value is mandatory when SELECTIVITY_ACTION='UPDATE'.

WEIGHT
Percentage of executions in which the selectivity instance applies, as a value 0 - 1. This value is mandatory when SELECTIVITY_ACTION='UPDATE'.

The following example shows the format of the PredicateSelectivityInstances array:

```
<key>PredicateSelectivityInstances</key>
<array>
  <dict>
    <key>QBLOCKNO</key><string>1</string>
    <key>Predicates</key>
    <array>
      <dict>
        <key>PREDNO</key><string>2</string>
        <key>SelectivityInstances</key>
        <array>
          <dict>
            <key>SELECTIVITY_ACTION</key><string>UPDATE</string>
            <key>INSTANCE</key><string>1</string>
            <key>SELECTIVITY</key><string>0.1111</string>
            <key>WEIGHT</key><string>0.11111</string>
          </dict>
          <dict>
            <key>INSTANCE</key><string>2</string>
            <key>SELECTIVITY</key><string>0.1222</string>
            <key>WEIGHT</key><string>0.12222</string>
          </dict>
        </array>
      </dict>
      <dict>
        <key>PREDNO</key><string>3</string>
        <key>SelectivityInstances</key>
        <array>
          <dict>
            <key>INSTANCE</key><string>3</string>
            <key>SELECTIVITY</key><string>0.1333</string>
            <key>WEIGHT</key><string>0.13333</string>
          </dict>
        </array>
      </dict>
    </array>
  </dict>
</array>
```
<key>ExistingPredicateSelectivityIdentifier</key>

Identifies the EXPLAIN tables rows that are copied to input tables for the BIND QUERY operation. ExistingPredicateSelectivityIdentifier applies only to hints that override selectivities.

**PLAN_SCHEMA**

The schema of the following EXPLAIN tables: PLAN_TABLE, DSN_PREDICAT_TABLE, and DSN_PREDICATE_SELECTIVITY tables.

**EXPLAIN_TIME**

The time that the row was inserted by EXPLAIN.

**QUERYNO**

The identifier of the statement.

The following example shows the format of the ExistingPredicateSelectivityIdentifier dictionary:

```xml
<key>ExistingPredicateSelectivityIdentifier</key>
<dict>
  <key>QUERYNO</key><string>100</string>
  <key>EXPLAIN_TIME</key><string>2013-03-20-14.29.55.660000</string>
  <key>PLAN_SCHEMA</key><string>ADMF001</string>
</dict>
```

**xml_filter**

An input parameter of type BLOB(4K). Specifies a valid XPath query string to retrieve a single value from an XML output document.

**xml_output**

An output parameter of type BLOB(2G)

When the mode is VALIDATE for hints other than selectivity overrides,xml_output has the following format:

```xml
<?xml version="1.0" encoding="UTF-8"?>
.plist version="1.0">
<key>Document Type Name</key><string>Data Server Hint Management Output</string>
<key>Document Type Major Version</key><integer>1</integer>
<key>Document Type Minor Version</key><integer>0</integer>
<key>Data Server Product Name</key><string>DSN</string>
<key>Data Server Product Version</key><string>10.1.5</string>
<key>Data Server Major Version</key><integer>10</integer>
<key>Data Server Minor Version</key><integer>1</integer>
<key>Data Server Platform</key><string>z/OS</string>
<key>Document Locale</key><string>en_US</string>
<key>Hint Validation</key>
<dict>
  <key>Display Name</key><string>Hint Validation</string>
  <key>EXPLAIN SQLCODE</key>
</dict>
```
<key>Display Name</key><string>EXPLAIN SQLCODE</string>
<key>Value</key><string>394</string>
</dict>

When the mode is CREATE, MODIFY, or DELETE for PLAN_TABLE access path hints, xml_output has the following format:

```xml
<?xml version="1.0" encoding="UTF-8"?>
<plist version="1.0">
    <dict>
        <key>Document Type Name</key><string>Data Server Hint Management Output</string>
        <key>Document Type Major Version</key><integer>1</integer>
        <key>Document Type Minor Version</key><integer>0</integer>
        <key>Data Server Product Name</key><string>DSN</string>
        <key>Data Server Product Version</key><string>10.1.5</string>
        <key>Data Server Major Version</key><integer>10</integer>
        <key>Data Server Minor Version</key><integer>1</integer>
        <key>Data Server Platform</key><string>z/OS</string>
        <key>Document Locale</key><string>en_US</string>
        <key>Hint Deployment</key>
        <dict>
            <key>Display Name</key><string>Hint Deployment</string>
            <key>SQLCODE</key>
            <dict>
                <key>Display Name</key><string>SQLCODE</string>
                <key>Value</key><string>0</string>
                <key>Hint</key><string/>
            </dict>
            <key>Hint</key><string/>
        </dict>
    </dict>
</plist>
```

When the mode is CREATE or MODIFY for statement-level hints, xml_output has the following format:

```xml
<?xml version="1.0" encoding="UTF-8"?>
<plist version="1.0">
    <dict>
        <key>Document Type Name</key><string>Data Server Hint Management Output</string>
        <key>Document Type Major Version</key><integer>1</integer>
        <key>Document Type Minor Version</key><integer>0</integer>
        <key>Data Server Product Name</key><string>DSN</string>
        <key>Data Server Product Version</key><string>10.1.5</string>
        <key>Data Server Major Version</key><integer>10</integer>
        <key>Data Server Minor Version</key><integer>1</integer>
        <key>Data Server Platform</key><string>z/OS</string>
        <key>Document Locale</key><string>en_US</string>
        <key>Hint Deployment</key>
        <dict>
            <key>Display Name</key><string>Hint Deployment</string>
            <key>Hint</key><string/>
        </dict>
    </dict>
</plist>
```
When the mode is DELETE for statement-level hints, xml_output has the following format. The format is different for statement-level selectivity overrides when preexisting optimization parameters are specified.

```xml
<?xml version="1.0" encoding="UTF-8"?>
<plist version="1.0">
  <dict>
    <key>Document Type Name</key><string>Data Server Hint Management Output</string>
    <key>Document Type Major Version</key><integer>1</integer>
    <key>Document Type Minor Version</key><integer>0</integer>
    <key>Data Server Product Name</key><string>DSN</string>
    <key>Data Server Product Version</key><string>10.1.5</string>
    <key>Data Server Major Version</key><integer>10</integer>
    <key>Data Server Minor Version</key><integer>1</integer>
    <key>Data Server Platform</key><string>z/OS</string>
    <key>Document Locale</key><string,en_US</string>
    <key>Hint Deployment</key>
      <dict>
        <key>Display Name</key><string>Hint Deployment</string>
        <key>FREE QUERY Message</key>
          <dict>
            <key>Display Name</key><string>FREE QUERY Message</string>
            <key>Value</key>
              <string>DSNT280I @ FREE QUERY FOR QUERYID = 6 SUCCESSFUL DSNT290I @ FREE QUERY COMMAND COMPLETED</string>
            <key>Hint</key><string/>
          </dict>
        <key>Hint</key><string/>
      </dict>
    <key>Hint</key><string/>
  </dict>
</plist>
```

When the mode is DELETE for statement-level predicate selectivity overrides and preexisting optimization parameters are specified, xml_output has the following format:

```xml
<?xml version="1.0" encoding="UTF-8"?>
<plist version="1.0">
  <dict>
    <key>Document Type Name</key><string>Data Server Hint Management Output</string>
    <key>Document Type Major Version</key><integer>1</integer>
    <key>Document Type Minor Version</key><integer>0</integer>
    <key>Data Server Product Name</key><string>DSN</string>
    <key>Data Server Product Version</key><string>11.1.5</string>
    <key>Data Server Major Version</key><integer>11</integer>
    <key>Data Server Minor Version</key><integer>1</integer>
  </dict>
</plist>
```
xml_message

An output parameter of type BLOB(2G). The output is an XML document with the following format:

<?xml version="1.0" encoding="UTF-8"?>
<plist version="1.0">
  <key>Document Type Name</key>
  <string>Data Server Message</string>
  <key>Document Type Major Version</key><integer>1</integer>
  <key>Document Type Minor Version</key><integer>0</integer>
  <key>Data Server Product Name</key><string>DSN</string>
  <key>Data Server Product Version</key><string>10.1.5</string>
  <key>Data Server Major Version</key><integer>10</integer>
  <key>Data Server Minor Version</key><integer>1</integer>
  <key>Data Server Platform</key><string>z/OS</string>
  <key>Document Locale</key><string>en_US</string>
  <key>Short Message Text</key>
  <dict>
    <key>Display Name</key><string>Short Message Text</string>
    <key>Value</key>

SQLJ.ALTER_JAVA_PATH stored procedure

SQLJ.ALTER_JAVA_PATH modifies the class resolution path of an installed JAR.

SQLJ.ALTER_JAVA_PATH specifies the class resolution path that the JVM uses when a JAR file that is part of a Java stored procedure references a class that is neither contained in that JAR file, found in the CLASSPATH, nor system-supplied.

SQLJ.ALTER_JAVA_PATH authorization

Privilege set: If the CALL statement is embedded in an application program, the privilege set consists of the privileges that are held by the owner of the plan or package. If the statement is dynamically prepared, the privilege set consists of the privileges that are held by the authorization IDs of the process.

For calling SQLJ.ALTER_JAVA_PATH, the privilege set must include at least one of the following items:

- EXECUTE privilege on SQLJ.ALTER_JAVA_PATH
- Ownership of SQLJ.ALTER_JAVA_PATH
- SYSADM authority

The privilege set must also include the authority to alter a JAR, which consists of at least one of the following items:

- Ownership of the JAR
- ALTERIN privilege on the schema of the JAR
  The authorization ID that matches the schema name implicitly has the ALTERIN privilege on the schema.
- SYSADM or SYSCTRL authority

For referring to JAR jar2 in the Java path, the privilege set must include at least one of the following items:

- Ownership of jar2
• USAGE privilege on jar2
• SYSADM authority

**SQLJ.ALTER_JAVA_PATH syntax**

```
CALL SQLJ.ALTER_JAVA_PATH( JAR-name1, 'path', 'blanks' )
```

**path:**

```
path-element
```

**path-element:**

```
Java-package-name, JAR-name2
```

**Java-package-name:**

```
Java-identifier
```

**class-name:**

```
Java-identifier
```

**SQLJ.ALTER_JAVA_PATH parameters**

**JAR-name1**

A VARCHAR(257) input parameter that contains the Db2 name of the JAR whose path is to be altered, in the form `schema.JAR-id` or `JAR-id`. **JAR-name1** is the name that you use when you refer to the JAR in SQL statements. If you omit `schema`, Db2 uses the SQL authorization ID that is in the CURRENT SCHEMA special register.

**path**

A VARCHAR(2048) input parameter that specifies the class resolution path that the JVM uses when **JAR-name1** references a class that is neither contained in **JAR-name1**, found in the CLASSPATH, nor system-supplied.

During execution of the Java routine, when Db2 encounters an unresolved class reference, Db2 compares each path element in the path to the class reference. If a path element matches the class reference, Db2 searches for the class in the JAR that is specified by the path element.

* Indicates that any class reference can be searched for in the JAR that is
identified by JAR-name2. If an error prevents the class from being found, the search terminates, and a java.lang.ClassNotFoundException is thrown to report that error. If the class is not found in the JAR, the search continues with the next path element.

**Java-package-name.***
Indicates that class references for classes that are in the package named Java-package-name are searched for in the JAR that is identified by JAR-name2. If an error prevents a class from being found, the search terminates, and a java.lang.ClassNotFoundException is thrown to report that error. If a class is not found in the JAR, the search continues with the next path element.

**Java-package-name.class-name or class-name**
Indicates that class references for classes whose fully qualified name matches Java-package-name.class-name or class-name are searched for in the JAR that is identified by JAR-name2. Class references for classes that are in packages within the package named Java-package-name are not searched for in the JAR that is identified by JAR-name2. If an error prevents a class from being found, the search terminates, and a java.lang.ClassNotFoundException is thrown to report that error. If a class is not found in the JAR, the search terminates and a java.lang.NoClassDefFoundError is thrown.

If the class reference is to a class in a different package, the search continues with the next path element.

**JAR-name2**
Specifies the Db2 name of the JAR that is to be searched. The form of JAR-name2 is schema.JAR-id or JAR-id. If schema is omitted, the JAR name is implicitly qualified with the schema name in the CURRENT SCHEMA special register. JAR JAR-name2 must exist at the current server. JAR-name2 must not be the same as JAR-name1.

**SQLJ.ALTER_JAVA_PATH usage notes**

*Stored procedures that reference classes in multiple JAR files:* A stored procedure that is packaged as a JAR file might reference classes that are in other JAR files, and the referenced JAR files might reference classes in still other JAR files. You need to specify class resolution paths for all dependencies among JAR files that the stored procedure uses. For any JAR files that the stored procedure uses that cannot be found in the CLASSPATH, and are not system-supplied, you need to use SQLJ.ALTER_JAVA_PATH to define the class resolution path. For example, suppose that stored procedure SP, which is packaged in JAR file JARSP, references classes in JAR files JAR1 and JAR2. Classes in JAR file JAR1 reference classes that are in JAR file JAR2. None of the JAR files are in the CLASSPATH or are system-supplied. You need to call SQLJ.ALTER_JAVA_PATH twice, to define the following class resolution paths:

- From JARSP to JAR1 and JAR2
- From JAR1 to JAR2

**SQLJ.ALTER_JAVA_PATH example**

Suppose that the JAR file that is named DB2INST3.BUILDPLAN references classes that are in a previously installed JAR that is named DB2INST3.BUILDPLAN2. Those classes are in Java package buildPlan2. The following Java program calls
import java.sql.*; // JDBC classes
import java.io.IOException;
import java.io.File;
import java.io.FileInputStream;
class SimpleInstallJar
{
    public static void main(String argv[])
    {
        String url = "jdbc:db2://sysmvs1.stl.ibm.com:5021";
        String jarname = "DB2INST3.BUILDPLAN";
        String resolutionPath = "(buildPlan2.*,DB2INST3.BUILDPLAN2)";
        try
        {
            Class.forName("com.ibm.db2.jcc.DB2Driver").newInstance();
            Connection con = DriverManager.getConnection(url, "MYID", "MYPW");
            CallableStatement stmt;
            String sql = "Call SQLJ.ALTER_JAVA_PATH(?,?)";
            stmt = con.prepareCall(sql);
            stmt.setString(1, jarname);
            stmt.setString(2, resolutionPath);
            boolean isrs = stmt.execute();
            stmt.close();
            System.out.println("Alteration of JAR resolution path succeeded");
            con.commit();
            con.close();
        }
        catch (Exception e)
        {
            System.out.println("Alteration of JAR resolution path failed");
            e.printStackTrace();
        }
    }
}

SQLJ.DB2_INSTALL_JAR stored procedure

SQLJ.DB2_INSTALL_JAR creates a new definition of a JAR file in the local Db2 catalog or in a remote Db2 catalog.

To install a JAR file at a remote location, you need to execute a CONNECT statement to connect to that location before you call SQLJ.DB2_INSTALL_JAR.

SQLJ.DB2_INSTALL_JAR authorization

Privilege set: If the CALL statement is embedded in an application program, the privilege set consists of the privileges that are held by the authorization ID of the owner of the plan or package. If the statement is dynamically prepared, the privilege set consists of the privileges that are held by the authorization IDs of the process.

For calling SQLJ.DB2_INSTALL_JAR, the privilege set must include at least one of the following items:

- EXECUTE privilege on SQLJ.DB2_INSTALL_JAR
• Ownership of SQLJ.DB2_INSTALL_JAR
• SYSADM authority

The privilege set must also include the authority to install a JAR, which consists of at least one of the following items:

• CREATEIN privilege on the schema of the JAR
  The authorization ID that matches the schema name implicitly has the CREATEIN privilege on the schema.

• SYSADM or SYSCTRL authority

**SQLJ.DB2_INSTALL_JAR syntax**

```
CALL SQLJ.DB2_INSTALL_JAR(—Jar-locator,—JAR-name,—deploy—)
```

**SQLJ.DB2_INSTALL_JAR parameters**

**Jar-locator**
A BLOB locator input parameter that points to the JAR file that is to be installed in the Db2 catalog.

**JAR-name**
A VARCHAR(257) input parameter that contains the Db2 name of the JAR, in the form `schema.JAR-id` or `JAR-id`. `JAR-name` is the name that you use when you refer to the JAR in SQL statements. If you omit `schema`, Db2 uses the SQL authorization ID that is in the CURRENT SCHEMA special register. The owner of the JAR is the authorization ID in the CURRENT SQLID special register.

**deploy**
An INTEGER input parameter that indicates whether additional actions are to be performed after the JAR file is installed. Additional actions are not supported, so this value is 0.

**SQLJ.DB2_INSTALL_JAR example**

Suppose that you want to install the JAR file that is in path `/u/db2inst3/apps/BUILDPLAN/BUILDPLAN.jar`. You want to refer to the JAR file as `DB2INST3.BUILDPLAN` in SQL statements. The following Java program installs that JAR file.

```java
import java.sql.*; // JDBC classes
import java.io.IOException;
import java.io.File;
import java.io.FileInputStream;
class SimpleInstallJar
{
    public static void main(String argv[])
    {
        String url = "jdbc:db2://sysmvs1.stl.ibm.com:5021";
        String jarname = "DB2INST3.BUILDPLAN";
        String jarfile = "/u/db2inst3/apps/BUILDPLAN/BUILDPLAN.jar";
        try
        { 
            Class.forName("com.ibm.db2.jcc.DB2Driver").newInstance();
            Connection con = DriverManager.getConnection(url, "MYID", "MYPW");
            File aFile = new File(jarfile);
            FileInputStream inputStream = new FileInputStream(aFile);
            CallableStatement stmt;
            String sql = "Call SQLJ.DB2_INSTALL_JAR(? , ? , ?)";
```

Chapter 5. Procedures that are supplied with Db2 1049
stmt = con.prepareCall(sql);
stmt.setBinaryStream(1, inputStream, (int)aFile.length());
stmt.setString(2, jarname);
stmt.setInt(3, 0);
boolean isrs = stmt.execute();
stmt.close();
System.out.println("Installation of JAR succeeded");
con.commit();
con.close();
}
catch (Exception e)
{
  System.out.println("Installation of JAR failed");
e.printStackTrace();
}
}

**SQLJ.DB2_REPLACE_JAR stored procedure**

SQLJ.DB2_REPLACE_JAR replaces an existing JAR file in the local Db2 catalog or in a remote Db2 catalog.

To replace a JAR file at a remote location, you need to execute a CONNECT statement to connect to that location before you call SQLJ.DB2_REPLACE_JAR.

**SQLJ.DB2_REPLACE_JAR authorization**

Privilege set: If the CALL statement is embedded in an application program, the privilege set consists of the privileges that are held by the owner of the plan or package. If the statement is dynamically prepared, the privilege set consists of the privileges that are held by the authorization IDs of the process.

For calling SQLJ.DB2_REPLACE_JAR, the privilege set must include at least one of the following items:
- EXECUTE privilege on SQLJ.DB2_REPLACE_JAR
- Ownership of SQLJ.DB2_REPLACE_JAR
- SYSADM authority

The privilege set must also include the authority to replace a JAR, which consists of at least one of the following items:
- Ownership of the JAR
- ALTERIN privilege on the schema of the JAR
  The authorization ID that matches the schema name implicitly has the ALTERIN privilege on the schema.
- SYSADM or SYSCTRL authority

**SQLJ.DB2_REPLACE_JAR syntax**

```
CALL SQLJ.DB2_REPLACE_JAR(JAR-locator, JAR-name)
```
SQLJ.DB2_REPLACE_JAR parameters

**JAR-locator**
A BLOB locator input parameter that points to the JAR file that is to be replaced in the Db2 catalog.

**JAR-name**
A VARCHAR(257) input parameter that contains the Db2 name of the JAR, in the form `schema.JAR-id` or `JAR-id`. JAR-name is the name that you use when you refer to the JAR in SQL statements. If you omit `schema`, Db2 uses the SQL authorization ID that is in the CURRENT SCHEMA special register.

SQLJ.DB2_REPLACE_JAR example

Suppose that you want to replace a previously installed JAR file that is named DB2INST3.BUILDPLAN with the JAR file that is in path `/u/db2inst3/apps/BUILDPLAN2/BUILDPLAN.jar`. The following Java program replaces the JAR file.

```java
import java.sql.*; // JDBC classes
import java.io.IOException;
import java.io.File;
import java.io.FileInputStream;
class SimpleInstallJar {
    public static void main(String argv[]) {
        String url = "jdbc:db2://sysmvs1.stl.ibm.com:5021";
        String jarname = "DB2INST3.BUILDPLAN";
        String jarfile = "/u/db2inst3/apps/BUILDPLAN2/BUILDPLAN.jar";
        try {
            Class.forName("com.ibm.db2.jcc.DB2Driver").newInstance();
            Connection con = DriverManager.getConnection(url, "MYID", "MYPW");
            File aFile = new File(jarfile);
            FileInputStream inputStream = new FileInputStream(aFile);
            CallableStatement stmt;
            String sql = "Call SQLJ.DB2_REPLACE_JAR(?, ?)"
            stmt = con.prepareCall(sql);
            stmt.setBinaryStream(1, inputStream, (int)aFile.length());
            stmt.setString(2, jarname);
            boolean isrs = stmt.execute();
            stmt.close();
            System.out.println("Replacement of JAR succeeded");
            con.commit();
            con.close();
        } catch (Exception e) {
            System.out.println("Replacement of JAR failed");
            e.printStackTrace();
        }
    }
}
```

SQLJ.INSTALL_JAR stored procedure

SQLJ.INSTALL_JAR creates a new definition of a JAR file in the local Db2 catalog.
SQLJ.INSTALL_JAR authorization

Privilege set: If the CALL statement is embedded in an application program, the privilege set consists of the privileges that are held by the authorization ID of the owner of the plan or package. If the statement is dynamically prepared, the privilege set consists of the privileges that are held by the authorization IDs of the process.

For calling SQLJ.INSTALL_JAR, the privilege set must include at least one of the following items:

- EXECUTE privilege on SQLJ.INSTALL_JAR
- Ownership of SQLJ.INSTALL_JAR
- SYSADM authority

The privilege set must also include the authority to install a JAR, which consists of at least one of the following items:

- CREATEIN privilege on the schema of the JAR
  The authorization ID that matches the schema name implicitly has the CREATEIN privilege on the schema.
- SYSADM or SYSCTRL authority

SQLJ.INSTALL_JAR syntax

```sql
CALL SQLJ.INSTALL_JAR(url, JAR-name, deploy)
```

SQLJ.INSTALL_JAR parameters

- **url**
  A VARCHAR(1024) input parameter that identifies the z/OS UNIX System Services full path name for the JAR file that is to be installed in the Db2 catalog. The format is file://path-name or file:/path-name.

- **JAR-name**
  A VARCHAR(257) input parameter that contains the Db2 name of the JAR, in the form schema.JAR-id or JAR-id. JAR-name is the name that you use when you refer to the JAR in SQL statements. If you omit schema, Db2 uses the SQL authorization ID that is in the CURRENT SCHEMA special register. The owner of the JAR is the authorization ID in the CURRENT SQLID special register.

- **deploy**
  An INTEGER input parameter that indicates whether additional actions are to be performed after the JAR file is installed. Additional actions are not supported, so this value is 0.

SQLJ.INSTALL_JAR example

Suppose that you want to install the JAR file that is in path /u/db2inst3/apps/BUILDPLAN/BUILDPLAN.jar. You want to refer to the JAR file as DB2INST3.BUILDPLAN in SQL statements. Use a CALL statement similar to this one.

```sql
CALL SQLJ.INSTALL_JAR('file:/u/db2inst3/apps/BUILDPLAN/BUILDPLAN.jar', 'DB2INST3.BUILDPLAN', 0)
```

Related concepts:
Definition of a JAR file for a Java routine to Db2 (Db2 Application Programming for Java)

**SQLJ.REMOVE_JAR stored procedure**

SQLJ.REMOVE_JAR deletes a JAR file from the local Db2 catalog or from a remote Db2 catalog.

To delete a JAR file at a remote location, you need to execute a CONNECT statement to connect to that location before you call SQLJ.REMOVE_JAR.

The JAR cannot be referenced in the EXTERNAL NAME clause of an existing routine, or in the path of an installed JAR.

**SQLJ.REMOVE_JAR authorization**

*Privilege set:* If the CALL statement is embedded in an application program, the privilege set consists of the privileges that are held by the authorization ID of the owner of the plan or package. If the statement is dynamically prepared, the privilege set consists of the privileges that are held by the authorization IDs of the process.

For calling SQLJ.REMOVE_JAR, the privilege set must include at least one of the following items:

- EXECUTE privilege on SQLJ.REMOVE_JAR
- Ownership of SQLJ.REMOVE_JAR
- SYSADM authority

The privilege set must also include the authority to remove a JAR, which consists of at least one of the following items:

- Ownership of the JAR
- DROPIN privilege on the schema of the JAR
  
  The authorization ID that matches the schema name implicitly has the DROPIN privilege on the schema.
- SYSADM or SYSCTRL authority

**SQLJ.REMOVE_JAR syntax**

```
CALL SQLJ.REMOVE_JAR(JAR-name, undeploy)
```

**SQLJ.REMOVE_JAR parameters**

**JAR-name**

A VARCHAR(257) input parameter that contains the Db2 name of the JAR that is to be removed from the catalog, in the form schema.JAR-id or JAR-id. JAR-name is the name that you use when you refer to the JAR in SQL statements. If you omit schema, Db2 uses the SQL authorization ID that is in the CURRENT SCHEMA special register.

**undeploy**

An INTEGER input parameter that indicates whether additional actions should be performed before the JAR file is removed. Additional actions are not supported, so this value is 0.
Suppose that you want to remove a previously installed JAR file that is named DB2INST3.BUILDPLAN. Use a CALL statement similar to this one.

```sql
CALL SQLJ.REMOVE_JAR('DB2INST3.BUILDPLAN', 0)
```

Definition of a JAR file for a Java routine to Db2 (Db2 Application Programming for Java)

WLM_REFRESH stored procedure

The WLM_REFRESH stored procedure refreshes a WLM environment. This stored procedure can recycle the environment in which it runs and in any other WLM environment.

Environment for WLM_REFRESH

The load module for WLM_REFRESH, DSNTWR, must reside in an APF-authorized library.

DSNTWR runs module DSNTWRE as a subtask. DSNTWRE retrieves a copy of the Db2 environment information block (EIB) for the Db2 subsystem. The DSNTWRE module has no APF-authorization requirement, but it must reside in an APF-authorized library to be available to DSNTWR.

Recommendation: Use WLM environment DSNWLM_GENERAL for running WLM_REFRESH. Installation job DSNTIJMV creates an address space procedure called DSNWLMG for this environment.

Authorization required for WLM_REFRESH

To execute the CALL statement, the SQL authorization ID of the process must have READ access or higher to the z/OS Security Server System Authorization Facility (SAF) resource profile ssid.WLM_REFRESH.WLM-environment-name in resource class DSNR. This is a different resource profile from the ssid.WLMENV.WLM-environment-name resource profile, which Db2 uses to determine whether a stored procedure or user-defined function is authorized to run in the specified WLM environment.

WLM_REFRESH uses an extended MCS console to monitor the operating system response to a WLM environment refresh request. The privilege to create an extended MCS console is controlled by the resource profile MVS.MCSOPER.* in the OPERCMDS class. If the MVS.MCSOPER.* profile exists, or if the specific profile MVS.MCSOPER.DSNTWR exists, the task ID that is associated with the WLM environment in which WLM_REFRESH runs must have READ access to it.

If the MVS.VARY.* profile exists, or if the specific profile MVS.VARY.WLM exists, the task ID that is associated with the WLM environment in which WLM_REFRESH runs must have CONTROL access to it.
WLM_REFRESH syntax diagram

The WLM_REFRESH stored procedure refreshes a WLM environment. WLM_REFRESH can recycle the environment in which it runs, as well as any other WLM environment.

The following syntax diagram shows the SQL CALL statement for invoking WLM_REFRESH. The linkage convention for WLM_REFRESH is GENERAL WITH NULLS.

```
CALL WLM_REFRESH(WLM-environment, ssid, status-message, return-code)
```

WLM_REFRESH option descriptions

**WLM-environment**
Specifies the name of the WLM environment that you want to refresh. This is an input parameter of type VARCHAR(32).

**ssid**
Specifies the subsystem ID of the Db2 subsystem with which the WLM environment is associated. If this parameter is NULL or blank, Db2 uses one of the following values for this parameter:

- In a non-data sharing environment, Db2 uses the subsystem ID of the subsystem on which WLM_REFRESH runs.
- In a data sharing environment, Db2 uses the group attach name for the data sharing group in which WLM_REFRESH runs.

This is an input parameter of type VARCHAR(4).

**status-message**
Contains an informational message about the execution of the WLM refresh. This is an output parameter of type VARCHAR(120).

**return-code**
Contains the return code from the WLM_REFRESH call, which is one of the following values:

- **0** WLM_REFRESH executed successfully.
- **4** One of the following conditions exists:
  - The SAF resource profile ssid.WLM_REFRESH.wlm-environment is not defined in resource class DSNR.
  - The SQL authorization ID of the process (CURRENT SQLID) is not defined to SAF.
  - The wait time to obtain a response from z/OS was exceeded.
- **8** The SQL authorization ID of the process (CURRENT SQLID) is not authorized to refresh the WLM environment.
- **990** DSNTWR received an unexpected SQLCODE while determining the current SQLID.
- **993** One of the following conditions exists:
• The WLM-environment parameter value is null, blank, or contains invalid characters.
• The ssid value contains invalid characters.

The extended MCS console was not activated within the number of seconds indicated by message DSNT5461.

DSNTWR is not running as an authorized program.

DSNTWR could not activate an extended MCS console. See message DSNT533I for more information.

DSNTWR made an unsuccessful request for a message from its extended MCS console. See message DSNT533I for more information.

The extended MCS console for DSNTWR posted an alert. See message DSNT534I for more information.

The operating system denied an authorized WLM_REFRESH request. See message DSNT545I for more information.

return-code is an output parameter of type INTEGER.

Example of WLM_REFRESH invocation

Suppose that you want to refresh WLM environment WLMENV1, which is associated with a Db2 subsystem with ID DSN. Assume that you already have READ access to the DSN.WLM_REFRESH.WLMENV1 SAF profile. The CALL statement for WLM_REFRESH looks like this:

```c
strcpy(WLMENV, "WLMENV1");
strcpy(SSID, "DSN");
EXEC SQL CALL SYSPROC.WLM_REFRESH(:WLMENV, :SSID, :MSGTEXT, :RC);
```

For a complete example of setting up access to an SAF profile and calling WLM_REFRESH, see job DSNTEJ6W, which is in data set prefix.SDSNSAMP.

Controlling extended MCS consoles using RACF (z/OS MVS Planning: Operations)

WLM_SET_CLIENT_INFO stored procedure

This procedure allows the caller to set client information that is associated with the current connection at the Db2 for z/OS server.

The following Db2 for z/OS client special registers can be changed:

• CURRENT CLIENT_ACCTNG
• CURRENT CLIENT_USERID
• CURRENT CLIENT_WRKSTNNAME
• CURRENT CLIENT_APPLNAME

The existing behavior of the CLIENT_ACCTNG register is unchanged. It gets its value from the accounting token for DSN requesters, and from the accounting string for SQL and other requesters.

Setting the CLIENT_ACCTNG special register updates the suffix portion of the accounting string. The accounting suffix information is limited to 255 bytes for distributed clients.
This procedure is not under transaction control and client information changes made by the procedure are independent of committing or rolling back units of work.

**Environment**

WLM_SET_CLIENT_INFO runs in a WLM-established stored procedures address space.

**Authorization**

To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges on each package that the stored procedure uses:

- The EXECUTE privilege on the package for DSNADMSI
- Ownership of the package
- PACKADM authority for the package collection
- SYSADM authority

**Syntax**

```sql
WLM_SET_CLIENT_INFO (client_userid NULL, client_wrkstnname NULL, client_applname NULL, client_acctstr NULL)
```

The schema is SYSPROC.

**Procedure parameters**

*client_userid*

An input argument of type VARCHAR(255) that specifies the user ID for the client. If NULL is specified, the value remains unchanged. If an empty string ("") is specified, the user ID for the client is reset to the default value.

If the value specified exceeds 128 bytes, it is truncated to 128 bytes.

*client_wrkstnname*

An input argument of type VARCHAR(255) that specifies the workstation name for the client. If NULL is specified, the value remains unchanged. If an empty string ("") is specified, the workstation name for the client is reset to the default value.

*client_applname*

An input argument of type VARCHAR(255) that specifies the application name for the client. If NULL is specified, the value remains unchanged. If an empty string ("") is specified, the application name for the client is reset to the default value.

*client_acctstr*

An input argument of type VARCHAR(255) that specifies the accounting string for the client. If NULL is specified, the value remains unchanged. If an empty string ("") is specified, the accounting string for the client is reset to the default value.
Examples

Set the user ID, workstation name, application name, and accounting string for the client.

```c
strcpy(user_id, "db2user");
strcpy(wkstn_name, "mywkstn");
strcpy(appl_name, "db2bp.exe");
strcpy(acct_str, "myacctstr");
iuser_id = 0;
iwkstn_name = 0;
iappl_name = 0;
iacct_str = 0;
EXEC SQL CALL SYSPROC.WLM_SET_CLIENT_INFO(:user_id:iuser_id,
:wkstn_name:iwkstn_name,
:appl_name:iappl_name,
:acct_str:iacct_str);
```

Set the user ID to db2user for the client without setting the other client attributes.

```c
strcpy(user_id, "db2user");
iuser_id = 0;
iwkstn_name = -1;
iappl_name = -1;
iacct_str = -1;
EXEC SQL CALL SYSPROC.WLM_SET_CLIENT_INFO(:user_id:iuser_id,
:wkstn_name:iwkstn_name,
:appl_name:iappl_name,
:acct_str:iacct_str);
```

Reset the user ID for the client to blank without modifying the values of the other client attributes.

```c
strcpy(user_id, "");
iuser_id = 0;
iwkstn_name = -1;
iappl_name = -1;
iacct_str = -1;
EXEC SQL CALL SYSPROC.WLM_SET_CLIENT_INFO(:user_id:iuser_id,
:wkstn_name:iwkstn_name,
:appl_name:iappl_name,
:acct_str:iacct_str);
```

XSR_ADDSCHEMADOC stored procedure

The XSR_ADDSCHEMADOC stored procedure adds every XML schema, other than the primary XML schema document, to the XSR.

Each XML schema in the XSR can consist of one or more XML schema documents. When an XML schema consists of multiple documents, you need to call XSR_ADDSCHEMADOC for the additional documents.

Environment for XSR_ADDSCHEMADOC

XSR_ADDSCHEMADOC runs in a WLM-established stored procedures address space.

**Recommendation:** Use WLM environment DSNWLM_XML for running XSR_ADDSCHEMADOC. The startup procedure for this environment, DSNWLMX, can be configured during installation, using installation panel DSNTIPRJ, XML schema processing routines.

Authorization required for XSR_ADDSCHEMADOC

The user ID of the caller of the procedure must have the EXECUTE privilege on the XSR_ADDSCHEMADOC stored procedure.
XSR_ADDSCHEMADOC syntax diagram

The following syntax diagram shows the CALL statement for invoking XSR_ADDSCHEMADOC.

```
CALL SYSPROC.XSR_ADDSCHEMADOC(rschema, name, schemalocation, content, docproperty)
```

XSR_ADDSCHEMADOC option descriptions

**rschema**
An input argument of type VARCHAR(128) that specifies the SQL schema for the XML schema. If a value is specified, it must be SYSXSR. Rules for valid characters and delimiters that apply to any SQL identifier also apply to this argument.

**name**
An input argument of type VARCHAR(128) that specifies the name of the XML schema. The complete SQL identifier for the XML schema is "rschema.name". The XML schema name must already exist as a result of calling the XSR_REGISTER stored procedure, and XML schema registration cannot yet be completed. This argument cannot have a NULL value. Rules for valid characters and delimiters that apply to any SQL identifier also apply to this argument.

**schemalocation**
An input argument of type VARCHAR(1000), which can have a NULL value, that indicates the schema location of the primary XML schema document to which the XML schema document is being added. This argument is the "external name" of the XML schema, that is, the primary document can be identified in the XML instance documents with the xsi:schemaLocation attribute. The document that references the schemalocation must use valid a URI format.

**content**
An input parameter of type BLOB(30M) that contains the content of the XML schema document being added. This argument cannot have a NULL value. An XML schema document must be supplied. The content of the XML schema document must be encoded in Unicode.

**docproperty**
An input parameter of type BLOB(5M) that indicates the properties for the XML schema document being added. This parameter can have a NULL value; otherwise, the value is an XML document.

Example of XSR_ADDSCHEMADOC

The following example calls the XSR_ADDSCHEMADOC stored procedure:
CALL SYSPROC.XSR_ADDSCHEMADOC(
    'SYSXSR',
    'POschema',
    'http://myPOschema/PO.xsd',
    :schema_content,
    :schema_properties)

In this example, XSR_ADDSCHEMADOC folds the name POschema to uppercase, so the name of the XML schema that is added is POSCHEMA. If you do not want XSR_ADDSCHEMADOC to fold POschema to uppercase, you need to delimit the name with double quotation marks ("), as in the following example.

CALL SYSPROC.XSR_ADDSCHEMADOC(
    'SYSXSR',
    '"POschema"',
    'http://myPOschema/PO.xsd',
    :schema_content,
    :schema_properties)

---

**XSR_COMPLETE stored procedure**

The XSR_COMPLETE procedure is the final stored procedure to be called as part of the XML schema registration process, which registers XML schemas with the XSR.

An XML schema is not available for validation until the schema registration completes through a call to this stored procedure.

**Environment for XSR_COMPLETE**

XSR_COMPLETE requires a WLM-established stored procedures address space that is configured for running Java routines.

**Recommendation:** Use WLM environment DSNWLM_JAVA for running XSR_COMPLETE. The startup procedure for this environment, DSNWLMJ, can be configured during installation, using installation panel DSNTIPRH, XML schema processing routines.

**Authorization required for XSR_COMPLETE**

The user ID of the caller of the procedure must have the EXECUTE privilege on the XSR_COMPLETE stored procedure.

**XSR_COMPLETE syntax diagram**

The following syntax diagram shows the CALL statement for invoking XSR_COMPLETE.
XSR_COMPLETE option descriptions

rschema
An input argument of type VARCHAR(128) that specifies the SQL schema for the XML schema. If a value is specified, it must be SYSXSR. Rules for valid characters and delimiters that apply to any SQL identifier also apply to this argument.

name
An input argument of type VARCHAR(128) that specifies the name of the XML schema. The complete SQL identifier for the XML schema, for which a completion check is to be performed, is rschema.name. The XML schema name must already exist as a result of calling the XSR_REGISTER stored procedure. This argument cannot have a NULL value. Rules for valid characters and delimiters that apply to any SQL identifier also apply to this argument.

schema-properties
An input argument of type BLOB(5M) that specifies properties, if any, associated with the XML schema. The value for this argument is either NULL, if there are no associated properties, or an XML document representing the properties for the XML schema.

for-decomposition
This value must be 0. XML schema decomposition is not supported.

Example of XSR_COMPLETE

The following example calls the XSR_COMPLETE stored procedure:

```sql
CALL SYSPROC.XSR_COMPLETE(
    'SYSXSR',
    'POschema',
    :schemaproperty_host_var,
    0)
```

In this example, XSR_COMPLETE folds the name POschema to uppercase, so the name of the XML schema for which registration is completed is POSCHEMA. If you do not want XSR_COMPLETE to fold POschema to uppercase, you need to delimit the name with double quotation marks ("), as in the following example.

```sql
CALL SYSPROC.XSR_COMPLETE(
    'SYSXSR',
    "POschema",
    :schemaproperty_host_var,
    0)
```

XSR_REGISTER stored procedure

The XSR_REGISTER procedure is the first stored procedure to be called as part of the XML schema registration process, which registers XML schemas with the XSR.

The user that calls this stored procedure is considered the creator of this XML schema. Db2 obtains the namespace attribute from the schema document when XSR_COMPLETE is invoked.

Environment for XSR_REGISTER

XSR_REGISTER runs in a WLM-established stored procedures address space.

Recommendation: Use WLM environment DSNWLM_XML for running XSR_REGISTER. The startup procedure for this environment, DSNWLMX, can be configured during installation, using installation panel DSNTIPRJ, XML schema processing routines.

Authorization required for XSR_REGISTER

The user ID of the caller of the procedure must have the EXECUTE privilege on the XSR_REGISTER stored procedure.

XSR_REGISTER syntax diagram

The following syntax diagram shows the CALL statement for invoking XSR_REGISTER.

```
CALL SYSPROC.XSR_REGISTER( rschema, name, schemalocation, content, docproperty)
```

XSR_REGISTER option descriptions

`rschema`

An input argument of type VARCHAR(128) that specifies the SQL schema for the XML schema. If a value is specified, it must be SYSXSR. Rules for valid characters and delimiters that apply to any SQL identifier also apply to this argument.

`name`

An input and output argument of type VARCHAR(128) that specifies the name of the XML schema. The complete SQL identifier for the XML schema is "rschema.name" and should be unique among all objects in the XSR. This argument accepts a NULL value. When a NULL value is provided for this
argument, a unique value is generated and stored within the XSR. Rules for valid characters and delimiters that apply to any SQL identifier also apply to this argument.

`schemalocation`  
An input argument of type VARCHAR(1000), which can have a NULL value, that indicates the schema location of the primary XML schema document. This argument is the "external name" of the XML schema, that is, the primary document can be identified in the XML instance documents with the xsi:schemaLocation attribute.

`content`  
An input parameter of type BLOB(30M) that contains the content of the primary XML schema document. This argument cannot have a NULL value; an XML schema document must be supplied. The content of the XML schema document must be encoded in Unicode.

`docproperty`  
An input parameter of type BLOB(5M) that indicates the properties for the primary XML schema document. This parameter can have a NULL value; otherwise, the value is an XML document.

**Example of XSR_REGISTER**

The following example calls the XSR_REGISTER stored procedure:

```sql
CALL SYSPROC.XSR_REGISTER(
  'SYXSR',
  'POschema',
  'http://myPOschema/PO.xsd',
  :content_host_var,
  :docproperty_host_var)
```

In this example, XSR_REGISTER folds the name POschema to uppercase, so the registered schema name is POSCHEMA. If you do not want XSR_REGISTER to fold POschema to uppercase, you need to delimit the name with double quotation marks ("), as in the following example.

```sql
CALL SYSPROC.XSR_REGISTER(
  'SYXSR',
  '"POschema"',
  'http://myPOschema/PO.xsd',
  :content_host_var,
  :docproperty_host_var)
```

**Related concepts:**

**XSR_REMOVE stored procedure**

The XSR_REMOVE procedure is used to remove all components of an XML schema. After the XML schema is removed, you can reuse the name of the removed XML schema when you register a new XML schema.

**Environment for XSR_REMOVE**

XSR_REMOVE runs in a WLM-established stored procedures address space.
**Recommendation:** Use WLM environment DSNWLM.XML for running XSR_REMOVE. The startup procedure for this environment, DSNWLMX, can be configured during installation, using installation panel DSNTIPRJ, XML schema processing routines.

**Authorization required for XSR_REMOVE**

The user ID of the caller of the procedure must have the EXECUTE privilege on the XSR_REMOVE stored procedure.

**XSR_REMOVE syntax diagram**

The following syntax diagram shows the CALL statement for invoking XSR_REMOVE.

```
CALL SYSPROC.XSR_REMOVE('rschema', 'name')
```

**XSR_REMOVE option descriptions**

`rschema`
An input argument of type VARCHAR (128) that specifies the SQL schema for the XML schema. If a value is specified, it must be SYSXSR. Rules for valid characters and delimiters that apply to any SQL identifier also apply to this argument.

`name`
An input argument of type VARCHAR (128) that specifies the name of the XML schema. The complete SQL identifier for the XML schema, for which a completion check is to be performed, is "rschema.name". The XML schema name must already exist as a result of calling the XSR_REGISTER stored procedure, and XML schema registration cannot yet be completed. This argument cannot have a NULL value. Rules for valid characters and delimiters that apply to any SQL identifier also apply to this argument.

**XSR_REMOVE notes**

If you run XSR_REMOVE against an XML schema that is part of an XML type modifier for a table column, an error occurs.

**Example of XSR_REMOVE**

The following example calls the XSR_REMOVE stored procedure:

```
CALL SYSPROC.XSR_REMOVE('SYSXSR', 'POschema')
```

In this example, XSR_REMOVE folds the name POschema to uppercase, so the name of the XML schema that is removed is POSCHEMA. If you do not want XSR_REMOVE to fold POschema to uppercase, you need to delimit the name with double quotation marks (""), as in the following example.

```
CALL SYSPROC.XSR_REMOVE('SYSXSR', '"POschema"')
```

Chapter 6. Queries

A query specifies a result table or an intermediate table. A query is a component of certain SQL statements. A query can have one of three forms.

- **Subselect**
- **Fullselect**
- 

A query can have one of three forms.

A subselect is a subset of a fullselect, and a fullselect is a subset of a select-statement.

**Restriction:** For all three forms of a query, you cannot reference both a system-period temporal table and an archive-enabled table in the same query.

**Authorization** describes the privilege set that is required to use any form of a query.

Another SQL statement that can be used to retrieve at most a single row is described in “SELECT INTO” on page 2274. SELECT INTO is not a subselect, fullselect, or a select-statement.

**Related concepts:**

- [Types of tables (Introduction to Db2 for z/OS)]
- [Temporal tables and data versioning (Db2 Administration Guide)]
- [Archive-enabled tables and archive tables (Introduction to Db2 for z/OS)]

### Authorization

For any form of a query, the privilege set that is defined below must include one of the following:

- For each table or view identified in the statement, the privilege set must include one of the following:
  - Ownership of the table or view
  - The SELECT privilege on the table or view
  - DBADM authority for the database (tables only)

  If the database is implicitly created, the database privileges must be on the implicit database or on DSNDB04.
- SYSADM authority
- SYSCTRL authority (catalog tables only)
- DATAACCESS authority
- Installation SYSOPR authority (catalog tables and system tables only)

If a query includes a user-defined function, the privileges that are held by the authorization ID of the statement must include at least one of the following:

- For each user-defined function that is identified in the statement, one of the following:
  - The EXECUTE privilege on the function
  - Ownership of the function
• SYSADM authority
• DATAACCESS authority

If the select-statement is part of a DECLARE CURSOR statement, the privilege set is the privileges that are held by the authorization ID of the owner of the plan or package.

If the select-statement contains an SQL data change statement, the privilege set must include the SELECT privilege and the appropriate privileges for the SQL data change statement (insert, update, or delete privileges) on the target table or view.

If the select-statement references a table that contain an active row or column access control, and row permissions or column masks are defined for the table, the authorization ID or role of the statement does not need authority to reference objects that are specified in the definitions of those row permissions or column masks.

For dynamically prepared statements, the privilege set depends on the dynamic SQL statement behavior, which is specified by option DYNAMICRULES:

**Run behavior**

The privilege set is the union of the privilege sets that are held by each authorization ID of the process.

**Bind behavior**

The privilege set is the privileges that are held by the authorization ID of the owner of the plan or package.

**Define behavior**

The privilege set is the privileges that are held by the authorization ID of the owner of the stored procedure or user-defined function.

**Invoke behavior**

The privilege set is the privileges that are held by the authorization ID of the invoker of the stored procedure or user-defined function.

For a list of the DYNAMICRULES values that specify run, bind, define, or invoke behavior, see Table 14 on page 103.

When any form of a query is used as a component of another statement, the authorization rules that apply to the query are specified in the description of that statement. For example, see “CREATE VIEW” on page 1947 for the authorization rules that apply to the subselect component of CREATE VIEW.

If your installation uses the access control authorization exit (DSNX@XAC), that exit might be controlling the authorization rules instead of the rules that are listed here.
### subselect

The subselect is a component of the fullselect. A subselect specifies a result table that is derived from the tables or views that are identified in the FROM clause.

The derivation of the result table can be described as a sequence of operations in which the result of each operation is input for the next. (This is only a way of describing the subselect. The method that is used to perform the derivation might be quite different from this description. If portions of the subselect do not actually need to be executed for the correct result to be obtained, they might not be executed.)

When a subselect directly or indirectly references a table for which row or column access control is enforced, the rules that are defined in the row permissions or column masks affect how the rows in the result table are derived. Typically those rules are based on the authorization ID or role of the process.

A scalar-subselect is a subselect, enclosed in parentheses, that returns a single result row and a single result column. If the result of the subselect is no rows, the null value is returned. An error is returned if the result contains more than one row.

The clauses of the subselect are processed in the following sequence:

1. FROM clause
2. WHERE clause
3. GROUP BY clause
4. HAVING clause
5. SELECT clause
6. ORDER BY clause
7. OFFSET clause
8. FETCH clause

### select-clause

The SELECT clause specifies the columns of the final result table. The column values are produced by the application of the select list to R. The select list is a list of names and expressions specified in the SELECT clause, and R is the result of the previous operation of the subselect. For example, if SELECT, FROM, and WHERE are the only clauses specified, then R is the result of that WHERE clause.
ALL
Retains all rows of the final result table and does not eliminate redundant duplicates. This is the default.

DISTINCT
Eliminates all but one of each set of duplicate rows of the final result table.

Two rows are duplicates of one another only if each value in the first row is equal to the corresponding value in the second row. For determining duplicate rows, two null values are considered equal.

When SELECT DISTINCT is specified, no column or expression in the implicit or explicit list can return a value that is a LOB or XML data type. When a column or expression in the list returns a value that is a DECIMAL data type and multiple bit representations of the same number exists in the intermediate result, the value that is returned is unpredictable. See Numeric comparisons for additional information.

Column access controls do not affect the operation of SELECT DISTINCT. The elimination of duplicated rows is based on the original column values, not the masked values. However, after the application of column masks, the masked values in the final result table might not reflect the uniqueness that is enforced by SELECT DISTINCT.

If a column mask is applied to a column that directly or indirectly derives the result of SELECT DISTINCT, SELECT DISTINCT can return a result that is not deterministic. The following conditions are a few examples of when a result that is not deterministic might be returned:

- The definition of the column mask references other columns of the table to which the column mask is applied.
- The column is referenced in the argument of a built-in scalar function, such as COALESCE, IFNULL, NULLIF, MAX, MIN, LOCATE, TOTALORDER, etc.
- The column is referenced in the argument of an aggregation function.
- The column is embedded in an expression and the expression contains a function that is not deterministic or has an external action.

For compatibility with other SQL implementations, UNIQUE can be specified as a synonym for DISTINCT.

Select list notation:

* Represents a list of columns of table R, excluding any columns that are defined with the IMPLICITLY HIDDEN attribute. The list of names is established when
the statement containing the SELECT clause is prepared. Therefore, * does not identify any columns that have been added to a table after the statement has been prepared.

A column that is defined with the IMPLICITLY HIDDEN attribute can be explicitly referenced in the select list.

* cannot be used in the definition of a row permission or a column mask.

**expression**

Specifies the values of a result column. Each column-name in the expression must unambiguously identify a column of the intermediate result table.

The result of the expression must not be an array type, except in the following contexts:

- The outer select list of a fullselect that does not include a set operator other than UNION ALL, in the definition of a cursor that is not scrollable
- The outer select list of a SELECT INTO statement, when the target for the corresponding column of the result table of the fullselect is an array variable
- The outer select list of a scalar fullselect that does not include a set operator on the right side of a SET assignment-statement or SQL PL assignment-statement statement, when the corresponding target of the assignment is an array variable

**AS new-column-name**

Names or renames the result column. The name must not be qualified and does not have to be unique. new-column-name is an SQL identifier of 128 UTF-8 bytes or less.

**name.***

Represents a list of columns of name, excluding any columns that are defined as implicitly hidden, in the order the columns are produced by the FROM clause. name can be a table name, view name, or correlation name, and must designate an exposed table, view, or correlation name in the FROM clause that immediately follows the SELECT clause. The first name in the list identifies the first column of the table or view, the second name in the list identifies the second column of the table or view, and so on.

The list of names is established when the statement that contains the SELECT clause is prepared. Therefore, * does not identify any columns that have been added to a table after the statement has been prepared.

name.* cannot be used in the definition of a row permission or a column mask.

SQL statements can be implicitly or explicitly prepared again. The effect of another prepare on statements that include * or name.* is that the list of names is re-established. Therefore, the number of columns returned by the statement might change.

The number of columns in the result of SELECT is the same as the number of expressions in the operational form of the select list (that is, the list established at the time the statement is prepared), and cannot exceed 750. The result of a subquery must be a single column unless the subquery is used in an EXISTS predicate.

**Notes:**

If the FROM clause contains a MERGE statement:

The SELECT list must not implicitly or explicitly refer to a column that has
a LOB data type, a ROWID data type (or a distinct type that is based on a LOB, or ROWID), or an XML data type.

**Implicitly hidden columns in the select list:**
The result for SELECT * does not include any columns that are defined with the IMPLICITLY HIDDEN attribute. To be included in the result, implicitly hidden columns must be explicitly specified in the select list.

**VARBINARY data:**
If the identified table has an index on a VARBINARY column or a column that is a distinct type that is based on VARBINARY data type, that index column cannot specify the DESC attribute. To query the identified table, either drop the index or alter the data type of the column to BINARY and then rebuild the index.

**Applying the select list:**
Some of the results of applying the select list to R depend on whether GROUP BY or HAVING is used. The following three lists describe the results.

**IF neither GROUP BY nor HAVING is used:**
- The select list can include aggregate functions only if it includes other aggregate functions, constants, or expressions that only involve constants.
- If the select list does not include aggregate functions, it is applied to each row of R and the result contains as many rows as there are rows in R.
- If the select list includes aggregate functions, R is the source of the arguments of the functions and the result of applying the select list is one row, even when R has no rows.
- If a column mask is used to mask the values in the final result table, and the select list includes aggregate functions, the definition of the column mask must not reference the following:
  - A scalar fullselect
  - An aggregate function

**If HAVING is used and GROUP BY is not used:**
Each expression or column-name in an expression in the select list must be specified within an aggregate function. Constants or expressions that involve only constants can also be in the select list.

If a column mask is used to mask the values in the final result table, the definition of the column mask must not reference the following:
- A scalar fullselect
- An aggregate function

**If GROUP BY is used:**
- Each expression in the select list must use one or more grouping expressions. Or, each expression or column-name in an expression must:
  - Unambiguously identify a grouping column of R.
  - Be specified within an aggregate function.
  - Be a correlated reference. (A column-name is a correlated reference if it identifies a column of a table or view identified in an outer subselect.)
If an expression in the select list is a scalar fullselect, a correlated reference from the scalar fullselect to a group R must either identify a grouping column or be contained within an aggregate function. For example, the following query fails because the correlated reference T1.C1 || T1.C2 in the select list of the scalar fullselect does not match a grouping column from the outer subselect. (Matching the grouping expression T1.C1 || T1.C2 is not supported.)

```sql
SELECT MAX(T1.C2) AS X1,
      (SELECT T1.C1 || T1.C2 FROM T2 GROUP BY T2.C1) AS Y1
FROM T1 GROUP BY T1.C1, T1.C1 || T1.C2;
```

You cannot use GROUP BY with a name defined using the AS clause unless the name is defined in a nested table expression. Example 6 demonstrates the valid use of AS and GROUP BY in a SELECT statement.

In either case, the nth column of the result contains the values specified by applying the nth expression in the operational form of the select list.

If a column mask is used to mask the column values in the final result table, a column for which the column mask is applied must satisfy one of the following conditions:

- The column must be specified in an aggregate function and the definition of the column mask must not reference the following:
  - A scalar fullselect
  - An aggregate function

- The column must identify a column-name in the GROUP BY clause and the column must not be referenced in an expression in the GROUP BY clause. In addition, any columns of the same table as the column for which the column mask is applied and are referenced in the definition of the column mask must be identified with a column-name in the GROUP BY clause. These columns must not be referenced in an expression in the GROUP BY clause.

- A column of a non-base tables in the select list must be specified in an aggregate function if a column mask is used to mask the column values in the final result table, and the column of a non-base table maps directly or indirectly to a column name or to an expression in a materialized table expression or view to the table where the column mask is applied.

**Effect of column masks on result columns:**

When column masks are enabled, they determine the values in the final result table of an outermost select list. When a column mask is enabled for a column, if the column appears in the outermost select list (either implicitly or explicitly), the column mask is applied to the column to produce the values for the final result table. If the column itself does not appear in the outermost select list, but is included in the output (for example, it appears in a materialized table expression or a view), the masked value is included in the result table of the table expression or view so that it can be used in the final result table.

The enabled column masks do not interfere with the operations of other clauses within the statement, such as the WHERE, GROUP BY, HAVING, SELECT DISTINCT, and ORDER BY clauses.
The rows that are returned in the final result table remain the same, except that the values in the result rows might be masked. As such, if a column with masked values also appears in an ORDER BY clause with a sort-key expression, the order is based on the original column values (the masked values in the final result table might not reflect that order). Similarly, the masked values might not reflect the uniqueness enforced by a SELECT DISTINCT. If the masked column is embedded in an expression, the result of the expression might be different because the column mask is applied to the column before the expression is evaluated. For example, a column mask on column SSN can change the result of the function COUNT(DISTINCT SSN) because the DISTINCT operation is performed on the masked values. However, if the expression in the query is the same as the expression that is used to mask the column value in the definition of the column mask, the result of the expression might remain unchanged. For example, the expression in the query is 'XXX-XX-' || SUBSTR(SSN, 8, 4) and the same expression is used in the column mask definition. In this particular example, the expression in the query can be replaced with column SSN to avoid the same expression being evaluated twice.

If a CASE expression appears in the outermost select list, column masks are not applied to the search-condition of the WHEN clause.

When the definition of a column mask is applied to an SQL statement to mask column values in the final result table, the semantics of the column mask might conflict with certain SQL semantics in the statement. In these situations, the combination of the statement and the column mask might return an error.

See ALTER TABLE for more information about the application of enabled column masks.

Null attributes of result columns:
Result columns allow null values if they are derived from one of the following:

- Any aggregate function except COUNT or COUNT_BIG
- A column that allows null values
- A view column in an outer select list that is derived from an arithmetic expression
- An arithmetic expression in an outer select list
- An arithmetic expression that allows nulls
- A scalar function or string expression that allows null values
- A host variable that has an indicator variable, an SQL parameter or variable, a global variable, or in the case of Java, a host variable or expression whose type is able to represent a Java null value
- A result of a set operator if at least one of the corresponding items in the select list is nullable

Names of result columns:
In the following cases a result column is considered a named column:

- If the AS clause is specified, the name of the result column is the name specified on the AS clause.
- If the AS clause is not specified and a column list is specified in the correlation clause, the name of the result column is the corresponding name in the correlation column list.
- If neither an AS clause nor a column list in the correlation clause is specified and the result column is derived only from a single column (without any functions or operators), the result column name is the unqualified name of that column.
If neither an AS clause nor a column list in the correlation clause is specified and the result column is derived only from a single SQL variable, global variable, or SQL parameter (without any functions or operators), the result column name is the unqualified name of that SQL variable, global variable, or SQL parameter.

In all other cases, a result column is an unnamed column.

Names of result columns, SQL variables, and global variables are placed into the SQL descriptor area (SQLDA) when the DESCRIBE statement is executed. This allows an interactive SQL processor such as SPUFI, the command line processor, or QMF to use the column names when displaying the results. The names in the SQLDA include those specified by the AS clause.

**Data types of result columns:**

Each column of the result of SELECT acquires a data type from the expression from which it is derived. The following table shows the data types of result columns.

<table>
<thead>
<tr>
<th>When the expression is…</th>
<th>The data type of the result column is…</th>
</tr>
</thead>
<tbody>
<tr>
<td>The name of any numeric column</td>
<td>The same as the data type of the column, with the same precision and scale for decimal columns.</td>
</tr>
<tr>
<td>An integer constant</td>
<td>INTEGER.</td>
</tr>
<tr>
<td>A decimal or floating-point constant</td>
<td>The same as the data type of the constant, with the same precision and scale for decimal constants. For floating-point constants, the data type is <strong>DOUBLE PRECISION</strong>.</td>
</tr>
<tr>
<td>A decimal floating point constant</td>
<td><strong>DECFLOAT(34)</strong></td>
</tr>
<tr>
<td>The name of any numeric host variable</td>
<td>The same as the data type of the variable, with the same precision and scale for decimal variables. The result is decimal if the data type of the host variable is not an SQL data type; for example, DISPLAY SIGN LEADING SEPARATE in COBOL.</td>
</tr>
<tr>
<td>An arithmetic or string expression</td>
<td>The same as the data type of the result, with the same precision and scale for decimal results as described in <a href="#">Expressions</a>.</td>
</tr>
<tr>
<td>Any function</td>
<td><strong>The data type of the result of the function. For a built-in function, see <a href="#">Built-in functions</a> to determine the data type of the result. For a user-defined function, the data type of the result is what was defined in the CREATE FUNCTION statement for the function.</strong></td>
</tr>
<tr>
<td>The name of any string column</td>
<td>The same as the data type of the column, with the same length attribute.</td>
</tr>
<tr>
<td>The name of any string host variable</td>
<td>The same as the data type of the variable, with a length attribute equal to the length of the variable. The result is a varying-length character string if the data type of the host variable is not an SQL data type; for example, a NUL-terminated string in C.</td>
</tr>
<tr>
<td>A character string constant of length ( n )</td>
<td><strong>VARCHAR(( n )).</strong></td>
</tr>
<tr>
<td>A binary string constant of length ( n )</td>
<td><strong>VARBINARY(( n )).</strong></td>
</tr>
<tr>
<td>A graphic string constant of length ( n )</td>
<td><strong>VARGRAPHIC(( n )).</strong></td>
</tr>
<tr>
<td>The name of a datetime column</td>
<td>The same as the data type of the column.</td>
</tr>
<tr>
<td>The name of a ROWID column</td>
<td>Row ID.</td>
</tr>
<tr>
<td>The name of a distinct type column</td>
<td>The same as the distinct type of the column, with the same length, precision, and scale attributes, if any.</td>
</tr>
</tbody>
</table>
For information about the CCSID of the result column, see [Rules for result data types].

**Related reference:**
[Examples of subselects]

**unpacked-row**
An *unpacked-row* specifies a row that is the result of an invocation of the UNPACK built-in function.

```plaintext
unpacked-row:

\[ \text{UNPACK-function-invocation} \ast \text{AS}\left( \text{field-name} \text{ data-type}\right) \]
```

**UNPACK-function-invocation**
Specifies an invocation of the UNPACK built-in function. The number of specified *field-names* and *field-types* must be the same as the number of fields that are returned by the UNPACK function invocation.

**field-name**
Names the field that is returned from the UNPACK function. A name must not be qualified, and it does not have to be unique.

**data-type**
Specifies the built-in data type of the field. The specified data type, length, and CCSID must correspond to the data type, length, and CCSID of the data when the argument was initially encoded with the PACK function.

The CCSID 1208 and CCSID 1200 clauses must not be specified for *unpacked-row*.

The following table provides the supported data type mappings from the packed string data:

**Table 159. Data type mappings from packed string data**

<table>
<thead>
<tr>
<th>Data type of an encoded value in the packed string for UNPACK</th>
<th>Data type specified for UNPACK</th>
</tr>
</thead>
<tbody>
<tr>
<td>SMALLINT</td>
<td>SMALLINT, INTEGER, BIGINT</td>
</tr>
<tr>
<td>INTEGER</td>
<td>INTEGER, BIGINT</td>
</tr>
<tr>
<td>BIGINT</td>
<td>BIGINT</td>
</tr>
<tr>
<td>decimal ((p,s)))</td>
<td>decimal((p',s')) if (s'&lt;s) (s-s') digits are truncated. An error occurs if there are more than (p'-s') significant digits.</td>
</tr>
<tr>
<td>real(^2) or double(^3)</td>
<td>double</td>
</tr>
<tr>
<td>CHAR((n)) or VARCHAR((n))</td>
<td>CHAR((m)), VARCHAR((m))</td>
</tr>
<tr>
<td></td>
<td>If (m &lt; n) and any of the (n-m) characters is not a blank, an error occurs. Otherwise, the (n-m) blanks are truncated. If (m &gt; n) and the specified data type is CHAR, (m-n) blanks are appended.</td>
</tr>
</tbody>
</table>

\(^1\) For decimal \((p,s)\), \(p\) is the precision and \(s\) is the scale.
\(^2\) For real data type, single precision is specified.
\(^3\) For double data type, double precision is specified.
Table 159. Data type mappings from packed string data (continued)

<table>
<thead>
<tr>
<th>Data type of an encoded value in the packed string for UNPACK</th>
<th>Data type specified for UNPACK</th>
</tr>
</thead>
<tbody>
<tr>
<td>BINARY((n)) or VARBINARY((n))</td>
<td>BINARY((m)), VARBINARY((m))</td>
</tr>
<tr>
<td>If (m &lt; n), an error occurs. If (m &gt; n) and the UNPACK target is BINARY, (m-n) (X'00') bytes are appended.</td>
<td></td>
</tr>
<tr>
<td>DATE</td>
<td>DATE</td>
</tr>
<tr>
<td>TIME</td>
<td>TIME</td>
</tr>
<tr>
<td>TIMESTAMP((p)) WITHOUT TIME ZONE</td>
<td>TIMESTAMP((p')) WITHOUT TIME ZONE. If (p' &gt; p), (p'-p) zeros are appended. If (p' &lt; p), (p'-p) digits are truncated.</td>
</tr>
<tr>
<td>TIMESTAMP((p)) WITH TIME ZONE</td>
<td>TIMESTAMP((p')) WITH TIME ZONE. If (p' &gt; p), (p'-p) zeros are appended. If (p' &lt; p), (p'-p) digits are truncated.</td>
</tr>
</tbody>
</table>

Note: The data types in lower case are defined as follows:
1. decimal = DECIMAL\((p,s)\) or NUMERIC\((p,s)\)
2. real = REAL or FLOAT\((n)\) where \(n\) is the specification for a single precision floating point
3. double = DOUBLE, DOUBLE PRECISION, FLOAT or FLOAT\((n)\) where \(n\) is the specification for a double precision floating point

The synonyms for the data types, in either long or short form, are considered the same as those that are listed.

PACK
UNPACK

from-clause

The FROM clause specifies an intermediate result table.

from-clause

If only one table-reference is specified, the intermediate result table is simply the result of that table-reference. If more than one table-reference is specified, the intermediate result table consists of all possible combinations of the rows of the result of each specified table-reference.

Each row of the result is a row from the result of the first table-reference concatenated with a row from the result of the second table-reference, concatenated with a row from the result of the third table-reference, and so on. The number of rows in the result is the product of the number of rows in the result of each table-reference. Thus, if the result of any table-reference is empty, the result is empty.
If more than one table-reference is specified, the referenced tables and views must not include both inclusive-exclusive BUSINESS_TIME periods and inclusive-inclusive BUSINESS_TIME periods.

If `table-reference` has row access controls enforced, `table-reference` has at least one row permission: the default row permission. When there are multiple row permissions defined for a `table-reference`, a row access control search condition is derived by applying the logical OR operator to the search condition in each enabled permission. This derived search condition acts as a filter to the `table-reference` to determine the result table of the `table-reference` that is accessible to the authorization ID or role of the subselect.

If a `table-reference` contains a security label column, Db2 compares the security label of the user to the security label of each row. Results are returned according to the following rules:

- If the security label of the user dominates the security label of the row, Db2 returns the row.
- If the security label of the user does not dominate the security label of the row, Db2 does not return the data from that row, and Db2 does not generate an error report.

Examples of subselects

**table-reference**

A `table-reference` specifies a result table as either a table or view, or an intermediate table.

**table-reference:**

```
    ▶▶ single-table-reference
    ◀◀
    ▶▶ single-view-reference
    ◀◀
    ▶▶ nested-table-expression
    ◀◀
    ▶▶ data-change-table-reference
    ◀◀
    ▶▶ table-function-reference
    ◀◀
    ▶▶ table-locator-reference
    ◀◀
    ▶▶ xmltable-expression
    ◀◀
    ▶▶ collection-derived-table
    ◀◀
    ▶▶ joined-table
    ◀◀
```

**single-table-reference:**

```
    ▶▶ table-name
    ◀◀
    ▶▶ period-specification
    ◀◀
    ▶▶ correlation-clause
    ◀◀
```

**single-view-reference:**
period-specification:

(1) FOR SYSTEM_TIME AS OF value

(2) FROM value1 TO value2 BETWEEN value1 AND value2

Notes:
1. AS OF TIMESTAMP can be specified as an alternative and is treated as if FOR SYSTEM_TIME AS OF had been specified.
2. SYSTEM_TIME and BUSINESS_TIME cannot be specified more than one time per table.

nested-table-expression:

data-change-table-reference:

table-function-reference:
Notes:
1. The `typed-correlation-clause` is required for generic table functions. This clause cannot be specified for any other table functions.

**A table-reference specifies an intermediate result table.**

- If a `single-table-reference` is specified and it is not an archive-enabled table or a temporal table, the intermediate result table is the specified table. If a `period-specification` is also specified, the intermediate result table consists of the rows of the temporal table where the period matches the specification.

- If a `single-table-reference` is specified and it is an archive-enabled table, the setting of the SYSIBMADM.GET_ARCHIVE global variable and the ARCHIVESENSITIVE bind option determine the contents of the intermediate result table. If the global variable is set to Y and the bind option is set to YES, the intermediate result table includes the rows in the associated archive table. Otherwise, the intermediate result table does not include rows in the associated archive table.

- If a `single-view-reference` is specified without a `period-specification`, the intermediate result table is that view. If a `period-specification` is specified, temporal table references in the view consider only the rows where the period matches the specification.
If a nested-table-expression is specified, the result table is the result of the specified fullselect. The columns of the result do not need unique names, but a column with a non-unique name cannot be explicitly referenced.

If a data-change-table-reference is specified, the intermediate result table is the set of rows that are directly affected by the data change statement.

If a table-function-reference is specified, the intermediate result table is the set of rows that are returned by the table function.

If a table-locator-reference is specified, the host variable represents the intermediate result table. The intermediate result table has the same structure as the table identified in table-name.

If a collection-derived-table is specified, the intermediate result table is a set of rows from one or more array values. For more information, see collection-derived-table.

If an xmltable-expression is specified, the intermediate result table is the set of rows that are returned by the XMLTABLE function.

If a joined-table is specified, the intermediate result table is the result of one or more join operations. For more information, see joined-table.

Each table-name or view-name specified in every FROM clause of the same SQL statement must identify a table or view that exists at the same Db2 subsystem. If a FROM clause is specified in a subquery of a basic predicate, a view that includes GROUP BY or HAVING must not be identified.

A table-reference must not identify a table that was implicitly created for an XML column.

table-locator-variable

Table-locator-variable must specify a variable with a table locator type. The only way to assign a value to a table locator is to pass the old or new transition table of a trigger to a user-defined function or stored procedure. A table locator host variable must not have a null indicator. A table locator variable must not be a parameter marker. In addition, a table locator can be used only in a manipulative SQL statement. table-locator-reference must not be specified in the body of a trigger.

Table-name must refer to an EBCDIC table with a Unicode column if the transition table that is identified by table-locator-variable is for a trigger that is defined on an EBCDIC table with a Unicode column.

nested-table-expression

A fullselect in parentheses is called a nested table expression. If a nested table expression is specified, the result table is the result of that nested-table-expression. The columns of the result do not need unique names, but a column with a non-unique name cannot be referenced. At any time, the table consists of the rows that would result if the fullselect were executed.

table-function-reference

If a function-name is specified, the result table is the set of rows returned by the table function.

Expression must not contain a scalar fullselect, a function, or a reference to a column.

Each function-name, together with the types of its arguments, must resolve to a table function that exists at the same Db2 subsystem. An algorithm called function resolution, which is described in “Function resolution” on page 251, uses the function name and the arguments to determine the exact function to
use. Unless given column names in the correlation-clause, the column names for a table function are those specified on the RETURNS clause of the CREATE FUNCTION statement. This is analogous to the column names of a table, which are defined in the CREATE TABLE statement.

If a column mask is used to mask the column values in the final result table, and if the result of the table function is used to derive the final result table, the column mask cannot be applied to a column that is specified in the argument of the table function.

table-UDF-cardinality-clause

The table-UDF-cardinality-clause can be specified to each user-defined table function reference within the table spec of the FROM clause in a subselect. This option indicates the expected number of rows to be returned only for the SELECT statement that contains it.

CARDINALITY integer-constant specifies an estimate of the expected number of rows returned by the reference to the user-defined function. The value of integer-constant must range 0 - 2147483647.

The value set in the CARDINALITY field of SYSIBM.SYSROUTINES for the table function name is used as the reference cardinality value. The product of the specified CARDINALITY MULTIPLIER numeric-constant and the reference cardinality value are used by Db2 as the expected number of rows returned by the table function reference.

In this case, the numeric-constant can be in the integer, decimal, or floating-point format. The value must be greater than or equal to zero. If the decimal number notation is used, the number of digits can be up to 31. An integer value is treated as a decimal number with no fraction. The maximum value allowed for a floating-point number is about 7.237E + 75.

If no value has been set in the CARDINALITY field of SYSIBM.SYSROUTINES, its default value is used as the reference cardinality value. If zero is specified or the computed cardinality is less than 1, Db2 assumes that the cardinality of the reference to the user-defined table function is 1.

Only a numeric constant can follow the keyword CARDINALITY or CARDINALITY MULTIPLIER. No host variable or parameter marker is allowed in a cardinality option. Specifying a cardinality option in a table function reference does not change the corresponding CARDINALITY field in SYSIBM.SYSROUTINES. The CARDINALITY field value in SYSIBM.SYSROUTINES can be initialized by the CARDINALITY option in the CREATE FUNCTION (external table) statement when a user-defined table function is created. It can be changed by the CARDINALITY option in the ALTER FUNCTION statement or by a direct update operation to SYSIBM.SYSROUTINES.

data-change-table-reference

A data-change-table-reference clause specifies an intermediate result table. This table is based on the rows that are directly changed by the SQL data change statement that is included in the clause. A data-change-table-reference can only be specified as the only table-reference in the FROM clause of the outer fullselect that is used in a select-statement and that fullselect must be in a subselect, or a SELECT INTO statement. A data-change-table-reference in a SELECT statement of a cursor makes the cursor read only. The target table or view of the SQL data change statement is a table or view that is reference in the query. The privileges that are held by the authorization ID of the statement must include the SELECT privilege on that target table or view. The encoding scheme of the
result table of the SELECT must be the same as the encoding scheme of the target table or view of the \textit{data-change-table-reference}.

If row access control is enforced for the target of the data change statement, the rows in the intermediate result table already satisfy the rules that are specified in the enabled row permissions. If column access control is enforced for the target of the data change statement, the enabled column masks are applied to the outermost select list. See \textit{“select-clause” on page 1069} for more information. If an INCLUDE clause is specified as part of the SQL data change statement, and these additional columns appear in the outermost select list, the column values must not be derived from columns for which column masks are defined.

Expressions in the select list of a view in a table reference can only be selected if OLD TABLE is specified or if the expression does not include any of the following objects:

- a function that is defined to read or modify SQL data
- a function that is defined as not deterministic or has an external action
- a NEXT VALUE expression for a sequence

**FINAL TABLE**

Specifies that the rows of the intermediate result table represent the set of rows that are changed by the SQL data change statement as they appear at the completion of the SQL data change statement. If there are \textit{AFTER} triggers that result in further operations on the table that is the target of the SQL data change statement, an error is returned. If the target of the SQL data change statement is a view that is defined with an \textit{INSTEAD OF} trigger for the type of data change, an error is returned.

**OLD TABLE**

The rows of the intermediate result table represent the set of affected rows as they exist prior to the application of the SQL data change statement.

**INSERT statement**

Specifies an INSERT statement as described in \textit{“INSERT” on page 2145}. A fullselect in the INSERT statement cannot contain correlated references to columns that are outside of the fullselect of the INSERT statement. The target of the INSERT statement must be a base table, a view that is defined with the \textit{WITH CASCADED CHECK} clause, or a view where the view definition has no \textit{WHERE} clause. If there are input variables elsewhere in the fullselect, the INSERT statement cannot be a multiple row not atomic insert, or a multiple row atomic insert that specifies the \textit{USING DESCRIPTOR} clause.

**MERGE statement**

Specifies a MERGE statement as described in \textit{“MERGE” on page 2169}. The MERGE statement must conform to the following rules:

- The target of the MERGE statement must be a base table, a view that is defined with the \textit{WITH CASCADED CHECK} clause, or a view where the view definition has no \textit{WHERE} clause.
- The target table or view of the MERGE statement must not have a column with a ROWID data type. Additionally, when NOT ATOMIC \textit{CONTINUE ON SQLEXCEPTION} is specified, the target table or view of the MERGE statement must not have a column with a LOB or XML data type.
If table-reference is specified in the MERGE statement, it must not contain correlated references to columns that are outside of the table reference in the MERGE statement.

If table-reference is specified in the MERGE statement, AFTER triggers that result in further operations on the target table must not exist.

When NOT ATOMIC CONTINUE ON SQLEXCEPTION is specified in the MERGE statement, or the NOT ATOMIC CONTINUE ON SQLEXCEPTION clause is not specified, and source-values (VALUES) is specified, the MERGE statement must not include a delete operation.

searched UPDATE statement
Specifies a searched UPDATE statement as described in "UPDATE" on page 2339. A WHERE clause or a SET clause in the UPDATE statement cannot contain correlated referenced to columns that are outside of the UPDATE statement. The target of the UPDATE statement must be a base table, a symmetric view, or a view where the view definition has no WHERE clause.

If the searched UPDATE statement is used in the SELECT statement and the UPDATE statement references a view, the view must be defined using the WITH CASCADED CHECK OPTION clause.

A searched UPDATE statement in a SELECT statement will not clear the AREO\* status of a table.

AFTER triggers that result in further operations on the target table cannot exist on the target table.

searched DELETE statement
Specifies a searched DELETE statement as described in "DELETE" on page 1992. A WHERE clause in the DELETE statement cannot contain correlated references to columns that are outside of the DELETE statement. The target of the DELETE statement must be a base table, a symmetric view, or a view where the view definition has no WHERE clause.

If the searched DELETE statement is used in the SELECT statement and the DELETE statement references a view, the view must be defined using the WITH CASCADED CHECK OPTION clause.

AFTER triggers that result in further operations on the target table cannot exist on the target table.

The content of the intermediate result table for a table reference that contains an SQL data change statement is determined when the cursor is opened. The intermediate result table includes a column for each of the columns of the target table (including implicitly hidden columns) or view. All of the columns of the target table or view of an SQL data change statement are accessible by using the names of the columns from the target table or view unless the columns are renamed by using the correlation clause. If an INCLUDE clause is specified as part of the SQL data change statement, the intermediate result table will contain these additional columns.

correlation-clause
Each correlation-name in a correlation-clause defines a designator for the immediately preceding result table, which can be used to qualify references to the columns of the table. See "correlation-clause" on page 1091 for more information.

The exposed names of all table references in the FROM clause should be unique. An exposed name is considered to be any of the following names:
• A correlation-name
• A table-name that is not followed by a correlation-name
• A view-name that is not followed by a correlation-name
• A function-name that is not followed by a correlation-name
• The table name that is specified after LIKE when a table-locator is not followed by a correlation-name
• The target table or view name for a data-change-table-reference that is not followed by a correlation-name
• An alias-name that is not followed by a correlation-name
• A synonym-name that is not followed by a correlation-name

If a correlation-clause does not follow an xmltable-expression reference, a nested-table-expression reference, or a collection-derived-table-reference, there is no exposed name for that table reference.

Any qualified reference to a column must use the exposed name. If the same name is specified twice, at least one specification should be followed by a correlation-name. The correlation-name is used to qualify references to the columns of the table or view. When a correlation-name is specified, column names can also be specified to give names to the columns of the table reference. If the correlation-clause does not include column names, the exposed column names are determined as follows:

• Column names of the referenced table or view when the table-reference is table-name, view-name, alias-name, or synonym-name
• Column names specified in the RETURNS clause of the CREATE FUNCTION statement when the table-reference is a function-name reference
• Column names of the table referenced after LIKE when the table-reference is a table-locator
• Column names specified in the COLUMNS clause of the xmltable-expression when the table-reference is an xmltable-expression
• Column names returned by the fullselect when the table-reference is a nested-table-expression
• Column names from the target table of the data change statement, along with any defined INCLUDE columns, when the table-reference is a data-change-table-reference

Otherwise, there are no exposed names for the columns of that table reference.

typed-correlation-clause
A typed-correlation-clause defines the appearance and contents of the table generated by a generic table function. This clause must be specified when the table-function-reference is a generic table function and cannot be specified for any other table reference. See “typed-correlation-clause” on page 1092 for more information.

xmltable-expression
Specifies an invocation of the built-in XMLTABLE function. See XMLTABLE for more information.

If a column mask is used to mask the column values in the final result table, and if the result of the XMLTABLE function is used to derive the final result table, the column mask cannot be applied to a column that is specified in the PASSING clause of the XMLTABLE function.

collection-derived-table
A collection-derived-table is used to convert the elements of one or more arrays
into column values in separate rows of an intermediate result table, as explained in "collection-derived-table” on page 1093.

**Joined-table**

If a joined-table is specified, the result table is the result of one or more join operations as explained in “joined-table” on page 1096.

**Period-specification**

Specifies that a period specification applies to the table-reference. The same period name (SYSTEM_TIME or BUSINESS_TIME) must not be specified more than one time for the same table. If the table reference specifies a view, the definition of that view must not reference a user-defined function.

The rows of the table reference are derived by application of the specified period specification. The intermediate result table does not include rows in the associated history table that were added for the ON DELETE ADD EXTRA ROW attribute in the system-period temporal table definition.

**Note:** History tables are intended to include only rows that Db2 stores to record the history of the associated system-period temporal table. However, if the history table contains other rows with the same value in the two columns that correspond to the row-begin and row-end columns in the system-period temporal table, the intermediate result table might include these rows. These rows might be included in the following cases:

- The system-period temporal table is defined with the ON DELETE ADD EXTRA ROW attribute, the table contains a DATA CHANGE OPERATION column, and the value of the corresponding column in the history table is not ‘D’.
- The system-period temporal table is not defined with the ON DELETE ADD EXTRA ROW attribute.

The rows of a view reference are derived by application of the specified period specifications to all of the temporal tables that are accessed when computing the result table of the view. If the view does not access any temporal tables, the period specification has no effect on the result table of the view.

If the table is a bitemporal table and a period-specification is not specified for both SYSTEM_TIME or BUSINESS_TIME, the table reference includes all current rows of the table and does not include any historical rows of the table.

If the CURRENT TEMPORAL SYSTEM_TIME special register is set to a value other than the null value, a period-specification for a table or view cannot reference SYSTEM_TIME. This restriction applies even if the view body does not reference a system-period temporal table. The exception is if the value in effect for the SYSTIMSENSITIVE bind option is NO. In this case, the period-specification can reference SYSTEM_TIME.

If the CURRENT TEMPORAL BUSINESS_TIME special register is set to a value other than the null value, a period-specification for a table or view cannot reference BUSINESS_TIME. This restriction applies even if the view body does not reference an application-period temporal table. The exception is if the value in effect for the BUSTIMSENSITIVE bind option is NO. In this case, the period-specification can reference BUSINESS_TIME.

**Related information:**

- **CURRENT TEMPORAL BUSINESS_TIME**
- **CURRENT TEMPORAL SYSTEM_TIME**
FOR SYSTEM_TIME
   Specifies that the SYSTEM_TIME period is used for the \textit{period-specification}. The table reference must be a system-period temporal table or a view.

   Do not specify FOR SYSTEM_TIME if the value of the CURRENT TEMPORAL SYSTEM_TIME special register is not NULL and the SYSTIMESENSITIVE bind option is set to \texttt{YES}.

FOR BUSINESS_TIME
   Specifies that the BUSINESS_TIME period is used for the \textit{period-specification}. The table reference must be an application-period temporal table or a view.

   Do not specify FOR BUSINESS_TIME if the value of the CURRENT TEMPORAL BUSINESS_TIME special register is not NULL and the BUSTIMESENSITIVE bind option is set to \texttt{YES}.

AS OF \textit{value}
   Specifies that the \textit{table-reference} includes rows that exist at the time that is specified by \textit{value} as follows:

   - For an inclusive-exclusive period, a row is included if the begin value for the specified period is less than or equal to \textit{value}, and the end value for the period is greater than \textit{value}. If \textit{value} is the null value, the table reference is an empty table.

   - For an inclusive-inclusive period, a row is included if the begin value for the specified period is less than or equal to \textit{value}, and the end value for the period is greater than or equal to \textit{value}. If \textit{value} is the null value, the table reference is an empty table.

\textit{value}
   Specifies an expression that returns a value of a built-in data type. The result of the expression must be comparable to the data type of the columns of the \textit{specified period} according to the comparison rules specified in Assignment and comparison.

   The expression must not have a timestamp precision that is greater than the precision of the columns for the period.

   If the begin and end columns of the period are defined as \texttt{TIMESTAMP WITHOUT TIME ZONE}, the expression must not return a value of a timestamp with a time zone. The expression can contain any of the following supported operands:

   - A constant
   - A special register
   - A variable
   - An array element specification
   - A built-in scalar function whose arguments are supported operands
   - A CAST specification where the cast operand is a supported operand
   - An expression that uses arithmetic operators and operands

   A period specification for a view must not contain an untyped parameter marker.

FROM \textit{value1} TO \textit{value2}
   Specifies that the \textit{table-reference} includes rows that exist for the period that is specified from \textit{value1} up to \textit{value2}.

   - For an inclusive-exclusive period, a row is included in the \textit{table-reference} if the start value for the period in the row is less than \textit{value2}, and the
end value for the period in the row is greater than value1. The
table-reference contains zero rows if value1 is greater than or equal to
value2. If value1 or value2 is the null value, the table reference is an
empty table.

- For an inclusive-inclusive period, a row is included in the table-reference
  if the start value for the period in the row is less than value2, and the
  end value for the period in the row is greater than or equal to value1.
The table-reference contains zero rows if value1 is greater than or equal
to value2. If value1 or value2 is the null value, the table reference is an
empty table.

value1 or value2
Specifies an expression that returns a value of a built-in data type. The
result of the expression must be comparable to the data type of the
columns of the specified period according to the comparison rules
specified in Assignment and comparison.

The expression must not have a timestamp precision that is greater
than the precision of the columns for the period.

If the begin and end columns of the period are defined as
TIMESTAMP WITHOUT TIME ZONE, the expression must not return
a value of a timestamp with a time zone. The expression can contain
any of the following supported operands:
- A constant
- A special register
- A variable
- An array element specification
- A built-in scalar function whose arguments are supported operands
- A CAST specification where the cast operand is a supported operand
- An expression that uses arithmetic operators and operands

A period specification for a view must not contain an untyped
parameter marker.

BETWEEN value1 AND value2
Specifies that the table-reference includes rows in which the specified period
overlaps at any point in time between value1 and value2.

- For an inclusive-exclusive period, a row is included in the table-reference
  if the start value for the period in the row is less than or equal to value2
  and the end value for the period in the row is greater than value1. The
  table-reference contains zero rows if value1 is greater than value2. If value1
  = value2, the expression is equivalent to AS OF value1. If value1 or value2
  is the null value, the table-reference is an empty table.

- For an inclusive-inclusive period, a row is included in the table-reference
  if the start value for the period in the row is less than or equal to value2
  and the end value for the period in the row is greater than or equal to
  value1. The table-reference contains zero rows if value1 is greater than
  value2. If value1 = value2, the expression is equivalent to AS OF value1. If
  value1 or value2 is the null value, the table-reference is an empty table.

value1 or value2
Specifies an expression that returns a value of a built-in data type. The
result of the expression must be comparable to the data type of the
columns of the specified period according to the comparison rules
specified in Assignment and comparison.
The expression must not have a timestamp precision that is greater than the precision of the columns for the period.

If the begin and end columns of the period are defined as TIMESTAMP WITHOUT TIME ZONE, the expression must not return a value of a timestamp with a time zone. The expression can contain any of the following supported operands:

- A constant
- A special register
- A variable
- An array element specification
- A built-in scalar function whose arguments are supported operands
- A CAST specification where the cast operand is a supported operand
- An expression that uses arithmetic operators and operands

A period specification for a view must not contain an untyped parameter marker.

Notes

Correlated references in table-reference:

In general, nested table expressions and table functions can be specified in any FROM clause. Columns from the nested table expressions and table functions can be referenced in the select list and in the rest of the fullselect using the correlation name. The scope of this correlation name is the same as correlation names for other table or view names in the FROM clause. The basic rule that applies for both these cases is that the correlated reference must be from a table-reference at a higher level in the hierarchy of subqueries.

Nested table expressions can be used in place of a view to avoid creating a view when general use of the view is not required. They can also be used when the result table is based on host variables.

For table functions, an additional capability exists. A table function can contain one or more correlated references to other tables in the same FROM clause if the referenced tables precede the reference in the left-to-right order of the tables in the FROM clause. The same capability exists for nested table expressions if the optional keyword TABLE is specified; otherwise, only references to higher levels in the hierarchy of subqueries is allowed.

A nested table expression or table function that contains correlated references to other tables in the same FROM clause:

- Cannot participate in a FULL OUTER JOIN or a RIGHT OUTER JOIN
- Can participate in LEFT OUTER JOIN or an INNER JOIN if the referenced tables precede the reference in the left-to-right order of the tables in the FROM clause

The following table shows some examples of valid and invalid correlated references. TABF1 and TABF2 represent table functions.

<table>
<thead>
<tr>
<th>Subselect</th>
<th>Valid</th>
<th>Reason</th>
</tr>
</thead>
<tbody>
<tr>
<td>SELECT T.C1, Z.C5</td>
<td>No</td>
<td>T.C2 cannot be resolved because T does not precede TABF1 in FROM</td>
</tr>
<tr>
<td>FROM TABLE(TABF1(T.C2)) AS Z, T</td>
<td></td>
<td>T does not precede TABF1 in FROM</td>
</tr>
<tr>
<td>WHERE T.C3 = Z.C4;</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Chapter 6. Queries 1089
**Table 160. Examples of correlated references (continued)**

<table>
<thead>
<tr>
<th>Subselect</th>
<th>Valid</th>
<th>Reason</th>
</tr>
</thead>
<tbody>
<tr>
<td>SELECT T.C1, Z.C5 FROM T, TABLE(TABF1(T.C2)) AS Z WHERE T.C3 = Z.C4;</td>
<td>Yes</td>
<td>T precedes TABF1 in FROM, making T.C2 known</td>
</tr>
<tr>
<td>SELECT A.C1, B.C5 FROM TABLE(TABF1(B.C2)) AS A, TABLE(TABF1(A.C6)) AS B WHERE A.C3 = B.C4;</td>
<td>No</td>
<td>B in B.C2 cannot be resolved because the table function that would resolve it, TABF1, follows its reference in TABF2 in FROM</td>
</tr>
<tr>
<td>SELECT D.DEPTNO, D.DEPTNAME, EMPINFO.AVGSAL, EMPINFO.EMPCOUNT FROM DEPT D, (SELECT AVG(E.SALARY) AS AVGSAL, COUNT(*) AS EMPCOUNT FROM EMP E WHERE E.WORKDEPT = D.DEPTNO) AS EMPINFO;</td>
<td>No</td>
<td>DEPT precedes nested table expression, but keyword TABLE is not specified, making D.DEPTNO unknown</td>
</tr>
<tr>
<td>SELECT D.DEPTNO, D.DEPTNAME, EMPINFO.AVGSAL, EMPINFO.EMPCOUNT FROM DEPT D, TABLE (SELECT AVG(E.SALARY) AS AVGSAL, COUNT(*) AS EMPCOUNT FROM EMP E WHERE E.WORKDEPT = D.DEPTNO) AS EMPINFO;</td>
<td>Yes</td>
<td>DEPT precedes nested table expression and keyword TABLE is specified, making D.DEPTNO known</td>
</tr>
</tbody>
</table>

**Affects of special registers:**

The setting of the CURRENT TEMPORAL BUSINESS_TIME and CURRENT TEMPORAL SYSTEM_TIME special registers might affect the result of a query, as described in the following situations:

- Assume the following conditions:
  - A table reference is an application-period temporal table.
  - The columns of the BUSINESS_TIME period are defined as TIMESTAMP(6).
  - The CURRENT TEMPORAL BUSINESS_TIME special register is set to a non-null value.

  In this case, a query is executed as if it contained the following specification:

  ```sql
  FOR BUSINESS_TIME AS OF CURRENT TEMPORAL BUSINESS_TIME
  ```

- Assume the following conditions:
  - A table reference is an application-period temporal table.
  - The columns of the BUSINESS_TIME period are defined as DATE.
  - The CURRENT TEMPORAL BUSINESS_TIME special register is set to a non-null value.

  In this case, a query is executed as if it contained the following specification:

  ```sql
  FOR BUSINESS_TIME AS OF CAST(CURRENT TEMPORAL BUSINESS_TIME AS DATE)
  ```

- If the CURRENT TEMPORAL SYSTEM_TIME special register is set to a non-null value, a query is executed as if it contained the following specification:

  ```sql
  FOR SYSTEM_TIME AS OF CURRENT TEMPORAL SYSTEM_TIME
  ```

**Related reference:**

1090 SQL Reference
Examples of subselects

correlation-clause:

Each correlation-name in a correlation-clause defines a designator for the immediately preceding result table, which can be used to qualify references to the columns of the table.

The preceding result table is one of the following objects:

- A table
- A view
- A nested table expression
- A table function
- A data-change table reference
- A collection-derived table

new-column-name is an SQL identifier of 128 UTF-8 bytes or less. Using new-column-name to list and rename the columns is optional. A correlation name must be specified for nested table expressions and references to table functions.

If correlation-name is not specified for a data-change table reference, the correlation name is the name of the target table or view of the SQL data change statement. Otherwise, the correlation name is correlation-name.

If a new-column-name list is specified in correlation-clause, the number of names must be the same as the number of columns in the corresponding object. Each name must be unique and unqualified. If columns are added to an underlying table of a table-reference, the number of columns in the result of the table-reference no longer matches the number of names in its correlation-clause. Therefore, when a rebind of a package containing the query in question is attempted, Db2 returns an error and the rebind fails. At that point, change the correlation-clause of the embedded SQL statement in the application program so that the number of names matches the number of columns. Then prepare the modified program again.

An exposed name is a correlation-name or a table-name or view name that is not followed by a correlation-name. The exposed names in a FROM clause must be unique. Any qualified reference to a column for a table, view, nested table expression, table function, data-change table reference, or collection-derived table must use the exposed name.

If the same table name or view name is specified twice, at least one specification must be followed by a correlation-name. The correlation-name is used to qualify references to the columns of the table or view.
When a correlation-name is specified, column names can also be specified to give names to the columns of the table-name, view-name, nested-table-expression, table-function, data-change-table-reference, or collection-derived-table. If a column list is specified, there must be a name in the column list for each column in the table or view and for each result column in the table-function, data-change-table-reference, or collection-derived-table.

For more information, see “Correlation names” on page 228.

In general, nested-table-expression, table-function, data-change-table-reference, or collection-derived-table can be specified in any FROM clause. Columns from the nested-table-expression, table-function, data-change-table-reference, or collection-derived-table can be referenced in the SELECT list and in the rest of the subselect using a correlation name. The scope of this correlation name is the same as correlation names for other table or view names in the FROM clause.

- SET assignment-statement
- table-reference

**typed-correlation-clause:**

A typed-correlation-clause defines the appearance and contents of the table generated by a generic table function.

**typed-correlation-clause:**

```
AS correlation-name (column-name data-type)
```

**data-type:**
**typed-correlation-clause**

The *typed-correlation-clause* defines the appearance and contents of the table that is generated by a generic table function. *typed-correlation-clause* must be specified when the *table-function-reference* is a generic table function and cannot be specified for any other table reference.

The maximum number of columns specified in the *typed-correlation-clause* is 750, an error is returned if the number of specified columns exceeds the limit.

An error is returned if duplicate column names are specified in a *typed-correlation-clause*.

An error is returned if the data type that is specified for a column name is not one of the supported data types for a generic table function.

**Related reference:**

[CREATE FUNCTION (external table)]

**collection-derived-table**

A *collection-derived table* is used to convert the elements of one or more arrays into column values in separate rows of an intermediate result table.
collection-derived-table:

```
UNNEST(ordinary-array-expression) WITH ORDINALITY
```

Notes:

1. WITH ORDINALITY can be specified only if the argument to UNNEST is ordinary-array-expression. associative-array-expression must not be specified when WITH ORDINALITY is also specified.

WITH ORDINALITY

Specifies that an extra column of data type INTEGER is returned as the last column in the result table. This column contains the position of the element in the array.

correlation-clause

Specifies the correlation name that is to be used as a table designator for the result table of the collection derived table, and a list of column names for the result table. The correlation name can be used to qualify references to the columns of the result table.

The result columns can be referenced in the SELECT list, and in the rest of the subselect by using the names that are specified for the columns in the correlation clause.

A collection-derived table can be specified as a table reference in a FROM clause, in a context where arrays are supported.

The intermediate result table is derived as follows:

- If a single expression that returns an ordinary array is specified, the intermediate result table is a single-column table with a column data type that matches the array element data type.
- If multiple expressions that return an ordinary array are specified:
  - The first array provides the first column in the result table, the second array provides the second column, and so on.
  - The data type of each column matches the data type of the array elements of the corresponding array argument.
  - If the cardinalities of the arrays are not identical, the cardinality of the resulting table is the same as the array with the largest cardinality.
  - The column values in the table are set to the null value for all rows whose array index value is greater than the cardinality of the corresponding array. In other words, if each array is viewed as a table with two columns, one for the array indexes and one for the data, UNNEST performs an outer join among the arrays, using equality on the array indexes as a join predicate.
If a single *associative-array-expression* or an *array-function-invocation* that returns an associative array is specified:
- The intermediate result table is a table with two columns, where the first column data type matches the array index data type, and the second column data type matches the array element data type.
- The first column contains the indexes of the elements in the array.
- The second column contains the elements in the array.
- The columns can be referenced in the SELECT list and the in rest of the subselect by using the names that are specified for the columns in the *correlation-clause*.

If all arguments are null arrays, the result is an empty table.

The intermediate result table that is produced by an invocation of UNNEST must not result in more than 750 columns.

An *array-function-invocation* is a function invocation that resolves to a function that returns an ordinary or an associative array type. An *array-function-invocation* must not include a reference to a column of a common table expression.

**ordinary-array-expression**
Specifies one of the following items:
- An SQL variable
- An SQL parameter
- A global variable of an ordinary array type
- An *array-function-invocation*
- A CAST specification of a parameter marker to an ordinary array type

**associative-array-expression**
Specifies one of the following items:
- An SQL variable
- An SQL parameter
- A global variable of an associative array type
- An *array-function-invocation*
- A CAST specification of a parameter marker to an associative array type

Names for the result columns that are produced by an UNNEST specification can be provided as part of the *correlation-clause* of the *collection-derived-table* clause.

*Example 1:* Suppose that PHONENUMBERS is a user-defined array type that is defined as an ordinary array. RECENT_CALLS is an array variable of the PHONENUMBERS type. RECENT_CALLS contains the following phone numbers:
- 9055553907
- 4165554213
- 4085553678

The following SELECT statement uses UNNEST to retrieve the list of phone numbers from the array:
```
SELECT T.ID, T.NUM
FROM UNNEST(RECENT_CALLS) WITH ORDINALITY AS T(NUM, ID);
```

The WITH ORDINALITY clause indicates that the result table is to include an additional column that reflects the ordinal position of each array element in the array. The additional column is the last column of the result table from the
UNNEST operation. The correlation clause that follows the WITH ORDINALITY clause specifies that the additional column is named ID, and the array element column is named NUM. These column names can be explicitly referenced in the SELECT list of the query. The SELECT list in this example reorders the columns from the result of UNNEST. The result table looks like this:

<table>
<thead>
<tr>
<th>ID</th>
<th>NUM</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>9055553907</td>
</tr>
<tr>
<td>2</td>
<td>4165554213</td>
</tr>
<tr>
<td>3</td>
<td>4085553678</td>
</tr>
</tbody>
</table>

In the SELECT statement, the columns that result from the UNNEST operation have been reordered in the SELECT list, so that the column that reflects the position of each array element is the first column of the final result table.

**Example 2:** Suppose that PERSONAL_PHONENUMBERS is a user-defined array type that is defined as an associative array. PHONELIST is an array variable of the PERSONAL_PHONENUMBERS type. Values have been assigned to the elements of PHONELIST with the following statements:

```sql
SET PHONELIST['Home'] = '4443051234';
SET PHONELIST['Work'] = '4443052345';
SET PHONELIST['Cell'] = '4447893456';
```

The following SELECT statement is executed:

```sql
SELECT T.ID, TPHONE
  FROM UNNEST(PHONELIST) AS T(ID, PHONE);
```

The result table looks like this, although the order of rows might differ:

<table>
<thead>
<tr>
<th>ID</th>
<th>PHONE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cell</td>
<td>4447893456</td>
</tr>
<tr>
<td>Home</td>
<td>4443051234</td>
</tr>
<tr>
<td>Work</td>
<td>4443052345</td>
</tr>
</tbody>
</table>

**Example 3:** Suppose that PHONES and IDS are two SQL variables with array values of the same cardinality. The following SQL statement converts the array contents into a table with three columns (one for each array and one for the position), and one row for each array element.

The following SELECT statement is executed:

```sql
SELECT T.PHONE, T.ID, T.INDEX
  FROM UNNEST(PHONES, IDS)
  WITH ORDINALITY AS T(PHONE, ID, INDEX)
  ORDER BY T.INDEX;
```

**Related reference:**
- [SET assignment-statement]
- [table-reference]

**joined-table**

A *joined-table* specifies an intermediate result table that is the result of either an inner join, an outer join, or a cross join. The table is derived by applying one of the join operators: INNER, LEFT OUTER, RIGHT OUTER, FULL OUTER, or CROSS to its operands.
Cross joins represent the cross product of the tables, where each row of the left table is combined with every row of the right table. Inner joins can be thought of as the cross product of the tables, keeping only the rows where the join condition is true. The result table might be missing rows from either or both of the joined tables. Outer joins include the rows produced by the inner join as well as the missing rows, depending on the type of outer join as follows:

**Left outer join**
Includes rows from the left table that were missing from the inner join.

**Right outer join**
Includes rows from the right table that were missing from the inner join.

**Full outer join**
Includes rows from both the left and right tables that were missing from the inner join.

If a join operator is not specified, INNER is the default. The order in which a LEFT OUTER JOIN or RIGHT OUTER JOIN is performed can affect the result.

*A joined-table* can be used in any context in which any form of the SELECT statement is used. Both a view and a cursor is read-only if its SELECT statement includes a *joined-table*.

If LEFT OUTER JOIN, RIGHT OUTER JOIN, or FULL OUTER JOIN is specified:
- A ROW CHANGE TIMESTAMP expression can only be referenced in a subselect of the outer join if the table designator identifies a base table that includes a row change timestamp column.
- The RID built-in function and the ROW CHANGE TOKEN expression must not be specified in the subselect that contains the FROM clause.

**Related concepts:**
- Investigating join operations (Db2 Performance)

**Related tasks:**
- Joining data from more than one table (Db2 Application programming and SQL)

**Related reference:**
- Examples of subselects
**join-condition:**

*join-condition* specifies the conditions of a join that is used in a query.

**join-condition**

For INNER, LEFT OUTER, and RIGHT OUTER joins:

```
search-condition
```

For FULL OUTER joins:

```
AND
```

```
full-join-expression = full-join-expression
```

**full-join-expression:**

```
cast-function
```

```
COALESCE(column-name, column-name)
```

**Notes:**

1. *cast-function* must only contain a column and the casting data type must be a distinct type or the data type upon which the distinct type was based.

For INNER, LEFT OUTER, and RIGHT OUTER joins, the *join-condition* is a *search-condition* that must conform to these rules:

- With one exception, it cannot contain any subqueries. If the *join-table* that contains the *join-condition* in the associated FROM clause is composed of only INNER joins, the *join-condition* can contain subqueries.
• Any column that is referenced in an expression of the join-condition must be a column of one of the operand tables of the associated join operator (in the scope of the same joined-table clause).

For a FULL OUTER (or FULL) join, the join-condition is a search condition in which the predicates can only be combined with AND. In addition, each predicate must have the form 'expression = expression', where one expression references only columns of one of the operand tables of the associated join operator, and the other expression references only columns of the other operand table. The values of the expressions must be comparable. Implicit cast between numeric and string data types is not supported for FULL OUTER join.

Each full-join-expression in a FULL OUTER join must include a column name or a cast function that references a column. The COALESCE function is allowed.

For any type of join, column references in an expression of the join-condition are resolved using the rules for resolution of column name qualifiers specified in "Resolution of column name qualifiers and column names” on page 232 before any rules about which tables the columns must belong to are applied.

Related reference:
Examples of subselects

Join operations:

A join-condition specifies pairings of T1 and T2, where T1 and T2 are the left and right operand tables of its associated JOIN operator. For all possible combinations of rows T1 and T2, a row of T1 is paired with a row of T2 if the join-condition is true.

When a row of T1 is joined with a row of T2, a row in the result consists of the values of that row of T1 concatenated with the values of that row of T2. The execution might involve the generation of a null row. The null row of a table consists of a null value for each column of the table, regardless of whether the columns allow null values.

The following summarizes the results of the join operations:
• The result of T1 INNER JOIN T2 consists of their paired rows.
• The result of T1 LEFT OUTER JOIN T2 consists of their paired rows and, for each unpaired row of T1, the concatenation of that row with the null row of T2. All columns derived from T2 allow null values.
• The result of T1 RIGHT OUTER JOIN T2 consists of their paired rows and, for each unpaired row of T2, the concatenation of that row with the null row of T1. All columns derived from T1 allow null values.
• The result of T1 FULL OUTER JOIN T2 consists of their paired rows and, for each unpaired row of T1, the concatenation of that row with the null row of T2, and for each unpaired row of T2, the concatenation of that row with the null row in T1. All columns of the result table allow null values.
• The result of T1 CROSS JOIN T2 consists of each row of T1 paired with each row of T2. CROSS JOIN is also known as Cartesian product.

A join operation is part of a FROM clause. For the purpose of predicting which rows will be returned from a SELECT statement containing a join operation, assume that the join operation is performed before the other clauses in the statement.
A cross join can also be specified without the CROSS JOIN syntax, by listing the two tables in the FROM clause separated by commas without using a WHERE clause to supply join criteria.

Related reference:
Examples of subselects

where-clause
The WHERE clause specifies a result table that consists of those rows of R for which the search condition is true. R is the result of the FROM clause of the subselect.

The search condition must conform to the following rules:
- Each column name must unambiguously identify a column of R or be a correlated reference. A column name is a correlated reference if it identifies a column of a table, view, common-table-expression, or nested-table-expression that is identified in an outer subselect.
- An aggregate function must not be specified unless the WHERE clause is specified in a subquery of a HAVING clause and the argument of the function is a correlated reference to a group.

Any subquery in the search-condition is effectively executed for each row of R and the results are used in the application of the search-condition to the given row of R. A subquery is actually executed for each row of R only if it includes a correlated reference. In fact, a subquery with no correlated references is executed just one time, whereas a subquery with a correlated reference might have to be executed one time for each row.

If row access controls are enabled for a table and no other row permission is defined, the row access control search condition is the default row permission, 1 = 0. If only one row permission is defined, the row access control search condition is the search conditions that are specified by that permission. Otherwise, if multiple row permissions are defined for a table, the row access control search condition is derived by application of the logical OR operator to the search conditions that are specified by each row permission. This row access control search condition, as a whole, is connected by application of the logical AND operator to the search conditions specified by the WHERE clause and has the same precedence level as other search conditions in the WHERE clause. This process is repeated for each table-reference in the FROM clause of the subselect for which row access controls are enabled.

The row access control search condition acts as a filter to the table-reference to determine the results of the table-reference that are accessible to the authorization ID or role of the subselect. Because the order in which operators are evaluated is undefined for operators at the same precedence level, other search conditions in the WHERE clause might be evaluated before the row access control search condition. So, the other search conditions have access to the rows that are restricted by the row permission rules. To ensure that sensitive data is protected, the
predicates that reference user-defined functions that are defined with the NOT SECURED option are always evaluated after the row access control search condition.

The column access control does not affect the operation of the WHERE clause.

Related tasks:
- Writing efficient subqueries (Db2 Performance)

Related reference:
- Examples of subselects

**group-by-clause**

The GROUP BY clause specifies a result table that consists of a grouping of the rows of intermediate result table that is the result of the previous clause.

In its simplest form, a GROUP BY clause contains a grouping-expression.

**grouping-expression**

A grouping-expression is an expression that defines the grouping of R. The following restrictions apply to grouping-expression:

- If grouping-expression is a single column, the column name must unambiguously identify a column of R.
- The result of grouping-expression cannot be a LOB data type (or a distinct type that is based on a LOB) or an XML data type.
- grouping-expression cannot include any of the following items:
  - A correlated column
  - A host variable
  - An aggregate function
  - Any function or expression that is not deterministic or that is defined to have an external action
  - A scalar fullselect
  - A CASE expression whose searched-when-clause contains a quantified predicate, an IN predicate using a fullselect, or an EXISTS predicate

More complex forms of the GROUP BY clause include grouping-sets and super-groups.

The result of GROUP BY is a set of groups of rows. In each group of more than one row, all values of each grouping-expression are equal, and all rows with the
same set of values of the grouping-expression are in the same group. For grouping, all null values for a grouping-expression are considered equal.

If a grouping-expression contains DECFLOAT values, the DECFLOAT values with the same value will be in the same group. But the number of digits returned for each group is unpredictable.

Because every row of a group contains the same value of any grouping-expression, a grouping-expression can be used in a search condition in a HAVING clause or an expression in a SELECT clause, or in a sort-key-expression of an ORDER BY clause. In each case, the reference specifies only one value for each group. For example, if grouping-expression is col1+col2, col1+col2+3 would be an allowed expression in the select list. Associative rules for expressions do not allow the similar expression of 3+col1+col2, unless parentheses are used to ensure that the corresponding expression is evaluated in the same order. Thus, 3+(col1+col2) would also be allowed in the select list. If the concatenation operator is used, grouping-expression must be used exactly as the expression was specified in the select list.

If a grouping-expression contains varying-length strings with trailing blanks, the values in the group can differ in the number of trailing blanks and might not all have the same length. In that case, a reference to grouping-expression still specifies only one value for each group, but the value for a group is chosen arbitrarily from the available set of values. Thus, the actual length of the result value is unpredictable.

Row access controls do not affect the operation of the GROUP BY clause.

Related links:
- select-clause
- Examples of subselects

**grouping-sets**

A grouping-sets specification can be used to specify multiple grouping clauses in a single statement. This can be thought of as the union of two or more groups of rows into a single result set. It is logically equivalent to the union of multiple subselects with the GROUP BY clause in each subselect corresponding to one grouping set. A grouping set can be a single element or can be a list of elements delimited by parentheses, where an element is either a grouping-expression or a super-group. The groups can be computed with a single pass over the base table using grouping-sets.

Grouping sets are the fundamental building blocks for GROUP BY operations. A simple GROUP BY with a single column can be considered a grouping set with one element. For example, the following clauses are equivalent:
Simple GROUP BY clause | Equivalent GROUPING SETS clause
---|---
GROUP BY a | GROUP BY GROUPING SETS((a))
GROUP BY a,b,c | GROUP BY GROUPING SETS((a,b,c))

Non-aggregation columns from the select list of the subselect that are excluded from a grouping set will return a null for such columns for each row generated for that grouping set. This reflects the fact that aggregation was done without considering the values for those columns.

If GROUPING SETS is specified, a table-reference in the associated FROM clause must not contain a column defined with a field procedure.

Related links:
- Examples of grouping sets, rollup, and cube queries

**super-groups**

ROLLUP (grouping-expression-list)

CUBE (grouping-expression-list)

grand-total:

Notes:
1. Alternate specification when used alone in a group-by-clause is: grouping-expression-list WITH ROLLUP.
2. Alternate specification when used alone in group-by-clause is: grouping-expression-list WITH CUBE.

ROLLUP (grouping-expression-list)

A ROLLUP grouping produces a result set that contains sub-total rows in addition to the “regular” grouped rows. Sub-total rows are “super-aggregate” rows that contain further aggregates whose values are derived by applying the same aggregate functions that were used to obtain the grouped rows. These rows are called sub-total rows, because that is their most common use. However, any aggregate function can be used for the aggregation.

A ROLLUP grouping is a series of grouping-sets. The $n$ elements of the ROLLUP translate to $n+1$ grouping sets.
The general specification of a ROLLUP with \( n \) elements, as shown in the first column of the following table, is equivalent to the \( n+1 \) grouping sets as shown in the second column of the table:

<table>
<thead>
<tr>
<th>ROLLUP clause with ( n ) elements</th>
<th>Equivalent GROUPING SETS clause</th>
</tr>
</thead>
</table>
| GROUP BY ROLLUP\((C_1, C_2, \ldots, C_{n-1}, C_n)\) | GROUP BY GROUPING SETS\(((C_1, C_2, \ldots, C_{n-1}, C_n)\)\)  
| \( \vdots \) | \( (C_1, C_2) \)  
| \( (C_j) \) | \( () \) |

**Note:** The order in which the elements of the grouping-expression-list are specified is significant for ROLLUP. As the following table shows, the initial element in the grouping-expression-list for the ROLLUP is the final element in the GROUPING SET.

<table>
<thead>
<tr>
<th>ROLLUP clause</th>
<th>Equivalent GROUPING SETS clause</th>
</tr>
</thead>
<tbody>
<tr>
<td>GROUP BY ROLLUP((a, b))</td>
<td>GROUP BY GROUPING SETS(((a, b)) ( (a) ) ( () )</td>
</tr>
<tr>
<td>GROUP BY ROLLUP((b, a))</td>
<td>GROUP BY GROUPING SETS(((b, a)) ( (b) ) ( () )</td>
</tr>
</tbody>
</table>

The ORDER BY clause is the only way to guarantee the order of the rows in the result set.

**Related links:**
- GROUPING
- order-by-clause
- Examples of grouping sets, rollup, and cube queries

**CUBE** (grouping-expression-list)

A CUBE grouping produces a result set that contains all the rows of a ROLLUP aggregation and, in addition, contains “cross-tabulation” rows. Cross-tabulation rows are additional “super-aggregate” rows that are not part of an aggregation with sub-totals.

Similar to a ROLLUP, a CUBE grouping can also be thought of as a series of grouping-sets. In the case of a CUBE, all permutations of the cubed grouping-expression-list are computed along with the grand total. Therefore, the \( n \) elements of a CUBE translate to \( 2^n \) grouping-sets.

For example, the following clauses are equivalent:

<table>
<thead>
<tr>
<th>CUBE clause</th>
<th>Equivalent GROUPING SETS clause</th>
</tr>
</thead>
<tbody>
<tr>
<td>GROUP BY CUBE((a, b, c))</td>
<td>GROUP BY GROUPING SETS(((a, b, c)) ( (a, b) ) ( (a, c) ) ( (b, c) ) ( (a) ) ( (b) ) ( (c) ) ( () )</td>
</tr>
</tbody>
</table>

**Note:** The three elements of the CUBE translate into eight grouping sets.
The order specified for the elements does not matter for CUBE. CUBE (DayOfYear, Sales_Person) and CUBE (Sales_Person, DayOfYear) yield the same result sets (the result sets might not be in the same order).

The ORDER BY clause is the only way to guarantee the order of the rows in the result set.

**Related links:**
- [GROUPING](#)
- [orderBy-clause](#)
- [Examples of grouping sets, rollup, and cube queries](#)

**grouping-expression-list**

A grouping-expression-list is used within a ROLLUP or CUBE clause to define the number of elements in the ROLLUP or CUBE operation. The number of elements is controlled by using parentheses to delimit elements with multiple grouping-expression elements.

For example, suppose that a query is to return the total expenses for the ROLLUP of City within Province but not within County. Without a grouping-expression-list, the following clause results in unwanted subtotal rows for County:

```
GROUP BY ROLLUP(Province, County, City)
```

Compare the equivalent GROUPING SETS clause:

```
GROUP BY GROUPING SETS((Province, County, City)
                     (Province, County)
                     (Province)
                     () )
```

In the following clause, the composite (County, City) forms one element in the ROLLUP clause and, therefore, a query that uses the following clause will yield the required result:

```
GROUP BY ROLLUP(Province, (County, City))
```

In other words, this is a two-element ROLLUP, which is equivalent to the following GROUPING SETS clause:

```
GROUP BY GROUPING SETS((Province, County, City)
                     (Province)
                     () )
```

**Related links:**
- [GROUPING](#)
- [orderBy-clause](#)
- [Examples of grouping sets, rollup, and cube queries](#)

**grand-total**

Both ROLLUP and CUBE return a row which is the overall aggregation (grand total). This can be separately specified with empty parentheses within the GROUPING SETS clause. It can also be specified directly in the GROUP BY clause, although there is no effect on the result of the query.

**Related links:**
- [Examples of grouping sets, rollup, and cube queries](#)
Combined groupings

The different types of GROUP BY clause can be combined. When simple grouping-expression expressions are combined with other groups, those expressions are prepended to the resulting grouping sets. When ROLLUP or CUBE expressions are combined, those expressions form additional grouping set entries on the remaining expression, according to the definition of either a ROLLUP expression or a CUBE expression.

Table 161. Combined grouping-expression and equivalent GROUPING SETS clauses

<table>
<thead>
<tr>
<th>GROUP BY clause with combined grouping-expression</th>
<th>Equivalent GROUP BY clause with GROUPING SETS clause</th>
</tr>
</thead>
<tbody>
<tr>
<td>GROUP BY a, ROLLUP(b,c)</td>
<td>GROUP BY GROUPING SETS((a,b,c) (a,b) (a))</td>
</tr>
<tr>
<td>GROUP BY a, b, ROLLUP(c,d)</td>
<td>GROUP BY GROUPING SETS((a,b,c,d) (a,b,c) (a,b))</td>
</tr>
<tr>
<td>GROUP BY ROLLUP(a), ROLLUP(b,c)</td>
<td>GROUP BY GROUPING SETS((a,b,c) (a,b) (a) (b,c) (b) (c) (a))</td>
</tr>
<tr>
<td>GROUP BY ROLLUP(a), CUBE(b,c)</td>
<td>GROUP BY GROUPING SETS((a,b,c) (a,b) (a,c) (a) (b,c) (b) (c) (a))</td>
</tr>
<tr>
<td>GROUP BY CUBE(a,b), ROLLUP(c,d)</td>
<td>GROUP BY GROUPING SETS((a,b,c,d) (a,b,c) (a,b) (a,c) (a,c,d) (a,c) (a) (b,c,d) (b,c) (b,c) (c,d) (c) (c) (a) (b) (c) (d) (a))</td>
</tr>
<tr>
<td>GROUP BY a, ROLLUP(a,b)</td>
<td>GROUP BY GROUPING SETS((a,b) (a))</td>
</tr>
</tbody>
</table>

1. Combined grouping sets also eliminate duplicates within each grouping set.

A more complete example of combining grouping sets is to construct a result set that eliminates certain rows that might be returned for a full CUBE aggregation. For example, consider the following GROUP BY clause:

GROUP BY Region,
ROLLUP(Sales_Person, WEEK(Sales_Date)),
CUBE(YEAR(Sales_Date), MONTH(Sales_Date))
The column listed immediately to the right of GROUP BY is grouped, the columns within the parenthesis following ROLLUP are rolled up, and the columns within the parenthesis following CUBE are cubed. Thus, the GROUP BY clause results in a cube of MONTH within YEAR which is then rolled up within WEEK within Sales_Person within the Region aggregation. This GROUP BY does not result in any grand total row or any cross-tabulation rows on Region, Sales_Person or WEEK(Sales_Date), so it produces fewer rows than the following clause:

```
GROUP BY ROLLUP (Region, Sales_Person, WEEK(Sales_Date),
                 YEAR(Sales_Date), MONTH(Sales_Date))
```

**having-clause**

The HAVING clause specifies a result table that consists of those groups of the intermediate result table for which the search-condition is true. The intermediate result table is the result of the previous clause. If this clause is not GROUP BY, the intermediate result table is considered a single group with no grouping columns of the previous clause of the subselect.

**having-clause**

```
HAVING—search-condition
```

Each `column-name` in `search-condition` must be one of the following:

- Unambiguously identify a grouping column of the intermediate result table
- Be specified within an aggregate function
- Be a correlated reference. A `column-name` is a correlated reference if it identifies a column of a table, view, `common-table-expression`, or `nested-table-expression` that is identified in an outer subselect

A group of the intermediate result table to which the search condition is applied supplies the argument for each function in the search condition, except for any function whose argument is a correlated reference.

If the search condition contains a subquery, the subquery can be thought of as being executed each time the search condition is applied to a group of the intermediate result table, and the results used in applying the search condition. In actuality, the subquery is executed for each group only if it contains a correlated reference. For an illustration of the difference, see [Example 4](#) and [Example 5](#).

A correlated reference to a group of the intermediate result table must either identify a grouping column or be contained within an aggregate function.

When HAVING is used without GROUP BY, any expression or column name in the select list must appear within an aggregate function.

The RID built-in function and the ROW CHANGE expression cannot be specified in a HAVING clause unless they are within an aggregate function.

Row access controls do not affect the operation of the HAVING clause.

**Related concepts:**

24. See [Chapter 4, “Built-in functions,” on page 361](#) for restrictions that apply to the use of aggregate functions.
Related tasks:
- Writing efficient subqueries (Db2 Performance)

Related reference:
- Examples of subselects

**order-by-clause**

The **ORDER BY** clause specifies an ordering of the rows of the result table.

```
ORDER BY sort-key
```

**sort-key:**

```
column-name
```

A subselect that contains an **ORDER BY** clause cannot be specified in the outermost fullselect of a view.

If the subselect is not enclosed within parentheses and is not the outermost fullselect, the **ORDER BY** clause cannot be specified. The **ORDER BY** clause cannot be used in an outermost fullselect that contains a **FOR UPDATE** clause.

An **ORDER BY** clause that is specified in a subselect only affects the order of the rows that are returned by the query if the subselect is the outermost fullselect, except when a nested subselect includes an **ORDER BY** clause and the outermost fullselect specifies that the ordering of the rows should be retained (by using the **ORDER OF table-designator** clause).

Multiple **ORDER BY** clauses can be specified in the same subselect if each clause is separated with parentheses.

**INPUT SEQUENCE**

Indicates that the result table reflects the input order of the rows specified in
the VALUES clause of an INSERT statement. INPUT SEQUENCE ordering can be specified only when an INSERT statement is specified in a FROM-clause.

ORDER OF table-designator

Specifies that the same ordering of the rows for the result table that is designated by table-designator should be applied to the result table of the subselect (or fullselect) that contains the ORDER OF specification. There must be a table reference in the FROM clause of the subselect (or fullselect) that specifies this clause and matches table-designator.

For an ORDER BY clause in an OLAP specification, table-designator must not specify a table function, a collection-derived table, a materialized view, a nested table expression that is materialized, an alias, or a synonym.

sort-key

A column-name, integer, or sort-key-expression that specifies the value that is to be used to order the rows of the result of the subselect.

If a single sort-key is identified, the rows are ordered by the values of that sort-key. If more than one sort-key is identified, the rows are ordered by the values of the first sort-key, then by the values of the second sort-key, and so on. A sort-key cannot be a LOB or XML expression.

The result table can be ordered by a named column in the select list by specifying a sort-key that is an integer or the column name. The result table can be ordered by an unnamed column in the select list by specifying a sort-key that is an integer or, in some cases, by a sort-key-expression that matches the expression in the select list.

column-name

An identifier that usually identifies a column of the result table. In this case, column-name must be the name of a named column in the select list. If the fullselect includes a set operator, the column name cannot be qualified.

If the query is a subselect, the column-name can also identify a column name of a table, view, or nested table expression identified in the FROM clause, including a column that is defined as implicitly hidden. The subselect must not include any of the following:
- DISTINCT in the select list
- Aggregate functions in the select list
- GROUP BY clause

integer

An unsigned integer that must be greater than 0 and not greater than the number of columns in the result table. The integer n identifies the nth column of the result table.

sort-key-expression

An expression that is not simply a column-name or unsigned integer constant. The query to which ordering is applied must be a subselect to use this form of the sort-key.

The sort-key-expression cannot include an expression that is not deterministic or a function that is defined to have an external action except for the RID built-in function and the ROW CHANGE expression. Any column name in the expression must conform to the rules described Column names in sort keys If sort-key-expression includes an aggregate function, the input arguments to that function must not reference a named column in the select list that is derived from an aggregate function.
If DISTINCT is used in the select list of the subselect, sort-key-expression must match an expression in the select list of the subselect. Scalar-fullselects are never matched.

If the subselect is grouped, the sort-key-expression might or might not be in the select list of the subselect. When sort-key-expression is not in the select list the following rules apply:

- Each expression in the ORDER BY clause must either:
  - Use one or more grouping expressions
  - Use a column name that either unambiguously identifies a grouping column of R or is specified within a aggregate function.
- Each expression in the ORDER BY clause must not contain a scalar fullselect.

ASC

Uses the values of the sort-key in ascending order.

ASC is the default.

DESC

Uses the values of the sort-key in descending order.

Ordering is performed in accordance with the comparison rules described in Chapter 2, “Language elements,” on page 81, beginning on page “Numeric comparisons” on page 164. The null value is higher than all other values. If your ordering specification does not determine a complete ordering, rows with duplicate values of the last identified sort-key have an arbitrary order. If you do not specify ORDER BY, the rows of the result table have an arbitrary order.

Column access controls do not effect the operation of the ORDER BY clause. The order is based on the original column values. However, after column masks are applied, the masked values in the final result table might not reflect the order of the original column values.

Column names in sort keys: A column name in a sort-key must conform to the following rules:

- If the column name is qualified, the query must be a subselect. The column name must unambiguously identify a column of a table, view, or nested table expression in the FROM clause of the subselect; its value is used to compute the value of the sort specification.
- If the column name is unqualified and the query is a subselect:
  - If the column name is identical to the name of more than one column of the result table, the column name must unambiguously identify a column of some table, view, or nested table expression in the FROM clause of the ordering subselect.
  - If the column name is identical is one column of the result table, its value is used to compute the value of the sort specification.
  - If the column name is not identical to a column in the result table, it must unambiguously identify a column of a table, view, or nested table expression in the FROM clause of the subselect. If the column name is identical to one column of a table, view, or nested table expression in the FROM clause of the subselect, its value is used to compute the value of the sort specification.

Related reference:

Examples of subselects
offset-clause

The OFFSET clause specifies the number of rows of the result table to skip before any rows are retrieved.

OFFSET offset-row-count

The offset clause specifies that the number of rows specified by offset-row-count should be skipped before rows are retrieved. If offset-clause is not specified, the default is equivalent to OFFSET 0 ROWS. If offset-row-count specifies more rows than the number of rows in the intermediate result table, the intermediate result table is treated as an empty result table.

offset-row-count

A constant or variable that specifies the number of rows to skip before any rows are retrieved. offset-row-count must be a numeric value that is a positive number or zero. If the value is not a BIGINT value, the value is cast to a BIGINT value. offset-row-count must not be the null value.

When the OFFSET clause is specified as a prepare attribute, offset-row-count must not reference a variable.

A subselect or fullselect that contains an offset-clause is only allowed as the outermost fullselect in a prepared SQL statement or a DECLARE CURSOR statement. A subselect or fullselect that contains an offset-clause is not allowed in other contexts including the following contexts:

- The definition of a view
- The definition of a materialized query table
- The RETURN statement of an SQL table function
- The definition of a row permission
- The definition of a column mask
- The outermost fullselect for a sensitive dynamic cursor

An offset-clause can also be specified in a SELECT INTO statement.

If a subselect, fullselect, or SELECT INTO statement includes an offset-clause, the select list of that subselect, fullselect, or SELECT INTO statement must not contain an expression that is not deterministic or that has external action.

If the fullselect contains an SQL data change statement in the FROM clause, all rows of the result table are modified regardless of the number of rows to skip.

The OFFSET clause must not be specified in the outer fullselect for a sensitive dynamic scrollable cursor.

Determining a predictable set of rows to skip requires the specification of an ORDER BY clause with sort keys that uniquely identify the sort order of each row.
in the intermediate result table. If the intermediate result table includes duplicate sort keys for some rows, the order of these rows is not deterministic. If there is no ORDER BY clause, the intermediate result table is not in a deterministic order. If the order of the intermediate result table is not deterministic, the set of skipped rows is unpredictable.

If both the offset-clause and the ORDER BY clause are specified, the ordering is performed on the entire result table prior to skipping the specified number of rows.

Row access controls can indirectly affect the offset-clause because row access controls affect the rows that are accessible to the authorization ID or role of the fullselect. Column access controls do not affect the offset-clause.

The offset-clause can be used to return rows from a point in the result table to the end of the result table. In this case, the fetch-clause is not specified.

Notes
Syntax alternatives:
See the fetch-clause for alternative syntax to set the number of rows to skip when specifying the maximum number of rows to retrieve.

Related tasks:
Fetching a limited number of rows (Db2 Performance)

Related reference:
Examples of subselects

fetch-clause
The fetch-clause clause limits the number of rows that can be fetched.

| ►► FETCH | FIRST | NEXT | fetch-row-count | ROW | ONLY | ROWS |

The fetch-clause sets a maximum number of rows that can be retrieved. It specifies that an application does not want to retrieve more than fetch-row-count rows, regardless of how many rows there might be in the intermediate result table when this clause is not specified. An attempt to fetch beyond fetch-row-count rows is handled the same way as normal end of data.

A subselect or fullselect that contains a fetch-clause cannot be specified in the following objects:
- The outermost fullselect of a view
- The definition of a materialized query table

A fetch-clause can also be specified in a SELECT INTO statement.

Determining a predictable set of rows to retrieve requires the specification of an ORDER BY clause with sort keys that would uniquely identify the sort order of
each row in the intermediate result table. If the intermediate result table includes
duplicate sort keys for some rows, the order of these rows is not deterministic. If
there is no ORDER BY clause, the intermediate result table is not in a deterministic
order. If the order of the intermediate result table is not deterministic, the set of
rows retrieved is unpredictable. If both the fetch-clause and the ORDER BY clause
are specified, the fetch-clause is processed on the ordered data.

If the fullselect contains an SQL data change statement in the FROM clause, all the
rows are modified regardless of the number of rows fetched.

`fetch-row-count`
A constant or variable that specifies the maximum number of rows to
retrieve. `fetch-row-count` must be a numeric value that is a positive number
or zero. If the value is not BIGINT, the value is cast to a BIGINT value.
`fetch-row-count` must not be the null value.

Use of the fetch-clause with a constant for `fetch-row-count` that is not greater than
the maximum big integer influences query optimization of the subselect or
fullselect, based on the fact that, at most, a known number of rows will be
retrieved.

Limiting the result table to a specified number of rows can improve performance.
In some cases, the database manager will cease processing the query when it has
determined the specified number of rows. If the `offset-clause` is also specified with a
constant for `offset-row-count`, the database manager will also consider the offset
value constant in determining when to cease processing.

Row access controls can indirectly affect the fetch-clause because row access
controls affect the rows that are accessible to the authorization ID or role of the
subselect or fullselect. Column access controls do no affect the fetch-clause.

**Notes:**

**Syntax alternatives:**

- The keywords FIRST and NEXT can be used interchangeably. The result
  is unchanged; however, using the keyword NEXT is generally more
  readable when using the `offset-clause`.
- The keywords ROW and ROWS can be used interchangeably. The result
  is unchanged, however, using ROWS is generally more readable when
  associated with a number of rows other than 1.
- The following alternatives are supported for compatibility with SQL
  used by other database products. These alternatives are non-standard
  and should not be used.

<table>
<thead>
<tr>
<th>Alternative syntax</th>
<th>Equivalent syntax</th>
</tr>
</thead>
<tbody>
<tr>
<td>LIMIT x</td>
<td>FETCH FIRST x ROWS ONLY</td>
</tr>
<tr>
<td>LIMIT x OFFSET y</td>
<td>OFFSET y ROWS FETCH NEXT x ROWS ONLY</td>
</tr>
<tr>
<td>LIMIT y, x</td>
<td>OFFSET y ROWS FETCH NEXT x ROWS ONLY</td>
</tr>
</tbody>
</table>

**Related concepts:**

- [Fast implicit close (Db2 Performance)](#)

**Related tasks:**
Examples of subselects

Examples of subselects can illustrate how to use the various clauses of the subselect to construct queries.

**Example 1:** Show all rows of the table DSN8C10.EMP.

```
SELECT * FROM DSN8C10.EMP;
```

**Example 2:** Show the job code, maximum salary, and minimum salary for each group of rows of DSN8C10.EMP with the same job code, but only for groups with more than one row and with a maximum salary greater than 50000.

```
SELECT JOB, MAX(SALARY), MIN(SALARY)
FROM DSN8C10.EMP
GROUP BY JOB
HAVING COUNT(*) > 1 AND MAX(SALARY) > 50000;
```

**Example 3:** For each employee in department E11, get the following information from the table DSN8C10.EMPPROJECT: employee number, activity number, activity start date, and activity end date. Using the CHAR function, convert the start and end dates to their USA formats. Get the needed department information from the table DSN8C10.EMP.

```
SELECT EMPNO, ACTNO, CHAR(EMSTDATE,USA), CHAR(EMENDATE,USA)
FROM DSN8C10.EMPPROJECT
WHERE EMPNO IN (SELECT EMPNO FROM DSN8C10.EMP
                  WHERE WORKDEPT = 'E11');
```

**Example 4:** Show the department number and maximum departmental salary for all departments whose maximum salary is less than the average salary for all employees. (In this example, the subquery would be executed only one time.)

```
SELECT WORKDEPT, MAX(SALARY)
FROM DSN8C10.EMP
GROUP BY WORKDEPT
HAVING MAX(SALARY) < (SELECT AVG(SALARY)
                        FROM DSN8C10.EMP);
```

**Example 5:** Show the department number and maximum departmental salary for all departments whose maximum salary is less than the average salary for employees in all other departments. (In contrast to Example 4, the subquery in this statement, containing a correlated reference, would need to be executed for each group.)

```
SELECT WORKDEPT, MAX(SALARY)
FROM DSN8C10.EMP AS Q
GROUP BY WORKDEPT
HAVING MAX(SALARY) < (SELECT AVG(SALARY)
                        FROM DSN8C10.EMP
                        WHERE NOT WORKDEPT = Q.WORKDEPT);
```

**Example 6:** For each group of employees hired during the same year, show the year-of-hire and current average salary. (This example demonstrates how to use the AS clause in a FROM clause to name a derived column that you want to refer to in a GROUP BY clause.)
SELECT HIREYEAR, AVG(SALARY)
FROM (SELECT YEAR(HIREDATE) AS HIREYEAR, SALARY
      FROM DSN8C10.EMP) AS NEWEMP
GROUP BY HIREYEAR;

Example 7: For an example of how to group the results of a query by an expression in the SELECT clause without having to retype the expression, see Example 4 for CASE expressions.

Example 8: Get the employee number and employee name for all the employees in DSN8C10.EMP. Order the results by the date of hire.

SELECT EMPNO, FIRSTNME, LASTNAME
FROM DSN8C10.EMP
ORDER BY HIREDATE;

Example 9: Select all the rows from tables T1 and T2 and order the rows such that the rows from table T1 are first and are ordered by column C1, followed by the rows from T2, which are ordered by column C2. The rows of T1 are retrieved by one subselect which is connected to the results of another subselect that retrieves the rows from T2. Each subselect specifies the ordering for the rows from the referenced table. Note that both subselects need to be enclosed in parenthesis because each subselect is not the outermost fullselect.

(SELECT * FROM T1 ORDER BY C1)
UNION
(SELECT * FROM T2 ORDER BY C2);

Example 10: Specify the ORDER BY clause to order the results of a union using the second column of the result table if the union. In this example, the second ORDER BY clause applies to the results of the outermost fullselect (the result of the union) rather than to the second subselect. If the intent is to apply the second ORDER BY clause to the second subselect, the second subselect should be enclosed within parentheses as shown in Example 9.

(SELECT * FROM T1 ORDER BY C1)
UNION
SELECT * FROM T2 ORDER BY C2

Example 11: Retrieve all rows of table T1 with no specific ordering) and connect the result table to the rows of table T2, which have been ordered by the first column of table T2. The ORDER BY ORDER OF clause in the fullselect specifies that the order of the rows in the result table of the union is to be inherited by the final result.

SELECT *
FROM (SELECT * FROM T1
      UNION ALL
      (SELECT * FROM T2 ORDER BY 1)
    ) AS UTABLE
ORDER BY ORDER OF UTABLE;

Example 12: The following example uses a query to join data from a table to the result table of a nested table expression. The query uses the ORDER BY ORDER OF clause to order the rows of the result table using the order of the rows of the nested table expression.

SELECT T1.C1, T1.C2, TEMP.Cy, TEMP.Cx
FROM T1,
     (SELECT T2.C1, T2.C2 FROM T2 ORDER BY 2) AS TEMP(Cx, Cy)
WHERE Cy = T1.C1
ORDER BY ORDER OF TEMP;
Example 13: Using the EMP_ACT table, find the project numbers that have an employee whose salary is in the top three salaries for all employees.

```
SELECT EMP_ACT.EMPNO, PROJNO
FROM EMP_ACT
WHERE EMP_ACT.EMPNO IN
  (SELECT EMPLOYEE.EMPNO
   FROM EMPLOYEE
   ORDER BY SALARY DESC
   FETCH FIRST 3 ROWS ONLY);
```

Example 14: Assume that an external function named ADDYEARS exists. For a given date, the function adds a given number of years and returns a new date. (The data types of the two input parameters to the function are DATE and INTEGER.) Get the employee number and employee name for all employees who have been hired within the last 5 years.

```
SELECT EMPNO, FIRSTNME, LASTNAME
FROM DSN8C10.EMP
WHERE ADDYEARS(HIREDATE, 5) > CURRENT DATE;
```

To distinguish the different types of joins, to show nested table expressions, and to demonstrate how to combine join columns, the remaining examples use these two tables:

<table>
<thead>
<tr>
<th>The PARTS table</th>
<th>The PRODUCTS table</th>
</tr>
</thead>
<tbody>
<tr>
<td>PART</td>
<td>PROD#</td>
</tr>
<tr>
<td>WIRE</td>
<td>10</td>
</tr>
<tr>
<td>OIL</td>
<td>160</td>
</tr>
<tr>
<td>MAGNETS</td>
<td>10</td>
</tr>
<tr>
<td>PLASTIC</td>
<td>30</td>
</tr>
<tr>
<td>BLADES</td>
<td>205</td>
</tr>
</tbody>
</table>

Example 15: Join the tables on the PROD# column to get a table of parts with their suppliers and the products that use the parts:

```
SELECT PART, SUPPLIER, PARTS.PROD#, PRODUCT
FROM PARTS, PRODUCTS
WHERE PARTS.PROD# = PRODUCTS.PROD#;
```

or

```
SELECT PART, SUPPLIER, PARTS.PROD#, PRODUCT
FROM PARTS INNER JOIN PRODUCTS
ON PARTS.PROD# = PRODUCTS.PROD#;
```

Either one of these two statements give this result:

<table>
<thead>
<tr>
<th>PART</th>
<th>SUPPLIER</th>
<th>PROD#</th>
<th>PRODUCT</th>
</tr>
</thead>
<tbody>
<tr>
<td>WIRE</td>
<td>ACWF</td>
<td>10</td>
<td>GENERATOR</td>
</tr>
<tr>
<td>MAGNETS</td>
<td>BATEMAN</td>
<td>10</td>
<td>GENERATOR</td>
</tr>
<tr>
<td>PLASTIC</td>
<td>PLASTIK_CORP</td>
<td>30</td>
<td>RELAY</td>
</tr>
<tr>
<td>BLADES</td>
<td>ACE_STEEL</td>
<td>205</td>
<td>SAW</td>
</tr>
</tbody>
</table>

Notice two things about the example:

- There is a part in the parts table (OIL) whose product (#160) is not listed in the products table. There is a product (SCREWDRIVER, #505) that has no parts listed in the parts table. Neither OIL nor SCREWDRIVER appears in the result of the join.
- An outer join, however, includes rows where the values in the joined columns do not match.
There is explicit syntax to express that this familiar join is not an outer join but an inner join. You can use INNER JOIN in the FROM clause instead of the comma. Use ON when you explicitly join tables in the FROM clause.

You can specify more complicated join conditions to obtain different sets of results. For example, eliminate the suppliers that begin with the letter A from the table of parts, suppliers, product numbers and products:

```sql
SELECT PART, SUPPLIER, PARTS.PROD#, PRODUCT
FROM PARTS INNER JOIN PRODUCTS
    ON PARTS.PROD# = PRODUCTS.PROD#
    AND SUPPLIER NOT LIKE 'A%';
```

The result of the query is all rows that do not have a supplier that begins with A:

<table>
<thead>
<tr>
<th>PART</th>
<th>SUPPLIER</th>
<th>PROD#</th>
<th>PRODUCT</th>
</tr>
</thead>
<tbody>
<tr>
<td>MAGNETS</td>
<td>BATEMAN</td>
<td>10</td>
<td>GENERATOR</td>
</tr>
<tr>
<td>PLASTIC</td>
<td>PLASTIK_CORP</td>
<td>30</td>
<td>RELAY</td>
</tr>
</tbody>
</table>

Example 16: Join the tables on the PROD# column to get a table of all parts and products, showing the supplier information, if any.

```sql
SELECT PART, SUPPLIER, PARTS.PROD#, PRODUCT
FROM PARTS FULL OUTER JOIN PRODUCTS
    ON PARTS.PROD# = PRODUCTS.PROD#;
```

The result is:

<table>
<thead>
<tr>
<th>PART</th>
<th>SUPPLIER</th>
<th>PROD#</th>
<th>PRODUCT</th>
</tr>
</thead>
<tbody>
<tr>
<td>WIRE</td>
<td>ACWF</td>
<td>10</td>
<td>GENERATOR</td>
</tr>
<tr>
<td>MAGNETS</td>
<td>BATEMAN</td>
<td>10</td>
<td>GENERATOR</td>
</tr>
<tr>
<td>PLASTIC</td>
<td>PLASTIK_CORP</td>
<td>30</td>
<td>RELAY</td>
</tr>
<tr>
<td>BLADES</td>
<td>ACE_STEEL</td>
<td>205</td>
<td>SAW</td>
</tr>
<tr>
<td>OIL</td>
<td>WESTERN_CHEM</td>
<td>160</td>
<td>(null)</td>
</tr>
<tr>
<td>(null)</td>
<td>(null)</td>
<td>(null)</td>
<td>SCREWDRIVER</td>
</tr>
</tbody>
</table>

The clause FULL OUTER JOIN includes unmatched rows from both tables. Missing values in a row of the result table are filled with nulls.

Example 17: Join the tables on the PROD# column to get a table of all parts, showing what products, if any, the parts are used in:

```sql
SELECT PART, SUPPLIER, PARTS.PROD#, PRODUCT
FROM PARTS LEFT OUTER JOIN PRODUCTS
    ON PARTS.PROD# = PRODUCTS.PROD#;
```

The result is:

<table>
<thead>
<tr>
<th>PART</th>
<th>SUPPLIER</th>
<th>PROD#</th>
<th>PRODUCT</th>
</tr>
</thead>
<tbody>
<tr>
<td>WIRE</td>
<td>ACWF</td>
<td>10</td>
<td>GENERATOR</td>
</tr>
<tr>
<td>MAGNETS</td>
<td>BATEMAN</td>
<td>10</td>
<td>GENERATOR</td>
</tr>
<tr>
<td>PLASTIC</td>
<td>PLASTIK_CORP</td>
<td>30</td>
<td>RELAY</td>
</tr>
<tr>
<td>BLADES</td>
<td>ACE_STEEL</td>
<td>205</td>
<td>SAW</td>
</tr>
<tr>
<td>OIL</td>
<td>WESTERN_CHEM</td>
<td>160</td>
<td>(null)</td>
</tr>
<tr>
<td>(null)</td>
<td>(null)</td>
<td>(null)</td>
<td>SCREWDRIVER</td>
</tr>
</tbody>
</table>

The clause LEFT OUTER JOIN includes rows from the table identified before it where the values in the joined columns are not matched by values in the joined columns of the table identified after it.

Example 18: Join the tables on the PROD# column to get a table of all products, showing the parts used in that product, if any, and the supplier.
SELECT PART, SUPPLIER, PRODUCTS.PROD#, PRODUCT
FROM PARTS RIGHT OUTER JOIN PRODUCTS
ON PARTS.PROD# = PRODUCTS.PROD#

The result is:

<table>
<thead>
<tr>
<th>PART</th>
<th>SUPPLIER</th>
<th>PROD#</th>
<th>PRODUCT</th>
</tr>
</thead>
<tbody>
<tr>
<td>WIRE</td>
<td>ACWF</td>
<td>10</td>
<td>GENERATOR</td>
</tr>
<tr>
<td>MAGNETS</td>
<td>BATEMAN</td>
<td>10</td>
<td>GENERATOR</td>
</tr>
<tr>
<td>PLASTIC</td>
<td>PLASTIK_CORP</td>
<td>30</td>
<td>RELAY</td>
</tr>
<tr>
<td>BLADES</td>
<td>ACE STEEL</td>
<td>205</td>
<td>SAW</td>
</tr>
<tr>
<td>OIL</td>
<td>WESTERN_CHEM</td>
<td>160</td>
<td>(null)</td>
</tr>
<tr>
<td>(null)</td>
<td>(null)</td>
<td>505</td>
<td>SCREWDRIVER</td>
</tr>
</tbody>
</table>

The clause RIGHT OUTER JOIN includes rows from the table identified after it where the values in the joined columns are not matched by values in the joined columns of the table identified before it.

Example 19: The result of Example 16 (a full outer join) shows the product number for SCREWDRIVER as null, even though the PRODUCTS table contains a product number for it. This is because PRODUCTS.PROD# was not listed in the SELECT list of the query. Revise the query using COALESCE so that all part numbers from both tables are shown.

SELECT PART, SUPPLIER,
    COALESCE(PARTS.PROD#, PRODUCTS.PROD#) AS PRODNUM,
    PRODUCT
FROM PARTS FULL OUTER JOIN PRODUCTS
ON PARTS.PROD# = PRODUCTS.PROD#;

In the result, notice that the AS clause (AS PRODNUM), provides a name for the result of the COALESCE function:

<table>
<thead>
<tr>
<th>PART</th>
<th>SUPPLIER</th>
<th>PRODNUM</th>
<th>PRODUCT</th>
</tr>
</thead>
<tbody>
<tr>
<td>WIRE</td>
<td>ACWF</td>
<td>10</td>
<td>GENERATOR</td>
</tr>
<tr>
<td>MAGNETS</td>
<td>BATEMAN</td>
<td>10</td>
<td>GENERATOR</td>
</tr>
<tr>
<td>PLASTIC</td>
<td>PLASTIK_CORP</td>
<td>30</td>
<td>RELAY</td>
</tr>
<tr>
<td>BLADES</td>
<td>ACE STEEL</td>
<td>205</td>
<td>SAW</td>
</tr>
<tr>
<td>OIL</td>
<td>WESTERN_CHEM</td>
<td>160</td>
<td>(null)</td>
</tr>
<tr>
<td>(null)</td>
<td>(null)</td>
<td>505</td>
<td>SCREWDRIVER</td>
</tr>
</tbody>
</table>

Example 20: For all parts that are used in product numbers less than 200, show the part, the part supplier, the product number, and the product name. Use a nested table expression.

SELECT PART, SUPPLIER, PRODNUM, PRODUCT
FROM (SELECT PART, PROD# AS PRODNUM, SUPPLIER
    FROM PARTS
    WHERE PROD# < 200) AS PARTX
LEFT OUTER JOIN PRODUCTS
ON PRODNUM = PROD#;

The result is:

<table>
<thead>
<tr>
<th>PART</th>
<th>SUPPLIER</th>
<th>PRODNUM</th>
<th>PRODUCT</th>
</tr>
</thead>
<tbody>
<tr>
<td>WIRE</td>
<td>ACWF</td>
<td>10</td>
<td>GENERATOR</td>
</tr>
<tr>
<td>MAGNETS</td>
<td>BATEMAN</td>
<td>10</td>
<td>GENERATOR</td>
</tr>
<tr>
<td>PLASTIC</td>
<td>PLASTIK_CORP</td>
<td>30</td>
<td>RELAY</td>
</tr>
<tr>
<td>OIL</td>
<td>WESTERN_CHEM</td>
<td>160</td>
<td>(null)</td>
</tr>
<tr>
<td>(null)</td>
<td>(null)</td>
<td>505</td>
<td>SCREWDRIVER</td>
</tr>
</tbody>
</table>

Example 21: Examples of statements with DISTINCT specified more than once in a subselect:

SELECT DISTINCT COUNT(DISTINCT A1), COUNT(A2)
FROM T1;
SELECT COUNT(DISTINCT A))
FROM T1
WHERE A3 > 0
HAVING AVG(DISTINCT A4) > 1;

Example 22: **Examples of cross join to combine information for all customers with all states.**

Use a cross join to combine information for all customers with all of the states. The cross join combines all rows in both tables and creates a Cartesian product. Assume that the following tables exist:

**Customer:**

<table>
<thead>
<tr>
<th>ACOL1</th>
<th>ACOL2</th>
</tr>
</thead>
<tbody>
<tr>
<td>A1</td>
<td>AA1</td>
</tr>
<tr>
<td>A2</td>
<td>AA2</td>
</tr>
<tr>
<td>A3</td>
<td>AA3</td>
</tr>
</tbody>
</table>

**States:**

<table>
<thead>
<tr>
<th>BCOL1</th>
<th>BCOL2</th>
</tr>
</thead>
<tbody>
<tr>
<td>B1</td>
<td>BB1</td>
</tr>
<tr>
<td>B2</td>
<td>BB2</td>
</tr>
</tbody>
</table>

The following two select statements produce identical results:

**SELECT * FROM customer CROSS JOIN states**

**SELECT * FROM A, B**

The result table for either of these select statements looks like the following:

<table>
<thead>
<tr>
<th>ACOL1</th>
<th>ACOL2</th>
<th>BCOL1</th>
<th>BCOL2</th>
</tr>
</thead>
<tbody>
<tr>
<td>A1</td>
<td>AA1</td>
<td>B1</td>
<td>BB1</td>
</tr>
<tr>
<td>A1</td>
<td>AA1</td>
<td>B2</td>
<td>BB2</td>
</tr>
<tr>
<td>A2</td>
<td>AA2</td>
<td>B1</td>
<td>BB1</td>
</tr>
<tr>
<td>A2</td>
<td>AA2</td>
<td>B2</td>
<td>BB2</td>
</tr>
<tr>
<td>A3</td>
<td>AA3</td>
<td>B1</td>
<td>BB1</td>
</tr>
<tr>
<td>A3</td>
<td>AA3</td>
<td>B2</td>
<td>BB2</td>
</tr>
</tbody>
</table>

Example 22: **Example of using a typed-correlation-clause when referencing a generic table function.**

In the following select statement, 'tf6' is a generic table function defined using the CREATE FUNCTION (external table) statement. The typed-correlation-clause is used to define the column names and data types of the result table.

```sql
SELECT c1, c2
FROM T1(tf6('abcd'))
AS z (c1 int, c2 varchar(100));
```

Examples of grouping sets, rollup, and cube queries

The following examples illustrate the use of GROUPING SETS, ROLLUP, and CUBE clauses of the GROUP BY clause in subselect queries.

The queries in Example 1 through Example 4 use a subset of the rows in the SALES tables based on the predicate 'WEEK(SALES_DATE) = 13'. The other examples do not specify this predicate.
SELECT WEEK(SALES_DATE) AS WEEK,  
       DAYOFWEEK(SALES_DATE) AS DAY_WEEK,  
       SALES_PERSON,  
       SUM(SALES) AS UNITS_SOLD  
FROM SALES  
WHERE WEEK(SALES_DATE) = 13;  

The previous query returns results similar to the following:

<table>
<thead>
<tr>
<th>WEEK</th>
<th>DAY_WEEK</th>
<th>SALES_PERSON</th>
<th>UNITS_SOLD</th>
</tr>
</thead>
<tbody>
<tr>
<td>13</td>
<td>6</td>
<td>LUCCHESSI</td>
<td>3</td>
</tr>
<tr>
<td>13</td>
<td>6</td>
<td>LUCCHESSI</td>
<td>1</td>
</tr>
<tr>
<td>13</td>
<td>6</td>
<td>LEE</td>
<td>2</td>
</tr>
<tr>
<td>13</td>
<td>6</td>
<td>LEE</td>
<td>2</td>
</tr>
<tr>
<td>13</td>
<td>6</td>
<td>LEE</td>
<td>3</td>
</tr>
<tr>
<td>13</td>
<td>6</td>
<td>LEE</td>
<td>5</td>
</tr>
<tr>
<td>13</td>
<td>6</td>
<td>GOUNOT</td>
<td>3</td>
</tr>
<tr>
<td>13</td>
<td>6</td>
<td>GOUNOT</td>
<td>1</td>
</tr>
<tr>
<td>13</td>
<td>6</td>
<td>GOUNOT</td>
<td>7</td>
</tr>
<tr>
<td>13</td>
<td>7</td>
<td>LUCCHESSI</td>
<td>1</td>
</tr>
<tr>
<td>13</td>
<td>7</td>
<td>LUCCHESSI</td>
<td>2</td>
</tr>
<tr>
<td>13</td>
<td>7</td>
<td>LUCCHESSI</td>
<td>1</td>
</tr>
<tr>
<td>13</td>
<td>7</td>
<td>LEE</td>
<td>7</td>
</tr>
<tr>
<td>13</td>
<td>7</td>
<td>LEE</td>
<td>3</td>
</tr>
<tr>
<td>13</td>
<td>7</td>
<td>LEE</td>
<td>7</td>
</tr>
<tr>
<td>13</td>
<td>7</td>
<td>LEE</td>
<td>4</td>
</tr>
<tr>
<td>13</td>
<td>7</td>
<td>GOUNOT</td>
<td>2</td>
</tr>
<tr>
<td>13</td>
<td>7</td>
<td>GOUNOT</td>
<td>18</td>
</tr>
<tr>
<td>13</td>
<td>7</td>
<td>GOUNOT</td>
<td>1</td>
</tr>
</tbody>
</table>

Example 1:
A query with a basic GROUP BY clause over 3 columns:

```sql
SELECT WEEK(SALES_DATE) AS WEEK,  
       DAYOFWEEK(SALES_DATE) AS DAY_WEEK,  
       SALES_PERSON,  
       SUM(SALES) AS UNITS_SOLD  
FROM SALES  
WHERE WEEK(SALES_DATE) = 13  
GROUP BY WEEK(SALES_DATE), DAYOFWEEK(SALES_DATE), SALES_PERSON  
ORDER BY WEEK, DAY_WEEK, SALES_PERSON;
```

The previous query returns results similar to the following:

<table>
<thead>
<tr>
<th>WEEK</th>
<th>DAY_WEEK</th>
<th>SALES_PERSON</th>
<th>UNITS_SOLD</th>
</tr>
</thead>
<tbody>
<tr>
<td>13</td>
<td>6</td>
<td>GOUNOT</td>
<td>11</td>
</tr>
<tr>
<td>13</td>
<td>6</td>
<td>LEE</td>
<td>12</td>
</tr>
<tr>
<td>13</td>
<td>6</td>
<td>LUCCHESSI</td>
<td>4</td>
</tr>
<tr>
<td>13</td>
<td>7</td>
<td>GOUNOT</td>
<td>21</td>
</tr>
<tr>
<td>13</td>
<td>7</td>
<td>LEE</td>
<td>21</td>
</tr>
<tr>
<td>13</td>
<td>7</td>
<td>LUCCHESSI</td>
<td>4</td>
</tr>
</tbody>
</table>

Example 2:
The following query produces the result based on two different grouping sets of rows from the SALES table.

```sql
SELECT WEEK(SALES_DATE) AS WEEK,  
       DAYOFWEEK(SALES_DATE) AS DAY_WEEK,  
       SALES_PERSON,  
       SUM(SALES) AS UNITS_SOLD  
FROM SALES  
WHERE WEEK(SALES_DATE) = 13  
GROUP BY GROUPING SETS ((WEEK(SALES_DATE), SALES_PERSON), (DAYOFWEEK(SALES_DATE), SALES_PERSON))  
ORDER BY WEEK, DAY_WEEK, SALES_PERSON;
```

The previous query returns results similar to the following:
The rows with WEEK 13 are from the first grouping set while the other rows are from the second grouping set.

**Example 3:**

If you use the three distinct columns involved in the grouping sets in Example 2 in a ROLLUP clause, you can see grouping sets for (WEEK,DAY_WEEK,SALES_PERSON), (WEEK, DAY_WEEK), (WEEK), and grand-total.

```sql
SELECT WEEK(SALES_DATE) AS WEEK,
       DAYOFWEEK(SALES_DATE) AS DAY_WEEK,
       SALES_PERSON,
       SUM(SALES) AS UNITS_SOLD
FROM SALES
WHERE WEEK(SALES_DATE) = 13
GROUP BY ROLLUP (WEEK(SALES_DATE), DAYOFWEEK(SALES_DATE), SALES_PERSON)
ORDER BY WEEK, DAY_WEEK, SALES_PERSON;
```

The previous query returns results similar to the following:

<table>
<thead>
<tr>
<th>WEEK</th>
<th>DAY_WEEK</th>
<th>SALES_PERSON</th>
<th>UNITS_SOLD</th>
</tr>
</thead>
<tbody>
<tr>
<td>13</td>
<td>6</td>
<td>GOUNOT</td>
<td>11</td>
</tr>
<tr>
<td>13</td>
<td>6</td>
<td>LEE</td>
<td>12</td>
</tr>
<tr>
<td>13</td>
<td>6</td>
<td>LUCCHESI</td>
<td>4</td>
</tr>
<tr>
<td>13</td>
<td>7</td>
<td>GOUNOT</td>
<td>21</td>
</tr>
<tr>
<td>13</td>
<td>7</td>
<td>LEE</td>
<td>21</td>
</tr>
<tr>
<td>13</td>
<td>7</td>
<td>LUCCHESI</td>
<td>4</td>
</tr>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>-</td>
</tr>
</tbody>
</table>

**Example 4:**

The same query as Example 3, using CUBE instead of ROLLUP results in additional grouping sets for (WEEK,SALES_PERSON), (DAY_WEEK,SALES_PERSON), (DAY_WEEK), and (SALES_PERSON) in the result.

```sql
SELECT WEEK(SALES_DATE) AS WEEK,
       DAYOFWEEK(SALES_DATE) AS DAY_WEEK,
       SALES_PERSON,
       SUM(SALES) AS UNITS_SOLD
FROM SALES
WHERE WEEK(SALES_DATE) = 13
GROUP BY CUBE (WEEK(SALES_DATE), DAYOFWEEK(SALES_DATE), SALES_PERSON)
ORDER BY WEEK, DAY_WEEK, SALES_PERSON;
```

The previous query returns results similar to the following:

<table>
<thead>
<tr>
<th>WEEK</th>
<th>DAY_WEEK</th>
<th>SALES_PERSON</th>
<th>UNITS_SOLD</th>
</tr>
</thead>
<tbody>
<tr>
<td>13</td>
<td>6</td>
<td>GOUNOT</td>
<td>11</td>
</tr>
<tr>
<td>13</td>
<td>6</td>
<td>LEE</td>
<td>12</td>
</tr>
<tr>
<td>13</td>
<td>6</td>
<td>LUCCHESI</td>
<td>4</td>
</tr>
<tr>
<td>13</td>
<td>7</td>
<td>GOUNOT</td>
<td>21</td>
</tr>
<tr>
<td>13</td>
<td>7</td>
<td>LEE</td>
<td>21</td>
</tr>
<tr>
<td>13</td>
<td>7</td>
<td>LUCCHESI</td>
<td>4</td>
</tr>
</tbody>
</table>
Example 5:
The following query returns a result set that includes a *grand-total* of the selected rows from the SALES table together with a group of rows aggregated by SALES_PERSON and MONTH.

```
SELECT SALES_PERSON,
       MONTH(SALES_DATE) AS MONTH,
       SUM(SALES) AS UNITS_SOLD
FROM SALES
GROUP BY GROUPING SETS ((SALES_PERSON, MONTH(SALES_DATE)),
                          ( ),
                          )
ORDER BY SALES_PERSON, MONTH;
```

The previous query returns results similar to the following:

<table>
<thead>
<tr>
<th>SALES_PERSON</th>
<th>MONTH</th>
<th>UNITS_SOLD</th>
</tr>
</thead>
<tbody>
<tr>
<td>GOUNOT</td>
<td>3</td>
<td>35</td>
</tr>
<tr>
<td>GOUNOT</td>
<td>4</td>
<td>14</td>
</tr>
<tr>
<td>GOUNOT</td>
<td>12</td>
<td>1</td>
</tr>
<tr>
<td>LEE</td>
<td>3</td>
<td>60</td>
</tr>
<tr>
<td>LEE</td>
<td>4</td>
<td>25</td>
</tr>
<tr>
<td>LEE</td>
<td>12</td>
<td>6</td>
</tr>
<tr>
<td>LUCCHESI</td>
<td>3</td>
<td>9</td>
</tr>
<tr>
<td>LUCCHESI</td>
<td>4</td>
<td>4</td>
</tr>
<tr>
<td>LUCCHESI</td>
<td>12</td>
<td>1</td>
</tr>
<tr>
<td>-</td>
<td>-</td>
<td>155</td>
</tr>
</tbody>
</table>

Example 6:
This example shows two simple ROLLUP queries followed by a query which treats the two ROLLUP clauses as grouping sets in a single result set and specifies row ordering for each column involved in the grouping sets.

Example 6-1:
```
SELECT WEEK(SALES_DATE) AS WEEK,
       DAYOFWEEK(SALES_DATE) AS DAY_WEEK,
       SUM(SALES) AS UNITS_SOLD
FROM SALES
GROUP BY ROLLUP (WEEK(SALES_DATE), DAYOFWEEK(SALES_DATE))
ORDER BY WEEK, DAY_WEEK;
```

The previous query returns results similar to the following:

<table>
<thead>
<tr>
<th>WEEK</th>
<th>DAY_WEEK</th>
<th>UNITS_SOLD</th>
</tr>
</thead>
<tbody>
<tr>
<td>13</td>
<td>6</td>
<td>27</td>
</tr>
<tr>
<td>13</td>
<td>7</td>
<td>46</td>
</tr>
<tr>
<td>13</td>
<td>-</td>
<td>73</td>
</tr>
</tbody>
</table>
Example 6-2:

```
SELECT
    MONTH(SALES_DATE) AS MONTH,
    REGION,
    SUM(SALES) AS UNITS_SOLD
FROM
    SALES
GROUP BY
    ROLLUP (MONTH(SALES_DATE), REGION)
ORDER BY
    MONTH, REGION;
```

The previous query returns results similar to the following:

<table>
<thead>
<tr>
<th>MONTH</th>
<th>REGION</th>
<th>UNITS_SOLD</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>Manitoba</td>
<td>22</td>
</tr>
<tr>
<td>3</td>
<td>Ontario-North</td>
<td>8</td>
</tr>
<tr>
<td>3</td>
<td>Ontario-South</td>
<td>34</td>
</tr>
<tr>
<td>3</td>
<td>Quebec</td>
<td>40</td>
</tr>
<tr>
<td>3</td>
<td>-</td>
<td>104</td>
</tr>
<tr>
<td>4</td>
<td>Manitoba</td>
<td>17</td>
</tr>
<tr>
<td>4</td>
<td>Ontario-North</td>
<td>1</td>
</tr>
<tr>
<td>4</td>
<td>Ontario-South</td>
<td>14</td>
</tr>
<tr>
<td>4</td>
<td>Quebec</td>
<td>11</td>
</tr>
<tr>
<td>4</td>
<td>-</td>
<td>43</td>
</tr>
<tr>
<td>12</td>
<td>Manitoba</td>
<td>2</td>
</tr>
<tr>
<td>12</td>
<td>Ontario-South</td>
<td>4</td>
</tr>
<tr>
<td>12</td>
<td>Quebec</td>
<td>2</td>
</tr>
<tr>
<td>12</td>
<td>-</td>
<td>8</td>
</tr>
<tr>
<td>-</td>
<td>-</td>
<td>155</td>
</tr>
</tbody>
</table>

Example 6-3:

```
SELECT
    WEEK(SALES_DATE) AS WEEK,
    DAYOFWEEK(SALES_DATE) AS DAY_WEEK,
    MONTH(SALES_DATE) AS MONTH,
    REGION,
    SUM(SALES) AS UNITS_SOLD
FROM
    SALES
GROUP BY
    GROUPING SETS
        (ROLLUP(WEEK(SALES_DATE),
            DAYOFWEEK(SALES_DATE)),
        ROLLUP(MONTH(SALES_DATE), REGION))
ORDER BY
    WEEK, DAY_WEEK, MONTH, REGION;
```

The previous query returns results similar to the following:

<table>
<thead>
<tr>
<th>WEEK</th>
<th>DAY_WEEK</th>
<th>MONTH</th>
<th>REGION</th>
<th>UNITS_SOLD</th>
</tr>
</thead>
<tbody>
<tr>
<td>13</td>
<td>6</td>
<td>-</td>
<td>-</td>
<td>27</td>
</tr>
<tr>
<td>13</td>
<td>7</td>
<td>-</td>
<td>-</td>
<td>46</td>
</tr>
<tr>
<td>13</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>73</td>
</tr>
<tr>
<td>14</td>
<td>1</td>
<td>-</td>
<td>-</td>
<td>31</td>
</tr>
<tr>
<td>14</td>
<td>2</td>
<td>-</td>
<td>-</td>
<td>43</td>
</tr>
<tr>
<td>14</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>74</td>
</tr>
<tr>
<td>53</td>
<td>1</td>
<td>-</td>
<td>-</td>
<td>8</td>
</tr>
<tr>
<td>53</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>8</td>
</tr>
<tr>
<td>-</td>
<td>-</td>
<td>3</td>
<td>Manitoba</td>
<td>22</td>
</tr>
<tr>
<td>-</td>
<td>-</td>
<td>3</td>
<td>Ontario-North</td>
<td>8</td>
</tr>
<tr>
<td>-</td>
<td>-</td>
<td>3</td>
<td>Ontario-South</td>
<td>34</td>
</tr>
<tr>
<td>-</td>
<td>-</td>
<td>3</td>
<td>Quebec</td>
<td>40</td>
</tr>
<tr>
<td>-</td>
<td>-</td>
<td>3</td>
<td>-</td>
<td>104</td>
</tr>
<tr>
<td>-</td>
<td>-</td>
<td>4</td>
<td>Manitoba</td>
<td>17</td>
</tr>
<tr>
<td>-</td>
<td>-</td>
<td>4</td>
<td>Ontario-North</td>
<td>1</td>
</tr>
<tr>
<td>-</td>
<td>-</td>
<td>4</td>
<td>Ontario-South</td>
<td>14</td>
</tr>
<tr>
<td>-</td>
<td>-</td>
<td>4</td>
<td>Quebec</td>
<td>11</td>
</tr>
</tbody>
</table>
Using the two ROLLUP clauses as grouping sets causes the result to include duplicate rows. There are even two grand total rows.

Observe how the use of ORDER BY has affected the results:

- In the first grouped set, week 53 has been repositioned to the end.
- In the second grouped set, month 12 has now been positioned to the end and the regions now display in alphabetic order.
- Null values are sorted high.

Example 7:
In queries that perform multiple ROLLUP operations in a single pass (such as Example 6-3) you might need to indicate which grouping set produced each row. The following steps demonstrate how to provide a column (called GROUP) which indicates the origin of each row in the result set.

**Origin** means which of the two grouping sets produced the row in the result set.

**Step 1:**
Introduce a way of generating new data values, using a query which selects from the SYSDUMMY1 table. The following query shows how a table (named “X”) can be derived with two columns, “R1” and “R2”, and one row of data.

```sql
SELECT R1, R2
FROM (SELECT 'GROUP 1' as R1, 'GROUP 2' as R2
      FROM SYSIBM.SYSDUMMY1) AS X(R1, R2);
```

The results are similar to the following:

<table>
<thead>
<tr>
<th>R1</th>
<th>R2</th>
</tr>
</thead>
<tbody>
<tr>
<td>GROUP 1</td>
<td>GROUP 2</td>
</tr>
</tbody>
</table>

**Step 2:**
Form the cross product of the table “X” with the SALES table. The following query adds columns “R1” and “R2” to every row.

```sql
SELECT R1, R2, WEEK(SALES_DATE) AS WEEK,
      DAYOFWEEK(SALES_DATE) AS DAY_WEEK,
      MONTH(SALES_DATE) AS MONTH,
      REGION,
      SALES AS UNITS_SOLD
FROM SALES, (SELECT 'GROUP 1' as R1, 'GROUP 2' as R2
             FROM SYSIBM.SYSDUMMY1) AS X(R1, R2);
```

**Step 3:**
Now the “R1” and “R2” columns can be combined with the grouping sets to include “R1” and “R2” in the rollup analysis.

```sql
SELECT R1, R2,
      WEEK(SALES_DATE) AS WEEK,
      DAYOFWEEK(SALES_DATE) AS DAY_WEEK,
      MONTH(SALES_DATE) AS MONTH,
      REGION,
      SUM(SALES) AS UNITS_SOLD
FROM SALES, (SELECT 'GROUP 1' as R1, 'GROUP 2' as R2
             FROM SYSIBM.SYSDUMMY1) AS X(R1, R2)
GROUP BY GROUPING SETS ((R1, ROLLUP(WEEK(SALES_DATE)),
```
The previous query returns results similar to the following:

<table>
<thead>
<tr>
<th>GROUP 1</th>
<th>GROUP 2</th>
<th>WEEK</th>
<th>DAY_WEEK</th>
<th>MONTH</th>
<th>REGION</th>
<th>UNITS_SOLD</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>-</td>
<td>13</td>
<td>6</td>
<td>-</td>
<td>-</td>
<td>27</td>
</tr>
<tr>
<td>1</td>
<td>-</td>
<td>13</td>
<td>7</td>
<td>-</td>
<td>-</td>
<td>46</td>
</tr>
<tr>
<td>1</td>
<td>-</td>
<td>13</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>73</td>
</tr>

<td>155</td>
</tr>
<tr>
<td>GROUP 1</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td></td>
<td>155</td>
</tr>
</tbody>
</table>

Step 4:
Because “R1” and “R2” are used in different grouping sets, whenever “R1” is non-null in the result, “R2” is null and whenever “R2” is non-null in the result, “R1” is null. You can consolidate these columns into a single column (“GROUP”) using the COALESCE function. You can also use the “GROUP” column in the ORDER BY clause to keep the results of the two grouping sets together.

```sql
SELECT COALESCE(R1, R2) AS GROUP,
       WEEK(SALES_DATE) AS WEEK,
       DAYOFWEEK(SALES_DATE) AS DAY_WEEK,
       MONTH(SALES_DATE) AS MONTH,
       REGION, SUM(SALES) AS UNITS_SOLD
FROM SALES, (SELECT 'GROUP 1' as R1, 'GROUP 2' as R2
             FROM SYSDUMMY1) AS X(R1, R2)
GROUP BY GROUPING SETS ((R1, ROLLUP(WEEK(SALES_DATE),
       DAYOFWEEK(SALES_DATE)),
         (R2, ROLLUP(MONTH(SALES_DATE),
         REGION)))
ORDER BY GROUP, WEEK, DAY_WEEK, MONTH, REGION;
```

The previous query returns results similar to the following:

<table>
<thead>
<tr>
<th>GROUP 1</th>
<th>GROUP 2</th>
<th>WEEK</th>
<th>DAY_WEEK</th>
<th>MONTH</th>
<th>REGION</th>
<th>UNITS_SOLD</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>-</td>
<td>13</td>
<td>6</td>
<td>-</td>
<td>-</td>
<td>27</td>
</tr>
<tr>
<td>1</td>
<td>-</td>
<td>13</td>
<td>7</td>
<td>-</td>
<td>-</td>
<td>46</td>
</tr>
<tr>
<td>1</td>
<td>-</td>
<td>13</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>73</td>
</tr>
<tr>
<td>1</td>
<td>-</td>
<td>14</td>
<td>1</td>
<td>-</td>
<td>-</td>
<td>31</td>
</tr>
<tr>
<td>1</td>
<td>-</td>
<td>14</td>
<td>2</td>
<td>-</td>
<td>-</td>
<td>43</td>
</tr>
<tr>
<td>1</td>
<td>-</td>
<td>14</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>74</td>
</tr>
<tr>
<td>1</td>
<td>-</td>
<td>53</td>
<td>1</td>
<td>-</td>
<td>-</td>
<td>8</td>
</tr>
<tr>
<td>1</td>
<td>-</td>
<td>53</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>8</td>
</tr>
</tbody>
</table>
Example 8:
The following example illustrates the use of various aggregate functions when using a CUBE clause. The example also makes use of cast functions and rounding to produce a decimal result with reasonable precision and scale.

```sql
SELECT MONTH(SALES_DATE) AS MONTH,
       REGION,
       SUM(SALES) AS UNITS_SOLD,
       MAX(SALES) AS BEST_SALE,
       CAST(ROUND(AVG(DECIMAL(SALES)),2) AS DECIMAL(5,2)) AS AVG_UNITS_SOLD
FROM SALES
GROUP BY CUBE(MONTH(SALES_DATE),REGION)
ORDER BY MONTH, REGION;
```

The previous query returns results similar to the following:

<table>
<thead>
<tr>
<th>MONTH</th>
<th>REGION</th>
<th>UNITS_SOLD</th>
<th>BEST_SALE</th>
<th>AVG_UNITS_SOLD</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>Manitoba</td>
<td>22</td>
<td>7</td>
<td>3.14</td>
</tr>
<tr>

[fullselect](#)

### fullselect

The fullselect is a component of the select-statement, ALTER TABLE statement for the definition of a materialized query table, CREATE TABLE statement, CREATE VIEW statement, DECLARE GLOBAL TEMPORARY TABLE statement, INSERT statement, UPDATE statement, and MERGE statement.
A fullselect that is enclosed in parentheses is called a subquery. For example, a subquery can be used in a search condition.

A scalar-fullselect is a fullselect, enclosed in parentheses, that returns a single result row and a single result column. If the result of the fullselect is no rows, then the null value is returned. An error is returned if there is more than one row in the result. For example, a scalar-fullselect can be used in the assignment clause of the DELETE, UPDATE and MERGE statements.

A row-fullselect is a fullselect that returns a single row. An error is returned if there is more than one row in the result. For example, a row-fullselect can be used in the assignment clause of the DELETE and UPDATE statements.

**UNION, EXCEPT, or INTERSECT**

The set operators, UNION, EXCEPT, and INTERSECT, correspond to the relational operators union, difference, and intersection. A fullselect specifies a result table. If a set operator is not used, the result of the fullselect is the result of the specified subselect. Otherwise, the result table is derived by combining the two other result tables (R1 and R2) subject to the specified set operator.

**UNION DISTINCT or UNION ALL**

If UNION ALL is specified, the result consists of all rows in R1 and R2. With UNION DISTINCT, the result is the set of all rows in either R1 or R2 with the redundant duplicate rows eliminated. In either case, each row of the result table of the union is either a row from R1 or a row from R2.
The expression that corresponds to the \( n \)th column in R1 and R2 can reference columns with column masks. The \( n \)th column of the result of the union can be derived from the masked values in R1 or R2.

With UNION DISTINCT, the elimination of the duplicate rows is based on the unmasked values in R1 and R2. Because all rows are from R1 or R2, the output values in the result table of the union may vary when one or more of the following conditions occur:

- The expression corresponding to the \( n \)th column in R1 references columns with column masks, but the expression corresponding to the \( n \)th column in R2 does not, or vice versa.
- The expressions corresponding to the \( n \)th column in R1 and R2 reference columns with different column masks.
- The column mask definition references columns that are not the same target column for which the column mask is defined, and those columns are not part of the UNION DISTINCT operation. It is recommended that the column mask definition does not reference other columns from the target table.

For example, a row in R1 is derived from the masked value, and a row in R2 is derived from the unmasked value. If the row in the result table is from R1, the masked value is returned. If the row in the result table is from R2, the unmasked value is returned.

EXCEPT and INTERSECT can be intermixed with UNION if the rows in R1 and R2 for EXCEPT and INTERSECT do not reference columns with column masks.

For compatibility with other SQL implementations, UNIQUE can be specified as a synonym for DISTINCT.

**EXCEPT DISTINCT or EXCEPT ALL**

If EXCEPT ALL is specified, the result consists of all rows from only R1, including significant redundant duplicate rows. With EXCEPT DISTINCT, the result consists of all rows that are only in R1, with redundant duplicate rows eliminated. In either case, each row in the result table of the difference is a row from R1 that does not have a matching row in R2.

Column masks cannot be applied to the select lists that derive the final result table of set operations if any of the set operators that are used to derive the final result table is EXCEPT ALL or EXCEPT DISTINCT.

For compatibility with other SQL implementations, MINUS can be specified as a synonym for EXCEPT, and UNIQUE can be specified as a synonym for DISTINCT.

**INTERSECT DISTINCT or INTERSECT ALL**

If INTERSECT ALL is specified, the result consists of all rows that are both in R1 and R2, including significant redundant duplicate rows. With INTERSECT DISTINCT, the result consists of all rows that are in both R1 and R2, with redundant duplicate rows eliminated. In either case, each row of the result table of the intersection is a row that exists in both R1 and R2.

Column masks cannot be applied to the select lists that derive the final result table of set operations if any of the set operators that are used to derive the final result table is INTERSECT ALL or INTERSECT DISTINCT.

For compatibility with other SQL implementations, UNIQUE can be specified as a synonym for DISTINCT.
values-clause

Derives a result table by specifying the actual values, using sequence expressions, for each column of a row in the result table.

A values-clause is specified by:

- A single sequence expression for a single-column result table.
- \( n \) sequence expressions, separated by commas and enclosed in parentheses. \( n \) is the number of columns in the result table.

All result columns in a values-clause are unnamed.

order-by-clause

See subselect for details of the order-by-clause. A fullselect that contains an order-by-clause cannot be specified in the following contexts:

- The outermost fullselect of a view

Note: An ORDER BY clause in a fullselect might not affect the order of the rows returned by a query. An ORDER BY clause only affects the order of the rows returned in a query if it is specified in the outermost fullselect. An order-by-clause should be specified to ensure a predictable order for determining the set of rows from the fullselect if the offset-clause or the fetch-clause are specified.

- In the outer fullselect in the RETURN statement of an SQL table function

offset-clause

See offset-clause for details of the offset-clause. A fullselect that contains an offset-clause cannot be specified in the following contexts:

- The definition of a view
- The definition of a materialized query table
- In the RETURN statement of an SQL table function
- The definition of a row permission
- The definition of a column mask
- The outermost fullselect for a sensitive dynamic cursor

fetch-clause

See fetch-clause for details of the fetch-clause. A fullselect that contains a fetch-clause cannot be specified in the following contexts:

- The definition of a materialized query table
- The outermost fullselect of the definition of a view
- The outer fullselect in the RETURN statement of an SQL table function
- The outermost fullselect for a sensitive dynamic cursor

Rules for columns:

- R1 and R2 must have the same number of columns, and the data type of the \( n \)th column of R1 must be compatible with the data type of the \( n \)th column of R2.
- The \( n \)th column of the result of a set operator is derived from the \( n \)th columns of R1 and R2. The attributes of the result columns are determined using the rules for result columns.
- R1 and R2 must not include columns having a data type of CLOB, BLOB, DBCLOB, XML, or a distinct type that is based on any of these types. However, this rule is not applicable when UNION ALL is used with the set operator.
If the \( n \)th column of R1 and the \( n \)th column of R2 have the same result column name, the \( n \)th column of the result table of the set operation has the same result column name. Otherwise, the \( n \)th column of the result table of the set operation is unnamed.

- Qualified column names cannot be used in the ORDER BY clause when the set operators are specified.

For information on the valid combinations of operand columns and the data type of the result column, see “Rules for result data types” on page 174.

Duplicate rows: Two rows are duplicates if the value in each column in the first row is equal to the corresponding value of the second row. For determining duplicates, two null values are considered equal.

The DECFLOAT data type allows for multiple bit representations of the same number. For example 2.00 and 2.0 are two numbers with the same coefficient, but different exponent values. See “Numeric comparisons” on page 164 for more information. So if the result table of UNION contains a DECFLOAT column and multiple bit representations of the same number exist, the one returned is unpredictable.

Operator precedence: When multiple set operations are combined in an expression, set operations within parentheses are performed first. If the order is not specified by parentheses, set operations are performed from left to right with the exception that all INTERSECT operations are performed before any UNION or any EXCEPT operations.

Results of set operators: The following table illustrates the results of all set operations, with rows from result table R1 and R2 as the first two columns and the result of each operation on R1 and R2 under the corresponding column heading.

<table>

</tbody>
</table>
Examples of fullselects

Example 1: A query specifies the union of result tables R1 and R2. A column in R1 has the data type CHAR(10) and the subtype BIT. The corresponding column in R2 has the data type CHAR(15) and the subtype SBCS. Hence, the column in the union has the data type CHAR(15) and the subtype BIT. Values from the first column are converted to CHAR(15) by adding five trailing blanks.

Example 2: Show all the rows from DSN8C10.EMP.

```sql
SELECT * FROM DSN8C10.EMP;
```

Example 3: Using sample tables DSN8C10.EMP and DSN8C10.EMPPROJACT, list the employee numbers of all employees for which either of the following statements are true:

- Their department numbers begin with 'D'.
- They are assigned to projects whose project numbers begin with 'AD'.

```sql
SELECT EMPNO FROM DSN8C10.EMP
WHERE WORKDEPT LIKE 'D%'
UNION
SELECT EMPNO FROM DSN8C10.EMPPROJACT
WHERE PROJNO LIKE 'AD%';
```

The result is the union of two result tables, one formed from the sample table DSN8C10.EMP, the other formed from the sample table DSN8C10.EMPPROJACT. The result—a one-column table—is a list of employee numbers. Because UNION, rather than UNION ALL, was used, the entries in the list are distinct. If instead UNION ALL were used, certain employee numbers would appear in the list more than once. These would be the numbers for employees in departments that begin with 'D' while their projects begin with 'AD'.

Example 4: Specify a series of unions and order the results by the first column of the final result table.

```sql
SELECT * FROM T1
UNION
SELECT * FROM T2
ORDER BY 1;
```

Example 5: Specify a series of unions and order the results by the first column of the final result table. The first ORDER BY clause order the rows of the result of the first union by the first column of that result table. The second ORDER BY clause is applied as part of the outer fullselect and it causes the rows of the final result table to be ordered by the first column of the final result table.

```sql
(SELECT * FROM T1
UNION
SELECT * FROM T2)
ORDER BY 1;
```
Example 6: Assume that tables T1 and T2 exist and each contain the same number of columns named C1, C2, and so on. This example of the EXCEPT operator produces all rows that are in T1 but not in T2, with duplicate rows removed:

(SELECT * FROM T1)
EXCEPT DISTINCT
(SELECT * FROM T2);

Example 7: Assume that tables T1 and T2 exist and each contain the same number of columns named C1, C2, and so on. This example of the INTERSECT operator produces all rows that are in both table T1 and table T2, with duplicate rows removed:

(SELECT * FROM T1)
INTERSECT DISTINCT
(SELECT * FROM T2);

Example 8: Retrieve the most recently generated value for the sequence MYSEQ1:
VALUES PREVIOUS VALUE FOR MYSEQ1;

Example 9: Retrieve the next value for the sequence MYSEQ1:
VALUES NEXT VALUE FOR MYSEQ1;

Character conversion in set operations and concatenations

The SQL operations that combine strings include concatenation, set operators, and the IN list of an IN predicate. Within an SQL statement, concatenation combines two or more strings into a new string. Within a fullselect, set operation, or the IN list of an IN predicate combine two or more string columns resulting from the subselects into results column.

All such operations have the following in common:
• The choice of a result CCSID for the string or column
• The possible conversion of one or more of the component strings or columns to the result CCSID

For all such operations, the rules for those two actions are the same, as described in Selecting the result CCSID. These rules also apply to the COALESCE scalar function.

Selecting the result CCSID

The result CCSID is selected at package prepare time. The result CCSID is the CCSID of one of the operands.

Two operands: When two operands are used, the result CCSID is determined by the operand types, their CCSIDs, and their relative positions in the operation. When a CCSID is X’FFFF’, the result CCSID is always X’FFFF’, and no character conversions take place. When neither CCSID is X’FFFF’, the rules for selecting the result CCSID are identical to the ones for string comparison. See Conversion rules for comparisons.

Three or more operands:
If all the operands have the same CCSID, the result CCSID is the common CCSID.

If at least one of the CCSIDs has the value X'FFFF', the result CCSID also has the value X'FFFF'.

Otherwise, selection proceeds as follows:
1. The rules for a pair of operands are applied to the first two operands. This picks a “candidate” for the second step. The candidate is the operand that would furnish the result CCSID if just the first two operands were involved in the operation.
2. The rules are applied to the Step 1 candidate and the third operand, thereby selecting a second candidate.
3. If a fourth operand is involved, the rules are applied to the second candidate and fourth operand, to select a third candidate, and so on.

The process continues until all operands have been used. The remaining candidate is the one that furnishes the result CCSID. Whenever the rules for a pair are applied to a candidate and an operand, the candidate is considered to be the first operand.

Consider, for example, the following concatenation:

```
A CONCAT B CONCAT C
```

Here, the rules are first applied to the strings A and B. Suppose that the string selected as candidate is A. Then the rules are applied to A and C. If the string selected is again A, then A furnishes the result CCSID. Otherwise, C furnishes the result CCSID.

**Character conversion of components:** An operand of concatenation or the selected argument of the COALESCE scalar function is converted, if necessary, to the coded character set of the result string. Each string of an operand of a set operation is converted, if necessary, to the coded character set of the result column. In either case, the coded character set is the one identified by the result CCSID. Character conversion is necessary only if all of the following are true:

- The result and operand CCSIDs are different.
- Neither CCSID is X'FFFF' (neither string is defined as BIT data).
- The string is neither null nor empty.
- The SYSSTRINGS catalog table indicates that conversion is necessary.

An error occurs if a character of a string cannot be converted, SYSSTRINGS is used but contains no information about the CCSID pair, or Db2 cannot do the conversion through z/OS support for Unicode. A warning occurs if a character of a string is converted to the substitution character.

---

**select-statement**

The select-statement is the form of a query that can be directly specified in a DECLARE CURSOR statement or FOR statement, prepared and then referenced in a DECLARE CURSOR statement, or directly specified in an SQLJ assignment clause. It can also be issued using SPUFI or the command line processor which causes a result table to be displayed at your terminal. In any case, the result table specified by a select-statement is the result of the fullselect.
Notes:
1 The `read-only-clause` must not be specified if `update-clause` is specified.
2 The same clause must not be specified more than one time.

The tables and view identified in a select statement can be at the current server or any Db2 subsystem with which the current server can establish a connection.

For local queries on Db2 for z/OS or remote queries in which the server and requester are Db2 for z/OS, if a table is encoded as ASCII or Unicode, the retrieved data is encoded in EBCDIC. For information on retrieving data encoded in ASCII or Unicode, see *Db2 Application Programming and SQL Guide*.

A select statement can implicitly or explicitly invoke user-defined functions or implicitly invoke stored procedures. This technique is known as *nesting* of SQL statements. A function or procedure is implicitly invoked in a select statement when it is invoked at a lower level. For instance, if you invoke a user-defined function from a select statement and the user-defined function invokes a stored procedure, you are implicitly invoking the stored procedure.

**common-table-expression**

A *common table expression* defines a result table with `table-identifier` that can be referenced in any FROM clause of the `fullselect` that follows.

Multiple common table expressions can be specified following the single WITH keyword. Each specified common table expression can also be referenced by name in the FROM clause of subsequent common table expressions.

If a list of columns is specified, it must consist of as many names as there are columns in the result table of the fullselect. Each `column-name` must be unique and
unqualified. If these column names are not specified, the names are derived from the select list of the `fullselect` used to define the common table expression.

`table-identifier` must be an unqualified SQL identifier, and it must be different from any other `table-identifier` in the same statement. If the common table expression is specified in an INSERT statement, the `table-identifier` must not be the same as the table or view name that is the object of the insert. If the common table expression is specified in a CREATE VIEW statement, the `table-identifier` must not be the same as the view name that is created. A common table expression `table-identifier` can be specified as a table name in any FROM clause throughout the `fullselect`.

If more than one common table expression is defined in the same statement, cyclic references between the common table expressions are not permitted. A cyclic reference occurs when two common table expressions `dt1` and `dt2` are created such that `dt1` refers to `dt2` and `dt2` refers to `dt1`. Furthermore, a common table expression defined before cannot refer to subsequent common table expressions.

A common table expression name can only be referenced in the `select-statement`, SELECT INTO statement, INSERT statement, CREATE VIEW statement, or RETURN statement that defines it.

If a `select-statement`, SELECT INTO statement, INSERT statement, or CREATE VIEW statement that is not contained in a trigger definition refers to a unqualified table name, the following rules are applied to determine which table is actually being referenced:

- If the unqualified name corresponds to one or more common table expression names that are specified in the `select-statement`, the name identifies the common table expression that is in the innermost scope.
- Otherwise, the name identifies a persistent table, a temporary table, or a view that is present in the default schema.

If a `select-statement`, SELECT INTO statement, INSERT statement, or CREATE VIEW statement that is contained in a trigger definition refers to a unqualified table name, the following rules are applied to determine which table is actually being referenced:

- If the unqualified name corresponds to one or more common table expression names that are specified in the `select-statement`, the name identifies the common table expression that is in the innermost scope.
- If the unqualified name corresponds to a transition table name, the name identifies that transition table.
- Otherwise, the name identifies a persistent table, a temporary table, or a view that is present in the default schema.

The common table expression is also optional prior to the `fullselect` in the CREATE VIEW and INSERT statements. However, the use of common table expressions is not allowed in an INSERT within SELECT statement.

A common table expression can be used:

- In place of a view to avoid creating the view (when general use of the view is not required and positioned updates or deletes are not used)
- When the result table that you want is based on host variables
- When the same result table needs to be shared in a `fullselect`
- When the result needs to be derived using recursion
If a `fullselect` of a common table expression contains a reference to itself in a FROM clause, the common table expression is a recursive common table expression. Queries using recursion are useful in supporting applications such as bill of materials (BOM), reservation systems, and network planning.

The following must be true of a recursive common table expression:

- Each `fullselect` that is part of the recursion cycle must start with SELECT or SELECT ALL. Use of SELECT DISTINCT is not allowed. Furthermore, the set operators must use the ALL keyword.
- The column names must be specified following the table-name of the common table expression.
- The first `fullselect` of the first set operator (the initialization `fullselect`) must not include a reference to the common table expression itself in any FROM clause).
- If a column name of the common table expression is referred to in the iterative `fullselect`, the data type, length, and CCSID for the column are determined based on the initialization `fullselect`. The corresponding column in the iterative `fullselect` must have the same data type and length as the data type and length determined based on the initialization `fullselect` and the CCSID must match. However, for character string types, the length of the two data types can differ. In this case, the column in the iterative `fullselect` must have a length that would always be assignable to the length determined from the initialization `fullselect`. If a column of a recursive common table expression is not used recursively in its definition, the data type, length, and CCSID for the column are determined by applying rules associated with non-recursive queries.
- Each `fullselect` that is part of the recursion cycle must not include any aggregate functions, GROUP BY clauses, HAVING clauses, ORDER BY clauses, OFFSET clauses, or FETCH FIRST clauses. The FROM clauses of these `fullselects` can include at most one reference to a common table expression that is part of a recursion cycle.
- Subqueries (scalar or quantified) must not be part of any recursion cycles.
- Outer join must not be part of any recursion cycles.

All columns referenced in a recursive common table expression are nullable for the query, even if they are defined as NOT NULL.

When developing recursive common table expressions, remember that an infinite recursion cycle (loop) can be created. Check that recursion cycles will terminate. This is especially important if the data involved is cyclic. A recursive common table expression is expected to include a predicate that will prevent an infinite loop. The recursive common table expression is expected to include:

- In the iterative `fullselect`, an integer column incremented by a constant.
- A predicate in the WHERE clause of the iterative `fullselect` in the form of "counter_col < constant" or "counter_col < :hostvar". A warning is issued if this syntax is not found.

If the result of a recursive common table expression is used to derive the final result table, and if a column mask is used to mask the column values in the final result table, the column mask cannot be applied to a column that is specified in the `fullselect` of the recursive common table expression.

**update-clause**

The optional FOR UPDATE clause identifies the columns that can appear as targets in an assignment clause in a later positioned UPDATE statement.
Each column name must be unqualified and must identify a column of the table or view identified in the first `FROM` clause of the fullselect. The clause must not be specified if the result table of the fullselect is read-only.

If `FOR UPDATE` clause is specified with a `column-name` list `column-name` must be an updatable column.

If the `FOR UPDATE` clause is specified without a `column-name` list, the implicit list of column names consists of all updatable columns of the table or view that is identified in the first `FROM` clause of the fullselect.

If a dynamically prepared select-statement does not contain a `FOR UPDATE` clause, the cursor that is associated with the select statement cannot be referenced in a positioned `UPDATE` statement.

If a statically prepared `select-statement` does not contain a `FOR UPDATE` clause and its result table is not read-only, an implicit `UPDATE` clause will result. The implicit list of column names consists of all updatable columns of the table or view that is identified in the first `FROM` clause of the fullselect.

The declaration of a cursor referenced in a positioned `UPDATE` statement need not include an `UPDATE` clause if the `STDSQL(YES)` or `NOFOR SQL` processing option is specified when the program is prepared. For more on the subject, see "Positioned updates of columns" on page 348.

When `FOR UPDATE` is used, FETCH operations referencing the cursor acquire U or X locks rather than S locks when:

- The isolation level of the statement is cursor stability.
- The isolation level of the statement is repeatable read or read stability and field U LOCK FOR RR/RS on installation panel DSNTIPI is set to get U locks.
- The isolation level of the statement is repeatable read or read stability and USE AND KEEP EXCLUSIVE LOCKS or USE AND KEEP UPDATE LOCKS is specified in the SQL statement, an X lock or a U lock, respectively, is acquired at fetch time.

No locks are acquired on declared temporary tables. For a discussion of U locks and S locks, see *Managing Performance*.

**read-only-clause**

The read-only clause specifies that the result table is read-only. Therefore, the cursor cannot be referred to in positioned `UPDATE` or `DELETE` statements.
Some result tables are read-only by nature (for example, a table based on a read-only view.) FOR READ ONLY can still be specified for such tables, but the specification has no effect.

For tables in which updates and deletes are allowed, specifying FOR READ ONLY can possibly improve the performance of FETCH operations as Db2 can do blocking and avoid exclusive locks. For example, in programs that contain dynamic SQL statements without the FOR READ ONLY or ORDER BY clause, Db2 might open cursors as if the UPDATE clause was specified.

A read-only result table must not be referred to in an UPDATE or DELETE statement, whether it is read-only by nature or specified as FOR READ ONLY.

To take advantage of the possibly improved performance of FETCH operations while guaranteeing that selected data is not modified and preventing some types of deadlocks, you can specify FOR READ ONLY in combination with the optional syntax of USE AND KEEP ... LOCKS on the isolation-clause.

_Alternative syntax and synonyms_: FOR FETCH ONLY can be specified as a synonym for FOR READ ONLY.

- isolation-clause

**optimize-clause**

The OPTIMIZE clause requests special optimization of the select-statement.
The `optimize-clause` tells Db2 to assume that the program does not intend to retrieve more than `integer` rows from the result table. Without this clause, Db2 assumes that all rows of the result table will be retrieved, unless the `FETCH FIRST` clause is specified. Optimizing for `integer` rows can improve performance. If this clause is omitted and the `FETCH FIRST` is specified, `OPTIMIZE FOR integer ROWS` is assumed, where `integer` is the value that is specified in the `FETCH FIRST` clause. Db2 will optimize the query based on the specified number of rows.

The clause does not limit the number of rows that can be fetched, change the result table, or change the order in which the rows are fetched. Any number of rows can be fetched, but performance can possibly degrade after `integer` fetches. In general, if you are retrieving only a few rows, specify `OPTIMIZE FOR 1 ROW` to influence the access path that Db2 selects.

The value of `integer` must be a positive integer (not zero).

Row access controls indirectly affect the `OPTIMIZE FOR` clause because row access controls affect the rows that are accessible to the authorization ID or role of the subselect.

Column access controls do not affect the `OPTIMIZE FOR` clause.

If the `optimize-clause` is not specified, a default of `OPTIMIZE FOR integer ROWS`, `integer` is determined from the following table. The Db2 subsystem uses this value for access path optimization.

<table>
<thead>
<tr>
<th>OFFSET mROWS</th>
<th>FETCH FIRST n ROWS ONLY</th>
<th>OPTIMIZE FOR o ROWS</th>
</tr>
</thead>
<tbody>
<tr>
<td>constant</td>
<td>constant</td>
<td>o</td>
</tr>
<tr>
<td>Not specified</td>
<td>constant</td>
<td>o</td>
</tr>
<tr>
<td>All other combinations of OFFSET and FETCH FIRST clauses</td>
<td>o</td>
<td>All rows</td>
</tr>
</tbody>
</table>

Table 163. Determination of integer for OPTIMIZE clause.

### isolation-clause

The `isolation-clause` specifies the isolation level at which the statement is executed. (Isolation level does not apply to declared temporary tables because no locks are acquired.)
**lock-clause:**

- **RR**  Repeatable read
- **RR lock-clause**  Repeatable read, using and keeping the type of lock that is specified in lock-clause on all accessed pages and rows
- **RS**  Read stability
- **RS lock-clause**  Read stability, using and keeping the type of lock that is specified in lock-clause on all accessed pages and rows
- **CS**  Cursor stability
- **UR**  Uncommitted read

**lock-clause**

Specifies the type of lock.

- **USE AND KEEP EXCLUSIVE LOCKS**
- **USE AND KEEP UPDATE LOCKS**
- **USE AND KEEP SHARE LOCKS**

Specifies that Db2 is to acquire and hold X, U, or S locks, respectively.

WITH UR can be specified only if the result table of the fullselect or the SELECT INTO statement is read-only.

In an ODBC application, the SQLSetStmtAttr function can be used to set statement attributes that interact with the lock-clause. If SQLSetStmtAttr is invoked with a cursor's statement handle and specifying that its SQL_ATTR_CLOSE_BEHAVIOR is SQL_CC_RELEASE (locks are to be released when the cursor is closed), then irrespective of any lock-clause, lock used by the cursor that are not needed to protect the integrity of changed data are released.

Although requesting an UPDATE or EXCLUSIVE LOCK can reduce concurrency, it can prevent some types of deadlocks.

The **default** isolation level of the statement depends on:

- The isolation of the package or plan that the statement is bound in
- Whether the result table is read-only

[Table 164 on page 1141] shows the default isolation level of the statement.
Table 164. Default isolation level based on the isolation level of the package or plan and whether the result table is read-only

<table>
<thead>
<tr>
<th>If package isolation is:</th>
<th>And plan isolation is:</th>
<th>And the result table is:</th>
<th>Then the default isolation is:</th>
</tr>
</thead>
<tbody>
<tr>
<td>RR</td>
<td>Any</td>
<td>Any</td>
<td>RR</td>
</tr>
<tr>
<td>RS</td>
<td>Any</td>
<td>Any</td>
<td>RS</td>
</tr>
<tr>
<td>CS</td>
<td>Any</td>
<td>Any</td>
<td>CS</td>
</tr>
<tr>
<td>UR</td>
<td>Any</td>
<td>Read-only</td>
<td>UR</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Not read-only</td>
<td>CS</td>
</tr>
<tr>
<td>Not specified</td>
<td>Not specified</td>
<td>Any</td>
<td>RR</td>
</tr>
<tr>
<td>RR</td>
<td>Any</td>
<td></td>
<td>RR</td>
</tr>
<tr>
<td>RS</td>
<td>Any</td>
<td></td>
<td>RS</td>
</tr>
<tr>
<td>CS</td>
<td>Any</td>
<td></td>
<td>CS</td>
</tr>
<tr>
<td>UR</td>
<td>Read-only</td>
<td></td>
<td>UR</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Not read-only</td>
<td>CS</td>
</tr>
</tbody>
</table>

A simple way to ensure that a result table is read-only is to specify FOR READ ONLY in the SQL statement.

Alternative syntax and synonyms: KEEP UPDATE LOCKS can be specified as a synonym for USE AND KEEP EXCLUSIVE LOCKS. However, KEEP UPDATE LOCKS can be specified only if FOR UPDATE OF is specified, and it is not supported in the SELECT INTO statement.

**queryno-clause**

The QUERYNO clause specifies the number to be used for this SQL statement in EXPLAIN output and trace records. The number is used for the QUERYNO columns of the plan tables for the rows that contain information about this SQL statement. This number is also used in the QUERYNO column of the SYSIBM.SYSSTMT and SYSIBM.SYSPACKSTMT catalog tables.

**queryno-clause**

```
QUERYNO—integer
```

*integer* is the value to be used to identify this SQL statement in EXPLAIN output and trace records.
If the clause is omitted, the number associated with the SQL statement is the statement number assigned during precompilation. Thus, if the application program is changed and then precompiled, that statement number might change.

Using the QUERYNO clause to assign unique numbers to the SQL statements in a program is helpful:
- For simplifying the use of optimization hints for access path selection
- For correlating SQL statement text with EXPLAIN output in the plan table

For information on using optimization hints, such as enabling the system for optimization hints and setting valid hint values, and for information on accessing the plan table, see Managing Performance.

**SKIP LOCKED DATA**

The SKIP LOCKED DATA clause specifies that rows are skipped when incompatible locks that would block the progress of the statement are held on the rows by other transactions. These rows can belong to any accessed table that is specified in the statement. SKIP LOCKED DATA can be used only with isolation CS or RS and applies only to row level or page level locks.

**Important:** The recommendation is to not rely on the SKIP LOCKED DATA option to remove rows from results returned by a query. The SKIP LOCKED DATA option is meant only to prevent possibly incompatible locks from impeding the progress of queries that can tolerate possibly incomplete results. However, Db2 might use lock avoidance techniques to avoid taking certain locks.

SKIP LOCKED DATA is ignored if it is specified when the isolation level that is in effect is repeatable read (WITH RR) or uncommitted read (WITH UR). The default isolation level of the statement depends on the isolation level of the package or plan with which the statement is bound, and whether the result table is read-only.

Examples of SELECT statements

Introductory concepts

How a SELECT statement works (Introduction to Db2 for z/OS)

Example 1: Select all the rows from DSN8C10.EMP.

```
SELECT * FROM DSN8C10.EMP;
```

Example 2: Select all the rows from DSN8C10.EMP, arranging the result table in chronological order by date of hiring.

```
SELECT * FROM DSN8C10.EMP
ORDER BY HIREDATE;
```

Example 3: Select the department number (WORKDEPT) and average departmental salary (SALARY) for all departments in the table DSN8C10.EMP. Arrange the result table in ascending order by average departmental salary.

```
SELECT WORKDEPT, AVG(SALARY) FROM DSN8C10.EMP
GROUP BY WORKDEPT
ORDER BY 2;
```

Example 4: Change various salaries, bonuses, and commissions in the table DSN8C10.EMP. Confine the changes to employees in departments D11 and D21. Use positioned updates to do this with a cursor named UP_CUR. Use a FOR UPDATE clause in the cursor declaration to indicate that all updatable columns are updated. Below is the declaration for a PL/I program.

```
EXEC SQL DECLARE UP_CUR CURSOR FOR
    SELECT WORKDEPT, EMPNO, SALARY, BONUS, COMM
    FROM DSN8C10.EMP
    WHERE WORKDEPT IN ('D11','D21')
    FOR UPDATE;
```

Beginning where the cursor is declared, all updatable columns would be updated. If only specific columns needed to be updated, such as only the salary column, the FOR UPDATE clause could be used to specify the salary column (FOR UPDATE OF SALARY).

Example 5: Find the maximum, minimum, and average bonus in the table DSN8C10.EMP. Execute the statement with uncommitted read isolation, regardless of the value of ISOLATION with which the plan or package containing the statement is bound. Assign 13 as the query number for the SELECT statement.

```
EXEC SQL
    SELECT MAX(BONUS), MIN(BONUS), AVG(BONUS)
    INTO :MAX, :MIN, :AVG
    FROM DSN8C10.EMP
    WITH UR
    QUERYNO 13;
```

If bind option EXPLAIN(YES) is specified, rows are inserted into the plan table. The value used for the QUERYNO column for these rows is 13.

Example 6: The cursor declaration shown below is in a PL/I program. In the query within the declaration, X.RMT_TAB is an alias for a table at some other Db2. Hence, when the query is used, it is processed using DRDA access. See "Distributed data" on page 73.
The declaration indicates that no positioned updates or deletes will be done with the query's cursor. It also specifies that the access path for the query be optimized for the retrieval of at most 50 rows. Even so, the program can retrieve more than 50 rows from the result table, which consists of the entire table identified by the alias. However, when more than 50 rows are retrieved, performance could possibly degrade.

```sql
EXEC SQL DECLARE C1 CURSOR FOR
   SELECT * FROM X.RMT_TAB
   OPTIMIZE FOR 50 ROWS
   FOR READ ONLY;
```

The FETCH FIRST clause could be used instead of the OPTIMIZE FOR clause to ensure that only 50 rows are retrieved as in the following example:

```sql
EXEC SQL DECLARE C1 CURSOR FOR
   SELECT * FROM X.RMT_TAB
   FETCH FIRST 50 ROWS ONLY;
```

**Example 7:** Assume that table DSN8C10.EMP has 1000 rows and you want to see the first five EMP_ROWID values that were inserted into DSN8C10.EMP_PHOTO_RESUME.

```sql
EXEC SQL DECLARE CS1 CURSOR FOR
   SELECT EMP_ROWID
   FROM FINAL TABLE (INSERT INTO DSN8C10.EMP_PHOTO_RESUME (EMPNO)
      SELECT EMPNO FROM DSN8C10.EMP)
   FETCH FIRST 5 ROWS ONLY;
```

All 1000 rows are inserted into DSN8C10.EMP_PHOTO_RESUME, but only the first five are returned.

### How SQL statements are invoked

SQL statements are invoked in different ways depending on whether the statement is an executable or nonexecutable statement or the select-statement.

The SQL statements are classified as executable or nonexecutable. The description of each statement includes a heading on invocation that indicates whether or not the statement is executable.

**Executable statements** can be invoked in the following ways:

- Embedded in an application program
- Dynamically prepared and executed
- Dynamically prepared and executed using Db2 ODBC function calls
- Issued interactively

Depending on the statement, you can use some or all of these methods. The section on invocation in the description of each statement tells you which methods can be used.

A nonexecutable statement can only be embedded in an application program.

The select-statement is an additional SQL statement construct. (See select-statement) It is used in a different way from other statements.

A select-statement can be invoked in the following ways:

- Included in DECLARE CURSOR and implicitly executed by OPEN
- Dynamically prepared, referred to in DECLARE CURSOR, and implicitly executed by OPEN
- Dynamically executed (no PREPARE required) using a Db2 ODBC function call
- Issued interactively
The first two methods are called, respectively, the static and the dynamic invocation of select-statement.

Related concepts:
- Submitting SQL statements to Db2 (Introduction to Db2 for z/OS)
- The Db2 command line processor (Db2 Commands)

Related tasks:
- Executing SQL by using SPUFI (Db2 Application programming and SQL)
- Overview of programming applications that access Db2 for z/OS data (Db2 Application programming and SQL)

Embedding a statement in an application program

You can include SQL statements in a source program that will be submitted to the Db2 precompiler or coprocessor. Such statements are said to be embedded in the application program. An embedded statement can be placed anywhere in the application program where a host language statement is allowed. Each embedded statement must be preceded by a keyword (or keywords) to indicate that the statement is an SQL statement.

- In C and COBOL, each embedded statement must be preceded by the keywords EXEC SQL.
- In Java, each embedded statement must be preceded by the keywords #sql.
- In REXX, each embedded statement must be preceded by the keyword EXECSQL.

Executable statements: An executable statement embedded in an application program is executed every time a statement of the host language would be executed if specified in the same place. (Thus, for example, a statement within a loop is executed every time the loop is executed, and a statement within a conditional construct is executed only when the condition is satisfied.)

An embedded statement can contain references to host variables. A host variable referred to in this way can be used in one of two ways:

As input
The current value of the host variable is used in the execution of the statement.

As output
The variable is assigned a new value as a result of executing the statement.

In particular, all references to host variables in expressions and predicates are effectively replaced by current values of the variables; that is, the variables are used as input. The treatment of other references is described individually for each statement.

The successful or unsuccessful execution of the statement is indicated by setting the SQLCODE and SQLSTATE fields in the SQLCA. You must therefore follow all executable statements by a test of SQLCODE or SQLSTATE. Alternatively, you can use the WHENEVER statement (which is itself nonexecutable) to change the flow of control immediately after the execution of an embedded statement.

25. SQLCODE and SQLSTATE cannot be in the SQLCA when the SQL processing option STDSQL(YES) is in effect. See SQL standard language.
**Nonexecutable statements:** An embedded nonexecutable statement is processed only by the precompiler or coprocessor. The precompiler or coprocessor reports any errors encountered in the statement. The statement is never executed, and acts as a no-operation if placed among executable statements of the application program. Therefore, do not follow such statements with a test of an SQL return code.

**Dynamic preparation and execution**

Your application program can dynamically build an SQL statement in the form of a character string placed in a host variable. In general, the statement is built from some data available to the application program (for example, input from a workstation).

In non-Java languages, the statement so constructed can be prepared for execution by means of the (embedded) statement PREPARE and executed by means of the (embedded) statement EXECUTE, as described in Dynamically executing an SQL statement by using PREPARE and EXECUTE (Db2 Application programming and SQL). Alternatively, you can use the (embedded) statement EXECUTE IMMEDIATE to prepare and execute a statement in one step. In Java, the statement can be prepared for execution by means of the Statement, PreparedStatement, and CallableStatement classes, and executed by means of their respective execute() methods.

The statement can also be prepared by calling the Db2 ODBC SQLPrepare function and then executed by calling the Db2 ODBC SQLExecute function. In both cases, the application does not contain an embedded PREPARE or EXECUTE statement. You can execute the statement, without preparation, by passing the statement to the Db2 ODBC SQLExecDirect function. Introduction to Db2 ODBC (Db2 Programming for ODBC) describes the APIs supported with this interface.

A statement that is going to be prepared must not contain references to host variables. It can instead contain parameter markers. (See Parameter markers in the description of the PREPARE statement for rules concerning parameter markers.) When the prepared statement is executed, the parameter markers are effectively replaced by current values of the host variables specified in the EXECUTE statement. (See the EXECUTE statement for rules concerning this replacement.) After it is prepared, a statement can be executed several times with different values of host variables. Parameter markers are not allowed in the SQL statement prepared and executed using EXECUTE IMMEDIATE.

In non-Java languages, the successful or unsuccessful execution of the statement is indicated by the values returned in the SQLCODE and SQLSTATE fields in the SQLCA after the EXECUTE (or EXECUTE IMMEDIATE) statement. You should check the fields as described above for embedded statements. In Java, the successful or unsuccessful execution of the statement is handled by Java Exceptions.

As explained in Authorization IDs and dynamic SQL, the DYNAMICRULES behavior in effect determines the privilege set that is used for authorization checking when dynamic SQL statements are processed. The following table summarizes those privilege sets. (See Authorization IDs and dynamic SQL for a list of the DYNAMICRULES bind option values that determine which behavior is in effect).
Table 166. DYNAMICRULES behaviors and authorization checking

<table>
<thead>
<tr>
<th>DYNAMICRULES behavior</th>
<th>Privilege set</th>
</tr>
</thead>
<tbody>
<tr>
<td>Run behavior</td>
<td>The union of the set of privileges held by each authorization ID of the process if the dynamically prepared statement is other than an ALTER, CREATE, DROP, GRANT, RENAME, or REVOKE statement. The privileges that are held by the SQL authorization ID of the process or the role of the primary authorization ID (if the process is running in a trusted context that is defined with the ROLE AS OBJECT OWNER clause), if the dynamic SQL statement is a CREATE, GRANT, or REVOKE statement.</td>
</tr>
<tr>
<td>Bind behavior</td>
<td>The privileges that are held by the primary authorization ID of the owner of the package or plan.</td>
</tr>
<tr>
<td>Define behavior</td>
<td>The privileges that are held by the authorization ID of the stored procedure or user-defined function owner (definer).</td>
</tr>
<tr>
<td>Invoke behavior</td>
<td>The privileges that are held by the authorization ID of the stored procedure or user-defined function invoker. However, if the invoker is the primary authorization ID of the process or the CURRENT SQLID value, secondary authorization IDs are also checked if they are needed for the required authorization. Therefore, in that case, the privilege set is the union of the set of privileges that are held by each authorization ID or role (if running in a trusted context).</td>
</tr>
</tbody>
</table>

Static invocation of a SELECT statement

A SELECT statement can be invoked statically in different ways.

You can include a SELECT statement as a part of the (nonexecutable) statement DECLARE CURSOR. Such a statement is executed every time you open the cursor by means of the (embedded) statement OPEN. After the cursor is open, you can retrieve the result table a row at a time by successive executions of the (embedded) SQL FETCH statement.

If the application is using Db2 ODBC, the SELECT statement is first prepared with the SQLPrepare function call. It is then executed with the SQLExecute function call. Data is then fetched with the SQLFetch function call. The application does not explicitly open the cursor.

The SELECT statement used in this way can contain references to host variables. These references are effectively replaced by the values that the variables have at the moment of executing OPEN.

The successful or unsuccessful execution of the SELECT statement is indicated by the values returned in the SQLCODE and SQLSTATE fields in the SQLCA after the OPEN. You should check the fields as described above for embedded statements.

If the application is using Db2 ODBC, the successful execution of the SELECT statement is indicated by the return code from the SQLExecute function call. If necessary, the application can retrieve the SQLCA by calling the SQLGetSQLCA function.
Dynamic invocation of a SELECT statement

Your application program can dynamically build a SELECT statement in the form of a character string placed in a host variable. In general, the statement is built from some data available to the application program (for example, a query obtained from a terminal).

The statement so constructed can be prepared for execution by means of the (embedded) statement PREPARE, and referred to by a (nonexecutable) statement DECLARE CURSOR. The statement is then executed every time you open the cursor by means of the (embedded) statement OPEN. After the cursor is open, you can retrieve the result table a row at a time by successive executions of the (embedded) SQL FETCH statement.

The SELECT statement used in that way must not contain references to host variables. It can instead contain parameter markers. (See “Notes” in PREPARE for rules concerning parameter markers.) The parameter markers are effectively replaced by the values of the host variables specified in the OPEN statement. (See OPEN for rules concerning this replacement.)

The successful or unsuccessful execution of the SELECT statement is indicated by the values returned in the SQLCODE and SQLSTATE fields in the SQLCA after the OPEN. You should check the fields as described above for embedded statements.

Interactive invocation

An SQL statement submitted to Db2 from a terminal is said to be issued interactively.

IBM relational database management systems allow you to enter SQL statements from a terminal. Db2 for z/OS provides SPUFI to prepare and execute SQL statements. Other products are also available. A statement entered in this way is said to be issued interactively.

A statement issued interactively must not contain parameter markers or references to host variables, because these make sense only in the context of an application program. For the same reason, there is no SQLCA involved.

Related concepts:
- Interactive SQL (Introduction to Db2 for z/OS)
- The Db2 command line processor (Db2 Commands)

Related tasks:
- Executing SQL by using SPUFI (Db2 Application programming and SQL)

SQL diagnostics information

Db2 uses a diagnostics area to store status information and diagnostics information about the execution of an executable SQL statement.

When an SQL statement other than GET DIAGNOSTICS or compound-statement is processed, the current diagnostics area is cleared before processing the SQL statement. As each SQL statement is processed, information about the execution of that SQL statement is recorded in the current diagnostics area as one or more completion conditions or exception conditions.
A completion condition indicates that the SQL statement completed successfully, completed with a warning condition, or completed with a not found condition. An exception condition indicates that the statement was not successful. The GET DIAGNOSTICS statement can be executed in most languages to return conditions and other information about the previously executed SQL statement from the diagnostics area. Additionally, the condition information is provided through language specific mechanisms for SQL procedures, and host language applications.

**Related concepts:**
- [Detecting and processing error and warning conditions in host language applications](#)

**Related reference:**
- [GET DIAGNOSTICS](#)
- [SQL-procedure-statement](#)

## Detecting and processing error and warning conditions in host language applications

Errors and warnings conditions in host language applications can be checked by using the SQLCODE or SQLSTATE host variables or by using the SQLCA.

Each host language provides a mechanism for handling diagnostic information.

- In Assembler, C, COBOL, Fortran, and PL/I, an application program that contains executable SQL statements must provide at least one of the following:
  - A structure named SQLCA, which can be provided by using the INCLUDE SQLCA statement
  - A stand-alone CHAR(5) (CHAR(6) in C) variable named SQLSTATE (SQLSTT in Fortran)
  - A stand-alone integer variable named SQLCODE (SQLCOD in Fortran)

- In Java, for error conditions, the getSQLState method of the JDBC SQLException class can be used to get the SQLSTATE and the getErrorCode method can be used to get the SQLCODE.

- In REXX, an SQLCA is provided automatically.

Whether you define stand-alone SQLCODE and SQLSTATE host variables or an SQLCA in your program depends on the Db2 precompiler option you choose.

If the application is using Db2 ODBC and it calls the SQLGetSQLCA function, it need only include an SQLCA. Otherwise, all notification of success or errors is specified with return codes for the various function calls.

When you specify STDSQL(YES), which indicates conformance to the SQL standard, you should not define an SQLCA. The stand-alone variable for SQLCODE must be a valid host variable in the DECLARE SECTION of a program. It can also be declared outside of the DECLARE SECTION when no variable is defined for SQLSTATE. The stand-alone variable for SQLSTATE must be declared in the DECLARE SECTION. It must not be declared as an element of a structure.

Use a stand-alone SQLSTATE to conform with the SQL 2003 Core standard. When you specify STDSQL(NO), which indicates conformance to Db2 rules, you must include an SQLCA explicitly to have access to the SQLSTATE and SQLCODE information.
**SQLSTATE**
Db2 sets SQLSTATE after each SQL statement (other than GET DIAGNOSTICS or a compound statement) is executed. Db2 returns values that conform to the error specification in the SQL standard. Thus, application programs can check the execution of SQL statements by testing SQLSTATE instead of SQLCODE.

SQLSTATE provides application programs with common codes for common error conditions (the values of SQLSTATE are product-specific if the error or warning is product-specific). Furthermore, SQLSTATE is designed so that application programs can test for specific errors or classes of errors. The coding scheme is the same for all IBM implementations of SQL. The SQLSTATE values are based on the SQLSTATE specifications contained in the SQL standard. Error messages and the tokens that are substituted for variables in error messages are associated with SQLCODE values, not SQLSTATE values.

In the case of a LOOP statement, the SQLSTATE is set after the END LOOP portion of the LOOP statement completes. With the REPEAT statement, the SQLSTATE is set after the UNTIL and END REPEAT portions of the REPEAT statement completes.

If the application is using Db2 ODBC, the SQLSTATE returned conforms to the ODBC Version 2.0 specification.

**SQLCODE**
The SQLCODE is also set by Db2 after each SQL statement is executed.

Db2 conforms to the SQL standard as follows:
- If SQLCODE = 0 and SQLWARN0 is blank, execution was successful.
- If SQLCODE = 100, "no data" was found. For example, a FETCH statement returned no data because the cursor was positioned after the last row of the result table.
- If SQLCODE > 0 and not = 100, execution was successful with a warning.
- If SQLCODE = 0 and SQLWARN0 = 'W', execution was successful with a warning.
- If SQLCODE < 0, execution was not successful.

In the case of a LOOP statement, the SQLSTATE is set after the END LOOP portion of the LOOP statement completes. With the REPEAT statement, the SQLSTATE is set after the UNTIL and END REPEAT portions of the REPEAT statement completes.

The SQL standard does not define the meaning of any other specific positive or negative values of SQLCODE, and the meaning of these values is not the same in all implementations of SQL.

If the application is using Db2 ODBC, an SQLCODE is only returned if the application issues the SQLGetSQLCA function.

---

**SQL comments**
Static SQL statements can include host language or SQL comments. Dynamic SQL statements can include SQL comments. There are two types of SQL comments, simple comments and bracketed comments.
simple comments
Simple comments are introduced with two consecutive hyphens (--) and end with the end of a line. The following rules apply to the use of simple comments:

- The two hyphens must be on the same line and must not be separated by a space.
- Simple comments can be started whenever a space is valid (except within a delimiter token or between ‘EXEC’ and ‘SQL’).
- Simple comments cannot be continued to the next line.
- In COBOL, the hyphen must be preceded by a space.

bracketed comments
Bracketed comments are introduced with /* and end with */. The following rules apply to the use of bracketed comments:

- The /* must be on the same line and not separated by a space.
- The */ must be on the same line and not separated by a space.
- Bracketed comments can be started wherever a space is valid (except within a delimiter token or between ‘EXEC’ and ‘SQL’).
- Bracketed comments can be continued to the next line.
- Bracketed comments can be nested within other bracketed comments. However, nested bracketed comments are not supported by DSNTEP2, DSNTEP4, SPUFI, or the command line processor.
- Bracketed comments are not allowed in static SQL statements in a COBOL, Fortran, or Assembler program.

Example: This example shows how to include comments in an SQL statement within a C program. The example uses both simple and bracketed comments:

```
EXEC SQL
CREATE VIEW PRJ_MAXPER --projects with most support personnel
    /*
    * Returns number and name of the project
    */
    AS SELECT PROJNO, PROJNAME -- number and name of project
    FROM DSN8910.PROJ
    /*
    * E21 is the systems support dept code
    */
    WHERE DEPTNO = 'E21' -- systems support dept code
    AND PRSTAFF > 1;
```

For information about host language comments, refer to *Db2 Application Programming and SQL Guide*.

---

**ALLOCATE CURSOR**

The ALLOCATE CURSOR statement defines a cursor and associates it with a result set locator variable.

**Invocation**

This statement can be embedded in an application program. It is an executable statement that can be dynamically prepared. It cannot be issued interactively.

**Authorization**

None required.
Syntax

ALLOCATE cursor-name CURSOR FOR RESULT SET rs-locator-variable

Description

cursor-name
Names the cursor. The name must not identify a cursor that has already been declared in the source program.

CURSOR FOR RESULT SET rs-locator-variable
Specifies a result set locator variable that has been declared in the application program according to the rules for declaring result set locator variables.

The result set locator variable must contain a valid result set locator value, as returned by the ASSOCIATE LOCATORS or DESCRIBE PROCEDURE SQL statement. The value of the result set locator variable is used at the time the cursor is allocated. Subsequent changes to the value of the result set locator have no affect on the allocated cursor. The result set locator value must not be the same as a value used for another cursor allocated in the source program.

Notes

Dynamically prepared ALLOCATE CURSOR statements: The EXECUTE statement with the USING clause must be used to execute a dynamically prepared ALLOCATE CURSOR statement. In a dynamically prepared statement, references to host variables are represented by parameter markers (question marks). In the ALLOCATE CURSOR statement, rs-locator-variable is always a host variable. Thus, for a dynamically prepared ALLOCATE CURSOR statement, the USING clause of the EXECUTE statement must identify the host variable whose value is to be substituted for the parameter marker that represents rs-locator-variable.

You cannot prepare an ALLOCATE CURSOR statement with a statement identifier that has already been used in a DECLARE CURSOR statement. For example, the following SQL statements are invalid because the PREPARE statement uses STMT1 as an identifier for the ALLOCATE CURSOR statement and STMT1 has already been used for a DECLARE CURSOR statement.

DECLARE CURSOR C1 FOR STMT1;
PREPARE STMT1 FROM INVALID
 'ALLOCATE C2 CURSOR FOR RESULT SET ?';

Rules for using an allocated cursor: The following rules apply when you use an allocated cursor:

• You cannot open an allocated cursor with the OPEN statement.
• You can close an allocated cursor with the CLOSE statement. Closing an allocated cursor closes the associated cursor defined in the stored procedure.
• You can allocate only one cursor to each result set.

The life of an allocated cursor: A rollback operation, an implicit close, or an explicit close destroy allocated cursors. A commit operation destroys allocated cursors that are not defined WITH HOLD by the stored procedure. Destroying an allocated cursor closes the associated cursor defined in the stored procedure.
**Considerations for scrollable cursors:** Following an ALLOCATE CURSOR statement, a GET DIAGNOSTICS statement can be used to get the attributes of the cursor such as the following information (for more information, see "GET DIAGNOSTICS" on page 2098):

- **DB2_SQL_ATTR_CURSOR_HOLD.** Whether the cursor was defined with the WITH HOLD attribute.
- **DB2_SQL_ATTR_CURSOR_SCROLLABLE.** Scrollability of the cursor.
- **DB2_SQL_ATTR_CURSOR_SENSITIVITY.** Effective sensitivity of the cursor.
  The sensitivity information can be used by applications (such as an ODBC driver) to determine what type of FETCH (INSENSITIVE or SENSITIVE) to issue for a cursor defined as ASENSITIVE.
- **DB2_SQL_ATTR_CURSOR_ROWSET.** Whether the cursor can be used to access rowsets.
- **DB2_SQL_ATTR_CURSOR_TYPE.** Whether a cursor type is forward-only, static, or dynamic.
  - The scrollability of the cursor is in SQLWARN1.
  - The sensitivity of the cursor is in SQLWARN4.
  - The effective capability of the cursor is in SQLWARN5.

**Example**

The statement in the following example is assumed to be in a PL/I program.

Define and associate cursor C1 with the result set locator variable LOC1 and the related result set returned by the stored procedure:

```sql
EXEC SQL ALLOCATE C1 CURSOR FOR RESULT SET :LOC1;
```

---

**ALTER DATABASE**

The ALTER DATABASE statement changes the description of a database at the current server.

**Invocation**

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

**Authorization**

The privilege set that is defined below must include at least one of the following:

- The DROP privilege on the database
- Ownership of the database
- DBADM or DBCTRL authority for the database
- SYSADM or SYSCTRL authority
- System DBADM
- Installation SYSOPR authority (when the current SQLID of the process is set to SYSINSTL)

If the database is implicitly created, the privileges must be on the implicit database or on DSNDB04.

**Privilege set:** If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the package. If the
statement is dynamically prepared, the privilege set is the union of the privilege sets that are held by each authorization ID and role of the process.

**Syntax**

```
ALTER DATABASE database-name
  BUFFERPOOL bpname
  INDEXBP bpname
  STOGROUP stogroup-name
  CCSID ccsid-value
```

**Notes:**
1. The same clause must not be specified more than one time.

**Description**

**DATABASE database-name**

Identifies the database that is to be altered. The name must identify a database that exists at the current server and must not identify an implicitly created system database.

**BUFFERPOOL bpname**

Identifies the default buffer pool for the table spaces within the database. It does not apply to table spaces that already exist within the database.

If the database is a work file database, 8 KB and 16 KB buffer pools cannot be specified.

If the table space is implicitly created, Db2 selects the buffer pool as described in "Implicitly defined table spaces (Db2 Administration Guide)."

See “Naming conventions” on page 85 for more details about bpname.

**INDEXBP bpname**

Identifies the default buffer pool for the indexes within the database. It does not apply to indexes that already exist within the database. The name can identify a 4 KB, 8 KB, 16 KB, or 32 KB buffer pool. See “Naming conventions” on page 85 for more details about bpname.

**STOGROUP stogroup-name**

Identifies the storage group to be used, as required, as a default storage group to support DASD space requirements for table spaces and indexes within the database. It does not apply to table spaces and indexes that already exist within the database.

**CCSID ccsid-value**

Identifies the default CCSID for table spaces within the database. It does not apply to existing table spaces in the database. ccsid-value must identify a CCSID value that is compatible with the current value of the CCSID for the database. "Notes” on page 1160 contains a list that shows the CCSID to which a given CCSID can be altered.

CCSID cannot be specified for a work file database.
Notes

Altering the CCSID: The ability to alter the default CCSID enables you to change to a CCSID that supports the Euro symbol. You can only convert between specific CCSIDs that do and do not define the Euro symbol. In most cases, the code point that supports the Euro symbol replaces an existing code point, such as the International Currency Symbol (ICS).

Changing a CCSID can be disruptive to the system and requires several steps. For each encoding scheme of a system (ASCII, EBCDIC, and Unicode), Db2 supports SBCS, DBCS, and mixed CCSIDs. Therefore, the CCSIDs for all databases and all table spaces within an encoding scheme should be altered at the same time. Otherwise, unpredictable results might occur.

The recommended method for changing the CCSID requires that the data be unloaded and reloaded. See Db2 Installation Guide for the steps needed to change the CCSID, such as running an installation CLIST to modify the CCSID data in DSNHDECP, when to drop and re-create views, and when to rebind invalidated packages.

The following lists show the CCSIDs that can be converted. The second CCSID in each pair is the CCSID with the Euro symbol. The CCSID can be changed from the CCSID that does not support the Euro symbol to the CCSID that does, and vice versa. For example, if the current CCSID is 500, it can be changed to 1148.

EBCDIC CCSIDs

<table>
<thead>

</tr>
</tbody>
</table>

Example

Change the default buffer pool for both table spaces and indexes within database ABCDE to BP2.

```
ALTER DATABASE ABCDE
  BUFFERPOOL BP2
  INDEXBP BP2;
```
ALTER FUNCTION (external)

The ALTER FUNCTION statement changes the description of a user-defined external scalar function or external table function at the current server.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

Authorization

The privilege set defined below must include at least one of the following:

- Ownership of the function
- The ALTERIN privilege on the schema
- SYSADM or SYSCTRL authority
- System DBADM
- Installation SYSOPR authority (when the current SQLID of the process is set to SYSINSTL)

The authorization ID that matches the schema name implicitly has the ALTERIN privilege on the schema.

If the authorization ID that is used to alter the function has the installation SYSADM authority or the installation SYSOPR authority and if the current SQLID is set to SYSINSTL, the function is identified as system-defined function when the function definition is reevaluated.

At least one of the following privileges is required if the SECURED option is specified or if the function is currently secured and the NOT SECURED option is specified:

- SECADM authority
- CREATE_SECURE_OBJECT privilege

For external scalar functions, when LANGUAGE is JAVA and a jar-name is specified in the EXTERNAL NAME clause, the privilege set must include USAGE on the JAR file.

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the package.

If the statement is dynamically prepared, the privilege set is the set of privileges that are held by the SQL authorization IDs of the process. The specified routine name can include a schema name (a qualifier). However, if the schema name is not the same as one of these SQL authorization IDs, one of the following conditions must be met:

1. The privilege set includes SYSADM authority
2. The privilege set includes SYSCTRL authority
3. The SQL authorization ID of the process has the ALTERIN privilege on the schema
If the environment in which the function is to be run is being changed, the authorization ID must have authority to use the WLM environment specified. The required authorization is obtained from an external security product, such as RACF.

### Syntax

```
ALTER FUNCTION function-name
  (parameter-type)
  option-list
  SPECIFIC FUNCTION specific-name
```

**parameter-type:**

```
data-type
  AS LOCATOR (1)
```

**Notes:**

1. **AS LOCATOR** can be specified only for a LOB data type or a distinct type based on a LOB data type.

**data-type:**

```
built-in-type
  distinct-type-name
```

**built-in-type:**
option-list: (Specify options in any order. Specify at least one option. Do not specify the same option more than once.)

</tbody>
</table>

Notes:
1. If `LANGUAGE` is `JAVA`, `EXTERNAL NAME` must be specified with a valid `external-java-routine-name`.
2. When `LANGUAGE JAVA` is specified, `PARAMETER STYLE JAVA` must also be specified. When `PARAMETER STYLE JAVA` is specified, `LANGUAGE JAVA` must also be specified.
3. `LANGUAGE JAVA`, `PARAMETER STYLE JAVA`, `MODIFIES SQL DATA`, and `ALLOW PARALLEL` are not supported for `external table functions`.
4. `CARDINALITY` is not supported for `external scalar functions`.
Description

One of the following three clauses identifies the function to be changed.

**FUNCTION function-name**

Identifies the external function by its function name. `function-name` must identify a function that exists at the current server. The function must be a user-defined external function, and there must be exactly one function with `function-name` in the schema.

The function can have any number of input parameters. If the schema does not contain a function with `function-name` or contains more than one function with this name, an error occurs.

**FUNCTION function-name (parameter-type,...)**

Identifies the external function by its function signature, which uniquely identifies the function.

`function-name`

Identifies the function by its name.

Notes:
1. The slash (/) is supported for compatibility with previous releases of Db2 for z/OS.
2. The exclamation point (!) is supported for compatibility with other products in the Db2 family.
If function-name() is specified, the function that is identified must have zero parameters.

\((\text{parameter-type}, \ldots)\)

Identifies the number of input parameters of the function and their data types.

The data type of each parameter must match the data type that was specified in the CREATE FUNCTION statement for the parameter in the corresponding position. The number of data types and the logical concatenation of the data types are used to uniquely identify the function. Therefore, you cannot change the number of parameters or the data types of the parameters.

For data types that have a length, precision, or scale attribute, you can use a set of empty parentheses, specify a value, or accept the default values:

If the function was defined with a table parameter (the LIKE TABLE name AS LOCATOR clause was specified in the CREATE FUNCTION statement to indicate that one of the input parameters is a transition table), the function signature cannot be used to uniquely identify the function. Instead, use one of the other syntax variations to identify the function with its function name, if unique, or its specific name.

- Empty parentheses indicate that Db2 is to ignore the attribute when determining whether the data types match.
  For example, DEC() will be considered a match for a parameter of a function defined with a data type of DEC(7,2). Similarly DECFLOAT() will be considered a match for DECFLOAT(16) or DECFLOAT(34). FLOAT cannot be specified with empty parentheses because its parameter value indicates different data types (REAL or DOUBLE).

- If you use a specific value for a length, precision, or scale attribute, the value must exactly match the value that was specified (implicitly or explicitly) in the CREATE FUNCTION statement.
  The specific value for FLOAT\(n\) does not have to exactly match the defined value of the source function because \(1\leq n\leq21\) indicates REAL and \(22\leq n\leq53\) indicates DOUBLE. Matching is based on whether the data type is REAL or DOUBLE.

- If length, precision, or scale is not explicitly specified and empty parentheses are not specified, the default length of the data type is implied. The implicit length must exactly match the value that was specified (implicitly or explicitly) in the CREATE FUNCTION statement.

For data types with a subtype or encoding scheme attribute, specifying the FOR subtype DATA clause or the CCSID clause is optional. Omission of either clause indicates that Db2 is to ignore the attribute when determining whether the data types match. If you specify either clause, it must match the value that was implicitly or explicitly specified in the CREATE FUNCTION statement.

See CREATE FUNCTION for more information on the specification of the parameter list.

A function with the function signature must exist in the explicitly or implicitly specified schema.

**SPECIFIC FUNCTION specific-name**

Identifies the external function by its specific name. A function with the specific name must exist in the schema.
The following clauses change the description of the function that has been identified to be changed.

**EXTERNAL NAME** `external-program-name` or `identifier`

Identifies the user-written code (program) that runs when the function is invoked.

If `LANGUAGE` is `JAVA`, `external-program-name` must be specified and enclosed in single quotation marks, with no extraneous blanks within the single quotation marks. It must specify a valid `external-java-routine-name`. If multiple `external-program-name` values are specified, the total length of all of them must not be greater than 1305 bytes and they must be separated by a space or a line break. Do not specify a JAR file for a Java function for which `NO SQL` is in effect.

An `external-java-routine-name` contains the following parts:

- **jar-name**
  Identifies the name given to the JAR file when it was installed in the database. The name contains `jar-id`, which can optionally be qualified with a schema. Examples are "myJar" and "mySchema.myJar." The unqualified `jar-id` is implicitly qualified with a schema name according to the following rules:
  - If the statement is embedded in a program, the schema name is the authorization ID in the QUALIFIER option of the `BIND` subcommand for a package or plan when the package or plan was created or last changed. The schema name can also be the authorization ID in the QUALIFIER option of the CREATE PROCEDURE or ALTER PROCEDURE statement for a native SQL procedure when the procedure was created or last changed. If the QUALIFIER is not specified, the schema name is the owner of the package, plan, or native SQL procedure.
  - If the statement is dynamically prepared, the schema name is the SQL authorization ID in the CURRENT SCHEMA special register.

If `jar-name` is specified, it must exist when the `ALTER FUNCTION` statement is processed.

If `jar-name` is not specified, the function is loaded from the class file directly. Db2 searches the directories in the CLASSPATH associated with the WLM Environment. Environmental variables for Java routines are specified in a data set identified in a JAVAENV DD card on the JCL used to start the address space for a WLM-managed function.

- **method-name**
  Identifies the name of the method and must not be longer than 254 bytes. Its package, class, and method IDs are specific to Java and as such are not limited to 18 bytes. In addition, the rules for what method IDs can contain are not necessarily the same as the rules for an SQL ordinary identifier.

- **package-id**
  Identifies a package. The concatenated list of `package-ids` identifies the package that the class identifier is part of. If the class is part of a package, the method name must include the complete package prefix, such as "myPacks.UserFuncs." The Java virtual machine looks in the directory "/myPacks/UserFuncs/" for the classes.

- **class-id**
  Identifies the class identifier of the Java object.
method-id
Identifies the method identifier with the Java class to be invoked.

method-signature
Identifies a list of zero or more Java data types for the parameter list and must not be longer than 1024 bytes. Specify the method-signature if the user-defined function involves any input or output parameters that can be NULL. When the function that is being created is called, Db2 searches for a Java method with the exact method-signature. The number of java-datatype elements that are specified indicates how many parameters that the Java method must have.

A Java procedure can have no parameters. In this case, you code an empty set of parentheses for method-signature. If a Java method-signature is not specified, Db2 searches for a Java method with a signature derived from the default JDBC types associated with the SQL types specified in the parameter list of the ALTER FUNCTION statement.

For other values of LANGUAGE, the value must conform to the naming conventions for load modules: the value must be less than or equal to 8 bytes, and it must conform to the rules for an ordinary identifier with the exception that it must not contain an underscore.

LANGUAGE
Specifies the application programming language in which the function is written. All programs must be designed to run in IBM's Language Environment environment.

ASSEMBLE
The function is written in Assembler.

C
The function is written in C or C++.

COBOL
The function is written in COBOL, including the object-oriented language extensions.

JAVA
The user-defined function is written in Java and is executed in the Java virtual machine. If the ALTER FUNCTION statement results in changing LANGUAGE to JAVA, PARAMETER STYLE JAVA and an EXTERNAL NAME clause must be specified to provide the appropriate values. When LANGUAGE JAVA is specified, the EXTERNAL NAME clause must also be specified with a valid external-java-routine-name and PARAMETER STYLE must be specified with JAVA.

Do not specify LANGUAGE JAVA when SCRATCHPAD, FINAL CALL, DBINFO, PROGRAM TYPE MAIN, or RUN OPTIONS is specified. Do not specify LANGUAGE JAVA for a table function.

PLI
The function is written in PL/I.

PARAMETER STYLE
Specifies the linkage convention that the function program uses to receive input parameters from and pass return values to the invoking SQL statement.

SQL
Specifies the parameter passing convention that supports passing null values both as input and for output. The parameters that are passed between the invoking SQL statement and the function include:
• Input parameters. The first $n$ parameters are the input parameters that are specified for the function.
• Result parameters. For an external scalar function, a parameter for the result of the function. For an external table function, the next $m$ parameters that are specified on the RETURNS TABLE clause of the CREATE statement that defined the function.
• Input parameter indicator variables. $n$ parameters for the indicator variables for the input parameters.
• Result parameter indicator variables. For an external scalar function, a parameter for the indicator variable for the result of the function that is specified on the RETURNS clause of the CREATE statement that defined the function. For an external table function, $m$ parameters for the indicator variables of the result columns of the function that are specified on the RETURNS TABLE clause of the CREATE statement that defined the function.
• The SQLSTATE to be returned to Db2.
• The qualified name of the function.
• The specific name of the function.
• The SQL diagnostic string to be returned to Db2.
• The scratchpad, if SCRATCHPAD is specified.
• The call type. For an external scalar function, the call type is passed only if FINAL CALL is specified. The call type is always passed for an external table function.
• The DBINFO structure, if DBINFO is specified.

JAVA
Indicates that the user-defined function uses a convention for passing parameters that conforms to the Java and SQLJ specifications. If the ALTER FUNCTION statement results in changing LANGUAGE to JAVA, PARAMETER STYLE JAVA and an EXTERNAL NAME clause must be specified to provide the appropriate values. PARAMETER STYLE JAVA can be specified only if LANGUAGE is JAVA. JAVA must be specified for PARAMETER STYLE when LANGUAGE is JAVA.

Do not specify PARAMETER STYLE JAVA for a table function.

NOT DETERMINISTIC or DETERMINISTIC
Specifies whether the function returns the same results each time that the function is invoked with the same input arguments.

NOT DETERMINISTIC
The function might not return the same result each time that the function is invoked with the same input arguments. The function depends on some state values that affect the results. Db2 uses this information to disable the merging of views and table expressions when processing SELECT or SQL data change statements that refer to this function. An example of a function that is not deterministic is one that generates random numbers, or any function that contains SQL statements.

Some SQL functions that invoke functions that are not deterministic can receive incorrect results if the function is executed by parallel tasks. Specify the DISALLOW PARALLEL clause for these functions.
If a view or a materialized query table definition refers to the function, the function cannot be changed to **NOT DETERMINISTIC**. To change the function, drop any views or materialized query tables that refer to the function first.

**DETERMINISTIC**
The function always returns the same result each time that the function is invoked with the same input arguments. An example of a deterministic function is a function that calculates the square root of the input. Db2 uses this information to enable the merging of views and table expressions for SELECT or SQL data change statements that refer to this function. If applicable, specify **DETERMINISTIC** to prevent non-optimal access paths from being chosen for SQL statements that refer to this function.

Db2 does not verify that the function program is consistent with the specification of **DETERMINISTIC** or **NOT DETERMINISTIC**.

**RETURNS NULL ON NULL INPUT or CALLED ON NULL INPUT**
Specifies whether the function is called if any of the input arguments is null at execution time.

**RETURNS NULL ON NULL INPUT**
The function is not called if any of the input arguments is null. For an external scalar function, the result is the null value. For an external table function, the result is an empty table, which is a table with no rows.

**CALLED ON NULL INPUT**
The function is called regardless of whether any of the input arguments are null, making the function responsible for testing for null argument values. For an external scalar function, the function can return a null or nonnull value. For an external table function, the function can return an empty table, depending on its logic.

**MODIFIES SQL DATA, READS SQL DATA, CONTAINS SQL, or NO SQL**
Specifies the classification of SQL statements and nested routines that this routine can execute or invoke. The database manager verifies that the SQL statements issued by the function, and all routines locally invoked by the routine, are consistent with this specification; the verification is not performed when nested remote routines are invoked. For the classification of each statement, see [SQL statement data access classification for routines](#).

**MODIFIES SQL DATA**
Specifies that the function can execute any SQL statement except the statements that are not supported in functions. Do not specify **MODIFIES SQL DATA** when **ALLOW PARALLEL** is in effect.

If a **MODIFIES SQL DATA** function is invoked in a subselect, the results are unpredictable since the number of times the function is invoked will vary depending on the access plan used.

**Recommendation:** If you invoke a function defined with the **MODIFIES SQL DATA** option in a subselect, make sure that the SQL statements inside the function do not modify any object that is referenced by that subselect.

**READS SQL DATA**
Specifies that the function can execute statements with a data access indication of **READS SQL DATA, CONTAINS SQL, or NO SQL**. The function cannot execute SQL statements that modify data.
CONTAINS SQL
Specifies that the function can execute only SQL statements with a data classification of CONTAINS SQL or NO SQL. SQL statements that neither read nor modify SQL data can be executed by the function. Statements that are not supported in any function return a different error.

NO SQL
Specifies that the function can execute only SQL statements with a data access classification of NO SQL. Do not specify NO SQL for a Java function that uses a JAR file.

NO EXTERNAL ACTION or EXTERNAL ACTION
Specifies whether the function takes an action that changes the state of an object that Db2 does not manage. An example of an external action is sending a message or writing a record to a file.

Because Db2 uses the RRS attachment for external functions, Db2 can participate in two-phase commit with any other resource manager that uses RRS. For resource managers that do not use RRS, there is no coordination of commit or rollback operations on non-Db2 resources.

NO EXTERNAL ACTION
The function does not take any action that changes the state of an object that Db2 does not manage. Db2 uses this information to enable the merging of views and table expressions for SELECT or SQL data change statements that refer to this function. If applicable, specify NO EXTERNAL ACTION to prevent non-optimal access paths from being chosen for SQL statements that refer to this function.

EXTERNAL ACTION
The function can take an action that changes the state of an object that Db2 does not manage.

Some SQL statements that invoke functions with external actions can result in incorrect results if parallel tasks execute the function. For example, if the function sends a note for each initial call to it, one note is sent for each parallel task instead of once for the function. Specify the DISALLOW PARALLEL clause for functions that do not work correctly with parallelism.

If you specify EXTERNAL ACTION, Db2:
• Materializes the views and table expressions in SELECT or SQL data change statements that refer to the function. This materialization can adversely affect the access paths that are chosen for the SQL statements that refer to this function. Do not specify EXTERNAL ACTION if the function does not have an external action.
• Does not move the function from one task control block (TCB) to another between FETCH operations.
• Does not allow another function or stored procedure to use the TCB until the cursor is closed. This is also applicable for cursors declared WITH HOLD.

The only changes to resources made outside of Db2 that are under the control of commit and rollback operations are those changes made under RRS control.

If a view or a materialized query table definition refers to the function, the function cannot be changed to EXTERNAL ACTION. To change the function, drop any views or materialized query tables that refer to the function first.
Db2 does not verify that the function program is consistent with the specification of EXTERNAL ACTION or NO EXTERNAL ACTION.

**NO PACKAGE PATH or PACKAGE PATH package-path**

Identifies the package path to use when the function is run. This is the list of the possible package collections into which the DBRM that is associated with the function is bound.

**NO PACKAGE PATH**

Specifies that the list of package collections for the function is the same as the list of package collections for the program that invokes the function. If the program that invokes the function does not use a package, Db2 resolves the package by using the CURRENT PACKAGE PATH special register, the CURRENT PACKAGESET special register, or the PKLIST bind option (in this order). For information about how Db2 uses these three items, see *Db2 Application Programming and SQL Guide.*

**PACKAGE PATH package-path**

Specifies a list of package collections, in the same format as used in the SET CURRENT PACKAGE PATH statement.

If the COLLID clause is specified with PACKAGE PATH, the COLLID clause is ignored when the function is invoked.

The package-path value that is associated with the function definition is checked when the function is invoked. If package-path contains SESSION_USER (or USER), PATH, or PACKAGE PATH, an error is returned when the package-path value is checked.

**NO SCRATCHPAD or SCRATCHPAD**

Specifies whether Db2 is to provide a scratchpad for the function. Using reentrant external functions and a scratchpad (which provides an area for the function to save information from one invocation to the next) is strongly recommended.

**NO SCRATCHPAD**

A scratchpad is not allocated and passed to the function.

**SCRATCHPAD length**

When the function is invoked for the first time, Db2 allocates memory for a scratchpad. A scratchpad has the following characteristics:

- **length** must be between 1 and 32767. The default value is 100 bytes.
- Db2 initializes the scratchpad to all binary zeros (X'00').
- The scope of a scratchpad is the SQL statement. For each reference to the function in an SQL statement, there is one scratchpad.

For example, assuming that user-defined function UDFX is a scalar function that is defined with the SCRATCHPAD option, three scratchpads are allocated for the three references to UDFX in the following SQL statement:

```sql
SELECT A, UDFX(A) FROM TABLEB
WHERE UDFX(A) > 103 OR UDFX(A) < 19;
```

For another example, assume that UDFX is a user-defined table function that is defined with the SCRATCHPAD option. Two scratchpads are allocated for the two references to function UDFX in the following SQL statement:

```sql
SELECT *
FROM TABLE (UDFX(A)), TABLE (UDFX(B));
```
If the function is run under parallel tasks, one scratchpad is allocated for each parallel task of each reference to the function in the SQL statement. This can lead to unpredictable results. For example, if a function uses the scratchpad to count the number of times that it is invoked, the count reflects the number of invocations done by the parallel task and not the SQL statement. Specify the DISALLOW PARALLEL clause for functions that do not work correctly with parallelism.

- The scratchpad is persistent. Db2 preserves its content from one invocation of the function to the next. Any changes that the function makes to the scratchpad on one call are still there on the next call. Db2 initializes the scratchpads when it begins to execute an SQL statement. Db2 does not reset scratchpads when a correlated subquery begins to execute.

- The scratchpad can be a central point for the system resources that the function acquires. If the function acquires system resources, specify FINAL CALL to ensure that Db2 calls the function one more time so that the function can free those system resources.

Each time that the function is invoked, Db2 passes an additional argument to the function that contains the address of the scratchpad.

If you specify SCRATCHPAD, Db2:

- Does not move the function from one TCB or address space to another between FETCH operations.
- Does not allow another function or stored procedure to use the TCB until the cursor is closed. This is also applicable for cursors declared WITH HOLD.

Do not specify SCRATCHPAD when LANGUAGE JAVA is specified.

**NO FINAL CALL or FINAL CALL**

Specifies whether a final call is made to the function. A final call enables the function to free any system resources that it has acquired. A final call is useful when the function has been defined with the SCRATCHPAD keyword and the function acquires system resource and anchors them in the scratchpad.

The effect of NO FINAL CALL or FINAL CALL depends on whether the external function is a scalar function or a table function.

For an external scalar function:

**NO FINAL CALL**

A final call is not made to the external scalar function. The function does not receive an additional argument that specifies the type of call.

**FINAL CALL**

A final call is made to the external scalar function. See the following description of call types for the characteristics of a final call. When FINAL CALL is specified, the function receives an additional argument that specifies the type of call to enable the function to differentiate between a final call and another type of call. Do not specify FINAL CALL when LANGUAGE JAVA is specified.

For more information on NO FINAL CALL and FINAL CALL for external scalar functions, including the types of calls, see the description of the option for CREATE FUNCTION (external scalar).

For an external table function:
NO FINAL CALL
A first and final call are not made to the external table function.

FINAL CALL
A first call and final call are made to the external table function in addition to one or more other types of calls.

For both NO FINAL CALL and FINAL CALL, the function receives an additional argument that specifies the type of call. For more information on NO FINAL CALL and FINAL CALL for external table functions, including the types of calls, see the description of the option for CREATE FUNCTION.

ALLOW or DISALLOW PARALLEL
Specifies whether, for a single reference to the function, the function can be executed in parallel. If the function is defined with MODIFIES SQL DATA, specify DISALLOW PARALLEL, not ALLOW PARALLEL.

ALLOW PARALLEL
Specifies that Db2 can consider parallelism for the function. Parallelism is not forced on the SQL statement that invokes the function or on any SQL statement in the function. Existing restrictions on parallelism apply.

See SCRATCHPAD, EXTERNAL ACTION, and FINAL CALL for considerations when specifying ALLOW PARALLEL.

DISALLOW PARALLEL
Specifies that Db2 does not consider parallelism for the function.

NO DBINFO or DBINFO
Specifies whether additional status information is passed to the function when it is invoked.

NO DBINFO
Additional information is not passed.

DBINFO
An additional argument is passed when the function is invoked. The argument is a structure that contains information such as the application run time authorization ID, the schema name, the name of a table or column that the function might be inserting into or updating, and identification of the database server that invoked the function. For details about the argument and its structure, see Db2 Application Programming and SQL Guide.

Do not specify DBINFO when LANGUAGE JAVA is specified.

CARDINALITY integer
Specifies an estimate of the expected number of rows that the function returns. The number is used for optimization purposes. The value of integer must range 0 - 2147483647.

If a function has an infinite cardinality (which means that the function never returns the “end-of-table” condition and always returns a row), a query that requires the end-of-table condition to work correctly needs to be interrupted. Thus, avoid using such functions in queries that involve GROUP BY and ORDER BY.

Do not specify CARDINALITY for external scalar functions.
**NO COLLID or COLLID collection-id**

Identifies the package collection that is to be used when the function is executed. This is the package collection into which the DBRM that is associated with the function is bound.

**NO COLLID**

Specifies the package collection for the function is the same as the package collection of the program that invokes the function. If a trigger invokes the function, the collection of the trigger package is used. If the invoking program does not use a package, Db2 resolves the package by using the CURRENT PACKAGE PATH special register, the CURRENT PACKAGESET special register, or the PKLIST bind option (in this order). For details about how Db2 uses these three items, see the information on package resolution in Db2 Application Programming and SQL Guide.

**COLLID collection-id**

Specifies the name of the package collection that is to be used when the function is executed.

**WLM ENVIRONMENT**

An SQL identifier that identifies the name of the WLM (workload manager) application environment in which the function is to run.

(name)

The WLM environment in which the function must run. If the user-defined function is nested and if the calling stored procedure or invoking user-defined function is not running in an address space associated with the specified WLM environment, Db2 routes the function request to a different address space.

((name,)*)

When an SQL application program calls the function, name specifies the WLM environment in which the function runs.

If another user-defined function or a stored procedure calls the function, the function runs in the same environment that the calling routine uses. In this case, authorization to run the function in the WLM environment is not checked because the authorization of the calling routine suffices.

The name of the WLM environment is an SQL identifier.

To change the environment in which the function is to run, you must have appropriate authority for the WLM environment. For an example of a RACF command that provides this authorization, see Running stored procedures.

**ASUTIME**

Specifies the total amount of processor time, in CPU service units, that a single invocation of the function can run. The value is unrelated to the ASUTIME column of the resource limit specification table.

When you are debugging a function, setting a limit can be helpful if the function gets caught in a loop. For information on service units, see z/OS MVS Initialization and Tuning Guide.

**NO LIMIT**

There is no limit on the service units.

**LIMIT integer**

The limit on the number of CPU service units is a positive integer in the range 1 - 2147483647. If the procedure uses more service units than the
specified value, Db2 cancels the procedure. The CPU cycles that are consumed by parallel tasks in a procedure do not contribute towards the specified ASUTIME LIMIT.

**STAY RESIDENT**

Specifies whether the load module for the function is to remain resident in memory when the function ends.

**NO**

The load module is deleted from memory after the function ends. Use **NO** for non-reentrant functions.

**YES**

The load module remains resident in memory after the function ends. Use **YES** for reentrant functions.

**PROGRAM TYPE**

Specifies whether the function program runs as a main routine or a subroutine.

**SUB**

The function runs as a subroutine.

**MAIN**

The function runs as a main routine.

Do not specify **PROGRAM TYPE MAIN** when **LANGUAGE JAVA** is in effect.

**SECURITY**

Specifies how the function interacts with an external security product, such as RACF, to control access to non-SQL resources.

**DB2**

The function does not require an external security environment. If the function accesses resources that an external security product protects, the access is performed using the authorization ID associated with the WLM-established stored procedure address space.

**USER**

An external security environment should be used with the function. If the function accesses resources that the external security product protects, the access is performed using the primary authorization ID of the process that invoked the function.

**DEFINER**

An external security environment should be used with the function. If the function accesses resources that the external security product protects, the access is performed using the authorization ID of the owner of the function.

**STOP AFTER SYSTEM DEFAULT FAILURES, STOP AFTER nn FAILURES, or CONTINUE AFTER FAILURE**

Specifies whether the routine is to be put in a stopped state after some number of failures. The following options must not be specified for SQL functions or sourced functions.

**STOP AFTER SYSTEM DEFAULT FAILURES**

Specifies that this routine should be placed in a stopped state after the number of failures indicated by the value of field MAX ABEND COUNT on installation panel DSNTIPX.

**STOP AFTER nn FAILURES**

Specifies that this routine should be placed in a stopped state after **nn** failures. The value **nn** can be an integer from 1 to 32767.
CONTINUE AFTER FAILURE
Specifies that this routine should not be placed in a stopped state after any failure.

RUN OPTIONS run-time-options
Specifies the Language Environment run time options to be used for the function. You must specify run-time-options as a character string that is no longer than 254 bytes. To replace any existing run time options with no options, specify an empty string with RUN OPTIONS. When you specify an empty string, Db2 does not pass any run time options to Language Environment, and Language Environment uses its installation defaults.

For a description of the Language Environment run time options, see z/OS Language Environment Programming Reference.

Do not specify RUN OPTIONS when LANGUAGE JAVA is specified.

INHERIT SPECIAL REGISTERS or DEFAULT SPECIAL REGISTERS
Specifies how special registers are set on entry to the routine.

INHERIT SPECIAL REGISTERS
Specifies that special registers should be inherited according to the rules listed in the table for characteristics of special registers in a user-defined function or a stored procedure.

DEFAULT SPECIAL REGISTERS
Specifies that special registers should be initialized to the default values, as indicated by the rules in the table for characteristics of special registers in a user-defined function or a stored procedure.

STATIC DISPATCH
At function resolution time, Db2 chooses a function based on the static (or declared) types of the function parameters.

SECURED or NOT SECURED
Specifies whether the function is considered secure.

SECURED
Specifies that the function is considered secure.

Use of this clause or keyword might invalidate packages that depend on the target object, or packages that depend on related objects through cascading effects. See Changes that invalidate packages (Db2 Application programming and SQL).

NOT SECURED
Specifies that the function is considered not secure. NOT SECURED must not be specified when a row permission or a column mask depends on the function.

When the function is invoked, the arguments of the function must not reference a column for which a column mask is enabled when the table is using active column access control.

Use of this clause or keyword might invalidate packages that depend on the target object, or packages that depend on related objects through cascading effects. See Changes that invalidate packages (Db2 Application programming and SQL).
Notes

Invalidation of packages:
This statement might invalidate all packages that depend on target objects, and sometimes other related objects through cascading effects, depending on the clauses and keywords specified and other factors. For more information, see [Changes that invalidate packages (Db2 Application programming and SQL)].

LANGUAGE C and the PARAMETER VARCHAR clause:
The ALTER statement does not allow you to alter the value of the PARAMETER VARCHAR or PARAMETER CCSID clauses that are associated with the function definition. However, you can alter the LANGUAGE clause for the function. If the PARAMETER VARCHAR clause is specified for the creation of a LANGUAGE C function, the catalog information for that option is not affected by a subsequent ALTER function statement. The function might be changed to a language other than C, in which case the PARAMETER VARCHAR setting is ignored. If the function is later changed back to LANGUAGE C, the setting of the PARAMETER VARCHAR option that was specified during the CREATE FUNCTION statement will be used.

Altering a function from NOT SECURED to SECURED:
Typically, the security administrator will examine the data that is accessed by a function, ensure that it is secure, and grant the CREATE_SECURE_OBJECT privilege to the user that requires privileges to change the user-defined function to be secured. After the function is changed to SECURED, the security administrator will revoke the CREATE_SECURE_OBJECT privilege from the owner of the function. The function is considered secure after the ALTER FUNCTION statement is executed. Db2 treats the SECURED attribute as an assertion that declares that the security administrator has established an audit procedure for all changes to the user-defined function. Db2 assumes that such a control audit procedure is in place for all subsequent ALTER FUNCTION statements or changes to external packages.

Packages and statements in the dynamic statement cache that reference the function are invalidated.

Altering a function from SECURED to NOT SECURED:
Packages and statements in the dynamic statement cache that reference the function are invalidated when the function is changed from SECURED to NOT SECURED. An function that is not secured might negatively impact performance if that function accesses data in a table that is using row access control or column access control. To minimize the performance impact, either change the function to use the SECURED option or deactivate row access control or column access control for the table that the function is accessing.

Invoking other user-defined functions in a secure function:
When a secure user-defined function is referenced in an SQL data change statement that references a table that is using row access control or column access control, and if the secure user-defined function invokes other user-defined functions, the nested user-defined functions are not validated as secure. If those nested functions can access sensitive data, the security administrator needs to ensure that those functions are allowed to access sensitive data and should ensure that a change control audit procedure has been established for all changes to those functions.
The SECURE column in the DSN_FUNCTION_TABLE EXPLAIN table:

The SECURE column in the DSN_FUNCTION_TABLE EXPLAIN table indicates if a user-defined function is considered secure.

Alternative syntax and synonyms:

To provide compatibility with previous releases of Db2 or other products in the Db2 family, Db2 supports the following keywords:

- VARIANT as a synonym for NOT DETERMINISTIC
- NOT VARIANT as a synonym for DETERMINISTIC
- NOT NULL CALL as a synonym for RETURNS NULL ON NULL INPUT
- NULL CALL as a synonym for CALLED ON NULL INPUT
- PARAMETER STYLE DB2SQL as a synonym for PARAMETER STYLE SQL
- TIMEZONE can be specified as an alternative to TIME ZONE.

Examples

Example 1: Assume that two functions CENTER are in the PELLOW schema. The first function has two input parameters with INTEGER and FLOAT data types, respectively. The specific name for the first function is FOCUS1. The second function has three parameters with CHAR(25), DEC(5,2), and INTEGER data types.

Using the specific name to identify the function, change the WLM environment in which the first function runs from WLMENVNAME1 to WLMENVNAME2:

```
ALTER SPECIFIC FUNCTION ENGLES.FOCUS1 WLM ENVIRONMENT WLMENVNAME2;
```

Example 2: Change the second function that is described in Example 1 so that it is not invoked when any of the arguments are null. Use the function signature to identify the function:

```
ALTER FUNCTION ENGLES.CENTER (CHAR(25), DEC(5,2), INTEGER)
    RETURNS NULL ON NULL INPUT;
```

You can also code the ALTER FUNCTION statement without the exact values for the CHAR and DEC data types:

```
ALTER FUNCTION ENGLES.CENTER (CHAR(), DEC(), INTEGER)
    RETURNS NULL ON NULL INPUT;
```

If you use empty parentheses, Db2 is to ignore the length, precision, and scale attributes when looking for matching data types to find the function.

**ALTER FUNCTION (compiled SQL scalar)**

The ALTER FUNCTION (compiled SQL scalar) statement changes the description of a user-defined compiled SQL scalar function at the current server. The function options, parameter names, and routine body can be changed and additional versions of the procedure can be defined and maintained using the ALTER FUNCTION statement.

**Invocation**

This statement can only be dynamically prepared and the DYNAMICRULES run behavior must be specified implicitly or explicitly.
Authorization

The privilege set defined below must include at least one of the following:

- Ownership of the function
- The ALTERIN privilege on the schema
- System DBADM authority
- SYSCTRL authority
- SYSADM
- Installation SYSOPR authority (when the current SQLID of the process is set to SYSINSTL)

The authorization ID that matches the schema name implicitly has the ALTERIN privilege on the schema.

If the authorization ID that is used to alter the function has the installation SYSADM authority or the installation SYSOPR authority and if the current SQLID is set to SYSINSTL, the function is identified as system-defined function when the function definition is reevaluated.

Additional privileges might be required in the following situations:

- If SQL-routine-body is specified, the privilege set must include the privileges that are required to execute the statements in SQL-routine-body.
- If a user-defined type is referenced (i.e. as the data type of an SQL variable in the body of the function), the privilege set must include at least one of the following:
  - Ownership of the distinct type
  - The USAGE privilege on the user-defined type
  - System DBADM authority
  - DATAACCESS authority
  - SYSADM authority
- If the function uses a table as a parameter, the privilege set must also include at least one of the following:
  - Ownership of the table
  - The SELECT privilege on the table
  - DATAACCESS authority
  - SYSADM authority
- If you specify the WLM ENVIRONMENT FOR DEBUG MODE clause, RACF or an external security product is invoked to check the required authority for defining programs in the WLM environment. If the WLM environment access is protected in RACF, the privilege set must include the required authority.
- When replacing an SQL scalar function, the privilege set must include the required authorization to add a new package or a new version of an existing package depending on the value of the BIND NEW PACKAGE field on installation panel DSNTIPP, or the privilege set must include SYSADM or SYSCTRL authority.

Additional authorization might be required on the SYSDUMMYx tables depending on the content of the function definition. For details, see SYSDUMMYx tables (Introduction to Db2 for z/OS).
At least one of the following privileges is required if the SECURED option is specified or if the function is currently secured and the NOT SECURED option is specified:

- SECADM authority
- CREATE_SECURE_OBJECT privilege

At least one of those privileges is also required if the function is currently secure and the ALTER ACTIVE VERSION, ALTER VERSION \textit{routine-version-id}, ADD VERSION, or REPLACE clause is specified.

**Privilege set:** If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the package.

If the statement is dynamically prepared, the privilege set is the set of privileges that are held by the SQL authorization IDs of the process. The specified routine name can include a schema name (a qualifier). However, if the schema name is not the same as one of these SQL authorization IDs, one of the following conditions must be met:

1. The privilege set includes SYSADM authority
2. The privilege set includes SYSCTRL authority
3. The SQL authorization ID of the process has the ALTERIN privilege on the schema

When ALTER FUNCTION is issued in a trusted context that has the ROLE AS PACKAGE OWNER clause, the package owner is determined as follows:

- If the PACKAGE OWNER option is not specified, the role associated with the binder becomes the package owner.
- If the PACKAGE OWNER option is specified, the role specified in the PACKAGE OWNER option becomes the package owner. In a trusted context, the PACKAGE OWNER specified must be a role.

**Syntax**

```
ALTER function-designator

ALTER
  active version
  all versions
  version routine-version-id

replace
  version routine-version-id

add version routine-version-id

activate version routine-version-id

regenerate
  version routine-version-id

using application compatibility applcompat-value

drop version routine-version-id
```

function-designator:
routine-specification:

data-type, data-type2:

built-in-type:
### SQL-routine-body:

```plaintext
SQL-control-statement
```

**option-list:** (Specify options in any order. Specify at least one option. Do not specify the same option more than one time.)

```plaintext
NOT DETERMINISTIC  EXTERNAL ACTION  READS SQL DATA
DETERMINISTIC      NO EXTERNAL ACTION CONTAINS SQL MODIFIES SQL DATA
```
Description

One of the following three clauses identifies the function to be changed.

**FUNCTION function-name**

Identifies the SQL function by its function name.

The identified function must be an SQL scalar function. There must be exactly one function with `function-name` in the schema. The function can have any number of input parameters. If the schema does not contain a function with `function-name` or contains more than one function with this name, an error occurs.

The function must not be obfuscated.

**FUNCTION function-name (parameter-type,...)**

Identifies the SQL function by its function signature, which uniquely identifies the function.

`function-name`

Gives the function name of the SQL function.

If `function-name()` is specified, the function that is identified must have zero parameters.

`(parameter-type,...)`

Specifies the number of input parameters of the function and the name and data type of each parameter.

If the function was defined with a table parameter (the **LIKE TABLE name AS LOCATOR** clause was specified in the CREATE FUNCTION statement to indicate that one of the input parameters is a transition table), the function signature cannot be used to uniquely identify the function.

Instead, use one of the other syntax variations to identify the function with its function name, if unique, or its specific name.

`(data-type,...)`

Identifies the number of input parameters of the function and the data type of each parameter. The data type of each parameter must match the data type that was specified in the CREATE FUNCTION statement for the parameter in the corresponding position. The number of data types and

---

26. If the function has more than 30 parameters, only the first 30 parameters are used to determine whether the function is unique.
the logical concatenation of the data types are used to uniquely identify the function. Therefore, you cannot change the number of parameters or the data types of the parameters.

For data types that have a length, precision, or scale attribute, you can use a set of empty parentheses, specify a value, or accept the default values:

- Empty parentheses indicate that Db2 is to ignore the attribute when determining whether the data types match.
  
  For example, DEC() will be considered a match for a parameter of a function defined with a data type of DEC(7,2). Similarly DECFLOAT() will be considered a match for DECFLOAT(16) or DECFLOAT(34).

- If you use a specific value for a length, precision, or scale attribute, the value must exactly match the value that was specified (implicitly or explicitly) in the CREATE FUNCTION statement.
  
  The specific value for FLOAT(n) does not have to exactly match the defined value of the source function because \(1 \leq n \leq 21\) indicates REAL and \(22 \leq n \leq 53\) indicates DOUBLE. Matching is based on whether the data type is REAL or DOUBLE.

- If length, precision, or scale is not explicitly specified and empty parentheses are not specified, the default length of the data type is implied. The implicit length must exactly match the value that was specified (implicitly or explicitly) in the CREATE FUNCTION statement.

For data types with a subtype or encoding scheme attribute, specifying the FOR subtype DATA clause or the CCSID clause is optional. Omission of either clause indicates that Db2 is to ignore the attribute when determining whether the data types match. If you specify either clause, it must match the value that was implicitly or explicitly specified in the CREATE FUNCTION statement.

See CREATE FUNCTION for more information on the specification of the parameter list.

A function with the function signature must exist in the explicitly or implicitly specified schema.

**SPECIFIC FUNCTION** specific-name

Identifies a particular user-defined function by its specific name. The name is implicitly or explicitly qualified with a schema name. A compiled SQL scalar function with the specific name must exist in the schema. If the specific name is not qualified, it is implicitly qualified with a schema name as described in the description for FUNCTION function-name.

**ALTER ACTIVE VERSION, ALL VERSIONS, or VERSION** routine-version-id

Specifies that a version of the function is to be changed. When you change a function using ALTER option-list, any option that is not explicitly specified will use the existing value from the version of the function that is being changed.

**ACTIVE VERSION, ALL VERSION or, VERSION** routine-version-id

Identifies the version of the function that is to be changed.

**ACTIVE VERSION**

Specifies that the currently active version of the function is to be changed, replaced, or regenerated. If the function is secure, the changed, replaced, or regenerated version remains secure.
**ACTIVE VERSION** is the default.

**ALL VERSIONS**
Specifies that all of the versions of the function are to be changed. SECURED and NOT SECURED are the only options that can be changed when ALL VERSIONS is specified.

**VERSION** `routine-version-id`
Identifies the version of the function that is to be changed, replaced, or regenerated. `routine-version-id` is the version identifier that is assigned when the version of the function is defined. `routine-version-id` must identify a version of the specified function that exists at the current server. If the function is secure, the changed, replaced, or regenerated version remains secure.

**REPLACE ACTIVE VERSION or VERSION** `routine-version-id`
Specifies that a version of the function is to be replaced.

Binding the replaced version of the function might result in a new access path even if the routine body is not being changed.

When you replace a function, the data types, CCSID specifications, and character data attributes (FOR BIT/SBCS/MIXED DATA) of the parameters must be the same as the attributes of the corresponding parameters for the currently active version of the function. For options that are not explicitly specified, the system default values for those options are used, even if those options were explicitly specified for the version of the function that is being replaced. This is not the case for versions of the function that specified DISABLE DEBUG MODE. If DISABLE DEBUG MODE is specified for a version of a function, it cannot be changed by using the REPLACE clause. When a function definition is replaced, any existing comments in the catalog for that definition of the function are removed.

**ACTIVE VERSION or VERSION** `routine-version-id`
Identifies the version of the function that is to be replaced.

**ACTIVE VERSION**
Specifies that the currently active version of the function is to be changed, replaced, or regenerated. If the function is secure, the changed, replaced, or regenerated version remains secure.

**ACTIVE VERSION** is the default.

**VERSION** `routine-version-id`
Identifies the version of the function that is to be changed, replaced, or regenerated. `routine-version-id` is the version identifier that is assigned when the version of the function is defined. `routine-version-id` must identify a version of the specified function that exists at the current server. If the function is secure, the changed, replaced, or regenerated version remains secure.

**ADD VERSION** `routine-version-id`
Specifies that a new version of the function is to be created. `routine-version-id` is the version identifier for the new version of the function. `routine-version-id` must not identify a version of the specified function that already exists at the current server.

When a new version of a function is created, the comment that is recorded in the catalog for the new version will be the same as the comment that is in the catalog for the currently active version.
When you add a new version of a function, the data types, CCSID specifications, and character data attributes (FOR BIT/SBCS/MIXED DATA) of the parameters must be the same as the attributes of the corresponding parameters for the currently active version of the function. The parameter names can differ from the other versions of the function. For options that are not explicitly specified, the system default values will be used.

If the function is secure, the new version is considered secure.

**ACTIVATE VERSION** *routine-version-id*

Specifies the version of the function that is to be the currently active version. *routine-version-id* is the version identifier that is assigned when the version of the function is defined. The version that is specified with *routine-version-id* is the version that will be invoked by a function invocation. *routine-version-id* must identify a version of the function that exists at the current server.

**REGENERATE ACTIVE VERSION** or **VERSION** *routine-version-id*

Specifies that a version of the function is to be regenerated. When Db2 maintenance is applied that changes how an SQL function is generated, the function might need to be regenerated to process the changes from applying the maintenance.

**REGENERATE** automatically rebinds, at the current server, the package for the SQL control statements for the function and rebinds the package for the SQL statements that are included in the body of the function.

**REGENERATE** is different than the **REBIND PACKAGE** command. **REBIND PACKAGE** rebinds the SQL statements (usually to generate better access paths for those statement) but the SQL control statements in the function definition are not rebound.

When a function definition is regenerated, any existing comments in the catalog for that definition of the function are not removed.

**ACTIVE VERSION** or **VERSION** *routine-version-id*

Identifies the version of the function that is to be regenerated.

**ACTIVE VERSION**

Specifies that the currently active version of the function is to be changed, replaced, or regenerated. If the function is secure, the changed, replaced, or regenerated version remains secure. **ACTIVE VERSION** is the default.

**VERSION** *routine-version-id*

Identifies the version of the function that is to be changed, replaced, or regenerated. *routine-version-id* is the version identifier that is assigned when the version of the function is defined. *routine-version-id* must identify a version of the specified function that exists at the current server. If the function is secure, the changed, replaced, or regenerated version remains secure.

**USING APPLICATION COMPATIBILITY** *applcompat-value*

Specifies that the object is regenerated under *applcompat-value* application compatibility rules. The **ALTER** statement fails if it includes any syntax, semantics, or options that require a higher application compatibility level.

If **USING APPLICATION COMPATIBILITY** is omitted, the regeneration uses the APPLCOMPAT value of the applicable SYSIBM.SYSPACKAGE catalog table row.

The following *applcompat-value* values can be specified:
function-level
Specifies the application compatibility behavior of the function level. The equivalent function level or higher must be activated.

The format is \texttt{VvvRrMmmm}, where \textit{vv} is the version, \textit{r} is the release, and \textit{mmm} is the modification level. For example:

\texttt{V12R1M504}
Identifies compatibility with the current highest available function level, function level 504.

\texttt{V12R1M500}
Identifies compatibility with the function level that enables new function in the initial Db2 12 release, function level 500.
\texttt{V12R1M500} is the same as \texttt{V12R1}.

\texttt{V12R1M100}
Identifies compatibility with the function level before you activate new function, after migration to Db2 12, function level 100.
\texttt{V12R1M100} is the same as \texttt{V11R1}.

For a list of supported function-level values, see \texttt{What's new in Db2 12 function levels (Db2 for z/OS What's New?)}.

\texttt{V11R1}
Specifies Db2 11 compatibility behavior.

\texttt{V10R1}
Specifies Db2 10 compatibility behavior.

DROP VERSION \texttt{routine-version-id}
Drops the version of the function that is identified with \texttt{routine-version-id}. \texttt{routine-version-id} is the version identifier that is assigned when the version is defined. \texttt{routine-version-id} must identify a version of the function that exists at the current server and must not identify the currently active version of the function. Only the identified version of the function is dropped.

When only a single version of the function exists at the current server, use the DROP FUNCTION statement to drop the function.

RETURNS
Identifies the output of the function.

data-type2
Specifies the data type of the output. The data type must match the data type that was specified in the RETURNS clause of the CREATE FUNCTION statement.

NOT DETERMINISTIC or DETERMINISTIC
Specifies whether the function returns the same results each time that the function is invoked with the same input arguments.

NOT DETERMINISTIC
The function might not return the same result each time that the function is invoked with the same input arguments. The function depends on some state values that affect the results. Db2 uses this information to disable the merging of views and table expressions when processing SELECT or SQL data change statements that refer to this function. An example of a function that is not deterministic is one that generates random numbers.
NOT DETERMINISTIC must be specified explicitly or implicitly if the function program accesses a special register or invokes another function that is not deterministic.

DETERMINISTIC
The function always returns the same result each time that the function is invoked with the same input arguments. An example of a deterministic function is a function that calculates the square root of the input. Db2 uses this information to enable the merging of views and table expressions for SELECT or SQL data change statements that refer to this function. If applicable, specify DETERMINISTIC to prevent non-optimal access paths from being chosen for SQL statements that refer to this function.

Db2 does not verify that the function program is consistent with the specification of DETERMINISTIC or NOT DETERMINISTIC.

EXTERNAL ACTION or NO EXTERNAL ACTION
Specifies whether the function takes an action that changes the state of an object that Db2 does not manage. An example of an external action is sending a message or writing a record to a file.

EXTERNAL ACTION
The function can take an action that changes the state of an object that Db2 does not manage.

Some SQL statements that invoke functions with external actions can result in incorrect results if parallel tasks execute the function. For example, if the function sends a note for each initial call to it, one note is sent for each parallel task instead of once for the function.

If you specify EXTERNAL ACTION, Db2:
• Materializes the views and table expressions in SELECT or SQL data change statements that refer to the function. This materialization can adversely affect the access paths that are chosen for the SQL statements that refer to this function. Do not specify EXTERNAL ACTION if the function does not have an external action.
• Does not move the function from one task control block (TCB) to another between FETCH operations.
• Does not allow another function or stored procedure to use the TCB until the cursor is closed. This is also applicable for cursors declared WITH HOLD.

The only changes to resources made outside of Db2 that are under the control of commit and rollback operations are those changes made under RRS control.

EXTERNAL ACTION must be specified implicitly or explicitly specified if the SQL routine body invokes a function that is defined with EXTERNAL ACTION.

NO EXTERNAL ACTION
The function does not take any action that changes the state of an object that Db2 does not manage. Db2 uses this information to enable the merging of views and table expressions for SELECT or SQL data change statements that refer to this function. If applicable, specify NO EXTERNAL ACTION to prevent non-optimal access paths from being chosen for SQL statements that refer to this function.
Db2 does not verify that the function program is consistent with the specification of EXTERNAL ACTION or NO EXTERNAL ACTION.

**MODIFIES SQL DATA, READS SQL DATA, or CONTAINS SQL**
Specifies the classification of SQL statements and nested routines that this routine can execute or invoke. The database manager verifies that the SQL statements issued by the function, and all routines locally invoked by the routine, are consistent with this specification; the verification is not performed when nested remote routines are invoked. For the classification of each statement, see [SQL statement data access classification for routines](#).

**MODIFIES SQL DATA**
Specifies that the function can execute any SQL statement except the statements that are not supported in functions. Do not specify MODIFIES SQL DATA when ALLOW PARALLEL is in effect.

If a MODIFIES SQL DATA function is invoked in a subselect, the results are unpredictable since the number of times the function is invoked will vary depending on the access plan used.

**Recommendation:** If you invoke a function defined with the MODIFIES SQL DATA option in a subselect, make sure that the SQL statements inside the function do not modify any object that is referenced by that subselect.

**READS SQL DATA**
Specifies that the function can execute statements with a data access classification of READS SQL DATA, CONTAINS SQL, or NO SQL. The function cannot execute SQL statements that modify data.

**READS SQL DATA** is the default.

**CONTAINS SQL**
Specifies that the function can execute only SQL statements with a data access classification of CONTAINS SQL or NO SQL. The function cannot execute SQL statements the read or modify data.

**CALLED ON NULL INPUT or RETURNS NULL ON NULL INPUT**
Specifies whether the function is invoked if any of the input arguments is null at execution time.

**CALLED ON NULL INPUT**
Specifies that the function is to be invoked, if any, or all, argument values are null. This specification means that the body of the function must be coded to test for null argument values.

**CALLED ON NULL INPUT** is the default.

**RETURNS NULL ON NULL INPUT**
Specifies that the function is not invoked and returns the null value if any of the input arguments is null.

**STATIC DISPATCH**
At function resolution time, Db2 chooses a function based on the static (or declared) types of the function parameters.

**STATIC DISPATCH** is the default.

**ALLOW PARALLEL or DISALLOW PARALLEL**
Specifies if the function can be run in parallel. The default is DISALLOW PARALLEL, if you specify one or more of the following clauses:

- NOT DETERMINISTIC
- EXTERNAL ACTION
- MODIFIES SQL DATA

Otherwise, ALLOW PARALLEL is the default.

**ALLOW PARALLEL**

Specifies that the function can be run in parallel.

**DISALLOW PARALLEL**

Specifies that the function cannot be run in parallel.

**ALLOW DEBUG MODE, DISALLOW DEBUG MODE, or DISABLE DEBUG MODE**

Specifies whether this version of the routine can be run in debugging mode. The default is determined using the value of the CURRENT DEBUG MODE special register.

**ALLOW DEBUG MODE**

Specifies that this version of the routine can be run in debugging mode. When this version of the routine is invoked and debugging is attempted, a WLM environment must be available.

**DISALLOW DEBUG MODE**

Specifies that this version of the routine cannot be run in debugging mode.

You can use an ALTER statement to change this option to ALLOW DEBUG MODE for this initial version of the routine.

**DISABLE DEBUG MODE**

Specifies that this version of the routine can never be run in debugging mode.

This version of the routine cannot be changed to specify ALLOW DEBUG MODE or DISALLOW DEBUG MODE after this version of the routine has been created or altered to use DISABLE DEBUG MODE. To change this option, drop the routine and create it again using the option that you want. An alternative to dropping and recreating the routine is to create a version of the routine that uses the option that you want and making that version the active version.

When DISABLE DEBUG MODE is in effect, the WLM ENVIRONMENT FOR DEBUG MODE is ignored.

**QUALIFIER schema-name**

Specifies the implicit qualifier that is used for unqualified object names that are referenced in the procedure body. See [Unqualified alias, index, JAR file, sequence, table, trigger, and view names](#) for information about how the default for this option is determined.

**PACKAGE OWNER authorization-name**

Specifies the owner of the package that is associated with the version of the routine. The SQL authorization ID of the process is the default value.

**ASUTIME**

Specifies the total amount of processor time, in CPU service units, that a single invocation of a routine can run. The value is unrelated to the ASUTIME column of the resource limit specification table.

When you are debugging a routine, setting a limit can be helpful in case the routine gets caught in a loop. For information on service units, see [z/OS MVS Initialization and Tuning Guide](#).

**NO LIMIT**

Specifies that there is no limit on the service units.

**NO LIMIT** is the default.
**LIMIT integer**
The limit on the number of CPU service units is a positive integer in the range 1 - 2 147 483 647. If the procedure uses more service units than the specified value, Db2 cancels the procedure. The CPU cycles that are consumed by parallel tasks in a procedure do not contribute towards the specified ASUTIME LIMIT.

**INHERIT SPECIAL REGISTERS or DEFAULT SPECIAL REGISTERS**
Specifies how special registers are set on entry to the routine.

**INHERIT SPECIAL REGISTERS**
Specifies that the values of special registers are inherited, according to the rules that are listed in the table for characteristics of special registers in a routine in Table 48 on page 225. INHERIT SPECIAL REGISTERS is the default.

**DEFAULT SPECIAL REGISTERS**
Specifies that special registers are initialized to the default values, as indicated by the rules in the table for characteristics of special registers in a routine in Table 48 on page 225.

**WLM ENVIRONMENT FOR DEBUG MODE name**
Specifies the WLM (workload manager) application environment that is used by Db2 when debugging the routine. The name of the WLM environment is an SQL identifier.

If you do not specify WLM ENVIRONMENT FOR DEBUG MODE, Db2 uses the default WLM-established stored procedure address space specified at installation time.

To define a routine that is to run in a specified WLM application environment, you must have the appropriate authority for the WLM application environment. For an example of a RACF command that provides this authorization, see Running stored procedures.

The WLM ENVIRONMENT FOR DEBUG MODE value is ignored when DISABLE DEBUG MODE is in effect.

**CURRENT DATA YES or CURRENT DATA NO**
Specifies whether to require data currency for read-only and ambiguous cursors when the isolation level of cursor stability is in effect. CURRENT DATA also determines whether block fetch can be used for distributed, ambiguous cursors.

**CURRENT DATA YES**
Specifies that data currency is required for read-only and ambiguous cursors. Db2 acquired page or row locks to ensure data currency. Block fetch is ignored for distributed, ambiguous cursors.

**CURRENT DATA NO**
Specifies that data currency is not required for read-only and ambiguous cursors. Block fetch is allowed for distributed, ambiguous cursors. Use of CURRENT DATA NO is not recommended if the routine attempts to dynamically prepare and execute a DELETE WHERE CURRENT OF statement against an ambiguous cursor after that cursor is opened. You receive a negative SQLCODE if your routine attempts to use a DELETE WHERE CURRENT OF statement for any of the following cursors:
- A cursor that is using block fetch
- A cursor that is using query parallelism
• A cursor that is positioned on a row that is modified by this or another application process

**CURRENT DATA NO** is the default.

**DEGREE**

Specifies whether to attempt to run a query using parallel processing to maximize performance.

1 Specifies that parallel processing should not be used.

1 is the default.

**ANY**

Specifies that parallel processing can be used.

**CONCURRENT ACCESS RESOLUTION**

Specifies the whether processing uses only committed data or whether it will wait for commit or rollback of data that is in the process of being updated.

**WAIT FOR OUTCOME**

Specifies that processing will wait for the commit or rollback of data that is in the process of being updated.

**USE CURRENTLY COMMITTED**

Specifies that processing use the currently committed version of the data when data that is in the process of being updated is encountered. **USE CURRENTLY COMMITTED** is applicable on scans that access tables that are defined in universal table spaces with row or page level lock size.

When there is lock contention between a read transaction and an insert transaction, **USE CURRENTLY COMMITTED** is applicable to scans with isolation level CS or RS. Applicable scans include intent read scans for read-only and ambiguous queries and for updatable cursors. **USE CURRENTLY COMMITTED** is also applicable to scans initiated from WHERE predicates of UPDATE or DELETE statements and the subselect of INSERT statements.

When there is lock contention is between a read transaction and a delete transaction, **USE CURRENTLY COMMITTED** is applicable to scans with isolation level CS and when **CURRENT DATA NO** is specified.

**DYNAMICRULES**

Specifies the values that apply, at run time, for the following dynamic SQL attributes:

• The authorization ID that is used to check authorization
• The qualifier that is used for unqualified objects
• The source for application programming options that Db2 uses to parse and semantically verify dynamic SQL statements

**DYNAMICRULES** also specifies whether dynamic SQL statements can include GRANT, REVOKE, ALTER, CREATE, DROP, and RENAME statements.

In addition to the value of the **DYNAMICRULES** clause, the run time environment of a routine controls how dynamic SQL statements behave at run time. The combination of the **DYNAMICRULES** value and the run time environment determines the value for the dynamic SQL attributes. That set of attribute values is called the dynamic SQL statement behavior. The following values can be specified:
RUN
Specifies that dynamic SQL statements are to be processed using run behavior.

RUN is the default.

BIND
Specifies that dynamic SQL statements are to be processed using bind behavior.

DEFINEBIND
Specifies that dynamic SQL statements are to be processed using either define behavior or bind behavior.

DEFINERUN
Specifies that dynamic SQL statements are to be processed using either define behavior or run behavior.

INVOKEBIND
Specifies that dynamic SQL statements are to be processed using either invoke behavior or bind behavior.

INVOKERUN
Specifies that dynamic SQL statements are to be processed using either invoke behavior or run behavior.

APPLICATION ENCODING SCHEME
Specifies the default encoding scheme for SQL variables in static SQL statements in the routine body. The value is used for defining an SQL variable in a compound statement if the CCSID clause is not specified as part of the data type, and the PARAMETER CCSID routine option is not specified.

ASCII
 Specifies that the data is encoded using the ASCII CCSIDs of the server.

EBCDIC
 Specifies that the data is encoded using the EBCDIC CCSIDs of the server.

UNICODE
 Specifies that the data is encoded using the Unicode CCSIDs of the server.

See the ENCODING bind option in ENCODING bind option (Db2 Commands) for information about how the default for this option is determined.

WITH EXPLAIN or WITHOUT EXPLAIN
Specifies whether information will be provided about how SQL statements in the routine will execute.

WITHOUT EXPLAIN
Specifies that information will not be provided about how SQL statements in the routine will execute.

You can get EXPLAIN output for a statement that is embedded in a routine that is specified using WITHOUT EXPLAIN by embedding the SQL statement EXPLAIN in the routine body. Otherwise, the value of the EXPLAIN option applies to all explainable SQL statements in the routine body, and to the fullselect portion of any DECLARE CURSOR statements.

WITHOUT EXPLAIN is the default.
WITH EXPLAIN
Specifications that information will be provided about how SQL statements in the routine will execute. Information is inserted into the table
owner.PLAN_TABLE. owner is the authorization ID of the owner of the routine. Alternatively, the authorization ID of the owner of the routine can have an alias as owner.PLAN_TABLE that points to the base table, PLAN_TABLE. owner must also have the appropriate SELECT and INSERT privileges on that table. WITH EXPLAIN does not obtain information for statements that access remote objects. PLAN_TABLE must have a base table and can have multiple aliases with the same table name, PLAN_TABLE, but have different schema qualifiers. It cannot be a view or a synonym and should exist before the version is added or replaced. In all inserts to owner.PLAN_TABLE, the value of QUERYNO is the statement number that is assigned by Db2.

The WITH EXPLAIN option also populates two optional tables if they exist: DSN_STATEMENT_TABLE and DSN_FUNCTION_TABLE. DSN_STATEMENT_TABLE contains an estimate of the processing cost for an SQL statement. See Db2 Application Programming and SQL Guide for more information. DSN_FUNCTION_TABLE contains information about function resolution. See Db2 Application Programming and SQL Guide for more information.

For more information about the EXPLAIN statement, including a description of the tables that are populated by the WITH EXPLAIN option, see "EXPLAIN" on page 2059.

WITH IMMEDIATE WRITE or WITHOUT IMMEDIATE WRITE
Specifications whether immediate writes are to be done for updates that are made to group buffer pool dependent page sets or partitions. This option is only applicable for data sharing environments. The IMMEDWRITE subsystem parameter has no affect of this option. IMMEDWRITE bind option (Db2 Commands) shows the implied hierarchy of the IMMEDWRITE bind option (which is similar to this routine option) as it affects run time.

WITHOUT IMMEDIATE WRITE
Specifications that normal write activity is performed. Updated pages that are group buffer pool dependent are written at or before phase one of commit or at the end of abort for transactions that have been rolled back.

WITHOUT IMMEDIATE WRITE is the default.

WITH IMMEDIATE WRITE
Specifications that updated pages that are group buffer pool dependent are immediately written as soon as the buffer update completes. Updated pages are written immediately even if the buffer is updated during forward progress or during the rollback of a transaction. WITH IMMEDIATE WRITE might impact performance.

ISOLATION LEVEL RR, RS, CS, or UR
Specifications how far to isolate the routine from the effects of other running applications. For information about isolation levels, see Managing Performance.

RR Specifications repeatable read.

RS Specifications read stability.

CS Specifications cursor stability. CS is the default.

UR Specifications uncommitted read.
**OPTHINT** `string-constant`

Specifies whether query optimization hints are used for static SQL statements that are contained within the body of the routine.

`string-constant` is a character string of up to 128 bytes in length, which is used by the Db2 subsystem when searching the PLAN_TABLE for rows to use as input. The default value is an empty string, which indicates that the Db2 subsystem does not use optimization hints for static SQL statements.

Optimization hints are only used if optimization hints are enabled for your system. See *Db2 Installation Guide* for information about enabling optimization hints.

**SQL PATH**

Specifies the SQL path that the Db2 subsystem uses to resolve unqualified user-defined types, functions, and procedure names (in CALL statements) in the body of the routine. The default value is "SYSIBM", "SYSFUN", "SYSPROC", "SYSTMADM", and the value of the QUALIFIER option, which is the qualifier for the trigger that is the target of the statement. The maximum length of the SQL path is 2048 bytes. Db2 calculates the length by taking each `schema-name` that is specified and removing any trailing blanks from it, adding two delimiters around it, and adding one comma after each schema name except for the last name. The length of the resulting string cannot exceed 2048 bytes.

`schema-name`

Identifies a schema. Db2 does not verify that the schema exists when the ALTER statement is processed. The same schema name should not appear more than one time in the list of schema names.

```
SYSPUBLIC must not be specified for the SQL path.
```

**SYSTEM PATH**

Specifies the schema names "SYSIBM", "SYSFUN", "SYSPROC", "SYSTMADM".

**SESSION USER or USER**

Specifies the value of the SESSION_USER (or USER) special register. At the time the ALTER statement is processed, the actual length is included in the total length of the list of schema names that is specified for the SQL PATH option.

**REOPT**

Specifies if Db2 will determine the access path at run time by using the values of SQL variables or SQL parameters, parameter markers, and special registers.

**NONE**

Specifies that Db2 does not determine the access path at run time by using the values of SQL variables or SQL parameters, parameter markers, and special registers.

```
NONE is the default.
```

**ALWAYS**

Specifies that Db2 always determines the access path at run time each time an SQL statement is run. Do not specify REOPT ALWAYS with the WITH KEEP DYNAMIC or NODEFER PREPARE clauses.

**ONCE**

Specifies that Db2 determine the access path for any dynamic SQL statements only once, at the first time the statement is opened. This access path is used until the prepared statement is invalidated or removed from the dynamic statement cache and need to be prepared again.
QUERY ACCELERATION

Specifies whether a static SQL query is bound for acceleration, and if so, with what behavior.

NONE

Specifies that no static SQL query in the application is bound for acceleration or will be accelerated when the application is run.

ENABLE

Specifies that a static SQL query is bound for acceleration if it satisfies the acceleration criteria, including the cost and heuristics criteria. The query is routed to an accelerator when the application runs. Otherwise, if the static query does not satisfy the acceleration criteria, the query is bound for execution in Db2.

If an error condition, such as one of the following examples, occurs while executing the accelerated static query when the application is run, Db2 fails the static query and returns a negative SQL code to the application:

• A failure occurs while running the static query on the accelerator.
• The accelerator returns an error for the query.
• The accelerator is not started and Db2 cannot route the static query to the accelerator for execution.

ENABLE WITH FAILBACK

Results in the same behavior as ENABLE, except if one of the error conditions occurs on the first OPEN of the accelerated static query when the application is run. In this case, instead of failing the static query and returning a negative SQL code to the application, Db2 performs a temporary statement-level incremental bind of the query and runs the query in Db2. The application does not see the acceleration failure. Failback to Db2 is not possible after the application does a successful OPEN for the query on the accelerator.

ELIGIBLE

Specifies that a static SQL query is bound for acceleration if the query meets the basic acceleration criteria, regardless of the cost or heuristics criteria. The query is routed to the accelerator when the application runs.

Like the behavior for ENABLE, if an error condition occurs while executing the accelerated static query when the application is run, Db2 fails the static query and returns a negative SQL code to the application.

ALL

Specifies that all of the static SQL queries in the application are to be bound for acceleration and routed to the accelerator when the application runs. If Db2 determines that a static query cannot be bound to run on the accelerator and the query references a user base table or view, the BIND or REBIND PACKAGE operation fails with an error message for that query.

(A failure exception is made for declared global temporary tables (DGTTs) and created global temporary tables and (CGTTs) because these tables cannot be accelerated.)

Like the behavior for ENABLE, if an error condition occurs while executing the accelerated static query when the application is run, Db2 fails the static query and returns a negative SQL code to the application.

This bind option does not apply to a fullselect or WITH common-table-expression that is specified in a RETURN statement for the routine, or in a SET
host-variable-assignment that is used in the routine. The queries that are specified in these cases cannot be accelerated.

**GET_ACCEL_ARCHIVE**

Specifies whether a static SQL query that is bound for acceleration retrieves archived data on the accelerator, instead of active data.

**NO**  Specifies that no static SQL query is bound to retrieve archived data from the accelerator. If the static query also is not bound for acceleration, the query is bound to run in Db2.

If the static query is bound for acceleration because the QUERYACCELERATION bind option was specified, the query is routed to the accelerator when the application runs; however, the query does not retrieve any archived data.

**YES**  Specifies that if all of the following criteria are met, the query is bound for acceleration and retrieves the archived data on the accelerator when the application runs:

- The QUERYACCELERATION bind option is also specified.
- The static SQL query references an accelerated table that has partitioned data archived on an accelerator.
- The static query satisfies the acceleration criteria that is specified by the QUERYACCELERATION bind option.

If the static query does not satisfy the acceleration criteria that is specified by the QUERYACCELERATION bind option, the BIND or REBIND PACKAGE operation fails with an error message for that query.

This bind option does not apply to a fullselect or WITH common-table-expression that is specified in a RETURN statement for the routine, or in a SET host-variable-assignment that is used in the routine. The queries that are specified in these cases cannot be accelerated.

**ACCELERATOR**

Specifies an accelerator server that, if enabled and available, Db2 will consider sending eligible SQL queries to before sending the queries to other accelerator servers. If the specified accelerator server is not enabled or available, Db2 will consider sending the queries to other available accelerator servers.

**VALIDATE RUN or VALIDATE BIND**

Specifies whether to recheck, at run time, errors of the type "OBJECT NOT FOUND" and "NOT AUTHORIZED" that are found during bind or rebinding. The option has no effect if all objects and needed privileges exist.

**VALIDATE RUN**  Specifies that if needed objects or privileges do not exist when the CREATE statement is processed, warning messages are returned, but the CREATE statement succeeds. The Db2 subsystem rechecks for the objects and privileges at run time for those SQL statements that failed the checks during processing of the CREATE statement. The authorization checks the use of the authorization ID of the owner of the routine.

**VALIDATE RUN** is the default.

**VALIDATE BIND**  Specifies that if needed objects or privileges do not exist at the time the CREATE statement is processed, an error is issued and the CREATE statement fails.
ROUNDING
Specifies the rounding mode for manipulation of DECFLOAT data. The default value is taken from the DEFAULT DECIMAL FLOATING POINT ROUNDDING MODE in DECP.

DEC_ROUND_CEILING
Specifies numbers are rounded towards positive infinity.

DEC_ROUND_DOWN
Specifies numbers are rounded towards 0 (truncation).

DEC_ROUND_FLOOR
Specifies numbers are rounded towards negative infinity.

DEC_ROUND_HALF_DOWN
Specifies numbers are rounded to nearest; if equidistant, round down.

DEC_ROUND_HALF_EVEN
Specifies numbers are rounded to nearest; if equidistant, round so that the final digit is even.

DEC_ROUND_HALF_UP
Specifies numbers are rounded to nearest; if equidistant, round up.

DEC_ROUND_UP
Specifies numbers are rounded away from 0.

DATE FORMAT ISO, EUR, USA, JIS, or LOCAL
Specifies the date format for result values that are string representations of date or time values. See “String representations of datetime values” on page 130 for more information.

The default format is specified in the DATE FORMAT field of installation panel DSNTIP4 of the system where the routine is defined. You cannot use the LOCAL option unless you have a date exit routine.

DECIMAL(15), DECIMAL(31), DECIMAL(15,s), or DECIMAL(31,s)
Specifies the maximum precision that is to be used for decimal arithmetic operations. See “Arithmetic with two decimal operands” on page 261 for more information. The default format is specified in the DECIMAL ARITHMETIC field of installation panel DSNTIPF of the system where the routine is defined. If the form pp.s is specified, s must be a number between 1 and 9. s represents the minimum scale that is to be used for division.

FOR UPDATE CLAUSE OPTIONAL or FOR UPDATE CLAUSE REQUIRED
Specifies whether the FOR UPDATE clause is required for a DECLARE CURSOR statement if the cursor is to be used to perform positioned updates.

FOR UPDATE CLAUSE REQUIRED
Specifies that a FOR UPDATE clause must be specified as part of the cursor definition if the cursor will be used to make positioned updates.

FOR UPDATE CLAUSE REQUIRED is the default.

FOR UPDATE CLAUSE OPTIONAL
Specifies that the FOR UPDATE clause does not need to be specified in order for a cursor to be used for positioned updates. The routine body can include positioned UPDATE statements that update columns that the user is authorized to update.

aThe FOR UPDATE clause with no column list applies to static or dynamic SQL statements. Even if you do not use this clause, you can specify FOR
UPDATE OF with a column list to restrict updates to only the columns that are identified in the FOR UPDATE clause and to specify the acquisition of update locks.

**TIME FORMAT ISO, EUR, USA, JIS, or LOCAL**

Specifies the time format for result values that are string representations of date or time values. See “String representations of datetime values” on page 130 for more information.

The default format is specified in the TIME FORMAT field of installation panel DSNTIP4 of the system where the routine is defined. You cannot use the LOCAL option unless you have a date exit routine.

**SECURED or NOT SECURED**

Specifies if the function is considered secure. When the option is specified with the ALL VERSIONS clause, it applies to all existing versions and to any future versions of the function. When it is specified with other clauses such as ADD VERSION, or REPLACE, the value must be the same as the value that is in effect for the function that is being changed.

**SECURED**

Specifies that the function is considered secure.

Use of this clause or keyword might invalidate packages that depend on the target object, or packages that depend on related objects through cascading effects. See Changes that invalidate packages (Db2 Application programming and SQL).

**NOT SECURED**

Specifies that the function is considered not secure. NOT SECURED must not be specified when a row permission or a column mask depends on the function.

When the function is invoked, the arguments of the function must not reference a column for which a column mask is enabled when the table is using active column access control.

Use of this clause or keyword might invalidate packages that depend on the target object, or packages that depend on related objects through cascading effects. See Changes that invalidate packages (Db2 Application programming and SQL).

**BUSINESS_TIME SENSITIVE**

Determines whether references to application-period temporal tables in both static and dynamic SQL statements are affected by the value of the CURRENT TEMPORAL BUSINESS_TIME special register.

**YES**

References to application-period temporal tables are affected by the value of the CURRENT TEMPORAL BUSINESS_TIME special register. YES is the default value.

**NO**

References to application-period temporal tables are not affected by the value of the CURRENT TEMPORAL BUSINESS_TIME special register.

**SYSTEM_TIME SENSITIVE**

Determines whether references to system-period temporal tables in both static and dynamic SQL statements are affected by the value of the CURRENT TEMPORAL SYSTEM_TIME special register.
**YES**

References to system-period temporal tables are affected by the value of the CURRENT TEMPORAL SYSTEM_TIME special register. YES is the default value.

**NO**

References to system-period temporal tables are not affected by the value of the CURRENT TEMPORAL SYSTEM_TIME special register.

**Related information:**

- **CURRENT TEMPORAL SYSTEM_TIME**

**ARCHIVE SENSITIVE**

Determines whether references to archive-enabled tables in SQL statements are affected by the value of the SYSIBMADM.GET_ARCHIVE global variable.

**YES**

References to archive-enabled tables are affected by the value of the SYSIBMADM.GET_ARCHIVE global variable. YES is the default value.

**NO**

References to archive-enabled tables are not affected by the value of the SYSIBMADM.GET_ARCHIVE global variable.

**Related information:**

- **Built-in global variables**

**APPLCOMPAT applcompat-value**

Specifies the application compatibility level behavior for static SQL statements in the package. If this option is not specified then the behavior is determined, in priority order, by the applcompat-value of the previous bind of the package if one exists, or the APPLCOMPAT subsystem parameter. The following applcompat-value values can be specified:

- **function-level**
  
  Specifies the application compatibility behavior of the function-level function level. The equivalent function level or higher must be activated.

  The format is $vvRrMmmm$, where $vv$ is the version, $r$ is the release, and $mmm$ is the modification level. For example:

  - **V12R1M504**
    
    Identifies compatibility with the current highest available function level, function level 504.

  - **V12R1M500**
    
    Identifies compatibility with the function level that enables new function in the initial Db2 12 release, function level 500. V12R1M500 is the same as V12R1.

  - **V12R1M100**
    
    Identifies compatibility with the function level before you activate new function, after migration to Db2 12, function level 100. V12R1M100 is the same as V11R1.

  For a list of supported function-level values, see [What's new in Db2 12 function levels (Db2 for z/OS What's New?)]

- **V11R1**
  
  Specifies Db2 11 compatibility behavior.

- **V10R1**
  
  Specifies Db2 10 compatibility behavior.
CONCENTRATE STATEMENTS OFF or CONCENTRATE STATEMENTS WITH LITERALS

Specifies whether each dynamic SQL statement in the routine that specifies literal constants will be cached as a separate unique statement entry in the dynamic statement cache, instead of sharing an existing statement in the cache. Dynamic SQL statements are eligible to share an existing statement in the cache if the new statement meets all of the conditions for sharing a cached version of the same dynamic statement, except that the new statement specifies one or more literal constants that are different than the cached statement.

CONCENTRATE STATEMENTS OFF

Specifies that each dynamic SQL statement that specifies literal constants will be cached as a unique statement entry if it specifies one or more constants that are different than the cached version of the same dynamic statement. CONCENTRATE STATEMENTS OFF is the default dynamic statement caching behavior.

CONCENTRATE STATEMENTS WITH LITERALS

Specifies that each dynamic SQL statement that specifies literal constants will share a cached version of the same dynamic statement that is also prepared using the CONCENTRATE STATEMENTS WITH LITERALS option, if the new dynamic statement meets all of the conditions for sharing the cached statement, and the constants that are specified can be reused in place of the constants in the cached statement.

SQL-routine-body

 Specifies a single SQL control statement, including a compound-statement. See SQL control statements for SQL routines and triggers for more information about defining SQL functions.

A call to a procedure that issues a COMMIT, ROLLBACK, CONNECT, RELEASE, or SET CONNECTION statement is not allowed in a function.

If the SQL-routine-body is a compound statement, it must contain at least one RETURN statement and a RETURN statement must be executed when the function is invoked.

An ALTER FUNCTION (compiled SQL scalar) statement or an ALTER PROCEDURE (SQL native) statement with an ADD VERSION or REPLACE clause is not allowed in an SQL-routine-body.

Notes

The order of options and the RETURNS clause

The RETURNS clause must precede the options-list. If the body of the function contains only a RETURN-statement, RETURN-statement must be specified after the RETURNS clause and the options-list in the routine body.

ALTER FUNCTION for in use functions:

ALTER FUNCTION will be locked out from making changes if the function is in use. For example, if a query that is currently running is referencing an SQL scalar function named 'fn1' (routine-version-id is 'v1'), an ALTER FUNCTION fn1 ACTIVATE VERSION v2 statement will wait for the query that is currently running to complete before making 'v2' the active version for function 'fn1'. This wait for completion behavior happens even if the query invokes the function multiple times for processing multiple rows or if the query contains multiple references to the function that is being changed.
Considerations for changing a version of a function:
To change a version of a function, the environment settings that are in effect when the ALTER FUNCTION statement is issued must be the same as the environment settings that are in effect when the version of the function is first created using the CREATE FUNCTION or ALTER FUNCTION statement if one of the following options is specified:

- QUALIFIER
- PACKAGE OWNER
- WLM ENVIRONMENT FOR DEBUG MODE
- OPTHINT
- SQL PATH
- DECIMAL (if the value includes a comma)

Considerations for catalog comments for a routine definition:
When a function definition is replaced, any existing comment in the catalog for the definition is removed. However, when a function definition is regenerated, any existing comment in the catalog for the definition is retained.

Identifier resolution:
See Chapter 8, “SQL control statements for SQL routines and triggers,” on page 2371 for information on how names are resolved to columns, variables, or SQL parameters within an SQL routine.

If duplicate names are used for columns, variables, and parameters, qualify the duplicate names by using the table designator for columns, the routine name for parameters, the label name for SQL variables, and the schema name for global variables.

Characteristics of the package that is generated for a function:
The package that is associated with a version of a function is named as follows:

- location is set to the value of the CURRENT SERVER special register
- collection-id (schema) for the package is the same as the schema qualifier of the function
- package-id is the same as the specific name of the function
- version-id is the same as the version identifier for the version of the function

The package is generated using the bind options that correspond to the implicitly or explicitly specified function options. In addition to the corresponding bind options, the package is generated using the following bind options:

- FLAG(I)
- SQLERROR(NOPACKAGE)
- ENABLE(*)

Correspondence of function options to bind command options:
The following table lists options for CREATE FUNCTION and ALTER FUNCTION and the corresponding bind command option. See BIND and REBIND options for packages, plans, and services (Db2 Commands) for information about the BIND command options.
<table>

**Invalidation of packages:**

When a version of an SQL function is altered to change any option that is specified for the active version, all packages that refer to that function are
marked invalid. In addition, when certain attributes of an SQL function are changed, the body of the function might be rebound or regenerated. The following table summarizes when implicit rebind and regeneration occurs when specific options are changed. A value of 'Y' in a row indicates that a rebind or regeneration occurs if the option is changed for a version of the function. A value of 'N' in a row indicates that a rebind or regeneration does not occur.

Table 168. `CREATE FUNCTION` and `ALTER FUNCTION` options that result in rebind or regeneration of the function when changed

**Note:**
1. The function package is rebound or regenerated if a value of ALLOW DEBUG MODE is changed to DISALLOW DEBUG MODE
2. Invoking applications are invalidated if a value of DISALLOW DEBUG MODE is changed to DISABLE DEBUG MODE

### Considerations for SQL processor programs:

SQL processor programs (such as SPUFI, the command line processor, and DSNTEP2) might not correctly parse SQL statements in the routine body that are ended with semicolons. These processor programs accept multiple SQL statements as input when each statement is separated with a terminator character. Processor programs that use a semicolon as the SQL statement terminator might truncate an ALTER FUNCTION statement with embedded semicolons and pass only a portion of the statement to Db2. Therefore, you might need to change to SQL terminator character for these processor programs.

### Considerations for the SYSENVIRONMENTS catalog table:

An ALTER statement that specifies new environment settings will result in a new row being added to the SYSENVIRONMENTS catalog table. The new row will be added even if an error is subsequently encountered during processing of the statement. Thus, a new SYSENVIRONMENT row might be added to the table even for an ALTER statement that fails.

### Dependent objects:

An SQL routine is dependent on objects that are referenced in the routine body.

### Altering a function from NOT SECURED to SECURED:

Typically, the security administrator will examine the data that is accessed by a function, ensure that it is secure, and grant the CREATE_SECURE_OBJECT privilege to the user that requires privileges to
change the user-defined function to be secured. After the function is changed to SECURED, the security administrator will revoke the CREATE_SECURE_OBJECT privilege from the owner of the function.

The function is considered secure after the ALTER FUNCTION statement is executed. Db2 treats the SECURED attribute as an assertion that declares that the security administrator has established an audit procedure for all changes to the user-defined function. Db2 assumes that such a control audit procedure is in place for all subsequent ALTER FUNCTION statements or changes to external packages.

Packages and statements in the dynamic statement cache that reference the function are invalidated.

**Altering a function from SECURED to NOT SECURED:**

Packages and statements in the dynamic statement cache that reference the function are invalidated when the function is changed from SECURED to NOT SECURED. An function that is not secured might negatively impact performance if that function accesses data in a table that is using row access control or column access control. To minimize the performance impact, either change the function to use the SECURED option or deactivate row access control or column access control for the table that the function is accessing.

**Invoking other user-defined functions in a secure function:**

When a secure user-defined function is referenced in an SQL data change statement that references a table that is using row access control or column access control, and if the secure user-defined function invokes other user-defined functions, the nested user-defined functions are not validated as secure. If those nested functions can access sensitive data, the security administrator needs to ensure that those functions are allowed to access sensitive data and should ensure that a change control audit procedure has been established for all changes to those functions.

**The SECURE column in the DSN_FUNCTION_TABLE EXPLAIN table:**

The SECURE column in the DSN_FUNCTION_TABLE EXPLAIN table indicates if a user-defined function is considered secure.

**Altering obfuscated functions:**

Obfuscated functions cannot be altered in any way.

**Deploying a compiled SQL function:**

When a BIND DEPLOY command is issued to deploy a compiled SQL function to a target location, the SECURED and NOT SECURED options are included in the deployment process.

When deploying a compiled SQL function, if a function with the same target name does not exist at the target location, the deployed function is created as a new function at the target location with the same SECURED or NOT SECURED option that is specified (or the default of NOT SECURED is used) in the source function of the deployment.

When deploying a compiled SQL function, if a function with the same target name already exists at the target location, the deployed function is either added as a new version of the function or is used to replace an existing version of the function. The SECURED or NOT SECURED option of the deployed function must be the same as that of the existing function at the target location.
Compatibilities:
For compatibility with the CREATE FUNCTION (SQL scalar) statement, the following clause can be specified, but will be ignored:

- LANGUAGE SQL

Optional syntax:
To provide compatibility with the syntax of the CREATE FUNCTION statement, the following options can also be specified:

- SPECIFIC
- PARAMETER CCSID

However, if these options are specified, the value for the option must be the same as the value that is already in effect for the function.

Alternative syntax and synonyms:
To provide compatibility with previous releases of Db2 or other products in the Db2 family, Db2 supports the following keywords:

- VARIANT as a synonym for NOT DETERMINISTIC
- NOT VARIANT as a synonym for DETERMINISTIC
- NULL CALL as a synonym for CALLED ON NULL INPUT
- NOT NULL CALL as a synonym for RETURNS NULL ON NULL INPUT
- TIMEZONE can be specified as an alternative to TIME ZONE

Examples

Example 1: Modify the definition for an SQL function to indicate that the function is deterministic.

```sql
ALTER FUNCTION MY_UDF1
DETERMINISTIC;
```

Example 2: The following statement changes the existing function options for the active version of the REVERSE SQL function. If you need to change a different version of the function, you would specify VERSION routine-version-id in place of ACTIVE VERSION. Note, the ALTER clause that precedes the version specification can be omitted:

```sql
ALTER FUNCTION REVERSE
ALTER ACTIVE VERSION
NOT DETERMINISTIC
ALLOW DEBUG MODE;
```

Example 3: To change the function body of any existing version of a function, you need to use the REPLACE clause. The following statement changes both the function body and the existing SQL data access option for the version V2 of the REVERSE function. The list of parameters is specified even though no changes are made to the list. To replace an existing version of the function, you must specify the list of parameters, RETURNS clause, any options that are to have non-default values (even if those options are already specified in the version of the function that you are replacing), and the body of the function, as in the following statement:

```sql
ALTER FUNCTION REVERSE(INSTR VARCHAR(4000))
REPLACE VERSION V2 (INSTR VARCHAR(4000))
RETURNS VARCHAR(4000)
DETERMINISTIC
NO EXTERNAL ACTION
CONTAINS SQL
BEGIN
    DECLARE REVSTR, RESTSTR VARCHAR(4000) DEFAULT '';
    DECLARE LEN INT;
```
IF INSTR IS NULL THEN
    RETURN NULL;
END IF;
SET RESTSTR = INSTR;
SET LEN = LENGTH(INSTR);
WHILE LEN > 0 DO
    SET (REVSTR, RESTSTR, LEN) = (SUBSTR(RESTSTR, 1, 1) CONCAT REVSTR, SUBSTR(RESTSTR, 2, LEN - 1), LEN - 1);
END WHILE;
RETURN REVSTR;
END

Example 4: To add a new version of an existing function, use the ADD VERSION clause. The following statement adds a new version of the REVERSE function to combine two SET statements into one SET statement. The list of parameters is specified even though the new version of the function uses the same parameters as the existing version of the function. To add a new version of the function, you must specify the list of parameters, RETURNS clause, any options that will have non-default values, and the body of the function, as in the following statement, which creates version V3 of the REVERSE function:

ALTER FUNCTION REVERSE(INSTR VARCHAR(4000))
ADD VERSION V3 (INSTR VARCHAR(4000))
RETURNS VARCHAR(4000)
DETERMINISTIC
NO EXTERNAL ACTION
CONTAINS SQL
BEGIN
DECLARE REVSTR, RESTSTR VARCHAR(4000) DEFAULT '';
DECLARE LEN INT;
IF INSTR IS NULL THEN
    RETURN NULL;
END IF;
SET (RESRSTR, LEN) = (INSTR, LENGTH(INSTR));
WHILE LEN > 0 DO
    SET (REVSTR, RESTSTR, LEN) = (SUBSTR(RESTSTR, 1, 1) CONCAT REVSTR, SUBSTR(RESTSTR, 2, LEN - 1), LEN - 1);
END WHILE;
RETURN REVSTR;
END

Example 5: To change the currently active version of the function, you must specify the ACTIVATE VERSION clause on the ALTER FUNCTION statement, even if the version you want to be the active version has just been defined. The following statement causes version V3 of the REVERSE SQL function to be the currently active version:

ALTER FUNCTION REVERSE(INSTR VARCHAR(4000))
ACTIVATE VERSION V3;

Example 6: To regenerate the currently active version of the function, you must specify the REGENERATE clause, as in the following statement:

ALTER FUNCTION REVERSE(INSTR VARCHAR(4000))
REGENERATE ACTIVE VERSION;

ALTER FUNCTION (inlined SQL scalar)
The ALTER FUNCTION (inlined SQL scalar) statement changes the description of a user-defined inlined SQL scalar function at the current server.
Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

Authorization

The privilege set defined below must include at least one of the following:

- Ownership of the function
- The ALTERIN privilege on the schema
- SYSADM authority
-SYSCTRL authority
- System DBADM
- Installation SYSOPR authority (when the current SQLID of the process is set to SYSINSTL)

The authorization ID that matches the schema name implicitly has the ALTERIN privilege on the schema.

If the authorization ID that is used to alter the function has the installation SYSADM authority or the installation SYSOPR authority and if the current SQLID is set to SYSINSTL, the function is identified as system-defined function when the function definition is reevaluated.

Additional privileges might be required in the following situations:

- If SQL-routine-body is specified, the privilege set must include the privileges that are required to execute the statements in SQL-routine-body.
- If a user-defined type is referenced (for example, as the data type of a parameter), the privilege set must include at least one of the following:
  - Ownership of the user-defined type
  - The USAGE privilege on the user-defined type
  - SYSADM authority

At least one of the following privileges is required if the SECURED option is specified or if the function is currently secured and the NOT SECURED option is specified:

- SECADM authority
- CREATE_SECURE_OBJECT privilege

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the package.

If the statement is dynamically prepared, the privilege set is the set of privileges that are held by the SQL authorization IDs of the process. The specified routine name can include a schema name (a qualifier). However, if the schema name is not the same as one of these SQL authorization IDs, one of the following conditions must be met:

1. The privilege set includes SYSADM authority
2. The privilege set includes SYSCTRL authority
3. The SQL authorization ID of the process has the ALTERIN privilege on the schema
Syntax

```

```

built-in-type:
option-list: (Specify options in any order. Specify at least one option. Do not specify the same option more than one time.)

Description

One of the following three clauses identifies the function to be changed.
**FUNCTION** function-name

Identifies the SQL function by its function name.

The identified function must be an inlined SQL scalar function. There must be exactly one function with function-name in the schema. The function can have any number of input parameters.\(^{27}\) If the schema does not contain a function with function-name or contains more than one function with this name, an error occurs.

The function must not be obfuscated.

**FUNCTION** function-name (parameter-type,...)

Identifies the SQL function by its function signature, which uniquely identifies the function.

*function-name*

Gives the function name of the inlined SQL scalar function.

If function-name() is specified, the function that is identified must have zero parameters.

*(parameter-type,...)*

Specifies the number of input parameters of the function and the name and data type of each parameter.

*(data-type,...)*

Identifies the number of input parameters of the function and the data type of each parameter. The data type of each parameter must match the data type that was specified in the CREATE FUNCTION statement for the parameter in the corresponding position. The number of data types and the logical concatenation of the data types are used to uniquely identify the function. Therefore, you cannot change the number of parameters or the data types of the parameters.

For data types that have a length, precision, or scale attribute, you can use a set of empty parentheses, specify a value, or accept the default values:

- Empty parentheses indicate that Db2 is to ignore the attribute when determining whether the data types match.
  
  For example, DEC() will be considered a match for a parameter of a function defined with a data type of DEC(7,2). Similarly DECFLOAT() will be considered a match for DECFLOAT(16) or DECFLOAT(34).
  
  FLOAT cannot be specified with empty parentheses because its parameter value indicates different data types (REAL or DOUBLE).

- If you use a specific value for a length, precision, or scale attribute, the value must exactly match the value that was specified (implicitly or explicitly) in the CREATE FUNCTION statement.
  
  The specific value for FLOAT(\(n\)) does not have to exactly match the defined value of the source function because \(1<=n<=21\) indicates REAL and \(22<=n<=53\) indicates DOUBLE. Matching is based on whether the data type is REAL or DOUBLE.

- If length, precision, or scale is not explicitly specified and empty parentheses are not specified, the default length of the data type is implied. The implicit length must exactly match the value that was specified (implicitly or explicitly) in the CREATE FUNCTION statement.

---

\(^{27}\) If the function has more than 30 parameters, only the first 30 parameters are used to determine whether the function is unique.
For data types with a subtype or encoding scheme attribute, specifying the
FOR subtype DATA clause or the CCSID clause is optional. Omission of
either clause indicates that Db2 is to ignore the attribute when determining
whether the data types match. If you specify either clause, it must match
the value that was implicitly or explicitly specified in the CREATE
FUNCTION statement.

See CREATE FUNCTION for more information on the specification of the
parameter list.

A function with the function signature must exist in the explicitly or implicitly
specified schema.

SPECIFIC FUNCTION specific-name
Identifies a particular user-defined function by its specific name. The name is
implicitly or explicitly qualified with a schema name. An inlined SQL scalar
function with the specific name must exist in the schema. If the specific name
is not qualified, it is implicitly qualified with a schema name as described in
the description for FUNCTION function-name.

NOT DETERMINISTIC or DETERMINISTIC
Specifies whether the function returns the same results each time that the
function is invoked with the same input arguments.

NOT DETERMINISTIC
The function might not return the same result each time that the function
is invoked with the same input arguments. The function depends on some
state values that affect the results. Db2 uses this information to disable the
merging of views and table expressions when processing SELECT or SQL
data change statements that refer to this function. An example of a
function that is not deterministic is one that generates random numbers.

NOT DETERMINISTIC must be specified explicitly or implicitly if the
function program accesses a special register or invokes another function
that is not deterministic.

DETERMINISTIC
The function always returns the same result each time that the function is
invoked with the same input arguments. An example of a deterministic
function is a function that calculates the square root of the input. Db2 uses
this information to enable the merging of views and table expressions for
SELECT or SQL data change statements that refer to this function. If
applicable, specify DETERMINISTIC to prevent non-optimal access paths
from being chosen for SQL statements that refer to this function.

EXTERNAL ACTION or NO EXTERNAL ACTION
Specifies whether the function takes an action that changes the state of an
object that Db2 does not manage. An example of an external action is sending
a message or writing a record to a file.

EXTERNAL ACTION
The function can take an action that changes the state of an object that Db2
does not manage.

Some SQL statements that invoke functions with external actions can result
in incorrect results if parallel tasks execute the function. For example, if the
function sends a note for each initial call to it, one note is sent for each
parallel task instead of once for the function.

If you specify EXTERNAL ACTION, Db2:
Materializes the views and table expressions in SELECT or SQL data change statements that refer to the function. This materialization can adversely affect the access paths that are chosen for the SQL statements that refer to this function. Do not specify EXTERNAL ACTION if the function does not have an external action.

• Does not move the function from one task control block (TCB) to another between FETCH operations.
• Does not allow another function or stored procedure to use the TCB until the cursor is closed. This is also applicable for cursors declared WITH HOLD.

The only changes to resources made outside of Db2 that are under the control of commit and rollback operations are those changes made under RRS control.

EXTERNAL ACTION must be specified implicitly or explicitly specified if the SQL routine body invokes a function that is defined with EXTERNAL ACTION.

NO EXTERNAL ACTION
The function does not take any action that changes the state of an object that Db2 does not manage. Db2 uses this information to enable the merging of views and table expressions for SELECT or SQL data change statements that refer to this function. If applicable, specify NO EXTERNAL ACTION to prevent non-optimal access paths from being chosen for SQL statements that refer to this function.

Db2 does not verify that the function program is consistent with the specification of EXTERNAL ACTION or NO EXTERNAL ACTION.

READS SQL DATA or CONTAINS SQL
Specifies the classification of SQL statements and nested routines that this routine can execute or invoke. The database manager verifies that the SQL statements issued by the function, and all routines locally invoked by the routine, are consistent with this specification; the verification is not performed when nested remote routines are invoked. For the classification of each statement, see SQL statement data access classification for routines.

READS SQL DATA
Specifies that the function can execute statements with a data access classification of READS SQL DATA, CONTAINS SQL, or NO SQL. The function cannot execute SQL statements that modify data.

READS SQL DATA is the default.

CONTAINS SQL
Specifies that the function can execute only SQL statements with a data access classification of CONTAINS SQL or NO SQL. The function cannot execute SQL statements the read or modify data.

STATIC DISPATCH
At function resolution time, Db2 chooses a function based on the static (or declared) types of the function parameters.

CALLED ON NULL INPUT
The function is called regardless of whether any of the input arguments are null, making the function responsible for testing for null arguments. The function can return null.
SECURED or NOT SECURED

Specifies if the function is considered secure.

SECURED

Specifies that the function is considered secure.

Use of this clause or keyword might invalidate packages that depend on the target object, or packages that depend on related objects through cascading effects. See Changes that invalidate packages (Db2 Application programming and SQL).

NOT SECURED

Specifies that the function is considered not secure. NOT SECURED must not be specified when a row permission or a column mask depends on the function.

When the function is invoked, the arguments of the function must not reference a column for which a column mask is enabled when the table is using active column access control.

Use of this clause or keyword might invalidate packages that depend on the target object, or packages that depend on related objects through cascading effects. See Changes that invalidate packages (Db2 Application programming and SQL).

Notes

ALTER FUNCTION for in use functions:
ALTER FUNCTION will be locked out from making changes if the function is in use. This wait for completion behavior happens even if the query invokes the function multiple times for processing multiple rows or if the query contains multiple references to the function that is being changed.

Invalidation of plans and packages:
When an inlined SQL function is altered, all the plans and packages that refer to that function are marked invalid.

Dependent objects:
An SQL routine is dependent on objects that are referenced in the routine body.

Altering a function from NOT SECURED to SECURED:
Typically, the security administrator will examine the data that is accessed by a function, ensure that it is secure, and grant the CREATE_SECURE_OBJECT privilege to the user that requires privileges to change the user-defined function to be secured. After the function is changed to SECURED, the security administrator will revoke the CREATE_SECURE_OBJECT privilege from the owner of the function.

The function is considered secure after the ALTER FUNCTION statement is executed. Db2 treats the SECURED attribute as an assertion that declares that the security administrator has established an audit procedure for all changes to the user-defined function. Db2 assumes that such a control audit procedure is in place for all subsequent ALTER FUNCTION statements or changes to external packages.

Packages and statements in the dynamic statement cache that reference the function are invalidated.

Altering a function from SECURED to NOT SECURED:
Packages and statements in the dynamic statement cache that reference the
function are invalidated when the function is changed from SECURED to NOT SECURED. An function that is not secured might negatively impact performance if that function accesses data in a table that is using row access control or column access control. To minimize the performance impact, either change the function to use the SECURED option or deactivate row access control or column access control for the table that the function is accessing.

**Invoking other user-defined functions in a secure function:**
When a secure user-defined function is referenced in an SQL data change statement that references a table that is using row access control or column access control, and if the secure user-defined function invokes other user-defined functions, the nested user-defined functions are not validated as secure. If those nested functions can access sensitive data, the security administrator needs to ensure that those functions are allowed to access sensitive data and should ensure that a change control audit procedure has been established for all changes to those functions.

**The SECURE column in the DSN_FUNCTION_TABLE EXPLAIN table:**
The SECURE column in the DSN_FUNCTION_TABLE EXPLAIN table indicates if a user-defined function is considered secure.

**Alternating obfuscated functions:**
Obfuscated functions cannot be altered in any way.

**Compatibilities:**
For compatibility with the CREATE FUNCTION (SQL scalar) statement, the following clause can be specified, but will be ignored:
- LANGUAGE SQL

**Optional syntax:**
To provide compatibility with the syntax of the CREATE FUNCTION statement, the following options can also be specified:
- SPECIFIC
- PARAMETER CCSID

However, if these options are specified, the value for the option must be the same as the value that is already in effect for the function.

**Alternative syntax and synonyms:**
To provide compatibility with previous releases of Db2 or other products in the Db2 family, Db2 supports the following keywords:
- VARIANT as a synonym for NOT DETERMINISTIC
- NOT VARIANT as a synonym for DETERMINISTIC
- NULL CALL as a synonym for CALLED ON NULL INPUT

**Examples**

*Example 1:* Modify the definition for an SQL function to indicate that the function is deterministic.

```sql
ALTER FUNCTION MY_UDF1
DETERMINISTIC;
```

**ALTER FUNCTION (SQL table)**
The ALTER FUNCTION (SQL table) statement changes the description of a user-defined SQL table function at the current server.
Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

Authorization

The privilege set that is defined below must include at least one of the following privileges or authorities:
- Ownership of the function
- The ALTERIN privilege on the schema
- SYSADM authority
- SYSCTRL authority
- System DBADM
- Installation SYSOPR authority (when the current SQLID of the process is set to SYSINSTL)

The authorization ID that matches the schema name implicitly has the ALTERIN privilege on the schema.

If the authorization ID that is used to alter the function has the installation SYSADM authority or the installation SYSOPR authority and if the current SQLID is set to SYSINSTL, the function is identified as system-defined function when the function definition is reevaluated.

If a distinct type is referenced (i.e. as the data type of an SQL variable in the body of the function), the privilege set must also include at least one of the following:
- Ownership of the distinct type
- The USAGE privilege on the distinct type
- SYSADM authority

At least one of the following privileges is required if the SECURED option is specified or if the function is currently secured and the NOT SECURED option is specified:
- SECADM authority
- CREATE_SECURE_OBJECT privilege

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the package.

If the statement is dynamically prepared, the privilege set is the set of privileges that are held by the SQL authorization IDs of the process. The specified routine name can include a schema name (a qualifier). However, if the schema name is not the same as one of these SQL authorization IDs, one of the following conditions must be met:

1. The privilege set includes SYSADM authority
2. The privilege set includes SYSCTRL authority
3. The SQL authorization ID of the process has the ALTERIN privilege on the schema

Chapter 7. Statements 1221
**Description**

**FUNCTION** *function-name*

Identifies the SQL table function by its function name. The identified function must be an SQL table function.

There must be exactly one function with *function-name* in the schema. The function can have any number of input parameters. If the schema does not contain a function with *function-name*, or contains more than one function with this name, an error is returned.

The function must not be obfuscated.

**FUNCTION** *function-name* *(parameter-type, ...)*

Identifies the SQL function by its function signature, which uniquely identifies the function.

A function with the function signature must exist in the explicitly or implicitly specified schema.

*function-name*

Identifies the function name of the SQL function. If the function was defined with a table parameter (the LIKE TABLE *name* AS LOCATOR clause was specified in the CREATE FUNCTION statement to indicate that one of the input parameters is a transition table), the function signature cannot be used to uniquely identify the function. Instead, use one of the other syntax variations to identify the function with its function name, if unique, or its specified parameters.

If *function-name()* is specified, the function that is identified must have zero parameters.

*parameter-type*

Identifies the number of parameters of the function.

*data-type*

Identifies the data type of each input parameter of the function. The data type of each parameter must match the data type that was specified in the
CREATE FUNCTION statement for the parameter in the corresponding position. The number of data types and the logical concatenation of the data types are used to uniquely identify the function. Therefore, you cannot change the number of parameters or the data types of the parameters.

For data types that have a length, precision, or scale attribute, you can use a set of empty parentheses, specify a value, or accept the default values:

- Empty parentheses indicate that Db2 is to ignore the attribute when determining whether the data types match.

  For example, DEC() will be considered a match for a parameter of a function defined with a data type of DEC(7,2). Similarly DECFLOAT() will be considered a match for DECFLOAT(16) or DECFLOAT(34).

  FLOAT cannot be specified with empty parentheses because its parameter value indicates different data types (REAL or DOUBLE).

- If you use a specific value for a length, precision, or scale attribute, the value must exactly match the value that was specified (implicitly or explicitly) in the CREATE FUNCTION statement.

  The specific value for FLOAT(n) does not have to exactly match the defined value of the source function because 1<=n<=21 indicates REAL and 22<=n<=53 indicates DOUBLE. Matching is based on whether the data type is REAL or DOUBLE.

- If length, precision, or scale is not explicitly specified and empty parentheses are not specified, the default length of the data type is implied. The implicit length must exactly match the value that was specified (implicitly or explicitly) in the CREATE FUNCTION statement.

For data types with a subtype or encoding scheme attribute, specifying the FOR subtype DATA clause or the CCSID clause is optional. Omission of either clause indicates that Db2 is to ignore the attribute when determining whether the data types match. If you specify either clause, it must match the value that was implicitly or explicitly specified in the CREATE FUNCTION statement.

See CREATE FUNCTION for more information on the specification of the parameter list.

RESTRICT
Indicates that the function will not be altered or replaced if it is referenced by any dependent package, function, materialized query table, or view.

Exception: When the ALTER statement specifies only DETERMINISTIC or NOT DETERMINISTIC, the function is altered, and all dependent packages are invalidated.

NOT DETERMINISTIC or DETERMINISTIC
Specifies whether the function returns the same results each time that the function is invoked with the same input arguments. Db2 does not verify that the function program is consistent with the specification of NOT DETERMINISTIC or DETERMINISTIC.

NOT DETERMINISTIC
Specifies that the function might not return the same result table each time that the function is invoked with the same input arguments, even when the referenced data in the database has not changed. The function depends on some state values that might affect the results. Db2 uses this information to disable the merging of views and table expressions when
processing SELECT and SQL data change statements that refer to this function. An example of a table function that is not deterministic is one which references special registers, other functions that are not deterministic, or a sequence in a way that affects the table function's result table. Use of this clause or keyword might invalidate packages that depend on the target object, or packages that depend on related objects through cascading effects. See [Changes that invalidate packages (Db2 Application programming and SQL)].

**DETERMINISTIC**

Specifies that the function always returns the same result table each time that the function is invoked with the same input arguments (provided that the referenced data in the database has not changed). Db2 uses this information to enable the merging of views and table expressions for SELECT and SQL data change statements that refer to this function. Use of this clause or keyword might invalidate packages that depend on the target object, or packages that depend on related objects through cascading effects. See [Changes that invalidate packages (Db2 Application programming and SQL)].

If applicable, specify DETERMINISTIC to prevent non-optimal access paths from being chosen for SQL statements that refer to this function.

**EXTERNAL ACTION or NO EXTERNAL ACTION**

Specifies whether the function contains an external action. Db2 does not verify that the function program is consistent with the specification of EXTERNAL ACTION or NO EXTERNAL ACTION.

**EXTERNAL ACTION**

The function performs some external action (outside the scope of the function program). Thus, the function must be invoked with each successive function invocation. EXTERNAL ACTION must be specified if the function invokes another function that has external actions.

**NO EXTERNAL ACTION**

The function does not perform any external action. It need not be called with each successive function invocation. Functions that are defined with NO EXTERNAL ACTION might perform better than functions that are defined with EXTERNAL ACTION because the function might not be invoked for each successive function invocation.

**READS SQL DATA or CONTAINS SQL**

Specifies the classification of SQL statements and nested routines that this routine can execute or invoke. The database manager verifies that the SQL statements issued by the function, and all routines locally invoked by the routine, are consistent with this specification; the verification is not performed when nested remote routines are invoked. For the classification of each statement, see [“SQL statement data access classification for routines” on page 2437].

**READS SQL DATA**

Specifies that the function can execute statements with a data access indication of READS SQL DATA or CONTAINS SQL. The function cannot execute SQL statements that modify data.

**CONTAINS SQL**

Specifies that the function can execute only SQL statements with a data access indication of CONTAINS SQL. The function cannot execute statements that read or modify data.
CALL ON NULL INPUT
Specifies that the function is called regardless of whether any of the input argument values are null, making the function responsible for testing for null argument values. The function might return an empty table, depending on the logic in the body of the function.

INHERIT SPECIAL REGISTERS
Specifies that existing values of special registers are inherited upon entry to the function.

STATIC DISPATCH
Specifies that at function resolution time, Db2 chooses a function based on the static (or declared) types of the function parameters.

CARDINALITY integer
Specifies an estimate of the expected number of rows that the function returns. The number is used for optimization purposes. The value of integer must be between 0 and 2147483647.

If a function has an infinite cardinality (the function never returns the end-of-table condition and always returns a row), a query that requires the end-of-table condition to work correctly will need to be interrupted.

SECURED or NOT SECURED
Specifies whether the function is considered secure.

SECURED
Specifies that the function is considered secure.

NOT SECURED
Specifies that the function is considered not secure. NOT SECURED must not be specified when a row permission or a column mask depends on the function.

When the function is invoked, the arguments of the function must not reference a column for which a column mask is enabled when the table is using active column access control.

Notes
Invalidation of packages:
This statement might invalidate all packages that depend on target objects, and sometimes other related objects through cascading effects, depending on the clauses and keywords specified and other factors. For more information, see Changes that invalidate packages (Db2 Application programming and SQL).

Dependent objects:
An SQL routine is dependent on objects that are referenced in the routine body.
Altering a function from NOT SECURED to SECURED:
Typically, the security administrator will examine the data that is accessed by a function, ensure that it is secure, and grant the CREATE_SECURE_OBJECT privilege to the user that requires privileges to change the user-defined function to be secured. After the function is changed to SECURED, the security administrator will revoke the CREATE_SECURE_OBJECT privilege from the owner of the function.

The function is considered secure after the ALTER FUNCTION statement is executed. Db2 treats the SECURED attribute as an assertion that declares that the security administrator has established an audit procedure for all changes to the user-defined function. Db2 assumes that such a control audit procedure is in place for all subsequent ALTER FUNCTION statements or changes to external packages.

Packages and statements in the dynamic statement cache that reference the function are invalidated.

Altering a function from SECURED to NOT SECURED:
Packages and statements in the dynamic statement cache that reference the function are invalidated when the function is changed from SECURED to NOT SECURED. An function that is not secured might negatively impact performance if that function accesses data in a table that is using row access control or column access control. To minimize the performance impact, either change the function to use the SECURED option or deactivate row access control or column access control for the table that the function is accessing.

Invoking other user-defined functions in a secure function:
When a secure user-defined function is referenced in an SQL data change statement that references a table that is using row access control or column access control, and if the secure user-defined function invokes other user-defined functions, the nested user-defined functions are not validated as secure. If those nested functions can access sensitive data, the security administrator needs to ensure that those functions are allowed to access sensitive data and should ensure that a change control audit procedure has been established for all changes to those functions.

The SECURE column in the DSN_FUNCTION_TABLE EXPLAIN table:
The SECURE column in the DSN_FUNCTION_TABLE EXPLAIN table indicates if a user-defined function is considered secure.

Altering obfuscated functions:
Obfuscated functions cannot be altered in any way.

Compatibilities:
For compatibility with the CREATE FUNCTION (SQL table) statement, the following clause can be specified, but will be ignored:
• LANGUAGE SQL

Alternative syntax and synonyms:
To provide compatibility with previously releases of Db2 or other products in the Db2 family, Db2 supports the following keywords:
• VARIANT as a synonym for NOT DETERMINISTIC
• NOT VARIANT as a synonym for DETERMINISTIC
• NULL CALL as a synonym for CALLED ON NULL INPUT
Examples

Example 1: The following statement modifies the definition of an SQL table function to set the estimated cardinality to 10,000.

```
ALTER FUNCTION GET_TABLE
RESTRICT CARDINALITY 10000;
```

**ALTER INDEX**

The ALTER INDEX statement changes the description of an index at the current server.

**Invocation**

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

**Authorization**

The privilege set that is defined below must include one of the following:

- Ownership of the index
- Ownership of the table on which the index is defined
- DBADM authority for the database that contains the table
- SYSADM or SYSCTRL authority
- System DBADM
- Installation SYSOPR authority (when the current SQLID of the process is set to SYSINSTD)

If the database is implicitly created, the database privileges must be on the implicit database or on DSNDB04.

If BUFFERPOOL or USING STOGROUP is specified, additional privileges could be needed, as explained in the description of those clauses.

**Privilege set**: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the package. If the statement is dynamically prepared, the privilege set is the union of the privilege sets that are held by each authorization ID and role of the process.

**Syntax**

```
(1)
```

```
ALTER INDEX—index-name
```

```
(2)
```

```
REGENERATE
USING APPLICATION COMPATIBILITY—applicompid
```
Notes:
1. At least one clause must be specified after index-name. It can be from the optional list or it can be ALTER PARTITION.
2. If REGENERATE is specified, it must be the only clause specified on the ALTER INDEX statement.
3. If ADD COLUMN and PADDED or NOT PADDED are specified, ADD COLUMN must be specified before PADDED or NOT PADDED.
4. The same clause must not be specified more than one time.
5. The ALTER clause can only be specified for partitioned indexes. The ALTER clause must be specified last.

using-specification:
USING VCAT catalog-name STOGROUP stogroup-name PRIQTY integer SECQTY integer ERASE YES NO

Notes:
1 The same clause must not be specified more than one time.

free-specification:

FREEPAGE integer PCTFREE integer

Notes:
1 The same clause must not be specified more than one time.

gbpcache-specification:

GBPCACHE CHANGED GBPCACHE ALL GBPCACHE NONE

partition-element:

PARTITION integer ENDING AT (constant) INCLUSIVE MAXVALUE MINVALUE

Notes:
1 If PARTITION is specified, either the ENDING clause, using-specification, free-specification, or gbpcache-specification should also be specified.

Description

index-name

Identifies the index to be changed or regenerated. The name must identify a
user-created index that exists at the current server. The name must not identify an index that is defined on a declared temporary table.

**REGENERATE**

Specifies that the index will be regenerated. The structure that represents the index definition is regenerated. The index definition will be composed from the catalog. Existing authorities and dependencies, if any, are retained. The catalog is updated with the regenerated index definition. The index is put into rebuild-pending state and catalog entries for the index statistics are deleted.

Use of this clause or keyword might invalidate packages that depend on the target object, or packages that depend on related objects through cascading effects. See [Changes that invalidate packages (Db2 Application programming and SQL)](https://www.ibm.com/docs/en/db2)

If the index cannot be successfully regenerated, an error is returned. In this case, the index must be dropped and re-created.

**USING APPLICATION COMPATIBILITY** *applcompat-value*

Specifies that the object is regenerated under *applcompat-value* application compatibility rules. The ALTER statement fails if it includes any syntax, semantics, or options that require a higher application compatibility level.

If USING APPLICATION COMPATIBILITY is omitted, the regeneration uses the APPLCOMPAT value of the applicable SYSIBM.SYSENVIRONMENT catalog table row.

The following *applcompat-value* values can be specified:

**function-level**

Specifies the application compatibility behavior of the function-level function level. The equivalent function level or higher must be activated.

The format is *VvvRrMmm*, where *vv* is the version, *r* is the release, and *mmm* is the modification level. For example:

**V12R1M504**

Identifies compatibility with the current highest available function level, function level 504.

**V12R1M500**

Identifies compatibility with the function level that enables new function in the initial Db2 12 release, function level 500.

V12R1M500 is the same as V12R1.

**V12R1M100**

Identifies compatibility with the function level before you activate new function, after migration to Db2 12, function level 100.

V12R1M100 is the same as V11R1.

For a list of supported *function-level* values, see [What's new in Db2 12 function levels (Db2 for z/OS What's New?)](https://www.ibm.com/docs/en/db2)

**V11R1**

Specifies Db2 11 compatibility behavior.

**V10R1**

Specifies Db2 10 compatibility behavior.

**BUFFERPOOL** *bpname*

Identifies the buffer pool that is to be used for the index. *bpname* must identify
an activated 4K, 8 KB, 16 KB, or 32 KB buffer pool, and the privilege set must include SYSADM authority, SYSCTRL authority, or the USE privilege for the buffer pool.

A buffer pool with a smaller size should be chosen for indexes with random insert patterns. A buffer pool with a larger size should be chosen for indexes with sequential insert patterns.

If the index is changed to use index compression (the COMPRESS YES clause), the buffer pool must be 8 KB, 16 KB, or 32 KB in size.

The change is a pending definition change if all of the following conditions are true:

- The data sets of the index are created
- The index is defined on one of the following:
  - A table that is in a universal table space, or a table that is in a table space for which a pending definition change will convert the table space to a universal table space
  - An XML table that is associated with a base table that is in a universal table space, or an XML table that is in a table space for which a pending definition change will convert the table space to a universal table space
  - One of the following types of auxiliary tables:
    - An auxiliary table that is associated with a base table that is in a universal table space
    - An auxiliary table that is associated with a base table that is in a table space for which a pending definition change will convert the table space to a universal table space
- The buffer pool is changed to a buffer pool with a different size, or the buffer pool is changed to a buffer pool with the same size and the table space or objects in the table space have pending definition changes.

If any of the previous conditions are not true, the change is an immediate change.

If the change is an immediate change, the change to the description of the index takes effect the next time the data sets of the index space are opened. The data sets can be closed and reopened by a STOP DATABASE command to stop the index followed by a START DATABASE command to start the index.

If the buffer pool is changed to a buffer pool with a different page size, and the change is an immediate change, the index is placed into REBUILD-pending status.

If the change is a pending definition change, the change is not reflected in the current definition or data at the time of the alter. Instead, the index is placed in an advisory REORG-pending (AREOR) state. A subsequent reorganization of the entire index with an appropriate utility will materialize the changes and apply the pending definition changes to the catalog and data.

CLOSE

Specifies whether the data set is eligible to be closed when the index is not being used and the limit on the number of open data sets is reached. The change to the close rule takes effect the next time the data sets of the index space are opened.

YES

Eligible for closing.

NO

Not eligible for closing.
If DSMAX is reached and there are no CLOSE YES page sets to close, CLOSE NO page sets will be closed.

**COPY**

Indicates whether the COPY utility is allowed for the index.

**NO**

Does not allow full image or concurrent copies or the use of the RECOVER utility on the index.

**YES**

Allows full image or concurrent copies and the use of the RECOVER utility on the index. For data sharing, changing COPY to YES causes additional SCA (Shared Communications Area) storage to be used until the next full or incremental image copy is taken or until COPY is set back to NO.

**DSSIZE integer G**

Specifies the maximum size for each partition of a partitioned index. Any integer 1 - 1024 can be specified (for example, 1G – 1024G). DSSIZE can be specified only if the index uses relative page numbering. This keyword is not valid for nonpartitioned secondary indexes.

The change is immediate if the DSSIZE that is specified is larger than the DSSIZE in the catalog and there are no pending ALTER statements for the table space or partition.

The DSSIZE value that is specified at the index level is applied to each of the partitions of the index.

If the data sets of the index are already created, you cannot specify a partition-level DSSIZE value that is smaller than the current DSSIZE value of the specified partition, or an index-level DSSIZE value that is smaller than the current DSSIZE value for any partition.

The value of DSSIZE for a particular partition is given by the first of these choices that applies:

- The value of DSSIZE given in the PARTITION clause for that partition.
- The value given by a DSSIZE keyword that is not in any PARTITION clause.
- The default value is inherited from the base table space.

**PIECESIZE integer**

Specifies the maximum addressability of each data set for a non-partitioned index. The PIECESIZE clause can only be specified for non-partitioned indexes.

Be aware that when you alter the PIECESIZE value, the index is placed into page set REBUILD-pending (PSRBD) status. The entire index space becomes inaccessible. You must run the REBUILD INDEX or the REORG TABLESPACE utility to remove that status.

The subsequent keyword K, M, or G, indicates the units of the value that is specified in integer.

**K**

Indicates that the integer value is to be multiplied by 1024 to specify the maximum data set size in bytes. integer must be a power of two between 1 and 268435456.

**M**

Indicates that the integer value is to be multiplied by 1048576 to specify the maximum data set size in bytes. integer must be a power of two between 1 and 262144.
Indicates that the integer value is to be multiplied by 1073741824 to specify the maximum data set size in bytes. integer must be a power of two between 1 and 256.

Table 169 shows the valid values for data set size, which depend on the size of the table space.

Table 169. Valid values of PIECESIZE clause

</table>

The data set size limit for partitioned table spaces with more than 256 partitions is 4096.

begin using-specification block

The components of the using-specification are discussed below, first for non-partitioned indexes and then for partitioned indexes.

USING (specification for nonpartitioned indexes)

For nonpartitioned indexes, the USING clause specifies whether the data sets for the index are to be managed by the user or managed by Db2. The USING clause applies to every data set that can be used for the index.

If you specify USING, the index must be in the stopped state when the ALTER INDEX statement is executed. See Altering storage attributes to determine how and when changes take effect.

VCAT catalog-name

Specifies a user-managed data set.
The data sets are linear VSAM data sets cataloged in the integrated catalog facility catalog that `catalog-name` identifies. For more information about `catalog-name` values, see `Naming conventions`.

More than one Db2 subsystem can share the integrated catalog facility catalogs with the current server. To avoid the chance of those subsystems attempting to assign the same name to different data sets, specify a `catalog-name` value that is not used by the other Db2 subsystems.

**STOGROUP** `stogroup-name`

Specifies using a Db2-managed data set that resides on a volume of the specified storage group. `stogroup-name` must identify a storage group that exists at the current server and the privilege set must include SYSADM authority, SYSCTRL authority, or the USE privilege for the storage group. When the new description of the index is applied, the description of the storage group must include at least one volume serial number. Each volume serial number must identify a volume that is accessible to z/OS for dynamic allocation of the data set, and all identified volumes must be of the same device type. Furthermore, the integrated catalog facility catalog used for the storage group must not contain an entry for the data set.

If you specify **USING STOGROUP** and the current data set is Db2-managed, omission of the **PRIQTY**, **SECQTY**, or **ERASE** clause is an implicit specification of the current value of the omitted clause.

If you specify **USING STOGROUP** to convert from user-managed data sets to Db2-managed data sets:

- Omission of the **PRIQTY** clause is an implicit specification of the default value. For information on how Db2 determines the default value, see `Rules for primary and secondary space allocation`.
- Omission of the **SECQTY** clause is an implicit specification of the default value. For information on how Db2 determines the default value, see `Rules for primary and secondary space allocation`.
- Omission of the **ERASE** clause is an implicit specification of **ERASE NO**.

**PRIQTY** `integer`

Specifies the minimum primary space allocation for a Db2-managed data set. `integer` must be a positive integer, or -1. This clause can be specified only if the data set is currently managed by Db2 and **USING VCAT** is not specified.

When you specify **PRIQTY** with a positive integer value, the primary space allocation is at least `n` kilobytes, where `n` is:

- **12** If `integer` is less than 12
- `integer`
  - If `integer` is between 12 and 4194304
  - **2097152** If both of the following conditions are true:
    - `integer` is greater than 2097152.
    - The index is a non-partitioned index on a table space that is not defined with the LARGE or DSSIZE attribute.
  - **4194304** If `integer` is greater than 4194304

If you specify **PRIQTY** with a value of -1, Db2 uses a default value for the primary space allocation. For information on how Db2 determines the default value for primary space allocation, see `Rules for primary and secondary space allocation`. 

---

1234 SQL Reference
If USING STOGROUP is specified and PRIQTY is omitted, the value of PRIQTY is its current value. (However, if the current data set is being changed from being user-managed to Db2-managed, the value is its default value. See the description of USING STOGROUP.)

If you specify PRIQTY and do not specify a value of -1, Db2 specifies the primary space allocation to access method services using the smallest multiple of 4 KB not less than \( n \), where \( n \) is defined as in the PRIQTY description. The allocated space can be greater than the amount of space requested by Db2. For example, it could be the smallest number of tracks that will accommodate the space requested. To more closely estimate the actual amount of storage, see DEFINE CLUSTER command (DFSMS Access Method Services for Catalogs).

When determining a suitable value for PRIQTY, be aware that two of the pages of the primary space could be used by Db2 for purposes other than storing index entries.

SECQTY integer
Specifies the minimum secondary space allocation for a Db2-managed data set. integer must be a positive integer, 0, or -1. This clause can be specified only if the data set is currently managed by Db2 and USING VCAT is not specified.

If you specify SECQTY with a value of -1, Db2 uses a default value for the secondary space allocation.

If USING STOGROUP is specified and SECQTY is omitted, the value of SECQTY is its current value. (However, if the current data set is being changed from being user-managed to Db2-managed, the value is its default value. See the description of USING STOGROUP.)

For information on the actual value that is used for secondary space allocation, whether you specify a value or Db2 uses a default value, see Rules for primary and secondary space allocation.

If you specify SECQTY, and do not specify a value of -1, Db2 specifies the secondary space allocation to access method services using the smallest multiple of 4 KB not less than integer. The allocated space can be greater than the amount of space requested by Db2. For example, it could be the smallest number of tracks that will accommodate the space requested. To more closely estimate the actual amount of storage, see DEFINE CLUSTER command (DFSMS Access Method Services for Catalogs).

ERASE
Indicates whether the Db2-managed data sets are to be erased when they are deleted during the execution of a utility or an SQL statement that drops the index.

NO Does not erase the data sets. Operations involving data set deletion will perform better than ERASE YES. However, the data is still accessible, though not through Db2.

YES Erases the data sets. As a security measure, Db2 overwrites all data in the data sets with zeros before they are deleted.

This clause can be specified only if the data set is currently managed by Db2 and USING VCAT is not specified. If you specify ERASE, the index must be in the stopped state when the ALTER INDEX statement is executed. See Altering storage attributes to determine how and when changes take effect.
USING (specification for partitioned indexes:)

For a partitioned index, there is an optional PARTITION clause for each partition. A using-specification can be specified at the global level or at the partition level. A using-specification within a PARTITION clause applies only to that partition. A using-specification specified before any PARTITION clauses applies to every partition except those with a PARTITION clause with a using-specification.

For Db2-managed data sets, the values of PRIQTY, SECQTY, and ERASE for each partition are given by the first of these choices that applies:

- The values of PRIQTY, SECQTY, and ERASE given in the using-specification within the PARTITION clause for the partition. Do not use more than one using-specification in any PARTITION clause.
- The values of PRIQTY, SECQTY, and ERASE given in the using-specification before any PARTITION clause
- The current values of PRIQTY, SECQTY, and ERASE

For data sets that are being changed from user-managed to Db2-managed, the values of PRIQTY, SECQTY, and ERASE for each partition are given by the first of these choices that applies:

- The values of PRIQTY, SECQTY, and ERASE given in the using-specification within the PARTITION clause for the partition. Do not use more than one using-specification in any PARTITION clause.
- The values of PRIQTY, SECQTY, and ERASE given in a using-specification before any PARTITION clauses
- The default values of PRIQTY, SECQTY, and ERASE, which are:
  - PRIQTY 12
  - SECQTY 12, if PRIQTY is not specified in either using-specification, or 10% of PRIQTY or 3 times the index page size (whichever is larger) when PRIQTY is specified
  - ERASE NO

Any partition for which USING or ERASE is specified (either explicitly at the partition level or implicitly at the global level) must be in the stopped state when the ALTER INDEX statement is executed. See Altering storage attributes to determine how and when changes take effect.

VCAT catalog-name

Specifies a user-managed data set with a name that starts with the specified catalog name. You must specify the catalog name in the form of an SQL identifier. Thus, you must specify an alias if the name of the integrated catalog facility catalog is longer than eight characters.

If n is the number of the partition, the identified integrated catalog facility catalog must already contain an entry for the vth data set of the index, conforming to the Db2 naming convention for data sets described in Db2 Administration Guide.

One or more Db2 subsystems could share integrated catalog facility catalogs with the current server. To avoid the chance of having one of those subsystems attempt to assign the same name to different data sets, select a value for catalog-name that is not used by the other Db2 subsystems.

Db2 assumes one and only one data set for each partition.

STOGROUP stogroup-name

If USING STOGROUP is used, stogroup-name must identify a storage
group that exists at the current server and the privilege set must include
SYSADM authority, SYSCtrl authority, or the USE privilege for the
storage group.

Db2 assumes one and only one data set for each partition.

For information on the PRIQTY, SECQTY, and ERASE clauses, see the
description of those clauses in the using-specification for secondary indexes.

end using-specification block

begin free-specification block

FREEPAGE  integer
   Specifies how often to leave a page of free space when index entries are
   created as the result of executing a Db2 utility. One free page is left for every
   integer pages. The value of integer can range from 0 to 255. The change to the
description of the index or partition has no effect until it is loaded or
reorganized using a Db2 utility. Do not specify FREEPAGE for an implicitly
created XML index.

PCTFREE  integer
   Determines the percentage of free space to leave in each nonleaf page and leaf
   page when entries are added to the index or partition as the result of executing
   a Db2 utility. The first entry in a page is loaded without restriction. When
   additional entries are placed in a nonleaf or leaf page, the percentage of free
   space is at least as great as integer.

   The value of integer can range from 0 to 99, however, if a value greater than 10
   is specified, only 10 percent of free space will be left in nonleaf pages. The
   change to the description of the index or partition has no effect until it is
   loaded or reorganized using a Db2 utility. Do not specify PCTFREE for an
   implicitly created XML index.

   If the index is partitioned, the values of FREEPAGE and PCTFREE for a
   particular partition are given by the first of these choices that applies:
   
   • The values of FREEPAGE and PCTFREE given in the PARTITION clause
     for that partition. Do not use more than one free-specification in any
     PARTITION clause.
   • The values given in a free-specification before any PARTITION clauses.
   • The current values of FREEPAGE and PCTFREE for that partition.

end free-specification block

begin gbpcache-specification block

GBPCACHE
   Specifies what index pages are written to the group buffer pool in a data
   sharing environment. In a non-data-sharing environment, you can specify this
   option, but it is ignored.

   CHANGED
   When there is inter-Db2 read-write interest on the index or partition,
   updated pages are written to the group buffer pool. When there is no
   inter-Db2 read-write interest, the group buffer pool is not used. Inter-Db2
   read-write interest exists when more than one member in the data sharing
   group has the index or partition open, and at least one member has it open
   for update.
If the index is in a group buffer pool that is defined as GBPCACHE(NO), CHANGED is ignored and no pages are cached to the group buffer pool.

**ALL**
Indicates that pages are to be cached to the group buffer pool as they are read in from DASD, with one exception. When the page set is not GBP-dependent and one Db2 data sharing member has exclusive read-write interest in that page set (no other group members have any interest in the page set), no pages are cached in the group buffer pool.

If the index is in a group buffer pool that is defined as GBPCACHE(NO), ALL is ignored and no pages are cached to the group buffer pool.

**NONE**
Indicates that no pages are to be cached to the group buffer pool. Db2 uses the group buffer pool only for cross-invalidation.

If you specify NONE, the index or partition must not be in group buffer pool recover-pending (GRECP) status.

If the index is partitioned, the value of GBPCACHE for a particular partition is given by the first of these choices that applies:

1. The value of GBPCACHE given in the PARTITION clause for that partition. Do not use more than one gbpcache-specification in any PARTITION clause.
2. The value given in a gbpcache-specification before any PARTITION clauses.
3. The current value of GBPCACHE for that partition.

If you specify GBPCACHE in a data sharing environment, the index or partition must be in the stopped state when the ALTER INDEX statement is executed. You cannot alter the GBPCACHE value for certain indexes on Db2 catalog tables; for more information, see SQL statements allowed on the catalog.

end gbpcache-specification block

**CLUSTER or NOT CLUSTER**
Specifies whether the index is the clustering index for the table.

**CLUSTER**
The index is used as the clustering index for the table. This change takes effect immediately. Any subsequent insert operations will use the new clustering index. Existing data remains clustered by the previous clustering index until the table space is reorganized.

The implicit or explicit clustering index is ignored when data is inserted into a table space that is defined with MEMBER CLUSTER. Instead of using cluster order, Db2 chooses where to locate the data, based on available space. The MEMBER CLUSTER attribute affects only data that is inserted with an insert operation; data is always loaded and reorganized in cluster order.

Do not specify CLUSTER in the following cases:
- The index is for an auxiliary table.
- CLUSTER was used already for a different index on the table.
- The index is an XML index.
- The index includes expressions.
- The index is for a table that uses hash organization.
The index is the hash overflow index for a table.

**NOT CLUSTER**
The index is not used as the clustering index of the table. If the index is already defined as the clustering index, it continues to be used as the clustering index by Db2 and the REORG utility until clustering is explicitly changed by specifying `CLUSTER` for a different index.

Specifying **NOT CLUSTER** for an index that is not a clustering index is ignored.

If the index is the partitioning index for a table that uses index-controlled partitioning, the table is converted to use table-controlled partitioning. The high limit key for the last partition is set to the highest possible value for ascending key columns or the lowest possible value for descending key columns. Use of this clause or keyword might invalidate packages that depend on the target object, or packages that depend on related objects through cascading effects. See [Changes that invalidate packages (Db2 Application programming and SQL)](Application programming and SQL).

**COMPRESS NO** or **COMPRESS YES**
Specifies whether the index data will be compressed. If the index is partitioned, this option will apply to all partitions.

When an index is changed from one compression option to another (either from **COMPRESS YES** to **COMPRESS NO**, or from **COMPRESS NO** to **COMPRESS YES**), the index is marked as rebuild pending. For a non-partitioned index, the index will be placed in a page set rebuilding state. For a partitioned index, the index will be placed in rebuilding state.

However, for indexes in universal table spaces, alterations to index compression are a pending change that place the index in advisory REORG-pending (AREOR) status. If the index is defined with the **DEFINE NO** attribute and data sets are not created yet, the alteration is still immediate. Also, for an index that is not in a universal table space, an alteration to index compression can be a pending change if other pending changes exist at the index, table, or table space level when the **ALTER INDEX COMPRESS** statement runs.

**COMPRESS NO**
Specifies that index compression will be turned off.

**COMPRESS YES**
Specifies that the index will use index compression. **COMPRESS YES** can be specified for user-managed data sets only if the control interval size is 4K.

**NOT PADDED or PADDED**
Specifies how varying-length string columns are to be stored in the index. If the index contains no varying-length columns, this option is ignored, and a warning message is returned.

**NOT PADDED**
Specifies that varying-length string columns are not to be padded to their maximum length in the index. The length information for a varying-length column is stored with the key. **NOT PADDED** is ignored and has no effect if the index is on an auxiliary table. Indexes on auxiliary tables are always padded.

When **PADDED** is changed to **NOT PADDED**, the maximum key length is recalculated with the varying-length formula \((2000 - n - 2m, \text{where } n\text{ is})\)
the number of columns that can contain null values and \( m \) is the number
of varying-length columns in the key). If it is possible that the index key
length might exceed the maximum length (because when it was padded,
the formula \( 2000 - n \) was used), an error occurs.

**PADDED**

Specifies that varying-length string columns within the index are always
padded with the default pad character to their maximum length.

When an index with at least one varying-length column is changed from
**PADDED** to **NOT PADDED**, or vice versa, the index is placed in restricted
rebuild-pending status (RBDP). The index cannot be accessed until it is rebuilt
from the table (using the REBUILD INDEX, REORG TABLESPACE, or LOAD
REPLACE utility). For nonpartitioned secondary indexes (NPSIs), the index is
placed in page set rebuild-pending status (PSRBD), and the entire index must
be rebuilt. In addition, dynamically cached statements that are dependent on
the index are invalidated. Use of this clause or keyword might invalidate
packages that depend on the target object, or packages that depend on related
objects through cascading effects. See [Changes that invalidate packages (Db2)](Application programming and SQL). Do not specify **PADDED** if the index is an XML index.

**ADD COLUMN** *column-name*

Adds *column-name* to the index.

*column-name* must be unqualified, must identify a column of the table, and
must not be one of the existing columns of the index.

The column cannot be:

- a DECFLOAT column, or a distinct-type column that is based on a
  DECFLOAT data type
- a LOB column, or a distinct-type column that is based on a LOB data type
- A timestamp with time zone column or a column with a distinct-type that is
  based on the timestamp with time zone data type, if the PARTITION or
  PARTITION BY RANGE clause is also specified
- a VARBINARY column or a distinct-type column that is based on a
  VARBINARY data type, if the column is defined with the DESC attribute or
  if the index is defined with the PADDED attribute
- a row change timestamp column for a range partitioned index

A character or graphic string column that is added to an index must have the
same encoding scheme as other character or graphic string columns in the
index.

The index must not already be defined with the BUSINESS_TIME WITHOUT
OVERLAPS specification.

A temporal referential constraint must not be dependent on the index.

The total number of columns for the index cannot exceed 64.

If a column is added to an index that is defined with the EXCLUDE NULL
KEYS clause, the index is placed in REBUILD-pending status.

If the index is defined with the EXCLUDE NULL KEYS clause, the specified
column must allow null values.

For **PADDED** indexes, the sum of the length attributes of the columns must
not be greater than \( 2000 - n \), where \( n \) is the number of columns that can
contain null values. For **NOT PADDED** indexes, the sum of the length

---

**Note:**

- The number of columns that can contain null values is calculated based on the
  maximum length of the index key. If the key length exceeds this limit after padding,
  an error occurs.
- When changing an index from **PADDED** to **NOT PADDED**, or vice versa, the index
  must be rebuilt to ensure accurate data access. Similarly, if the index is
  nonpartitioned and changes from **PADDED** to **NOT PADDED**, it enters a
  restricted rebuild-pending status (RBDP).
- The **ADD COLUMN** command allows the addition of new columns to an index,
  subject to specific constraints regarding the type and usage of the columns.
- Character and graphic string columns added to an index must maintain the same
  encoding scheme as other columns in the index.
- Temporal referential constraints cannot be dependent on an index defined with
  **PADDED** or **NOT PADDED** attributes.
- The total number of columns in an index is limited to 64, and if an index is
  defined to exclude null keys, columns added must either be nullable or
  non-nullable as per the index definition.
attributes of the columns must not be greater than \(2000 - n - 2m\), where \(n\) is the number of nullable columns and \(m\) is the number of varying-length columns.

The index cannot be any of the following types of indexes:

- A system-defined catalog index
- An index that enforces a primary key, unique key, or referential constraint
- An index that enforces a temporal referential constraint
- A partitioning index when index-controlled partitioning is being used
- A unique index required for a ROWID column defined as GENERATED BY DEFAULT
- An auxiliary index
- An XML index
- An index that includes expressions
- The hash overflow index for a table

The index is put into rebuild-pending (RBDP) status in the following cases:

- \(column-name\) specifies is a ROWID column
- a column is added to a table, rows are inserted into the table, and the same column is added to an associated index all within the same commit scope
- a column is added to a table and then is added to an associated index in a separate commit scope

Otherwise, the index is put into an advisory reorg-pending (AREO*) state.

**ASC**

Index entries are put in ascending order by the column.

**DESC**

Index entries are put in descending order by the column.

**RANDOM**

Index entries are put in a random order by the column. **RANDOM** cannot be specified in the following cases:

- A varying length column is part of the index key and the index is defined with the NOT PADDED option.
- A column of the index key is defined as TIMESTAMP WITH TIME ZONE.
- The index is part of a partitioning key.

**ADD INCLUDE** (\(column-name\))

Specifies an additional column to append to the set of index key columns of a unique index. Any column that is specified using **INCLUDE column-name**, is not used to enforce uniqueness. The included column might improve performance for some queries using index only access.

Columns that are specified in the ADD INCLUDE clause count towards the limits for the number of columns and the limits on the sum of the length attributes of the columns that are specified in the index. The total number of columns for the index cannot exceed 64.

\(column-name\) must be unqualified, must identify a column of the specified table, and must not be one of the existing columns of the index. \(column-name\) must not identify a LOB or DECFLOAT column (or a distinct type that is based on one of those types).

The INCLUDE clause cannot be specified for the following types of indexes:
- A system defined catalog index
- A non-unique index
- A partitioning index when index-controlled partitioning is used
- An auxiliary index
- An index on a foreign key
- An XML index
- An extended index
- An index that includes expressions
- An index that is created with the EXCLUDE NULL KEYS clause
- An index that is required for a temporal referential constraint

If a column is added to both a table and an associated index within the same commit scope and the column is not a ROWID column, the index is placed in an advisory reorg-pending state (AREO*). Otherwise, the index is placed in a rebuild-pending state (RBDP).

Columns in the INCLUDE list that are defined as character or graphic string data types must be defined with the same encoding scheme as other key columns with character or graphic string data types.

**ALTER PARTITION** *integer*

Identifies the partition of the index to be altered. For an index that has *n* partitions, you must specify an integer in the range 1 to *n*. You must not use this clause under the following conditions:

- If the index is nonpartitioned
- If the index is defined on a table that contains an XML column and uses index-controlled partitioning

You must use this clause if the index is partitioned and you specify the ENDING AT clause.

**ENDING AT(constant), MAXVALUE, or MINVALUE**

Specifies the highest value of the index key for the identified partition of the partitioning index. In this context, highest means highest in the sorting sequence of the index columns. In a column defined as ascending (ASC), highest and lowest have the usual meanings. In a column defined as descending (DESC), the lowest actual value is highest in the sorting sequence.

You must use at least one value (constant, MAXVALUE, or MINVALUE) after ENDING AT in each PARTITION clause. You can use as many values as there are columns in the key. The concatenation of all the values is the highest value of the key in the corresponding partition of the index. The length of each highest key value (also called the limit key) is the same as the length of the partitioning index.

**constant**

Specifies a constant value with a data type that must conform to the rules for assigning that value to the column. If a string constant is longer or shorter than required by the length attribute of its column, the constant is either truncated or padded on the right to the required length. If the column is ascending, the padding character is X'FF'. If the column is descending, the padding character is X'00'. The precision and scale of a decimal constant must not be greater than the precision and scale of its corresponding column. A hexadecimal string constant (GX) cannot be specified.
MAXVALUE
Specifies a value greater than the maximum value for the limit key of a partition boundary (that is, all X'FF' regardless of whether the column is ascending or descending). If all of the columns in the partitioning key are ascending, a constant or the MINVALUE clause cannot be specified following MAXVALUE. After MAXVALUE is specified, all subsequent columns must be MAXVALUE.

MINVALUE
Specifies a value that is smaller than the minimum value for the limit key of a partition boundary (that is, all X'00' regardless of whether the column is ascending or descending). If all of the columns in the partitioning key are descending, a constant or the MAXVALUE clause cannot be specified following MAXVALUE. After MINVALUE is specified, all subsequent columns must be MINVALUE.

The key values are subject to the following rules:

• The first value corresponds to the first column of the key, the second value to the second column, and so on.
• If a key includes a ROWID column (or a column with a distinct type that is based on a ROWID data type), the values of the ROWID column are assumed to be in the range of X'000...00' to X'FFF...FF'. Only the first 17 bytes of the value that is specified for the corresponding ROWID column are considered.
• Using fewer values than there are columns in the key has the same effect as using the highest possible values for all omitted columns for an ascending index.
• If the key exceeds 255 bytes, only the first 255 bytes are considered.
• The highest value of the key in any partition must be lower than the highest value of the key in the next partition.
• The highest value of the key in the last partition depends on how the table space was defined. For table spaces created without the LARGE or DSSIZE option, the constants you specify after ENDING AT are not enforced. The highest value of the key that can be placed in the table is the highest possible value of the key.

For table spaces created with the LARGE or DSSIZE options, the constants you specify after ENDING AT are enforced. The value specified for the last partition is the highest value of the key that can be placed in the table. Any keys that are made invalid after the ALTER TABLE statement is executed are placed in a discard data set when you run the REORG utility. If the last partition is in reorg-pending status, regardless of whether you changed its limiting key values, you must specify a discard data set when you run the REORG utility.

ENDING AT must not be specified for any indexes defined on a table that uses table-controlled partitioning. Use ALTER TABLE ALTER PARTITION to modify the partitioning boundaries for a table that uses table-controlled partitioning.

INCLUSIVE
Specifies that the specified range values are included in the data partition.
Notes

Pending definition changes:
The following ALTER INDEX options can cause pending changes to the
definition of the specified index under certain conditions:
- BUFFERPOOL
- COMPRESS
- DSSIZE

When ALTER INDEX causes a pending definition change, semantic
validation and authorization checking are performed for the statement.
However, the current definition of the index is not changed, and the index
is placed in advisory REORG-pending (AREOR) state. If there are no
pending definition changes for the table space, you can run the REORG
INDEX utility with SHRLEVEL CHANGE or the REORG TABLESPACE
utility with SHRLEVEL CHANGE or REFERENCE to enable the changes to
the definition of the index. If pending definition changes also exist for the
table space, you must run the REORG TABLESPACE utility with
SHRLEVEL CHANGE or REFERENCE to enable the changes to the
definition of the index (and the pending table space definition).

Restrictions involving pending definition changes:
ALTER INDEX statements that result in a pending definition change are
not allowed in the following cases:
- On the catalog, system objects, or objects in a workfile database
- If the definition of the table space is incomplete
- If the definition of the table on which the index is defined is incomplete
- If the ALTER INDEX statement also specifies options that will cause an
  immediate definition change
- If there are already pending definition changes to a column that is
  referenced by the index, ALTER INDEX to NOT Padded is not
  allowed.
- If there are already pending definition changes to the index, ALTER
  INDEX to change from COMPRESS NO to COMPRESS YES is not
  allowed.
- If there are already pending definition changes to the index or the table
  space that contains the index, the following are not allowed:
  - ALTER INDEX (with or without ALTER PARTITION) to change from
    a Db2-managed data set to a user-managed data set
  - ALTER INDEX to change the value of PIECESIZE
- If there are already pending definition changes to the containing table
  space or any objects within the table space, the following are not
  allowed:
  - ALTER INDEX REGENERATE to regenerate the index
  - ALTER INDEX ADD COLUMN to add a column to the index

Altering storage attributes:
The USING, PRIQTY, SECQTY, and ERASE clauses define the storage
attributes of the index or partition. If you specify the USING or ERASE
clause when altering storage attributes, the index or partition must be in
the stopped state when the ALTER INDEX statement is executed. A STOP
DATABASE...SPACENAM... command can be used to stop the index or
partition.
If the catalog name changes, the changes take effect after you move the data and start the index or partition using the `START DATABASE...SPACENAME...` command. The catalog name can be implicitly or explicitly changed by the `ALTER INDEX` statement. The catalog name also changes when you move the data to a different device. See the procedures for moving data in *Db2 Administration Guide*.

Changes to the secondary space allocation (SECQTY) take effect the next time Db2 extends the data set; however, the new value is not reflected in the integrated catalog until you use the `REORG`, `RECOVER`, or `LOAD REPLACE` utility on the index or partition. Changes to the other storage attributes take effect the next time you use the `REORG`, `RECOVER`, or `LOAD REPLACE` utility on the index or partition. If you change the primary space allocation parameters or erase rule, you can have the changes take effect earlier if you move the data before you start the index or partition.

**Altering indexes on Db2 catalog tables:**
For details on altering options on catalog tables, see [SQL statements allowed on the catalog](#).

**Size restriction for the object descriptor of an index:**
The following case might result in an error being returned if the `ALTER INDEX` statement results in a versioned object descriptor that is larger than 30,000 bytes being added (or updated):

- An `ALTER INDEX` statement that results in the first version of the object descriptor being generated for the index

You might need to drop and re-create the index if the object descriptor for the index exceeds 30,000 bytes.

**Invalidation of packages:**
This statement might invalidate all packages that depend on target objects, and sometimes other related objects through cascading effects, depending on the clauses and keywords specified and other factors. For more information, see [Changes that invalidate packages (Db2 Application programming and SQL)](#).

**Altering limit keys:**
If you specify `ALTER PARTITION integer ENDING AT` to change the limit key values of a partitioning index, the packages that are dependent on that index are marked invalid and go through automatic rebind the next time they are run.

**Restictions on SQL data change statements in the same commit scope as ALTER INDEX:**
SQL data change statements that affect an index cannot be performed in the same commit scope as `ALTER INDEX` statements that affect that index.

**Altering indexes for tables that are involved in a clone relationship:**
You cannot change any index for a table that is involved in a clone relationship (base table or clone table). If a change to an index is required, the clone table must be dropped before the index can be changed. After the index is changed, the clone table can be created again.

**Adding a varying length column to a key for a system with NOT PADDED as the default:**
If the system default is NOT PADDED (the value of field PAD INDEXES BY DEFAULT on installation panel DSNTIPE is NO), no varying length columns are in the key, and the PADDED or NOT PADDED option is not
explicitly specified when the index is created, the Padded column of the SYSIBM.SYSINDEXES catalog table is populated with a blank value. If a varying length column is later added to the key, the value of the Padded column in SYSIBM.SYSINDEXES is changed to ‘Y’ to indicate that the index is now a Padded index.

Running utilities:
You cannot execute the ALTER INDEX statement while a Db2 utility has control of the index or its associated table space.

Alternative syntax and synonyms:
To provide compatibility with previous releases of Db2 or other products in the Db2 family, Db2 supports the following keywords when altering the partitions of a partitioned index:

- PART can be specified as a synonym for PARTITION. In addition, the ALTER keyword that precedes PARTITION is optional. In addition, if you alter more than one partition, specifying a comma between each ALTER PARTITION integer clause is optional.
- VALUES can be specified as a synonym for ENDING AT.

Although these keywords are supported as alternatives, they are not the preferred syntax.

Examples

Example 1: Alter the index DSN8C10.XEMP1. Indicate that Db2 is not to close the data sets that support the index when there are no current users of the index.

```
ALTER INDEX DSN8C10.XEMP1
CLOSE NO;
```

Example 2: Alter the index DSN8C10.XPROJ1. Use BP1 as the buffer pool that is to be associated with the index, indicate that full image or concurrent copies on the index are allowed, and change the maximum size of each data set to 8 megabytes.

```
ALTER INDEX DSN8C10.XPROJ1
BUFFERPOOL BP1
COPY YES
PIECESIZE 8M;
```

Example 3: Assume that index X1 contains at least one varying-length column and is a padded index. Alter the index to an index that is not padded.

```
ALTER INDEX X1
NOT Padded;
```

The index is placed in restricted rebuild-pending status (RBDP) and cannot be accessed until it is rebuilt from the table.

Example 4: Alter partitioned index DSN8C10.DEPT1. For partition 3, leave one page of free space for every 13 pages and 13 percent of free space per page. For partition 5, leave one page for every 25 pages and 25 percent of free space. For all the other partitions, leave one page of free space for every 6 pages and 11 percent of free space. Ensure that index pages are cached to the group buffer pool for all partitions except partition 4. For partition 4, write pages only when there is inter-Db2 read-write interest on the partition.

```
ALTER INDEX DSN8C10.XDEPT1
BUFFERPOOL BP1
CLOSE YES
COPY YES
USING VCAT CATLGG
```
ALTER MASK

The ALTER MASK statement changes a column mask that exists at the current server.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

Authorization

The privilege set that is defined below must include the following authority:
- SECADM authority

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the package. If the statement is dynamically prepared, the privilege set is the union of the privilege sets that are held by each authorization ID and role of the process.

Syntax

```
ALTER MASK <mask-name> [ENABLE | DISABLE | REGENERATE] [USING APPLICATION COMPATIBILITY <applcompat-value>]
```

Description

- `<mask-name>`
  Identifies the column mask to be altered. The name must identify a mask that exists at the current server.

- `ENABLE`
  Specifies that the column mask is to be enabled for column access control. If column access control is not currently activated for the table, the column mask will become effective when column access control is activated for the table. If column access control is currently activated for the table, the column mask becomes effective immediately and dynamic cached statements that reference
the table are invalidated. Use of this clause or keyword might invalidate
packages that depend on the target object, or packages that depend on related
objects through cascading effects. See Changes that invalidate packages (Db2
Application programming and SQL).

A column mask with a regeneration error cannot be enabled. To clear the status
of the column mask, the column mask must be dropped and re-created with a
modified definition.

ENABLE is ignored if the column mask is already defined as enabled for
column access control.

DISABLE
Specifies that the column mask is to be disabled for column access control. If
column access control is not currently activated for the table, the column mask
will remain ineffective when column access control is activated for the table. If
column access control is currently activated for the table, the column mask
becomes ineffective immediately and all dynamic cached statements that
reference the table are invalidated. Use of this clause or keyword might
invalidate packages that depend on the target object, or packages that depend
on related objects through cascading effects. See Changes that invalidate
packages (Db2 Application programming and SQL).

DISABLE is ignored if the column mask is already defined as disabled for
column access control.

REGENERATE
Specifies that the column mask is to be regenerated. The column mask
definition in the catalog is used, and existing dependencies and authorization,
if any, are retained. The column mask definition is reevaluated as if the column
mask was being created. The user-defined functions that are referenced in the
column mask definition must be resolved to the same secure UDFs as that
were resolved during the column mask creation.

USING APPLICATION COMPATIBILITY applcompat-value
Specifies that the object is regenerated under applcompat-value application
compatibility rules. The ALTER statement fails if it includes any syntax,
semantics, or options that require a higher application compatibility level.

If USING APPLICATION COMAPTIBILITY is omitted, the regeneration uses
the APPLCOMPAT value of the applicable SYSIBM.SYSENVIRONMENT
catalog table row.

The following applcompat-value values can be specified:

function-level
Specifies the application compatibility behavior of the function-level
function level. The equivalent function level or higher must be activated.

The format is VvvRrMmmm, where v is the version, r is the release, and mmm
is the modification level. For example:

V12R1M504
Identifies compatibility with the current highest available function
level, function level 504.

V12R1M500
Identifies compatibility with the function level that enables new
function in the initial Db2 12 release, function level 500.
V12R1M500 is the same as V12R1.
Identifies compatibility with the function level before you activate new function, after migration to Db2 12, function level 100.

V12R1M100 is the same as V11R1.

For a list of supported function-level values, see What's new in Db2 12 function levels (Db2 for z/OS What's New?).

V11R1
Specifies Db2 11 compatibility behavior.

V10R1
Specifies Db2 10 compatibility behavior.

Notes
Applying Db2 maintenance:
When Db2 maintenance is applied that affects how a column mask is generated, the column mask might need to be regenerated to ensure the column mask is still valid.

If the column mask is regenerated successfully, the status of the column mask is set to a blank in the catalog table. If the column mask is enabled and column access control is currently activated for the table all dynamic cached statements that reference the table are invalidated.

If the column mask cannot be regenerated successfully, an error is returned. The regeneration status of the column mask is an error. If the column mask is enabled and column access control is currently activated for the table, all packages and dynamic cached statements that reference the table are marked invalidated. To clear the status of the column mask, the column mask must be dropped and re-created with a modified definition. Or the column mask can be disabled if not disabled yet. A disabled column mask becomes ineffective to a column access control enforced table.

When the table is referenced in a data manipulation statement, the statement returns an error if any enabled column mask has a regeneration error.

Invalidation of packages:
This statement might invalidate all packages that depend on target objects, and sometimes other related objects through cascading effects, depending on the clauses and keywords specified and other factors. For more information, see Changes that invalidate packages (Db2 Application programming and SQL).

Examples
Example 1:
Enable column mask M1.
ALTER MASK M1 ENABLE;

Example 2:
Regenerate column mask M1.
ALTER MASK M1 REGENERATE;

COMMIT;
ALTER PERMISSION

The ALTER PERMISSION statement alters a row permission that exists at the current server.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

Authorization

The privilege set that is defined below must include the following authority:

SECADM authority

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the package. If the statement is dynamically prepared, the privilege set is the union of the privilege sets that are held by each authorization ID and role of the process.

Syntax

```
ALTER PERMISSION permission-name

ENABLE
DISABLE
REGENERATE

USING APPLICATION COMPATIBILITY applcompat-value
```

Description

permission-name

Identifies the permission to be altered. The name must identify a row permission that exists at the current server. The name must not identify a default row permission that is created implicitly by Db2.

ENABLE

Specifies that the row permission is to be enabled for row access control. If row access control is not currently activated for the table, the row permission will become effective when row access control is activated for the table. Use of this clause or keyword might invalidate packages that depend on the target object, or packages that depend on related objects through cascading effects. See [Changes that invalidate packages (Db2 Application programming and SQL)](#).

A row permission with a regeneration error cannot be enabled. To clear the status of the row permission, the row permission must be dropped and re-created with a modified definition.

ENABLE is ignored if the row permission is already defined as enabled for row access control.

DISABLE

Specifies that the row permission is to be disabled for row access control. If row access control is not currently activated for the table, the row permission
will remain ineffective when row access control is activated for the table. Use
of this clause or keyword might invalidate packages that depend on the target
object, or packages that depend on related objects through cascading effects.
See Changes that invalidate packages (Db2 Application programming and
SQL).

DISABLE is ignored if the row permission is already defined as disabled for
row access control.

REGENERATE
Specifies that the row permission is to be regenerated. The row permission
definition in the catalog is used, and existing authorizations and dependencies,
if any, are retained. The user-defined functions that are referenced in the row
permission definition must be resolved to the same secure UDFs as that were
resolved during the row permission creation.

USING APPLICATION COMPATIBILITY applcompat-value
Specifies that the object is regenerated under applcompat-value application
compatibility rules. The ALTER statement fails if it includes any syntax,
semantics, or options that require a higher application compatibility level.

If USING APPLICATION COMPATIBILITY is omitted, the regeneration uses
the APPLCOMPAT value of the applicable SYSIBM.SYSENVIRONMENT
catalog table row.

The following applcompat-value values can be specified:

function-level
Specifies the application compatibility behavior of the function-level
function level. The equivalent function level or higher must be activated.

The format is VvvRrMmmm, where v is the version, r is the release, and mmmm
is the modification level. For example:

V12R1M504
Identifies compatibility with the current highest available function
level, function level 504.

V12R1M500
Identifies compatibility with the function level that enables new
function in the initial Db2 12 release, function level 500.
V12R1M500 is the same as V12R1.

V12R1M100
Identifies compatibility with the function level before you activate
new function, after migration to Db2 12, function level 100.
V12R1M100 is the same as V11R1.

For a list of supported function-level values, see What's new in Db2 12
function levels (Db2 for z/OS What's New?).

V11R1
Specifies Db2 11 compatibility behavior.

V10R1
Specifies Db2 10 compatibility behavior.

Notes
Invalidation of packages:
This statement might invalidate all packages that depend on target objects,
and sometimes other related objects through cascading effects, depending
on the clauses and keywords specified and other factors. For more information, see Changes that invalidate packages (Db2 Application programming and SQL).

Invalidation of cached dynamic SQL statements:
This statement might invalidate cached dynamic SQL statements that depend on target objects, and sometimes other related objects through cascading effects. For more information, see Invalidation of cached dynamic statements (Db2 Performance).

Applying Db2 maintenance:
When Db2 maintenance is applied that affects how a row permission is generated, the row permission might need to be regenerated to ensure the row permission is still valid.

If the row permission is regenerated successfully, the status of the row permission is set to a blank in the catalog table.

If the row permission cannot be regenerated successfully, an error is returned. The regeneration status of the row permission is set to an error. To clear the status of the row permission, the row permission must be dropped and re-created with a modified definition. Or the row permission can be disabled if not disabled yet. A disabled row permission becomes ineffective to a row access control enforced table.

When the table is referenced in a data manipulation statement, the statement returns an error if any enabled row permission has an regeneration error.

Examples

Example 1:
Enable permission P1.
ALTER PERMISSION P1 ENABLE;

Example 2:
Regenerate permission P1.
ALTER PERMISSION P1 REGENERATE;

ALTER PROCEDURE (external)

The ALTER PROCEDURE statement changes the description of an external stored procedure at the current server.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

Authorization

The privilege set that is defined below must include at least one of the following:

- Ownership of the stored procedure
- The ALTERIN privilege on the schema
- SYSADM or SYSCTRL authority
- System DBADM
- Installation SYSOPR authority (when the current SQLID of the process is set to SYSINSTL)
The authorization ID that matches the schema name implicitly has the ALTERIN privilege on the schema.

If the authorization ID that is used to alter the procedure has the installation
SYSADM authority or the installation SYSOPR authority and if the current SQLID
is set to SYSINSTL, the procedure is identified as system-defined procedure when
the procedure definition is reevaluated.

When LANGUAGE is JAVA and a jar-name is specified in the EXTERNAL NAME
clause, the privilege set must include USAGE on the JAR file, the Java archive file.

**Privilege set:** If the statement is embedded in an application program, the
privilege set is the privileges that are held by the owner of the package.

If the statement is dynamically prepared, the privilege set is the set of privileges
that are held by the SQL authorization IDs of the process. The specified routine
name can include a schema name (a qualifier). However, if the schema name is not
the same as one of these SQL authorization IDs, one of the following conditions
must be met:
1. The privilege set includes SYSADM authority
2. The privilege set includes SYSCTRL authority
3. The SQL authorization ID of the process has the ALTERIN privilege on the
   schema

If the environment in which the stored procedure is to run is being changed, the
authorization ID must have authority to use the WLM environment. This
authorization is obtained from an external security product, such as RACF.

**Syntax**

```
ALTER PROCEDURE procedure-name option-list
```

**option-list:** (Specify options in any order. Specify at least one option. Do not specify the same option more than
once.)
Notes:
1. If **LANGUAGE** is **JAVA**, **EXTERNAL NAME** must be specified with a valid external-java-routine-name.
external-java-routine-name:
  jar-name: method-name method-signature

jar-name:
  schema-name, jar-id

method-name:
  package-id / class-id (1) method-id (2)

method-signature:
  ( java-datatype

Notes:
1. The slash (/) is supported for compatibility with previous releases of Db2 for z/OS.
2. The exclamation point (!) is supported for compatibility with other products in the Db2 family.

Description

procedure-name
  Identifies the stored procedure to be altered.

DYNAMIC RESULT SETS integer
  Specifies the maximum number of query result sets that the stored procedure can return. The value must be between 0 and 32767.

EXTERNAL NAME external-program-name or identifier
  Specifies the name of the MVS load module for the program that runs when the procedure name is specified in an SQL CALL statement.

If LANGUAGE is JAVA, external-program-name must be specified and enclosed in single quotation marks, with no extraneous blanks within the single quotation marks. It must specify a valid external-java-routine-name. If multiple external-program-name values are specified, the total length of all of the values must not be greater than 1305 bytes and each value must be separated by a space or a line break. Do not specify a JAR file for a Java procedure for which NO SQL is in effect.

An external-java-routine-name contains the following parts:
**jar-name**

Identifies the name given to the JAR file when it was installed in the database. The name contains **jar-id**, which can optionally be qualified with a schema. Examples are "myJar" and "mySchema.myJar." The unqualified **jar-id** is implicitly qualified with a schema name according to the following rules:

- If the statement is embedded in a program, the schema name is the authorization ID in the QUALIFIER bind option when the package or plan was created or last rebound. If the QUALIFIER was not specified, the schema name is the owner of the package or plan.
- If the statement is dynamically prepared, the schema name is the SQL authorization ID in the CURRENT SCHEMA special register.

If **jar-name** is specified, it must exist when the ALTER PROCEDURE statement is processed.

If **jar-name** is not specified, the procedure is loaded from the class file directly instead of being loaded from a JAR file. Db2 searches the directories in the CLASSPATH associated with the WLM Environment. Environmental variables for Java routines are specified in a data set identified in a JAVAENV DD card on the JCL used to start the address space for a WLM-managed stored procedure.

**method-name**

Identifies the name of the method and must not be longer than 254 bytes. Its package, class, and method ID's are specific to Java and as such are not limited to 18 bytes. In addition, the rules for what these can contain are not necessarily the same as the rules for an SQL ordinary identifier.

**package-id**

Identifies a package. The concatenated list of **package-ids** identifies the package that the class identifier is part of. If the class is part of a package, the method name must include the complete package prefix, such as "myPacks.StoredProcs." The Java virtual machine looks in the directory "/myPacks/StoredProcs/" for the classes.

**class-id**

Identifies the class identifier of the Java object.

**method-id**

Identifies the method identifier with the Java class to be invoked.

**method-signature**

Identifies a list of zero or more Java data types for the parameter list and must not be longer than 1024 bytes. Specify the **method-signature** if the procedure involves any input or output parameters that can be NULL. When the stored procedure being created is called, Db2 searches for a Java method with the exact **method-signature**. The number of **java-datatype** elements specified indicates how many parameters that the Java method must have.

A Java procedure can have no parameters. In this case, you code an empty set of parentheses for **method-signature**. If a Java **method-signature** is not specified, Db2 searches for a Java method with a signature derived from the default JDBC types associated with the SQL types specified in the parameter list of the ALTER PROCEDURE statement.

For other values of **LANGUAGE**, the value must conform to the naming conventions for MVS load modules: the value must be less than or equal to 8
bytes, and it must conform to the rules for an ordinary identifier with the exception that it must not contain an underscore.

**LANGUAGE**

Specifies the application programming language in which the stored procedure is written. Assembler, C, COBOL, and PL/I programs must be designed to run in IBM’s Language Environment.

**ASSEMBLE**

The stored procedure is written in Assembler.

**C**

The stored procedure is written in C or C++.

**COBOL**

The stored procedure is written in COBOL, including the OO-COBOL language extensions.

**JAVA**

The stored procedure is written in Java and is executed in the Java Virtual Machine. When **LANGUAGE JAVA** is specified, the **EXTERNAL NAME** clause must also be specified with a valid `external-java-routine-name` and **PARAMETER STYLE** must be specified with **JAVA**. The procedure must be a public static method of the specified Java class.

Do not specify **LANGUAGE JAVA** when **DBINFO**, **PROGRAM TYPE MAIN**, or **RUN OPTIONS** is in effect.

**PLI**

The stored procedure is written in PL/I.

**REXX**

The stored procedure is written in REXX. Do not specify **LANGUAGE REXX** when **PARAMETER STYLE SQL** is specified.

**PARAMETER STYLE**

Identifies the linkage convention used to pass parameters to and return values from the stored procedure. All of the linkage conventions provide arguments to the stored procedure that contain the parameters specified on the CALL statement. Some of the linkage conventions pass additional arguments to the stored procedure that provide more information to the stored procedure. For more information on linkage conventions, see *Db2 Application Programming and SQL Guide*.

**SQL**

Specifies that, in addition to the parameters on the CALL statement, several additional parameters are passed to the stored procedure. The following parameters are passed:

- The first \( n \) parameters that are specified on the CREATE PROCEDURE statement.
- \( n \) parameters for indicator variables for the parameters.
- The SQLSTATE to be returned.
- The qualified name of the stored procedure.
- The specific name of the stored procedure.
- The SQL diagnostic string to be returned to Db2.
- If **DBINFO** is specified, the **DBINFO** structure.

Do not specify **PARAMETER STYLE SQL** when **LANGUAGE REXX** is specified.
GENERAL
Specifies that the stored procedure uses a parameter passing mechanism where the stored procedure receives only the parameters specified on the CALL statement. Arguments to procedures defined with this parameter style cannot be null.

GENERAL WITH NULLS
Specifies that, in addition to the parameters on the CALL statement as specified in GENERAL, another argument is also passed to the stored procedure. The additional argument contains an indicator array with an element for each of the parameters on the CALL statement. In C, this is an array of short integers. The indicator array enables the stored procedure to accept or return null parameter values.

JAVA
Specifies that the stored procedure uses a parameter passing convention that conforms to the Java and SQLJ Routines specifications. PARAMETER STYLE JAVA can be specified only if LANGUAGE is JAVA. If the ALTER PROCEDURE statement results in changing LANGUAGE to JAVA, PARAMETER STYLE JAVA, and an EXTERNAL NAME clause might need to be specified to provide appropriate values. JAVA must be specified for PARAMETER STYLE when LANGUAGE is JAVA.

INOUT and OUT parameters are passed as single-entry arrays. The INOUT and OUT parameters are declared in the Java method as single-element arrays of the Java type.

PARAMETER STYLE SQL cannot be used with LANGUAGE REXX.

DETERMINISTIC or NOT DETERMINISTIC
Specifies whether the stored procedure returns the same results each time the stored procedure is called with the same IN and INOUT arguments.

DETERMINISTIC
The stored procedure always returns the same results each time the stored procedure is called with the same IN and INOUT arguments, if the referenced data in the database has not changed.

NOT DETERMINISTIC
The stored procedure might not return the same result each time the procedure is called with the same IN and INOUT arguments, even when the referenced data in the database has not changed.

Db2 does not verify that the stored procedure code is consistent with the specification of DETERMINISTIC or NOT DETERMINISTIC.

NO PACKAGE PATH or PACKAGE PATH package-path
Identifies the package path to use when the procedure is run. This is the list of the possible package collections into which the DBRM this is associated with the procedure is bound.

NO PACKAGE PATH
Specifies that the list of package collections for the procedure is the same as the list of package collections for the calling program. If the calling program does not use a package, Db2 resolves the package by using the CURRENT PACKAGE PATH special register, the CURRENT PACKAGESET special register, or the PKLIST bind option (in this order). For information about how Db2 uses these three items, see Db2 Application Programming and SQL Guide.
PACKAGE PATH *package-path*

Specifies a list of package collections, in the same format as used in the CURRENT PACKAGE PATH special register.

If the COLLID clause is specified with PACKAGE PATH, the COLLID clause is ignored when the routine is invoked.

The *package-path* value that is associated with the procedure definition is checked when the procedure is invoked. If *package-path* contains SESSION_USER, USER, PATH, or PACKAGE PATH, an error is returned when the *package-path* value is checked.

**MODIFIES SQL DATA, READS SQL DATA, CONTAINS SQL, or NO SQL**

Specifies the classification of SQL statements and nested routines that this routine can execute or invoke. The database manager verifies that the SQL statements issued by the procedure, and all routines locally invoked by the routine, are consistent with this specification; the verification is not performed when nested remote routines are invoked. For the classification of each statement, see "SQL statement data access classification for routines" on page 2437.

**MODIFIES SQL DATA**

Specifies that the procedure can execute any SQL statement except statements that are not supported in procedures.

**READS SQL DATA**

Specifies that procedure can execute statements with a data access indication of READS SQL DATA, CONTAINS SQL, or NO SQL. The procedure cannot execute SQL statements that modify data.

**CONTAINS SQL**

Specifies that the procedure can execute only SQL statements with an access indication of CONTAINS SQL. The procedure cannot execute statements that read or modify data.

**NO SQL**

Specifies that the procedure can execute only SQL statements with a data access classification of NO SQL. Do not specify NO SQL for a Java procedure that uses a JAR file.

**NO DBINFO or DBINFO**

Specifies whether additional status information is passed to the stored procedure when it is invoked.

**NO DBINFO**

Additional information is not passed.

**DBINFO**

An additional argument is passed when the stored procedure is invoked. The argument is a structure that contains information such as the application run time authorization ID, the schema name, the name of a table or column that the procedure might be inserting into or updating, and identification of the database server that invoked the procedure. For details about the argument and its structure, see *Db2 Application Programming and SQL Guide*.

DBINFO can be specified only if PARAMETER STYLE SQL is specified.

**NO COLLID or COLLID *collection-id***

Identifies the package collection that is to be used when the stored procedure is executed. This is the package collection into which the DBRM that is associated with the stored procedure is bound.
NO COLLID

Specifies that the package collection for the stored procedure is the same as the package collection of the calling program. If the invoking program does not use a package, Db2 resolves the package by using the CURRENT PACKAGE PATH special register, the CURRENT PACKAGESET special register, or the PKLIST bind option (in this order). For details about how Db2 uses these three items, see the information on package resolution in Db2 Application Programming and SQL Guide.

COLLID collection-id

Identifies the package collection that is to be used when the stored procedure is executed. It is the name of the package collection into which the DBRM associated with the stored procedure is bound.

For REXX stored procedures, collection-id can be DSNREXRR, DSNREXRS, DSNREXCR, or DSNREXCS.

WLM ENVIRONMENT

Identifies the WLM (workload manager) environment in which the stored procedure is to run when the Db2 stored procedure address space is WLM-established. The name of the WLM environment is an SQL identifier.

(name)

The WLM environment in which the stored procedure must run. If another stored procedure or a user-defined function calls the stored procedure and that calling routine is running in an address space that is not associated with the specified WLM environment, Db2 routes the stored procedure request to a different address space.

(name, *)

When the stored procedure is called directly by an SQL application program, the WLM environment in which the stored procedure runs.

If another stored procedure or a user-defined function calls the stored procedure, the stored procedure runs in the same WLM environment that the calling routine uses.

To change the environment in which the procedure is to run, you must have appropriate authority for the WLM environment. For an example of a RACF command that provides this authorization, see Running stored procedures.

ASUTIME

Specifies the total amount of processor time, in CPU service units, that a single invocation of a stored procedure can run. The value is unrelated to the ASUTIME column in the resource limit specification table.

When you are debugging a stored procedure, setting a limit can be helpful in case the stored procedure gets caught in a loop. For information on CPU service units, see z/OS MVS Initialization and Tuning Guide.

NO LIMIT

There is no limit on the service units.

LIMIT integer

The limit on the service units is a positive integer in the range 1 - 2147483647. If the stored procedure uses more service units than the specified value, Db2 cancels the stored procedure.

STAY RESIDENT

Specifies whether the stored procedure load module is to remain resident in memory when the stored procedure ends.
**NO**  The load module is deleted from memory after the stored procedure ends. Use **NO** for non-reentrant stored procedures.

**YES**  The load module remains resident in memory after the stored procedure ends.

**PROGRAM TYPE**
Specifies whether the stored procedure runs as a main routine or a subroutine. If **PROGRAM TYPE** is altered, the stored procedure needs to be re-compiled for the change to take effect.

**SUB**
The stored procedure runs as a subroutine.

Do not specify **PROGRAM TYPE SUB** for stored procedures with a **LANGUAGE** value of **REXX**.

**MAIN**
The stored procedure runs as a main routine.

Do not specify **PROGRAM TYPE MAIN** when **LANGUAGE JAVA** is specified.

**SECURITY**
Specifies how the stored procedure interacts with an external security product, such as RACF, to control access to non-SQL resources.

**DB2**
The stored procedure does not require a special external security environment. If the stored procedure accesses resources that an external security product protects, the access is performed using the authorization ID associated with the stored procedure address space.

**USER**
An external security environment should be established for the stored procedure. If the stored procedure accesses resources that the external security product protects, the access is performed using the authorization ID of the user who invoked the stored procedure.

**DEFINER**
An external security environment should be established for the stored procedure. If the stored procedure accesses resources that the external security product protects, the access is performed using the authorization ID of the owner of the stored procedure.

**RUN OPTIONS**  `run-time-options`
Specifies the Language Environment run time options to be used for the stored procedure. For a REXX stored procedure, specifies the Language Environment run time options to be passed to the REXX language interface to Db2. You must specify `run-time-options` as a character string that is no longer than 254 bytes. To replace any existing run time options with no options, specify an empty string with **RUN OPTIONS**. When you specify an empty string, Db2 does not pass any run time options to Language Environment, and Language Environment uses its installation defaults. For a description of the Language Environment run time options, see **z/OS Language Environment Programming Reference**.

Do not specify **RUN OPTIONS** when **LANGUAGE JAVA** is specified.
COMMIT ON RETURN
Indicates whether Db2 is to commit the transaction immediately on return from the stored procedure.

NO Db2 does not issue a commit when the stored procedure returns.

YES Db2 issues a commit when the stored procedure returns if the following statements are true:
• The SQLCODE that is returned by the CALL statement is not negative.
• The stored procedure is not in a must abort state.

The commit operation includes the work that is performed by the calling application process and the stored procedure.

If the stored procedure returns result sets, the cursors that are associated with the result sets must have been defined WITH HOLD to be usable after the commit.

INHERIT SPECIAL REGISTERS or DEFAULT SPECIAL REGISTERS
Specifies how special registers are set on entry to the routine.

INHERIT SPECIAL REGISTERS
Indicates that values of special registers are inherited according to the rules listed in the table for characteristics of special registers in a stored procedure in Special registers in a user-defined function or a stored procedure.

DEFAULT SPECIAL REGISTERS
Indicates that special registers are initialized to the default values, as indicated by the rules in the table for characteristics of special registers in a stored procedure in Special registers in a user-defined function or a stored procedure.

CALLED ON NULL INPUT
Specifies that the procedure is to be called even if any or all of the argument values are null, which means that the procedure must be coded to test for null argument values. The procedure can return null or nonnull values.

STOP AFTER SYSTEM DEFAULT FAILURES, STOP AFTER nn FAILURES, or CONTINUE AFTER FAILURE
Specifies whether the routine is to be put in a stopped state after some number of failures.

STOP AFTER SYSTEM DEFAULT FAILURES
Specifies that this routine should be placed in a stopped state after the number of failures indicated by the value of field MAX ABEND COUNT on installation field DSNTIPX.

STOP AFTER nn FAILURES
Specifies that this routine should be placed in a stopped state after nn failures. The value nn can be an integer from 1 to 32767.

CONTINUE AFTER FAILURE
Specifies that this routine should not be placed in a stopped state after any failure.

ALLOW DEBUG MODE, DISALLOW DEBUG MODE, or DISABLE DEBUG MODE
Specifies whether the procedure can be run in debugging mode.

Do not specify this option unless the procedure is defined with LANGUAGE JAVA.
ALLOW DEBUG MODE
Specifications that the procedure can be run in debugging mode.

DISALLOW DEBUG MODE
Specifications that the procedure cannot be run in debugging mode.

You can use a subsequent ALTER PROCEDURE statement to change this
option to ALLOW DEBUG MODE.

DISABLE DEBUG MODE
Specifications that the procedure can never be run in debugging mode.

The procedure cannot be changed to specify ALLOW DEBUG MODE or
DISALLOW DEBUG MODE when the procedure has been created or
altered to use DISABLE DEBUG MODE. To change this option, you must
drop and re-create the procedure using the option that you want.

Notes

Invalidation of packages: When an external procedure is altered, all the packages
that refer to that procedure are marked invalid.

LANGUAGE C and the PARAMETER VARCHAR clause: The ALTER
PROCEDURE statement does not allow you to alter the value of the PARAMETER
VARCHAR or PARAMETER CCSID clauses that are associated with the
procedure definition. However, you can alter the LANGUAGE clause for the
procedure. If the PARAMETER VARCHAR clause is specified for the creation of a
LANGUAGE C procedure, the catalog information for that option is not affected
by subsequent ALTER PROCEDURE statements. The procedure might be changed
to a language other than C, in which case the PARAMETER VARCHAR setting is
ignored. If the procedure is later changed back to LANGUAGE C, the setting of
the PARAMETER VARCHAR option that was specified for the CREATE
PROCEDURE statement (which is still in the catalog) will be used.

Alternative syntax and synonyms: To provide compatibility with previous releases
of Db2 or other products in the Db2 family, Db2 supports the following keywords:

• DYNAMIC RESULT SET, RESULT SET, and RESULT SETS as synonyms for
  DYNAMIC RESULT SETS
• STANDARD CALL as a synonym for DB2SQL
• SIMPLE CALL as a synonym for GENERAL
• SIMPLE CALL WITH NULLS as a synonym for GENERAL WITH NULLS
• VARIANT as a synonym for NOT DETERMINISTIC
• NOT VARIANT as a synonym for DETERMINISTIC
• NULL CALL as a synonym for CALLED ON NULL INPUT
• PARAMETER STYLE DB2SQL as a synonym for PARAMETER STYLE SQL

Example

Assume that stored procedure SYSPROC.MYPROC is currently defined to run in
WLM environment PARTSA and that you have appropriate authority on that WLM
environment and WLM environment PARTSEC. Change the definition of the stored
procedure so that it runs in PARTSEC.

ALTER PROCEDURE SYSPROC.MYPROC WLM ENVIRONMENT PARTSEC;
ALTER PROCEDURE (SQL - external)

The ALTER PROCEDURE statement changes the description, at the current server, of an external SQL procedure.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

Authorization

The privilege set that is defined below must include at least one of the following:
- Ownership of the stored procedure
- The ALTERIN privilege on the schema
- SYSADM or SYSCTRL authority
- System DBADM
- Installation SYSOPR authority (when the current SQLID of the process is set to SYSINSL)

The authorization ID that matches the schema name implicitly has the ALTERIN privilege on the schema.

If the authorization ID that is used to alter the procedure has the installation SYSADM authority or the installation SYSOPR authority and if the current SQLID is set to SYSINSL, the procedure is identified as system-defined procedure when the procedure definition is reevaluated.

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the package.

If the statement is dynamically prepared, the privilege set is the set of privileges that are held by the SQL authorization IDs of the process. The specified routine name can include a schema name (a qualifier). However, if the schema name is not the same as one of these SQL authorization IDs, one of the following conditions must be met:
1. The privilege set includes SYSADM authority
2. The privilege set includes SYSCTRL authority
3. The SQL authorization ID of the process has the ALTERIN privilege on the schema

The SQL authorization ID that is used to alter the procedure definition must have appropriate authority for the WLM environment in which the procedure is currently defined to run. This authorization is obtained from an external security product, such as RACF.

Syntax

```
ALTER PROCEDURE procedure-name option-list
```
option-list: (Specify options in any order. Specify at least one option. Do not specify the same option more than once.)

```
DYNAMIC RESULT SETS integer—EXTERNAL NAME external-program-name or identifier—NOT DETERMINISTIC or DETERMINISTIC

MODIFIES SQL DATA—NO COLLID—READS SQL DATA—COLLID collection-id—CONTAINS SQL—WLM ENVIRONMENT name

ASUTIME—NO LIMIT—STAY RESIDENT NO or YES—PROGRAM TYPE SUB or MAIN

SECURITY DB2 USER or DEFINER—COMMIT ON RETURN NO or YES—RUN OPTIONS run-time-options

INHERIT SPECIAL REGISTERS—STOP AFTER SYSTEM DEFAULT FAILURES
DEFAULT SPECIAL REGISTERS—STOP AFTER integer FAILURES—CONTINUE AFTER FAILURES
```

**Description**

* procedure-name
  Identifies the stored procedure to be altered.

**DYNAMIC RESULT SETS integer**

Specifies the maximum number of query result sets that the procedure can return. The value must be between 0 and 32767.

**EXTERNAL NAME external-program-name or identifier**

Specifies the name of the MVS load module for the program that runs when the procedure name is specified in an SQL CALL statement. The value must conform to the naming conventions for MVS load modules: the value must be less than or equal to 8 bytes, and it must conform to the rules for an ordinary identifier with the exception that it must not contain an underscore.

**NOT DETERMINISTIC or DETERMINISTIC**

Specifies whether the procedure returns the same results each time the procedure is called with the same IN and INOUT arguments.

**NOT DETERMINISTIC**

The procedure might not return the same result each time the procedure is called with the same IN and INOUT arguments, even when the referenced data in the database has not changed.

**DETERMINISTIC**

The procedure always returns the same results each time the procedure is called with the same IN and INOUT arguments, if the referenced data in the database has not changed.

Db2 does not verify that the procedure code is consistent with the specification of **DETERMINISTIC or NOT DETERMINISTIC**.

**MODIFIES SQL DATA, READS SQL DATA, or CONTAINS SQL**

Specifies the classification of SQL statements and nested routines that this
routine can execute or invoke. The database manager verifies that the SQL
data and, all routines locally invoked by the
database, and all routines locally invoked by the
routine, are consistent with this specification; the verification is not performed
when nested remote routines are invoked. For the classification of each
statement, see SQL statement data access classification for routines.
Statements that are not supported in any procedure will return an error.

MODIFIES SQL DATA
  Specifies that the procedure can execute any SQL statement except
  statements that are not supported in procedures.

READS SQL DATA
  Specifies that procedure can execute statements with a data access
  indication of READS SQL DATA or CONTAINS SQL. The procedure
cannot execute SQL statements that modify data.

CONTAINS SQL
  Specifies that the procedure can execute only SQL statements with an
  access indication of CONTAINS SQL. The procedure cannot execute
  statements that read or modify data.

NO COLLID or COLLID collection-id
  Identifies the package collection that is to be used when the procedure is
  executed. This is the package collection into which the DBRM that is associated
  with the procedure is bound.

NO COLLID
  Indicates that the package collection for the procedure is the same as the
  package collection of the calling program. If the invoking program does
  not use a package, Db2 resolves the package by using the CURRENT
  PACKAGE PATH special register, the CURRENT PACKAGESET special
  register, or the PKLIST
  bind option (in this order). For details about how
  Db2 uses these three items, see the information on package resolution in
  Db2 Application Programming and SQL Guide.

COLLID collection-id
  Specifies the package collection for the procedure.

WLM ENVIRONMENT name or (name,*)
  Identifies the WLM (workload manager) environment in which the procedure
  is to run when the Db2 stored procedure address space is WLM-established.
The name of the WLM environment is an SQL identifier.

name
  Specifies the WLM environment in which the procedure must run. If
  another routine calls the procedure and that calling routine is running in
  an address space that is not associated with the specified WLM
  environment, Db2 routes the procedure request to a different address
  space.

(name,*)
  When an SQL application program directly calls a procedure, name
  specifies the WLM environment in which the stored procedure runs.
  If another routine calls the procedure, the procedure runs in the same
  WLM environment that the calling routine uses.

To change the environment in which the procedure is to run, you must have
appropriate authority for the WLM environment. For an example of a RACF
command that provides this authorization, see Running stored procedures.
ASUTIME
Specifies the total amount of processor time, in CPU service units, that a single
invocation of a procedure can run. The value is unrelated to the ASUTIME
column of the resource limit specification table.

When you are debugging a procedure, setting a limit can be helpful in case the
procedure gets caught in a loop. For information on service units, see z/OS
MVS Initialization and Tuning Guide.

NO LIMIT
There is no limit on the number of CPU service units that the procedure
can run.

LIMIT integer
The limit on the number of CPU service units is a positive integer in the
range 1 - 2147483647. If the procedure uses more service units than the
specified value, Db2 cancels the procedure. The CPU cycles that are
consumed by parallel tasks in a procedure do not contribute towards the
specified ASUTIME LIMIT.

STAY RESIDENT
Specifies whether the load module for the procedure is to remain resident in
memory when the procedure ends.

NO The load module is deleted from memory after the procedure ends.

YES The load module remains resident in memory after the procedure ends.

PROGRAM TYPE
Specifies whether the procedure runs as a main routine or a subroutine. If
PROGRAM TYPE is altered, the stored procedure needs to be re-compiled for
the change to take effect.

SUB The procedure runs as a subroutine.

MAIN The procedure runs as a main routine.

SECURITY
Specifies how the procedure interacts with an external security product, such
as RACF, to control access to non-SQL resources.

DB2
The procedure does not require a special external security environment. If
the procedure accesses resources that an external security product protects,
the access is performed using the authorization ID that is associated with
the address space in which the procedure runs.

USER
An external security environment should be established for the procedure.
If the procedure accesses resources that the external security product
protects, the access is performed using the authorization ID of the user
who invoked the procedure.

DEFINER
An external security environment should be established for the procedure.
If the procedure accesses resources that the external security product
protects, the access is performed using the authorization ID of the owner
of the procedure.
**RUN OPTIONS run-time-options**

Specifies the Language Environment run time options that are to be used for the procedure. You must specify *run-time-options* as a character string that is no longer than 254 bytes. If you do not specify RUN OPTIONS or pass an empty string, Db2 does not pass any run time options to Language Environment, and Language Environment uses its installation defaults.

For a description of the Language Environment run time options, see z/OS Language Environment Programming Reference.

**COMMIT ON RETURN**

Indicates whether Db2 commits the transaction immediately on return from the procedure.

- **NO**  
  Db2 does not issue a commit when the procedure returns.

- **YES**  
  Db2 issues a commit when the procedure returns if the following statements are true:
  - A positive SQLCODE is returned by the CALL statement.
  - The procedure is not in a must abort state.

  The commit operation includes the work that is performed by the calling application process and the procedure.

  If the procedure returns result sets, the cursors that are associated with the result sets must have been defined as WITH HOLD to be usable after the commit.

**INHERIT SPECIAL REGISTERS or DEFAULT SPECIAL REGISTERS**

Specifies how special registers are set on entry to the routine.

- **INHERIT SPECIAL REGISTERS**  
  Specifies that special registers should be inherited according to the rules listed in the table for characteristics of special registers in a procedure in Table 48 on page 225.

- **DEFAULT SPECIAL REGISTERS**  
  Specifies that special registers should be initialized to the default values, as indicated by the rules in the table for characteristics of special registers in a procedure in Table 48 on page 225.

**STOP AFTER SYSTEM DEFAULT FAILURES, STOP AFTER *nn* FAILURES, or CONTINUE AFTER FAILURE**

Specifies if the routine is stopped after failures.

- **STOP AFTER SYSTEM DEFAULT FAILURES**  
  Specifies that this routine should be placed in a stopped state after the number of failures indicated by the value of field MAX ABEND COUNT on installation panel DSNTIPX.

- **STOP AFTER *nn* FAILURES**  
  Specifies that this routine should be placed in a stopped state after *nn* failures. The value *nn* can be an integer from 1 to 32767.

- **CONTINUE AFTER FAILURES**  
  Specifies that this routine should not be placed in a stopped state after any failure.
Notes

Changing to a native SQL procedure: You cannot change an external SQL procedure to a native SQL procedure. You can drop the procedure that you want to change using the DROP statement and create a native SQL procedure with a similar definition using the CREATE PROCEDURE statement. Alternatively, you can create a native SQL procedure using a different schema.

Invalidation of packages: When an SQL procedure is altered, all packages that refer to that procedure are marked invalid.

Alternative syntax and synonyms: To provide compatibility with previous releases of Db2 or other products in the Db2 UDB family, Db2 supports the following keywords:

- **RESULT SET, RESULT SETS**, and **DYNAMIC RESULT SET** as synonyms for **DYNAMIC RESULT SETS**.
- **VARIANT** as a synonym for **NOT DETERMINISTIC**
- **NOT VARIANT** as a synonym for **DETERMINISTIC**

Example

Modify the definition for an SQL procedure so that SQL changes are committed on return from the SQL procedure and the SQL procedure runs in the WLM environment named WLMSQLP:

```
ALTER PROCEDURE UPDATE_SALARY_1
  COMMIT ON RETURN YES
  WLM ENVIRONMENT WLMSQLP;
```

**ALTER PROCEDURE (SQL - native)**

The ALTER PROCEDURE statement changes the definition of an SQL procedure at the current server. The procedure options, parameter names, and routine body can be changed and additional versions of the procedure can be defined and maintained using the ALTER PROCEDURE statement.

For information about the SQL control statements that are supported in native SQL procedures, refer to [SQL control statements for SQL routines and triggers](#).

Invocation

This statement can only be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

Authorization

The privilege set that is defined below must include at least one of the following:

- Ownership of the procedure
- The ALTERIN privilege on the schema
- System DBADM
- SYSCTRL authority
- SYSADM
- Installation SYSOPR authority (when the current SQLID of the process is set to SYSINSTL)

The authorization ID that matches the schema name implicitly has the ALTERIN privilege on the schema.
If the authorization ID that is used to alter the procedure has the installation SYSADM authority or the installation SYSOPR authority and if the current SQLID is set to SYSINSTL, the procedure is identified as system-defined procedure when the procedure definition is reevaluated.

Additional privileges might be required in the following situations:

- If SQL-routine-body is specified, the privilege set must include the privileges that are required to execute the statements in SQL-routine-body.
- If a user-defined type is referenced (as the data type of a parameter or SQL variable), the privilege set must also include at least one of the following privileges or authorities:
  - Ownership of the user-defined type
  - The USAGE privilege on the user-defined type
  - System DBADM authority
  - DATAACCESS authority
  - SYSADM authority
- If the procedure uses a table as a parameter, the privilege set must also include at least one of the following privileges or authorities:
  - Ownership of the table
  - The SELECT privilege on the table
  - DATAACCESS authority
  - SYSADM authority
- If you specify the WLM ENVIRONMENT FOR DEBUG MODE clause, RACF or an external security product is invoked to check the required authority for defining programs in the WLM environment. If the WLM environment access is protected in RACF, the privilege set must include the required authority.
- When defining a new version of a procedure (using the ADD VERSION clause) or when replacing an existing version (using the REPLACE VERSION clause), the privilege set must include the required authorization to add a new package or a new version of an existing package depending on the value of the BIND NEW PACKAGE field on installation panel DSNTIPP, or the privilege set must include SYSADM or SYSCTRL authority.

Additional authorization may be required on the SYSDUMMYx tables depending on the content of the procedure definition. See SYSDUMMYx tables.

**Privilege set:** If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the package.

If the statement is dynamically prepared, the privilege set is the set of privileges that are held by the SQL authorization IDs of the process. The specified routine name can include a schema name (a qualifier). However, if the schema name is not the same as one of these SQL authorization IDs, one of the following conditions must be met:

1. The privilege set includes SYSADM authority
2. The privilege set includes SYSCTRL authority
3. The SQL authorization ID of the process has the ALTERIN privilege on the schema

When ALTER PROCEDURE is issued in a trusted context that has the ROLE AS OBJECT OWNER clause, the package owner is determined as follows:
• If the PACKAGE OWNER option is not specified, the role associated with the binder becomes the package owner.
• If the PACKAGE OWNER option is specified, the role specified in the PACKAGE OWNER option becomes the package owner. In a trusted context, the PACKAGE OWNER specified must be a role.

**Syntax**

```
ALTER PROCEDURE procedure-name
```

**routine-specification:**

```
(1)
```

**Notes:**
1. All versions of the procedure must have the same number of parameters.

**parameter-declaration:**

```
IN
OUT
INOUT
```

**data-type:**
**built-in-type:**

SQL-routine-body:

Chapter 7. Statements 1273
### Description

```
procedure-name
```

Identifies the procedure to alter. The procedure that is identified in `procedure-name` must exist at the current server.

The procedure must not be obfuscated.

### Notes:

1. An **ALTER FUNCTION** (SQL scalar) statement or an **ALTER PROCEDURE** (SQL native) statement with an ADD VERSION or REPLACE clause is not allowed in an SQL-routine-body.

2. The **COMMIT** statement and the **ROLLBACK** statement (without the TO SAVEPOINT clause) must not be issued in a routine body if the routine is in the calling chain of an SQL routine, an external routine, or a trigger.
**ACTIVE VERSION** or **ALL VERSIONS** or **VERSION** routine-version-id

Identifies the version of the procedure that is to be changed, replaced, or regenerated depending on whether the **ALTER**, **REPLACE**, or **REGENERATE** keyword is specified.

**Important:** Do not create additional versions of procedures that are supplied with Db2 by specifying the **VERSION** keyword. Only versions that are supplied with Db2 are supported. Additional versions of such routines cause the installation and configuration of the supplied routines to fail.

**ACTIVE VERSION**

Specifies that the currently active version of the procedure is to be changed, replaced, or regenerated.

ACTIVE VERSION is the default value.

**ALL VERSIONS**

Specifies that all of the versions of the procedure are to be changed. Only the following options can be changed when this option is specified:

- **AUTONOMOUS** or **COMMIT ON RETURN**

**VERSION** routine-version-id

Identifies the version of the procedure that is to be changed, replaced, or regenerated. routine-version-id is the version identifier that is assigned when the version is defined. routine-version-id must identify a version of the specified procedure that exists at the current server.

**ALTER**

Specifies that a version of the procedure is to be changed.

When you change a procedure to add or replace a version of the procedure, any option that is not explicitly specified will use the existing value from the version of the procedure that is being changed.

**REPLACE**

Specifies that a version of the procedure is to be replaced.

Binding the replaced version of the procedure might result in a new access path even if the routine body is not changed.

When you replace a procedure, the data types, CCSID specifications, and character data attributes (FOR BIT/SBCS/MIXED DATA) of the parameters must be the same as the attributes of the corresponding parameters for the currently active version of the procedure. For options that are not explicitly specified, the system default values for those options are used, even if those options were explicitly specified for the version of the procedure that is being replaced. This is not the case for versions of the procedure that specified **DISABLE DEBUG MODE**. If **DISABLE DEBUG MODE** is specified for a version of a procedure, it cannot be changed by the REPLACE clause.

**ADD VERSION** routine-version-id

Specifies that a new version of the procedure is to be created. routine-version-id is the version identifier for the new version of the procedure. routine-version-id must not identify a version of the specified procedure that already exists at the current server.

When a new version of a procedure is created, the comment that is recorded in the catalog for the new version will be the same as the comment that is in the catalog for the currently active version.

When you add a new version of a procedure the data types, CCSID specifications, and character data attributes (FOR BIT/SBCS/MIXED DATA) of
the parameters must be the same as the attributes of the corresponding parameters for the currently active version of the procedure. The parameter names can differ from the other versions of the procedure. For options that are not explicitly specified, the system default values will be used.

**ACTIVATE VERSION** `routine-version-id`

Specifies the version of the procedure that is to be the currently active version of the procedure. `routine-version-id` is the version identifier that is assigned when the version of the procedure is defined. The version that is specified with `routine-version-id` is the version that will be invoked by the CALL statement, unless the value of the CURRENT ROUTINE VERSION special register overrides the currently active version of the procedure when the procedure is invoked. `routine-version-id` must identify a version of the procedure that already exists at the current server.

**REGENERATE**

Regenerates a version of the procedure. When Db2 maintenance is applied that changes how an SQL procedure is generated, the procedure might need to be regenerated to process the maintenance changes.

REGENERATE automatically rebinds, at the local server, the package for the SQL control statements for the procedure and rebinds the package for the SQL statements that are included in the procedure body. If a remote bind is also needed, the BIND PACKAGE COPY command must be explicitly done for all of the remote servers.

REGENERATE is different from a REBIND PACKAGE command where the SQL statements are rebound (i.e. to generate better access paths for those statements), but the SQL control statements in the procedure definition remain the same.

**USING APPLICATION COMPATIBILITY** `applcompat-value`

Specifies that the object is regenerated under `applcompat-value` application compatibility rules. The ALTER statement fails if it includes any syntax, semantics, or options that require a higher application compatibility level.

If USING APPLICATION COMPATIBILITY is omitted, the regeneration uses the APPLCOMPAT value of the applicable SYSIBM.SYSPACKAGE catalog table row.

The following `applcompat-value` values can be specified:

- `function-level` specifies the application compatibility behavior of the `function-level` function level. The equivalent function level or higher must be activated.

  The format is `VvvRrMmmm`, where `vv` is the version, `r` is the release, and `mmm` is the modification level. For example:

  **V12R1M504**

  Identifies compatibility with the current highest available function level, function level 504.

  **V12R1M500**

  Identifies compatibility with the function level that enables new function in the initial Db2 12 release, function level 500.

  V12R1M500 is the same as V12R1.

  **V12R1M100**

  Identifies compatibility with the function level before you activate new function, after migration to Db2 12, function level 100.

  V12R1M100 is the same as V11R1.
For a list of supported function-level values, see What's new in Db2 12 function levels (Db2 for z/OS What's New?).

V11R1
Specifies Db2 11 compatibility behavior.

V10R1
Specifies Db2 10 compatibility behavior.

DROP VERSION routine-version-id

Drops the version of the procedure that is identified with routine-version-id. routine-version-id is the version identifier that is assigned when the version is defined. routine-version-id must identify a version of the procedure that already exists at the current server and must not identify the currently active version of the procedure. Only the identified version of the procedure is dropped.

When only a single version of the procedure exists at the current server, use the DROP PROCEDURE statement to drop the procedure. A version of the procedure for which the version identifier is the same as the contents of the CURRENT ROUTINE VERSION special register can be dropped if that version is not the currently active version of the procedure.

(parameter-declaration,...)

Specifies the number of parameters of the procedure, the data type and usage of each parameter, and the name of each parameter for the version of the procedure that is being defined or changed. The number of parameters and the specified data type and usage of each parameter must match the data types in the corresponding position of the parameter for all other versions of this procedure. Synonyms for data types are considered to be a match.

IN, OUT, and INOUT specify the usage of the parameter. The usage of the parameters must match the implicit or explicit usage of the parameters of other versions of the same procedure.

IN
Identifies the parameter as an input parameter to the procedure. The value of the parameter on entry to the procedure is the value that is returned to the calling SQL application, even if changes are made to the parameter within the procedure.

IN is the default.

OUT
Identifies the parameter as an output parameter that is returned by the procedure. If the parameter is not set within the procedure, the null value is returned.

INOUT
Identifies the parameter as both an input and output parameter for the procedure. If the parameter is not set within the procedure, its input value is returned.

parameter-name
Names the parameter for use as an SQL variable. The name cannot be the same as the name of any other parameter-name for this version of the procedure. The name of the parameter in this version of the procedure can be different than the name of the corresponding parameter for other versions of this procedure.

built-in-type
Specifies the data type of the parameter. See CREATE PROCEDURE (SQL - native) for more information on data type specifications.
distinct-type-name
The data type of the input parameter is a distinct type. Any length, precision, scale, subtype, or encoding scheme attributes for the parameter are those of the source type of the distinct type. The distinct type must not be based on a LOB data type.

array-type-name
The data type of the input parameter is a user-defined array type.

If you specify array-type-name without a schema name, Db2 resolves the array type by searching the schemas in the SQL path.

NOT DETERMINISTIC or DETERMINISTIC
Specifies whether the procedure returns the same results each time it is called with the same IN and INOUT arguments.

NOT DETERMINISTIC
The procedure might not return the same result each time it is called with the same IN and INOUT arguments, even when the data that is referenced in the database has not changed.

NOT DETERMINISTIC is the default.

DETERMINISTIC
The procedure always returns the same results each time it is called with the same IN and INOUT arguments if the data that is referenced in the database has not changed.

Db2 does not verify that the procedure code is consistent with the specification of DETERMINISTIC or NOT DETERMINISTIC.

MODIFIES SQL DATA, READS SQL DATA, or CONTAINS SQL
Specifies the classification of SQL statements and nested routines that this routine can execute or invoke. The database manager verifies that the SQL statements issued by the procedure, and all routines locally invoked by the routine, are consistent with this specification; the verification is not performed when nested remote routines are invoked. For the classification of each statement, see “SQL statement data access classification for routines” on page 2437.

MODIFIES SQL DATA
Specifies that the procedure can execute any SQL statement except statements that are not supported in procedures.

MODIFIES SQL DATA is the default.

READS SQL DATA
Specifies that procedure can execute statements with a data access indication of READS SQL DATA or CONTAINS SQL. The procedure cannot execute SQL statements that modify data.

CONTAINS SQL
Specifies that the procedure can execute only SQL statements with an access indication of CONTAINS SQL. The procedure cannot execute statements that read or modify data.

CALLED ON NULL INPUT
Specifies that the procedure will be called if any, or even if all parameter values are null.

DYNAMIC RESULT SETS integer
Specifies the maximum number of query result sets that the procedure can
return. The default is DYNAMIC RESULT SETS 0, which indicates that there are no result sets. The value must be between 0 and 32767.

**ALLOW DEBUG MODE, DISALLOW DEBUG MODE, or DISABLE DEBUG MODE**

Specifies whether the version of the procedure can be run in debugging mode. The default for a new version of a procedure is determined using the value of the CURRENT DEBUG MODE special register.

**ALLOW DEBUG MODE**

Specifies that this version of the procedure can be run in debugging mode. When this version of the procedure is invoked and debugging is attempted, a WLM environment must be available.

**DISALLOW DEBUG MODE**

Specifies that the version of the procedure cannot be run in debugging mode.

You can use a subsequent ALTER PROCEDURE statement to change this option to ALLOW DEBUG MODE.

**DISABLE DEBUG MODE**

Specifies that the version of the procedure can never be run in debugging mode.

The version of the procedure cannot be changed to specify ALLOW DEBUG MODE or DISALLOW DEBUG MODE after the version of the procedure has been created, replaced, or altered to use DISABLE DEBUG MODE. To change DEBUG MODE for a version of a procedure that specifies DISABLE DEBUG MODE, you must drop and re-create the version of the procedure using the option that you want.

When DISABLE DEBUG MODE is in effect, the WLM ENVIRONMENT FOR DEBUG MODE option is ignored.

**PARAMETER CCSID**

Indicates whether the encoding scheme for character or graphic string parameters is ASCII, EBCDIC, or UNICODE. The default encoding scheme is the value that is specified in the CCSID clauses of the parameter list or in the field DEF ENCODING SCHEME on installation panel DSNTIPF.

This clause provides a convenient way to specify the encoding scheme for character or graphic string parameters. If individual CCSID clauses are specified for individual parameters in addition to this PARAMETER CCSID clause, the value that is specified in all of the CCSID clauses must be the same value that is specified in this clause.

If the data type for a parameter is a user-defined distinct type that is defined as a character or graphic type string, the CCSID of the distinct type must be the same as the value that is specified in this clause.

If the data type for a parameter is a user-defined array type that is defined with character or graphic string array elements, or a character string array index, the CCSID of these array attributes must be the same as the value that is specified in this clause.

This clause also specifies the encoding scheme that will be used for system-generated parameters of the routine.

**QUALIFIER schema-name**

Specifies the implicit qualifier that is used for unqualified object names that are
referred in the procedure body. See Unqualified alias, index, JAR file, sequence, table, trigger, and view names for information about how the default for this option is determined.

**PACKAGE OWNER** *authorization-name*

Specifies the owner of the package that is associated with the version of the procedure. The SQL authorization ID of the process is the default value.

This authorization ID must have the privileges required to execute the SQL statements that are contained in the body of the routine and must contain the necessary bind privileges. The value of the PACKAGE OWNER option is subject to translation when sent to a remote system.

If the privilege set lacks SYSADM or SYSCTRL authority, *authorization-name* must be the same as one of the authorization IDs of the process. If the privilege set includes SYSADM or SYSCTRL authority, *authorization-name* can be any authorization ID that contains the necessary bind privileges.

**ASUTIME**

Specifies the total amount of processor time, in CPU service units, that a single invocation of a procedure can run. The value is unrelated to the ASUTIME column of the resource limit specification table.

When you are debugging a procedure, setting a limit can be helpful in case the procedure gets caught in a loop. For information on service units, see z/OS MVS Initialization and Tuning Guide.

**NO LIMIT**

Specifies that there is no limit on the number of CPU service units that the procedure can run.

NO LIMIT is the default.

**LIMIT** *integer*

The limit on the number of CPU service units is a positive *integer* in the range 1 - 2147483647. If the procedure uses more service units than the specified value, Db2 cancels the procedure. The CPU cycles that are consumed by parallel tasks in a procedure do not contribute towards the specified ASUTIME LIMIT.

**COMMIT ON RETURN** *NO, COMMIT ON RETURN** *YES, or AUTONOMOUS*

Indicates whether Db2 commits the transaction immediately on return from the procedure.

**COMMIT ON RETURN** *NO*

Db2 does not issue a commit when the procedure returns. NO is the default.

**COMMIT ON RETURN** *YES, or AUTONOMOUS*

Db2 issues a commit when the procedure returns if the following statements are true:

- The SQLCODE that is returned by the CALL statement is not negative.
- The procedure is not in a must-abort state.

The commit operation includes the work that is performed by the calling application process and by the procedure.

If the procedure returns result sets, the cursors that are associated with the result sets must have been defined as WITH HOLD to be usable after the commit.
AUTONOMOUS
Db2 executes the SQL procedure in a unit of work that is independent from the calling application. When this option is specified the procedure follows the rules of the COMMIT ON RETURN YES option before returning to the calling application. However, it does not commit changes in the calling application. When autonomous is specified:

- DYNAMIC RESULT SETS 0 must be in effect.
- Stored procedure parameters must not be defined as:
  - A LOB type
  - The XML data type
  - A distinct data type that is based on a LOB or XML value
  - An array type that is defined with array elements that are a LOB type

A value must not be assigned to a global variable when an autonomous procedure is executing.

INHERIT SPECIAL REGISTERS or DEFAULT SPECIAL REGISTERS
Specifies how special registers are set on entry to the routine.

INHERIT SPECIAL REGISTERS
Specifies that the values of special registers are inherited, according to the rules that are listed in the table for characteristics of special registers in a procedure in Special registers in a user-defined function or a stored procedure.

INHERIT SPECIAL REGISTERS is the default.

DEFAULT SPECIAL REGISTERS
Specifies that special registers are initialized to the default values, as indicated by the rules in the table for characteristics of special registers in a procedure in Special registers in a user-defined function or a stored procedure.

WLM ENVIRONMENT FOR DEBUG MODE name
Specifies the WLM (workload manager) application environment used by Db2 when debugging the procedure. The name of the WLM environment is an SQL identifier.

If you do not specify WLM ENVIRONMENT FOR DEBUG MODE, Db2 uses the default WLM-established stored procedure address space that is specified at installation time.

The WLM ENVIRONMENT FOR DEBUG MODE value is ignored when DISABLE DEBUG MODE is in effect.

To change the environment that Db2 uses for debugging this procedure, you must have the appropriate authority for the WLM application environment. For an example of a RACF command that provides this authorization, see Running stored procedures.

DEFER PREPARE or NODEFER PREPARE
Specifies whether to defer preparation of dynamic SQL statements that refer to remote objects, or to prepare them immediately.

The default depends on the value that is specified for the REOPT option. If REOPT NONE is specified, the default is NODEFER PREPARE. Otherwise, the default is DEFER PREPARE.
DEFER PREPARE
Specifies that the preparation of dynamic SQL statements that refer to remote objects will be deferred.

For considerations with distributed processing, see [DEFER and NODEFER bind options (Db2 Commands)]

NODEFER PREPARE
Specifies that the preparation of dynamic SQL statements that refer to remote objects will not be deferred.

CURRENT DATA
Specifies whether to require data currency for read-only and ambiguous cursors when the isolation level of cursor stability is in effect. CURRENT DATA also determines whether block fetch can be used for distributed, ambiguous cursors. For more information about updating the current row of a cursor, block fetch, and data currency, see Db2 Application Programming and SQL Guide.

YES
Specifies that data currency is required for read-only and ambiguous cursors. Db2 acquired page or row locks to ensure data currency. Block fetch is not allowed for distributed, ambiguous cursors.

NO
Specifies that data currency is not required for read-only and ambiguous cursors. Block fetch is allowed for distributed, ambiguous cursors. Use of CURRENT DATA(NO) is not recommended if the procedure attempts to dynamically prepare and execute a DELETE WHERE CURRENT OF statement against an ambiguous cursor after that cursor is opened. You receive a negative SQLCODE if your procedure attempts to use a DELETE WHERE CURRENT OF statement for any of the following cursors:

- A cursor that is using block fetch
- A cursor that is using query parallelism
- A cursor that is positioned on a row that is modified by this or another application process

No is the default.

DEGREE
Specifies whether to attempt to run a query using parallel processing to maximize performance.

1
Specifies that parallel processing should not be used.

1 is the default.

ANY
Specifies that parallel processing can be used.

CONCURRENT ACCESS RESOLUTION
Specifies the whether processing uses only committed data or whether it will wait for commit or rollback of data that is in the process of being updated.

WAIT FOR OUTCOME
Specifies that processing will wait for the commit or rollback of data that is in the process of being updated.

USE CURRENTLY COMMITTED
Specifies that processing use the currently committed version of the data when data that is in the process of being updated is encountered. USE CURRENTLY COMMITTED is applicable on scans that access tables that are defined in universal table spaces with row or page level lock size.
When there is lock contention between a read transaction and an insert transaction, **USE CURRENTLY COMMITTED** is applicable to scans with isolation level CS or RS. Applicable scans include intent read scans for read-only and ambiguous queries and for updatable cursors. **USE CURRENTLY COMMITTED** is also applicable to scans initiated from WHERE predicates of UPDATE or DELETE statements and the subselect of INSERT statements.

When there is lock contention between a read transaction and a delete transaction, **USE CURRENTLY COMMITTED** is applicable to scans with isolation level CS and when CURRENT DATA NO is specified.

**DYNAMICRULES**

Specifies the values that apply, at run time, for the following dynamic SQL attributes:

- The authorization ID that is used to check authorization
- The qualifier that is used for unqualified objects
- The source for application programming options that Db2 uses to parse and semantically verify dynamic SQL statements

**DYNAMICRULES** also specifies whether dynamic SQL statements can include GRANT, REVOKE, ALTER, CREATE, DROP, and RENAME statements.

In addition to the value of the **DYNAMICRULES** clause, the run time environment of a native SQL procedure controls how dynamic SQL statements behave at run time. The combination of the **DYNAMICRULES** value and the run time environment determines the value for the dynamic SQL attributes. That set of attribute values is called the dynamic SQL statement behavior. The following values can be specified:

**RUN**

Specifies that dynamic SQL statements are to be processed using run behavior.

RUN is the default.

**BIND**

Specifies that dynamic SQL statements are to be processed using bind behavior.

**DEFINEBIND**

Specifies that dynamic SQL statements are to be processed using either define behavior or bind behavior.

**DEFINERUN**

Specifies that dynamic SQL statements are to be processed using either define behavior or run behavior.

**INVOKEBIND**

Specifies that dynamic SQL statements are to be processed using either invoke behavior or bind behavior.

**INVKERUN**

Specifies that dynamic SQL statements are to be processed using either invoke behavior or run behavior.

See [Authorization IDs and dynamic SQL](Authorization%20IDs%20and%20dynamic%20SQL) for information on the effects of these options.

**APPLICATION ENCODING SCHEME**

Specifies the default encoding scheme for SQL variables in static SQL.
statements in the procedure body. The value is used for defining an SQL variable in a compound statement if the CCSID clause is not specified as part of the data type, and the PARAMETER CCSID routine option is not specified.

**ASCII**
Specifications that the data is encoded using the ASCII CCSIDs of the server.

**EBCDIC**
Specifications that the data is encoded using the EBCDIC CCSIDs of the server.

**UNICODE**
Specifications that the data is encoded using the Unicode CCSIDs of the server.

For information about how the default for this option is determined, see [ENCODING bind option (Db2 Commands)](https://www.ibm.com/support/knowledgecenter/en/SSGMF8_10.0.0/com.ibm.db2.luw.admin.lang.doc/doc/r_encbindopt.html).

**WITH EXPLAIN or WITHOUT EXPLAIN**
Specifications whether information will be provided about how SQL statements in the procedure will execute.

**WITHOUT EXPLAIN**
Specifications that information will not be provided about how SQL statements in the procedure will execute.

You can get EXPLAIN output for a statement that is embedded in a native SQL procedure that is specified using WITHOUT EXPLAIN by embedding the SQL statement EXPLAIN in the procedure body. Otherwise, the value of the EXPLAIN option applies to all explainable SQL statements in the procedure body, and to the fullselect portion of any DECLARE CURSOR statements.

WITHOUT EXPLAIN is the default.

**WITH EXPLAIN**
Specifications that information will be provided about how SQL statements in the procedure will execute. Information is inserted into the table owner.PLAN_TABLE. owner is the authorization ID of the owner of the procedure package. Alternatively, the authorization ID of the owner of the procedure can have an alias as owner.PLAN_TABLE that points to the base table, PLAN_TABLE. owner must also have the appropriate SELECT and INSERT privileges on that table. WITH EXPLAIN does not obtain information for statements that access remote objects. PLAN_TABLE must have a base table and can have multiple aliases with the same table name, PLAN_TABLE, but have different schema qualifiers; it cannot be a view or a synonym. It should exist before the version is added or replaced. In all inserts to owner.PLAN_TABLE, the value of QUERYNO is the statement number that is assigned by Db2.

The WITH EXPLAIN option also populates two optional tables, if they exist: DSN_STATEMENT_TABLE and DSN_FUNCTION_TABLE. DSN_STATEMENT_TABLE contains an estimate of the processing cost for an SQL statement.

For more information about the EXPLAIN statement, including a description of the tables that are populated by the WITH EXPLAIN option, see "EXPLAIN" on page 2059.

**WITH IMMEDIATE WRITE or WITHOUT IMMEDIATE WRITE**
Specifications whether immediate writes are to be done for updates that are made to group buffer pool dependent page sets or partitions. This option is only applicable for data sharing environments. The IMMEDWRITE subsystem
IMMEDWRITE bind option (Db2 Commands) shows the implied hierarchy of the IMMEDWRITE bind option (which is similar to this procedure option) as it affects run time.

**WITHOUT IMMEDIATE WRITE**

Specifies that normal write activity is performed. Updated pages that are group buffer pool dependent are written at or before phase one of commit or at the end of abort for transactions that have been rolled back.

**WITH IMMEDIATE WRITE**

Specifies that updated pages that are group buffer pool dependent are immediately written as soon as the buffer update completes. Updated pages are written immediately even if the buffer is updated during forward progress or during the rollback of a transaction. **WITH IMMEDIATE WRITE** might impact performance.

**ISOLATION LEVEL RR, RS, CS, or UR**

Specifies how far to isolate the procedure from the effects of other running applications. For information about isolation levels, see *Managing Performance*.

- **RR** Specifies repeatable read.
- **RS** Specifies read stability.
- **CS** Specifies cursor stability. **CS** is the default.
- **UR** Specifies uncommitted read.

**WITH KEEP DYNAMIC or WITHOUT KEEP DYNAMIC**

Specifies whether Db2 keeps dynamic SQL statements after commit points.

**WITHOUT KEEP DYNAMIC**

Specifies that Db2 does not keep dynamic SQL statements after commit points.

**WITH KEEP DYNAMIC**

Specifies that Db2 keeps dynamic SQL statements after commit points. If you specify **WITH KEEP DYNAMIC**, the application does not need to prepare an SQL statement after every commit point. Db2 keeps the dynamic SQL statement until one of the following occurs:

- The application process ends
- A rollback operations occurs
- The application executes an explicit PREPARE statement with the same statement identifier as the dynamic SQL statement

If you specify **WITH KEEP DYNAMIC**, and the prepared statement cache is active, the Db2 subsystem keeps a copy of the prepared statement in the cache. If the prepared statement cache is not active, the subsystem keeps only the SQL statement string past a commit point. If the application executes an OPEN, EXECUTE, or DESCRIBE operation for that statement, the statement is implicitly prepared.

If you specify **WITH KEEP DYNAMIC**, DDF server threads that are used to execute procedures or packages that have this option in effect will remain active. Active DDF server threads are subject to idle thread time outs, as described in *Db2 Installation Guide* for installation panel DSNTIPR.
If you specify WITH KEEP DYNAMIC, you must not specify REOPT ALWAYS. WITH KEEP DYNAMIC and REOPT ALWAYS are mutually exclusive. However, you can specify WITH KEEP DYNAMIC and REOPT ONCE.

Use WITH KEEP DYNAMIC to improve performance if your DRDA client application uses a cursor that is defined as WITH HOLD. The Db2 subsystem automatically closes a held cursor when there are no more rows to retrieve, which eliminates an extra network message.

**OPTHINT** *string-constant*

Specifies whether query optimization hints are used for static SQL statements that are contained within the body of the procedure.

*string-constant* is a character string of up to 128 bytes in length, which is used by the Db2 subsystem when searching the PLAN_TABLE for rows to use as input. The default value is an empty string, which indicates that the Db2 subsystem does not use optimization hints for static SQL statements.

Optimization hints are only used if optimization hints are enabled for your system. See *Db2 Installation Guide* for information about enabling optimization hints.

**SQL PATH**

Specifies the SQL path that the Db2 subsystem uses to resolve unqualified user-defined types, functions, and procedure names (in CALL statements) in the body of the procedure. The default value is "SYSIBM", "SYSFUN", "SYSPROC", "SYSIBMADM", and the value of the QUALIFIER option.

The maximum length of the SQL path is 2048 bytes. Db2 calculates the length by taking each *schema-name* specified and removing any trailing blanks from it, adding two delimiters around it, and adding one comma after each schema name except for the last one. The length of the resulting string cannot exceed 2048 bytes.

*schema-name*

Specifies a schema. Db2 does not validate that the specified schema actually exists when the ALTER statement is processed.

SYSPUBLIC must not be specified for the SQL path.

*schema-name-list*

Specifies a comma separated list of schema names. The same schema name should not appear more than one time in the list of schema names. The number of schema names that you can specify is limited by the maximum length of the resulting SQL path.

SYSPUBLIC must not be specified for the SQL path.

**SYSTEM PATH**

Specifies the schema names "SYSIBM", "SYSFUN", "SYSPROC", "SYSIBMADM".

**SESSION_USER** or **USER**

Specifies the value of the SESSION_USER (or USER) special register. At the time the ALTER statement is processed, the actual length is included in the total length of the list of schema names that is specified for the PATH option. If you specify SESSION_USER (or USER) in a list of schema names, do not use delimiters around the SESSION_USER (or USER) keyword.
RELEASE AT
Specifies when to release resources that the procedure uses: either at each commit point or when the procedure terminates.

COMMIT
Specifies that resources will be released at each commit point.
COMMIT is the default.

DEALLOCATE
Specifies that resources will be released only when the procedure terminates. DEALLOCATE has no effect on packages that run on a Db2 server through a DRDA connection with a client system. DEALLOCATE also has no effect on dynamic SQL statements, which always use RELEASE AT COMMIT, with this exception: When you use the RELEASE AT DEALLOCATE clause and the WITH KEEP DYNAMIC clause, and the subsystem is installed with a value of YES for the field CACHE DYNAMIC SQL on installation panel DSNTIP8, the RELEASE AT DEALLOCATE option is honored for dynamic SELECT and SQL data change statements.

Locks that are acquired for dynamic statements are held until one of the following events occurs:

- The application process ends.
- The application process issues a PREPARE statement with the same statement identifier. (Locks are released at the next commit point).
- The statement is removed from the prepared statement cache because the statement has not been used. (Locks are released at the next commit point).
- An object that the statement is dependent on is dropped or altered, or a privilege that the statement needs is revoked. (Locks are released at the next commit point).

RELEASE AT DEALLOCATE can increase the package size because additional items become resident in the package. For more information about how the RELEASE clause affects locking and concurrency, see Managing Performance.

QUERY ACCELERATION
Specifies whether a static SQL query is bound for acceleration, and if so, with what behavior.

NONE
Specifies that no static SQL query in the application is bound for acceleration or will be accelerated when the application is run.

ENABLE
Specifies that a static SQL query is bound for acceleration if it satisfies the acceleration criteria, including the cost and heuristics criteria. The query is routed to an accelerator when the application runs. Otherwise, if the static query does not satisfy the acceleration criteria, the query is bound for execution in Db2.

If an error condition, such as one of the following examples, occurs while executing the accelerated static query when the application is run, Db2 fails the static query and returns a negative SQL code to the application:

- A failure occurs while running the static query on the accelerator.
- The accelerator returns an error for the query.
- The accelerator is not started and Db2 cannot route the static query to the accelerator for execution.
ENABLE WITH FAILBACK
Results in the same behavior as ENABLE, except if one of the error conditions occurs on the first OPEN of the accelerated static query when the application is run. In this case, instead of failing the static query and returning a negative SQL code to the application, Db2 performs a temporary statement-level incremental bind of the query and runs the query in Db2. The application does not see the acceleration failure. Failback to Db2 is not possible after the application does a successful OPEN for the query on the accelerator.

ELIGIBLE
Specifies that a static SQL query is bound for acceleration if the query meets the basic acceleration criteria, regardless of the cost or heuristics criteria. The query is routed to the accelerator when the application runs.

Like the behavior for ENABLE, if an error condition occurs while executing the accelerated static query when the application is run, Db2 fails the static query and returns a negative SQL code to the application.

ALL
Specifies that all of the static SQL queries in the application are to be bound for acceleration and routed to the accelerator when the application runs. If Db2 determines that a static query cannot be bound to run on the accelerator and the query references a user base table or view, the BIND or REBIND PACKAGE operation fails with an error message for that query. (A failure exception is made for declared global temporary tables (DGT Ts) and created global temporary tables and (CGTTs) because these tables cannot be accelerated.)

Like the behavior for ENABLE, if an error condition occurs while executing the accelerated static query when the application is run, Db2 fails the static query and returns a negative SQL code to the application.

This bind option does not apply to a fullselect or WITH common-table-expression that is specified in a RETURN statement for the routine, or in a SET host-variable-assignment that is used in the routine. The queries that are specified in these cases cannot be accelerated.

GET_ACCEL_ARCHIVE
Specifies whether a static SQL query that is bound for acceleration retrieves archived data on the accelerator, instead of active data.

NO
Specifies that no static SQL query is bound to retrieve archived data from the accelerator. If the static query also is not bound for acceleration, the query is bound to run in Db2.

If the static query is bound for acceleration because the QUERYACCELERATION bind option was specified, the query is routed to the accelerator when the application runs; however, the query does not retrieve any archived data.

YES
Specifies that if all of the following criteria are met, the query is bound for acceleration and retrieves the archived data on the accelerator when the application runs:

• The QUERYACCELERATION bind option is also specified.
• The static SQL query references an accelerated table that has partitioned data archived on an accelerator.
• The static query satisfies the acceleration criteria that is specified by the QUERYACCELERATION bind option.

If the static query does not satisfy the acceleration criteria that is specified by the QUERYACCELERATION bind option, the BIND or REBIND PACKAGE operation fails with an error message for that query.

This bind option does not apply to a fullselect or WITH common-table-expression that is specified in a RETURN statement for the routine, or in a SET host-variable-assignment that is used in the routine. The queries that are specified in these cases cannot be accelerated.

ACCELERATOR
Specifies an accelerator server that, if enabled and available, Db2 will consider sending eligible SQL queries to before sending the queries to other accelerator servers. If the specified accelerator server is not enabled or available, Db2 will consider sending the queries to other available accelerator servers.

REOPT
Specifies if Db2 will determine the access path at run time by using the values of SQL variables or SQL parameters, parameter markers, and special registers.

NONE
Specifies that Db2 does not determine the access path at run time by using the values of SQL variables or SQL parameters, parameter markers, and special registers.

NONE is the default.

ALWAYS
Specifies that Db2 always determine the access path at run time each time an SQL statement is run.

ONCE
Specifies that Db2 determine the access path for any dynamic SQL statements only one time, at the first time the statement is opened. This access path is used until the prepared statement is invalidated or removed from the dynamic statement cache and needs to be prepared again.

VALIDATE RUN or VALIDATE BIND
Specifies whether to recheck, at run time, errors of the type "OBJECT not FOUND" and NOT AUTHORIZED" that are found during bind or rebind. The option has no effect if all objects and needed privileges exist.

VALIDATE RUN
Specifies that if needed objects or privileges do not exist when the ALTER PROCEDURE statement is processed, warning messages are returned, but the ALTER PROCEDURE statement succeeds. The Db2 subsystem rechecks for the objects and privileges at run time for those SQL statements that failed the checks during processing of the ALTER PROCEDURE statement. The authorization checks the use of the authorization ID of the owner of the procedure package.

VALIDATE RUN is the default.

VALIDATE BIND
Specifies that if needed objects or privileges do not exist at the time the ALTER PROCEDURE statement is processed, an error is issued and the ALTER PROCEDURE statement fails.
ROUNDING
Specifies the rounding mode for manipulation of DECFLOAT data.

DEC_ROUND_CEILING
Specifies numbers are rounded towards positive infinity.

DEC_ROUND_DOWN
Specifies numbers are rounded towards 0 (truncation).

DEC_ROUND_FLOOR
Specifies numbers are rounded towards negative infinity.

DEC_ROUND_HALF_DOWN
Specifies numbers are rounded to nearest; if equidistant, round down.

DEC_ROUND_HALF_EVEN
Specifies numbers are rounded to nearest; if equidistant, round so that the final digit is even.

DEC_ROUND_HALF_UP
Specifies numbers are rounded to nearest; if equidistant, round up.

DEC_ROUND_UP
Specifies numbers are rounded away from 0.

DATE FORMAT ISO, EUR, USA, JIS, or LOCAL
Specifies the date format for result values that are string representations of date or time values. See String representations of datetime values for more information.

The default format is specified in the DATE FORMAT field of installation panel DSNTIP4 of the system where the procedure is defined. You cannot use the LOCAL option unless you have a date exit routine.

DECIMAL(15), DECIMAL(31), DECIMAL(15,s), or DECIMAL(31,s)
Specifies the maximum precision that is to be used for decimal arithmetic operations. See Arithmetic with two decimal operands for more information.

The default format is specified in the DECIMAL ARITHMETIC field of installation panel DSNTIPF of the system where the procedure is defined. If the form pp.s is specified, s must be a number between 1 and 9. s represents the minimum scale that is to be used for division.

FOR UPDATE CLAUSE OPTIONAL or FOR UPDATE CLAUSE REQUIRED
Specifies whether the FOR UPDATE clause is required for a DECLARE CURSOR statement if the cursor is to be used to perform positioned updates.

FOR UPDATE CLAUSE REQUIRED
Specifies that a FOR UPDATE clause must be specified as part of the cursor definition if the cursor will be used to make positioned updates.

FOR UPDATE CLAUSE REQUIRED is the default.

FOR UPDATE CLAUSE OPTIONAL
Specifies that the FOR UPDATE clause does not need to be specified in order for a cursor to be used for positioned updates. The procedure body can include positioned UPDATE statements that update columns that the user is authorized to update.

If the resulting DBRM for the procedure is very large, you might need extra storage when you specify FOR UPDATE CLAUSE OPTIONAL.

The FOR UPDATE clause of the select-statement with no column list applies to static or dynamic SQL statements. You can specify the FOR UPDATE OF clause...
of the select-statement with a column list to restrict updates to only the
columns that are named in the column list and to specify the acquisition of
update locks.

**TIME FORMAT ISO, EUR, USA, JIS, or LOCAL**
Specifies the time format for result values that are string representations of
date or time values. See String representations of datetime values for more
information.

The default format is specified in the TIME FORMAT field of installation panel
DSNTP4 of the system where the procedure is defined. You cannot use the
LOCAL option unless you have a date exit routine.

**BUSINESS_TIME SENSITIVE**
Determines whether references to application-period temporal tables in both
static and dynamic SQL statements are affected by the value of the CURRENT
TEMPORAL BUSINESS_TIME special register.

**YES**
References to application-period temporal tables are affected by the value
of the CURRENT TEMPORAL BUSINESS_TIME special register. YES is the
default value.

**NO** References to application-period temporal tables are not affected by the
value of the CURRENT TEMPORAL BUSINESS_TIME special register.

Related information:

CURRENT TEMPORAL BUSINESS_TIME

**SYSTEM_TIME SENSITIVE**
Determines whether references to system-period temporal tables in both static
and dynamic SQL statements are affected by the value of the CURRENT
TEMPORAL SYSTEM_TIME special register.

**YES**
References to system-period temporal tables are affected by the value
of the CURRENT TEMPORAL SYSTEM_TIME special register. YES is the
default value.

**NO** References to system-period temporal tables are not affected by the value
of the CURRENT TEMPORAL SYSTEM_TIME special register.

Related information:

CURRENT TEMPORAL SYSTEM_TIME

**ARCHIVE SENSITIVE**
Determines whether references to archive-enabled tables in SQL statements are
affected by the value of the SYSIBMADM.GET_ARCHIVE global variable.

**YES**
References to archive-enabled tables are affected by the value of the
SYSIBMADM.GET_ARCHIVE global variable. YES is the default value.

**NO** References to archive-enabled tables are not affected by the value of the
SYSIBMADM.GET_ARCHIVE global variable.

Related information:

Built-in global variables

**APPLCOMPAT applcompat-value**
Specifies the application compatibility level behavior for static SQL statements
in the package. If this option is not specified then the behavior is determined, in priority order, by the \textit{applcompat-value} of the previous bind of the package if one exists, or the APPLCOMPAT subsystem parameter. The following \textit{applcompat-value} values can be specified:

\textbf{function-level}

Specifies the application compatibility behavior of the \textit{function-level} function level. The equivalent function level or higher must be activated.

The format is \texttt{VvvRrMmm}, where \texttt{vv} is the version, \texttt{r} is the release, and \texttt{mmm} is the modification level. For example:

- \textbf{V12R1M504}
  Identifies compatibility with the current highest available function level, function level 504.

- \textbf{V12R1M500}
  Identifies compatibility with the function level that enables new function in the initial Db2 12 release, function level 500. V12R1M500 is the same as V12R1.

- \textbf{V12R1M100}
  Identifies compatibility with the function level before you activate new function, after migration to Db2 12, function level 100. V12R1M100 is the same as V11R1.

For a list of supported \textit{function-level} values, see What's new in Db2 12 function levels (Db2 for z/OS What's New?)

\textbf{V11R1}

Specifies Db2 11 compatibility behavior.

\textbf{V10R1}

Specifies Db2 10 compatibility behavior.

\textbf{CONCENTRATE STATEMENTS OFF} or \textbf{CONCENTRATE STATEMENTS WITH LITERALS}

Specifies whether each dynamic SQL statement in the routine that specifies literal constants will be cached as a separate unique statement entry in the dynamic statement cache, instead of sharing an existing statement in the cache. Dynamic SQL statements are eligible to share an existing statement in the cache if the new statement meets all of the conditions for sharing a cached version of the same dynamic statement, except that the new statement specifies one or more literal constants that are different than the cached statement.

\textit{CONCENTRATE STATEMENTS OFF}

Specifies that each dynamic SQL statement that specifies literal constants will be cached as a unique statement entry if it specifies one or more constants that are different than the cached version of the same dynamic statement. CONCENTRATE STATEMENTS OFF is the default dynamic statement caching behavior.

\textit{CONCENTRATE STATEMENTS WITH LITERALS}

Specifies that each dynamic SQL statement that specifies literal constants will share a cached version of the same dynamic statement that is also prepared using the CONCENTRATE STATEMENTS WITH LITERALS option, if the new dynamic statement meets all of the conditions for sharing the cached statement, and the constants that are specified can be reused in place of the constants in the cached statement.
**SQL-routine-body**

Specifies the statements that define the body of the SQL procedure. For information on the SQL control statements that are supported in native SQL procedures, see [SQL control statements for SQL routines and triggers](#). If an *SQL-procedure-statement* is the only statement in the procedure body, the statement must not end with a semicolon.

**Notes**

**Considerations for altering a version of a procedure:**

To alter a version of a procedure, the environment settings that are in effect when the *ALTER PROCEDURE* statement is issued must be the same as the environment settings that are in effect when the version of the procedure is first created using the *CREATE PROCEDURE* or *ALTER PROCEDURE* statements if one of the following options is specified:

- QUALIFIER
- PACKAGE OWNER
- WLM ENVIRONMENT FOR DEBUG MODE
- OPTHINT
- SQL PATH
- DECIMAL (if the value includes a comma)

**Changing to a native SQL procedure:**

You cannot change an external SQL procedure to a native SQL procedure. You can drop the external SQL procedure that you want to change by using the *DROP* statement and create a native SQL procedure with a similar definition using the *CREATE PROCEDURE* statement. Alternatively, you can create a native SQL procedure using a different schema.

**Identifier resolution**

See [SQL control statements for SQL routines and triggers](#) for information on how names are resolved to columns, SQL variables, or SQL routines for native SQL procedures. Name resolution is unchanged for external SQL procedures.

If duplicate names are used for columns and SQL variables and parameters, qualify the duplicate names by using the table designator for columns, the procedure name for parameters, and the label name for SQL variables.

**Characteristics of the package that is generated for a version of a procedure:**

The package that is associated with a version of a procedure is named as follows:

- *location* is set to the value of the CURRENT SERVER special register
- *collection-id* (schema) for the package is the same as the schema qualifier of the procedure
- *package-id* is the same as the specific name of the procedure
- *version-id* is the same as the version identifier for the initial version of the procedure

The package is generated using the bind options that correspond to the implicitly or explicitly specified procedure options. See [Table 170 on page 1294](#) for more information. In addition to the corresponding bind options, the package is generated using the following bind options:

- DBPROTOCAL(DRDA)
Considerations for a procedure that is defined using a TABLE LIKE name AS LOCATOR clause:

If a procedure is defined with a table parameter (the TABLE LIKE name AS LOCATOR clause was specified in the CREATE PROCEDURE statement to indicate that one of the input parameters is a transition table), the procedure cannot be changed with an ALTER PROCEDURE statement if the change requires that the parameter list be specified. For example, to add or replace a version of a native SQL procedure, the procedure must be dropped and re-created.

Considerations for SQL processor programs:

SQL processor programs, such as SPUFI, the command line processor, and DSNTEP2, might not correctly parse SQL statements in the routine body that end with semicolons. These processor programs accept multiple SQL statements as input, with each statement separated with a terminator character. Processor programs that use a semicolon as the SQL statement terminator can truncate a CREATE FUNCTION statement with embedded semicolons and pass only a portion of it to Db2. Therefore, you might need to change the SQL terminator character for these processor programs. For information on changing the terminator character for SPUFI and DSNTEP2, see Setting the SQL terminator character in a SPUFI input data set (Db2 Application programming and SQL) and DSNTEP2 and DSNTEP4 (Db2 Application programming and SQL).

Correspondence of procedure options to BIND options

The following table lists options for CREATE PROCEDURE and ALTER PROCEDURE and the corresponding options for the bind commands. For more information about bind options, see BIND and REBIND options for packages, plans, and services (Db2 Commands).

Invalidation of packages:

When a version of an SQL procedure is altered to change any option that is specified for the active version, all the packages that refer to that procedure are marked invalid. Additionally, when certain attributes of a native SQL procedure are changed, the body of the procedure might be rebound or regenerated. The following table summarizes when implicit rebind and regeneration occurs when specific options are changed. A value of Y in a row indicates that a rebind or regeneration occurs if the option is changed for a version of the procedure. A value of N in a row indicates that a rebind or regeneration does not occur.

Table 171. CREATE PROCEDURE and ALTER PROCEDURE options that result in rebind or regeneration when changed.

<table>
<thead>
<tr>
<th>CREATE PROCEDURE or ALTER PROCEDURE option</th>

</table>

Note:
1. The procedure package is rebound or regenerated if a value of ALLOW DEBUG MODE is changed to DISALLOW DEBUG MODE.
2. Invoking applications are invalidated if a value of DISALLOW DEBUG MODE is changed to DISABLE DEBUG MODE.

Considerations for SYSENVIRONMENTS catalog table:

An ALTER statement that specifies a new environment settings will result
in a new row being added to the SYSENVIRONMENTS catalog table. The new row will be added even if an error is subsequently encountered during processing of the ALTER statement. Thus, a new SYSENVIRONMENTS row might be added even for an ALTER statement that fails.

Comaptibilities:
For compatibility with previous versions of Db2, when any of the following options are implicitly or explicitly specified as part of option-list, a warning is issued, but the statement is executed. However, if REPLACE or ADD VERSION is specified with one of the following options, an error is issued, and the statement does not execute. For example, if ADD VERSION and STAY RESIDENT are specified, an error is issued.

- STAY RESIDENT
- PROGRAM TYPE
- RUN OPTIONS
- NO DBINFO
- COLLID or NOCOLLID
- SECURITY
- PARAMETER STYLE GENERAL WITH NULLS
- STOP AFTER SYSTEM DEFAULT FAILURES
- STOP AFTER nn FAILURES
- CONTINUE AFTER FAILURES

If WLM ENVIRONMENT is specified for a native SQL procedure, WLM ENVIRONMENT FOR DEBUG MODE must be specified.

For compatibility with the CREATE PROCEDURE statement, the following clause can be specified, but will be ignored:

- LANGUAGE SQL

Altering obfuscated procedures:
Obfuscated procedures cannot be altered in any way.

Alternative syntax and synonyms:
To provide compatibility with previous releases of Db2 or other products in the Db2 family, Db2 supports the following keywords:

- RESULT SET, RESULT SETS, and DYNAMIC RESULT SET as synonyms for DYNAMIC RESULT SETS.
- VARIANT as a synonym for NOT DETERMINISTIC
- NOT VARIANT as a synonym for DETERMINISTIC

Considerations for catalog comments for a routine definition:
When a function definition is replaced any existing comment in the catalog for the definition is removed, and when a function definition is regenerated any existing comment in the catalog for the definition is retained.

Example

Example 1: The following statement changes the existing procedure options for the active version of the UPDATE_SALARY_1 native SQL procedure. If you need to change a different version of the procedure, you would specify VERSION routine-version-id in place of ACTIVE VERSION. Note that the ALTER clause that precedes the version specification can be omitted.
ALTER PROCEDURE UPDATE_SALARY_1
   ALTER ACTIVE VERSION
   NOT DETERMINISTIC
   CALLED ON NULL INPUT
   ALLOW DEBUG MODE
   ASUTIME LIMIT 10

Example 2: To change the procedure body of any existing version of a procedure, you need to use the REPLACE clause. The following statement changes both the procedure body and the existing SQL data access option for version V2 of the UPDATE_SALARY_1 SQL procedure. Note that the list of parameters is specified even though no changes are made to the list. To replace an existing version of a procedure, you must specify the list of parameters, any options that are to have non-default values (even if those options are specified in the version of the procedure that you are replacing), and the body of the procedure.

ALTER PROCEDURE UPDATE_SALARY_1
   REPLACE VERSION V2 (P1 INTEGER, P2 CHAR(5))
   MODIFIES SQL DATA
   UPDATE EMP SET SALARY = SALARY * RATE
       WHERE EMPNO = EMPLOYEE_NUMBER;

Example 3: To add a new version of an existing procedure, use the ADD VERSION clause. The following statement adds a new version of the UPDATE_SALARY_1 procedure to apply a larger salary increase. Note that the list of parameters is specified even though the new version of the procedure uses the same parameters as the existing version of the procedure. To add a new version of a procedure, you must specify the list of parameters, any options that will have non-default values, and the body of the procedure.

ALTER PROCEDURE UPDATE_SALARY_1
   ADD VERSION V3 (P1 INTEGER, P2 CHAR(5))
   UPDATE EMP_SET SALARY = SALARY * (RATE*10)
       WHERE EMPNO = EMPLOYEE_NUMBER;

Example 4: When the new version of the procedure has been defined, as in Example 3, you must use the ALTER PROCEDURE statement with the ACTIVATE VERSION clause if the new version of the procedure is to be the currently active version, as in the following example.

ALTER PROCEDURE UPDATE_SALARY_1
   ACTIVATE VERSION V3;

Example 5: To regenerate the currently active version of a procedure, use the following statement.

ALTER PROCEDURE UPDATE_SALARY_1
   REGENERATE ACTIVE VERSION;

ALTER SEQUENCE

The ALTER SEQUENCE statement changes the attributes of a sequence at the current server. Only future values of the sequence are affected by the ALTER SEQUENCE statement.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.
**Authorization**

The privilege set that is defined below must include at least one of the following:
- Ownership of the sequence
- The ALTER privilege for the sequence
- The ALTERIN privilege on the schema
- SYSADM or SYSCTRL authority
- System DBADM
- Installation SYSOPR authority (when the current SQLID of the process is set to SYSINSTL)

Installation SYSADM privilege is required to alter the SYSIBM.DSNSEQ_IMPLICITDB sequence (which specifies the maximum number of implicitly created databases).

The authorization ID that matches the schema name implicitly has the ALTERIN privilege on the schema.

**Privilege set:** If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the package. If the statement is dynamically prepared, the privilege set is the union of the privilege sets that are held by each authorization ID and role of the process.

**Syntax**

```
ALTER SEQUENCE sequence-name

(1)
  RESTART WITH numeric-constant
  INCREMENT BY numeric-constant
  NO MINVALUE
  MINVALUE numeric-constant
  NO MAXVALUE
  MAXVALUE numeric-constant
  NO CYCLE
  CYCLE
  NO CACHE
  CACHE integer-constant
  NO ORDER
  ORDER
```

**Notes:**
1. At least one option must be specified and the same clause must not be specified more than once.
2. Separator commas can be specified between sequence attributes when a sequence is defined.

**Description**

`sequence-name`

Identifies the sequence. The combination of sequence name and the implicit or explicit qualifier must identify an existing sequence at the current server. `sequence-name` must not identify a sequence that is generated by Db2 for an identity column or a DB2_GENERATED_DOCID_FOR_XML column.
RESTART

Restarts the sequence. If numeric-constant is not specified, the sequence is restarted at the value specified implicitly or explicitly as the starting value on the CREATE SEQUENCE statement that originally created the sequence. RESTART does not change the original START WITH value.

WITH numeric-constant

Specifies the value at which to restart the sequence. The value can be any positive or negative value that could be assigned to a column of the data type that is associated with the sequence without non-zero digits existing to the right of the decimal point. The range used for cycles is defined by MINVALUE and MAXVALUE. MAXVALUE and MINVALUE do not constrain the numeric-constant value. That is, the RESTART WITH clause can be used to start the generation of values outside the range that is used for cycles. However, the next generated value after the specified RESTART WITH value is MINVALUE for an ascending identity column or MAXVALUE for a descending identity column.

If RESTART is not specified, the sequence is not restarted. Instead, it resumes with the current values in effect for all the options after the ALTER statement is issued.

After a sequence is restarted or changed to allow cycling, sequence numbers might be duplicates of values generated by the sequence previously.

INCREMENT BY numeric-constant

Specifies the interval between consecutive values of the sequence. The value can be any positive or negative value (including 0) that could be assigned to a column of the data type that is associated with the sequence without any non-zero digits existing to the right of the decimal point.

If INCREMENT BY numeric-constant is positive, the sequence ascends. If INCREMENT BY numeric-constant is negative, the sequence descends. If INCREMENT BY numeric-constant is 0, the sequence is treated as an ascending sequence.

The absolute value of INCREMENT BY can be greater than the difference between MAXVALUE and MINVALUE.

NO MINVALUE or MINVALUE

Specifies whether or not there is a minimum end point of the range of values for the sequence.

NO MINVALUE

Specifies that the minimum end point of the range of values for the sequence has not been specified explicitly. In such a case, the value for MINVALUE becomes one of the following:

- For an ascending sequence, the value is the original starting value.
- For a descending sequence, the value is the minimum of the data type that is associated with the sequence.

MINVALUE numeric-constant

Specifies the minimum value at which a descending sequence either cycles or stops generating values, or an ascending sequence cycles to after reaching the maximum value. The last value that is generated for a cycle of a descending sequence will be equal to or greater than this value. MINVALUE is the value to which an ascending sequence cycles to after reaching the maximum value.
The value can be any positive or negative value that could be assigned to the a column of the data type that is associated with the sequence without non-zero digits existing to the right of the decimal point. The value must be less than or equal to the maximum value.

**NO MAXVALUE or MAXVALUE**

Specifies whether or not there is a maximum end point of the range of values for the sequence.

**NO MAXVALUE**

Specifies either explicitly or implicitly that the minimum end point of the range of values for the sequence has not be set. In such a case, the default value for MAXVALUE becomes one of the following:

- For an ascending sequence, the value is the maximum value of the data type that is associated with the sequence
- For a descending sequence, the value is the original starting value.

If NO MAXVALUE is explicitly specified in the ALTER SEQUENCE statement, the value of the MAXVALUE column in the catalog table is reset to the maximum value of the data type associated with the sequence if the sequence is ascending or the value stored in the START column of the catalog table if the sequence is descending. Whether the sequence is ascending or descending depends on whether or not the INCREMENT BY option is reset. If it is, the new INCREMENT BY VALUE determines if the sequence is ascending or descending. If it is not explicitly reset, the value stored in the INCREMENT column of the catalog table determines if the sequence is ascending or descending.

**MAXVALUE numeric-constant**

Specifies the maximum value at which an ascending sequence either cycles or stops generating values or a descending sequence cycles to after reaching the minimum value. The last value that is generated for a cycle of an ascending sequence will be less than or equal to this value. MAXVALUE is the value to which a descending sequence cycles to after reaching the minimum value.

The value can be any positive or negative value that could be assigned to the a column of the data type that is associated with the sequence without non-zero digits existing to the right of the decimal point. The value must be greater than or equal to the minimum value.

**NO CYCLE or CYCLE**

Specifies whether or not the sequence should continue to generate values after reaching either its maximum or minimum value. The boundary of the sequence can be reached either with the next value landing exactly on the boundary condition or by overshooting it.

**NO CYCLE**

Specifies that the sequence cannot generate more values once the maximum or minimum value for the sequence has been reached.

**CYCLE**

Specifies that the sequence continue to generate values after either the maximum or minimum value has been reached. If this option is used, after an ascending sequence reaches its maximum value, it generates its minimum value. After a descending sequence reaches its minimum value, it generates its maximum value. The maximum and minimum values for the sequence defined by the MINVALUE and MAXVALUE options determine the range that is used for cycling.
When CYCLE is in effect, duplicate values can be generated by the sequence. When a sequence is defined with CYCLE, any application conversion tools for converting applications from other vendor platforms to Db2 should also explicitly specify MINVALUE, MAXVALUE, and START WITH values.

**NO CACHE or CACHE**
Specifies whether or not to keep some preallocated values in memory for faster access. This is a performance and tuning option.

**NO CACHE**
Specifies that values of the sequence are not to be preallocated. This option ensures that there is not a loss of values in the case of a system failure. When NO CACHE is specified, the values of the sequence are not stored in the cache. In this case, every request for a new value for the sequence results in synchronous I/O to the log.

**CACHE integer-constant**
Specifies the maximum number of sequence values that Db2 can preallocate and keep in memory. Preallocating values in the cache reduces synchronous I/O when values are generated for the sequence. The actual number of values that Db2 caches is always the lesser of the number in effect for the CACHE option and the number of remaining values within the logical range. Thus, the CACHE value is essentially an upper limit for the size of the cache.

In the event the system is shut down (either normally or through a system failure), all cached sequence values that have not been used in committed statements are lost (that is, they will never be used). The value specified for the CACHE option is the maximum number of sequence values that could be lost when the system is shut down.

The minimum value is 2.

In a data sharing environment, you can use the CACHE and NO ORDER options to allow multiple Db2 members to cache sequence values simultaneously.

**NO ORDER or ORDER**
Specifies whether the sequence numbers must be generated in order of request.

**NO ORDER**
Specifies that the sequence numbers do not need to be generated in order of request.

**ORDER**
Specifies that the sequence numbers are generated in order of request. Specifying ORDER might disable the caching of values. There is no guarantee that values are assigned in order across the entire server unless NO CACHE is also specified. ORDER applies only to a single-application process.

In a data sharing environment, if the CACHE and NO ORDER options are in effect, multiple caches can be active simultaneously, and the requests for next value assignments from different Db2 members might not result in the assignment of values in strict numeric order. For example, if members DB2A and DB2B are using the same sequence, and DB2A gets the cache values 1 to 20 and DB2B gets the cache values 21 to 40, the actual order of values assigned would be 1,21,2 if DB2A requested for next value first,
then DB2B requested, and then DB2A again requested. Therefore, to
guarantee that sequence numbers are generated in strict numeric order
among multiple Db2 members using the same sequence concurrently,
specify the ORDER option.

Notes

*Altering a sequence:* The changes to the attributes of a sequence take effect after
the ALTER SEQUENCE statement is committed. Only future sequence numbers are
affected by the ALTER SEQUENCE statement. If the ALTER SEQUENCE request
results in an error or is rolled back, nothing is changed; however, unused cache
values might be lost.

- The data type of a sequence cannot be changed. Instead, drop and re-create the
  sequence specifying the desired data type for the new sequence.
- All cached values are lost when a sequence is altered.
- After restarting a sequence or changing it to cycle, it is possible that a generated
  value will duplicate a value previously generated for that sequence.

*Alternative syntax and synonyms:* To provide compatibility with previous releases
of Db2 or other products in the Db2 family, Db2 supports the following keywords:

- NOCACHE (single key word) as a synonym for NO CACHE
- NOCYCLE (single key word) as a synonym for NO CYCLE
- NOMINVALUE (single key word) as a synonym for NO MINVALUE
- NOMAXVALUE (single key word) as a synonym for NO MAXVALUE
- NOORDER (single key word) as a synonym for NO ORDER

Examples

*Example 1:* Reset a sequence to the START WITH value to generate the numbers
from 1 up to the number of rows in the table:

```
ALTER SEQUENCE org_seq
RESTART;
```

**ALTER STOGROUP**

The ALTER STOGROUP statement changes the description of a storage group at
the current server.

Invocation

This statement can be embedded in an application program or issued interactively.
It is an executable statement that can be dynamically prepared only if
DYNAMICRULES run behavior is implicitly or explicitly specified.

Authorization

The privilege set that is defined below must include one of the following:

- Ownership of the storage group
- SYSADM or SYSCTRL authority
- Installation SYSOPR authority (when the current SQLID of the process is set to
  SYSINSTL)
Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the package. If the statement is dynamically prepared, the privilege set is the union of the privilege sets that are held by each authorization ID and role of the process.

Syntax

```
ALTER STOGROUP stogroup-name
   ADD VOLUMES (volume-id,...)
   REMOVE VOLUMES (volume-id,...)
   NO KEY LABEL
   KEY LABEL key-label-name
   DATACLASS dc-name
   MGMTCLASS mc-name
   STORCLASS sc-name
```

Notes:
1. The same clause must not be specified more than once.
2. The same volume-id must not be specified more than once in the same clause.

Description

`stogroup-name`
Identifies the storage group to be altered. The name must identify a storage group that exists at the current server.

`ADD VOLUMES(volume-id,...) or ADD VOLUMES('*,...)`
Adds volumes to the storage group. Each `volume-id` is the volume serial number of a storage volume to be added. It can have a maximum of six characters and is specified as an identifier or a string constant.

A `volume-id` must not be specified if any volume of the storage group is designated by an asterisk (*). An asterisk must not be specified if any volume of the storage group is designated by a `volume-id`.

You cannot add a volume that is already in the storage group unless you first remove it with REMOVE VOLUMES.

Asterisks are recognized only by Storage Management Subsystem (SMS). If the data set that is associated with the storage group is non SMS managed, either ADD VOLUMES or REMOVE VOLUMES must be specified. Neither ADD VOLUMES or REMOVE VOLUMES is required if DATACLASS, MGMTCLASS,
or STORCLAS is specified. SMS usage is recommended, rather than using Db2 to allocate data to specific volumes. Having Db2 select the volume requires non-SMS usage or assigning an SMS Storage Class with guaranteed space. However, because guaranteed space reduces the benefits of SMS allocation, it is not recommended.

If you do choose to use specific volume assignments, additional manual space management must be performed. Free space must be managed for each individual volume to prevent failures during the initial allocation and extension. This process generally requires more time for space management and results in more space shortages. Guaranteed space should be used only where the space needs are relatively small and do not change.

**REMOVE VOLUMES**(volume-id,...) or **REMOVE VOLUMES**(‘*’,...)

Removes volumes from the storage group. Each volume-id is the volume serial number of a storage volume to be removed. Each volume-id must identify a volume that is in the storage group.

The REMOVE VOLUMES clause is applied to the current list of volumes before the ADD VOLUMES clause is applied. Removing a volume from a storage group does not affect existing data, but a volume that has been removed is not used again when the storage group is used to allocate storage for table spaces or index spaces.

Asterisks are recognized only by Storage Management Subsystem (SMS). If the data set that is associated with the storage group is non SMS managed, either ADD VOLUMES or REMOVE VOLUMES must be specified. Neither ADD VOLUMES or REMOVE VOLUMES is required if DATACLAS, MGMTCLAS, or STORCLAS is specified.

**DATACLAS** dc-name

Identifies the name of the SMS data class to associate with the Db2 storage group. The SMS data class name must be from 1-8 characters in length. The SMS storage administrator defines the data class that can be used. DATACLAS must not be specified more than one time.

**MGMTCLAS** mc-name

Identifies the name of the SMS management class to associate with the Db2 storage group. The SMS management class name must be from 1-8 characters in length. The SMS storage administrator defines the management class that can be used. MGMTCLAS must not be specified more than one time.

**STORCLAS** sc-name

Identifies the name of the SMS storage class to associate with the Db2 storage group. The SMS storage class name must be from 1-8 characters in length. The SMS storage administrator defines the storage class that can be used. STORCLAS must not be specified more than one time.

**(FL 502)KEY LABEL** key-label-name or **NO KEY LABEL**

Specifies whether a key label is specified at the storage group level for encryption. For the changed KEY LABEL value to take effect, a subsequent REORG of the table spaces or indexes that use the storage group is required.

**KEY LABEL** key-label-name

Specifies the default key label that is used to encrypt any data set allocated for the table spaces and index spaces using the storage group.

The Db2 address space RACF user ID or group must be permitted access to the key label in RACF.
The key label can be overridden when the data set is allocated. For details about the order of precedence, see "Notes."

**NO KEY LABEL**

Indicates that there is no key label specified at the storage group level for encryption.

**Notes**

**Work file databases:**
If the storage group altered contains data sets in a work file database, the database must be stopped and restarted for the effects of the ALTER to be recognized. To stop and restart a database, issue the following commands:

-STOP DATABASE(database-name)
-START DATABASE(database-name)

**Device types:**
When the storage group is used at run time, an error can occur if the volumes in the storage group are of different device types, or if a volume is not available to z/OS for dynamic allocation of data sets.

When a storage group is used to extend a data set, all volumes in the storage group must be of the same device type as the volumes used when the data set was defined. Otherwise, an extend failure occurs if an attempt is made to extend the data set.

**Number of volumes:**
There is no specific limit on the number of volumes that can be defined for a storage group. However, the maximum number of volumes that can be managed for a storage group is 133.

If the VOLUMES clause is specified, the maximum number of volumes is 59.

**Verifying the existence of volumes and classes:**
When processing the VOLUMES, DATACLAS, MGMTCLAS, or STORCLAS clauses, Db2 does not check the existence of the volumes or classes or determine the types of devices that are identified or if SMS is active. Later, when the storage group allocates data sets, the list of volumes is passed in the specified order to Data Facilities (DFSMSdfp). See *Db2 Administration Guide* for more information about creating Db2 storage groups.

**SMS data set management:**
You can have Storage Management Subsystem (SMS) manage the storage needed for the objects that the storage group supports. To do so, specify ADD VOLUMES(“*”) and REMOVE VOLUMES(current-vols) in the ALTER statement, where current-vols is the list of the volumes currently assigned to the storage group. SMS manages every data set created later for the storage group. SMS does not manage data sets created before the execution of the statement.

You can also specify ADD VOLUMES(volume-id) and REMOVE VOLUMES(“*”) to make the opposite change.

See *Db2 Administration Guide* for considerations for using SMS to manage data sets.
Key label requirement

To use a key label for encryption, the VSAM data sets for the page sets need to be associated with an SMS Data Class that has extended format capability (EF enabled).

Determining a key label for base table space and associated objects

When a key label is specified at the table level, Db2 provides the key label to DFSMS to encrypt all the table spaces and index spaces associated with the table. This includes base table space, auxiliary table spaces, XML table spaces, index spaces, and clone table space, regardless of whether the base table space or associated objects are explicitly or implicitly created. Db2 does not enforce any key label relationship between the base table and an associated history or archive table. The key label for the archive and the history tables has to be set independent of the base table. If there is no key label specified at the table level, Db2 will provide the key label to DFSMS specified for the storage group.

When Db2 calls DFSMS to allocate the dataset for table space or index space, DFSMS uses its order of precedence to determine the key label and can override the key label specified by Db2.

DFSMS order of precedence:
- RACF data set profile
- JCL, dynamic allocation, TSO ALLOCATE
- SMS data class construct

If the security administrator has specified a key label for the RACF data set profile, that key label takes precedence over the Db2 provided key label. The REPORT utility can be run to determine the key label used for encryption.

Examples

Example 1: Alter storage group DSN8G120. Add volumes DSNV04 and DSNV05.

```sql
ALTER STOGROUP DSN8G120
   ADD VOLUMES (DSNV04,DSNV05);
```

Example 2: Alter storage group DSN8G120. Remove volumes DSNV04 and DSNV05.

```sql
ALTER STOGROUP DSN8G120
   REMOVE VOLUMES (DSNV04,DSNV05);
```

Example 3: Alter storage group DSNCG120 to remove the key label.

```sql
ALTER STOGROUP DSNCG120
   NO KEY LABEL;
```

ALTER TABLE

The ALTER TABLE statement changes the description of a table at the current server.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.
Authorization

The privilege set that is defined below must include at least one of the following:

- The ALTER privilege on the table
- Ownership of the table
- DBADM authority for the database
- SYSADM or SYSCTRL authority
- System DBADM
- Installation SYSOPR authority (when the current SQLID of the process is set to SYSINSTL)

To alter a system-period temporal table when one or more of the changes also result in changes to the associated history table, the privileges that are held by the authorization ID of the statement must also include at least one of the following:

- The ALTER privilege on the history table
- Ownership of the history table
- DBADM authority for the database
- SYSADM or SYSCTRL authority
- System DBADM
- Installation SYSOPR authority (when the current SQLID of the process is set to SYSINSTL)

If the database is implicitly created, the database privileges must be on the implicit database or on DSNDB04.

The privilege set must include SECADM authority if one of the following clauses is specified:

- ACTIVATE
- DEACTIVATE

Additional privileges might be required in the following situations:

- FOREIGN KEY, ADD PRIMARY KEY, ADD UNIQUE, DROP PRIMARY KEY, DROP FOREIGN KEY, or DROP CONSTRAINT is specified.
- The data type of a column that is added to the table is a distinct type.
- A fullselect is specified.
- A column is defined as a security label column.
- A column is defined as ROWID GENERATED BY DEFAULT.

See the description of the appropriate clauses for the details about these privileges.

**Privilege set:** If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the package. If the statement is dynamically prepared, the privilege set is the union of the privilege sets that are held by each authorization ID and role of the process.
Syntax

ALTER TABLE table-name

(1) (2) (3)

ADD COLUMN column-definition

ALTER COLUMN column-alteration

RENAME COLUMN source-column-name TO target-column-name

DROP COLUMN column-name

ADD PERIOD FOR period-definition

ADD unique-constraint

REFERENTIAL-CONSTRAINT

CHECK-CONSTRAINT

DROP UNIQUE

FOREIGN KEY

CONSTRAINT

ADD PARTITION BY partitioning-clause

ADD PARTITION

ALTER PARTITION partition-clause

ALTER PARTITION partition-clause

ROTATE PARTITION FIRST TO LAST (5)

DROP ORGANIZATION

ALTER-HASH-ORGANIZATION

SYSTEM

ADD VERSIONING USE HISTORY TABLE history-table-name extra-row-option

DROP SYSTEM VERSIONING

MATERIALIZED QUERY

ADD MATERIALIZED QUERY materialized-query-definition

ALTER MATERIALIZED QUERY materialized-query-alteration

DROP MATERIALIZED QUERY

options (continued)

Notes:

1 The same clause must not be specified more than one time, except for the ADD COLUMN or ALTER COLUMN clauses. If multiple ADD COLUMN clauses are specified in the same statement, at most one ADD COLUMN clause can contain a references-clause. If ALTER COLUMN SET DATA TYPE is specified, it must be specified first.

2 The ADD PARTITION and ALTER PARTITION clauses can be specified together only when adding a new partition between existing logical partitions. Otherwise, the ALTER COLUMN, ADD PARTITION, ALTER PARTITION, and ROTATE PARTITION clauses are mutually exclusive with each other.

3 If ADD CLONE, DROP CLONE, RENAME COLUMN, ALTER ORGANIZATION, DROP ORGANIZATION, ADD VERSIONING, DROP VERSIONING, DROP COLUMN, ACTIVATE, DEACTIVATE, ENABLE ARCHIVE, or DISABLE ARCHIVE is specified, no other clause is allowed on the ALTER TABLE statement.

4 The ADD keyword is optional for referential-constraint or unique-constraint if it is the first clause specified in the statement. Otherwise, ADD is required.

5 Hash-organized tables are deprecated. Beginning in Db2 12, packages bound with APPLCOMPAT( V12R1M504) or higher cannot create hash-organized tables or alter existing tables to use hash-organization. Existing hash organized tables remain supported, but they are likely to be unsupported in the future.
ALTER TABLE options (continued):

<table>
<thead>
<tr>
<th>(1)</th>
<th>(2)</th>
</tr>
</thead>
<tbody>
<tr>
<td>DATA CAPTURE</td>
<td>none</td>
</tr>
<tr>
<td>VOLATILE</td>
<td>NOT VOLATILE</td>
</tr>
<tr>
<td>ADD CLONE—clone-table-name</td>
<td>DROP CLONE</td>
</tr>
<tr>
<td>ADD RESTRICT ON DROP</td>
<td>DROP RESTRICT ON DROP</td>
</tr>
<tr>
<td>ACTIVATE—ROW ACCESS CONTROL</td>
<td>DEACTIVATE—COLUMN ACCESS CONTROL</td>
</tr>
<tr>
<td>APPEND</td>
<td>NO</td>
</tr>
<tr>
<td>AUDIT</td>
<td>NONE</td>
</tr>
<tr>
<td>VALIDPROC—program-name</td>
<td>VALIDPROC—program-name</td>
</tr>
<tr>
<td>ENABLE ARCHIVE—USE—archive-table-name</td>
<td>DISABLE ARCHIVE—archive-table-name</td>
</tr>
<tr>
<td>KEY LABEL—key-label-name</td>
<td></td>
</tr>
</tbody>
</table>

Notes:

1. The same clause must not be specified more than one time, except for the ADD COLUMN or ALTER COLUMN clauses. If multiple ADD COLUMN clauses are specified in the same statement, at most one ADD COLUMN clause can contain a references-clause. If ALTER COLUMN SET DATA TYPE is specified, it must be specified first.

2. If ADD CLONE, DROP CLONE, RENAME COLUMN, ALTER ORGANIZATION, DROP ORGANIZATION, ADD VERSIONING, DROP VERSIONING, DROP COLUMN, ACTIVATE, DEACTIVATE, ENABLE ARCHIVE, or DISABLE ARCHIVE is specified, no other clause is allowed on the ALTER TABLE statement.
column-definition:

- column-name
- data-type
- (1)
- (2)
- default-clause
- NOT NULL
- column-constraint
- generated-clause
- IMPLICITLY HIDDEN
- AS SECURITY LABEL
- FIELDPROC—program-name
- (constant)
- INLINE LENGTH—integer

Notes:
1. *data-type* is optional if *as-row-change-timestamp-clause* is specified.
2. The same clause must not be specified more than one time.
3. *AS SECURITY LABEL* can be specified only for a CHAR(8) data type and requires that the *NOT NULL* and WITH DEFAULT clauses be specified.
4. *INLINE LENGTH* only applies to a column with a LOB data type or a distinct type that is based on a LOB data type.

data-type:

- built-in-type
- distinct-type-name

built-in-type:
Notes:

1  The CCSID clause must only be specified for a character string or graphic string column in an EBCDIC table when the ADD COLUMN clause is also specified.

XML-type-modifier:
XML-schema-specification:

```
ID: registered-XML-schema-name
URL: target-namespace
NO NAMESPACE
LOCATION: schema-location
```

default-clause:

```
WITH DEFAULT
```

```
constant
- SESSION_USER
- USER
- CURRENT SQLID
- NULL

(1)

- cast-function-name
  - constant
    - SESSION_USER
    - USER
    - CURRENT SQLID
    - NULL
```

Notes:

1. The `cast-function-name` form of the DEFAULT value can only be used with a column that is defined as a distinct type.
generated-clause:

as-identity-clause:

as-row-change-timestamp-clause:

as-row-transaction-start-id-clause:

Notes:
1 Separator commas can be specified between attributes when an identity column is defined.
as-row-transaction-timestamp-clause:

►► AS ROW
   ▼ START
   ★★ END

as-generated-expression-clause:

►► AS
   ▼ non-deterministic-expression

non-deterministic-expression:

►► DATA CHANGE OPERATION
   ▼ special-register
   ★★ session-variable

special-register:

(1)

- CURRENT CLIENT_ACCTNG
- CURRENT CLIENT_APPLNAME
- CURRENT CLIENT_CORR_TOKEN
- CURRENT CLIENT_USERID
- CURRENT CLIENT_WKSTNNAME
- CURRENT SERVER
- CURRENT SQLID
- SESSION_USER

Notes:
1. This definition of special register is specific to this context, as part of non-deterministic-expression.
2. USER can be specified as a synonym for SESSION_USER.
session-variable:

(1)

- SYSIBM.PACKAGE_NAME
- SYSIBM.PACKAGE_SCHEMA
- SYSIBM.PACKAGE_VERSION

Notes:
1. This definition of session variable is specific to this context, as part of non-deterministic-expression.

column-alteration:

- column-name
- SET
- DATA TYPE
- altered-data-type
- default-clause
- INLINE LENGTH
- integer
- GENERATED
- ALWAYS
- as-row-transaction-timestamp-clause
- as-row-transaction-id-clause
- DROP DEFAULT
- BY DEFAULT
- identity-alteration
- ALWAYS

Notes:
1. INLINE LENGTH can only be specified for LOB columns in tables that are in universal table spaces. INLINE LENGTH cannot be specified if FOR SBCS DATA or FOR MIXED DATA is also specified.

altered-data-type:
XML-type-modifier:
XML-schema-specification:

- **ID** — registered-XML-schema-name
- **URL** — target-namespace
- **NO NAMESPACE**
- **LOCATION** — schema-location

**identity-alteration:**

(1)

- **RESTART**
- **SET INCREMENT BY** — numeric-constant
- **SET** — NO MINVALUE
- **SET** — MINVALUE — numeric-constant
- **SET** — NO MAXVALUE
- **SET** — MAXVALUE — numeric-constant
- **SET** — NO CYCLE
- **SET** — CYCLE
- **SET** — NO CACHE
- **SET** — CACHE — integer-constant
- **SET** — NO ORDER
  
Notes:

1. At least one option must be specified and the same clause must not be specified more than one time.

**unique-constraint:**

- **CONSTRAINT** — constraint-name
- **UNIQUE**

- **column-name**

- **BUSINESS_TIME** — WITHOUT OVERLAPS
Notes:
1 For compatibility with prior releases, when the CONSTRAINT clause (shown above) is not specified, a constraint-name can be specified following FOREIGN KEY.
Notes:

1. Hash-organized tables are deprecated. Beginning in Db2 12, packages bound with APPLCOMPAT(V12R1M504) or higher cannot create hash-organized tables or alter existing tables to use hash-organization. Existing hash organized tables remain supported, but they are likely to be unsupported in the future.

2. The ENDING clause must not be specified for a partition-by-growth table space, but must be specified for a range partitioned table space.

(FL 504)
rotate-partition-clause:

```
rotate-partition-clause:
  ENDING AT (constant) INCLUSIVE
  MAXVALUE MINVALUE
  RESET
```

extra-row-option:

```
extra-row-option:
  ON DELETE ADD EXTRA ROW
```

materialized-query-definition:

```
materialized-query-definition:
  (fullselect) refreshable-table-options
```

refreshable-table-options:

```
refreshable-table-options:
  DATA INITIALLY DEFERRED REFRESH DEFERRED
  (1)
```

Notes:
1. The same clause must not be specified more than one time.
**materialized-query-table-alteration:**

```
(1) SET
  MAINTAINED BY SYSTEM
  MAINTAINED BY USER
  ENABLE QUERY OPTIMIZATION
  DISABLE QUERY OPTIMIZATION
```

**Notes:**

1. The same clause must not be specified more than one time.

**period-definition:**

```
SYSTEM_TIME((begin-column-name, end-column-name))
BUSINESS_TIME((begin-column-name, end-column-name))
```

**Description**

*table-name*

Identifies the table to be altered. The name must identify a table that exists at the current server. The name must not identify a declared temporary table, a directory table, a view, or a table that was implicitly created for an XML column. If the name identifies a catalog table, DATA CAPTURE CHANGES is the only clause that can be specified. If the name identifies an accelerator-only table, ADD RESTRICT ON DROP or DROP RESTRICT ON DROP are the only clauses that can be specified.

If *table-name* identifies an auxiliary table, alterations are limited to the following clauses:

- APPEND

If *table-name* identifies a materialized query table, alterations are limited to the following clauses:

- AUDIT
- DATA CAPTURE
- ALTER MATERIALIZED QUERY
- ALTER PARTITION
- DROP MATERIALIZED QUERY
- ADD RESTRICT ON DROP
- DROP RESTRICT ON DROP
- ROTATE PARTITION
- KEY LABEL
- NO KEY LABEL

**FL 502** KEY LABEL *key-label-name* or NO KEY LABEL

Specifies whether key label is specified at the table level for encryption. For the
changed KEY LABEL value to take effect, a subsequent REORG of the existing
associated table spaces and index spaces is required. The table-name must
identify a table that resides in a universal table space or a partitioned table
space.

**KEY LABEL** key-label-name
Specifies the default key label that is used to encrypt all the table spaces
and index spaces associated with the table. This includes base table spaces,
auxiliary table spaces, XML table spaces, index spaces, and table spaces for
cloned tables, regardless of whether it is explicitly or implicitly created.
Users must set the key label for archive or history tables independently.
The data set must be Db2-managed for all the table spaces and index
spaces associated with the table.
The table-name must not identify one of the following:
• A catalog table.
• A directory table.
• A clone table.
• An auxiliary table.
• A table that was implicitly created for an XML column.
• A created global temporary table.
The key label must be defined in ICSF. The Db2 address space RACF user
ID or group must be permitted access to the key label in RACF.
The key label can be inherited or overridden when the data set is allocated.
For details about the order of precedence, see [Determining a key label for
base table space and associated objects](#).

**NO KEY LABEL**
Indicates that there is no key label specified at the table level for
encryption. Any existing table level key label is removed.

**ADD COLUMN**

**ADD COLUMN** column-definition
Adds a column to the table. Except for the following columns, all values of the
column in existing rows are set to its default value:
• ROWID column
• Identity column
• Row change timestamp column
• Row-begin column
• Row-end column
• Transaction-start-ID column
If the table has n columns, the ordinality of the new column is n+1. The value
of n cannot be greater than 749. For a dependent table, n cannot be greater
than 748.
The column cannot be added if the increase in the total byte count of the
columns exceeds the maximum row size. The maximum row size for the table
is eight less than the maximum record size as described in [Maximum record
size](#).
If you add a LOB column and the table does not already have a ROWID
column, Db2 creates an implicitly hidden ROWID column. For details about
adding a LOB column, such as the other objects that might be implicitly
created or need to be explicitly created, see [Creating a table with LOB columns]. For more information about adding a ROWID column, see [Adding a ROWID column].

For implicitly created LOB objects, the privilege set requires CREATETAB and CREATETS privileges on the database that contains the table (DSNDB04 if the database is implicitly created) and the USE privilege on the buffer pool and the storage group that is used by the auxiliary table and the LOB table space. The implicitly created objects are owned by the owner of the base table.

If you add an XML column, the privilege set requires the CREATETAB and CREATETS privileges on the database that contains the table (DSNDB04 if the database is implicitly created), INDEX on the base table for the first DOCID column that is added, and USE privilege on the buffer pool and the storage group that is used by the XML objects. These privileges are required for implicitly created XML objects. The implicitly created objects are owned by the owner of the base table.

If you add an XML column to an existing table, the underlying XML table space is implicitly created according to the PAGENUM attribute of the associated base table.

When you add a column to a table, the table space is placed in advisory REORG-pending (AREOR) status. However, if you add an identity column to a table that is not empty, the table space is placed in REORG-pending (REORP) status.

The table must not be a history table or archive table.

If the table is a system-period temporal table, the column is also added to the associated history table. If the table is an archive-enabled table, the column is also added to the associated archive table. The following attributes of the column in the associated table are the same as the attributes of the corresponding column of the table that is being altered:

- Name
- Data type
- Length (including inline LOB lengths), precision, scale
- FOR BIT, SBCS, or MIXED DATA attribute for a character string column
- Null attribute
- Hidden attribute
- Field procedure

You cannot add the following columns:

- A column to a table that has an edit procedure that is defined as WITH ROW ATTRIBUTES.
- A ROWID column to a table that already has an explicitly defined ROWID column
- An identity column to a table that has an identity column
- A security label column to a table that already has a security label column
- A security label column to a system-period temporal table or archive-enabled table
- A row change timestamp column to a table that already has a row change timestamp column
- A LOB, ROWID, identity column, or row change timestamp column to a created temporary table
- A GRAPHIC, VARGRAPHIC, DBCLOB, or CHAR FOR MIXED DATA column, in an EBCDIC or ASCII table, when the setting for installation

Chapter 7. Statements 1325
option MIXED DATA is NO. An exception is that a Unicode column can be added to an EBCDIC table even when the installation option MIXED DATA is NO.

If the column that is being added is a security label column, row permissions, including the default row permission, cannot exist for the table.

column-name
Names of the column you want to add to the table. The name must not be the same as the name of an existing column of the table or the name of a period in the table. A column named SYSTEM_TIME or BUSINESS_TIME cannot be added to a table that is defined as a system-period temporal table or a history table. Do not qualify column-name.

data-type
Specifies the data type of the column. The data type can be a built-in data type or a distinct type.

built-in-type
Specifies that the data type of the column is one of the built-in data types. See built-in-type for information about the built-in data types that can be used when adding a column to a table.

distinct-type-name
Specifies the distinct type (user-defined data type) of the column. The length and scale of the column are respectively the length and scale of the source type of the distinct type. The privilege set must implicitly or explicitly include the USAGE privilege on the distinct type.

The encoding scheme of the distinct type must be the same as the encoding scheme of the table.

If the column is to be used in the definition of the foreign key of a referential constraint, the data type of the corresponding column of the parent key must have the same distinct type.

NOT NULL
Prevents the column from containing null values. If NOT NULL is specified, the DEFAULT clause must be used to specify a non-null default value for the column unless the column has a row ID data type or is an identity column. For a ROWID column, NOT NULL must be specified, and DEFAULT must not be specified. For an identity column, although NOT NULL can be specified, DEFAULT must not be specified.

DEFAULT
Specifies the default value that is assigned to the column in the absence of a value specified in a data change statement, or LOAD. Do not specify DEFAULT for the following types of columns:

- A ROWID column (Db2 generates default values)
- An identity column (Db2 generates default values)
- An XML column
- A row change timestamp column

Do not specify a value after the DEFAULT keyword for a security label column. Db2 provides the default for a security label column.

If a value is not specified after the DEFAULT keyword, the default value depends on the data type of the column:

Data Type

```
Default Value
```
Numeric
0

Fixed-length character or graphic string
  Blanks

Fixed-length binary string
  Hexadecimal zeros

Varying-length string
  A string of length 0

Inline BLOB
  Hexadecimal zeros

Inline CLOB
  Blanks

Inline DBCLOB
  Blanks

Date
  For existing rows, a date corresponding to 1 January 0001. For added rows, CURRENT DATE.

  Use of this clause or keyword might invalidate packages that depend on the target object, or packages that depend on related objects through cascading effects. See Changes that invalidate packages (Db2 Application programming and SQL).

Time
  For existing rows, a time corresponding to 0 hours, 0 minutes, and 0 seconds. For added rows, CURRENT TIME.

  Use of this clause or keyword might invalidate packages that depend on the target object, or packages that depend on related objects through cascading effects. See Changes that invalidate packages (Db2 Application programming and SQL).

Timestamp without time zone
  For existing rows, a date corresponding to 1 January 0001, and a time corresponding to 0 hours, 0 minutes, 0 seconds, and zeros for fractional seconds up to the timestamp precision. For added rows, CURRENT_TIMESTAMP(p) WITHOUT TIME ZONE where p is the corresponding timestamp precision. Use of this clause or keyword might invalidate packages that depend on the target object, or packages that depend on related objects through cascading effects. See Changes that invalidate packages (Db2 Application programming and SQL).

Timestamp with time zone
  For existing rows, a date corresponding to 1 January 0001, and a time corresponding to 0 hours, 0 minutes, 0 seconds, and zeros for fractional seconds up to the timestamp precision, 0 time zone hours, 0 time zone minutes. For added rows, CURRENT_TIMESTAMP(p) WITH TIME ZONE where p is the corresponding timestamp precision.

  If the column is defined as timestamp with time zone, the default value must include a time zone.

  Use of this clause or keyword might invalidate packages that depend on the target object, or packages that depend on related objects through cascading effects. See Changes that invalidate packages (Db2 Application programming and SQL).
In a given column definition:

- DEFAULT and FIELDPROC cannot both be specified.
- NOT NULL and DEFAULT NULL cannot both be specified.
- Omission of NOT NULL and DEFAULT for a column other than an identity column is an implicit specification of DEFAULT NULL. For an identity column, it is an implicit specification of NOT NULL, and Db2 generates default values.

A default value other than the one that is listed above can be specified in one of the following forms:

- WITH DEFAULT for a default value of an empty string
- DEFAULT NULL for a default value of null

**constant**

Specifies a constant as the default value for the column. The value of the constant must conform to the rules for assigning that value to the column.

A character or string constant must be short enough so that its UTF-8 representation requires no more than 1536 bytes. A hexadecimal graphic string (GX) constant cannot be specified.

In addition, the length of the constant value cannot be greater than the INLINE LENGTH attribute for LOB columns.

**SESSION_USER or USER**

Specifies the value of the SESSION_USER (USER) special register at the time of an SQL data change statement or LOAD, as the default for the column. If SESSION_USER is specified, the data type of the column must be a character string with a length attribute greater than or equal to 8 characters when the value is expressed in CCSID 37. If the data type of the column is an inline CLOB, the INLINE LENGTH attribute must be greater than or equal to 8 characters when the value is expressed as CCSID 37. For existing rows, the value is that of the SESSION_USER special register at the time the ALTER TABLE statement is processed.

**CURRENT SQLID**

Specifies the value of the SQL authorization ID of the process at the time of an SQL data change statement or LOAD, as the default for the column. If CURRENT SQLID is specified, the data type of the column must be a character string with a length attribute greater than or equal to the length attribute of the CURRENT SQLID special register. If the data type of the column is an inline CLOB, the INLINE LENGTH attribute must be greater than or equal to the length attribute of the CURRENT SQLID special register. For existing rows, the value is the SQL authorization ID of the process at the time the ALTER TABLE statement is processed.

**NULL**

Specifies null as the default value for the column.

**cast-function-name**

The name of the cast function that matches the name of the distinct type for the column. A cast function can be specified only if the data type of the column is a distinct type.

The schema name of the cast function, whether it is explicitly specified or implicitly resolved through function resolution, must be the same as the explicitly or implicitly specified schema name of the distinct type.
**constant**

Specifies a constant as the argument. The constant must conform to the rules of a constant for the source type of the distinct type. The length of the constant cannot be greater than the INLINE LENGTH attribute for LOB columns.

**SESSION_USER or USER**

Specifies the value of the SESSION_USER (USER) special register at the time a row is inserted as the default for the column. The source type of the distinct type of the column must be a CHAR, VARCHAR, or inline CLOB with a length attribute (inline length attribute for CLOB) that is greater than or equal to the length attribute of the SESSION_USER special register.

**CURRENT SQLID**

Specifies the value of the CURRENT SQLID special register at the time a row is inserted as the default for the column. The source type of the distinct type of the column must be a CHAR, VARCHAR, or inline CLOB with a length attribute (or inline length attribute for CLOB) that is greater than or equal to the length attribute of the CURRENT SQLID special register.

**NULL**

Specifies the NULL value as the argument.

**GENERATED**

Specifies that Db2 generates values for the column.

GENERATED is applicable only to the following columns:

- ROWID columns
- Identity columns
- Row change timestamp columns
- Row-begin columns
- Row-end columns
- Transaction-start-ID columns
- Generated expression columns

If the table is a system-period temporal table or an archive-enabled table, GENERATED must not be specified for the column that is to be added, unless the column is a ROWID column. The default is GENERATED ALWAYS.

**ALWAYS**

Specifies that Db2 will generate a value for the column when a row is inserted into the table. ALWAYS is the recommended value unless you are using data propagation.

**BY DEFAULT**

Specifies that Db2 will generate a value for the column when a row is inserted unless a value was specified for the column on the data change statement.

If a user-supplied value is specified for a ROWID column, Db2 uses the value only if both of the following conditions are true:

- The value is a valid row ID value that was previously generated by Db2.
- The column has a unique, single-column index.
Until this index is created on the ROWID column, the insert, and update operations and the LOAD utility cannot be used to add rows to the table. If the table space name is not specified on the CREATE TABLE statement, Db2 implicitly creates the necessary object to make the table complete, including the index. The name of this index is 'I' followed by the first ten characters of the column name followed by seven randomly generated characters. If the column name is less than ten characters, Db2 adds underscore characters to the end of the name until it has ten characters. The implicitly created index has the COPY NO attribute.

For an identity column, Db2 inserts a specified value but does not verify that it is a unique value for the column unless the identity column has a unique, single-column index.

If a user-supplied value is specified for an identity column, Db2 inserts the specified value but does not perform any special validation on that value beyond the normal validation that is performed for any column. Db2 does not check how the specified value affects the sequential properties that are defined for the identity column. To ensure the uniqueness of an identity column that is defined as GENERATED BY DEFAULT, define a unique index on the identity column.

BY DEFAULT is the recommended value only when you are using data propagation.

**AS IDENTITY**

Specifies that the column is an identity column for the table. A table can have only one identity column. AS IDENTITY can be specified only if the data type for the column is an exact numeric type with a scale of zero (SMALLINT, INTEGER, BIGINT, DECIMAL with a scale of zero, or a distinct type that is based on one of these types).

Separator commas between identity column attribute specifications are optional when the identity column is defined.

An identity column is implicitly NOT NULL. When adding an identity column to a table, you must also specify GENERATED ALWAYS or GENERATED BY DEFAULT.

Defining a column AS IDENTITY does not necessarily guarantee uniqueness of the values. To ensure uniqueness of the values, define a unique, single-column index on the identity column.

**START WITH numeric-constant**

Specifies the first value that is generated for the identity column. The value can be any positive or negative value that could be assigned to the column without non-zero digits existing to the right of the decimal point.

If a value is not explicitly specified when the identity column is defined, the default is the MINVALUE for an ascending identity column and the MAXVALUE for a descending identity column. This value is not necessarily the value that would be cycled to after reaching the maximum or minimum value for the identity column.

The range used for cycles is defined by MINVALUE and MAXVALUE. MAXVALUE and MINVALUE do not constrain the numeric-constant value. That is, the START WITH clause can be used to start the generation of values outside the range that is used for cycles. However, the next generated value after the specified
START WITH value is MINVALUE for an ascending identity column or MAXVALUE for a descending identity column.

**INCREMENT BY numeric-constant**

Specifies the interval between consecutive values of the identity column. The value can be any positive or negative value (including 0) that does not exceed the value of a large integer constant and can be assigned to the column without any non-zero digits to the right of the decimal point. The default is 1.

If the value is positive or zero, the sequence of values for the identity column ascends. If the value is negative, the sequence of values descends.

**MINVALUE or NO MINVALUE**

Specifies the minimum value at which a descending identity column either cycles or stops generating values or an ascending identity column cycles to after reaching the maximum value.

**NO MINVALUE**

Specifies that the minimum end point of the range of values for the identity column is not set. In this case, the default value for MINVALUE becomes one of the following values:

- For an ascending identity column, the value is the START WITH value or 1 if START WITH was not specified.
- For a descending identity column, the value is the minimum value of the data type of the column.

**MINVALUE numeric-constant**

Specifies the numeric constant that is the minimum value that is generated for this identity column. This value can be any positive or negative value that can be assigned to this column without non-zero digits to the right of the decimal point. The value must be less than or equal to the maximum value.

**MAXVALUE or NO MAXVALUE**

Specifies the maximum value at which an ascending identity column either cycles or stops generating values or a descending identity column cycles to after reaching the minimum value.

**NO MAXVALUE**

Specifies that the minimum end point of the range of values for the identity column is not set. In such a case, the default value for MAXVALUE becomes one of the following values:

- For an ascending identity column, the value is the maximum value of the data type of the column.
- For a descending identity column, the value is the START WITH value or -1 if START WITH is not specified.

**MAXVALUE numeric-constant**

Specifies the numeric constant that is the maximum value that is generated for this identity column. This value can be any positive or negative value that can be assigned to this column without non-zero digits to the right of the decimal point. The value must be greater than or equal to the minimum value.

**CYCLE or NO CYCLE**

Specifies whether this identity column is to continue to generate values after reaching either its maximum or minimum value.
**NO CYCLE**
Specifies that values will not be generated for the identity column after the maximum or minimum value has been reached. NO CYCLE is the default.

**CYCLE**
Specifies that values continue to be generated for this column after the maximum or minimum value has been reached. If this option is used, after an ascending identity column reaches the maximum value, it generates its minimum value. After a descending identity column reaches its minimum value, it generates its maximum value. The maximum and minimum values for the identity column determine the range that is used for cycling.

When CYCLE is in effect, duplicate values can be generated by Db2 for an identity column. However, if a unique index exists on the identity column and a non-unique value is generated for it, an error occurs.

**CACHE or NO CACHE**
Specifies whether to keep some preallocated values in memory. Preallocating and storing values in the cache improves the performance of inserting rows into a table. The default is CACHE 20.

**NO CACHE**
Specifies that values for the identity column are not preallocated and stored in the cache, ensuring that values will not be lost in the case of a system failure. In this case, every request for a new value for the identity column results in synchronous I/O.

**CACHE integer-constant**
Specifies the maximum number of values of the identity column sequence that Db2 can preallocate and keep in memory.

During a system failure, all cached identity column values that are yet to be assigned might be lost and will not be used. Therefore, the value that is specified for CACHE also represents the maximum number of values for the identity column that could be lost during a system failure.

The minimum value is 2.

In a data sharing environment, you can use the CACHE and NO ORDER options to allow multiple Db2 members to cache sequence values simultaneously.

**ORDER or NO ORDER**
Specifies whether the identity column values must be generated in order of request. The default is NO ORDER.

**NO ORDER**
Specifies that the values do not need to be generated in order of request.

**ORDER**
Specifies that the values are generated in order of request.
Specifying ORDER might disable the caching of values.
ORDER applies only to a single-application process.

In a data sharing environment, if the CACHE and NO ORDER options are in effect, multiple caches can be active simultaneously, and the requests for identity values from different Db2 members might not result in the assignment of values in strict numeric order. For example, suppose that members DB2A and DB2B are using the identity column, DB2A gets the cache values 1 to 20, and DB2B gets the cache values 21 to 40. If DB2A requested a value first, then DB2B requested, and then DB2A again requested, the actual order of values that are assigned would be 1,21,2 . Therefore, to guarantee that identity values are generated in strict numeric order among multiple Db2 members using the same identity column, specify the ORDER option.

**FOR EACH ROW ON UPDATE AS ROW CHANGE TIMESTAMP**
Specifies that the column is a timestamp and the values will be generated by Db2. Db2 generates a value for the column for each row as a row is inserted, and for any row for which any column is updated. The value that is generated for a row change timestamp column is a timestamp that corresponds to the time of the insert or update of the row. If multiple rows are inserted or updated with a single statement, the value of the row change timestamp column might be different for each row.

Adding a row change timestamp column to an existing table means that existing rows might be affected, and that an AREO* state might be set for the table space until a REORG is completed. For each existing row, a timestamp value is assigned for the new row change timestamp column.

*If data-type is specified, it must be TIMESTAMP WITHOUT TIME ZONE with a precision of 6. You must specify NOT NULL with a row change timestamp column.*

**AS ROW BEGIN**
Specifies that a timestamp value is assigned to the column whenever a row is inserted or any column in the row is updated. If the value of the SYSIBM.TEMPORAL_LOGICAL_TRANSACTION_TIME built-in global variable at the time of the insert or update is null, the value is generated using a reading of the time-of-day clock during execution of the first data change statement in the unit of work that requires a value to be assigned to a row-begin column or transaction-start-ID column in a table, or a row in a system-period temporal table is deleted. Otherwise, the row-begin column is assigned the value of the SYSIBM.TEMPORAL_LOGICAL_TRANSACTION_TIME built-in global variable at the time of the insert or update.

A row-begin column is intended to be used for a system-period temporal table.

A table can have only one row-begin column. If data-type is not specified, the column is defined as TIMESTAMP(12) WITHOUT TIME ZONE. If data-type is specified, it must be TIMESTAMP(12) WITHOUT TIME ZONE or TIMESTAMP(12) WITH TIME ZONE. If the column is defined as TIMESTAMP WITH TIME ZONE, the values are stored in UTC, with a time zone of +00:00. The column cannot have a DEFAULT clause, and must be defined as NOT NULL.
A `row-begin` column is not updatable.

A value for a `row-begin` column is composed of a TIMESTAMP(9) value that is unique per transaction per data sharing member followed by 3 digits that indicate the data sharing member number.

**AS ROW END**

Specifies that a value for the data type of the column is assigned when a row is inserted or any column in the row is updated. The value that is assigned for a timestamp without time zone column is TIMESTAMP '9999-12-30-00.00.00.000000000000'. The value that is assigned for a timestamp with time zone column is TIMESTAMP '9999-12-30.00.00.00.000000000000 +00:00'.

A `row-end` column is intended to be used for a system-period temporal table.

For a table with system-period data versioning, when a row is deleted as the result of an update or delete operation, the value of the `row-end` column in the historical row reflects when the row was deleted. The value that is generated for the column in the historical row is a timestamp that corresponds to the most recent transaction start time that is associated with the transaction. If a row that is to be updated would result in a value for the `row-end` column that is less than or equal to the value for the corresponding `row-begin` column, the timestamp value for the `row-end` column is adjusted. If multiple rows are deleted with a single SQL statement, the values for the column in the historical rows are the same.

A table can have only one `row-end` column. If `data-type` is not specified, the column is defined as TIMESTAMP(12) WITHOUT TIME ZONE. If `data-type` is specified, it must be TIMESTAMP(12) WITHOUT TIME ZONE or TIMESTAMP(12) WITH TIME ZONE. If the column is defined as TIMESTAMP WITH TIME ZONE, the values are stored in UTC, with a time zone of +00:00. The column cannot have a DEFAULT clause.

A `row-end` column is not updatable.

**AS TRANSACTION START ID**

Specifies that a timestamp value is assigned when the row is inserted or any column in the row is updated. If the value of the `row-begin` column is unique from `row-begin` column values that are generated for other transactions, the `row-begin` column value is assigned to the `transaction-start-ID` column. Otherwise, the value of the `transaction-start-ID` column is derived from the `row-begin` column value and adjusted to make it unique from `transaction-start-ID` column values that are generated for other transactions.

A `transaction-start-ID` column is intended to be used for a system-period temporal table.

A table can have only one `transaction-start-id` column. If `data-type` is not specified, the column is defined as TIMESTAMP(12) WITHOUT TIME ZONE. If `data-type` is specified, it must be TIMESTAMP(12) WITHOUT TIME ZONE or TIMESTAMP(12) WITH TIME ZONE. If the column is defined as TIMESTAMP WITH TIME ZONE, the values are stored in UTC, with a time zone of +00:00. The column cannot have a DEFAULT clause.

A `transaction-start-id` column is not updatable.
as-generated-expression-clause
Specifies that values for the column are generated by Db2. The
generated value is assigned to the column whenever a row is inserted,
or any column in the row is updated.

DATA CHANGE OPERATION
Specifies that the database manager generates one of the following
values, depending on the data change statement that changes the
row:

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>I</td>
<td>Insert operation</td>
</tr>
<tr>
<td>U</td>
<td>Update operation.</td>
</tr>
<tr>
<td>D</td>
<td>Delete operation.</td>
</tr>
</tbody>
</table>

A table can have only one DATA CHANGE OPERATION column. The column must be defined as CHAR(1). The column cannot have
a DEFAULT clause and must not be defined as NOT NULL.

The column is a non-deterministic generated expression column.

Do not specify any of the following clauses for the column:

- CCSID 1200
- CCSID 1208
- FIELDPROC

special-register
Specifies the value of the special register. This column is to contain
the value of the special register at the time of the data change
statement that assigns the value to the column. If multiple rows are
inserted or updated with a single SQL statement, the value for the
column is the same for all of the rows.

special-register must be one of the following special registers, and
the column must use the required data type.

<table>
<thead>
<tr>
<th>Special register</th>
<th>Data type for the column</th>
</tr>
</thead>
<tbody>
<tr>
<td>CURRENT CLIENT_ACCTNG</td>
<td>VARCHAR(255)</td>
</tr>
<tr>
<td>CURRENT CLIENT_APPLNAME</td>
<td>VARCHAR(255)</td>
</tr>
<tr>
<td>CURRENT CLIENT_CORR_TOKEN</td>
<td>VARCHAR(255)</td>
</tr>
<tr>
<td>CURRENT CLIENT_USERID</td>
<td>VARCHAR(255)</td>
</tr>
<tr>
<td>CURRENT CLIENT_WRKSTNNAME</td>
<td>VARCHAR(255)</td>
</tr>
<tr>
<td>CURRENT SERVER</td>
<td>CHAR(16)</td>
</tr>
<tr>
<td>CURRENT SQLID</td>
<td>VARCHAR(n) where n ≥ 8</td>
</tr>
<tr>
<td>SESSION_USER or USER</td>
<td>VARCHAR(128)</td>
</tr>
</tbody>
</table>

This column cannot have a DEFAULT clause and must not be
defined as NOT NULL.

The column is a non-deterministic generated expression column.

Do not specify any of the following clauses for the column:

- CCSID 1200
- CCSID 1208
Related information:

**session-variable**

Specifies the value of a built-in session variable. The fully qualified name of the session variable must be specified. The value of the session variable is obtained from the `GETVARIABLE` function at the time of the data change operation that assigns the value to the column. If multiple rows are changed with a single SQL statement, the value for the column is the same for all of the rows.

`session-variable` must be one of the following session variables, and the column must use the required data type.

<table>
<thead>
<tr>
<th>Session variable</th>
<th>Data type for the column</th>
</tr>
</thead>
<tbody>
<tr>
<td>SYSIBM.PACKAGE_NAME</td>
<td>VARCHAR(128)</td>
</tr>
<tr>
<td>SYSIBM.PACKAGE_SCHEMA</td>
<td>VARCHAR(128)</td>
</tr>
<tr>
<td>SYSIBM.PACKAGE_VERSION</td>
<td>VARCHAR(122)</td>
</tr>
</tbody>
</table>

The column cannot have a DEFAULT clause and must not be defined as NOT NULL.

The column is a non-deterministic generated expression column.

Do not specify any of the following clauses for the column:

- CCSID 1200
- CCSID 1208
- FIELDPROC

Related information:

**IMPLICITLY HIDDEN**

Specifies that the column is not visible in the results of SQL statements unless you refer explicitly to the column by name. For example, assume that table T1 includes a column that is defined with the IMPLICITLY HIDDEN clause. The result of `SELECT * FROM T1` would not include the implicitly hidden column. However, the result of a SELECT statement that explicitly refers to the name of the implicitly hidden column would include that column in the result table.

IMPLICITLY HIDDEN must not be specified for a column that is defined as a ROWID, or a distinct type that is based on a ROWID.

**column-constraint**

Provides a shorthand method of defining a constraint composed of a single column. If a `column-constraint` is specified in the definition of column C, the effect is the same as if that constraint were specified as a `unique-constraint`, `referential-constraint`, or `check-constraint` in which column C is the only identified column.

**references-clause**

The `references-clause` of a `column-definition` provides a shorthand method
of defining a foreign key composed of a single column. Thus, if references-clause is specified in the definition of column C, the effect is the same as if that references-clause were specified as part of a FOREIGN KEY clause in which C is the only identified column.

Do not specify references-clause in the definition of the following types of columns because these types of columns cannot be a foreign key:

- LOB columns
- ROWID columns
- XML columns
- DECFLOAT columns
- Row change timestamp columns
- Security label columns

**check-constraint**

The check-constraint of a column-definition has the same effect as specifying a check constraint in a separate ADD check-constraint clause. For conformance with the SQL standard, a check constraint specified in the definition of column C should not reference any columns other than C.

Do not specify a check constraint in the definition of the following types of columns:

- LOB columns
- ROWID columns
- XML columns
- DECFLOAT columns
- Security label columns

**AS SECURITY LABEL**

Specifies that the table is defined with multilevel security with row level granularity and specifies that the column will contain the security label values. A table can have only one security label column. To define a table with a security label column, the primary authorization ID of the statement must have a valid security label, and the RACF SECLABEL class must be active. In addition, the following conditions are also required:

- The data type of the column must be CHAR(8).
- The subtype of the column must be SBCS.
- The column does not have any field procedures, check constraints, or referential constraints.
- The column must be defined as NOT NULL and WITH DEFAULT clauses.
- The WITH DEFAULT clause must not be specified with a default value (Db2 provides the default value).
- The table does not have an edit procedure that is defined as WITH ROW ATTRIBUTES.
- The column must not be a Unicode column in an EBCDIC table.
- The table is not the source table for a materialized query table.

For existing rows in the table, the value of the security label column defaults to the security label of the user at the time the ALTER statement is executed.

**FIELDPROC program-name**

Designates program-name as the field procedure exit routine for the column. A field procedure can be specified only for a column with a length
attribute that is not greater than 255 bytes. FIELDPROC can only be specified for columns that are a built-in character string or graphic string data types. The column must not be one of the following:

- a LOB column
- a security label column
- a row change timestamp column
- a column with the TIMESTAMP WITH TIME ZONE data type

The field procedure encodes and decodes column values. Before a value is inserted in the column, it is passed to the field procedure for encoding. Before a value from the column is used by a program, it is passed to the field procedure for decoding. A field procedure could be used, for example, to alter the sorting sequence of values entered in the column.

The field procedure is also invoked during the processing of the ALTER TABLE statement. When so invoked, the procedure provides Db2 with the column's field description. The field description defines the data characteristics of the encoded values. By contrast, the information you supply for the column in the ALTER TABLE statement defines the data characteristics of the decoded values.

If you omit FIELDPROC, the column has no field procedure.

**Related information:**

- [Field procedures (Db2 Administration Guide)]

**constant**

Is a parameter that is passed to the field procedure when it is invoked. A parameter list is optional. The \( \text{n} \)th parameter specified in the FIELDPROC clause on ALTER TABLE corresponds to the \( \text{n} \)th parameter of the specified field procedure. The maximum length of the parameter list is 255 bytes, including commas but excluding insignificant blanks and the delimiting parentheses.

**INLINE LENGTH** \( \text{integer} \)

Specifies the maximum length of the inline portion of a LOB column value. The inline portion is the portion that is stored in the base table space.

INLINE LENGTH cannot be specified if the column is not a LOB column (or a distinct type that is based on a LOB), if the table is not in a universal table space, or if the table is an accelerator-only table.

For BLOB and CLOB columns, \( \text{integer} \) specifies the maximum number of bytes that are stored in the base table space for the column. \( \text{integer} \) must be between 0 and 32680 (inclusive) for a BLOB or CLOB column.

For a DBCLOB column, \( \text{integer} \) specifies the maximum number of double-byte characters that are stored in the table space for the column. \( \text{integer} \) must be between 0 and 16340 (inclusive) for a DBCLOB column.

If INLINE LENGTH is specified, the value of \( \text{integer} \) cannot be greater than the maximum length of the LOB column.

If the INLINE LENGTH clause is not specified, the maximum length of the LOB column depends on the following conditions:

- If a distinct type is not used or the distinct type that is used has been created without the INLINE LENGTH attribute, the LOB column will use the value of the LOB INLINE LENGTH parameter on installation panel DSNTIPD as the default inline length when the value of LOB INLINE LENGTH does not exceed the maximum length of the LOB
column. If the value of LOB INLINE LENGTH exceeds the maximum
length of the LOB column, the maximum length is the inline length of
this LOB column.

• If a distinct type that has been created with the INLINE LENGTH
attribute is used, the LOB column inherits the inline length from the
distinct type.

Regardless of how the length is determined, the inline length of the LOB
cannot be greater than its maximum length.

Be aware that specifying the ADD COLUMN clause might affect subsequent
requests to recover to a point in time. See Point-in-time recovery (Db2 Utilities) for
information about possible restrictions, effects on recovery status, and other
considerations.

**ALTER COLUMN**

**ALTER COLUMN column-alteration**

Alters the definition of an existing column, including the attributes of an
existing identity column. Only the attributes specified are altered. Other
attributes remain unchanged. Only future values of the column are affected by
the changes made with an ALTER TABLE ALTER COLUMN statement.

The table being altered must not be in an incomplete state because of a missing
unique index on a unique constraint (primary or unique key). An ALTER
TABLE ALTER COLUMN statement might not be processed in the same unit
of work as a data change statement. A column cannot be altered if any of the
following conditions are true:

• The table has an edit procedure that is defined as WITH ROW ATTRIBUTES
  or a validation exit procedure
• The table is used in a materialized query table definition
• The table is a materialized query table
• The table is a system-period temporal table that is enabled for system-period
data versioning
• The table is a history table
• The table is an archive-enabled table or an archive table
• The table is a created temporary table.
• There is an extended index that depends on that column
• The column is referenced in a field procedure
• The column is referenced in a referential constraint
• The column is referenced in a check constraint
• The column is referenced in the definition of a SYSTEM_TIME or
  BUSINESS_TIME period
• The column is defined as a transaction-start-ID column
• The column is defined as a security label column
• The column is defined as a row change timestamp column
• The column is a generated expression column.

A Db2 11 Unicode column in an EBCDIC table can only be altered to the same
data type, length, and CCSID. This type of alteration migrates the Db2 11
Unicode column to a Db2 12 Unicode column, which is available beginning in
Db2 12 with new function activated.
You can modify all the attributes of an existing identity column, except for the data type of the column. To change the data type of an identity column, drop the table containing the column and recreate it. When the attributes of an identity column are altered, the column of the specified column-name must exist in the specified table and must have been defined with the IDENTITY attribute.

column-name

Identifies the column to be altered. The name must not be qualified and must identify an existing column in the table being altered when the ALTER statement is processed. The name must not identify a column that is being added in the same ALTER TABLE statement.

A column can only be referenced in one ALTER COLUMN clause in a single ALTER TABLE statement. However, that same column can be referenced multiple times for adding or dropping constraints in the same ALTER TABLE statement.

SET DATA TYPE (altered-data-type)

Specifies the new data type of the column to be altered. For a character column, you can also use the clause to change the definition of the subtype that is stored in the Db2 catalog and OBD.

The following restrictions apply to use of the SET DATA TYPE clause:

- The data type of a column cannot be altered if the column is an identity column or is part of a hash key.
- The existing data type of the column cannot be a ROWID, date, time, or distinct type.
- The new data type must be compatible with the existing data type of the column.
- When the source data type is a LOB, the target data type must be the same LOB data type. If the source data type is a LOB and the maximum length is altered, the new maximum length must be at least as large as the existing length attribute.
- If the column is a partitioning column, and the existing data type is CHAR or VARCHAR FOR BIT DATA, the new data type cannot be VARBINARY or BINARY.
- If the column is CHAR FOR BIT DATA, VARCHAR FOR BIT DATA, or BINARY, the new data type cannot be VARBINARY if the column is part of an index and is defined with the DESC attribute.
- If the column is a Unicode column, the new data type cannot specify FOR BIT DATA, FOR MIXED DATA, or FOR SBCS DATA.
- If altered-data-type is XML, the old data type of the altered column must also be XML.
- A row in a table with PAGENUM RELATIVE or in a table space with PAGENUM RELATIVE must have a minimum data size of 3 bytes. If an ALTER TABLE ALTER COLUMN results in row size that is less than the minimum size, it will not be valid.

For more information on the compatibility of data types, see “Assignment and comparison” on page 151.

A TIMESTAMP column can only be altered to TIMESTAMP with a larger precision. A TIMESTAMP WITH TIME ZONE column can only be altered to TIMESTAMP WITH TIME ZONE with a larger precision. If the precision of a timestamp column is increased, the fractional seconds of existing data
values are extended with zeros so that the number of fractional second
digits matches the specified timestamp precision.

If any numeric data type is being converted to DECFLOAT, the ALTER
statement will fail if there is a partitioning key, index, or a unique
constraint on the column.

If the data type is a character or graphic string, the new length attribute
must be at least as large as the existing length attribute of the column. If
the data type is a numeric data type, the specified precision and scale must
be at least as large as the existing precision and scale. If a decimal fraction
is being converted to floating point, the ALTER statement will fail if there
is a unique index or a unique constraint on the column.

If the specified column has a default value, the existing default value must
represent a value that could be assigned to a column with the new data
type in accordance with the rules for assignment. The default value is
updated to reflect the new data type.

If the column is specified in an index, the new column length must not
exceed the limit on an index size. For PADDED indexes, the sum of the
length attributes of the columns must not be greater than 2000-\(n\), where \(n\)
is the number of columns that can contain null values. For NOT PADDED
indexes, the sum of the length attributes of the columns must not be
greater than 2000-\(n\)-2\(m\), where \(n\) is the number of nullable columns and \(m\)
is the number of varying length columns.

The total byte count of columns after the alteration must not exceed the
maximum row size. If the column is in the partitioning key, the new
partitioning key cannot exceed 255-\(n\).

Table 174 shows the numeric data type alterations that are supported for
SET DATA TYPE:

<table>
<thead>
<tr>
<th>From/To</th>
<th>SMALLINT</th>
<th>INTEGER</th>
<th>BIGINT</th>

<td>Y</td>
<td>Y</td>
</tr>
<tr>
<td>BINARY(n)</td>
<td>Y</td>
<td>Y</td>
</tr>
<tr>
<td>VARBINARY(n)</td>
<td>Y¹</td>
<td>Y</td>
</tr>
</tbody>
</table>

Note: ALTER from VARBINARY to BINARY is not allowed when the column is part of a unique index.

Altering the data type, length, precision, or scale of a column is a pending change to the definition of the table space if all of the following conditions are true:

- Subsystem parameter DDL_MATERIALIZATION is set to ALWAYS_PENDING.
- The base table space is a universal table space.
- The data sets of the base table space are already created.

Otherwise, the change takes effect immediately. If the alteration results in the generation of a new table version, the table space that contains the table that is being changed is left in an advisory REORG-pending (AREO) status.

If the change is a pending change to the definition of a table, the definition of the containing table space must not be in an incomplete state. Pending changes are not reflected in the definition or data at the time that the ALTER TABLE statement is issued. Instead, the entire table space is placed in an advisory REORG-pending state (AREOR). A subsequent reorganization of the entire table space applies the pending definition changes to the definition and data of the table.

For subtype DATA

Alters the subtype of a character column. This clause does not change the data. The clause only updates the definition of the subtype as it is...
stored in the Db2 catalog and the OBD. The length and data type that are specified must match the existing length and data type of the column.

Only character strings are valid when subtype is BIT.

For more information on the subtype values (SBCS, MIXED, and BIT), see the subtype information under built-in-type.

**INLINE LENGTH** integer

Specifies the new inline length for the column. INLINE LENGTH can only be specified for an inline LOB column in a table that is in a universal table space. INLINE LENGTH cannot be specified if FOR SBCS DATA or FOR MIXED DATA is also specified in the same ALTER TABLE statement. Inline LOB columns cannot be added to a table that is in a table space that has basic row format. The new length can be smaller or larger than the original length. integer is a value between 0 and 32680 bytes (inclusive) for a BLOB or CLOB column or between 0 and 16340 characters (inclusive) for a DBCLOB column. The inline length cannot be changed in the following cases:

- The LOB column is referenced in an expression-based index or a spatial index.
- If the column has a default value, the new inline length is less than the length of the default value for the column.
- The new inline length is greater than the maximum length of the LOB column.

When the base table space is not empty, increasing the length puts the table space in an advisory REORG-pending state, and decreasing the length puts the table space in a REORG-pending state.

No expression-based indexes can be created after the inline length is changed until the REORG utility is run on the base table space.

**SET INLINE LENGTH** integer

Specifies the new inline length for the column. SET INLINE LENGTH can only be specified for an inline LOB column in a table that is in a universal table space. INLINE LENGTH cannot be specified if FOR SBCS DATA or FOR MIXED DATA is also specified in the same ALTER TABLE statement. Inline LOB columns cannot be added to a table that is in a table space that has basic row format. The new length can be smaller or larger than the original length. integer is a value between 0 and 32680 bytes (inclusive) for a BLOB or CLOB column or between 0 and 16340 characters (inclusive) for a DBCLOB column. The inline length cannot be changed in the following cases:

- The LOB column is referenced in an expression-based index or a spatial index.
- If the column has a default value, the new inline length is less than the length of the default value for the column.
- The new inline length is greater than the maximum length of the LOB column.

When the base table space is not empty, increasing the length puts the table space in an advisory REORG-pending state, and decreasing the length puts the table space in a REORG-pending state.

No expression-based indexes can be created after the inline length is changed until the REORG utility is run on the base table space.
**SET default-clause**

Specifies the new default value of the column to be altered. The new default value must conform to the current rules for assigning that value to the column. Existing rows will retain their current value. The new default value will be reflected only in the rows that are inserted after the alter.

The table must not be referenced by a view. The table must not be defined with the DATA CAPTURE CHANGES attribute when the subsystem parameter RESTRICT_ALT_COL_FOR_DCC is set to YES.

If the column is specified in a unique constraint (unique key or primary key) or unique index, the default value might be altered to the same value as an existing row of that column. However, subsequent data change operations will fail in the absence of a value specified for that column on the insert operation.

For LOB columns, default values can be changed only for inline LOB. The length of the new default value cannot be greater than the inline length.

If an ALTER TABLE statement with an ADD COLUMN clause that specifies a default value is successful, you cannot request a subsequent point-in-time recovery to a time that precedes processing of the ALTER TABLE statement.

**DROP DEFAULT**

Drops the current default value of the column. For columns that are not nullable, the specified column must be defined with a default value. For columns that are nullable, the specified column cannot have a null default value. For columns that are nullable, the new default value is the null value.

The table that contains the specified column must not be referenced in a view. The table must not be defined with the DATA CAPTURE CHANGES attribute when the subsystem parameter RESTRICT_ALT_COL_FOR_DCC is set to YES.

Follow these steps to remove the default value for a column that was defined using ALTER TABLE with the ADD COLUMN clause:

1. Run the REORG utility or the UPDATE statement to reset the AREO* state:
   - Run the REORG utility on the table space that contains the table
   - If the table is in a universal table space and the table does not have row access control activated, run an UPDATE statement without the SKIP LOCKED DATA or WHERE clauses specified. The update operation must be done with a searched UPDATE statement and the expression in the SET clause cannot be a scalar-fullselect or a row-fullselect. An update operation within a SELECT statement will not reset the AREO* status.

2. Issue the ALTER TABLE statement that specifies the DROP DEFAULT clause

   If the REORG is not done before the ALTER TABLE, or the UPDATE statement does not reset the AREO* statue, an error is returned for the ALTER TABLE statement.

   If an ALTER TABLE statement with an ALTER COLUMN clause that specifies DROP DEFAULT is successful, you cannot request a subsequent point-in-time recovery to a time that precedes processing of the ALTER TABLE statement.
SET GENERATED
Specifies that Db2 generates values for the column. SET GENERATED must not be specified for a column of a history table or for a column that already has the GENERATED attribute.

ALWAYS
Specifies that Db2 always generates a value for the column when a row is inserted or updated and a default value must be generated.

BY DEFAULT
Specifies that Db2 generates a value for the column when a row is inserted or updated and a default value must be generated, unless an explicit value is specified. For a row change timestamp column, Db2 inserts or updates a specified value but does not verify that it is a unique value for the column unless the row change timestamp column has a unique constraint or a unique index that solely specifies the row change timestamp column.

RESTART
Specifies the next value for the identity column, If numeric-constant is not specified, the sequence is restarted at the value that is specified implicitly or explicitly as the starting value when the identity column was originally created. RESTART does not change the original START WITH value.

WITH numeric-constant
Specifies that, when it is time to generate the next value for this identity column, numeric-constant will be used as the next value for the column. This value can be any positive or negative value (including 0) that could be assigned to this column without nonzero digits existing to the right of the decimal point. The range used for cycles is defined by MINVALUE and MAXVALUE. MAXVALUE and MINVALUE do not constrain the numeric-constant value. That is, the RESTART WITH clause can be used to start the generation of values outside the range that is used for cycles. However, the next generated value after the specified RESTART WITH value is MINVALUE for an ascending identity column or MAXVALUE for a descending identity column.

If RESTART is not specified, the sequence is not restarted. Instead, it resumes with the current values that are in effect for all the options after the ALTER statement is issued.

After an identity column is restarted or changed to allow cycling, sequence numbers might be duplicates of values generated previously.

SET INCREMENT BY numeric-constant
For a definition, see the description of INCREMENT BY numeric-constant for defining an identity column.

SET MINVALUE or NO MINVALUE
For a definition, see the description of MINVALUE or NO MINVALUE for defining an identity column.

SET MAXVALUE or NO MAXVALUE
For a definition, see the description of MAXVALUE or NO MAXVALUE for defining an identity column.

SET CYCLE or NO CYCLE
For a definition, see the description of CYCLE or NO CYCLE for defining an identity column.
SET CACHE or NO CACHE
For a definition, see the description of CACHE or NO CACHE for defining
an identity column.

SET ORDER or NO ORDER
For a definition, see the description of ORDER or NO ORDER for defining
an identity column.

Be aware that specifying the ALTER COLUMN clause might affect subsequent
requests to recover to a point in time. For information about possible restrictions,
effects on recovery status, and other considerations, see Point-in-time recovery
(Db2 Utilities).

RENAME COLUMN:
RENAME COLUMN source-column-name TO target-column-name
Renames the specified column. The names must not be qualified.

source-column-name
Identifies the column that is to be renamed. The name must identify an
existing column of the table.

target-column-name
Specifies the new name for the column. The name must not identify a
column that already exists in the table, or the name of a period that exists
in the table.

You cannot rename a column if any of the following conditions apply:
• The column is referenced in a view
• The column is referenced in the expression of an index definition
• The column is referenced in the definition of a row permission or a column
  mask
• The column is referenced in an SQL table user-defined function
• The column has a check constraint defined
• The column has a field procedure defined
• The table has a trigger
• The table is a materialized query table or is referenced by a materialized
  query table
• The table has a valid procedure, or an edit procedure that is defined as
  WITH ROW ATTRIBUTES
• The table is a Db2 catalog table
• The table is a system-period temporal table or a history table
• The table is an archive-enabled table or an archive table

DROP COLUMN
DROP COLUMN column-name
Drops the identified column from the table. Any privileges that are associated
with the column are revoked.

A column cannot be dropped if any of the following conditions are true:
• The containing table space is not a universal table space
• The table is a created global temporary table
• The table is a system-period temporal table
• The table is a history table
• The table is an archive-enabled table
• The table is an archive table
• The table has an edit procedure or a validation exit procedure
• The table contains check constraints
• The table is a materialized query table
• The table is referenced in a materialized query table definition
• The column is defined as a security label column
• The column is an XML column
• The column is a DOCID column
• The column is an implicitly generated hidden ROWID column
• The column is defined as ROWID GENERATED BY DEFAULT, and the table contains an implicitly generated hidden ROWID column
• The column is a ROWID column on which there is a dependent LOB column
• The column is part of the table partitioning key
• The column is part of the hash key
• A row contains less than the minimum data size of 3 bytes
• All of the remaining columns in the table are hidden
• A view depends on the column
• A view that is dependent on the table has INSTEAD OF triggers
• A trigger is defined on the table
• Any of the following objects are dependent on the table:
  – Extended indexes
  – Row permissions
  – Column masks
  – SQL table functions

column-name

Identifies the column that is to be dropped. The column name must not be qualified. The name must identify a column of the specified table. The name must not identify the only column of the table or a column that is referenced in the definition of a period. The table definition must not be in an incomplete state.

If the column is a LOB column, any auxiliary tables that are associated with the column and the indexes on the auxiliary tables are also dropped. Any LOB table spaces that were implicitly created for the auxiliary tables are also dropped. If the column is the last LOB column in the table, any implicitly created ROWID column in the table is also dropped.

Dropping a column is a pending change to the definition of the table if the data sets of the table space are already created, otherwise, the change takes effect immediately.

If the change is a pending change to the definition of the table, the definition of the containing table space must not be in an incomplete state. Pending changes are not reflected in the definition or data at the time the ALTER TABLE statement is issued. Instead, the entire table space is placed in an advisory REORG-pending state (AREOR). A subsequent reorganization of the entire table space will apply the pending definition changes to the definition and data of the table. If the change is a pending change, a new table version is generated.
Use of this clause or keyword might invalidate packages that depend on the
target object, or packages that depend on related objects through cascading
effects. See Changes that invalidate packages (Db2 Application programming
and SQL).

When pending definition changes are materialized during REORG
TABLESPACE with the SHRLEVEL REFERENCE or SHRLEVEL CHANGE
option, statistics for both the containing table space and associated indexes are
collected and updated in the Db2 catalog.

RESTRICT
Specifies that the column cannot be dropped if any views, indexes, unique
constraints, or referential constraints are dependent on the column.

Be aware that specifying the DROP COLUMN clause might affect subsequent
requests to recover to a point in time. See Point-in-time recovery (Db2 Utilities) for
information about possible restrictions, effect on recovery status, and other
considerations.

ADD PERIOD:

ADD PERIOD FOR period-definition
Adds a period to the table.

The table must not be an archive-enabled table or an archive table.

begin-column-name must not be the same as end-column-name. The data type,
precision, and scale for begin-column-name must be the same as for
end-column-name.

SYSTEM_TIME(begin-column-name, end-column-name)
Names the period SYSTEM_TIME. The name must not identify an existing
column in the table. A table can have only one SYSTEM_TIME period.

The begin-column-name must specify a row-begin column and the
end-column-name must specify a row-end column. Both columns must be
defined as GENERATED ALWAYS. A column mask or row permission
must not be defined for the table.

BUSINESS_TIME(begin-column-name, end-column-name)
Names the period BUSINESS_TIME. The name must not identify an
existing column in the table. A table can have only one BUSINESS_TIME
period.

An implicit check constraint is generated to ensure the relationship of the
value of end-column-name to the value of begin-column-name as follows:

• For an inclusive-exclusive BUSINESS_TIME period, the value of
  end-column-name is greater than the value of begin-column-name.
• For an inclusive-inclusive BUSINESS_TIME period, the value of
  end-column-name is greater than or equal to the value of
  begin-column-name.

The name of the implicitly created check constraint is
DB2_GENERATED_CHECK_CONSTRAINT_FOR_BUSINESS_TIME, and
that name must not be defined as the name of an existing check constraint.

The columns that are specified for begin-column-name and end-column-name
must be defined as DATE or TIMESTAMP(6) WITHOUT TIME ZONE, and
must be defined as NOT NULL. The columns that are specified for
begin-column-name and end-column-name must not identify a column that is
defined with a GENERATED clause.
Use of this clause or keyword might invalidate packages that depend on
the target object, or packages that depend on related objects through
cascading effects. See Changes that invalidate packages (Db2 Application
programming and SQL).

begin-column-name
Identifies the column that records the start value for the period. The name
must identify an existing column in the table. begin-column-name must not
be the same as a column that is used in the definition of another period for
the table.

descend-column-name
Identifies the column that records the end value for the period. The name
must identify an existing column in the table. end-column-name must not be
the same as a column that is used in the definition of another period for
the table.

EXCLUSIVE
Specifies that the value of the end column is not included in the period.
The BUSINESS_TIME period is defined as inclusive-exclusive.

INCLUSIVE
Specifies that the value of the end column is included in the period. The
BUSINESS_TIME period is defined as inclusive-inclusive.

ADD unique-constraint:

CONSTRAINT constraint-name
Names the primary key or unique key constraint. If a constraint name is not
specified, a unique constraint name is generated. If a name is specified, it must
be different from the names of any referential, check, primary key, or unique
key constraints previously specified on the table. If the table space is implicitly
created, the enforcing primary key and unique key indexes are also implicitly
created.

PRIMARY KEY(column-name,...)
Defines a primary key composed of the identified columns. Each column name
must be an unqualified name that identifies a column of the table. The same
column must not be identified more than one time. The following types of
columns cannot be specified in a PRIMARY KEY clause:

* a LOB column
* a ROWID column
* a DECFLOAT column
* an XML column
* a distinct type column that is based on a LOB, ROWID, or DECFLOAT data
type
* a row change timestamp column

All character and graphic string columns in the key must use the same
encoding scheme.

The number of identified columns must not exceed 64. In addition, the sum of
the length attributes of the columns must not be greater than 2000 -2m, where
m is the number of varying-length columns in the key. The table must not have
a primary key and the identified columns must be defined as NOT NULL.

The set of columns in the primary key cannot be the same as the set of
columns of another unique key.
The table must have a unique index with a unique key that is identical to the primary key. The keys are identical only if they have the same number of columns and the \( n \)th column name of one is the same as the \( n \)th column name of the other. If the table is in a table space that is implicitly created, and no unique index is defined on the identified columns, Db2 will automatically create a primary index. The privilege set must include the INDEX privilege on the table and the USE privilege on the buffer pool and the storage group. The implicitly created primary key index is owned by the owner of the base table.

The identified columns are defined as the primary key of the table. The description of the index is changed to indicate that it is a primary index. If the table has more than one unique index with a key that is identical to the primary key, the selection of the primary index is arbitrary.

**BUSINESS_TIME WITHOUT OVERLAPS**

BUSINESS_TIME WITHOUT OVERLAPS can be specified as the last item in the list. If BUSINESS_TIME WITHOUT OVERLAPS is specified, the list must include at least one column-name or key-expression. When WITHOUT OVERLAPS is specified, the values for the rest of the specified keys are unique with respect to the time for the BUSINESS_TIME period. When BUSINESS_TIME WITHOUT OVERLAPS is specified, the columns of the BUSINESS_TIME period must not be specified as part of the constraint.

The specification of BUSINESS_TIME WITHOUT OVERLAPS adds the following to the constraint:

- The end column of the BUSINESS_TIME period in ascending order
- The start column of the BUSINESS_TIME period in ascending order

**UNIQUE(column-name,...)**

Defines a unique key composed of the identified columns with the specified constraint-name. If a constraint-name is not specified, a name is generated. Each column name must be an unqualified name that identifies a column of the table. The same column must not be identified more than one time. The following types of columns cannot be specified in a UNIQUE clause:

- a LOB column
- a ROWID column
- a DECFLOAT column
- an XML column
- a distinct type column that is based on a LOB, ROWID, or DECFLOAT data type

Each identified column must be defined as NOT NULL. The number of identified columns must not exceed 64. In addition, the sum of the length attributes of the columns must not be greater than 2000 - \( n \) for padded indexes and 2000 - \( n \) - 2\( m \) for nonpadded indexes, where \( n \) is the number of columns that can contain null values and \( m \) is the number of varying-length columns in the key.

The set of columns in the unique key cannot be the same as the set of columns of the primary key or another unique key. A unique key is a duplicate if it is the same as the primary key or a previously defined unique key. The specification of a duplicate unique key is ignored with a warning.

The table must have a unique index with a key that is identical to the unique key. The keys are identical only if they have the same number of columns and the \( n \)th column name of one is the same as the \( n \)th column name of the other. If the table is in a table space that is implicitly created, and no unique index is defined on the identified columns, Db2 will automatically create a unique
index to enforce the unique key constraint. The privilege set must include the INDEX privilege on the table and the USE privilege on the buffer pool and the storage group. The implicitly created unique key index is owned by the owner of the base table.

The identified columns are defined as a unique key of the table. The description of the index is changed to indicate that it is enforcing a unique key constraint. If the table has more than one unique index with a key that is identical to the unique key, the selection of the enforcing index is arbitrary.

**BUSINESS_TIME WITHOUT OVERLAPS**

BUSINESS_TIME WITHOUT OVERLAPS can be specified as the last item in the list. If BUSINESS_TIME WITHOUT OVERLAPS is specified, the list must include at least one column-name or key-expression. When WITHOUT OVERLAPS is specified, the values for the rest of the specified keys are unique with respect to the time for the BUSINESS_TIME period. When BUSINESS_TIME WITHOUT OVERLAPS is specified, the columns of the BUSINESS_TIME period must not be specified as part of the constraint. The specification of BUSINESS_TIME WITHOUT OVERLAPS adds the following to the constraint:

- The end column of the BUSINESS_TIME period in ascending order
- The start column of the BUSINESS_TIME period in ascending order

**ADD referential-constraint:**

**CONSTRAINT constraint-name**

Names the referential constraint. If a constraint name is not specified, a unique constraint name is generated. If a name is specified, it must be different from the names of any referential, check, primary key, or unique key constraints previously specified on the table.

**FOREIGN KEY (column-name,...) references-clause**

Specifies a referential constraint with the specified constraint-name.

FOREIGN KEY cannot be specified if the table is a history table or an archive table.

Let T1 denote the object table of the ALTER TABLE statement. T1 is the child table for the referential constraint.

The foreign key of the referential constraint is composed of the identified columns and the columns of the BUSINESS_TIME period if the clause PERIOD BUSINESS_TIME is specified. Each column-name must be an unqualified name that identifies a column of T1. The same column must not be identified more than one time. If PERIOD BUSINESS_TIME is specified, the columns of the BUSINESS_TIME period must not be specified as part of the constraint. The following types of columns cannot be specified in the FOREIGN KEY clause:

- a LOB column
- a ROWID column
- a DECFLOAT column
- an XML column
- a distinct type column that is based on a LOB, ROWID, or DECFLOAT data type
- a security label column
- a row change timestamp column

The number of identified columns, and the columns of the BUSINESS_TIME period if the clause PERIOD BUSINESS_TIME is specified, must not exceed 64,
and the sum of their length attributes must not exceed 255 minus the number of columns that allow null values. The referential constraint is a duplicate if the FOREIGN KEY and the parent table are the same as the FOREIGN KEY and parent table of an existing referential constraint on T1. The specification of a duplicate referential constraint is ignored with a warning. An exception is that a duplicate referential constraint is not allowed if the definition of the constraint includes the PERIOD BUSINESS_TIME clause.

If PERIOD BUSINESS_TIME is specified in the FOREIGN KEY clause, then PERIOD BUSINESS_TIME must also be specified in the REFERENCES clause. If PERIOD BUSINESS_TIME is not specified in the FOREIGN KEY clause, then PERIOD BUSINESS_TIME must also not be specified in the REFERENCES clause.

If PERIOD BUSINESS_TIME is specified in the FOREIGN KEY clause, then the semantic for the BUSINESS_TIME period in both the parent and child tables must be the same.

The foreign key of the referential constraint cannot reference a parent key that contains BUSINESS_TIME WITHOUT OVERLAPS.

REFERENCES table-name (column-name,...)

The table name specified after REFERENCES is the parent table for the referential constraint. The table-name value must identify a table that exists at the current server. This table is referred to as the parent table in the constraint relationship.

Table-name must not identify:

- A catalog table
- A directory table
- A declared global temporary table
- A history table
- An archive table

Let T2 denote the identified parent table and let T1 denote the table that is being changed (T1 and T2 can be the same table).

T2 must have a unique index. The privilege set on T2 must include the ALTER or REFERENCES privilege on the parent table, or the REFERENCES privilege on the columns of the nominated parent key, including the columns of the BUSINESS_TIME period if the PERIOD BUSINESS_TIME clause is specified.

The parent key of the referential constraint is composed of the identified columns, or columns of the BUSINESS_TIME period if PERIOD BUSINESS_TIME is specified. Each column-name must be an unqualified name that identifies a column of T2. The same column must not be identified more than one time. If PERIOD BUSINESS_TIME is specified, the columns of the BUSINESS_TIME period must not be specified as part of the constraint. The following types of columns cannot be specified in a REFERENCES clause:

- a LOB column
- a ROWID column
- a DECFLOAT column
- an XML column
- a distinct type column that is based on a LOB, ROWID, or DECFLOAT data type
- a security label column
- a row change timestamp column
The list of column names in the parent key must match the list of column names in a primary key or unique key in the parent table T2. The column names must be specified in the same order as in the primary key or unique key. If PERIOD BUSINESS_TIME was specified for the primary key or unique key of the parent table T2, then PERIOD BUSINESS_TIME must also be specified for the foreign key clause for T1. If any of the referenced columns in T2 has a non-numeric data type, T2 and T1 must use the same encoding scheme, unless T2 is a Unicode table, and T1 is an EBCDIC table with Unicode key columns. In that case, for each character or graphic string column in T1, the CCSID must be the same as the corresponding column in T2.

If a list of column names is not specified, then T2 must have a primary key. Omission of a list of column names is an implicit specification of the columns of the primary key for T2.

The specified foreign key must have the same number of columns as the parent key of T2 and, except for their names, default values, null attributes and check constraints, the description of the nth column of the foreign key must be identical to the description of the nth column of the nominated parent key. If the foreign key includes a column defined as a distinct type, the corresponding column of the nominated parent key must be the same distinct type. If a column of the foreign key has a field procedure, the corresponding column of the nominated parent key must have the same field procedure and an identical field description. A field description is a description of the encoded value as it is stored in the database for a column that has been defined to have an associated field procedure.

The table space that contains T1 must be available to Db2. If T1 is populated, its table space is placed in a check pending status. A table in a segmented table space is populated if the table is not empty. A table in a table space that is not segmented is considered populated if the table space has ever contained any records.

The referential constraint specified by the FOREIGN KEY clause defines a relationship in which T2 is the parent and T1 is the dependent. A description of the referential constraint is recorded in the catalog.

**PERIOD BUSINESS_TIME**

Specifies that the BUSINESS_TIME period is considered part of the referential constraint. When PERIOD BUSINESS_TIME is specified, the values for the rest of the specified columns are unique with respect to the specified point of time.

PERIOD BUSINESS_TIME can be specified as the last key expression. If PERIOD BUSINESS_TIME is not the last key expression, an error is returned. If PERIOD BUSINESS_TIME is specified, the columns of the BUSINESS_TIME period must not be specified as part of the constraint.

When PERIOD BUSINESS_TIME is specified, the following columns are implicitly added to the end of the constraint:

- The end column of the BUSINESS_TIME period.
- The start column of the BUSINESS_TIME period.

The PERIOD BUSINESS_TIME clause specifies that there must not be a row in the child table for which the period of time represented by the BUSINESS_TIME period values for that row is not contained in the BUSINESS_TIME period of a corresponding row in the parent table. Furthermore, it is not necessary that there be exactly one corresponding row in the parent table where the BUSINESS_TIME period contains the BUSINESS_TIME period of the child row. As long as the BUSINESS_TIME
period of a row in the child table is contained in the union of the
BUSINESS_TIME periods of two or more contiguous matching rows in the
parent table, the referential constraint is considered satisfied.

When the FOREIGN KEY clause specifies the PERIOD BUSINESS_TIME clause,
the following conditions apply:

- The corresponding REFERENCES clause must also specify the PERIOD
  BUSINESS_TIME clause.
- A unique index with the BUSINESS_TIME WITHOUT OVERLAPS clause
  must be defined on the table. The table is marked as unavailable until the
  index is created.
- A unique index must be defined on the parent table with the
  BUSINESS_TIME WITHOUT OVERLAPS clause.

ON DELETE RESTRICT must be specified when PERIOD BUSINESS_TIME is
also specified.

ON DELETE

The delete rule of the relationship is determined by the ON DELETE clause.
 For more on the concepts used here, see "Referential constraints" on page 12.

If T1 and T2 are the same table, CASCADE or NO ACTION must be specified.
SET NULL must not be specified unless some column of the foreign key allows
null values. Also, SET NULL must not be specified if any nullable column of
the foreign key is a column of the key of a partitioning index. The default
value for the rule depends on the value of the CURRENT RULES special
register when the ALTER TABLE statement is processed. If the value of the
register is 'Db2', the delete rule defaults to RESTRICT; if the value is 'SQL', the
delete rule defaults to NO ACTION.

The delete rule applies when a row of T2 is the object of a DELETE or
propagated delete operation and that row has dependents in T1. Let p denote
such a row of T2.

- If RESTRICT or NO ACTION is specified, an error occurs and no rows are
deleted.
- If CASCADE is specified, the delete operation is propagated to the
  dependents of p in T1.
- If SET NULL is specified, each nullable column of the foreign key of each
  dependent of p in T1 is set to null.

A cycle involving two or more tables must not cause a table to be
delete-connected to itself. Thus, if the relationship would form a cycle:

- The referential constraint cannot be defined if each of the existing
  relationships that would be part of the cycle have a delete rule of
  CASCADE.
- CASCADE must not be specified if T2 is delete-connected to T1.

If T1 is delete-connected to T2 through multiple paths, those relationships in
which T1 is a dependent and which form all or part of those paths must have
the same delete rule and it must not be SET NULL. For example, assume that
T1 is a dependent of T3 in a relationship with a delete rule of r and that one of
the following is true:

- T2 and T3 are the same table.
- T2 is a descendent of T3 and the deletion of rows from T3 cascades to T2.
- T2 and T3 are both descendents of the same table and the deletion of rows
  from that table cascades to both T2 and T3.
In this case, the referential constraint cannot be defined when \( r \) is SET NULL. When \( r \) is other than SET NULL, the referential constraint can be defined, but the delete rule that is implicitly or explicitly specified in the FOREIGN KEY clause must be the same as \( r \).

**ENFORCED or NOT ENFORCED**

Indicates whether or not the referential constraint is enforced by Db2 during normal operations, such as insert, update, or delete.

**ENFORCED**

Specifies that the referential constraint is enforced by Db2 during normal operations (such as data change operations) and that it is guaranteed to be correct. ENFORCED is the default.

**NOT ENFORCED**

Specifies that the referential constraint is not enforced by Db2 during normal operations (such as data change operations). NOT ENFORCED should only be used when the data that is stored in the table is verified to conform to the constraint by some other method than relying on Db2.

**ENABLE QUERY OPTIMIZATION**

Specifies that the constraint can be used for query optimization. Db2 uses the information in query optimization using materialized query tables with the assumption that the constraint is correct. This is the default.

**ADD check-constraint:**

**CONSTRAINT**  \( \text{constraint-name} \)

Names the check constraint. If \( \text{constraint-name} \) is not specified, a unique constraint name is derived from the name of the first column in the \( \text{check-condition} \) specified in the definition of the check constraint. If a name is specified, it must be different from the names of any referential, check, primary key, or unique key constraints previously specified on the table.

**CHECK**  \( \text{check-condition} \)

Defines a check constraint. At any time, \( \text{check-condition} \) must be true or unknown for every row of the table. A \( \text{check-condition} \) can evaluate to unknown if a column that is an operand of the predicate is null. A \( \text{check-condition} \) that evaluates to unknown does not violate the check constraint. A \( \text{check-condition} \) is a search condition, with the following restrictions:

- It can refer only to the columns of table \( \text{table-name} \).
- The columns cannot be any of the following types of columns:
  - LOB columns
  - ROWID columns
  - DECFLOAT columns
  - XML columns
  - distinct type columns that are based on LOB, ROWID, and DECFLOAT data types
  - security label columns
- It must not result in CCSID conversion.
- It can be up to 7400 bytes long, not including redundant blanks.
- It must not contain any of the following:
  - Subselects
  - Built-in or user-defined functions
  - CAST specifications
- Cast functions other than those created when the distinct type was created
- Host variables
- Global variables
- Parameter markers
- Special registers
- Columns that include a field procedure
- CASE expressions
- ROW CHANGE expressions
- Row expressions
- DISTINCT predicates
- GX constants (hexadecimal graphic string constants)
- Sequence references
- OLAP specifications

- If a check-condition refers to a LOB column (including a distinct type that is based on a LOB), the reference must occur within a LIKE predicate.
- The AND and OR logical operators can be used between predicates. The NOT logical operator cannot be used.
- The first operand of every predicate must be the column name of a column in the table.
- The second operand in the check-condition must be either a constant or a column name of a column in the table.
  - If the second operand of a predicate is a constant, and if the constant is:
    - A floating-point number, then the column data type must be floating point.
    - A decimal number, then the column data type must be either floating point or decimal.
    - A big integer number, then the column data type must not be an integer or a small integer
    - An integer number, then the column data type must not be a small integer.
    - A small integer number, then the column data type must be small integer.
    - A decimal constant, then its precision must not be larger than the precision of the column.
  - If the second operand of a predicate is a column, then both columns of the predicate must have:
    - The same data type
    - Identical descriptions with the exception that the specification of the NOT NULL and DEFAULT clauses for the columns can be different, and that string columns with the same data type can have different length attributes

**Effects of defining a check constraint on a populated table:** When a check constraint is defined on a populated table and the value of the special register CURRENT RULES is 'Db2', the check constraint is not immediately enforced on the table. The check constraint is added to the description of the table, and the table space that contains the table is placed in a check pending status. For a description of the check pending status and the implications for utility operations, see [CHECK-pending status (Db2 Utilities)](#)

When a check constraint is defined on a populated table and the value of the special register CURRENT RULES is 'STD', the check constraint is checked against all rows of the table. If no violations occur, the check constraint is added to the table. If any rows violate the new check constraint, an error occurs and the description of the table is unchanged.
DROP constraint:

DROP PRIMARY KEY
Drops the definition of the primary key and all referential constraints in which the primary key is a parent key. The table must have a primary key and the privilege set must include the ALTER or REFERENCES privilege on every dependent table of the table.

The description of the primary index is changed to indicate that it is not a primary index. If the table space was implicitly created, the corresponding enforcing index is dropped if the primary key is dropped.

DROP UNIQUE constraint-name
Drops the definition of the unique key constraint and all referential constraints in which the unique key is a parent key. The table must have a unique key. The privilege set must include the ALTER or REFERENCES privilege on every dependent table of the table. The description of the enforcing index is changed to indicate that it is not enforcing a unique key constraint. If the table space is implicitly created, the corresponding enforcing index is dropped if the unique key is dropped.

DROP FOREIGN KEY constraint-name
Drops the referential constraint constraint-name. The constraint-name must identify a referential constraint in which the table is the dependent table, and the privilege set must include the ALTER or REFERENCES privilege on the parent table of that relationship, or the REFERENCES privilege on the columns of the parent table of that relationship.

DROP CHECK constraint-name
Drops the check constraint constraint-name. The constraint-name must identify an existing check constraint defined on the table.

DROP CONSTRAINT constraint-name
Drops the constraint constraint-name. The constraint-name must identify an existing primary key, unique key, check, or referential constraint defined on the table.

DROP CONSTRAINT must not be used on the same ALTER TABLE statement as DROP PRIMARY KEY, DROP UNIQUE KEY, DROP FOREIGN KEY or DROP CHECK.

ADD partitioning:

ADD PARTITION BY RANGE
Specifies the range partitioning scheme for the table (the columns used to partition the data). When this clause is specified, the table uses table-controlled partitioning. The number of partitions specified in the ADD PARTITION BY RANGE clause has to be the same as the number of partitions defined in the table space.

This clause applies only to tables in a partitioned table space. If the table is already complete by having established either table-controlled partitioning or index-controlled partitioning, the ADD PARTITION BY RANGE clause is not allowed. If this clause is used, then the ENDING AT clause cannot be used on a subsequent CREATE INDEX statement for this table.

The high limit key for the last partition is set to the highest possible value for ascending key columns or the lowest possible value for descending key columns. Db2 enforces the high limit key for table-controlled partitioning, so any existing key values that are greater than the high limit key are placed into the discard data set when REORG is run.
**partition-expression**

Specifies the key data over which the range is defined to determine the target data partition of the data.

**column-name**

Specifies the columns of the key. Each column-name must identify a column of the table. Do not specify more than 64 columns, the same column more than one time, a qualified column name, or any of the following types of columns:

- a BINARY or VARBINARY column
- a LOB column
- a DECIMAL column
- an XML column
- a column with a distinct type that is based on any of the preceding data types

All character and graphic string columns in the key must use the same encoding scheme.

The sum of length attributes of the columns must not be greater than 255 - n, where n is the number of columns that can contain null values.

A timestamp with time zone column (or a column with a distinct type that is based on the timestamp with time zone data type) can only be specified as the last column in a partitioning key.

**NULLS LAST**

Specifies that null values are treated as positive infinity for purposes of comparison.

**ASC**

Puts the entries in ascending order by the column. ASC is the default.

**DESC**

Puts the entries in descending order by the column.

**partition-element**

Specifies ranges for a data partitioning key and the table space where rows of the table in the range will be stored.

**PARTITION integer**

Specifies a number of a physical partition in the table space. A PARTITION clause must be specified for every partition of the table space. In the context, highest means highest in the sorting sequence of the columns. In a column that is defined as ascending (ASC), highest and lowest have the usual meanings. In a column that is defined as descending (DESC), the lowest actual value is the highest in the sorting sequence.

**ENDING AT (constant, MAXVALUE, or MINVALUE...)**

Specifies the limit key for a partition boundary. Specify at least one value (constant, MAXVALUE, or MINVALUE) after ENDING AT in each PARTITION clause. You can use as many values as there are columns in the key. The concatenation of all the values is the highest value of the key for ascending and the lowest for descending.

**constant**

Specifies a constant value with a data type that must conform to the rules for assigning that value to the column. If a string constant is longer or shorter than required by the length attribute of its
column, the constant is either truncated or padded on the right to
the required length. If the column is ascending, the padding
character is X'FF'. If the column is descending, the padding
character is X'00'. The precision and scale of a decimal constant
must not be greater than the precision and scale of its
corresponding column. A hexadecimal string constant (GX) cannot
be specified.

MAXVALUE
Specifies a value greater than the maximum value for the limit key
of a partition boundary (that is, all X'FF' regardless of whether the
column is ascending or descending). If all of the columns in the
partitioning key are ascending, a constant or the MINVALUE
clause cannot be specified following MAXVALUE. After
MAXVALUE is specified, all subsequent columns must specify
MAXVALUE.

MINVALUE
Specifies a value that is smaller than the minimum value for the
limit key of a partition boundary (that is, all X'00' regardless of
whether the column is ascending or descending). If all of the
columns in the partitioning key are descending, a constant or the
MAXVALUE clause cannot be specified following MINVALUE.
After MINVALUE is specified, all subsequent columns must be
MINVALUE.

The key values are subject to the following rules:

• The first value corresponds to the first column of the key, the second
 value to the second column, and so on. Using fewer values than
 there are columns in the key has the same effect as using the highest
 or lowest values for the omitted columns, depending on whether
 they are ascending or descending.

• The highest value of the key in any partition must be lower than the
 highest value of the key in the next partition.

• The values specified for the last partition are enforced. The value
 specified for the last partition is the highest value of the key that can
 be placed in the table. If the limit was not previously enforced, any
 existing key values that are greater than the value that is specified
 for the added partition are placed into the discard data set when
 REORG is run.

• If a key includes a ROWID column or a column with a distinct type
 that is based on a ROWID data type, 17 bytes of the constant that is
 specified for the corresponding ROWID column are considered.

• The combination of the number of table space partitions and the
 corresponding limit key size cannot exceed the number of partitions
 \* (106 + limit key size in bytes) < 65394

• If the concatenation of all the values exceeds 255 bytes, only the first
 255 bytes are considered.

INCLUSIVE
Specifies that the specified range values are included in the data
partition.

ADD PARTITION:
ADD PARTITION
Specifies that a partition is added to the table and each partitioned index on
the table. A partition can be added as the last logical partition of any
partitioned table space. Partitions can also be added between existing logical
partitions in partition-by-range table spaces. The new partition is the next
physical partition not being used until the maximum for the table space has
been reached. ADD PARTITION must not be specified for nonpartitioned
tables. Adding a partition is not allowed if the table is a materialized query
table, or if a materialized query table is defined on the table. However, adding
a partition is allowed if an accelerated query table is defined on the table.

Adding a partition as the last logical partition of a table specifies that a
partition is added to the table and each partitioned index on the table. A
partition added as the last logical partition is always an immediate definition
change. A partition cannot be added if the table space definition is incomplete
because a partitioning key or partitioning index is missing. If the table uses
index-controlled partitioning, it is converted to use table-controlled
partitioning. In addition, adding a partition to the end of the table is not
allowed if there are any outstanding pending definition changes on the
partitions.

Adding a partition between existing logical partitions is supported only for
partition-by-range table spaces. A partition added between existing logical
partitions is a pending definition change if the data sets are already defined.
Otherwise, the change is immediate. When inserting a new partition between
existing partitions, the following rules apply:

- If ADD PARTITION ENDING with the optional ALTER PARTITION clause
  is used to add a new partition between existing partitions, the ALTER
  PARTITION clause must specify the very next logical partition to the
  partition being added. The high limit key value specified in the ALTER
  PARTITION clause must be the existing high limit key value for the very
  next logical partition. The high limit key value cannot be altered in the same
  statement when inserting a new partition.

- Any pending definition changes for the high limit key of the last logical
  partition must be materialized before a partition can be added between
  existing partitions in the same table.

- After a new partition is added between existing partitions of a table, altering
  the limit key is not allowed for any partition in the same table until the
  newly inserted partition is materialized by a REORG execution.

- A partition cannot be inserted on any table that contains a LOB column, or a
  distinct type column that is based on a LOB data type.

- A partition cannot be inserted on any table that contains an XML column.

If the table is in a partition-by-growth table space, a new partition can be
added until the number of partitions reaches the MAXPARTITIONS limit. The
total number of table space partitions cannot exceed the value that is specified
for MAXPARTITIONS for the table space.

The default DSSIZE is determined by the value in SYSIBM.SYSTABLESPACE
catalog table. The maximum number of partitions allowed is shown in the
following table.

Table 177. Maximum number of partitions allowed

<table>
<thead>
<tr>
<th>DSSIZE</th>
<th>Page size 4 KB</th>
<th>Page size 8 KB</th>
<th>Page size 16 KB</th>
<th>Page size 32 KB</th>
</tr>
</thead>
<tbody>
<tr>
<td>1GB-4GB</td>
<td>4096</td>
<td>4096</td>
<td>4096</td>
<td>4096</td>
</tr>
<tr>
<td>8GB</td>
<td>2048</td>
<td>4096</td>
<td>4096</td>
<td>4096</td>
</tr>
</tbody>
</table>
Table 177. Maximum number of partitions allowed (continued)

<table>
<thead>

<td>512</td>
</tr>
</tbody>
</table>

If LARGE was specified when the table space was created, the maximum number of partitions is shown in the fourth row of Table 178. For more than 254 partitions when LARGE or DSSIZE is not specified, the maximum number of partitions is determined by the page size of the table space.

Table 178. Maximum number of partitions when DSSIZE = 0

<table>
<thead>
<tr>
<th>Type of table space</th>
<th>Number of existing partitions</th>

</tr>
</tbody>
</table>

The attributes of the new partition are inherited or calculated. The sources of inherited values might differ based on factors such as where the new partition is added, and whether the table space was migrated from a previous release. Generally, for partitions added after the last logical partition, most attribute values are inherited from the last logical partition. However, some attributes are inherited from the table space. For partitions added between existing logical partitions, most attribute values are inherited from the table space, but they might also be inherited from the last logical partition. If it is necessary to change specific attributes for the new partition, you must issue separate ALTER TABLESPACE and ALTER INDEX statements after adding the partition.

If the table uses index-controlled partitioning, it is converted to use table-controlled partitioning. Db2 enforces the high limit key for table-controlled partitioning, so any existing key values that are greater than the high limit key are placed into the discard data set when REORG is run.

HASH SPACE cannot be specified with ADD PARTITION. For partition-by-growth table spaces, the hash space value is not applicable at the partition level.

**ENDING AT (constant, MAXVALUE, or MINVALUE, ...)**

Specifies the high key limit for the new partition.

Specify at least one value after ENDING AT in the PARTITION clause. You can specify as many values as there are columns in the key. The concatenation of all the values is the highest value of the key in the corresponding partition of the index. ENDING AT cannot be specified for a table in a partition-by-growth table space, but must be specified if the table is in a partition-by-range table space.

**constant**

Specifies a constant value with a data type that must conform to the rules for assigning that value to the column. If a string constant is longer or
shorter than required by the length attribute of its column, the constant is either truncated or padded on the right to the required length. If the column is ascending, the padding character is X'FF'. If the column is descending, the padding character is X'00'. The precision and scale of a decimal constant must not be greater than the precision and scale of its corresponding column. A hexadecimal string constant (GX) cannot be specified.

**MAXVALUE**

Specifies a value greater than the maximum value for the limit key of a partition boundary (that is, all X'FF' regardless of whether the column is ascending or descending). If all of the columns in the partitioning key are ascending, a constant or the MINVALUE clause cannot be specified following MAXVALUE. After MAXVALUE is specified, all subsequent columns must specify MAXVALUE.

**MINVALUE**

Specifies a value that is smaller than the minimum value for the limit key of a partition boundary (that is, all X'00' regardless of whether the column is ascending or descending). If all of the columns in the partitioning key are descending, a constant or the MAXVALUE clause cannot be specified following MINVALUE. After MINVALUE is specified, all subsequent columns must be MINVALUE.

The key values are subject to the following rules:

- The first value corresponds to the first column of the key, the second value to the second column, and so on. Using fewer values than there are columns in the key has the same effect as using the highest or lowest values for the omitted columns, depending on whether they are ascending or descending.

- The highest value of the key in any partition must be lower than the highest value of the key in the next partition.

- The values specified for the last partition are enforced. The value specified for the last partition is the highest value of the key that can be placed in the table. If the limit was not previously enforced, any existing key values that are greater than the value that is specified for the added partition are placed into the discard data set when REORG is run.

- If a key includes a ROWID column or a column with a distinct type that is based on a ROWID data type, 17 bytes of the constant that is specified for the corresponding ROWID column are considered.

- The combination of the number of table space partitions and the corresponding limit key size cannot exceed the number of partitions * (106 + limit key size in bytes) < 65394

- If the concatenation of all the values exceeds 255 bytes, only the first 255 bytes are considered.

**INCLUSIVE**

Specifies that the specified range values are included in the data partition.

**partition-hash-space**

See [partition-hash-space](#).

Be aware that specifying the ADD PARTITION clause might affect subsequent requests to recover to a point in time. See [Point-in-time recovery (Db2 Utilities)](# for information about possible restrictions, effects on recovery status, and other considerations.
ALTER PARTITION:

ALTER PARTITION

Specifies that the partitioning limit key for the identified partition is to be changed.

This clause applies only to tables in a partitioned table space. ALTER PARTITION must not be specified for a table in a partition-by-growth table space or for tables that have XML columns. If there are any pending definition changes to insert a new partition in the middle of the table for a partition-by-range table space, altering the limit key is not allowed for any partition in the same table until the newly inserted partition is materialized by a REORG execution.

If the table uses index-controlled partitioning, it is converted to use table-controlled partitioning. The high limit key for the last partition is set to the highest possible value for ascending key columns or the lowest possible value for descending key columns. The alteration is immediate and the altered partition is placed in REORG-pending (REORP) status. If the altered partition is not the last logical partition, the next logical partition is also placed in REORP (REORP) status.

integer

Identifies the physical partition number in the range 1 - n, where n is the number of partitions in the table. integer is the physical partition number.

If the following conditions are met, the changes are immediate and the partitions are not placed in any pending state:

• The alteration does not discard or move any data between partitions
• No other pending definition change exists on the identified partition
• No pending definition changes exist on the previous logical partition if the range of data for the identified partition is decreased, or on the next logical partition if the range of data is increased.

If the following conditions are met, the changes are immediate and the partition is placed in REORG-pending (REORP) status:

• integer identifies the last logical partition
• The alteration results in discarded data
• No other pending definition change exists on the identified partition or the previous logical partition
• The values in the limit key for the last logical partition are all altered from MAXVALUE to a value less than MAXVALUE, or from MINVALUE to a value greater than MINVALUE

Otherwise, the changes are pending and the altered partition is placed in advisory REORG-pending (AREOR) status. If the altered partition is not the last logical partition, the next logical partition is also placed in AREOR status.

ENDING AT (constant, MAXVALUE, or MINVALUE...)

Specifies the highest value of the partitioning key for the identified partition.

In this context, highest means highest in the sorting sequences of the columns. In a column defined as ascending (ASC), highest and lowest have their usual meanings. In a column defined as descending (DESC) the lowest actual value is highest in the sorting sequence.
Specify at least one value after ENDING AT in each ALTER PARTITION clause. You can use as many values as there are columns in the key. The concatenation of all the values is the highest value of the key in the corresponding partition. The length of each highest key value (the limit key) is the same as the length of the partitioning key.

**constant**

Specifies a constant value with a data type that must conform to the rules for assigning that value to the column. If a string constant is longer or shorter than required by the length attribute of its column, the constant is either truncated or padded on the right to the required length. If the column is ascending, the padding character is X'FF'. If the column is descending, the padding character is X'00'. The precision and scale of a decimal constant must not be greater than the precision and scale of its corresponding column. A hexadecimal string constant (GX) cannot be specified.

**MAXVALUE**

Specifies a value greater than the maximum value for the limit key of a partition boundary (that is, all X'FF' regardless of whether the column is ascending or descending). If all of the columns in the partitioning key are ascending, a constant or the MINVALUE clause cannot be specified following MAXVALUE. After MAXVALUE is specified, all subsequent columns must specify MAXVALUE.

**MINVALUE**

Specifies a value that is smaller than the minimum value for the limit key of a partition boundary (that is, all X'00' regardless of whether the column is ascending or descending). If all of the columns in the partitioning key are descending, a constant or the MAXVALUE clause cannot be specified following MINVALUE. After MINVALUE is specified, all subsequent columns must be MINVALUE.

The key values are subject to the following rules:

- The first value corresponds to the first column of the key, the second value to the second column, and so on. Using fewer values than there are columns in the key has the same effect as using the highest or lowest values for the omitted columns, depending on whether they are ascending or descending.
- The highest value of the key in any partition must be lower than the highest value of the key in the next partition.
- The values specified for the last partition are enforced. The value specified for the last partition is the highest value of the key that can be placed in the table. If the limit was not previously enforced, any existing key values that are greater than the value that is specified for the added partition are placed into the discard data set when REORG is run.
- If a key includes a ROWID column or a column with a distinct type that is based on a ROWID data type, 17 bytes of the constant that is specified for the corresponding ROWID column are considered.
- The combination of the number of table space partitions and the corresponding limit key size cannot exceed the number of partitions * (106 + limit key size in bytes) < 65394
- If the concatenation of all the values exceeds 255 bytes, only the first 255 bytes are considered.

The value that is specified must not be equal to or beyond the range of the partition boundaries of the adjacent partitions.
INCLUSIVE
Specifies that the specified range values are included in the data partition.

partition-hash-space
See partition-hash-space.

Be aware that specifying the ALTER PARTITION clause might affect subsequent requests to recover to a point in time. See Point-in-time recovery (Db2 Utilities) for information about possible restrictions, effects on recovery status, and other considerations.

ROTATE PARTITION:

ROTATE PARTITION FIRST or integer TO LAST
 Specifies that the first logical partition or the physical partition that corresponds to integer is to be rotated to become the last partition. Processing resets the specified partition to empty, and the limit key that is associated with the partition is set to the constant that is specified with the boundary specification clause. For ascending limit keys, the new limit key must be higher than the limit key for the preexisting last logical partition prior to this statement being processed. For descending limit keys, the new limit must be lower than the limit for the preexisting last logical partition prior to this statement being processed.

The table definition must be complete and must contain more than one partition. This clause must be followed by the ENDING AT clause, which specifies the new high key limit for this partition, which is now logically last.

Rotating a partition occurs immediately. If there is a referential constraint with DELETE RESTRICT on the table, the ROTATE might fail. If the table uses index-controlled partitioning, it is converted to use table-controlled partitioning.

After an ALTER TABLE statement with the ROTATE PARTITION clause is run, the RUNSTATS utility or the REORG utility with the STATISTICS option should be run on the table space to ensure effective access paths are available for selection.

If the table has a security label column, the user must have a valid security label to rotate partitions. In addition, if write-down is in effect, the user must have the write-down privilege.

ROTATE PARTITION must not be specified in the following situations:
• The table is in a partition-by-growth table space.
• The table has XML columns.
• The table is a system-period temporal table or a history table.
• The table is an archive-enabled table or an archive table.

Adding a partition is allowed if an accelerated query table is defined on the table.

If the table uses index-controlled partitioning, it is converted to use table-controlled partitioning. Db2 enforces the high limit key for table-controlled partitioning, so any existing key values that are greater than the high limit key are placed into the discard data set when REORG is run.

integer
Specifies a positive integer that represents a physical partition number as identified by the PARTITION column of the SYSIBM.SYSTABLEPART catalog.
The partition must be a data partition that exists in the table. The partition cannot be the last partition of the table.

**ENDING AT (constant, MAXVALUE, or MINVALUE...)**

The ENDING AT clause specifies the new high key limit for the existing partition holding the oldest data.

In this context, highest means highest in the sorting sequences of the columns. In a column defined as ascending (ASC), highest and lowest have their usual meanings. In a column defined as descending (DESC) the lowest actual value is highest in the sorting sequence.

Specify at least one value after ENDING AT. You can use as many values as there are columns in the key. The concatenation of all the values is the highest value of the key in the corresponding partition. The length of each highest key value (the limit key) is the same as the length of the partitioning key.

*constant*

Specifies a constant value with a data type that must conform to the rules for assigning that value to the column. If a string constant is longer or shorter than required by the length attribute of its column, the constant is either truncated or padded on the right to the required length. If the column is ascending, the padding character is X'FF'. If the column is descending, the padding character is X'00'. The precision and scale of a decimal constant must not be greater than the precision and scale of its corresponding column. A hexadecimal string constant (GX) cannot be specified.

**MAXVALUE**

Specifies a value greater than the maximum value for the limit key of a partition boundary (that is, all X'FF' regardless of whether the column is ascending or descending). If all of the columns in the partitioning key are ascending, a constant or the MINVALUE clause cannot be specified following MAXVALUE. After MAXVALUE is specified, all subsequent columns must specify MAXVALUE.

**MINVALUE**

Specifies a value that is smaller than the minimum value for the limit key of a partition boundary (that is, all X'00' regardless of whether the column is ascending or descending). If all of the columns in the partitioning key are descending, a constant or the MAXVALUE clause cannot be specified following MINVALUE. After MINVALUE is specified, all subsequent columns must be MINVALUE.

The key values are subject to the following rules:

- The first value corresponds to the first column of the key, the second value to the second column, and so on. Using fewer values than there are columns in the key has the same effect as using the highest or lowest values for the omitted columns, depending on whether they are ascending or descending.

- The highest value of the key in any partition must be lower than the highest value of the key in the next partition.

- The values specified for the last partition are enforced. The value specified for the last partition is the highest value of the key that can be placed in the table. If the limit was not previously enforced, any existing key values that are greater than the value that is specified for the added partition are placed into the discard data set when REORG is run.
• If a key includes a ROWID column or a column with a distinct type that is based on a ROWID data type, 17 bytes of the constant that is specified for the corresponding ROWID column are considered.

• The combination of the number of table space partitions and the corresponding limit key size cannot exceed the number of partitions * (106 + limit key size in bytes) < 65394

• If the concatenation of all the values exceeds 255 bytes, only the first 255 bytes are considered.

INCLUSIVE
Specifies that the specified range values are included in the data partition.

RESET
Specifies that the existing data in the first logical partition is deleted. Also, the key entries from the associated physical and logical index partitions are deleted. In a partitioned table with limit values that are in ascending sequence, ALTER TABLE ROTATE PARTITION FIRST TO LAST logically operates as if the partition with the lowest high key limit were dropped and then a new partition was added with the specified high key limit. The new key limit for the partition must be higher than any other partition in the table. For descending limit keys, the rotation operates as the partition with the highest limit values becomes the partition with the lowest limit values.

If the partition contains any of the following attributes, each data row in the partition must be deleted individually:
• Referential integrity parent relationships
• DATA CAPTURE logging enabled
• Delete row triggers

If the table resides in a partition-by-range table space and does not have any of the previous attribute, the data rows can be removed using mass delete processing (individual data rows are neither touched nor logged).

Be aware that specifying the ROTATE PARTITION clause might affect subsequent requests to recover to a point in time. See Point-in-time recovery (Db2 Utilities) for information about possible restrictions, effects on recovery status, and other considerations.

DROP ORGANIZATION:

DROP ORGANIZATION
Specifies that the data organization definition for the table is dropped. The entire table becomes inaccessible and is placed in REORG-pending status. REORG must be run to make the table accessible. If the table is in a partition by range universal table space, the entire table space must be reorganized at one time.

If any type of clustering is required, you must create the clustering index or add the MEMBER CLUSTER clause to the table.

After the next time the REORG utility is run, the hash space value will be cleared and the implicitly created hash overflow index will be dropped.

DROP ORGANIZATION must only be specified for has-organized tables.

Use of this clause or keyword might invalidate packages that depend on the target object, or packages that depend on related objects through cascading effects. See Changes that invalidate packages (Db2 Application programming and SQL)
ADD ORGANIZE BY HASH or ALTER ORGANIZATION:

Deprecated function: [FL 504] Hash-organized tables are deprecated. Beginning in Db2 12, packages bound with APPLCOMPAT(V12R1M504) or higher cannot create hash-organized tables or alter existing tables to use hash-organization. Existing hash organized tables remain supported, but they are likely to be unsupported in the future.

For information, see hash-organization

ADD VERSIONING:

ADD VERSIONING

Specifies that the table is a system-period temporal table.

The table must not already be defined as a system-period temporal table, a history table, an archive-enabled table, or an archive table.

A SYSTEM_TIME period and a transaction-start-ID column must be defined for the table. The data type, length, precision, and scale for a transaction-start-ID column must be defined the same as the row-begin column and row-end column of the SYSTEM_TIME period in the table. The table must be the only table in the table space. The table must not be a materialized query table, an incomplete table, an auxiliary table, a table that is involved in a clone relationship, a table that was implicitly created for an XML column, or a table that contains a security label column. ADD VERSIONING must not be specified with other clauses on the ALTER TABLE statement.

The privilege set must include the privileges to issue an ALTER TABLE statement for the associated history table.

Historical versions of the rows in the table are retained by Db2. A system-period temporal table contains extra information that indicates when a row is inserted into the table, and when it is updated or deleted. An associated history table is used to store the historical rows of the table. When data in the system-period temporal table is updated, the previous version of the row is kept in the associated history table. When data in a system-period temporal table is deleted, the last version of the row is inserted into the history table.

References to the table can include a period clause to indicate which versions of the data are returned.

Use of this clause or keyword might invalidate packages that depend on the target object, or packages that depend on related objects through cascading effects. See Changes that invalidate packages (Db2 Application programming and SQL).

USE HISTORY TABLE history-table-name

Specifies a history table in which to keep the historical rows of the system-period temporal table.

If the history table contains data, ensure that the data accurately represents historical rows. If the data does not accurately represent historical rows, the results of temporal queries might be unexpected.

history-table-name must identify a table that exists at the current server and must not identify one of the following tables:

- A catalog table.
• A system-period temporal table. The table was defined as a system-period temporal table by a previous statement, or the current statement defines the table as a system-period temporal table.
• An existing history table.
• An archive-enabled table.
• An archive table.
• A declared global temporary table.
• A created global temporary table.
• A materialized query table.
• A view.
• An auxiliary table.
• A table that was implicitly created for an XML column.
• A table that is involved in a clone relationship.

The history table must be the only table in the table space.

**Restrictions:**

• The history table must not contain any of the following columns:
  • Identity column
  • Row change timestamp column
  • Row-begin column
  • Row-end column
  • Transaction-start-ID column
  • Generated expression column
  • Column mask
  • Security label column.
• The history table must not include a period.
• The history table must not have an incomplete table definition.
• A row permission must not be defined for the history table.

The encoding scheme and CCSID for the system-period temporal table and identified history table must be the same.

The system-period temporal table and the identified history table must have the same number and order of columns. The following attributes of the corresponding columns of the two tables must be the same:
• name
• data type
• length (excluding inline LOB length), precision, and scale
• subtype and CCSID
• null attribute
• hidden attribute
• field procedure

If a column of the system-period temporal table is defined as ROWID GENERATED ALWAYS, the corresponding history column should be defined as ROWID GENERATED ALWAYS.

If a column of the system-period temporal table is defined as GENERATED ALWAYS FOR EACH ROW ON UPDATE OF ROW CHANGE TIMESTAMP or
GENERATED AS IDENTITY, the corresponding column in the history table cannot be defined with a GENERATED attribute.

**ON DELETE ADD EXTRA ROW**

Specifies that an additional row is inserted into the associated history table when a row is deleted from a system-period temporal table. These additional history rows are not returned for a query with a period specification for a system-period temporal table. The content of the columns of the additional row in the history table are determined as follows:

- New values are generated for each column that corresponds to a non-deterministic generated expression column.
- The column that corresponds to the row-begin column is set to the same value as the column that corresponds to the row-end column.
- The other columns are set to the same value as in the row inserted into the history table for the delete.

The ON DELETE ADD EXTRA ROW clause is intended to be used when the system-period temporal table contains a non-deterministic generated expression column. The generated expression columns in an extra row contain information about the delete operation that resulted in that extra row in the history table.

Related information:

(Temporal tables and data versioning (Db2 Administration Guide)

**DROP VERSIONING:**

**DROP VERSIONING**

Specifies that the table is no longer a system-period temporal table. *table-name* must identify a system-period temporal table. Historical data will no longer be recorded and maintained for the table. The definition of the columns and data of the table *table-name* are not changed, but the table is no longer treated as a system-period temporal table. The SYSTEM_TIME period is retained. The relationship between the system-period temporal table and history table is removed. The history table is not dropped, only the relationship between the two tables is removed. Subsequent queries that reference the table must not specify a SYSTEM_TIME period specification for the table.

Use of this clause or keyword might invalidate packages that depend on the target object, or packages that depend on related objects through cascading effects. See Changes that invalidate packages (Db2 Application programming and SQL).

Versioning cannot be dropped if there are any views, materialized query table definitions, or SQL table functions that depend on the SYSTEM_TIME period.

DROP VERSIONING must not be specified with any other clauses on the ALTER TABLE statement.

The privilege set must include the privileges to issue an ALTER TABLE statement for the associated history table.

**ADD MATERIALIZED QUERY:**

**ADD MATERIALIZED QUERY** *materialized-query-definition*

Changes a base table to a materialized query table. Supplies a definition for a
regular table to make it a materialized query table. The table specified by
\textit{table-name} and the result columns of the \textit{fullselect} must not have the following characteristics:

- Be already defined as a materialized query table
- Have any primary keys, unique constraints (unique indexes), referential constraints (foreign keys), check constraints, or triggers defined
- Be referenced in the definition of another materialized query table
- Be directly or indirectly referenced in the \textit{fullselect}
- Be in an incomplete state
- Be a system-period temporal table or a history table
- Be a base table that has been activated for the row access controls or column access controls
- Be a base table for which a row permission or a column mask has been defined
- Be an archive-enabled table or an archive table

If \textit{table-name} does not meet these criteria, an error occurs.

The \textit{fullselect} must not contain a period specification.

The object that is specified in the \textit{FROM} clause of the \textit{fullselect} cannot be a view with columns of length 0.

\textit{fullselect}

Defines the query on which the table is based. The columns of the existing table must meet the following characteristics:

- Have the same number of columns
- Have exactly the same column definitions
- Have the same column names in the same ordinal positions

The \textit{fullselect} must not directly or indirectly reference a base table that has been activated for the row access controls or column access controls or reference a base table for which a row permission or a column mask has been defined.

The \textit{fullselect} cannot contain a reference to a created global temporary table, a declared global temporary table, an accelerator-only table, a directory table, or another materialized query table.

The outermost SELECT clause of \textit{fullselect} must not result in a column that is an array.

The outermost SELECT list of the \textit{fullselect} can include result columns that are defined as EBCDIC columns and result columns that are defined as Unicode columns. In this case, the materialized query table is an EBCDIC table with one or more Unicode columns.

If \textit{fullselect} is specified, the owner of the table being altered must have the SELECT privilege on the tables or views referenced in the \textit{fullselect}. Having SELECT privilege means that the owner has at least one of the following authorizations:

- Ownership of the tables or views referenced in the \textit{fullselect}
- The SELECT privilege on the tables and views referenced in the \textit{fullselect}
- SYSADM authority
• DBADM authority for the database in which the table of the fullselect reside

Additional privileges might be necessary for accessing other objects that are referenced in the fullselect.

If the owner of the table does not have the SELECT privilege, the following authorization IDs must have SYSADM authority or DBADM authority for the database in which the tables of the fullselect reside:
• For embedded statements, the authorization ID of the owner of the plan or package
• For dynamically prepared statements, the SQL authorization ID of the process

For details about specifying fullselect for a materialized query table, see the definition of fullselect in the “CREATE TABLE” on page 1769 statement.

Use of this clause or keyword might invalidate packages that depend on the target object, or packages that depend on related objects through cascading effects. See Changes that invalidate packages (Db2 Application programming and SQL).

refreshable-table-options
Specifies the materialized query table options for altering a regular table to a materialized query table. The ORDER BY clause is allowed, but it is used only by REFRESH. The ORDER BY clause can improve the locality of reference of data in the materialized query table.

DATA INITIALLY DEFERRED
Specifies that the data in the table is not validated as part of the ALTER TABLE statement. A REFRESH TABLE statement can be used to make sure the data in the materialized query table is the same as the result of the query in which the table is based.

REFRESH DEFERRED
Specifies that the data in the table can be refreshed at any time using the REFRESH TABLE statement. The data in the table only reflects the result of the query as a snapshot at the time when the REFRESH TABLE statement is processed or as updated by the user for a user-maintained materialized query table.

MAINTAINED BY SYSTEM or MAINTAINED BY USER
Specifies how the data in the materialized query table is maintained.

MAINTAINED BY SYSTEM
Specifies that the data in the materialized query table table-name is to be maintained by the system. Only the REFRESH TABLE statement is allowed on the table.

MAINTAINED BY USER
Specifies that the data in materialized query table table-name is to be maintained by the user, who can use LOAD utility or SQL data change statements and REFRESH TABLE statements on the table.

ENABLE QUERY OPTIMIZATION or DISABLE QUERY OPTIMIZATION
Specifies whether this materialized query table can be used for optimization.

ENABLE QUERY OPTIMIZATION
Specifies that the materialized query table can be used for query optimization. If the fullselect specified does not satisfy the
restrictions for query optimization, an error occurs. For detailed rules to satisfy query optimization, see materialized-query-definition in the “CREATE TABLE” on page 1769 statement.

DISABLE QUERY OPTIMIZATION
Specifies that the materialized query table cannot be used for query optimization. The table can still be queried directly.

ALTER MATERIALIZED QUERY:

ALTER MATERIALIZED QUERY materialized-query-table-alteration
Changes attributes of a materialized query table. The table-name must identify a materialized query table.

SET refreshable-table-alteration
Changes how the table is maintained or whether the table can be used in query optimization.

MAINTAINED BY SYSTEM
Specifies that the data in a materialized query table table-name is to be maintained by the system.

MAINTAINED BY USER
Specifies that the data in the materialized query table table-name is to be maintained by the user.

ENABLE QUERY OPTIMIZATION
Specifies that materialized query table table-name can be used in query optimization. If the fullselect specified for the materialized query table does not satisfy the restrictions for automatic query optimization, an error occurs. For detailed rules to satisfy query optimization, see “CREATE TABLE” on page 1769.

DISABLE QUERY OPTIMIZATION
Specifies that materialized query table table-name cannot be used for query optimization. The table can still be queried directly.

Use of this clause or keyword might invalidate packages that depend on the target object, or packages that depend on related objects through cascading effects. See Changes that invalidate packages (Db2 Application programming and SQL).

DROP MATERIALIZED QUERY:

DROP MATERIALIZED QUERY
Changes a materialized query table so that it is no longer considered a materialized query table. The table specified by table-name must be defined as a materialized query table. The definition of columns and data of the name are not changed, but the table can no longer be used for query optimization and is no longer valid for use with the REFRESH TABLE statement.

Use of this clause or keyword might invalidate packages that depend on the target object, or packages that depend on related objects through cascading effects. See Changes that invalidate packages (Db2 Application programming and SQL).

DATA CAPTURE:

DATA CAPTURE
Specifies whether the logging of the following actions on the table is augmented by additional information:
• SQL data change operations
• Adding columns (using the ADD COLUMN clause)
• Changing columns (using the ALTER COLUMN clause)

For guidance on intended uses of the expanded log records, see:
• The description of data propagation to IMS in *IMS DataPropagator: An Introduction*
• The instructions for using Remote Recovery Data Facility (RRDF) in *Remote Recovery Data Facility Program Description and Operations*
• The instructions for reading log records in *Db2 Administration Guide*

**NONE**

Do not record additional information to the log.

**CHANGES**

Write additional data about SQL updates to the log. Information about the values that are represented by any LOB or XML columns is not available.

Do not specify DATA CAPTURE CHANGES for tables that reside in table spaces that specify NOT LOGGED.

The DATA CAPTURE CHANGES clause can be specified for a table for which row access controls or column access control are active. However, the access controls do not protect data that is written to the log.

For details about the recording of additional data for logged updates to catalog tables, see “Notes” on page 1304.

**VOLATILE:**

**VOLATILE or NOT VOLATILE**

Specifies how Db2 is to choose access to the table.

**VOLATILE**

Specifies that Db2 is to use index access to the table whenever possible for SQL operations. However, be aware that list prefetch and certain other optimization techniques might be disabled when VOLATILE is used.

One instance in which you might want to use VOLATILE is for a table whose size can vary greatly. If statistics are taken when the table is empty or has only a few rows, those statistics might not be appropriate when the table has many rows.

Another instance in which you might want to use VOLATILE is for a table that contains groups of rows, as defined by the primary key on the table. All but the last column of the primary key of such a table indicate the group to which a given row belongs. The last column of the primary key is the sequence number indicating the order in which the rows are to be read from the group. VOLATILE maximizes concurrency of operations on rows within each group, since rows are usually accessed in the same order for each operation. For this usage, the primary index must be the only index that is defined on the table, and list prefetch is disabled to ensure the sequence in which the rows are locked.

**NOT VOLATILE**

Specifies that Db2 is to base SQL access to the table on the current statistics.

**CARDINALITY**

An optional keyword that currently has no effect, but that is provided for Db2 family compatibility.
ADD CLONE:

ADD CLONE clone-table-name

Specifies that a clone table, identified by clone-table-name, is created for the table that is being altered. The name, including the implicit or explicit qualifiers, must not identify a table, view, alias, or synonym that exists at the current server. The name must not identify a table that exists in the SYS_PENDING_OBJECTS catalog table. The clone table is created in the same table space as the base table and has the same structure as the base table. This includes, but is not limited to, column names, data types, null attributes, check constraints, indexes. When ADD CLONE is used to create a clone of the specified base table, the base table must conform to the following rules:

- Reside in a universal table space that is managed by Db2.
- If the table space or any of its dependent objects (LOBs, XMLs, or indexes) is created with the DEFINE NO clause, all data sets must already be created
- Be the only table in the table space
- Not be defined with a clone table
- Not be defined to use hash organization.
- Not be involved in any referential constraint
- Not be defined with any after triggers
- Not be a materialized query table
- Not have any pending changes
- Not have more than one table space version or index version in use. For information about how to remove in-use versions, see Removing in-use table space versions (Db2 Administration Guide) and Recycling index version numbers (Db2 Administration Guide)
- Not have an incomplete definition
- Not be a created global temporary table or a declared global temporary table
- Not be a system-period temporal table or a history table
- Not be an archive-enabled table or an archive table
- Not be altered to a clone table, if the base table uses relative numbering

The base table and the clone table are considered unrelated with regard to access controls. Row access control or column access control can be activated independently for the base table, the clone table, or both. The ownership can be transferred independently for the base table and the clone table.

DROP CLONE:

DROP CLONE

Specifies that the clone table that is associated with the specified base table is dropped. table-name must identify a base table that exists at the current server and the table must have a clone table defined.

When a clone table is dropped, any row permissions or column masks that are defined for the clone table are also dropped. If the clone table is referenced in the definition of a row permission or a column mask, the ALTER statement returns an error

RESTRICT ON DROP:

ADD RESTRICT ON DROP

Restricts dropping the table and the database and table space that contain the table.
DROP RESTRICT ON DROP

Removes the restriction on dropping the table and the database and table space that contain the table.

ROW ACCESS CONTROL:

ACTIVATE ROW ACCESS CONTROL

Specifies that row access control should be activated for the table. If the table is an alias or a synonym, row access control is activated for the base table.

The table must not be one of the following tables:

- A created temporary table
- A table that is directly or indirectly referenced in the definition of a materialized query table
- A table that has a security label column
- A system-period temporal table
- A history table
- An archive-enabled table
- An archive table

If a trigger exists for the table, the trigger must be defined with the SECURED clause.

The table must not be referenced in the definition of a view if the following conditions are true:

- The view is defined with the WITH CHECK OPTION clause
- An INSTEAD OF trigger exists for the view and the trigger is not defined with the SECURED clause.

A default row permission is implicitly created for the table and allows no access to any of the rows of the table, unless there is another row permission that is enabled and that provides access for the authorization IDs or roles that are specified in the definition of the row permission. A query that references the table before such a row permission exists and is enabled will return a warning that there is no data in the table.

ACTIVATE ROW ACCESS CONTROL must not be specified if a period is defined for the table, because a default row permission cannot be defined for a table with a period specification.

When the table is referenced in a SELECT, INSERT, UPDATE, DELETE, or MERGE statement, all row permissions that are enabled for the table, including the default row permission, are applied to control the set of rows that are accessible for the table. If any row permission that is enable is invalid because a previous attempt to regenerate the row permission was unsuccessful, row access control cannot be activated.

ACTIVATE ROW ACCESS CONTROL is ignored if row access control is already activated for the table.

Use of this clause or keyword might invalidate packages that depend on the target object, or packages that depend on related objects through cascading effects. See [Changes that invalidate packages (Db2 Application programming and SQL)]

DEACTIVATE ROW ACCESS CONTROL

Specifies that row access control for the table is deactivated. When the table is referenced in a SELECT, INSERT, UPDATE, DELETE, or MERGE statement,
any existing row permissions for the table that are enable are not applied to
control the set of rows that are accessible for the table.

DEACTIVATE ROW ACCESS CONTROL is ignored if row access control is
already defined as not activated for the table.

Use of this clause or keyword might invalidate packages that depend on the
target object, or packages that depend on related objects through cascading
effects. See Changes that invalidate packages (Db2 Application programming
and SQL).

COLUMN ACCESS CONTROL:

ACTIVATE COLUMN ACCESS CONTROL
  Specifies that column access control should be activated for the table. If the
table is an alias or a synonym, column access control is activated for the base
table.

The table must not be one of the following tables:
  • A created temporary table
  • A table that is directly or indirectly referenced in the definition of a
    materialized query table
  • A system-period temporal table
  • A history table
  • An archive-enabled table
  • An archive table

If a trigger exists for the table, the trigger must be defined with the SECURED
clause.

The table must not be referenced in the definition of a view if the following
conditions are true:
  • The view is defined with the WITH CHECK OPTION clause
  • An INSTEAD OF trigger exists for the view and the trigger is not defined
    with the SECURED clause.

When column access control is activated, access to the table is not restricted.
However, when the table is referenced in a SELECT, INSERT, UPDATE,
DELETE, or MERGE statement, all column masks that are enabled for the table
are applied to mask the values that are returned for the columns that are
referenced in the final result table or to determine the new values that are used
in the SQL data change statements. If any enabled column mask is invalid
because a previous attempt to regenerate it was unsuccessful, column access
control cannot be activated

ACTIVATE COLUMN ACCESS CONTROL is ignored if column access control
is already activated for the table.

Use of this clause or keyword might invalidate packages that depend on the
target object, or packages that depend on related objects through cascading
effects. See Changes that invalidate packages (Db2 Application programming
and SQL).

DEACTIVATE COLUMN ACCESS CONTROL
  Specifies that column access control for the table is deactivated. When the table
is referenced in a SELECT, INSERT, UPDATE, DELETE, or MERGE statement,
any existing column masks that are enabled for the table are not applied to
control the values that are returned for the columns that are referenced in the final result table or to determine if the new values can be used in the SQL data change statements.

DEACTIVATE COLUMN ACCESS CONTROL is ignored if column access control is already defined as not activated for the table.

Use of this clause or keyword might invalidate packages that depend on the target object, or packages that depend on related objects through cascading effects. See Changes that invalidate packages (Db2 Application programming and SQL).

APPEND:

APPEND NO or APPEND YES
Specifies whether append processing is used for the table. The APPEND clause must not be specified for a table in a work file table space.

If the base table is in a partition-by-range table space, the APPEND option on the LOB table might be different for each partition (depending if the LOB table space and associated objects for each partition are created explicitly or implicitly). If the base table is in a partition-by-growth table space, the APPEND attributes of LOB table will be inherited by each partition.

NO Specifies that append processing is not used for the table. For insert and LOAD operations, Db2 attempts to place data rows in a well clustered manner with respect to the value in the row’s cluster key columns.

YES Specifies that data rows are placed into the table without regard to clustering during the insert and LOAD operations.

AUDIT:

AUDIT
Alters the auditing attribute of the table. For information about audit trace classes, see Db2 Administration Guide.

NONE Specifies that no auditing is to be done when the table is accessed.

CHANGES Specifies that auditing is to be done when the table is accessed during the first insert, update, or delete operation. However, the auditing is done only if the appropriate audit trace class is active.

ALL Specifies that auditing is to be done when the table is accessed during the first operation of any kind performed by a utility or application process. However, the auditing is done only if the appropriate audit trace class is active and the access is not performed with COPY, RECOVER, REPAIR, or any stand-alone utility.

The ALTER TABLE statement is audited for successful and failed attempts in the following cases, if the appropriate audit trace class is active:

• AUDIT attribute is changed to NONE, CHANGES, or ALL on an audited or non-audited table.
• AUDIT CHANGES or AUDIT ALL is in effect.
VALIDPROC:

VALIDPROC
Names a validation procedure for the table or inhibits the execution of any existing validation procedure.

program-name
Designates program-name as the new validation exit routine for the table.

The validation procedure can inhibit a data change operation on any row of the table. Before the operation takes place, the row is passed to the procedure. The values that are represented by any LOB or XML columns in the table are not passed to the validation procedure. On an insert or update operation, if the table has a security label column and the user does not have write-down privilege, the user’s security label value is passed to the validation routine as the value of the column. After examining the row, the procedure returns a value that indicates whether the operation should proceed. A typical use is to impose restrictions on the values that can appear in various columns.

A table can have only one validation procedure at a time. When you name a new procedure, any existing procedure is no longer used. The new procedure is not used to validate existing table rows. It is used only to validate rows that are loaded, inserted, updated, or deleted after execution of the ALTER TABLE statement.

Related information:

Validation routines (Db2 Administration Guide)

NULL
Discontinues the use of any validation routine for the table.

ENABLE ARCHIVE:

ENABLE ARCHIVE
Specifies that the table is an archive-enabled table.

The table must satisfy the following criteria:

• The table must not already be defined as an archive-enabled table or an archive table.
• The table must not contain a period.
• The table must be the only table in the table space.
• The table must not have a column mask or row permission defined.
• The table must not be one of the following tables:
  − A materialized query table
  − An incomplete table
  − An auxiliary table
  − A table that is involved in a clone relationship
  − A table that was implicitly created for an XML column
  − A table that contains a security label column
  − A system-period temporal table
  − A history table

ENABLE ARCHIVE must not be specified with other clauses on the ALTER TABLE statement.
The privilege set must include the privileges to issue an ALTER TABLE statement for the associated archive table.

For archive-enabled tables, Db2 retains archived versions of the rows. When data in an archive-enabled table is deleted, and the SYSIBMADM.MOVE_TO_ARCHIVE global variable is set to Y, the last version of the row is inserted into the archive table.

The SYSIBMADM.GET_ARCHIVE global variable and the ARCHIVESENSITIVE bind option determine whether rows in the associated archive table are included when an archive-enabled table is referenced in a table-reference.

Related information:
- Archive-enabled tables and archive tables (Introduction to Db2 for z/OS)
- Built-in global variables
- ARCHIVESENSITIVE bind option (Db2 Commands)

**USE archive-table-name**

Specifies an archive table in which to keep archived rows of the archive-enabled table.

*archive-table-name* must identify a table that exists at the current server. The table must satisfy the following criteria:

- The table must be the only table in the table space.
- The table must not have an incomplete table definition.
- The table must not be defined as the parent or child in an existing referential constraint.
- The table must not include a period.
- The table must not include a row permission or column mask.
- The table cannot be one of the following tables:
  - A catalog table.
  - An archive-enabled table. The table was defined as an archive-enabled table by a previous statement, or the current statement defines the table as an archive-enabled table.
  - An existing archive table.
  - A system-period temporal table.
  - A history table.
  - A declared global temporary table.
  - A created global temporary table.
  - A materialized query table.
  - A view.
  - An auxiliary table.
  - A table that was implicitly created for an XML column.
  - A clone table.
  - A table that has a clone defined on it.
- The table must not contain any of the following columns:
  - An identity column
  - A row-begin column
  - A row-end column
  - A transaction-start-ID column
- A generated expression column
- A security label column

The privilege set must include the privileges to issue an ALTER TABLE statement for the associated archive table.

The archive-enabled table and the associated archive table must have the same number and order of columns. The following attributes for the corresponding columns of the two tables must be the same:

- Name
- Data type
- Length (excluding inline LOB length or XML length in the base table), precision, and scale
- FOR BIT, SBCS, or MIXED DATA attribute for character string columns
- Null attribute
- Hidden attribute
- CCSID
- Field procedure

If a column of an archive-enabled table is defined as ROWID, the corresponding column of the archive table must also be defined as ROWID with the GENERATED ALWAYS attribute.

If a column of an archive-enabled table is defined as row change timestamp, the corresponding column of the archive table must also be defined as row change timestamp with the GENERATED ALWAYS attribute.

**DISABLE ARCHIVE:**

**DISABLE ARCHIVE**

Specifies that the table is no longer an archive-enabled table.

$table-name$ must identify an archive-enabled table. The definition of the columns and data of the table $table-name$ are not changed, but the table is no longer treated as an archive-enabled table. The relationship between the archive-enabled table and the associated archive table is removed. The archive table is not dropped. However, by removing the relationship between the archive table and the archive-enabled table, the behavior of the archive-enabled table changes as follows:

- Subsequent queries that reference the table do not consider rows in the archive table regardless of the setting of the SYSIBMADM.GET_ARCHIVE global variable or the ARCHIVESENSITIVE bind option.
- Deleted rows are not moved to the archive table regardless of the setting of the SYSIBMADM.MOVE_TO_ARCHIVE global variable.

Use of this clause or keyword might invalidate packages that depend on the target object, or packages that depend on related objects through cascading effects. See [Changes that invalidate packages (Db2 Application programming and SQL)](Changes that invalidate packages (Db2 Application programming and SQL)).

DISABLE ARCHIVE must not be specified with any other clauses on the ALTER TABLE statement.

The privilege set must include the privileges to issue an ALTER TABLE statement for the associated archive table.
Notes

Order of processing of clauses:
When there is more than one clause, they are processed in the following order:

1. VALIDPROC
2. AUDIT
3. DATA CAPTURE
4. ROTATE
5. VOLATILE clauses
6. APPEND clauses
7. DROP clauses
8. ALTER clauses
9. RENAME clause
10. ADD clauses

Within each of these stages, the order in which the user specifies the clauses is the order in which they are performed.

Altering the data type, length, precision, or scale of a column:
When you change the data type, length, precision, or scale of a column, consider the following information:

- Altering character data.
  When columns are converted from CHAR to VARCHAR, normal assignment rules apply, which means that trailing blanks are kept instead of being stripped out. If you want varying length character strings without trailing blanks, use the STRIP function for data in the column after changing the data type to VARCHAR.

  When a CHAR FOR BIT DATA column is converted to a BINARY data type, the following applies:
  - The existing space characters in the table will not be changed to hexadecimal zeros (X'00')
  - If the new length attribute is greater than current length attribute of the column, the values in the table are padded with hexadecimal zeros (X'00')

  When a CHAR FOR BIT DATA or VARCHAR FOR BIT DATA column is converted to a BINARY or VARBINARY data type, the existing default value will be cast as a binary string. The resulting binary string will be at least twice the original size. The alter will fail if the resulting binary string length exceeds 1536 UTF-8 bytes.

- Altering fixed-length to varying-length or increasing varying-length column.
  When you change a column from a fixed to varying length or change the length of a varying-length column, process the ALTER TABLE statements in the same unit of work or do a reorganization between the ALTER TABLE statements to avoid anomalies with the lengths and padding of individual values.

- Altering DECIMAL(19,0) to BIGINT.
  In releases of Db2 prior to DB2 9, use of the DECIMAL(19,0) data type for applications that work with BIGINT data was encouraged. For performance reasons, columns it is best to alter the DECIMAL(19,0) columns to BIGINT. Note that altering from DECIMAL(19,0) to BIGINT
is provided only for DECIMAL(19,0) columns that are used for applications that work with BIGINT (thus, the data in those columns is within the range of the BIGINT).

When altering from DECIMAL(19,0) to BIGINT you should ensure that all values in the DECIMAL(19,0) column are within the range of BIGINT before the alter. The following query or a similar query can be run to determine which rows (if any) contain values that are outside of the range of BIGINT:

```sql
SELECT * FROM table_name
WHERE dec19_0_column > 9223372036854775807
  OR dec19_0_column < -9223372036854775808;
```

### Altering a column in a partitioning key.

When a partitioning key column with a numeric data type is altered to a larger numeric data type, and the limit key value for the original numeric data type of the column is X'FF', the limit key value for the new numeric data type of the column is left-padded with X'FF'. For example, if a column is converted from SMALLINT to INTEGER, and a limit key value for the SMALLINT column is 32767 (which is 2 bytes of X'FF'), the limit key for the INTEGER column is 2147483647 (which is 4 bytes of X'FF').

When a partitioning key column with a character data type is altered to a longer character data type, and the limit key value for the original character data type of the column (excluding the first NULL byte if the column is nullable) is neither all X'FF' nor all X'00', the limit key value for the new character data type of the column is right-padded with blank(s) of the encoding scheme of the table. For example, if a column is converted from CHAR(1) to VARCHAR(2), and a limit key value for the CHAR(1) column is 'A' (which is X'C1'), the limit key for the VARCHAR(2) column is 'A ' (which is X'C140' when the encoding scheme of the table is EBCDIC, or is X'C120' when the encoding scheme of the table is UNICODE or ASCII).

When a partitioning key column with a character data type is altered to a longer character data type, and the limit key value for the original character data type of the column (excluding the first NULL byte if the column is nullable) is all X'FF', the limit key value for the new character data type of the column is right-padded with X'FF' and the table space that contains the table being altered is left in REORG-pending (REORP) status.

When a partitioning key column with a character data type is altered to a longer character data type, and the limit key value for the original character data type of the column (excluding the first NULL byte if the column is nullable) is all X'00', the limit key value for the new character data type of the column is right-padded with X'00' and the table space that contains the table being altered is left in REORG-pending (REORP) status.

### Statistics.

Statistics. New COLUMN statistics should be collected for all altered columns. Even though the COLCARDF value is valid, the HIGH2KEY and LOW2KEY values are invalid, and any SYSCOLSTATS catalog entries for the column are removed. Any frequencies or histogram statistics which include this column should also be collected again.

### Considerations for altering an XML column

If the altered-data-type is XML, the old data type of the altered column must also be XML:
• If the old data type has no XML type modifier and the new data type does, you should ensure that all values in the XML column are valid according to the XML schema that is specified in the type modifier. The XML table space for the column that is being changed is left in CHECK-pending status.

• If the old data type has the XML type modifier but the new data type has no type modifier, the existing values do not need to be re-validated. The state of the table space is not changed.

  If the XML schemas that are specified in the old XML type modifier are a subset of the XML schemas that are specified in the new XML type modifier, the existing values do not need to be re-validated. The state of the XML table space is not changed.

• If the XML schemas that are specified in the old XML type modifier are NOT a subset of the XML schemas that are specified in the new XML type modifier, the XML table space for the column that is being changed is left in the CHECK-pending status.

**Recovering to a point in time after an alteration**

Some alterations might affect subsequent requests to recover to a point in time. For details about possible restrictions, effects on recovery status, and other considerations, see [Point-in-time recovery (Db2 Utilities)](https://www.ibm.com/support/knowledgecenter/SSEPGG_10.1.0/com.ibm.db2.luw.sql.ref.doc/doc/rsqlrptm.html).

For example, for an ALTER TABLE statement that includes a DROP COLUMN, ALTER COLUMN, or ROTATE PARTITION clause, certain considerations or restrictions might apply to subsequent requests to recover to a point in time.

**Referencing columns in ADD, ALTER, and RENAME clauses:**

A column can only be referenced once in an ADD COLUMN, an ALTER COLUMN, or a RENAME COLUMN clause in a single ALTER TABLE statement. However, that same column can be referenced multiple times for adding or dropping constraints in the same ALTER TABLE statement.

Because a distinct type is subject to the same restrictions as its source type, all the syntactic rules that apply to LOB, ROWID, and DECFLOAT columns apply to distinct type columns that are based on LOBs, row IDs, and DECFLOATs. For example, if a table has an explicitly created ROWID column, you cannot add a column with a distinct type that is sourced on a row ID.

Adding a column to table T only changes the description of T. If the catalog description of T is used to create a table T’ and a facility such as DSN1COPY is used to effectively copy T into T’, queries that refer to the added column in T’ will fail because the data does not match its description. To avoid this problem, run the REORG utility against the table space of T before making the copy.

**Restrictions on a clone table:**

Tables that are involved in a clone relationship (base tables and their associated clone tables) have the following restrictions:

• You cannot use the RUNSTATS utility on a clone table.

• Objects that are involved in a clone relationship do not use the FASTSWITCH data set switching method when the REORG utility is run and the switch phase happens normally. This includes both the base table and the clone table objects (data and index), as well as LOB and XML objects. In addition, specification of FASTSWITCH YES together with CLONE in a REORG utility control statement is not allowed.
For a partitioned table, if a mixture of 'I' and 'J' data sets exists when a clone table is created, the mixture of 'I' and 'J' data sets can be changed only by first dropping the clone table.

Catalog and directory tables cannot have clone tables.

Indexes cannot be created on a clone table. When an index is created on a base table that is involved in a clone relationship, the index on the clone table will be created implicitly and will be put into rebuild-pending status.

Implicitly created auxiliary table spaces (table spaces for LOB and XML columns) and auxiliary indexes for the base table are always created as DEFINE YES.

Before triggers cannot be created on a clone table. Before triggers that are created on a base table apply to both the base table and the clone table.

You cannot rename a base table that has a clone and you cannot rename a clone table.

Real-time statistics tables cannot have clone tables.

You cannot drop an auxiliary table or an auxiliary index of an object that is involved in a clone relationship.

If the table is involved in a clone relationship, no other table altering can take place. If a table change is required, the clone table objects must be dropped so that the base table object attributes can be modified. After the table and index changes and such are completed, the clone table objects can be recreated.

**Size restriction for the object descriptor of a table:**

The following cases might result in an error being returned if the ALTER TABLE statement results in a versioned object descriptor that is larger than 30,000 bytes being added (or updated):

- An ALTER TABLE statement that results in the first version of the object descriptor being generated for the table
- An ALTER TABLE statement that results in the first version of the object descriptor being generated for one or more of the indexes that are defined on the table
- An ALTER TABLE ALTER COLUMN SET DATA TYPE statement on an existing decimal column on a versioned table

You might need to drop and recreate the table if the object descriptor for the table exceeds 30,000 bytes. Alternatively, you can reduce the size of the object descriptor for the table by reducing the size of the default value for varying-length columns in the table by issuing an ALTER TABLE ALTER COLUMN SET DEFAULT statement. You can also drop unnecessary column defaults to reduce the size of the object descriptor for the table.

**Altering the attributes of an existing identity column:**

Existing values for the identity column are unaffected by the ALTER TABLE statement. The changed identity column attributes affect values generated after the ALTER statement has executed. Db2 does not validate any of the existing identity column values against the new identity column attributes. For example, duplicate values might be generated even if NO CYCLE is in effect, such as when an ascending identity column altered to become a descending identity column.
Any existing values in the cache that have not yet been used might be lost. Loss of cached values can also occur if the ALTER statement returns an error or is rolled back.

**Pending changes to the definition of a table:**
Issuing the ALTER TABLE statement with certain options can cause a pending change to the definition of a table. When an ALTER TABLE statement that causes pending changes to the definition is executed, semantic validation and authorization checking are performed. However, changes to the table definition and data are not applied and the table space is placed in advisory REORG-pending state (AREOR). The pending changes are recorded in the SYSIBM.SYSPENDINGDDL catalog table. Run the REORG utility with the SHRLEVEL CHANGE or SHRLEVEL REFERENCE options on the table space to apply the pending changes to the definition and data of the table space. When the pending changes are applied, the corresponding entries in the SYSIBM.SYSPENDINGDDL catalog table are removed, and the advisory REORG-pending state is removed.

The following ALTER TABLE options can cause pending changes to the definition of the table under certain conditions:

- **ALTER COLUMN**, to change the data type, precision, scale, or length, if the data sets of the table space are already created, and if subsystem parameter DDL_MATERIALIZATION indicates to execute the alteration as a pending change.
- **DROP COLUMN**, if the data sets of the table space are already created
- **ALTER PARTITION**, to change the limit keys for the following types of partitioned table spaces:
  - partition-by-range spaces
  - Partitioned table spaces (non-UTS) with table-controlled partitioning

**Restrictions when objects have pending definition changes:**
The following statements cannot be executed if the table space, or any objects within that table space, has pending definition changes:

- **ALTER TABLE** with immediate options, except the KEY LABEL option
- **CREATE INDEX** on the table
- **ALTER INDEX ADD COLUMN** or **ADD INCLUDE COLUMN** of any index defined on the table
- **ALTER INDEX REGENERATE** of any index defined on the table

The following statements cannot be executed if the table has pending definition changes:

- **CREATE TRIGGER** on the table
- **CREATE TRIGGER** of an INSTEAD OF trigger on a view that is dependent the table
- **CREATE PERMISSION** on the table or that references the table
- **CREATE MASK** on the table or that references the table
- **CREATE FUNCTION** of an SQL table function that references the table
- **CREATE TABLE** or **ALTER TABLE** that defines a materialized query table that references the table

The following statements cannot be executed if the table contains any columns with pending definition changes:
CREATE VIEW that references a column with pending definition changes
ALTER TABLE with the ADD VERSIONING clause that references a history table that contains columns with pending definition changes
ALTER TABLE with the ENABLE ARCHIVE clause that references an archive table that contains columns with pending definition changes
ALTER INDEX with the NOT Padded clause, where the index references a column with pending definition changes
CREATE TABLE or ALTER TABLE that specifies a FOREIGN KEY that references a parent column with pending definition changes

Adding a LOB column:
If the table space that contains the table is implicitly created and you add a LOB column to the table, the following object are implicitly created:
- A LOB table space
- An auxiliary table
- An auxiliary index

If the base table is involved in a clone relationship, implicitly created LOB table spaces and implicitly created indexes are always created with the DEFINE YES attribute.

Adding a ROWID column:
When you add a ROWID column to an existing table, Db2 ensures that the same, unique row ID value is returned for a row whenever it is accessed. If the table already has an implicitly hidden ROWID column, Db2 also ensures that the values in the two ROWID columns are identical.

If the table space that contains the table is implicitly created and you add a ROWID column that is defined as GENERATED BY DEFAULT to the table, an enforcing index for the ROWID column is implicitly created. If the table already has an implicitly hidden ROWID column and the ROWID column that you add is defined as GENERATED BY DEFAULT, Db2 changes the implicitly hidden ROWID column to have the GENERATED BY DEFAULT attribute and does not implicitly create an enforcing index for the ROWID column.

When you add a ROWID column that is defined as GENERATED BY DEFAULT and the ROWID index is implicitly created, the privilege set requires the INDEX privilege on the table and the USE privilege on the buffer pool and the storage group. The implicitly created ROWID index is owned by the owner of the table.

Reorganizing a table space has no effect on the values in a ROWID column.

Adding an identity column:
When you add an identity column to a table that is not empty, Db2 places the table space that contains the table in the REORG pending (REORP) status. When the REORG utility is subsequently run, Db2 generates the values for the identity column in all existing rows and then removes the REORG-pending (REORP) status. These values are guaranteed to be unique, and their order is system-determined.

Adding a row change timestamp column:
When you add a row change timestamp column to an existing table, the initial value for existing rows is not stored at the time of the ALTER statement. Db2 places the table space into an advisory-REORG pending
state. For existing rows' row change timestamp column values, the LRSN or the RBA derives an implicit ROW CHANGE TIMESTAMP expression. When any row on the page is updated or changed, the implicit ROW CHANGE TIMESTAMP expression is changed. When the REORG utility is subsequently run, Db2 generates the values for the row change timestamp column in all existing rows and then removes the REORG pending status. These values will not change unless the row is updated.

**XML version support when adding an XML column:**

When an XML column is added to a table that is in a universal table space, the XML column and the associated XML table will support XML versions if it is the first XML column in the table or if all the other XML columns in the table support XML versions. Similarly, when a clone table is associated with the base table, any XML columns and associated XML tables will support XML versions if the existing XML columns in the base table support XML versions.

**Effect of adding a column on views:**

Adding a column to a table has no effect on existing views.

**Considerations for implicitly hidden columns:**

A column that is defined as implicitly hidden can be explicitly referenced on the ALTER statement. For example, an implicitly hidden column can be altered, can be specified as part of a referential constraint or a check constraint, or a materialized query table definition.

**Cascaded effects of adding or altering a column:**

Adding a column to a table has no cascaded effects to views that reference the table. For example, adding a column to a table does not cause the column to be added to any dependent views, even if those views were created with a SELECT clause. But altering a column can cause other cascaded effects. The following table lists the cascaded effect of altering the data type, precision, scale, or length of a column.

<table>
<thead>
<tr>
<th>Operation</th>
<th>Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>Alter of a column referenced by a view</td>
<td>If the data type, length, precision, or scale for a column is altered, all the views that are dependent on the altered table are reevaluated at alter time with the new column attributes. If errors are encountered during the view regeneration process, the ALTER TABLE statement fails. The new internal structure of each dependent view is not saved at alter time, and subsequent references to a dependent view will cause the view to be regenerated again. Use the ALTER VIEW statement to regenerate a dependent view and have the new internal structure saved.</td>
</tr>
<tr>
<td>Alter of a column referenced in the key of an index or a unique constraint (unique key or primary key)</td>
<td>The alter is allowed unless DECIMAL with a fraction is being converted to a floating value. In this case, the loss of precision can result in a loss of uniqueness. For numeric data type conversions, the index is placed in REBUILD-pending status. For character data type conversions, the index key columns are converted on first-write access. The index is not placed in REBUILD-pending status.</td>
</tr>
</tbody>
</table>
Table 179. Cascaded effect of altering a column’s data type, precision, scale, or length (continued)

<table>
<thead>
<tr>
<th>Operation</th>
<th>Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>Alter of a column referenced in a package</td>
<td>The alter is allowed. All packages dependent on the table in which the column is being altered are invalidated.</td>
</tr>
<tr>
<td>Alter of a column referenced in the body of a user-defined function or procedure</td>
<td>Alter is allowed. If there is a package associated with the function or procedure, it is invalidated. If the function is an SQL table function, the function is reevaluated at alter time with the new column attributes. If errors are encountered during the reevaluation process, the ALTER TABLE statement fails.</td>
</tr>
<tr>
<td>Alter of a column referenced in the parameter list of a user-defined function or procedure</td>
<td>Alter is allowed. The attributes of the existing function or procedure are unchanged. To access the new definition of the column, the function or procedure must be dropped and recreated. If the function is an SQL table function, the function is reevaluated at alter time with the new column attributes. If errors are encountered during the reevaluation process, the ALTER TABLE statement fails.</td>
</tr>
<tr>
<td>Alter of a column referenced by a trigger</td>
<td>Alter is allowed. All trigger packages that are dependent on the table of the column are invalidated.</td>
</tr>
<tr>
<td></td>
<td>If the trigger is an advanced trigger, the trigger is regenerated, and a rebind occurs for the SQL control statements, as well as non-SQL control statements that are included in the trigger body, at the local server. When a trigger is regenerated, any unqualified names in the trigger body are resolved using the name resolution process.</td>
</tr>
</tbody>
</table>

Table 180. Informational settings for ALTER COLUMN when the column is in an
index (continued)

<table>
<thead>
<tr>
<th>Alteration type</th>
<th>Exception state for index</th>
</tr>
</thead>
</table>

Notes:
1. An index on a nonpartitioned table, or a partitioned index on a partitioned table is set to RBDP status. A nonpartitioned index on a partitioned table is set to PSRBD status.

For information about resetting informational or restrictive exception states after schema changes, see [Reorganizing table spaces for schema changes](Db2 Administration Guide).

Adding a partition:
When you add a partition to a table, if the boundary for the last partition was not previously enforced, it is enforced after the partition is added, and the last two logical partitions are left in REORG-pending (REORP) status. If the last partition before the new one is added was in REORG-pending status, the added partition is also placed in REORG-pending status.

Adding a partition for a table that is in a partition-by-growth table space and has LOB columns:
If a table resides in the partition-by-growth table space that has LOB columns, its associated LOB table spaces can be created either explicitly or implicitly when the base table is created, depending on value that is in effect for SQLRULES:

- When SQLRULES = STD, the LOB table space is created implicitly for the first partition or for the number of partitions in the NUMPARTS clause, if it is specified in the CREATE TABLESPACE statement.
- When SQLRULES = Db2, the table definition will remain incomplete until the LOB table space is explicitly created for the first partition or for the number of partitions in the NUMPARTS clause, if it is specified in the CREATE TABLESPACE statement. In this case, if the LOB table space is not created before the first SQL data change statement operates against the table, the table that resides in the partition-by-growth table space remains with its definition in incomplete state. The table cannot be updated through SQL or LOAD.

Attributes that are inherited from the previous LOB table space partition when a LOB table space is created implicitly:
The following attributes apply to implicitly created LOB table space:
- BUFFERPOOL
- DATASET
- ERASERULE
- GBPCACHE
- LOCKMAX
- LOG
- CLOSE
- DSSIZE
- LOCKSIZE

Row format for newly added partitions:
When the value of the RRF subsystem parameter is ENABLE, newly added partitions that are created using the ADD PARTITION clause (or partitions that are added because the table space is partition-by-growth) will be created in re-ordered row format. When the value of the RRF subsystem parameter is DISABLE, the row format for newly added partitions will be ordered row format.
parameter is DISABLE, newly added partitions will be created in basic row format, except for the following table spaces:

- For table spaces that are already using basic row format and that contain tables with edit procedures, newly created partition will always be in basic row format regardless of value of the RRF parameter.
- For table spaces that are already using re-ordered row format and that contain tables with edit procedures, newly created partition will always be in re-ordered row format regardless of value of the RRF parameter.
- Newly created partitions of an XML table space will always be in re-ordered format.

Rotating a partition from first to last:
Running ALTER TABLE to rotate the first logical partition to become the last logical partition can be very time consuming. During the reset operation, all rows from the partition are deleted. In addition, the keys for the deleted rows are also deleted from all nonpartitioned indexes, which requires that each nonpartitioned index must be scanned.

When you rotate partitions, if the boundary for the last partition was not previously enforced, it is enforced after ROTATE FIRST TO LAST is issued, and the last two logical partitions are left in REORG-pending (REORP) status. If the last partition before ROTATE FIRST TO LAST was issued was in REORG-pending status, the last two logical partitions are left in REORG-pending status.

Effect of changes on applications:
Applications might need to be changed to correspond to changes to the columns in a table. For example, if you increase the length of a column, you need to increase the length of variables into which that column is fetched. If you change the data type of a column, you also might need to change the data type of the corresponding variable to avoid performance degradation.

If you rename or drop a column, you need to change any references to that column to avoid unexpected results.

Invalidation of packages:
This statement might invalidate all packages that depend on target objects, and sometimes other related objects through cascading effects, depending on the clauses and keywords specified and other factors. For more information, see Changes that invalidate packages (Db2 Application programming and SQL).

Dropping constraints and check pending status:
If a table space or partition is in check pending status because it contains a table with rows that violate constraints, dropping the constraints removes the check pending status.

Altering materialized query tables:
The ALTER TABLE statement can be used to register an existing table at the current server as a materialized query table, change the attributes of an existing materialized query table, or change an existing materialized query table into a base table.

The isolation level at the time when a base table is first altered to become a materialized query table by the ALTER TABLE statement is the isolation level for the materialized query table.

Altering a table to change it to a materialized query table with query optimization enabled makes the table eligible for use in query rewrite.
immediately. Therefore, pay attention to the accuracy of the data in the table. If necessary, the table should be altered to a materialized query table with query optimization disabled, and then the table should be refreshed and enabled with query optimization.

When a base table is altered into a materialized query table or a user-maintained query table is altered into a system-maintained one, the REFRESH_TIME column of the row for the table in SYSIBM.SYSVIEWS contains the current timestamp. When a system-maintained materialized query table is altered into a user-maintained materialized query table, the REFRESH_TIME column of the row for the table in SYSIBM.SYSVIEWS does not change.

The LOAD utility is not allowed on a system-maintained query table, but it is allowed on a user-maintained materialized query table.

**Considerations for running utilities while altering tables:**

You cannot execute the ALTER TABLE statement while a utility has control of the table space that contains the table.

**Restrictions on field procedures, edit procedures, and validation exit procedures:**

Field procedures, edit procedures that are defined as WITH ROW ATTRIBUTES, and validation exit procedures cannot be used on tables that have column names that are larger than 18 EBCDIC bytes. If you have tables that have field procedures or validation exit procedures and you add a column where the column name is larger than 18 bytes, the field procedures and validation exit procedures for the table are invalidated.

Consider using triggers to replace the functionality on field procedures, edit procedures that are defined as WITH ROW ATTRIBUTES, and validation exit procedures on tables where the column names are larger than 18 EBCDIC bytes.

**Restrictions on SQL data change statements in the same commit scope as ALTER TABLE:**

SQL data change statements that affect an index cannot be performed in the same commit scope as ALTER TABLE statements that affect that index.

**Restrictions on DATA CAPTURE CHANGES:**

If the table is in advisory REORG-pending state, you cannot alter the table to use the DATA CAPTURE CHANGES clause.

**Capturing changes to the Db2 catalog:**

To have logged changes to a Db2 catalog table augmented with information for data capture, specify ALTER TABLE xxx DATA CAPTURE CHANGES where xxx is the name of a catalog table (SYSIBM.xxx). Data capture of catalog table changes provides the possibility of creating and managing a shadow of the catalog.

**Restrictions for tables with dropped columns:**

Dropping of table columns is a pending definition change. A table space that contains a table with dropped columns cannot be recovered to a point in time before dropping of those columns was materialized.

**Row access control that is activated explicitly:**

The ACTIVATE ROW ACCESS CONTROL clause is used to activate row access control for a table. When this happens, a default row permission is implicitly created and allows no access to any rows of the table, unless later another enabled row permission exists that provides access for the authorization IDs or roles that are specified in the definition of the permission. The default row permission is always enabled.
When the table is referenced in a data manipulation statement, all enabled row permissions that have been created for the table, including the default row permission, are implicitly applied by Db2 to control which rows in the table are accessible. A row access control search condition is derived by application of the logical OR operator to the search condition in each enabled row permission. This derived search condition acts as a filter to the table before any user specified operations such as predicates, grouping, ordering, etc. are processed. This derived search condition permits the authorization IDs or roles that are specified in the permission definitions to access certain rows in the table. See the description of subselect for information on how the application of enabled row permissions affects the fetch operation. See the data change statements for information on how the application of enabled row permissions affects the data change operation.

Row access control remains enforced until the DEACTIVATE ROW ACCESS CONTROL clause is used to stop enforcing it.

**Implicit object that is created when row access control is activated for a table:**
When the ACTIVATE ROW ACCESS CONTROL clause is used to activate row access control for a table, Db2 implicitly creates a default row permission for the table. The default row permission prevents all access to the table. The implicitly created row permission is in the same schema of the base table and has a name in the form of SYS_DEFAULT_ROW_PERMISSION__table-name ... up to 128 UTF-8 bytes. Notice two underscores after 'PERMISSION'. If this name is not unique, the last 4 bytes are reserved for a unique number 'nnnn', where 'nnnn' is a four alphanumeric characters starting at '0000' and is incremented by 1 value each time until a unique name is found. The owner of the default row permission is SYSIBM.

The default row permission is always enabled.

The default row permission is dropped when row access control is deactivated or when the table is dropped.

**Activating column access control:**
The ACTIVATE COLUMN ACCESS CONTROL clause is used to activate column access control for a table. The access to the table is not restricted but when the table is referenced in a data manipulation statement, all enabled column masks that have been created for the table are applied to mask the column values referenced in the final result table of the queries or to determine the new values used in the data change statements.

When column masks are used to mask the column values, they determine the values in the final result table. If a column has a column mask and the column (a simple reference to a column name or embedded in an expression) appears in the outermost select list, the column mask is applied to the column to produce the values for the final result table. If the column does not appear in the outermost select list but it participates in the final result table, for example, it appears in a materialized table expression or view, the column mask is applied to the column in such a way that the masked value is included in the result table of the materialized table expression or view so that it can be used in the final result table.

The application of column masks does not interfere with the operations of other clauses within the statement such as the WHERE, GROUP BY, HAVING, SELECT DISTINCT, and ORDER BY. The rows returned in the final result table remain the same, except that the values in the resultant...
rows might have been masked by the column masks. As such, if the masked column also appears in an ORDER BY sort-key, the order is based on the original column values and the masked values in the final result table might not reflect that order; similarly, the masked values might not reflect the uniqueness enforced by SELECT DISTINCT. If the masked column is embedded in an expression, the result of the expression can become different because the column mask is applied on the column before the expression evaluation can take place. If the expression in a query is the same as the expression used to mask the column value in the column mask definition, the result of the expression in the query might remain unchanged. For example, the expression in the query is 'XXX-XX-' || SUBSTR(SSN, 8, 4) and the same expression appears in the column mask definition. In this particular example, the user can replace the expression in the query with column SSN to avoid the same expression gets evaluated twice.

The following are the contexts where the column masks are used by Db2 to mask the column values for the result of a query. Certain restrictions might apply to some contexts. Those restrictions are described in a separate list.

- The outermost SELECT clause of a SELECT or SELECT INTO statement, or if the column does not appear in the outermost select list but it participates in the final result table, the outermost SELECT clause of the corresponding materialized table expression or view where the column appears.
- The outermost SELECT clause of a SELECT FROM INSERT, UPDATE, DELETE, or MERGE statement
- The outermost SELECT clause that are used to derive the new values for an INSERT, UPDATE, or MERGE statement, or a SET transition-variable assignment statement
- The same applies to a scalar-fullselect expression that does not use set operators and appears in the outermost SELECT clause of the above statements, the right side of a SET variable assignment statement, the VALUES INTO statement, or the VALUES statement.
- The same applies to the SQL statements or the equivalences such as the assignment statement that appears in a native SQL procedure or a compiled user-defined SQL scalar function.

If a CASE expression appears in the above contexts, the column masks are not applied in the search conditions of the WHEN clauses.

A column mask is created as a stand-alone object without knowing all of the contexts in which it might be used. To mask a column value in the final result table, the column mask definition is merged into the statement by Db2. When the column mask definition is brought into the context of the statement, it might conflict with certain SQL semantics in the statement. Therefore, in some situations, the combination of the statement and the application of a column mask can return an error. The following describes when the error might be returned:

1. The column masks cannot be applied to the columns in the select lists that derive the final result table of set operations because one of the set operators that are used to derive the final result table is EXCEPT ALL, EXCEPT DISTINCT, INTERSECT ALL, or INTERSECT DISTINCT.
2. The column mask cannot be applied to the column in the select lists of a scalar-fullselect expression if the result of scalar-fullselect expression is derived from set operation EXCEPT or INTERSECT.

3. If the subselect contains a GROUP BY clause, the column mask cannot be applied to a column in the corresponding select list if none of the following conditions is satisfied:
   • The column must identify a column-name in the GROUP BY clause and the column must not be referenced in an expression in the GROUP BY clause. Furthermore, its column mask definition must satisfy the following condition:
     – any columns that are referenced in the column mask definition that come from the same table of the column to which the column mask is applied must identify a column-name in the GROUP BY clause
     – the column mask must not be referenced in an expression in the GROUP BY clause
   • The column must be specified under an aggregate function and its column mask definition must satisfy the following conditions:
     – The column mask definition must not reference a scalar-fullselect
     – The column mask definition must not reference an aggregate function

4. If the subselect contains a GROUP BY clause, and a column in the corresponding select list maps directly or indirectly to a column name or an expression in a materialized table expression or view, the column in the subselect where the GROUP BY is specified must be specified under an aggregate function.

5. If the subselect does not contain a GROUP BY clause, and a column in the corresponding select list is specified under an aggregate function, the column mask cannot be applied if the column mask definition references:
   • a scalar-fullselect
   • an aggregate function

6. If the FROM clause in a subselect references a recursive common table expression, and if the result of the recursive common table expression is used to derive the final result table, the column mask cannot be applied to a column that is referenced in the fullselect of the recursive common table expression.

7. If the FROM clause in a subselect contains a data-change-table-reference, and if an INCLUDE clause is specified as part of the SQL data change statement, the column mask cannot be applied to the columns that are used to derive the values for these additional columns in the outermost select list.

8. If the FROM clause in a subselect references an external table user-defined function or an SQL table user-defined function, and if the result of the function is used to derive the final result table, the column mask cannot be applied to the column that is an argument of the function.

9. If an OLAP specification is referenced in a select list that derives the final result table, the column mask cannot be applied to the column that is referenced in the partitioning expression or the sort key expression of the OLAP specification.
10. If a user-defined function is defined with the NOT SECURED option, the argument of the function must not reference a column for which a column mask is enabled and the column access control is activated for its table. This rule applies to user-defined functions that are referenced anywhere in the statement.

To avoid the above error situations at bind time, one of the following actions must be taken:

- modify or remove the above contexts from the statement
- disable the column mask
- drop the column mask, modify the definition, and recreate the column mask
- deactivate the column access control for the table

In other situations, if the statement contains a SELECT DISTINCT, and a column mask is applied to a column that directly or indirectly derives the result of SELECT DISTINCT, the statement might return a result that is not deterministic. The following examples illustrate when such results might be returned:

1. If the column mask definition references other columns from the same table of the column to which the column mask is applied, the result of SELECT DISTINCT can not be deterministic.

2. If the column is referenced in the argument of built-in scalar functions (such as COALESCE, IFNULL, NULLIF, MAX, MIN, LOCATE, TOTALORDER), the result of SELECT DISTINCT might not be deterministic.

3. If the column is referenced in the argument of an aggregation function, the result of SELECT DISTINCT might not be deterministic. If DISTINCT is specified, the argument of the function must not reference a column with a column mask.

4. If the column is embedded in an expression and the expression contains a function that is not deterministic or has an external action, the result of SELECT DISTINCT might not be deterministic.

With UNION DISTINCT, the elimination of the duplicate rows is based on the unmasked values in R1 and R2. Because all rows are from R1 or R2, the output values in the result table of the union may vary when one or more of the following conditions occur:

- The expression corresponding to the \( n \)th column in R1 references columns with column masks, but the expression corresponding to the \( n \)th column in R2 does not, or vice versa.

- The expressions corresponding to the \( n \)th column in R1 and R2 reference columns with different column masks.

- The column mask definition references columns that are not the same target column for which the column mask is defined, and those columns are not part of the UNION DISTINCT operation. It is recommended that the column mask definition does not reference other columns from the target table.

For example, a row in R1 is derived from the masked value, and a row in R2 is derived from the unmasked value. If the row in the result table is from R1, the masked value is returned. If the row in the result table is from R2, the unmasked value is returned.
EXCEPT and INTERSECT can be intermixed with UNION if the rows in R1 and R2 for EXCEPT and INTERSECT do not reference columns with column masks.

If the column is not nullable, most likely its column mask definition will not consider a null value for the column. After the column access control is activated for the target table, if the target table is the null-padded table in an outer join operation, the column value in the final result table might be a null.

When the columns are used to derive the new values for an INSERT, UPDATE, MERGE, or a SET transition-variable assignment statement, the original column values, not the masked values, are used. If the columns have column masks, those column masks are applied to ensure the evaluation of the access control rules at run time masks the column to itself, not to a constant or an expression. This is to ensure the masked values are the same as the original column values. If a column mask does not mask the column to itself, the existing row is not updated or the new row is not inserted and an error is returned at run time. The rules that are used to apply column masks in order to derive the new values follow the same rules described above for the final result table of a query. See the data change statements for how the column masks are used to affect the insertability and updatability.

A column mask can be applied only to a base table column. If a materialized table expression, materialized view, or common table expression column is involved in the final result table, the above error situations can occur inside the materialized table expression, materialized view, or common table expression definition.

Column access control does not affect the XMLTABLE built-in function. If the input to the XMLTABLE function is a column with a column mask, the column mask is not applied.

Column access control remains activated until the DEACTIVATE COLUMN ACCESS CONTROL clause is used to stop enforcing it.

Row and column access control are not enforced when EXPLAIN tables are populated by Db2:

Row and column access control can be enforced for EXPLAIN tables. However, the enabled row permissions and column masks are not applied when Db2 inserts rows into those tables.

Stop enforcing row or column access control:

The DEACTIVATE ROW ACCESS CONTROL clause is used to stop enforcing row access control for a table. The default row permission is dropped. Thereafter, when the table is referenced in a data manipulation statement, explicitly created row permissions are not applied. The table is accessible based on the granted privileges.

The DEACTIVATE COLUMN ACCESS CONTROL clause is used to stop enforcing column access control for a table. Thereafter, when the table is referenced in a data manipulation statement, the column masks are not applied. The unmasked column values are used for the final result table.

The explicitly created row permissions or column masks, if any, remain but have no effect.

Secure triggers for row and column access control:

Triggers are used for database integrity, and as such a balance between row and column access control (security) and database integrity is needed.
Enabled row permissions and column masks are not applied to the initial values of transition variables and transition tables. Row and column access control enforced for the triggering table is also ignored for any transition variables or transition tables referenced in the trigger body. To ensure there is no security concern for SQL statements in the trigger action to access sensitive data in transition variables and transition tables, the trigger must be created or altered with the SECURED option. If a trigger is not secure, row and column access control cannot be enforced for the triggering table.

**Secure user-defined functions for row and column access control:**

If a row permission or column mask definition references a user-defined function, the function must be altered with the SECURED option because the sensitive data might be passed as arguments to the function.

Db2 considers the SECURED option an assertion that declares the user has established a change control audit procedure for all changes to the user-defined function. It is assumed that such a control audit procedure is in place for all versions of the user-defined function, and that all subsequent ALTER FUNCTION statements or changes to external packages are being reviewed by this audit process.

**Database operations where row and column access control is not applicable:**

Row and column access control must not compromise database integrity. Columns involved in primary keys, unique keys, indexes, check constraints, and referential integrity (RI) must not be subject to row and column access control. Column masks can be defined for those columns but they are not applied during the process of key building or constraint or RI enforcement.

**Read-only cursors and read-only views:**

The rules that are used to determine a read-only cursor or a read-only view remain unaffected by row and column access control because those rules are determined at bind time. The effect of application of enabled column masks is not known until run time. Therefore, the data change operation on a writable cursor or a writable view could still fail at run time.

**Considerations for adding a column to a system-period temporal table or archive-enabled table:**

- If the data type of the column is a distinct type:
  - The owner of the history table or archive table must implicitly or explicitly have the USAGE privilege on the distinct type.
  - If the distinct type is unqualified, its schema matches the schema for the following objects:
    - The implicit schema for the distinct type for the column in the history table is the same as the implicit schema that is determined for the distinct type in the system-period temporal table.
    - The implicit schema for the distinct type for the column in the archive table is the same as the implicit schema that is determined for the distinct type in the archive-enabled table.
- The syntax LONG VARCHAR or LONG VARGRAPHIC must not be specified when you add a column to these types of tables. Use VARCHAR or VARGRAPHIC instead.
- If the data type of the column is a LOB and the INLINE LENGTH clause is not specified, Db2 determines the length. The implicit inline length
that is used for the column in the system-period temporal table or archive-enabled table is also used for the corresponding column in the history table or archive table.

- If the data type of the column is a LOB, auxiliary objects are implicitly created for it in the system-period temporal table or archive-enabled table. Auxiliary objects are also created for the corresponding column of the history table or archive table.

**Effect of renaming a column on statistics profiles:**
When you execute ALTER TABLE with RENAME COLUMN, statistics profiles that refer to that column are no longer valid. An error occurs when RUNSTATS is run with a profile that contains a renamed column. After you execute ALTER TABLE with RENAME COLUMN, complete these tasks:

1. Delete any statistics profiles that refer to the renamed column.
2. Create the statistics profiles again.

**Related information:**
- RUNSTATS TABLESPACE syntax and options (Db2 Utilities)
- Statistics profile syntax (Db2 Utilities)
- Deleting statistics profiles (Db2 Performance)
- Creating statistics profiles (Db2 Performance)

**Key label requirement**
To use a key label for encryption, the VSAM data sets for the page sets need to be associated with an SMS Data Class that has extended format capability (EF enabled).

**Determining a key label for base table space and associated objects**
When a key label is specified at the table level, Db2 provides the key label to DFSMS to encrypt all the table spaces and index spaces associated with the table. This includes base table space, auxiliary table spaces, XML table spaces, index spaces, and clone table space, regardless of whether the base table space or associated objects are explicitly or implicitly created. Db2 does not enforce any key label relationship between the base table and an associated history or archive table. The key label for the archive and the history tables has to be set independent of the base table. If there is no key label specified at the table level, Db2 will provide the key label to DFSMS specified for the storage group.

When Db2 calls DFSMS to allocate the dataset for table space or index space, DFSMS uses its order of precedence to determine the key label and can override the key label specified by Db2.

DFSMS order of precedence:
- RACF data set profile
- JCL, dynamic allocation, TSO ALLOCATE
- SMS data class construct

If the security administrator has specified a key label for the RACF data set profile, that key label takes precedence over the Db2 provided key label. The REPORT utility can be run to determine the key label used for encryption.

**Description of key label in effect in DB2**
**Table 181. Example scenarios for a partition-by-growth table space, that describe the key label in effect in DB2. This is the key label provided to DFSMS during allocation of data set for table spaces and index spaces.**

<table>
<thead>
<tr>
<th>Scenarios</th>
<th>Catalog key label value</th>
<th>Key label provided to DFSMS during data set allocation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create storage group, SG01 with key label, SGKL01.</td>
<td>SYSSTOGROUP record - KEY LABEL: SGKL01</td>
<td>SGKL01</td>
</tr>
<tr>
<td>Create table space, TBSP01 using storage group, SG01 – Creates Partition 1</td>
<td>SYSTABLESPACE record for TBSP01 / SYSTABLES record for TBKL01 – KEY LABEL: TBKL01</td>
<td>TBKL01</td>
</tr>
<tr>
<td>REORG TABLESPACE TBSP01 – Reorgs Partition 1</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Create index, IX01 on table, TB01 creates index space</td>
<td>SYSINDEXES record for IX01 – KEY LABEL: TBKL01</td>
<td>TBKL01</td>
</tr>
<tr>
<td>Insert data into TB01 – Creates Partition 2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Alter table, TB01 to specify NO KEY LABEL</td>
<td>SYSTABLESPACE record for TBSP01 / SYSTABLES record for TBKL01 / SYSINDEXES record for IX01 – KEY LABEL: Empty string</td>
<td></td>
</tr>
<tr>
<td>Insert data into TB01 – Creates partition 3</td>
<td></td>
<td>SGKL01</td>
</tr>
<tr>
<td>REORG TABLESPACE TBSP01 with REUSE option – Resets and reuses DB2-managed data sets. No change to key label</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Key label considerations**

If the last table is dropped from a segmented table space, the table space and its underlying data set will remain. If key label is in effect, the KEYLABEL column for the table space’s SYSTABLESPACE record will be cleared. If a new table is created in this table space, it will be encrypted with the previous key label. If the table has to be created as unencrypted, execute the REORG TABLESPACE utility for the table space.

If a table space is explicitly created with the DEFINE YES option and a table with a key label is defined in that table space, then the data sets associated with the table space will not be encrypted. A subsequent REORG is necessary to encrypt the data sets. Users that want immediate encryption of the data sets associated with the table space must to define table spaces with the DEFINE NO option.

**Syntax and descriptions for hash organization (deprecated)**

**Deprecated function:** [FL 504] Hash-organized tables are deprecated. Beginning in Db2 12, packages bound with APPLCOMPAT( V12R1M504) or higher cannot create hash-organized tables or alter existing tables to use hash-organization. Existing hash organized tables remain supported, but they are likely to be unsupported in the future.

`alter-hash-organization`
ADD ORGANIZE BY HASH

Specifies that a hash is to be used for the data organization of the table.

ADD ORGANIZE BY HASH must not be specified if the table is already defined with the APPEND YES clause, or if the table space is defined with the MEMBER CLUSTER clause.

ALTER TABLE ADD ORGANIZE BY HASH is allowed only if the table is in either a partition-by-growth table space or a partition-by-range table space.

ALTER TABLE ADD ORGANIZE BY HASH is not allowed for table spaces with relative numbering.

ADD ORGANIZE BY HASH must not be specified on tables that are using basic row format.

ADD ORGANIZE BY HASH must not be specified if a user specified clustering index exists.

ADD ORGANIZE BY HASH must not be specified for global temporary tables.

After ALTER TABLE with ADD ORGANIZE BY HASH runs:

- All columns that are part of the hash key are no longer updatable. SQL statements that update a column of the hash key return an error.
- The entire table space that contains the table must be reorganized.

Use of this clause or keyword might invalidate packages that depend on the target object, or packages that depend on related objects through cascading effects. See Changes that invalidate packages (Db2 Application programming and SQL).

UNIQUE

Specifies that Db2 enforces uniqueness of the hash key columns, preventing the table from containing two or more rows with the same value of the hash key.

\[(column-name, \ldots)\]

The list of column names defines the hash key that is used to determine where a row will be placed.

Each column-name must be an unqualified name that identifies a column of the table. The same column must not be specified more than one time and the specified columns must be defined as NOT NULL. The number of specified
columns must not exceed 64, and the sum of their length attributes must not exceed 255. A specified column cannot be any of the following types of columns:

- a LOB column
- a DECFLOAT column
- an XML column
- a distinct type column that is based on one of the preceding data types

All character and graphic string columns in the key must use the same encoding scheme.

If the table is defined as partition by range, the list of column names must specify all of the column names that are specified in the partition-expression for the table, and must specify the column names in the same order as partition-expression. If the ORGANIZE BY clause contains more columns than the partition-expression for the table, partition-expression determines the partition number.

**HASH SPACE integerK|M|G**

Specifies the amount of fixed hash space to preallocate for the table. If the table is partition-by-range, this is the space for each partition.

The default is 64M for a table in a partition-by-growth table space or 64M for each partition of a partition-by-range table space.

- **K** Indicates that the integer value is multiplied by 1024 to specify the hash space size in bytes. The integer value must be between 256 and 268,435,456.
- **M** Indicates that the integer value is multiplied by 1,048,576 to specify the hash space size in bytes. The integer value must be between 1 and 262,144.
- **G** Indicates that the integer value is to be multiplied by 1,073,741,824 to specify the hash space size in bytes. The integer value must be between 1 and 131,072 for a partition by range table and must be between 1 and 131,072 for a non-partitioned table.

If a value greater than 4G is specified, the data sets for the table space are associated with a DFSMS data class that has been specified with extended format and extended addressability.

**ALTER ORGANIZATION SET HASH SPACE integer**

Changes the fixed hash space that is used for the data organization for the table. The table must be defined to use hash organization.

If the table is defined as partition-by-range, the value specified by integer is per partition and applies to each partition of the table. For tables that are not partition-by-range, integer applies to the whole table.

The new hash space value will be applied when the table space is reorganized using the REORG utility.
HASH SPACE integer\(K|M|G\)

Specifies the amount of fixed hash space to preallocate for the table. If the table is partition-by-range, this is the space for each partition.

\(K\) Indicates that the integer value is multiplied by 1024 to specify the hash space size in bytes. The integer value must be between 256 and 268,435,456.

\(M\) Indicates that the integer value is multiplied by 1,048,576 to specify the hash space size in bytes. The integer value must be between 1 and 262,144.

\(G\) Indicates that the integer value is to be multiplied by 1,073,741,824 to specify the hash space size in bytes. The integer value must be between 1 and 131,072 for a partition by range table and must be between 1 and 131,072 for a non-partitioned table.

If a value greater than 4G is specified, the data sets for the table space are associated with a DFSMS data class that has been specified with extended format and extended addressability.

Be aware that specifying the ALTER ORGANIZATION clause might affect subsequent requests to recover to a point in time. For information about possible restrictions, effects on recovery status, and other considerations, see [Point-in-time recovery](#).

DROP ORGANIZATION
See “DROP ORGANIZATION:” on page 1367.

partition-hash-space

Notes:

1. The HASH SPACE clause can only be specified for the ALTER PARTITION clause.

HASH SPACE integer\(K|M|G\)

Specifies the amount of fixed hash space to preallocate for the partition that is associated with the partition element. If HASH SPACE is omitted from the partition element, the HASH SPACE value that is specified in the ORGANIZE BYCLAUSE is used.

The HASH SPACE keyword in the partition-element must only be specified if the table is defined to use hash organization.

\(K\) Indicates that the integer value is multiplied by 1024 to specify the hash space size in bytes. The integer value must be between 256 and 268,435,456.
Indicates that the integer value is multiplied by 1,048,576 to specify the hash space size in bytes. The integer value must be between 1 and 262,144.

G Indicates that the integer value is to be multiplied by 1,073,741,824 to specify the hash space size in bytes. The integer value must be between 1 and 256 for a partition by range table and must be between 1 and 131,072 for a non-partitioned table.

If a value greater than 4G is specified, the data sets for the table space are associated with a DFSMS data class that has been specified with extended format and extended addressability.

Notes for hash organization (deprecated)

Deprecation policy: [FL 504] Hash-organized tables are deprecated. Beginning in Db2 12, packages bound with APPLCOMPAT (V12R1M504) or higher cannot create hash-organized tables or alter existing tables to use hash-organization. Existing hash organized tables remain supported, but they are likely to be unsupported in the future.

When changes to the hash organization of a table take place:
An alter of the table that uses hash organization will take effect immediately in terms of enforcing the unique hash key. However, the physical organization of the table space is converted to hash organization after REORG.

In a partition-by-range table space, if individual partitions are altered to specify HASH SPACE, the new hash space values take effect after the REORG utility is run on the individual partitions.

Buffer pool, DSSIZE, and MAXPARTITIONS considerations for tables using hash organization:
Db2 calculates an optimum buffer pool size for hash organization based on the definition of the table and validate the calculated buffer pool size with the buffer pool of the explicitly created table space. If the buffer pool sizes are different, Db2 returns an error.

If the table is a partition-by-range table space, the DSSIZE value for the table space must be large enough to fit the HASH SPACE specification for each partition.

If the table is in a partition-by-growth table space, the total space calculated from the DSSIZE and MAXPARTITIONS values for the table space must be large enough for the implicitly or explicitly specified HASH SPACE.

Changing the hash space value:
To change the HASH SPACE value for all partitions of a partition-by-range table space or to change the total HASH SPACE for a partition-by-growth table space, use the ALTER ORGANIZATION SET HASH SPACE (integer) clause. To change HASH SPACE value for more than one, but not all partitions of a partition-by-range table space you must specify separate ALTER TABLE statements for each partition and specify the ALTER PARTITION (integer) and HASH SPACE (integer) clauses.
Hash space and Db2 page size:
If the specified hash space is less than or equal to 64 MB (the Db2 default), Db2 will add extra space for Db2 system pages. If the specified hash space is greater than 64 MB, Db2 will use part of the hash space for Db2 system pages. The amount of space needed for Db2 system pages depends on SEGSIZE and PAGESIZE. The larger the SEGSIZE and/or PAGESIZE becomes, the larger the requirement for Db2 system pages. Db2 can reserve up to 5 MB for system pages for the highest SEGSIZE value (64) and PAGESIZE value (32K).

Hash space and DSSIZE:
Depending on certain table space characteristics, Db2 needs to reserve space for the hash overflow area. Therefore, the amount of hash space cannot be equal to the DSSIZE value. The maximum amount of hash space that can be specified is approximately 20% less than the DSSIZE value. Db2 returns an error if the amount of hash space is too large. If the amount of hash space is too large, specify a larger value of DSSIZE, or decrease the amount of hash space.

Specifying APPEND for hash-organized tables:
Append processing is not applicable to tables with hash organization since there is no key clustering in hash organization. For insert operations into tables with hash organization, Db2 will use the internal hash algorithm to determine the location of the row.

Restrictions for tables with hash organization:
Tables that use hash organization are subject to the following restrictions:
• If the table already uses hash organization, Db2 will returns an error.
• A table that is defined to use hash organization cannot be created in a LOB table space or XML table space.
• The data type of columns that are specified in a hash key cannot be changed.
• Partition level REORG is not allowed after the table is changed using the ALTER ADD HASH ORGANIZATION clause or the ALTER DROP ORGANIZATION clause.
• The MAXROWS clause is applicable only to the hash overflow area of the table space for tables with hash organization. The fixed hash area of each page will contain as many rows as it can hold, up to a maximum of 255.

Alternative syntax and synonyms:
To provide compatibility with previous releases of Db2 or other products in the Db2 family, Db2 supports the following clauses:
• NOCACHE (single clause) as a synonym for NO CACHE
• NOCYCLE (single clause) as a synonym for NO CYCLE
• NOMINVALUE (single clause) as a synonym for NO MINVALUE
• NOMAXVALUE (single clause) as a synonym for NO MAXVALUE
• NOORDER (single clause) as a synonym for NO ORDER
• PART integer VALUES can be specified as an alternative to PARTITION integer ENDING AT.
VALUES as a synonym for ENDING AT
DEFINITION ONLY as a synonym for WITH NO DATA
SET MATERIALIZED QUERY AS DEFINITION ONLY as a synonym for DROP MATERIALIZED QUERY
SET SUMMARY AS DEFINITION ONLY as a synonym for DROP MATERIALIZED QUERY
SET MATERIALIZED QUERY AS (fullselect) as a synonym for ADD MATERIALIZED QUERY (fullselect)
SET SUMMARY AS (fullselect) as a synonym for ADD MATERIALIZED QUERY (fullselect)
TIMEZONE can be specified as an alternative to TIME ZONE.

Examples

Example 1: Column DEPTNAME in table DSN8C10.DEPT was created as a VARCHAR(36). Increase its length to 50 bytes. Also, add the column BLDG to the table DSN8C10.DEPT. Describe the new column as a character string column that holds SBCS data.

```sql
ALTER TABLE DSN8C10.DEPT
ALTER COLUMN DEPTNAME SET DATA TYPE VARCHAR(50)
ADD BLDG CHAR(3) FOR SBCS DATA;
```

Example 2: Assign a validation procedure named DSN8EAEM to the table DSN8C10.EMP.

```sql
ALTER TABLE DSN8C10.EMP
VALIDPROC DSN8EAEM;
```

Example 3: Disassociate the current validation procedure from the table DSN8C10.EMP. After the statement is executed, the table no longer has a validation procedure.

```sql
ALTER TABLE DSN8C10.EMP
VALIDPROC NULL;
```

Example 4: Define ADMRDEPT as the foreign key of a self-referencing constraint on DSN8C10.DEPT.

```sql
ALTER TABLE DSN8C10.DEPT
FOREIGN KEY(ADMRDEPT) REFERENCES DSN8C10.DEPT ON DELETE CASCADE;
```

Example 5: Add a check constraint to the table DSN8C10.EMP which checks that the minimum salary an employee can have is $10,000.

```sql
ALTER TABLE DSN8C10.EMP
ADD CHECK (SALARY >= 10000);
```

Example 6: Alter the PRODINFO table to define a foreign key that references a non-primary unique key in the product version table (PRODVER_1). The columns of the unique key are VERNAME, RELNO.

```sql
ALTER TABLE PRODINFO
FOREIGN KEY (PRODNAME, PRODVERNO)
REFERENCES PRODVER_1 (VERNAME, RELNO) ON DELETE RESTRICT;
```

Example 7: Assume that table DEPT has a unique index defined on column DEPTNAME. Add a unique key constraint named KEY_DEPTNAME consisting of column DEPTNAME to the DEPT table:

```sql
ALTER TABLE DSN8C10.DEPT
ADD CONSTRAINT KEY_DEPTNAME UNIQUE (DEPTNAME);
```
Example 8: Register the base table TRANSCOUNT as a materialized query table. The result of the fullselect must provide a set of columns that match the columns in the existing table (same number of columns, same column definitions, and same names). So that you can maintain the table with insert, update, and delete operations as well as the REFRESH TABLE statement, define the materialized query table as user-maintained.

```
ALTER TABLE TRANSCOUNT ADD MATERIALIZED QUERY
    (SELECT ACCTID, LOCID, YEAR, COUNT(*) as cnt
     FROM TRANS
     GROUP BY ACCTID, LOCID, YEAR )
    DATA INITIALLY DEFERRED
    REFRESH DEFERRED
    MAINTAINED BY USER;
```

Example 9: Assume that table TB1 has a column, COL1 that is defined as CHAR(4) FOR BIT DATA WITH DEFAULT 'AB'. The value that is stored in the table will be X'C1C24040'. After the following ALTER TABLE statement is run, the resulting value that is stored in the table will be BX'C1C240400000':

```
ALTER TABLE TB1
ALTER COLUMN COL1
SET DATA TYPE BINARY(6);
```

Example 10: Add a key label to the table space, DSN8C10.EMP to encrypt all the table spaces and index spaces associated with the table.

```
ALTER TABLE DSN8C10.EMP
    KEY LABEL SECUREKEY01;
```

Examples for column access controls

Example 1:
Based on the data in the CUSTOMER table, the SELECT DISTINCT statement returns one row with the SALARY value 100,000. A column mask, SALARY_MASK, is created to mask the salary value. After column access control is activated for the CUSTOMER table, the column mask is applied to SALARY column. A user with the 'MGR' ID (or role) issues a SELECT DISTINCT statement. The SELECT DISTINCT statement still returns one row because the removal of duplicates is based on the unmasked value of the SALARY column, but the value that is returned in that row is based on the masked SALARY value, which can be either 125,000 or 110,000.

The table CUSTOMER contains:

<table>
<thead>
<tr>
<th>SALARY</th>
<th>COMMISSION</th>
<th>EMPID</th>
</tr>
</thead>
<tbody>
<tr>
<td>100,000</td>
<td>25,000</td>
<td>123456</td>
</tr>
<tr>
<td>100,000</td>
<td>10,000</td>
<td>654321</td>
</tr>
</tbody>
</table>

```
CREATE MASK SALARY_MASK ON CUSTOMER
FOR COLUMN SALARY RETURN
    CASE WHEN(SESSION_USER = 'MGR')
        THEN SALARY + COMMISSION
    ELSE SALARY
    END
ENABLE;
COMMIT;

ALTER TABLE CUSTOMER
    ACTIVATE COLUMN ACCESS CONTROL;
```
Example 2:
Based on the data in T1 and T2 tables, the SELECT DISTINCT statement using the COALESCE function returns one row with the T1.C1 value of 1. A column mask, C1_MASK, is created to mask the value of T1.C1. After column access control is activated for table T1, the column mask is applied to column C1 of table T1. A user with the 'EMP' ID (or role) issues a SELECT DISTINCT statement. The SELECT DISTINCT statement still returns one row because the removal of duplicates is based on the unmasked value of T1.C1 from the COALESCE function, but the value that is returned in that row is based on the masked value of T1.C1 from the COALESCE function. The returned value can be either 2 or 3.

```
INSERT INTO T1(C1) VALUES(1);
INSERT INTO T1(C1) VALUES(1);
INSERT INTO T2(C1) VALUES(2);
INSERT INTO T2(C1) VALUES(3);

CREATE MASK C1_MASK ON T1
FOR COLUMN C1 RETURN
CASE WHEN(SESSION_USER = 'EMP')
    THEN NULL
    ELSE C1
END
ENABLE;

INSERT INTO T1(C1) VALUES(1);
INSERT INTO T1(C1) VALUES(1);
INSERT INTO T2(C1) VALUES(2);
INSERT INTO T2(C1) VALUES(3);

SELECT DISTINCT COALESCE(T1.C1, T2.C1) FROM T1, T2;
```

Example 3:
Based on the data in the CUSTOMER table, the maximum income is the same in the states CA and IL, 50,000, thus, the SELECT DISTINCT statement returns one row. A column mask, INCOME_MASK, is created to mask the income value. After column access control is activated for the CUSTOMER table, the column mask is applied to the INCOME column before the MAX aggregate function is evaluated. However, the INCOME_MASK column mask, masks the income value of 0 as 100,000 in state IL. As a result, the maximum income becomes 100,000 for state IL, but the maximum income is still 50,000 for state CA. X.B is used in a predicate in the SELECT DISTINCT statement, therefore, the original INCOME values and the original results of the MAX(INCOME) function must be preserved. So the SELECT DISTINCT statement still returns one row, but the value in that row might not be deterministic, that is, the value might be 50,000 from the 'CA' row or might be 100,000 from the 'IL' row.

The CUSTOMER table contains:

<table>
<thead>
<tr>
<th>STATE</th>
<th>INCOME</th>
</tr>
</thead>
<tbody>
<tr>
<td>CA</td>
<td>40,000</td>
</tr>
<tr>
<td>CA</td>
<td>50,000</td>
</tr>
<tr>
<td>IL</td>
<td>0</td>
</tr>
</tbody>
</table>
CREATE MASK INCOME_MASK ON CUSTOMER
  FOR COLUMN INCOME RETURN
  CASE WHEN(INCOME = 0)
    THEN 100000
    ELSE INCOME
  END
  ENABLE;
COMMIT;

ALTER TABLE CUSTOMER
  ACTIVATE COLUMN ACCESS CONTROL;
COMMIT;

SELECT DISTINCT B FROM
  (SELECT STATE, MAX(INCOME) FROM CUSTOMER
    GROUP BY STATE)
  X(A, B)
WHERE B > 10000;

Example 4:
The expression INCOME + RAND() is not deterministic because the RAND function is not deterministic. Based on the data in the CUSTOMER table, the SELECT DISTINCT statement will, most likely, return two distinct rows. However, it could return only one row. A column mask, INCOME_MASK, is created to mask the income value. After column access control is activated for the CUSTOMER table, the column mask is applied to the INCOME column, which causes the masked value for both rows to be the same. Because the RAND function is not deterministic, the SELECT DISTINCT statement will, most likely, still return two distinct rows, but it could return only one row. The uncertainty caused by the RAND function causes the result of the SELECT DISTINCT statement to not be deterministic.

The CUSTOMER table contains:

<table>
<thead>
<tr>
<th>STATE</th>
<th>INCOME</th>
</tr>
</thead>
<tbody>
<tr>
<td>IL</td>
<td>10,000</td>
</tr>
<tr>
<td>IL</td>
<td>50,000</td>
</tr>
</tbody>
</table>

CREATE MASK INCOME_MASK ON CUSTOMER
  FOR COLUMN INCOME RETURN
  CASE WHEN(INCOME = 40,000)
    THEN 50000
    ELSE INCOME
  END
  ENABLE;
COMMIT;

ALTER TABLE CUSTOMER
  ACTIVATE COLUMN ACCESS CONTROL;
COMMIT;
SELECT DISTINCT A FROM
(SELECT INCOME + RAND() FROM CUSTOMER)
X(A)
WHERE A > 10000;

Example 5:
A column mask, STATE_MASK, is created for the STATE column of the
CUSTOMER table to return a value that shows the city name with the state
if the city is SJ, SFO, or OKLD. Otherwise the city is not returned, just the
state. After column access control is activated for the CUSTOMER table, a
SELECT statement which groups results using the STATE column is issued.
However, because the CITY column that is referenced in the STATE_MASK
column mask is not a grouping column, a bind time error is returned to
signify that the STATE_MASK column mask is not appropriate for this
statement.

The CUSTOMER table contains:

<table>
<thead>
<tr>
<th>STATE</th>
<th>CITY</th>
<th>INCOME</th>
</tr>
</thead>
<tbody>
<tr>
<td>CA</td>
<td>SJ</td>
<td>40,000</td>
</tr>
<tr>
<td>CA</td>
<td>SC</td>
<td>30,000</td>
</tr>
<tr>
<td>CA</td>
<td>SB</td>
<td>60,000</td>
</tr>
<tr>
<td>CA</td>
<td>SFO</td>
<td>80,000</td>
</tr>
<tr>
<td>CA</td>
<td>OKLD</td>
<td>50,000</td>
</tr>
<tr>
<td>CA</td>
<td>SJ</td>
<td>70,000</td>
</tr>
<tr>
<td>NY</td>
<td>NY</td>
<td>50,000</td>
</tr>
</tbody>
</table>

CREATE MASK STATE_MASK ON CUSTOMER
FOR COLUMN STATE RETURN
CASE WHEN(CITY = 'SJ')
    THEN CITY||',.||STATE
WHEN(CITY = 'SFO')
    THEN CITY||',.||STATE
WHEN(CITY = 'OKLD')
    THEN CITY||',.||STATE
    ELSE ' ,.||STATE
END
ENABLE;

COMMIT;

ALTER TABLE CUSTOMER
ACTIVATE COLUMN ACCESS CONTROL;

COMMIT;

SELECT STATE, AVG(INCOME) FROM CUSTOMER
GROUP BY STATE
HAVING STATE = 'CA';

Unicode column in an EBCDIC table

ALTER TABLESPACE

The ALTER TABLESPACE statement changes the description of a table space at the
current server.

Chapter 7. Statements  1411
Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

Authorization

The privilege set that is defined below must include at least one of the following:

- Ownership of the table space
- DBADM authority for its database
- SYSADM or SYSCTRL authority
- System DBADM
- Installation SYSOPR authority (when the current SQLID of the process is set to SYSINSTL)

If the database is implicitly created, the database privileges must be on the implicit database or on DSNDB04.

If BUFFERPOOL or USING STOGROUP is specified, additional privileges might be required, as explained in the description of those clauses.

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the package. If the statement is dynamically prepared, the privilege set is the union of the privilege sets that are held by each authorization ID and role of the process.
Notes:
1 If you specify DROP PENDING CHANGES, DSSIZE, or SEGSIZE, no other clauses can be specified in the same ALTER TABLESPACE statement.
2 The same clause must not be specified more than one time in a single ALTER TABLESPACE statement.
3 The same clause must not be specified more than one time for each altered partition.
4 A clause that it specified at the partition level must not be specified at the table space level.
5 Can be specified only for a table space with relative page numbering (PAGENUM RELATIVE).

using-block:
**database-name.table-space-name**

Identifies the table space that is to be altered. The name must identify a table space that exists at the current server. Omission of `database-name` is an implicit specification of DSNDB04.

If you identify a partitioned table space, you can use the `ALTER PARTITION` clause.

A table space cannot be altered if it is associated with an accelerator-only table or a directory table.

**BUFFERPOOL bpname**

Identifies the buffer pool that is to be used for the table space. `bpname` must identify an activated buffer pool.

The privilege set must include SYSADM or SYSCTRL authority or the USE privilege for the buffer pool.

If `bpname` specifies a buffer pool with a smaller page size than the current page size, the maximum record size of all tables in the table space must fit in the smaller page size.

If `bpname` specifies a buffer pool with a different page size, the table space must be one of the following types:
• A universal table space (excluding XML table spaces)
• A table space for which a pending definition change will convert the table space to a universal table space
• A LOB table space

If the table space is a partition-by-growth table space, the page size must be valid depending on the values that are in effect for the MAXPARTITIONS and DSSIZE options of the table space. If the table space is a partition-by-range table space, the page size must be valid depending on the values that are in effect for the current number of partitions and the DSSIZE option of the table space. For more information about the relationship between DSSIZE, MAXPARTITIONS, buffer pool page size and table space size, see Maximum number of partitions and table space size.

The buffer pool change is a pending change to the definition of the table space if the data sets of the table space are already created and if one of the following conditions is true:
• Pending definition changes already exist for the table space or any objects within the base table space.
• The specified buffer pool has a different page size than the buffer pool that is currently being used for the table space.

Otherwise, the change is considered an immediate change.

For an immediate change for which the page size of both buffer pools is the same, the table space and all data sets are immediately available. The data sets do not need to be closed and reopened for the table space to be available. In addition, Db2 automatically closes required data sets. The description of the table space takes effect the next time the data sets of the table space are opened.

If the change is a pending change to the definition of the table space, the changes are not reflected in the definition or data at the time the ALTER TABLESPACE statement is issued. Instead, the entire table space is placed in an advisory REORG-pending state (AREOR). A subsequent reorganization of the entire table space will apply the pending definition changes to the definition and data of the table space.

When the pending page size change is applied, if the table space is a universal table space that uses partition-by-growth organization, the number of partitions is determined based on the amount of existing data and the new page size value. Changing the page size to be larger can cause automatic creation of additional partitions. If LOB columns exist, additional LOB table spaces and auxiliary objects are implicitly created for the newly-created partitions independent of whether SQLRULES (DB2) or SQLRULES (STD) is in effect or whether the table space was explicitly or implicitly created. The new LOB objects inherit the buffer pool attribute and authorization from the existing LOB objects.

**CCSID ccsid-value**

Identifies the CCSID value to be used for the table space. ccsid-value must identify a CCSID value that is compatible with the current value of the CCSID for the table space. See ALTER DATABASE for a list that shows the CCSID to which a given CCSID can be changed and details about changing it.

Do not specify CCSID for a LOB table space, a table space that is implicitly created for an XML column, or a table space in a work file database.
The CCSID of a table space cannot be changed if any of the following conditions are true:

- The table space contains any table that has an index that contains expressions.
- The table space contains a system-period temporal table or a history table.
- The table space contains an archive-enabled table or an archive table.

CLOSE
When the limit on the number of open data sets is reached, specifies the priority in which data sets are closed.

YES
Eligible for closing before CLOSE NO data sets. This is the default unless the table space is in a work file database.

NO
Eligible for closing after all eligible CLOSE YES data sets are closed.

For a table space in a work file database, Db2 uses CLOSE NO regardless of the value specified.

COMpress
Specifies whether data compression applies to the rows of the table space or partition.

Do not specify COMPRESS for a table space in a work file database.

YES
Specifies data compression. The rows are not compressed until the LOAD or REORG utility is run on the table in the table space or partition, or until an insert operation is performed through the INSERT statement or the MERGE statement.

When COMPRESS YES is specified for a LOB table space, the base table space must be a universal table space.

NO
Specifies no data compression. Inserted rows will not be compressed. Updated rows will be decompressed. The dictionary used for compression will be erased when the LOAD REPLACE, LOAD RESUME NO, or REORG utility is run. See Managing Performance for more information about the dictionary and data compression.

DROP PENDING CHANGES
Drops pending changes to the definition of the table space and any objects within the table space. Pending changes to the definition of the table space or any object within the table space must exist.

When the DROP PENDING CHANGES clause is specified, no other options are allowed in the same ALTER TABLESPACE statement.

The DROP PENDING CHANGES clause also resets advisory REORG-pending (AREOR) status except for tables that are converting to hash access.

DSSIZE integer G

Specifies the maximum data set size in gigabytes. DSSIZE can be specified only for these types of table spaces:

- A partition-by-growth or partition-by-range table space
- A table space for which a pending definition change will convert the table space to a universal table space
- A LOB table space
Therefore, the DSSIZE value specifies the maximum size of a partition of a universal table space or the maximum size of any data set in a LOB table space. When DSSIZE is specified, no other options are allowed in the same ALTER TABLESPACE statement.

To specify a value greater than 4G, the data sets for the table space must be associated with a DFSMS data class that has been specified with extended format and extended addressability.

DSSIZE that is specified at the table space level is applied to each of the partitions of the table space.

The accepted values that you can specify depend on the type of table space.

**Partition-by-growth**

Specify a power-of-two value in the range 1G - 256G.

**Partition-by-range with relative page numbers**

Specify any value 1G - 1024G. The following values determine the DSSIZE value for each partition, in the order of precedence shown:

1. The DSSIZE value in the PARTITION clause for that partition.
2. The DSSIZE value specified at the table space level, not inside a PARTITION clause.
3. The default value 4G.

**Partition-by-range with absolute page numbers**

Specify a power-of-two value 1G - 256G.

The change to the DSSIZE is a pending change to the definition of the table space if the data sets of the table space are already created and if one of the following conditions is true:

- Pending definition changes already exist for the table space or for any objects in the table space.
- The table space uses relative page numbering, and the DSSIZE value that is specified at the table space level is smaller than the value that is currently being used for one or more of the partitions in the table space.
- The table space uses absolute page numbering, and the specified DSSIZE value is different than the value that is currently being used for the table space.

Otherwise, the change takes effect immediately.

If the change is a pending change to the definition of the table space, the changes are not reflected in the definition or data at the time the ALTER TABLESPACE statement is issued. Instead, the entire table space is placed in an advisory REORG-pending state (AREOR). A subsequent reorganization of the entire table space will apply the pending definition changes to the definition and data of the table space.

If the table space is a partition-by-growth table space with the pending DSSIZE change is applied, the number of partitions is determined based on the amount of existing data in the table space and the new DSSIZE value. Changing the DSSIZE value to be smaller might cause automatic growth of additional partitions. If LOB columns exist, additional LOB table spaces and auxiliary objects are implicitly created for the newly-grown partitions independently of whether SQLRULES(Db2) or SQLRULES(STD) is in effect or whether the table space was explicitly or implicitly created. The new LOB objects inherit the buffer pool attribute and authorization from the existing LOB objects.
**INSERT ALGORITHM level**

Specifies the algorithm that is used when rows are inserted into tables in this table space. The insert algorithm level is used only where applicable (MEMBER CLUSTER UTS). Altering the insert algorithm for a table space occurs immediately.

1. Specifies the basic insert algorithm is used.
2. Specifies that insert algorithm 2 is used.

**Important:** The insert algorithm level can be changed only to level 1 or 2. Level 0, which is supported by CREATE TABLESPACE, is not supported by ALTER TABLESPACE.

**LOCKMAX**

Specifies the maximum number of page, row, or LOB locks an application process can hold simultaneously in the table space. If a program requests more than that number, locks are escalated. The page, row, or LOB locks are released and the intent lock on the table space or segmented (non-UTS) table is promoted to S or X mode. If you specify LOCKMAX a for table space in a work file database, Db2 ignores the value because these types of locks are not used.

*integer*

Specifies the number of locks allowed before escalating, in the range 0 - 2147483647.

Zero (0) indicates that the number of locks on the table or table space are not counted and escalation does not occur.

**SYSTEM**

Indicates that the value of field LOCKS PER TABLE(SPACE) on installation panel DSNTIPJ specifies the maximum number of page, row, or LOB locks a program can hold simultaneously in the table or table space.

If you change LOCKSIZE and omit LOCKMAX, the following results occur:

<table>
<thead>
<tr>
<th>LOCKSIZE</th>
<th>Resultant LOCKMAX</th>
</tr>
</thead>
<tbody>
<tr>
<td>TABLESPACE or TABLE</td>
<td>0</td>
</tr>
<tr>
<td>PAGE, ROW, or LOB</td>
<td>Unchanged</td>
</tr>
<tr>
<td>ANY</td>
<td>SYSTEM</td>
</tr>
</tbody>
</table>

If the lock size is TABLESPACE or TABLE, LOCKMAX must be omitted, or its operand must be 0.

**LOCKSIZE**

Specifies the size of locks used within the table space and, in some cases, also the threshold at which lock escalation occurs. Do not specify LOCKSIZE for a table space in a work file database.

**ANY**

Specifies that Db2 can use any lock size.

In most cases, Db2 uses LOCKSIZE PAGE LOCKMAX SYSTEM for non-LOB table spaces and LOCKSIZE LOB LOCKMAX SYSTEM for LOB table spaces. However, when the number of locks acquired for the table space exceeds the maximum number of locks allowed for a table space (an installation parameter), the page or LOB locks are released and locking is
set at the next higher level. If the table space is segmented, the next higher level is the table. If the table space is not segmented, the next higher level is the table space.

**TABLESPACE**
Specifies table space locks.

**TABLE**
Specifies table locks. Use TABLE only for a segmented (non-UTS) table space. Do not use TABLE for a universal table space.

**PAGE**
Specifies page locks. Do not use PAGE for a LOB table space.

**ROW**
Specifies row locks. Do not use ROW for a LOB table space.

**LOB**
Specifies LOB locks. Use LOB only for a LOB table space.

The LOCKSIZE change affects a dynamic SQL statement if the statement is prepared and executed after the change. The LOCKSIZE change affects a static SQL statement if the statement is executed after the change.

**LOGGED or NOT LOGGED**
Specifies whether changes that are made to the data in the specified table space are recorded in the log.

**LOGGED**
Specifies that changes that are made to the data in the specified table space are recorded in the log. This applies to all tables in the specified table space and to all indexes of those tables. Table spaces and indexes that are created for XML columns inherit the logging attribute from the associated base table space. Auxiliary indexes inherit the logging attribute from the associated base table space. This can affect the logging attribute of associated LOB table spaces. See **Notes** on page 1429 for more information.

If the base table space is in informational copy-pending status (meaning updates have been made to the table space) when you change from NOT LOGGED to LOGGED, the base table space is placed in copy-pending status. All indexes of tables in the table space are unchanged from their current state; that is, if an index is currently in informational copy-pending status, it will remain in information copy-pending status.

Specifying LOGGED for a LOB table space requires that the base table space also specifies the LOGGED parameter.

LOGGED cannot be specified for XML table spaces. The logging attribute of an XML table space is inherited from its base table space.

LOGGED cannot be specified for table spaces in DSND806 (the Db2 catalog) or in a work file database.

**NOT LOGGED**
Specifies that changes that are made to data in the specified table space are not recorded in the log. This applies to all tables in the specified table space and to all indexes of those tables. Table spaces and indexes that are created for XML columns inherit the logging attribute from the associated base table space. Auxiliary indexes inherit the logging attribute from the
associated base table space. This parameter can affect the logging attribute of associated LOB table spaces. See “Notes” on page 1429 for more information.

NOT LOGGED prevents undo and redo information from being recorded in the log for the base table space; however, control information for the specified base table space will continue to be recorded in the log. For a LOB table space, changes to system pages and to auxiliary indexes are logged.

NOT LOGGED is mutually exclusive with the DATA CAPTURE CHANGES parameter of CREATE TABLE and ALTER TABLE. NOT LOGGED will not be applied to the table space if any table in the table space specifies DATA CAPTURE CHANGES.

NOT LOGGED cannot be specified for XML table spaces.

NOT LOGGED cannot be specified for table spaces in the following databases:

- DSNDB06 (the Db2 catalog)
- a work file database

**MAXROWS integer**

Specifies the maximum number of rows that Db2 will consider placing on each data page. The integer can range from 1 through 255.

The change takes effect immediately for new rows added. However, the space class settings for some pages might be incorrect and could cause unproductive page visits. It is highly recommended to reorganize the table space after altering MAXROWS.

After ALTER TABLESPACE with MAXROWS is run, the table space is placed into an advisory REORG-pending status. Run the REORG TABLESPACE utility to remove the status.

Do not specify MAXROWS for a LOB table space, a table space that is implicitly created for an XML column, a table space in a work file database, or the Db2 catalog table spaces that are listed under SQL statements allowed on the catalog.

**MAXPARTITIONS integer**

Specifies that the table space is partition-by-growth. integer specifies the maximum number of partitions to which the table space can grow or shrink. integer must be in the range of 1 to 4096, depending on the value that is in effect for DSSIZE and the page size of the table space, and must not be less than the number of physical partitions that are already allocated for the table space. For more information about the relationship between DSSIZE, MAXPARTITIONS, buffer pool page size and table space size, see Maximum number of partitions and table space size.

MAXPARTITIONS can be specified only for a simple table space that contains only one table, a segmented (non-UTS) table space that contains only one table, or a partitioned-by-growth table space. The table space must have Db2-managed data sets.

Although physical data sets are not defined when the MAXPARTITIONS value is issued, there can be storage and CPU overhead. If an increase in the number of partitions is expected by using the MAXPARTITIONS clause, be aware that specifying a value larger than necessary, such as 4096 (the maximum value), as a default for all of your partition-by-growth table spaces can cause larger than expected storage requests.
The change to the value of MAXPARTITIONS is a pending change to the definition of the table space if the data sets of the table space are already created and one of the following conditions is true:

- Pending changes to the definition of the table space or associated indexes already exist.
- The table space is converted from a simple table space to a partition-by-growth table space.
- The table space is converted from a segmented (non-UTS) table space to a partition-by-growth table space.

Otherwise, the change is an immediate change.

If the change is a pending change to the definition of the table space, the changes are not reflected in the definition or data at the time the ALTER TABLESPACE statement is issued. Instead, the entire table space is placed in an advisory REORG-pending state (AREOR). A subsequent reorganization of the entire table space will apply the pending definition changes to the definition and data of the table space.

If MAXPARTITIONS is specified on a simple or segmented (non-UTS) table space, the table space is converted to a partition-by-growth table space that can grow to a maximum number of integer partitions. The SEGSIZE is set to the default of 32 if the SEGSIZE prior to conversion is less than 32. Otherwise, the value of SEGSIZE is inherited from the original table space. The DSSIZE is set to the default 4 gigabytes.

If the data sets of the table space are not defined, the number of partitions is set to 1 during the conversion to a partition-by-growth table space from a simple or segmented (non-UTS) table space.

If the data sets of the table space are created, the number of partitions is determined based on amount of existing data at the time the pending change to the definition of the table space is applied. Partition growth can happen. If LOB columns exist, additional LOB table spaces and auxiliary objects are implicitly created for the newly-grown partitions, regardless of whether SQLRULES(Db2) or SQLRULES(STD) is in effect or whether the table space was explicitly or implicitly created. The new LOB objects inherit the buffer pool attribute and thereby authorization from the existing LOB objects.

If the table space is defined with LOCKSIZE TABLE, the lock size will be reset to LOCKSIZE TABLESPACE during conversion to a partition-by-growth table space.

**MEMBER CLUSTER YES** or **MEMBER CLUSTER NO**

Specifies whether the table space uses the MEMBER CLUSTER page set structure. The MEMBER CLUSTER clause can be specified only for a partition-by-growth or partition-by-range table space, or for a table space for which a pending definition change will convert the table space to a universal table space.

The change to MEMBER CLUSTER is a pending change to the definition of the table space if the data sets are already created and if one of the following conditions is true:

- Pending definition changes already exist for the table space or for any objects in the table space.
- The specified MEMBER CLUSTER value is different than the value that is currently being used for the table space.
If the change is a pending change to the definition of the table space, the table is placed in advisory REORG-pending state (AREOR). Running a utility like REORG with SHRLEVEL(CHANGE) or SHRLEVEL(REFERENCE) on the entire table space resets this state.

**MEMBER CLUSTER YES**
Specifies that the MEMBER CLUSTER page set structure is to be used for the specified table space when the table space is already defined as a partition-by-growth or partition-by-range table space.

MEMBER CLUSTER YES cannot be specified for LOB, workfile, or XML table spaces, or for table spaces that are organized for hash access.

**MEMBER CLUSTER NO**
Specifies that the table space does not use the MEMBER CLUSTER page set structure when the table space is already defined as a partition-by-growth or partition-by-range table space. If the universal table space is already defined to use the MEMBER CLUSTER page set structure, specifying MEMBER CLUSTER NO on the ALTER TABLESPACE statement removes the MEMBER CLUSTER page set structure from the table space.

**SEGSIZE integer**
Specifies that the table space is a universal table space, where integer specifies the number of pages that are to be assigned to each segment of the table space. integer must be a multiple of 4 between 4 and 64 (inclusive). When SEGSIZE is specified, no other options are allowed in the same ALTER TABLESPACE statement.

SEGSIZE can be specified only for a universal table space or a partitioned table space that uses table-controlled partitioning.

The change to the value of SEGSIZE is a pending change to the definition of the table space if the data sets of the table space are already created and one of the following conditions is true:

- Pending definition changes already exist for the table space or for any objects in the table space.
- The specified SEGSIZE value for a universal table space is different than the existing value.
- The table space is converted from a partitioned (non-UTS) table space to a partition-by-range (UTS) table space.

Otherwise, the change is an immediate change.

If the change is a pending change to the definition of the table space, the changes are not reflected in the definition or data at the time the ALTER TABLESPACE statement is issued. Instead, the entire table space is placed in an advisory REORG-pending state (AREOR). A subsequent reorganization of the entire table space will apply the pending definition changes to the definition and data of the table space.

If the existing FREEPAGE value (the number of pages to be left free) is greater than or equal to the new SEGSIZE value, the number of pages is adjusted to be one less than the new SEGSIZE value.

If the table space is a partitioned table space, the partitioned table space is converted to a partition-by-range (UTS) table space with a segment size specified by integer. The MEMBER CLUSTER attribute is inherited from the original table space. The number of partitions is inherited from the original
If the original DSSIZE attribute has a value of 0, the DSSIZE is set to the original maximum partition size. Otherwise, the DSSIZE attribute is inherited from the original table space.

If the table space is a partition-by-growth table space when the pending SEGSIZE change is applied, the number of partitions is determined based on the amount of existing data in the table space and the new SEGSIZE value. Changing the SEGSIZE value to be smaller might cause automatic growth of additional partitions. If LOB columns exist, additional LOB table spaces and auxiliary objects are implicitly created for the newly-grown partitions independently of whether SQLRULES(DB2) or SQLRULES(STD) is in effect or whether the table space was explicitly or implicitly created. The new LOB objects inherit the buffer pool attribute and authorization from the existing LOB objects.

**TRACKMOD**

Specifies whether Db2 tracks modified pages in the space map pages of the table space or partition. Do not specify TRACKMOD for a LOB table space or a table space in a work file database.

For the changed TRACKMOD option to take effect, the table space or partition needs to be stopped and restarted. The table space or partition can be stopped and restarted by running the STOP DATABASE command followed by the START DATABASE command, or by running the REORG utility on the table space or partition. For more information, see [STOP DATABASE (Db2) (Db2 Commands)](http://www.ibm.com/support/knowledgecenter/SSPSQP_10.5.0/com.ibm.db2.luw.admin.cmd.ref.doc/doc/c0011003.html) [START DATABASE (Db2) (Db2 Commands)](http://www.ibm.com/support/knowledgecenter/SSPSQP_10.5.0/com.ibm.db2.luw.admin.cmd.ref.doc/doc/c0011010.html).

**YES**

Db2 tracks changed pages in the space map pages to improve the performance of incremental image copy. For data sharing, changing TRACKMOD to YES causes additional SCA (shared communication area) storage to be used until after the next full or incremental image copy is taken or until TRACKMOD is set back to NO.

**NO**

Db2 does not track changed pages in the space map pages. It uses the LRSN value in each page to determine whether a page has been changed.

**FREEPAGE integer**

Specifies how often to leave a page of free space when the table space is loaded or reorganized. One free page is left after every integer pages; integer can range 0 - 255. FREEPAGE 0 leaves no free pages. Do not specify FREEPAGE for a LOB table space, a table space that is implicitly created for an XML column, or a table space in a work file database.

If the table space is segmented, the number of pages left free must be less than the SEGSIZE value. If the number of pages to be left free is greater than or equal to the SEGSIZE value, then the number of pages is adjusted downward to one less than the SEGSIZE value.

This change to the description of the table space or partition has no effect until data in the table space or partition is loaded or reorganized. For XML table spaces, this change has no effect until data in the table space is reorganized.

**Related information:**

**PCTFREE smallint**

Specifies what percentage of each page to leave as free space when the table space is loaded or reorganized. The default value is PCTFREE 5, which
specifies that 5% of the space on each data page is reserved as free space. The first record on each page is loaded without restriction. When additional records are loaded, at least integer percent of free space is left on each page. integer can range 0 - 99. Do not specify PCTFREE for a LOB table space, a table space that is implicitly created for an XML column, or a table space in a work file database.

**FOR UPDATE smallint**

Specifies the percentage of space to reserve as free space on each page, for use by subsequent UPDATE operations. The smallint value is an integer in the range -1 to 99. FOR UPDATE -1 specifies that 5% of free space is reserved initially, and the amount of free spaces is calculated automatically based on certain real-time statistics values. The first record on each page is always loaded without restriction.

If this value is not specified, the value of the PCTFREE_UPD subsystem parameter is used.

The value is recorded in the PCTFREE_UPD column of the SYSIBM.SYSTABLEPART catalog table.

The FOR UPDATE smallint values do not apply to LOB table spaces, XML table spaces, or table spaces that use hash organization.

The sum of the values for PCTFREE smallint and FOR UPDATE smallint must be less than or equal to 99.

If FOR UPDATE smallint is not specified and the sum of PCTFREE smallint and the PCTFREE_UPD subsystem parameter value is greater than or equal to 99, Db2 uses a smaller value for PCTFREE_UPD.

This change to the description of the table space or partition has no effect until data in the table space or partition is loaded or reorganized. For XML table spaces, this change has no effect until data in the table space is reorganized.

**Related information:**

- Reserving free space for table spaces (Db2 Performance)
- Reserving free spaces for indexes (Db2 Performance)

**USING**

Specifies whether a data set for the table space or partition is managed by the user or is managed by the Db2 system. If the table space is partitioned, USING applies to the data set for the partition that is identified in the ALTER PARTITION clause. If the table space is a partition-by-growth table space, USING can be specified only at the table space level. If the table space is not partitioned, USING applies to every data set that is eligible for the table space. (A nonpartitioned table space can have more than one data set if PRIQTY+1×SECQTY is at least 2 gigabytes.)

If the USING clause is specified, the table space or partition must be in the stopped state when the ALTER TABLESPACE statement is executed. See Altering storage attributes to determine how and when changes take effect. Do not specify the USING clause if the table space is in a work file database.

**VCAT catalog-name**

Specifies user-managed data sets for the table space.

The data sets are linear VSAM data sets cataloged in the integrated catalog facility catalog that catalog-name identifies. For more information about catalog-name values, see Naming conventions.
More than one Db2 subsystem can share the integrated catalog facility catalogs with the current server. To avoid the chance of those subsystems attempting to assign the same name to different data sets, specify a catalog-name value that is not used by the other Db2 subsystems.

The VCAT clause must not be specified if the table space is a partition-by-growth table space.

**STOGROUP stogroup-name**

Specifies a Db2-managed data set that resides on a volume of the identified storage group. stogroup-name must identify a storage group that exists at the current server and the privilege set must include SYSADM authority, SYSCTRL authority, or the USE privilege for the storage group. When the new description of the table space is applied, the description of the storage group must include at least one volume serial number, each volume serial number must identify a volume that is accessible to z/OS for dynamic allocation of the data set, and all identified volumes must be of the same device type. Furthermore, the integrated catalog facility catalog used for the storage group must not contain an entry for the data set.

If you specify USING STOGROUP and the current data set for the table space or partition is managed by Db2:

- Omission of the PRIQTY clause is an implicit specification of the current PRIQTY value.
- Omission of the SECQTY clause is an implicit specification of the current SECQTY value.
- Omission of the ERASE clause is an implicit specification of the current ERASE rule.

If you specify USING STOGROUP to convert from user-managed data sets to Db2-managed data sets:

- Omission of the PRIQTY clause is an implicit specification of the default value. For information on how Db2 determines the default value, see Rules for primary and secondary space allocation.
- Omission of the SECQTY clause is an implicit specification of the default value. For information on how Db2 determines the default value, see Rules for primary and secondary space allocation.
- Omission of the ERASE clause is an implicit specification of ERASE NO.

**PRIQTY integer**

Specifies the minimum primary space allocation for a Db2-managed data set of the table space or partition. integer must be a positive integer, or -1. This clause can be specified only if the data set is managed by Db2, and if one of the following is true:

- USING STOGROUP is specified.
- A USING clause is not specified.

In general, when you specify PRIQTY with a positive integer value, the primary space allocation is at least n kilobytes, where n is the value of integer. However, the following exceptions exist:

- For non-LOB table spaces, the exceptions are:
  - For 4KB page sizes, if integer is greater than 0 and less than 12, n is 12.
  - For 8KB page sizes, if integer is greater than 0 and less than 24, n is 24.
  - For 16KB page sizes, if integer is greater than 0 and less than 48, n is 48.
  - For 32KB page sizes, if integer is greater than 0 and less than 96, n is 96.
  - For any page size, if integer is greater than 67108864, n is 67108864.
For LOB table spaces, the exceptions are:

- For 4KB page sizes, if integer is greater than 0 and less than 200, n is 200.
- For 8KB page sizes, if integer is greater than 0 and less than 400, n is 400.
- For 16KB page sizes, if integer is greater than 0 and less than 800, n is 800.
- For 32KB page sizes, if integer is greater than 0 and less than 1600, n is 1600.
- For any page size, if integer is greater than 67108864, n is 67108864.

The maximum value allowed for PRIQTY is 64GB (67108864 kilobytes).

If you specify PRIQTY with a value of -1, Db2 uses a default value for the primary space allocation. For information on how Db2 determines the default value for primary space allocation, see Rules for primary and secondary space allocation.

If PRIQTY is omitted and USING STOGROUP is specified, the value of PRIQTY is its current value. (However, if the current data set is being changed from being user-managed to Db2-managed, the value is its default value. See the description of USING STOGROUP.)

If you specify PRIQTY, and do not specify a value of -1, Db2 specifies the primary space allocation to access method services using the smallest multiple of p KB not less than integer, where p is the page size of the table space. The allocated space can be greater than the amount of space requested by Db2. For example, it could be the smallest number of tracks that will accommodate the request. To more closely estimate the actual amount of storage, see DEFINE CLUSTER command (DFSMS Access Method Services for Catalogs).

At least one of the volumes of the identified storage group must have enough available space for the primary quantity. Otherwise, the primary space allocation will fail.

See Altering storage attributes to determine how and when changes to PRIQTY take effect.

SECQTY integer

Specifies the minimum secondary space allocation for a Db2-managed data set of the table space or partition. integer must be a positive integer, 0, or -1. This clause can be specified only if the data set is managed by Db2, and if one of the following is true:

- USING STOGROUP is specified.
- A USING clause is not specified.

If you specify SECQTY with a value of -1, Db2 uses a default value for the secondary space allocation.

If USING STOGROUP is specified and SECQTY is omitted, the value of SECQTY is its current value. (However, if the current data set is being changed from being user-managed to Db2-managed, the value is its default value. See the description of USING STOGROUP.)

For information on the actual value that is used for secondary space allocation, whether you specify a value or Db2 uses a default value, see Rules for primary and secondary space allocation.

If you specify SECQTY, and do not specify a value of -1, Db2 specifies the secondary space allocation to access method services using the smallest multiple of p KB not less than integer, where p is the page size of the table space. The allocated space can be greater than the amount of space requested by Db2. For example, it could be the smallest number of tracks that will accommodate the request. To more closely estimate the actual amount of
See the description of the **DEFINE CLUSTER command** ([DFSMS Access Method Services for Catalogs](https://www.ibm.com)) for z/OS DFSMS Access Method Services for catalogs.

See [Altering storage attributes](#) to determine how and when changes to SECQTY take effect.

### ERASE

Indicates whether the Db2-managed data sets for the table space or partition are to be erased before they are deleted during the execution of a utility or an SQL statement that drops the table space.

**NO**

Does not erase the data sets. Operations involving data set deletion will perform better than ERASE YES. However, the data is still accessible, though not through Db2.

**YES**

Erases the data sets. As a security measure, Db2 overwrites all data in the data sets with zeros before they are deleted.

This clause can be specified only if the data set is managed by Db2, and if one of the following is true:

- Using STOGROUP is specified.
- A USING clause is not specified.

If you specify ERASE, the table space or partition must be in the stopped state when the ALTER TABLESPACE statement is executed. If you specify ERASE for a partitioned table space, you must also specify the ALTER PARTITION clause. See [Altering storage attributes](#) to determine how and when changes take effect.

### GBPCACHE

In a data sharing environment, specifies what pages of the table space or partition are written to the group buffer pool in a data sharing environment. In a non-data-sharing environment, you can specify GBPCACHE for a table space other than one in a work file database, but it is ignored. Do not specify GBPCACHE for a table space in a work file database in either environment (data sharing or not). In addition, you cannot alter the GBPCACHE value of some Db2 catalog table spaces; for a list of these table spaces, see [SQL statements allowed on the catalog](#).

### CHANGED

When there is inter-Db2 R/W interest on the table space or partition, updated pages are written to the group buffer pool. When there is no inter-Db2 R/W interest, the group buffer pool is not used. Inter-Db2 R/W interest exists when more than one member in the data sharing group has the table space or partition open, and at least one member has it open for update.

If the table space is in a group buffer pool that is defined to be used only for cross-invalidation (GBPCACHE NO), CHANGED is ignored and no pages are cached to the group buffer pool.

**ALL**

Indicates that pages are to be cached in the group buffer pool as they are read in from DASD.

**Exception:** In the case of a single updating Db2 when no other Db2 subsystems have any interest in the page set, no pages are cached in the group buffer pool.
If the table space is in a group buffer pool that is defined to be used only for cross-invalidation (GBPCACHE NO), ALL is ignored and no pages are cached to the group buffer pool.

**SYSTEM**
Indicates that only changed system pages within the LOB table space are to be cached to the group buffer pool. A system page is a space map page or any other page that does not contain actual data values.

Use SYSTEM only for a LOB table space.

**NONE**
Indicates that no pages are to be cached to the group buffer pool. Db2 uses the group buffer pool only for cross-invalidation.

If you specify NONE, the table space or partition must not be in recover pending status when the ALTER TABLESPACE statement is executed.

If you specify GBPCACHE in a data sharing environment, the table space or partition must be in the stopped state when the ALTER TABLESPACE statement is executed.

**PAGENUM**
Specifies the type of page numbering that is used when you alter a partition-by-range table space.

**RELATIVE**
Indicates that internal page numbering is kept as a 4-byte value without a partition number. The page number is a relative page from the start of the partition, and the partition number is kept only in the header page.

The table space cannot be altered to relative page numbering if the table has truncated limit key values.

The change to the PAGENUM attribute is a pending change to the definition of the table space if the data sets of the table space are already created and if one of the following conditions is true:

- Pending definition changes already exist for the table space or any associated indexes.
- The specified PAGENUM attribute is different from the value that is currently being used for the table space.

Otherwise, the change takes effect immediately.

If the change is a pending change to the definition of the table space, the changes are not reflected in the definition or data at the time the ALTER TABLESPACE statement is issued. Instead, the entire table space is placed in an advisory REORG-pending state (AREOR). A subsequent reorganization of the entire table space applies the pending definition changes to the definition and data of the table space.

**ALTER PARTITION** integer
Specifies that the identified partition of the table space is to be changed. For a table space that has n partitions, you must specify an integer in the range 1 to n. You must not use this clause for a nonpartitioned table space, for a LOB table space, or a partition-by-growth table space. At least one of the following clauses must be specified:

- COMPRESS
- DSSIZE
- ERASE
The changes specified by these clauses affect only the identified partition.

Do not specify the following clauses for ALTER PARTITION for partitions of a table space that is implicitly created for an XML column.

- CCSID
- FREEPAGE
- MAXROWS
- PCTFREE

Notes

ALTER TABLESPACE and insert operations in the same commit scope:

You might encounter problems when an ALTER TABLESPACE statement is followed by an insert operation in the same commit scope. If that happens, add a COMMIT statement between the ALTER TABLESPACE and insert operations.

Running utilities:

You cannot execute the ALTER TABLESPACE statement while a Db2 utility has control of the table space.

Altering more than one partition:

To change FREEPAGE, PCTFREE, USING, PRIQTY, SECQTY, COMPRESS, ERASE, or GBPCACHE for more than one partition, you must use separate ALTER TABLESPACE statements.

Altering storage attributes:

The USING, PRIQTY, SECQTY, and ERASE clauses define the storage attributes of the table space or partition. If you specify USING or ERASE when altering storage attributes, the table space or partition must be in the stopped state when the ALTER TABLESPACE statement is executed. You can use a STOP DATABASE...SPACENAM... command to stop the table space or partition.

If the catalog name changes, the changes take effect after you move the data and start the table space or partition using the START DATABASE...SPACENAM... command. The catalog name can be implicitly or explicitly changed by the ALTER TABLESPACE statement. The catalog name also changes when you move the data to a different device. See the procedures for moving data in Db2 Administration Guide.

Changes to the secondary space allocation (SECQTY) take effect the next time Db2 extends the data set; however, the new value is not reflected in the integrated catalog until you use the REORG, RECOVER, or LOAD REPLACE utility on the table space or partition. The changes to the other storage attributes take effect the next time the page set is reset. For a non-LOB table space, the page set is reset when you use the REORG, RECOVER, or LOAD REPLACE utilities on the table space or partition. For a LOB table space, the page set is reset when RECOVER is run on the LOB table space or LOAD REPLACE is run on its associated base table space. If there is not enough storage to satisfy the primary space allocation, a REORG might fail. If you change the primary space allocation parameters
or erase rule, you can have the changes take effect earlier if you move the data before you start the table space or partition.

**Recommended GBPCACHE setting for LOB table spaces:**
For LOB table spaces, use the GBPCACHE CHANGED option instead of the GBPCACHE SYSTEM option. Due to the usage patterns of LOBs, the use of GBPCACHE CHANGED can help avoid excessive and synchronous writes to disk and the group buffer pool.

**Increasing the size of a partitioned table space:**
Depending on the needs of your applications, you might need to increase the size of a partitioned table space by taking one of the following actions:

- Adding partitions (Db2 Administration Guide)
- Increasing partition size (Db2 Administration Guide)

**Altering table spaces for tables that use hash organization:**
Certain attributes of the table space, such as buffer pool and page size, might affect performance of tables that use hash organization. Changes related to the hash organization of a table will be validated and might generate error messages as described in [CREATE TABLE](https://www.ibm.com/docs/en/db2?topic=sql-reference) and [ALTER TABLE](https://www.ibm.com/docs/en/db2?topic=sql-reference).

**Deprecated function:** (FL 504) Hash-organized tables are deprecated. Beginning in Db2 12, packages bound with APPLCOMPAT( V12R1M504) or higher cannot create hash-organized tables or alter existing tables to use hash-organization. Existing hash organized tables remain supported, but they are likely to be unsupported in the future.

**Altering the logging attribute of a table space:**
If the logging attribute (specified with the LOGGED or NOT LOGGED parameter) of a table space is altered frequently, the size of SYSIBM.SYSCOPY might need to be increased.

The logging attribute of the table space cannot be altered if the table space has been updated in the same unit of recovery.

A full image copy of the table space should be taken:
- Before altering a table space to NOT LOGGED
- After altering a table space to LOGGED

If a table space has data changes after an image copy is taken (the table space is in informational COPY-pending state), and the table space is altered from NOT LOGGED to LOGGED, the table space is marked COPY-pending and a full image copy of the table space must be taken.

An XML table space with the LOGGED logging attribute has its logging attribute altered to NOT LOGGED when the logging attribute of the associated base table space is altered from LOGGED to NOT LOGGED. When this happens, the logging attribute of the XML table space is said to be linked to the logging attribute of the base table space. When the logging attribute of the base table space is altered back to LOGGED, all logging attributes that are linked for the associated XML table spaces are altered back to LOGGED, and all of these links are dissolved.

A LOB table space with the LOGGED logging attribute has its logging attribute altered to NOT LOGGED when the logging attribute of the associated base table space is altered from LOGGED to NOT LOGGED. When this happens, the logging attribute of the LOB table space is said to be linked to the logging attribute of the base table space. When the logging
attribute of the base table space is altered back to LOGGED, all logging attributes that are linked for the associated LOB table spaces are altered back to LOGGED, and all of these links are dissolved.

You can dissolve the link between these logging attributes by altering the logging attribute of the LOB table space to NOT LOGGED, even though it has already been implicitly given this logging attribute. After such an alter, the logging attribute of the LOB table space is unaffected when the logging attribute of the base table is altered back to LOGGED. A LOB table space with the NOT LOGGED logging attribute does not have this attribute changed in any way if the logging attribute of the associated base table space is altered from LOGGED to NOT LOGGED. When altered in this way, the logging attributes of the LOB table space and the base table space are not linked. If the base table space is altered back to LOGGED, the logging attribute of any LOB table spaces that are not linked to the logging attribute of the base table space remain unchanged.

**Altering table spaces for Db2 catalog tables:**
For details on altering options on catalog tables, see SQL statements allowed on the catalog.

**Invalidation of packages:**
This statement might invalidate all packages that depend on target objects, and sometimes other related objects through cascading effects, depending on the clauses and keywords specified and other factors. For more information, see Changes that invalidate packages (Db2 Application programming and SQL).

**Pending changes to the definition of a table space:**
Issuing the ALTER TABLESPACE statement with certain options can cause a pending change to the definition of a table space. When an ALTER TABLESPACE statement that causes pending changes to the definition is executed, semantic validation and authorization checking are performed. However, changes to the table space definition and data are not applied and the table space is placed in advisory REORG-pending state (AREOR). The pending changes are recorded in the SYSIBM.SYSPENDINGDDL catalog table. The REORG utility that specifies SHRLEVEL CHANGE or REFERENCE should be run on the table space to apply the pending changes to the definition and data of the table space. When the pending changes are applied, dependent packages are invalidated, the corresponding entries in the SYSIBM.SYSPENDINGDDL catalog table are removed, and the advisory REORG-pending state is removed.

The following ALTER TABLESPACE options can cause pending changes to the definition of the table space under certain conditions:
- BUFFERPOOL
- DSSIZE
- MAXPARTITIONS
- MEMBER CLUSTER
- MENGNUM
- SEGSIZE

The changes that are caused by all other options occur when the ALTER TABLESPACE statement is executed.

**Restrictions on ALTER TABLESPACE statements that cause pending changes:**
ALTER TABLESPACE statements that cause pending changes have the following restrictions:
• Options that cause pending changes cannot be specified with options that take effect immediately
• Options that cause pending changes cannot be specified for the following objects:
  – The catalog
  – System objects
  – Objects in a workfile database
• The DROP PENDING CHANGES clause cannot be specified for a catalog table space
• If there are pending changes to the table space, you cannot use ALTER TABLESPACE to change from a Db2-managed data set to a user-managed data set
• If there are pending changes to the table space, you cannot specify the following clauses:
  – FREEPAGE
  – ALTER PARTITION FREEPAGE
• If there are pending changes to the table space, or to tables contained in the table space, you cannot specify the CCSID clause
• If the table space, or any table it contains is in an incomplete state, you cannot specify options that cause pending changes

### Maximum number of partitions and table space size

For partition-by-growth table spaces and partition-by-range table spaces with absolute page numbers, the following tables show how the maximum number of partitions and the total table space size depend on the buffer pool page size and DSSIZE value, with 5-byte extended addressability (EA) storage.

#### 4 KB page size

*Table 182. Maximum number of partitions and table space size by DSSIZE, with 4 KB page size*

<table>
<thead>
<tr>
<th>DSSIZE</th>
<th>Maximum number of partitions</th>
<th>Total table space size</th>
</tr>
</thead>
<tbody>
<tr>
<td>1G</td>
<td>4096</td>
<td>4TB</td>
</tr>
<tr>
<td>2G</td>
<td>4096</td>

<td>256G</td>
<td>512</td>
<td>128TB</td>
</tr>
</tbody>
</table>
Notes:
1. For 5-byte non-EA storage, the maximum values for 4 KB page size are DSSIZE 4G, 4096 partitions, and 16 TB for total table space.

Alternative syntax and synonyms:
For compatibility with previous releases of Db2, the following keywords are supported:

- You can specify the LOCKPART clause, but it has no effect. Db2 treats all partitioned table spaces as if they were defined as LOCKPART YES. LOCKPART YES specifies the use of selective partition locking. When all the conditions for selective partition locking are met, Db2 locks only the partitions that are accessed. When the conditions for selective partition locking are not met, Db2 locks every partition of the table space.
- When altering the partitions of a partitioned table space, the ALTER keyword that precedes the PARTITION keyword is optional and if the ALTER keyword is omitted, then you can specify PART as a synonym for PARTITION.
- You can specify LOG YES as a synonym for LOGGED and LOG NO as a synonym for NOT LOGGED.

Examples

Example 1: Alter table space DSN8S12D in database DSN8D12A. BP2 is the buffer pool associated with the table space. PAGE is the level at which locking is to take place.

   ALTER TABLESPACE DSN8D12A.DSN8S12D
       BUFFERPOOL BP2
       LOCKSIZE PAGE;

Example 2: Alter table space DSN8S12E in database DSN8D12A. The table space is partitioned. Indicate that the data sets of the table space are not to be closed when there are no current users of the table space. Also, change all of the partitions so that Db2 will use a formula to determine any secondary space allocations, and change partition 1 to use a PCTFREE value of 20.

   ALTER TABLESPACE DSN8D12A.DSN8S12E
       CLOSE NO
       SECQTY = 1
       ALTER PARTITION 1 PCTFREE 20;

Example 3: The following statement changes the maximum number of partitions in a partition-by-growth table space:

   ALTER TABLESPACE TS01DB.TS01TS
       MAXPARTITIONS 30;

ALTER TRIGGER (advanced)

The ALTER TRIGGER (advanced) statement changes the description of an advanced trigger at the current server.

For a description of the differences between basic and advanced triggers, see Triggers (Introduction to Db2 for z/OS)
Invocation

This statement can be issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

Authorization

The privilege set that is defined below must include at least one of the following:
- Ownership of the trigger
- The ALTERIN privilege on the schema
- System DBADM authority
- SYSCTRL authority
- SYSADM authority
- Installation SYSOPR authority (when the current SQLID of the process is set to SYSINSTL)

The authorization ID that matches the schema name implicitly has the ALTERIN privilege on the schema.

Additional privileges might be required in the following situations:
- If trigger-specification is specified:
  - The privilege set must include at least one of the following:
    - Ownership of the trigger
    - DATAACCESS authority
    - SYSADM authority
  - The owner of the trigger must have SYSADM authority or each one of the following:
    - The SELECT privilege on the table or view on which the trigger is defined.
    - The SELECT privilege on any table or view in the search-condition of the triggered-action.
    - The privileges that are required to execute the statements in SQL-trigger-body
- If the SECURED option is specified, the privilege set must include SECADM authority or the CREATE_SECURE_OBJECT privilege.
- If the WLM ENVIRONMENT FOR DEBUG MODE clause is specified, RACF or an external security product is invoked to check the required authority for defining programs in the WLM environment. If the WLM environment access is protected in RACF, the user that issued the ALTER statement must have the required authority.

Additional authorization may be required on the SYSDUMMYx tables depending on the content of the trigger definition. See SYSDUMMYx tables.

Privilege set: The privilege set is the set of privileges that are held by the SQL authorization ID of the process. The specified trigger name can include a schema name (a qualifier). However, if the schema name is not the same as one of the authorization ID of the process, one of the following conditions must be met:
- The privilege set includes SYSADM authority, SYSCTRL authority, or system DBADM authority.
- The authorization ID of the process has the ALTERIN privilege on the schema.
Note: If the SEPARATE SECURITY subsystem parameter is set to NO, SYSADM authority has implicit SECADM authority.

Syntax

```
ALTER TRIGGER trigger-name
  option-list
  (1)
REPLACE TRIGGER trigger-name
  option-list
  (1)
ADD VERSION trigger-version-id trigger-specification
ACTIVATE VERSION trigger-version-id
ACTIVATE VERSION trigger-version-id
REPLACE trigger-specification
ADD VERSION trigger-version-id trigger-specification
ACTIVATE VERSION trigger-version-id
REGENERATE VERSION trigger-version-id USING APPLICATION COMPATIBILITY applcompat-value
DROP VERSION trigger-version-id
```

Notes:
1. An ALTER TRIGGER statement with an ADD VERSION or REPLACE clause is not allowed in an SQL-trigger-body.

trigger-specification:

```
trigger-activation-time trigger-event ON table-name | view-name
  (1)
  (1)
  (1)
REFERENCING OLD ROW AS correlation-name
  (1)
NEW ROW AS correlation-name
OLD_TABLE AS table-identifier
NEW_TABLE AS table-identifier
trigger-granularity option-list triggered-action
```

trigger-activation-time

```
NO CASCADE BEFORE
  (1)
AFTER
  (1)
INSTEAD OF
```

trigger-event
trigger-granularity

option-list: (The options can be specified in any order, but each one can only be specified one time.)
triggered-action

SQL-trigger-body

- WHEN (search-condition) SQL-trigger-body

---

1438 SQL Reference
Description

trigger-name

Identifies the trigger that is to be changed. The name, including the implicit or explicit schema name, must exist at the current server. The name must identify an advanced trigger.

The trigger must not be obfuscated.

ACTIVE VERSION or VERSION trigger-version-id

Identifies the version of the trigger that is to be changed, replaced, or regenerated depending on whether the ALTER, REPLACE, or REGENERATE keyword is specified.

ACTIVE VERSION

Specifies that the currently active version of the trigger is to be changed, replaced, or regenerated.

VERSION trigger-version-id

Identifies the version of the trigger that is to be changed, replaced, or regenerated. trigger-version-id is the version identifier that is assigned when the version is defined. trigger-version-id must identify a version of the specified trigger that exists at the current server.

ALTER

Specifies that the trigger is to be changed. When you change one or more trigger options, any option that is not explicitly specified uses the existing value from the trigger that is being changed.

REPLACE

Specifies that a version of the trigger is to be replaced.

When you replace a trigger, the following trigger attributes must be the same as the corresponding attributes for the currently active version of the trigger: trigger-activation-time, trigger-event, table or view name, and trigger-granularity.

The content of the REFERENCING clause can differ from the other versions of the trigger. For options that are not explicitly specified, the system default values for those options are used, even if those options were explicitly specified for the version of the trigger that is being replaced. This is not the case for versions of the trigger that specified DISABLE DEBUG MODE. If DISABLE DEBUG MODE is specified for a version of a trigger, the option cannot be changed using the REPLACE clause.

Binding the replaced version of the trigger might result in a new access path even if the trigger body is not changed.

ADD VERSION trigger-version-id

Specifies that a new version of the trigger is to be created. trigger-version-id is the version identifier for the new version of the trigger. trigger-version-id must not identify a version of the specified trigger that already exists at the current server.

When a new version of a trigger is created, the comment that is recorded in the catalog for the new version will be the same as the comment that is in the catalog for the currently active version.
When you add a new version of a trigger, the following trigger attributes must be the same as the corresponding attributes for the currently active version of the trigger: `trigger-activation-time`, `trigger-event`, table or view name, and `trigger-granularity`. The content of the REFERENCING clause can differ from the other versions of the trigger. For options that are not explicitly specified, the system default values are used.

**ACTIVATE VERSION trigger-version-id**
Specifies the version of the trigger that is to be the currently active version of the trigger. `trigger-version-id` is the version identifier that is assigned when the version of the trigger is defined. The version that is specified with `trigger-version-id` is the version that will be invoked when the trigger is activated. `trigger-version-id` must identify a version of the trigger that already exists at the current server.

**REGENERATE**
Specifies that the trigger package is to be regenerated. When Db2 maintenance is applied that changes how a trigger is generated, the trigger might need to be regenerated to process the maintenance changes.

The REGENERATE keyword on the ALTER TRIGGER statement is used to rebind the SQL control statements, as well as non-SQL-control statements that are included in the trigger body, at the local server. When a trigger is regenerated, any unqualified names in the trigger body are resolved using the name resolution process.

Using an ALTER TRIGGER statement with the REGENERATE keyword is different from a REBIND PACKAGE command. The REBIND PACKAGE command rebinds only the non-SQL-control statements to generate better access paths for those statements, using the statement text from the SYSIBM.SYSPACKSTMTS catalog table.

When a trigger definition is regenerated, any existing comments in the catalog for that definition of the trigger are not removed.

**DROP VERSION trigger-version-id**
Drops the version of the trigger that is identified with `trigger-version-id`. `trigger-version-id` is the version identifier that is assigned when the version is defined. `trigger-version-id` must identify a version of the trigger that already exists at the current server and must not identify the currently active version of the trigger. Only the identified version of the trigger is dropped.

When only a single version of the trigger exists at the current server, use the DROP TRIGGER statement to drop the trigger.

**trigger-event**
Specifies that the triggered action that is associated with the trigger is to be executed when the trigger event is applied to the subject table or view.

**INSERT**
Specifies that the trigger is an insert trigger. Db2 executes the triggered action whenever there is an insert operation on the subject table. However, if the insert trigger is defined on any explain table, and the insert operation was caused by Db2 adding a row to the table, the triggered action is not executed.

**DELETE**
Specifies that the trigger is a delete trigger. Db2 executes the triggered action whenever there is a delete operation on the subject table.
UPDATE
Specifies that the trigger is an update trigger. Db2 executes the triggered
action whenever there is an update operation on the subject table.

If you do not specify a list of column names, an update operation on any
column of the subject table, including columns that are subsequently
added with the ALTER TABLE statement, activates the triggered action.

**OF column-name,**...
Each column-name that you specify must be a column of the subject
table and must appear in the list only once. An update operation on
any of the listed columns activates the triggered action.

UPDATE OF column-name cannot be specified for an INSTEAD OF
trigger.

**trigger-activation-time**

**NO CASCADE**
NO CASCADE is allowed for compatibility with prior releases and other
products.

**BEFORE**
Specifies that the trigger is a before trigger. Db2 executes the triggered
action before it applies any changes caused by an insert, delete, or update
operation on the subject table. It also specifies that the triggered action
does not activate other triggers because the triggered action of a before
trigger cannot contain any updates, REFRESH TABLE, or TRUNCATE SQL
statements.

BEFORE must not be specified when **view-name** is also specified. **FOR**
EACH ROW must be specified for a BEFORE trigger.

**AFTER**
Specifies that the trigger is an after trigger. Db2 executes the triggered
action after it applies any changes caused by an insert, delete, or update
operation on the subject table. **AFTER** must not be specified if **view-name** is
also specified.

**INSTEAD OF**
Specifies that the trigger is an instead of trigger. The associated triggered
action replaces the action against the subject view. Only one INSTEAD OF
trigger is allowed for each type of operation on a given subject view. Db2
executes the triggered-action instead of the insert, update, or delete
operation on the subject view.

INSTEAD OF must not be specified when **table-name** is also specified. The
**WHEN** clause can not be specified for an INSTEAD OF trigger. **FOR**
EACH ROW must be specified for an INSTEAD OF trigger.

**REFERENCING**
Specifies the correlation names for the transition variables and the table names
for the transition tables. For the rows in the subject table that are modified by
the triggering SQL operation (insert, delete, or update), a correlation name
identifies the columns of a specific row. **table-identifiers** identify the complete set
of affected rows. Transition variables with XML types cannot be referenced
inside of a trigger. If the column of a transition table is referenced, the data
type of the column cannot be XML.

Each row that is affected by the triggering SQL operation is available to the
triggered action by qualifying column names with **correlation-names** that are
specified as follows:
OLD ROW AS correlation-name

Specifies the correlation name that identifies the transition variables containing the values in the row prior to the triggering SQL operation.

NEW ROW AS correlation-name

Specifies the correlation name that identifies the transition variables containing the values in the row as modified by the triggering SQL operation and by any assignment statement in a before trigger that has already been executed.

If OLD and NEW are both specified, a reference to a transition variable must be qualified with the associated correlation name.

The complete set of rows that are affected by the triggering operation is available as a transition table to the triggered action. Specify a table-identifier to refer to the transition table as follows:

OLD_TABLE AS table-identifier

Specifies the name of a temporary table that identifies the values in the complete set of rows that are modified rows by the triggering SQL operation prior to any actual changes.

NEW_TABLE AS table-identifier

Specifies the name of a temporary table that identifies the values in the complete set of rows as modified by the triggering SQL operation and by any assignment statement in a before trigger that has already been executed.

Only one OLD and one NEW correlation-name can be specified for a trigger. Only one OLD_TABLE and one NEW_TABLE table-identifier can be specified for a trigger. All of the correlation-names and table-identifiers must be unique from one another.

Table 186 on page 1443 summarizes the allowable combinations of transition variables and transition tables that you can specify for the various trigger types. The OLD correlation-name and the OLD_TABLE table-identifier are valid only if the triggering event is either a delete operation or an update operation. For a delete operation, the OLD correlation-name captures the values of the columns in the deleted row, and the OLD_TABLE table-identifier captures the values in the set of deleted rows. For an update operation, the OLD correlation-name captures the values of the columns of a row before the update operation, and the OLD_TABLE table-identifier captures the values in the set of rows before the update operation.

The NEW correlation-name and the NEW_TABLE table-identifier are valid only if the triggering event is either an insert operation or an update operation. For both operations, the NEW correlation-name captures the values of the columns in the inserted or updated row and the NEW_TABLE table-identifier captures the values in the set of inserted or updated rows. For BEFORE triggers, the values of the updated rows include the changes from any assignment statements in the triggered action of BEFORE triggers.
Table 186. Allowable combinations of attributes in a trigger definition

</table>

Note:
1. If a transition table or variable is referenced where it is not allowed, an error is returned.

A transition variable that has a character data type inherits the subtype and CCSID of the column of the subject table. During the execution of the triggered action, the transition variables are treated like host variables. Therefore, character conversion might occur. However, unlike a host variable, a transition variable can have the bit data attribute, and character conversion never occurs for bit data. A transition variable is considered to be bit data if the column of the table to which it corresponds is bit data.

You cannot modify a transition table; transition tables are read-only. Although a transition table does not inherit any edit or validation procedures from the subject table, it does inherit the encoding scheme and field procedures of the subject table.

The scope of each correlation-name and each table-identifier is the entire trigger definition.

**trigger-granularity**

**FOR EACH ROW or FOR EACH STATEMENT**

Specifies the conditions for which Db2 executes the triggered action.

**FOR EACH ROW**

Specifies that Db2 executes the triggered action for each row of the subject table that the triggering SQL operation modifies. If the triggering SQL operation does not modify any rows, the triggered action is not executed.

**FOR EACH STATEMENT**

Specifies that Db2 executes the triggered action only one time for the triggering operation. Even if the triggering operation does not modify or delete any rows, the triggered action is executed one time.

FOR EACH STATEMENT must not be specified for a BEFORE or INSTEAD OF trigger.
ALLOW DEBUG MODE, DISALLOW DEBUG MODE, or DISABLE DEBUG MODE

Specifies whether this version of the trigger can be run in debugging mode. The default is determined using the value of the CURRENT DEBUG MODE special register.

ALLOW DEBUG MODE

Specifies that this version of the trigger can be run in debugging mode.
When ALLOW DEBUG MODE is in effect, a WLM environment must be available. If you do not specify WLM ENVIRONMENT FOR DEBUG MODE, Db2 uses the default WLM-established stored procedure address space specified at installation time.

DISALLOW DEBUG MODE

Specifies that this version of the trigger cannot be run in debugging mode.
You can use an ALTER statement to change this option to ALLOW DEBUG MODE. When DISALLOW DEBUG MODE is in effect, a WLM environment must be available. If you do not specify WLM ENVIRONMENT FOR DEBUG MODE, Db2 uses the default WLM-established stored procedure address space specified at installation time.

DISABLE DEBUG MODE

Specifies that this version of the trigger can never be run in debugging mode.

This version of the trigger cannot be changed to specify ALLOW DEBUG MODE or DISALLOW DEBUG MODE after this version of the trigger has been created or altered to use DISABLE DEBUG MODE. To change this option, drop the trigger, and create it again using the option that you want. An alternative to dropping and recreating the trigger is to create a version of the trigger that uses the option that you want, and making that version the active version.

When DISABLE DEBUG MODE is in effect, the WLM ENVIRONMENT FOR DEBUG MODE is ignored.

QUALIFIER schema-name

Specifies the implicit qualifier that is used for unqualified object names that are referenced in the trigger body. See Unqualified alias, index, JAR file, sequence, table, trigger, and view names for information about how the default for this option is determined.

ASUTIME

Specifies the total amount of processor time, in CPU service units, that a single invocation of this version of the trigger can run. The value is unrelated to the ASUTIME column of the resource limit specification table.

When you are debugging a trigger, setting a limit can be helpful in case the trigger gets caught in a loop. For information on service units, see z/OS MVS Initialization and Tuning Guide.

NO LIMIT

Specifies that there is no limit on the service units.
NO LIMIT is the default.

LIMIT integer

The limit on the number of CPU service units is a positive integer in the range 1 - 2147483647. If the trigger uses more service units than the
specified value, Db2 cancels the trigger. The CPU cycles that are consumed by parallel tasks in a trigger do not contribute towards the specified ASUTIME LIMIT.

**WLM ENVIRONMENT FOR DEBUG MODE name**

Specifies the WLM (workload manager) application environment that is used by Db2 when debugging the trigger. The name of the WLM environment is an SQL identifier.

If you do not specify WLM ENVIRONMENT FOR DEBUG MODE, Db2 uses the default WLM-established stored procedure address space specified at installation time.

To define a trigger that is to run in a specified WLM application environment, you must have the appropriate authority for the WLM application environment. For an example of a RACF command that provides this authorization, see [Running stored procedures](#).

The WLM ENVIRONMENT FOR DEBUG MODE value is ignored when DISABLE DEBUG MODE is in effect.

**CURRENT DATA YES or CURRENT DATA NO**

Specifies whether to require data currency for read-only and ambiguous cursors when the isolation level of cursor stability is in effect. CURRENT DATA also determines whether block fetch can be used for distributed, ambiguous cursors.

**CURRENT DATA YES**

Specifies that data currency is required for read-only and ambiguous cursors. Db2 acquires page or row locks to ensure data currency. Block fetch is ignored for distributed, ambiguous cursors.

**CURRENT DATA NO**

Specifies that data currency is not required for read-only and ambiguous cursors. Block fetch is allowed for distributed, ambiguous cursors. Use of CURRENT DATA NO is not recommended if the trigger attempts to dynamically prepare and execute a DELETE WHERE CURRENT OF statement against an ambiguous cursor after that cursor is opened. You receive an error if your trigger attempts to use a DELETE WHERE CURRENT OF statement for any of the following cursors:

- A cursor that is using block fetch
- A cursor that is using query parallelism
- A cursor that is positioned on a row that is modified by this or another application process

CURRENT DATA NO is the default.

**CONCURRENT ACCESS RESOLUTION**

Specifies the whether processing uses only committed data or whether it will wait for commit or rollback of data that is in the process of being updated.

**WAIT FOR OUTCOME**

Specifies that processing will wait for the commit or rollback of data that is in the process of being updated.

**USE CURRENTLY COMMITTED**

Specifies that processing use the currently committed version of the data when data that is in the process of being updated is encountered. USE CURRENTLY COMMITTED is applicable on scans that access tables that are defined in universal table spaces with row or page level lock size.
When there is lock contention between a read transaction and an insert transaction, **USE CURRENTLY COMMITTED** is applicable to scans with isolation level CS or RS. Applicable scans include intent read scans for read-only and ambiguous queries and for updatable cursors. **USE CURRENTLY COMMITTED** is also applicable to scans initiated from WHERE predicates of UPDATE or DELETE statements and the subselect of INSERT statements.

When there is lock contention is between a read transaction and a delete transaction, **USE CURRENTLY COMMITTED** is applicable to scans with isolation level CS and when CURRENT DATA NO is specified.

**DYNAMICRULES**

Specifies the values that apply, at run time, for the following dynamic SQL attributes:

- The authorization ID that is used to check authorization
- The qualifier that is used for unqualified objects
- The source for application programming options that Db2 uses to parse and semantically verify dynamic SQL statements

In the context of a trigger, DYNAMICRULES also specifies whether dynamic SQL statements can include ALTER, CREATE, and DROP statements.

In addition to the value of the DYNAMICRULES clause, the run time environment of a trigger controls how dynamic SQL statements behave at run time. The combination of the DYNAMICRULES value and the run time environment determines the value for the dynamic SQL attributes. That set of attribute values is called the dynamic SQL statement behavior. The following values can be specified:

**RUN**

Specifies that dynamic SQL statements are to be processed using run behavior.

RUN is the default.

**BIND**

Specifies that dynamic SQL statements are to be processed using bind behavior.

See [Authorization IDs and dynamic SQL](#) for information on the effects of these options.

**APPLICATION ENCODING SCHEME**

Specifies the default encoding scheme for SQL variables in static SQL statements in the trigger body. The value is used for defining an SQL variable in a compound statement if the CCSID clause is not specified as part of the data type.

**ASCII**

Specifies that the data is encoded using the ASCII CCSIDs of the server.

**EBCDIC**

Specifies that the data is encoded using the EBCDIC CCSIDs of the server.

**UNICODE**

Specifies that the data is encoded using the Unicode CCSIDs of the server.

See [ENCODING bind option (Db2 Commands)](#) for information about how the default for this option is determined.
WITH EXPLAIN or WITHOUT EXPLAIN

Specifies whether information will be provided about how SQL statements in the trigger will execute.

WITHOUT EXPLAIN

Specifies that information will not be provided about how SQL statements in the trigger will execute.

You can get EXPLAIN output for a statement that is embedded in a trigger that is specified using WITHOUT EXPLAIN by embedding the SQL statement EXPLAIN in the trigger body. Otherwise, the value of the EXPLAIN option applies to all explainable SQL statements in the trigger body, and to the fullselect portion of any DECLARE CURSOR statements.

WITHOUT EXPLAIN is the default.

WITH EXPLAIN

Specifies that information will be provided about how SQL statements in the trigger will execute. Information is inserted into the table owner.PLAN_TABLE. owner is the authorization ID of the owner of the trigger. Alternatively, the authorization ID of the owner of the trigger can have an alias as owner.PLAN_TABLE that points to the base table, PLAN_TABLE. owner must also have the appropriate SELECT and INSERT privileges on that table. PLAN_TABLE must have a base table and can have multiple aliases with the same table name, PLAN_TABLE, but have different schema qualifiers. It cannot be a view or a synonym and should exist before the version is added or replaced. In all inserts to owner.PLAN_TABLE, the value of QUERYNO is the statement number that is assigned by Db2.

The WITH EXPLAIN option also populates two optional tables, if they exist: DSN_STATEMT_TABLE and DSN_FUNCTION_TABLE. DSN_STATEMT_TABLE contains an estimate of the processing cost for an SQL statement. See Estimating the cost of SQL statements (Db2 Performance) for more information. DSN_FUNCTION_TABLE contains information about function resolution. See Checking how Db2 resolves functions by using DSN_FUNCTION_TABLE (Db2 Application programming and SQL) for more information.

For more information about the EXPLAIN statement, including a description of the tables that are populated by the WITH EXPLAIN option, see “EXPLAIN” on page 2059.

WITH IMMEDIATE WRITE or WITHOUT IMMEDIATE WRITE

Specifies whether immediate writes are to be done for updates that are made to group buffer pool dependent page sets or partitions. This option is only applicable for data sharing environments. The IMMEDWRITE subsystem parameter has no affect of this option. IMMEDWRITE bind option (Db2 Commands) shows the implied hierarchy of the IMMEDWRITE bind option (which is similar to this trigger option) as it affects run time.

WITHOUT IMMEDIATE WRITE

Specifies that normal write activity is performed. Updated pages that are group buffer pool dependent are written at or before phase one of commit or at the end of abort for transactions that have been rolled back.

WITHOUT IMMEDIATE WRITE is the default.

WITH IMMEDIATE WRITE

Specifies that updated pages that are group buffer pool dependent are immediately written as soon as the buffer update completes. Updated
pages are written immediately even if the buffer is updated during forward progress or during the rollback of a transaction. WITH IMMEDIATE WRITE might impact performance.

**ISOLATION LEVEL RR, RS, CS, or UR**

Specifies how far to isolate the trigger from the effects of other running applications. For information about isolation levels, see [Choosing an ISOLATION option (Db2 Performance)](Choosing an ISOLATION option (Db2 Performance)).

- **RR** Specifies repeatable read.
- **RS** Specifies read stability.
- **CS** Specifies cursor stability. CS is the default.
- **UR** Specifies uncommitted read.

**OPTHINT string-constant**

Specifies whether query optimization hints are used for static SQL statements that are contained within the body of the trigger.

`string-constant` is a character string of up to 128 bytes in length, which is used by the Db2 subsystem when searching the PLAN_TABLE for rows to use as input. The default value is an empty string, which indicates that the Db2 subsystem does not use optimization hints for static SQL statements.

Optimization hints are only used if optimization hints are enabled for your system. See [Preparing to influence access paths (Db2 Performance)](Preparing to influence access paths (Db2 Performance)) for information about enabling optimization hints.

**SQL PATH**

Specifies the SQL path that Db2 uses to resolve unqualified user-defined types, functions, and procedure names in the body of the trigger. The default value is "SYSIBM", "SYSFUN", "SYSPROC", "SYSIBMADM", and the value of the QUALIFIER option.

Schemas "SYSIBM", "SYSFUN", "SYSPROC", "SYSIBMADM" do not need to be explicitly specified. If any of these schemas is not explicitly specified, it is implicitly assumed at the beginning the SQL path, in the order listed.

Db2 calculates the length by taking each `schema-name` specified and removing any trailing blanks from it, adding two delimiters around it, and adding one comma after each schema name, except for the last one. The length of the resulting string cannot exceed the length of the CURRENT SCHEMA special register. If you do not specify the "SYSIBM", "SYSFUN", "SYSPROC", "SYSIBMADM", schemas, they are not included in the length of the SQL path. If the total length of the SQL path exceeds the length of the CURRENT PATH special register, Db2 returns an error.

**Related information:**

- [SQL path](SQL path)
- [CURRENT SCHEMA](CURRENT SCHEMA)
- [CURRENT PATH](CURRENT PATH)

**schema-name**

Identifies a schema. Db2 does not verify that the schema exists when the ALTER statement is processed. The same schema name should not appear more than once in the list of schema names.

SYSPUBLIC must not be specified for the SQL path.
SYSTEM PATH

Specifies the schema names "SYSIBM", "SYSFUN", "SYSPROC", "SYSIMADM".

SESSION_USER or USER

Specifies the value of the SESSION_USER or USER special register, which represents a maximum 8-byte (in EBCDIC) schema-name. At the time the ALTER statement is processed, this length is included in the total length of the list of schema names that is specified for the SQL PATH option.

If you specify SESSION_USER (or USER) in a list of schema names, do not use delimiters around the SESSION_USER (or USER) keyword.

RELEASE AT

Specifies when to release resources that the trigger uses: either at each commit point or when the trigger terminates.

COMMIT

Specifies that resources will be released at each commit point. COMMIT is the default.

DEALLOCATE

Specifies that resources will be released only when the thread terminates. DEALLOCATE has no effect on dynamic SQL statements, which always use RELEASE AT COMMIT, with this exception: When you use the RELEASE AT DEALLOCATE clause and the WITH KEEP DYNAMIC clause, and the subsystem is installed with a value of YES for the field CACHE DYNAMIC SQL on installation panel DSNTIP8, the RELEASE AT DEALLOCATE option is honored for dynamic SELECT and data change statements.

Locks that are acquired for dynamic statements are held until one of the following events occurs:

• The application process ends.
• The application process issues a PREPARE statement with the same statement identifier. (Locks are released at the next commit point.)
• The statement is removed from the prepared statement cache because the statement has not been used. (Locks are released at the next commit point.)
• An object that the statement is dependent on is dropped or altered, or a privilege that the statement needs is revoked. (Locks are released at the next commit point.)

RELEASE AT DEALLOCATE can increase the package or plan size because additional items become resident in the package or plan.

Related information:

[Choosing a RELEASE option (Db2 Performance)]

ROUNDING

Specifies the rounding mode for manipulation of DECIMAL data. The default value is taken from the DEFAULT DECIMAL FLOATING POINT ROUNDING MODE in the application programming defaults module.

DEC_ROUND_CEILING

Specifies numbers are rounded towards positive infinity.

DEC_ROUND_DOWN

Specifies numbers are rounded towards 0 (truncation).
**DEC_ROUND_FLOOR**

Specifies numbers are rounded towards negative infinity.

**DEC_ROUND_HALF_DOWN**

Specifies numbers are rounded to nearest; if equidistant, round down.

**DEC_ROUND_HALF_EVEN**

Specifies numbers are rounded to nearest; if equidistant, round so that the final digit is even.

**DEC_ROUND_HALF_UP**

Specifies numbers are rounded to nearest; if equidistant, round up.

**DEC_ROUND_UP**

Specifies numbers are rounded away from 0.

**DATE FORMAT ISO, EUR, USA, JIS, or LOCAL**

Specifies the date format for result values that are string representations of date or time values. See [String representations of datetime values](#) for more information.

The default format is specified in the DATE FORMAT field of installation panel DSNTIP4 of the system where the routine is defined. You cannot use the LOCAL option unless you have a date exit routine.

**DECIMAL(15), DECIMAL(31), DECIMAL(15,s), or DECIMAL(31,s)**

Specifies the maximum precision that is to be used for decimal arithmetic operations. See [Arithmetic with two decimal operands](#) for more information.

The default format is specified in the DECIMAL ARITHMETIC field of installation panel DSNTIPIF of the system where the routine is defined. If the form pp.s is specified, s must be a number between 1 and 9. s represents the minimum scale that is to be used for division.

**TIME FORMAT ISO, EUR, USA, JIS, or LOCAL**

Specifies the time format for result values that are string representations of date or time values. See [String representations of datetime values](#) for more information.

The default format is specified in the TIME FORMAT field of installation panel DSNTIP4 of the system where the routine is defined. You cannot use the LOCAL option unless you have a date exit routine.

**FOR UPDATE CLAUSE OPTIONAL or FOR UPDATE CLAUSE REQUIRED**

Specifies whether the FOR UPDATE clause is required for a DECLARE CURSOR statement if the cursor is to be used to perform positioned updates.

**FOR UPDATE CLAUSE REQUIRED**

Specifies that a FOR UPDATE clause must be specified as part of the cursor definition if the cursor will be used to make positioned updates.

FOR UPDATE CLAUSE REQUIRED is the default.

**FOR UPDATE CLAUSE OPTIONAL**

Specifies that the FOR UPDATE clause does not need to be specified in order for a cursor to be used for positioned updates. The trigger body can include positioned UPDATE statements that update columns that the user is authorized to update.

The FOR UPDATE clause with no column list applies to static or dynamic SQL statements. Even if you do not use this clause, you can specify FOR UPDATE
OF with a column list to restrict updates to only the columns that are
identified in the FOR UPDATE clause and to specify the acquisition of update
locks.

SECURED or NOT SECURED
Specifies that the trigger is to be changed to be secure or not secure. Changing
a trigger between SECURED and NOT SECURED causes an implicit rebind of
the trigger package. If an error is encountered during the implicit rebind of the
trigger package, the ALTER TRIGGER statement returns the error.

SECURED
Specifies the trigger is considered secure.
SECURED must be specified for a trigger if its subject table is using row
access control or column access control. SECURED must also be specified
for a trigger that is created for a view and one or more of the underlying
tables in the view definition is using row access control or column access
control.

NOT SECURED
Specifies the trigger is considered not secure.
NOT SECURED must not be specified for a trigger whose subject table is
using row access control or column access control. NOT SECURED must
also not be specified for a trigger that is created for a view and one or
more of the underlying tables in the view definition is using row access
control or column access control.

BUSINESS_TIME SENSITIVE
Determines whether references to application-period temporal tables in both
static and dynamic SQL statements are affected by the value of the CURRENT
TEMPORAL BUSINESS_TIME special register.

YES
References to application-period temporal tables are affected by the value
of the CURRENT TEMPORAL BUSINESS_TIME special register. YES is the
default value.

NO References to application-period temporal tables are not affected by the
value of the CURRENT TEMPORAL BUSINESS_TIME special register.

Related information:
CURRENT TEMPORAL BUSINESS_TIME

SYSTEM_TIME SENSITIVE
Determines whether references to system-period temporal tables in both static
and dynamic SQL statements are affected by the value of the CURRENT
TEMPORAL SYSTEM_TIME special register.

YES
References to system-period temporal tables are affected by the value of
the CURRENT TEMPORAL SYSTEM_TIME special register. YES is the
default value.

NO References to system-period temporal tables are not affected by the value
of the CURRENT TEMPORAL SYSTEM_TIME special register.

Related information:
CURRENT TEMPORAL SYSTEM_TIME
ARCHIVE SENSITIVE
Determines whether references to archive-enabled tables in SQL statements are
affected by the value of the SYSIBMADM.GET_ARCHIVE global variable.

YES
References to archive-enabled tables are affected by the value of the
SYSIBMADM.GET_ARCHIVE global variable. YES is the default value.

NO References to archive-enabled tables are not affected by the value of the
SYSIBMADM.GET_ARCHIVE global variable.

Related information:
Built-in global variables

APPLCOMPAT applcompat-value
Specifies the application compatibility level behavior for static SQL statements
in the package. If this option is not specified, the behavior is determined, in
priority order, by the applcompat-value of the previous bind of the package, if
one exists, or V12R1M500.

CONCENTRATE STATEMENTS OFF or CONCENTRATE STATEMENTS WITH LITERALS
Specifies whether a dynamic SQL statement that specifies literal constants will
be cached as a separate unique statement entry in the dynamic statement cache
instead of sharing an existing statement in the cache. Dynamic SQL statements
are eligible to share an existing statement in the cache if the new statement
meets all of the conditions for sharing a cached version of the same dynamic
statement except that the new statement specifies one or more literal constants
that are different than the cached statement.

CONCENTRATE STATEMENTS OFF
Specifies that the dynamic SQL statement that specifies literal constants
will be cached as a unique statement entry if it specifies one or more
constants that are different than the cached version of the same dynamic
statement. CONCENTRATE STATEMENTS OFF is the default dynamic
statement caching behavior.

CONCENTRATE STATEMENTS WITH LITERALS
Specifies that the dynamic SQL statement that specifies literal constants
will share a cached version of the same dynamic statement that is also
prepared using the CONCENTRATE STATEMENTS WITH LITERALS
option if the new dynamic statement meets all of the conditions for sharing
the cached statement and the constants that are specified can be reused in
place of the constants in the cached statement.

triggered-action
Specifies the action to be performed when the trigger is activated. The
triggered-action is composed of one or more SQL statements and an optional
condition that controls whether the statements are executed.

WHEN (search-condition)
Specifies a condition that evaluates to true, false, or unknown. The
triggered SQL statements are executed only if the search-condition evaluates
to true. If the WHEN clause is omitted, the associated SQL statements are
always executed.

The WHEN clause must not be specified for an INSTEAD OF trigger.

search-condition must not reference the following items:

• A system-period temporal table, if the trigger package is generated with
the SYSTIMESSENSITIVE(YES) bind option.
An archive-enabled table, if the trigger package is generated with the ARCHIVESENSITIVE(YES) bind option.

**SQL-trigger-body**

Specifies a single SQL-control-statement, including a compound statement, or triggered-SQL-statement that is to be executed for the triggered-action. See SQL control statements for SQL routines and triggers for more information about defining SQL triggers.

**SQL-control-statement**

Specifies an SQL control statement, which can include nested control statements and other SQL statements specified in the syntax diagram for SQL-procedure-statement. The statements that can be specified for SQL-procedure-statement are subject to the syntax notes relating to triggers.

**triggered-SQL-statement**

Specifies an SQL statement that is the only statement in a trigger body.

Only certain SQL statements can be specified in the SQL-trigger-body.

The trigger body must not contain a statement that is not supported.

- A statement in the trigger body must not refer to host variables, undefined transition variables, or declared temporary tables.
- A statement in the trigger body must only refer to a table or view that is at the current server.
- A statement in the trigger body must only invoke a stored procedure or user-defined function that is at the current server. An invoked routine can, however, access a server other than the current server.
- A statement in the trigger body must not modify a column that is part of a BUSINESS_TIME period.
- The trigger body must not, directly or indirectly, issue a CALL statement for a procedure that contains one of the following statements:
  - COMMIT
  - CONNECT
  - RELEASE connection
  - RELEASE SAVEPOINT
  - ROLLBACK (without TO SAVEPOINT)
  - SAVEPOINT
  - SET CONNECTION
- The trigger body must not, directly or indirectly, issue a CALL statement for a procedure that is defined with the COMMIT ON RETURN option.

- If the trigger is a before trigger:
  - The trigger body must not contain a DELETE, INSERT, MERGE, REFRESH TABLE, TRUNCATE, UPDATE statement, or SELECT FROM data-change-statement.
  - The trigger body must not, directly or indirectly, invoke a routine containing one of the following statements:
    - ALTER
    - COMMENT
    - CREATE
    - DECLARE GLOBAL TEMPORARY TABLE
A CREATE TRIGGER statement (or ALTER TRIGGER statement) cannot contain a hexadecimal graphic string (GX) constant.

The triggered action can refer to the values in the set of affected rows. This action is supported through the use of transition variables and transition tables.

All tables, views, aliases, sequences, roles, user-defined data types, user-defined functions, and procedures referenced in the triggered-action must exist at the current server when the trigger is created, or the version of the trigger is defined. The table or view that an alias refers to must also exist when the trigger is created, or the version of the trigger is defined.

**Notes**

**Changing to an advanced trigger:**
You cannot use an ALTER TRIGGER statement to change a basic trigger into an advanced trigger. You can drop the existing trigger you want to change using the DROP statement and then create an advanced trigger with a similar definition using the CREATE TRIGGER statement in Db2 12 with new function activated, or you can use the CREATE TRIGGER statement with the OR REPLACE clause. Alternatively, you can create an advanced trigger using a different schema. To define an advanced trigger, omit the MODE DB2SQL clause in the CREATE TRIGGER statement.

**Changes are immediate:**
Any changes that the ALTER TRIGGER statement causes to the definition of a trigger take effect immediately. The changed definition is used the next time that the trigger is activated.

**Identifier resolution:**
See [SQL control statements for SQL routines and triggers](#) for information on how names are resolved to columns, SQL variables, transition variables, or global variables within a trigger body.

If non-unique names are used for columns, SQL variables, transition variables, or global variables, qualify the non-unique names by using the table designator for columns, the label name for SQL variables, correlation name for transition variables, and schema for global variables.
Transition variables and transition tables:
The triggered action can refer to the values in the set of affected rows. This
action is supported through the use of transition variables and transition
tables.
A transition variable has the same name and data type as the
corresponding column of the table that the trigger is defined on, and is
nullable. A transition variable contains the value of a column in an affected
row. A transition variable is qualified by a correlation name that identifies
whether the reference is to the old value (before the update) or the new
value (after the update). A transition variable can be referenced in the
search condition, or in an SQL statement in the trigger body wherever a
table would be allowed if the reference was made outside the body of a
trigger. A new transition variable can be assigned a value in a before
update or insert trigger. The values of the updated rows include the
changes from any assignments to transition variables in the triggered
action of a before trigger.
A transition table contains the complete set of affected rows with either the
old values (before the update) or the new values (after the update).
Transition tables are read only and can be referenced in the triggered
action of an after or instead of trigger. Transition tables also use the name
of columns of the subject table but have an associated table identifier that
allows the complete set of affected rows to be treated as a table. Separate
table identifiers can be specified for the old and new transition tables.
Transition tables can be referenced in the triggered action in a search
condition, or in an SQL statement in the trigger body wherever a variable
would be allowed if the reference was made outside the body of a trigger.
In addition, a transition table can be passed as an argument to a
user-defined function or procedure specifying the TABLE keyword before
the table identifier for the transition table. When the function or procedure
is invoked, a table locator is passed for the transition table.

Altering a trigger from NOT SECURED to SECURED:
Typically, the security administrator will examine the data that is accessed
by a trigger, ensure that it is secure, and grant the
CREATE_SECURE_OBJECT privilege to the owner of the trigger. After the
trigger is changed to SECURED, the security administrator will revoke the
CREATE_SECURE_OBJECT privilege from the owner of the trigger.
The trigger is considered secure after the ALTER TRIGGER statement is
executed. Db2 treats the SECURED attribute as an assertion that declares
that the user has established an audit procedure for all activities in the
trigger body. If a secure trigger references user-defined functions, Db2
assumes those functions are secure without validation. If those functions
can access sensitive data, the user with SECADM authority needs to ensure
that those functions are allowed to access that data and that an audit
procedure is in place for all versions of those functions, and that all
subsequent ALTER FUNCTION statements or changes to external packages
are being reviewed by this audit process.
A trigger must be secure if its subject table is using row access control or
column access control. SECURED must also be specified for a trigger that
is created for a view and one or more of the underlying tables in the view
definition is using row access control or column access control.

Altering a trigger from SECURED to NOT SECURED:
The ALTER TRIGGER statement returns an error if the subject table of the
trigger is using row access control or column access control, or if the
trigger is for a view and one or more of the underlying tables in the view definition is using row access control or column access control.

**Altering obfuscated triggers:**

Obfuscated triggers cannot be altered in any way.

**Row access control and column access control that is not enforced for transition variables and transition tables:**

If row access control or column access control is enforced for the subject table of the trigger, row permissions and column masks are not applied to the initial values of transition variables and transition tables. Row access control and column access control is enforced for the triggering table, but is ignored for transition variables and transition tables that are referenced in the body of the trigger body or are passed as arguments to user-defined functions that are invoked in the body of the trigger. To ensure that there are no security concerns for SQL statements accessing sensitive data in transition variables and transition tables in the trigger action, the trigger must be changed to use the SECURED option. If a trigger is not secure, row access control and column access control cannot be enforced for the triggering table.

**Correspondence of trigger options to bind options**

The following table lists options for CREATE TRIGGER and ALTER TRIGGER, and the corresponding options for the bind commands. See [BIND and REBIND options for packages, plans, and services (Db2 Commands)](link) for more information about the effects of the bind options.

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

**Considerations for packages:**

When certain attributes of a trigger are changed, the body of the trigger might be rebound or regenerated. However, there is no impact to existing packages that might cause the activation of the trigger, and such packages are not invalidated. No additional bind-related privileges are required for an implicit rebound or regeneration of the trigger body.

If an error is encountered during an implicit rebound, the ALTER TRIGGER statement fails and returns the error.

When execution of a package causes the activation of the trigger, the rebound or regenerated trigger package executes.

**Table 188** summarizes when implicit rebound and regeneration occurs when specific options are changed. A value of Y in a row indicates that a rebound or regeneration will occur if the option is changed for a trigger.

### Table 188. ALTER TRIGGER (advanced) options that result in rebound or regeneration when changed

<table>
<thead>
<tr>
<th>ALTER TRIGGER (advanced) option</th>

Table 188. ALTER TRIGGER (advanced) options that result in rebind or regeneration when changed (continued)

<table>
<thead>
<tr>
<th>ALTER TRIGGER (advanced) option</th>
<th>Change results in implicit rebind of the non-control statements of the body of the trigger?</th>
<th>Change results in implicit regeneration of the entire body of the trigger?</th>
</tr>
</thead>
<tbody>
<tr>
<td>DATE FORMAT</td>
<td>Y</td>
<td>Y</td>
</tr>
<tr>
<td>DECIMAL</td>
<td>Y</td>
<td>Y</td>
</tr>
<tr>
<td>DYNAMICRULES BIND OR RUN</td>
<td>Y</td>
<td>N</td>
</tr>
<tr>
<td>FOR UPDATE CLAUSE OPTIONAL or FOR UPDATE CLAUSE REQUIRED</td>
<td>Y</td>
<td>N</td>
</tr>
<tr>
<td>ISOLATION LEVEL</td>
<td>Y</td>
<td>N</td>
</tr>
<tr>
<td>OPTHINT</td>
<td>Y</td>
<td>N</td>
</tr>
<tr>
<td>QUALIFIER</td>
<td>Y</td>
<td>N</td>
</tr>
<tr>
<td>RELEASE</td>
<td>Y</td>
<td>N</td>
</tr>
<tr>
<td>ROUNDDING</td>
<td>Y</td>
<td>Y</td>
</tr>
<tr>
<td>SECURED OR NOT SECURED</td>
<td>Y</td>
<td>N</td>
</tr>
<tr>
<td>SQL PATH</td>
<td>Y</td>
<td>Y</td>
</tr>
<tr>
<td>SYSTEM_TIME SENSITIVE</td>
<td>Y</td>
<td>Y</td>
</tr>
<tr>
<td>TIME FORMAT</td>
<td>Y</td>
<td>Y</td>
</tr>
<tr>
<td>WITH EXPLAIN OR WITHOUT EXPLAIN</td>
<td>Y</td>
<td>N</td>
</tr>
<tr>
<td>WITH IMMEDIATE WRITE OR WITHOUT IMMEDIATE WRITE</td>
<td>Y</td>
<td>N</td>
</tr>
<tr>
<td>WLM ENVIRONMENT FOR DEBUG MODE</td>
<td>N</td>
<td>N</td>
</tr>
</tbody>
</table>

Note:
1. When an implicit rebind of the non-control statements in the body of the trigger occurs, the QUALIFIER and SQL PATH options are not re-evaluated.
2. The trigger package is rebound and regenerated if a value of ALLOW DEBUG MODE is changed to DISALLOW DEBUG MODE.

Considerations for the SYSENVIRONMENTS catalog table:
An ALTER statement that specifies new environment settings will result in a new row being added to the SYSENVIRONMENTS catalog table. The new row will be added even if an error is subsequently encountered during processing of the ALTER statement. Thus, a new SYSENVIRONMENTS row might be added even for an ALTER statement that fails.

Dependent objects:
A trigger is dependent on the triggering table and objects that are referenced in the trigger body.

Error handling in triggers:
A trigger can return errors like other SQL statements. Applications should be aware of the possible errors that can be expected when a trigger is invoked. Any exception SQLSTATE that is not handled within the trigger body (using a handler), results in the exception SQLSTATE being returned to the statement that caused the trigger to be activated. For example, if a SIGNAL statement (RESIGNAL statement or RAISE_ERROR function) raises a non-severe error in the SQL-trigger-body and the condition is not handled within the trigger body, SQLCODE -438 and the specified SQLSTATE will be returned. Other non-severe errors are returned with
SQLCODE -723 and SQLSTATE 09000. Severe errors that occur during the execution of triggered SQL statements are returned with SQLCODE -901, -906, -911, and -913 and the corresponding SQLSTATE. Warnings are not returned.

Examples

**Example 1**: Change the definition of trigger TRIGGER1 to secured:
```
ALTER TRIGGER TRIGGER1
SECURED;
```

**Example 2**: Alter the definition of trigger TRIGGER1 to allow it to be run in debugging mode:
```
ALTER TRIGGER TRIGGER1
ALLOW DEBUG MODE;
```

**Example 3**: When the new version of the trigger has been defined, you must use the ALTER TRIGGER statement with the ACTIVATE VERSION clause if the new version of the trigger is to be the currently active version, as in the following example:
```
ALTER TRIGGER TRIGGER1
ACTIVATE VERSION V3;
```

**Example 4**: To regenerate the currently active version of a trigger, use the following statement:
```
ALTER TRIGGER TRIGGER1
REGENERATE ACTIVE VERSION;
```

### ALTER TRIGGER (basic)

The ALTER TRIGGER (basic) statement changes the description of a basic trigger at the current server.

For a description of the differences between basic and advanced triggers, see [Triggers (Introduction to Db2 for z/OS)](https://www.ibm.com).  

### Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

### Authorization

The privilege set that is defined below must include at least one of the following:
- Ownership of the trigger
- The ALTERIN privilege on the schema
- SYSADM authority
- SYSCTRL authority
- System DBADM
- Installation SYSOPR authority (when the current SQLID of the process is set to SYSINSTL)
The authorization ID that matches the schema name implicitly has the ALTERIN privilege on the schema.

**Privilege set:** If the statement is embedded in an application program, the privilege set is the set of privileges that are held by the owner of the plan or package. If the statement is dynamically prepared, the privilege set is the set of privileges that are held by the SQL authorization ID of the process. The specified trigger name can include a schema name (a qualifier). However, if the schema name is not the same as one of the authorization ID of the process, one of the following conditions must be met:

- The privilege set includes SYSADM authority, SYSCTRL authority, or system DBADM authority.
- The authorization ID of the process has the ALTERIN privilege on the schema.

If the SECURED option is specified, at least one of the following privileges is required:

- SECADM authority
- CREATE_SECURE_OBJECT privilege

**Note:** If the SEPARATE SECURITY subsystem parameter is set to NO, SYSADM authority has implicit SECADM authority.

**Syntax**

```
ALTER TRIGGER trigger-name option-list
```

**Description**

**trigger-name**

Identifies the trigger that is to be changed. The name, including the implicit or explicit schema name, must exist at the current server. The name must identify a basic trigger.

The trigger must not be obfuscated.

**SECURED or NOT SECURED**

Specifies that the trigger is to be changed to be secure or not secure. Changing a trigger between SECURED and NOT SECURED causes an implicit rebind of the trigger package. If an error is encountered during the implicit rebind of the trigger package, the ALTER TRIGGER statement returns the error.

**SECURED**

Specifies the trigger is considered secure.

SECURED must be specified for a trigger if its subject table is using row access control or column access control. SECURED must also be specified
for a trigger that is created for a view and one or more of the underlying tables in the view definition is using row access control or column access control.

**NOT SECURED**
Specifies the trigger is considered not secure.

NOT SECURED must not be specified for a trigger whose subject table is using row access control or column access control. NOT SECURED must also not be specified for a trigger that is created for a view and one or more of the underlying tables in the view definition is using row access control or column access control.

**Notes**

**Changing an existing trigger into an advanced trigger:**
To change a basic trigger or a trigger defined prior to Db2 12 with new function activated into an advanced trigger, use one of the following methods:

- issue a DROP TRIGGER statement followed by a CREATE TRIGGER (advanced) statement, specifying the desired definition of the advanced trigger to redefine it. The existing trigger is effectively dropped, and a new advanced trigger is defined. This affects the trigger activation order for the table on which the trigger is defined.

- issue a CREATE TRIGGER (advanced) statement with the OR REPLACE clause, and specify the desired definition of the advanced trigger. The existing trigger is effectively dropped, and a new advanced trigger is defined. This affects the trigger activation order for the table on which the trigger is defined.

**Changes are immediate:**
Any changes that the ALTER TRIGGER statement causes to the definition of a trigger take effect immediately. The changed definition is used the next time that the trigger is activated.

**Altering a trigger from NOT SECURED to SECURED:**
Typically, the security administrator will examine the data that is accessed by a trigger, ensure that it is secure, and grant the CREATE_SECURE_OBJECT privilege to the owner of the trigger. After the trigger is changed to SECURED, the security administrator will revoke the CREATE_SECURE_OBJECT privilege from the owner of the trigger.

The trigger is considered secure after the ALTER TRIGGER statement is executed. Db2 treats the SECURED attribute as an assertion that declares that the user has established an audit procedure for all activities in the trigger body. If a secure trigger references user-defined functions, Db2 assumes those functions are secure without validation. If those functions can access sensitive data, the user with SECADM authority needs to ensure that those functions are allowed to access that data and that an audit procedure is in place for all versions of those functions, and that all subsequent ALTER FUNCTION statements or changes to external packages are being reviewed by this audit process.

A trigger must be secure if its subject table is using row access control or column access control. SECURED must also be specified for a trigger that is created for a view and one or more of the underlying tables in the view definition is using row access control or column access control.
Altering a trigger from SECURED to NOT SECURED:
The ALTER TRIGGER statement returns an error if the subject table of the trigger is using row access control or column access control, or if the trigger is for a view and one or more of the underlying tables in the view definition is using row access control or column access control.

Altering obfuscated triggers:
Obfuscated triggers cannot be altered in any way.

Row access control and column access control that is not enforced for transition variables and transition tables:
If row access control or column access control is enforced for the subject table of the trigger, row permissions and column masks are not applied to the initial values of transition variables and transition tables. Row access control and column access control is enforced for the triggering table, but is ignored for transition variables and transition tables that are referenced in the body of the trigger body or are passed as arguments to user-defined functions that are invoked in the body of the trigger. To ensure that there are no security concerns for SQL statements accessing sensitive data in transition variables and transition tables in the trigger action, the trigger must be changed to use the SECURED option. If a trigger is not secure, row access control and column access control cannot be enforced for the triggering table.

Examples

Example 1: Change the definition of trigger TRIGGER1 to secured:
ALTER TRIGGER TRIGGER1 SECURED;

ALTER TRUSTED CONTEXT

The ALTER TRUSTED CONTEXT statement modifies the definition of a trusted context at the current server.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

Authorization

The privilege set that is defined below must include at least one of the following:
• SYSADM authority
• SECADM authority

Privilege set: If the statement is embedded in an application program, the privilege set is the set of privileges that are held by the owner of the plan or package.

If the statement is dynamically prepared, the privilege set is the union of the set of privileges that are held by each authorization ID of the process. If the statement is run in a trusted context with a role, the privilege set is the union of the set of privileges that are held by the role that is associated with the primary
authorization ID and the set of privileges that are held by each authorization ID of the process.

**Syntax**

```
ALTER TRUSTED CONTEXT context-name

(1) ALTER SYSTEM AUTHID authorization-name
    NO DEFAULT ROLE
    DEFAULT ROLE role-name
    ENABLE
    DISABLE
    NO DEFAULT SECURITY LABEL
    DEFAULT SECURITY LABEL seclabel-name
    ATTRIBUTES (ADDRESS address-value)
    (2) ENCRYPTION encryption-value
    (3) SERVAUTH servauth-value
    (4) JOBNAME jobname-value

ADD ATTRIBUTES (ADDRESS address-value)
    SERVAUTH servauth-value
    JOBNAME jobname-value

DROP ATTRIBUTES (ADDRESS address-value)
    SERVAUTH servauth-value
    JOBNAME jobname-value
```

**Notes:**

1. These clauses can be specified in any order. Each clause must not be specified more than one time.

2. This clause and the clauses that follow can be specified in any order. Each clause must not be specified more than one time.

3. ENCRYPTION must not be specified more than one time.

4. JOBNAME must not be specified with ADDRESS, ENCRYPTION, or SERVAUTH.

5. Each pair of attribute name and corresponding value must be unique.
use-options:

- ROLE role-name
- SECURITY LABEL seclabel-name

Description

context-name

Identifies the trusted context to alter. context-name must refer to a trusted context that exists at the current server.

ALTER

Specifies that changes are to be made to the definition of an existing trusted context.

SYSTEM AUTHID authorization-name

Specifies that authorization-name is the system authorization ID for the trusted context. The system authorization ID is the primary authorization ID of the Db2 system that establishes the connection. For a remote connection, the authorization ID is derived from the system used ID that is provided by the external entity, such as a middleware server. For a local connection, the system authorization ID is derived depending on the sources, as specified in Table 189.

Table 189. System authorization ID for a local connection

<table>
<thead>
<tr>
<th>Source of local connection</th>
<th>System authorization ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>Started task (RRSAF)</td>
<td>USER parameter on JOB statement or RACF USER.</td>
</tr>
<tr>
<td>TSO</td>
<td>TSO logon ID</td>
</tr>
<tr>
<td>BATCH</td>
<td>USER parameter on JOB statement</td>
</tr>
</tbody>
</table>
authorization-name must not be associated with an existing trusted context.

**NO DEFAULT ROLE or DEFAULT ROLE role-name**

Specifies whether a default role is associated with a trusted connection that is based on the specified trusted context. If a trusted connection for the specified context is active, the change goes into effect at the next connection reuse attempt or when a new connection is requested.

**NO DEFAULT ROLE**

Specifies that the trusted context does not have a default role. The authorization ID of the process is the owner of any object that is created using a trusted connection that is based on this trusted context. That authorization ID must possess all of the privileges that are necessary to create that object.

**DEFAULT ROLE role-name**

Specifies that role-name is the role for the trusted context. role-name must identify a role that exists at the current server. This role is used with the user in a trusted connection that is based on the specified trusted context when the user does not have a user-specified role that is defined as part of the definition of this trusted context.

**WITHOUT ROLE AS OBJECT OWNER or WITH ROLE AS OBJECT OWNER AND QUALIFIER**

Specifies whether a role is used as the owner of objects that are created using a trusted connection that is based on the specified trusted context. If a trusted connection for the specified context is active, the change goes into effect at the next connection reuse attempt or when a new connection is requested.

**WITHOUT ROLE AS OBJECT OWNER**

Specifies that a role is not used as the owner of the objects that are created using a trusted connection that is based on the specified trusted context. The authorization ID of the process is the owner of any object that is the created using a trusted connection that is based on this trusted context. That authorization ID must possess all of the privileges that are necessary to create the object.

WITHOUT ROLE AS OBJECT OWNER is the default.

**WITH ROLE AS OBJECT OWNER AND QUALIFIER**

Specifies that the context assigned role is the owner of the objects that are created using a trusted connection that is based on this trusted context. That role must possess all of the privileges that are necessary to create the object. The context assigned role is the role that is defined for the user within this trusted context, if one is defined. Otherwise, the role is the default role that is associated with the trusted context. The role is also used as the grantor for any GRANT statements that are issued, and the revoker for any REVOKE statement that are issued using a trusted connection that is based on this trusted context.

**AND QUALIFIER**

Specifies that the role-name will be used as the default for the CURRENT SCHEMA special register. The role-name will also be included in the SQL PATH (in place of CURRENT SQLID).

When WITH ROLE AS OBJECT OWNER AND QUALIFIER is not specified, there is no change to the default of the CURRENT SCHEMA special register and SQL PATH.

**DISABLE or ENABLE**

Specifies whether the trusted context is in the enabled or disabled state.
DISABLE
Specified that the trusted context is disabled. A trusted context that is disabled is not considered when a trusted connection is established.

ENABLE
Specifies that the trusted context is enabled.

NO DEFAULT SECURITY LABEL or DEFAULT SECURITY LABEL seclabel-name
Specifies whether a default security label is associated with a trusted connection that is based on this trusted context. If a trusted connection for the specified context is active, the change goes into effect at the next connection reuse attempt or when a new connection is requested.

NO DEFAULT SECURITY LABEL
Specifies that the trusted context does not have a default security label.

DEFAULT SECURITY LABEL seclabel-name
Specifies that seclabel-name is the default security label for the trusted context. seclabel-name is the security label that is used for multilevel security verification. seclabel-name must identify one of the RACF SECLABEL values that is defined for the SYSTEM AUTHID. This security label is used in a trusted connection that is based on the specified trusted context when the user does not have a specific security label defined as part of the definition of this trusted context. In this case, seclabel-name must also identify one of the RACF SECLABEL values that is defined for the user.

ALTER ATTRIBUTES or ADD ATTRIBUTES
Specifies a list of one or more connection trust attributes to change or add to the definition of a trusted context. The connection trust attributes are used to define the trusted context. If ALTER ATTRIBUTES is specified and the attribute is not currently part of the definition of the specified trusted context, an error is returned. Existing specifications for the specified attributes are changed to the new value if ALTER is specified. Attributes that are not specified retain the previously specified values.

ADDRESS address-value
Specifies the actual communication address that is used by the connection to communicate with the database manager. The protocol supported is only for TCP/IP. Previously specified ADDRESS values are removed when ALTER ATTRIBUTES is specified. The ADDRESS attribute can be specified multiple times, but each address-value must be unique.

When establishing a trusted connection, if multiple values are defined for the ADDRESS attribute for a trusted context, a candidate connection is considered to match this attribute if the address that is used by a connection matches any of the values that are defined for the ADDRESS attribute of the trusted context.

address-value specifies a string constant that contains the value that is associated with the ADDRESS trust attribute. address-value must be an IPv4 address, an IPv6 address, or a secure domain name with a length no greater than 254 bytes. No validation of address-value is done at the time the ALTER TRUSTED CONTEXT statement is processed. address-value must be left justified within the string constant.

- An IPv4 address is represented as a dotted decimal address. An example of an IPv4 address is 9.112.46.111.
• An IPv6 address is represented as a colon hexadecimal address. An example of an IPv6 address is 2001:0DB8:0000:0008:0800:200C:417A. This address can also be express in a compressed form as 2001:DB8::8:800:200C:417A.

• A domain name is converted to an IP address by the domain name server where a resulting IPv4 or IPv6 address is determined. An example of a domain name is www.ibm.com. The gethostbyname socket call is used to resolve the domain name.

**ENCRIPTION** encryption-value

Specifies the minimum level of encryption of the data stream (network encryption) for the connection.

*encryption-value* specifies a string constant that contains the value that is associated with the ENCRYPTION trust attribute. *encryption-value* must be left justified within the string constant. ENCRYPTION must not be specified more than one time in the statement. *encryption-value* must be one of the following:

- NONE, which specifies that no specific level of encryption is required.
- LOW, which specifies that a minimum of light encryption is required. LOW corresponds to 64-bit DRDA encryption.
- HIGH, which specifies that strong encryption is required. HIGH corresponds to SSL encryption.

ENCRYPTION cannot be specified if ADD ATTRIBUTES is specified. See “CREATE TRUSTED CONTEXT” on page 1921 for more information about the ENCRYPTION attribute.

**JOBNAME** jobname-value

Specifies the z/OS job name or started task name (depending on the source of the address space) for local applications. Previously specified values for JOBNAME are removed when ALTER ATTRIBUTES is specified. The JOBNAME attribute can be specified multiple times, but each jobname-value must be unique.

*jobname-value* specifies a string constant that contains the value that is associated with the JOBNAME trust attribute. *jobname-value* is an EBCDIC 8 byte job name or started task name. *jobname-value* must be left justified within the string constant. The last character in the name can be a wildcard character (*) if the first character is an alphabetic character. If the job name ends with a wildcard, any job names that match the specified characters are considered for establishing the trusted connection.

The following table lists possible values for the job name depending on the source of the address space).

<table>
<thead>
<tr>
<th>Source of the address space</th>
<th>Job name</th>
</tr>
</thead>
<tbody>
<tr>
<td>RRSAF</td>
<td>Job name or started task name</td>
</tr>
<tr>
<td>TSO</td>
<td>TSO logon ID</td>
</tr>
<tr>
<td>BATCH</td>
<td>Job name on JOB statement</td>
</tr>
</tbody>
</table>

**SERVAUTH** servauth-value

Specifies the name of a resource in the RACF SERVAUTH class. This resource is the network access security zone name that contains the IP address of the connection that is used to communicate with Db2. Previously specified values for SERVAUTH are removed when ALTER
ATTRIBUTES is specified. The SERVAUTH attribute can be specified multiple times but each servauth-value must be unique.

servauth-value specifies a string constant that contains the value that is associated with the SERVAUTH trust attribute. servauth-value is an EBCDIC 64 byte RACF SERVAUTH CLASS resource name. servauth-value must be left justified in the string constant. No validation of servauth-value is done at the time the ALTER TRUSTED CONTEXT statement is processed.

DROP ATTRIBUTES
Specifies that one or more attributes are dropped from the definition of a trusted context. If the attribute is not currently specified as part of the definition of a trusted context, an error is returned. The specification of DROP ATTRIBUTES must not attempt to drop all of the existing attributes for a trusted context.

ADDRESS address-value
Specifies that the identified communication address is removed from the definition of the trusted context. address-value specifies a string constant that contains the value of an existing ADDRESS trust attribute.

JOBNAME jobname-value
Specifies that the identified job name is removed from the definition of the trusted context. jobname-value specifies a string constant that contains the value of an existing JOBNAME trust attribute.

SERVAUTH servauth-value
Specifies that the identified servauth that is removed from the definition of the trusted context. servauth-value specifies a string constant that contains the value of an existing SERVAUTH trust attribute.

ADD USE FOR
Specifies additional users who can use a trusted connection that is based on the specified trusted context.

authorization-name
Specifies that the trusted connection can be used by the specified authorization-name. This is the Db2 primary authorization ID. The authorization-name must not identify an authorization ID that is already defined to use the trusted context, and must not be specified more than one time in the ADD USE FOR clause.

ROLE role-name
Specifies that role-name is the role that is used when a trusted connection is used by the specified authorization-name. The role-name must identify a role that exists at the current server. The role that is explicitly specified for the user overrides any default role that is associated with the trusted context.

SECURITY LABEL seclabel-name
Specifies that seclabel-name is the security label to use for multilevel security verification when the trusted connection is used by the specified authorization-name. The seclabel-name must be one of the RACF SECLABEL values that is defined for the user. The security label that is explicitly specified for the user overrides any default security label that is associated with the trusted context.

EXTERNAL SECURITY PROFILE profile-name
Specifies that the trusted connection can be used by the Db2 primary authorization IDs that are permitted to use the specified profile-name in RACF. profile-name must not already be defined to use the trusted context,
and must not be specified more than one time in the ADD USE FOR clause. If an authorization ID is permitted to use more than one specified profile-name, the role that is specified for profile-name can be associated with the process if the user authentication satisfies the AUTHENTICATION definition. This role can hold additional privileges that are available to the process.

After you specify an external security profile, any user who is permitted access to the RACF profile can use the trusted context in addition to any users that are specified using the ADD USE FOR authorization-name clause.

**ROLE role-name**
Specifies that role-name is the role that is used when a trusted connection is used by any authorization ID that is permitted to use the specified profile-name in RACF. The role-name must identify a role that exists at the current server. The role that is explicitly specified for the profile overrides any default role that is associated with the trusted context.

**SECURITY LABEL seclabel-name**
Specifies that seclabel-name is the security label to use for multilevel security verification when the trusted connection is used by any authorization ID that is permitted to use the specified profile-name in RACF. The seclabel-name must be one of the RACF SECLABEL values that is defined for the user. The security label that is explicitly specified for the profile overrides any default security label that is associated with the trusted context.

**PUBLIC**
Specifies that a trusted connection that is based on the specified trusted context can be used by any user. PUBLIC must not already be defined to use the trusted context and must not be specified more than one time in the ADD USE FOR clause.

All users that are using a trusted connection that is defined with PUBLIC use the privileges that are associated with the default role for the associated trusted context. If the default role is not defined for the trusted context, there is no role associated with the users that use a trusted connection that is based on the specified trusted context.

If the default security label for the trusted context is defined, all users that are using the trusted context must have the security label defined as one of the RACF SECLABEL values for the user. The default security label is used for multilevel security verification with all users that are using the trusted context.

The specifications for a user are determined in the following order of precedence:
- authorization-name
- EXTERNAL SECURITY PROFILE profile-name
- PUBLIC

For example, assume that a trusted context is defined with use for JOE WITH AUTHENTICATION, EXTERNAL SECURITY PROFILE SPROFILE WITHOUT AUTHENTICATION (with JOE and SAM permitted to use the RACF PROFILE SPROFILE), and PUBLIC WITH AUTHENTICATION. If the trusted connection is used by JOE, authentication is required. If the
trusted connection is used by SAM, authentication is not required. However, if the trusted connection is used by SALLY, authentication is required.

REPLACE USE FOR
Specifies a change to the specified user or PUBLIC for who can use the trusted context.

authorization-name
Specifies the authorization-name that is changed for use of the trusted context. The trusted context must already be defined to allow use by authorization-name, and authorization-name must not be specified more than one time in the REPLACE USE FOR clause. The information that is associated with authorization-name is changed as indicated.

ROLE role-name
Specifies that role-name is the role that is used when a trusted connection is using the specified trusted context. The role-name must identify a role that exists at the current server. The role that is explicitly specified for the user overrides any default role that is associated with the trusted context.

SECURITY LABEL seclabel-name
Specifies that seclabel-name is the security label to use for multilevel security verification when the trusted connection is used by the specified authorization-name. The seclabel-name must be one of the RACF SECLABEL values that is defined for the user. The security label that is explicitly specified for the user overrides any default security label that is associated with the trusted context.

EXTERNAL SECURITY PROFILE profile-name
Specifies the profile-name to change attributes for use of the trusted connection. The trusted context must already be defined to allow the use of profile-name. profile-name must not be specified more than one time in the REPLACE USE FOR clause. The information that is associated with the profile name is changed as indicated.

ROLE role-name
Specifies that role-name is the role that is used when a trusted connection is used by any authorization ID that is permitted to use the specified profile-name in RACF. The role name must identify a role that exists at the current server. The role that is explicitly specified for the profile overrides any default role that is associated with the trusted context.

SECURITY LABEL seclabel-name
Specifies that seclabel-name is the security label to use for multilevel security verification when the trusted connection is used by any authorization ID that is permitted to use the specified profile-name in RACF. The seclabel-name must be one of the RACF SECLABEL values that is defined for the user. The security label that is explicitly specified for the user overrides any default security label that is associated with the trusted context.

PUBLIC
Specifies that the attributes for use of the trusted connection by PUBLIC are to be changed. PUBLIC must already be defined to use the trusted context, and PUBLIC must not be specified more than one time in the REPLACE USE FOR clause.
All users that are using a trusted connection that is defined with PUBLIC use the privileges that are associated with the default role for the associated trusted context. If the default role is not defined for the trusted context, there is no role associated with the users that use a trusted connection that is based on the specified trusted context.

If the default security label for the trusted context is defined, all users that are using the trusted context must have the security label defined as one of the RACF SECLABEL values for the user. The default security label is used for multilevel security verification with all users that are using the trusted context.

**WITHOUT AUTHENTICATION or WITH AUTHENTICATION**

Specifies whether use of the trusted connection requires authentication of the user.

**WITHOUT AUTHENTICATION**

Specifies that use of a trusted connection by the user does not require authentication. WITHOUT AUTHENTICATION is the default.

**WITH AUTHENTICATION**

Specifies that use of a trusted connection requires the authentication token with the authorization ID to authenticate the user.

**DROP USE FOR**

Specifies who can no longer use the trusted context. The users that are removed from the definition of the trusted context are the specified users (or PUBLIC) that are currently allowed to use the trusted context. If multiple users are specified to be dropped, and one or more of those users cannot be dropped, those users that can be dropped are dropped and a warning is returned. If none of the specified users can be removed from the definition of the trusted context, an error is returned.

*authorization-name*

Specifies the *authorization-name* that will no longer be able to use this trusted context.

*EXTERNAL SECURITY PROFILE* *profile-name*

Removes the ability for the specified *profile-name* to use the trusted context.

*PUBLIC*

Specifies that PUBLIC users will no longer be able to use this trusted context. The system authorization ID and individual authorization IDs that have been explicitly enabled can still use the trusted context.

**Notes**

_Precedence for authorization-name and authentication requirements:_ If the *authorization-name* that is specified in the SYSTEM AUTHID clause is the same authorization name that is specified in the ADD or REPLACE USE FOR *authorization-name* clauses, the role or the security label that is specified for the *authorization-name* takes precedence over the default value and the value that is specified for the EXTERNAL SECURITY PROFILE *profile-name* (if one is specified). If the authorization name that is specified in the SYSTEM AUTHID clause is permitted to use one of the specified profile names and is not specified in ADD or REPLACE USE for *authorization-name*, the role or the security label that is specified for that *profile-name* takes precedence over the default value.

Authentication is required for SYSTEM AUTHID if the AUTHENTICATION clause is specified in the ADD or REPLACE USE FOR clauses, or if the subsystem...
parameter TCP/IP Already Verified is set to NO. For example, if authorization-name is the same as the authorization name that is specified in the SYSTEM AUTHID clause and the WITHOUT AUTHENTICATION clause is specified, but the TCP/IP Already Verified subsystem parameter is set to NO, authentication is required for SYSTEM AUTHID when the remote trusted connection is established. If authorization-name is the SYSTEM AUTHID and the WITH AUTHENTICATION clause is specified, but the TCP/IP Already Verified subsystem parameter is set to YES, authentication is still required for SYSTEM AUTHID.

Order of precedence for users of a trusted connection: The specifications for a user are determined in the following order of precedence:

- authorization-name
- EXTERNAL SECURITY PROFILE profile-name
- PUBLIC

For example, assume that a trusted context is defined with use for JOE WITH AUTHENTICATION, EXTERNAL SECURITY PROFILE SPROFILE WITHOUT AUTHENTICATION, and PUBLIC WITH AUTHENTICATION. Users JOE and SAM are permitted to use the RACF PROFILE SPROFILE. If the trusted connection is used by JOE, authentication is required. If the trusted connection is used by SAM, authentication is not required. However, if user SALLY uses the trusted connection, authentication is required.

User-clause SYSTEM AUTHID considerations: If the authorization-name that is specified in the SYSTEM AUTHID clause is the same as the authorization-name that is specified in the user-clause authorization-name, the role or the security label that is specified for authorization-name takes precedence over the default value. The value that is specified for the profile-name, is permitted to use the profile. If the authorization name that is specified in the SYSTEM AUTHID clause is permitted to use one of the profile names and is not defined in authorization-name, the role or the security label that is specified for that profile-name takes precedence over the default value.

If authentication is required for SYSTEM AUTHID, either by specification of the AUTHENTICATION clause in the user-clause or by setting the value of the TCP/IP Already Verified subsystem parameter to NO, the authentication requirement takes precedence when establishing a remote trusted connection. For example, if authorization-name is the same as the authorization name that is specified for SYSTEM AUTHID and the WITHOUT AUTHENTICATION clause is specified, but the TCP/IP Already Verified subsystem parameter is set to NO, an authentication token is required for SYSTEM AUTHID when the remote trusted connection is established. If authorization-name is the SYSTEM AUTHID and the WITH AUTHENTICATION clause is specified, but the TCP/IP Already Verified subsystem parameter is set to YES, an authentication token is still required for SYSTEM AUTHID.

Order of operations: The order in which the clauses of the ALTER TRUSTED CONTEXT statement are applied are as follows:

- DROP ATTRIBUTES
- DROP USE FOR
- ALTER
- ADD ATTRIBUTES
- ADD USE FOR
- REPLACE USE FOR
Effect of changes on existing trusted connections: If trusted connections exist for the trusted context that is changed, the connections continue to use the unchanged definition of the trusted context until the connection is terminated or an attempt at reuse is made. If the trusted context is disabled while there are active trusted connections that are based on this trusted context, the connections continue to be used until terminated or an attempt at reuse is made. If the trust attributes are changed, trusted connections that exist at the time that the trusted context is changed will continue to be used.

When changes to a trusted context take place: The changes to the definition of a trusted context take effect after the ALTER TRUSTED CONTEXT statement is committed. If the ALTER TRUSTED CONTEXT statement results in an error or is rolled back, the trusted context is not changed.

Role privileges: If no role is associated with the user or the trusted context, only the privileges that are associated with the user are applicable. This is the same as not using a trusted context.

Examples

Example 1: The following statement updates the default role of the trusted context CTX1:

```
ALTER TRUSTED CONTEXT CTX1
  ALTER DEFAULT ROLE CTXROLE2;
```

Example 2: The following statement changes the CTX3 trusted context to allow use for BILL, and it also puts the trusted context into the disabled state:

```
ALTER TRUSTED CONTEXT CTX3
  DISABLE
  ADD USE FOR BILL;
```

Example 3: The following statement changes the CTX4 trusted context to allow the previously defined user JOE to use the trusted context without authentication. The statement also adds use for PUBLIC with authentication and TOM with a role of SPLROLE:

```
ALTER TRUSTED CONTEXT CTX4
  REPLACE USE FOR JOE WITHOUT AUTHENTICATION
  ADD USE FOR PUBLIC WITH AUTHENTICATION,
  TOM ROLE SPLROLE;
```

Example 4: The following statement changes the REMOTECTX to use a different IPv4 address than it was originally defined to use. It also changes the encryption settings from NONE to LOW. After the ALTER statement is processed, the connection will be considered trusted only when it is established from 9.12.155.200 with low encryption. The connection will no longer be considered trusted if it is established from the previously defined addresses:

```
ALTER TRUSTED CONTEXT REMOTECTX
  ALTER ATTRIBUTES (ADDRESS '9.12.155.200',
                   ENCRYPTION 'LOW');
```

ALTER VIEW

The ALTER VIEW statement regenerates a view using an existing view definition at the current server. ALTER VIEW is primarily used during Db2 migration or when Db2 maintenance is applied. To change a view definition (for example, to add additional columns), you must drop the view and create a new view using the CREATE VIEW statement.
Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

Authorization

The privilege set that is defined below must include at least one of the following:

- Ownership of the view
- SYSADM authority
- SYSCTRL authority
- System DBADM

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the package. If the statement is dynamically prepared, the privilege set is the union of the privilege sets that are held by each authorization ID and role of the process.

Syntax

```
ALTER VIEW view-name REGENERATE USING APPLICATION COMPATIBILITY applcompat-value
```

Description

**view-name**

Identifies the view to be regenerated. The name must identify a view that exists at the current server.

**REGENERATE**

Specifies that the view is to be regenerated. The view definition in the catalog is used, and existing authorizations and dependent views are retained. The catalog is updated with the regenerated view definition. If the view cannot be successfully regenerated, an error is returned.

**USING APPLICATION COMPATIBILITY applcompat-value**

Specifies that the object is regenerated under applcompat-value application compatibility rules. The ALTER statement fails if it includes any syntax, semantics, or options that require a higher application compatibility level.

If USING APPLICATION COMPATIBILITY is omitted, the regeneration uses the APPLCOMPAT value of the applicable SYSIBM.SYSENVIRONMENT catalog table row.

The following applcompat-value values can be specified:

**function-level**

Specifies the application compatibility behavior of the function-level function level. The equivalent function level or higher must be activated.

The format is VvvRrMmm, where Vv is the version, r is the release, and Mmm is the modification level. For example:
V12R1M504

Identifies compatibility with the current highest available function level, function level 504.

V12R1M500

Identifies compatibility with the function level that enables new function in the initial Db2 12 release, function level 500.

V12R1M500 is the same as V12R1.

V12R1M100

Identifies compatibility with the function level before you activate new function, after migration to Db2 12, function level 100.

V12R1M100 is the same as V11R1.

For a list of supported function-level values, see [What’s new in Db2 12 function levels (Db2 for z/OS What’s New?)](#).

V11R1

Specifies Db2 11 compatibility behavior.

V10R1

Specifies Db2 10 compatibility behavior.

Examples

Check the catalog to find any views that were marked with view regeneration errors during catalog migration:

```sql
SELECT CREATOR,NAME FROM SYSIBM.SYSTABLES
WHERE TYPE = 'V' AND STATUS = 'R' AND TABLESTATUS = 'V';
```

Assume that the query returned MYVIEW as the name of a view with a regeneration error. Issue an ALTER VIEW statement to regenerate the view:

```sql
ALTER VIEW MYVIEW REGENERATE;
```

ASSOCIATE LOCATORS

The ASSOCIATE LOCATORS statement gets the result set locator value for each result set returned by a stored procedure.

Invocation

This statement can be embedded in an application program. It is an executable statement that can be dynamically prepared. It cannot be issued interactively.

Authorization

None required.
Syntax

```
ASSOCIATE (rs-locator-variable)

WITH PROCEDURE procedure-name or host-variable
```

Description

*rs-locator-variable*

Identifies a result set locator variable that has been declared according to the rules for declaring result set locator variables.

**WITH PROCEDURE procedure-name or host-variable**

Identifies the stored procedure that returned one or more result sets. When the ASSOCIATE LOCATORS statement is executed, the procedure name must identify a stored procedure that the requester has already invoked using the SQL CALL statement. The procedure name can be specified as a one-part, two-part, or three-part name. The procedure name in the ASSOCIATE LOCATORS statement must be specified the same way that it was specified on the CALL statement. For example, if a two-part procedure name was specified on the CALL statement, you must specify a two-part procedure name in the ASSOCIATE LOCATORS statement.

If a host variable is used to specify the name:

* It must be a character string variable with a length attribute that is not greater than 255.
* It must not be followed by an indicator variable.
* The value of the host variable is a specification that depends on the server. Regardless of the server, the specification must:
  - Be left justified within the host variable
  - Not contain embedded blanks
  - Be padded on the right with blanks if its length is less than that of the host variable

Notes

**Assignment of locator values:** If the ASSOCIATE LOCATORS statement specifies multiple locator variables, locator values are assigned to the locator variables in the order that the associated cursors are opened regardless of whether they are still open or not at run time. Locator values are assigned to the locator variables in the same order that they would be placed in the SQLVAR entries in the SQLDA as a result of a DESCRIBE PROCEDURE statement.

Locator values are not provided for cursors that are closed when control is returned to the invoking application. If a cursor was closed and later opened again before returning to the invoking application, the most recently executed OPEN CURSOR statement for the cursor is used to determine the order in which the
locator values are returned for the procedure result sets. For example, assume procedure P1 opens three cursors A, B, C, closes cursor B and then issues another OPEN CURSOR statement for cursor B before returning to the invoking application. The locator values assigned for the following ASSOCIATE LOCATORS statement will be in the order A, C, B:

ASSOCIATE RESULT SET LOCATORS (:loc1, :loc2, :loc3) WITH PROCEDURE P1;
-- assigns locators for result set cursors A, C, and B

More than one locator can be associated with a result set. You can issue multiple ASSOCIATE LOCATORS statements for the same stored procedure with different result set locator variables to associate multiple locators with each result set.

- If the number of result set locator variables specified in the ASSOCIATE LOCATORS statement is less than the number of result sets returned by the stored procedure, all locator variables specified in the statement are assigned a value, and a warning is issued. For example, assume procedure P1 exists and returns four result sets. Each of the following ASSOCIATE LOCATORS statement returns information on the first result set along with a warning that not enough locators were provided to obtain information about all the result sets.

CALL P1;
ASSOCIATE RESULT SET LOCATORS (:loc1) WITH PROCEDURE P1;
-- :loc1 is assigned a value for first result set, and a warning is returned
ASSOCIATE RESULT SET LOCATORS (:loc2) WITH PROCEDURE P1;
-- :loc2 is assigned a value for first result set, and a warning is returned
ASSOCIATE RESULT SET LOCATORS (:loc3) WITH PROCEDURE P1;
-- :loc3 is assigned a value for first result set, and a warning is returned
ASSOCIATE RESULT SET LOCATORS (:loc4) WITH PROCEDURE P1;
-- :loc4 is assigned a value for first result set, and a warning is returned

- If the number of result set locator variables that are listed in the ASSOCIATE LOCATORS statement is greater than the number of locators returned by the stored procedure, the extra locator variables are assigned a value of 0.

Accessing result sets from multiple CALL statements: An application can access to result sets created by multiple CALL statements. The result sets can be created by different procedure or by the same procedure invoked multiple times.

- Invoking different procedures: Invoking different procedures with the same name can be done either explicitly by specifying the different collections or implicitly with the use of the PACKAGE PATH. For example, to identify the different collections explicitly, specify qualified names on the CALL statement. Although both procedures are named P2, they are different procedures. After the second CALL statement, result sets from both procedures are accessible to the application.

CALL X.P2;
CALL Y.P2;

The collections for the two different procedures can also be determined implicitly from the PACKAGE PATH when unqualified procedure names are specified as part of the CALL statement. For example, assume that procedure P4 exists in collections X and Z. An application contains two CALL statements to invoke procedure P4. The references to procedure P4 in the CALL statements are unqualified. So, the PACKAGE PATH special register is used to resolve the procedure name. Procedure X.P4 is invoked for the first CALL statement and procedure Z.P4 is invoked by the second CALL statement. Following the second CALL statement, result sets from both procedures are accessible to the application.
Invoking the same procedure multiple times: If the server and requester are both the same version of Db2, you can call a stored procedure multiple times within an application and at the same nesting level. Each call to the same stored procedure causes a unique instance of the stored procedure to run. If the stored procedure returns result sets, each instance of the stored procedure opens its own set of result set cursors. For more information on this situation, see [Multiple calls to the same stored procedure](#).

When a procedure is invoked multiple times in an application and there is a need to process the result sets from the different instances at the same time, be sure to use the ASSOCIATE LOCATORS statement after each CALL statement to capture the locator values returned from each invocation of the procedure. For example, assume that procedure P exists in collection Z and that an application contains two CALL statements to invoke procedure P. The PACKAGE PATH is used to determine the collection for the procedure in the first CALL statement, and the collection is explicitly specified in the second CALL statement. Result sets from both procedures can be accessible to the application following both CALL statements if the locators for the result sets produced by the first CALL statement are captured with an ASSOCIATE LOCATOR statement before invoking the procedure the second time.

Using host variables: If the ASSOCIATE LOCATORS statement contains host variables, the following conditions apply:

- If the statement is executed statically, the contents of the host variables are assumed to be in the encoding scheme that was specified in the ENCODING parameter when the package or plan that contains the statement was bound.
- If the statement is executed dynamically, the contents of the host variables are assumed to be in the encoding scheme that is specified in the APPLICATION ENCODING bind option.

Examples

The statements in the following examples are assumed to be in PL/I programs.

Example 1: Use result set locator variables LOC1 and LOC2 to get the result set locator values for the two result sets returned by stored procedure P1. Assume that the stored procedure is called with a one-part name from current server SITE2.

```pli
EXEC SQL CONNECT TO SITE2;
EXEC SQL CALL P1;
EXEC SQL ASSOCIATE RESULT SET LOCATORS (:LOC1, :LOC2) WITH PROCEDURE P1;
```

Example 2: Repeat the scenario in Example 1, but use a two-part name to specify an explicit schema name for the stored procedure to ensure that stored procedure P1 in schema MYSCHEMA is used.
EXEC SQL CONNECT TO SITE2;
EXEC SQL CALL MYSHEMA,P1;
EXEC SQL ASSOCIATE RESULT SET LOCATORS (:LOC1, :LOC2)
    WITH PROCEDURE MYSHEMA.P1;

Example 3: Use result set locator variables LOC1 and LOC2 to get the result set
locator values for the two result sets that are returned by the stored procedure
named by host variable HV1. Assume that host variable HV1 contains the value
SITE2.MYSHEMA,P1 and the stored procedure is called with a three-part name.

EXEC SQL CALL SITE2.MYSHEMA,P1;
EXEC SQL ASSOCIATE LOCATORS (:LOC1, :LOC2)
    WITH PROCEDURE :HV1;

The preceding example would be invalid if host variable HV1 had contained the
value MYSHEMA,P1, a two-part name. For the example to be valid with that
two-part name in host variable HV1, the current server must be the same as the
location name that is specified on the CALL statement as the following statements
demonstrate. This is the only condition under which the names do not have to be
specified the same way and a three-part name on the CALL statement can be used
with a two-part name on the ASSOCIATE LOCATORS statement.

EXEC SQL CONNECT TO SITE2;
EXEC SQL CALL SITE2.MYSHEMA,P1;
EXEC SQL ASSOCIATE LOCATORS (:LOC1, :LOC2)
    WITH PROCEDURE :HV1;

BEGIN DECLARE SECTION

The BEGIN DECLARE SECTION statement marks the beginning of an SQL declare
section. An SQL declare section contains declarations of host variables that are
eligible to be used as host variables in SQL statements in a program.

Invocation

This statement can only be embedded in an application program. It is not an
executable statement. It must not be specified in Java or REXX.

Authorization

None required.

Syntax

BEGIN DECLARE SECTION

Description

The BEGIN DECLARE SECTION statement can be coded in the application
program wherever variable declarations can appear in accordance with the rules of
the host language. It is used to indicate the beginning of a host variable declaration
section. A host variable section ends with an END DECLARE SECTION statement,
described in END DECLARE SECTION.
The following rules are enforced by the precompiler only if the host language is C or the STDSQL(YES) SQL processing option is specified:

- A variable referred to in an SQL statement must be declared within a host variable declaration section of the source program in all host languages, other than Java and REXX. Furthermore, the declaration of each variable must appear before the first reference to the variable. Host variables are declared without the use of these statements in Java, and they are not declared at all in REXX.
- BEGIN DECLARE SECTION and END DECLARE SECTION statements must be paired and must not be nested.
- Host variable declaration sections can contain only host variable declarations, SQL INCLUDE statements that include host variable declarations, or DECLARE VARIABLE statements.

Notes

Host variable declaration sections are only required if the STDSQL(YES) option is specified or the host language is C. However, declare sections can be specified for any host language so that the source program can conform to IBM SQL. If declare sections are used, but not required, variables declared outside a declare section must not have the same name as variables declared within a declare section.

Example

```sql
EXEC SQL BEGIN DECLARE SECTION;
-- host variable declarations
EXEC SQL END DECLARE SECTION;
```

CALL

The CALL statement invokes a stored procedure.

Invocation

This statement can be embedded in an application program. This statement can be executed interactively using the command line processor. Refer to [Command line processor CALL statement (Db2 Application programming and SQL)] for information about using the command line processor with the CALL statement. This statement can also be dynamically prepared, but only from an ODBC or CLI driver that supports dynamic CALL statements. IBM's ODBC and CLI drivers provide this capability.

Authorization

Invoking a stored procedure requires the EXECUTE privilege on the following:

- The stored procedure
  You do not need the EXECUTE privilege on a stored procedure that was created prior to Version 6 of Db2 for z/OS.
- Additional authority is needed for the stored procedure package and most packages that run in the stored procedure.
  The authorization that is required for which packages is explained in detail in [Authorization to execute packages under the stored procedure]

Authorization to execute the stored procedure
The authorization ID or role that must have the EXECUTE privilege on the stored procedure depends on the form of the CALL statement:

- For static SQL programs that use the syntax CALL procedure, the owner of the plan or package that contains the CALL statement must have one of the following:
  - The EXECUTE privilege on the stored procedure
  - Ownership of the stored procedure
  - DATAACCESS authority
  - SYSADM authority

- For static SQL programs that use the syntax CALL variable, the authorization ID or role of the plan or package that contains the CALL statement must have one of the following:
  - The EXECUTE privilege on the stored procedure
  - Ownership of the stored procedure
  - DATAACCESS authority
  - SYSADM authority

The DYNAMICRULES behavior for the plan or package that contains the CALL statement determines both the authorization ID or role and the privilege set that is held by that authorization ID or role:

**Run behavior**

The privilege set is the union of the set of privileges that are held by the SQL authorization ID and each authorization ID or role of the process.

**Bind behavior**

The privilege set is the privileges that are held by the primary authorization ID of the owner of the package or plan.

**Define behavior**

The privilege set is the privileges that are held by the authorization ID or role of the owner (definer) of the stored procedure or user-defined function that issued the CALL statement.

**Invoke behavior**

The privilege set is the privileges that are held by the authorization ID or role of the invoker of the stored procedure or user-defined function that issued the CALL statement. However, if the invoker is the primary authorization ID of the process or the CURRENT SQLID value, the privilege set is the union of the set of privileges that are held by each authorization ID or role.

For a list of the DYNAMICRULES values that specify run, bind, define, or invoke behavior, see [Table 14 on page 103](#).

**Authorization to execute packages under the stored procedure (including nested stored procedures)**

The authorization that is required to run the stored procedure package and any packages that are used under the stored procedure (including nested stored procedures) apply to any form of the CALL statement as follows:

- **Stored procedure package:** One of the authorization IDs or roles that are defined in the set of authorization IDs must have at least one of the following privileges or authorities on the stored procedure package:
  - The EXECUTE privilege
Ownership of the package
PACKADM authority for the package's collection
SYSADM authority

A PKLIST entry is not required for the stored procedure package.

User-defined function packages and trigger packages: If a stored procedure or any application under the stored procedure invokes a user-defined function, Db2 requires only the owner (the definer), and not the invoker of the user-defined function, to have EXECUTE authority on the user-defined function package. However, the authorization ID or role of the SQL statement that invokes the user-defined function must have EXECUTE authority on the function. Similarly, if a trigger is used under a stored procedure, Db2 does not require EXECUTE authority on the trigger package; however, the authorization ID or role of the SQL statement that activates the trigger must have EXECUTE authority on the trigger. PKLIST entries are not required for any user-defined function packages or trigger packages that are used under the stored procedure.

Packages other than user-defined function, trigger, and stored procedure packages: One of the authorization IDs or roles that is defined below under Set of authorization IDs must have at least one of the following privileges or authorities on any packages other than user-defined function and trigger packages that are used under the stored procedure:
- The EXECUTE privilege
- Ownership of the package
- PACKADM authority for the package's collection
- SYSADM authority

PKLIST entries are required for any of these packages that are used under the stored procedure.

For improved performance and simplicity, consider granting the EXECUTE ON PACKAGE privilege for the stored procedure package, and for any packages that run under the stored procedure, to the owner of the stored procedure.

Set of authorization IDs: Db2 checks the following authorization IDs, in the order in which they are listed, for the required authorization to execute the stored procedure package and any packages that run under the stored procedure other than user-defined function and trigger packages as described previously. Authorization checking ends after the first authorization ID that has EXECUTE ON PACKAGE privileges for the target package is found.
- The owner (the definer) of the stored procedure.
- The owner of the plan that contains the CALL statement that invokes the stored procedure if either of the following conditions is true:
  - The calling application (a package or a DBRM that is bound directly to the plan) is local.
  - The calling application is distributed, the Db2 subsystem is both the requester and the server, and the PRIVATE_PROTOCOL subsystem parameter is not set to NO.
- The owner of the package that contains the CALL statement that invokes the stored procedure if the calling application is distributed and either of the following conditions is true:
  - The Db2 subsystem is the server but not the requester.
The Db2 subsystem is both the server and the requester and the PRIVATE_PROTocol subsystem parameter is set to NO.

The calling application uses Recoverable Resources Management Services attachment facility (RRSAF) and has no plan.

- The authorization ID as determined by the value of the DYNAMICRULES bind option for the plan or package that contains the CALL statement if the CALL statement is in the form of CALL variable.
- If the calling application is bound with the DYNAMICRULES(RUN) option, Db2 checks either the authorization ID of the process at run time and its secondary authorization IDs or the single authorization ID that is determined by the other DYNAMICRULES bind option values.
- If the calling application is bound with a value other than DYNAMICRULES(RUN), Db2 checks only a single authorization ID, even if that ID fails the EXECUTE ON PACKAGE authorization check.
- If the calling application is a package and is bound with DYNAMICRULES(BIND), Db2 checks the authorization ID of the package owner. Db2 does not check the authorization ID of the plan owner.

### Syntax

```
CALL procedure-name (
  expression
  NULL
  TABLE transition-table-name
  USING DESCRIPTOR descriptor-name
)
```

### Description

**procedure-name** or **variable**

Identifies the procedure to call by the specified procedure-name or the procedure name contained in the variable. The identified procedure must exist at the current server.

If procedure-name specifies any of the three special characters that are alphabetic extenders for national languages, $#@, specify the procedure name with a variable.

If a variable is used:

- It must be a CHAR or VARCHAR variable with a length attribute that is not greater than 254.
- It must not be followed by an indicator variable.
- The value of the variable is a specification that depends on the server. Regardless of the server, the specification must:
  - Be left justified within the variable
  - Not contain embedded blanks
  - Be padded on the right with blanks if its length is less than that of the variable

In addition, the specification can:
− Contain upper and lowercase characters. Lowercase characters are not folded to uppercase.
− Use a delimited identifier for any part of a three-part procedure name.

If the server is Db2 for z/OS, the specification must be a procedure name as defined above.

When the CALL statement is executed, the procedure name or specification must identify a stored procedure that exists at the server.

When the package that contains the CALL statement is bound, the stored procedure that is invoked must be created if VALIDATE(BIND) is specified. Although the stored procedure does not need to be created at bind time if VALIDATE(RUN) is specified, it must be created when the CALL statement is executed.

expression, NULL, or TABLE transition-table-name
Identifies a list of values to be passed as arguments to the stored procedure. The nth value corresponds to the nth parameter in the procedure. Each parameter that is defined using CREATE PROCEDURE as OUT or INOUT must be specified as a variable.

The number of arguments that are specified must be the same as the number of parameters of a procedure that is defined at the current server with the specified procedure name.

If USING DESCRIPTOR is specified, each variable described by the identified SQLDA is an argument, or part of an expression that is an argument of the CALL statement. If host structures are not specified in the CALL statement, the nth argument of the CALL statement corresponds to the nth parameter in the stored procedure, and the number in each must be the same. Otherwise, each reference to a host structure is replaced by a reference to each of the variables contained in that host structure, and the resulting number of arguments must be the same as the number of parameters defined for the stored procedure.

However, a character FOR BIT DATA argument cannot be passed as input for a parameter that is not defined as character FOR BIT DATA. Likewise, a character argument that is not FOR BIT DATA cannot be passed as input for a parameter that is defined as character FOR BIT DATA.

The attributes of the parameters are determined by the current server. In addition to attributes such as data type and length, the description of each parameter indicates how the stored procedure uses it:
• IN means as an input value
• OUT means as an output value
• INOUT means both as an input and an output value

All parameters that are not variables are assumed to be input parameters (IN).

expression
The argument is the result of the specified expression, which is evaluated before the stored procedure is invoked.

If expression is a single variable, the corresponding parameter of the procedure can be defined as IN, INOUT, or OUT. Otherwise, the corresponding parameter of the procedure must be defined as IN. An expression can contain any of the following items:
• Variable
• Constant
• Special register
• Session global variable
• Cast function with a variable or constant argument

A variable can identify a structure. Any variable or structure that is specified must be described in the application program according to the rules for declaring host structures and variables. A reference to a host structure is replaced by a reference to each of the variables contained in the host structure.

If the result of the expression can be the null value, either the description of the procedure must allow for null parameters or the corresponding parameter of the stored procedure must be defined as OUT.

expression must not reference an associative array value as an argument to a function if the procedure is remote.

The following additional rules apply depending on how the corresponding parameter was defined in the CREATE PROCEDURE statement for the procedure:

• IN expression can contain references to multiple variables. In addition to the rules stated in "Expressions" on page 257 for expression, expression cannot include a column name, a scalar subselect, a file reference variable, an aggregate function, or a user-defined function that is sourced on an aggregate function.

• INOUT or OUT expression can only be a single variable. expression cannot include a file reference variable or an array element.

**NULL**

The parameter is a null value. The corresponding parameter of the procedure must be defined as IN and the description of the procedure must allow for null parameters.

**TABLE transition-table-name**

The parameter is a transition table, and it is passed to the procedure as a table locator. You can use the CALL statement with the TABLE clause only within the definition of the triggered action of a trigger. The name of a transition table must be specified in the CALL statement if the corresponding parameter of the procedure was defined in the TABLE LIKE clause of the CREATE PROCEDURE statement. For information about creating a trigger, see "CREATE TRIGGER (basic)" on page 1901 and Db2 Application Programming and SQL Guide.

There is no effect on the transition table on the return from the procedure regardless of whether the parameter was defined as IN, INOUT, or OUT, because transition tables are read-only.

**USING DESCRIPTOR descriptor-name**

Identifies an SQLDA that contains a valid description of the variables that are to be passed as parameters to the stored procedure. If the stored procedure has no parameters, an SQLDA is ignored.

Before the CALL statement is processed, the user must set the following fields in the SQLDA:

• SQLN to indicate the number of SQLVAR occurrences provided in the SQLDA. This number must not be less than SQLD. This field is not part of the REXX SQLDA and therefore does not need to be set for REXX programs.
• SQLDABC to indicate the number of bytes of storage allocated for the SQLDA. This number must be not be less than SQLN*44+16. This field is not part of the REXX SQLDA and therefore does not need to be set for REXX programs.
• SQLD to indicate the number of variables used in the SQLDA when processing the statement. This number must be the same as the number of parameters of the stored procedure.
• SQLVAR occurrences to indicate the attributes of the variables.

There are additional considerations for setting the fields of the SQLDA when a variable that is passed as a parameter to the stored procedure has a LOB data type or is a LOB locator. For more information, see “SQL descriptor area (SQLDA)” on page 2475.

The SQL CALL statement ignores distinct type information in the SQLDA. Only the base SQL type information is used to process the input and output parameters described by the SQLDA.

In REXX, only variables USING DESCRIPTOR is supported. Since global variables are not supported within the SQLDA, global variable are not supported in REXX.

See “Identifying an SQLDA in C or C++” on page 2492 for how to represent descriptor-name in C.

Notes

Parameter assignments: When the CALL statement is executed, the value of each of its arguments is assigned with storage assignment rules to the corresponding IN or INOUT parameter of the stored procedure. In cases where the arguments of the CALL statement are not an exact match to the data types of the parameters of the stored procedure, each argument specified in the CALL statement is converted to the data type of the corresponding parameter of the stored procedure at execution. The conversion occurs according to the same rules as assignment to columns.

Control is passed to the stored procedure according to the calling conventions of the host language.

When execution of the stored procedure is complete, the value of each parameter of the stored procedure defined as OUT or INOUT is assigned to the corresponding argument of the CALL statement. If an error is returned by the procedure, OUT arguments are undefined, and INOUT arguments are unchanged.

A timestamp without time zone value must not be assigned to a timestamp with time zone target.

The following rules apply when the value of an array argument is assigned to the corresponding array parameter:
• For a local procedure call: The argument and the parameter must be defined as the same array type.
• For a remote procedure call: The data type of the elements of the array argument must be the same as the data type of the elements of the array parameter. In addition, for IN or OUT parameters, all of the relevant conditions in one of the rows in the following table must be true. For INOUT parameters, all of the relevant conditions in row 1 of the following table must be true, or all of the relevant conditions in rows 2 and 3 must be true. A relevant condition is indicated with Y.
<table>
<thead>
<tr>
<th>Relationship of argument to associated parameter</th>
<th>Relationship applies to IN parameter</th>
<th>Relationship applies to OUT parameter</th>
<th>Relationship applies to INOUT parameter</th>
</tr>
</thead>
<tbody>
<tr>
<td>The argument is an ordinary array, the parameter is an ordinary array, and the argument and parameter are defined with the same data type for the array indexes.</td>
<td>Y</td>
<td>Y</td>
<td>Y</td>
</tr>
<tr>
<td>The argument is an ordinary array, the parameter is an associative array type, the parameter is an IN or INOUT parameter, and the data type of the array indexes is INTEGER. The associative array parameter is assigned an associative array value that is derived from the ordinary array argument value. The values of the array elements in the ordinary array are assigned to the target associative array parameter, in the same order as their order in the ordinary array argument. The index values in the target associative array parameter are assigned from 1 to the cardinality of the ordinary array argument value.</td>
<td>Y</td>
<td></td>
<td></td>
</tr>
<tr>
<td>The argument is an ordinary array type, the parameter is an associative array type, and the parameter is an INOUT or OUT parameter. The argument is assigned an ordinary array value that is derived from the associative array parameter value. The values of the array elements in the associative array value are assigned to the target ordinary array, in an order determined by Db2. The index values in the target ordinary array argument are assigned from 1 to the cardinality of the associative array parameter value. The index values from the associative array parameter value are ignored.</td>
<td></td>
<td>Y</td>
<td>Y</td>
</tr>
</tbody>
</table>

For details on the rules used to assign parameters, see “Assignment and comparison” on page 151.

Conversion can occur when precision, scale, length, encoding scheme, or CCSID differ between the argument specified in the CALL statement and the data type of the corresponding parameter of the stored procedure. Conversion might occur for a
character string argument specified in the CALL statement when the corresponding parameter of the stored procedure has a different encoding scheme or CCSID. For example, an error occurs when the CALL statement passes an argument of mixed data that actually contains DBCS characters as input for a parameter of the stored procedure that is defined as FOR SBCS DATA. Likewise, an error occurs when the stored procedure returns mixed data that actually contains DBCS characters for an argument of the CALL statement that is defined as FOR SBCS DATA.

Procedure signatures: A procedure is identified by its schema, a procedure name, and its number of parameters. This is called a procedure signature, which must be unique within the database. Db2 for z/OS does not support overloaded procedure names (procedures with the same schema and procedure name, but with different numbers of parameters).

SQL path: A procedure can be invoked by referring to a qualified name (schema and procedure name), followed by an optional list of arguments that are enclosed in parentheses. A procedure can also be invoked without the schema name, which results in a choice of possible procedures in different schemas that have the same procedure name and same number of parameters. In this case, the SQL path is used to assist in procedure resolution. The SQL path is a list of schemas that is searched to identify a procedure with the same name and number of parameters as the procedure in the CALL statement. For CALL statements that explicitly specify a procedure name, the SQL path is specified by using the platform-specific bind option. For CALL variable statements, the SQL path is the value of the CURRENT PATH special register when the procedure is invoked.

Procedure resolution: Given a procedure invocation, the database manager must decide which of the possible procedures that has the same name to call.

A procedure name is a qualified or unqualified name. Each part of the name must be composed of SBCS characters:

- A fully qualified procedure name is a three-part name. The first part is an SQL identifier that contains the location name that identifies the DBMS at which the procedure is stored. The second part is an SQL identifier that contains the schema name of the stored procedure. The last part is an SQL identifier that contains the name of the stored procedure. A period must separate each of the parts. Any or all of the parts can be a delimited identifier.
- A two-part procedure name has one implicit qualifier. The implicit qualifier is the location name of the current server. The two parts identify the schema name and the name of the stored procedure. A period must separate the two parts.
- An unqualified procedure name is a one-part name with two implicit qualifiers. The first implicit qualifier is the location name of the current server. The second implicit qualifier depends on the server. If the server is Db2 for z/OS, the implicit qualifier is the schema name. Db2 uses the SQL path to determine the value of the schema name.
  - If the procedure name is specified as a string constant on the CALL statement (CALL procedure-name), the SQL path is the value of the PATH bind option that is associated with the calling package or plan.
  - If a variable is specified for the procedure name on the CALL statement (CALL variable), the SQL path is the value of the CURRENT PATH special register.
Db2 searches the schema names in the SQL path from left to right until a stored procedure with the specified schema name is found in the Db2 catalog. When a matching schema.procedure-name is found, the search stops only if the following conditions are true:

- The user is authorized to call the stored procedure.
- The number of parameters in the definition of the stored procedure matches the number of parameters specified on the CALL statement.

If the list of schemas in the SQL path is exhausted before the procedure name is resolved, an error is returned.

When the procedure is resolved depends on how the procedure name is specified. For a CALL statement that specifies the procedure name using a variable, procedure resolution occurs at run time. For a CALL statement that contains the name of the procedure as an identifier, procedure resolution occurs when the CALL statement is bound.

Procedure resolution is done by the database manager using the following steps:

1. Find all procedures from the catalog where all of the following conditions are true:
   - For invocations where the schema name is specified (qualified references), the schema name and the procedure name match the invocation name.
   - For invocations where the schema name is not specified (unqualified references), the procedure name matches the invocation name, and the procedure has a schema name that matches one of the schemas in the SQL path.
   - The number of defined parameters matches the number of arguments that are specified in the invocation.
   - The invoker has the EXECUTE privilege on the procedure.

2. Of the candidate procedures that remain from step 1, choose the procedure whose schema is first in the SQL path. If no candidate procedures remain after step 1, an error is returned.

3. For CALL statements that use a variable to specify the procedure name, the CURRENT ROUTINE VERSION special register can affect which version of the native SQL procedure is invoked. If the CURRENT ROUTINE VERSION special register is set, check if there is a version of the procedure with that version name. If not, choose the currently active version of the procedure.

   For CALL statements that do not use a variable to specify the procedure name, choose the currently active version of the procedure.

Version resolution: Normally, the currently active version of a native SQL procedure will be used on a CALL statement. However, if the CALL statement is a recursive call inside the body of the same stored procedure, and the original CALL statement uses a version that is different from the currently active version, the active version will not be used. The version from the original CALL statement will be used for any recursive CALL statements until the entire stored procedure finishes executing. This preserves the semantics of the version that is used by the original CALL statement. This includes the case where the recursive call is indirect. For example, assume that procedure SP1 call procedure SP2, which in turn recursively calls SP1. The second invocation of procedure SP1 will use the version of the procedure that is active at the time of the original CALL statement that invoked procedure SP1.
Since the currently active version can be used at the next CALL statement, it is possible that two or more versions of the same procedure can run at the same time. There could be different versions of an SQL procedure loaded by a given thread. For example, a CALL SP1 statement in an application will cause the currently active version, SP1_V1, to load and execute. After this CALL statement has completed, an ALTER PROCEDURE ALTER ACTIVE VERSION could execute and change the active version of the procedure SP1 to version SP1_V2. Subsequent CALL SP1 statements from the same thread will load the currently active version of the procedure, SP1_V2, and execute it.

Parameter assignments: When the CALL statement is executed, the value of each of its parameters is assigned with storage assignment rules to the corresponding parameter of the procedure. Control is passed to the procedure according to the calling conventions of the host language. When execution of the procedure is complete, the value of each parameter of the procedure is assigned with storage assignment rules to the corresponding parameter of the CALL statement defined as OUT or INOUT. If an error is returned by the procedure, OUT arguments are undefined and INOUT arguments are unchanged. For details on the assignment rules, see “Assignment and comparison” on page 151.

Cursors and prepared statements in procedures: All cursors opened in the called procedure that are not result set cursors are closed and all statements prepared in the called procedure are destroyed when the procedure ends.

Result sets from procedures: Any cursors specified using the WITH RETURN clause that the procedure leaves open when it returns identifies a result set. In a procedure written in Java, all cursors are implicitly defined WITH RETURN.

Results sets are returned only when the procedure is called from CLI, JDBC, or SQLJ. If the procedure was invoked from CLI or Java, and more than one cursor is left open, the result sets can only be processed in the order in which the cursors were opened. Only unread rows are available to be fetched. For example, if the result set of a cursor has 500 rows, and 150 of those rows have been read by the procedure at the time the procedure is terminated, then rows 151 through 500 will be returned to the procedure.

Errors from procedures: A procedure can return errors or warnings using an SQLSTATE like other SQL statements. Applications should be aware of the possible SQLSTATEs that can be expected when a procedure is invoked. The possible SQLSTATEs depend on how the procedure is coded. Procedures might also return SQLSTATEs such as those that begin with '38' or '39' if Db2 encounters problems executing the procedure. Applications should therefore be prepared to handle any error SQLSTATE that can result from issuing a CALL statement.

Improving performance: The capability of calling stored procedures is provided to improve the performance of DRDA distributed access. The capability is also useful for local operations. The server can be the local Db2. In which case, packages are still required.

All values of all parameters are passed from the requester to the server. To improve the performance of this operation, variables that correspond to OUT parameters and have lengths of more than a few bytes should be set to null before the CALL statement is executed.
Using the CALL statement in a trigger: When a trigger issues a CALL statement to invoke a stored procedure, the parameters that are specified in the CALL statement cannot be variables and the USING DESCRIPTOR clause cannot be specified.

Nesting CALL statements: A program that is executing as a stored procedure, a user-defined function, or a trigger can issue a CALL statement. When a stored procedure, user-defined function, or trigger calls a stored procedure, user-defined function, or trigger, the call is considered to be nested. Stored procedures, user-defined functions, and triggers can be nested up to 64 levels deep on a single system. Nesting can occur within a single Db2 subsystem or when a stored procedure or user-defined function is invoked at a remote server.

If a stored procedure returns any query result sets, the result sets are returned to the caller of the stored procedure. If the SQL CALL statement is nested, the result sets are visible only to the program that is at the previous nesting level. For example, [Figure 31] illustrates a scenario in which a client program calls stored procedure PROCA, which in turn calls stored procedure PROCB. Only PROCA can access any result sets that PROCB returns; the client program has no access to the query result sets. The number of query result sets that PROCB returns does not count toward the maximum number of query results that PROCA can return.

![Figure 31. Nested CALL statements](image)

Some stored procedures cannot be nested. A stored procedure, user-defined function, or trigger cannot call a stored procedure that is defined with the COMMIT ON RETURN attribute. Procedures that are defined with the AUTONOMOUS attribute cannot call other procedures that are defined with the AUTONOMOUS attribute.

Multiple calls to the same stored procedure: You can call a stored procedure multiple times within an application and at the same nesting level. Each call to the same stored procedure causes a unique instance of the stored procedure to run. If the stored procedure returns result sets, each instance of the stored procedure opens its own set of result set cursors.

The application might receive a "resource unavailable message" if the CALL statement causes the values of the maximum number of active stored procedures or maximum number open cursors to be exceeded. The value of field MAX STORED PROCEDURES (on installation panel DSNTIPX) defines the maximum number of active stored procedures that are allowed per thread. The value of field MAX OPEN CURSORS (on installation panel DSNTIPX) defines the maximum number of open cursors (both result set cursors and regular cursors) that are allowed per thread.
If you make multiple calls to the same stored procedure within an application, be aware of the following considerations:

- A DESCRIBE PROCEDURE statement describes the last instance of the stored procedure.
- The ASSOCIATE LOCATORS statement works on the last instance of the stored procedure.
- The ALLOCATE CURSOR statement must specify a unique cursor name for a result set returned from an instance of the stored procedure. Otherwise, you will lose the data from the result sets that are returned from prior instances or calls to the stored procedure.

You should issue an ASSOCIATE LOCATORS statement (or DESCRIBE PROCEDURE statement) after each call to the stored procedure to get a unique locator value for each result set.

**Using variables:** If the CALL statement contains variables, the contents of the variables are assumed to be in the encoding scheme that was specified in the ENCODING parameter when the package or plan that contains the statement was bound.

**Examples**

*Example 1:* A PL/I application has been precompiled on Db2 ALPHA and a package was created at Db2 BETA with the BIND subcommand. A CREATE PROCEDURE statement was issued at BETA to define the procedure SUMARIZE, which allows nulls and has two parameters. The first parameter is defined as IN and the second parameter is defined as OUT. Some of the statements that the application that runs at Db2 ALPHA might use to call stored procedure SUMARIZE include:

```
EXEC SQL CONNECT TO BETA;
V1 = 528671;
IV = -1;
EXEC SQL CALL SUMARIZE(:V1,:V2 INDICATOR :IV);
```

*Example 2:* Suppose that stored procedure MYPROC exists and produces several result sets. An application might include statements like the following to access the result sets produced by MYPROC:

```
-- Invoke stored procedure MYPROC that returns several result sets
EXEC SQL CALL MYPROC (....);
-- Copy the locator values for the result sets into result set locator variables
EXEC SQL ASSOCIATE RESULT SET LOCATORS (:RS1, :RS2, :RS3) WITH PROCEDURE MYPROC;
-- Allocate cursors for the result set cursors
EXEC SQL ALLOCATE CSR1 CURSOR FOR RESULT SET :RS1;
EXEC SQL ALLOCATE CSR2 CURSOR FOR RESULT SET :RS2;
EXEC SQL ALLOCATE CSR3 CURSOR FOR RESULT SET :RS3;
-- Process data returned with the result set cursors
DO WHILE (SQLCODE = 0);
   EXEC SQL FETCH CSR1 INTO ......
END;
EXEC SQL CLOSE CSR1;
-- do similar processing with other result sets ...
```

*Example 3:* Suppose that procedure FIND_CUSTOMERS has the following parameters:

- An IN parameter that is an array of phone numbers
- An IN parameter that is a prefix value to search for a match
• An OUT parameter that returns an array of phone numbers

FIND_CUSTOMERS searches the input array variable for phone numbers that match the prefix value, and returns an array that contains the phone numbers that match the prefix value.

The input and output array variables are defined as follows:

```sql
CREATE TYPE PHONENUMBERS AS VARCHAR(20) CCSID UNICODE ARRAY[10];
CREATE VARIABLE PNUMBER_ARRAY PHONENUMBERS; -- Create input array variable
CREATE VARIABLE PNUMBER_ARRAY_OUT PHONENUMBERS; -- Create output array variable
```

FIND_CUSTOMERS looks like this:

```sql
CREATE PROCEDURE FIND_CUSTOMERS(
    IN NUMBERS_IN PHONENUMBERS,
    IN PREFIX CHAR(3),
    OUT NUMBERS_OUT PHONENUMBERS)
BEGIN
    DECLARE I, J INTEGER;
    SET I = 1;
    SET J = 1;

    -- Initialize NUMBERS_OUT to an empty array using an array constructor
    -- with no elements
    SET NUMBERS_OUT = ARRAY[ ];
    WHILE i < CARDINALITY(NUMBERS_IN) DO
        IF SUBSTR(NUMBERS_IN[I], 1, 3) = PREFIX THEN
            SET NUMBERS_OUT[J] = NUMBERS_IN[I];
            SET J = J + 1;
        END IF;
        SET I = I + 1;
    END WHILE;
END %
```

In the client program, initialize the input array with values from an array constructor, and then invoke the procedure:

```sql
SET PNUMBER_ARRAY = ARRAY['416-305-3745',
    '905-414-4565',
    '416-305-3746'];
CALL FIND_CUSTOMERS(PNUMBER_ARRAY, -- NUMBERS_IN parameter (IN parm)
    '416', -- PREFIX parameter (IN parm)
    PNUMBER_ARRAY_OUT); -- NUMBERS_OUT parameter (OUT parm)
```

The CALL statement returns an array value with the following information in the argument corresponding to the NUMBERS_OUT parameter, which sets the PNUMBER_ARRAY_OUT variable:

```sql
['416-305-3745',
    '416-305-3746']
```

CLOSE

The CLOSE statement closes a cursor. If a temporary copy of a result table was created when the cursor was opened, that table is destroyed.
Invocation

This statement can only be embedded in an application program. It is an executable statement that cannot be dynamically prepared. It must not be specified in Java.

Authorization

See DECLARE CURSOR for the authorization required to use a cursor.

Syntax

```
CLOSE cursor-name
```

Description

cursor-name

Identifies the cursor to be closed. The cursor name must identify a declared cursor as explained in DECLARE CURSOR. When the CLOSE statement is executed, the cursor must be in the open state.

Notes

Implicit cursor close: At the end of a unit of work, all open cursors declared without the WITH HOLD option that belong to an application process are implicitly closed.

Close cursors for performance: Explicitly closing cursors as soon as possible can improve performance.

Procedure considerations: Special rules apply to cursors within procedures that have not been closed before returning to the calling program. For more information, see CALL.

Allocated cursors: The cursor could have been allocated. See ALLOCATE CURSOR.

Example

A cursor is used to fetch one row at a time into the application program variables DNUM, DNAME, and MNUM. Finally, the cursor is closed. If the cursor is reopened, it is again located at the beginning of the rows to be fetched.

```
EXEC SQL DECLARE C1 CURSOR FOR
   SELECT DEPTNO, DEPTNAME, MGRNO
   FROM DSNBC10.DEPT
   WHERE ADMRDEPT = 'A00'
END-EXEC.

EXEC SQL OPEN C1 END-EXEC.

EXEC SQL FETCH C1 INTO :DNUM, :DNAME, :MNUM END-EXEC.

IF SQLCODE = 100
   PERFORM DATA-NOT-FOUND
```
ELSE
PERFORM GET-REST-OF-DEPT
UNTIL SQLCODE IS NOT EQUAL TO ZERO.

EXEC SQL CLOSE C1 END-EXEC.

GET-REST-OF-DEPT.
EXEC SQL FETCH C1 INTO :DNUM, :DNAME, :MNUM END-EXEC.

**COMMENT**

The COMMENT statement adds or replaces comments in the descriptions of various objects in the Db2 catalog at the current server.

**Invocation**

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

**Authorization**

For a comment on the following objects, the privilege set must include at least one of the listed authorities or privileges:

**Table, view, index, column, or alias for a table or view:**
- Ownership of the table, view, alias, or index
- DBADM authority for its database (tables and indexes only)
- SYSADM or SYSCTRL authority
- System DBADM
- SECADM authority (if the table has an activated row permission or column access control)

If the database is implicitly created, the database privileges must be on the implicit database or on DSNDB04.

**Distinct type, stored procedure, trigger, or user-defined function:**
- Ownership of the distinct type, stored procedure, trigger, or user-defined function
- The ALTERIN privilege on the schema (for the addition of comments)
- SYSADM or SYSCTRL authority
- System DBADM

**Secure trigger or secure user-defined function:**
- SECADM authority
- CREATE_SECURE_OBJECT privilege

**Package:**
- Ownership of the package
- The BINDAGENT privilege granted from the package owner
- PACKADM authority for the collection or for all collections
- SYSADM or SYSCTRL authority
- System DBADM

**Role or a trusted context:**
- Ownership of the object
- SYSADM or SYSCTRL authority
If the installation parameter SEPARATE SECURITY is NO, SYSADM authority has implicit SECADM and SYSCTRL authority and can drop a role or trusted context.

Sequence or alias for a sequence:
- Ownership of the sequence
- The ALTER privilege for the sequence if the target is a sequence
- The ALTERIN privilege on the schema
- SYSADM or SYSCTRL authority
- System DBADM

The authorization ID that matches the schema name implicitly has the ALTERIN privilege on the schema.

Row permission or column mask:
- SECADM authority

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the statement is dynamically prepared, the privilege set is determined by the DYNAMICRULES behavior in effect (run, bind, define, or invoke) and is summarized in Dynamic preparation and execution. (For more information on these behaviors, including a list of the DYNAMICRULES bind option values that determine them, see Authorization IDs and dynamic SQL.)

Syntax
alias-designator

Notes:
1. If PUBLIC is specified, FOR SEQUENCE must also be specified.

multiple-column-list

function-designator

parameter-type

Notes:
1. AS LOCATOR can be specified only for a LOB data type or a distinct type that is based on a LOB data type.

data-type
Description

ALIAS alias-name
Indicates a comment will be added or replaced for an alias. The name must identify an alias that exists at the current server.
If the PUBLIC keyword is specified, alias-name must identify a public alias that exists at the current server. The comment is applied to a public alias.

**FOR TABLE**
Specifies that the alias is for a table or a view. The comment replaces the value of the REMARKS column of the SYSIBM.SYSTABLES catalog table for the row that describes the alias.

**FOR SEQUENCE**
Specifies that the alias is for a sequence. The comment replaces the value of the REMARKS column of the SYSIBM.SYSEQUENCES catalog table for the row that describes the alias.

**COLUMN** table-name.column-name or view-name.column-name
Identifies the column to which the comment applies. The name must identify a column of a table or view that exists at the current server. The name must not identify a column of a declared temporary table. The comment is placed into the REMARKS column of the SYSIBM.SYSCOLUMNS catalog table, for the row that describes the column.

**Do not use TABLE or COLUMN to comment on more than one column in a table or view.** Give the table or view name and then, in parentheses, a list in the form:

```
column-name IS string-constant,
column-name IS string-constant,...
```

The column names must not be qualified, each name must identify a column of the specified table or view, and that table or view must exist at the current server.

**FUNCTION or SPECIFIC FUNCTION**
Identifies the function to which the comment applies. The function must exist at the current server, and it must be a function that was defined with the CREATE FUNCTION statement or a cast function that was generated by a CREATE TYPE statement. The comment is placed in the REMARKS column of the SYSIBM.SYSRUTINES catalog table for the row that describes the function.

The function can be identified by its name, function signature, or specific name. If the function was defined with a table parameter (the LIKE TABLE was specified in the CREATE FUNCTION statement to indicate that one of the input parameters is a transition table), you must identify the function with its function name, if it is unique, or with its specific name.

**FUNCTION** function-name
Identifies the function by its function name. There must be exactly one function with function-name in the schema. The function can have any number of input parameters. If the schema does not contain a function with function-name, or if the schema contains more than one function with this name, and error is returned.

**FUNCTION** function-name (parameter-type,...)
Identifies the SQL function by its function signature, which uniquely identifies the function. A function with the function signature must exist in the explicitly or implicitly specified schema.

If function-name() is specified, the function that is identified must have zero parameters.

function-name
Identifies the name of the function. If the function was defined with a
table parameter (the LIKE TABLE name AS LOCATOR clause was specified in the CREATE FUNCTION statement to indicate that one of the input parameters is a transition table), the function signature cannot be used to uniquely identify the function. Instead, use one of the other syntax variations to identify the function with its function name, if unique, or with its specific name.

(parameter-type,...)
Specifies the number of input parameters of the function and the name and data type of each parameter.

data-type,...)
Identifies the number of input parameters of the function and the data type of each parameter. The data type of each parameter must match the data type that was specified in the CREATE FUNCTION statement for the parameter in the corresponding position. The number of data types and the logical concatenation of the data types are used to uniquely identify the function.

For data types that have a length, precision, or scale attribute, you can use a set of empty parentheses, specify a value, or accept the default values:

- Empty parentheses indicate that Db2 is to ignore the attribute when determining whether the data types match.
  For example, DEC() will be considered a match for a parameter of a function defined with a data type of DEC(7,2). Similarly DECFLOAT() will be considered a match for DECFLOAT(16) or DECFLOAT(34).
  FLOAT cannot be specified with empty parentheses because its parameter value indicates different data types (REAL or DOUBLE).
- If you use a specific value for a length, precision, or scale attribute, the value must exactly match the value that was specified (implicitly or explicitly) in the CREATE FUNCTION statement.
  The specific value for FLOAT(n) does not have to exactly match the defined value of the source function because 1<=n<=21 indicates REAL and 22<=n<=53 indicates DOUBLE. Matching is based on whether the data type is REAL or DOUBLE.
- If length, precision, or scale is not explicitly specified and empty parentheses are not specified, the default length of the data type is implied. The implicit length must exactly match the value that was specified (implicitly or explicitly) in the CREATE FUNCTION statement.

For data types with a subtype or encoding scheme attribute, specifying the FOR subtype DATA clause or the CCSID clause is optional. Omission of either clause indicates that Db2 is to ignore the attribute when determining whether the data types match. If you specify either clause, it must match the value that was implicitly or explicitly specified in the CREATE FUNCTION statement.

AS LOCATOR
Specifies that the function is defined to receive a locator for this parameter. If AS LOCATOR is specified, the data type must be a LOB or a distinct type based on a LOB.

SPECIFIC FUNCTION specific-name
Identifies a particular user-defined function by its specific name. The name
is implicitly or explicitly qualified with a schema name. A function with the specific name must exist in the schema. If the specific name is not qualified, it is implicitly qualified with a schema name as described in the description for FUNCTION function-name.

**ACTIVE VERSION**

Specifies that the comment applies to the currently active version of the routine that is specified by function-name.

**ACTIVE VERSION** is the default.

**VERSION routine-version-id**

Specifies that the comment applies only to the version of the routine that is identified by routine-version-id. routine-version-id must identify a version of the specified routine that already exists at the current server.

**INDEX index-name**

Identifies the index to which the comment applies. index-name must identify an index that exists at the current server. The comment is placed in the REMARKS column of the SYSIBM.SYSINDEXES catalog table for the row that describes the index.

**MASK mask-name**

Identifies the column mask to which the comment applies. mask-name must identify a column mask that exists at the current server. The comment is placed in the REMARKS column of the SYSIBM.SYSCONTROLS catalog table for the row that describes the column mask.

**PACKAGE collection-id.package-name**

Identifies the package to which the comment applies. You must qualify the package name with a collection ID. collection-id.package-name must identify a package that exists at the current server. The name plus the implicitly or explicitly specified version-id must identify a package that exists at the current server. Omission of the version-id is an implicit specification of the null version.

The name must not identify a trigger package or a package that is associated with an SQL routine. Specify this clause to comment on a package that was created as the result of a BIND COPY command used to deploy a version of a native SQL procedure.

**VERSION version-id**

version-id is the version identifier that was assigned to the package's DBRM when the DBRM was created. If version-id is not specified, a null version is used as the version identifier.

Delimit the version identifier when it:

- Is generated by the VERSION(AUTO) precompiler option
- Begins with a digit
- Contains lowercase or mixed-case letters

For more on version identifiers, see the information on preparing an application program for execution in Db2 Application Programming and SQL Guide.

**PERMISSION permission-name**

Identifies the row permission to which the comment applies. permission-name must identify a row permission that exists at the current server. The comment is placed in the REMARKS column of the SYSIBM.SYSCONTROLS catalog table for the row that describes the row permission.
PLAN plan-name
Identifies the plan to which the comment applies. plan-name must identify a plan that exists at the current server.

PROCEDURE procedure-name
Identifies the procedure to which the comment applies. procedure-name must identify a procedure that exists at the current server.

ACTIVE VERSION Specifies that the comment applies to the currently active version of the routine that is specified by procedure-name.
ACTIVE VERSION is the default.

VERSION routine-version-id
Specifies that the comment applies only to the version of the routine that is identified by routine-version-id. routine-version-id must identify a version of the specified routine that already exists at the current server.

ROLE role-name
Identifies the role to which the comment applies. role-name must identify a role that exists at the current server. The comment is placed in the REMARKS column of the SYSIBM.SYSROLES catalog table for the row that describes the role.

SEQUENCE sequence-name
Identifies the sequence to which the comment applies.
sequence-name must identify a sequence that exists at the current server.
sequence-name must not be the name of an internal sequence object that is used by Db2. The comment is placed in the REMARKS column of the SYSIBM.SYSSEQUENCES catalog table for the row that describes the sequence.

TABLE table-name or view-name
Identifies the table or view to which the comment applies. table-name or view-name must identify a table, auxiliary table, or view that exists at the current server. table-name must not identify a declared temporary table. The comment is placed in the REMARKS column of the SYSIBM.SYSTABLES catalog table for the row that describes the table or view.

TRIGGER trigger-name
Identifies the trigger to which the comment applies. trigger-name must identify a trigger that exists at the current server. The comment is placed in the REMARKS column of the SYSIBM.SYSTRIGGERS catalog table for the row that describes the trigger or version of the trigger.

ACTIVE VERSION Specifies that the comment applies to the currently active version of the trigger that is specified by trigger-name.
ACTIVE VERSION is the default.

VERSION trigger-version-id
Specifies that the comment applies only to the version of the trigger that is identified by trigger-version-id. trigger-version-id must identify a version of the specified trigger that already exists at the current server.
VERSION must only be specified for an advanced trigger.

TRUSTED CONTEXT context-name
Identifies the trusted context to which the comment applies. context-name must
identify a trusted context that exists at the current server. The comment is placed in the REMARKS column of the SYSIBM.SYSCONTEXT catalog table for the row that describes the trusted context.

**TYPE type-name**
Identifies the user-defined type to which the comment applies. *type-name* must identify a user-defined type that exists at the current server. The comment is placed in the REMARKS column of the SYSIBM.SYSDATATYPES catalog table for the row that describes the user-defined type.

**VARIABLE variable-name**
Identifies the global variable to which the comment applies. *variable-name* must identify a global variable that exists at the current server. *variable-name* must not identify a built-in global variable.

**IS string-constant**
Introduces the comment that you want to make. *string-constant* can be any SQL character string constant of up to 762 bytes.

**multiple-column-list**
To comment on more than one column in a table or view with a single COMMENT statement, specify the table or view name, followed by a list in parentheses of the form:

```
(column-name IS string-constant,
 column-name IS string-constant,
 ...
)
```

Each column name must not be qualified, and must identify a column of the specified table or view that exists at the current server.

**Notes**

*Alternative syntax and synonyms:*
To provide compatibility with previous releases of Db2 or other products in the Db2 family, Db2 supports the following syntax alternatives:

* • DATA TYPE or DISTINCT TYPE as a synonym for TYPE
* • COMMENT ON ALIAS SYSPUBLIC.*name* can be specified as an alternative to COMMENT ON PUBLIC ALIAS SYSPUBLIC.*name*

**Examples**

*Example 1:* Enter a comment on table DSN8C10.EMP.

```
COMMENT ON TABLE DSN8C10.EMP
 IS 'REFLECTS 1ST QTR 81 REORG';
```

*Example 2:* Enter a comment on view DSN8C10.VDEPT.

```
COMMENT ON TABLE DSN8C10.VDEPT
 IS 'VIEW OF TABLE DSN8C10.DEPT';
```

*Example 3:* Enter a comment on the DEPTNO column of table DSN8C10.DEPT.

```
COMMENT ON COLUMN DSN8C10.DEPT.DEPTNO
 IS 'DEPARTMENT ID - UNIQUE';
```

*Example 4:* Enter comments on the two columns in table DSN8C10.DEPT.

```
COMMENT ON DSN8C10.DEPT
 (MGRNO IS 'EMPLOYEE NUMBER OF DEPARTMENT MANAGER',
  ADMRDEPT IS 'DEPARTMENT NUMBER OF ADMINISTERING DEPARTMENT');
```
Example 5: Assume that you are SMITH and that you created the distinct type DOCUMENT in schema SMITH. Enter comments on DOCUMENT.

```sql
COMMENT ON TYPE DOCUMENT IS 'CONTAINS DATE, TABLE OF CONTENTS, BODY, INDEX, and GLOSSARY';
```

Example 6: Assume that you are SMITH and you know that ATOMIC_WEIGHT is the only function with that name in schema CHEM. Enter comments on ATOMIC_WEIGHT.

```sql
COMMENT ON FUNCTION CHEM.ATOMIC_WEIGHT IS 'TAKES ATOMIC NUMBER AND GIVES ATOMIC WEIGHT';
```

Example 7: Assume that you are SMITH and that you created the function CENTER in schema SMITH. Enter comments on CENTER, using the signature to uniquely identify the function instance.

```sql
COMMENT ON FUNCTION CENTER (INTEGER, FLOAT) IS 'USES THE CHEBYCHEV METHOD';
```

Example 8: Assume that you are SMITH and that you created another function named CENTER in schema JOHNSON. You gave the function the specific name FOCUS97. Enter comments on CENTER, using the specific name to identify the function instance.

```sql
COMMENT ON SPECIFIC FUNCTION JOHNSON.FOCUS97 IS 'USES THE SQUARING TECHNIQUE';
```

Example 9: Assume that you are SMITH and that procedure OSMOSIS is in schema BIOLOGY. Enter comments on OSMOSIS. Your comments will apply to the currently active version of the procedure OSMOSIS.

```sql
COMMENT ON PROCEDURE BIOLOGY.OSMOSIS IS 'CALCULATIONS THAT MODEL OSMOSIS';
```

Example 11: Assume that you are SMITH and that trigger BONUS is in your schema. Enter comments on BONUS.

```sql
COMMENT ON TRIGGER BONUS IS 'LIMITS BONUSES TO 10% OF SALARY';
```

Example 12: Provide a comment for package MYPKG, which is in collection COLLIDA.

```sql
COMMENT ON COLLIDA.MYPKG IS 'THIS IS MY PACKAGE';
```

Example 14: Provide a comment on role ROLE1:

```sql
COMMENT ON ROLE ROLE1 IS 'Role defined for trusted context, ctx1';
```

Example 15: Provide a comment on trusted context CTX1:

```sql
COMMENT ON TRUSTED CONTEXT CTX1 IS 'WEBSPHERE SERVER';
```

Example 15: Provide a comment on column mask M1:

```sql
COMMENT ON MASK M1 IS 'Column mask for column EMP.SALARY';
```
COMMIT

The COMMIT statement ends the unit of recovery in which it is executed and a new unit of recovery is started for the process. The statement commits all changes made by SQL schema statements and SQL data change statements during the unit of work.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared. It cannot be used in the IMS or CICS environment.

Authorization

None required.

Syntax

```
COMMIT
```

Description

The COMMIT statement ends the unit of recovery in which it is executed and a new unit of recovery is started for the process. The statement commits all changes made by SQL schema statements and SQL data change statements during the unit of work. For more information see Chapter 7, “Statements,” on page 1145.

Notes

Recommended coding practices: Code an explicit COMMIT or ROLLBACK statement at the end of an application process. Either an implicit commit or rollback operation will be performed at the end of an application process depending on the application environment. Thus, a portable application should explicitly execute a COMMIT or ROLLBACK statement before execution ends in those environments where explicit COMMIT or ROLLBACK is permitted.

Effect of COMMIT: All savepoints that are set within the unit of recovery are released, and all changes are committed for the following statements that are executed during the unit of recovery:

- ALTER
- COMMENT
- CREATE
- DELETE
- DROP
- EXPLAIN
- GRANT
- INSERT
- LABEL
• MERGE
• RENAME
• REVOKE
• UPDATE
• SELECT INTO with an SQL data change statement
• subselect with an SQL data change statement

SQL connections are ended when any of the following conditions apply:
• The connection is in the release pending status
• The connection is not in the release pending status but it is a remote connection and:
  – The DISCONNECT(AUTOMATIC) bind option is in effect, or
  – The DISCONNECT(CONDITIONAL) bind option is in effect and an open WITH HOLD cursor is not associated with the connection.

For existing connections, all LOB locators are disassociated, except for those locators for which a HOLD LOCATOR statement has been issued without a corresponding FREE LOCATOR statement. All open cursors that were declared without the WITH HOLD option are closed. All open cursors that were declared with the WITH HOLD option are preserved, along with any SELECT statements that were prepared for those cursors.

Static and dynamic INSERT, UPDATE, DELETE, and MERGE statements that reference declared global temporary tables that were defined without ON COMMIT DROP TABLE and are bound with or use the RELEASE(DEALLOCATE) option are kept past commit points. The statement is not kept across the commit point if one of the following conditions is true:
• The declared global temporary table is defined with the ON COMMIT DROP TABLE option.
• The statement uses the RELEASE(COMMIT) bind option.
• The statement also references a Db2 base object (for example, a table or view), and one of the following statements is true:
  – The base object reference is for a Db2 catalog table.
  – At the commit point, Db2 determines that another Db2 thread is waiting for an X-lock on the base object’s database descriptor (DBD).
  – The statement references an XML function or operation, and at the commit point Db2 determines that the base object DBD S-lock for the XML operation must be released.
  – At the commit point, Db2 determines that a base object DBD S-lock that is used by the statement must be released and cannot be maintained across the commit point.
  – Db2 determines that another Db2 thread is waiting for an X-lock on the Db2 package that contains the statement.

Prepared dynamic statements are kept past commit points if one of the following conditions is true:
• Dynamic caching is enabled for your system. In that case, all prepared SELECT and data change statements that are bound with KEEPDYNAMIC(YES) are kept past the commit point.
• The statements reference a declared global temporary table that was defined without ON COMMIT DROP TABLE, and the package was bound with or uses
the RELEASE DEALLOCATE option. In that case, all prepared INSERT, UPDATE, DELETE, and MERGE statements that reference the declared global temporary table are kept across the commit point.

Prepared statements cannot be kept past a commit if any of the following conditions is true:

- SQL RELEASE has been issued for that site.
- Bind option DISCONNECT AUTOMATIC was used.
- Bind option DISCONNECT CONDITIONAL was used and there are no open WITH HOLD cursors for that site.
- The statement references a declared global temporary table, has no open WITH HOLD cursor, and is in a package that is bound with the RELEASE COMMIT option.
- The statement references a declared global temporary table that was defined with the ON COMMIT DROP TABLE option. The statement also has no open WITH HOLD cursor, and the statement’s package is bound with or uses the RELEASE DEALLOCATE option.

All implicitly acquired locks are released, except for the following locks:

- Locks that are required for the cursors that were not closed
- Table and table space locks when the RELEASE parameter on the bind command was not RELEASE COMMIT
- LOB locks and LOB table space locks that are required for held LOB locators

For an explanation of the duration of explicitly acquired locks, see Managing Performance.

All rows of every created temporary table of the application process are deleted with the exception that the rows of a created temporary table are not deleted if any program in the application process has an open WITH HOLD cursor that is dependent on that table. In addition, if RELEASE COMMIT is in effect, the logical work files for the created temporary tables whose rows are deleted are also deleted.

All rows of every declared temporary table of the application process are deleted with these exceptions:

- The rows of a declared temporary table that is defined with the ON COMMIT PRESERVE ROWS attribute are not deleted.
- The rows of a declared temporary table that is defined with the ON COMMIT DELETE ROWS attribute are not deleted if any program in the application process has an open WITH HOLD cursor that is dependent on that table.

**Implicit commit operations:** In all Db2 environments, the normal termination of a process is an implicit commit operation.

**Restrictions on the use of COMMIT:** The COMMIT statement cannot be used in the IMS or CICS environment. To cause a commit operation in these environments, SQL programs must use the call prescribed by their transaction manager. The effect of these commit operations on Db2 data is the same as that of the SQL COMMIT statement.
The COMMIT statement cannot be used in a stored procedure if the procedure is in the calling chain of a user-defined function or a trigger or Db2 is not the commit coordinator.

*Effect of commit on special registers:* Issuing a COMMIT statement may cause special registers to be re-initialized. Whether one of these special registers is affected by a commit depends on whether the special register has been explicitly set within the application process. For example, assume that the PATH special register has not been explicitly set with a SET PATH statement in the application process. After a commit, the value of PATH is re-initialized. For information on the initialization of PATH, which can take the current value of CURRENT SQLID into consideration, see “CURRENT PATH” on page 208.

*Effect of commit on global variables:* Global variables are not controlled at the transaction level. Issuing a COMMIT statement does not effect the contents of a global variable.

**Example**

Commit all Db2 database changes made since the unit of recovery was started.

```
COMMIT WORK;
```

**CONNECT**

The CONNECT statement connects an application process to a database server. This server becomes the *current server* for the process. The CONNECT statement of Db2 for z/OS is equivalent to CONNECT (Type 2) in IBM Db2 SQL Reference for Cross-Platform Development.

Refer to “Distributed data” on page 73 for complete information about connections, the current server, commit processing, and distributed and remote units of work.

**Invocation**

This statement can only be embedded within an application program. It is an executable statement that cannot be dynamically prepared. It must not be specified in Java.

**Authorization**

The primary authorization ID of the process or the authorization ID that is specified in this statement must be authorized to connect to the specified server. The server performs the authorization check when the statement is executed, and determines the specific authorization that is required. See *Db2 Administration Guide* for further information.
Syntax

CONNECT TO location-name

- host-variable

authorization

- RESET

authorization

Description

**TO location-name or host-variable**

Identifies the server by the specified location name or by the location name that is contained in the host variable. If a host variable is specified:

- It must be a CHAR or VARCHAR variable with a length attribute that is not greater than 16. (A C NUL-terminated character string can be up to 17 bytes long.)
- It must not be followed by an indicator variable.
- The location name must be left-justified within the host variable and must conform to the rules for forming an ordinary identifier.
- If the length of the location name is less than the length of the host variable, it must be padded on the right with blanks.
- It must not contain lowercase characters.
- If used with an SQL procedure language application, host variable must be a qualified SQL-variable name or a qualified SQL-parameter name.

When the CONNECT statement is executed:

- The location name must identify a server known to the local Db2 subsystem. Hence, the location name must be the location name of the local Db2 subsystem or it must appear in the LOCATION column of the SYSIBM.LOCATIONS table.
- The application process must not have an existing connection to the specified server, if the SQLRULES(STD) bind option is in effect.
- The application process must be in a connectable state, if the transaction is participating in a remote unit of work.

**RESET**

CONNECT RESET is equivalent to CONNECT TO x where x is the location name of the local Db2 subsystem.

- If the SQLRULES(Db2) bind option is in effect, CONNECT RESET establishes the local Db2 subsystem as the current SQL connection.
- If the SQLRULES(STD) bind option is in effect, CONNECT RESET establishes the local Db2 subsystem as the current SQL connection only if the connection does not exist.
authorization

Specifies an authorization ID and a password that is used to verify that the authorization ID is authorized to connect to the server. Authorization cannot be specified when the connection type is IMS or CICS for a connection to the local Db2 subsystem. An attempt to do so causes an SQL error.

USER host-variable

Identifies the authorization name to use when connecting to the server. The value of host-variable must satisfy the following rules:

- The value must be a CHAR or VARCHAR variable with a length attribute that is not greater than 128.
- The value must be left-justified within the host variable and must conform to the rules for forming an authorization name.
- The value must not be followed by an indicator variable.
- The value must be padded on the right with blanks if the length of the authorization name is less than the length of the host variable.

For a connection to the local Db2 subsystem, a user ID that is longer than 8 characters causes an SQL error.

USING host-variable

Identifies the password of the authorization name to use when connecting to the server. The value of host-variable must satisfy the following rules:

- The value must be a CHAR or VARCHAR variable with a length attribute that is not greater than 128.
- The value must be left-justified.
- The value must not include an indicator variable.
- The value must be padded on the right with blanks if the length of the password is less than the length of the host variable.
- The value must not contain lowercase characters.

For a connection to a Db2 subsystem, a password that is longer than 8 characters causes an SQL error.

CONNECT USER/USING is equivalent to CONNECT TO \textit{x} USER/USING where \textit{x} is the location name of the local Db2 subsystem (which has the semantic of CONNECT RESET).

CONNECT with no operand

This form of the CONNECT statement returns information about the current server in the SQLERRP field of the SQLCA. SQLERRP returns blanks if the application process is in the unconnected state.

Executing a CONNECT with no operand has no effect on connection states.

In a remote unit of work, this form of CONNECT does not require the application process to be in a connectable state.

Notes

Successful connection: With the exception of a CONNECT with no operand statement, if execution of the CONNECT statement is successful:

- One of the following scenarios takes place in a distributed unit of work:
  - If the location name does not identify a server to which the application process is already connected, an SQL connection to the server is created and placed in the current and held state. The previously current SQL connection, if any, is placed in the dormant state.
– If the location name identifies a server to which the application process is already connected, the associated SQL connection is dormant, and the SQLRULES(Db2) option is in effect, the SQL connection is placed in the current state. The previously current SQL connection, if any, is placed in the dormant state.

– If the location name identifies a server to which the application process is already connected, the associated SQL connection is current, and the SQLRULES(Db2) option is in effect, the states of all SQL connections of the application process are unchanged.

• The following actions occur in a remote unit of work:
  – The application process is connected to the specified server.
  – An existing SQL connection of the application process is ended. As a result, all cursors of that SQL connection are closed, all prepared statements of that connection are destroyed, and so on.

• The location name is placed in the CURRENT SERVER special register.

• When CONNECT is used to connect back to the local Db2 subsystem, the CURRENT SQLID special register is reinitialized if the USER/USING clause is specified.

• Information about the server is placed in the SQLERRP field of the SQLCA. If the server is a Db2 product, the information has the form pppvvrrm.

The format of product identifier values is pppvvrrm, where ppp is a 3-letter product code (such as DSN for Db2), vv is the version, rr is the release, and m is the modification level. For example, DSN12015 identifies Db2 12 after the activation of function level 500 or higher. The product code (ppp) is one of the following values:

- **AQT** for IBM Db2 Analytics Accelerator for z/OS
- **ARI** for DB2 Server for VSE & VM
- **DSN** for Db2 for z/OS
- **JCC** for IBM Data Server Driver for JDBC and SQLJ
- **QSQ** for DB2 for i
- **SQL** for Db2 for Linux, UNIX, and Windows

Modification (m) values have the following meanings:

- **0** Function level 100 or 100*.
- **5** Function level 500 or higher.

• Additional information about the connection is placed in the SQLERRMC field of the SQLCA. The contents are product-specific.

  **Tip:** Use the GET DIAGNOSTICS statement to get detailed diagnostic information about the last SQL statement that was executed.

**Unsuccessful connection:** With the exception of a CONNECT with no operand statement, if execution of the CONNECT statement is unsuccessful:

• In a distributed unit of work, the connection state of the application process and the states of its SQL connections are unchanged unless the failure was because an authorization check failed. If this is the case, the connection is placed in the connectable and unconnected state.

• In a remote unit of work, the SQLERRP field of the SQLCA is set to the name of the Db2 requester module that detected the error.

If execution of the CONNECT statement is unsuccessful because the application process is not in the connectable state, the connection state of the application process is unchanged. If execution of the CONNECT statement is unsuccessful
for any other reason, CURRENT SERVER is set to blanks and the application process is placed in the connectable and unconnected state.

**Authorization:** If the server is a Db2 subsystem, a user is authenticated in the following way:

- Db2 invokes RACF via the RACROUTE macro with REQUEST=VERIFY to verify the password.
- If the password is verified, Db2 then invokes RACF again via the RACROUTE macro with REQUEST=AUTH, to check whether the authorization ID is allowed to use Db2 resources defined to RACF.
- Db2 then invokes the connection exit routine if one has been defined.
- The connection then has a primary authorization ID, possibly one or more secondary IDs, and an SQL ID.

If the server is a remote Db2 subsystem, the requester generates authentication tokens and sends them to the remote site in the following way:

- The SECURITY_OUT column in SYSIBM.LUNAMES for SNA or the SECURITY_OUT column in SYSIBM.IP NAMES for TCP/IP must have one of the following values:
  - ‘A’ (already verified)
  - ‘D’ (userid and security-sensitive data encryption; TCP/IP only)
  - ‘E’ (userid, password, and security-sensitive data encryption; TCP/IP only)
  - ‘P’ (password)

When the value is ‘A’, the user ID and password specified on the CONNECT is still sent.

When the value is ‘D’, ‘E’, or ‘P’, the requester encrypts the user ID and password specified on the CONNECT for TCP/IP. However, if the Integrated Cryptographic Service Facility (ICSF) is not configured at the requester or if the server does not support encryption, one of the following actions occurs:

- If the value of SECURITY_OUT in SYSIBM.IP NAMES is ‘D’ or ‘E’, SQLCODE -904 is returned if ICSF is not configured at the requester, and SQLCODE -30082 is returned if the server does not support encryption.
- If the value of SECURITY_OUT in SYSIBM.IP NAMES is ‘P’, the requester does not encrypt the user ID and password and flows the tokens in clear text.

- For SNA, the ENCRYPTPSWDS column in SYSIBM.SYSLUNAMES must be not contain ‘Y’.

- The authorization ID and password are verified at the server.
- In all cases, outbound translation—as specified in SYSIBM.USERNAMES—is not done.

**Distributed unit of work:** In general, the following are true:

- A CONNECT statement with the TO clause and the USER/USING clause can be executed only if no current or dormant connection to the named server exists. However, if the named server is the local Db2 subsystem and the CONNECT statement is the first SQL statement that is executed after the Db2 thread is created, the CONNECT statement executes successfully.

- A CONNECT statement without the TO clause but with the USER/USING clause can be executed only if no current or dormant connection to the local Db2 subsystem exists. However, if the CONNECT statement is the first SQL statement that is executed after the Db2 thread is created, the CONNECT statement executes successfully.
Remote unit of work: If the authorization check fails, the connection is placed in the connectable and unconnected state.

Precompiler options: Regardless of whether a program is precompiled with the CONNECT(1) or CONNECT(2) option, Db2 for z/OS negotiates with the remote server during the connection process to determine how to perform commits. If the remote server does not support the two-phase commit protocol, Db2 downgrades to perform one-phase commits.

Programs containing CONNECT statements that are precompiled with different CONNECT precompiler options cannot execute as part of the same application process. An error occurs when an attempt is made to execute the invalid CONNECT statement.

Host variables: If a CONNECT statement contains host variables, the contents of the host variables are assumed to be in the encoding scheme that was specified in the ENCODING parameter when the package or plan that contains the statement was bound.

Error processing: A CONNECT statement can return and indicate a successful execution even when no physical connection yet exists. Db2 delays the physical connection process, when possible, to economize on the number of messages it sends to a server. Therefore, errors in CONNECT statement processing can be reported following the next executable SQL statement, not immediately following the CONNECT statement.

Restrictions on array types and array variables: In any SQL statement other than a CALL statement, array types and array variables must not be referenced after a connection at a remote server has been established. This restriction includes an SQL statement that executes at a remote server as a result of a three-part name or alias that resolves to an object at a remote server. An exception is that an array element can be the target of a FETCH, SELECT INTO, SET assignment-statement, or VALUES INTO statement in an SQL routine even when the statement is executed at a remote server.

Examples

Example 1: Connect an application to a DBMS. The location name is in the character-string variable LOCNAME, the authorization identifier is in the character-string variable AUTHID, and the password is in the character-string variable PASSWORD.

EXEC SQL CONNECT TO :LOCNAME USER :AUTHID USING :PASSWORD;

Example 2: Obtain information about the current server.

EXEC SQL CONNECT;

Example 3: Execute SQL statements in a distributed unit of work. The first CONNECT statement creates a connection to the EASTDB server. The second CONNECT statement creates a connection to the WESTDB server, and places the SQL connection to EASTDB in the dormant state.

EXEC SQL CONNECT TO EASTDB;
-- execute statements referencing objects at EASTDB
EXEC SQL CONNECT TO WESTDB;
-- execute statements referencing objects at WESTDB
Example 4: Connect the application to a DBMS whose location identifier is in the character-string variable LOC using the authorization identifier in the character-string variable AUTHID and the password in the character-string variable PASSWORD. Perform work for the user, and then release the connection and connect again using a different user ID and password.

    EXEC SQL CONNECT TO :LOC USER :AUTHID USING :PASSWORD;  -- execute SQL statements accessing data on the server
    RELEASE :LOC;
    EXEC SQL COMMIT;
    -- set AUTHID and PASSWORD to new values
    EXEC SQL CONNECT TO :LOC USER :AUTHID USING :PASSWORD;
    -- execute SQL statements accessing data on the server

Example 5: Change servers in a remote unit of work. Assume that the application connected to a remote Db2 server, opened a cursor, and fetched rows from the cursor’s result table. Subsequently, to connect to the local Db2 subsystem, the application executes the following statements:

    EXEC SQL COMMIT WORK;
    EXEC SQL CONNECT RESET;

The COMMIT is required because opening the cursor caused the application to enter the unconnectable and connected state. The unconnectable state means that the connection has started a transaction and cannot connect to another server until the transaction completes. Issuing a COMMIT statement ends the transaction. Issuing a CONNECT statement with the RESET option reconnects the application to the local server and returns the application to the unconnectable and connected state.

If the cursor was declared with the WITH HOLD clause and was not closed with a CLOSE statement, it would still be open even after execution of the COMMIT statement. However, it would be closed with the execution of the CONNECT statement.

Related concepts:

- Explicit CONNECT statements (Introduction to Db2 for z/OS)
- Distributed data (Introduction to Db2 for z/OS)

Related tasks:

- Accessing distributed data by using explicit CONNECT statements (Db2 Application programming and SQL)
- Reusing a local trusted connection through the SQL CONNECT statement (Managing Security)

CREATE ALIAS

The CREATE ALIAS statement defines an alias for a table, a view, or a sequence. The definition is recorded in the Db2 catalog at the current server.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.
Authorization

To create an alias, the privilege set must include at least one of the listed authorities or privileges:

To create an alias for a table or a view:

- The CREATEALIAS privilege
- SYSADM or SYSCTRL authority
- System DBADM authority
- DBADM or DBCTRL authority on the database that contains the table, if the alias is for a table and the value of field DBADM CREATE AUTH on installation panel DSNTIPP is YES
- Installation SYSOPR authority (when the current SQLID of the process is set to SYSINSTL)

To create an alias for a sequence:

- The CREATEIN privilege on the schema
- SYSADM or SYSCTRL authority
- System DBADM authority
- Installation SYSOPR authority (when the current SQLID of the process is set to SYSINSTL)

If the database is implicitly created, the database privileges must be on the implicit database or on DSND04.

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the owner of the plan or package is a role, this role must hold the privileges for the privilege set. If the specified alias name includes a qualifier that is not the same as this authorization ID, the privilege set must include one of the following authorities:

- SYSADM or SYSCTRL authority
- System DBADM authority
- DBADM or DBCTRL authority on the database that contains the table, if the alias is for a table and the value of field DBADM CREATE AUTH on installation panel DSNTIPP is YES

If ROLE AS OBJECT OWNER is in effect, the schema qualifier must be the same as the role, unless the role has the CREATEIN privilege on the schema, SYSADM authority, SYSCTRL authority, or system DBADM authority.

If ROLE AS OBJECT OWNER is not in effect, one of the following rules applies:

- If the privilege set lacks the CREATEIN privilege on the schema, SYSADM authority, SYSCTRL authority, or system DBADM authority, the schema qualifier (implicit or explicit) must be the same as one of the authorization IDs of the process.
- If the privilege set includes SYSADM authority, SYSCTRL authority, or system DBADM authority, the schema qualifier can be any valid schema name.

If the statement is dynamically prepared, the privilege set is the privileges that are held by the SQL authorization ID of the process unless the process is within a trusted context and the ROLE AS OBJECT OWNER clause is specified. If the
process is not running in a trusted context that is defined with the ROLE AS
OBJECT OWNER clause and the specified alias name includes a qualifier that is
not the same as this authorization ID:

- The privilege set must include SYSADM, SYSCTRL, or system DBADM
  authority.
- The privilege set must include DBADM or DBCTRL authority on the database
  that contains the table, if the alias is for a table and the value of field DBADM
  CREATE AUTH on installation panel DSNTIPP is YES.
- The qualifier must be the same as one of the authorization IDs of the process
  and the privileges that are held by that authorization ID must include the
  CREATEALIAS privilege. This is an exception to the rule that the privilege set is
  the privileges that are held by the SQL authorization ID of the process.

**Syntax**

```
CREATE ALIAS table-alias PUBLIC
```

**table-alias**

```
alias-name FOR TABLE table-name
```

Notes:

1. If alias-name2 is specified, it must not resolve to the fully-qualified form of alias-name, and
alias-name2 must not be an alias that exists at the current server.

**sequence-alias**

```
alias-name FOR SEQUENCE sequence-name
```

**Description**

**PUBLIC**

Specifies that the alias is an object in the system schema SYSPUBLIC.

The PUBLIC keyword is used to create a public alias. If the keyword PUBLIC
is not specified, the alias that is created is a private alias.

PUBLIC can be specified only for a sequence.

*alias-name*

Names the alias.
For a table alias, the name, including the implicit or explicit qualifier, must not identify a table, view, or table alias that exists at the current server, or a table that exists in the SYSIBM.SYSPENDINGOBJECTS catalog table.

For a sequence alias, the name, including the implicit or explicit qualifier, must not identify a sequence or sequence alias that exists at the current server.

If a two-part name is specified, the schema name cannot begin with 'SYS', except if PUBLIC is specified, in which case the schema name must be SYSPUBLIC. The unqualified name must not be the same as an existing synonym.

If the name is qualified, the name can be a two-part or three-part name. If a three-part name is used, the first part must match the value of the field Db2 LOCATION NAME on installation panel DSNTIPR at the current server. (If the current server is not the local Db2, this name is not necessarily the name in the CURRENT SERVER special register.)

When an application uses three-part name aliases for remote objects and DRDA access, the application program must be bound at each location that is specified in the three-part names.

**FOR TABLE** `table-name, view-name, or alias-name2`

Identifies the table, view, or alias for which `alias-name` is defined. The table, view or alias need not exist at the time the alias is defined. If it does not exist when the alias is created, a warning is returned. However, the referenced object must exist when a SQL statement that contains the alias is used, otherwise an error is returned. If the table or view does exist, the referenced object can be at the current server or at another server.

If `alias-name2` is specified it must be a three-part name. The first part of the three-part name must be the location name for a remote server. If the alias exists, the alias must exist at the remote server identified by the location name.

If a table is identified, it must not be an auxiliary table, a declared temporary table, or a table that is implicitly created for an XML column.

If `alias-name2` is specified, it must not resolve to the fully-qualified form of `alias-name`, and `alias-name2` must not be an alias that exists at the current server.

**FOR SEQUENCE** `sequence-name`

Identifies the sequence for which `alias-name` is defined. The `sequence-name` must not be a sequence that is generated by the Db2 subsystem for an identity column or a DOCID column. The schema name must not begin with 'SYS' unless the schema name is 'SYSADM'. `sequence-name` must not be an existing alias for a sequence.

The sequence need not exist at the time the alias is defined. If `sequence-name` does not exist when the alias is created, a warning is returned. However, the referenced object must exist when a SQL statement that contains the alias is used, otherwise an error is returned.

**Notes**

**Owner privileges:**

There are no specific privileges on an alias. For more information about ownership of an object, see [Authorization, privileges, permissions, masks, and object ownership](#).

**PUBLIC aliases:**

If the PUBLIC keyword is specified or if SYSPUBLIC is explicitly specified as the schema qualifier for `alias-name`, a public alias is created.
Resolving an unqualified name:
When an unqualified name is resolved, private aliases are considered before public aliases.

Examples

Example 1: Create an alias for a catalog table at a Db2 with location name DB2USCALABOA5281.
CREATE ALIAS LATABLES FOR DB2USCALABOA5281.SYSIBM.SYSTABLES;

Example 2: Create a public alias called SEQS for a sequence named JOE.JOESSEQ.
CREATE PUBLIC ALIAS SEQS FOR SEQUENCE JOE.JOESSEQ;

The alias can be referenced as SYSPUBLIC.SEQS, or simply as SEQS if a private sequence or alias named SEQS does not exist.

CREATE AUXILIARY TABLE

The CREATE AUXILIARY TABLE statement creates an auxiliary table at the current server for storing LOB data.

Invocation

This statement can be embedded in an application program or issued interactively if the value of special register CURRENT RULES is 'Db2' and the table space is explicitly created when the statement is executed. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

Do not use this statement if the value of special register CURRENT RULES is 'STD' or if the table space is implicitly created. When the values of the CURRENT RULES special register is 'STD' and a base table is created with LOB columns or altered such that LOB columns are added, Db2 automatically creates the LOB table space, auxiliary table, and index on the auxiliary table for each LOB column. Db2 also automatically creates the LOB table space, auxiliary table, and index on the auxiliary table for each LOB column if the table space is implicitly created. Db2 chooses the names and characteristics of these objects. For more information about the names and the characteristics, see Creating a table with LOB columns.

Authorization

The privilege set that is defined below must include at least one of the following:

- The CREATETAB privilege for the database implicitly or explicitly specified by the IN clause
- DBADM, DBCTRL, or DBMAINT authority for the database
- SYSADM or SYSCTRL authority
- System DBADM
- Installation SYSPR authority (when the current SQLID of the process is set to SYSINSTL)

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the application is bound in a trusted context with the ROLE AS OBJECT OWNER clause specifies, a role is the owner. Otherwise, an authorization ID is the owner. If
the specified table name includes a qualifier that is not the same as this authorization ID, the privilege set must include SYSADM or SYSCTRL authority, DBADM authority for the database, or DBCTRL authority for the database.

If ROLE AS OBJECT OWNER is in effect, the schema qualifier must be the same as the role, unless the role has the CREATEIN privilege on the schema, SYSADM authority, or SYSCTRL authority.

If ROLE AS OBJECT OWNER is not in effect, one of the following rules applies:

- If the privilege set lacks the CREATETABLE privilege on the schema, SYSADM authority, or SYSCTRL authority, the schema qualifier (implicit or explicit) must be the same as one of the authorization IDs of the process.
- If the privilege set includes SYSADM authority or SYSCTRL authority, the schema qualifier can be any valid schema name.

If the statement is dynamically prepared, the privilege set is the privileges that are held by the SQL authorization ID of the process unless the process is within a trusted context and the ROLE AS OBJECT OWNER clause is specified. In that case, the privilege set is the set of privileges that are held by the role that is associated with the primary authorization ID of the process. If the process is in a trusted context, any authorization ID can be the qualifier. However, if the process is not in a trusted context and if the specified table name includes a qualifier that is not the same as the SQL authorization ID of the process, the following rules apply:

- If the privilege set includes SYSADM or SYSCTRL authority (or DBADM authority for the database, or DBCTRL authority for the database when creating a table), the schema qualifier can be any valid schema name.
- If the privilege set lacks SYSADM or SYSCTRL authority (or DBADM authority for the database, or DBCTRL authority for the database when creating a table), the schema qualifier is valid only if it is the same as one of the authorization IDs of the process and the privilege set that are held by that authorization ID includes all privileges needed to create the table.

Syntax

```
CREATE AUXILIARY TABLE aux-table-name AUX IN table-space-name database-name

STORES table-name APPEND NO APPEND YES COLUMN column-name PART integer
```

Description

**AUXILIARY or AUX**

Specifies a table that is used to store the LOB data for a LOB column (or a column with a distinct type that is based on a LOB data type).

---

28. Exception: The CREATETABLE privilege is checked on the SQL authorization ID of the process.
aux-table-name
Names the auxiliary table. The name, including the implicit or explicit
qualifiers, must not identify a table, view, alias, or synonym that exists at the
current server, or a table that exists in the SYSIBM.SYSPENDINGOBJECTS
catalog table.

IN database-name.table-space-name or IN table-space-name
Identifies the table space in which the auxiliary table is created. The name
must identify an empty LOB table space that currently exists at the current
server. The LOB table space must be in the same database as the associated
base table.

If you specify a database and a table space, the table space must belong to the
specified database. If you specify only a table space, it must belong to the
database that contains the specified table space. If you specify only a table
space, this table space must belong to DSNDB04. This type of table space is
only created when SET CURRENT RULES='Db2' is specified.

STORES table-name COLUMN column-name
Identifies the base table and the column of that table that is to be stored in the
auxiliary table. If the base table is nonpartitioned, an auxiliary table must not
already exist for the specified column. If the base table is partitioned, an
auxiliary table must not already exist for the specified column and specified
partition.

The encoding scheme for the LOB data stored in the auxiliary table is the same
as the encoding scheme for the base table. It is either ASCII, EBCDIC, or
UNICODE depending on the value of the CCSID clause when the base table
was created.

APPEND NO or APPEND YES
Specifies whether append processing is used for the table. The APPEND clause
must not be specified for a table in a work file table space.

If the base table is in a partition-by-range table space, the APPEND option on
the LOB table might be different for each partition (depending if the LOB table
space and associated objects for each partition are created explicitly or
implicitly). If the base table is in a partition-by-growth table space, the
APPEND attributes of LOB table will be inherited by each partition.

APPEND NO
Specifies that append processing is not used for the table. For insert and
LOAD operations, Db2 will attempt to place data rows in a well clustered
manner with respect to the value in the row’s cluster key columns.

APPEND NO is the default

APPEND YES
Specifies that data rows are placed into the table without regard to
clustering during the insert and LOAD operations.

PART integer
Specifies the partition of the base table for which the auxiliary table is to store
the specified column. You can specify PART only if the base table is defined in
a partitioned table space, and no other auxiliary table exists for the same LOB
column of the base table.

Notes
Owner privileges:
There are no specific privileges on an auxiliary table. For more information
about ownership of an object, see “Authorization, privileges, permissions, masks, and object ownership” on page 97.

Determining the number of auxiliary tables to create:
If the base table is nonpartitioned, you might need to create one LOB table space and one auxiliary table for each LOB column in the base table. If the base table is partitioned, for each LOB column, you might need to create one LOB table space and one auxiliary table for each partition. For example if your base table has three partitions and two LOB columns, you might need to create three LOB table spaces and three auxiliary tables for each LOB column. In other words, you might need a total of six LOB table spaces and six auxiliary tables.

Auxiliary tables in LOB table spaces that are logged:
When you create an auxiliary table in a LOB table space that is LOGGED, and the associated base table space is NOT LOGGED, the logging attribute of the LOB table space is implicitly changed to NOT LOGGED and the logging attributes of the base table space and the LOB table space are linked.

Append processing and unused free space in a table:
An update or delete of LOB data creates some free space in the LOB table that can be used by the next insert. If the table uses append processing, any free space that is not at the end of the table space will not be reused during the insert operation. Any unused free space in the table can be reclaimed by running the REORG utility with either the SHRELEVEL REFERENCE or SHRELEVEL CHANGE keywords. The REORG utility is not influenced by the APPEND option.

Example

Assume that a column named EMP_PHOTO with a data type of BLOB(110K) has been added to sample employee table DSN8C10.EMP for each employee’s photo. Create auxiliary table EMP_PHOTO_ATAB to store the BLOB data for the BLOB column in LOB table space DSN8D12A.PHOTOLT

```
CREATE AUX TABLE EMP_PHOTO_ATAB
IN DSN8D12A.PHOTOLT
STORES DSN8C10.EMP
COLUMN EMP_PHOTO;
```

- LOB table spaces (Introduction to Db2 for z/OS)

Related tasks:
- Storing LOB data in a table (Db2 Application programming and SQL)

Related reference:
CREATE LOB TABLESPACE
CREATE TABLE

CREATE DATABASE

The CREATE DATABASE statement defines a Db2 database at the current server.
Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

Authorization

The privilege set that is defined below must include at least one of the following:

- The CREATEDBA privilege
- The CREATEDBC privilege
- SYSADM or SYSCTRL authority
- System DBADM
- Installation SYSOPR authority (when the current SQLID of the process is set to SYSINSTL)

If the database is created as a workfile database, the privilege set that is defined below must include SYSADM authority.

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package.

If the statement is dynamically prepared, the privilege set is the privileges that are held by the SQL authorization ID of the process unless the process is within a trusted context and the ROLE AS OBJECT OWNER clause is specified. In that case, the privilege set is the set of privileges that are held by the role that is associated with the primary authorization ID of the process.

See “Notes” on page 1524 for the authorization effect of a successful CREATE DATABASE statement.

Syntax

```
CREATE DATABASE database-name (1)
  BUFFERPOOL bname
  INDEXBP bname
  AS WORKFILE FOR member-name
  STOGROUP stogroup-name
  CCSID ASCII EBCDIC UNICODE
```

Notes:

1. The same clause must not be specified more than one time.
Description

database-name

Names the database. The name must not start with DSNDB and must not identify a database that exists at the current server. database-name must not be in the form of eight characters that start with DSN followed by exactly five digits. If the database is to be a work file database in a data sharing environment, DSNDB07 is an acceptable work file database name. However, only one member of a data sharing group can use DSNDB07 as the name of its work file database.

BUFFERPOOL bname

Specifies the default buffer pool name to be used for table spaces created within the database. If the database is a work file database, 8KB and 16KB buffer pools cannot be specified. See Naming conventions for more details about bname.

If you omit the BUFFERPOOL clause, the buffer pool for the TBSBPOOL subsystem parameter value is used. If the table space is implicitly created, Db2 selects the buffer pool as described in Implicitly defined table spaces (Db2 Administration Guide).

INDEXBP bname

Specifies the default buffer pool name to be used for the indexes created within the database. The name can identify a 4KB, 8KB, 16KB, or 32KB buffer pool. See Naming conventions for more details about bname.

If you omit the INDEXBP clause, the buffer pool specified for user indexes on installation panel DSNTIP1 is used. The default value for the user indexes field on that panel is BP0.

AS WORKFILE

Specifies the database is a work file database. AS WORKFILE can be specified only in a data sharing environment. Only one work file database can be created for each Db2 subsystem. The work file database is used for work files, created global temporary table, declared temporary tables, and sensitive static scrollable cursors.

PUBLIC implicitly receives the CREATETAB privilege (without GRANT authority) to define a declared temporary table in the work file database. This implicit privilege is not recorded in the Db2 catalog and cannot be revoked.

The CCSID clause is not supported for a work file database. If you specify AS WORKFILE, do not use the CCSID clause.

FOR member-name

Specifies the member for which this database is to be created. Specify FOR member-name only in a data sharing environment.

If FOR member-name is not specified, the member is the Db2 subsystem on which the CREATE DATABASE statement is executed.

STOGROUP stogroup-name

Specifies the storage group to be used, as required, as a default storage group to support DASD space requirements for table spaces and indexes within the database. The default is SYSDEFLT.

CCSID encoding-scheme

Specifies the default encoding scheme for data stored in the database. The default applies to table spaces created in the database. All tables stored within a table space must use the same encoding scheme.
ASCII  Specifies that the data must be encoded using the ASCII CCSIDs of the server.

EBCDIC  Specifies that the data must be encoded using the EBCDIC CCSIDs of the server.

UNICODE  Specifies that the data must be encoded using the UNICODE CCSIDs of the server.

Usually, each encoding scheme requires only a single CCSID. Additional CCSIDs are needed when mixed, graphic, or UNICODE data is used.

The option defaults to the value of field DEF ENCODING SCHEME on installation panel DSNTIPF.

Do not use the CCSID clause if you specify the AS WORKFILE clause.

Notes

If the statement is embedded in an application program, the owner of the plan or package is the owner of the database. If the statement is dynamically prepared, the SQL authorization ID of the process is the owner of the database.

If the owner of the database has the CREATEDBA, SYSADM, or SYSCTRL authority, the owner acquires DBADM authority for the database. DBADM authority for a database includes table privileges on all tables in that database. Thus, if a user with SYSCTRL authority creates a database, that user has table privileges on all tables in that database. This is an exception to the rule that SYSCTRL authority does not include table privileges.

If the owner of the database has the CREATEDBC privilege, but not the CREATEDBA privilege, the owner acquires DBCTRL authority for the database. In this case, no authorization ID has DBADM authority for the database until it is granted by an authorization ID with SYSADM authority.

Examples

Example 1: Create database DSN8D12P. Specify DSN8G120 as the default storage group to be used for the table spaces and indexes in the database. Specify 8KB buffer pool BP8K1 as the default buffer pool to be used for table spaces in the database, and BP2 as the default buffer pool to be used for indexes in the database.

```sql
CREATE DATABASE DSN8D12P
  STOGROUP DSN8G120
  BUFFERPOOL BP8K1
  INDEXBP BP2;
```

Example 2: Create database DSN8TEMP. Use the defaults for the default storage group and default buffer pool names. Specify ASCII as the default encoding scheme for data stored in the database.

```sql
CREATE DATABASE DSN8TEMP
  CCSID ASCII;
```

CREATE FUNCTION

The CREATE FUNCTION statement registers a user-defined function with a database server. Each type of function that you can register with this statement is described separately.
External scalar

The function is written in a programming language and returns a scalar value. The external executable routine (package) is registered with a database server along with various attributes of the function. When the function is invoked, the package is invoked. See “CREATE FUNCTION (external scalar)” on page 1557.

External table

The function is written in a programming language. It returns a table to the subselect from which it was started by returning one row at a time, each time that the function is started. The external executable routine (package) is registered with a database server along with various attributes of the function. When the function is invoked, the package is invoked. See “CREATE FUNCTION (external table)” on page 1579.

Sourced

The function is implemented by invoking another function (either built-in, external, SQL, or sourced) that exists at the server. The function inherits the attributes of the underlying source function. A sourced function does not have an associated package. See “CREATE FUNCTION (sourced)” on page 1608.

SQL scalar

The function is written exclusively in SQL statements and returns a scalar value. The body of an SQL scalar function is written in the SQL procedural language. The function is defined at the current server along with various attributes of the function.

Db2 supports two types of SQL scalar functions, inlined and compiled:

- Inlined SQL scalar functions contain a single RETURN statement, which returns the value of a simple expression. The function is not invoked as part of a query; instead, the expression in the RETURN statement of the function is copied (inlined) into the query itself. Therefore, a package is not generated for an inlined SQL scalar function.
- Compiled SQL scalar functions support a larger set of functionality, including all of the SQL PL statements. A package is generated for a compiled SQL scalar function.

When a CREATE FUNCTION statement for an SQL scalar function is processed, Db2 attempts to create an inlined SQL scalar function. If the function cannot be created as an inlined function, Db2 attempts to create a compiled SQL scalar function. For more information on the syntax and rules for these types of functions, see “CREATE FUNCTION (inlined SQL scalar)” on page 1599 and “CREATE FUNCTION (compiled SQL scalar)” on page 1530.

To determine what type of SQL scalar function is created, refer to the INLINE column of the SYSIBM.SYSROUTINES catalog table.

SQL table

The function is written exclusively as an SQL RETURN statement and returns a set of rows. The body of an SQL table function is written in the SQL procedural language. The function is defined at the current server along with various attributes. The function is not invoked as part of a query. Instead, the expression in the RETURN statement of the function is copied (inlined) into the query itself. Therefore, a package is not generated for an SQL table function. See “CREATE FUNCTION (SQL table)” on page 1620.
Notes for all CREATE FUNCTION types

The following considerations apply for creating all types of functions:

**Owner privileges:**
For all functions except for sourced functions, the owner is authorized to execute the function (EXECUTE privilege) and has the ability to grant these privileges to others. For more information, see [GRANT (function or procedure privileges)](https://www.ibm.com/support/knowledgecenter/en/SSDK47_10.1.0/com.ibm.db2.z10.base.doc/doc/r0000671.html). For more information about ownership of the object, see [Authorization, privileges, permissions, masks, and object ownership](https://www.ibm.com/support/knowledgecenter/en/SSDK47_10.1.0/com.ibm.db2.z10.base.doc/doc/r0000671.html).

**Choosing the schema and function name:**

The combination of name, schema name, the number of parameters, and the data type of each parameter (without regard for any length, precision, scale, subtype or encoding scheme attributes of the data type) must not identify a user-defined function that exists at the current server. If the function has more than 30 parameters, only the first 30 parameters are used to determine whether the function is unique.

You can use the same name for more than one function if the function signature of each function is unique.

- The unqualified form of *function-name* must not be any of the following system-reserved keywords even if you specify them as delimited identifiers:
  - ALL
  - LIKE
  - UNIQUE
  - AND
  - MATCH
  - UNKNOWN
  - ANY
  - NOT
  - =
  - BETWEEN
  - NULL
  - ¬=
  - DISTINCT
  - ONLY
  - <
  - EXCEPT
  - OR
  - <=
  - EXISTS
  - OVERLAPS
  - ¬<
  - FALSE
  - SIMILAR
  - >
  - FOR
  - SOME
  - >=
  - FROM
  - TABLE
  - ¬>
  - IN
  - TRUE
  - <>
  - IS
  - TYPE

The schema name can be ‘SYSTOOLS’ or ‘SYSFUN’ if the privilege set includes the SYSADM or SYSCTRL privilege. Otherwise, the schema name must not begin with ‘SYS’ unless the schema name is ‘SYSADM’.

**Defining the parameters**

The input parameters for the function are specified as a list within parentheses.

The maximum number of parameters allowed in CREATE FUNCTION is 90. For more information, see [Limits in Db2 for z/OS](https://www.ibm.com/support/knowledgecenter/en/SSDK47_10.1.0/com.ibm.db2.z10.base.doc/doc/r0000671.html). Db2 uses only the first 30 characters to ensure uniqueness.

A function can have no input parameters. In this case, an empty set of parentheses must be specified, for example:

```
CREATE FUNCTION WOOFER()
```

The data type of the result of the function is specified in the RETURNS clause for the function.

**Choosing data types for parameters:**

When you choose the data types of the input and output parameters for your function, consider the rules of promotion that can affect the values of the parameters. (See [Promotion of data types](https://www.ibm.com/support/knowledgecenter/en/SSDK47_10.1.0/com.ibm.db2.z10.base.doc/doc/r0000671.html). For example, a constant that is one of the input arguments
to the function might have a built-in data type that is different from the data type that the function expects, and more significantly, might not be promotable to that expected data type. Based on the rules of promotion, consider using the following data types for parameters:

- INTEGER instead of SMALLINT
- DOUBLE instead of REAL
- VARCHAR instead of CHAR
- VARGRAPHIC instead of GRAPHIC
- VARBINARY instead of BINARY

For portability of functions across platforms that are not Db2 for z/OS, do not use the following data types, which might have different representations on different platforms:

- FLOAT. Use DOUBLE or REAL instead.
- NUMERIC. Use DECIMAL instead.

**Specifying AS LOCATOR for a parameter:**

Passing a locator instead of a value can result in fewer bytes being passed in or out of the function. This can be useful when the value of the parameter is very large. The AS LOCATOR clause specifies that a locator to the value of the parameter is passed instead of the actual value. Specify AS LOCATOR only for parameters that have a LOB data type or a distinct type that is based on a LOB data type and only when LANGUAGE JAVA is not in effect.

The AS LOCATOR clause has no effect on determining whether data types can be promoted, nor does it affect the function signature, which is used in function resolution.

AS LOCATOR must not be specified for a sourced or SQL function.

AS LOCATOR must not be specified if the function is defined with NO SQL.

**Considerations for a function that is defined using a TABLE LIKE name AS LOCATOR clause:**

If a function is defined with a table parameter (the TABLE LIKE name AS LOCATOR clause was specified in the CREATE FUNCTION statement to indicate that one of the input parameters is a transition table), no ALTER FUNCTION statement that specifies a parameter list as part of the alteration can change the function. For example, a parameter list is required as part of the routine specification when adding or replacing a version of a function. In such cases, the function must be dropped and re-created.

**Determining the uniqueness of functions in a schema:**

At the current server, the function signature of each function, which is the qualified function name combined with the number and data types of the input parameters, must be unique. If the function has more than 30 input parameters, only the data types of the first 30 are used to determine uniqueness. This means that two different schemas can each contain a function with the same name that have the same data types for all of their corresponding data types. However, a single schema must not contain multiple functions with the same name that have the same data types for all of their corresponding data types.
When determining whether corresponding data types match, Db2 does not consider any length, precision, or scale attributes in the comparison. Db2 considers the synonyms of data types as a match. For example, REAL and FLOAT, and DOUBLE and FLOAT are considered a match. Therefore, CHAR(8) and CHAR(35) are considered to be the same, as are DECIMAL(11,2), DECIMAL(4,3), DECFLOAT(16) and DECFLOAT(34), TIMESTAMP(6) and TIMESTAMP(9), TIMESTAMP(6) WITH TIME ZONE and TIMESTAMP(9) WITH TIME ZONE. Furthermore, the character and graphic types, and the timestamp types are considered to be the same. For example, the following are considered to be the same type: CHAR and GRAPHIC, VARCHAR and VARGRAPHIC, CLOB and DBCLOB, TIMESTAMP WITHOUT TIME ZONE and TIMESTAMP WITH TIME ZONE. CHAR(13) and GRAPHIC(8) are considered to be the same type.

An error is returned if the signature of the function being created is a duplicate of a signature for an existing user-defined function with the same name and schema.

Assume that the following statements are executed to create four functions in the same schema. The second and fourth statements fail because they create functions that are duplicates of the functions that the first and third statements created.

```
CREATE FUNCTION PART (INT, CHAR(15)) ...  
CREATE FUNCTION PART (INTEGER, CHAR(40)) ...  
CREATE FUNCTION ANGLE (DECIMAL(12,2)) ...  
CREATE FUNCTION ANGLE (DEC(10,7)) ...  
```

Specifying a specific name for a function:

When defining multiple functions with the same name and schema (with different parameter lists), it is recommended that a specific name also be specified.

The specific name can be used to uniquely identify the function such as when sourcing on this function, dropping the function, or commenting on the function. However, the function cannot be invoked by its specific name.

The specific name is implicitly or explicitly qualified with a schema name. If a schema name is not specified on CREATE FUNCTION, it is the same as the explicit or implicit schema name of the function name (function-name). If a schema name is specified, it must be the same as the explicit or implicit schema name of the function name. The name, including the schema name must not identify the specific name of another function or procedure that exists at the current server.

If the SPECIFIC clause is not specified, a specific name is generated.

Extending or overriding a built-in function

Giving a user-defined external function the same name as a built-in function is not a recommended practice unless the functionality of the built-in function needs to be extended or overridden.

If you do intend to create a function with the same name as a built-in function, be careful to maintain the uniqueness of its function signature. If your function has the same name and data types of the corresponding parameters of the built-in function but implements different logic, Db2 might choose the wrong function when the function is invoked with an unqualified function name. For example, If the schema for the new function appears in the SQL path before the system schemas, Db2 might choose a user-defined function rather than the built-in function. An application that uses the unqualified name and was previously successful using the built-in function of that name might fail. It might also appear to
run successfully but provide a different result if Db2 chooses the built-in function instead of the built-in function. This situation can occur with dynamic SQL statements, or when static SQL statements are rebound.

**Extending the functionality of existing built-in functions**

Create the new user-defined function with the same name as the built-in function, and a unique function signature. For example, a user-defined function similar to the built-in function ROUND that accepts the distinct type MONEY as input rather than the built-in numeric types might be necessary. In this case, the signature for the new user-defined function named ROUND is different from all the function signatures supported by the built-in ROUND function.

**Overriding a built-in function:**

Create the new user-defined function with the same name and signature as a built-in function. The new function has the same name and data type as the corresponding parameters of the built-in function but implements different logic.

For example, it might be useful to use different rules for rounding that the built-in ROUND function. In this case, the signature for the new user-defined function named ROUND will be the same as a signature that is supported by the built-in ROUND function.

Another case for overriding a built-in function is to use its functionality when an argument is not a built-in data type. Instead of explicitly casting the argument to a built-in data type, you can define a sourced function that accepts the user-defined data type argument and passes it to the underlying built-in function. A sourced function is defined with a reference to a built-in function or another user-defined function. For more information about sourced functions, see "CREATE FUNCTION (sourced)."

The DISTINCT keyword can be passed on the invocation of a user-defined function that is sourced on one of the built-in aggregate functions. For example, assume that MY_AVG is a user-defined function that is sourced on built-in AVG function. The user-defined function could be invoked with 'MY_AVG (DISTINCT expression)' This results in the underlying built-in AVG function being invoked with the DISTINCT keyword.

**Special registers in functions**

The settings of the special registers of the invoker are inherited by the function on invocation and restored upon return to the invoker. Special registers may be changed in a function that can execute SQL statements, but these changes do not affect the caller.

**Global variables in functions:**

The content of global variables that are referenced in a function are inherited from the invoking environment.

**Scrollable cursors specified with user-defined functions:**

A row can be fetched more than once with a scrollable cursor. Therefore, if a SELECT statement of a scrollable cursor invokes a function that is not deterministic in the select list, a row can be fetched multiple times with different results for each fetch. Similarly, if the SELECT statement of a scrollable cursor invokes a user-defined function defined with external action, the action is executed with every fetch.
Considerations for secure functions:

To create a secure function, the security administrator usually examines the data that is accessed by a function, ensures that it is secure, and grants the CREATE_SECURE_OBJECT privilege to someone who currently requires the privileges to create a secure user-defined function. After the function is created, they revoke the CREATE_SECURE_OBJECT privilege from the function owner.

A sourced function cannot be created as a secure function.

If a row permission or a column mask definition references a user-defined function, the user-defined function must be secure because the sensitive data might be passed as arguments to the function. The SECURE column in the DSN_FUNCTION_TABLE indicates whether a user-defined function is considered secure.

If a secure user-defined function invokes other user-defined functions, Db2 does not validate whether those nested user-defined functions have the SECURED attribute. If those nested functions can access sensitive data, the security administrator must ensure that those functions are allowed to access the sensitive data and should ensure that a change control audit procedure is established for all changes to those functions.

CREATE FUNCTION (compiled SQL scalar)

The CREATE FUNCTION (compiled SQL scalar) statement defines a compiled SQL scalar function at the current server and specifies the source statements for the function. The body of the function is written in the SQL procedural language. The function returns a single value each time it is invoked.

A package is created for a compiled SQL scalar function.

For compiled SQL scalar functions, you can define multiple versions of the function. Use CREATE FUNCTION (compiled SQL scalar) to define the initial version, and ALTER FUNCTION to define subsequent versions. For information about the SQL statements that are supported in SQL functions, refer to SQL-procedure-statement.

Invocation

For a compiled SQL function, this statement can only be dynamically prepared but the DYNAMICRULES run behavior must be specified implicitly or explicitly.

Authorization

The privilege set defined below must include at least one of the following:

- The CREATEIN privilege on the schema and the required authorization to add a new package or a new version of an existing package, depending on the value of the BIND NEW PACKAGE field on installation panel DSNTIPP
- SYSADM or SYSCTRL authority
• System DBADM
• Installation SYSOPR authority (when the current SQLID of the process is set to SYSINSTL)

The authorization ID that matches the schema name implicitly has the CREATEIN privilege on the schema.

If the authorization ID that is used to create the function has the installation SYSADM authority or the installation SYSOPR authority and if the current SQLID is set to SYSINSTL, the function is identified as system-defined function.

If a user-defined type is referenced (as the data type of a parameter or an SQL variable), the privilege set must also include at least one of the following:
• Ownership of the user-defined type
• The USAGE privilege on the user-defined type
• SYSTEM DBADM authority
• DATAACCESS AUTHORITY
• SYSADM authority

If the function uses a table as a parameter, the privilege set must also include at least one of the following:
• Ownership of the table
• The SELECT privilege on the table
• DATAACCESS authority
• SYSADM authority

Additional authorization may be required on the SYSDUMMYx tables depending on the content of the function definition. See SYSDUMMYx tables.

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the package owner is a role, the implicit schema match does not apply and this role needs to include one of the previously listed conditions.

If the statement is dynamically prepared and is not running in a trusted context for which the ROLE AS OBJECT OWNER clause is specified, the privilege set is the set of privileges that are held by the SQL authorization ID of the process. If the schema name is not the same as the SQL authorization ID of the process, one of the following conditions must be met:
• The privilege set includes SYSADM or SYSCTRL authority.
• The SQL authorization ID of the process has the CREATEIN privilege on the schema.

When CREATE FUNCTION is issued in a trusted context that has the ROLE AS OBJECT OWNER clause, the package owner is determined as follows:
• If the PACKAGE OWNER option is not specified, the role associated with the binder becomes the package owner.
• If the PACKAGE OWNER option is specified, the role specified in the PACKAGE OWNER option becomes the package owner. In a trusted context, the PACKAGE OWNER specified must be a role.
If you specify the WLM ENVIRONMENT FOR DEBUG MODE clause, RACF or an external security product is invoked to check the required authority for defining programs in the WLM environment. If the WLM environment access is protected in RACF, the privilege set must include the required authority.

At least one of the following additional privileges is required if the SECURED option is specified

- SECADM authority
- CREATE_SECURE_OBJECT privilege

**Syntax**

```
CREATE FUNCTION function-name (parameter-declaration)

function-definition

WRAPPED obfuscated-statement-text
```

**parameter-declaration:**

```
parameter-name parameter-type
```

**parameter-type:**

```
data-type

TABLE LIKE table-name AS LOCATOR

view-name
```

**data-type:**

```
built-in-type

distinct-type-name

array-type-name
```

**built-in-type:**
SQL-routine-body:

```
  SQL-control-statement
```

**option-list:** (The options in the *option-list* can be specified in any order, but each one can only be specified one time)
Description

function-name

Names the function. If function-name already exists with the specified signature, an error is returned even if VERSION is specified with a routine-version-id that is different from any existing version identifier for the function that is specified in function-name. For more information, see “Choosing the schema and function names” and “Determining the uniqueness of functions in a schema” in CREATE FUNCTION.

(parameter-declaration,...)

Specifies the number of input parameters of the function and the name and data type of each parameter. Each parameter-declaration specifies an input parameter for the function. A function can have zero or more input parameters. There must be one entry in the list for each parameter that the function expects to receive. All of the parameters for a function are input parameters and are nullable. If the function has more than 30 parameters, only the first 30 parameters are used to determine if the function is unique.

parameter-name

Specifies the name of the input parameter. The name is an SQL identifier, and each name in the parameter list must not be the same as any other name.

data-type

Specifies the data type of the input parameter. The data type can be a built-in data type or a user-defined type.

built-in-type

The data type of the input parameter is a built-in data type.

For information on the data types, see built-in-type.

For parameters with a character or graphic data type, the PARAMETER CCSID clause or CCSID clause indicates the encoding scheme of the parameter. If you do not specify either of these clauses, the encoding scheme is the value of field DEF ENCODING SCHEME on installation panel DSNTIPF.

distinct-type-name

The data type of the input parameter is a distinct type. Any length, precision, scale, subtype, or encoding scheme attributes for the parameter are those of the source type of the distinct type. The distinct type must not be based on a LOB data type.

If you specify the name of the distinct type without a schema name, Db2 resolves the distinct type by searching the schemas in the SQL path.

TABLE LIKE table-name AS LOCATOR

Specifies that the parameter is a transition table. However, when the function is invoked, the actual values in the transition table are not passed to the function. A single value is passed instead. This value is a locator for the table, which the function uses to access the columns of the transition table. The table that is identified can contain XML columns; however, the function cannot reference those XML columns.

A function with a table parameter can only be invoked from the triggered action of a trigger.
**array-type-name**

The data type of the input parameter is a user-defined array type.

If you specify `array-type-name` without a schema name, Db2 resolves the array type by searching the schemas in the SQL path.

The implicitly or explicitly specified encoding scheme of all of the parameters with a character or graphic string data type must be the same—either all ASCII, all EBCDIC, or all UNICODE.

Although parameters with a character data type have an implicitly or explicitly specified subtype (BIT, SBCS, or MIXED), the function program can receive character data of any subtype. Therefore, conversion of the input data to the subtype of the parameter might occur when the function is invoked. An error occurs if mixed data that actually contains DBCS characters is used as the value for an input parameter that is declared with an SBCS subtype.

Parameters with a datetime data type or a distinct type are passed to the function as a different data type:

- A datetime type parameter is passed as a character data type, and the data is passed in ISO format.
  
The encoding scheme for a datetime type parameter is the same as the implicitly or explicitly specified encoding scheme of any character or graphic string parameters. If no character or graphic string parameters are passed, the encoding scheme is the value of field DEF ENCODING SCHEME on installation panel DSNTIPF.

- A distinct type parameter is passed as the source type of the distinct type.

**RETURNS**

Identifies the output of the function.

`data-type2`

Specifies the data type of the output. The output is nullable.

The same considerations that apply to the data type of input parameter, as described under `data-type`, apply to the data type of the output of the function.

**VERSION routine-version-id**

Specifies the version identifier for the first version of the function that is to be generated. You can use an ALTER FUNCTION statement with the ADD VERSION clause or the BIND DEPLOY command to create additional versions of the function.

`routine-version-id`

An SQL identifier of up to 64 EBCDIC bytes that designates a version of a routine. The UTF-8 representation of the identifier must not exceed 122 bytes.

V1 is the default version identifier.

**LANGUAGE SQL**

Specifies that the function is written exclusively in SQL.

**SPECIFIC specific-name**

Specifies a unique name for the function. The name is implicitly or explicitly qualified with a schema name. The name, including the schema name, must not identify the specific name of another function that exists at the current server.
The unqualified form of `specific-name` is an SQL identifier. The qualified form is an SQL identifier (the schema name) followed by a period and an SQL identifier.

If you do not specify a schema name, it is the same as the explicit or implicit schema name of the function name (`function-name`). If you specify a schema name, it must be the same as the explicit or implicit schema name of the function name.

If you do not specify the SPECIFIC clause, the default specific name is the name of the function. However, if the function name does not provide a unique specific name or if the function name is a single asterisk, Db2 generates a specific name in the form of:

```
SQLxxxxxxxxxxxx
```

where `xxxxxxxxxxxx` is a string of 12 characters that make the name unique.

The specific name is stored in the SPECIFIC column of the SYSROUTINES catalog table. The specific name can be used to uniquely identify the function in several SQL statements (such as ALTER FUNCTION, COMMENT, DROP, GRANT, and REVOKE) and must be used in Db2 commands (START FUNCTION, STOP FUNCTION, and DISPLAY FUNCTION). However, the function cannot be invoked by its specific name.

**NOT DETERMINISTIC or DETERMINISTIC**

Specifies whether the function returns the same results each time that the function is invoked with the same input arguments.

**NOT DETERMINISTIC**

The function might not return the same result each time that the function is invoked with the same input arguments. The function depends on some state values that affect the results. Db2 uses this information to disable the merging of views and table expressions when processing SELECT and SQL data change statements that refer to this function. An example of a function that is not deterministic is one that generates random numbers.

NOT DETERMINISTIC must be specified explicitly or implicitly if the function program accesses a special register or invokes another function that is not deterministic. NOT DETERMINISTIC is the default.

**DETERMINISTIC**

The function always returns the same result function each time that the function is invoked with the same input arguments. An example of a deterministic function is a function that calculates the square root of the input. Db2 uses this information to enable the merging of views and table expressions for SELECT and SQL data change statements that refer to this function. DETERMINISTIC is not the default. If applicable, specify DETERMINISTIC to prevent non-optimal access paths from being chosen for SQL statements that refer to this function.

Db2 does not verify that the function program is consistent with the specification of DETERMINISTIC or NOT DETERMINISTIC.

**EXTERNAL ACTION or NO EXTERNAL ACTION**

Specifies whether the function takes an action that changes the state of an object that Db2 does not manage. An example of an external action is sending a message or writing a record to a file.
EXTERNAL ACTION
The function can take an action that changes the state of an object that Db2 does not manage.

Some SQL statements that invoke functions with external actions can result in incorrect results if parallel tasks execute the function. For example, if the function sends a note for each initial call to it, one note is sent for each parallel task instead of once for the function. Specify the DISALLOW PARALLEL clause for functions that do not work correctly with parallelism.

If you specify EXTERNAL ACTION, then Db2:
- Materializes the views and table expressions in SELECT and SQL data change statements that refer to the function. This materialization can adversely affect the access paths that are chosen for the SQL statements that refer to this function. Do not specify EXTERNAL ACTION if the function does not have an external action.
- Does not move the function from one task control block (TCB) to another between FETCH operations.
- Does not allow another function or stored procedure to use the TCB until the cursor is closed. This is also applicable for cursors declared WITH HOLD.

The only changes to resources made outside of Db2 that are under the control of commit and rollback operations are those changes made under RRS control.

EXTERNAL ACTION must be specified implicitly or explicitly specified if the SQL routine body invokes a function that is defined with EXTERNAL ACTION. EXTERNAL ACTION is the default.

NO EXTERNAL ACTION
The function does not take any action that changes the state of an object that Db2 does not manage. Db2 uses this information to enable the merging of views and table expressions for SELECT and SQL data change statements that refer to this function. If applicable, specify NO EXTERNAL ACTION to prevent non-optimal access paths from being chosen for SQL statements that refer to this function.

Although the scope of global variables are beyond the scope of the routine, global variables can be set in the routine body when NO EXTERNAL ACTION is specified.

Db2 does not verify that the function program is consistent with the specification of EXTERNAL ACTION or NO EXTERNAL ACTION.

MODIFIES SQL DATA, READS SQL DATA, or CONTAINS SQL
Specifies the classification of SQL statements and nested routines that this routine can execute or invoke. The database manager verifies that the SQL statements issued by the function, and all routines locally invoked by the routine, are consistent with this specification; the verification is not performed when nested remote routines are invoked. For the classification of each statement, see SQL statement data access classification for routines.

MODIFIES SQL DATA
Specifies that the function can execute any SQL statement except the statements that are not supported in functions. Do not specify MODIFIES SQL DATA when ALLOW PARALLEL is in effect.
If a MODIFIES SQL DATA function is invoked in a subselect, the results are unpredictable since the number of times the function is invoked will vary depending on the access plan used.

**Recommendation:** If you invoke a function defined with the MODIFIES SQL DATA option in a subselect, make sure that the SQL statements inside the function do not modify any object that is referenced by that subselect.

**READS SQL DATA**
- Specifies that the function can execute statements with a data access classification of READS SQL DATA, CONTAINS SQL, or NO SQL. The function cannot execute SQL statements that modify data.

**READS SQL DATA** is the default.

**CONTAINS SQL**
- Specifies that the function can execute only SQL statements with a data access classification of CONTAINS SQL or NO SQL. The function cannot execute SQL statements that read or modify data.

**CALLED ON NULL INPUT or RETURNS NULL ON NULL INPUT**
- Specifies whether the function is invoked if any of the input arguments is null at execution time.

**CALLED ON NULL INPUT**
- Specifies that the function is to be invoked if any, or if all, of the argument values are null. Specifying CALLED ON NULL INPUT means that the body of the function must be coded to test for null argument values.

**CALLED ON NULL INPUT** is the default.

**RETURNS NULL ON NULL INPUT**
- Specifies that the function is not invoked and returns the null value if any of the input argument values is null.

**STATIC DISPATCH**
- At function resolution time, Db2 chooses a function based on the static (or declared) types of the function parameters. **STATIC DISPATCH** is the default.

**ALLOW PARALLEL or DISALLOW PARALLEL**
- Specifies if the function can be run in parallel. The default is DISALLOW PARALLEL, if you specify one or more of the following clauses:
  - NOT DETERMINISTIC
  - EXTERNAL ACTION
  - MODIFIES SQL DATA

Otherwise, ALLOW PARALLEL is the default.

**ALLOW PARALLEL**
- Specifies that the function can be run in parallel.

**DISALLOW PARALLEL**
- Specifies that the function cannot be run in parallel.

**ALLOW DEBUG MODE, DISALLOW DEBUG MODE, or DISABLE DEBUG MODE**
- Specifies whether this version of the routine can be run in debugging mode. The default is determined using the value of the CURRENT DEBUG MODE special register.
ALLOW DEBUG MODE
Specifies that this version of the routine can be run in debugging mode.
When this version of the routine is invoked and debugging is attempted, a
WLM environment must be available.

DISALLOW DEBUG MODE
Specifies that this version of the routine cannot be run in debugging mode.
You can use an ALTER statement to change this option to ALLOW DEBUG
MODE for this initial version of the routine.

DISABLE DEBUG MODE
Specifies that this version of the routine can never be run in debugging
mode.
This version of the routine cannot be changed to specify ALLOW DEBUG
MODE or DISALLOW DEBUG MODE after this version of the routine has
been created or altered to use DISABLE DEBUG MODE. To change this
option, drop the routine and create it again using the option that you want.
An alternative to dropping and recreating the routine is to create a version
of the routine that uses the option that you want and making that version
the active version.

When DISABLE DEBUG MODE is in effect, the WLM ENVIRONMENT
FOR DEBUG MODE is ignored.

PARAMETER CCSID
Specifies that the encoding scheme for character or graphic string parameters is
ASCII, EBCDIC, or UNICODE. The default encoding scheme is the value that
is specified in the CCSID clauses of the parameter list or RETURNS clause, or
in the DEF ENCODING SCHEME field on installation panel DSNTIPF.

This clause provides a convenient way to specify the encoding scheme for
character or graphic string parameters. If individual CCSID clauses are
specified for individual parameters in addition to this PARAMETER CCSID
clause, the value that is specified in all of the CCSID clauses must be the same
value that is specified in this clause. This clause also specifies the encoding
scheme that is used for system-generated parameters of the routine, such as
message tokens and DBINFO.

If the data type for a parameter is a user-defined distinct type that is defined
as a character or graphic type string, the CCSID of the distinct type must be
the same as the value that is specified in this clause.

If the data type for a parameter is a user-defined array type that is defined
with character or graphic string array elements, or a character string array
index, the CCSID of these array attributes must be the same as the value that
is specified in this clause.

This clause also specifies the encoding scheme that will be used for
system-generated parameters of the routine.

QUALIFIER schema-name
Specifies the implicit qualifier that is used for unqualified object names that are
referred to in the procedure body. See Unqualified alias, index, JAR file,
sequence, table, trigger, and view names for information about how the default
for this option is determined.

PACKAGE OWNER authorization-name
Specifies the owner of the package that is associated with the version of the
routine. The SQL authorization ID of the process is the default value.
**ASUTIME**

Specifies the total amount of processor time, in CPU service units, that a single invocation of a routine can run. The value is unrelated to the ASUTIME column of the resource limit specification table.

When you are debugging a routine, setting a limit can be helpful in case the routine gets caught in a loop. For information on service units, see z/OS MVS Initialization and Tuning Guide.

**NO LIMIT**

Specifies that there is no limit on the service units.

**NO LIMIT** is the default.

**LIMIT integer**

The limit on the number of CPU service units is a positive integer in the range 1 - 2,147,483,647. If the procedure uses more service units than the specified value, Db2 cancels the procedure. The CPU cycles that are consumed by parallel tasks in a procedure do not contribute towards the specified ASUTIME LIMIT.

**INHERIT SPECIAL REGISTERS or DEFAULT SPECIAL REGISTERS**

Specifies how special registers are set on entry to the routine.

**INHERIT SPECIAL REGISTERS**

Specifies that the values of special registers are inherited, according to the rules that are listed in the table for characteristics of special registers in a routine in Table 48 on page 225.

**INHERIT SPECIAL REGISTERS** is the default.

**DEFAULT SPECIAL REGISTERS**

Specifies that special registers are initialized to the default values, as indicated by the rules in the table for characteristics of special registers in a routine in Table 48 on page 225.

**WLM ENVIRONMENT FOR DEBUG MODE name**

Specifies the WLM (workload manager) application environment that is used by Db2 when debugging the routine. The name of the WLM environment is an SQL identifier.

If you do not specify WLM ENVIRONMENT FOR DEBUG MODE, Db2 uses the default WLM-established stored procedure address space specified at installation time.

To define a routine that is to run in a specified WLM application environment, you must have the appropriate authority for the WLM application environment. For an example of a RACF command that provides this authorization, see Running stored procedures.

The WLM ENVIRONMENT FOR DEBUG MODE value is ignored when DISABLE DEBUG MODE is in effect.

**CURRENT DATA YES or CURRENT DATA NO**

Specifies whether to require data currency for read-only and ambiguous cursors when the isolation level of cursor stability is in effect. CURRENT DATA also determines whether block fetch can be used for distributed, ambiguous cursors.

**CURRENT DATA YES**

Specifies that data currency is required for read-only and ambiguous cursors. Db2 acquired page or row locks to ensure data currency. Block fetch is ignored for distributed, ambiguous cursors.
**CURRENT DATA NO**

Specifies that data currency is not required for read-only and ambiguous cursors. Block fetch is allowed for distributed, ambiguous cursors. Use of **CURRENT DATA NO** is not recommended if the routine attempts to dynamically prepare and execute a DELETE WHERE CURRENT OF statement against an ambiguous cursor after that cursor is opened. You receive a negative SQLCODE if your routine attempts to use a DELETE WHERE CURRENT OF statement for any of the following cursors:

- A cursor that is using block fetch
- A cursor that is using query parallelism
- A cursor that is positioned on a row that is modified by this or another application process

**CURRENT DATA NO** is the default.

**DEGREE**

Specifies whether to attempt to run a query using parallel processing to maximize performance.

- **1** Specifies that parallel processing should not be used.
  - 1 is the default.
- **ANY** Specifies that parallel processing can be used.

**CONCURRENT ACCESS RESOLUTION**

Specifies the whether processing uses only committed data or whether it will wait for commit or rollback of data that is in the process of being updated.

**WAIT FOR OUTCOME**

Specifies that processing will wait for the commit or rollback of data that is in the process of being updated.

**USE CURRENTLY COMMITTED**

Specifies that processing use the currently committed version of the data when data that is in the process of being updated is encountered. **USE CURRENTLY COMMITTED** is applicable on scans that access tables that are defined in universal table spaces with row or page level lock size.

When there is lock contention between a read transaction and an insert transaction, **USE CURRENTLY COMMITTED** is applicable to scans with isolation level CS or RS. Applicable scans include intent read scans for read-only and ambiguous queries and for updatable cursors. **USE CURRENTLY COMMITTED** is also applicable to scans initiated from WHERE predicates of UPDATE or DELETE statements and the subselect of INSERT statements.

When there is lock contention is between a read transaction and a delete transaction, **USE CURRENTLY COMMITTED** is applicable to scans with isolation level CS and when CURRENT DATA NO is specified.

**DYNAMICRULES**

Specifies the values that apply, at run time, for the following dynamic SQL attributes:

- The authorization ID that is used to check authorization
- The qualifier that is used for unqualified objects
- The source for application programming options that Db2 uses to parse and semantically verify dynamic SQL statements
DYNAMICRULES also specifies whether dynamic SQL statements can include GRANT, REVOKE, ALTER, CREATE, DROP, and RENAME statements.

In addition to the value of the DYNAMICRULES clause, the run time environment of a routine controls how dynamic SQL statements behave at run time. The combination of the DYNAMICRULES value and the run time environment determines the value for the dynamic SQL attributes. That set of attribute values is called the dynamic SQL statement behavior. The following values can be specified:

**RUN**
- Specifies that dynamic SQL statements are to be processed using run behavior.
- **RUN** is the default.

**BIND**
- Specifies that dynamic SQL statements are to be processed using bind behavior.

**DEFINEBIND**
- Specifies that dynamic SQL statements are to be processed using either define behavior or bind behavior.

**DEFINERUN**
- Specifies that dynamic SQL statements are to be processed using either define behavior or run behavior.

**INVOKEBIND**
- Specifies that dynamic SQL statements are to be processed using either invoke behavior or bind behavior.

**INVOKERUN**
- Specifies that dynamic SQL statements are to be processed using either invoke behavior or run behavior.

See “Authorization IDs and dynamic SQL” on page 102 for information on the effects of these options.

**APPLICATION ENCODING SCHEME**
- Specifies the default encoding scheme for SQL variables in static SQL statements in the routine body. The value is used for defining an SQL variable in a compound statement if the CCSID clause is not specified as part of the data type, and the PARAMETER CCSID routine option is not specified.

**ASCII**
- Specifies that the data is encoded using the ASCII CCSIDs of the server.

**EBCDIC**
- Specifies that the data is encoded using the EBCDIC CCSIDs of the server.

**UNICODE**
- Specifies that the data is encoded using the Unicode CCSIDs of the server.

See the ENCODING bind option in ENCODING bind option (Db2 Commands) for information about how the default for this option is determined.

**WITH EXPLAIN or WITHOUT EXPLAIN**
- Specifies whether information will be provided about how SQL statements in the routine will execute.
**WITHOUT EXPLAIN**

Specifies that information will not be provided about how SQL statements in the routine will execute.

You can get EXPLAIN output for a statement that is embedded in a routine that is specified using WITHOUT EXPLAIN by embedding the SQL statement EXPLAIN in the routine body. Otherwise, the value of the EXPLAIN option applies to all explainable SQL statements in the routine body, and to the fullselect portion of any DECLARE CURSOR statements.

**WITHOUT EXPLAIN** is the default.

**WITH EXPLAIN**

Specifies that information will be provided about how SQL statements in the routine will execute. Information is inserted into the table `owner.PLAN_TABLE`. `owner` is the authorization ID of the owner of the routine. Alternatively, the authorization ID of the owner of the routine can have an alias as `owner.PLAN_TABLE` that points to the base table, `PLAN_TABLE`. `owner` must also have the appropriate SELECT and INSERT privileges on that table. WITH EXPLAIN does not obtain information for statements that access remote objects. `PLAN_TABLE` must have a base table and can have multiple aliases with the same table name, `PLAN_TABLE`, but have different schema qualifiers. It cannot be a view or a synonym and should exist before the version is added or replaced. In all inserts to `owner.PLAN_TABLE`, the value of QUERYNO is the statement number that is assigned by Db2.

The WITH EXPLAIN option also populates two optional tables if they exist: DSN_STMTNT_TABLE and DSN_FUNCTION_TABLE. DSN_STMTNT_TABLE contains an estimate of the processing cost for an SQL statement. See Db2 Application Programming and SQL Guide for more information. DSN_FUNCTION_TABLE contains information about function resolution. See Db2 Application Programming and SQL Guide for more information.

For more information about the EXPLAIN statement, including a description of the tables that are populated by the WITH EXPLAIN option, see "EXPLAIN" on page 2059.

**WITH IMMEDIATE WRITE or WITHOUT IMMEDIATE WRITE**

Specifies whether immediate writes are to be done for updates that are made to group buffer pool dependent page sets or partitions. This option is only applicable for data sharing environments. The IMMEDWRITE subsystem parameter has no effect of this option. IMMEDWRITE bind option (Db2 Commands) shows the implied hierarchy of the IMMEDWRITE bind option (which is similar to this routine option) as it affects run time.

**WITHOUT IMMEDIATE WRITE**

Specifies that normal write activity is performed. Updated pages that are group buffer pool dependent are written at or before phase one of commit or at the end of abort for transactions that have been rolled back.

**WITHOUT IMMEDIATE WRITE** is the default.

**WITH IMMEDIATE WRITE**

Specifies that updated pages that are group buffer pool dependent are immediately written as soon as the buffer update completes. Updated pages are written immediately even if the buffer is updated during forward progress or during the rollback of a transaction. **WITH IMMEDIATE WRITE** might impact performance.
**ISOLATION LEVEL RR, RS, CS, or UR**

Specifies how far to isolate the routine from the effects of other running applications. For information about isolation levels, see *Managing Performance*.

- **RR** Specifies repeatable read.
- **RS** Specifies read stability.
- **CS** Specifies cursor stability. **CS** is the default.
- **UR** Specifies uncommitted read.

**OPTHINT string-constant**

Specifies whether query optimization hints are used for static SQL statements that are contained within the body of the routine.

`string-constant` is a character string of up to 128 bytes in length, which is used by the Db2 subsystem when searching the PLAN_TABLE for rows to use as input. The default value is an empty string, which indicates that the Db2 subsystem does not use optimization hints for static SQL statements.

Optimization hints are only used if optimization hints are enabled for your system. See *Db2 Installation Guide* for information about enabling optimization hints.

**SQL PATH**

 Specifies the SQL path that the Db2 subsystem uses to resolve unqualified user-defined data types, functions, and procedure names (in CALL statements) in the body of the routine. The default value is "SYSIBM", "SYSFUN", "SYSPROC", "SYSBMADM", and the value of the QUALIFIER option, which is the qualifier for the trigger that is the target of the statement. The maximum length of the SQL path is 2048 bytes. Db2 calculates the length by taking each `schema-name` that is specified and removing any trailing blanks from it, adding a delimiter on the left and right sides, and adding one comma after each schema name except for the last name. The length of the resulting string cannot exceed 2048 bytes.

`schema-name`

Identifies a schema. Db2 does not verify that the schema exists when the CREATE statement is processed. The same schema name should not appear more than one time in the list of schema names.

`SYSPUBLIC` must not be specified for the SQL path.

**SYSTEM PATH**

Specifies the schema names "SYSIBM", "SYSFUN", "SYSPROC", "SYSBMADM".

**SESSION_USER or USER**

Specifies the value of the SESSION_USER (or USER) special register. At the time the CREATE statement is processed, the actual length is included in the total length of the list of schema names that is specified for the SQL PATH option.

**REOPT**

Specifies if Db2 will determine the access path at run time by using the values of SQL variables or SQL parameters, parameter markers, and special registers.

- **NONE** Specifies that Db2 does not determine the access path at run time by using the values of SQL variables or SQL parameters, parameter markers, and special registers.
ALWAYS
Specifies that Db2 always determines the access path at run time each time an SQL statement is run. Do not specify REOPT ALWAYS with the WITH KEEP DYNAMIC or NODEFER PREPARE clauses.

ONCE
Specifies that Db2 determine the access path for any dynamic SQL statements only once, at the first time the statement is opened. This access path is used until the prepared statement is invalidated or removed from the dynamic statement cache and need to be prepared again.

QUERY ACCELERATION
Specifies whether a static SQL query is bound for acceleration, and if so, with what behavior.

NONE
Specifies that no static SQL query in the application is bound for acceleration or will be accelerated when the application is run.

ENABLE
Specifies that a static SQL query is bound for acceleration if it satisfies the acceleration criteria, including the cost and heuristics criteria. The query is routed to an accelerator when the application runs. Otherwise, if the static query does not satisfy the acceleration criteria, the query is bound for execution in Db2.

If an error condition, such as one of the following examples, occurs while executing the accelerated static query when the application is run, Db2 fails the static query and returns a negative SQL code to the application:

- A failure occurs while running the static query on the accelerator.
- The accelerator returns an error for the query.
- The accelerator is not started and Db2 cannot route the static query to the accelerator for execution.

ENABLE WITH FAILBACK
Results in the same behavior as ENABLE, except if one of the error conditions occurs on the first OPEN of the accelerated static query when the application is run. In this case, instead of failing the static query and returning a negative SQL code to the application, Db2 performs a temporary statement-level incremental bind of the query and runs the query in Db2. The application does not see the acceleration failure. Failback to Db2 is not possible after the application does a successful OPEN for the query on the accelerator.

ELIGIBLE
Specifies that a static SQL query is bound for acceleration if the query meets the basic acceleration criteria, regardless of the cost or heuristics criteria. The query is routed to the accelerator when the application runs.

Like the behavior for ENABLE, if an error condition occurs while executing the accelerated static query when the application is run, Db2 fails the static query and returns a negative SQL code to the application.

ALL
Specifies that all of the static SQL queries in the application are to be bound for acceleration and routed to the accelerator when the application runs. If Db2 determines that a static query cannot be bound to run on the accelerator and the query references a user base table or view, the BIND or
REBIND PACKAGE operation fails with an error message for that query. (A failure exception is made for declared global temporary tables (DGTTs) and created global temporary tables and (CGTTs) because these tables cannot be accelerated.)

Like the behavior for ENABLE, if an error condition occurs while executing the accelerated static query when the application is run, Db2 fails the static query and returns a negative SQL code to the application.

This bind option does not apply to a fullselect or WITH common-table-expression that is specified in a RETURN statement for the routine, or in a SET host-variable-assignment that is used in the routine. The queries that are specified in these cases cannot be accelerated.

GET_ACCEL_ARCHIVE  
Specifies whether a static SQL query that is bound for acceleration retrieves archived data on the accelerator, instead of active data.  

NO  Specifies that no static SQL query is bound to retrieve archived data from the accelerator. If the static query also is not bound for acceleration, the query is bound to run in Db2.  

If the static query is bound for acceleration because the QUERYACCELERATION bind option was specified, the query is routed to the accelerator when the application runs; however, the query does not retrieve any archived data.  

YES  Specifies that if all of the following criteria are met, the query is bound for acceleration and retrieves the archived data on the accelerator when the application runs:  
• The QUERYACCELERATION bind option is also specified.  
• The static SQL query references an accelerated table that has partitioned data archived on an accelerator.  
• The static query satisfies the acceleration criteria that is specified by the QUERYACCELERATION bind option.  

If the static query does not satisfy the acceleration criteria that is specified by the QUERYACCELERATION bind option, the BIND or REBIND PACKAGE operation fails with an error message for that query.

This bind option does not apply to a fullselect or WITH common-table-expression that is specified in a RETURN statement for the routine, or in a SET host-variable-assignment that is used in the routine. The queries that are specified in these cases cannot be accelerated.

ACCELERATOR  
Specifies an accelerator server that, if enabled and available, Db2 will consider sending eligible SQL queries to before sending the queries to other accelerator servers. If the specified accelerator server is not enabled or available, Db2 will consider sending the queries to other available accelerator servers.

VALIDATE RUN or VALIDATE BIND  
Specifies whether to recheck, at run time, errors of the type "OBJECT NOT FOUND" and "NOT AUTHORIZED" that are found during bind or rebind. The option has no effect if all objects and needed privileges exist.

VALIDATE RUN  
Specifies that if needed objects or privileges do not exist when the
CREATE statement is processed, warning messages are returned, but the
CREATE statement succeeds. The Db2 subsystem rechecks for the objects
and privileges at run time for those SQL statements that failed the checks
during processing of the CREATE statement. The authorization checks the
use of the authorization ID of the owner of the routine.

**VALIDATE RUN** is the default.

**VALIDATE BIND**
Specifies that if needed objects or privileges do not exist at the time the
CREATE statement is processed, an error is issued and the CREATE
statement fails.

**ROUNDING**
Specifies the rounding mode for manipulation of DECFLOAT data. The default
value is taken from the DEFAULT DECIMAL FLOATING POINT ROUNDMODE in DECP.

**DEC_ROUND_CEILING**
Specifies numbers are rounded towards positive infinity.

**DEC_ROUND_DOWN**
Specifies numbers are rounded towards 0 (truncation).

**DEC_ROUND_FLOOR**
Specifies numbers are rounded towards negative infinity.

**DEC_ROUND_HALF_DOWN**
Specifies numbers are rounded to nearest; if equidistant, round down.

**DEC_ROUND_HALF_EVEN**
Specifies numbers are rounded to nearest; if equidistant, round so that the
final digit is even.

**DEC_ROUND_HALF_UP**
Specifies numbers are rounded to nearest; if equidistant, round up.

**DEC_ROUND_UP**
Specifies numbers are rounded away from 0.

**DATE FORMAT ISO, EUR, USA, JIS, or LOCAL**
Specifies the date format for result values that are string representations of
date or time values. See "String representations of datetime values" on page
130 for more information.

The default format is specified in the DATE FORMAT field of installation panel
DSNTIP4 of the system where the routine is defined. You cannot use the
LOCAL option unless you have a date exit routine.

**DECIMAL(15), DECIMAL(31), DECIMAL(15,s), or DECIMAL(31,s)**
Specifies the maximum precision that is to be used for decimal arithmetic
operations. See "Arithmetic with two decimal operands" on page 261 for more
information. The default format is specified in the DECIMAL ARITHMETIC
field of installation panel DSNTIPF of the system where the routine is defined.
If the form **pp.s** is specified, **s** must be a number between 1 and 9. **s** represents
the minimum scale that is to be used for division.

**FOR UPDATE CLAUSE OPTIONAL or FOR UPDATE CLAUSE REQUIRED**
Specifies whether the FOR UPDATE clause is required for a DECLARE
cursor statement if the cursor is to be used to perform positioned updates.
FOR UPDATE CLAUSE REQUIRED

Specifies that a FOR UPDATE clause must be specified as part of the cursor definition if the cursor will be used to make positioned updates.

FOR UPDATE CLAUSE REQUIRED is the default.

FOR UPDATE CLAUSE OPTIONAL

Specifies that the FOR UPDATE clause does not need to be specified in order for a cursor to be used for positioned updates. The routine body can include positioned UPDATE statements that update columns that the user is authorized to update.

The FOR UPDATE clause with no column list applies to static or dynamic SQL statements. Even if you do not use this clause, you can specify FOR UPDATE OF with a column list to restrict updates to only the columns that are identified in the FOR UPDATE clause and to specify the acquisition of update locks.

TIME FORMAT ISO, EUR, USA, JIS, or LOCAL

Specifies the time format for result values that are string representations of date or time values. See “String representations of datetime values” on page 130 for more information.

The default format is specified in the TIME FORMAT field of installation panel DSNTIP4 of the system where the routine is defined. You cannot use the LOCAL option unless you have a date exit routine.

NOT SECURED or SECURED

Specifies if the function is considered secure for row access control and column access control. The SECURED or NOT SECURED option applies to all future versions of the function.

NOT SECURED

Specifies that the function is not considered secure for row access control and column access control.

NOT SECURED is the default.

When the function is invoked, the arguments of the function must not reference a column for which a column mask is enabled when the table is using active column access control.

SECURED

Specifies that the function is considered secure for row access control and column access control.

The function must be secure when it is referenced in a row permission or a column mask.

BUSINESS_TIME SENSITIVE

Determines whether references to application-period temporal tables in both static and dynamic SQL statements are affected by the value of the CURRENT TEMPORAL BUSINESS_TIME special register.

YES

References to application-period temporal tables are affected by the value of the CURRENT TEMPORAL BUSINESS_TIME special register. YES is the default value.

NO

References to application-period temporal tables are not affected by the value of the CURRENT TEMPORAL BUSINESS_TIME special register.
Related information:

**CURRENT TEMPORAL BUSINESS_TIME**

**SYSTEM_TIME SENSITIVE**
Determines whether references to system-period temporal tables in both static and dynamic SQL statements are affected by the value of the CURRENT TEMPORAL SYSTEM_TIME special register.

**YES**
References to system-period temporal tables are affected by the value of the CURRENT TEMPORAL SYSTEM_TIME special register. YES is the default value.

**NO**
References to system-period temporal tables are not affected by the value of the CURRENT TEMPORAL SYSTEM_TIME special register.

Related information:

**CURRENT TEMPORAL SYSTEM_TIME**

**ARCHIVE SENSITIVE**
Determines whether references to archive-enabled tables in SQL statements are affected by the value of the SYSIBMADM.GET_ARCHIVE global variable.

**YES**
References to archive-enabled tables are affected by the value of the SYSIBMADM.GET_ARCHIVE global variable. YES is the default value.

**NO**
References to archive-enabled tables are not affected by the value of the SYSIBMADM.GET_ARCHIVE global variable.

Related information:

**Built-in global variables**

**APPLCOMPAT applcompat-value**
Specifies the application compatibility level behavior for static SQL statements in the package. If this option is not specified, the behavior is determined by the APPLCOMPAT subsystem parameter. The following applcompat-value values can be specified:

**function-level**
Specifies the application compatibility behavior of the function-level function level. The equivalent function level or higher must be activated. The format of a function level identifier is VvnRrrMmmmm, where vv is the version, rr is the release, and mmmm is the modification level. For example:

- **V12R1M501**
  Identifies compatibility with a specific available function level, in this case, function level 501.

- **V12R1M500**
  Identifies compatibility with the function level that enables new function in the initial Db2 12 release. V12R1M500 is the same as V12R1.

- **V12R1M100**
  Identifies compatibility with the function level before you activate new function, after migration to Db2 12, function level 100. V12R1M100 is the same as V11R1.

For a list of supported function-level values, see [What’s new in Db2 12 function levels (Db2 for z/OS What’s New?)](#).

Chapter 7. Statements 1551
V11R1
Specifies Db2 11 compatibility behavior.

V10R1
Specifies DB2 10 compatibility behavior.

CONCENTRATE STATEMENTS OFF or CONCENTRATE STATEMENTS WITH LITERALS
Specifies whether each dynamic SQL statement in the routine that specifies literal constants will be cached as a separate unique statement entry in the dynamic statement cache, instead of sharing an existing statement in the cache. Dynamic SQL statements are eligible to share an existing statement in the cache if the new statement meets all of the conditions for sharing a cached version of the same dynamic statement, except that the new statement specifies one or more literal constants that are different than the cached statement.

CONCENTRATE STATEMENTS OFF
Specifies that each dynamic SQL statement that specifies literal constants will be cached as a unique statement entry if it specifies one or more constants that are different than the cached version of the same dynamic statement. CONCENTRATE STATEMENTS OFF is the default dynamic statement caching behavior.

CONCENTRATE STATEMENTS WITH LITERALS
Specifies that each dynamic SQL statement that specifies literal constants will share a cached version of the same dynamic statement that is also prepared using the CONCENTRATE STATEMENTS WITH LITERALS option, if the new dynamic statement meets all of the conditions for sharing the cached statement, and the constants that are specified can be reused in place of the constants in the cached statement.

SQL-routine-body
Specifies a single SQL control statement, including a compound-statement. See SQL control statements for SQL routines and triggers for more information about defining SQL functions.

An error is issued if an SQL function calls a procedure and the procedure issues a COMMIT, ROLLBACK, CONNECT, RELEASE, or SET CONNECTION statement.

If the SQL-routine-body is a compound statement, it must contain at least one RETURN statement and a RETURN statement must be executed when the function is invoked.

SQL-routine-body must not contain a period specification or period clause.

An ALTER FUNCTION (compiled SQL scalar) statement or an ALTER PROCEDURE (SQL native) statement with an ADD VERSION clause or a REPLACE clause is not allowed in an SQL-routine-body.

WRAPPED obfuscated-statement-text
Specifies the encoded definition of the function. A CREATE FUNCTION statement can be encoded using the WRAP scalar function.

WRAPPED must not be specified on a static CREATE statement.

Notes
Considerations for all types of user-defined functions:
For considerations that apply to all types of user-defined functions, see CREATE FUNCTION.
Types of SQL scalar functions:
If the syntax of the CREATE FUNCTION statement conforms to the syntax diagrams and descriptions for CREATE FUNCTION (inlined SQL scalar), Db2 defines an inlined function, and a package is not created. When an inlined SQL scalar function is invoked, the expression in the RETURN statement of the function is copied (inlined) into the query itself; the function is not invoked. The attributes of an inlined SQL scalar function are described in "CREATE FUNCTION (inlined SQL scalar)" on page 1599.

Otherwise, Db2 attempts to define a compiled function with an associated package. For example, if the RETURN statement contains a scalar fullselect, Db2 attempts to define a compiled function. The attributes of a compiled SQL scalar function are described in "CREATE FUNCTION (compiled SQL scalar)" on page 1530.

To determine what type of SQL scalar function is created, refer to the INLINE column of the SYSIBM.SYSROUTINES catalog table. In the INLINE column, a value of Y indicates that the function is an inlined function, and a value of N indicates that the function is a compiled function.

Considerations for functions defined with MODIFIES SQL DATA:
If a function is specified in a subselect, and the function is defined as MODIFIES SQL DATA, the number of times the function is invoked is invoked will vary depending on the access plan used.

Self-referencing function:
The body of an SQL function (that is, the expression or NULL in the RETURN statement in the body of the CREATE FUNCTION statement) cannot contain a recursive invocation of itself or to another function that invokes it, because such a function would not exist to be referenced.

Dependent objects:
An SQL routine is dependent on objects that are referenced in the routine body.

Obfuscated statements:
A CREATE FUNCTION statement can be executed in obfuscated form. In an obfuscated statement, only the function name, parameters, and the WRAPPED keyword are readable. The rest of the statement is encoded in such a way that it is not readable but can be decoded by a database server that supports obfuscated statements. The WRAP scalar function produces obfuscated statements. Any debug options that are specified when the function is created from an obfuscated statement are ignored.

Identifier resolution:
See Chapter 8, "SQL control statements for SQL routines and triggers," on page 2371 for information on how names are resolved to columns, variables, or SQL parameters within an SQL routine.

If duplicate names are used for columns, variables, and parameters, qualify the duplicate names by using the table designator for columns, the routine name for parameters, the label name for SQL variables, and the schema name for global variables.

Error handling in SQL functions:
You should consider the possible exceptions that can occur for each SQL statement in the body of a compiled SQL function. Any exception SQLSTATE that is not handled within the function (using a handler),
results in the exception SQLSTATE being returned for the SQL statement that caused the function to be invoked.

**Lines within the SQL function definition:**

When a compiled SQL function is created, information is retained on lines in the CREATE statement. Lines are determined by the presence of the new line control character.

In a compiled SQL scalar function, a *new line control character* is a special character that is used for a new line. The new line control characters for a compiled SQL scalar function include:

- Line feed
- New line
- Carriage return
- Carriage return, followed by a line feed
- Carriage return, followed by a new line

For more information about control characters, see [Tokens](#).

**Considerations for SQL processor programs:**

SQL processor programs, such as SPUFI, the command line processor, and DSNTEP2, might not correctly parse SQL statements in the routine body that end with semicolons. These processor programs accept multiple SQL statements as input, with each statement separated with a terminator character. Processor programs that use a semicolon as the SQL statement terminator can truncate a CREATE FUNCTION statement with embedded semicolons and pass only a portion of it to Db2. Therefore, you might need to change the SQL terminator character for these processor programs. For information on changing the terminator character for SPUFI and DSNTEP2, see [Setting the SQL terminator character in a SPUFI input data set](#) (Db2 Application programming and SQL).

**Considerations for packages:**

A package is generated for compiled SQL scalar functions. The package that is associated with the first version of a function is named as follows:

- *location* is set to the value of the CURRENT SERVER special register.
- *collection-id* (schema) for the package is the same as the schema qualifier of the function.
- *package-id* is the same as the specific name of the function.
- *version-id* is the same as the version identifier for the initial version of the function.

The package is generated using the bind options that correspond to the implicitly or explicitly specified function options. In addition to the corresponding bind options, the package is generated using the following bind options:

- **FLAG(I)**
- **SQLERROR(NOPACKAGE)**
- **ENABLE(*)**

**Correspondence of function options to bind command options:**

The following table lists options for CREATE FUNCTION and ALTER FUNCTION and the corresponding bind command option. See [BIND and REBIND options for packages, plans, and services](#) (Db2 Commands) for information about the BIND command options.

Deploying a compiled SQL scalar function:

When a BIND DEPLOY command is issued to deploy a compiled SQL
scalar function to a target location, the SECURED and NOT SECURED options are included in the deployment process.

When deploying a compiled SQL scalar function, if a function with the same target name does not exist at the target location, the deployed function is created as a new function at the target location with the same SECURED or NOT SECURED option that is specified (or the default of NOT SECURED is used) in the source of the deployment.

When deploying a compiled SQL scalar function, if a function with the same target name already exists at the target location, the deployed function is either added as a new version of the function, or the deployed function is used to replace an existing version of the function. The SECURED or NOT SECURED option of the deployed function must be the same as that of the existing function at the target location.

Versions of a function:
The CREATE FUNCTION statement for an SQL function defines the initial version of the function. You can define additional versions using the ADD VERSION clause of the ALTER FUNCTION statement. All versions of a function share the same function signature and the same specific name. However, the parameters names can differ between versions of a function. Only one version of the function can be considered to be the active version of the function.

Alternative syntax and synonyms:
To provide compatibility with previously releases of Db2 or other products in the Db2 family, Db2 supports the following alternative syntax:

- VARIANT as a synonym for NOT DETERMINISTIC
- NOT VARIANT as a synonym for DETERMINISTIC
- NOT NULL CALL as a synonym for RETURNS NULL ON NULL INPUT
- NULL CALL as a synonym for CALLED ON NULL INPUT
- TIMEZONE can be specified as an alternative to TIME ZONE.

Examples

Example: Define a scalar function that returns the text of an input string, in reverse order:

```
CREATE FUNCTION REVERSE(INSTR VARCHAR(4000))
RETURNS VARCHAR(4000)
DETERMINISTIC NO EXTERNAL ACTION CONTAINS SQL
BEGIN
DECLARE REVSTR, RESTSTR VARCHAR(4000) DEFAULT '';
DECLARE LEN INT;
IF INSTR IS NULL THEN
RETURN NULL;
END IF;
SET (RESTSTR, LEN) = (INSTR, LENGTH(INSTR));
WHILE LEN > 0 DO
SET (REVSTR, RESTSTR, LEN)
= (SUBSTR(RESTSTR, 1, 1) CONCAT REVSTR,
SUBSTR(RESTSTR, 2, LEN - 1),
LEN - 1);
END WHILE;
RETURN REVSTR;
END#
```
CREATE FUNCTION (external scalar)

This CREATE FUNCTION statement registers a user-defined external scalar function with a database server. A scalar function returns a single value each time it is invoked.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

Authorization

The privilege set defined below must include at least one of the following:

- The CREATEIN privilege on the schema
- SYSADM or SYSCTRL authority
- System DBADM
- Installation SYSOPR authority (when the current SQLID of the process is set to SYSINSTL)

The authorization ID that matches the schema name implicitly has the CREATEIN privilege on the schema.

If the authorization ID that is used to create the function has the installation SYSADM authority or the installation SYSOPR authority and if the current SQLID is set to SYSINSTL, the function is identified as system-defined function.

Additional privileges are required if the function uses a table as a parameter, refers to a distinct type, or is to run in a WLM (workload manager) environment. These privileges are:

- The SELECT privilege on any table that is an input parameter to the function.
- The USAGE privilege on each distinct type that the function references.
- Authority to create programs in the specified WLM environment. This authorization is obtained from an external security product, such as RACF.

At least one of the following additional privileges is required if the SECURED option is specified

- SECADM authority
- CREATE_SECURE_OBJECT privilege

When LANGUAGE is JAVA and a jar-name is specified in the EXTERNAL NAME clause, the privilege set must include USAGE on the JAR file.

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the owner is a role, the implicit schema match does not apply and this role needs to include one of the previously listed conditions.

If the statement is dynamically prepared and is not running in a trusted context for which the ROLE AS OBJECT OWNER clause is specified, the privilege set is the set of privileges that are held by the SQL authorization ID of the process. If the schema name is not the same as the SQL authorization ID of the process, one of the following conditions must be met:
- The privilege set includes SYSADM or SYSCTRL authority.
- The SQL authorization ID of the process has the CREATEIN privilege on the schema.

**Syntax**

```
CREATE FUNCTION function-name (parameter-declaration)
RETURNS data-type2 AS LOCATOR data-type3
  AS LOCATOR FROM data-type4

Notes:
1. This clause and the clauses that follow in the option-list can be specified in any order.
2. AS LOCATOR can be specified only for a LOB data type or a distinct type based on a LOB data type.
```

**parameter-declaration:**

```
parameter-name AS LOCATOR TABLE LIKE table-name AS LOCATOR
  view-name

Notes:
1. AS LOCATOR can be specified only for a LOB data type or a distinct type based on a LOB data type.
```

**data-type:**

```
built-in-type
distinct-type-name
```

**built-in-type:**
option-list: (The clauses in the option list can be specified in any order)
Notes:

1. The same clause must not be specified more than one time.

2. If NOT DETERMINISTIC, EXTERNAL ACTION, SCRATCHPAD, or FINAL CALL is specified, DISALLOW PARALLEL is the default.
**Description**

*function-name*

Names the user-defined function. The name is implicitly or explicitly qualified by a schema name. For more information, see “Choosing the schema and function names” and “Determining the uniqueness of functions in a schema” in CREATE FUNCTION

*parameter-declaration,...*)

Identifies the number of input parameters of the function, and specifies the data type of each parameter. All of the parameters for a function are input parameters and are nullable. There must be one entry in the list for each parameter that the function expects to receive. Although not required, you can give each parameter a name.

A function can have no parameters. In this case, you must code an empty set of parentheses, for example:

```
CREATE FUNCTION WOOFER()
```
**parameter-name**

Specifies the name of the input parameter. The name is an SQL identifier, and each name in the parameter list must not be the same as any other name.

**data-type**

Specifies the data type of the input parameter. The data type can be a built-in data type or a distinct type.

**built-in-type**

The data type of the input parameter is a built-in data type.

For information on the data types, see [built-in-type](#). For parameters with a character or graphic data type, the \texttt{PARAMETER CCSID} clause or \texttt{CCSID} clause indicates the encoding scheme of the parameter. If you do not specify either of these clauses, the encoding scheme is the value of field DEF ENCODING SCHEME on installation panel DSNTIPF.

**distinct-type-name**

The data type of the input parameter is a distinct type. Any length, precision, scale, subtype, or encoding scheme attributes for the parameter are those of the source type of the distinct type.

If you specify the name of the distinct type without a schema name, Db2 resolves the schema name by searching the schemas in the SQL path.

The implicitly or explicitly specified encoding scheme of all of the parameters with a character or graphic string data type must be the same—either all ASCII, all EBCDIC, or all UNICODE.

Although parameters with a character data type have an implicitly or explicitly specified subtype (BIT, SBCS, or MIXED), the function program can receive character data of any subtype. Therefore, conversion of the input data to the subtype of the parameter might occur when the function is invoked. An error occurs if mixed data that actually contains DBCS characters is used as the value for an input parameter that is declared with an SBCS subtype.

Parameters with a datetime data type or a distinct type are passed to the function as a different data type:

- A datetime type parameter is passed as a character data type, and the data is passed in ISO format.

  The encoding scheme for a datetime type parameter is the same as the implicitly or explicitly specified encoding scheme of any character or graphic string parameters. If no character or graphic string parameters are passed, the encoding scheme is the value of field DEF ENCODING SCHEME on installation panel DSNTIPF.

- A distinct type parameter is passed as the source type of the distinct type.

**AS LOCATOR**

Specifies that a locator to the value of the parameter is passed to the function instead of the actual value. Specify AS LOCATOR only for parameters with a LOB data type or a distinct type based on a LOB data type. Passing locators instead of values can result in fewer bytes being passed to the function, especially when the value of the parameter is very large.
The AS LOCATOR clause has no effect on determining whether data types can be promoted, nor does it affect the function signature, which is used in function resolution.

**TABLE LIKE table-name or view-name AS LOCATOR**

Specifies that the parameter is a transition table. However, when the function is invoked, the actual values in the transition table are not passed to the function. A single value is passed instead. This single value is a locator to the table, which the function uses to access the columns of the transition table. A function with a table parameter can only be invoked from the triggered action of a trigger.

The use of TABLE LIKE provides an implicit definition of the transition table. It specifies that the transition table has the same number of columns as the identified table or view. If a table is specified, the transition table includes columns that are defined as implicitly hidden in the table. The columns have the same data type, length, precision, scale, subtype, and encoding scheme as the identified table or view, as they are described in catalog tables SYSCOLUMNS and SYSTABLESPACE. The number of columns and the attributes of those columns are determined at the time the CREATE FUNCTION statement is processed. Any subsequent changes to the number of columns in the table or the attributes of those columns do not affect the parameters of the function.

*table-name or view-name* must identify a table or view that exists at the current server. A view cannot have columns of length 0. The name must not identify a declared temporary table. The table that is identified can contain XML columns; however, the function cannot reference those XML columns. The name does not have to be the same name as the table that is associated with the transition table for the trigger. An unqualified table or view name is implicitly qualified according to the following rules:

- If the CREATE FUNCTION statement is embedded in a program, the implicit qualifier is the authorization ID in the QUALIFIER bind option when the plan or package was created or last rebound. If QUALIFIER was not used, the implicit qualifier is the owner of the plan or package.
- If the CREATE FUNCTION statement is dynamically prepared, the implicit qualifier is the SQL authorization ID in the CURRENT SCHEMA special register.

When the function is invoked, the corresponding columns of the transition table identified by the table locator and the table or view identified in the TABLE LIKE clause must have the same definition. The data type, length, precision, scale, and encoding scheme of these columns must match exactly. The description of the table or view at the time the CREATE FUNCTION statement was executed is used.

Additionally, a character FOR BIT DATA column of the transition table cannot be passed as input for a table parameter for which the corresponding column of the table specified at the definition is not defined as character FOR BIT DATA. (The definition occurs with the CREATE FUNCTION statement.) Likewise, a character column of the transition table that is not FOR BIT DATA cannot be passed as input for a table parameter for which the corresponding column of the table specified at the definition is defined as character FOR BIT DATA.

For more information about using table locators, see *Db2 Application Programming and SQL Guide*. 

Chapter 7. Statements 1563
**RETURNS**

Specifies the data type for the result of the function. Consider this clause in conjunction with the optional CAST FROM clause.

*data-type2*

Specifies the data type of the output. The output parameter is nullable.

The same considerations that apply to the data type and nullability of input parameter, as described under *data-type*, apply to the data type of the result of the function.

**AS LOCATOR**

Specifies that the function returns a locator to the value rather than the actual value. You can specify AS LOCATOR only if the output from the function has a LOB data type or a distinct type based on a LOB data type.

*data-type3* **CAST FROM** *data-type4*

Specifies the data type of the output of the function (*data-type4*) and the data type in which that output is returned to the invoking statement (*data-type3*). The two data types can be different. For example, for the following definition, the function returns a DOUBLE value, which Db2 converts to a DECIMAL value and then passes to the statement that invoked the function:

```sql
CREATE FUNCTION SQRT(DECIMAL(15,0))
    RETURNS DECIMAL(15,0) CAST FROM DOUBLE
    ...
```

The value of *data-type4* can be any built-in data type and must be castable to *data-type3*. The value for *data-type3* can be any built-in data type. (For information on casting data types, see [Casting between data types](#).) The encoding scheme of the parameters, if they are string data types, must be the same.

If the PARAMETER VARCHAR clause is specified, *data-type3* and *data-type4* should be specified as VARCHAR.

**AS LOCATOR**

Specifies that the function returns a locator to the value rather than the value. You can specify AS LOCATOR only if *data-type4* is a LOB data type or a distinct type based on a LOB data type.

**SPECIFIC** *specific-name*

Specifies a unique name for the function. The name is implicitly or explicitly qualified with a schema name. The name, including the schema name, must not identify the specific name of another function that exists at the current server.

The unqualified form of *specific-name* is an SQL identifier. The qualified form is an SQL identifier (the schema name) followed by a period and an SQL identifier.

If you do not specify a schema name, it is the same as the explicit or implicit schema name of the function name (*function-name*). If you specify a schema name, it must be the same as the explicit or implicit schema name of the function name.

If you do not specify the SPECIFIC clause, the default specific name is the name of the function. However, if the function name does not provide a unique specific name or if the function name is a single asterisk, Db2 generates a specific name in the form of:
where 'xxxxxxxxxxxx' is a string of 12 characters that make the name unique.

The specific name is stored in the SPECIFIC column of the SYSROUTINES catalog table. The specific name can be used to uniquely identify the function in several SQL statements (such as ALTER FUNCTION, COMMENT, DROP, GRANT, and REVOKE) and must be used in Db2 commands (START FUNCTION, STOP FUNCTION, and DISPLAY FUNCTION). However, the function cannot be invoked by its specific name.

**PARAMETER CCSID or VARCHAR**

Specifies the encoding scheme for character and graphic string parameters, and in the case of LANGUAGE C, specifies that representation of variable length string parameters.

**CCSID**

Indicates whether the encoding scheme for character and graphic string parameters is ASCII, EBCDIC, or UNICODE. The default encoding scheme is the value specified in the CCSID clauses of the parameter list or RETURNS clause, or in the field DEF ENCODING SCHEME on installation panel DSNTIPF.

This clause provides a convenient way to specify the encoding scheme for all string parameters. If individual CCSID clauses are specified for individual parameters in addition to this PARAMETER CCSID clause, the value specified in all of the CCSID clauses must be the same value that is specified in this clause.

This clause also specifies the encoding scheme to be used for system-generated parameters of the routine such as message tokens and DBINFO.

**VARCHAR**

Specifies that the representation of the values of varying length character string-parameters, including, if applicable, the output of the function, for functions which specify LANGUAGE C.

This option can only be specified if LANGUAGE C is also specified.

**NULTERM**

Specifies that variable length character string parameters are represented in a NUL-terminated string form.

**STRUCTURE**

Specifies that variable length character string parameters are represented in a VARCHAR structure form.

Using the PARAMETER VARCHAR clause, there is no way to specify the VARCHAR form of an individual parameter as there is with the PARAMETER CCSID clause. The PARAMETER VARCHAR clause only applies to parameters in the parameter list of a function and in the RETURNS clause. It does not apply to system-generated parameters of the routine such as message tokens and DBINFO.

In a data sharing environment, you should not specify the PARAMETER VARCHAR clause until all members of the data sharing group support the clause. If some group members support this clause and others do not, and PARAMETER VARCHAR is specified in an external routine, the routine will encounter different parameter forms depending on which group member invokes the routine.
EXTERNAL

Specifies that the CREATE FUNCTION statement is being used to define a new function that is based on code that is written in an external programming language.

Db2 loads the load module when the function is invoked. The load module is created when the program that contains the function body is compiled and link-edited. The load module does not need to exist when the CREATE FUNCTION statement is executed. However, it must exist and be accessible by the current server when the function is invoked.

You can specify the EXTERNAL clause in one of the following ways:

| EXTERNAL
| EXTERNAL NAME PKJVSP1
| EXTERNAL NAME 'PKJVSP1'

If you specify an external program name, you must use the NAME keyword. For example, this syntax is not valid:

| EXTERNAL PKJVSP1

NAME external-program-name or identifier

Identifies the user-written code that implements the user-defined function.

If LANGUAGE is JAVA, external-program-name must be specified and enclosed in single quotation marks, with no extraneous blanks within the single quotation marks. It must specify a valid external-java-routine-name. If multiple external-program-names are specified, the total length of all of them must not be greater than 1305 bytes and they must be separated by a space or a line break. Do not specify a JAR file for a JAVA function for which NO SQL is also specified.

An external-java-routine-name contains the following parts:

jar-name

Identifies the name given to the JAR file when it was installed in the database. The name contains jar-id, which can optionally be qualified with a schema. Examples are "myJar" and "mySchema.myJar." The unqualified jar-id is implicitly qualified with a schema name according to the following rules:

- If the statement is embedded in a program, the schema name is the authorization ID in the QUALIFIER bind option when the package or plan was created or last rebound. If the QUALIFIER was not specified, the schema name is the owner of the package or plan.
- If the statement is dynamically prepared, the schema name is the SQL authorization ID in the CURRENT SCHEMA special register.

If jar-name is specified, it must exist when the CREATE FUNCTION statement is processed.

If jar-name is not specified, the function is loaded from the class file directly instead of being loaded from a JAR file. Db2 searches the directories in the CLASSPATH associated with the WLM Environment. Environmental variables for Java routines are specified in a data set identified in a JAVAENV DD card on the JCL used to start the address space for a WLM-managed function.

method-name

Identifies the name of the method and must not be longer than 254 bytes. Its package, class, and method ID's are specific to Java and as
such are not limited to 18 bytes. In addition, the rules for what these can contain are not necessarily the same as the rules for an SQL ordinary identifier.

package-id

Identifies a package. The concatenated list of package-ids identifies the package that the class identifier is part of. If the class is part of a package, the method name must include the complete package prefix, such as "myPacks.UserFuncs." The Java virtual machine looks in the directory "/myPacks/UserFuncs/" for the classes.

class-id

Identifies the class identifier of the Java object.

method-id

Identifies the method identifier with the Java class to be invoked.

method-signature

Identifies a list of zero or more Java data types for the parameter list and must not be longer than 1024 bytes. Specify the method-signature if the user-defined function involves any input or output parameters that can be NULL. When the function being created is called, Db2 searches for a Java method with the exact method-signature. The number of java-datatype elements specified indicates how many parameters that the Java method must have.

A Java procedure can have no parameters. In this case, you code an empty set of parentheses for method-signature. If a Java method-signature is not specified, Db2 searches for a Java method with a signature derived from the default JDBC types associated with the SQL types specified in the parameter list of the CREATE FUNCTION statement.

For other values of LANGUAGE, the name can be a string constant that is no longer than 8 characters. It must conform to the naming conventions for load modules. Alphabetical extenders for national languages can be used as the first character and as subsequent characters in the load module name.

If you do not specify the NAME clause, 'NAME function-name' is implicit. In this case, function-name must not be longer than 8 characters.

LANGUAGE

Specifies the language interface convention to which the body of the function is written. All programs must be designed to run in IBM’s Language Environment environment.

ASSEMBLE

The function is written in Assembler.

C

The function is written in C or C++.

COBOL

The function is written in COBOL, including the object-oriented language extensions.

JAVA

The user-defined function is written in Java and is executed in the Java Virtual Machine. When LANGUAGE JAVA is specified, the EXTERNAL NAME clause must also be specified with a valid external-java-routine-name and PARAMETER STYLE must be specified with JAVA.
Do not specify LANGUAGE JAVA when SCRATCHPAD, FINAL CALL, DBINFO, PROGRAM TYPE MAIN, or RUN OPTIONS is in effect.

**PLI**
The function is written in PL/I.

**PARAMETER STYLE**
Specifies the conventions for passing parameters to and returning a value from the function.

**SQL**
Specifies the parameter passing convention that supports passing null values both as input and for output. The parameters that are passed between the invoking SQL statement and the function include:

- $n$ parameters for the input parameters that are specified for the function
- A parameter for the result of the function
- $n$ parameters for the indicator variables for the input parameters
- A parameter for the indicator variable for the result
- The SQLSTATE to be returned to Db2
- The qualified name of the function
- The specific name of the function
- The SQL diagnostic string to be returned to Db2
- The function can also pass from zero to three additional parameters:
  - The scratchpad, if SCRATCHPAD is specified
  - The call type, if FINAL CALL is specified
  - The DBINFO structure, if DBINFO is specified

**JAVA**
Indicates that the user-defined function uses a convention for passing parameters that conforms to the Java and SQLJ specifications. PARAMETER STYLE JAVA can be specified only if LANGUAGE is specified as JAVA. JAVA must be specified for PARAMETER STYLE when LANGUAGE JAVA is specified.

**NOT DETERMINISTIC or DETERMINISTIC**
Specifies whether the function returns the same results each time that the function is invoked with the same input arguments.

**NOT DETERMINISTIC**
The function might not return the same result each time that the function is invoked with the same input arguments. The function depends on some state values that affect the results. Db2 uses this information to disable the merging of views and table expressions when processing SELECT or SQL data change statements that refer to this function. An example of a function that is not deterministic is one that generates random numbers, or any function that contains SQL statements.

NOT DETERMINISTIC is the default.

Some functions that are not deterministic can receive incorrect results if the function is executed by parallel tasks. Specify the DISALLOW PARALLEL clause for these functions.

**DETERMINISTIC**
The function always returns the same result each time that the function is invoked with the same input arguments. An example of a deterministic function is a function that calculates the square root of the input. Db2 uses
this information to enable the merging of views and table expressions for SELECT or SQL data change statements that refer to this function.

DETERMINISTIC is not the default. If applicable, specify DETERMINISTIC to prevent non-optimal access paths from being chosen for SQL statements that refer to this function.

Db2 does not verify that the function program is consistent with the specification of DETERMINISTIC or NOT DETERMINISTIC.

**FENCED**

Specifies that the external function runs in an external address space to prevent the function from corrupting Db2 storage.

FENCED is the default.

**RETURNS NULL ON NULL INPUT or CALLED ON NULL INPUT**

Specifies whether the function is called if any of the input arguments is null at execution time.

**RETURNS NULL ON NULL INPUT**

The function is not called if any of the input arguments is null. The result is the null value. RETURNS NULL ON INPUT is the default.

**CALLED ON NULL INPUT**

The function is called regardless of whether any of the input arguments are null, making the function responsible for testing for null argument values. The function can return a null or nonnull value.

**MODIFIES SQL DATA, READS SQL DATA, CONTAINS SQL, or NO SQL**

Specifies the classification of SQL statements and nested routines that this routine can execute or invoke. The database manager verifies that the SQL statements issued by the function, and all routines locally invoked by the routine, are consistent with this specification; the verification is not performed when nested remote routines are invoked. For the classification of each statement, see [SQL statement data access classification for routines](#).

**MODIFIES SQL DATA**

Specifies that the function can execute any SQL statement except the statements that are not supported in functions. Do not specify MODIFIES SQL DATA when ALLOW PARALLEL is in effect.

If a MODIFIES SQL DATA function is invoked in a subselect, the results are unpredictable since the number of times the function is invoked will vary depending on the access plan used.

**Recommendation:** If you invoke a function defined with the MODIFIES SQL DATA option in a subselect, make sure that the SQL statements inside the function do not modify any object that is referenced by that subselect.

**READS SQL DATA**

Specifies that the function can execute statements with a data access indication of READS SQL DATA, CONTAINS SQL, or NO SQL. The function cannot execute SQL statements that modify data. The default is READS SQL DATA.

**CONTAINS SQL**

Specifies that the function can execute only SQL statements with an access indication of CONTAINS SQL or NO SQL. The function cannot execute statements that read or modify data.
NO SQL
Specifies that the function can execute only SQL statements with a data access classification of NO SQL. Do not specify NO SQL for a JAVA function that uses a JAR file.

EXTERNAL ACTION or NO EXTERNAL ACTION
Specifies whether the function takes an action that changes the state of an object that Db2 does not manage. An example of an external action is sending a message or writing a record to a file.

Because Db2 uses the RRS attachment for external functions, Db2 can participate in two-phase commit with any other resource manager that uses RRS. For resource managers that do not use RRS, there is no coordination of commit or rollback operations on non-Db2 resources.

EXTERNAL ACTION
Specifies that the function can take an action that changes the state of an object that Db2 does not manage.

Some SQL statements that invoke functions with external actions can result in incorrect results if parallel tasks execute the function. For example, if the function sends a note for each initial call to it, one note is sent for each parallel task instead of once for the function. Specify the DISALLOW PARALLEL clause for functions that do not work correctly with parallelism.

If you specify EXTERNAL ACTION, Db2:

• Materializes the views and table expressions in SELECT or data change statements that refer to the function. This materialization can adversely affect the access paths that are chosen for the SQL statements that refer to this function. Do not specify EXTERNAL ACTION if the function does not have an external action.

• Does not move the function from one task control block (TCB) to another between FETCH operations.

• Does not allow another function or stored procedure to use the TCB until the cursor is closed. This is also applicable for cursors declared WITH HOLD.

The only changes to resources made outside of Db2 that are under the control of commit and rollback operations are those changes made under RRS control.

EXTERNAL ACTION is the default.

NO EXTERNAL ACTION
Specifies that the function does not take any action that changes the state of an object that Db2 does not manage. Db2 uses this information to enable the merging of views and table expressions for SELECT and data change statements that refer to this function. If applicable, specify NO EXTERNAL ACTION to prevent non-optimal access paths from being chosen for SQL statements that refer to this function.

Although the scope of global variables are beyond the scope of the routine, global variables can be set in the routine body when NO EXTERNAL ACTION is specified.

Db2 does not verify that the function program is consistent with the specification of EXTERNAL ACTION or NO EXTERNAL ACTION.
NO PACKAGE PATH or PACKAGE PATH package-path
Specifies the package path to use when the function is run. This is the list of the possible package collections into which the DBRM this is associated with the function is bound.

NO PACKAGE PATH
Specifies that the list of package collections for the function is the same as the list of package collection IDs for the program that invokes the function. If the program that invokes the function does not use a package, Db2 resolves the package by using the CURRENT PACKAGE PATH special register, the CURRENT PACKAGESET special register, or the PKLIST bind option (in this order). For information about how Db2 uses these three items, see Db2 Application Programming and SQL Guide.

PACKAGE PATH package-path
Specifies a list of package collections, in the same format as the SET CURRENT PACKAGE PATH special register.

If the COLLID clause is specified with PACKAGE PATH, the COLLID clause is ignored when the function is invoked.

The package-path value that is provided when the function is created is checked when the function is invoked. If package-path contains SESSION_USER (or USER), PATH, or PACKAGE PATH, an error is returned when the package-path value is checked.

NO SCRATCHPAD or SCRATCHPAD
Specifies whether Db2 is to provide a scratchpad for the function. It is strongly recommended that external functions be reentrant, and a scratchpad provides an area for the function to save information from one invocation to the next.

NO SCRATCHPAD
Specifies that a scratchpad is not allocated and passed to the function. NO SCRATCHPAD is the default.

SCRATCHPAD length
Specifies when the function is invoked for the first time, Db2 allocates memory for a scratchpad. A scratchpad has the following characteristics:

- length must be between 1 and 32767. The default value is 100 bytes.
- Db2 initializes the scratchpad to all binary zeros (X'00's).
- The scope of a scratchpad is the SQL statement. For each reference to the function in an SQL statement, there is one scratchpad. For example, assuming that function UDFX was defined with the SCRATCHPAD keyword, three scratchpads are allocated for the three references to UDFX in the following SQL statement:

```sql
SELECT A, UDFX(A) FROM TABLEB
WHERE UDFX(A) > 103 OR UDFX(A) < 19;
```

If the function is run under parallel tasks, one scratchpad is allocated for each parallel task of each reference to the function in the SQL statement. This can lead to unpredictable results. For example, if a function uses the scratchpad to count the number of times that it is invoked, the count reflects the number of invocations done by the parallel task and not the SQL statement. Specify the DISALLOW PARALLEL clause for functions that will not work correctly with parallelism.

- The scratchpad is persistent. Db2 preserves its content from one invocation of the function to the next. Any changes that the function makes to the scratchpad on one call are still there on the next call. Db2
initializes the scratchpads when it begins to execute an SQL statement. Db2 does not reset scratchpads when a correlated subquery begins to execute.

- The scratchpad can be a central point for the system resources that the function acquires. If the function acquires system resources, specify FINAL CALL to ensure that Db2 calls the function one more time so that the function can free those system resources.

Each time the function invoked, Db2 passes an additional argument to the function that contains the address of the scratchpad.

If you specify SCRATCHPAD, Db2:
- Does not move the function from one task control block (TCB) to another between FETCH operations.
- Does not allow another function or stored procedure to use the TCB until the cursor is closed. This is also applicable for cursors declared WITH HOLD.

Do not specify SCRATCHPAD when LANGUAGE JAVA is in effect.

**NO FINAL CALL or FINAL CALL**
Specifies whether a final call is made to the function. A final call enables the function to free any system resources that it has acquired. A final call is useful when the function has been defined with the SCRATCHPAD keyword and the function acquires system resource and anchors them in the scratchpad.

**NO FINAL CALL**
Specifies that a final call is not made to the function. The function does not receive an additional argument that specifies the type of call. NO FINAL CALL is the default.

**FINAL CALL**
Specifies that a final call is made to the function. To differentiate between final calls and other calls, the function receives an additional argument that specifies the type of call. The types of calls are:

**First call**
Specifies that the first call to the function for this reference to the function in this SQL statement. A first call is a normal call—SQL arguments are passed and the function is expected to return a result.

**Normal call**
Specifies that SQL arguments are passed and the function is expected to return a result.

**Final call**
Specifies that the last call to the function to enable the function to free resources. A final call is not a normal call. If an error occurs, Db2 attempts to make the final call unless the function abended. A final call occurs at these times:
- *End of statement:* When the cursor is closed for cursor-oriented statements, or the execution of the statement has completed.
- *End of a parallel task:* When the function is executed by parallel tasks.
- *End of transaction:* When normal end of statement processing does not occur. For example, the logic of an application, for some reason, bypasses closing the cursor.
If a commit operation occurs while a cursor defined as WITH HOLD is open, a final call is made when the cursor is closed or the application ends. If a commit occurs at the end of a parallel task, a final call is made regardless of whether a cursor defined as WITH HOLD is open.

If a commit, rollback, or abort operation causes the final call, the function cannot issue any SQL statements when it is invoked.

Some functions that use a final call can receive incorrect results if parallel tasks execute the function. For example, if a function sends a note for each final call to it, one note is sent for each parallel task instead of once for the function. Specify the DISALLOW PARALLEL clause for functions that have inappropriate actions when executed in parallel.

Do not specify FINAL CALL when LANGUAGE JAVA is in effect.

ALLOW or DISALLOW PARALLEL
For a single reference to the function, specifies whether parallelism can be used when the function is invoked. Although parallelism can be used for most scalar functions, some functions such as those that depend on a single copy of the scratchpad cannot be invoked with parallel tasks.

Consider these characteristics when determining which clause to use:

- If all invocations of the function are completely independent from one another, specify ALLOW PARALLEL.
- If each invocation of the function updates the scratchpad, providing values that are of interest to the next invocation, such as incrementing a counter, specify DISALLOW PARALLEL.
- If the scratchpad is used only so that some expensive initialization processing is performed a minimal number of times, specify ALLOW PARALLEL.
- If the function performs some external action that should apply to only one partition, specify DISALLOW PARALLEL.
- If the function is defined with MODIFIES SQL DATA, specify DISALLOW PARALLEL, not ALLOW PARALLEL.

ALLOW PARALLEL is the default unless NOT DETERMINISTIC, EXTERNAL ACTION, SCRATCHPAD, or FINAL CALL is specified, in which case, DISALLOW PARALLEL is the default.

ALLOW PARALLEL
Specifies that Db2 can consider parallelism for the function. Parallelism is not forced on the SQL statement that invokes the function or on any SQL statement in the function. Existing restrictions on parallelism apply.

DISALLOW PARALLEL
Specifies that Db2 does not consider parallelism for the function.

NO DBINFO or DBINFO
Specifies whether additional status information is passed to the function when it is invoked.

NO DBINFO
No additional information is passed. NO DBINFO is the default.

DBINFO
An additional argument is passed when the function is invoked. The argument is a structure that contains information such as the application runtime authorization ID, the schema name, the name of a table or column.
that the function might be inserting into or updating, and identification of
the database server that invoked the function. For details about the
argument and its structure, see *Db2 Application Programming and SQL Guide*.

Do not specify DBINFO when LANGUAGE JAVA is in effect.

**NO COLLID or COLLID collection-id**
Identifies the package collection that is to be used when the function is
executed. This is the package collection into which the DBRM that is associated
with the function program is bound.

**NO COLLID**
The package collection for the function is the same as the package
collection of the program that invokes the function. If a trigger invokes the
function, the collection of the trigger package is used. If the invoking
program does not use a package, Db2 resolves the package by using the
CURRENT PACKAGE PATH special register, the CURRENT PACKAGESET
special register, or the PKLIST bind option (in this order). For details about
how Db2 uses these three items, see the information on package resolution
in *Db2 Application Programming and SQL Guide*.

NO COLLID is the default.

**COLLID collection-id**
The name of the package collection that is to be used when the function is
executed.

**WLM ENVIRONMENT**
Identifies the WLM (workload manager) application environment in which the
function is to run. The name of the WLM environment is an SQL identifier.

If you do not specify WLM ENVIRONMENT, the function runs in the
WLM-established stored procedure address space that is specified at
installation time. When LANGUAGE is JAVA, you must specify WLM
ENVIRONMENT, and the WLM environment in which the function is to run
must be Java-enabled.

**name**
The WLM environment in which the function must run. If another
user-defined function or a stored procedure calls the function and that
calling routine is running in an address space that is not associated with
the WLM environment, Db2 routes the function request to a different
address space.

**name,**
When an SQL application program directly invokes the function, the WLM
environment in which the function runs.

If another user-defined function or a stored procedure calls the function,
the function runs in same environment that the calling routine uses. In this
case, authorization to run the function in the WLM environment is not
checked because the authorization of the calling routine suffices.

Users must have the appropriate authorization to execute functions in the
specified WLM environment. For an example of a RACF command that
provides this authorization, see [Running external functions in WLM](#).

**ASUTIME**
Specifies the total amount of processor time, in CPU service units, that a single
invocation of the function can run. The value is unrelated to the ASUTIME column of the resource limit specification table. This option is ignored if LANGUAGE JAVA is specified.

When you are debugging a function, setting a limit can be helpful if the function gets caught in a loop. For information on service units, see z/OS MVS Initialization and Tuning Guide.

**NO LIMIT**
There is no limit on the service units. NO LIMIT is the default.

**LIMIT integer**
The limit on the number of CPU service units is a positive integer in the range 1 - 2147483647. If the procedure uses more service units than the specified value, Db2 cancels the procedure. The CPU cycles that are consumed by parallel tasks in a procedure do not contribute towards the specified ASUTIME LIMIT.

**STAY RESIDENT**
Specifies whether the load module for the function is to remain resident in memory when the function ends. This option is ignored if LANGUAGE JAVA is specified.

**NO**
The load module is deleted from memory after the function ends. Use NO for non-reentrant functions. NO is the default.

**YES**
The load module remains resident in memory after the function ends. Use YES for reentrant functions.

**PROGRAM TYPE**
Specifies whether the function program runs as a main routine or a subroutine.

**SUB**
The function runs as a subroutine. With LANGUAGE JAVA, PROGRAM TYPE SUB is the only valid option. SUB is the default.

**MAIN**
The function runs as a main routine.

**SECURITY**
Specifies how the function interacts with an external security product, such as RACF, to control access to non-SQL resources.

**Db2**
The function does not require an external security environment. If the function accesses resources that an external security product protects, the access is performed using the authorization ID that is associated with the WLM-established stored procedure address space.

Db2 is the default.

**USER**
An external security environment should be established for the function. If the function accesses resources that the external security product protects, the access is performed using the primary authorization ID of the process that invoked the function.

**DEFINER**
An external security environment should be established for the function. If the function accesses resources that the external security product protects, the access is performed using the authorization ID of the owner of the function.
STOP AFTER SYSTEM DEFAULT FAILURES, STOP AFTER \( nn \) FAILURES, or CONTINUE AFTER FAILURE

Specifies whether the routine is to be put in a stopped state after some number of failures.

STOP AFTER SYSTEM DEFAULT FAILURES

Specifies that this routine should be placed in a stopped state after the number of failures indicated by the value of field MAX ABEND COUNT on installation panel DSNTIPX. This is the default.

STOP AFTER \( nn \) FAILURES

Specifies that this routine should be placed in a stopped state after \( nn \) failures. The value \( nn \) can be an integer from 1 to 32767.

CONTINUE AFTER FAILURE

Specifies that this routine should not be placed in a stopped state after any failure.

RUN OPTIONS \( \text{runtime-options} \)

Specifies the Language Environment runtime options to be used for the function. You must specify \( \text{runtime-options} \) as a character string that is no longer than 254 bytes. If you do not specify RUN OPTIONS or pass an empty string, Db2 does not pass any runtime options to Language Environment, and Language Environment uses its installation defaults. For a description of the Language Environment runtime options, see z/OS Language Environment Programming Reference.

Do not specify RUN OPTIONS when LANGUAGE JAVA is in effect.

INHERIT SPECIAL REGISTERS or DEFAULT SPECIAL REGISTERS

Specifies how special registers are set on entry to the routine.

INHERIT SPECIAL REGISTERS

Specifies that the values of special registers are inherited according to the rules listed in the table for characteristics of special registers in a user-defined function in Special registers in a user-defined function or a stored procedure

DEFAULT SPECIAL REGISTERS

Specifies that special registers are initialized to the default values, as indicated by the rules in the table for characteristics of special registers in a user-defined function in Special registers in a user-defined function or a stored procedure

STATIC DISPATCH

At function resolution time, Db2 chooses a function based on the static (or declared) types of the function parameters. STATIC DISPATCH is the default.

NOT SECURED or SECURED

Specifies if the function is considered secure for row access control and column access control.

NOT SECURED

Specifies that the function is not considered as secure for row access control and column access control.

NOT SECURED is the default.

When the function is invoked, the arguments of the function must not reference a column for which a column mask is enabled when the table is using active column access control.
**SECURED**
Specifies that the function is considered secure for row access control and column access control.

The function must be defined with SECURED when it is referenced in a row permission or a column mask.

**Notes**

**Considerations for all types of user-defined functions:**
For considerations that apply to all types of user-defined functions, see [CREATE FUNCTION](#).

**Character string representation considerations:**
The PARAMETER VARCHAR clause is specific to LANGUAGE C functions because of the native use of NUL-terminated strings in C. VARCHAR structure representation is useful when character string data is known to contain embedded NUL-termionators. It is also useful when it cannot be guaranteed that character string data does not contain embedded NUL-termionators.

PARAMETER VARCHAR does not apply to fixed length character strings, VARCHAR FOR BIT DATA, CLOB, DBCLOB, or implicitly generated parameters. The clause does not apply to VARCHAR FOR BIT DATA because BIT DATA can contain X'00' characters, and its value representation starts with length information. It does not apply to LOB data because a LOB value representation starts with length information.

PARAMETER VARCHAR does not apply to optional parameters that are implicitly provided to an external function. For example, a CREATE FUNCTION statement for LANGUAGE C must also specify PARAMETER STYLE SQL, which returns an SQLSTATE NUL-terminated character string; that SQLSTATE will not be represented in VARCHAR structured form. Likewise, none of the parameters that represent the qualified name of the function, the specific name of the function, or the SQL diagnostic string that is returned to the database manager will be represented in VARCHAR structured form.

**Running external functions in WLM environments:**
You can use the WLM ENVIRONMENT clause to identify the address space in which a function or is to run. Using different WLM environments lets you isolate one group of programs from another. For example, you might choose to isolate programs based on security requirements and place all payroll applications in one WLM environment because those applications deal with data, such as employee salaries.

To prevent a user from defining functions in sensitive WLM environments, Db2 invokes the external security manager to determine whether the user has authorization to issue CREATE FUNCTION statements that refer to the specified WLM environment. The following example shows the RACF command that authorizes Db2 user DB2USER1 to register a function on Db2 subsystem DB2A that runs in the WLM environment named PAYROLL.

```
PERMIT DB2A.WLMENV.PAYROLL CLASS(OSNR) ID(DB2USER1) ACCESS(READ)
```

**Considerations for accessing message tokens and DBINFO:**
Db2 returns system-generated parameters from a routine, such as message tokens and DBINFO. The message tokens and DBINFO are character string data. The CCSID for system-generated string parameters is determined from the CCSID that is in effect for string parameters that are defined for
the routine. If the parameter list for the routine does not include any character or graphic string parameters, the CCSID for system-generated string parameters is determined from the PARAMETER CCSID option that is in effect for the routine. For example, with a Unicode database, you can specify PARAMETER CCSID EBCDIC to have the system-generated string parameters returned to the invoking application in EBCDIC.

**Alternative syntax and synonyms:**

To provide compatibility with previously releases of Db2 or other products in the Db2 family, Db2 supports the following alternative syntax:

- VARIANT as a synonym for NOT DETERMINISTIC
- NOT VARIANT as a synonym for DETERMINISTIC
- NOT NULL CALL as a synonym for RETURNS NULL ON NULL INPUT
- NULL CALL as a synonym for CALLED ON NULL INPUT
- PARAMETER STYLE DB2SQL as a synonym for PARAMETER STYLE SQL
- TIMEZONE can be specified as an alternative to TIME ZONE.

**Examples**

**Example 1:** Assume that you want to write an external function program in C that implements the following logic:

\[
\text{output} = 2 \times \text{input} - 4
\]

The function should return a null value if and only if one of the input arguments is null. The simplest way to avoid a function call and get a null result when an input value is null is to specify RETURNS NULL ON NULL INPUT on the CREATE FUNCTION statement or allow it to be the default. Write the statement needed to register the function, using the specific name MINENULL1.

```
CREATE FUNCTION NTEST1(SMALLINT)
RETURNS SMALLINT
EXTERNAL NAME 'NTESTMOD'
SPECIFIC MINENULL1
LANGUAGE C
DETERMINISTIC
NO SQL
FENCED
PARAMETER STYLE SQL
RETURNS NULL ON NULL INPUT
NOEXTERNAL ACTION;
```

**Example 2:** Assume that user Smith wants to register an external function named CENTER in schema SMITH. The function program will be written in C and will be reentrant. Write the statement that Smith needs to register the function, letting Db2 generate a specific name for the function.

```
CREATE FUNCTION CENTER(INTEGER, FLOAT)
RETURNS FLOAT
EXTERNAL NAME 'MIDDLE'
LANGUAGE C
DETERMINISTIC
NO SQL
FENCED
PARAMETER STYLE SQL
NOEXTERNAL ACTION
STAY RESIDENT YES;
```

**Example 3:** Assume that user McBride (who has administrative authority) wants to register an external function named CENTER in the SMITH schema. McBride plans
to give the function specific name FOCUS98. The function program uses a
scratchpad to perform some one-time only initialization and save the results. The
function program returns a value with a FLOAT data type. Write the statement
McBride needs to register the function and ensure that when the function is
invoked, it returns a value with a data type of DECIMAL(8,4).

```
CREATE FUNCTION SMITH.CENTER (FLOAT, FLOAT, FLOAT)
    RETURNS DECIMAL(8,4) CAST FROM FLOAT
    EXTERNAL NAME 'CMOD'
    SPECIFIC FOCUS98
    LANGUAGE C
    DETERMINISTIC
    NO SQL
    FENCED
    PARAMETER STYLE SQL
    NO EXTERNAL ACTION
    SCRATCHPAD
    NO FINAL CALL;
```

Example 4: The following example registers a Java user-defined function that
returns the position of the first vowel in a string. The user-defined function is
written in Java, is to be run fenced, and is the FINDVWL method of class
JAVAUDFS.

```
CREATE FUNCTION FINDV (CLOB(100K))
    RETURNS INTEGER
    FENCED
    LANGUAGE JAVA
    PARAMETER STYLE JAVA
    EXTERNAL NAME 'JAVAUDFS.FINDVWL'
    NO EXTERNAL ACTION
    CALLED ON NULL INPUT
    DETERMINISTIC
    NO SQL;
```

---

**CREATE FUNCTION (external table)**

This CREATE FUNCTION statement registers a user-defined external table
function with a database server. A user-defined external table function can be used
in the FROM clause of a subselect. It returns a table to the subselect by returning
one row at a time each time it is invoked.

**Invocation**

This statement can be embedded in an application program or issued interactively.
It is an executable statement that can be dynamically prepared only if
DYNAMICRULES run behavior is implicitly or explicitly specified.

**Authorization**

The privilege set defined below must include at least one of the following:

- The CREATEIN privilege on the schema
- SYSADM or SYSCTRL authority
- System DBADM
- Installation SYSOPR authority (when the current SQLID of the process is set to
  SYSINSTL)

The authorization ID that matches the schema name implicitly has the CREATEIN
privilege on the schema.
If the authorization ID that is used to create the function has the installation SYSADM authority or the installation SYSOPR authority and if the current SQLID is set to SYSINSTL, the function is identified as system-defined function.

Additional privileges are required if the function uses a table as a parameter, refers to a distinct type, or is to run in a WLM (workload manager) environment. These privileges are:

- The SELECT privilege on any table that is an input parameter to the function.
- The USAGE privilege on each distinct type that the function references.
- Authority to create programs in the specified WLM environment. This authorization is obtained from an external security product, such as RACF.

At least one of the following additional privileges is required if the SECURED option is specified

- SECADM authority
- CREATE_SECURE_OBJECT privilege

**Privilege set:** If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the owner is a role, the implicit schema match does not apply and this role needs to include one of the previously listed conditions.

If the statement is dynamically prepared and is not running in a trusted context for which the ROLE AS OBJECT OWNER clause is specified, the privilege set is the set of privileges that are held by the SQL authorization ID of the process. If the schema name is not the same as the SQL authorization ID of the process, one of the following conditions must be met:

- The privilege set includes SYSADM or SYSCTRL authority.
- The SQL authorization ID of the process has the CREATEIN privilege on the schema.
Syntax

 CREATE FUNCTION function-name (parameter-declaration) RETURNS TABLE (
  column-name data-type,
  GENERIC TABLE AS LOCATOR
) (1) AS LOCATOR GENERIC TABLE option-list (2)

Notes:
1 AS LOCATOR can be specified only for a LOB data type or a distinct type based on a LOB data type.
2 This clause and the clauses that follow in the option-list can be specified in any order.

parameter-declaration:

parameter-type:

data-type:

Notes:
1 AS LOCATOR can be specified only for a LOB data type or a distinct type based on a LOB data type.
option-list: (The clauses in the option-list can be specified in any order.)
**Description**

`function-name`

Names the user-defined function. The name is implicitly or explicitly qualified.

Notes:
1. The same clause must not be specified more than one time.
by a schema name. For more information, see “Choosing the schema and function names” and “Determining the uniqueness of functions in a schema” in CREATE FUNCTION.

(\texttt{parameter-declaration,...})

Identifies the number of input parameters of the function, and specifies the data type of each parameter. All of the parameters for a function are input parameters and are nullable. There must be one entry in the list for each parameter that the function expects to receive. Although not required, you can give each parameter a name.

A function can have no parameters. In this case, you must code an empty set of parentheses, for example:

\begin{verbatim}
CREATE FUNCTION WOOFER()
\end{verbatim}

\texttt{parameter-name}

Specifies the name of the input parameter. The name is an SQL identifier, and each name in the parameter list must not be the same as any other name. The same name cannot be used for a parameter name and a column name.

\texttt{data-type}

Specifies the data type of the input parameter. The data type can be a built-in data type or a user-defined type.

\texttt{built-in-type}

The data type of the input parameter is a built-in data type.

For information on the data types, see \texttt{built-in-type}.

For parameters with a character or graphic data type, the \texttt{PARAMETER CCSID} clause or \texttt{CCSID} clause indicates the encoding scheme of the parameter. If you do not specify either of these clauses, the encoding scheme is the value of field \texttt{DEF ENCODING SCHEME} on installation panel DSNTIPF.

\texttt{distinct-type-name}

The data type of the input parameter is a distinct type. Any length, precision, scale, subtype, or encoding scheme attributes for the parameter are those of the source type of the distinct type.

If you specify the name of the distinct type without a schema name, Db2 resolves the schema name by searching the schemas in the SQL path.

Although parameters with a character data type have an implicitly or explicitly specified subtype (BIT, SBCS, or MIXED), the function program can receive character data of any subtype. Therefore, conversion of the input data to the subtype of the parameter might occur when the function is invoked. An error occurs if mixed data that actually contains DBCS characters is used as the value for an input parameter that is declared with an SBCS subtype.

Parameters with a datetime data type or a distinct type are passed to the function as a different data type:

- A datetime type parameter is passed as a character data type, and the data is passed in ISO format.

The encoding scheme for a datetime type parameter is the same as the implicitly or explicitly specified encoding scheme of any character or graphic string parameters. If no character or graphic string parameters
are passed, the encoding scheme is the value of field DEF ENCODING SCHEME on installation panel DSNTIPF.

- A distinct type parameter is passed as the source type of the distinct type.

**AS LOCATOR**

Specifies that a locator to the value of the parameter is passed to the function instead of the actual value. Specify AS LOCATOR only for parameters with a LOB data type or a distinct type that is based on a LOB data type. Passing locators instead of values can result in fewer bytes being passed to the function, especially when the value of the parameter is very large.

The AS LOCATOR clause has no effect on determining whether data types can be promoted, nor does it affect the function signature, which is used in function resolution.

**TABLE LIKE table-name or view-name AS LOCATOR**

Specifies that the parameter is a transition table. However, when the function is invoked, the actual values in the transition table are not passed to the function. A single value is passed instead. This single value is a locator to the table, which the function uses to access the columns of the transition table. A function with a table parameter can only be invoked from the triggered action of a trigger.

The use of TABLE LIKE provides an implicit definition of the transition table. It specifies that the transition table has the same number of columns as the identified table or view. If a table is specified, the transition table includes columns that are defined as implicitly hidden in the table. The columns have the same data type, length, precision, scale, subtype, and encoding scheme as the identified table or view, as they are described in catalog tables SYSCOLUMNS and SYSTABLESPACE. The number of columns and the attributes of those columns are determined at the time the CREATE FUNCTION statement is processed. Any subsequent changes to the number of columns in the table or the attributes of those columns do not affect the parameters of the function.

`table-name` or `view-name` must identify a table or view that exists at the current server. A view cannot have columns of length 0. The name must not identify a declared temporary table. The table that is identified can contain XML columns; however, the function cannot reference those XML columns. The name does not have to be the same name as the table that is associated with the transition table for the trigger. An unqualified table or view name is implicitly qualified according to the following rules:

- If the CREATE FUNCTION statement is embedded in a program, the implicit qualifier is the authorization ID in the QUALIFIER bind option when the plan or package was created or last rebound. If QUALIFIER was not used, the implicit qualifier is the owner of the plan or package.
- If the CREATE FUNCTION statement is dynamically prepared, the implicit qualifier is the SQL authorization ID in the CURRENT SCHEMA special register.

When the function is invoked, the corresponding columns of the transition table identified by the table locator and the table or view identified in the TABLE LIKE clause must have the same definition. The data type, length, precision, scale, and encoding scheme of these columns must match exactly. The description of the table or view at the time the CREATE FUNCTION statement was executed is used.
Additionally, a character FOR BIT DATA column of the transition table cannot be passed as input for a table parameter for which the corresponding column of the table specified at the definition is not defined as character FOR BIT DATA. (The definition occurs with the CREATE FUNCTION statement.) Likewise, a character column of the transition table that is not FOR BIT DATA cannot be passed as input for a table parameter for which the corresponding column of the table specified at the definition is defined as character FOR BIT DATA.

For more information about using table locators, see *Db2 Application Programming and SQL Guide*.

**RETURNS TABLE**(column-name data-type ...)

Identifies that the output of the function is a table. The parentheses that follow the keyword enclose the list of names and data types of the columns of the table.

*column-name*

Specifies the name of the column. The name is an SQL identifier and must be unique within the RETURNS TABLE clause for the function.

*data-type*

Specifies the data type of the column. The column is nullable.

**AS LOCATOR**

Specifies that the function returns a locator to the value rather than the actual value. You can specify AS LOCATOR only for a LOB data type or a distinct type based on a LOB data type.

**RETURNS GENERIC TABLE**

Specifies that the output of the function is a generic table. This option can only be specified if LANGUAGE C is also specified.

The names and data types of the columns must be declared when the table function is references using the **typed-correlation-clause** of the subselect.

**Related information:**

*typed-correlation-clause*

**SPECIFIC** specific-name

Specifies a unique name for the function. The name is implicitly or explicitly qualified with a schema name. The name, including the schema name, must not identify the specific name of another function that exists at the current server.

The unqualified form of specific-name is an SQL identifier. The qualified form is an SQL identifier (the schema name) followed by a period and an SQL identifier.

If you do not specify a schema name, it is the same as the explicit or implicit schema name of the function name (function-name). If you specify a schema name, it must be the same as the explicit or implicit schema name of the function name.

If you do not specify the SPECIFIC clause, the default specific name is the name of the function. However, if the function name does not provide a unique specific name or if the function name is a single asterisk, Db2 generates a specific name in the form of:

SQLxxxxxxxxxxxx

where 'xxxxxxxxxxxx' is a string of 12 characters that make the name unique.
The specific name is stored in the SPECIFIC column of the SYSROUTINES catalog table. The specific name can be used to uniquely identify the function in several SQL statements (such as ALTER FUNCTION, COMMENT, DROP, GRANT, and REVOKE) and in Db2 commands (START FUNCTION, STOP FUNCTION, and DISPLAY FUNCTION). However, the function cannot be invoked by its specific name.

**PARAMETER CCSID or VARCHAR**

**CCSID**

Indicates whether the encoding scheme for character or graphic string parameters is ASCII, EBCDIC, or UNICODE. The default encoding scheme is the value specified in the CCSID clauses of the parameter list or RETURNS TABLE clause, or in the field DEF ENCODING SCHEME on installation panel DSNTIPF.

This clause provides a convenient way to specify the encoding scheme for character or graphic string parameters. If individual CCSID clauses are specified for individual parameters in addition to this PARAMETER CCSID clause, the value specified in all of the CCSID clauses must be the same value that is specified in this clause.

This clause also specifies the encoding scheme to be used for system-generated parameters of the routine such as message tokens and DBINFO.

**VARCHAR**

Specifies that the representation of the values of varying length character string-parameters, including, if applicable, the output of the function, for functions which specify LANGUAGE C.

This option can only be specified if LANGUAGE C is also specified.

**NULTERM**

Specifies that variable length character string parameters are represented in a NUL-terminated string form.

**STRUCTURE**

Specifies that variable length character string parameters are represented in a VARCHAR structure form.

Using the PARAMETER VARCHAR clause, there is no way to specify the VARCHAR form of an individual parameter as these is with PARAMETER CCSID. The PARAMETER VARCHAR clause only applies to parameters in the parameter list of a function and in the RETURNS TABLE clause. It does not apply to system-generated parameters of the routine such as message tokens and DBINFO.

In a data sharing environment, you should not specify the PARAMETER VARCHAR clause until all members of the data sharing group support the clause. If some group members support this clause and others do not, and PARAMETER VARCHAR is specified in an external routine, the routine will encounter different parameter forms depending on which group member invokes the routine.

**EXTERNAL**

Specifies that the function being registered is based on code that is written in an external programming language and adheres to the documented linkage conventions and interface of that language.
If you do not specify the NAME clause, 'NAME function-name' is implicit. In this case, function-name must not be longer than 8 characters.

**NAME string or identifier**

Identifies the name of the load module that contains the user-written code that implements the logic of the function.

For other values of LANGUAGE, the name can be a string constant that is no longer than 8 characters. It must conform to the naming conventions for load modules. Alphabetical extenders for national languages can be used as the first character and as subsequent characters in the load module name.

Db2 loads the load module when the function is invoked. The load module is created when the program that contains the function body is compiled and link-edited. The load module does not need to exist when the CREATE FUNCTION statement is executed. However, it must exist and be accessible by the current server when the function is invoked.

You can specify the EXTERNAL clause in one of the following ways:

```
EXTERNAL
EXTERNAL NAME PKJVSP1
EXTERNAL NAME 'PKJVSP1'
```

If you specify an external program name, you must use the NAME keyword. For example, this syntax is not valid:

```
EXTERNAL PKJVSP1
```

**LANGUAGE**

Specifies the application programming language in which the function program is written. All programs must be designed to run in IBM's Language Environment environment.

**ASSEMBLE**

The function is written in Assembler.

**C**

The function is written in C or C++. The VARCHAR clause can only be specified is LANGUAGE C is specified.

**COBOL**

The function is written in COBOL, including the object-oriented language extensions.

**PL/I**

The function is written in PL/I.

**PARAMETER STYLE SQL**

Specifies the linkage convention that the function program uses to receive input parameters from and pass return values to the invoking SQL statement.

PARAMETER STYLE SQL specifies the parameter passing convention that supports passing null values both as input and for output.

If the RETURNS TABLE clause is specified, the parameters that are passed between the invoking SQL statement and the function include:

- $n$ parameters for the input parameters that are specified for the function
- $m$ parameters for the result columns of the function that are specified on the RETURNS TABLE clause
- $n$ parameters for the indicator variables for the input parameters
- $m$ parameters for the indicator variables of the result columns of the function that are specified on the RETURNS TABLE clause
• The SQLSTATE to be returned to Db2
• The qualified name of the function
• The specific name of the function
• The SQL diagnostic string to be returned to Db2
• The scratchpad, if SCRATCHPAD is specified
• The call type
• The DBINFO structure, if DBINFO is specified

If the RETURNS GENERIC TABLE clause is specified, the parameters that are passed between the invoking SQL statement and the function include:

• $n$ parameters for the input parameters that are specified for the function
• $n$ parameters for the indicator variables for the input parameters

• $m$ parameters for the result columns of the function that are specified on the RETURNS GENERIC TABLE clause

• A result table descriptor that contains the following:
  • $m$ result columns of the function that are specified in the typed-correlation-clause of the table-function-reference in a SELECT statement
  • An array of $m$, 4-byte addresses to the values of the result columns
  • An array of $m$, null indicators of the result columns

• The SQLSTATE to be returned to Db2
• The qualified name of the function
• The specific name of the function
• The SQL diagnostic string to be returned to Db2
• The scratchpad, if SCRATCHPAD is specified
• The call type
• The DBINFO structure, if DBINFO is specified

For complete details about the structure of the parameter list that is passed, see Db2 Application Programming and SQL Guide.

**NOT DETERMINISTIC or DETERMINISTIC**

Specifies whether the function returns function returns the same results each time that the function is invoked with the same input arguments.

**NOT DETERMINISTIC**

The function might not return the same results each time that the function is invoked with the same input arguments. The function depends on some state values that affect the results. Db2 uses this information to disable the merging of views and table expressions when processing SELECT and SQL data change statements that refer to this function. An example of a function that is not deterministic is one that generates random numbers, or any function that contains SQL statements.

NOT DETERMINISTIC is the default.

**DETERMINISTIC**

The function always returns the same result each time that the function is invoked with the same input arguments. An example of a deterministic function is a function that calculates the square root of the input. Db2 uses this information to enable the merging of views and table expressions for SELECT and SQL data change statements that refer to this function.

DETERMINISTIC is not the default. If applicable, specify DETERMINISTIC to prevent non-optimal access paths from being chosen for SQL statements that refer to this function.
Db2 does not verify that the function program is consistent with the specification of DETERMINISTIC or NOT DETERMINISTIC.

FENCED
 Specifies that the function runs in an external address space to prevent the function from corrupting Db2 storage.

FENCED is the default.

RETURNS NULL ON NULL INPUT or CALLED ON NULL INPUT
 Specifies whether the function is called if any of the input arguments is null at execution time.

RETURNS NULL ON NULL INPUT
 The function is not called if any of the input arguments is null. The result is an empty table, which is a table with no rows. RETURNS NULL ON INPUT is the default.

CALLED ON NULL INPUT
 The function is called regardless of whether any of the input arguments are null, making the function responsible for testing for null argument values. The function can return an empty table, depending on its logic.

READS SQL DATA, CONTAINS SQL, or NO SQL
 Specifies the classification of SQL statements and nested routines that this routine can execute or invoke. The database manager verifies that the SQL statements issued by the function, and all routines locally invoked by the routine, are consistent with this specification; the verification is not performed when nested remote routines are invoked. For the classification of each statement, see [SQL statement data access classification for routines](#).

READS SQL DATA
 Specifies that the function can execute statements with a data access indication of READS SQL DATA, CONTAINS SQL, or NO SQL. The function cannot execute SQL statements that modify data.

CONTAINS SQL
 Specifies that the function can execute only SQL statements with an access indication of CONTAINS SQL or NO SQL. The function cannot execute statements that read or modify data.

NO SQL
 Specifies that the function can execute only SQL statements with a data access classification of NO SQL.

EXTERNAL ACTION or NO EXTERNAL ACTION
 Specifies whether the function takes an action that changes the state of an object that Db2 does not manage. An example of an external action is sending a message or writing a record to a file.

Because Db2 uses the RRS attachment for functions, Db2 can participate in two-phase commit with any other resource manager that uses RRS. For resource managers that do not use RRS, there is no coordination of commit or rollback operations on non-Db2 resources.

EXTERNAL ACTION
 The function can take an action that changes the state of an object that Db2 does not manage.

If you specify EXTERNAL ACTION, Db2:
  • Materializes the views and table expressions in SELECT and SQL data change statements that refer to the function. This materialization can
adversely affect the access paths that are chosen for the SQL statements that refer to this function. Do not specify EXTERNAL ACTION if the function does not have an external action.

- Does not move the function from one task control block (TCB) to another between FETCH operations.
- Does not allow another function or stored procedure to use the TCB until the cursor is closed. This is also applicable for cursors declared WITH HOLD.

The only changes to resources made outside of Db2 that are under the control of commit and rollback operations are those changes made under RRS control.

EXTERNAL ACTION is the default.

**NO EXTERNAL ACTION**

The function does not take any action that changes the state of an object that Db2 does not manage. Db2 uses this information to enable the merging of views and table expressions for SELECT and SQL data change statements that refer to this function. If applicable, specify NO EXTERNAL ACTION to prevent non-optimal access paths from being chosen for SQL statements that refer to this function.

Although the scope of global variables are beyond the scope of the routine, global variables can be set in the routine body when NO EXTERNAL ACTION is specified.

**NO PACKAGE PATH or PACKAGE PATH**

Specifies the package path to use when the function is run. This is the list of the possible package collections into which the DBRM this is associated with the function is bound.

**NO PACKAGE PATH**

Specifies that the list of package collections for the function is the same as the list of package collection IDs for the program that invokes the function. If the program that invokes the function does not use a package, Db2 resolves the package by using the CURRENT PACKAGE PATH special register, the CURRENT PACKAGESET special register, or the PKLIST bind option (in this order). For information about how Db2 uses these three items, see *Db2 Application Programming and SQL Guide*.

**PACKAGE PATH**

Specifies a list of package collections, in the same format as the SET CURRENT PACKAGE PATH special register.

If the COLLID clause is specified with PACKAGE PATH, the COLLID clause is ignored when the function is invoked.

The package-path value that is provided when the function is created is checked when the function is invoked. If package-path contains SESSION_USER (or USER), PATH, or PACKAGE PATH, an error is returned when the package-path value is checked.

**NO SCRATCHPAD or SCRATCHPAD**

Specifies whether Db2 provides a scratchpad for the function. It is strongly recommended that functions be reentrant, and a scratchpad provides an area for the function to save information from one invocation to the next.

**NO SCRATCHPAD**

Specifies that a scratchpad is not allocated and passed to the function. NO SCRATCHPAD is the default.
**SCRATCHPAD length**

Specifies that when the function is invoked for the first time, Db2 allocates memory for a scratchpad. A scratchpad has the following characteristics:

- `length` must be between 1 and 32767. The default value is 100 bytes.
- Db2 initializes the scratchpad to all binary zeros (X’00’ s).
- The scope of a scratchpad is the SQL statement. Each reference to the function in an SQL statement has a scratchpad. For example, assuming that function UDFX was defined with the SCRATCHPAD keyword, two scratchpads are allocated for the two references to UDFX in the following SQL statement:

  ```sql
  SELECT *
  FROM TABLE (UDFX(A)), TABLE (UDFX(B));
  ```

- Db2 initializes the scratchpads when it begins to execute an SQL statement. Db2 does not reset scratchpads when a correlated subquery begins to execute.
- The scratchpad can be a central point for the system resources that the function acquires. If the function acquires system resources, specify FINAL CALL to ensure that Db2 calls the function one more time so that the function can free those system resources.

Each time the function invoked, Db2 passes an additional argument to the function that contains the address of the scratchpad.

If you specify SCRATCHPAD, Db2:

- Does not move the function from one task control block (TCB) to another between FETCH operations.
- Does not allow another function or stored procedure to use the TCB until the cursor is closed. This is also applicable for cursors declared WITH HOLD.

**NO FINAL CALL or FINAL CALL**

Specifies whether a first call and a final call are made to the function.

**NO FINAL CALL**

A first call and final call are not made to the function. NO FINAL CALL is the default.

**FINAL CALL**

A first call and final call are made to the function in addition to one or more open, fetch, or close calls.

The types of calls are:

**First call**

A first call occurs only if the function was defined with FINAL CALL. Before a first call, the scratchpad is set to binary zeros. Argument values are passed to the function, and the function might acquire memory or perform other one-time only resource initialization. However, the function should not return any data to Db2, but it can set return values for the SQL-state and diagnostic-message arguments.

**Open call**

An open call occurs unless the function returns an error. The scratchpad is set to binary zeros only if the function was defined with NO FINAL
CALL. Argument values are passed to the function, and the function might perform any one-time initialization actions that are required. However, the function should not return any data to Db2.

Fetch call
A fetch call occurs unless the function returns an error during the first call or open call. Argument values are passed to the function, and Db2 expects the function to return a row of data or the end-of-table condition. If a scratchpad is also passed to the function, it remains untouched from the previous call.

Close call
A close call occurs unless the function returns an error during the first call, open call, or fetch call. No SQL-argument or SQL-argument-ind values are passed to the function, and if the function attempts to examine these values, unpredictable results might occur. If a scratchpad is also passed to the function, it remains untouched from the previous call.

The function should not return any data to Db2, but it can set return values for the SQL-state and diagnostic-message arguments. Also on close call, a function that is defined with NO FINAL CALL should release any system resources that it acquired. (A function that is defined with FINAL CALL should release any acquired resources on the final call.)

Final
The final call balances the first call, and like the first call, occurs only if the function was defined with FINAL CALL. The function can set return values for the SQL-state and diagnostic-message arguments. The function should also release any system resources that it acquired. A final call occurs at these times:

- End of statement: When the cursor is closed for cursor-oriented statements, or the execution of the statement has completed.
- End of transaction: When normal end of statement processing does not occur. For example, the logic of an application, for some reason, bypasses closing the cursor.

If a commit, rollback, or abort operation causes the final call, the function cannot issue any SQL statements when it is invoked.

DISALLOW PARALLEL
Specifies that Db2 does not consider parallelism for the function.

NO DBINFO or DBINFO
Specifies whether additional status information is passed to the function when it is invoked.

NO DBINFO
No additional information is passed. NO DBINFO is the default.

DBINFO
An additional argument is passed when the function is invoked. The argument is a structure that contains information such as the application run time authorization ID, the schema name, the name of a table or column that the function might be inserting into or updating, and identification of the database server that invoked the function. For details about the argument and its structure, see Db2 Application Programming and SQL Guide.
CARDINALITY integer
Specifies an estimate of the expected number of rows that the function returns. The number is used for optimization purposes. The value of integer must range 0 - 2147483647.

If you do not specify CARDINALITY, Db2 assumes a finite value. The finite value is the same value that Db2 assumes for tables for which the RUNSTATS utility has not gathered statistics.

If a function has an infinite cardinality—the function never returns the "end-of-table" condition and always returns a row, then a query that requires the “end-of-table” to work correctly will need to be interrupted. Thus, avoid using such functions in queries that involve GROUP BY and ORDER BY.

NO COLLID or COLLID collection-id
Identifies the package collection that is to be used when the function is executed. This is the package collection into which the DBRM that is associated with the function program is bound.

NO COLLID
The package collection for the function is the same as the package collection of the program that invokes the function. If a trigger invokes the function, the collection of the trigger package is used. If the invoking program does not use a package, Db2 resolves the package by using the CURRENT PACKAGE PATH special register, the CURRENT PACKAGESET special register, or the PKLIST bind option (in this order). For details about how Db2 uses these three items, see the information on package resolution in Db2 Application Programming and SQL Guide.

NO COLLID is the default.

COLLID collection-id
The name of the package collection that is to be used when the external is executed.

WLM ENVIRONMENT
Identifies the WLM (workload manager) application environment in which the function is to run. The name of the WLM environment is an SQL identifier.

If you do not specify WLM ENVIRONMENT, the function runs in the WLM-established stored procedure address space that is specified at installation time.

name
The WLM environment in which the function must run. If another user-defined function or a stored procedure calls the function and that calling routine is running in an address space that is not associated with the WLM environment, Db2 routes the function request to a different address space.

(name,*)
When an SQL application program directly invokes the function, the WLM environment in which the function runs.

If another user-defined function or a stored procedure calls the function, the function runs in same environment that the calling routine uses. In this case, authorization to run the function in the WLM environment is not checked because the authorization of the calling routine suffices.
Users must have the appropriate authorization to execute functions in the specified WLM environment. For an example of a RACF command that provides this authorization, see Running external functions in WLM environments.

**ASUTIME**

Specifies the total amount of processor time, in CPU service units, that a single invocation of the function can run. The value is unrelated to the ASUTIME column of the resource limit specification table.

When you are debugging a function, setting a limit can be helpful if the function gets caught in a loop. For information on service units, see z/OS MVS Initialization and Tuning Guide.

**NO LIMIT**

There is no limit on the service units. NO LIMIT is the default.

**LIMIT integer**

The limit on the number of CPU service units is a positive integer in the range 1 - 2147483647. If the procedure uses more service units than the specified value, Db2 cancels the procedure. The CPU cycles that are consumed by parallel tasks in a procedure do not contribute towards the specified ASUTIME LIMIT.

**STAY RESIDENT**

Specifies whether the load module for the function is to remain resident in memory when the function ends.

**NO**

The load module is deleted from memory after the function ends. Use NO for non-reentrant functions. NO is the default.

**YES**

The load module remains resident in memory after the function ends. Use YES for reentrant functions.

**PROGRAM TYPE**

Specifies whether the function program runs as a main routine or a subroutine.

**SUB**

The function runs as a subroutine. SUB is the default.

**MAIN**

The function runs as a main routine.

**SECURITY**

Specifies how the function interacts with an external security product, such as RACF, to control access to non-SQL resources.

**Db2**

The function does not require an external security environment. If the function accesses resources that an external security product protects, the access is performed using the authorization ID that is associated with the WLM-established stored procedure address space.

Db2 is the default.

**USER**

An external security environment should be established for the function. If the function accesses resources that the external security product protects, the access is performed using the primary authorization ID of the process that invoked the function.
DEFINER
An external security environment should be established for the function. If the function accesses resources that the external security product protects, the access is performed using the authorization ID of the owner of the function.

RUN OPTIONS runtime-options
Specifies the Language Environment run time options to be used for the function. You must specify runtime-options as a character string that is no longer than 254 bytes. If you do not specify RUN OPTIONS or pass an empty string, Db2 does not pass any run time options to Language Environment, and Language Environment uses its installation defaults.

For a description of the Language Environment run time options, see z/OS Language Environment Programming Reference.

INHERIT SPECIAL REGISTERS or DEFAULT SPECIAL REGISTERS
Specifies how special registers are set on entry to the routine.

INHERIT SPECIAL REGISTERS
Specifies that the values of special registers are inherited according to the rules listed in the table for characteristics of special registers in a user-defined function in [Special registers in a user-defined function or a stored procedure].

DEFAULT SPECIAL REGISTERS
Specifies that special registers are initialized to the default values, as indicated by the rules in the table for characteristics of special registers in a user-defined function in [Special registers in a user-defined function or a stored procedure].

STATIC DISPATCH
At function resolution time, Db2 chooses a function based on the static (or declared) types of the function parameters. STATIC DISPATCH is the default.

STOP AFTER SYSTEM DEFAULT FAILURES, STOP AFTER nn FAILURES, or CONTINUE AFTER FAILURE
Specifies whether the routine is to be put in a stopped state after some number of failures.

STOP AFTER SYSTEM DEFAULT FAILURES
Specifies that this routine should be placed in a stopped state after the number of failures indicated by the value of field MAX ABEND COUNT on installation panel DSNTPFX. This is the default.

STOP AFTER nn FAILURES
Specifies that this routine should be placed in a stopped state after nn failures. The value nn can be an integer from 1 to 32767.

CONTINUE AFTER FAILURE
Specifies that this routine should not be placed in a stopped state after any failure.

NOT SECURED or SECURED
Specifies if the function is considered secure for row access control and column access control.

NOT SECURED
Specifies that the function is not considered as secure for row access control and column access control.

NOT SECURED is the default.
When the function is invoked, the arguments of the function must not reference a column for which a column mask is enabled when the table is using active column access control.

**SECURED**

Specifies that the function is considered secure for row access control and column access control.

The function must be defined with SECURED when it is referenced in a row permission or a column mask.

**Notes**

**Considerations for all types of user-defined functions:**

For considerations that apply to all types of user-defined functions, see `CREATE FUNCTION`.

**Character string representation considerations:**

The `PARAMETER VARCHAR` clause is specific to `LANGUAGE C` functions because of the native use of NUL-terminated strings in C. `VARCHAR` structure representation is useful when character string data is known to contain embedded NUL-terminators. It is also useful when it cannot be guaranteed that character string data does not contain embedded NUL-terminators.

`PARAMETER VARCHAR` does not apply to fixed length character strings, `VARCHAR FOR BIT DATA`, `CLOB`, `DBCLOB`, or implicitly generated parameters. The clause does not apply to `VARCHAR FOR BIT DATA` because `BIT DATA` can contain X’00’ characters, and its value representation starts with length information. It does not apply to `LOB` data because a `LOB` value representation starts with length information.

`PARAMETER VARCHAR` does not apply to optional parameters that are implicitly provided to an external function. For example, a `CREATE FUNCTION` statement for `LANGUAGE C` must also specify `PARAMETER STYLE SQL`, which returns an `SQLSTATE NUL-terminated character string`; that `SQLSTATE` will not be represented in `VARCHAR` structured form. Likewise, none of the parameters that represent the qualified name of the function, the specific name of the function, or the SQL diagnostic string that is returned to the database manager will be represented in `VARCHAR` structured form.

**Running external functions in WLM environments:**

You can use the `WLM ENVIRONMENT` clause to identify the address space in which a function or is to run. Using different WLM environments lets you isolate one group of programs from another. For example, you might choose to isolate programs based on security requirements and place all payroll applications in one WLM environment because those applications deal with data, such as employee salaries.

To prevent a user from defining functions in sensitive WLM environments, Db2 invokes the external security manager to determine whether the user has authorization to issue `CREATE FUNCTION` statements that refer to the specified WLM environment. The following example shows the RACF command that authorizes Db2 user `DB2USER1` to register a function on Db2 subsystem `DB2A` that runs in the WLM environment named `PAYROLL`.

```
PERMIT DB2A.WLMENV.PAYROLL CLASS(OSNR) ID(DB2USER1) ACCESS(READ)
```
Determining if a table function is a generic table function:
To identify if a table function is a generic table function, you can query the SYSIBM.SYSROUTINES catalog table. The function is a generic table function if the value of the RESULT_COLS column is 0 (zero) when the value of the ROUTINETYPE column is 'F' and the value of the FUNCTIONTYPE column is 'T'.

Alternative syntax and synonyms:
To provide compatibility with previously releases of Db2 or other products in the Db2 family, Db2 supports the following alternative syntax:
- VARIANT as a synonym for NOT DETERMINISTIC
- NOT VARIANT as a synonym for DETERMINISTIC
- NOT NULL CALL as a synonym for RETURNS NULL ON NULL INPUT
- NULL CALL as a synonym for CALLED ON NULL INPUT
- PARAMETER STYLE DB2SQL as a synonym for PARAMETER STYLE SQL
- TIMEZONE can be specified as an alternative to TIME ZONE.

Example

Example 1: The following example registers a table function written to return a row consisting of a single document identifier column for each known document in a text management system. The first parameter matches a given subject area and the second parameter contains a given string.

Within the context of a single session, the table function always returns the same table; therefore, it is defined as DETERMINISTIC. In addition, the DISALLOW PARALLEL keyword is added because table functions cannot operate in parallel.

Although the size of the output for DOCMATCH is highly variable, CARDINALITY 20 is a representative value and is specified to help Db2.

```
CREATE FUNCTION DOCMATCH (VARCHAR(30), VARCHAR(255))
RETURNS TABLE (DOC_ID CHAR(16))
EXTERNAL NAME ABC
LANGUAGE C
PARAMETER STYLE SQL
NO SQL
DETERMINISTIC
NO EXTERNAL ACTION
FENCED
SCRATCHPAD
FINAL CALL
DISALLOW PARALLEL
CARDINALITY 20;
```

Example 2: The following example registers a generic table function:

```
CREATE FUNCTION tf6(p1 VARCHAR(10))
RETURNS GENERIC TABLE
EXTERNAL NAME 'tf6'
LANGUAGE C
PARAMETER STYLE SQL
DETERMINISTIC
NO EXTERNAL ACTION
FENCED
SCRATCHPAD
FINAL CALL;
```
Note that LANGUAGE C must be specified, and the names and data type of the result columns must be declared when the table function is referenced in the SELECT clause.

**CREATE FUNCTION (inlined SQL scalar)**

The CREATE FUNCTION (inlined SQL scalar) statement defines an SQL scalar function at the current server and specifies an SQL procedural language RETURN statement for the body of the function. The function returns a single value each time it is invoked.

A package is not created for an inlined SQL scalar function. The function is not invoked as part of a query; instead, the expression in the RETURN statement of the function is copied (inlined) into the query itself.

**Invocation**

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

**Authorization**

The privilege set defined below must include at least one of the following:

- The CREATEIN privilege on the schema
- SYSADM or SYSCTRL authority
- System DBADM
- Installation SYSOPR authority (when the current SQLID of the process is set to SYSINSEL)

The authorization ID that matches the schema name implicitly has the CREATEIN privilege on the schema.

If the authorization ID that is used to create the function has the installation SYSADM authority or the installation SYSOPR authority and if the current SQLID is set to SYSINSEL, the function is identified as system-defined function.

If a user-defined type is referenced (as the data type of a parameter), the privilege set must also include at least one of the following:

- Ownership of the user-defined type
- The USAGE privilege on the user-defined type
- SYSADM authority

At least one of the following additional privileges is required if the SECURED option is specified:

- SECADM authority
- CREATE_SECURE_OBJECT privilege

**Privilege set:** If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the owner is a role, the implicit schema match does not apply and this role needs to include one of the previously listed conditions.
If the statement is dynamically prepared and is not running in a trusted context for which the ROLE AS OBJECT OWNER clause is specified, the privilege set is the set of privileges that are held by the SQL authorization ID of the process. If the schema name is not the same as the SQL authorization ID of the process, one of the following conditions must be met:

- The privilege set includes SYSADM or SYSCTRL authority.
- The SQL authorization ID of the process has the CREATEIN privilege on the schema.

**Syntax**

```
CREATE FUNCTION function-name (parameter-declaration)
  function-definition
  WRAPPED—obfuscated-statement-text
```

**parameter-declaration:**

```
parameter-name data-type
```

**Notes:**

1. Note that the `parameter-name` is required for SQL functions.

**data-type:**

```
built-in-type
distinct-type-name
```
Notes:
1 This clause and the other clauses in the option-list can be specified in any order. However, the same clause cannot be specified more than one time.

function-definition

Notes:
1 The RETURNS clause, the RETURN-statement, and the clauses in the option-list can be specified in any order. However, the same clause cannot be specified more than one time.

SQL-routine-body

Description

*function-name*

Names the user-defined function. The name is implicitly or explicitly qualified by a schema name. For more information, see “Choosing the schema and function names” and “Determining the uniqueness of functions in a schema” in [CREATE FUNCTION](#).

*(parameter-declaration,...)*

Specifies the number of input parameters of the function and the name and data type of each parameter. Each parameter-declaration specifies an input parameter for the function. A function can have zero or more input parameters. There must be one entry in the list for each parameter that the function expects to receive. All of the parameters for a function are input parameters and are nullable. If the function has more than 30 parameters, only the first 30 parameters are used to determine if the function is unique.
**parameter-name**
Specifies the name of the input parameter. The name is an SQL identifier, and each name in the parameter list must not be the same as any other name.

**data-type**
Specifies the data type of the input parameter. The data type can be a built-in data type or a user-defined type.

**built-in-type**
The data type of the input parameter is a built-in data type.

For information on the data types, see [built-in-type](#).

For parameters with a character or graphic data type, the PARAMETER CCSID clause or CCSID clause indicates the encoding scheme of the parameter. If you do not specify either of these clauses, the encoding scheme is the value of field DEF ENCODING SCHEME on installation panel DSNTIPF.

**distinct-type-name**
The data type of the input parameter is a distinct type. Any length, precision, scale, subtype, or encoding scheme attributes for the parameter are those of the source type of the distinct type. The distinct type must not be based on a LOB data type.

If you specify the name of the distinct type without a schema name, Db2 resolves the distinct type by searching the schemas in the SQL path.

The implicitly or explicitly specified encoding scheme of all of the parameters with a character or graphic string data type must be the same—either all ASCII, all EBCDIC, or all UNICODE.

Although parameters with a character data type have an implicitly or explicitly specified subtype (BIT, SBCS, or MIXED), the function program can receive character data of any subtype. Therefore, conversion of the input data to the subtype of the parameter might occur when the function is invoked. An error occurs if mixed data that actually contains DBCS characters is used as the value for an input parameter that is declared with an SBCS subtype.

Parameters with a datetime data type or a distinct type are passed to the function as a different data type:

- A datetime type parameter is passed as a character data type, and the data is passed in ISO format.

  The encoding scheme for a datetime type parameter is the same as the implicitly or explicitly specified encoding scheme of any character or graphic string parameters. If no character or graphic string parameters are passed, the encoding scheme is the value of field DEF ENCODING SCHEME on installation panel DSNTIPF.

- A distinct type parameter is passed as the source type of the distinct type.

**RETURNS**
Identifies the output of the function.

**data-type2**
Specifies the data type of the output. The output is nullable.
The same considerations that apply to the data type of input parameter, as described under [data-type], apply to the data type of the output of the function.

**LANGUAGE SQL**

Specifies that the function is written exclusively in SQL.

**SPECIFIC specific-name**

Specifies a unique name for the function. The name is implicitly or explicitly qualified with a schema name. The name, including the schema name, must not identify the specific name of another function that exists at the current server.

The unqualified form of specific-name is an SQL identifier. The qualified form is an SQL identifier (the schema name) followed by a period and an SQL identifier.

If you do not specify a schema name, it is the same as the explicit or implicit schema name of the function name (function-name). If you specify a schema name, it must be the same as the explicit or implicit schema name of the function name.

If you do not specify the SPECIFIC clause, the default specific name is the name of the function. However, if the function name does not provide a unique specific name or if the function name is a single asterisk, Db2 generates a specific name in the form of:

```
SQLxxxxxxxxxxxx
```

where 'xxxxxxxxxxxx' is a string of 12 characters that make the name unique.

The specific name is stored in the SPECIFIC column of the SYSROUTINES catalog table. The specific name can be used to uniquely identify the function in several SQL statements (such as ALTER FUNCTION, COMMENT, DROP, GRANT, and REVOKE) and must be used in Db2 commands (START FUNCTION, STOP FUNCTION, and DISPLAY FUNCTION). However, the function cannot be invoked by its specific name.

**PARAMETER CCSID**

Indicates whether the encoding scheme for character and graphic string parameters is ASCII, EBCDIC, or UNICODE. The default encoding scheme is the value specified in the CCSID clauses of the parameter list or RETURNS clause, or in the field DEF ENCODING SCHEME on installation panel DSNTIPF.

This clause provides a convenient way to specify the encoding scheme for character and graphic string parameters. If individual CCSID clauses are specified for individual parameters in addition to this PARAMETER CCSID clause, the value specified in all of the CCSID clauses must be the same value that is specified in this clause.

This clause also specifies the encoding scheme to be used for system-generated parameters of the routine such as message tokens and DBINFO.

**NOT DETERMINISTIC or DETERMINISTIC**

Specifies whether the function returns the same results each time that the function is invoked with the same input arguments.

**NOT DETERMINISTIC**

The function might not return the same result each time that the function is invoked with the same input arguments. The function depends on some state values that affect the results. Db2 uses this information to disable the
merging of views and table expressions when processing SELECT and SQL data change statements that refer to this function. An example of a function that is not deterministic is one that generates random numbers.

NOT DETERMINISTIC must be specified explicitly or implicitly if the function program accesses a special register or invokes another function that is not deterministic. NOT DETERMINISTIC is the default.

DETERMINISTIC
The function always returns the same result function each time that the function is invoked with the same input arguments. An example of a deterministic function is a function that calculates the square root of the input. Db2 uses this information to enable the merging of views and table expressions for SELECT and SQL data change statements that refer to this function. DETERMINISTIC is not the default. If applicable, specify DETERMINISTIC to prevent non-optimal access paths from being chosen for SQL statements that refer to this function.

Db2 does not verify that the function program is consistent with the specification of DETERMINISTIC or NOT DETERMINISTIC.

EXTERNAL ACTION or NO EXTERNAL ACTION
Specifies whether the function takes an action that changes the state of an object that Db2 does not manage. An example of an external action is sending a message or writing a record to a file.

EXTERNAL ACTION
The function can take an action that changes the state of an object that Db2 does not manage.

Some SQL statements that invoke functions with external actions can result in incorrect results if parallel tasks execute the function. For example, if the function sends a note for each initial call to it, one note is sent for each parallel task instead of once for the function. Specify the DISALLOW PARALLEL clause for functions that do not work correctly with parallelism.

If you specify EXTERNAL ACTION, then Db2:
- Materializes the views and table expressions in SELECT and SQL data change statements that refer to the function. This materialization can adversely affect the access paths that are chosen for the SQL statements that refer to this function. Do not specify EXTERNAL ACTION if the function does not have an external action.
- Does not move the function from one task control block (TCB) to another between FETCH operations.
- Does not allow another function or stored procedure to use the TCB until the cursor is closed. This is also applicable for cursors declared WITH HOLD.

The only changes to resources made outside of Db2 that are under the control of commit and rollback operations are those changes made under RRS control.

EXTERNAL ACTION must be specified implicitly or explicitly specified if the SQL routine body invokes a function that is defined with EXTERNAL ACTION. EXTERNAL ACTION is the default.

NO EXTERNAL ACTION
The function does not take any action that changes the state of an object that Db2 does not manage. Db2 uses this information to enable the
merging of views and table expressions for SELECT and SQL data change statements that refer to this function. If applicable, specify NO EXTERNAL ACTION to prevent non-optimal access paths from being chosen for SQL statements that refer to this function.

Although the scope of global variables are beyond the scope of the routine, global variables can be set in the routine body when NO EXTERNAL ACTION is specified.

Db2 does not verify that the function program is consistent with the specification of EXTERNAL ACTION or NO EXTERNAL ACTION.

**READS SQL DATA or CONTAINS SQL**

Specifies the classification of SQL statements and nested routines that this routine can execute or invoke. The database manager verifies that the SQL statements issued by the function, and all routines locally invoked by the routine, are consistent with this specification; the verification is not performed when nested remote routines are invoked. For the classification of each statement, see “SQL statement data access classification for routines” on page 2437.

**READS SQL DATA**

Specifies that the function can execute statements with a data access classification of READS SQL DATA, CONTAINS SQL, or NO SQL. The function cannot execute SQL statements that modify data.

**READS SQL DATA** is the default.

**CONTAINS SQL**

Specifies that the function can execute only SQL statements with a data access classification of CONTAINS SQL or NO SQL. The function cannot execute SQL statements that read or modify data.

**STATIC DISPATCH**

At function resolution time, Db2 chooses a function based on the static (or declared) types of the function parameters. **STATIC DISPATCH** is the default.

**CALLED ON NULL INPUT**

Specifies that the function is to be invoked if any, or if all, of the argument values are null. Specifying CALLED ON NULL INPUT means that the body of the function must be coded to test for null argument values.

**CALLED ON NULL INPUT** is the default.

**NOT SECURED or SECURED**

Specifies if the function is considered secure for row access control and column access control. The SECURED or NOT SECURED option applies to all future versions of the function.

**NOT SECURED**

Specifies that the function is not considered secure for row access control and column access control.

**NOT SECURED** is the default.

When the function is invoked, the arguments of the function must not reference a column for which a column mask is enabled when the table is using active column access control.

**SECURED**

Specifies that the function is considered secure for row access control and column access control.
The function must be secure when it is referenced in a row permission or a column mask.

**SQL-routine-body**

Specifies a single RETURN statement. For more information, see "RETURN statement" on page 2408.

If the RETURN statement includes a scalar fullselect, Db2 attempts to define a compiled function. For more information, see CREATE FUNCTION (compiled SQL scalar).

To determine what type of SQL scalar function is created, refer to the INLINE column of the SYSIBM.SYSAUTONINES catalog table.

**WRAPPED obfuscated-statement-text**

Specifies the encoded definition of the function. A CREATE FUNCTION statement can be encoded using the WRAP scalar function.

WRAPPED must not be specified on a static CREATE statement.

**Notes**

**Considerations for all types of user-defined functions:**

For considerations that apply to all types of user-defined functions, see CREATE FUNCTION.

**Types of SQL scalar functions:**

If the syntax of the CREATE FUNCTION statement conforms to the syntax diagrams and descriptions for CREATE FUNCTION (inlined SQL scalar), Db2 defines an inlined function, and a package is not created. When an inlined SQL scalar function is invoked, the expression in the RETURN statement of the function is copied (inlined) into the query itself; the function is not invoked. The attributes of an inlined SQL scalar function are described in "CREATE FUNCTION (inlined SQL scalar)" on page 1599.

Otherwise, Db2 attempts to define a compiled function with an associated package. For example, if the RETURN statement contains a scalar fullselect, Db2 attempts to define a compiled function. The attributes of a compiled SQL scalar function are described in "CREATE FUNCTION (compiled SQL scalar)" on page 1530.

To determine what type of SQL scalar function is created, refer to the INLINE column of the SYSIBM.SYSAUTONINES catalog table. In the INLINE column, a value of Y indicates that the function is an inlined function, and a value of N indicates that the function is a compiled function.

**Considerations for functions defined with MODIFIES SQL DATA:**

If a function is specified in a subselect, and the function is defined as MODIFIES SQL DATA, the number of times the function is invoked is invoked will vary depending on the access plan used.

**Self-referencing function:**

The body of an SQL function (that is, the expression or NULL in the RETURN statement in the body of the CREATE FUNCTION statement) cannot contain a recursive invocation of itself or to another function that invokes it, because such a function would not exist to be referenced.

**Dependent objects:**

An SQL routine is dependent on objects that are referenced in the routine body.
Obfuscated statements:

A CREATE FUNCTION statement can be executed in obfuscated form. In an obfuscated statement, only the function name, parameters, and the WRAPPED keyword are readable. The rest of the statement is encoded in such a way that it is not readable but can be decoded by a database server that supports obfuscated statements. The WRAP scalar function produces obfuscated statements. Any debug options that are specified when the function is created from an obfuscated statement are ignored.

Resolution of object names:

Db2 resolves object names inside the body of the function according to the rules in "Resolution of unqualified object names" on page 93 and the type of the object. The name resolution occurs when the function is created.

Referencing date and time special registers:

If an SQL function contains multiple references to any of the date or time special registers, all references return the same value. In addition, this value is the same value that is returned by the retrieving value of the special register in the statement that invoked the function.

Self-referencing function:

The body of an SQL function (that is, the expression or NULL in the RETURN clause of the CREATE FUNCTION (inlined SQL scalar) statement) cannot contain a recursive invocation of itself or to another function that invokes it, because such a function would not exist to be referenced.

Dependent objects:

An SQL routine is dependent on objects that are referenced in the routine body.

Alternative syntax and synonyms:

To provide compatibility with previously releases of Db2 or other products in the Db2 family, Db2 supports the following alternative syntax:

- VARIANT as a synonym for NOT DETERMINISTIC
- NOT VARIANT as a synonym for DETERMINISTIC
- NULL CALL as a synonym for CALLED ON NULL INPUT
- TIMEZONE can be specified as an alternative to TIME ZONE.

For an inlined SQL scalar function, the RETURNS clause and the clauses in the option-list can be specified in any order.

Examples

Example 1: Define a scalar function that returns the tangent of a value using existing SIN and COS built-in functions:

```sql
CREATE FUNCTION TAN (X DOUBLE) RETURNS DOUBLE
  LANGUAGE SQL
  CONTAINS SQL
  NO EXTERNAL ACTION
  DETERMINISTIC
  RETURN SIN(X)/COS(X);
```

CREATE FUNCTION (sourced)

This CREATE FUNCTION statement registers a user-defined function that is based on an existing scalar or aggregate function with a database server.
Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

Authorization

The privilege set defined below must include at least one of the following:

- The CREATEIN privilege on the schema
- SYSADM or SYSCTRL authority
- System DBADM
- Installation SYSOPR authority (when the current SQLID of the process is set to SYSINSTL)

The authorization ID that matches the schema name implicitly has the CREATEIN privilege on the schema.

If the authorization ID that is used to create the function has the installation SYSADM authority or the installation SYSOPR authority and if the current SQLID is set to SYSINSTL, the function is identified as system-defined function.

Additional privileges are required for the source function, and other privileges are also needed if the function uses a table as a parameter, or refers to a distinct type. These privileges are:

- The EXECUTE privilege for the function that the SOURCE clause references.
- The SELECT privilege on any table that is an input parameter to the function.
- The USAGE privilege on each distinct type that the function references.

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the owner is a role, the implicit schema match does not apply and this role needs to include one of the previously listed conditions.

If the statement is dynamically prepared and is not running in a trusted context for which the ROLE AS OBJECT OWNER clause is specified, the privilege set is the set of privileges that are held by the SQL authorization ID of the process. If the schema name is not the same as the SQL authorization ID of the process, one of the following conditions must be met:

- The privilege set includes SYSADM or SYSCTRL authority.
- The SQL authorization ID of the process has the CREATEIN privilege on the schema.
Syntax

```
CREATE FUNCTION function-name (parameter-declaration) 
  RETURNS data-type2 
  AS LOCATOR SPECIFIC specific-name 
  PARAMETER CCSID ASCII EBCDIC UNICODE
```

Notes:
1. RETURNS, SPECIFIC, and SOURCE can be specified in any order.
2. AS LOCATOR can be specified only for a LOB data type or a distinct type based on a LOB data type.

Parameter-declaration:

```
parameter-name parameter-type
```

Parameter-type:

```
data-type
  AS LOCATOR
  TABLE LIKE table-name AS LOCATOR
  view-name
```

Notes:
1. AS LOCATOR can be specified only for a LOB data type or a distinct type based on a LOB data type.
2. The TABLE LIKE name AS LOCATOR clause can only be specified for the parameter list of the function that is being defined.
### Description

*function-name*

Names the user-defined function. The name is implicitly or explicitly qualified.
by a schema name. For more information, see “Choosing the schema and function names” and “Determining the uniqueness of functions in a schema” in CREATE FUNCTION.

\[(\text{parameter-declaration,...})\]
Specifies the number of input parameters of the function and the data type of each parameter. All of the parameters for a function are input parameters and are nullable. There must be one entry in the list for each parameter that the function expects to receive. Although not required, you can give each parameter a name.

A function can have no parameters. In this case, you must code an empty set of parentheses, for example:

\[
\text{CREATE FUNCTION WOOFER()}
\]

\text{parameter-name}
Specifies the name of the input parameter. The name is an SQL identifier, and each name in the parameter list must not be the same as any other name.

\text{data-type}
Specifies the data type of the input parameter. The data type can be a built-in data type or a distinct type.

\text{built-in-type}
The data type of the input parameter is a built-in data type.

For information on the data types, see built-in-type.

For parameters with a character or graphic data type, the PARAMETER CCSID clause or CCSID clause indicates the encoding scheme of the parameter. If you do not specify either of these clauses, the encoding scheme is the value of field DEF ENCODING SCHEME on installation panel DSNTIPF.

\text{distinct-type-name}
The data type of the input parameter is a distinct type. Any length, precision, scale, subtype, or encoding scheme attributes for the parameter are those of the source type of the distinct type.

The implicitly or explicitly specified encoding scheme of all of the parameters with a character or graphic string data type must be the same—either all ASCII, all EBCDIC, or all UNICODE.

Although parameters with a character data type have an implicitly or explicitly specified subtype (BIT, SBCS, or MIXED), the function program can receive character data of any subtype. Therefore, conversion of the input data to the subtype of the parameter might occur when the function is invoked.

Parameters with a datetime data type or a distinct type are passed to the function as a different data type:

- A datetime type parameter is passed as a character data type, and the data is passed in ISO format.

The encoding scheme for a datetime type parameter is the same as the implicitly or explicitly specified encoding scheme of any character or graphic string parameters. If no character or graphic string parameters are passed, the encoding scheme is the value of field DEF ENCODING SCHEME on installation panel DSNTIPF.
A distinct type parameter is passed as the source type of the distinct type.

You can specify any built-in data type or distinct type that matches or can be cast to the data type of the corresponding parameter of the source function (the function that is identified in the SOURCE clause). (For information on casting data types, see [Casting between data types](#)).

Length, precision, or scale attributes do not have to be specified for data types with these attributes. When specifying data types with these attributes, follow these rules:

- An empty set of parentheses can be used to indicate that the length, precision, or scale is the same as the source function.
- If length, precision, or scale is not explicitly specified, and empty parentheses are not specified, the default values are used.

**AS LOCATOR**

Specifies that a locator to the value of the parameter is passed to the function instead of the actual value. Specify AS LOCATOR only for parameters with a LOB data type or a distinct type based on a LOB data type. Passing locators instead of values can result in fewer bytes being passed to the function, especially when the value of the parameter is very large.

The AS LOCATOR clause has no effect on determining whether data types can be promoted, nor does it affect the function signature, which is used in function resolution.

**TABLE LIKE** *table-name* or *view-name* **AS LOCATOR**

Specifies that the parameter is a transition table. However, when the function is invoked, the actual values in the transition table are not passed to the function. A single value is passed instead. This single value is a locator to the table, which the function uses to access the columns of the transition table. A function with a table parameter can only be invoked from the triggered action of a trigger.

The use of TABLE LIKE provides an implicit definition of the transition table. It specifies that the transition table has the same number of columns as the identified table or view. If a table is specified, the transition table includes columns that are defined as implicitly hidden in the table. The columns have the same data type, length, precision, scale, subtype, and encoding scheme as the identified table or view, as they are described in catalog tables SYSCOLUMNS and SYSTABLESPACE. The number of columns and the attributes of those columns are determined at the time the CREATE FUNCTION statement is processed. Any subsequent changes to the number of columns in the table or the attributes of those columns do not affect the parameters of the function.

*table-name* or *view-name* must identify a table or view that exists at the current server. A view cannot have columns of length 0. The name must not identify a declared temporary table. The table that is identified can contain XML columns; however, the function cannot reference those XML columns. The name does not have to be the same name as the table that is associated with the transition table for the trigger. An unqualified table or view name is implicitly qualified according to the following rules:

- If the CREATE FUNCTION statement is embedded in a program, the implicit qualifier is the authorization ID in the QUALIFIER bind option when the plan or package was created or last rebound. If QUALIFIER was not used, the implicit qualifier is the owner of the plan or package.
• If the CREATE FUNCTION statement is dynamically prepared, the
  implicit qualifier is the SQL authorization ID in the CURRENT SCHEMA
  special register.

When the function is invoked, the corresponding columns of the transition
table identified by the table locator and the table or view identified in the
TABLE LIKE clause must have the same definition. The data type, length,
precision, scale, and encoding scheme of these columns must match
exactly. The description of the table or view at the time the CREATE
FUNCTION statement was executed is used.

Additionally, a character FOR BIT DATA column of the transition table
cannot be passed as input for a table parameter for which the

  corresponding column of the table specified at the definition is not defined
as character FOR BIT DATA. (The definition occurs with the CREATE
FUNCTION statement.) Likewise, a character column of the transition table
that is not FOR BIT DATA cannot be passed as input for a table parameter
for which the corresponding column of the table specified at the definition
is defined as character FOR BIT DATA.

For more information about using table locators, see Db2 Application
Programming and SQL Guide.

RETURNS
Identifies the output of the function.

data-type2
  Specifies the data type of the output. The output is nullable.

You can specify any built-in data type or distinct type that can be cast from
the data type of the result of the source function. (For information on
casting data types, see Casting between data types.) For additional rules
that apply to the data type that you can specify, see Rules for creating
sourced functions.

AS LOCATOR
  Specifies that the function returns a locator to the value rather than the
actual value. You can specify AS LOCATOR only if the output from the
function has a LOB data type or a distinct type based on a LOB data
type.

SPECIFIC specific-name
  Provides a unique name for the function. The name is implicitly or explicitly
qualified with a schema name. The name, including the schema name, must
not identify the specific name of another function that exists at the current
server.

The unqualified form of specific-name is an SQL identifier. The qualified form is
an SQL identifier (the schema name) followed by a period and an SQL
identifier.

If you do not specify a schema name, it is the same as the explicit or implicit
schema name of the function name (function-name). If you specify a schema
name, it must be the same as the explicit or implicit schema name of the
function name.

If you do not specify the SPECIFIC clause, the default specific name is the
name of the function. However, if the function name does not provide a
unique specific name or if the function name is a single asterisk, Db2 generates
a specific name in the form of:
SQLxxxxxxxxxxxxx
where 'xxxxxxxxxxxx' is a string of 12 characters that make the name unique.

The specific name is stored in the SPECIFIC column of the SYSROUTINES catalog table. The specific name can be used to uniquely identify the function in several SQL statements (such as ALTER FUNCTION, COMMENT, DROP, GRANT, and REVOKE) and in Db2 commands (START FUNCTION, STOP FUNCTION, and DISPLAY FUNCTION). However, the function cannot be invoked by its specific name.

**PARAMETER CCSID**

Indicates whether the encoding scheme for character and graphic string parameters is ASCII, EBCDIC, or UNICODE. The default encoding scheme is the value specified in the CCSID clauses of the parameter list or RETURNS clause, or in the field DEF ENCODING SCHEME on installation panel DSNTIPF.

This clause provides a convenient way to specify the encoding scheme for character and graphic string parameters. If individual CCSID clauses are specified for individual parameters in addition to this PARAMETER CCSID clause, the value specified in all of the CCSID clauses must be the same value that is specified in this clause.

This clause also specifies the encoding scheme to be used for system-generated parameters of the routine such as message tokens and DBINFO.

**SOURCE**

Specifies that the new function is being defined as a sourced function. A *sourced function* is implemented by another function (the *source function*). The source function must be a scalar or aggregate function that exists at the current server, and it must be one of the following types of functions:

- A function that was defined with a CREATE FUNCTION statement
- A cast function that was generated by a CREATE TYPE statement for a distinct type
- A built-in function

If the source function is not a built-in function, the particular function can be identified by its name, function signature, or specific name.

If the source function is a built-in function, the SOURCE clause must include a function signature for the built-in function.

The source function must not be any of the built-in functions (if a particular syntax is shown, only the indicated form cannot be specified):

- ARRAY_AGG
- ARRAY_DELETE
- ARRAY_FIRST
- ARRAY_LAST
- ARRAY_NEXT
- ARRAY_PRIOR
- CARDINALITY
- CHAR(datetime-expression, second-argument) where second-argument is ISO, USA, EUR, JIS, or LOCAL or if CHAR is specified with OCTETS, CODEUNITS16, or CODEUNITS32.
- CHARACTER_LENGTH
- CLOB if OCTETS, CODEUNITS16, or CODEUNITS32 is specified
- COALESCE if a parameter is an array
COUNT(*)
COUNT_BIG(*)
DBCLOB if OCTETS, CODEUNITS16, or CODEUNITS32 is specified
DECODE
DECRYPT_BIT where the second argument is DEFAULT
DECRYPT_CHAR where the second argument is DEFAULT
DECRYPT_DB where the second argument is DEFAULT
EXTRACT
GETVARIABLE where the second argument is DEFAULT
GRAPHIC if OCTETS, CODEUNITS16, or CODEUNITS32 is specified, or if the first argument is numeric
IFNULL if a parameter is an array
INSERT if OCTETS, CODEUNITS16, or CODEUNITS32 is specified
LEFT if OCTETS, CODEUNITS16, or CODEUNITS32 is specified
LIST
LOCAL
LOCATE if OCTETS, CODEUNITS16, or CODEUNITS32 is specified
MAX
MAX_CARDINALITY
MIN
NULLIF
POSITION
RID
RIGHT if OCTETS, CODEUNITS16, or CODEUNITS32 is specified
STRIP where multiple arguments are specified
SUBSTRING
TRIM where the first argument is BOTH, B, LEADING, L, TRAILING, T, or the first or second argument is FROM
TRIM_ARRAY
VARCHAR if OCTETS, CODEUNITS16, or CODEUNITS32 is specified
VARGRAPHIC if OCTETS, CODEUNITS16, or CODEUNITS32 is specified, or if the first argument is numeric.
XMLAGG
XMLCONCAT
XMLELEMENT
XMLFOREST
XMLNAMESPACES

If you base the sourced function directly or indirectly on an external scalar function, the sourced function inherits the attributes of the external scalar function. This can involve several layers of sourced functions. For example, assume that function A is sourced on function B, which in turn is sourced on function C. Function C is an external scalar function. Functions A and B inherit all of the attributes that are specified on the EXTERNAL clause of the CREATE FUNCTION statement for function C.

`function-name`  
Identifies the function that is to be used as the source function. The source
function can be defined with any number of parameters. If more than one function is defined with the specified name in the specified or implicit schema, an error is returned.

If you specify an unqualified function-name, Db2 searches the schemas of the SQL path. Db2 selects the first schema that has only one function with this name on which the user has EXECUTE authority. An error is returned if a function is not found or a schema has more than one function with this name.

**function-name (parameter-type,...)**

Identifies the function that is to be used as the source function by its function signature, which uniquely identifies the function. The function-name (parameter-type,...) must identify a function with the specified signature. The specified parameters must match the data types in the corresponding position that were specified when the function was created. Db2 uses the number of data types and the logical concatenation of the data types to identify the specific function instance. Synonyms for data types are considered a match.

If the function was defined with a table parameter (the LIKE TABLE name AS LOCATOR clause was specified in the CREATE FUNCTION statement to indicate that one of the input parameters is a transition table), the function signature cannot be used to uniquely identify the function. Instead, use one of the other syntax variations to identify the function with its function name, if unique, or its specific name.

If function-name() is specified, the identified function must have zero parameters.

**function-name**

Identifies the function name of the source function. If you specify an unqualified name, Db2 searches the schemas of the SQL path. Otherwise, Db2 searches for the function in the specified schema.

**parameter-type,...**

Identifies the parameters of the function.

If an unqualified distinct type name is specified, Db2 searches the SQL path to resolve the schema name for the distinct type.

Empty parentheses are allowed for some data types that are specified in this context. For data types that have a length, precision, or scale attribute, use one of the following specifications:

- Empty parentheses indicate that Db2 ignores the attribute when determining whether the data types match. For example, DEC() is considered a match for a parameter of a function that is defined with a data type of DEC(7,2). However, FLOAT cannot be specified with empty parentheses because its parameter value indicates a specific data type (REAL or DOUBLE).
- If a specific value for a length, precision, or scale attribute is specified, the value must exactly match the value that was specified (implicitly or explicitly) in the CREATE FUNCTION statement. If the data type is FLOAT, the precision does not need to exactly match the value that was specified because matching is based on the data type (REAL or DOUBLE).
- If length, precision, or scale is not explicitly specified, and empty parentheses are not specified, the default attributes of the data type
are implied. The implicit length must exactly match the value that was specified (implicitly or explicitly) in the CREATE FUNCTION statement.

If you omit the FOR subtype DATA clause or the CCSID clause for data types with a subtype or encoding scheme attribute, Db2 is to ignore the attribute when determining whether the data types match. An exception to ignoring the attribute is FOR BIT DATA. A character FOR BIT DATA parameter of the new function cannot correspond to a parameter of the source function that is not defined as character FOR BIT DATA. Likewise, a character parameter of the new function that is not FOR BIT DATA cannot correspond to a parameter of the source function that is defined as character FOR BIT DATA.

The number of input parameters in the function that is being created must be the same as the number of parameters in the source function. If the data type of each input parameter is not the same as or castable to the corresponding parameter of the source function, an error occurs. The data type of the final result of the source function must match or be castable to the result of the sourced function.

**AS LOCATOR**

Specifies that the function is defined to receive a locator for this parameter. If AS LOCATOR is specified, the data type must be a LOB or distinct type that is based on a LOB.

**SPECIFIC specific-name**

Identifies the function to be used as the source function by its specific name.

If you specify an unqualified specific-name, Db2 searches the SQL path to locate the schema. Db2 selects the first schema that contains a function with this specific name for which the user has EXECUTE authority. Db2 returns an error if it cannot find a function with the specific name in one of the schemas in the SQL path.

If you specify a qualified specific-name, Db2 searches the named schema for the function. Db2 returns an error if it cannot find a function with the specific name.

### Notes

**Considerations for all types of user-defined functions:**

For considerations that apply to all types of user-defined functions, see CREATE FUNCTION.

**Owner privileges for sourced functions:**

For sourced functions, the owner is authorized to execute the function (EXECUTE privilege) in the following cases:

- If the underlying function is a user-defined function, and the owner is authorized with the grant option to execute the underlying function, the privilege on the new function includes the grant option. Otherwise, the owner can execute the new function but cannot grant others the privilege to do so.
- If the underlying function is a built-in function, the owner is authorized with the grant option to execute the underlying built-in function and the privilege on the new function includes the grant option.
Rules for creating sourced functions:
Assume that the function that is being created is named NEWF and the source function is named SOURCEF. Consider the following rules when creating a sourced function:

- The unqualified names of the sourced function and source function can be different (NEWF and SOURCEF).
- The number of input parameters for NEWF and SOURCEF must be the same.
- When specifying the input parameters and output for NEWF, you can specify a value for the precision, scale, subtype, or encoding scheme for a data type with any of these attributes or use empty parentheses. Empty parentheses, such as VARCHAR(), indicate that the value of the attribute is the same as the attribute for the corresponding parameter of SOURCEF, or that is determined by data type promotion. If you specify any values for the attributes, Db2 checks the values against the corresponding input parameters and returned output of SOURCEF as described next.
- When the CREATE FUNCTION statement is executed, Db2 checks the input parameters of NEWF against those of SOURCEF. The data type of each input parameter of NEWF function must be either the same as, or promotable to, the data type of the corresponding parameter of SOURCEF. (For information on the promotion of data types, see Casting between data types.)

This checking does not guarantee that an error will not occur when NEWF is invoked. For example, an argument that matches the data type and length or precision attributes of a NEWF parameter might not be promotable if the corresponding SOURCEF parameter has a shorter length or less precision. In general, do not define the parameters of a sourced function with length or precision attributes that are greater than the attributes of the corresponding parameters of the source function.
- When the CREATE FUNCTION statement is executed, Db2 checks the data type identified in the RETURNS clause of NEWF against the data type that SOURCEF returns. The data type that SOURCEF returns must be either the same as, or promotable to, the RETURNS data type of NEWF.

This checking does not guarantee that an error will not occur when NEWF is invoked. For example, the value of a result that matches the data type and length or precision attributes of those specified for the SOURCEF result might not be promotable if the RETURNS data type of NEWF has a shorter length or less precision. Consider the possible effects of defining the RETURNS data type of a sourced function with length or precision attributes that are less than the attributes defined for the data type returned by source function.

Secure functions:
The sourced user-defined function inherits the SECURED or NOT SECURED attribute from the source function in which only the topmost user-defined function is considered. If the topmost user-defined function is secure, any nested user-defined functions are also considered secure. Db2 does not validate whether those nested user-defined functions are secure. If those nested functions can access sensitive data, the security administrator
needs to ensure that those functions are allowed to access sensitive data and should ensure that a change control audit procedure has been established for all changes to those functions.

If the sourced function is defined with the VERIFY_GROUP_FOR_USER or VERIFY_ROLE_FOR_USER function as its source, the sourced function must specify only two input parameters.

**Examples**

*Example 1:* Assume that you created a distinct type HATSIZE, which you based on the built-in data type INTEGER. You want to have an AVG function to compute the average hat size of different departments. Create a sourced function that is based on built-in function AVG.

```
CREATE FUNCTION AVE(HATSIZE) RETURNS HATSIZE
SOURCE SYSIBM.AVG(INTEGER);
```

When you created distinct type HATSIZE, two cast functions were generated, which allow HATSIZE to be cast to INTEGER for the argument and INTEGER to be cast to HATSIZE for the result of the function.

*Example 2:* After Smith registered the external scalar function CENTER in his schema, you decide that you want to use this function, but you want it to accept two INTEGER arguments instead of one INTEGER argument and one FLOAT argument. Create a sourced function that is based on CENTER.

```
CREATE FUNCTION MYCENTER(INTEGER, INTEGER)
RETURNS FLOAT
SOURCE SMITH.CENTER(INTEGER, FLOAT);
```

**CREATE FUNCTION (SQL table)**

The CREATE FUNCTION (SQL table) statement creates an SQL table function at the current server. The function returns a set of rows.

**Invocation**

This statement can only be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

**Authorization**

The privilege set that is defined below must include at least one of the following privileges or authorities:

- The CREATEIN privilege on the schema
- SYSADM authority
- SYSCTRL authority
- System DBADM
- Installation SYSOPR authority (when the current SQLID of the process is set to SYSINSTL)

The authorization ID that matches the schema name implicitly has the CREATEIN privilege on the schema.
If the authorization ID that is used to create the function has the installation SYSADM authority or the installation SYSOPR authority and if the current SQLID is set to SYSINSTL, the function is identified as system-defined function.

If a distinct type is referenced (i.e. as the data type of a parameter or SQL variable), the privilege set must also include at least one of the following:

- Ownership of the distinct type
- The USAGE privilege on the distinct type
- SYSADM authority
- SYSDBADM authority

If the function uses a table as a parameter, the privilege set must also include at least one of the following:

- Ownership of the table
- The SELECT privilege on the table
- SYSADM authority

At least one of the following additional privileges is required if the SECURED option is specified:

- SECADM authority
- CREATE_SECURE_OBJECT privilege

**Privilege set:** If the statement is embedded in an application program, the privilege set is the set of privileges that are held by the owner of the plan or package. If the owner is a role, matching of the implicit schema name does not apply and the role must include one of the previously listed privileges or authorities.

If the statement is dynamically prepared and is not running in a trusted context for which the ROLE AS OBJECT OWNER clause is specified, the privilege set is the set of privileges that are held by the SQL authorization ID of the process. If the schema name is not the same as the SQL authorization ID of the process, one of the following conditions must be met:

- The privilege set includes SYSADM authority
- The privilege set includes SYSCTRL authority
- The SQL authorization ID of the process has the CREATEIN privilege on the schema

**Syntax**

```
CREATE FUNCTION function-name (parameter-declaration)
function-definition
WRAPPED obfuscated-statement-text
```
<table>
<thead>
<tr>

NOT DETERMINISTIC EXTERNAL ACTION READS SQL DATA

DETERMINISTIC NO EXTERNAL ACTION CONTAINS SQL

CALLED ON NULL INPUT INHERIT SPECIAL REGISTERS

STATIC DISPATCH

CARDINALITY integer

PARAMETER CCSID

ASCII EBCDIC UNICODE

NOT SECURED

Parameters:
- `FUNCTION NAME` (function-name)
- `RETURN TABLE` (returns-table)
- `COLUMN NAME` (column-name)
- `DATA TYPE` (data-type)
- `OPTION LIST` (option-list)
- `SQL ROUTINE BODY` (sql-routine-body)
- `RETURN STATEMENT` (return-statement)
- `BEGIN-ATOMIC-RETURN STATEMENT-END` (begin-atomic-return-statement-end)

Notes:
1. The options in the option-list can be specified in any order. However, the same clause cannot be specified more than one time.

Description

`FUNCTION NAME`
Names the user-defined function. The name is implicitly or explicitly qualified by a schema name. The combination of the name, the schema name, the number of parameters, and the data type of each parameter (without regard to any length, precision, scale, subtype, or encoding scheme attribute of the data type) must not identify a user-defined function that exists at the current server.
For more information, see “Choosing the schema and function names” and “Determining the uniqueness of functions in a schema” in **CREATE FUNCTION**

\[(\text{parameter-declaration},...)\]

Identifies the number of input parameters of the function, and specifies the name and data type of each parameter. All of the parameters for a function are input parameters and are nullable. There must be one entry in the list for each parameter that the function expects to receive.

\text{parameter-name} \\
Specifies the name of the input parameter. Each name in the parameter list must not be the same as any other name.

\text{data-type} \\
Specifies the data type of the input parameter. The data type can be a built-in data type or a distinct type.

\text{built-in-type} \\
The data type of the parameter is a built-in data type.

For more information on the data types, including the subtype of character data types (the FOR subtype DATA clause), see **built-in types**. However, the varying length string data types have different maximum lengths for this statement than for the CREATE TABLE statement. The maximum lengths for parameters (and SQL variables) are as follows:

- VARCHAR or VARBINARY: 32704
- VARGRAPHIC: 16352

For parameters with a character or graphic data type, the PARAMETER CCSID clause or the CCSID clause indicates the encoding scheme of the parameter. If you do not specify either of the CCSID clauses, the encoding scheme is the value of the DEFENCODING SCHEME field on installation panel DSNTIPF.

Although an input parameter with a character data type has an implicitly or explicitly specified subtype (BIT, SBCS, or MIXED), the value that is actually passed in the input parameter can have any subtype. Therefore, conversion of the input data to the subtype of the parameter might occur when the function is invoked. With ASCII or EBCDIC, an error occurs if mixed data that actually contains DBCS characters is used as the value for an input parameter that is declared with an SBCS subtype.

\text{distinct-type-name} \\
The data type of the parameter is a distinct type. Any length, precision, scale, subtype, or encoding scheme attributes for the parameter are those of the source type for the distinct type.

**TABLE LIKE table-name AS LOCATOR** \\
Specifies that the parameter is a transition table. However, when the function is invoked, the actual values in the transition table are not passed to the function. A single value is passed instead. This value is a locator for the table, which the function uses to access the columns of the transition table. The table that is identified can contain XML columns; however, the function cannot reference those XML columns.

A function with a table parameter can only be invoked from the triggered action of a trigger.
RETURNS TABLE
    Specifies that the output of the function is a table. The RETURN statement in
    an SQL table function must return a table result. The parentheses that follow
    the RETURNS TABLE keyword delimit a list of name and data type pairs of
    the columns of the output table. All columns of the output table are nullable.

column-name
    Specifies the name of the column. The name cannot be qualified, and must
    be unique within the RETURNS TABLE clause for the function.

data-type
    Specifies the data type and attributes of the column of the output table.
    For SQL table functions, the result table of the function might include
    multiple encoding schemes – similar to what a view definition can include.

LANGUAGE SQL
    Specifies that the function is written exclusively in SQL.

SPECIFIC specific-name
    Specifies a unique name for the function.

NOT DETERMINISTIC or DETERMINISTIC
    Specifies whether the function returns the same results each time that the
    function is invoked with the same input arguments. Db2 does not verify that
    the function program is consistent with the specification of NOT
    DETERMINISTIC or DETERMINISTIC.

NOT DETERMINISTIC
    Specifies that the function might not return the same result table each time
    that the function is invoked with the same input arguments, even when
    the referenced data in the database has not changed. The function depends
    on some state values that might affect the results. When the
    MATERIALIZE_NODET_SQLTUDF subsystem parameter is set to YES,
    Db2 disables the merging of SQL table functions that are defined with this
    option. An example of a table function that is not deterministic is one
    which references special registers, other functions that are not
    deterministic, or a sequence in a way that affects the table function’s result
    table. NOT DETERMINISTIC is the default.

DETERMINISTIC
    Specifies that the function always returns the same result table each time
    that the function is invoked with the same input arguments (provided that
    the referenced data in the database has not changed). Db2 enables the
    merging of SQL table functions that are defined with this option.

EXTERNAL ACTION or NO EXTERNAL ACTION
    Specifies whether the function contains an external action. Db2 does not verify
    that the function program is consistent with the specification of EXTERNAL
    ACTION or NO EXTERNAL ACTION.

EXTERNAL ACTION
    The function performs some external action (outside the scope of the
    function program). Thus, the function must be invoked with each
    successive function invocation. EXTERNAL ACTION must be specified if
    the function invokes another function that has external actions.
    EXTERNAL ACTION is the default.

NO EXTERNAL ACTION
    The function does not perform any external action. It need not be called
    with each successive function invocation. Functions that are defined with
NO EXTERNAL ACTION might perform better than functions that are defined with EXTERNAL ACTION because the function might not be invoked for each successive function invocation.

Although the scope of global variables are beyond the scope of the routine, global variables can be set in the routine body when NO EXTERNAL ACTION is specified.

**READS SQL DATA or CONTAINS SQL**

Specifies the classification of SQL statements and nested routines that this routine can execute or invoke. The database manager verifies that the SQL statements issued by the function, and all routines locally invoked by the routine, are consistent with this specification; the verification is not performed when nested remote routines are invoked. For the classification of each statement, see [SQL statement data access classification for routines](#).

**READS SQL DATA**

Specifies that the function can execute statements with a data access indication of READS SQL DATA or CONTAINS SQL. The function cannot execute SQL statements that modify data.

READS SQL DATA is the default.

**CONTAINS SQL**

Specifies that the function can execute only SQL statements with a data access indication of CONTAINS SQL. The function cannot execute statements that read or modify data.

**CALLED ON NULL INPUT**

Specifies that the function is called regardless of whether any of the input arguments are null, making the function responsible for testing for null argument values. The function can return an empty table, depending on its logic.

CALLED ON NULL INPUT is the default.

**INHERIT SPECIAL REGISTERS**

Specifies that existing values of special registers are inherited upon entry to the function. INHERIT SPECIAL REGISTERS is the default.

**STATIC DISPATCH**

At function resolution time, Db2 chooses a function based on the static (or declared) types of the function parameters. STATIC DISPATCH is the default.

**CARDINALITY integer**

Specifies an estimate of the expected number of rows that the function returns. The number is used for optimization purposes. The value of integer must be between 0 and 2147483647.

If you do not specify CARDINALITY, Db2 assumes a finite value. The finite value is the same value that Db2 assumes for tables for which the RUNSTATS utility has not gathered statistics.

If a function has an infinite cardinality (the function never returns the end-of-table condition and always returns a row), a query that requires the end-of-table condition to work correctly will need to be interrupted.

**PARAMETER CCSID**

Specifies the encoding scheme for character and graphic string parameters is ASCII, EBCDIC, or UNICODE. The default encoding scheme is the value that is specifies in the CCSID clauses of the parameter list or RETURNS clause, or in the DEF ENCODING SCHEME field on installation panel DSNTIPF. This
clause provides a convenient way to specify the encoding scheme for character and graphic string parameters. If individual CCSID clauses are specified for individual parameters in addition to this PARAMETER CCSID clause, the value specified in all of the CCSID clauses must be the same value that is specified in this clause. This clause also specifies the encoding scheme that is used for system-generated parameters of the routine such as message tokens and DBINFO.

**NOT SECURED or SECURED**

Specifies if the function is considered secure for row access control and column access control. The SECURED or NOT SECURED option applies to all future versions of the function.

**NOT SECURED**

Specifies that the function is not considered secure for row access control and column access control.

**NOT SECURED** is the default.

When the function is invoked, the arguments of the function must not reference a column for which a column mask is enabled when the table is using active column access control.

**SECURED**

Specifies that the function is considered secure for row access control and column access control.

The function must be secure when it is referenced in a row permission or a column mask.

**SQL-routine-body**

**RETURN-statement**

Specifies the return value of the function. A RETURN statement must be specified for an SQL table function.

**WRAPPED obfuscated-statement-text**

Specifies the encoded definition of the function. A CREATE FUNCTION statement can be encoded using the WRAP scalar function.

**WRAPPED** must not be specified on a static CREATE statement.

**ATOMIC**

ATOMIC indicates that an unhandled exception condition within the RETURN statement causes the statement to be rolled back.

**Notes**

**Considerations for all types of user-defined functions:**

For considerations that apply to all types of user-defined functions, see [CREATE FUNCTION](#).

**Self-referencing function:**

The body of an SQL function (that is, the expression or NULL in the RETURN statement in the body of the CREATE FUNCTION statement) cannot contain a recursive invocation of itself or to another function that invokes it, because such a function would not exist to be referenced.

**Dependent objects:**

An SQL routine is dependent on objects that are referenced in the routine body.
Obfuscated statements:
A CREATE FUNCTION statement can be executed in obfuscated form. In an obfuscated statement, only the function name, parameters, and the WRAPPED keyword are readable. The rest of the statement is encoded in such a way that it is not readable but can be decoded by a database server that supports obfuscated statements. The WRAP scalar function produces obfuscated statements. Any debug options that are specified when the function is created from an obfuscated statement are ignored.

Resolution of object names:
Db2 resolves object names inside the body of the function according to the rules in “Resolution of unqualified object names” on page 93 and the type of the object. The name resolution occurs when the function is created.

Referencing date and time special registers:
If an SQL function contains multiple references to any of the date or time special registers, all references return the same value. In addition, this value is the same value that is returned by the retrieving value of the special register in the statement that invoked the function.

Considerations for columns that are defined with a field procedure:
The body of an SQL table function must not reference a column that is defined with a field procedure, and the RETURNS clause of an SQL table function must not reference a column that is defined with a field procedure. An SQL table function must not be invoked with an expression that is derived from a column that is defined with a field procedure.

Restrictions involving pending definition changes:
The body of an SQL table function must not reference a table that has pending definition changes.

Alternative syntax and synonyms:
To provide compatibility with previously releases of Db2 or other products in the Db2 family, Db2 supports the following alternative syntax:
- VARIANT as a synonym for NOT DETERMINISTIC
- NOT VARIANT as a synonym for DETERMINISTIC
- NULL CALL as a synonym for CALLED ON NULL INPUT

Examples

Example 1: Define a table function, JTABLE, to return a table with 3 columns:

```
CREATE FUNCTION JTABLE (COLD_VALUE CHAR(9), T2_FLAG CHAR(1))
RETURNS TABLE (COLA INT, COLB INT, COLC INT)
LANGUAGE SQL
SPECIFIC DEPTINFO
NOT DETERMINISTIC
READS SQL DATA
RETURN
SELECT A.COLA, B.COLB, B.COLC
FROM TABLE1 AS A
LEFT OUTER JOIN
TABLE2 AS B
ON A.COL1 = B.COL1 AND T2_FLAG = 'Y'
WHERE A.COLD = COLD_VALUE;
```

Example 2: Define a table function that returns the employees in a specified department number. The function simply returns the employees for the requested department:

```
```
CREATE FUNCTION DEPTEMPLOYEES (DEPTNO CHAR(3))
RETURNS TABLE (EMPNO CHAR(6), LASTNAME VARCHAR(15), FIRSTNAME VARCHAR(12))
LANGUAGE SQL
READS SQL DATA
NO EXTERNAL ACTION
DETERMINISTIC
RETURN
SELECT EMPNO, LASTNAME, FIRSTNAME 
FROM YEMP 
WHERE YEMP.WORKDEPT = DEPTEMPLOYEES.DEPTNO;

CREATE GLOBAL TEMPORARY TABLE

The CREATE GLOBAL TEMPORARY TABLE statement creates a description of a temporary table at the current server.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

The privilege set that is defined below must include at least one of the following:

- The CREATETMTAB system privilege
- The CREATETAB database privilege for any database
- DBADM, DBCTRL, or DBMAINT authority for any database
- SYSADM or SYSCTRL authority
- System DBADM
- Installation SYSOPR authority (when the current SQLID of the process is set to SYSINSTL)

However, DBADM, DBCTRL, or DBMAINT authority is not sufficient authority if you are creating a temporary table for someone else and the table qualifier is not your authorization ID.

Additional privileges might be required when the data type of a column is a distinct type or the LIKE clause is specified. See the description of distinct-type and LIKE for the details.

Privilege set: The privilege set is the same as the privilege set for the CREATE TABLE statement. See information about CREATE TABLE Authorization for details.
Syntax

```
CREATE GLOBAL TEMPORARY TABLE <table-name>
    (column-definition)
    LIKE <table-name> <view-name>

column-definition:
```

```
<column-name> <data-type> [NOT NULL]
```

```
data-type:
```

```
built-in-type
    [distinct-type-name]
```

built-in-type:
Description

table-name

Names the temporary table. The name, including the implicit or explicit qualifier, must not identify a table, view, alias, synonym, or temporary table that exists at the database server, or a table that exists in the SYSIBM.SYSPENDINGOBJECTS catalog table.

The qualification rules for a temporary table are the same as for other tables.

The owner acquires ALL PRIVILEGES on the table WITH GRANT OPTION and the authority to drop the table.

column-definition

Defines the attributes of a column for each instance of the table. The number of

Notes:

1 The CCSID clause must only be specified for a character string or a graphic string column in an EBCDIC created global temporary table.
columns defined must not exceed 750. The maximum record size must not exceed 32714 bytes. The maximum row size must not exceed 32706 bytes (8 bytes less than the maximum record size).

column-name
Names the column. The name must not be qualified and must not be the same as the name of another column in the table.

data-type
Specifies the data type of the column. The data type can be a built-in data type or a distinct type.

built-in-type
The data type of the column is a built-in data type.

For more information on and the rules that apply to the data types, see built-in-type.

distinct-type
Any distinct type except one that is based on a LOB or ROWID data type. The privilege set must implicitly or explicitly include the USAGE privilege on the distinct type.

NOT NULL
Specifies that the column cannot contain nulls. Omission of NOT NULL indicates that the column can contain nulls.

LIKE table-name or view-name
Specifies that the columns of the table have exactly the same name and description as the columns of the identified table or view. The name specified after LIKE must identify a table, view, or temporary table that exists at the current server. The identified table must not be an accelerator-only table. A view cannot contain columns of length 0.

The privilege set must implicitly or explicitly include the SELECT privilege on the identified table or view.

This clause is similar to the LIKE clause on CREATE TABLE, but it has the following differences:

- If any column of the identified table or view has an attribute value that is not allowed for a column in a temporary table, that attribute value is ignored. The corresponding column in the new temporary table has the default value for that attribute unless otherwise indicated.
- If any column of the identified table or view allows a default value other than null, that default value is ignored and the corresponding column in the new temporary table has no default value. A default value other than null is not allowed for any column in a temporary table.

CCSID encoding-scheme
Specifies the encoding scheme for string data stored in the table.

ASCII
Specifies that the data must be encoded by using the ASCII CCSIDs of the server.

An error occurs if a valid ASCII CCSID has not been specified for the installation.

EBCDIC
Specifies that data must be encoded by using the EBCDIC CCSIDs of the server.
An error occurs if a valid EBCDIC CCSID has not been specified for the installation.

**UNICODE**

Specifies that data must be encoded by using the CCSIDs of the server for Unicode.

An error occurs if a valid CCSID for Unicode has not been specified for the installation.

Usually, each encoding scheme requires only a single CCSID. Additional CCSIDs are needed when mixed, graphic, or Unicode data is used. An error occurs if CCSIDs have not been defined.

The CCSID clause can be specified for the created temporary table, or for individual columns in the created temporary table. If a CCSID clause is specified for the table, that CCSID specifies the encoding scheme for the table, regardless of whether the LIKE clause is also specified. If a CCSID clause is not specified for the table, the encoding scheme for the table is EBCDIC.

If a CCSID clause is specified for a column, the encoding scheme for the created temporary table must be EBCDIC. If a CCSID clause is not specified for a column, and the LIKE clause is not specified for the table, the CCSID of the column is the same as the CCSID of the table. If the LIKE clause is specified, and the source table that is specified in the LIKE clause is an EBCDIC table with Unicode columns, the columns in the created temporary table that correspond to the Unicode columns in the source table are also Unicode.

**Notes**

*Owner privileges:* The owner of the table has all table privileges (see [“GRANT (table or view privileges)” on page 2136](#)) with the ability to grant these privileges to others. For more information about ownership of the object, see [“Authorization, privileges, permissions, masks, and object ownership” on page 97](#).

**Instantiation and termination:** Let T be a temporary table defined at the current server and let P denote an application process:

- An empty instance of T is created as a result of the first implicit or explicit reference to T in an OPEN, SELECT INTO or SQL data change operation that is executed by any program in P.
- Any program in P can reference T and any reference to T by a program in P is a reference to that instance of T.
  
  When a commit operation terminates a unit of work in P and no program in P has an open WITH HOLD cursor that is dependent on T, the commit includes the operation DELETE FROM T.
  
  When a rollback operation terminates a unit of work in P, the rollback includes the operation DELETE FROM T.
  
  When the connection to the database server at which an instance of T was created terminates, the instance of T is destroyed. However, the definition of T remains. A DROP TABLE statement must be executed to drop the definition of T.

**Restrictions and extensions:** Let T denote a temporary table:

- Columns of T cannot have default values other than null.
- A column of T cannot have a LOB or ROWID data type (or a distinct type based on one).
- T cannot have unique constraints, referential constraints, or check constraints.
• T cannot be defined as the parent in a referential constraint.
• T cannot be referenced in:
  – A CREATE INDEX statement.
  – A LOCK TABLE statement.
  – As the object of an UPDATE statement in which the object is T or a view of T. However, you can reference T in the WHERE clause of an UPDATE statement (including the update operation of the MERGE statement).
  – Db2 utility commands.
• If T is referenced in the fullselect of a CREATE VIEW statement, you cannot specify a WITH CHECK OPTION clause in the CREATE VIEW statement.
• ALTER TABLE T is valid only if the statement is used to add a column to T. Any column that you add to T must have a default value of null.
  When you alter T, any packages that refer to the table are invalidated, and Db2 automatically rebinds the packages the next time they are run.
• DELETE FROM T or a view of T is valid only if the statement does not include a WHERE or WHERE CURRENT OF clause. In addition, DELETE FROM view of T is valid only if the view was created (CREATE VIEW) without the WHERE clause. A DELETE FROM statement deletes all the rows from the table or view.
• You can refer to T in the FROM clause of any subselect. If you refer to T in the first FROM clause of a select-statement, you cannot specify a FOR UPDATE clause.
• You cannot use a DROP DATABASE statement to implicitly drop T. To drop T, reference T in a DROP TABLE statement.
• A temporary table instantiated by an SQL statement using a three-part table name can be accessed by another SQL statement using the same name in the same application process for as long as the Db2 connection which established the instantiation is not terminated.
• GRANT ALL PRIVILEGES ON T is valid, but you cannot grant specific privileges on T.
  Of the ALL privileges, only the ALTER, INSERT, DELETE, and SELECT privileges can actually be used on T.
• REVOKE ALL PRIVILEGES ON T is valid, but you cannot revoke specific privileges from T.
• A COMMIT operation deletes all rows of every temporary table of the application process, but the rows of T are not deleted if any program in the application process has an open WITH HOLD cursor that is dependent on T. In addition, if RELEASE(COMMIT) is in effect and no open WITH HOLD cursors are dependent on T, all logical work files for T are also deleted.
• A ROLLBACK operation deletes all rows and all logical work files of every temporary table of the application process.
• You can reuse threads when using a temporary table, and a logical work file for a temporary table name remains available until deallocation. A new logical work file is not allocated for that temporary table name when the thread is reused.
• You can refer to T in the following statements:

<table>
<thead>
<tr>
<th>ALTER FUNCTION</th>
<th>CREATE PROCEDURE</th>
<th>DECLARE TABLE</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALTER PROCEDURE</td>
<td>CREATE SYNONYM</td>
<td>DELETE (if it does not include a WHERE clause)</td>
</tr>
<tr>
<td>COMMENT</td>
<td>CREATE TABLE LIKE</td>
<td>DROP TABLE</td>
</tr>
<tr>
<td>CREATE ALIAS</td>
<td>CREATE VIEW</td>
<td>INSERT</td>
</tr>
<tr>
<td>CREATE FUNCTION</td>
<td>DESCRIBE TABLE</td>
<td>LABEL</td>
</tr>
<tr>
<td></td>
<td></td>
<td>SELECT INTO</td>
</tr>
</tbody>
</table>
Alternative syntax and synonyms: For compatibility with previous releases of Db2, you can specify LONG VARCHAR as a synonym for VARCHAR(integer) and LONG VARGRAPHIC as a synonym for VARGRAPHIC(integer) when defining the data type of a column. However, the use of these synonyms is not encouraged because after the statement is processed, Db2 considers a LONG VARCHAR column to be VARCHAR and a LONG VARGRAPHIC column to be VARGRAPHIC.

Examples

Example 1: Create a temporary table, CURRENTMAP. Name two columns, CODE and MEANING, both of which cannot contain nulls. CODE contains numeric data and MEANING has character data. Assuming a value of NO for the field MIXED DATA on installation panel DSNTIPF, column MEANING has a subtype of SBCS:

```
CREATE GLOBAL TEMPORARY TABLE CURRENTMAP
  (CODE INTEGER NOT NULL,
   MEANING VARCHAR(254) NOT NULL);
```

Example 2: Create a temporary table, EMP:

```
CREATE GLOBAL TEMPORARY TABLE EMP
  (TMPDEPTNO CHAR(3) NOT NULL,
   TMPDEPTNAME VARCHAR(36) NOT NULL,
   TMPMGRNO CHAR(6) ,
   TMPLOCATION CHAR(16) );
```

CREATE INDEX

The CREATE INDEX statement creates a partitioning index or a secondary index and an index space at the current server. The columns included in the key of the index are columns of a table at the current server.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

Authorization

The privilege set that is defined below must include at least one of the following:

- The INDEX privilege on the table
- Ownership of the table
- DBADM authority for the database that contains the table
- SYSADM or SYSCTRL authority
- System DBADM
- Installation SYSOPR authority (when the current SQLID of the process is set to SYSINSTL)

If the database is implicitly created, the database privileges must be on the implicit database or on DSNDB04.

If the index is created using an expression, the EXECUTE privilege is required on any user-defined function that is invoked in the index expression.
Additional privileges might be required, as explained in the description of the BUFFERPOOL and USING STOGROUP clauses.

**Privilege set:** If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the specified index name includes a qualifier that is not the same as this owner, the privilege set must include SYSADM or SYSCTRL authority, or DBADM or DBCTRL authority for the database.

If ROLE AS OBJECT OWNER is in effect, the schema qualifier must be the same as the role, unless the role has the CREATEIN privilege on the schema, SYSADM authority, or SYSCTRL authority.

If ROLE AS OBJECT OWNER is not in effect, one of the following rules applies:

- If the privilege set lacks the CREATEIN privilege on the schema, SYSADM authority, or SYSCTRL authority, the schema qualifier (implicit or explicit) must be the same as one of the authorization ids of the process.
- If the privilege set includes SYSADM authority or SYSCTRL authority, the schema qualifier can be any valid schema name.

If the statement is dynamically prepared, the privilege set is the privileges that are held by the SQL authorization ID of the process unless the process is within a trusted context and the ROLE AS OBJECT OWNER clause is specified. In that case, the privilege set is the set of privileges that are held by the role that is associated with the primary authorization ID of the process. However, if the specified index name includes a qualifier that is not the same as this authorization ID, the privilege set that are held by that authority ID includes all privileges needed to create the index. This is an exception to the rule that the privilege set is the privileges that are held by the SQL authorization ID of the process.
Syntax

```
CREATE UNIQUE INDEX index-name ON table-name (
  column-name ASC,
  key-expression DESC,
  BUSINESS_TIME WITHOUT OVERLAPS,
  RANDOM
  BUSINESS_TIME WITH OVERLAPS
) other-options
```

other-options:
Notes:
1 The same clause must not be specified more than one time.
2 The value of field PAD INDEXES BY DEFAULT (on installation panel DSNTIPE) determines the default. When the value is NO, NOT PAdded is the default. When the value is YES, PADDED is the default. For more information, see the description of the PADDED or NOT PADDED options.

XML-index-specification:
XML-pattern-clause:

prolog:

pattern-expression:

Notes:
1. pattern-expression cannot be an empty string.
function-step:

```
fn::upper-case(.)
fn::exists(
  element-name
  *nsprefix:*::*:NCName
  child::element-name
  child::*
  child::nsprefix::*
  child::*:NCName
  attribute::attribute-name
  @attribute::*
  attribute::*
```

SQL-data-type:

```
SQL VARCHAR(integer)
DECFLOAT (34)
DATE (12)
TIMESTAMP
```

using-specification:
### Notes:

1. The same clause must not be specified more than once.

#### free-specification:

- **FREEPAGE 0**
- **FREEPAGE**—integer
- **PCTFREE 10**
- **PCTFREE**—integer

#### gbpcache-specification:

- **GBPCACHE CHANGED**
- **GBPCACHE ALL**
- **NONE**

#### partition-element:

- **PARTITION**—integer
  - **ENDING**—AT
  - **constant**
  - **MAXVALUE**
  - **MINVALUE**
  - **INCLUSIVE**
Description

UNIQUE
Prevents the table from containing two or more rows with the same value of the index key. When UNIQUE is used, all null values for a column are considered equal. For example, if the key is a single column that can contain null values, that column can contain only one null value. The constraint is enforced when rows of the table are updated or new rows are inserted.

The constraint is also checked during the execution of the CREATE INDEX statement. If the table already contains rows with duplicate key values, the index is not created.

UNIQUE WHERE NOT NULL
Prevents the table from containing two or more rows with the same value of the index key where all null values for a column are not considered equal. Multiple null values are allowed. Otherwise, this is identical to UNIQUE.

INDEX index-name
Names the index. The name must not identify an index that exists at the current server, or is listed in the SYSIBM.SYSPENDINGOBJECTS catalog table, or is in an accelerator-only table.

The associated index space also has a name. That name appears as a qualifier in the names of data sets defined for the index. If the data sets are managed by the user, the name is the same as the second (or only) part of index-name. If this identifier consists of more than eight characters, only the first eight are used. The name of the index space must be unique among the names of the index spaces and table spaces of the database for the identified table. If the data sets are defined by Db2, Db2 derives a unique name.

If the index is an index on a declared temporary table, the qualifier, if explicitly specified, must be SESSION. If the index name is unqualified, Db2 uses SESSION as the implicit qualifier.

ON table-name or aux-table-name
Identifies the table on which the index is created. The name can identify a base table, a materialized query table, a declared temporary table, or an auxiliary table.

table-name
Identifies the base table, materialized query table, or declared temporary table on which the index is created. The name must identify a table that exists at the current server. (The name of a declared temporary table must be qualified with SESSION.)

The name must not identify a clone table. The name must not identify a created temporary table or a table that is implicitly created for an XML column. If the index that is being created is for XML values, the table can contain an XML column, otherwise, the table must not contain an XML column. The name must not identify a catalog table or declared temporary table if the index is created using expressions. The name must not identify an accelerator-only table or a directory table.

If the table has enforced row or column access controls, the row permissions and column masks are not applied during key generation.

column-name,...
Specifies the columns of the index key.
Each column-name must identify a column of the table. Do not specify more than 64 columns or the same column more than one time. Do not qualify column-name.

Do not specify a column for column-name that is defined as follows:

- a LOB column (or a column with a distinct type that is based on a LOB data type)
- a DECFLOAT column (or a column with a distinct type that is based on a DECFLOAT data type)
- a BINARY or VARBINARY column (or a column with a distinct type that is based on a BINARY or VARBINARY data type) when the PARTITION BY RANGE clause is also specified
- a VARBINARY column (or a column with a distinct type that is based on a VARBINARY data type) when the PADDED clause is also specified
- a row change timestamp column when the PARTITION BY RANGE or PARTITIONED clause is also specified.
- a timestamp with time zone column (or a column with a distinct type that is based on the timestamp with time zone data type) when the PARTITION or PARTITION BY RANGE clause is also specified.

A column with an XML type can only be specified if the XMLPATTERN clause is also specified. If the XMLPATTERN clause is specified, only one column can be identified and the column must be an XML type. The resulting index is an XML index.

If the table is an EBCDIC table with Unicode columns, character and graphic columns that are specified for the index key must be all EBCDIC or all Unicode.

The sum of the length attributes of the columns must not be greater than the following limits, where \( n \) is the number of columns that can contain null values and \( m \) is the number of varying-length columns in the key:

- \( 2000 - n \) for a padded, nonpartitioning index
- \( 2000 - n - 2m \) for a nonpadded, nonpartitioning index
- \( 255 - n \) for a partitioning index (padded or nonpadded)
- \( 255 - n - 2m \) for a nonpadded, partitioning index

**key-expression**

Specifies an expression that returns a scalar value. An index with a key that includes one or more expressions consisting of more than just a column name is an expression-based index. key-expression cannot be specified with the GENERATE KEY USING clause or the INCLUDE clause. key-expression has the following restrictions:

- Each key-expression must contain as least one reference to a column of table-name.

All references to columns of table-name must be unqualified. Referenced columns cannot include any FIELDPROCs or a SECURITY LABEL. Referenced columns cannot be implicitly hidden (that is, defined with the IMPPLICITLY HIDDEN attribute).

- key-expression must not include any of the following:
  - A subquery
  - An aggregate function
  - A function that is not deterministic function
A function that has an external action
– A user-defined function
– The VERIFY_GROUP_FOR_USER or VERIFY_ROLE_FOR_USER functions
– A sequence reference
– A host variable
– A parameter marker
– A global variable
– A special register
– An expression for which implicit time zone value apply (or example, cast a timestamp to a timestamp with time zone)
– A CASE expression
– An OLAP specification

• If key-expression invokes a cast function, the privilege set must implicitly include EXECUTE authority on the generated cast functions for the distinct type.

• If key-expression invokes the LOWER or UPPER functions, the input string-expression cannot be FOR BIT DATA, and the function invocation must contain the locale-name argument.

• If key-expression invokes the TRANSLATE function, the function invocation must contain the to-string argument.

• key-expression must not invoke a built-in function with an argument that references a LOB column, unless the function is SUBSTR or JSON_VAL. If key-expression invokes the SUBSTR function, an argument to the function that references a LOB column can reference only the inline portion of the LOB column.

• If key-expression invokes the JSON_VAL function, the function invocation must meet the following conditions:
  – The invocation of the JSON_VAL function must be the outermost expression for key-expression.
  – If the first argument is a column, that column must be contained in a table in a partition-by-growth table space.
  – The third argument must end with the string ‘:na’, to indicate that the first argument does not contain a JSON array.

• If key-expression invokes the JSON_VAL built-in function, the CREATE INDEX statement must not reference a LOB column other than the LOB column that is the argument to the JSON_VAL function. Such a CREATE INDEX statement can refer only to a single LOB column.

• The same expression cannot be used more than one time in the same index.

• The data type of the result of the expression cannot be a LOB, XML, DECFLOAT, or array value. However, the data type of an intermediate result can be a LOB or DECFLOAT value (or a distinct type that is based on one of these data types), but not an XML value. For an index with a DECFLOAT intermediate result, the rounding mode that was in effect when the index was created should also be in effect when the index is used.

• If a Unicode column in an EBCDIC table is referenced in a key-expression, the encoding scheme of the index keys must either be all Unicode or all EBCDIC. Otherwise, the encoding scheme of the result of a key-expression must be the same encoding scheme as the table.
The maximum length of the text string of each key-expression is 4000 bytes after conversion to UTF-8. The maximum number of key-expression in an extended index is 64.

**ASC**

Puts the index entries in ascending order by the column. ASC cannot be specified with the GENERATE KEY USING clause.

ASC is the default.

**DESC**

Puts the index entries in descending order by the column. DESC cannot be specified with the GENERATE KEY USING clause or if the ON clause contains key-expression.

**RANDOM**

Index entries are put in a random order by the column. RANDOM cannot be specified in the following cases:

- A varying length column is part of the index key and the index is defined with the NOT PADDED option
- A column of the index key is defined as TIMESTAMP WITH TIME ZONE
- The index is an XML index. An XML index is defined with the GENERATE KEY USING clause
- The index is part of the partitioning key
- The index is an expression-based index

**BUSINESS_TIME**

Specifies that the columns of the BUSINESS_TIME period are automatically added to the end of the index key in the following order:

- The end column of the BUSINESS_TIME period in ascending order
- The start column of the BUSINESS_TIME period in ascending order

BUSINESS_TIME can be specified as the last item in the list. The list must also include at least one column-name or key-expression. When BUSINESS_TIME is specified, the columns of the BUSINESS_TIME period must not be specified as column-name or a key-expression, or as columns in the partitioning key.

**WITH OR WITHOUT OVERLAPS**

Indicates whether multiple rows may exist with the same values for the non-period columns and expressions of the index key for a row, with overlapping time periods.

**WITH OVERLAPS**

Indicates that multiple rows may exist with the same values for the non-period columns and expressions of the index key for a row, with overlapping time periods. The BUSINESS_TIME WITH OVERLAPS clause is intended for use in defining an index for the foreign key of a temporal referential constraint.

BUSINESS_TIME WITH OVERLAPS must not be specified when UNIQUE is specified for the index definition.

BUSINESS_TIME WITHOUT OVERLAPS must not be specified if the table is defined with a partitioning key that includes any columns of the BUSINESS_TIME period.

**WITHOUT OVERLAPS**
Indicates that the values for the non-period columns and expressions of the index key for a row must be unique with respect to the time represented by the BUSINESS_TIME period for the row. Db2 enforces that multiple rows do not exist with the same key values for the columns or expressions of the index, with overlapping time periods. The BUSINESS_TIME WITHOUT OVERLAPS clause is intended for use in defining a unique index to enforce a primary key or unique constraint. BUSINESS_TIME WITHOUT OVERLAPS can only be specified for an index that is defined as UNIQUE.

**aux-table-name**

Identifies the auxiliary table on which the index is created. The name must identify an auxiliary table that exists at the current server. If the auxiliary table already has an index, do not create another one. An auxiliary table can only have one index.

Do not specify any columns for the index key. The key value is implicitly defined as a unique 19 byte value that is system generated.

If qualified, **table-name** or **aux-table-name** can be a two-part or three-part name. If a three-part name is used, the first part must match the value of the field Db2 LOCATION NAME of installation panel DSNTIPR at the current server. (If the current server is not the local Db2, this name is not necessarily the name in the CURRENT SERVER special register.) Whether the name is two-part or three-part, the authorization ID that qualifies the name is the owner of the index.

The table space that contains the named table must be available to Db2 so that its data sets can be opened. If the table space is EA-enabled, the data sets for the index must be defined to belong to a DFSMS data class that has the extended format and addressability attributes.

**GENERATE KEY USING**

Along with XMLPATTERN, GENERATE KEY USING is required to generate an XML index.

**XMLPATTERN**

When an XML column is indexed, only parts of the documents will be indexed. To identify those parts, a path expression that follows the XMLPATTERN clause is specified. Only values of those element, attribute, or text nodes which match the specified pattern are indexed. An XML pattern can be specified using an optional namespace declaration where namespace prefixes are mapped to namespace URIs and by providing a path expression. The path expression is similar to a path expression in XQuery except that the paths that are specified for the XML index can support child axis, self-or-descendant axis, wildcard expressions, or attribute only. The maximum length of an XML pattern text is 4000 bytes after being converted to UTF-8. For more information about XQuery, see [Overview of pureXML (Db2 Programming for XML)]

**prolog**

To use qualified names in the path-expression, namespace prefixes need to be declared. A default namespace can also be declared for use with unqualified names.

**declare namespace NCName=StringLiteral**

The namespace prefix, NCName, is mapped to a namespace URI that is identified in StringLiteral. Multiple namespaces can be declared, but each
namespace prefix must be unique within the list of namespace declarations. NCName is an XML name as defined by the XML 1.0 standard. NCName cannot include a colon character. The namespace URI cannot be http://www.w3.org/XML/1998/namespace or http://w3.org/2000/xmlns/.

declare default element namespace StringLiteral
Specifies the default namespace URI for unqualified names of elements and types. StringLiteral is a namespace URI. If no default element namespace is declared, unqualified names of element and types are in no namespace. Only one default namespace can be declared.

pattern-expression
Pattern-expression is used to identify those nodes in an XML document that are indexed. Pattern-expression cannot be an empty or invalid string, and the XQuery expression cannot be nested more than 50 levels. pattern-expression cannot be an XQuery updating expression.

/ (forward slash)
Separates path expression steps.

// (double forward slash)
Abbreviated syntax for /descendant-or-self::node()/

. (dot)
Abbreviated syntax for /self::node/

cchild:
Specifies children of the context node. child:: is the default if no forward axis is specified.

descendant:
Specifies the descendants of the context node.

sself:
Specifies the current context node.

descendant-or-self:
Specifies the context node and the descendents of the context node.

element-name
Identifies an element in an XML document. element-name is an XML QName that can have one of the following forms:

nsprefix:NCName
nsprefix explicitly specifies a namespace prefix that must be declared.

NCName
An unqualified XML name that uses the default namespace.

* (an asterisk)
Indicates any element name. If * is prefixed by attribute:: or @, * indicates any attribute name.

nsprefix:*
Indicates any NCName within the specified namespace.

*:NCName
Indicates a specific XML name in any of the currently declared namespaces.

attribute:: or @
Specifies attributes of the context node.
**attribute-name**

Identifies an attribute in an XML document. *attribute-name* is an XML QName that can have one of the following forms:

- **nsprefix:NCName**
  
  *nsprefix* explicitly specifies a namespace prefix that must be declared.

- **NCName**
  
  An unqualified XML name that uses the default namespace.

**text( )**

Matches any text node.

**fn:upper-case(.)**

Specifies an element node or an attribute node that identifies the key value for the index for each node that is specified by the context step (the part of *pattern-expression* that is specified prior to fn:upper-case).

The context step of fn:upper-case() must specify an element node or an attribute node. The argument of fn:upper-case() must be a self step. The key values of an XML value index must be specified as the SQL data type VARCHAR. The length of the VARCHAR value can be any value that is allowed in Db2.

**fn:exists()**

Specifies an element node that identifies the key value for the index for each node that is specified by the context step (the part of *pattern-expression* that is specified prior to fn:exists).

The context step of fn:exists() must specify an element node. The argument of fn:exists() must be either a single step of a child element node or an attribute node. The name test part can be a wildcard character for either the namespace prefix or NCName. The key values of an XML value index for an XPath expression that ends with fn:exists() must be specified as the SQL data type VARCHAR(1). The key value will be "T" or "F". "T" implies that fn:exists() evaluates to true and "F" implies that fn:exists() evaluates to false.

**AS SQL data-type**

 Specifies that indexed values are stored as an instance of the specified SQL data type. Casting to the specified data type can result in a loss of precision of the values. For example, a loss of precision can occur when an XML integer value is cast to the SQL data type DECIMAL. If the cast causes a loss of precision, the result will be rounded to the approximate value when it is stored in the index. The cast result cannot be outside of the range that is supported by the SQL data type. If the value cannot be cast to the specified data type, the document is still inserted into the table, but the index entry for that value is not created. No error or warning code is returned.

If the index is unique, the uniqueness is enforced on the value after it is cast to the specified type. Because rounding can occur during the cast to the SQL data type, if a value is cast to the same key value as a document that the table already contains, Db2 will return duplicate key errors at insert time, or fail to create the index.

**VARCHAR (integer)**

The length *integer* is a value in the range 1 - 1000 bytes. If VARCHAR is specified with a length, the specified length is treated as a constraint. If
documents are inserted into a table (or exist in the table at create index
time) that have nodes with values that are longer than the specified length,
the insert or index creation will fail.

**DECFLOAT**

DECFLOAT can be specified to index numeric values. For the cast to
succeed, the string must be a valid XML numeric type. Otherwise the
value will be ignored and no insert to the index will occur. The result of
the cast cannot be outside of the range that DECFLOAT can represent.
Because the XML Schema data type for numeric values allows greater
precision than the SQL data type, the result might be rounded to fit into
the SQL data type. The DECFLOAT values that are stored in the index are
the normalized numeric values.

**DATE**

The SQL DATE data type values will be normalized to UTC (Coordinated
Universal Time) before being stored in the index. For invalid xs:date
values, the value will be ignored without being inserted into the index. The
XML schema data type for DATE allows for greater precision than the SQL
data type. If an out-of-range value is encountered, an error is returned.

**TIMESTAMP (12)**

The SQL TIMESTAMP data type values will be normalized to UTC
(Coordinated Universal Time) before being stored in the index. If the value
that is specified in the document does not specify the time zone, Db2 will
use the implicit time zone to normalize the value to UTC. For invalid
xs:dateTime values, the value will be ignored without being inserted into the
index. The XML schema data type for timestamps allows for greater precision than the SQL data type. If an out-of-range value is encountered,
an error is returned. Only a precision of 12 fractional digits is allowed for
an SQL TIMESTAMP index key.

**INCLUDE** *(column-name)*

Specifies additional columns to append to the set of index key columns of a
unique index. Any column that is specified using **INCLUDE column-name** is
not used to enforce uniqueness. The included columns might improve
performance for some queries using index only access.

The UNIQUE clause must be specified when INCLUDE is specified. Columns
that are specified in the INCLUDE clause count towards the limits for the
number of columns and the limits on the sum of the length attributes of the
columns that are specified in the index. The total number of columns for the
index cannot exceed 64.

*column-name* must be distinct from the columns that are used to enforce
uniqueness and from other columns specified in the INCLUDE clause.
*column-name* must be unqualified, must identify a column of the specified
table, and must not be one of the existing columns of the index. *column-name*
must not identify a LOB or DECFLOAT column (or a distinct type that is
based on one of those types).

The INCLUDE clause cannot be specified for the following types of indexes:
- A non-unique index
- A partitioning index when index-controlled partitioning is used
- An auxiliary index
- An XML index
- An extended index
- An expression-based index
Columns in the INCLUDE list that are defined as character or graphic string data types must be defined with the same encoding scheme as other key columns with character or graphic string data types.

**CLUSTER or NOT CLUSTER**
Specifies whether the index is the clustering index for the table. This clause must not be specified for an index on an auxiliary table, or on a table that is defined to use hash organization.

**NOT CLUSTER**
The index is not to be used as the clustering index of the table.

**CLUSTER**
The index is to be used as the clustering index of the table. CLUSTER cannot be specified if XMLPATTERN or key-expression is specified.

**PARTITIONED**
Specifies that the index is data partitioned (that is, partitioned according to the partitioning scheme of the underlying data). A partitioned index can be created only on a partitioned table space, not on a partition-by-growth table space. PARTITIONED cannot be specified if XMLPATTERN is specified. The types of partitioned indexes are partitioning and secondary.

An index is considered a partitioning index if the specified index key columns match or comprise a superset of the columns specified in the partitioning key, are in the same order, and have the same ascending or descending attributes.

If PARTITION BY was not specified when the table was created, the CREATE INDEX statement must have the ENDING AT clause specified to define a partitioning index and use index-controlled partitioning. This index is created as a partitioned index even if the PARTITIONED keyword is not specified.

When a partitioning index is created, if both the PARTITIONED and ENDING AT keywords are omitted, the index will be non-partitioned. If PARTITIONED is specified, the USING specification with PRIQTY and SECQTY specifications are optional. If these space parameters are not specified, default values are used.

A secondary index is any index defined on a partitioned table space that does not meet the definition of the partitioning index. For partitioned secondary indexes (data-partitioned secondary indexes), the ENDING AT clause is not allowed because the partitioning scheme of the index is predetermined by that of the underlying data. UNIQUE and UNIQUE WHERE NOT NULL are allowed only if the columns in the index are a superset of the partitioning columns. All of the index columns must be specified in a table-name(column-name) clause, and not in an INCLUDE clause. If a partitioned secondary index is created on a table that uses index-controlled partitioning, the table is converted to use table-controlled partitioning.

Index-controlled partitioning cannot be used if the PREVENT_NEW_IXCTRL_PART subsystem parameter is set to YES.

**Related information:**
- PREVENT_NEW_IXCTRL_PART in macro DSN6SPRM (Db2 Installation and Migration)

**NOT PADDED or PADDED**
Specifies how varying-length string columns are to be stored in the index. If the index contains no varying-length columns, this option is ignored, and a warning message is returned. Indexes that do not have varying-length string columns are always created as physically padded indexes.
NOT PADDED
Specifies that varying-length string columns are not to be padded to their maximum length in the index. The length information for a varying-length column is stored with the key.

NOT PADDED is ignored and has no effect if the index is being created on an auxiliary table. Indexes on auxiliary tables are always padded.

PADDED
Specifies that varying-length string columns within the index are always padded with the default pad character to their maximum length. PADDED cannot be specified if XMLPATTERN is specified. PADDED cannot be specified for indexes that are defined on VARBINARY columns.

When the index contains at least one varying-length column, the default for the option depends on the value of field PAD INDEXES BY DEFAULT on installation panel DSNTIPE:
• When the value of this field is NO, new indexes are not padded unless PADDED is specified.
• When the value of this field is YES, new indexes are padded unless NOT PADDED is specified.

The components of the USING clause are discussed below, first for non-partitioned indexes and then for partitioned indexes.

Using clause for non-partitioned indexes
For non-partitioned indexes, the USING clause indicates whether the data sets for the index are to be managed by the user or managed by Db2. If Db2 definition is specified, the clause also gives space allocation parameters (PRIQTY and SECQTY) and an erase rule (ERASE).

If you omit USING, the data sets will be managed by Db2 on volumes listed in the default storage group of the database that is associated with the table. That default storage group must exist. With no USING clause, PRIQTY, SECQTY, and ERASE assume their default values.

VCAT catalog-name
Specifies that the first data set for the index is managed by the user, and that following data sets, if needed, are also managed by the user.

The data sets are linear VSAM data sets cataloged in the integrated catalog facility catalog that catalog-name identifies. For more information about catalog-name values, see Naming conventions.

More than one Db2 subsystem can share the integrated catalog facility catalogs with the current server. To avoid the chance of those subsystems attempting to assign the same name to different data sets, specify a catalog-name value that is not used by the other Db2 subsystems.

Do not specify VCAT in any of the following circumstances:
• For an index on a declared temporary table.
• If the table space is partition-by-growth, and the table space is not part of the Db2 catalog.

STOGROUP stogroup-name
Specifies that Db2 will define and manage the data sets for the index. Each data set will be defined on a volume listed in the identified storage group. The values specified (or the defaults) for PRIQTY and SECQTY determine the primary and secondary allocations for the data set. If
PRIQTY+118×SECQTY is 2 gigabytes or greater, more than one data set could eventually be used, but only the first is defined during execution of this statement.

To use USING STOGROUP, the privilege set must include SYSADM authority, SYSCTRL authority, or the USE privilege for that storage group. Moreover, stogroup-name must identify a storage group that exists at the current server and includes in its description at least one volume serial number. The description can indicate that the choice of volumes will be left to Storage Management Subsystem (SMS). Each volume specified in the storage group must be accessible to z/OS for dynamic allocation of the data set, and all these volumes must be of the same device type.

The integrated catalog facility catalog used for the storage group must not contain an entry for the first data set of the index. If the catalog is password protected, the description of the storage group must include a valid password.

The storage group supplies the data set name. The first level qualifier is also the name of, or an alias for, the integrated catalog facility catalog on which the data set is to be cataloged. The naming convention for the data set is the same as if the data set is managed by the user.

**PRIQTY integer**

Specifies the minimum primary space allocation for a Db2-managed data set. *integer* must be a positive integer, or -1. When you specify PRIQTY with a positive integer value, the primary space allocation is at least \( n \) kilobytes, where \( n \) is:

- 12 If *integer* is greater than 0 and less than 12.
- *integer* If *integer* is between 12 and 4194304.
- 2097152 If both of the following conditions are true:
  - *integer* is greater than 2097152.
  - The index is a non-partitioned index on a table space that is not defined with the LARGE or DSSIZE attribute.
- 4194304 If *integer* is greater than 4194304.

If you do not specify PRIQTY, or you specify a PRIQTY value of -1, Db2 uses a default value for the primary space allocation. For information on how Db2 determines the default value, see Rules for primary and secondary space allocation.

If you specify PRIQTY, and do not specify a value of -1, Db2 specifies the primary space allocation to access method services using the smallest multiple of 4KB not less than \( n \). The allocated space can be greater than the amount of space requested by Db2. For example, it could be the smallest number of tracks that will accommodate the space requested. To more closely estimate the actual amount of storage, see DEFINE CLUSTER command (DFSMS Access Method Services for Catalogs).

When determining a suitable value for PRIQTY, be aware that two of the pages of the primary space could be used by Db2 for purposes other than storing index entries.

**SECQTY integer**

Specifies the minimum secondary space allocation for a Db2-managed data set. *integer* must be a positive integer, 0, or -1. If you do not
specify SECQTY, or specify a SECQTY value of -1, Db2 uses a formula to determine a value. For information on the actual value that is used for secondary space allocation, whether you specify a value or not, see Rules for primary and secondary space allocation.

If you specify SECQTY, and do not specify a value of -1, Db2 specifies the secondary space allocation to access method services using the smallest multiple of 4KB not less than integer. The allocated space can be greater than the amount of space requested by Db2. For example, it could be the smallest number of tracks that will accommodate the space requested. To more closely estimate the actual amount of storage, see DEFINE CLUSTER command (DFSMS Access Method Services for Catalogs).

**ERASE**
Indicates whether the Db2-managed data sets are to be erased when they are deleted during the execution of a utility or an SQL statement that drops the index.

**NO** Does not erase the data sets. Operations involving data set deletion will perform better than ERASE YES. However, the data is still accessible, though not through Db2. This is the default.

**YES** Erases the data sets. As a security measure, Db2 overwrites all data in the data sets with zeros before they are deleted.

**USING clause for partitioned indexes:**
If the index is partitioned, there is a PARTITION clause for each partition. Within a PARTITION clause, a USING clause is optional. If a USING clause is present, it applies to that partition in the same way that a USING clause for a secondary index applies to the entire index.

When a USING specification is absent from a PARTITION clause, the USING clause parameters for the partition depend on whether a USING clause is specified before the PARTITION clauses.

- If the USING clause is specified, it applies to every PARTITION clause that does not include a USING clause.
- If the USING clause is not specified, the following defaults apply to the partition:
  - Data sets are managed by Db2
  - The default storage group for the database is used
  - A value of 12 is used for PRIQTY and SECQTY
  - A value of NO is used for ERASE

**VCAT catalog-name**
Specifies a user-managed data set with a name that starts with the specified catalog name. The identified integrated catalog facility catalog must already contain an entry for the nth data set of the index, where n is the partition number.

The data sets are linear VSAM data sets cataloged in the integrated catalog facility catalog that catalog-name identifies. For more information about catalog-name values, see Naming conventions.

More than one Db2 subsystem can share the integrated catalog facility catalogs with the current server. To avoid the chance of those subsystems attempting to assign the same name to different data sets, specify a catalog-name value that is not used by the other Db2 subsystems.
Db2 assumes one and only one data set for each partition.

**STOGROUP stogroup-name**

If USING STOGROUP is used, explicitly or by default, for a partition \( n \), Db2 defines the data set for the partition during the execution of the CREATE INDEX statement, using space from the named storage group. The privilege set must include SYSADM authority, SYSCTRL authority, or the USE privilege for that storage group. The integrated catalog facility catalog used for the storage group must NOT contain an entry for the \( n \)th data set of the index.

\( stogroup-name \) must identify a storage group that exists at the current server and the privilege set must include SYSADM authority, SYSCTRL authority, or the USE privilege for the storage group.

If you omit PRIQTY, SECQTY, or ERASE from a USING STOGROUP clause for some partition, their values are given by the next USING STOGROUP clause that governs that partition: either a USING clause that is not in any PARTITION clause, or a default USING clause. Db2 assumes one and only one data set for each partition.

**FREEPAGE integer**

Specifies how often to leave a page of free space when index entries are created as the result of executing a Db2 utility or when creating an index for a table with existing rows. One free page is left for every \( integer \) pages. The value of \( integer \) can range 0 - 255. The default is 0, leaving no free pages.

Do not specify FREEPAGE for an index on a declared temporary table.

**PCTFREE integer**

Determines the percentage of free space to leave in each nonleaf page and leaf page when entries are added to the index or index partition as the result of executing a Db2 utility or when creating an index for a table with existing rows. The first entry in a page is loaded without restriction. When additional entries are placed in a nonleaf or leaf page, the percentage of free space is at least as great as \( integer \).

The value of \( integer \) can range from 0 to 99, however, if a value greater than 10 is specified, only 10 percent of free space will be left in nonleaf pages. The default is 10.

Do not specify PCTFREE for an index on a declared temporary table.

If the index is partitioned, the values of FREEPAGE and PCTFREE for a particular partition are given by the first of these choices that applies:

- The values of FREEPAGE and PCTFREE given in the PARTITION clause for that partition. Do not use more than one \( free-specification \) in any PARTITION clause.
- The values given in a \( free-specification \) that is not in any PARTITION clause.
- The default values FREEPAGE 0 and PCTFREE 10.

**GBPCACHE**

In a data sharing environment, specifies what index pages are written to the group buffer pool. In a non-data-sharing environment, the option is ignored unless the index is on a declared temporary table. Do not specify GBPCACHE for an index on a declared temporary table in either environment (data sharing or non-data-sharing).

**CHANGED**

Specifies that updated pages are written to the group buffer pool, when
there is inter-Db2 R/W interest on the index or partition. When there is no
inter-Db2 R/W interest, the group buffer pool is not used. Inter-Db2 R/W
interest exists when more than one member in the data sharing group has
the index or partition open, and at least one member has it open for
update. GBPCACHE CHANGED is the default.

If the index is in a group buffer pool that is defined as GBPCACHE(NO),
CHANGED is ignored and no pages are written to the group buffer pool.

ALL
Indicates that pages are written to the group buffer pool as they are read in
from DASD.

Exception: In the case of a single updating Db2 subsystem when no other
Db2 subsystems have any interest in the page set, no pages are written to
the group buffer pool.

If the index is in a group buffer pool that is defined as GBPCACHE(NO),
ALL is ignored and no pages are written to the group buffer pool.

NONE
Indicates that no pages are written to the group buffer pool. Db2 uses the
group buffer pool only for cross-invalidation.

If the index is partitioned, the value of GBPCACHE for a particular partition
is given by the first of these choices that applies:
1. The value of GBPCACHE given in the PARTITION clause for that partition.
   Do not use more than one gbpcache-specification in any PARTITION clause.
2. The value given in a gbpcache-specification that is not in any PARTITION
   clause.
3. GBPCACHE CHANGED is the default value.

DEFINE
Specifies when the underlying data sets for the index are physically created.
The SPACE column in catalog table SYSINDEXPART is used to record the
status of the data sets (undefined or allocated). If the DEFINE keyword is not
specified, the define attribute is inherited from the current state of the base
table space.

YES
The data sets are created when the index is created (the CREATE INDEX
statement is executed).

NO
The data sets are not created until data is inserted into the index.

DEFINE NO is applicable only for Db2-managed data sets (USING
STOGROUP is specified). Use DEFINE NO especially when performance of
the CREATE INDEX statement is important or DASD resource is
constrained.

Do not use DEFINE NO on an index if you use a program outside of Db2
to propagate data into a table on which that index is defined. If you use
DEFINE NO on an index of a table and data is then propagated into the
table from a program that is outside of Db2, the index space data sets are
allocated, but the Db2 catalog will not reflect this fact. As a result, Db2
treats the data sets for the index space as if they have not yet been
allocated. The resulting inconsistency causes Db2 to deny application
programs access to the data until the inconsistency is resolved.
DEFINE NO is ignored for user-managed data sets (USING VCAT is specified). DEFINE NO is also ignored if the index is being created on a table that is not empty or on an auxiliary table.

Do not specify DEFINE NO if the index is created on a base table that is involved in a clone relationship.

Do not specify DEFINE NO for an index on a declared temporary table.

**COMPRESS NO or COMPRESS YES**

Specifies whether compression for index data will be used. If the index is partitioned, the clause will apply to all partitions.

**COMPRESS NO**

Specifies that no index compression will be used.

COMPRESS NO is the default.

**COMPRESS YES**

Specifies that index compression will be used. The bufferpool that is used to create the index must be 8K, 16K, or 32K in size. The physical page size on disk will be 4K. The index compression will take place immediately.

Index compression is recommended for applications that do sequential insert operations with few or no delete operations. Random inserts and deletes can adversely affect compression. Index compress is also recommended for applications where the indexes are created primarily for scan operations.

**INCLUDE NULL KEYS or EXCLUDE NULL KEYS**

Specifies whether an index entry will be created when every key column contains the NULL value.

**INCLUDE NULL KEYS**

Specifies that an index entry will be created when every key column contains the NULL value.

INCLUDE NULL KEYS is the default.

**EXCLUDE NULL KEYS**

Specifies that no index entry will be created when every key column contains the NULL value. If any key column is not null the index entry will be created.

EXCLUDE NULL KEYS must not be specified with the following:

- **UNIQUE**
- **BUSINESS_TIME WITHOUT OVERLAPS**
- **XML-index-specification**
- **key-expression**
- **INCLUDE (column-name)**

EXCLUDE NULL KEYS must also not be specified if any of the columns that are identified by column-name are defined as NOT NULL, or if the index is defined as a partitioning index for use with index-controlled partitioning.

**PARTITION BY RANGE**

Specifies the partitioning index for the table, which determines the partitioning scheme for the data in the table.

PARTITION BY RANGE should only be specified if the table space is partitioned and the partitioning schema has not already been established.
PARTITION BY RANGE must not be specified if the index is an extended index, is defined with the BUSINESS_TIME WITHOUT OVERLAPS, or if the table is in a universal table space (ranged-partitioned or partition-by-growth table space).

**partition-element**

Specifies the range for each partition.

**PARTITION**

A PARTITION clause specifies the highest value of the index key in one partition of a partitioning index. In this context, highest means highest in the sorting sequences of the index columns. In a column defined as *ascending* (ASC), highest and lowest have their usual meanings. In a column defined as *descending* (DESC), the lowest actual value is highest in the sorting sequence.

If you use CLUSTER, and the table is contained in a partitioned table space, you must use exactly one PARTITION clause for each partition (defined with NUMPARTS on CREATE TABLESPACE). If there are *p* partitions, the value of *integer* must range from 1 through *p*.

The length of the highest value of a partition (also called the limit key) is the same as the length of the partitioning index.

**ENDING AT(constant, MAXVALUE, or MINVALUE...)**

Specifies that this is the partitioning index and indicates how the data will be partitioned. The table space is marked complete after this partitioning index is created. You must use at least one value (constant, MAXVALUE, or MINVALUE) after ENDING AT in each PARTITION clause. You can use as many as there are columns in the key. The concatenation of all the values is the highest value of the key in the corresponding partition of the index unless the VALUES statement was already specified when the table or previous index was created.

**constant**

Specifies a constant value with a data type that must conform to the rules for assigning that value to the column. If a string constant is longer or shorter than required by the length attribute of its column, the constant is either truncated or padded on the right to the required length. If the column is ascending, the padding character is X'FF'. If the column is descending, the padding character is X'00'. The precision and scale of a decimal constant must not be greater than the precision and scale of its corresponding column. A hexadecimal string constant (GX) cannot be specified.

**MAXVALUE**

Specifies a value greater than the maximum value for the limit key of a partition boundary (that is, all X'FF' regardless of whether the column is ascending or descending). If all of the columns in the partitioning key are ascending, a constant or the MINVALUE clause cannot be specified following MAXVALUE. After MAXVALUE is specified, all subsequent columns must be MAXVALUE.

**MINVALUE**

Specifies a value that is smaller than the minimum value for the limit key of a partition boundary (that is, all X'00' regardless of whether the column is ascending or descending). If all of the columns in the partitioning key are descending, a constant or the
MAXVALUE clause cannot be specified following MAXVALUE. After MINVALUE is specified, all subsequent columns must be MINVALUE.

The key values are subject to the following rules:

- The first value corresponds to the first column of the key, the second value to the second column, and so on. Using fewer values than there are columns in the key has the same effect as using the highest or lowest values for the omitted columns, depending on whether they are ascending or descending.
- If a key includes a ROWID column or a column with a distinct type that is based on a ROWID data type, 17 bytes of the constant that is specified for the corresponding ROWID column are considered.
- The highest value of the key in any partition must be lower than the highest value of the key in the next partition.
- If the concatenation of all the values exceeds 255 bytes, only the first 255 bytes are considered.
- The highest value of the key in the last partition depends on how the table space is defined. For table spaces that are created without the LARGE or DSSIZE options, the values that you specify after VALUES are not enforced. The highest value of the key that can be placed in the table is the highest possible value of the key.

For large partitioned table space, the values you specify are enforced. The value specified for the last partition is the highest value of the key that can be placed in the table. Any key values greater than the value that is specified for the last partition are out of range.

ENDING AT can be specified only if the ENDING AT clause was not specified on a previous CREATE or ALTER TABLE statement for the underlying table.

**INCLUSIVE**

Specifies that the specified range values are included in the data partition.

**BUFFERPOOL bpname**

Identifies the buffer pool that is to be used for the index. The bpname must identify an activated 4KB, 8KB, 16KB, or 32KB buffer pool and the privilege set must include SYSADM or SYSCTRL authority or the USE privilege for the buffer pool.

The default is the default 4KB buffer pool for indexes in the database. A buffer pool with a smaller size should be chosen for indexes with random insert patterns. A buffer pool with a larger size should be chosen for indexes with sequential insert patterns.

For more details about bpname, see [Naming conventions](Naming conventions) For a description of active and inactive buffer pools, see [Controlling Db2 databases and buffer pools (Db2 Administration Guide)](Controlling Db2 databases and buffer pools (Db2 Administration Guide)).

**CLOSE**

Specifies whether or not the data set is eligible to be closed when the index is not being used and the limit on the number of open data sets is reached.

**YES**

Eligible for closing. This is the default unless the index is on a declared temporary table.
NO  Not eligible for closing.

If the limit on the number of open data sets is reached and there are no
page sets that specify CLOSE YES to close, page sets that specify CLOSE
NO will be closed.

For an index on a declared temporary table, Db2 uses CLOSE NO regardless of
the value specified.

DEFER
Indicates whether the index is built during the execution of the CREATE
INDEX statement. Regardless of the option specified, the description of the
index and its index space is added to the catalog. If the table is determined to
be empty and DEFER YES is specified, the index is neither built nor placed in
a rebuild-pending status. Refer to Db2 Administration Guide for more
information about using DEFER. Do not specify DEFER for an index on a
declared temporary table or an auxiliary table.

NO  The index is built. This is the default.

YES  The index is not built. If the table is populated, the index is placed in a
rebuild-pending status and a warning message is issued; the index must be
rebuilt by the REBUILD INDEX utility.

DSSIZE integer G
Specifies the maximum size for each partition of a partitioned index. Any
integer 1 - 1024 can be specified (for example, 1G – 1024G). This keyword is
not valid on nonpartitioned secondary indexes. You can only specify DSSIZE
on CREATE INDEX if the index is on a table space with relative page numbers.

To specify a value greater than 4G, the data sets for the table space must be
associated with a DFSMS data class that has been specified with extended
format and extended addressability.

If the index is a partitioned index using relative page numbering, the value of
DSSIZE for a particular partition is given by the first of these choices that
applies:
• The value of DSSIZE given in the PARTITION clause for that partition.
• The value given by a DSSIZE keyword that is not in any PARTITION clause.
• The default value is inherited from the base table space.

PIECESIZE integer
Specifies the maximum addressability of each data set for a non-partitioned
index. The subsequent keyword K, M, or G, indicates the units of the value
that is specified in integer.

K  Indicates that the integer value is to be multiplied by 1024 to specify
the maximum data set size in bytes. integer must be a power of two
between 1 and 268435456.

M  Indicates that the integer value is to be multiplied by 1048576 to specify
the maximum data set size in bytes. integer must be a power of two
between 1 and 262144.

G  Indicates that the integer value is to be multiplied by 1073741824 to
specify the maximum data set size in bytes. integer must be a power of
two between 1 and 256.

Table 192 on page 1661 shows the valid values for the data set size, which
depend on the size of the table space.

</tbody>
</table>

PIECESIZE has no effect on primary and secondary space allocation as it is only a specification of the maximum amount of data that a data set can hold and not the actual allocation of storage.

If you change the PIECESIZE value with the ALTER INDEX statement, the index is put into REBUILD-pending status.

See the following for additional information:

- Number of pieces and maximum piece size for non-partitioned indexes and data-partitioned secondary indexes
- Choosing a value for PIECESIZE

COPY

Indicates whether the COPY utility is allowed for the index. Do not specify COPY for an index on a declared temporary table.

- NO  Does not allow full image or concurrent copies or the use of the RECOVER utility on the index. NO is the default.
- YES Allows full image or concurrent copies and the use of the RECOVER utility on the index.

Notes

Owner privileges:
The owner of the table has all table privileges (see GRANT (table or view)
with the ability to grant these privileges to others. For more information about ownership of the object, see Authorization, privileges, permissions, masks, and object ownership.

Effects of the DEFER clause:
If DEFER NO is implicitly or explicitly specified, the CREATE INDEX statement cannot be executed while a Db2 utility has control of the table space that contains the identified table.

If the identified table already contains data and if the index build is not deferred, CREATE INDEX creates the index entries for it. If the table does not yet contain data, CREATE INDEX creates a description of the index; the index entries are created when data is inserted into the table.

Errors evaluating the expressions for an index:
Errors that occur during the evaluation of an expression for an index are returned when the expression is evaluated. This can occur on an SQL data change statement, SELECT from an SQL data change statement, or the REBUILD INDEX utility. For example, the evaluation of the expression $10 / column_1$ returns an error if the value in column_1 is 0. The error is returned during CREATE INDEX processing if the table is not empty and contains a row with a value of zero in column_1, otherwise the error is returned during the processing of the insert or update operation when a row with a value of zero in column_1 is inserted or updated.

Result length of expressions that return a string type:
If the result data type of key-expression is a string type and the result length cannot be calculated at bind time, the length is set to the maximum allowable length of that data type or the largest length that Db2 can estimate. In this case, the CREATE INDEX statement can fail because the total key length might exceed the limit of an index key.

For example, the result length of the expression REPEAT('A', CEIL(1.1)) is VARCHAR(32767) and the result length of the expression SUBSTR(DESCRIPTION,1,INTEGER(1.2)) is the length of the DESCRIPTION column. Therefore, a CREATE INDEX statement that uses any of these expressions as a key-expression might not be created because the total key length might exceed the limit of an index key.

Use of ASC or DESC on key columns:
There are no restrictions on the use of ASC or DESC for the columns of a parent key or foreign key. An index on a foreign key does not have to have the same ascending and descending attributes as the index of the corresponding parent key.

EBCDIC, ASCII, and UNICODE encoding schemes for an index:
In general, an index has the same encoding scheme as its associated table. However, if an index on an EBCDIC table consists of only Unicode columns, the encoding scheme of the index is Unicode.

Maximum partition size of a partitioned index
The size of a partitioned index depends on whether the corresponding partitioned table space is created with or without the LARGE or DSSIZE keywords, and on the number of partitions.

The following table provides information about partitioned indexes on table spaces that are created without the LARGE or DSSIZE keywords and with 64 or fewer partitions.
Table 193. Maximum number of pieces and the default size of a partitioned index on a partitioned table space that is created without the LARGE or DSSIZE clauses and with a NUMPARTS value of less than or equal to 64

<table>
<thead>
<tr>
<th>Definition of partitioned table space (non-large)</th>
<th>Maximum number of pieces for a partitioned index</th>
<th>Default size of a partitioned index, per data set</th>
</tr>
</thead>
<tbody>
<tr>
<td>NUMPARTS &lt;= 16</td>
<td>16</td>
<td>4G</td>
</tr>
<tr>
<td>NUMPARTS &gt;= 17 but NUMPARTS &lt;= 32</td>
<td>32</td>
<td>2G</td>
</tr>
<tr>
<td>NUMPARTS &gt;= 33</td>
<td>64</td>
<td>1G</td>
</tr>
</tbody>
</table>

The following table shows information about partitioned indexes on table spaces that are created with the LARGE or DSSIZE keywords and with more than 64 partitions.

Table 194. Maximum number of pieces and the default partitioned index size for a partitioned table space that is created with the LARGE or DSSIZE clauses or with a NUMPARTS value of greater than 64

<table>
<thead>
<tr>
<th>Definition of partitioned table space (large)</th>
<th>Maximum number of pieces for a partitioned index</th>
<th>Default index piece size for a partitioned index</th>
</tr>
</thead>
<tbody>
<tr>
<td>One or more of the following conditions are true:</td>
<td>Maximum number of partitions in the partitioned table space</td>
<td>4G</td>
</tr>
<tr>
<td>• LARGE clause - specified</td>
<td></td>
<td></td>
</tr>
<tr>
<td>• NUMPARTS greater than 64 but less than 256</td>
<td></td>
<td></td>
</tr>
<tr>
<td>One or more of the following conditions are true:</td>
<td>Maximum number of partitions in the partitioned table space</td>
<td>MIN(table space DSSIZE, (2^{32}/) (Maximum number of partitions in the table space) * index page size)</td>
</tr>
<tr>
<td>• DSSIZE clause - specified</td>
<td></td>
<td></td>
</tr>
<tr>
<td>• NUMPARTS greater than or equal to 256</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

To calculate the maximum data set size for a partitioned index, you need to first calculate the maximum number of partitions in the table space by using the following formula:

\[ \text{MIN}(4096, 2^{32}/ (\text{table space DSSIZE / table space page size})) \]

After you calculate the maximum number of partitions in the table space, you can calculate the maximum data set size for a partitioned index with the following formula, using the number of partitions that you calculated above:

\[ \text{MIN}(\text{table space DSSIZE, } 2^{32}/ (\text{Maximum number of partitions in the table space) * index page size}) \]

**Example:** Suppose that a table space and an index on that table space have the following characteristics:

- DSSIZE: 64 GB
- Page size: 32 KB
- Index page size: 4 KB
- Maximum number of partitions: 2048

Given those characteristics, you can begin by calculating the maximum number of partitions in the table space:
You can then use the value of 2048 to calculate the maximum data set size for the partitioned index:

\[
\text{MIN}(64 \text{ GB}, 2^{32} / 2048 \times 4\text{ KB}) = 8\text{GB}
\]

**Number of pieces and maximum piece size for non-partitioned indexes**

The largest amount of data that an index can hold is the maximum number of pieces for the index times the maximum amount of data that a piece can hold.

For a non-partitioned index, the maximum amount of data that an index can hold is defined by using the PIECESIZE parameter.

The default piece size for an index is as follows:

- 2 GB (PIECESIZE 2 G) for indexes of table spaces created without the LARGE or DSSIZE option
- 4 GB (PIECESIZE 4 G) for indexes of table spaces created with the LARGE or DSSIZE option
- 4 GB (PIECESIZE 4 G) for auxiliary indexes

The following tables list the maximum number of pieces and the default index piece size for various table spaces.

### Table 195. Maximum number of pieces and the default index piece size for a partitioned table space that is created without the LARGE or DSSIZE clauses and has a NUMPART value of less than or equal to 64.

<table>
<thead>
<tr>
<th>Definition of partitioned table space (non-large), NUMPART value</th>
<th>Maximum number of pieces in a non-partitioned index</th>
<th>Default index piece size for a non-partitioned index</th>

Choosing a value for PIECESIZE:
To choose a value for PIECESIZE, divide the size of the non-partitioned index by the number of data sets that you want. For example, to ensure that you have five data sets for the non-partitioned index, and your index is 10MB (and not likely to grow much), specify PIECESIZE 2 M. If your non-partitioned index is likely to grow, choose a larger value.

Remember that 32 data sets is the limit if the underlying table space is not defined as LARGE or with a DSSIZE parameter and that the limit is 4096 for objects with greater than 254 parts. For a non-partitioned index on a table space that is defined as LARGE or with a DSSIZE parameter, the maximum is MIN(4096, $2^{32} / (index\ piece\ size/index\ page\ size)$).

Keep the PIECESIZE value in mind when you are choosing values for primary and secondary quantities. Ideally, the value of your primary quantity plus the secondary quantities should be evenly divisible into PIECESIZE.

Dropping an index:
Partitioning indexes can be dropped. If the table space is using index-controlled partitioning, the table space is converted to table-controlled partitioning. Secondary indexes that are not indexes on auxiliary tables can be dropped simply by dropping the indexes. An empty index on an auxiliary table can be explicitly dropped; a populated index can be dropped only by dropping other objects. For details, see [Dropping an index on an auxiliary table and an auxiliary table](#). If the index is a unique index that enforces a primary key, unique key, or referential constraint, the constraint must be dropped before the index is dropped. See [DROP](#).

Unique indexes and enforcement of UNIQUE or PRIMARY KEY specifications for a table:
A table requires a unique index (that is not defined as UNIQUE WHERE NOT NULL) if you use the UNIQUE or PRIMARY KEY clause in the CREATE or ALTER TABLE statements, or if there is a ROWID column that
is defined as GENERATED BY DEFAULT. Db2 implicitly creates those unique indexes if the table space is explicitly created and the CREATE or ALTER TABLE statement is processed by the schema processor or if the table space is implicitly created; otherwise, you must explicitly create them. If any of the unique indexes that must be explicitly defined do not exist, the definition of the table is incomplete, and the following rules apply:

- Let K denote a key for which a required unique index does not exist and let n denote the number of unique indexes that remain to be created before the definition of the table is complete. (For a new table that has no indexes, K is its primary key or any of the keys defined in the CREATE or ALTER TABLE statement as UNIQUE and n is the number of such keys. After the definition of a table is complete, an index cannot be dropped if it is enforcing a primary key or unique key.)
- The creation of the unique index reduces n by one if the index key is identical to K. The keys are identical only if they have the same columns in the same order.
- If n is now zero, the creation of the index completes the definition of the table.
- If K is a primary key, the description of the index indicates that it is a primary index. If K is not a primary key, the description of the index indicates that it enforces the uniqueness of a key defined as UNIQUE in the CREATE or ALTER TABLE statement.

A unique index cannot be created on a materialized query table.

Unique indexes and XML columns:
If the index is an XML index on a unique XML column, the uniqueness applies to values of the specified pattern across all documents of that column, and the uniqueness is enforced on the value after the value is cast to the specified SQL data type. Because the data type conversion might result in a loss of precision and normalization, multiple values that appear unique in the XML document might still result in duplicate errors. If the index is defined using an expression, the uniqueness is enforced against the values that are stored in the index, not against the original values of the columns. The WHERE NOT NULL specification is ignored with a warning if XMLPATTERN is also specified, and the index is treated as if UNIQUE had been specified.

Defining an XML index using an XPath pattern-expression that includes functions:
An XPath pattern-expression that includes functions (including fn:exists() or fn:upper-case()) will have two parts. The first part is referred to as the context step and specifies the XPath of the element node or attribute node for which an index entry will be created (the element or attributes NodeID will be included in the index). The context step follows the same syntax as the XPath pattern-expression for an XML index, except that for fn:exists() it has to specify an element node, and for fn:upper-case() it has to specify an element node or an attribute node.

The second part is referred to as the function expression step and specifies the fn:exists() or fn:upper-case() XPath function. The function expression step is the right-most part of an XPath pattern-expression. For each node specified by the context step, the function expression step specifies the key value for the index. For example, in the XPath pattern-expression /purchaseOrder/items/item/fn:exists(shipDate), the context step is /purchaseOrder/items/item, and the function expression step is fn:exists(shipDate).
Use of `PARTITIONED` keyword:
When a partitioned index is created and no additional keywords are specified, the index is non-partitioned. If the keyword `PARTITIONED` is specified, the index is partitioned. If `PARTITION BY RANGE` is specified, the index is both data-partitioned and key-partitioned because it is defined on the partitioning columns of the table. Any index on a partitioned table space that does not meet the definition of a partitioning index is a secondary index. When a secondary index is created and no additional keywords are specified, the secondary index is non-partitioned (NPSI). If the keyword `PARTITIONED` is specified, the index is a data-partitioned secondary index (DPSI).

Creating a partitioning index for a table created without partition boundaries:
When a table is created without specifying partition boundaries using the `ENDING AT` clause, the table is incomplete until a partitioning index is created. The first index that is created for a table must specify both the `PARTITION` and the `ENDING AT` clauses.

When the `PARTITION` clause is specified while creating an index, either the `PARTITIONED` clause, or the `ENDING AT` clause must also be specified.

Considerations for tables that are involved in a clone relationship:
If an index is created on a base table that is involved in a clone relationship, an index with the same name is also created on the clone table. The index on the clone table will be placed in rebuild-pending status unless the clone table is empty when the index is created.

Considerations for tables that contain a row change timestamp column:
To create an index that refers to a row change timestamp column in the table, values must already exist in the column for all rows. Values are stored in row change timestamp columns whenever a row is inserted or updated in the table. If the row change timestamp column is added to an existing table that contains rows, the values for the row change timestamp column are not materialized and stored at the time of the `ALTER TABLE` statement. Values are materialized for these rows when they are updated, or when a `REORG` or a `LOAD REPLACE` utility is run on the table or table space.

Restriction on table spaces when there are pending changes to the definition:
A `CREATE INDEX` statement is not allowed if there are pending changes to the definition of the table space or to any objects in the table space. In addition, an index that references an expression cannot be created on a table where the inline length of a LOB column has been changed and the table space has not been reorganized.

Effects of `DEFINE NO` and `INCLUDE NULL KEYS` or `EXCLUDE NULL KEYS`:
When `INCLUDE NULL KEYS` is specified (implicitly or explicitly) with `DEFINE NO` and the table that is being indexed is populated, a warning is returned, the index is created, and the data set is defined. When `EXCLUDE NULL KEYS` is specified, it is possible that the data set will not be defined if the all rows for the table that is being indexed contain the NULL value for all key columns. The index will be empty after the `CREATE INDEX` statement. However, if `DEFINE NO` is specified with `EXCLUDE NULL KEYS` a warning is returned.

Creating indexes on Db2 catalog tables:
For details on creating indexes on catalog tables, see [SQL statements allowed on the catalog](#)
EA-enabled index data sets:
If an index is created for an EA-enabled table space, the data sets for the index must be set up to belong to a DFSMS data class that has the extended format and extended addressability attributes.

Alternative syntax and synonyms:
To provide compatibility with previous releases of Db2 or other products in the Db2 family, Db2 supports the following keywords when creating a partitioned index:

- **PART integer VALUES** as an alternative syntax for **PARTITION integer ENDING**. The **PARTITION BY RANGE** keyword that precedes the *partition-element* clause is optional.

Although these keywords are supported as alternatives, they are not the preferred syntax.

User-defined indexes on catalog tables:
If you issue CREATE INDEX for an index on a catalog table, and you specify the USING clause, Db2 ignores that clause. Instead, Db2 defines and manages the index data sets. The data sets are defined in the same SMS environment that is used for the catalog data sets with default space attributes.

Temporal referential constraints:
An index is required for the foreign key of a temporal referential constraint. The index must be defined in one of the following ways:

- Specify the **BUSINESS_TIME WITH OVERLAPS** clause after the columns and key expressions.
- Specify the end column of the **BUSINESS_TIME** period, followed by the begin column of the **BUSINESS_TIME** period as the last two keys of the index. ASC must be used for each of these columns.

When a temporal referential constraint is defined for a table, the first index that is created that meets the criteria for an index on the foreign key, is recorded as a dependency for the constraint. An index used for the foreign key of a temporal referential constraint cannot be dropped. A column cannot be added to an index used for a temporal referential constraint.

Examples

*Example 1:* Create a unique index, named DSN8C10.XDEPT1, on table DSN8C10.DEPT. Index entries are to be in ascending order by the single column DEPTNO. Db2 is to define the data sets for the index, using storage group DSN8G120. Each data set should hold 1 megabyte of data at most. Use 512 kilobytes as the primary space allocation for each data set and 64 kilobytes as the secondary space allocation. These specifications enable each data set to be extended up to 8 times before a new data set is used—512KB + (8*64KB)= 1024KB. Make the index padded.

The data sets can be closed when no one is using the index and do not need to be erased if the index is dropped.

```
CREATE UNIQUE INDEX DSN8C10.XDEPT1
  ON DSN8C10.DEPT
    (DEPTNO ASC)
  PADDED
  USING STOGROUP DSN8G120
  PRIQTY 512
  SECQTY 64
```
ERASE NO
BUFFERPOOL BP1
CLOSE YES
PIECESIZE 1M;

For the above example, the underlying data sets for the index will be created immediately, which is the default (DEFINE YES). Assuming that table DSN8C10.DEPT is empty, if you wanted to defer the creation of the data sets until data is first inserted into the index, you would specify DEFINE NO instead of accepting the default behavior. Specifying PADDED ensures that the varying-length character string columns in the index are padded with blanks.

Example 2: Create a cluster index, named XEMP2, on table EMP in database DSN8C10. Put the entries in ascending order by column EMPNO. Let Db2 define the data sets for each partition using storage group DSN8G120. Make the primary space allocation be 36 kilobytes, and allow Db2 to use the default value for SECQTY, which for this example is 12 kilobytes (3 times 4KB). If the index is dropped, the data sets need not be erased.

There are to be 4 partitions, with index entries divided among them as follows:
   Partition 1: entries up to H99
   Partition 2: entries above H99 up to P99
   Partition 3: entries above P99 up to Z99
   Partition 4: entries above Z99

Associate the index with buffer pool BP1 and allow the data sets to be closed when no one is using the index. Enable the use of the COPY utility for full image or concurrent copies and the RECOVER utility.

CREATE INDEX DSN8C10.XEMP2
ON DSN8C10.EMP
   (EMPNO ASC)
USING STOGROUP DSN8G120
   PRIQTY 36
   ERASE NO
   CLUSTER
   PARTITION BY RANGE
      (PARTITION 1 ENDING AT('H99'),
       PARTITION 2 ENDING AT('P99'),
       PARTITION 3 ENDING AT('Z99'),
       PARTITION 4 ENDING AT('999'))
BUFFERPOOL BP1
CLOSE YES
COPY YES;

Example 3: Create a secondary index, named DSN8C10.XDEPT1, on table DSN8C10.DEPT. Put the entries in ascending order by column DEPTNO. Assume that the data sets are managed by the user with catalog name DSNCAT and each data set is to hold 1GB of data, at most, before the next data set is used.

CREATE UNIQUE INDEX DSN8C10.XDEPT1
ON DSN8C10.DEPT
   (DEPTNO ASC)
USING VCAT DSNCAT
   PIECESIZE 1048576K;

Example 4: Assume that a column named EMP_PHOTO with a data type of BLOB(110K) was added to the sample employee table for each employee's photo and auxiliary table EMP_PHOTO_ATAB was created in LOB table space.
DSN8D12A.PHOTOLTS to store the BLOB data for the column. Create an index named XPHOTO on the auxiliary table. The data sets are to be user-managed with catalog name DSNCAT.

```
CREATE UNIQUE INDEX DSN8C10.XPHOTO
  ON DSN8C10.EMP_PHOTO_ATAB
  USING VCAT DSNCAT
  COPY YES;
```

In this example, no columns are specified for the key because auxiliary indexes have implicitly generated keys.

### CREATE LOB TABLESPACE

The CREATE LOB TABLESPACE statement defines a large object (LOB) table space at the current server. If your data for a table does not fit entirely within a data page, you can define one or more columns as LOB columns. Each LOB column must have an associated auxiliary table in a LOB table space. If the table space for the base table is partitioned, an associated auxiliary table in a LOB table space is required for each LOB column, for each partition of the table space for the base table.

For information about explicitly creating an auxiliary table, which defines the relationship between the LOB column of the base table and a LOB table space, see CREATE AUXILIARY TABLE.

For information about creating table spaces other than LOB table spaces, see “CREATE TABLESPACE” on page 1847.

### Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

### Authorization

The privilege set that is defined below must include at least one of the following:

- The CREATETETS privilege for the database
- DBADM, DBCTRL, or DBMAINT authority for the database
- SYSADM or SYSCTRL authority
- System DBADM
- Installation SYSOPR authority (when the current SQLID of the process is set to SYSINSTL)

If the database is implicitly created, the database privileges must be on the implicit database or on DSNDDB04.

Additional privileges might be required, as explained in the description of the BUFFERPOOL and USING STOGROUP clauses.

**Privilege set:** If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the application is bound in a trusted context with the ROLE AS OBJECT OWNER clause specified, a role is the owner. Otherwise, an authorization ID is the owner.
If the statement is dynamically prepared, the privilege set is the privileges that are held by the SQL authorization ID of the process unless the process is within a trusted context and the ROLE AS OBJECT OWNER clause is specified. In that case, the privileges set is the privileges that are held by the role that is associated with the primary authorization ID of the process.

**Syntax**

```sql
CREATE LOB TABLESPACE table-space-name
  IN DSNDB04
  IN database-name
  BUFFERPOOL bpname
  CLOSE YES
  CLOSE NO
  COMPRESS NO
  COMPRESS YES
  DEFINE YES
  DEFINE NO
  DSSIZE 4 G
  DSSIZE integer G
  gbpcache-block
  LOCKMAX SYSTEM integer
  locksize-block
  LOGGED
  NOT LOGGED
  using-block

Notes:
1. The same clause must not be specified more than one time.
```

gbpcache-block:

```sql
GBPCACHE CHANGED
GBPCACHE ALL
GBPCACHE SYSTEM
GBPCACHE NONE
```

locksize-block:
LOCKSIZE ANY

LOCKSIZE LOB

using-block:

USING VCAT catalog-name

STOGROUP stogroup-name

PRIQTY integer

SECQTY integer

ERASE NO

ERASE YES

Notes:
1 The same clause must not be specified more than one time.

\textit{table-space-name}

Names the table space. The name, qualified with the \textit{database-name} implicitly or explicitly specified by the \textit{IN} clause, must not identify a table space, index space, or LOB table space that exists at the current server, or that exists in the \texttt{SYSPENDINGOBJECTS} catalog table.

\textbf{IN \textit{database-name}}

Specifies the database in which the table space is created. The LOB table space must be in the same database as its associated base table space. \textit{database-name} must identify a database that exists at the current server and must not specify the following:

- DSNDB06
- A work file database
- A TEMP database
- An implicitly created database

DSNDB04 is the default.

\textbf{BUFFERPOOL \textit{bpname}}

Identifies the buffer pool to be used for the table space and determines the page size of the table space. For 4KB, 8KB, 16KB and 32KB page buffer pools, the page sizes are 4 KB, 8 KB, 16 KB, and 32 KB, respectively. The \textit{bpname} must identify an activated buffer pool, and the privilege set must include SYSADM or SYSCTRL authority, or the USE privilege on the buffer pool.

If you do not specify the \textit{BUFFERPOOL} clause, the default buffer pool is the buffer pool that is specified in the DEFAULT BUFFER POOL FOR USER LOB DATA field on installation panel DSNTIP1.

See [Naming conventions](#) for more details about \textit{bpname}. See \texttt{ALTER BUFFERPOOL (Db2) (Db2 Commands)} for a description of active and inactive buffer pools.
CLOSE
When the limit on the number of open data sets is reached, specifies the
priority in which data sets are closed.

YES
  Eligible for closing before CLOSE NO data sets. CLOSE YES is the default
  value.

NO  Eligible for closing after all eligible CLOSE YES data sets are closed.

COMPRESS
Specifies whether data compression applies to the LOB data in the table space.

For more information about data compression, see Compressing your data
(Db2 Performance)

YES
  Specifies data compression. The LOB data is not compressed until the
  LOAD or REORG utility is run on the table in the table space, or until an
  insert operation is performed through the insert operation.

NO  Specifies no data compression for the table space.

DEFINE
Specifies when the underlying data sets for the table space are physically
created.

YES
  The data sets are allocated when the table space is created (when the
  CREATE LOB TABLESPACE statement is executed). YES is the default.

NO  The data sets are not allocated until data is inserted into the table space.
    DEFINE NO is applicable only for Db2-managed data sets (USING
    STOGROUP is specified). DEFINE NO is ignored for user-managed data
    sets (USING VCAT is specified). Db2 uses the SPACE column in catalog
    table SYSTABLEPART to record the status of the data sets (undefined or
    allocated).

    DEFINE NO is not recommended if you intend to use any tools outside of
    Db2 to manipulate data, such as to load data, because data sets might then
    exist when Db2 does not expect them to exist. When Db2 encounters this
    inconsistent state, applications will receive an error.

    For table spaces that are created with DEFINE NO, point-in-time recover
    will not work before data sets exist and before a recovery copy exists.

DSSIZE  integer  G

Specifies the maximum size of each data set in integer gigabytes for each data
set in the LOB table space.

If DSSIZE is not specified, the default value is 4 G. The maximum number of
data sets is 254.

To specify a value greater than 4 G, the data sets for the table space must be
associated with a DFSMS data class that has been specified with extended
format and extended addressability.

For a description of the maximum size of a LOB table space (or the maximum
size of LOB data for each column of a base table), see LOB table spaces
(Introduction to Db2 for z/OS)
GBPCACHE

In a data sharing environment, specifies what pages of the table space are written to the group buffer pool. In a non-data-sharing environment, you can specify GBPCACHE, but it is ignored.

CHANGED

When there is inter-Db2 R/W interest on the table space, updated pages are written to the group buffer pool. When there is no inter-Db2 R/W interest, the group buffer pool is not used. Inter-Db2 R/W interest exists when more than one member in the data sharing group has the table space open, and at least one member has it open for update. GBPCACHE CHANGED is the default.

Recommendation: Use the GBPCACHE CHANGED option. Due to the usage patterns of LOBs, the use of GBPCACHE CHANGED can help avoid excessive and synchronous writes to disk and to the group buffer pool.

If the table space is in a group buffer pool that is defined to be used only for cross-invalidation (GBPCACHE NO), CHANGED is ignored and no pages are cached to the group buffer pool.

ALL

Indicates that pages are to be cached in the group buffer pool as they are read in from DASD.

Exception: In the case of a single updating Db2 member when no other Db2 member has any interest in the page set, no pages are cached in the group buffer pool.

If the table space is in a group buffer pool that is defined to be used only for cross-invalidation (GBPCACHE NO), ALL is ignored and no pages are cached to the group buffer pool.

SYSTEM

Indicates that only changed system pages within the LOB table space are to be cached to the group buffer pool. A system page is a space map page or any other page that does not contain actual data values.

NONE

Indicates that no pages are to be cached to the group buffer pool. Db2 uses the group buffer pool only for cross-invalidation.

LOCKMAX

Specifies the maximum number of locks an application process can hold simultaneously in the table space. If a program requests more than that number, locks are escalated. The locks are released and the intent lock on the table space is promoted to S or X mode.

integer

Specifies the number of locks allowed before escalating, in the range 0 - 2147483647.

Zero (0) indicates that the number of locks on the table space are not counted and escalation does not occur.

SYSTEM

Indicates that the value of NUMLKTS subsystem parameter value specifies the maximum number of locks that a program can hold simultaneously in the table or table space. For more information see [LOCKS PER TABLE(SPACE) field (NUMLKTS subsystem parameter) (Db2 Installation and Migration)](1674_SQL_Reference)
The following table summarizes the results of specifying a LOCKSIZE value while omitting LOCKMAX.

<table>
<thead>
<tr>
<th>LOCKSIZE</th>
<th>Resultant LOCKMAX</th>
</tr>
</thead>
<tbody>
<tr>
<td>ANY</td>
<td>SYSTEM</td>
</tr>
<tr>
<td>TABLESPACE, LOB</td>
<td>0</td>
</tr>
</tbody>
</table>

If the lock size is TABLESPACE, LOCKMAX must be omitted, or its value must be 0.

**LOCKSIZE**

Specifies the size of locks used within the table space and, in some cases, also the threshold at which lock escalation occurs.

**ANY**

Specifies that Db2 can use any lock size.

In most cases, Db2 uses LOCKSIZE LOB LOCKMAX SYSTEM for LOB table spaces. However, when the number of locks acquired for the table space exceeds the maximum number of locks allowed for a table space (the NUMLKTS subsystem parameter), the LOB locks are released and locking is set at the next higher level.

If the table space is implicitly created, Db2 uses LOCKSIZE ANY.

**TABLESPACE**

Specifies table space locks.

**LOB**

Specifies LOB locks.

**LOGGED or NOT LOGGED**

Specifies whether changes that are made to the data in the specified table space are recorded in the log. This setting applies to all indexes of the table. Auxiliary indexes inherit the logging attribute from the associated base table space.

**LOGGED**

Specifies that changes that are made to the data in the specified table space are recorded in the log.

LOGGED is the default.

**NOT LOGGED**

Specifies that changes that are made to data in the specified table space are not recorded in the log.

NOT LOGGED prevents undo and redo information from being recorded in the log; however, control information for the specified table space will continue to be recorded in the log.

**USING block**

If you omit USING, the default storage group of the database must exist. The USING clause indicates whether the data set for the table space is defined by you or by Db2. If Db2 is to define the data set, the clause also gives space allocation parameters and an erase rule.

If you omit USING, Db2 defines the data sets using the default storage group of the database and the defaults for PRIQTY, SECQTY, and ERASE.
VCAT  catalog-name
   Specifies that the first data set for the table space is managed by the user,
   and following data sets, if needed, are also managed by the user.

   The data sets are linear VSAM data sets cataloged in the integrated catalog
   facility catalog that catalog-name identifies. For more information about
   catalog-name values, see Naming conventions.

   More than one Db2 subsystem can share the integrated catalog facility
   catalogs with the current server. To avoid the chance of those subsystems
   attempting to assign the same name to different data sets, specify a
   catalog-name value that is not used by the other Db2 subsystems.

STOGROUP  stogroup-name
   Specifies that Db2 will define and manage the data sets for the table space.
   Each data set will be defined on a volume of the identified storage group.
   The values specified (or the defaults) for PRIQTY and SECQTY determine
   the primary and secondary allocations for the data set. The storage group
   supplies the name of a volume for the data set and the first-level qualifier
   for the data set name. The first-level qualifier is also the name of, or an
   alias29 for, the integrated catalog facility catalog on which the data set is to
   be cataloged. The naming conventions for the data set are the same as if
   the data set is managed by the user. As was mentioned above for VCAT,
   the first-level qualifier could cause naming conflicts if the local Db2 can
   share integrated catalog facility catalogs with other Db2 subsystems.

   stogroup-name must identify a storage group that exists at the current
   server. SYSADM or SYSCtrl authority, or the USE privilege on the storage
   group, is required.

   The description of the storage group must include at least one volume
   serial number, or it must indicate that the choice of volumes is left to
   Storage Management Subsystem (SMS). If volume serial numbers appear in
   the description, each must identify a volume that is accessible to z/OS for
   dynamic allocation of the data set, and all identified volumes must be of
   the same device type.

   The integrated catalog facility catalog used for the storage group must not
   contain an entry for the first data set of the table space. If the integrated
   catalog facility catalog is password protected, the description of the storage
   group must include a valid password.

PRIQTY  integer
   Specifies the minimum primary space allocation for a Db2-managed
   data set. integer must be a positive integer, or -1. In general, when you
   specify PRIQTY with a positive integer value, the primary space
   allocation is at least n kilobytes, where n is the value of integer.
   However, the following exceptions exist:
   • For 4KB page sizes, if integer is greater than 0 and less than 200, n is
     200.
   • For 8KB page sizes, if integer is greater than 0 and less than 400, n is
     400.
   • For 16KB page sizes, if integer is greater than 0 and less than 800, n
     is 800.
   • For 32KB page sizes, if integer is greater than 0 and less than 1600, n
     is 1600.

29. The alias of an integrated catalog facility catalog.
• For any page size, if integer is greater than 67108864, n is 67108864.

If you do not specify PRIQTY, or specify PRIQTY with a value of -1, Db2 uses a default value for the primary space allocation; for information on how Db2 determines the default value, see Rules for primary and secondary space allocation.

If you specify PRIQTY, and do not specify a value of -1, Db2 specifies the primary space allocation to access method services using the smallest multiple of p KB not less than n, where p is the page size of the table space. The allocated space can be greater than the amount of space requested by Db2. For example, it could be the smallest number of tracks that will accommodate the request. The amount of storage space requested must be available on some volume in the storage group based on VSAM space allocation restrictions. Otherwise, the primary space allocation will fail. To more closely estimate the actual amount of storage, see DEFINE CLUSTER command (DFSMS Access Method Services for Catalogs).

Executing this statement causes only one data set to be created. However, you might have more data than this one data set can hold. Db2 automatically defines more data sets when they are needed. Regardless of the value in PRIQTY, when a data set reaches its maximum size, Db2 creates a new one. To enable a data set to reach its maximum size without running out of extents, it is recommended that you allow Db2 to automatically choose the value of the secondary space allocations for extents.

If you do choose to explicitly specify SECQTY, to avoid wasting space, use the following formula to make sure that PRIQTY and its associated secondary extent values do not exceed the maximum size of the data set:

PRIQTY + (number of extents * SECQTY) <= DSIZE (implicit or explicit)

SECQTY integer
Specifies the minimum secondary space allocation for a Db2-managed data set. integer must be a positive integer, 0, or -1. If you do not specify SECQTY, or specify SECQTY with a value of -1, Db2 uses a formula to determine a value. For information on the actual value that is used for secondary space allocation, whether you specify a value or not, see Rules for primary and secondary space allocation.

If you specify SECQTY, and do not specify a value of -1, Db2 specifies the secondary space allocation to access method services using the smallest multiple of p KB not less than integer, where p is the page size of the table space. The allocated space can be greater than the amount of space requested by Db2. For example, it could be the smallest number of tracks that will accommodate the request. To more closely estimate the actual amount of storage, see DEFINE CLUSTER command (DFSMS Access Method Services for Catalogs).

ERASE
Indicates whether the Db2-managed data sets for the table space are to be erased when they are deleted during the execution of a utility or an SQL statement that drops the table space.

NO Does not erase the data sets. Operations involving data set deletion will perform better than ERASE YES. However, the data is still accessible, though not through Db2. This is the default.
YES

Erases the data sets. As a security measure, Db2 overwrites all data in the data sets with zeros before they are deleted.

Notes

Rules for primary and secondary space allocation:
You can specify the primary and secondary space allocation or let Db2 choose them. Having Db2 choose the values, especially the secondary space quantity, increases the possibility of reaching the maximum data set size before running out of extents. For more information, see Rules for primary and secondary space allocation (Introduction to Db2 for z/OS).

Alternative syntax and synonyms:
For compatibility with previous Db2 releases or function levels, the following keywords are supported:

- When specifying the logging attributes for a table space, you can specify LOG YES as a synonym for LOGGED, and you can specify LOG NO as a synonym for NOT LOGGED.

Although these keywords are supported as alternatives, they are not the preferred syntax.

Example

Assume that a column named EMP_PHOTO with a data type of BLOB(110K) has been added to the sample employee table for each employee's photo. Create LOB table space PHOTOLTS in database DSN8D12A for the auxiliary table that will hold the BLOB data.

Let Db2 define the data sets for the table space, using storage group DSN8G120. For each data set, the primary space allocation is 3200 kilobytes, and the secondary space allocation is 1600 kilobytes. The data sets do not need to be erased before they are deleted. (Because ERASE NO is the default, the clause does not have to be explicitly specified to get that behavior.)

CREATE LOB TABLESPACE PHOTOLTS
IN DSN8D12A
USING STOGROUP DSN8G120
PRIQTY 3200
SECQTY 1600
LOCKSIZE LOB
BUFFERPOOL BP16K0
GBPCACHE SYSTEM
NOT LOGGED
CLOSE NO;

Related concepts:
- LOB table spaces (Introduction to Db2 for z/OS)
- Creation of large objects (Introduction to Db2 for z/OS)

Related tasks:
- Storing LOB data in a table (Db2 Application programming and SQL)

Related reference:
- CREATE AUXILIARY TABLE
CREATE MASK

The CREATE MASK statement creates a column mask at the current server. A column mask is used for column access control and specifies the value that should be returned for a specified column.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

Authorization

The privilege set that is defined below must include the following authority:

SECADM authority

SECADM authority can create a column mask in any schema. Additional privileges are not needed to reference other objects in the mask definition. For example, the SELECT privilege is not needed to query a table, and the EXECUTE privilege is not needed to invoke a user-defined function.

Privilege set: If the statement is embedded in an application program, the privilege set is the set of privileges that are held by the owner of the package. If the statement is dynamically prepared, the privilege set is the set of privileges that are held by the SQL authorization ID of the process. However, if the process is running in a trusted context that is defined with the ROLE AS OBJECT OWNER AND QUALIFIER clause, the privilege set is the set of privileges that are held by the role that is in effect.

Syntax

```
CREATE MASK mask-name ON table-name AS correlation-name FOR COLUMN column-name
RETURN case-expression
DISABLE
ENABLE
```

Description

**mask-name**

Specifies the names the column mask. The name, including the implicit or explicit qualifier, must not identify a column mask or a row permission that already exists at the current server.

**ON table-name**

Identifies the table for which the column mask is created. The name must identify a table that exists at the current server. It must not identify any of the following objects:

- An auxiliary table
- A created or declared temporary table
- A view
- A catalog table
- An alias
- A synonym
- A materialized query table or table that is directly or indirectly referenced in the definition of a materialized query table
- A table that was implicitly created for an XML column
- A table that contains a period
- A history table
- An accelerator-only table
- An archive-enabled table
- An archive table

**correlation-name**
Specifies a correlation name that can be used within case-expression to designate the table. For information about correlation-name, see Correlation names.

**FOR COLUMN column-name**
Identifies the column to which the mask applies. column-name must be an unqualified name that identifies a column of the specified table. A mask must not already exist for the column. The column must not be:
- a LOB column or a distinct type column that is based on a LOB
- an XML column
- defined with a FIELDPROC

**RETURN case-expression**
Specifies a CASE expression that determines the value that is returned for the column. The result of the CASE expression is returned in place of the column value in a row. The result data type, null attribute, data length, subtype, encoding scheme, and CCSID of the CASE expression must be identical to those attributes of the column that is specified by column-name. If the data type of column-name is a user-defined data type, the result data type of the CASE expression must be the same user-defined type. The CASE expression must not reference any of the following objects:
- A remote object
- The table for which the column mask is being defined
- A created global temporary table or a declared global temporary table
- An auxiliary table
- A table that was implicitly created for an XML column
- A column that is defined with a FIELDPROC
- A LOB column or a distinct type column that is based on a LOB
- An XML column
- A select list notation * or name.* in the SELECT clause
- A table function
- A collection-derived table (UNNEST)
- A user-defined function that is defined as not secure
- A function that is not deterministic or that has an external action or is defined with the MODIFIES SQL DATA option
- An aggregate function, unless it is specified in a subquery
• A built-in table function
• An XML TABLE table function
• An XML EXISTS predicate
• An OLAP specification
• A ROW CHANGE expression
• A sequence reference
• A host variable, SQL variable, SQL parameter, or trigger transition variable
• A parameter marker
• A table reference that contains a period specification
• A view that includes any of the preceding restrictions in its definition
• An accelerator-only table

The encoding scheme of the table is used to evaluate the CASE expression. Tables and language elements that require multiple encoding scheme evaluation, other than EBCDIC tables with Unicode columns, must not be referenced in the CASE expression. See Determining the encoding scheme and CCSID of a string (Introduction to Db2 for z/OS) for language elements that require multiple evaluation.

If the CASE expression references tables for which row or column access control is active, access controls for those tables are not cascaded.

**DISABLE or ENABLE**

Specifies that the column mask is to be enabled or disabled for column access control.

**DISABLE**

Specifies that the column mask is to be disabled for column access control. The column mask will remain disabled regardless of whether column access control is activated for the table.

**DISABLE** is the default.

**ENABLE**

Specifies that the column mask is to be enabled for column access control. If column access control is not currently active for the table, the column mask will become enabled when column access control is activated for the table. If column access control is currently active for the table, the column mask becomes enabled immediately and all packages and statements in the dynamic statement cache that reference the table are invalidated.

**Notes**

**How column masks affect queries:**

The application of enabled column masks does not interfere with the operations of other clauses within the statement such as the WHERE, GROUP BY, HAVING, SELECT DISTINCT, or ORDER BY. The rows that are returned in the final result table remain the same, except that the values in the resulting rows might have been masked by the column masks. As such, if the masked column also appears in an ORDER BY clause with a sort-key expression, the order is based on the original values of the column and the masked values in the final result table might not reflect that order. Similarly, the masked values might not reflect the uniqueness enforced by a SELECT DISTINCT statement. If the masked column is embedded in an expression, the result of the expression might become different because the column mask is applied on the column before the expression evaluation can take place. For example, a column mask on
column SSN might change the result of the aggregate function
COUNT(DISTINCT SSN) because the DISTINCT operation is performed on the
unmasked values.

Conflicts between the definition of a column mask and SQL:
A column mask is created as a stand alone object, without knowing all of
the contexts in which it might be used. To mask the value of a column in
the final result table, the definition of the column mask is merged into a
query by Db2. When the definition of the column mask is brought into the
context of the statement, it might conflict with certain SQL semantics in the
statement. Therefore, in some situations, the combination of the statement
and the application of the column mask can return an error. When this
happens, either the statement needs to be modified or the column mask
must be dropped or re-created with a different definition. See [ALTER]
TABLE for those situations in which a bind time error might be issued for
the statement.

Column masks and null columns:
If the column is not nullable, the definition of its column mask will not,
most likely, consider a null value for the column. After the column access
control is activated for the table, if the table is the null-padded table in an
outer join, the value of the column in the final result table might be a null.
To ensure that the column mask can mask a null value, if the table is the
null-padded table in an outer join, Db2 will add "WHEN target-column IS
NULL THEN NULL" as the first WHEN clause to the column mask
definition. This forces a null value to always be masked as a null value.
For a nullable column, this removes the ability to mask a null value as
something else. Example 5 shows this added WHEN clause.

Column mask values for SQL data change statements
When columns are used to derive new values for an INSERT, UPDATE,
MERGE, or a SET transition-variable assignment statement, the original
values of the column, not the masked values, are used to derive the new
values. If the columns have column masks, those column masks are
applied to ensure that the evaluation of the access control rules at run time
masks the column to itself, not to a constant or an expression. This is to
ensure that the masked values are the same as the original column values.
If a column mask does not mask the column to itself, the existing row is
not updated or the new row is not inserted and an error is returned at run
time. The rules that are used to apply column masks in order to derive the
new values follow the same rules for the final result table of a query.

Column masks that are created before column access control is activated:
The CREATE MASK statement is an independent statement that can be
used to create a column access control mask before column access control
is activated for a table. The only requirement is that the table and the
columns exist before the mask is created. Multiple column masks can be
created for a table but a column can have one mask only.

The definition of a mask is stored in the Db2 catalog. Dependency on the
table for which the mask is being created and dependencies on other
objects referenced in the definition are recorded. No package or dynamic
cached statement is invalidated. A column mask can be created as enabled
or disabled for column access control. An enabled column mask does not
take effect until the ALTER TABLE statement with the ACTIVATE
COLUMN ACCESS CONTROL clause is used to activate column access
control for the table. SECADM authority is required to issue such an
ALTER TABLE statement. A disabled column mask remains ineffective.
even when column access control is activated for the table. The ALTER MASK statement can be used to alter between ENABLE and DISABLE.

After column access control is activated for a table, when the table is referenced in a data manipulation statement, all enabled column masks that have been created for the table are implicitly applied by Db2 to mask the values returned for the columns referenced in the final result table of the queries or to determine the new values used in the data change statements.

Creating column masks before activating column access control for a table is the recommended sequence to avoid multiple invalidations of packages and dynamic cached statements that reference the table.

**Column masks that are created after column access control is activated:**
The enabled column masks become effective as soon as they are committed. All the packages and dynamic cached statements that reference the table are invalidated. Thereafter, when the table is referenced in a data manipulation statement, all enabled column masks are implicitly applied by Db2 to the statement. Any disabled column mask remains ineffective even when column access control is activated for the table.

**No cascaded effect when column or row access control enforced tables are referenced in column mask definitions:**
A column mask definition may reference tables and columns that are currently enforced by row or column access control. Access control from those tables and columns are ignored when the table for which the column mask is being created is referenced in a data manipulation statement.

**Multiple column masks and row permissions sharing the same environment variables:**
Multiple column masks and row permissions can be created for a table. They must use the same set of environment variables. The set of environment variables is determined when the first column mask or row permission is created for the table.

The catalog table SYSENVIRONMENT contains the list of environment variables. The following table shows which environment variable must be the same among the multiple column masks and row permissions.

<table>
<thead>
<tr>
<th>Environment variables shown as SYSENVIRONMENT columns</th>
<th>Description</th>
<th>Static create statement</th>
<th>Dynamic create statement</th>
<th>Must be the same among multiple column masks and row permissions?</th>

</table>

Note: In a data sharing environment, if a separate DSNHDECP module is provided for each member of the group, the DSNHDECP settings for each environment variable should be the same in all members of the data sharing group, otherwise an error might be issued when multiple column masks or row permissions are created.

Ordinary SQL identifiers specified in a static CREATE MASK statement in a COBOL application:

If the CREATE MASK statement is a static statement in a COBOL application, the ordinary SQL identifiers used in the column mask definition must not follow the rules for naming COBOL words. They must follow the rules for naming SQL identifiers. For example, the COBOL word 1ST-TIME is not allowed as an ordinary SQL identifier in a column mask definition; change it to FIRST_TIME or put it in the delimiters.

Encoding scheme and CCSIDs of the data manipulation statement after column masks are applied:

The encoding scheme and CCSIDs of the data manipulation statement are not affected by the column masks that are implicitly applied by Db2 for the column access control. For a target table or a referenced table that is not an EBCDIC table with Unicode columns, the column mask definition is evaluated using its table's encoding scheme and CCSIDs. For a target table or a referenced table that is an EBCDIC table with Unicode columns, the column mask definition is evaluated using the rules for multiple encoding schemes.
Consideration for Db2 limits:
If the data manipulation statement already approaches some Db2 limits in the statement, it should be noted that the more enabled column masks and enabled row permissions are created, the more likely they would impact some limits. For example, they may cause the statement to exceed the maximum total length (32600 bytes) of columns of a query operation requiring sort and evaluating aggregate functions (MULTIPLE DISTINCT and GROUP BY). This is because the enabled column mask and enabled row permission definitions are implicitly merged into the statement when the table is referenced in a data manipulation statement. See "Limits in Db2 for z/OS" in SQL Reference for the limits of a statement.

Restrictions involving pending definition changes:
CREATE MASK is not allowed if the mask is defined on a table or references a table that has pending definition changes.

Examples

Example 1:
After column access control is activated for table EMPLOYEE, Paul from the payroll department can see the social security number of the employee whose employee number is 123456. Mary who is a manager can see the last four characters only of the social security number. Peter who is neither cannot see the social security number.

CREATE MASK SSN_MASK ON EMPLOYEE
   FOR COLUMN SSN RETURN
   CASE
      WHEN (VERIFY_GROUP_FOR_USER(SESSION_USER,'PAYROLL') = 1)
          THEN SSN
      WHEN (VERIFY_GROUP_FOR_USER(SESSION_USER,'MGR') = 1)
          THEN 'XXX-XX-' || SUBSTR(SSN,8,4)
      ELSE NULL
   END
   ENABLE;

COMMIT;

ALTER TABLE EMPLOYEE
   ACTIVATE COLUMN ACCESS CONTROL;

COMMIT;

SELECT SSN FROM EMPLOYEE
   WHERE EMPNO = 123456;

Example 2:
In the SELECT statement, column SSN is embedded in an expression that is the same as the expression used in the column mask SSN_MASK. After column access control is activated for table EMPLOYEE, the column mask SSN_MASK is applied to column SSN in the SELECT statement. For this particular expression, the SELECT statement produces the same result as before column access control is activated for all users. The user can replace the expression in the SELECT statement with column SSN to avoid the same expression gets evaluated twice.

CREATE MASK SSN_MASK ON EMPLOYEE
   FOR COLUMN SSN RETURN
   CASE
      WHEN (1 = 1)
          THEN 'XXX-XX-' || SUBSTR(SSN,8,4)
      ELSE NULL
   END
   1686
SQL Reference
CREATE MASK CITY MASK ON LIBRARY USAGE
  FOR COLUMN CITY RETURN
  CASE
    WHEN (LIBRARY_OPT = 'OPT-IN')
      THEN CITY
    ELSE ''
  END
ENABLE;
COMMIT;

ALTER TABLE LIBRARY USAGE
  ACTIVATE COLUMN ACCESS CONTROL;
COMMIT;

SELECT CITY, AVG(LIBRARY_TIME) FROM LIBRARY USAGE
  GROUP BY CITY;

Example 4:
Employee with EMPNO 123456 earns bonus $8000 and salary $80000 in May. When the manager retrieves his salary, the manager receives his salary, not the null value. This is because of no cascaded effect when column mask SALARY_MASK references column BONUS for which column mask BONUS MASK is defined.

CREATE MASK SALARY MASK ON EMPLOYEE
  FOR COLUMN SALARY RETURN
  CASE
    WHEN (BONUS < 10000)
      THEN SALARY
    ELSE NULL
  END
ENABLE;
COMMIT;

CREATE MASK BONUS MASK ON EMPLOYEE
  FOR COLUMN BONUS RETURN
CASE
  WHEN (BONUS > 5000)
    THEN NULL
  ELSE BONUS
END
ENABLE;

COMMIT;

ALTER TABLE EMPLOYEE
  ACTIVATE COLUMN ACCESS CONTROL;

COMMIT;

SELECT SALARY FROM EMPLOYEE
  WHERE EMPNO = 123456;

Example 5:
This example shows Db2 adds "WHEN target-column IS NULL THEN
NULL" as the first WHEN clause to the column mask definition then
merges the column mask definition into the statement.

CREATE EMPLOYEE (EMPID INT,
  DEPTID CHAR(8),
  SALARY DEC(9,2) NOT NULL,
  BONUS DEC(9,2));

CREATE MASK SALARY_MASK ON EMPLOYEE
  FOR COLUMN SALARY RETURN
  CASE
    WHEN SALARY < 10000
      THEN CAST(SALARY*2 AS DEC(9,2))
    ELSE COALESCE(CAST(SALARY/2 AS DEC(9,2)), BONUS)
  END
  ENABLE;

COMMIT;

CREATE MASK BONUS_MASK ON EMPLOYEE
  FOR COLUMN BONUS RETURN
  CASE
    WHEN BONUS > 1000
      THEN BONUS
    ELSE NULL
  END
  ENABLE;

COMMIT;

ALTER TABLE EMPLOYEE
  ACTIVATE COLUMN ACCESS CONTROL;

COMMIT;

SELECT SALARY FROM DEPT
  LEFT JOIN EMPLOYEE ON DEPTNO = DEPTID;

/* When SALARY_MASK is merged into the above statement,
  'WHEN SALARY IS NULL THEN NULL' is added as the
  first WHEN clause, as follows:
*/

SELECT CASE WHEN SALARY IS NULL THEN NULL
  WHEN SALARY < 10000 THEN CAST(SALARY*2 AS DEC(9,2))
  ELSE COALESCE(CAST(SALARY/2 AS DEC(9,2)), BONUS)
CREATE PERMISSION

The CREATE PERMISSION statement creates a row permission for row access control at the current server.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

Authorization

The privilege set that is defined below must include the following authority:

- SECADM authority

SECADM authority can create a row permission in any schema. Additional privileges are not needed to reference other objects in the permission definition. For example, the SELECT privilege is not needed to retrieve from a table, and the EXECUTE privilege is not needed to invoke a user-defined function.

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the package. If the statement is dynamically prepared, the privilege set is the set of privileges that are held by the SQL authorization ID of the process. However, if it is running in a trusted context defined with the ROLE AS OBJECT OWNER AND QUALIFIER clause, the privilege set is the set of privileges that are held by the role in effect.

Syntax

```
CREATE PERMISSION permission-name ON table-name AS correlation-name
FOR ROWS WHERE search-condition ENFORCED FOR ALL ACCESS
```

Description

**permission-name**

Names the row permission for row access control. The name, including the implicit or explicit qualifier, must not identify a row permission or a column mask that already exists at the current server.

**ON table-name**

Identifies the table on which the row permission is created. The name must identify a table that exists at the current server. It must not identify any of the following objects:
• An auxiliary table
• A created or declared temporary table
• A view
• A catalog table
• An alias
• A synonym
• A materialized query table or table that is directly or indirectly referenced in the definition of a materialized query table
• A table that was implicitly created for an XML column
• A table that contains a period
• A history table
• An accelerator-only table
• An archive-enabled table
• An archive table
• A table that has a security label column.

correlation-name
Can be used within search-condition to designate the table. For the explanation of correlation-name, see [Correlation names](#).

FOR ROWS WHERE
Indicates that a row permission is created. A row permission specifies a search condition under which rows of the table can be accessed.

search-condition
Specifies a condition that can be true, false, or unknown for a row of the table. search-condition follows the same rules that are used by the search condition in a WHERE clause of a subselect. In addition, the search condition must not reference any of the following objects:
• A remote object
• The table for which the row permission is being defined
• A table that has a security label column
• A created global temporary table or a declared global temporary table
• An auxiliary table
• A table that was implicitly created for an XML column
• A collection-derived table (UNNEST)
• A table function
• A host variable, SQL variable, SQL parameter, or trigger transition variable
• A user-defined function that is defined as not secure
• A function that is not deterministic or that has an external action or is defined with the MODIFIES SQL DATA option
• A parameter marker
• A column that is defined with a FIELDPROC
• A LOB column or a distinct type column that is based on a LOB
• An XML column
• An XML EXISTS predicate
• An OLAP specification
• A ROW CHANGE expression
• A sequence reference
- A select list notation * or name.* in the SELECT clause
- A table reference that contains a period specification
- A view that includes any of the preceding restrictions in its definition

The encoding scheme of the table is used to evaluate the search-condition. Tables and language elements that require multiple encoding scheme evaluation, other than EBCDIC tables with Unicode columns, must not be referenced in the search-condition. See Determining the encoding scheme and CCSID of a string (Introduction to Db2 for z/OS) for those language elements.

If the search-condition references tables for which row or column access control is activated, access control from those tables is not cascaded.

**ENFORCED FOR ALL ACCESS**

Specifies that the row permission applies to all references of the table. If row access control is activated for the table, when the table is referenced in a data manipulation statement, Db2 implicitly applies the row permission to control the access of the table. If the reference of the table is for a fetch operation such as SELECT, the application of the row permission determines what set of rows can be retrieved by the user who requested the fetch operation. If the reference of the table is for a data change operation such as INSERT, the application of the row permission determines whether all rows to be changed are insertable or updatable by the user who requested the data change operation.

**DISABLE or ENABLE**

Specifies that the row permission is to be enabled or disabled for row access control.

**DISABLE**

Specifies that the row permission is to be disabled for row access control. The row permission will remain ineffective regardless the row access control is activated for the table or not.

**DISABLE** is the default.

**ENABLE**

Specifies that the row permission is to be enabled for row access control. If row access control is not currently activated for the table, the row permission will become effective when row access control is activated for the table. If row access control is currently activated for the table, the row permission becomes effective immediately and all packages and dynamic cached statements that reference the table are invalidated.

**Notes**

**How row permission are applied and how they affect certain statements:**

See the ALTER TABLE statement with the ACTIVATE ROW ACCESS CONTROL clause for information on how to activate row access control and how row permissions are applied. See the description of subselect for information on how the application of row permissions affects the fetch operation. See the data change statements for information on how the application of row permissions affects the data change operation.

**Row permissions that are created before row access control is activated for a table:**

The CREATE PERMISSION statement is an independent statement that can be used to create a row permission before row access control is activated for a table. The only requirement is that the table and the columns exist before the permission is created. Multiple row permissions can be created for a table.
The definition of the row permission is stored in the Db2 catalog. Dependency on the table for which the permission is being created and dependencies on other objects referenced in the definition are recorded. No package or dynamic cached statement is invalidated. A row permission can be created as enabled or disabled for row access control. An enabled row permission does not take effect until the ALTER TABLE statement with the ACTIVATE ROW ACCESS CONTROL clause is used to activate row access control for the table. A disabled row permission remains ineffective even when row access control is activated for the table. The ALTER PERMISSION statement can be used to alter between ENABLE and DISABLE.

After row access control is activated for a table, when the table is referenced in a data manipulation statement, all enabled row permissions that are defined for the table are implicitly applied by Db2 to control access to the table.

**Tip:** Create row permissions before activating row access control for a table to avoid multiple invalidations of packages and dynamic cached statements that reference the table.

**Row permissions that are created after row access control is activated for a table:** An enabled row permission becomes effective as soon as it is committed. All the packages and dynamic cached statements that reference the table are invalidated. Thereafter, when the table is referenced in a data manipulation statement, all enabled row permissions are implicitly applied to the statement. Any disabled row permission remains ineffective even when row access control is activated for the table.

**No cascaded effect when row or column access control enforced tables are referenced in row permission definitions:** A row permission definition may reference tables and columns that are currently enforced by row or column access control. Access control from those tables are ignored when the table for which the row permission is being created is referenced in a data manipulation statement.

**Multiple column masks and row permissions sharing the same environment variables:**

Multiple column masks and row permissions can be created for a table. They must use the same set of environment variables. The set of environment variables is determined when the first column mask or row permission is created for the table.

The catalog table SYSENVIRONMENT contains the list of environment variables. The following table shows which environment variable must be the same among the multiple column masks and row permissions.

<table>
<thead>
<tr>
<th>Environment variables shown as SYSENVIRONMENT columns</th>
<th>Description</th>
<th>Static create statement</th>

</table>

Note: In a data sharing environment, if a separate DSNHDECP module is provided for each member of the group, the DSNHDECP settings for each environment variable should be the same in all members of the data sharing group, otherwise an error might be issued when multiple column masks or row permissions are created.

Ordinary SQL identifiers specified in a static CREATE PERMISSION statement in a COBOL application:

If the CREATE PERMISSION statement is a static statement in a COBOL application, the ordinary SQL identifiers used in the row permission definition must not follow the rules for naming COBOL words (DSNHN20474, reason code 14). They must follow the rules for naming SQL identifiers as described in the topic “SQL identifiers” in Db2 SQL Reference. For example, the COBOL word 1ST-TIME is not allowed as an
ordinary SQL identifier in a row permission definition; change it to FIRST_TIME or put it in the delimiters.

**Encoding scheme and CCSIDs of the data manipulation statement after row permissions are applied:**

The encoding scheme and CCSIDs of the data manipulation statement are not affected by the row permissions that are implicitly applied by Db2 for the row access control. For a target table or a referenced table that is not an EBCDIC table with Unicode columns, the row permission definition is evaluated using its table's encoding scheme and CCSIDs. For a target table or a referenced table that is an EBCDIC table with Unicode columns, the row permission definition is evaluated using the rules for multiple encoding schemes.

**Consideration for Db2 limits:**
If the data manipulation statement already approaches some Db2 limits in the statement, it should be noted that the more enabled row permissions and enabled column masks are created, the more likely they would impact some limits. For example, they may cause the statement to exceed the maximum total length (32600 bytes) of columns of a query operation requiring sort and evaluating aggregate functions (MULTIPLE DISTINCT and GROUP BY). This is because the enabled column mask and enabled row permission definitions are implicitly merged into the statement when the table is referenced in a data manipulation statement. See "Limits in Db2 for z/OS" in SQL Reference for the limits of a statement.

**Restrictions involving pending definition changes:**
CREATE PERMISSION is not allowed if the permission is defined on a table or references a table that has pending definition changes.

**Examples**

**Example 1:**
Secure user-defined function ACCOUNTING_UDF in row permission SALARY_ROW_ACCESS processes the sensitive data in column SALARY. After row access control is activated for table EMPLOYEE, Accountant Paul retrieves the salary of employee with EMPNO 123456 who is making $100,000 a year. Paul may or may not see the row depending on the output value from user-defined function ACCOUNTING_UDF.

```sql
CREATE PERMISSION SALARY_ROW_ACCESS ON EMPLOYEE
  FOR ROWS WHERE VERIFY_GROUP_FOR_USER(SESSION_USER, 'MGR', 'ACCOUNTING') = 1
  AND ACCOUNTING_UDF(SALARY) < 120000
  ENFORCED FOR ALL ACCESS ENABLE;

COMMIT;

ALTER TABLE EMPLOYEE
  ACTIVATE ROW ACCESS CONTROL;

COMMIT;

SELECT SALARY FROM EMPLOYEE
  WHERE EMPNO = 123456;
```

**Example 2:**
The tellers in a bank can only access customers from their branch. All tellers have secondary authorization ID TELLER. The customer service representatives are allowed to access all customers of the bank. All customer service representatives have secondary authorization ID CSR. A
row permission is created for each group of personnel in the bank accordingly to the access rule defined by SECADM authority. After row access control is activated for table CUSTOMER, in the SELECT statement the search conditions of both row permissions are merged into the statement and they are combined with the logic OR operator to control the set of rows accessible by each group.

```sql
CREATE PERMISSION TELLER_ROW_ACCESS ON CUSTOMER
  FOR ROWS WHERE VERIFY_GROUP_FOR_USER(SESSION_USER,'TELLER') = 1
  AND
  BRANCH = (SELECT HOME_BRANCH FROM INTERNAL_INFO
             WHERE EMP_ID = SESSION_USER)
    ENFORCED FOR ALL ACCESS
    ENABLE;
COMMIT;

CREATE PERMISSION CSR_ROW_ACCESS ON CUSTOMER
  FOR ROWS WHERE VERIFY_GROUP_FOR_USER(SESSION_USER,'CSR') = 1
    ENFORCED FOR ALL ACCESS
    ENABLE;
COMMIT;

ALTER TABLE CUSTOMER
  ACTIVATE ROW ACCESS CONTROL;
COMMIT;

SELECT * FROM CUSTOMER;
```

---

**CREATE PROCEDURE**

The CREATE PROCEDURE statement registers a stored procedure with a database server. You can register the following types of procedures with this statement, each of which is described separately.

**External procedures**

The procedure is written in a programming language such as C, COBOL, or Java. The external executable (package) is registered with a database server along with various attributes of the procedure. When the procedure is invoked, the package is invoked.

See “CREATE PROCEDURE (external)” on page 1698.

**SQL procedures**

The procedure is written exclusively in SQL statements. The body of an SQL procedure is written in the SQL procedural language. The procedure body is defined at the database server along with various attributes of the procedure. A package is generated for an SQL procedure. When the procedure is invoked, the package is invoked.

See “CREATE PROCEDURE (SQL - external)” on page 1716 and “CREATE PROCEDURE (SQL - native)” on page 1728.

**Notes for ALL procedure types**

**Owner privileges:**

The owner is authorized to call the procedure (EXECUTE privilege) and grant others the privilege to call the procedure. See GRANT (function or procedure privileges) For more information about ownership of the object, see Authorization, privileges, permissions, masks, and object ownership
Defining the parameters
The input parameters for the procedure are specified as a list within parentheses.

The maximum number of parameters allowed in CREATE PROCEDURE is 90. For more information, see [Limits in Db2 for z/OS](#).

A procedure can have no input parameters. In this case, an empty set of parentheses can be specified or omitted, for example:

```sql
CREATE PROCEDURE ASSEMBLY_PARTS()
```

or

```sql
CREATE PROCEDURE ASSEMBLY_PARTS
```

Choosing data types for parameters:
When you choose the data types of the parameters for your stored procedure, consider the rules of promotion that can affect the values of the parameters. (See [Promotion of data types](#)). For example, a constant that is one of the input arguments to the stored procedure might have a built-in data type that is different from the data type that the procedure expects, and more significantly, might not be promotable to that expected data type. Based on the rules of promotion, using the following data types for parameters is recommended:

- INTEGER instead of SMALLINT
- DOUBLE instead of REAL
- VARCHAR instead of CHAR
- VARCHAR GRAPHIC instead of GRAPHIC
- VARBINARY instead of BINARY

For portability of functions across platforms that are not Db2 for z/OS, do not use the following data types, which might have different representations on different platforms:

- FLOAT. Use DOUBLE or REAL instead.
- NUMERIC. Use DECIMAL instead.

Specifying the encoding scheme for parameters:
The encoding scheme of all of the parameters with a character or graphic string data type (both input and output parameters) must be the same—either all ASCII, all EBCDIC, or all UNICODE. If you specify the encoding scheme on the individual parameters, instead of using the PARAMETER CCSID to specify it for all parameters at once or allowing the encoding scheme to default to the system value, ensure that they all agree.

Specifying AS LOCATOR for a parameter
Passing a locator instead of a value can result in fewer bytes being passed in or out of the procedure. This can be useful when the value of the parameter is very large. The AS LOCATOR clause specifies that a locator to the value of the parameter is passed instead of the actual value. Specify AS LOCATOR only for parameters with a LOB data type or a distinct type that is based on a LOB data type.

AS LOCATOR cannot be specified for SQL procedures.
Accessing result sets from nested stored procedures:
A stored procedure, user-defined function, or trigger cannot call a stored procedure that is defined with the COMMIT ON RETURN clause.

Special registers in procedures
The settings of the special registers of the caller are inherited by the procedure when called and restored upon return to the caller. Special registers may be changed within a procedure, but these changes do not affect the caller.

Global variables in procedures:
