

IBM i
7.3

*Database
Db2 for i SQL Reference*

Note

Before using this information and the product it supports, read the information in [“Notices” on page 2011](#).

This edition applies to IBM i 7.3 (product number 5770-SS1) and to all subsequent releases and modifications until otherwise indicated in new editions. This version does not run on all reduced instruction set computer (RISC) models nor does it run on CISC models.

This document may contain references to Licensed Internal Code. Licensed Internal Code is Machine Code and is licensed to you under the terms of the IBM License Agreement for Machine Code.

Contents

About SQL reference.....	xix
Standards compliance.....	xix
Assumptions relating to examples of SQL statements.....	xx
How to read the syntax diagrams.....	xxi
Conventions used in this book.....	xxiii
SQL accessibility.....	xxiii
PDF file for SQL reference.....	xxv
What's new for IBM i 7.3.....	xxvii
Chapter 1. Concepts.....	1
Relational database.....	1
Structured Query Language.....	2
Schemas.....	4
Tables.....	4
Keys.....	5
Constraints.....	5
Unique constraints.....	6
Referential constraints.....	6
Check constraints.....	8
Indexes.....	8
Triggers.....	9
Views.....	11
User-defined types.....	11
Aliases.....	12
Packages and access plans.....	12
Routines.....	12
Sequences.....	14
Authorization, privileges and object ownership.....	15
Catalog.....	17
Application processes, concurrency, and recovery.....	17
Locking, commit, and rollback.....	19
Unit of work.....	20
Rolling back work.....	21
Threads.....	22
Isolation level.....	23
Repeatable read.....	25
Read stability.....	25
Cursor stability.....	26
Uncommitted read.....	26
No commit.....	26
Comparison of isolation levels.....	26
Storage Structures.....	28
Character conversion.....	28
Character sets and code pages.....	31
Coded character sets and CCSIDs.....	32
Default CCSID.....	32
Collating sequence.....	33
Distributed relational database.....	35

Application servers.....	36
CONNECT (type 1) and CONNECT (type 2).....	37
Remote unit of work.....	37
Application-directed distributed unit of work.....	38
Data representation considerations.....	41
Chapter 2. Language elements.....	43
Characters.....	43
Tokens.....	44
Identifiers.....	46
SQL identifiers.....	46
System identifiers.....	46
Host identifiers.....	47
Naming conventions.....	48
SQL path.....	57
Qualification of unqualified object names.....	57
Unqualified alias, constraint, external program, index, mask, nodegroup, package, permission, sequence, table, trigger, view, and XSR object names.....	57
Unqualified function, procedure, specific name, type, and variables.....	59
SQL names and system names: special considerations.....	59
Aliases.....	60
Authorization IDs and authorization names.....	61
Procedure resolution.....	63
Data types.....	65
Nulls.....	66
Numbers.....	66
Subnormal numbers and underflow.....	68
Character strings.....	69
Character encoding schemes.....	70
Graphic strings.....	71
Graphic encoding schemes.....	72
Binary strings.....	72
Large objects.....	73
Limitations on use of strings.....	74
Datetime values.....	74
Date.....	74
Time.....	75
Timestamp.....	75
Datetime variables.....	75
String representations of datetime values.....	75
Date strings.....	75
Time strings.....	77
Timestamp strings.....	79
XML Values.....	80
DataLink values.....	81
Row ID values.....	82
User-defined types.....	82
Promotion of data types.....	84
Casting between data types.....	86
Assignments and comparisons.....	89
Numeric assignments.....	90
String assignments.....	92
Binary string assignments.....	93
Character and graphic string assignments.....	93
Datetime assignments.....	95
XML assignments.....	96
DataLink assignments.....	96

Row ID assignments.....	97
Distinct type assignments.....	98
Array type assignments.....	99
Assignments to LOB locators.....	99
Numeric comparisons.....	99
String comparisons.....	100
Datetime comparisons.....	102
XML comparisons.....	103
DataLink comparisons.....	103
Row ID comparisons.....	103
Distinct type comparisons.....	103
Array type comparisons.....	104
Rules for result data types.....	105
Conversion rules for operations that combine strings.....	110
Constants.....	112
Integer constants.....	112
Decimal constants.....	112
Floating-point constants.....	112
Decimal floating-point constants.....	112
Character-string constants.....	113
Graphic-string constants.....	114
Binary-string constants.....	115
Datetime constants.....	116
Decimal point.....	116
Delimiters.....	117
Special registers.....	119
CURRENT CLIENT_ACCTNG.....	121
CURRENT CLIENT_APPLNAME.....	121
CURRENT CLIENT_PROGRAMID.....	121
CURRENT CLIENT_USERID.....	122
CURRENT CLIENT_WRKSTNNAME.....	122
CURRENT DATE.....	123
CURRENT DEBUG MODE.....	123
CURRENT DECFLOAT ROUNDING MODE.....	124
CURRENT DEGREE.....	125
CURRENT IMPLICIT XMLPARSE OPTION.....	125
CURRENT PATH.....	126
CURRENT SCHEMA.....	127
CURRENT SERVER.....	127
CURRENT TEMPORAL SYSTEM_TIME.....	127
CURRENT TIME.....	128
CURRENT TIMESTAMP.....	129
CURRENT USER.....	129
CURRENT TIMEZONE.....	129
SESSION_USER.....	130
SYSTEM_USER.....	130
USER.....	130
Column names.....	131
Qualified column names.....	131
Correlation names.....	131
Column name qualifiers to avoid ambiguity.....	133
Table designators.....	133
Avoiding undefined or ambiguous references.....	134
Column name qualifiers in correlated references.....	135
Unqualified column names in correlated references.....	136
Variables.....	137
Global variables.....	137
References to host variables.....	139

Variables in dynamic SQL.....	141
References to LOB or XML variables.....	142
References to LOB or XML locator variables.....	142
References to LOB or XML file reference variables.....	143
References to XML variables.....	143
Host structures.....	144
Host structure arrays.....	145
Functions.....	147
Types of functions.....	147
Function invocation.....	148
Function resolution.....	149
Determining the best fit.....	150
Best fit considerations.....	156
Expressions.....	158
Without operators.....	159
With arithmetic operators.....	159
Two integer operands.....	159
Integer and decimal operands.....	160
Two decimal operands.....	160
Decimal arithmetic in SQL.....	160
Floating-point operands.....	161
Decimal floating-point operands.....	161
General arithmetic operation rules for DECFLOAT.....	162
Distinct type operands.....	163
With the concatenation operator.....	163
Scalar fullselect.....	165
Datetime operands and durations.....	165
Datetime arithmetic in SQL.....	167
Date arithmetic.....	167
Time arithmetic.....	169
Timestamp arithmetic.....	170
Precedence of operations.....	171
ARRAY constructor	172
ARRAY element specification.....	173
CASE expression.....	174
CAST specification.....	176
OLAP specifications.....	181
ROW CHANGE expression.....	192
Sequence reference.....	193
XMLCAST specification.....	197
Predicates.....	198
Basic predicate.....	199
Quantified predicate.....	201
BETWEEN predicate.....	203
DISTINCT predicate.....	204
EXISTS predicate.....	206
IN predicate.....	207
IS JSON predicate.....	209
JSON_EXISTS predicate.....	211
sql-json-path-expression.....	213
LIKE predicate.....	215
NULL predicate.....	219
REGEXP_LIKE predicate.....	220
Trigger event predicates.....	226
Search conditions.....	227

Chapter 3. Built-in global variables..... 229

CLIENT_HOST.....	230
CLIENT_IPADDR.....	231
CLIENT_PORT.....	232
JOB_NAME.....	233
PACKAGE_NAME.....	234
PACKAGE_SCHEMA.....	235
PACKAGE_VERSION.....	236
PROCESS_ID.....	237
ROUTINE_SCHEMA.....	238
ROUTINE_SPECIFIC_NAME.....	239
ROUTINE_TYPE.....	240
SERVER_MODE_JOB_NAME.....	241
THREAD_ID.....	242

Chapter 4. Built-in functions..... 243

Aggregate functions.....	258
ARRAY_AGG.....	259
AVG.....	261
CORR or CORRELATION.....	262
COUNT.....	263
COUNT_BIG.....	264
COVARIANCE or COVAR.....	265
COVAR_SAMP or COVARIANCE_SAMP.....	266
GROUPING.....	267
JSON_ARRAYAGG.....	268
JSON_OBJECTAGG.....	273
LISTAGG.....	277
MAX.....	280
MEDIAN.....	281
MIN.....	282
PERCENTILE_CONT.....	283
PERCENTILE_DISC.....	285
Regression functions.....	287
STDDEV_POP or STDDEV.....	290
STDDEV_SAMP.....	291
SUM.....	292
VAR_POP or VARIANCE or VAR.....	293
VAR_SAMP or VARIANCE_SAMP.....	294
XMLAGG.....	295
XMLGROUP.....	297
Scalar functions.....	300
ABS or ABSVAL.....	301
ACOS.....	302
ADD_MONTHS.....	303
ANTILOG.....	305
ARRAY_MAX_CARDINALITY.....	306
ARRAY_TRIM.....	307
ASCII.....	308
ASIN.....	309
ATAN.....	310
ATANH.....	311
ATAN2.....	312
BASE64_DECODE.....	313
BASE64_ENCODE.....	314
BIGINT.....	315
BINARY.....	317
BITAND, BITANDNOT, BITOR, BITXOR, and BITNOT.....	318

BIT_LENGTH.....	320
BLOB.....	321
BSON_TO_JSON.....	322
CARDINALITY.....	323
CEILING or CEIL.....	324
CHAR.....	325
CHARACTER_LENGTH or CHAR_LENGTH.....	331
CHR.....	332
CLOB.....	333
COALESCE.....	338
COMPARE_DECFLOAT.....	339
CONCAT.....	340
CONTAINS.....	341
COS.....	344
COSH.....	345
COT.....	346
CURDATE.....	347
CURTIME.....	348

CREATE_WRAPPED.....	724
XDBDECOMPXML.....	726
XSR_ADDSCHEMADOC.....	728
XSR_COMPLETE.....	730
XSR_REGISTER.....	732
XSR_REMOVE.....	734

Chapter 6. Queries..... 735

Authorization.....	735
subselect.....	736
select-clause.....	737
Select list notation.....	737
Applying the select list.....	738
Null attributes of result columns.....	739
Names of result columns.....	740
Data types of result columns.....	740
from-clause.....	742
table-reference.....	742
joined-table.....	750
Hierarchical queries.....	753
hierarchical-query-clause.....	754
pseudo columns.....	757
CONNECT_BY_ROOT.....	758
PRIOR.....	759
SYS_CONNECT_BY_PATH.....	761
where-clause.....	762
group-by-clause.....	763
having-clause.....	776
order-by-clause.....	777
offset-clause.....	779
fetch-clause.....	780
Examples of a subselect.....	781
fullselect.....	783
Examples of a fullselect.....	787
select-statement.....	789
common-table-expression.....	790
Recursion example: bill of materials.....	793
update-clause.....	796
read-only-clause.....	797
optimize-clause.....	798
isolation-clause.....	799
concurrent-access-resolution-clause.....	801
Examples of a select-statement.....	802

Chapter 7. Statements..... 805

How SQL statements are invoked.....	812
Embedding a statement in an application program.....	812
Dynamic preparation and execution.....	813
Static invocation of a select-statement.....	813
Dynamic invocation of a select-statement.....	814
Interactive invocation.....	814
SQL diagnostic information.....	814
Detecting and processing error and warning conditions in host language applications.....	814
SQL comments.....	815
ALLOCATE CURSOR.....	817
ALLOCATE DESCRIPTOR.....	818

About SQL reference

This book defines Structured Query Language (SQL) as supported by Db2® for IBM® i. It contains reference information for the tasks of system administration, database administration, application programming, and operation. This manual includes syntax, usage notes, keywords, and examples for each of the SQL statements used on the system.

Standards compliance

Db2 for i conforms with IBM and industry SQL Standards.

Distributed relational database architecture

- Open Group Publications: DRDA V5 Vol. 1: Distributed Relational Database Architecture(DRDA), at <https://publications.opengroup.org/c112>
- Open Group Publications: DRDA V5 Vol. 2: Formatted Data Object Content Architecture(FD:OCA), at <https://publications.opengroup.org/c113>
- Open Group Publications: DRDA V5 Vol. 3: Distributed Data Management Architecture (DDM), at <https://publications.opengroup.org/c114>

Character data representation architecture

- Character Data Representation Architecture Reference and Registry, at <http://www-01.ibm.com/software/globalization/cdra/>

Unicode standard

- The Unicode Standard, at <http://www.unicode.org>

SQL standards

Db2 for i conforms with the following industry standards for SQL:

- *ISO/IEC 9075-1:2016, Information technology - Database languages - SQL - Part 1: Framework (SQL/ Framework)*
- *ISO/IEC 9075-2:2016, Information technology - Database languages - SQL - Part 2: Foundation (SQL/ Foundation)*
- *ISO/IEC 9075-3:2016, Information technology - Database languages - SQL - Part 3: Call-Level Interface (SQL/CLI)*
- *ISO/IEC 9075-4:2016, Information technology - Database languages - SQL - Part 4: Persistent Stored Modules (SQL/PSM)*
- *ISO/IEC 9075-10:2016, Information technology - Database languages - SQL - Part 10: Object Language Bindings (SQL/OLB)*
- *ISO/IEC 9075-11:2016, Information technology - Database languages - SQL - Part 11: Information and Definition Schemas (SQL/Schemata)*
- *ISO/IEC 9075-14:2016, Information technology - Database languages - SQL - Part 14: XML-Related Specifications (SQL/XML)*

Db2 for i conforms with the following industry technical report for SQL:

- *ISO/IEC TR 19075-6:2016, Information technology - Database languages - SQL Technical Reports - Part 6: SQL support for JavaScript Object Notation (JSON)*

For strict adherence to the standards, consider using the standards options. Standards options can be specified through the following interfaces:

<i>Table 1. Standards Option Interfaces</i>	
SQL Interface	Specification
Embedded SQL	SQLCURREULE(*STD) parameter on the Create SQL Program (CRTSQLxxx) commands. The SET OPTION statement can also be used to set the SQLCURREULE values. (For more information about CRTSQLxxx commands, see Embedded SQL Programming .)
Run SQL Statements	SQLCURREULE(*STD) parameter on the Run SQL Statements (RUNSQLSTM) command. (For more information about the RUNSQLSTM command, see SQL Programming .)
Call Level Interface (CLI) on the server	SQL_ATTR_HEX_LITERALS connection attribute (For more information about CLI, see SQL Call Level Interfaces (ODBC) .)
JDBC or SQLJ on the server using IBM Developer Kit for Java™	Translate Hex connection property object (For more information about JDBC and SQLJ, see IBM Developer Kit for Java .)
ODBC on a client using the IBM i Access Family ODBC Driver	Hex Parser Option in ODBC Setup (For more information about ODBC, see IBM i Access .)
OLE DB on a client using the IBM i Access Family OLE DB Provider	Hex Parser Option Connection Object Properties (For more information about OLE DB, see IBM i Access .)
ADO .NET on a client using the IBM i Access Family ADO .NET Provider	HexParserOption in Connection Object Properties (For more information about ADO .NET, see IBM i Access .)
JDBC on a client using the IBM Toolbox for Java	Interpret SQL hexadecimal constants as binary data in JDBC Setup (For more information about JDBC, see IBM i Access .) (For more information about the IBM Toolbox for Java, see IBM Toolbox for Java .)

Assumptions relating to examples of SQL statements

The examples of SQL statements shown in this guide assume the following.

- SQL keywords are highlighted.
- Table names used in the examples are the sample tables provided in the [SQL Programming](#) topic collection. Table names that are not provided in that appendix should use schemas that you create. You can create a set of sample tables in your own schema by issuing the following SQL statement:

```
CALL QSYS.CREATE_SQL_SAMPLE ('your-schema-name')
```

Some examples use tables containing XML data. You can create these tables in your own schema by issuing the following SQL statement:

If an optional item has a default when it is not specified, the default appears above the main path.

- An arrow returning to the left, above the main line, indicates an item that can be repeated.

If the repeat arrow contains a comma, you must separate repeated items with a comma.

A repeat arrow above a stack indicates that the items in the stack can be repeated.

- Keywords appear in uppercase (for example, FROM). They must be spelled exactly as shown. Variables appear in all lowercase letters (for example, *column-name*). They represent user-supplied names or values.
- If punctuation marks, parentheses, arithmetic operators, or other such symbols are shown, you must enter them as part of the syntax.
- The syntax diagrams only contain the preferred or standard keywords. If nonstandard synonyms are supported in addition to the standard keywords, they are described in the **Notes** sections instead of the syntax diagrams. For maximum portability, use the preferred or standard keywords.
- Sometimes a single variable represents a larger fragment of the syntax. For example, in the following diagram, the variable `parameter-block` represents the whole syntax fragment that is labeled **parameter-block**:

parameter-block

Conventions used in this book

This section specifies some conventions which are used throughout this manual.

Highlighting conventions

Bold	Indicates SQL keywords used in examples and when introducing descriptions involving the keyword.
<i>Italics</i>	Indicates one of the following: <ul style="list-style-type: none">• Variables that represent items from a syntax diagram.• The introduction of a new term.• A reference to another source of information.

Conventions for describing mixed data values

When mixed data values are shown in the examples, the following conventions apply:

Convention	Meaning
S_0	Represents the EBCDIC <i>shift-out</i> control character (X' 0E')
S_I	Represents the EBCDIC <i>shift-in</i> control character (X' 0F')
<i>sbc-string</i>	Represents a string of zero or more single-byte characters
<i>dbc-string</i>	Represents a string of zero or more double-byte characters
⌘	Represents a DBCS apostrophe (EBCDIC X' 427D')
G	Represents a DBCS G (EBCDIC X' 42C7')

Conventions for describing mixed data values description

Conventions for describing mixed data values. Shift-out character represented by X' 0E', shift-in characters represented by X' 0F', single-byte characters represented by *sbc-string*, double-byte characters represented by *dbc-string*, DBCS apostrophe represented by EBCDIC X' 427D, and DBCS G represented by EBCDIC X' 42C7.

Conventions for describing Unicode data

When a specific Unicode UTF-16 code point is referenced, it can be expressed as U+n, where n is 4 to 6 hexadecimal digits. Leading zeros are omitted, unless the code point has fewer than 4 hexadecimal digits. For example, the following values are valid representations of a UTF-16 code point:

```
U+00001 U+0012 U+0123 U+1234 U+12345 U+123456
```

SQL accessibility

IBM is committed to providing interfaces and documentation that are easily accessible to the disabled community.

For general information about IBM's Accessibility support visit the [Accessibility Center](http://www.ibm.com/able) at <http://www.ibm.com/able>. 🌐

SQL accessibility support falls in two main categories.

- System i® Navigator is graphical user interface to the IBM i operating system and Db2 for i. For information about the Accessibility features supported in Windows graphical user interfaces, see Accessibility in the Windows Help Index.
- Online documentation, online help, and prompted SQL interfaces can be accessed by a Windows Reader program such as the IBM Home Page Reader. For information about the IBM Home Page Reader and other tools, visit the [Accessibility Center](#) .

The IBM Home Page Reader can be used to access all descriptive text in this book, all articles in the SQL Information Center, and all SQL messages. Due to the complex nature of SQL syntax diagrams, however, the reader will skip syntax diagrams. Two alternatives are provided for better ease of use:

- Interactive SQL and Query Manager

Interactive SQL and Query Manager are traditional file interfaces that provide prompting for SQL statements. These are part of the IBM DB2® Query Manager and SQL Development Kit for i. For more information about Interactive SQL and Query Manager, see the [SQL Programming and Query Manager](#)

[Use](#)  topics.

- SQL Assist

SQL Assist is a graphical user interface that provides a prompted interface to SQL statements. This is part of System i Navigator. For more information, see the System i Navigator online help and the Information Center.

PDF file for SQL reference

Use this to view and print a PDF of this information.

To view or download the PDF version of this document, select [SQL reference](#).

Saving PDF files

To save a PDF on your workstation for viewing or printing:

1. Right-click the PDF link in your browser.
2. Click the option that saves the PDF locally.
3. Navigate to the directory in which you want to save the PDF.
4. Click **Save**.

Downloading Adobe Reader

You need Adobe Reader installed on your system to view or print these PDFs. You can download a free copy from the [Adobe Web site](http://get.adobe.com/reader/) (<http://get.adobe.com/reader/>) .

What's new for IBM i 7.3

This topic highlights the changes made to this topic collection for IBM i 7.3.

The major new features covered in this book include:

- System-period temporal tables
- Attach and detach partitions for a table
- Additional OLAP functions
- Additional aggregate functions
- PROCESS_ID and THREAD_ID built-in global variables
- Enhancements to ROUND, TRUNCATE, TIMESTAMP_FORMAT, and VARCHAR_FORMAT scalar functions
- Inlining for SQL table functions
- Support for the EXTIND option in SET OPTION for SQL functions, procedures, and triggers
- Required Db2 PTF Group level tracking added for static statements to SYSPROGRAMSTMTSTAT
- Increase maximum number of parameters for scalar functions and table functions to 2000
- Increase number of return columns for table functions to 8000

In addition, the following enhancements are new since 7.2:

- JOB_NAME and SERVER_MODE_JOB_NAME built-in global variables
- REGEXP_xxx scalar functions and REGEXP_LIKE predicate for regular expression handling
- OVERLAY and LOCATE_IN_STRING scalar functions
- VARBINARY_FORMAT and VARCHAR_FORMAT_BINARY scalar functions
- LIMIT and OFFSET support for queries
- REPLACE option for CREATE TABLE
- System name for CREATE VARIABLE
- Support for PIPE statement in SQL table functions
- Increase maximum number of indexes on a table to approximately 15000

What's new as of May 2022

- HTTP_PATCH and HTTP_PATCH_VERBOSE functions have been added in QSYS2: [“HTTP_PATCH”](#) on page 432 and [“HTTP_PATCH_VERBOSE”](#) on page 691

What's new as of September 2021

- New HTTP functions in QSYS2 can make HTTP requests that use web services. These functions use the HTTP Transport support provided by the AXISC APIs: [“HTTP_DELETE”](#) on page 427, [“HTTP_GET”](#) on page 428, [“HTTP_POST”](#) on page 433, [“HTTP_PUT”](#) on page 434, [“HTTP_DELETE_VERBOSE”](#) on page 689, [“HTTP_GET_VERBOSE”](#) on page 690, [“HTTP_POST_VERBOSE”](#) on page 692, [“HTTP_PUT_VERBOSE”](#) on page 693

What's new as of April 2021

- SYSCOLUMNS2 view returns attributes for DDS created files: [“SYSCOLUMNS2”](#) on page 1725
- SYSPACKAGESTAT returns an indication that the package contains single use statements: [“SYSPACKAGESTAT”](#) on page 1780

What's new as of October 2020

- For CREATE FUNCTION, an external name that is a service program name does not require a library qualifier when the string form of the name is used. [“Naming conventions” on page 48](#)
- The SELECTIVITY clause allows user hints for individual predicates: [“Search conditions” on page 227](#)
- CREATE SEQUENCE supports the FOR SYSTEM NAME clause: [“CREATE SEQUENCE” on page 1108](#)
- DROP supports the IF EXISTS clause: [“DROP” on page 1288](#)
- The WHENEVER statement can call an internal procedure when a monitored condition is encountered: [“WHENEVER” on page 1576](#)
- SYSCOLUMNS2_SESSION view returns columns in QTEMP: [“SYSCOLUMNS2_SESSION” on page 1736](#)

What's new as of April 2020

- The language used to define SQL functions, procedures, and triggers is referred to as SQL PL (SQL Procedural Language)
- Synonyms for existing functions: [“ARRAY_MAX_CARDINALITY” on page 306](#) and [“ARRAY_TRIM” on page 307](#)
- INTERPRET function assigns a data type to binary data: [“INTERPRET” on page 444](#)
- JSON_TABLE, JSON_QUERY, JSON_VALUE, JSON_TO_BSON, and BSON_TO_JSON have been modified to support a JSON expression that is an array: [“JSON_TABLE” on page 694](#), [“JSON_QUERY” on page 457](#), [“JSON_VALUE” on page 463](#), [“JSON_TO_BSON” on page 462](#), [“BSON_TO_JSON” on page 322](#)
- Extended indicators can be used in OPEN and EXECUTE to allow omitting host variables from the USING list: [“OPEN” on page 1429](#), [“EXECUTE” on page 1304](#)
- TAG statement added to complement WHENEVER statement for fully free form ILE RPG: [“TAG” on page 1554](#)
- Extended indicators supported in SQL PL: [“assignment-statement” on page 1590](#)
- Documented table SYSDUMMY1: [“SYSDUMMY1” on page 1747](#)
- Variable length segment and blocked insert information added to SYSPARTITIONSTAT and SYSTABLESTAT views: [“SYSPARTITIONSTAT” on page 1813](#), [“SYSTABLESTAT” on page 1858](#)

What's new as of October 2019

- ISNULL and NOTNULL are synonyms for the IS NULL and IS NOT NULL predicates: [“NULL predicate” on page 219](#)
- Synonyms for existing functions: NVL, POW, RANDOM, STRLEFT, STRRIGHT, STRPOS, TO_CLOB: [“NVL” on page 519](#), [“POWER or POW” on page 529](#), [“RANDOM or RAND” on page 535](#), [“STRLEFT” on page 578](#), [“STRRIGHT” on page 580](#), [“STRPOS” on page 579](#), and [“TO_CLOB” on page 602](#)
- CREATE FUNCTION (SQL scalar), CREATE_FUNCTION (SQL table), and CREATE PROCEDURE (SQL) support the PROGRAM NAME clause to allow the program or service program name to be specified: [“CREATE FUNCTION \(SQL scalar\)” on page 1028](#), [“CREATE FUNCTION \(SQL table\)” on page 1042](#), and [“CREATE PROCEDURE \(SQL\)” on page 1090](#)
- CREATE FUNCTION (external scalar), CREATE_FUNCTION (external table), and CREATE PROCEDURE (external) removed the limit of 32 routine attributes that can be saved in the associated program or service program object.
- Additional index invalidation information added to SYSINDEXSTAT, SYSPARTITIONINDEXES, and SYSPARTITIONINDEXSTAT: [“SYSINDEXSTAT” on page 1761](#), [“SYSPARTITIONINDEXES” on page 1796](#), and [“SYSPARTITIONINDEXSTAT” on page 1803](#)

What's new as of April 2019

- CREATE INDEX allows index columns to be renamed: [“CREATE INDEX” on page 1055](#)
- INSERT a row containing only default values: [“INSERT” on page 1395](#)

What's new as of August 2018

- The table correlation name for nested table expressions, table functions, JSON_TABLE, XMLTABLE, and UNNEST is optional: [“table-reference” on page 742](#)
- DECFLOAT_FORMAT scalar function: [“DECFLOAT_FORMAT” on page 371](#)
- JSON_OBJECT and JSON_OBJECTAGG have a new option for duplicate key behavior. The default is to allow duplicate keys: [“JSON_OBJECT” on page 453](#) and [“JSON_OBJECTAGG” on page 273](#)
- JSON_TABLE, JSON_QUERY, and JSON_VALUE tolerate duplicate keys: [“JSON_TABLE” on page 694](#), [“JSON_QUERY” on page 457](#), and [“JSON_VALUE” on page 463](#)
- EXTRACT function has more options: [“EXTRACT” on page 404](#)
- NOW function allows optional precision: [“NOW” on page 517](#)
- VARCHAR_FORMAT supports 2 new timestamp format string elements for microseconds and milliseconds: [“VARCHAR_FORMAT” on page 629](#)
- Unqualified functions, variables, and types within an SQL procedure or function will record a value of CURRENT_PATH in SYSROUTINEDEP: [“CREATE PROCEDURE \(SQL\)” on page 1090](#), [“CREATE FUNCTION \(SQL scalar\)” on page 1028](#), and [“CREATE FUNCTION \(SQL table\)” on page 1042](#)
- SYSPARTITIONSTAT returns information about partial transactions: [“SYSPARTITIONSTAT” on page 1813](#)

What's new as of October 2017

- JSON publishing and scalar functions: [“JSON_ARRAYAGG” on page 268](#), [“JSON_OBJECTAGG” on page 273](#), [“JSON_ARRAY” on page 449](#), [“JSON_OBJECT” on page 453](#), [“JSON_QUERY” on page 457](#), and [“JSON_VALUE” on page 463](#)
- LIMIT and OFFSET restrictions removed: [“fetch-clause” on page 780](#) and [“offset-clause” on page 779](#)
- DELETE and UPDATE allow ORDER BY, FETCH, and OFFSET: [“DELETE” on page 1259](#) and [“UPDATE” on page 1561](#)
- GRANT and REVOKE on schemas: [“GRANT \(schema privileges\)” on page 1368](#) and [“REVOKE \(schema privileges\)” on page 1469](#)

What's new as of March 2017

- IS JSON and JSON_EXISTS predicates
- LISTAGG aggregate function
- LTRIM and RTRIM functions support a second argument
- CREATE TRIGGER allows dynamic statements to use 3-part names

What's new as of October 2016

- New OLAP function: PERCENT_RANK
- REPLACE function's third argument is optional
- JSON_TABLE table function
- Functions can be defined as STATEMENT DETERMINISTIC
- INCLUDE statement supported for SQL procedures, functions, and triggers
- SYSPARTITIONSTAT returns the TEXT value
- SYSPROGRAMSTAT returns module name

How to see what's new or changed

To help you see where technical changes have been made, this information uses:

- The  image to mark where new or changed information begins.
- The  image to mark where new or changed information ends.

To find other information about what's new or changed this release, see the [Memo to users](#).

Chapter 1. Concepts

This chapter provides a high-level view of concepts that are important to understand when using Structured Query Language (SQL). The reference material contained in the rest of this manual provides a more detailed view.

Relational database

A *relational database* is a database that can be perceived as a set of tables and can be manipulated in accordance with the relational model of data. The relational database contains a set of objects used to store, access, and manage data. The set of objects includes tables, views, indexes, aliases, user defined types, functions, procedures, sequences, variables, and packages.

There are three types of relational databases a user can access from an IBM i.

system relational database

There is one default relational database on an IBM i. The system relational database is always local to that IBM i. It consists of all the database objects that exist on disk attached to the IBM i that are not stored on independent auxiliary storage pools. For more information on independent auxiliary storage pools, see the [System Management](#) category of the IBM i Information Center.

The name of the system relational database is, by default, the same as the IBM i system name. However, a different name can be assigned through the use of the ADDRDBDIRE (Add RDB Directory Entry) command or System i Navigator.

user relational database

The user may create additional relational databases on an IBM i by configuring independent auxiliary storage pools on the system. Each primary independent auxiliary storage pool is a relational database. It consists of all the database objects that exist on the independent auxiliary storage pool disks. Additionally, all database objects in the system relational database of the IBM i product to which the independent auxiliary storage pool is connected are logically included in a user relational database. Thus, the name of any schema created in a user relational database must not already exist in that user relational database or in the associated system relational database.

Although the objects in the system relational database are logically included in a user relational database, certain dependencies between the objects in the system relational database and the user relational database are not allowed:

- A view must be created into a schema that exists in the same relational database as its referenced tables and views, except that a view created into QTEMP can reference tables and views in the user relational database.
- An index must be created into a schema that exists in the same relational database as its referenced table.
- A trigger or constraint must be created into a schema that exists in the same relational database as its base table.
- The parent table and dependent table in a referential constraint must both exist in the same relational database.
- Any object in the system relational database can only reference functions, procedures, and types in the same system relational database. However, objects in the user relational database may reference functions, procedures, and types in the system relational database or the same user relational database. However, operations on such an object may fail if the other relational database is not available. For example, if a user relational database is varied off and then varied on to another system.

A user relational database is local to an IBM i while the independent auxiliary storage pool is varied on. Independent auxiliary storage pools can be varied off on one IBM i and then varied on to another IBM i. Hence, a user relational databases may be local to a given IBM i at one point in time and

remote at a different point in time. For more information on independent auxiliary storage pools, see the [System Management](#) category of the IBM i Information Center.

The name of the user relational database is, by default, the same as the independent auxiliary storage pool name. However, a different name can be assigned through the use of the ADDRDBDIRE (Add RDB Directory Entry) command or System i Navigator.

remote relational database

Relational databases on other IBM i and non-IBM i products can be accessed remotely. These relational databases must be registered through the use of the ADDRDBDIRE (Add RDB Directory Entry) command or System i Navigator.

The database manager is the name used generically to identify the IBM i Licensed Internal Code and the Db2 for i portion of the code that manages the relational database.

Structured Query Language

Structured Query Language (SQL) is a standardized language for defining and manipulating data in a relational database. In accordance with the relational model of data, the database is perceived as a set of tables, relationships are represented by values in tables, and data is retrieved by specifying a result table that can be derived from one or more base tables.

SQL statements are executed by a database manager. One of the functions of the database manager is to transform the specification of a result table into a sequence of internal operations that optimize data retrieval. This transformation occurs when the SQL statement is *prepared*. This transformation is also known as *binding*.

All executable SQL statements must be prepared before they can be executed. The result of preparation is the executable or *operational form* of the statement. The method of preparing an SQL statement and the persistence of its operational form distinguish *static SQL* from *dynamic SQL*.

Static SQL

The source form of a *static SQL* statement is embedded within an application program written in a host language such as COBOL, C, or Java. The statement is prepared before the program is executed and the operational form of the statement persists beyond the execution of the program.

A source program containing static SQL statements must be processed by an SQL precompiler before it is compiled. The precompiler checks the syntax of the SQL statements, turns them into host language comments, and generates host language statements to call the database manager.

The preparation of an SQL application program includes precompilation, the preparation of its static SQL statements, and compilation of the modified source program.

Dynamic SQL

Programs containing embedded *dynamic SQL* statements must be precompiled like those containing static SQL, but unlike static SQL, the dynamic SQL statements are constructed and prepared at run time. The source form of the statement is a character or graphic string that is passed to the database manager by the program using the static SQL PREPARE or EXECUTE IMMEDIATE statement. A statement prepared using the PREPARE statement can be referenced in a DECLARE CURSOR, DESCRIBE, or EXECUTE statement. The operational form of the statement persists for the duration of the connection or until the last SQL program leaves the call stack.

SQL statements embedded in a REXX application are dynamic SQL statements. SQL statements submitted to the interactive SQL facility and to the Call Level Interface (CLI) are also dynamic SQL statements.

Extended Dynamic SQL

An extended dynamic SQL statement is neither fully static nor fully dynamic. The QSQPRCED API provides users with extended dynamic SQL capability. Like dynamic SQL, statements can be prepared, described,

and executed using this API. Unlike dynamic SQL, SQL statements prepared into a package by this API persist until the package or statement is explicitly dropped. For more information, see the [Database and File APIs](#) information in the **Programming** category of the IBM i Information Center.

Interactive SQL

An interactive SQL facility is associated with every database manager. Essentially, every interactive SQL facility is an SQL application program that reads statements from a workstation, prepares and executes them dynamically, and displays the results to the user. Such SQL statements are said to be issued *interactively*.

The interactive facilities for Db2 for i are invoked by the STRSQL command, the STRQM command, or the Run SQL Script support of System i Navigator. For more information about the interactive facilities for

SQL, see the [SQL Programming and Query Manager Use](#)  books.

SQL Call Level Interface and Open Database Connectivity

The DB2 Call Level Interface (CLI) is an application programming interface in which functions are provided to application programs to process dynamic SQL statements. DB2 CLI allows users of any of the ILE languages to access SQL functions directly through procedure calls to a service program provided by Db2 for i. CLI programs can also be compiled using an Open Database Connectivity (ODBC) Software Developer's Kit, available from Microsoft or other vendors, enabling access to ODBC data sources. Unlike using embedded SQL, no precompilation is required. Applications developed using this interface may be executed on a variety of databases without being compiled against each of the databases. Through the interface, applications use procedure calls at execution time to connect to databases, to issue SQL statements, and to get returned data and status information.

The DB2 CLI interface provides many features not available in embedded SQL. For example:

- CLI provides function calls which support a consistent way to query and retrieve database system catalog information across the DB2 family of database management systems. This reduces the need to write application server specific catalog queries.
- Stored procedures called from application programs written using CLI can return result sets to those programs.

For a complete description of all the available functions, and their syntax, see [SQL Call Level Interfaces \(ODBC\)](#) book.

Java DataBase Connectivity (JDBC) and embedded SQL for Java (SQLJ) programs

Db2 for i implements two standards-based Java programming APIs: Java Database Connectivity (JDBC) and embedded SQL for Java (SQLJ). Both can be used to create Java applications and applets that access DB2.

JDBC calls are translated to calls to DB2 CLI through Java native methods. You can access Db2 for i databases through two JDBC drivers: IBM Developer Kit for Java driver or IBM Toolbox for Java JDBC driver. For specific information about the IBM Toolbox for Java JDBC driver, see [IBM Toolbox for Java](#).

Static SQL cannot be used by JDBC. SQLJ applications use JDBC as a foundation for such tasks as connecting to databases and handling SQL errors, but can also contain embedded static SQL statements in the SQLJ source files. An SQLJ source file has to be translated with the SQLJ translator before the resulting Java source code can be compiled.

For more information about JDBC and SQLJ applications, refer to the [Developer Kit for Java](#) book.

OLE DB and ADO (ActiveX Data Object)

IBM i Access for Windows includes OLE DB Providers, along with the Programmer's Toolkit to allow DB2 client/server application development quick and easy from the Windows client PC. For more information, refer to the IBM i Access for Windows OLE DB provider in the IBM i Information Center.

.NET

IBM i Access for Windows include a .NET Provider to allow DB2 client/server application development quick and easy from the Windows client PC. For more information, refer to the IBM i Access for Windows .NET provider in the IBM i Information Center.

Schemas

The objects in a relational database are organized into sets called schemas. A schema provides a logical classification of objects in a relational database.

A *schema name* is used as the qualifier of SQL object names such as tables, views, indexes, and triggers. A schema is also called a collection or library.

A schema has a name and may have a different system name. The system name is the name used by the IBM i operating system. Either name is acceptable wherever a schema-name is specified in SQL statements.

A schema is distinct from, and should not be confused with, an XML schema, which is a standard that describes the structure and validates the content of XML documents.

Each database manager supports a set of schemas that are reserved for use by the database manager. Such schemas are called *system schemas*. The schema SESSION and all schemas that start with 'SYS' and 'Q' are *system schemas*.

User objects must not be created in *system schemas*, other than SESSION. SESSION is always used as the schema name for declared temporary tables. Users should not create schemas that start with 'SYS' or 'Q'.

A schema is also an object in the relational database. It is explicitly created using the CREATE SCHEMA statement.¹ For more information, see [“CREATE SCHEMA” on page 1103](#).

An object that is contained in a schema is assigned to the schema when the object is created. The schema to which it is assigned is determined by the name of the object if specifically qualified with a schema name or by the default schema name if not qualified.

For example, a user creates a schema called C:

```
CREATE SCHEMA C
```

The user can then issue the following statement to create a table called X in schema C:

```
CREATE TABLE C.X (COL1 INT)
```

Tables

Tables are logical structures maintained by the database manager. Tables are made up of columns and rows. There is no inherent order of the rows within a table. At the intersection of every column and row is a specific data item called a *value*. A *column* is a set of values of the same type. A *row* is a sequence of values such that the *n*th value is a value of the *n*th column of the table.

There are three types of tables:

- A *base table* is created with the CREATE TABLE statement and is used to hold persistent user data. For more information see [“CREATE TABLE” on page 1115](#).

A base table has a name and may have a different system name. The system name is the name used by the IBM i operating system. Either name is acceptable wherever a *table-name* is specified in SQL statements.

¹ A schema can also be created using the CRTLIB CL command, however, the catalog views and journal and journal receiver created by using the CREATE SCHEMA statement will not be created with CRTLIB.

A column of a base table has a name and may have a different system column name. The system column name is the name used by the IBM i operating system. Either name is acceptable wherever *column-name* is specified in SQL statements. For more information see [“CREATE TABLE” on page 1115](#).

A *materialized query table* is a base table created with the CREATE TABLE statement and used to contain data that is derived (materialized) from a *select-statement*. A source table is a base table, view, table expression, or user-defined table function. The *select-statement* specifies the query that is used to refresh the data in the materialized query table.

Materialized query tables can be used to improve the performance of SQL queries. If the database manager determines that a portion of a query could be resolved by using the data in a materialized query table, the query may be rewritten by the database manager to use the materialized query table. For more information about creating materialized query tables, see [“CREATE TABLE” on page 1115](#).

A *temporal table* associates time-based state information with every change to the data in the table. The database stores the historical rows (deleted rows or the original values of rows that have been updated) in a *history table* so you can query the past state of your data. For more information about creating temporal tables, see [“ADD VERSIONING USE HISTORY TABLE history-table-name” on page 902](#).

A *partitioned table* is a table whose data is contained in one or more local partitions (members). There are two mechanisms that can be specified to determine into which partition a specific row will be inserted. Range partitioning allows a user to specify different ranges of values for each partition. When a row is inserted, the values specified in the row are compared to the specified ranges to determine which partition is appropriate. Hash partitioning allows a user to specify a partitioning key on which a hash algorithm is used to determine which partition is appropriate. The *partitioning key* is a set of one or more columns in a partitioned table that are used to determine in which partition a row belongs.

A *distributed table* is a table whose data is partitioned across a nodegroup. A *nodegroup* is an object that provides a logical grouping of a set of two or more systems. The *partitioning key* is a set of one or more columns in a distributed table that are used to determine on which system a row belongs. For more information about distributed tables, see the [DB2 Multisystem book](#).

- A *result table* is a set of rows that the database manager selects or generates from a query. For information on queries, see [Chapter 6, “Queries,” on page 735](#).
- A *declared temporary table* is created with a DECLARE GLOBAL TEMPORARY TABLE statement and is used to hold temporary data on behalf of a single application. This table is dropped implicitly when the application disconnects from the database.

Keys

A *key* is one or more expressions that are identified as such in the description of an index, unique constraint, or a referential constraint. The same expression can be part of more than one key.

A *composite key* is an ordered set of expressions of the same base table. The ordering of the expressions is not constrained by their ordering within the base table. The term *value* when used with respect to a composite key denotes a composite value. Thus, a rule such as “the value of the foreign key must be equal to the value of the primary key” means that each component of the value of the foreign key must be equal to the corresponding component of the value of the primary key.

Constraints

A *constraint* is a rule that the database manager enforces.

There are three types of constraints:

- A *unique constraint* is a rule that forbids duplicate values in one or more columns within a table. Unique and primary keys are the supported unique constraints. For example, a unique constraint can be defined on the supplier identifier in the supplier table to ensure that the same supplier identifier is not given to two suppliers.
- A *referential constraint* is a logical rule about values in one or more columns in one or more tables. For example, a set of tables shares information about a corporation's suppliers. Occasionally, a supplier's ID changes. You can define a referential constraint stating that the ID of the supplier in a table must match

a supplier ID in the supplier information. This constraint prevents insert, update, or delete operations that would otherwise result in missing supplier information.

- A *check constraint* sets restrictions on data added to a specific table. For example, a check constraint can ensure that the salary level for an employee is at least \$20 000 whenever salary data is added or updated in a table containing personnel information.

Unique constraints

A *unique constraint* is the rule that the values of a key are valid only if they are unique. A key that is constrained to have unique values is called a *unique key*. A unique constraint is enforced by using a unique index. The unique index is used by the database manager to enforce the uniqueness of the values of the key during the execution of INSERT and UPDATE statements.

There are two types of unique constraints:

- Unique keys can be defined as a primary key using a CREATE TABLE or ALTER TABLE statement. A base table cannot have more than one primary key. A CHECK constraint will be added implicitly to enforce the rule that the NULL value is not allowed in the columns that make up the primary key. A unique index on a primary key is called a *primary index*.
- Unique keys can be defined using the UNIQUE clause of the CREATE TABLE or ALTER TABLE statement. A base table can have more than one set of UNIQUE keys. Multiple null values are allowed.

A unique key that is referenced by the foreign key of a referential constraint is called the *parent key*. A parent key is either a primary key or a UNIQUE key. When a base table is defined as a parent in a referential constraint, the default parent key is its primary key.

The unique index that is used to enforce a unique constraint is implicitly created when the unique constraint is defined. Alternatively, it can be defined by using the CREATE UNIQUE INDEX statement.

For more information about defining unique constraints, see [“ALTER TABLE” on page 869](#) or [“CREATE TABLE” on page 1115](#).

Referential constraints

Referential integrity is the state of a database in which all values of all foreign keys are valid. A *foreign key* is a key that is part of the definition of a referential constraint.

A *referential constraint* is the rule that the values of the foreign key are valid only if:

- They appear as values of a parent key, or
- Some component of the foreign key is null.

The base table containing the parent key is called the *parent table* of the referential constraint, and the base table containing the foreign key is said to be a *dependent* of that table.

Referential constraints are optional and can be defined in CREATE TABLE statements and ALTER TABLE statements. Referential constraints are enforced by the database manager during the execution of INSERT, UPDATE, and DELETE statements. The enforcement is effectively performed at the completion of the statement except for delete and update rules of RESTRICT which are enforced as rows are processed.

Referential constraints with a delete or update rule of RESTRICT are always enforced before any other referential constraints. Other referential constraints are enforced in an order independent manner. That is, the order does not affect the result of the operation. Within an SQL statement:

- A row can be marked for deletion by any number of referential constraints with a delete rule of CASCADE.
- A row can only be updated by one referential constraint with a delete rule of SET NULL or SET DEFAULT.
- A row that was updated by a referential constraint cannot also be marked for deletion by another referential constraint with a delete rule of CASCADE.

The rules of referential integrity involve the following concepts and terminology:

Parent key

A primary key or unique key of a referential constraint.

Parent row

A row that has at least one dependent row.

Parent table

A base table that is a parent in at least one referential constraint. A base table can be defined as a parent in an arbitrary number of referential constraints.

Dependent table

A base table that is a dependent in at least one referential constraint. A base table can be defined as a dependent in an arbitrary number of referential constraints. A dependent table can also be a parent table.

Descendent table

A base table is a descendent of base table T if it is a dependent of T or a descendent of a dependent of T.

Dependent row

A row that has at least one parent row.

Descendent row

A row is a descendent of row p if it is a dependent of p or a descendent of a dependent of p.

Referential cycle

A set of referential constraints such that each table in the set is a descendent of itself.

Self-referencing row

A row that is a parent of itself.

Self-referencing table

A base table that is a parent and a dependent in the same referential constraint. The constraint is called a *self-referencing constraint*.

The insert rule of a referential constraint is that a nonnull insert value of the foreign key must match some value of the parent key of the parent table. The value of a composite foreign key is null if any component of the value is null.

The update rule of a referential constraint is specified when the referential constraint is defined. The choices are NO ACTION and RESTRICT. The update rule applies when a row of the parent or dependent table is updated. The update rule of a referential constraint is that a nonnull update value of a foreign key must match some value of the parent key of the parent table. The value of a composite foreign key is treated as null if any component of the value is null.

The delete rule of a referential constraint is specified when the referential constraint is defined. The choices are RESTRICT, NO ACTION, CASCADE, SET NULL or SET DEFAULT. SET NULL can be specified only if some column of the foreign key allows null values.

The delete rule of a referential constraint applies when a row of the parent table is deleted. More precisely, the rule applies when a row of the parent table is the object of a delete or propagated delete operation (defined below) and that row has dependents in the dependent table of the referential constraint. Let P denote the parent table, let D denote the dependent table, and let p denote a parent row that is the object of a delete or propagated delete operation. If the delete rule is:

- RESTRICT or NO ACTION, an error is returned and no rows are deleted
- CASCADE, the delete operation is propagated to the dependents of p in D
- SET NULL, each nullable column of the foreign key of each dependent of p in D is set to null
- SET DEFAULT, each column of the foreign key of each dependent of p in D is set to its default value

Each referential constraint in which a table is a parent has its own delete rule, and all applicable delete rules are used to determine the result of a delete operation. Thus, a row cannot be deleted if it has dependents in a referential constraint with a delete rule of RESTRICT or NO ACTION, or if the deletion cascades to any of its descendants that are dependents in a referential constraint with the delete rule of RESTRICT or NO ACTION.

The deletion of a row from parent table P involves other tables and may affect rows of these tables:

- If table D is a dependent of P and the delete rule is RESTRICT or NO ACTION, D is involved in the operation but is not affected by the operation.
- If D is a dependent of P and the delete rule is SET NULL, D is involved in the operation, and rows of D may be updated during the operation.
- If D is a dependent of P and the delete rule is SET DEFAULT, D is involved in the operation, and rows of D may be updated during the operation.
- If D is a dependent of P and the delete rule is CASCADE, D is involved in the operation and rows of D may be deleted during the operation.

If rows of D are deleted, the delete operation on P is said to be propagated to D. If D is also a parent table, the actions described in this list apply, in turn, to the dependents of D.

Any base table that may be involved in a delete operation on P is said to be *delete-connected* to P. Thus, a base table is delete-connected to base table P if it is a dependent of P or a dependent of a base table to which delete operations from P cascade.

For more information on defining referential constraints, see [“ALTER TABLE” on page 869](#) or [“CREATE TABLE” on page 1115](#).

Check constraints

A *check constraint* is a rule that specifies which values are allowed in every row of a base table. The definition of a check constraint contains a search condition that must not be FALSE for any row of the base table.

Each column referenced in the search condition of a check constraint on a table T must identify a column of T. For more information about search conditions, see [“Search conditions” on page 227](#).

A base table can have more than one check constraint. Each check constraint defined on a base table is enforced by the database manager when either of the following occur:

- A row is inserted into that base table.
- A row of that base table is updated.

A check constraint is enforced by applying its search condition to each row that is inserted or updated in that base table. An error is returned if the result of the search condition is FALSE for any row.

For more information about defining check constraints, see [“ALTER TABLE” on page 869](#) or [“CREATE TABLE” on page 1115](#).

Indexes

An *index* is a set of pointers to rows of a base table. Each index is based on the values of data in one or more table columns. An index is an object that is separate from the data in the table. When an index is created, the database manager builds this structure and maintains it automatically.

An index has a name and may have a different system name. The system name is the name used by the IBM i operating system. Either name is acceptable wherever an *index-name* is specified in SQL statements. For more information, see [“CREATE INDEX” on page 1055](#).

The database manager uses two types of indexes:

- Binary radix tree index

Binary radix tree indexes provide a specific order to the rows of a table. The database manager uses them to:

- Improve performance. In most cases, access to data is faster than without an index.
- Ensure uniqueness. A table with a unique index cannot have rows with identical keys.

- Encoded vector index

Encoded vector indexes do not provide a specific order to the rows of a table. The database manager only uses these indexes to improve performance.

An encoded vector access path works with the help of encoded vector indexes and provides access to a database file by assigning codes to distinct key values and then representing these values in an array. The elements of the array can be 1, 2, or 4 bytes in length, depending on the number of distinct values that must be represented. Because of their compact size and relative simplicity, encoded vector access paths provide for faster scans that can be more easily processed in parallel.

An *index* is created with the CREATE INDEX statement. For more information about creating indexes, see [“CREATE INDEX” on page 1055](#).

For more information about indexes, see [IBM Db2 for i indexing methods and strategies](#) .

Triggers

A *trigger* defines a set of actions that are executed automatically whenever a delete, insert, or update operation occurs on a specified table or view. When such an SQL operation is executed, the trigger is said to be activated.

The set of actions can include almost any operation allowed on the system. A few operations are not allowed, such as:

- Commit or rollback (if the same commitment definition is used for the trigger actions and the triggering event)
- CONNECT, SET CONNECTION, DISCONNECT, and RELEASE statements
- SET SESSION AUTHORIZATION

For a complete list of restrictions, see [“CREATE TRIGGER” on page 1170](#) and the [Database Programming book](#).

Triggers can be used along with referential constraints and check constraints to enforce data integrity rules. Triggers are more powerful than constraints because they can also be used to cause updates to other tables, automatically generate or transform values for inserted or updated rows, or invoke functions that perform operations both inside and outside of database manager. For example, instead of preventing an update to a column if the new value exceeds a certain amount, a trigger can substitute a valid value and send a notice to an administrator about the invalid update.

Triggers are a useful mechanism to define and enforce transitional business rules that involve different states of the data (for example, salary cannot be increased by more than 10 percent). Such a limit requires comparing the value of a salary before and after an increase. For rules that do not involve more than one state of the data, consider using referential and check constraints.

Triggers also move the application logic that is required to enforce business rules into the database, which can result in faster application development and easier maintenance because the business rule is no longer repeated in several applications, but one version is centralized to the trigger. With the logic in the database, for example, the previously mentioned limit on increases to the salary column of a table, database manager checks the validity of the changes that any application makes to the salary column. In addition, the application programs do not need to be changed when the logic changes.

For more information about creating triggers, see [“CREATE TRIGGER” on page 1170](#).²

Triggers are optional and are defined using the CREATE TRIGGER statement or the **Add Physical File Trigger (ADDPFTRG)** CL command. Triggers are dropped using the DROP TRIGGER statement or the **Remove Physical File Trigger (RMVPFTRG)** CL command. For more information about creating triggers, see the CREATE TRIGGER statement. For more information about triggers in general, see the [“CREATE TRIGGER” on page 1170](#) statement or the [SQL Programming and the Database Programming books](#).

² The ADDPFTRG CL command also defines a trigger, including triggers that are activated on any read operation.

There are a number of criteria that are defined when creating a trigger which are used to determine when a trigger should be activated.

- The *subject table* (also known as the triggering table) defines the table or view for which the trigger is defined.
- The *trigger event* defines a specific SQL operation that modifies the subject table. The operation could be delete, insert, or update.
- The *trigger activation time* defines whether the trigger should be activated before or after the trigger event is performed on the subject table.

The statement that causes a trigger to be activated will include a *set of affected rows*. These are the rows of the subject table that are being deleted, inserted or updated. The *trigger granularity* defines whether the actions of the trigger will be performed once for the statement or once for each of the rows in the set of affected rows.

The *trigger action* consists of an optional search condition and a set of SQL statements that are executed whenever the trigger is activated. The SQL statements are only executed if no search condition is specified or the specified search condition evaluates to true.

The triggered action may refer to the values in the set of affected rows. This is supported through the use of *transition variables*. Transition variables use the names of the columns in the subject table qualified by a specified name that identifies whether the reference is to the old value (prior to the update) or the new value (after the update). The new value can also be changed using the SET transition-variable statement in before update or insert triggers. Another means of referring to the values in the set of affected rows is using *transition tables*. Transition tables also use the names of the columns of the subject table but have a name specified that allows the complete set of affected rows to be treated as a table. Transition tables can only be used in after triggers. Separate transition tables can be defined for old and new values.

Multiple triggers can be specified for a combination of table, event, or activation time. The order in which the triggers are activated is the same as the order in which they were created. Thus, the most recently created trigger will be the last trigger activated.

The activation of a trigger may cause *trigger cascading*. This is the result of the activation of one trigger that executes SQL statements that cause the activation of other triggers or even the same trigger again. The triggered actions may also cause updates as a result of the original modification, which may result in the activation of additional triggers. With trigger cascading, a significant chain of triggers may be activated causing significant change to the database as a result of a single delete, insert or update statement.

The actions performed in the trigger are considered to be part of the operation that caused the trigger to be executed. Thus, when the isolation level is anything other than NC (No Commit) and the trigger actions are performed using the same commitment definition as the trigger event:

- The database manager ensures that the operation and the triggers executed as a result of that operation either all complete or are backed out. Operations that occurred prior to the triggering operation are not affected.
- The database manager effectively checks all constraints (except for a constraint with a RESTRICT delete rule) after the operation and the associated triggers have been executed.

A trigger has an attribute that specifies whether it is allowed to delete or update a row that has already been inserted or updated within the SQL statement that caused the trigger to be executed.

- If ALWREPCHG(*YES) is specified when the trigger is defined, then within an SQL statement:
 - The trigger is allowed to update or delete any row that was inserted or already updated by that same SQL statement. This also includes any rows inserted or updated by a trigger or referential constraint caused by the same SQL statement.
- If ALWREPCHG(*NO) is specified when the trigger is defined, then within an SQL statement:
 - A row can be deleted by a trigger only if that row has not been inserted or updated by that same SQL statement. If the isolation level is anything other than NC (No Commit) and the trigger actions are performed using the same commitment definition as the trigger event, this also includes any inserts or updates by a trigger or referential constraint caused by the same SQL statement.

- A row can be updated by a trigger only if that row has not already been inserted or updated by that same SQL statement. If the isolation level is anything other than NC (No Commit) and the trigger actions are performed using the same commitment definition as the trigger event, this also includes any inserts or updates by a trigger or referential constraint caused by the same SQL statement.

All triggers created by using the CREATE TRIGGER statement implicitly have the ALWREPCHG(*YES) attribute.

Views

A *view* provides an alternative way of looking at the data in one or more tables.

A view is a named specification of a result table. The specification is a SELECT statement that is effectively executed whenever the view is referenced in an SQL statement. Thus, a view can be thought of as having columns and rows just like a base table. For retrieval, all views can be used just like base tables. Whether a view can be used in an insert, update, or delete operation depends on its definition.

An index cannot be created for a view. However, an index created for a table on which a view is based may improve the performance of operations on the view.

When the column of a view is directly derived from a column of a base table, that column inherits any constraints that apply to the column of the base table. For example, if a view includes a foreign key of its base table, INSERT and UPDATE operations using that view are subject to the same referential constraints as the base table. Likewise, if the base table of a view is a parent table, DELETE operations using that view are subject to the same rules as DELETE operations on the base table. A view also inherits any triggers that apply to its base table. For example, if the base table of a view has an update trigger, the trigger is fired when an update is performed on the view.

A view has a name and may have a different system name. The system name is the name used by the IBM i operating system. Either name is acceptable wherever a *view-name* is specified in SQL statements.

A column of a view has a name and may have a different system column name. The system column name is the name used by the IBM i operating system. Either name is acceptable wherever *column-name* is specified in SQL statements.

A *view* is created with the CREATE VIEW statement. For more information about creating views, see [“CREATE VIEW” on page 1206](#).

User-defined types

A *user-defined type* is a data type that is defined to the database using a CREATE statement.

There are two types of user-defined data type:

- Distinct type
- Array type

A *distinct type* is a user-defined type that shares its internal representation with a built-in data type (its source type), but is considered to be a separate and incompatible data type for most operations. A distinct type is created with an SQL CREATE TYPE (Distinct) statement. A distinct type can be used to define a column of a table, or a parameter of a routine. For more information, see [“CREATE TYPE \(distinct\)” on page 1193](#) and [“User-defined types” on page 82](#).

An *array type* is a user-defined type that defines a one column array of a built-in data type. An array type is created with an SQL CREATE TYPE (Array) statement. An array type can be used as a parameter of a procedure or scalar function and as a variable in an SQL procedure or SQL scalar function. For more information, see [“CREATE TYPE \(array\)” on page 1188](#) and [“User-defined types” on page 82](#).

Aliases

An *alias* is an alternate name for a table or view.

An alias can be used to reference a table or view in cases where an existing table or view can be referenced.³ However, the option of referencing a table or view by an alias is not explicitly shown in the syntax diagrams or mentioned in the description of SQL statements. Like tables and views, an alias may be created, dropped, and have a comment or label associated with it. No authority is necessary to use an alias. Access to the tables and views that are referred to by the alias, however, still requires the appropriate authorization for the current statement.

An alias has a name and may have a different system name. The system name is the name used by the IBM i operating system. Either name is acceptable wherever an *alias-name* is specified in SQL statements.

An *alias* is created with the CREATE ALIAS statement. For more information about creating aliases, see [“CREATE ALIAS” on page 971](#).

Packages and access plans

A *package* is an object that contains control structures used to execute SQL statements.

Packages are produced during distributed program preparation. The control structures can be thought of as the bound or operational form of SQL statements.⁴ All control structures in a package are derived from the SQL statements embedded in a single source program.

In this book, the term *access plan* is used in general for packages, procedures, functions, triggers, and programs or service programs that contain control structures used to execute SQL statements. For example, the description of the DROP statement says that dropping an object also invalidates any access plans that reference the object (see [“DROP” on page 1288](#)). This means that any packages, procedures, functions, triggers, and programs or service programs containing control structures referencing the dropped object are invalidated.

An invalidated *access plan* will be implicitly rebuilt the next time its associated SQL statement is executed. For example, if an index is dropped that is used in an *access plan* for a SELECT INTO statement, the next time that SELECT INTO statement is executed, the access plan will be rebuilt.

A package can also be created by the Process Extended Dynamic SQL (QSQPRCED) API. Packages created by the Process Extended Dynamic SQL (QSQPRCED) API can only be used by the Process Extended Dynamic SQL (QSQPRCED) API. They cannot be used at an application server through DRDA protocols. For more information, see the [Database and File APIs](#) information in the **Programming** category of the IBM i Information Center.

The QSQPRCED API is used by IBM i Access for Windows to create packages for caching SQL statements executed via ODBC, JDBC, SQLJ, OLD DB, and .NET interfaces.

Routines

A *routine* is an executable SQL object.

There are two types of routines.

Functions

A *function* is a routine that can be invoked from within other SQL statements and returns a value or a table. For more information, see [“Functions” on page 147](#).

³ You cannot use an alias in all contexts. For example, an alias that refers to an individual member of a database file cannot be used in most SQL schema statements. For more information, see [“CREATE ALIAS” on page 971](#).

⁴ For non-distributed SQL programs, non-distributed service programs, SQL functions, and SQL procedures, the control structures used to execute SQL statements are stored in the associated space of the object.

Functions are classified as either SQL functions or external functions. SQL functions are written using SQL statements, which are also known collectively as SQL procedural language, SQL PL. External functions reference a host language program which may or may not contain SQL statements.

A *function* is created with the CREATE FUNCTION statement. For more information about creating functions, see [“CREATE FUNCTION” on page 975](#).

Procedures

A *procedure* (sometimes called a *stored procedure*) is a routine that can be called to perform operations that can include both host language statements and SQL statements.

Procedures are classified as either SQL procedures or external procedures. SQL procedures are written using SQL statements, which are also known collectively as SQL procedural language, SQL PL. External procedures reference a host language program which may or may not contain SQL statements.

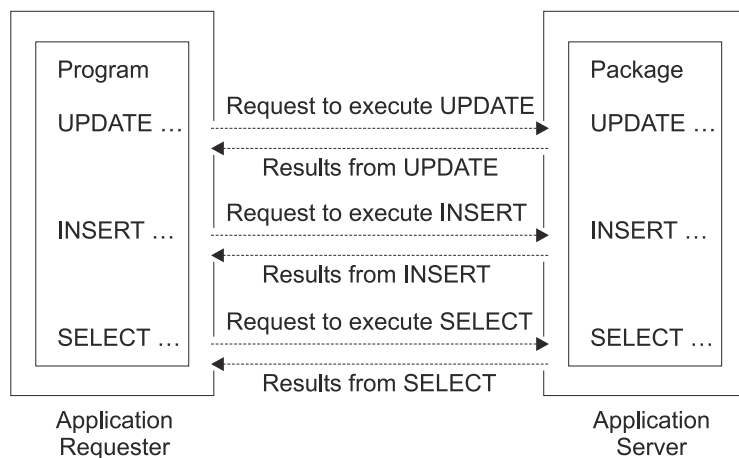

A *procedure* is created with the CREATE PROCEDURE statement. For more information about creating procedures, see [“CREATE PROCEDURE” on page 1074](#).

Procedures in SQL provide the same benefits as procedures in a host language. That is, a common piece of code need only be written and maintained once and can be called from several programs. Both host languages and SQL can call procedures that exist on the local system. However, SQL can also call a procedure that exists on a remote system. In fact, the major benefit of procedures in SQL is that they can be used to enhance the performance characteristics of distributed applications.

Assume that several SQL statements must be executed at a remote system. There are two ways this can be done. Without procedures, when the first SQL statement is executed, the application requester will send a request to an application server to perform the operation. It then waits for a reply that indicates whether the statement is executed successfully or not and optionally returns results. When the second and each subsequent SQL statement is executed, the application requester will send another request and wait for another reply.

If the same SQL statements are stored in a procedure at an application server, a CALL statement can be executed that references the remote procedure. When the CALL statement is executed, the application requester will send a single request to the current server to call the procedure. It will then wait for a single reply that indicates whether the procedure executed successfully or not and optionally returns results.

The following two figures illustrate the way stored procedures can be used in a distributed application to eliminate some of the remote requests. [Figure 1 on page 13](#) shows a program making many remote requests.

RBAL3505-0

Figure 1. Application Without Remote Procedure

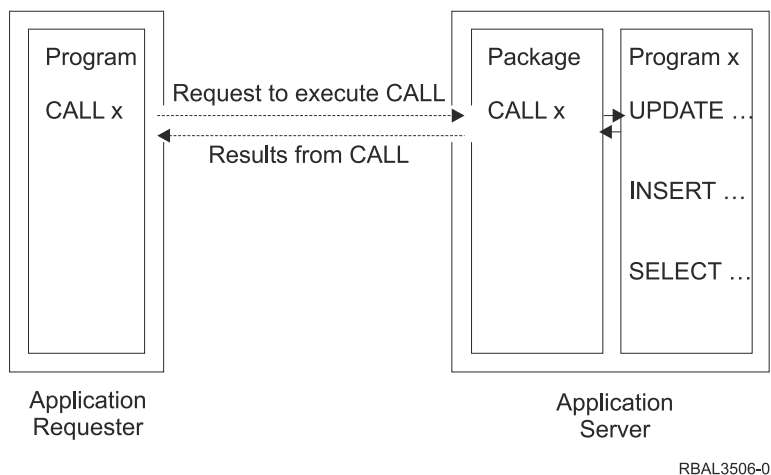

Figure 2. Application With Remote Procedure

Sequences

A sequence is a stored object that simply generates a sequence of numbers in a monotonically ascending (or descending) order. Sequences provide a way to have the database manager automatically generate unique integer and decimal primary keys, and to coordinate keys across multiple rows and tables.

A sequence can be used to exploit parallelization, instead of programmatically generating unique numbers by locking the most recently used value and then incrementing it.

Sequences are ideally suited to the task of generating unique key values. One sequence can be used for many tables, or a separate sequence can be created for each table requiring generated keys. A sequence has the following properties:

- Can have guaranteed, unique values, assuming that the sequence is not reset and does not allow the values to cycle.
- Can have increasing or decreasing values within a defined range.
- Can have an increment value other than 1 between consecutive values (the default is 1).
- Is recoverable.

Values for a given sequence are automatically generated by the database manager. Use of a sequence in the database avoids the performance bottleneck that results when an application implements sequences outside the database. The counter for the sequence is incremented (or decremented) independently from the transaction.

In some cases, gaps can be introduced in a sequence. A gap can occur when a given transaction increments a sequence two times. The transaction may see a gap in the two numbers that are generated because there may be other transactions concurrently incrementing the same sequence. A user may not realize that other users are drawing from the same sequence. Furthermore, it is possible that a given sequence can appear to have generated gaps in the numbers, because a transaction that may have generated a sequence number may have rolled back. Updating a sequence is not part of a transaction's unit of recovery.

A sequence is created with a CREATE SEQUENCE statement. A sequence can be referenced using a *sequence-reference*. A sequence reference can appear most places that an expression can appear. A sequence reference can specify whether the value to be returned is a newly generated value, or the previously generated value. For more information, see [“Sequence reference” on page 193](#) and [“CREATE SEQUENCE” on page 1108](#).

Although there are similarities, a sequence is different than an identity column. A sequence is an object, whereas an identity column is a part of a table. A sequence can be used with multiple tables, but an identity column is part of a single table.

Authorization, privileges and object ownership

Users (identified by an authorization ID) can successfully execute SQL statements only if they have the authority to perform the specified function. To create a table, a user must be authorized to create tables; to alter a table, a user must be authorized to alter the table; and so forth.

The two forms of authorization are administrative authority and privileges.

Administrative authority

The holder of an administrative authority is charged with the task of managing the relational database and is responsible for the safety and integrity of the data.

database administrator authority

The *database administrator authority* provides a user with the ability to create and manage all objects in a relational database. Those with *database administrator authority* implicitly have all privileges on all objects in the relational database.

The security officer and all users with *ALLOBJ authority have *database administrator authority*.

security administrator authority

The *security administrator authority* provides a user the ability to manage security in a relational database. The *security administrator authority* possesses the ability to grant and revoke all relational database privileges and authorities and transfer ownership of objects. Those with *security administrator authority* also manage security policies by enforcing row and column access control for tables that contain sensitive data.

The *security administrator authority* has no inherent privilege to access data stored in tables.

Users with the function usage QIBM_DB_SECADM have *security administrator authority*.

Privileges

Privileges are those activities that a user is allowed to perform. Authorized users can create objects, have access to objects they own, and can pass on *privileges* on their own objects to other users by using the GRANT statement.

Privileges may be granted to specific users or to PUBLIC. PUBLIC specifies that a privilege is granted to a set of users (authorization IDs). The set consists of those users (including future users) that do not have privately granted privileges on the table or view. This affects private grants. For example, if SELECT has been granted to PUBLIC, and UPDATE is then granted to HERNANDZ, this private grant prevents HERNANDZ from having the SELECT privilege.

The REVOKE statement can be used to REVOKE previously granted *privileges*. A revoke of a privilege from an authorization ID revokes the privilege granted by all authorization IDs. Revoking a privilege from an authorization ID will not revoke that same privilege from any other authorization IDs that were granted the privilege by that authorization ID.

Row permissions and column masks

A *row permission* expresses an access control rule for a row of a specific table. A row permission is in the form of a search condition that describes to which rows users have access. Row permissions are applied after table privileges (like SELECT or INSERT) are checked.

A *column mask* expresses an access control rule for a specific column in a table. A column mask is in the form of a CASE expression that describes to which column values users have access. Column masks are applied after table privileges (like SELECT or INSERT) are checked.

Row permissions and column masks can be created, changed, and dropped only by those with Database Security Administrator authority by using the CREATE MASK, CREATE PERMISSION, ALTER MASK, ALTER PERMISSION, and DROP statements. The definition of a permission or a mask can reference other objects. Those with Database Security Administrator authority do not need additional privileges to reference those objects, such as SELECT privilege to retrieve from a table or EXECUTE privilege to invoke

a user-defined function, in the definition of the row permission or column mask. Multiple row permissions and column masks can be created for a table. Only one column mask can be created for each column in a table. A row permission or a column mask can be created before row or column access control is enforced for a table. The definition of the row permission and the column mask is stored in the Db2 catalog. However, the permission and the mask do not take effect until the ALTER TABLE statement with the ACTIVATE ROW ACCESS CONTROL clause is used to enforce row access control or the ACTIVATE COLUMN ACCESS CONTROL clause is used to enforce column access control on the table.

When an ALTER TABLE statement is used to explicitly activate row access control for a table, a default row permission is implicitly created for the table which prevents all access to the table. After row access controls have been activated for a table, if the table is referenced explicitly in a data change statement and if multiple row permissions are defined for the table, a row access control search condition is derived by using the logical OR operator with the search condition of each defined row permission.

When an ALTER TABLE statement is used to explicitly activate column access control for a table, access to the table is not restricted. However, if the table is referenced in an SQL statement, all column masks that have been created for the table are applied to mask the column values that are referenced in the output of the queries or to determine the column values that are used in the data change statements.

The authorization ID for the SQL statement that references a table with row permissions or column masks does not need authority to reference objects that are specified in the definitions of those row permissions or column masks.

Ownership

When an object is created, the authorization ID of the statement must have the privilege to create objects in the implicitly or explicitly specified schema. The authorization ID of a statement has the privilege to create objects in the schema if:

- it is the owner of the schema, or
- it has the CREATEIN privilege on the schema.

When an object is created, one authorization ID is assigned *ownership* of the object. Ownership gives the user complete control over the object, including the privilege to drop the object. The privileges on the object can be granted by the owner, and can be revoked from the owner. In this case, the owner may temporarily be unable to perform an operation that requires that privilege. Because he is the owner, however, he is always allowed to grant the privilege back to himself.

When an object is created:

- If SQL names were specified, the *owner* of the object is the user profile with the same name as the schema into which the object is created, if a user profile with that name exists. Otherwise, the *owner* of the object is the user profile or group user profile of the thread executing the statement.
- If system names were specified, the *owner* of the object is the user profile or group user profile of the thread executing the statement.

Authority granted to *PUBLIC on SQL objects depends on the naming convention that is used at the time of object creation. If *SYS naming convention is used, *PUBLIC acquires the create authority (CRTAUT) of the library into which the object was created. If *SQL naming convention is used, *PUBLIC acquires *EXCLUDE authority.

In the Authorization sections of this book, it is assumed that the owner of an object has not had any privileges revoked from that object since it was initially created. If the object is a view, it is also assumed that the owner of the view has not had the system authority *READ revoked from any of the tables or views that this view is directly or indirectly dependent on. The owner has system authority *READ for all tables and views referenced in the view definition, and if a view is referenced, all tables and views referenced in its definition, and so forth. For more information about authority and privileges, see [Security Reference](#).

Catalog

The database manager maintains a set of tables containing information about objects in the database. These tables and views are collectively known as the *catalog*. The *catalog tables* contain information about objects such as tables, views, indexes, packages, and constraints.

Tables and views in the catalog are similar to any other database tables and views. Any user that has the SELECT privilege on a catalog table or view can read the data in the catalog table or view. A user cannot directly modify a catalog table or view, however. The database manager ensures that the catalog contains accurate descriptions of the objects in the database at all times.

The database manager provides a set of views that provide more consistency with the catalog views of other IBM SQL products and another set of catalog views that provide compatibility with the catalog views of the ANSI and ISO standard (called *Information Schema* in the standard).

If a schema is created using the CREATE SCHEMA statement, the schema will also contain a set of views that only contain information about objects in the schema.

For more information about catalog tables and views, see [Appendix F, “Db2 for i catalog views,” on page 1709](#).

Application processes, concurrency, and recovery

All SQL programs execute as part of an *application process*. In the IBM i operating system, an application process is called a job. In the case of ODBC, JDBC, OLE DB, .NET, and DRDA, the application process ends when the connection ends even though the job they are using does not end and may be reused.

An application process is made up of one or more activation groups. Each activation group involves the execution of one or more programs. Programs run under a non-default activation group or the default activation group. All programs except those created by ILE compilers run under the default activation group. For example, LANGUAGE JAVA external functions run under the default activation group.

For more information about activation groups, see the book [ILE Concepts](#) .

An application process that uses commitment control can run with one or more commitment definitions. A commitment definition provides a means to scope commitment control at an activation group level or at a job level. At any given time, an activation group that uses commitment control is associated with only one of the commitment definitions.

A commitment definition can be explicitly started through the Start Commitment Control (STRCMTCTL) command. If not already started, a commitment definition is implicitly started when the first SQL statement is executed under an isolation level different than COMMIT(*NONE). More than one activation group can share a job commitment definition.

[Figure 3 on page 18](#) shows the relationship of an application process, the activation groups in that application process, and the commitment definitions. Activation groups A and B run with commitment control scoped to the activation group. These activation groups have their own commitment definitions. Activation group C does not run with any commitment control and does not have a commitment definition.

Application Process Without Job-Level Commitment Definition

RV3F004-0

Figure 3. Activation Groups without Job Commitment Definition

Figure 4 on page 19 shows an application process, the activation groups in that application process, and the commitment definitions. Some of the activation groups are running with the job commitment definition. Activation groups A and B are running under the job commitment definition. Any commit or rollback operation in activation group A or B affects both because the commitment control is scoped to the same commitment definition. Activation group C in this example has a separate commitment definition. Commit and rollback operations performed in this activation group only affect operations within C.

Application Process With Job-Level Commitment Control

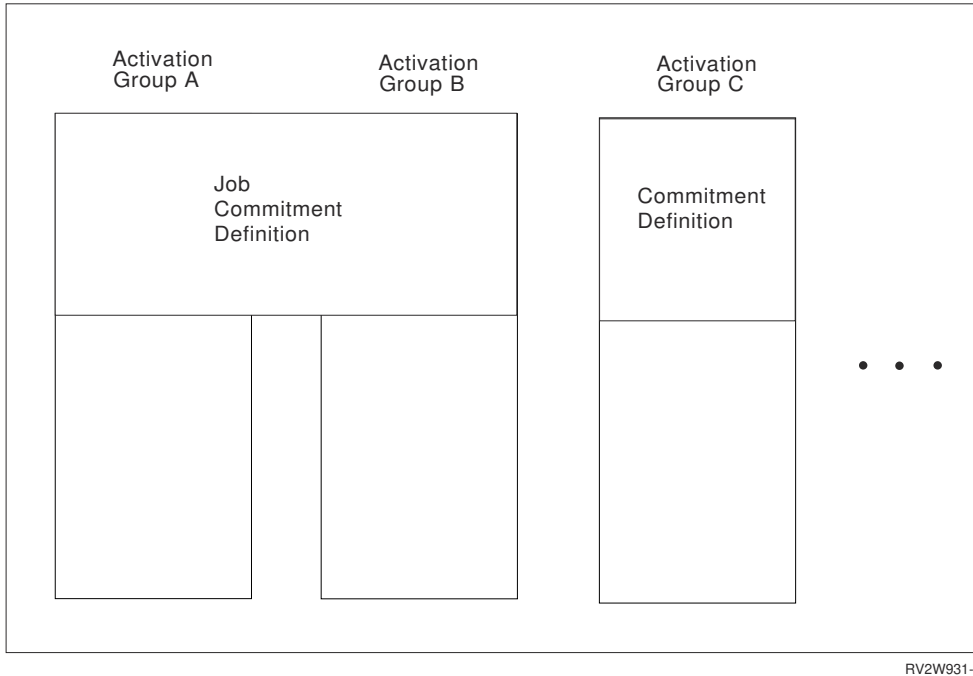

Figure 4. Activation Groups with Job Commitment Definition

For more information about commitment definitions, see the [Commitment control](#) topic.

Locking, commit, and rollback

Application processes and activation groups that use different commitment definitions can request access to the same data at the same time. *Locking* is used to maintain data integrity under such conditions. Locking prevents such things as two application processes updating the same row of data simultaneously.

The database manager acquires locks to keep the uncommitted changes of one activation group undetected by activation groups that use a different commitment definition. Object locks and other resources are allocated to an activation group. Row locks are allocated to a commitment definition.

When an activation group other than the default activation group ends *normally*, the database manager releases all locks obtained by the activation group. A user can also explicitly request that most locks be released sooner. This operation is called *commit*. Object locks associated with cursors that remain open after commit are not released.

The recovery functions of the database manager provide a means of backing out of uncommitted changes made in a commitment definition. The database manager may implicitly back out uncommitted changes under the following situations:

- When the application process ends, all changes performed under the commitment definition associated with the default activation group are backed out. When an activation group other than the default activation group ends *abnormally*, all changes performed under the commitment definition associated with that activation group are backed out.
- When using Distributed Unit of Work and a failure occurs while attempting to commit changes on a remote system, all changes performed under the commitment definition associated with remote connection are backed out.
- When using Distributed Unit of Work and a request to back out is received from a remote system because of a failure at that site, all changes performed under the commitment definition associated with remote connection are backed out.

A user can also explicitly request that their database changes be backed out. This operation is called *rollback*.

Locks acquired by the database manager on behalf of an activation group are held until the unit of work is ended. A lock explicitly acquired by a LOCK TABLE statement can be held past the end of a unit of work if COMMIT HOLD or ROLLBACK HOLD is used to end the unit of work.

A cursor can implicitly lock the row at which the cursor is positioned. This lock prevents:

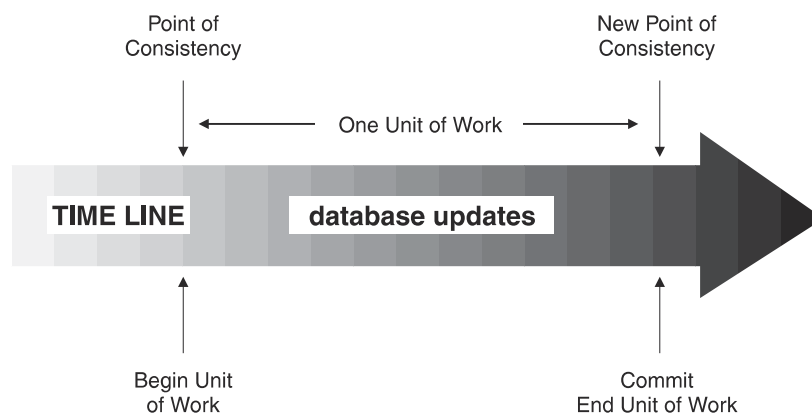

- Other cursors associated with a different commitment definition from locking the same row.
- A DELETE or UPDATE statement associated with a different commitment definition from locking the same row.

Unit of work

A *unit of work* (also known as a *transaction*, *logical unit of work*, or *unit of recovery*) is a recoverable sequence of operations. Each commitment definition involves the execution of one or more units of work. At any given time, a commitment definition has a single unit of work.

A unit of work is started either when the commitment definition is started, or when the previous unit of work is ended by a commit or rollback operation. A unit of work is ended by a commit operation, a rollback operation, or the ending of the activation group. A commit or rollback operation affects only the database changes made within the unit of work that the commit or rollback ends. While changes remain uncommitted, other activation groups using different commitment definitions running under isolation levels COMMIT(*CS), COMMIT(*RS), and COMMIT(*RR) cannot perceive the changes. The changes can be backed out until they are committed. Once changes are committed, other activation groups running in different commitment definitions can access them, and the changes can no longer be backed out.

The start and end of a unit of work defines points of consistency within an activation group. For example, a banking transaction might involve the transfer of funds from one account to another. Such a transaction would require that these funds be subtracted from the first account, and added to the second. Following the subtraction step, the data is inconsistent. Only after the funds are added to the second account is consistency established again. When both steps are complete, the commit operation can be used to end the unit of work. After the commit operation, the changes are available to activation groups that use different commitment definitions.

RV3F181-0

Figure 5. Unit of Work with a Commit Statement

Rolling back work

The database manager can back out all changes made in a unit of work or only selected changes. Only backing out all changes results in a point of consistency.

Rolling back all changes

The SQL ROLLBACK statement without the TO SAVEPOINT clause causes a full rollback operation. If such a rollback operation is successfully executed, database manager backs out uncommitted changes to restore the data consistency that it assumes existed when the unit of work was initiated. That is, the database manager undoes the work, as shown in the diagram below:

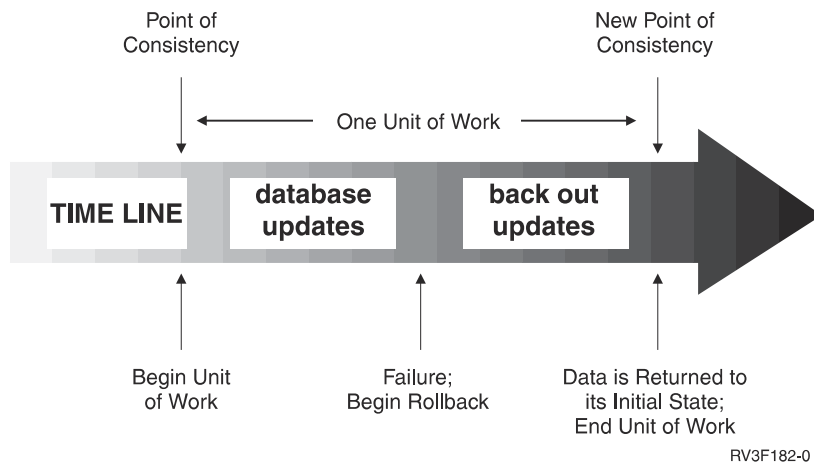

Figure 6. Unit of Work with a Rollback Statement

Rolling back selected changes using savepoints

A *savepoint* represents the state of data at some particular time during a unit of work. An application process can set savepoints within a unit of work, and then as logic dictates, roll back only the changes that were made after a savepoint was set. For example, part of a reservation transaction might involve booking an airline flight and then a hotel room. If a flight gets reserved but a hotel room cannot be reserved, the application process might want to undo the flight reservation without undoing any database changes made in the transaction prior to making the flight reservation. SQL programs can use the SQL SAVEPOINT statement to set savepoints, the SQL ROLLBACK statement with the TO SAVEPOINT clause to undo changes to a specific savepoint or the last savepoint that was set, and the RELEASE SAVEPOINT statement to delete a savepoint.

Figure 7. Unit of Work with a Rollback Statement and a Savepoint Statement

Threads

In the IBM i operating system, an application process can also consist of one or more threads. By default, a thread shares the same commitment definitions and locks as the other threads in the job. Thus, each thread can operate on the same unit of work so that when one thread commits or rolls back, it can commit or rollback all changes performed by all threads. This type of processing is useful if multiple threads are cooperating to perform a single task in parallel.

In other cases, it is useful for a thread to perform changes independent from other threads in the job. In this case, the thread would not want to share commitment definitions or lock with the other threads. Furthermore, a job can use SQL server mode in order to take more fine grain control of multiple database connections and transaction information. A typical multi-threaded job may require this control. There are several ways to accomplish this type of processing:

- Make sure the programs running in the thread use a separate activation group (be careful not to use ACTGRP(*NEW)).
- Make sure that the job is running in SQL server mode before issuing the first SQL statement. SQL server mode can be activated for a job by using one of the following mechanisms before data access occurs in the application:
 - Use the ODBC API, `SQLSetEnvAttr()` and set the `SQL_ATTR_SERVER_MODE` attribute to `SQL_TRUE` before doing any data access.
 - Use the Change Job API, `QWTCHGJB()`, and set the 'Server mode for Structured Query Language' key before doing any data access.
 - Use JAVA to access the database via JDBC. JDBC automatically uses server mode to preserve required semantics of JDBC.

When SQL server mode is established, all SQL statements are passed to an independent server job that will handle the requests. Server mode behavior for SQL behavior includes:

- For embedded SQL, each thread in a job implicitly gets one and only one connection to the database (and thus its own committable transaction).
- For ODBC/CLI, JDBC, OLE DB, and .NET, each connection represents a stand-alone connection to the database and can be committed and used as a separate entity.

For more information, see [SQL Call Level Interface \(ODBC\)](#).

The following SQL support is not threadsafe:

- Remote access through DRDA
- ALTER FUNCTION
- ALTER PROCEDURE
- ALTER SEQUENCE
- ALTER TABLE
- COMMENT
- CREATE ALIAS
- CREATE FUNCTION
- CREATE INDEX
- CREATE PROCEDURE
- CREATE SCHEMA
- CREATE SEQUENCE
- CREATE TABLE
- CREATE TRIGGER
- CREATE TYPE
- CREATE VARIABLE

- CREATE VIEW
- DECLARE GLOBAL TEMPORARY TABLE
- DROP
- GRANT
- LABEL
- REFRESH TABLE
- RENAME
- REVOKE

For more information, see [Multithreaded applications](#) in the Programming topic of the IBM i Information Center.

Isolation level

The *isolation level* used during the execution of SQL statements determines the degree to which the activation group is isolated from concurrently executing activation groups.

Thus, when activation group P executes an SQL statement, the isolation level determines:

- The degree to which rows retrieved by P and database changes made by P are available to other concurrently executing activation groups.
- The degree to which database changes made by concurrently executing activation groups can affect P.

The isolation level can be explicitly specified on a DELETE, INSERT, SELECT INTO, UPDATE, or select-statement. If the isolation level is not explicitly specified, the isolation level used when the SQL statement is executed is the *default isolation level*.

Db2 for i provides several ways to specify the *default isolation level*:

SQL Interface	Specification
Embedded SQL	<p>COMMIT parameter on the Create SQL Program (CRTSQLxxx) commands. The SET OPTION statement can also be used to set the COMMIT values.</p> <p>(For more information about CRTSQLxxx commands, see Embedded SQL Programming.)</p>
SQL functions and procedures	<p>Static SQL statements in SQL functions and procedures use the isolation level that was in effect at the time the SQL function or procedure was created. The SET OPTION statement (COMMIT) can be used to set the isolation level.</p>
Run SQL Statements	<p>COMMIT parameter on the Run SQL Statements (RUNSQLSTM) command.</p> <p>(For more information about the RUNSQLSTM command, see SQL Programming.)</p>

Table 2. Default Isolation Level Interfaces (continued)

SQL Interface	Specification
SET TRANSACTION SQL statement	<p>Overrides the default isolation level within a unit of work. When the unit of work ends, the isolation level returns to the value it had at the beginning of the unit of work. This statement overrides any other specification of isolation level for static and dynamic SQL statements in the unit of work.</p> <p>(For more information about the SET TRANSACTION statement, see “SET TRANSACTION” on page 1543.)</p>
<i>isolation-clause</i>	<p>The <i>isolation-clause</i> on the SELECT, SELECT INTO, INSERT, UPDATE, DELETE, and DECLARE CURSOR statements overrides the default isolation level for a specific statement or cursor. The isolation level is in effect only for the execution of the statement containing the <i>isolation-clause</i> and has no effect on any pending changes in the current unit of work.</p> <p>(For more information about the <i>isolation-clause</i>, see “isolation-clause” on page 799.)</p>
Call Level Interface (CLI) on the server	<p>SQL_ATTR_COMMIT or SQL_TXN_ISOLATION environment variable or connection options</p> <p>(For more information about CLI, see SQL Call Level Interfaces (ODBC).)</p>
JDBC or SQLJ on the server using IBM IBM Developer Kit for Java	<p>transaction isolation property object</p> <p>(For more information about JDBC and SQLJ, see IBM Developer Kit for Java.)</p>
ODBC on a client using the IBM i Access Family ODBC Driver	<p>Commit Mode in ODBC Setup</p> <p>(For more information about ODBC, see IBM i Access.)</p>
JDBC on a client using the IBM Toolbox for Java	<p>Isolation Level in JDBC Setup</p> <p>(For more information about JDBC, see IBM i Access.)</p> <p>(For more information about the IBM Toolbox for Java, see IBM Toolbox for Java.)</p>
OLE DB on a client using the IBM i Access Family OLE DB Provider	<p>IsolationLevel Connection Object Property</p> <p>(For more information about OLE DB, see IBM i Access.)</p>
ADO .NET on a client using the IBM i Access Family ADO .NET Provider	<p>IsolationLevel in Connection Object Properties</p> <p>(For more information about ADO .NET, see IBM i Access.)</p>

These isolation levels are supported by automatically locking the appropriate data. Depending on the type of lock, this limits or prevents access to the data by concurrent activation groups that use different commitment definitions. Each database manager supports at least two types of locks:

Share

Limits concurrent activation groups that use different commitment definitions to read-only operations on the data.

Exclusive

Prevents concurrent activation groups using different commitment definitions from updating or deleting the data. Prevents concurrent activation groups using different commitment definitions that are running COMMIT(*RS), COMMIT(*CS), or COMMIT(*RR) from reading the data. Concurrent activation groups using different commitment definitions that are running COMMIT(*UR) or COMMIT(*NC) are allowed to read the data.

The following descriptions of isolation levels refer to locking data in row units. Individual implementations can lock data in larger physical units than base table rows. However, logically, locking occurs at the base-table row level across all products. Similarly, a database manager can escalate a lock to a higher level. An activation group is guaranteed at least the minimum requested lock level.

For a detailed description of record lock durations, see the discussion and table in the [Commitment control](#) topic of the [SQL Programming](#) topic collection.

Db2 for i supports five isolation levels. For all isolation levels except No Commit, the database manager places exclusive locks on every row that is inserted, updated, or deleted. This ensures that any row changed during a unit of work is not changed by any other activation group that uses a different commitment definition until the unit of work is complete.

Repeatable read

The Repeatable Read (RR) isolation level ensures:

- Any row read during a unit of work is not changed by other activation groups that use different commitment definitions until the unit of work is complete.⁵
- Any row changed (or a row that is currently locked with an UPDATE row lock) by another activation group using a different commitment definition cannot be read until it is committed.

In addition to any exclusive locks, an activation group running at level RR acquires at least share locks on all the rows it reads. Furthermore, the locking is performed so that the activation group is completely isolated from the effects of concurrent activation groups that use different commitment definitions.

In the SQL 2003 Core standard, Repeatable Read is called Serializable.

Db2 for i supports repeatable read through COMMIT(*RR). Repeatable read isolation level is supported by locking the tables containing any rows that are read or updated.

Read stability

Like level RR, level Read Stability (RS) ensures that:

- Any row read during a unit of work is not changed by other activation groups that use different commitment definitions until the unit of work is complete.⁶
- Any row changed (or a row that is currently locked with an UPDATE row lock) by another activation group using a different commitment definition cannot be read until it is committed.

Unlike RR, RS does not completely isolate the activation group from the effects of concurrent activation groups that use a different commitment definition. At level RS, activation groups that issue the same query more than once might see additional rows. These additional rows are called *phantom rows*.

For example, a phantom row can occur in the following situation:

1. Activation group P1 reads the set of rows n that satisfy some search condition.

⁵ For **WITH HOLD** cursors, these rules apply to when the rows were actually read. For read-only **WITH HOLD** cursors, the rows may have actually been read in a prior unit of work.

⁶ For **WITH HOLD** cursors, these rules apply to when the rows were actually read. For read-only **WITH HOLD** cursors, the rows may have actually been read in a prior unit of work.

2. Activation group P2 then INSERTs one or more rows that satisfy the search condition and COMMITs those INSERTs.
3. P1 reads the set of rows again with the same search condition and obtains both the original rows and the rows inserted by P2.

In addition to any exclusive locks, an activation group running at level RS acquires at least share locks on all the rows it reads.

In the SQL 2003 Core standard, Read Stability is called Repeatable Read.

Db2 for i supports read stability through COMMIT(*ALL) or COMMIT(*RS).

Cursor stability

Like levels RR and RS, level Cursor Stability (CS) ensures that any row that was changed (or a row that is currently locked with an UPDATE row lock) by another activation group using a different commitment definition cannot be read until it is committed. Unlike RR and RS, level CS only ensures that the current row of every updatable cursor is not changed by other activation groups using different commitment definitions. Thus, the rows that were read during a unit of work can be changed by other activation groups that use a different commitment definition. In addition to any exclusive locks, an activation group running at level CS may acquire a share lock for the current row of every cursor.

In the SQL 2003 Core standard, Cursor Stability is called Read Committed.

Db2 for i supports cursor stability through COMMIT(*CS).

Uncommitted read

For a SELECT INTO, a FETCH with a read-only cursor, subquery, or fullselect used in an INSERT statement, level Uncommitted Read (UR) allows:

- Any row read during the unit of work to be changed by other activation groups that run under a different commitment definition.
- Any row changed (or a row that is currently locked with an UPDATE row lock) by another activation group running under a different commitment definition to be read even if the change has not been committed.

For other operations, the rules of level CS apply.

In the SQL 2003 Core standard, Uncommitted Read is called Read Uncommitted.

Db2 for i supports uncommitted read through COMMIT(*CHG) or COMMIT(*UR).

No commit

For all operations, the rules of level UR apply to No Commit (NC) except:

- Commit and rollback operations have no effect on SQL statements. Cursors are not closed, and LOCK TABLE locks are not released. However, connections in the release-pending state are ended.
- Any changes are effectively committed at the end of each successful change operation and can be immediately accessed or changed by other application groups using different commitment definitions.

Db2 for i supports No Commit through COMMIT(*NONE) or COMMIT(*NC).

Note: *(For distributed applications.)* When a requested isolation level is not supported by an application server, the isolation level is escalated to the next highest supported isolation level. For example, if RS is not supported by an application server, the RR isolation level is used.

Comparison of isolation levels

The following table summarizes information about isolation levels.

	NC	UR	CS	RS	RR
Can the application see uncommitted changes made by other application processes?	Yes	Yes	No ²	No ²	No
Can the application update uncommitted changes made by other application processes?	No	No	No	No	No
Can the re-execution of a statement be affected by other application processes? <i>See phenomenon P3 (phantom) below.</i>	Yes	Yes	Yes	Yes	No
Can “updated” rows be updated by other application processes?	Yes	No	No	No	No
Can “updated” rows be read by other application processes that are running at an isolation level other than UR and NC?	Yes	No	No	No	No
Can “updated” rows be read by other application processes that are running at the UR or NC isolation level?	Yes	Yes	Yes	Yes	Yes
Can “accessed” rows be updated by other application processes? For RS, “accessed rows” typically means rows selected. For RR, see the product-specific documentation. <i>See phenomenon P2 (nonrepeatable read) below.</i>	Yes	Yes	Yes	No	No
Can “accessed” rows be read by other application processes?	Yes	Yes	Yes	Yes	Yes
Can “current” row be updated or deleted by other application processes? <i>See phenomenon P1 (dirty-read) below.</i>	See Note 1	See Note 1	See Note 1	No	No

Note 1: This depends on whether the cursor that is positioned on the “current” row is updatable:

- If the cursor is updatable, the current row cannot be updated or deleted by other application processes
- If the cursor is not updatable,
 - For UR or NC, the current row can be updated or deleted by other application processes.
 - For CS, the current row may be updatable in some circumstances.

Note 2: The USE CURRENTLY COMMITTED clause should be used. In addition, when a query is implemented using a table scan, use the QAQQINI option CONCURRENT_ACCESS_BEHAVIOR with a value of *STRICTSCAN.

Examples of Phenomena:

P1

Dirty Read. Unit of work UW1 modifies a row. Unit of work UW2 reads that row before UW1 performs a COMMIT. UW1 then performs a ROLLBACK. UW2 has read a nonexistent row.

P2

Nonrepeatable Read. Unit of work UW1 reads a row. Unit of work UW2 modifies that row and performs a COMMIT. UW1 then re-reads the row and obtains the modified data value.

P3

Phantom. Unit of work UW1 reads the set of n rows that satisfies some search condition. Unit of work UW2 then INSERTs one or more rows that satisfies the search condition. UW1 then repeats the initial read with the same search condition and obtains the original rows plus the inserted rows.

Storage Structures

The IBM i product is an object-based system. All database objects in Db2 for i (tables and indexes for example) are objects in the IBM i operating system. The single-level storage manager manages all storage of objects of the database, so database specific storage structures (for example, table spaces) are unnecessary.

A distributed table allows data to be spread across different database partitions. The partitions included are determined by the nodegroup specified when the table is created or altered. A nodegroup is a group of one or more IBM i products. A partitioning map is associated with each nodegroup. The partitioning map is used by the database manager to determine which system from the nodegroup will store a given row of data. For more information about nodegroups and data partitioning see the [DB2 Multisystem](#) book.

A table can also include columns that register links to data that are stored in external files. The mechanism for this is the DataLink data type. A DataLink value which is recorded in a regular table points to a file that is stored in an external file server.

The Db2 File Manager on a file server works in conjunction with Db2 to provide the following optional functionality:

- Referential integrity to ensure that files currently linked to Db2 are not deleted or renamed.
- Security to ensure that only those with suitable SQL privileges on the DataLink column can read the files linked to that column.

The DataLinker comprises the following facilities:

DataLinks File Manager

Registers all the files in a particular file server that are linked to Db2.

DataLinks Filter

Filters file system commands to ensure that registered files are not deleted or renamed. Optionally, filters commands to ensure that proper access authority exists.

Character conversion

A *string* is a sequence of bytes that may represent characters. Within a string, all the characters are represented by a common coding representation. In some cases, it might be necessary to convert these characters to a different coding representation. The process of conversion is known as *character conversion*.

Character conversion can occur when an SQL statement is executed remotely.⁷ Consider, for example, these two cases:

⁷ Character conversion, when required, is automatic and is transparent to the application when it is successful. A knowledge of conversion is, therefore, unnecessary when all the strings involved in a

- The values of variables sent from the application requester to the current server.
- The values of result columns sent from the current server to the application requester.

In either case, the string could have a different representation at the sending and receiving systems. Conversion can also occur during string operations on the same system.

Note that SQL statements are strings and are therefore subject to character conversion.

The following list defines some of the terms used when discussing character conversion.

character set

A defined set of characters. For example, the following character set appears in several code pages:

- 26 non-accented letters A through Z
- 26 non-accented letters a through z
- digits 0 through 9
- . , ; ? () ' " / - _ & + = < >

code page

A set of assignments of characters to code points. In EBCDIC, for example, "A" is assigned code point X'C1' and "B" is assigned code point X'C2'. Within a code page, each code point has only one specific meaning.

code point

A unique bit pattern that represents a character within a code page.

coded character set

A set of unambiguous rules that establish a character set and the one-to-one relationships between the characters of the set and their coded representations.

encoding scheme

A set of rules used to represent character data. For example:

- Single-byte EBCDIC
- Single-byte ASCII
- Double-byte EBCDIC
- Mixed single- and double-byte ASCII⁸
- Unicode (UTF-8, UCS-2, and UTF-16 universal coded character sets).

substitution character

A unique character that is substituted during character conversion for any characters in the source coding representation that do not have a match in the target coding representation.

Unicode

A universal encoding scheme for written characters and text that enables the exchange of data internationally. It provides a character set standard that can be used all over the world. It uses a 16-bit encoding form that provides code points for more than 65,000 characters and an extension called UTF-16 that allows for encoding as many as a million more characters. It provides the ability to encode all characters used for the written languages of the world and treats alphabetic characters, ideographic characters, and symbols equivalently because it specifies a numeric value and a name for each of its characters. It includes punctuation marks, mathematical symbols, technical symbols, geometric shapes, and dingbats. Three encoding forms are supported:

- UTF-8: Unicode Transformation Format, a 8-bit encoding form designed for ease of use with existing ASCII-based systems. UTF-8 data is stored in character data types. The CCSID value for data in UTF-8 format is 1208.

statement's execution are represented in the same way. Thus, for many readers, character conversion may be irrelevant.

⁸ UTF-8 unicode data is also mixed data. In this book, however, mixed data refer to mixed single- and double-byte data.

A UTF-8 character can be 1,2,3 or 4 bytes in length. A UTF-8 data string can contain any combination of SBCS and DBCS data, including surrogates and combining characters.

- UCS-2: Universal Character Set coded in 2 octets, which means that characters are represented in 16-bits per character. UCS-2 data is stored in graphic data types. The CCSID value for data in UCS-2 format is 13488.

UCS-2 is a subset of UTF-16. UCS-2 is identical to UTF-16 except that UTF-16 also supports combining characters and surrogates. Since UCS-2 is a simpler form of UTF-16, UCS-2 data will typically perform better than UTF-16.⁹

- UTF-16: Unicode Transformation Format, a 16-bit encoding form designed to provide code values for over a million characters. UTF-16 data is stored in graphic data types. The CCSID value for data in UTF-16 format is 1200.

Both UTF-8 and UTF-16 data can contain *combining characters*. Combining character support allows a resulting character to be comprised of more than one character. After the first character, hundreds of different non-spacing accent characters (umlauts, accents, etc.) can follow in the data string. The resulting character may already be defined in the character set. In this case, there are multiple representations for the same character. For example, in UTF-16, an *é* can be represented either by X'00E9' (the normalized representation) or X'00650301' (the non-normalized combining character representation).

Since multiple representations of the same character will not compare equal, it is usually not a good idea to store both forms of the characters in the database. *Normalization* is a process that replaces the string of combining characters with equivalent characters that do not include combining characters. After normalization has occurred, only one representation of any specific character will exist in the data. For example, in UTF-16, any instances of X'00650301' (the non-normalized combining character representation of *é*) will be converted to X'00E9' (the normalized representation of *é*).¹⁰

In order to properly handle UTF-8 in predicates, normalization may occur.

Both UTF-8 and UTF-16 can contain 4 byte characters called *surrogates*. Surrogates are 4 byte sequences that can address one million more characters than would be available in a 2 byte character set.

⁹ UCS-2 can contain surrogates and combining characters, however, they are not recognized as such. Each 16-bits is considered to be a character.

¹⁰ Since normalization can significantly affect performance (from 2.5 to 25 percent extra CPU), the default in column definitions is NOT NORMALIZED.

Character sets and code pages

The following example shows how a typical character set might map to different code points in two different code pages.

Code-Page: pp1 (ASCII)

	0	1	2	3	4	5		E	F
0			0	@	P			Â	
1			1	A	Q			Ã	α
2			”	2	B	R		Å	β
3			3	C	S			Á	γ
4			4	D	T			Ä	δ
5			%	5	E	U		Ä	ε
E			.	>	N			5/8	ö
F			/	*	O			®	

Code Point: 2F

Character-Set ss1
(in code-page pp1)

Code-Page: pp2 (EBCDIC)

	0	1		A	B	C	D	E	F
0					#				0
1					\$	A	J		1
2				s	%	B	K	S	2
3				t	—	C	L	T	3
4				u	*	D	M	U	4
5				v	(E	N	V	5
E					!	:	Ä	}	
F				Ä	¢	:	Á	{	

Character-Set ss1
(in code-page pp2)

RV2F976-3

Even with the same encoding scheme there are many different coded character sets, and the same code point can represent a different character in different coded character sets. Furthermore, a byte in a character string does not necessarily represent a character from a single-byte character set (SBCS). Character strings are also used for mixed data (a mixture of single-byte characters and double-byte characters) and for data that is not associated with any character set (called bit data). This is not the case with graphic strings; the database manager assumes that every pair of bytes in every graphic string represents a character from a double-byte character set (DBCS) or universal coded character set (UCS-2 or UTF-16).

A coded character set identifier (CCSID) in a native encoding scheme is one of the coded character sets in which data may be stored at that site. A CCSID in a foreign encoding scheme is one of the coded character sets in which data cannot be stored at that site. For example, Db2 for i can store data in a CCSID with an EBCDIC encoding scheme, but not in an ASCII encoding scheme.

A variable containing data in a foreign encoding scheme (other than Unicode) is always converted to a CCSID in the native encoding scheme when the variable is used in a function or in the *select-list*. A variable containing data in a foreign encoding scheme is also effectively converted to a CCSID in the native encoding scheme when used in comparison or in an operation that combines strings. Which CCSID in the native encoding scheme the data is converted to is based on the foreign CCSID and the default CCSID.

For details on character conversion, see:

- [“Conversion rules for assignments” on page 94](#)
- [“Conversion rules for comparison:” on page 101](#)

- [“Conversion rules for operations that combine strings” on page 110](#)
- [“Data representation considerations” on page 41.](#)

Coded character sets and CCSIDs

IBM's Character Data Representation Architecture (CDRA) deals with the differences in string representation and encoding. The *Coded Character Set Identifier (CCSID)* is a key element of this architecture. A CCSID is a 2-byte (unsigned) binary number that uniquely identifies an encoding scheme and one or more pairs of character sets and code pages.

A CCSID is an attribute of strings, just as length is an attribute of strings. All values of the same string column have the same CCSID.

Character conversion is described in terms of CCSIDs of the source and target. Each database manager provides support to identify valid source and target combinations and to perform the conversion from one coded character set to another. In some cases, no conversion is necessary even though the strings involved have different CCSIDs.

Different types of conversions may be supported by the database manager. Round-trip conversions attempt to preserve characters in one CCSID that are not defined in the target CCSID so that if the data is subsequently converted back to the original CCSID, the same original characters result. Enforced subset match conversions do not attempt to preserve such characters. For more information, see IBM's Character Data Representation Architecture (CDRA).

Default CCSID

Every application server and application requester has a default CCSID (or default CCSIDs in installations that support DBCS data).

The CCSID of the following types of strings is determined at the current server:

- String constants (including string constants that represent datetime values) when the CCSID of the source is in a foreign encoding scheme
- Special registers with string values (such as USER and CURRENT SERVER)
- CAST specifications where the result is a character or graphic string
- Results of CHAR, DATAPARTITIONNAME, DAYNAME, DBPARTITIONNAME, DIGITS, HEX, MONTHNAME, SOUNDEX, SPACE, and VARCHAR_FORMAT scalar functions
- Results of DECRYPT_CHAR, DECRYPT_DB, CHAR, GRAPHIC, VARCHAR, and VARGRAPHIC scalar functions when a CCSID is not specified as an argument
- Results of the CLOB and DBCLOB scalar functions when a CCSID is not specified as an argument¹¹
- String columns defined by the CREATE TABLE or ALTER TABLE statements when an explicit CCSID is not specified for the column¹¹
- String columns defined by the DECLARE GLOBAL TEMPORARY TABLE statement when an explicit CCSID is not specified for the column¹¹
- Distinct types when the source type is a character or graphic string type
- String parameters defined by CREATE FUNCTION or CREATE PROCEDURE statements when an explicit CCSID is not specified for the parameter ¹¹

If one of the types of strings above is used in a CREATE VIEW statement, the default CCSID is determined at the time the view is created.

¹¹ If the default CCSID is 65535, the CCSID used will be the value of the DFTCCSID job attribute (or an associated CCSID of the DFTCCSID). If there is no associated mixed data CCSID,

- the CCSID used when FOR MIXED DATA is specified will be 65535,
- the CCSID for GRAPHIC and VARGRAPHIC will be 65535, and
- the CCSID for DBCLOB will be 1200.

In a distributed application, the default CCSID of variables is determined by the application requester. In a non-distributed application, the default CCSID of variables is determined by the application server. On the IBM i operating system, the default CCSID is determined by the CCSID job attribute. For more information about CCSIDs, see the [Work with CCSIDs](#) topic in the Globalization topic collection.

Collating sequence

A collating sequence (also called a sort sequence) defines how characters in a character set relate to each other when they are compared and ordered.

Different collating sequences are useful for those who want their data ordered for a specific language. For example, lists can be ordered as they are normally seen for a specific language. A collating sequence can also be used to treat certain characters as equivalent, for instance, **a** and **A**. A collating sequence works on all comparisons that involve:

- SBCS character data (including bit data)
- the SBCS portion of mixed data
- Unicode data (UTF-8, UCS-2, or UTF-16).

SBCS collating sequence support is implemented using a 256-byte table. Each byte in the table corresponds to a code point or character in a SBCS code page. Because the collating sequence is applicable to character data, a CCSID must be associated with the table. The bytes in the collating sequence table are set based on how each code point is to compare to other code points in that code page. For example, if the characters **a** and **A** are to be treated as equivalents for comparisons, the bytes in the collating sequence table for their code points contain the same value, or weight.

UCS-2 collating sequence support is implemented using a multi-byte table. A pair of bytes within the table corresponds to a character in the UCS-2 code page. Only a subset of the thousands of characters in UCS-2 are typically represented in the table. Only those characters that are to compare differently (and possibly other characters in the same ward) will be represented in the table. The bytes in the collating sequence table are set based on how each character is to compare with other characters in UCS-2.

When two or more bytes (or pair of bytes for UCS-2) in a collating sequence table have the same value, the collating sequence is a shared-weight collating sequence. If every byte (or pair of bytes for UCS-2) in a collating sequence table has a unique value, the collating sequence is a unique-weight collating sequence. For many languages, unique- and shared-weight collating sequences are shipped on the system as part of the operating system. If you need collating sequences for other languages or needs, you define them using the Create Table (CRTTBL) command.

UTF-8 and UTF-16 collating sequence support is implemented using ICU (International Components for Unicode). This is a standard API to sort Unicode. The API produces the same result for normalized and non-normalized data and returns a sort weight based on language specific rules. The IBM i operating system supports ICU 2.3.1, ICU 3.4, and ICU 4.0 collating sequences, but ICU 3.4 or ICU 4.0 should be used. The ICU collating sequence table I34en_us (United States locale) will sort data differently than I34fr_FR (French locale).

If ICU is used, the LIKE predicate and the LOCATE, POSITION, POSSTR, and POSITION scalar functions are not supported.

If ICU 2.3.1 is used, the query cannot contain:

- EXCEPT or INTERSECT operations,
- VALUES in a fullselect,
- OLAP specifications,
- recursive common table expressions,
- ORDER OF,
- scalar fullselects (scalar subselects are supported),
- full outer join,
- LOBs in a GROUP BY,

- grouping sets or super groups,
- ORDER BY or FETCH clause in a subselect,
- OFFSET clause, or FETCH clause with a variable for N rows,
- CORRELATION, COVARIANCE, COVARIANCE_SAMP, LISTAGG, MEDIAN, PERCENTILE_CONT, PERCENTILE_DISC, or Regression aggregate functions,
- VERIFY_GROUP_FOR_USER, LOCATE_IN_STRING, LTRIM or RTRIM with 2 arguments, EXTRACT function with EPOCH,
- BSON_TO_JSON, JSON_ARRAY, JSON_ARRAYAGG, JSON_OBJECT, JSON_OBJECTAGG, JSON_QUERY, JSON_TABLE, JSON_TO_BSON, and JSON_VALUE functions, and the IS JSON and JSON_EXISTS predicates,
- CONTAINS or SCORE functions,
- XMLAGG, XMLATTRIBUTES, XMLCOMMENT, XMLCONCAT, XMLDOCUMENT, XMLELEMENT, XMLFOREST, XMLGROUP, XMLNAMESPACES, XMLPI, XMLROW, or XMLTEXT functions,
- default values for user defined functions,
- global variables, or
- references to arrays.

An ICU collating sequence table will generally produce results that are more culturally correct, however:

- The performance of SQL statements that use an ICU collating sequence table will generally perform worse than when using either an SBCS or UCS-2 collating sequence table. Indexes can be created with an ICU collating sequence table, however, to improve performance. In this case, the index key values will contain the ICU weighted value which will greatly reduce the number of times the system's ICU support is called.
- The storage necessary for indexes that use an ICU collating sequence table will generally be greater than when using either an SBCS or UCS-2 collating sequence table. The key values can be up to 3 times longer than the length of SBCS data used to produce the key and up to 6 times longer than the length of DBCS data used to produce the key.

It is important to remember that the data itself is not altered by the collating sequence. Instead, a weighted representation of the data is used for the comparison. In SQL, a collating sequence is specified on the CRTSQLxxx, STRSQL, and RUNSQLSTM commands. The SET OPTION statement can be used to specify the collating sequence within the source of a program containing embedded SQL. The collating sequence applies to all character comparisons performed in the SQL statements. The default collating sequence on the system is the internal sequence that occurs when the hexadecimal representation of characters are used. This is the sequence you get when the SRTSEQ(*HEX) is specified. For programs precompiled with a release of the product that is earlier than Version 2 Release 3, the collating sequence is *HEX.

Collating sequences do not apply to FOR BIT DATA or binary string columns.

The collating sequence is not allowed for an index or unique constraint that contains a key column with a field procedure.

The *collating sequence* is explicitly specified through the following interfaces:

<i>Table 3. Collating Sequence Interfaces</i>	
SQL Interface	Specification
Embedded SQL	SRTSEQ parameter on the Create SQL Program (CRTSQLxxx) commands. The SET OPTION statement can also be used to set the SRTSEQ values. (For more information about CRTSQLxxx commands, see Embedded SQL Programming .)

Table 3. Collating Sequence Interfaces (continued)

SQL Interface	Specification
Run SQL Statements	SRTSEQ parameter on the Run SQL Statements (RUNSQLSTM) command. (For more information about the RUNSQLSTM command, see SQL Programming .)
Call Level Interface (CLI) on the server	SQL_ATTR_JOB_SORT_SEQUENCE environment variable (For more information about CLI, see SQL Call Level Interfaces (ODBC) .)
JDBC or SQLJ on the server using IBM IBM Developer Kit for Java	job.sort.sequence property object (For more information about JDBC and SQLJ, see IBM Developer Kit for Java .)
ODBC on a client using the IBM i Access Family ODBC Driver	Sort Type in ODBC Setup (For more information about ODBC, see IBM i Access .)
JDBC on a client using the IBM Toolbox for Java	Sort Sequence Table in JDBC Setup (For more information about JDBC, see IBM i Access .) (For more information about the IBM Toolbox for Java, see IBM Toolbox for Java .)
OLE DB on a client using the IBM i Access Family OLE DB Provider	Sort Sequence Connection Object Properties (For more information about OLE DB, see IBM i Access .)
ADO .NET on a client using the IBM i Access Family ADO .NET Provider	SortSequence in Connection Object Properties (For more information about ADO .NET, see IBM i Access .)

For more information about CCSIDs, see the [Work with CCSIDs](#) topic in the Globalization section of the IBM i Information Center. For more information about collating sequences and the sequences shipped with the system, see the [DB2 and SQL collating sequence](#) topic in the IBM i Information Center.

Distributed relational database

A *distributed relational database* consists of a set of tables and other objects that are spread across different but interconnected computer systems or logical partitions on the same computer system. Each computer system has a relational database manager that manages the tables in its environment. The database managers communicate and cooperate with each other in a way that allows a database manager to execute SQL statements on another computer system.

Distributed relational databases are built on formal requester-server protocols and functions. An *application requester* supports the application end of a connection. It transforms a database request from the application into communication protocols suitable for use in the distributed database network. These requests are received and processed by an *application server* at the other end of the connection.¹² Working together, the application requester and application server handle the communication and

¹² This is also known as a *an application server*.

location considerations so that the application is isolated from these considerations and can operate as if it were accessing a local database. A simple distributed relational database environment is illustrated in Figure 8 on page 36.

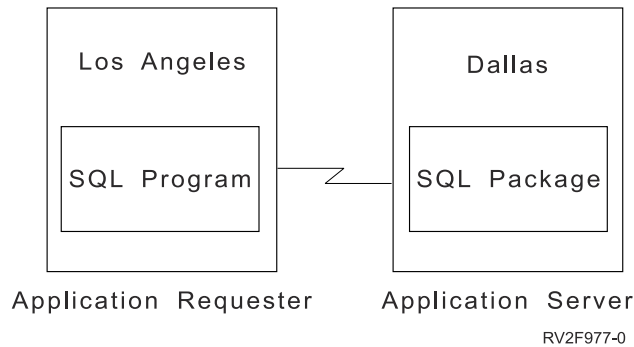

Figure 8. A Distributed Relational Database Environment

For more information about Distributed Relational Database Architecture™ (DRDA) communication protocols, see [Open Group Publications: DRDA Vol. 1: Distributed Relational Database Architecture \(DRDA\)](#) 

Application servers

An activation group must be connected to the application server of a database manager before SQL statements can be executed.

A *connection* is an association between an activation group and a local or remote application server. A connection is also known as a session or an SQL session. Connections are managed by the application. The CONNECT statement can be used to establish a connection to an application server and make that application server the current server of the activation group.

An implicit CONNECT operation may also establish a connection to the application server:

- An implicit CONNECT operation may occur when invoking a program, service program, or the STRSQL command. The application server is determined by the RDB parameter on the CRTSQLxxx and STRSQL commands.

In these cases, the implicit CONNECT operation will not occur if an implicit or explicit CONNECT operation has already successfully or unsuccessfully occurred in the activation group. Thus, an activation group cannot be implicitly connected to an application server more than once.

- An implicit CONNECT operation may occur when using a three-part object name or an alias that is defined to reference a three-part name of a table or view.

In these cases, an implicit CONNECT operation is only allowed if all the objects referenced in the SQL statement refer to the same relational database. The only exceptions are:

- The target table of an INSERT statement may be in one relational database and the tables referenced in the *select-statement* of the INSERT may be in another relational database.
- The new table for a CREATE TABLE or DECLARE GLOBAL TEMPORARY TABLE statement may be in one relational database and the tables referenced in the *select-statement* may be in another relational database.

The implicit CONNECT changes the current server for the statement. At the end of the statement the connection is set back to the prior current server.

- When creating three-part qualified SQL stored procedures or SQL functions, objects in the procedure body must exist on both the DRDA client and DRDA server. If the procedure body objects do not exist, object not found errors may be signalled.

An application server can be local to, or remote from, the environment where the activation group is started. (An application server is present, even when distributed relational databases are not used.) This environment includes a local directory that describes the application servers that can be identified

in a CONNECT statement. For more information about the directory, see the relational database folders in System i Navigator or the directory commands (ADDRDBDIRE, CHGRDBDIRE, DSPRDBDIRE, RMVRDBDIRE, and WRKRDBDIRE) in the following IBM i Information Center topics:

- [SQL Programming](#)
- [Distributed Database Programming](#)
- [CL commands](#)

To execute a static SQL statement that references tables or views, an application server uses the bound form of the statement. This bound statement is taken from a package that the database manager previously created through a bind operation. The appropriate package is determined by the combination of:

- The name of the package specified by the SQLPKG parameter on the CRTSQLxxx commands. See [Embedded SQL Programming](#) for a description of the CRTSQLxxx commands.
- The internal consistency token that makes certain the package and program were created from the same source at the same time.

A Db2 relational database product may support a feature that is not supported by the version of the Db2 product that is connecting to the application server. Some of these features are product-specific, and some are shared by more than one product.

For the most part, an application can use the statements and clauses that are supported by the database manager of the application server to which it is currently connected, even though that application is running via the application requester of a database manager that does not support some of those statements and clauses. Restrictions are listed in [Appendix B, “Characteristics of SQL statements,”](#) on page 1651.

CONNECT (type 1) and CONNECT (type 2)

There are two types of CONNECT statements with the same syntax but different semantics. CONNECT (type 1) is used for remote unit of work. CONNECT (type 2) is used for distributed unit of work.

See [“CONNECT \(type 1\) and CONNECT \(type 2\) differences”](#) on page 1662 for a summary of the differences.

Remote unit of work

The *remote unit of work* facility provides for the remote preparation and execution of SQL statements. An activation group at computer system A can connect to an application server at computer system B. Then, within one or more units of work, that activation group can execute any number of static or dynamic SQL statements that reference objects at B. After ending a unit of work at B, the activation group can connect to an application server at computer system C, and so on.

Most SQL statements can be remotely prepared and executed with the following restrictions:

- All objects referenced in a single SQL statement must be managed by the same application server.
- All of the SQL statements in a unit of work must be executed by the same application server.

Remote unit of work connection management

An activation group is in one of three states at any time:

- Connectable and connected
- Unconnectable and connected
- Connectable and unconnected

The following diagram shows the state transitions:

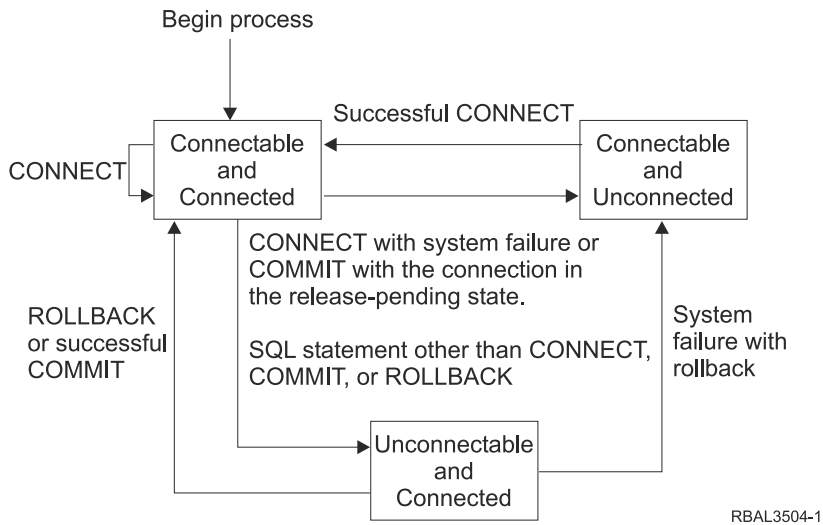

Figure 9. Remote Unit of Work Activation Group Connection State Transition

The initial state of an activation group is *connectable and connected*.

The connectable and connected state

An activation group is connected to an application server and CONNECT statements can be executed. The activation group enters this state when it completes a rollback or successful commit from the unconnectable and connected state, or a CONNECT statement is successfully executed from the connectable and unconnected state.

The unconnectable and connected state

An activation group is connected to an application server, but a CONNECT statement cannot be successfully executed to change application servers. The activation group enters this state from the connectable and connected state when it executes any SQL statement other than CONNECT, COMMIT, or ROLLBACK.

The connectable and unconnected state

An activation group is not connected to an application server. The only SQL statement that can be executed is CONNECT.

The activation group enters this state when:

- The connection was previously released and a successful COMMIT is executed.
- The connection is disconnected using the SQL DISCONNECT statement.
- The connection was in a connectable state, but the CONNECT statement was unsuccessful.

Consecutive CONNECT statements can be executed successfully because CONNECT does not remove the activation group from the connectable state. A CONNECT to the application server to which the activation group is currently connected is executed like any other CONNECT statement. CONNECT cannot execute successfully when it is preceded by any SQL statement other than CONNECT, COMMIT, DISCONNECT, SET CONNECTION, RELEASE, or ROLLBACK (unless running with COMMIT(*NC)). To avoid an error, execute a commit or rollback operation before a CONNECT statement is executed.

Application-directed distributed unit of work

The *application-directed distributed unit of work facility* also provides for the remote preparation and execution of SQL statements in the same fashion as remote unit of work. Like remote unit of work, an activation group at computer system A can connect to an application server at computer system B and execute any number of static or dynamic SQL statements that reference objects at B before ending the

unit of work. All objects referenced in a single SQL statement must be managed by the same application server. However, unlike remote unit of work, any number of application servers can participate in the same unit of work. A commit or rollback operation ends the unit of work.

Distributed unit of work is fully supported for APPC and TCP/IP connections.

Application-directed distributed unit of work connection management

At any time:

- An activation group is always in the *connected* or *unconnected* state and has a set of zero or more connections. Each connection of an activation group is uniquely identified by the name of the application server of the connection.
- An SQL connection is always in one of the following states:
 - Current and held
 - Current and release-pending
 - Dormant and held
 - Dormant and release-pending

Initial state of an activation group:

An activation group is initially in the connected state and has exactly one connection. The initial state of a connection is *current and held*.

The following diagram shows the state transitions:

RBAL3503-0

Figure 10. Application-Directed Distributed Unit of Work Connection and Activation Group Connection State Transitions

Connection states

If an application process successfully executes a CONNECT statement:

- The current connection is placed in the dormant state and held state.
- The server name is added to the set of connections and the new connection is placed in the current and held state.

If the server name is already in the set of existing connections of the activation group, an error is returned.

A connection in the dormant state is placed in the current state using the SET CONNECTION statement. When a connection is placed in the current state, the previous current connection, if any, is placed in the dormant state. No more than one connection in the set of existing connections of an activation group can be current at any time. Changing the state of a connection from current to dormant or from dormant to current has no effect on its held or release-pending state.

A connection is placed in the release-pending state by the RELEASE statement. When an activation group executes a commit operation, every release-pending connection of the activation group is ended. Changing the state of a connection from held to release-pending has no effect on its current or dormant state. Thus, a connection in the release-pending state can still be used until the next commit operation. There is no way to change the state of a connection from release-pending to held.

Activation group connection states

A different application server can be established by the explicit or implicit execution of a CONNECT statement. The following rules apply:

- An activation group cannot have more than one connection to the same application server at the same time.
- When an activation group executes a SET CONNECTION statement, the specified location name must be an existing connection in the set of connections of the activation group.
- When an activation group executes a CONNECT statement, the specified server name must not be an existing connection in the set of connections of the activation group.

If an activation group has a current connection, the activation group is in the *connected* state. The CURRENT SERVER special register contains the name of the application server of the current connection. The activation group can execute SQL statements that refer to objects managed by that application server.

An activation group in the unconnected state enters the connected state when it successfully executes a CONNECT or SET CONNECTION statement.

If an activation group does not have a current connection, the activation group is in the *unconnected* state. The CURRENT SERVER special register contents are equal to blanks. The only SQL statements that can be executed are CONNECT, DISCONNECT, SET CONNECTION, RELEASE, COMMIT, and ROLLBACK.

An activation group in the connected state enters the unconnected state when its current connection is intentionally ended or the execution of an SQL statement is unsuccessful because of a failure that causes a rollback operation at the current server and loss of the connection. Connections are intentionally ended when an activation group successfully executes a commit operation and the connection is in the release-pending state, or when an application process successfully executes the DISCONNECT statement.

When a connection is ended

When a connection is ended, all resources that were acquired by the activation group through the connection and all resources that were used to create and maintain the connection are deallocated. For example, if application process P has placed the connection to application server X in the application server state, all cursors of P at X will be closed and deallocated when the connection is ended during the next commit operation.

A connection can also be ended as a result of a communications failure in which case the activation group is placed in the unconnected state. All connections of an activation group are ended when the activation group ends.

Data representation considerations

Different systems represent data in different ways. When data is moved from one system to another, data conversion must sometimes be performed. Products supporting DRDA will automatically perform any necessary conversions at the receiving system.

With numeric data, the information needed to perform the conversion is the data type and the sending system's environment type. For example, when a floating-point variable from a Db2 for i application requester is assigned to a column of a table at an z/OS[®] application server, the number is converted from IEEE format to System/370* format.

With character and graphic data, the data type and the environment type of the sending system are not sufficient. Additional information is needed to convert character and graphic strings. String conversion depends on both the coded character set of the data and the operation to be done with that data. String conversions are done in accordance with the IBM Character Data Representation Architecture (CDRA). For more information about character conversion, refer to the book *Character Data Representation Architecture Reference and Registry*, SC09-2190.

Chapter 2. Language elements

This section defines the basic syntax of SQL and language elements that are common to many SQL statements.

Characters

The basic symbols of keywords and operators in the SQL language are single-byte characters that are part of all character sets supported by the IBM relational database products.

Characters of the language are classified as letters, digits, or special characters.¹³

A *letter* is any of the 26 uppercase (A through Z) and 26 lowercase (a through z) letters of the English alphabet.¹⁴

A *digit* is any of the characters 0 through 9.

A *special character* is any of the characters listed below:

	space or blank	-	minus sign
"	quotation mark or double-quote or double quotation mark	.	period
%	percent	/	slash
&	ampersand	:	colon
'	apostrophe or single quote or single quotation mark	;	semicolon
(left parenthesis	<	less than
)	right parenthesis	=	equals
*	asterisk	>	greater than
+	plus sign	?	question mark
,	comma	_	underline or underscore
	vertical bar ¹⁶	^	caret
!	exclamation mark ¹⁵	[left bracket
{	left brace]	right bracket
}	right brace	↯	not ¹⁵

¹³ Note that if the SQL statement is encoded as Unicode data, all characters of the statement except for string constants will be converted to single-byte characters prior to processing. Tokens representing string constants may be processed as UTF-16 graphic strings without conversion to single-byte.

¹⁴ Letters also include three code points reserved as alphabetic extenders for national languages (#, @, and \$ in the United States). These three code points should be avoided because they represent different characters depending on the CCSID.

¹⁵ Using the not symbol (↯) and the exclamation point symbol (!) might inhibit code portability between IBM relational database products. Avoid using them because they are variant characters. Instead of ↯= or != use <>. Instead of ↯> or !> use <=. Instead of ↯< or !< use >=.

¹⁶ Using the vertical bar (|) character might inhibit code portability between IBM relational database products. Use the CONCAT operator instead of the concatenation operator (||).

Tokens

The basic syntactical units of the language are called *tokens*. A token consists of one or more characters, excluding blanks, control characters, and characters within a string constant or delimited identifier. (These terms are defined later.)

Tokens are classified as *ordinary* or *delimiter* tokens:

- An *ordinary token* is a numeric constant, an ordinary identifier, a host identifier, or a keyword.

Examples

```
1      .1      +2      SELECT      E      3
```

- A *delimiter token* is a string constant, a delimited identifier, an operator symbol, or any of the special characters shown in the syntax diagrams. A question mark (?) is also a delimiter token when it serves as a parameter marker, as explained under “PREPARE” on page 1435.

Examples

```
,      'Myst Island'      "fld1"      =      .
```

Spaces:

A *space* is a sequence of one or more blank characters.

Control Characters:

A *control character* is a special character that is used for string alignment. The following table contains the control characters that are handled by the database manager:

Control Character	EBCDIC Hex Value	UTF-8 Hex Value	UCS-2 and UTF-16 Hex Value
Tab	05	09	U+0009
Form Feed	0C	0C	U+000C
Carriage Return	0D	0D	U+000D
New Line	15	C285	U+0085
Line Feed (New line)	25	0A	U+000A
DBCS Space	—	—	U+3000

Tokens, other than string constants and certain delimited identifiers, must not include a control character or space. A control character or space can follow a token. A delimiter token, a control character, or a space *must* follow every ordinary token. If the syntax does not allow a delimiter token to follow an ordinary token, then a control character or a space must follow that ordinary token. The following examples illustrate the rule that is stated in this paragraph.

Here are some examples of combinations of the above ordinary tokens that, in effect, change the tokens:

```
1.1      .1+2      SELECTE      .1E      E3      SELECT1
```

This demonstrates why ordinary tokens must be followed by a delimiter token or a space.

Here are some examples of combinations of the above ordinary tokens and the above delimiter tokens that, in effect, change the tokens:

```
1.      .3
```

The period (.) is a delimiter token when it is used as a separator in the qualification of names. Here the dot is used in combination with an ordinary token of a numeric constant. Thus, the syntax does not allow an ordinary token to be followed by a delimiter token. Instead, the ordinary token must be followed by a space.

If the decimal point has been defined to be the comma, as described in [“Decimal point” on page 116](#), the comma is interpreted as a decimal point in numeric constants. Here are some examples of these numeric constants:

```
1,2      ,1      1,      1,e1
```

If '1,2' and '1,e1' are meant to be two items, both the ordinary token (1) and the delimiter token (,) must be followed by a space, to prevent the comma from being interpreted as a decimal point. Although the comma is usually a delimiter token, the comma is part of the number when it is interpreted as a decimal point. Therefore, the syntax does not allow an ordinary token (1) to be followed by a delimiter token (,). Instead, an ordinary token must be followed by a space.

Comments:

Dynamic SQL statements can include SQL comments. Static SQL statements can include host language comments or SQL comments. Comments may be specified wherever a space may be specified, except within a delimiter token or between the keywords EXEC and SQL. In Java, SQL comments are not allowed within embedded Java expressions. There are two types of SQL comments:

simple comments

Simple comments are introduced by two consecutive hyphens (--). Simple comments cannot continue past the end of the line. For more information, see [“SQL comments” on page 815](#).

bracketed comments

Bracketed comments are introduced by /* and end with */. A bracketed comment can continue past the end of the line. For more information, see [“SQL comments” on page 815](#).

Uppercase and Lowercase:

Any token in an SQL statement may include lowercase letters, but a lowercase letter in an ordinary token is folded to uppercase, except for variables in the C and Java languages, which have case-sensitive identifiers. Delimiter tokens are never folded to uppercase. Thus, the statement:

```
select * from EMP where lastname = 'Smith';
```

is equivalent, after folding, to:

```
SELECT * FROM EMP WHERE LASTNAME = 'Smith';
```

Identifiers

An *identifier* is a token used to form a name. An identifier in an SQL statement is an SQL identifier, a system identifier, or a host identifier.

Note: \$, @, #, and all other variant characters should not be used in identifiers because the code points used to represent them vary depending on the CCSID of the string in which they are contained. If they are used, unpredictable results may occur. For more information about variant characters, see the [DB2 and SQL sort sequence](#) topic.

SQL identifiers

There are two types of SQL identifiers: *ordinary identifiers* and *delimited identifiers*.

- An *ordinary identifier* is an uppercase letter followed by zero or more characters, each of which is an uppercase letter, a digit, or the underscore character. Note that ordinary identifiers are converted to uppercase. An ordinary identifier should not be a reserved word. See [Appendix I, “Reserved schema names and reserved words,”](#) on page 2003 for a list of reserved words. If a reserved word is used as an identifier in SQL, it should be specified in uppercase and should be a delimited identifier or specified in a variable.
- A *delimited identifier* is a sequence of one or more characters enclosed within SQL escape characters. The sequence must consist of one or more characters. Leading blanks in the sequence are significant. Trailing blanks in the sequence are not significant. The length of a delimited identifier does not include the two SQL escape characters. Note that delimited identifiers are not converted to uppercase. The escape character is the quotation mark (") except in the following cases where the escape character is the apostrophe ('):
 - Interactive SQL when the SQL string delimiter is set to the quotation mark in COBOL syntax checking statement mode
 - Dynamic SQL in a COBOL program when the CRTSQLCBL or CRTSQLCBLI parameter OPTION(*QUOTESQL) specifies that the string delimiter is the quotation mark (")
 - COBOL application program when the CRTSQLCBL or CRTSQLCBLI parameter OPTION(*QUOTESQL) specifies that the string delimiter is the quotation mark (")

The following characters are not allowed within delimited identifiers:

- X'00' through X'3F' and X'FF'

System identifiers

A system identifier is used to form the name of system objects in the IBM i operating system. There are two types of system identifiers: ordinary identifiers and delimited identifiers.

- The rules for forming a system ordinary identifier are identical to the rules for forming an SQL ordinary identifier.
- The rules for forming a system delimited identifier are identical to those for forming SQL delimited identifiers, except:
 - The following special characters are not allowed in a delimited system identifier:
 - A blank (X'40')
 - An asterisk (X'5C')
 - An apostrophe (X'7D')
 - A question mark (X'6F')
 - A quotation mark (X'7F')
 - The bytes required for the escape characters are included in the length of the identifier unless the characters within the delimiters would form an ordinary identifier.

For example, “PRIVILEGES” is in uppercase and the characters within the delimiters form an ordinary identifier; therefore, it has a length of 10 bytes and is a valid system name for a column. Alternatively, “privileges” is in lowercase, has a length of 12 bytes, and is not a valid system name for a column because the bytes required for the delimiters must be included in the length of the identifier.

Examples

```
WKLYSAL    WKLY_SAL    "WKLY_SAL"    "UNION"    "wkly_sal"
```

See [“Naming conventions” on page 48](#) for information on the maximum length of identifiers.

Host identifiers

A *host-identifier* is a name declared in the host program.

The rules for forming a host-identifier are the rules of the host language; except that DBCS characters cannot be used. For example, the rules for forming a host-identifier in a COBOL program are the same as the rules for forming a user-defined word in COBOL. Names beginning with the characters 'SQ', 'SQL', 'sql', 'RDI', or 'DSN' should not be used because precompilers generate host variables that begin with these characters. In Java, do not use names beginning with ' __sJT_ '.

See [Table 5 on page 55](#) for the limits on the maximum size of the host identifier name imposed by Db2 for i.

¹⁷ 'SQ' is allowed in C, COBOL, and PL/I; it should not be used in RPG.

Naming conventions

The rules for forming a name depend on the type of the object designated by the name and the naming option (*SQL or *SYS). The naming option is specified on the CRTSQLxxx, RUNSQLSTM, and STRSQL commands. The SET OPTION statement can be used to specify the naming option within the source of a program containing embedded SQL. The syntax diagrams use different terms for different types of names.

The following list defines these terms.

alias-name

A qualified or unqualified name that designates an alias. The qualified form of an *alias-name* depends on the naming option. For SQL naming, the qualified form is a *schema-name* followed by a period (.) and an SQL identifier. For system naming, the qualified form is a *schema-name* followed by a slash (/) followed by an SQL identifier¹⁸.

The unqualified form of an *alias-name* is an SQL identifier. The unqualified form is implicitly qualified based on the rules specified in [“Qualification of unqualified object names” on page 57](#).

An *alias-name* can specify either the name of the alias or the system object name of the alias.

array-type-name

A qualified or unqualified name that designates an array type. The qualified form of a *array-type-name* depends upon the naming option. For SQL naming, the qualified form is a *schema-name* followed by a period (.) and an SQL identifier. For system naming, the qualified form is a *schema-name* followed by a slash (/) followed by an SQL identifier¹⁸.

The unqualified form of a *array-type-name* is an SQL identifier. The unqualified form is implicitly qualified based on the rules specified in [“Qualification of unqualified object names” on page 57](#).

For system naming, *array-type-names* cannot be qualified when used in a parameter data type of an SQL routine or in an SQL variable declaration in an SQL procedure.

authorization-name

A system identifier that designates a user or group of users. An *authorization-name* is a user profile name on the server. It must not be a delimited identifier that includes lowercase letters or special characters. See [“Authorization IDs and authorization names” on page 61](#) for the distinction between an *authorization-name* and an authorization ID.

column-name

A qualified or unqualified name that designates a column of a table or a view. The unqualified form of a *column-name* is an SQL identifier. The qualified form is a qualifier followed by a period and an SQL identifier. The qualifier is a table name, a view name, or a correlation name.

For system naming, column names can be qualified using the form *schema-name/table-name.column-name* when the name is used in the COMMENT and LABEL statements. If column names need to be qualified and correlation names are allowed in the statement, a correlation name can be used to qualify the column. The period form of qualification can also be used.

A *column-name* can specify either the column name or the system column name of a column of a table or view. If a *column-name* is delimited, the delimiters are considered to be part of the name when determining the length of the name.

constraint-name

A qualified or unqualified name that designates a constraint on a table. The qualified form of a *constraint-name* depends on the naming option. For SQL naming, the qualified form is a *schema-name* followed by a period (.) and an SQL identifier. For system naming, the qualified form is a *schema-name* followed by a slash (/) followed by an SQL identifier¹⁸.

The unqualified form of a *constraint-name* is an SQL identifier. The unqualified form is implicitly qualified based on the rules specified in [“Qualification of unqualified object names” on page 57](#).

The implicit or explicit qualifier must be the same as the schema name of the table.

¹⁸ For system naming, the qualified form that uses a period is also accepted.

correlation-name

An SQL identifier that designates a table, a view, or individual rows of a table or view.

cursor-name

An SQL identifier that designates an SQL cursor.

descriptor-name

A variable name or string constant that designates an SQL descriptor area (SQLDA). A variable that designates an SQL descriptor area must not have an indicator variable. The form *:host-variable:indicator-variable* is not allowed. See [“References to host variables” on page 139](#) for a description of a variable.

distinct-type-name

A qualified or unqualified name that designates a distinct type. The qualified form of a *distinct-type-name* depends upon the naming option. For SQL naming, the qualified form is a *schema-name* followed by a period (.) and an SQL identifier. For system naming, the qualified form is a *schema-name* followed by a slash (/) followed by an SQL identifier¹⁸.

The unqualified form of a *distinct-type-name* is an SQL identifier. The unqualified form is implicitly qualified based on the rules specified in [“Qualification of unqualified object names” on page 57](#).

For system naming, *distinct-type-names* cannot be qualified when used in a parameter data type of an SQL routine or in an SQL variable declaration in an SQL function, SQL procedure, or trigger.

external-program-name

A qualified name, unqualified name, or a character string that designates an external program. The qualified form of an *external-program-name* depends on the naming option. For SQL naming, the qualified form is a *system-schema-name* followed by a period (.) and a system identifier. For system naming, the qualified form is a *system-schema-name* followed by a slash (/) followed by a system identifier¹⁸.

The unqualified form of an *external-program-name* is a system identifier. The unqualified form is implicitly qualified based on the rules specified in [“Qualification of unqualified object names” on page 57](#).

For a service program name, the qualified form depends on the naming option. For SQL naming the qualified form is a *system-schema-name* followed by a period (.), followed by a system identifier for the service program name, followed by a left parenthesis, followed by an IBM i entry-point-name, followed by a right parenthesis (*library-name.service-program-name(entry-point-name)*). For system naming, the qualified form is a *system-schema-name* followed by a slash (/) followed by a system identifier for the service program name, followed by a left parenthesis, followed by an IBM i entry-point-name, followed by a right parenthesis (*library-name/service-program-name(entry-point-name)*)¹⁸. If the entry point name contains lowercase characters, it must be enclosed in quotes.

The unqualified form of an service program name is a system identifier followed by a left parenthesis, followed by an IBM i entry-point-name, followed by a right parenthesis. The unqualified form is implicitly qualified based on the rules specified in [“Qualification of unqualified object names” on page 57](#).

The format of the character string form is either:

- A IBM i qualified program name ('library-name/program-name').
- A IBM i qualified source file name, followed by a left parenthesis, followed by an IBM i member name, and a right parenthesis ('library-name/source-file-name(member-name)'). This form is only valid when calling a REXX procedure.
- A IBM i qualified or unqualified service program name, followed by a left parenthesis, followed by an IBM i entry-point-name, followed by a right parenthesis ('library-name/service-program-name(entry-point-name)' or 'service-program-name(entry-point-name)').
- In Java, an optional *jar-name*, followed by a class identifier, followed by an exclamation point or period, followed by a method identifier ('class-id!method-id' or 'class-id.method-id').

jar-name

The *jar-name* is a case-sensitive string that identifies the jar schema when it was installed in the database. It can be either a simple identifier, or a schema qualified identifier. Examples are 'myJar' and 'myCollection.myJar'.

class-id

The *class-id* identifies the class identifier of the Java object. If the class is part of a Java package, the class identifier must include the complete Java package prefix. For example, if the class identifier is 'myPackage.StoredProcs', the Java virtual machine will look in the following directory for the StoredProcs class:

```
'/QIBM/UserData/OS400/SQLLib/
Function/myPackage/StoredProcs/'
```

method-id

The *method-id* identifies the method name of the public, static Java method to be invoked.

This form is only valid for Java procedures and Java functions.

function-name

A qualified or unqualified name that designates a user-defined function, a cast function that was generated when a distinct type was created, or a built-in function. The qualified form of a *function-name* depends upon the naming option. For SQL naming, the qualified form is a *schema-name* followed by a period (.) and an SQL identifier. For system naming, the qualified form is a *schema-name* followed by a slash (/) followed by an SQL identifier¹⁸.

In a CREATE, COMMENT, DROP, GRANT, or REVOKE statement, the *schema-name* can be qualified with a *server-name*. In all other contexts, a *server-name* is not allowed.

The unqualified form of a *function-name* is an SQL identifier. The unqualified form is implicitly qualified based on the rules specified in [“Qualification of unqualified object names”](#) on page 57.

For system naming, functions names can only be qualified in the form *schema-name/function-name* when the name is used in a CREATE, COMMENT, DROP, GRANT, or REVOKE statement. The period form of qualification can be used in an expression.

host-label

A token that designates a label in a host program.

host-variable

A sequence of tokens that designates a host variable. A *host-variable* includes at least one *host-identifier*, as explained in [“References to host variables”](#) on page 139.

index-name

A qualified or unqualified name that designates an index. The qualified form of an *index-name* depends upon the naming option. For SQL naming, the qualified form is a *schema-name* followed by a period (.) and an SQL identifier. For system naming, the qualified form is a *schema-name* followed by a slash (/) followed by an SQL identifier¹⁸.

The unqualified form of an *index-name* is an SQL identifier. The unqualified form is implicitly qualified based on the rules specified in [“Qualification of unqualified object names”](#) on page 57.

mask-name

A qualified or unqualified name that designates a column mask. The qualified form of a *mask-name* depends upon the naming option. For SQL naming, the qualified form is a *schema-name* followed by a period (.) and an SQL identifier. For system naming, the qualified form is a *schema-name* followed by a slash (/) followed by an SQL identifier¹⁸.

The unqualified form of a *mask-name* is an SQL identifier. The unqualified form is implicitly qualified based on the rules specified in [“Qualification of unqualified object names” on page 57](#).

member-name

An identifier that designates a member of a database file. A member is also a partition of a partitioned table. A member name is a system identifier.

nodegroup-name

A qualified or unqualified name that designates a nodegroup. A nodegroup is a group of IBM i products across which a table will be distributed. For more information about distributed tables and nodegroups, see [DB2 Multisystem](#).

The qualified form of a *nodegroup-name* depends on the naming option. For SQL naming, the qualified form is a *schema-name* followed by a period (.) and a system identifier. For system naming, the qualified form is a *schema-name* followed by a slash (/) followed by a system identifier¹⁸.

The unqualified form of a *nodegroup-name* is a system identifier. The unqualified form is implicitly qualified based on the rules specified in [“Qualification of unqualified object names” on page 57](#).

package-name

A qualified or unqualified name that designates a package. The qualified form of a *package-name* depends upon the naming option. For SQL naming, the qualified form is a *schema-name* followed by a period (.) and a system identifier. For system naming, the qualified form is a *schema-name* followed by a slash (/) followed by a system identifier¹⁸.

The unqualified form of a *package-name* is a system identifier. The unqualified form is implicitly qualified based on the rules specified in [“Qualification of unqualified object names” on page 57](#).

parameter-name

An SQL identifier that designates a parameter for a function or procedure. If the *parameter-name* is for a procedure, the identifier may be preceded by a colon.

partition-name

An identifier that designates a partition of a partitioned table. A partition name is a system identifier.

permission-name

A qualified or unqualified name that designates a row permission. The qualified form of a *permission-name* depends upon the naming option. For SQL naming, the qualified form is a *schema-name* followed by a period (.) and an SQL identifier. For system naming, the qualified form is a *schema-name* followed by a slash (/) followed by an SQL identifier¹⁸.

The unqualified form of a *permission-name* is an SQL identifier. The unqualified form is implicitly qualified based on the rules specified in [“Qualification of unqualified object names” on page 57](#).

procedure-name

A qualified or unqualified name that designates a procedure. The qualified form of a *procedure-name* depends upon the naming option. For SQL naming, the qualified form is a *schema-name* followed by a period (.) and an SQL identifier. For system naming, the qualified form is a *schema-name* followed by a slash (/) followed by an SQL identifier¹⁸.

The unqualified form of a *procedure-name* is an SQL identifier. The unqualified form is implicitly qualified based on the rules specified in [“Qualification of unqualified object names” on page 57](#).

savepoint-name

An SQL identifier that designates a savepoint.

schema-name

A qualified or unqualified name that provides a logical grouping for SQL objects. A schema name is used as a qualifier of the name of a table, view, index, procedure, function, trigger, sequence, variable, constraint, alias, type, or package. The unqualified form of a *schema-name* is a system identifier. The qualified form of a *schema-name* depends on the naming option.

For SQL naming, the unqualified schema name in an SQL statement is implicitly qualified by the *server-name*. The qualified form is a *server-name* followed by a (.) and a system identifier.

For system naming, the unqualified schema name in an SQL statement is implicitly qualified by the *server-name*. The qualified form is a *server-name* followed by a slash (/) and an SQL identifier¹⁸.

If the *server-name* is used to qualify the name of the schema, the *server-name* may identify any supported remote server. Otherwise, the schema name is implicitly qualified with the current server.

Note: *schema-name* refers to either a schema created by the CREATE SCHEMA statement or to an IBM i library.

sequence-name

A qualified or unqualified name that designates a sequence. The qualified form of a *sequence-name* depends upon the naming option. For SQL naming, the qualified form is a *schema-name* followed by a period (.) and an SQL identifier. For system naming, the qualified form is a *schema-name* followed by a slash (/) followed by an SQL identifier¹⁸. For system naming, a *sequence-name* cannot be qualified with a slash when used in a NEXT VALUE or PREVIOUS VALUE expression (the slash-qualified form is only allowed in SQL schema statements). The period form of qualification can be used in a NEXT VALUE or PREVIOUS VALUE expression.

The unqualified form of a *sequence-name* is an SQL identifier. The unqualified form is implicitly qualified based on the rules specified in [“Qualification of unqualified object names” on page 57](#).

A *sequence-name* can specify either the name of the sequence or the system object name of the sequence.

server-name

An SQL identifier that designates an application server. The identifier must start with a letter and must not include lowercase letters or special characters.

A *server-name* may be the actual name of the relational database or a relational database alias. For more information see the Add RDB Directory Entry (ADDRDBDIRE) CL command. If a three-part name is specified directly in an SQL statement (other than the base table specified in a CREATE ALIAS statement) it can use either the actual relational database name or the relational database alias name.

For example, if the actual name of the relational database is ABC and a relational database alias name of MYABC also references ABC:

```
SELECT * FROM ABC.SCHEMA1.T1 -- This is valid.  
SELECT * FROM MYABC.SCHEMA1.T1 -- This is also valid.
```

specific-name

A qualified or unqualified name that uniquely identifies a procedure or function. The qualified form of a *specific-name* depends upon the naming option. For SQL naming, the qualified form is a *schema-name* followed by a period (.) and an SQL identifier. For system naming, the qualified form is a *schema-name* followed by a slash (/) followed by an SQL identifier¹⁸.

The unqualified form of a *specific-name* is an SQL identifier. The unqualified form is implicitly qualified based on the rules specified in [“Qualification of unqualified object names” on page 57](#).

SQL-condition-name

An SQL identifier that designates a condition in an SQL procedure, SQL function, or trigger body.

SQL-descriptor-name

A variable name or character or graphic string constant that designates an SQL descriptor that was allocated using the ALLOCATE DESCRIPTOR statement.

If a variable is used to designate the SQL descriptor:

- The variable must not be a CLOB or DBCLOB.
- If the variable is a graphic string, it must be a Unicode graphic string.

- The length of the contents of the variable must not exceed the maximum length for an *SQL-descriptor-name*.
- An indicator variable must not be specified. The form *:host-variable:indicator-variable* is not allowed.
- The contents of the variable are case-sensitive and are not converted to uppercase.

Leading and trailing blanks are trimmed from the variable or string. See [“References to host variables” on page 139](#) for a description of a variable.

If a string constant is used to designate the SQL descriptor, the length of the constant must not exceed the maximum length for an *SQL-descriptor-name*.

SQL-label

An SQL name that designates a label in an SQL procedure, SQL function, or trigger body.

SQL-parameter-name

A qualified or unqualified name that designates a parameter in an SQL routine body. The unqualified form of an *SQL-parameter-name* is an SQL identifier. The qualified form is a *procedure-name* followed by a period (.) and an SQL identifier.

SQL-variable-name

A qualified or unqualified name that designates a variable in an SQL routine body. The unqualified form of an *SQL-variable-name* is an SQL identifier. The qualified form is an *SQL-label* followed by a period (.) and an SQL identifier.

statement-name

An SQL identifier that designates a prepared SQL statement.

system-column-name

A name that designates the IBM i column name of a table or a view. A *system-column-name* is a system identifier. *System-column-names* can be delimited identifiers, but the characters within the delimiters must not include lowercase letters or special characters.

system-object-name

A name that designates the IBM i name of a table, view, index, sequence, variable, or alias. A *system-object-name* is a system identifier.

If the unqualified name of the table, view, index, sequence, variable, or alias is a valid system identifier, the *system-object-name* of the table, view, index, sequence, variable, or alias is the unqualified name of the table, view, index, sequence, or alias.

system-schema-name

A name that designates the IBM i name of a schema. A *system-schema-name* is a system identifier.

If the unqualified name of the schema is a valid system identifier, the *system-schema-name* of the schema is the unqualified name of the schema.

table-name

A qualified or unqualified name that designates a table. The qualified form of a *table-name* depends upon the naming option. For SQL naming, the qualified form is a *schema-name* followed by a period (.) and an SQL identifier. For system naming, the qualified form is a *schema-name* followed by a slash (/) followed by an SQL identifier¹⁸.

The unqualified form of a *table-name* is an SQL identifier. The unqualified form is implicitly qualified based on the rules specified in [“Qualification of unqualified object names” on page 57](#).

A *table-name* can specify either the name of the table or the system object name of the table.

trigger-name

A qualified or unqualified name that designates a trigger on a table. The qualified form of a *trigger-name* depends on the naming option. For SQL naming, the qualified form is a *schema-name* followed by a period (.) and a system identifier. For system naming, the qualified form is a *schema-name* followed by a slash (/) followed by an SQL identifier¹⁸.

The unqualified form of a *trigger-name* is an SQL identifier. The unqualified form is implicitly qualified based on the rules specified in [“Qualification of unqualified object names” on page 57](#).

variable-name

A qualified or unqualified name that designates a global variable. The qualified form of a *variable-name* depends upon the naming option. For SQL naming, the qualified form is a *schema-name* followed by a period (.) and an SQL identifier. For system naming, the qualified form is a *schema-name* followed by a slash (/) followed by an SQL identifier¹⁸. For system naming, a *variable-name* cannot be qualified with a slash when used in an expression (the slash-qualified form is only allowed in SQL schema statements). The period form of qualification can be used in an expression.

The unqualified form of a *variable-name* is an SQL identifier. The unqualified form is implicitly qualified based on the rules specified in [“Qualification of unqualified object names” on page 57](#).

A *variable-name* can specify either the name of the variable or the system object name of the variable.

version-id

An identifier of 1 to 64 characters that is assigned to a package when the package is created. A *version-id* is only assigned when packages are created from a server other than Db2 for i.

view-name

A qualified or unqualified name that designates a view. The qualified form of a *view-name* depends upon the naming option. For SQL naming, the qualified form is a *schema-name* followed by a period (.) and an SQL identifier. For system naming, the qualified form is a *schema-name* followed by a slash (/) followed by an SQL identifier¹⁸.

The unqualified form of a *view-name* is an SQL identifier. The unqualified form is implicitly qualified based on the rules specified in [“Qualification of unqualified object names” on page 57](#).

A *view-name* can specify either the name of the view or the system object name of the view.

xsobject-name

A qualified or unqualified name that designates an object in the XML schema repository. The qualified form of an *xsobject-name* depends upon the naming option. For SQL naming, the qualified form is a *schema-name* followed by a period (.) and an SQL identifier. For system naming, the qualified form is a *schema-name* followed by a slash (/) followed by an SQL identifier¹⁸.

The unqualified form of an *xsobject-name* is an SQL identifier. The unqualified form is implicitly qualified based on the rules specified in [“Qualification of unqualified object names” on page 57](#).

Table 5. Identifier Length Limits (in bytes)

Identifier Type	Maximum Length
Longest authorization name ¹⁹	10
Longest correlation name	128
Longest cursor name	128
Longest external program name (string form)	279
Longest external program name (unqualified form) ²⁰	10
Longest host identifier	64
Longest package version-id	64
Longest partition name	10
Longest savepoint name	128
Longest schema name	128
Longest server name	18
Longest SQL condition name	128
Longest SQL descriptor name	128
Longest SQL label	128
Longest statement name	128
Longest unqualified alias name	128
Longest unqualified array type name	128
Longest unqualified column name	128
Longest unqualified constraint name	128
Longest unqualified distinct type name	128
Longest unqualified function name	128
Longest unqualified index name	128
Longest unqualified mask name	128
Longest unqualified nodegroup name	10
Longest unqualified package name	10
Longest unqualified permission name	128
Longest unqualified procedure name	128
Longest unqualified sequence name	128
Longest unqualified specific name	128
Longest unqualified SQL parameter name	128
Longest unqualified SQL variable name	128
Longest unqualified system column name	10
Longest unqualified system object name	10
Longest unqualified system schema name	10

Table 5. Identifier Length Limits (in bytes) (continued)

Identifier Type	Maximum Length
Longest unqualified table and view name	128
Longest unqualified trigger name	128
Longest unqualified variable name	128
Longest unqualified XSR object name	128

¹⁹ As an application requester, the system can send an authorization name of up to 255 bytes.

²⁰ For REXX procedures, the limit is 33.

SQL path

The *SQL path* is an ordered list of schema names. The database manager uses the path to resolve the schema name for unqualified type names (built-in types, distinct types, and array types), function names, variable names, and procedure names that appear in any context other than as the main object of an ALTER, CREATE, DROP, COMMENT, LABEL, GRANT, or REVOKE statement.

For example, if the SQL path is SMITH, XGRAPHIC, QSYS, QSYS2 and an unqualified distinct type name MYTYPE was specified, database manager looks for MYTYPE first in schema SMITH, then XGRAPHIC, and then QSYS and QSYS2.

The SQL path used depends on the SQL statement:

- For static SQL statements (except for a CALL *variable* statement), the path used is the value of the SQLPATH parameter on the CRTSQLxxx command. The SQLPATH can also be set using the SET OPTION statement.

The path stored in programs, modules, service programs, routines, and triggers, is composed entirely of the *system-schema-names* associated with the schema names in the path. If the *system-schema-name* of a schema is renamed, it may be necessary to recreate these objects if they use SQL statements that depend on the path.

- For dynamic SQL statements (and for a CALL *variable* statement), the path used is the value of the CURRENT PATH special register. For more information about the CURRENT PATH special register, see [“CURRENT PATH” on page 126](#).

If the SQL path is not explicitly specified, the SQL path is the system path followed by the run-time authorization ID of the statement.

For more information about the SQL path for dynamic SQL, see [“CURRENT PATH” on page 126](#).

Qualification of unqualified object names

Unqualified object names are implicitly qualified. The rules for qualifying a name differ depending on the type of object that the name identifies.

Unqualified alias, constraint, external program, index, mask, nodegroup, package, permission, sequence, table, trigger, view, and XSR object names

Unqualified alias, constraint, external program, index, mask, nodegroup, package, permission, sequence, table, trigger, view, and XSR object names are implicitly qualified by the *default schema*.

The *default schema* is specified as follows:

- For static SQL statements:
 - If the DFTRDBCOL parameter is specified on the CRTSQLxxx command (or with the SET OPTION statement), the *default schema* is the *schema-name* that is specified for that parameter.
 - In all other cases, the *default schema* is based on the naming convention.
 - For SQL naming, the *default schema* is the authorization identifier of the statement.
 - For system naming, the *default schema* is the job library list (*LIBL).
- For dynamic SQL statements the *default schema* depends on whether a *default schema* has been explicitly specified. The mechanism for explicitly specifying this depends on the interface used to dynamically prepare and execute SQL statements.
 - If a *default schema* is not explicitly specified:
 - For SQL naming, the *default schema* is the run-time authorization identifier.
 - For system naming, the *default schema* is the job library list (*LIBL).
 - The *default schema* is explicitly specified through the following interfaces:

<i>Table 6. Default Schema Interfaces</i>	
SQL Interface	Specification
Embedded SQL	DFTRDBCOL parameter and DYNDFTCOL(*YES) on the Create SQL Program (CRTSQLxxx) and Create SQL Package (CRTSQLPKG) commands. The SET OPTION statement can also be used to set the DFTRDBCOL and DYNDFTCOL values. (For more information about CRTSQLxxx commands, see Embedded SQL Programming .)
Run SQL Statements	DFTRDBCOL parameter on the Run SQL Statements (RUNSQLSTM) command. (For more information about the RUNSQLSTM command, see SQL Programming .)
Call Level Interface (CLI) on the server	SQL_ATTR_DEFAULT_LIB or SQL_ATTR_DBC_DEFAULT_LIB environment or connection variables (For more information about CLI, see SQL Call Level Interfaces (ODBC) .)
JDBC or SQLJ on the server using IBM IBM Developer Kit for Java	libraries property object (For more information about JDBC and SQLJ, see IBM Developer Kit for Java .)
ODBC on a client using the IBM i Access Family ODBC Driver	SQL Default Schema in ODBC Setup (For more information about ODBC, see IBM i Access .)
JDBC on a client using the IBM Toolbox for Java	SQL Default Schema in JDBC Setup (For more information about JDBC, see IBM i Access .) (For more information about the IBM Toolbox for Java, see IBM Toolbox for Java .)
OLE DB on a client using the IBM i Access Family OLE DB Provider	DefaultCollection in Connection Object Properties (For more information about OLE DB, see IBM i Access .)
ADO .NET on a client using the IBM i Access Family ADO .NET Provider	DefaultCollection in Connection Object Properties (For more information about ADO .NET, see IBM i Access .)
All interfaces	SET SCHEMA or QSQCHGDC (Change Dynamic Default Collection) API (For more information about QSQCHGDC, see the File APIs category.)

Unqualified function, procedure, specific name, type, and variables

The qualification of function, procedure, specific name, type (built-in types, distinct types, and array types), and variables, depends on the SQL statement in which the unqualified name appears.

- If an unqualified name is the main object of an ALTER, CREATE, COMMENT, LABEL, DROP, GRANT, or REVOKE statement, the name is implicitly qualified using the same rules as for qualifying unqualified table names (See [“Unqualified alias, constraint, external program, index, mask, nodegroup, package, permission, sequence, table, trigger, view, and XSR object names”](#) on page 57).
- Otherwise, the implicit schema name is determined as follows:
 - For type names, database manager searches the SQL path and selects the first schema in the path such that the data type exists in the schema.
 - For variable names, database manager searches the SQL path and selects the first schema in the path such that the schema contains an authorized variable with the same name
 - For procedure names, database manager searches the SQL path and selects the first schema in the path such that the schema contains an authorized procedure with the same name and number of parameters.
 - For function names, database manager uses the SQL path in conjunction with function resolution, as described under [“Function resolution”](#) on page 149.
 - For specific names specified for sourced functions, see [“CREATE FUNCTION \(sourced\)”](#) on page 1018.

SQL names and system names: special considerations

The CL command Override Database File (OVRDBF) can be specified to override an SQL or system name with another object name for local data manipulation SQL statements. Overrides are ignored for data definition SQL statements and data manipulation SQL statements executing at a remote relational database.

See the [Database file management](#) topic for more information about the override function.

Aliases

An *alias* can be thought of as an alternative name for a table, partition of a table, view, or member of a database file. A table or view in an SQL statement can be referenced by its name or by an alias. An alias can refer to a table, partition of a table, view, or database file member within the same or a remote relational database.

An alias can be used wherever a table or view name can be used, except:

- Do not use an alias name where a new table or view name is expected, such as in the CREATE TABLE or CREATE VIEW statements. For example, if an alias name of PERSONNEL is created, then a subsequent statement such as CREATE TABLE PERSONNEL will cause an error.
- An alias that refers to an individual partition of a table or member of a database file can only be used in a select statement, CREATE INDEX, DELETE, INSERT, MERGE, SELECT INTO, SET variable, UPDATE, or VALUES INTO statement.

Aliases can also help avoid using file overrides. Not only does an alias perform better than an override, but an alias is also a permanent object that only need be created once.

An alias can be created even though the object that the alias refers to does not exist. However, the object must exist when a statement that references the alias is executed. A warning is returned if the object does not exist when the alias is created. An alias cannot refer to another alias.

Statements that use three-part names and refer to distributed data, result in DRDA access to the remote relational database. When an application program uses three-part name aliases for remote objects and DRDA access, the application program must be bound at each location that is specified in the three-part names. Also, each alias needs to be defined at the local site. An alias at a remote site can refer to yet another server as long as a referenced alias eventually refers to a table or view.

The option of referring to a table, partition of a table, view, or database file member by an alias name is not explicitly shown in the syntax diagrams or mentioned in the description of the SQL statements.

A new alias cannot have the same fully-qualified name as an existing table, view, index, file, or alias.

The effect of using an alias in an SQL statement is similar to that of text substitution. The alias, which must be defined before the SQL statement is executed, is replaced at statement preparation time by the qualified base table, partition of a table, view, or database file member name. For example, if PBIIRD.SALES is an alias for DSPN014.DIST4_SALES_148, then at statement run time:

```
SELECT * FROM PBIIRD.SALES
```

effectively becomes

```
SELECT * FROM DSPN014.DIST4_SALES_148
```

The effect of dropping an alias and recreating it to refer to another table depends on the statement that references the alias.

- SQL Data or SQL Data Change statements that refer to that alias will be implicitly rebound when they are next run.
- Indexes that reference the alias are not affected.
- Materialized query tables or views that reference the alias are not affected.

For syntax toleration of existing Db2 for z/OS applications, SYNONYM can be used in place of ALIAS in the CREATE ALIAS and DROP ALIAS statements.

Authorization IDs and authorization names

An *authorization ID* is a character string that is obtained by the database manager when a connection is established between the database manager and either an application process or a program preparation process. It designates a set of privileges. It may also designate a user or a group of users, but this property is not controlled by the database manager.

After a connection has been established, the authorization ID may be changed using the SET SESSION AUTHORIZATION statement.

Authorization ID's are used by the database manager to provide authorization checking of SQL statements.

When the authorization ID of the statement is the owner of the program or service program, that is known as adopted authority. The authorization ID adopts and uses the authority of the program owner in addition to the runtime authorization ID.

Multiple levels of adopted authority are possible when nested calls occur to programs or service programs that use the owner of the program as the statement authorization ID. Adopted authority is tracked at the thread level. The CURRENT USER special register can be used to return the authorization ID of the most recently adopted authority. The enforcement of statement authorization requirements will consider all levels of adopted authority. When a dynamic SQL statement is executed with DYNUSRPRF value of *USER, all levels of adopted authority are suppressed.

An authorization ID applies to every SQL statement. The authorization ID that is used for authorization checking for a static SQL statement depends on the USRPRF value specified on the precompiler command:

- If USRPRF(*OWNER) is specified, or if USRPRF(*NAMING) is specified and SQL naming mode is used, the authorization ID of the statement is the owner of the non-distributed SQL program. For distributed SQL programs, it is the owner of the SQL package.
- If USRPRF(*USER) is specified, or if USRPRF(*NAMING) is specified and system naming mode is used, the authorization ID of the statement is the authorization ID of the user running the non-distributed SQL program. For distributed SQL programs, it is the authorization ID of the user at the current server.

The authorization ID that is used for authorization checking for a dynamic SQL statement also depends on where and how the statement is executed:

- If the statement is prepared and executed from a non-distributed program:
 - If the USRPRF value is *USER and the DYNUSRPRF value is *USER for the program, the authorization ID that applies is the ID of the user running the non-distributed program. This is called the *run-time authorization ID*.
 - If the USRPRF value is *OWNER and the DYNUSRPRF value is *USER for the program, the authorization ID that applies is the ID of the user running the non-distributed program.
 - If the USRPRF value is *OWNER and the DYNUSRPRF value is *OWNER for the program, the authorization ID that applies is the ID of the owner of the non-distributed program.
- If the statement is prepared and executed from a distributed program:
 - If the USRPRF value is *USER and the DYNUSRPRF value is *USER for the SQL package, the authorization ID that applies is the ID of the user running the SQL package at the current server. This is also called the run-time authorization ID.
 - If the USRPRF value is *OWNER and the DYNUSRPRF value is *USER for the SQL package, the authorization ID that applies is the ID of the user running the SQL package at the current server.
 - If the USRPRF value is *OWNER and the DYNUSRPRF value is *OWNER for the SQL package, the authorization ID that applies is the ID of the owner of the SQL package at the current server.
- If the statement is issued interactively, the authorization ID that applies is the ID of the user that issued the Start SQL (STRSQL) command.

- If the statement is executed from the RUNSQLSTM command, the authorization ID that applies is the ID of the user that issued the RUNSQLSTM command.
- If the statement is executed from REXX, the authorization ID that applies is the ID of the user that issued the STRREXPRC command.

On the IBM i operating system, the run-time authorization ID is the user profile of the thread.

An *authorization-name* specified in an SQL statement should not be confused with the authorization ID of the statement. An authorization-name is an identifier that is used in GRANT and REVOKE statements to designate a target of the grant or revoke. The premise of a grant of privileges to *X* is that *X* will subsequently be the authorization ID of statements which require those privileges. A group user profile can also be used when checking authority for an SQL statement. For information about group user profiles, see [Security Reference](#).

Example

Assume SMITH is your user ID; then SMITH is the authorization ID when you execute the following statement interactively:

```
GRANT SELECT ON TDEPT TO KEENE
```

SMITH is the authorization ID of the statement. Thus, the authority to execute the statement is checked against SMITH.

KEENE is an authorization-name specified in the statement. KEENE is given the SELECT privilege on SMITH.TDEPT.

Procedure resolution

Given a procedure invocation, Db2 must decide which of the possible procedures with the same name to execute.

- Let A be the number of arguments in a procedure invocation.
- Let P be the number of parameters in a procedure signature.
- Let N be the number of parameters without a default.

Candidate procedures for resolution of a procedure invocation are selected based on the following criteria:

- Each candidate procedure has a matching name and an applicable number of parameters. An applicable number of parameters satisfies the condition $N \leq A \leq P$.
- Each candidate procedure has parameters such that for each named argument in the CALL statement there exists a parameter with a matching name that does not already correspond to a positional (or unnamed) argument.
- Each parameter of a candidate procedure that does not have a corresponding argument in the CALL statement, specified by either position or name, is defined with a default.
- Each candidate procedure from a set of one or more schemas has the EXECUTE privilege associated with the authorization ID of the CALL statement. The authorities of any objects referenced in a default expression are not considered.

In addition, the set of candidate procedures depends on how the procedure name is qualified.

- If the procedure name is unqualified, procedure resolution is done as follows:

Search all procedures with a schema in the SQL path for candidate procedures. If one or more candidate procedures are found in the schemas of the SQL path, then these candidate procedures are included in the candidate list. If there is a single candidate procedure in the list, resolution is complete. If there are multiple candidate procedures, choose the procedure whose schema is earliest in the SQL path. If there are still multiple candidate procedures, select the candidate procedure with the lowest number of parameters.

If there are no candidate procedures, an error is returned.

- If the procedure name is qualified, procedure resolution is done as follows:

Search within the schema specified by the qualifier for candidate procedures. If a single candidate procedure exists, resolution is complete. If there are multiple candidate procedures, choose the candidate procedure with the lowest number of parameters and resolution is complete. If the schema does not exist or there are no authorized candidate procedures, an error is returned.

Example 1: There are six FOO procedures, in four different schemas, registered as follows (note that not all required keywords appear):

```
CREATE PROCEDURE AUGUSTUS.FOO (INT) SPECIFIC FOO_1 ...
CREATE PROCEDURE AUGUSTUS.FOO (DOUBLE, DECIMAL(15, 3)) SPECIFIC FOO_2 ...
CREATE PROCEDURE JULIUS.FOO (INT) SPECIFIC FOO_3 ...
CREATE PROCEDURE JULIUS.FOO (INT, INT, INT) SPECIFIC FOO_4 ...
CREATE PROCEDURE CAESAR.FOO (INT, INT) SPECIFIC FOO_5 ...
CREATE PROCEDURE NERO.FOO (INT,INT) SPECIFIC FOO_6 ...
```

The procedure reference is as follows (where I1 and I2 are INTEGER values):

```
CALL FOO(I1, I2)
```

Assume that the application making this reference has an SQL path established as:

```
"JULIUS", "AUGUSTUS", "CAESAR"
```

Following through the algorithm, the procedure with specific name FOO_6 is eliminated as a candidate, because the schema "NERO" is not included in the SQL path. FOO_1, FOO_3, and FOO_4 are eliminated

as candidates, because they have the wrong number of parameters. The remaining candidates are considered in order, as determined by the SQL path. Note that the types of the arguments and parameters are ignored. The parameters of FOO_5 exactly match the arguments in the CALL, but FOO_2 is chosen because "AUGUSTUS" appears before "CAESAR" in the SQL path.

Example 2: The following examples illustrate procedure resolution using named parameters in the CALL statement:

```
CREATE PROCEDURE p1(i1 INT) ...  
CREATE PROCEDURE p1(i1 INT DEFAULT 0, i2 INT DEFAULT 0) ...  
CALL p1(i2=>1)
```

Since the argument names are taken into consideration during the candidate selection process, only the second version of p1 will be considered a candidate. Furthermore, it can be successfully called because i1 in this version of p1 is defined with a default, so only specifying i2 on the call to p1 is valid. The procedure will be passed a value of 0 for parameter i1.

```
CREATE PROCEDURE p2(i1 INT, i2 INT DEFAULT 0) ...  
CREATE PROCEDURE p2(i1 INT DEFAULT 0, i2 INT DEFAULT 0, i3 INT DEFAULT 0) ...  
CALL p2(i2=>1)
```

One of the criteria for a procedure parameter which does not have a corresponding argument in the CALL statement (specified by either position or name) is that the parameter is defined with a default value. Therefore, the first version of p2 is not considered a candidate since parameter i1 does not have a default defined. The second version of p2 will be selected and the default values for the first and third parameters will be passed.

Data types

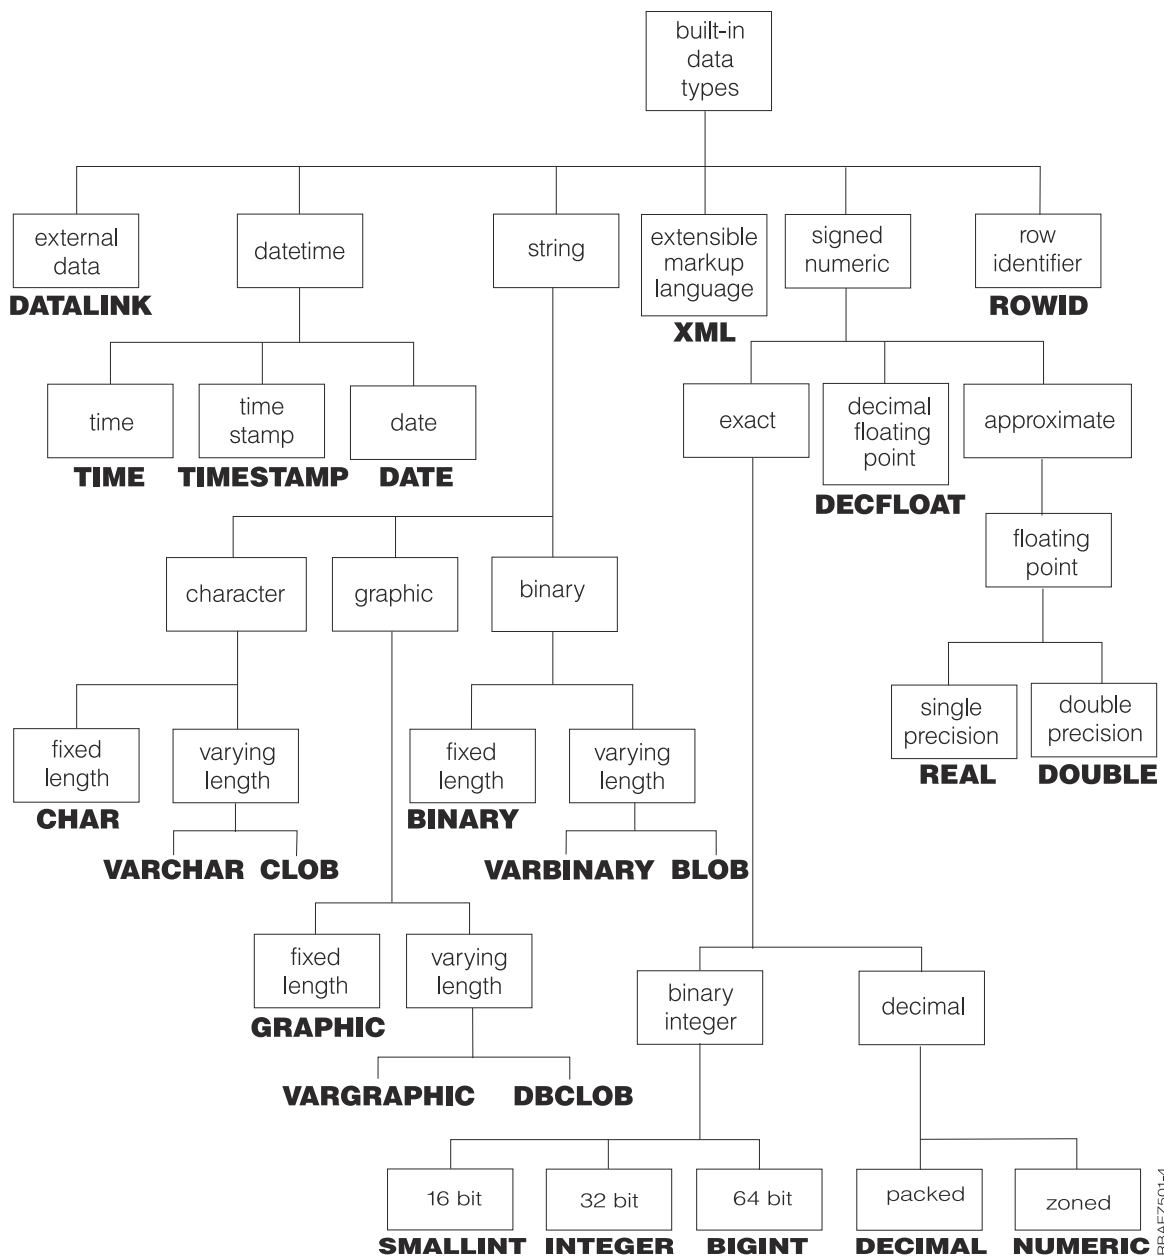

The smallest unit of data that can be manipulated in SQL is called a *value*.

How values are interpreted depends on the *attributes* of their source, which includes the data type, length, precision, scale, and CCSID. The sources of values are:

- Columns
- Constants
- Expressions
- Functions
- Special registers
- Variables (such as host variables, SQL variables, global variables, parameter markers and parameters of routines)

The Db2 relational database products support both built-in data types and user-defined data types. This section describes the built-in data types. For a description of distinct types, see [“User-defined types” on page 82](#).

The following figure illustrates the various built-in data types supported by Db2 for i.

For information about specifying the data types of columns, see [“CREATE TABLE”](#) on page 1115.

Nulls

All data types include the null value. Distinct from all non-null values, the null value is a special value that denotes the absence of a (non-null) value.

Except for grouping operations, a null value is also distinct from another null value. Although all data types include the null value, some sources of values cannot provide the null value. For example, constants and columns that are defined as NOT NULL cannot contain null values, the COUNT and COUNT_BIG functions cannot return a null value, and ROWID columns cannot store a null value although a null value can be returned for a ROWID column as the result of a query.

Numbers

The numeric data types are binary integer, decimal, decimal floating-point, and floating-point.

The numeric data types are categorized as follows:

- Exact numerics: binary integer and decimal
- Decimal floating-point
- Approximate numerics: floating-point

Binary integer includes small integer, large integer, and big integer. Binary numbers are exact representations of integers. Decimal numbers are exact representations of numbers with a fixed precision and scale. Binary and decimal numbers are considered exact numeric types.

Decimal floating-point numbers can have a precision of 16 or 34. Decimal floating-point supports both exact representations of real numbers and approximations of real numbers and so is not considered either an exact numeric type or an approximate numeric type.

Floating-point includes single precision and double precision. Floating-point numbers are approximations of real numbers and are considered approximate numeric types.

All numbers have a *sign*, a *precision*, and a *scale*. For all numbers except decimal floating-point, if a column or expression is zero, the sign is positive. Decimal floating-point numbers include negative and positive zeros. Decimal floating-point has distinct values for a number and the same number with various exponents (for example: 0.0, 0.00, 0.0E5, 1.0, 1.00, 1.0000). The precision is the total number of digits excluding the sign. The scale is the total number of digits to the right of the decimal point. If there is no decimal point, the scale is zero.

Small integer

A *small integer* is a binary number composed of 2 bytes with a precision of 5 digits. The range of small integers is -32 768 to +32 767.

For small integers, decimal precision and scale are supported by COBOL, RPG, and IBM i system files. For information concerning the precision and scale of binary integers, see the [DDS Reference](#) topic.

Large integer

A *large integer* is a binary number composed of 4 bytes with a precision of 10 digits. The range of large integers is -2 147 483 648 to +2 147 483 647.

For large integers, decimal precision and scale are supported by COBOL, RPG, and IBM i system files. For information concerning the precision and scale of binary integers, see the [DDS Reference](#) topic.

Big integer

A *big integer* is a binary number composed of 8 bytes with a precision of 19 digits. The range of big integers is -9 223 372 036 854 775 808 to +9 223 372 036 854 775 807.

Decimal

A *decimal* value is a packed decimal or zoned decimal number with an implicit decimal point. The position of the decimal point is determined by the precision and the scale of the number. The scale, which is the number of digits in the fractional part of the number, cannot be negative or greater than the precision. The maximum precision is 63 digits.

All values of a decimal column have the same precision and scale. The range of a decimal variable or the numbers in a decimal column is $-n$ to $+n$, where the absolute value of n is the largest number that can be represented with the applicable precision and scale.

The maximum range is negative $10^{63}+1$ to 10^{63} minus 1.

Floating-point

A *single-precision floating-point* number is a 32-bit approximate representation of a real number. The range of magnitude is approximately $1.17549436 \times 10^{-38}$ to $3.40282356 \times 10^{38}$.

A *double-precision floating-point* number is a IEEE 64-bit approximate representation of a real number. The range of magnitude is approximately $2.2250738585072014 \times 10^{-308}$ to $1.7976931348623158 \times 10^{308}$.

Single-precision floating-point is generally accurate to 7 digits of precision. Double-precision floating-point is generally accurate to 15 digits of precision.

Decimal floating-point

A *decimal floating-point* number is an IEEE 754R number with a decimal point. The position of the decimal point is stored in each decimal floating-point value. The maximum precision is 34 digits. The range of a decimal floating-point number is either 16 or 34 digits of precision, and an exponent range of 10^{-383} to 10^{384} or 10^{-6143} to 10^{6144} respectively.

The minimum exponent, E_{\min} , for DECFLOAT values is -383 for DECFLOAT(16) and -6143 for DECFLOAT(34). The maximum exponent, E_{\max} , for DECFLOAT values is 384 for DECFLOAT(16) and 6144 for DECFLOAT(34).

In addition to the finite numbers, decimal floating-point numbers can also represent the following three special values (see “[Decimal floating-point constants](#)” on page 112 for more information):

- Infinity - A value that represents a number whose magnitude is infinitely large.
- Quiet NaN - A value that represents undefined results which does not cause an invalid number warning.
- Signaling NaN - A value that represents undefined results which will cause an invalid number warning if used in any numerical operation.²¹

When a number has one of these special values, its coefficient and exponent are undefined. The sign of an infinity is significant (that is, it is possible to have both positive and negative infinity). The sign of a NaN has no meaning for arithmetic operations.

See [Table 128 on page 1644](#) for more information.

Numeric variables

Small and large binary integer variables can be used in all host languages. Big integer variables can only be used in C, C++, ILE COBOL, and ILE RPG. Floating-point variables can be used in all host languages except RPG/400[®] and COBOL/400. Decimal variables can be used in all supported host languages. Decimal floating-point variables can only be used in C.

String representations of numeric values

When a decimal, decimal floating-point, or floating-point number is cast to a string (for example, using a CAST specification) the implicit decimal point is replaced by the default decimal separator character in effect when the statement was prepared. When a string is cast to a decimal, decimal floating-point, or floating-point value (for example, using a CAST specification), the default decimal separator character in effect when the statement was prepared is used to interpret the string.

Subnormal numbers and underflow

The decimal floating-point data type has a set of non-zero numbers that fall outside the range of normal decimal floating-point values. These numbers are called subnormal.

Non-zero numbers whose adjusted exponents are less than E_{\min} (-6143 for DECFLOAT(34) or -383 for DECFLOAT(16)), are called subnormal numbers. These subnormal numbers are accepted as operands for all operations and may result from any operation. If a result is subnormal before any rounding, the subnormal warning is returned.²²

²¹ The warning is only returned if *YES is specified for the SQL_DECFLOAT_WARNINGS query option.

²² The warning is only returned if *YES is specified for the SQL_DECFLOAT_WARNINGS query option.

For a subnormal result, the minimum value of the exponent becomes $E_{\min} - (\text{precision} - 1)$, called E_{tiny} , where precision is the precision of the decimal floating-point number. Hence, the smallest value of the exponent $E_{\text{tiny}} = -6176$ for DECFloat(34) and -398 for DECFloat(16). As the exponent E_{tiny} gets smaller, the number of digits available in the mantissa also decreases. The number of digits available in the mantissa for subnormal numbers is $(\text{precision} - (-E_{\text{tiny}} + E_{\min}))$.

The result will be rounded, if necessary, to ensure that the exponent is no smaller than E_{tiny} . If, during this rounding, the result becomes inexact, an underflow warning is returned.²² A subnormal result does not always return the underflow warning but will always return the subnormal warning.

When a number underflows to zero during a calculation, its exponent will be E_{tiny} . The maximum value of the exponent is unaffected.

The maximum value of the exponent for subnormal numbers is the same as the minimum value of the exponent which can arise during operations that do not result in subnormal numbers. This occurs where the length of the coefficient in decimal digits is equal to the precision.

Character strings

A *character string* is a sequence of bytes. The length of the string is the number of bytes in the sequence. If the length is zero, the value is called the *empty string*. The empty string should not be confused with the null value.

Fixed-length character strings

When fixed-length character string distinct types, columns, and variables are defined, the length attribute is specified and all values have the same length. For a fixed-length character string, the length attribute must be between 1 through 32766 inclusive. See [Appendix A, “SQL limits,” on page 1643](#) for more information.

Varying-length character strings

The types of varying-length character strings are:

- VARCHAR
- CLOB

A *Character Large Object* (CLOB) column is useful for storing large amounts of character data, such as documents written using a single character set.

Distinct types, columns, and variables all have length attributes. When varying-length character-string distinct types, columns, and variables are defined, the maximum length is specified and this becomes the length attribute. Actual values may have a smaller length. For a varying-length character string, the length attribute must be between 1 through 32 740 inclusive. For a CLOB string, the length attribute must be between 1 through 2 147 483 647 inclusive. See [Appendix A, “SQL limits,” on page 1643](#) for more information.

For the restrictions that apply to the use of long varying-length strings, see [“Limitations on use of strings” on page 74](#).

Character-string variables

- Fixed-length character-string variables can be used in all host languages except REXX and Java. (In C or C++, fixed-length character-string variables are limited to a length of 1.)
- VARCHAR varying-length character-string variables can be used in C, C++, COBOL, PL/I, REXX, and RPG:
 - In PL/I, REXX, and ILE RPG, there is a varying-length character-string data type.
 - In COBOL, C, and C++ varying-length character strings are represented as structures.

- In C and C++, varying-length character-string variables can also be represented by NUL-terminated strings.
- In RPG/400, varying-length character-string variables can only be represented by VARCHAR columns included as a result of an externally described data structure.
- CLOB varying-length character-string variables can be defined in all host languages except REXX, RPG/400, and COBOL/400.
 - In ILE RPG, a CLOB varying-length character string is declared using the SQLTYPE keyword.
 - In all other languages, an SQL TYPE IS CLOB clause is used.

Character encoding schemes

Each character string is further defined as one of four types.

Bit data

Data that is not associated with a coded character set and is therefore never converted. The CCSID for bit data is 65535.

Note: Bit data is a form of character data. The pad character is a blank for assignments to bit data; the pad character is X'00' for assignments to binary data. It is recommended that the binary data type be used instead of character for bit data.

SBCS data

Data in which every character is represented by a single byte. Each SBCS data character string has an associated CCSID. If necessary, an SBCS string is converted before it is used in an operation with a character string that has a different CCSID.

Mixed data

Data that may contain a mixture of characters from a single-byte character set (SBCS) and a double-byte character set (DBCS). Each mixed string has an associated CCSID. If necessary, a mixed data character string is converted before an operation with a character string that has a different CCSID. If mixed data contains a DBCS character, it cannot be converted to SBCS data.

Unicode data

Data that contains characters represented by one or more bytes. Each Unicode character string is encoded using UTF-8. The CCSID for UTF-8 is 1208.

The database manager does not recognize subclasses of double-byte characters, and it does not assign any specific meaning to particular double-byte codes. However, if you choose to use mixed data, then two single-byte EBCDIC codes are given special meanings:

- X'0E', the “shift-out” character, is used to mark the beginning of a sequence of double-byte codes.
- X'0F', the “shift-in” character, is used to mark the end of a sequence of double-byte codes.

In order for the database manager to recognize double-byte characters in a mixed data character string, the following condition must be met:

- Within the string, the double-byte characters must be enclosed between paired shift-out and shift-in characters.

The pairing is detected as the string is read from left to right. The code X'0E' is recognized as a shift out character if X'0F' occurs later; otherwise, it is invalid. The first X'0F' following the X'0E' that is on a double-byte boundary is the paired shift-in character. Any X'0F' that is not on a double-byte boundary is not recognized.

There must be an even number of bytes between the paired characters, and each pair of bytes is considered to be a double-byte character. There can be more than one set of paired shift-out and shift-in characters in the string.

The length of a mixed data character string is its total number of bytes, counting two bytes for each double-byte character and one byte for each shift-out or shift-in character.

When the job CCSID indicates that DBCS is allowed, CREATE TABLE will create character columns as DBCS-Open fields, unless FOR BIT DATA, FOR SBCS DATA, or an SBCS CCSID is specified. The SQL user

will see these as character fields, but the system database support will see them as DBCS-Open fields. For a definition of a DBCS-Open field, see the [Database programming](#) topic collection.

Graphic strings

A *graphic string* is a sequence of double-byte characters. The length of the string is the number of its characters. Like character strings, graphic strings can be empty.

Fixed-length graphic strings

When fixed-length graphic-string distinct types, columns, and variables are defined, the length attribute is specified and all values have the same length. For a fixed-length graphic string, the length attribute must be between 1 through 16 383 inclusive. See [Appendix A, “SQL limits,”](#) on page 1643 for more information.

Varying-length graphic strings

- The types of varying-length graphic strings are:
- VARGRAPHIC
- DBCLOB

A *Double-Byte Character Large Object* (DBCLOB) column is useful for storing large amounts of double-byte character data, such as documents written using a double-byte character set.

Distinct types, columns, and variables all have length attributes. When varying-length graphic-string distinct types, columns, and variables are defined, the maximum length is specified and this becomes the length attribute. Actual values may have a smaller length. For a varying-length graphic string, the length attribute must be between 1 through 16 370 inclusive. For a DBCLOB string, the length attribute must be between 1 through 1 073 741 823 inclusive. See [Appendix A, “SQL limits,”](#) on page 1643 for more information.

For the restrictions that apply to the use of long varying-length strings, see [“Limitations on use of strings”](#) on page 74.

Graphic-string variables

- Fixed-length graphic-string variables can be defined in C, C++, ILE COBOL, and ILE RPG. (In C and C++, fixed-length graphic-string variables are limited to a length of 1.)

Although fixed-length graphic-string variables cannot be defined in PL/I, COBOL/400, and RPG/400, a character-string variable will be treated like a fixed-length graphic-string variable if it was generated in the source from a GRAPHIC column in the external definition of a file.

- VARGRAPHIC varying-length graphic-string variables can be defined in C, C++, ILE COBOL, REXX, and ILE RPG.
 - In REXX and ILE RPG, there is a varying-length graphic-string data type.
 - In C, C++, and ILE COBOL, varying-length graphic strings are represented as structures.
 - In C and C++, varying-length graphic-string variables can also be represented by NUL-terminated graphic strings.
 - Although varying-length graphic-string variables cannot be defined in PL/I, COBOL/400, and RPG/400, a character-string variable will be treated like a varying-length graphic-string variable if it was generated in the source from a VARGRAPHIC column in the external definition of a file.
- DBCLOB varying-length character-string variables can be defined in all host languages except REXX, RPG/400, and COBOL/400.
 - In ILE RPG, a DBCLOB varying-length character string is declared using the SQLTYPE keyword.
 - In all other languages, an SQL TYPE IS DBCLOB clause is used.

Graphic encoding schemes

Each graphic string is further defined as one of two types.

DBCS data

Data in which every character is represented by a character from the double-byte character set (DBCS) that does not include the shift-out or shift-in characters.

Every DBCS graphic string has a CCSID that identifies a double-byte coded character set. If necessary, a DBCS graphic string is converted before it is used in an operation with a DBCS graphic string that has a different DBCS CCSID.

Unicode data

Data that contains characters represented by two or more bytes. Each Unicode graphic string is encoded using either UCS-2 or UTF-16. UCS-2 is a subset of UTF-16. The CCSID for UCS-2 is 13488. The CCSID for UTF-16 is 1200.

NCHAR, NVARCHAR, and NCLOB are synonyms for Unicode graphic data with a CCSID of 1200.

When graphic-string variables are not explicitly tagged with a CCSID, the associated DBCS CCSID for the job CCSID is used. If no associated DBCS CCSID exists, the variable is tagged with 65535. A graphic-string variable is never implicitly tagged with a UTF-16 or UCS-2 CCSID. See the DECLARE VARIABLE statement for information on how to tag a graphic variable with a CCSID.

Binary strings

A *binary string* is a sequence of bytes. Unlike a character string which usually contains text data, a binary string is used to hold non-traditional data such as pictures. The length of a binary string is the number of bytes in the sequence. A binary string has a CCSID of 65535. Only character strings of FOR BIT DATA are compatible with binary strings.

Fixed-length binary strings

When fixed-length binary-string distinct types, columns, and variables are defined, the length attribute is specified and all values have the same length. For a fixed-length binary string, the length attribute must be between 1 through 32 766 inclusive. See [Appendix A, “SQL limits,” on page 1643](#) for more information.

Varying-length binary strings

The types of varying-length binary strings are:

- VARBINARY
- BLOB

A *Binary Large Object* (BLOB) column is useful for storing large amounts of noncharacter data, such as pictures, voice, and mixed media. Another use is to hold structured data for exploitation by distinct types and user-defined functions.

Distinct types, columns, and variables all have length attributes. When varying-length binary-string distinct types, columns, and variables are defined, the maximum length is specified and this becomes the length attribute. Actual values may have a smaller length. For a varying-length binary string, the length attribute must be between 1 through 32 740 bytes inclusive. For a BLOB string, the length attribute must be between 1 through 2 147 483 647 inclusive. See [Appendix A, “SQL limits,” on page 1643](#) for more information.

Binary-string variables

A variable with a binary string type can be defined in all host languages except REXX, RPG/400, and COBOL/400.

- BINARY fixed-length binary-string variables can be defined in all host languages except REXX, RPG/400, and COBOL/400.

- In ILE RPG, a BINARY fixed-length binary-string variable is declared using the SQLTYPE keyword.
- In all other languages, an SQL TYPE IS BINARY clause is used.
- VARBINARY varying-length binary-string variables can be defined in all host languages except REXX, RPG/400, and COBOL/400.
 - In ILE RPG, a VARBINARY varying-length binary-string variable is declared using the SQLTYPE keyword.
 - In all other languages, an SQL TYPE IS VARBINARY clause is used.
- BLOB varying-length binary-string variables can be defined in all host languages except REXX, RPG/400, and COBOL/400.
 - In ILE RPG, a BLOB varying-length binary-string variable is declared using the SQLTYPE keyword.
 - In all other languages, an SQL TYPE IS BLOB clause is used.

Large objects

The term *large object* and the generic acronym *LOB* are used to refer to any CLOB, DBCLOB, or BLOB data type.

Manipulating large objects with locators

Since LOB values can be very large, the transfer of these values from the database server to client application program variables can be time consuming. Also, application programs typically process LOB values a piece at a time, rather than as a whole. For these cases, the application can reference a LOB value via a large object locator (LOB locator).²³ When using a LOB locator, the application must be run under commitment control.

A *large object locator* or LOB locator is a variable with a value that represents a single LOB value in the database server. LOB locators were developed to provide users with a mechanism by which they could easily manipulate very large objects in application programs without requiring them to store the entire LOB value on the client machine where the application program may be running.

For example, when selecting a LOB value, an application program could select the entire LOB value and place it into an equally large variable (which is acceptable if the application program is going to process the entire LOB value at once), or it could instead select the LOB value into a LOB locator. Then, using the LOB locator, the application program can issue subsequent database operations on the LOB value by supplying the locator value as input. The resulting output of the locator operation, for example the amount of data assigned to a client variable, would then typically be a small subset of the input LOB value.

LOB locators may also represent more than just base values; they can also represent the value associated with a LOB expression. For example, a LOB locator might represent the value associated with:

```
SUBSTR(lob_value_1 CONCAT lob_value_2 CONCAT lob_value_3, 42, 6000000)
```

For non-locator-based host variables in an application program, when a null value is selected into that host variable, the indicator variable is set to -1, signifying that the value is null. In the case of LOB locators, however, the meaning of indicator variables is slightly different. Since a LOB locator host variable itself can never be null, a negative indicator variable value indicates that the LOB value represented by the LOB locator is null. The null information is kept local to the client by virtue of the indicator variable value -- the server does not track null values with valid LOB locators.

It is important to understand that a LOB locator represents a value, not a row or location in the database. Once a value is selected into a LOB locator, there is no operation that one can perform on the original row or table that will affect the value which is referenced by the LOB locator. The value associated with a LOB locator is valid until the transaction ends, or until the LOB locator is explicitly freed, whichever comes first.

²³ There is no ability within a Java application to distinguish between a CLOB or BLOB that is represented by a LOB locator and one that is not.

A LOB locator is only a mechanism used to refer to a LOB value during a transaction; it does not persist beyond the transaction in which it was created. Also, it is not a database type; it is never stored in the database and, as a result, cannot participate in views or check constraints. However, since a locator is a representation of a LOB type, there are SQLTYPEs for LOB locators so that they can be described within an SQLDA structure that is used by FETCH, OPEN, CALL, and EXECUTE statements.

For the restrictions that apply to the use of LOB strings, see [“Limitations on use of strings” on page 74](#).

Limitations on use of strings

Some varying-length string data types cannot be referenced in certain contexts.

The following varying-length string data types cannot be referenced in certain contexts:

- for character strings, any CLOB string
- for graphic strings, any DBCLOB string
- for binary strings, any BLOB string.

Table 7. Contexts for limitations on use of varying-length strings

Context of usage	LOB (CLOB, DBCLOB, or BLOB)
The CREATE INDEX statement	Not allowed
The definition of primary, unique, and foreign keys	Not allowed
Parameters of built-in functions	Some functions that allow varying-length character strings, varying-length graphic strings, or both types of strings as input arguments do not support CLOB or DBCLOB strings, or both as input. See the description of the individual functions in Chapter 4, “Built-in functions,” on page 243 for the data types that are allowed as input to each function.

Datetime values

Although datetime values can be used in certain arithmetic and string operations and are compatible with certain strings, they are neither strings nor numbers.

However, strings can represent datetime values; see [“String representations of datetime values” on page 75](#).

Date

A *date* is a three-part value (year, month, and day) designating a point in time under the Gregorian calendar, which is assumed to have been in effect from the year 1 A.D.

The range of the year part is 0001 to 9999.²⁴ The date formats *JUL, *MDY, *DMY, and *YMD can only represent dates in the range 1940 through 2039. The range of the month part is 1 to 12. The range of the day part is 1 to *x*, where *x* is 28, 29, 30, or 31, depending on the month and year.

The internal representation of a date is a string of 4 bytes that contains an integer. The integer (called the Scaliger number) represents the date.

The length of a DATE column as described in the SQLDA is 6, 8, or 10 bytes, depending on which format is used. These are the appropriate lengths for string representations for the value.

²⁴ Note that historical dates do not always follow the Gregorian calendar. Dates between 1582-10-04 and 1582-10-15 are accepted as valid dates although they never existed in the Gregorian calendar.

Time

A *time* is a three-part value (hour, minute, and second) designating a time of day using a 24-hour clock.

The range of the hour part is 0 to 24, while the range of the minute and second parts is 0 to 59. If the hour is 24, the minute and second specifications are both zero.

The internal representation of a time is a string of 3 bytes. Each byte consists of two packed decimal digits. The first byte represents the hour, the second byte the minute, and the last byte the second.

The length of a TIME column as described in the SQLDA is 8 bytes, which is the appropriate length for a string representation of the value.

Timestamp

A *timestamp* is a six or seven part value (year, month, day, hour, minute, second, and optional fractional second) that represents a date and time.

The time portion of a timestamp value can include a specification of fractional seconds. The number of digits in the fractional seconds is specified using an attribute in the range from 0 to 12 with a default of 6

The internal representation of a timestamp is a string of between 7 and 13 bytes. The first 4 bytes represent the date, the next 3 bytes the time, and the last 0 to 6 bytes the fractional seconds.

Datetime variables

Character string variables are normally used to contain date, time, and timestamp values.

The ILE RPG and ILE COBOL precompilers support datetime variables.

Date, time, and timestamp variables can also be specified in Java as `java.sql.Date`, `java.sql.Time`, and `java.sql.Timestamp`, respectively.

String representations of datetime values

Values whose data types are DATE, TIME, or TIMESTAMP are represented in an internal form that is transparent to the user of SQL. Dates, times, and timestamps, however, can also be represented by character or Unicode graphic strings.

To be retrieved, a datetime value can be assigned to a string variable. The format of the resulting string will depend on the *default date format* and the *default time format* in effect when the statement was prepared. The default date and time formats are set based on the date format (DATFMT), the date separator (DATSEP), the time format (TIMFMT), and the time separator (TIMSEP) parameters.

When a valid string representation of a datetime value is used in an operation with an internal datetime value, the string representation is converted to the internal form of the date, time, or timestamp before the operation is performed. The *default date format* and *default time format* specifies the date and time format that will be used to interpret the string. If the CCSID of the string represents a foreign encoding scheme (for example, ASCII), it is first converted to the coded character set identified by the default CCSID before the string is converted to the internal form of the datetime value.

The following sections define the valid string representations of datetime values.

Date strings

A string representation of a date is a character or a Unicode graphic string that starts with a digit and has a length of at least 6 characters. Trailing blanks can be included. Leading zeros can be omitted from the month and day portions when using the IBM SQL standard formats. Each IBM SQL standard format is identified by name and includes an associated abbreviation (for use by the CHAR function). Other formats do not have an abbreviation to be used by the CHAR function. The separators for two-digit year formats are controlled by the date separator (DATSEP) parameter.

Valid string formats for dates are listed in [Table 8 on page 76](#).

The database manager recognizes the string as a date when it is in one of the following formats:

- In the format specified by the default date format
- In one of the IBM SQL standard date formats
- In the unformatted Julian format

Table 8. Formats for String Representations of Dates

Format Name	Abbreviation	Date Format	Example
International Standards Organization (*ISO)	ISO	'yyyy-mm-dd'	'1987-10-12'
IBM USA standard (*USA)	USA	'mm/dd/yyyy'	'10/12/1987'
IBM European standard (*EUR)	EUR	'dd.mm.yyyy'	'12.10.1987'
Japanese industrial standard Christian era (*JIS)	JIS	'yyyy-mm-dd'	'1987-10-12'
Unformatted Julian	–	'yyyyddd'	'1987285'
Julian (*JUL)	–	'yy/ddd'	'87/285'
Month, day, year (*MDY)	–	'mm/dd/yy'	'10/12/87'
Day, month, year (*DMY)	–	'dd/mm/yy'	'12/10/87'
Year, month, day (*YMD)	–	'yy/mm/dd'	'87/12/10'

The default date format can be specified through the following interfaces:

Table 9. Default Date Format Interfaces

SQL Interface	Specification
Embedded SQL	<p>The DATFMT and DATSEP parameters are specified on the Create SQL Program (CRTSQLxxx) commands. The SET OPTION statement can also be used to specify the DATFMT and DATSEP parameters within the source of a program containing embedded SQL.</p> <p>(For more information about CRTSQLxxx commands, see the Embedded SQL programming topic collection.)</p>
Interactive SQL and Run SQL Statements	<p>The DATFMT and DATSEP parameters on the Start SQL (STRSQL) command or by changing the session attributes. The DATFMT and DATSEP parameters on the Run SQL Statements (RUNSQLSTM) command.</p> <p>(For more information about STRSQL and RUNSQLSTM commands, see SQL programming.)</p>
Call Level Interface (CLI) on the server	<p>SQL_ATTR_DATE_FMT and SQL_ATTR_DATE_SEP environment or connection variables</p> <p>(For more information about CLI, see SQL Call Level Interfaces (ODBC).)</p>
JDBC or SQLJ on the server using IBM IBM Developer Kit for Java	<p>Date Format and Date Separator connection property</p> <p>(For more information about JDBC and SQLJ, see IBM Developer Kit for Java.)</p>

Table 9. Default Date Format Interfaces (continued)

SQL Interface	Specification
ODBC on a client using the IBM i Access Family ODBC Driver	Date Format and Date Separator in the Advanced Server Options in ODBC Setup (For more information about ODBC, see IBM i Access .)
JDBC on a client using the IBM Toolbox for Java	Format in JDBC Setup (For more information about JDBC, see IBM i Access .) (For more information about the IBM Toolbox for Java, see IBM Toolbox for Java .)

Time strings

A string representation of a time is a character or a Unicode graphic string that starts with a digit and has a length of at least 4 characters. Trailing blanks can be included; a leading zero can be omitted from the hour part of the time and seconds can be omitted entirely. If you choose to omit seconds, an implicit specification of 0 seconds is assumed. Thus, 13.30 is equivalent to 13.30.00.

Valid string formats for times are listed in [Table 10 on page 77](#). Each IBM SQL standard format is identified by name and includes an associated abbreviation (for use by the CHAR function). The other format (*HMS) does not have an abbreviation to be used by the CHAR function. The separator for the *HMS format is controlled by the time separator (TIMSEP) parameter.

The database manager recognizes the string as a time when it is in one of the following formats:

- In the format specified by the default time format
- In one of the IBM SQL standard time formats

Table 10. Formats for String Representations of Times

Format Name	Abbreviation	Time Format	Example
International Standards Organization (*ISO)	ISO	'hh.mm.ss' ²⁵	'13.30.05'
IBM USA standard (*USA)	USA	'hh:mm AM' (or PM)	'1:30 PM'
IBM European standard (*EUR)	EUR	'hh.mm.ss'	'13.30.05'
Japanese industrial standard Christian era (*JIS)	JIS	'hh:mm:ss'	'13:30:05'
Hours, minutes, seconds (*HMS)	–	'hh:mm:ss'	'13:30:05'

The following additional rules apply to the USA time format:

- The hour must not be greater than 12 and cannot be 0 except for the special case of 00:00 AM.
- A single space character exists between the minutes portion of the time of day and the AM or PM.
- The minutes can be omitted entirely. If you choose to omit the minutes, an implicit specification of 0 minutes is assumed.

In the USA format, using the ISO format of the 24-hour clock, the correspondence between the USA format and the 24-hour clock is as follows:

²⁵ This is an earlier version of the ISO format. JIS can be used to get the current ISO format.

Table 11. USA Time Format

USA Format	24-Hour Clock
12:01 AM through 12:59 AM	00.01.00 through 00.59.00
01:00 AM through 11:59 AM	01:00.00 through 11:59.00
12:00 PM (noon) through 11:59 PM	12:00.00 through 23.59.00
12:00 AM (midnight)	24.00.00
00:00 AM (midnight)	00.00.00

The default time format can be specified through the following interfaces:

Table 12. Default Time Format Interfaces

SQL Interface	Specification
Embedded SQL	<p>The TIMFMT and TIMSEP parameters are specified on the Create SQL Program (CRTSQLxxx) commands. The SET OPTION statement can also be used to specify the TIMFMT and TIMSEP parameters within the source of a program containing embedded SQL.</p> <p>(For more information about CRTSQLxxx commands, see the Embedded SQL programming topic collection.)</p>
Interactive SQL and Run SQL Statements	<p>The TIMFMT and TIMSEP parameters on the Start SQL (STRSQL) command or by changing the session attributes. The TIMFMT and TIMSEP parameters on the Run SQL Statements (RUNSQLSTM) command.</p> <p>(For more information about STRSQL and RUNSQLSTM commands, see the SQL programming topic collection.)</p>
Call Level Interface (CLI) on the server	<p>SQL_ATTR_TIME_FMT and SQL_ATTR_TIME_SEP environment or connection variables</p> <p>(For more information about CLI, see the SQL Call Level Interfaces (ODBC) topic collection.)</p>
JDBC or SQLJ on the server using IBM IBM Developer Kit for Java	<p>Time Format and Time Separator connection property object</p> <p>(For more information about JDBC and SQLJ, see the IBM Developer Kit for Java topic collection.)</p>
ODBC on a client using the IBM i Access Family ODBC Driver	<p>Time Format and Time Separator in the Advanced Server Options in ODBC Setup</p> <p>(For more information about ODBC, see the IBM i Access Family topic collection.)</p>
JDBC on a client using the IBM Toolbox for Java	<p>Format in JDBC Setup</p> <p>(For more information about the IBM Toolbox for Java, see IBM Toolbox for Java topic collection.)</p>

Timestamp strings

A string representation of a timestamp is a character or a Unicode graphic string that starts with a digit and has a length of at least 14 characters.

The complete string representation of a timestamp has one of the following forms:

Table 13. Formats for String Representations of Timestamps

Format Name	Time Format	Example
ISO timestamp	'yyyy-mm-dd hh:mm:ss.nnnnnnnnnnnn'	'1990-03-02 08:30:00.010000000000'
IBM SQL	'yyyy-mm-dd-hh.mm.ss.nnnnnnnnnnnn'	'1990-03-02-08.30.00.010000000000'
14-26 character form	'yyyymmddhhmmssnnnnnnnnnnn'	'19900302083000'

The following rules apply:

- Leading blanks are not allowed.
- Trailing blanks can be included.
- Leading zeros can be omitted from the month, day, hour, minute, and second part of the timestamp when using the timestamp form with separators. An implicit specification of 0 is assumed for any digit that is omitted.
- The hour can be 24 if the minutes, seconds, and any fractional seconds are all zeros.
- Trailing zeros can be truncated or omitted entirely from fractional seconds.
- The number of digits of fractional seconds can vary from 0 to 12. An implicit specification of 0 is assumed if fractional seconds are omitted.
- The separator character that follows the seconds element can be omitted if fractional seconds are not included.

If a string representation of a timestamp is implicitly cast to a value with a `TIMESTAMP` data type, the timestamp precision of the result of the cast is determined by the operation. Digits in the string beyond the timestamp precision of the cast are truncated or any missing digits needed to reach the timestamp precision of the cast are assumed to be zeros. For example `1990-3-2-8.30.00` is equivalent to `1990-03-02-8.30.00.000000000000`. A string representation of a timestamp can be given a different timestamp precision by explicitly casting the value to a timestamp with a specified precision. In the case of a constant, the precision can be maintained by preceding the string with the `TIMESTAMP` keyword. For example, `TIMESTAMP '2007-03-28-14.50.35.123'` has the `TIMESTAMP(3)` data type.

XML Values

An XML value represents well-formed XML in the form of an XML document, XML content, or an XML sequence.

An XML value that is stored in a table as a value of a column defined with the XML data type must be a well-formed XML document. XML values are processed in an internal representation that is not comparable to any string value including another XML value. The only predicate that can be applied to the XML data type is the IS NULL predicate.

An XML value can be transformed into a serialized string value representing an XML document using the XMLSERIALIZE function. Similarly, a string value that represents an XML document can be transformed into an XML value using the XMLPARSE function. An XML value can be implicitly parsed or serialized when exchanged with application string and binary data types.

The XML data type has no defined maximum length. It does have an effective maximum length when treated as a serialized string value that represents XML which is the same as the limit for LOB data values. Like LOBs, there are also XML locators and XML file reference variables.

Restrictions when using XML values: With a few exceptions, you can use XML values in the same contexts in which you can use other data types. XML values are valid in:

- CAST a parameter marker, XML, or NULL to XML
- XMLCAST a parameter marker, XML, or NULL to XML
- IS NULL predicate
- COUNT and COUNT_BIG aggregate functions
- COALESCE, IFNULL, HEX, LENGTH, CONTAINS, and SCORE scalar functions
- XML scalar functions
- A SELECT list without DISTINCT
- INSERT VALUES clause, UPDATE SET clause, and MERGE
- SET and VALUES INTO
- Procedure parameters
- User-defined function arguments and result
- Trigger correlation variables
- Parameter marker values for a dynamically prepared statement

XML values cannot be used directly in the following places. Where expressions are allowed, an XML value can be used, for example, as the argument of XMLSERIALIZE:

- A SELECT list containing the DISTINCT keyword
- A GROUP BY clause
- An ORDER BY clause
- A subselect of a fullselect that is not UNION ALL
- A basic, quantified, BETWEEN, DISTINCT, IN, or LIKE predicate
- An aggregate function with the DISTINCT keyword
- A primary, unique, or foreign key
- A check constraint
- An index column

No host languages have a built-in data type for the XML data type.

For information on the XML data model and XML values, see [SQL XML programming](#).

Determining the CCSID for XML

XML data can be defined with any EBCDIC single byte or mixed CCSID or a Unicode CCSID of 1208, 1200, or 13488. 65535 is not allowed as a CCSID for XML data. The CCSID can be explicitly specified when defining an XML data type. If it is not explicitly specified, the CCSID will be assigned using the value of the SQL_XML_DATA_CCSID QAQQINI file option. If this value has not been set, the default is 1208 (UTF-8).

The CCSID will be established for XML data types used in SQL schema statements when the statement is run.

XML host variables that do not have a DECLARE VARIABLE that assigns a CCSID will have their CCSID assigned as follows:

- If it is XML AS DBCLOB, the CCSID will be 1200.
- If it is XML AS CLOB and the SQL_XML_DATA_CCSID QAQQINI value is 1200 or 13488, the CCSID will be 1208.
- Otherwise, the SQL_XML_DATA_CCSID QAQQINI value will be used as the CCSID.

Since all implicit and explicit XMLPARSE functions are performed using UTF-8 (1208) defining data in this CCSID removes the need to convert the data to UTF-8.

DataLink values

A DataLink value is an encapsulated value that contains a logical reference from the database to a file stored outside the database.

The attributes of this encapsulated value are as follows:

link type

The currently supported type of link is a URL (Uniform Resource Locator).

scheme

For URLs, this is a value such as HTTP or FILE. The value, no matter what case it is entered in, is stored in the database in upper case.

file server name

The complete address of the file server. The value, no matter what case it is entered in, is stored in the database in upper case.

file path

The identity of the file within the server. The value is case sensitive and therefore it is not converted to upper case when stored in the database.

access control token

When appropriate, the access token is embedded within the file path. It is generated dynamically and is not a permanent part of the DataLink value that is stored in the database.

comment

Up to 254 bytes of descriptive information. This is intended for application specific uses such as further or alternative identification of the location of the data.

The characters used in a DataLink value are limited to the set defined for a URL. These characters include the uppercase (A through Z) and lower case (a through z) letters, the digits (0 through 9) and a subset of special characters (\$, -, _, @, ., &, +, !, *, ", ', (,), =, :, /, #, ?, ;, space, and comma).

The first four attributes are collectively known as the linkage attributes. It is possible for a DataLink value to have only a comment attribute and no linkage attributes. Such a value may even be stored in a column but, of course, no file will be linked to such a column.

It is important to distinguish between these DataLink references to files and the LOB file reference variables described in [“References to LOB or XML file reference variables”](#) on page 143. The similarity is that they both contain a representation of a file. However:

- DataLinks are retained in the database and both the links and the data in the linked files can be considered as a natural extension of data in the database.

- File reference variables exist temporarily and they can be considered as an alternative to a host program buffer.

Built-in scalar functions are provided to build a DataLink value (DLVALUE) and to extract the encapsulated values from a DataLink value (DLCOMMENT, DLLINKTYPE, DLURLCOMPLETE, DLURLPATH, DLURLPATHONLY, DLURLSCHEME, DLURLSERVER).

Row ID values

A *row ID* is a value that uniquely identifies a row in a table. A column or a variable can have a row ID data type. A ROWID column enables queries to be written that navigate directly to a row in the table.

Each value in a ROWID column must be unique. The database manager maintains the values permanently, even across table reorganizations. When a row is inserted into the table, the database manager generates a value for the ROWID column unless one is supplied. If a value is supplied, it must be a valid row ID value that was previously generated by either Db2 for z/OS or Db2 for i.

The internal representation of a row ID value is transparent to the user. The value is never subject to CCSID conversion because it is considered to contain BIT data. The length attribute of a ROWID column is 40.

User-defined types

A user-defined type is a data type that is defined to the database using a CREATE TYPE statement. There are two types of user-defined type: distinct types and array types.

Distinct types

A *distinct type* is a user-defined data type that shares its internal representation with a built-in data type (its "source type"), but is considered to be a separate and incompatible type for most operations. For example, the semantics for a picture type, a text type, and an audio type that all use the built-in data type BLOB for their internal representation are quite different. A distinct type is created using [“CREATE TYPE \(distinct\)”](#) on page 1193.

For example, the following statement creates a distinct type named AUDIO:

```
CREATE TYPE AUDIO AS BLOB (1M)
```

Although AUDIO has the same representation as the built-in data type BLOB, it is considered to be a separate type that is not comparable to a BLOB or to any other type. This inability to compare AUDIO to other data types allows functions to be created specifically for AUDIO and assures that these functions cannot be applied to other data types (such as pictures or text).

The name of a distinct type is qualified with a schema name. The implicit schema name for an unqualified name depends upon the context in which the distinct type appears. If an unqualified distinct type name is used:

- In a CREATE TYPE statement or the object of the DROP, COMMENT, LABEL, GRANT, or REVOKE statement, the database manager uses the normal process of qualification by authorization ID to determine the schema name. For more information about qualification rules, see [“Unqualified function, procedure, specific name, type, and variables”](#) on page 59.
- In any other context, the database manager uses the SQL path to determine the schema name. The database manager searches the schemas in the path, in sequence, and selects the first schema that has a distinct type that matches. For a description of the SQL path, see [“SQL path”](#) on page 57.

A distinct type does not automatically acquire the functions and operators of its source type, since these may not be meaningful. (For example, the LENGTH function for an AUDIO type might return the length of its object in seconds rather than in bytes.) Instead, distinct types support *strong typing*. Strong typing ensures that only the functions and operators that are explicitly defined for a distinct type can be applied to that distinct type. However, a function or operator of the source type can be applied to the distinct type by creating an appropriate user-defined function. The user-defined function must be sourced on

the existing function that has the source type as a parameter. For example, the following series of SQL statements shows how to create a distinct type named MONEY based on data type DECIMAL(9,2), how to define the + operator for the distinct type, and how the operator might be applied to the distinct type:

```
CREATE TYPE MONEY AS DECIMAL(9,2) WITH COMPARISONS
CREATE FUNCTION "+" (MONEY, MONEY)
  RETURNS MONEY
  SOURCE "+" (DECIMAL(9,2), DECIMAL(9,2))
CREATE TABLE SALARY_TABLE
  (SALARY MONEY,
  COMMISSION MONEY)
SELECT "+" (SALARY, COMMISSION) FROM SALARY_TABLE
```

A distinct type is subject to the same restrictions as its source type. For example, a table can only have one ROWID column. Therefore, a table with a ROWID column cannot also have a column with distinct type that is sourced on a row ID.

The comparison operators are automatically generated for distinct types, except for distinct types that are sourced on a DataLink. In addition, the database manager automatically generates functions for a distinct type that support casting from the source type to the distinct type and from the distinct type to the source type. For example, for the AUDIO type created above, these are the generated cast functions:

Name of generated cast function	Parameter list	Returns data type
schema-name.BLOB	schema-name.AUDIO	BLOB
schema-name.AUDIO	BLOB	schema-name.AUDIO

Array types

An *array* is a structure that contains an ordered collection of data elements. All elements in an array have the same data type. The cardinality of the array is equal to the number of elements in the array.

The entire array can be referenced or an individual element of the array can be referenced by its ordinal position in the collection. If *N* is the cardinality of an array, the ordinal position associated with each element is an integer value greater than or equal to 1 and less than or equal to *N*.

An *array type* is a user-defined data type that is defined as an array. An SQL variable or SQL parameter can be defined as a user-defined array data type. Additionally, the result of an invocation of the TRIM_ARRAY function, or the result of a CAST specification, can be a user-defined array data type. An element of a user-defined array type can be referenced anywhere an expression returning the same data type as an element of that array can be used.

An unnamed array type is an array without an associated user-defined data type. The result of an invocation of the ARRAY_AGG aggregate function or an ARRAY constructor is an array without an associated user-defined data type. An element of an array without an associated user-defined array type cannot be directly referenced.

An array value can be empty (cardinality zero), null, or the individual elements in the array can be null or not null. An empty array is different than an array value of null, or an array for which all elements are the null value.

An array value cannot be stored in the database or be returned to an external application other than Java.

Promotion of data types

Data types can be classified into groups of related data types. Within such groups, an order of precedence exists where one data type is considered to precede another data type. This precedence enables the database manager to support the *promotion* of one data type to another data type that appears later in the precedence ordering. For example, the data type CHAR can be promoted to VARCHAR; INTEGER can be promoted to DOUBLE PRECISION; but CLOB is NOT promotable VARCHAR.

The database manager considers the promotion of data types when:

- performing function resolution (see [“Function resolution”](#) on page 149)
- casting distinct types (see [“Casting between data types”](#) on page 86)
- assigning distinct types to built-in data types (see [“Distinct type comparisons”](#) on page 103)

For each data type, [Table 14 on page 84](#) shows the precedence list (in order) that the database manager uses to determine the data types to which each data type can be promoted. The table indicates that the best choice is the same data type and not promotion to another data type. Note that the table also shows data types that are considered equivalent during the promotion process. For example, CHARACTER and GRAPHIC are considered to be equivalent data types.

Table 14. Data Type Precedence Table

Data Type	Data Type Precedence List (in best-to-worst order)
SMALLINT	SMALLINT, INTEGER, BIGINT, decimal, real, double, DECFLOAT
INTEGER	INTEGER, BIGINT, decimal, real, double, DECFLOAT
BIGINT	BIGINT, decimal, real, double, DECFLOAT
decimal	decimal, real, double, DECFLOAT
real	real, double, DECFLOAT
double	double, DECFLOAT
DECFLOAT	DECFLOAT
CHAR or GRAPHIC	CHAR or GRAPHIC, VARCHAR or VARGRAPHIC, CLOB or DBCLOB
VARCHAR or VARGRAPHIC	VARCHAR or VARGRAPHIC, CLOB or DBCLOB
CLOB or DBCLOB	CLOB or DBCLOB
CHAR FOR BIT DATA	CHAR, VARCHAR, CLOB, BINARY, VARBINARY, BLOB
VARCHAR FOR BIT DATA	VARCHAR, CLOB, VARBINARY, BLOB
BINARY	BINARY, VARBINARY, BLOB, CHAR FOR BIT DATA, VARCHAR FOR BIT DATA
VARBINARY	VARBINARY, BLOB, VARCHAR FOR BIT DATA
BLOB	BLOB
DATE	DATE, TIMESTAMP
TIME	TIME
TIMESTAMP	TIMESTAMP
DATALINK	DATALINK
ROWID	ROWID

Table 14. Data Type Precedence Table (continued)

Data Type	Data Type Precedence List (in best-to-worst order)
XML	XML
ARRAY	ARRAY
udt	same udt

Note:

The lower case types above are defined as follows:

decimal

= DECIMAL(p,s) or NUMERIC(p,s)

real

= REAL or FLOAT(*n*) where *n* is a specification for single precision floating point

double

= DOUBLE, DOUBLE PRECISION, FLOAT or FLOAT(*n*) where *n* is a specification for double precision floating point

udt

= a user-defined type

Shorter and longer form synonyms of the data types listed are considered to be the same as the synonym listed.

Character and graphic strings are only compatible for Unicode data.

Casting between data types

There are many occasions when a value with a given data type needs to be cast (changed) to a different data type or to the same data type with a different length, precision, or scale.

Data type promotion, as described in “Promotion of data types” on page 84, is one example of when a value with one data type needs to be cast to a new data type. A data type that can be changed to another data type is *castable* from the source data type to the target data type.

The casting of one data type to another can occur implicitly or explicitly. The cast functions or CAST specification (see “CAST specification” on page 176) can be used to explicitly change a data type. The database manager might implicitly cast data types during assignments that involve a distinct type (see “Distinct type assignments” on page 98). In addition, when you create a sourced user-defined function, the data types of the parameters of the source function must be castable to the data types of the function that you are creating (see “CREATE FUNCTION (sourced)” on page 1018).

If truncation occurs when a character or graphic string is cast to another data type, a warning occurs if any non-blank characters are truncated. This truncation behavior is similar to retrieval assignment of character or graphic strings (see “Retrieval assignment:” on page 94).

If truncation occurs when a binary string is cast to another data type, a warning occurs. This truncation behavior is similar to retrieval assignment of binary strings (see “Retrieval assignment” on page 93).

For casts that involve an array type, the source and target data type must both be the same array type.

For casts that involve a distinct type as either the data type to be cast to or from, Table 15 on page 86 shows the supported casts. For casts between built-in data types, Table 16 on page 87 shows the supported casts.

Table 15. Supported Casts When a Distinct Type is Involved

Data Type ...	Is Castable to Data Type ...
Distinct type <i>DT</i>	Source data type of distinct type <i>DT</i>
Source data type of distinct type <i>DT</i>	Distinct type <i>DT</i>
Distinct type <i>DT</i>	Distinct type <i>DT</i>
Data type <i>A</i>	Distinct type <i>DT</i> where <i>A</i> is promotable to the source data type of distinct type <i>DT</i> (see “Promotion of data types” on page 84)
INTEGER	Distinct type <i>DT</i> if <i>DT</i> 's source type is SMALLINT
DOUBLE	Distinct type <i>DT</i> if <i>DT</i> 's source data type is REAL
VARCHAR	Distinct type <i>DT</i> if <i>DT</i> 's source data type is CHAR or GRAPHIC
VARGRAPHIC	Distinct type <i>DT</i> if <i>DT</i> 's source data type is GRAPHIC or CHAR
VARBINARY	Distinct type <i>DT</i> if <i>DT</i> 's source data type is BINARY

Character and graphic strings are only compatible for Unicode data. Character bit data and graphic strings are not compatible.

When a distinct type is involved in a cast, a cast function that was generated when the distinct type was created is used. How the database manager chooses the function depends on whether function notation or the CAST specification syntax is used. For details, see “Function resolution” on page 149, and “CAST specification” on page 176. Function resolution is used for both. However, in a CAST specification, when an unqualified distinct type is specified as the target data type, the database manager resolves the schema name of the distinct type and then uses that schema name to locate the cast function.

The following table describes the supported casts between built-in data types.

Table 16. Supported Casts Between Built-In Data Types

Target Data Type →	SMALLINT	INTEGER	BIGINT	DECIMAL NUMERIC	REAL DOUBLE	DECFLOAT	CHAR VARCHAR CLOB	GRAPHIC VARGRAPHIC DBCLOB	BINARY VARBINARY BLOB	DATE	TIME	TIMESTAMP	ROWID	DATALINK	XML
Source Data Type ↓															
SMALLINT	Y	Y	Y	Y	Y	Y	Y	Y ¹	–	–	–	–	–	–	–
INTEGER	Y	Y	Y	Y	Y	Y	Y	Y ¹	–	–	–	–	–	–	–
BIGINT	Y	Y	Y	Y	Y	Y	Y	Y ¹	–	–	–	–	–	–	–
DECIMAL	Y	Y	Y	Y	Y	Y	Y	Y ¹	–	–	–	–	–	–	–
NUMERIC	Y	Y	Y	Y	Y	Y	Y	Y ¹	–	–	–	–	–	–	–
REAL	Y	Y	Y	Y	Y	Y	Y	Y ¹	–	–	–	–	–	–	–
DOUBLE	Y	Y	Y	Y	Y	Y	Y	Y ¹	–	–	–	–	–	–	–
DECFLOAT	Y	Y	Y	Y	Y	Y	Y	Y ¹	–	–	–	–	–	–	–
CHAR	Y	Y	Y	Y	Y	Y	Y	Y ¹	Y	Y	Y	Y	Y	–	–
VARCHAR	Y	Y	Y	Y	Y	Y	Y	Y ¹	Y	Y	Y	Y	Y	–	–
CLOB	Y	Y	Y	Y	Y	Y	Y	Y ¹	Y	Y	Y	Y	Y	–	–
GRAPHIC	Y ¹	Y ¹	Y ¹	Y ¹	Y ¹	Y ¹	Y ¹	Y	–	Y ¹	Y ¹	Y ¹	–	–	–
VARGRAPHIC	Y ¹	Y ¹	Y ¹	Y ¹	Y ¹	Y ¹	Y ¹	Y	–	Y ¹	Y ¹	Y ¹	–	–	–
DBCLOB	Y ¹	Y ¹	Y ¹	Y ¹	Y ¹	Y ¹	Y ¹	Y	–	Y ¹	Y ¹	Y ¹	–	–	–
BINARY	–	–	–	–	–	–	Y	–	Y	–	–	–	–	–	–
VARBINARY	–	–	–	–	–	–	Y	–	Y	–	–	–	–	–	–
BLOB	–	–	–	–	–	–	Y	–	Y	–	–	–	–	–	–
DATE	–	Y	Y	Y	–	–	Y	Y ¹	–	Y	–	Y	–	–	–
TIME	–	Y	Y	Y	–	–	Y	Y ¹	–	–	Y	Y	–	–	–
TIMESTAMP	–	–	Y	Y	–	–	Y	Y ¹	–	Y	Y	Y	–	–	–
ROWID	–	–	–	–	–	–	Y	–	Y	–	–	–	Y	–	–
DATALINK	–	–	–	–	–	–	–	–	–	–	–	–	–	Y	–
XML	–	–	–	–	–	–	–	–	–	–	–	–	–	–	Y

Notes:

¹ Conversion is only supported for Unicode graphic. If the other data type is FOR BIT DATA, conversion is not supported.

The following table describes the rules for casting to a data type:

Table 17. Rules for Casting to a Data Type

Target Data Type	Rules
SMALLINT	See “SMALLINT” on page 573.
INTEGER	See “INTEGER or INT” on page 442.
BIGINT	See “BIGINT” on page 315.
DECIMAL	See “DECIMAL or DEC” on page 374.
NUMERIC	See “ZONED” on page 683.
REAL	See “REAL” on page 536.
DOUBLE	See “DOUBLE_PRECISION or DOUBLE” on page 392.
DECFLOAT	See “DECFLOAT” on page 369
CHAR	See “CHAR” on page 325.
VARCHAR	See the “VARCHAR” on page 623.
CLOB	See “CLOB” on page 333.
GRAPHIC	If the source data type is a character string, see the rules for string assignment to a variable in “Assignments and comparisons” on page 89. Otherwise, see “GRAPHIC” on page 416.
VARGRAPHIC	If the source data type is a character string, see the rules for string assignment to a variable in “Assignments and comparisons” on page 89. Otherwise, see “VARGRAPHIC” on page 638.
DBCLOB	See “DBCLOB” on page 361.
BINARY	See “BINARY” on page 317.
VARBINARY	See “VARBINARY” on page 620.
BLOB	See “BLOB” on page 321.
DATE	See “DATE” on page 352.
TIME	See “TIME” on page 589.
TIMESTAMP	See “TIMESTAMP” on page 590, using the precision of the target data type as the second argument. If the source data type is a DATE, the timestamp is composed of the specified date and a time of 00:00:00. If the source data type is a TIME, the timestamp is composed of the CURRENT_DATE and the specified time.
DATALINK	See the rules for DataLink assignments in “Assignments and comparisons” on page 89.
ROWID	See “ROWID” on page 558.
XML	See the rules for XML assignments in “Assignments and comparisons” on page 89.

Assignments and comparisons

The basic operations of SQL are assignment and comparison. Assignment operations are performed during the execution of CALL, INSERT, UPDATE, FETCH, SELECT, SET variable, and VALUES INTO statements. Comparison operations are performed during the execution of statements that include predicates and other language elements such as MAX, MIN, DISTINCT, GROUP BY, and ORDER BY.

The basic rule for both operations is that the data type of the operands involved must be compatible. The compatibility rule also applies to UNION, EXCEPT, INTERSECT, concatenation, CASE expressions, and the CONCAT, VALUE, COALESCE, IFNULL, MIN, and MAX scalar functions. The compatibility matrix is as follows:

Table 18. Data Type Compatibility

Operands	Binary Integer	Decimal Number	Floating Point	Decimal Floating Point	Character String	Graphic String	Binary String	Date	Time	Timestamp	DataLink	Row ID	XML ⁷	User-defined Type
Binary Integer	Y	Y	Y	Y	Y	1	—	—	—	—	—	—	—	3
Decimal Number ⁴	Y	Y	Y	Y	Y	1	—	—	—	—	—	—	—	3
Floating Point	Y	Y	Y	Y	Y	1	—	—	—	—	—	—	—	3
Decimal Floating-Point	Y	Y	Y	Y	Y	1	—	—	—	—	—	—	—	3
Character String	Y	Y	Y	Y	Y	1	2	—	—	—	—	—	—	3
Graphic String	1	1	1	1	1	Y	—	1	1	1	—	—	—	3
Binary String	—	—	—	—	2	—	Y	—	—	—	—	—	—	3
Date	—	—	—	—	—	1	—	Y	—	Y	—	—	—	3
Time	—	—	—	—	—	1	—	—	Y	—	—	—	—	3
Timestamp	—	—	—	—	—	1	—	Y	—	Y	—	—	—	3
DataLink	—	—	—	—	—	—	—	—	—	—	5	—	—	3
Row ID	—	—	—	—	—	—	—	—	—	—	—	6	—	3
XML ⁷	—	—	—	—	—	—	—	—	—	—	—	—	Y	3
User-defined Type	3	3	3	3	3	3	3	3	3	3	3	3	3	3

Table 18. Data Type Compatibility (continued)

Operands	Binary Integer	Decimal Number	Floating Point	Decimal Floating Point	Character String	Graphic String	Binary String	Date	Time	Timestamp	DataLink	Row ID	XML ⁷	User-defined Type
----------	----------------	----------------	----------------	------------------------	------------------	----------------	---------------	------	------	-----------	----------	--------	------------------	-------------------

Notes:

1. Only Unicode graphic strings are compatible. Unicode and FOR BIT DATA are not compatible.
2. Character strings, except those with FOR BIT DATA, are not compatible with binary strings. FOR BIT DATA character strings and binary strings are considered compatible and any padding is performed based on the data type of the target. For example, when assigning a FOR BIT DATA column value to a fixed-length binary variable, any necessary padding uses a pad byte of X'00'.
3. A value with a distinct type is comparable only to a value that is defined with the same distinct type. In general, the database manager supports assignments between a distinct type value and its source data type. For additional information, see [“Distinct type assignments” on page 98](#).
A value with an array type is comparable only to a value that is defined with the same array type. A value with an array type can be assigned to an array of the same type. For additional information, see [“Array type assignments” on page 99](#).
4. Decimal refers to both packed and zoned decimal.
5. A DataLink operand can only be assigned to another DataLink operand and cannot be compared to any data type.
6. A ROWID operand can only be assigned to another ROWID operand and cannot be compared to any data type.
7. Character and graphic strings can be assigned to XML columns. However, XML cannot be assigned to a character or graphic string column. For comparisons, XML can only be compared using the IS NULL predicate.

A basic rule for assignment operations is that a null value cannot be assigned to:

- a column that cannot contain null values
- a host variable that does not have an associated indicator variable
- a Java host variable that is a primitive type.

See [“References to host variables” on page 139](#) for a discussion of indicator variables.

For any comparison that involves null values, see the description of the comparison operation for information about the specific handling of null values.

Numeric assignments

For numeric assignments, overflow is not allowed.

- When assigning to an exact numeric data type, overflow occurs if any digit of the whole part of the number would be eliminated. If necessary, the fractional part of a number is truncated.
- When assigning to an approximate numeric data type or decimal floating-point number, overflow occurs if the most significant digit of the whole part of the number is eliminated. For floating-point and decimal floating-point numbers, the whole part of the number is the number that would result if the floating-point or decimal floating-point number were converted to a decimal number with unlimited precision. If necessary, rounding may cause the least significant digits of the number to be eliminated.

For decimal floating-point numbers, truncation of the whole part of the number is allowed and results in infinity with a warning if *YES is specified for the SQL_DECFLOAT_WARNINGS query option.

For floating-point numbers, underflow is also not allowed. Underflow occurs for numbers between 1 and -1 if the most significant digit other than zero would be eliminated. For decimal floating point, underflow is allowed and depending on the rounding mode, results in zero or the smallest positive number or the largest negative number that can be represented. A warning is returned if *YES is specified for the SQL_DECFLOAT_WARNINGS query option.

For information about the decimal floating-point rounding mode, see [“CURRENT DECFLOAT ROUNDING MODE”](#) on page 124.

An overflow or underflow warning is returned instead of an error if an overflow or underflow occurs on assignment to a host variable with an indicator variable. In this case, the number is not assigned to the host variable and the indicator variable is set to negative 2.

Assignments to integer

When a decimal, floating-point, or decimal floating-point number is assigned to a binary integer column or variable, the fractional part of the number is eliminated. As a result, a number between 1 and -1 is reduced to 0.

Assignments to decimal

When an integer is assigned to a decimal column or variable, the number is first converted to a temporary decimal number and then, if necessary, to the precision and scale of the target. The precision and scale of the temporary decimal number is 5,0 for a small integer, 11,0 for a large integer, or 19,0 for a big integer.

When a decimal number is assigned to a decimal column or variable, the number is converted, if necessary, to the precision and the scale of the target. The necessary number of leading zeros is added, and in the fractional part of the decimal number the necessary number of trailing zeros is added, or the necessary number of trailing digits is eliminated.

When a floating-point number is assigned to a decimal column or variable, the number is first converted to a temporary decimal number of precision 63 and scale of $63 - (p-s)$ where p and s are the precision and scale of the decimal column or variable. Then, if necessary, the temporary number is truncated to the precision and scale of the target. As a result, a number between 1 and -1 that is less than the smallest positive number or greater than the largest negative number that can be represented in the decimal column or variable is reduced to 0.

When a decimal floating-point number is assigned to a decimal column or variable, the number is rounded to the precision and scale of the decimal column or variable. As a result, a number between 1 and -1 that is less than the smallest positive number or greater than the largest negative number that can be represented in the decimal column or variable is reduced to 0 or rounded to the smallest positive or largest negative value that can be represented in the decimal column or variable, depending on the rounding mode.

Note: Decimal refers to both packed and zoned decimal. A binary integer with scale follows the rules for a assignments to decimal.

Note: When fetching decimal data from a file that was *not* created by an SQL CREATE TABLE statement, a decimal field may contain data that is not valid. In this case, the data will be returned as stored, without any warning or error message being issued. A table that is created by the SQL CREATE TABLE statement does not allow decimal data that is not valid.

Assignments to floating-point

Floating-point numbers are approximations of real numbers. Hence, when an integer, decimal, floating-point, or decimal floating-point number is assigned to a floating-point column or variable, the result may not be identical to the original number. The number is rounded to the precision of the floating-point column or variable using floating-point arithmetic.

Assignments to decimal floating-point

When an integer number is assigned to a decimal floating-point column or variable, the number is first converted to a temporary decimal number and then to a decimal floating-point number. The precision and scale of the temporary decimal number is 5,0 for a small integer, 11,0 for a large integer, or 19,0 for a big integer. Rounding may occur when assigning a BIGINT to a DECFLOAT(16) column or variable.

When a decimal number is assigned to a decimal floating-point column or variable, the number is converted to the precision (16 or 34) of the target. Leading zeros are eliminated. Depending on the precision and scale of the decimal number and the precision of the target, the value might be rounded.

When a floating-point number is assigned to a decimal floating-point column or variable, the number is first converted to a temporary string representation of the floating-point number. The string representation of the number is then converted to decimal floating-point.

When a DECFLOAT(16) number is assigned to a DECFLOAT(34) column or variable, the resulting value is identical to the DECFLOAT(16) number.

When a DECFLOAT(34) number is assigned to a DECFLOAT(16) column or variable, the exponent of the source is converted to the corresponding exponent in the result format. The mantissa of the DECFLOAT(34) number is rounded to the precision of the target. For more information about the decimal floating-point rounding mode, see [“CURRENT DECFLOAT ROUNDING MODE” on page 124](#).

Assignments to COBOL and RPG integers

Assignment to COBOL and RPG small or large integer host variables takes into account any scale specified for the host variable. However, assignment to integer host variables uses the full size of the integer. Thus, the value placed in the COBOL data item or RPG field might be larger than the maximum precision specified for the host variable.

Examples:

- In COBOL, assume that COL1 contains a value of 12345. The following SQL statement results in the value 12345 being placed in A, even though A has been defined with only 4 digits:

```
01 A PIC S9999 BINARY.  
EXEC SQL SELECT COL1  
        INTO :A  
        FROM TABLEX  
END-EXEC.
```

- Notice, however, that the following COBOL statement results in 2345 (and not 12345) being placed in A:

```
MOVE 12345 TO A.
```

Assignments from strings to numeric

When a string is assigned to a numeric data type, it is converted to the target numeric data type using the rules for a CAST specification. For more information, see [“CAST specification” on page 176](#).

String assignments

There are two types of string assignments.

- *Storage assignment* is when a value is assigned to a column, a parameter of a function or procedure, or a transition variable.
- *Retrieval assignment* is when a value is assigned to a variable (but not a parameter or transition variable).²⁶

²⁶ If assigning to an SQL-variable or SQL-parameter and the standards option is specified, storage assignment rules apply. For information about the standards option, see [“Standards compliance” on page xix](#).

Binary string assignments

The following rules apply when the assignment target is a binary string.

Storage assignment

The basic rule is that the length of a string assigned to a column, parameter of a function or procedure, or transition variable must not be greater than the length attribute of the column or parameter. If the string is longer than the length attribute of that column, parameter, or transition variable, an error is returned. Trailing hexadecimal zeroes (X'00') are normally included in the length of the string. For storage assignments, however, trailing hexadecimal zeroes are not included in the length of the string.

When a string is assigned to a fixed-length binary-string column, parameter, or transition variable and the length of the string is less than the length attribute of the target, the string is padded on the right with the necessary number of hexadecimal zeroes.

Retrieval assignment

The length of a string assigned to a variable (but not a parameter or transition variable) can be greater than the length attribute of the variable. When a string is assigned to a variable and the string is longer than the length attribute of the variable, the string is truncated on the right by the necessary number of bytes. When this occurs, an SQLSTATE of '01004' is assigned to the RETURNED_SQLSTATE condition area item in the SQL Diagnostics Area (or the value 'W' is assigned to the SQLWARN1 field of the SQLCA).

When a string is assigned to a fixed-length binary-string variable and the length of the string is less than the length attribute of the target, the string is padded on the right with the necessary number of hexadecimal zeroes.

When a string of length n is assigned to a varying-length string variable with a maximum length greater than n , the bytes after the n th byte of the variable are undefined.

Character and graphic string assignments

The following rules apply when the assignment target is a string.

When a datetime data type is involved, see [“Datetime assignments”](#) on page 95. For the special considerations that apply when a distinct type is involved in an assignment, especially to a variable, see [“Distinct type assignments”](#) on page 98.

Assignments from numeric to strings

When a number is assigned to a string data type, it is converted to the target string data type using the rules for a CAST specification. For more information, see [“CAST specification”](#) on page 176.

Storage assignment:

The basic rule is that the length of a string assigned to a column, parameter of a function or procedure, or transition variable must not be greater than the length attribute of the column or parameter. If the string is longer than the length attribute of that column, parameter, or transition variable, an error is returned. Trailing blanks are normally included in the length of the string. For storage assignments, however, trailing blanks are not included in the length of the string.

When a string is assigned to a fixed-length string column, parameter, or transition variable and the length of the string is less than the length attribute of the target, the string is padded on the right with the necessary number of single-byte, double-byte, or UTF-16 or UCS-2 blanks.²⁷ The pad character is always a blank, even for bit data.

²⁷ UTF-16 or UCS-2 defines a blank character at code point X'0020' and X'3000'. The database manager pads with the blank at code point X'0020'. The database manager pads UTF-8 with a blank at code point X'20'

Retrieval assignment:

The length of a string assigned to a variable (but not a parameter or transition variable) can be greater than the length attribute of the variable. When a string is assigned to a variable and the string is longer than the length attribute of the variable, the string is truncated on the right by the necessary number of characters. When this occurs, an SQLSTATE of '01004' is assigned to the RETURNED_SQLSTATE condition area item in the SQL Diagnostics Area (or the value 'W' is assigned to the SQLWARN1 field of the SQLCA). Furthermore, if an indicator variable is provided, it is set to the original length of the string. If only the NUL-terminator is truncated for a C NUL-terminated host variable and the *NOCNULRQD option was specified on the CRTSQLCI or CRTSQLCPPI command (or CNULRQD(*NO) on the SET OPTION statement), an SQLSTATE of '01004' is assigned to the RETURNED_SQLSTATE condition area item in the SQL Diagnostics Area (or the value 'N' is assigned to the SQLWARN1 field of the SQLCA) and a NUL is not placed in the variable.

When a string is assigned to a fixed-length variable and the length of the string is less than the length attribute of the target, the string is padded on the right with the necessary number of single-byte, double-byte, or UTF-16 or UCS-2 blanks.²⁷ The pad character is always a blank, even for bit data.

When a string of length n is assigned to a varying-length string variable with a maximum length greater than n , the characters after the n th character of the variable are undefined.

Assignments to mixed strings:

If a string contains mixed data, the assignment rules may require truncation within a sequence of double-byte codes. To prevent the loss of the shift-in character that ends the double-byte sequence, additional characters may be truncated from the end of the string, and a shift-in character added. In the truncated result, there is always an even number of bytes between each shift-out character and its matching shift-in character.

Assignments to C NUL-terminated strings:

When a string of length n is assigned to a C NUL-terminated string variable with a length greater than $n+1$:

- If the *CNULRQD option was specified on the CRTSQLCI or CRTSQLCPPI command (or CNULRQD(*YES) on the SET OPTION statement), the string is padded on the right with $x-n-1$ blanks where x is the length of the variable. The padded string is then assigned to the variable and the NUL-terminator is placed in the next character position.
- If the *NOCNULRQD precompiler option was specified on the CRTSQLCI or CRTSQLCPPI command (or CNULRQD(*NO) on the SET OPTION statement), the string is not padded on the right. The string is assigned to the variable and the NUL-terminator is placed in the next character position.

Conversion rules for assignments

A string assigned to a column, variable, or parameter is first converted, if necessary, to the coded character set of the target. Character conversion is necessary only if all of the following are true:

- The CCSIDs are different.
- Neither CCSID is 65535.
- The string is neither null nor empty.
- Conversion between the two CCSIDs is required. For more information, see [“Coded character sets and CCSIDs” on page 32](#).

An error occurs if:

- Conversion between the pair of CCSIDs is not defined. For more information, see [“Coded character sets and CCSIDs” on page 32](#).
- A character of the string cannot be converted, and the operation is assignment to a column or assignment to a host variable without an indicator variable. For example, a double-byte character (DBCS) cannot be converted to a column or host variable with a single-byte character (SBCS) CCSID.

A warning occurs if:

- A character of the string is converted to the substitution character.
- A character of the string cannot be converted, and the assignment is not to a column or to a host variable without an indicator variable. For example, a DBCS character cannot be converted to a host variable with an SBCS CCSID. In this case, the string is not assigned to the host variable and the indicator variable is set to -2.

Datetime assignments

A value that is assigned to a date, time, or timestamp column or variable must be a date, time, or timestamp or a valid string representation of a date, a time, or a timestamp.

A value assigned to a DATE column or a DATE variable must be a date or timestamp or a valid string representation of a date or timestamp. When a timestamp value is assigned to a DATE data type, the date portion is extracted and the time portion is ignored. A date can be assigned only to a DATE or TIMESTAMP column, a string column, a DATE or TIMESTAMP variable, or a string variable.

A value assigned to a TIME column or a TIME variable must be a time or timestamp or a valid string representation of a time or timestamp. When a timestamp value is assigned to a TIME data type, the date portion is ignored and the time portion is extracted with the fractional seconds truncated. A time can be assigned only to a TIME column, a string column, a TIME variable, or a string variable.

A value assigned to a TIMESTAMP column or a TIMESTAMP variable must be a date or timestamp or a valid string representation of a date or timestamp. If a string representation of a date or timestamp is used, it is implicitly cast to a timestamp with the same precision as the target timestamp. When a date value is assigned to a TIMESTAMP data type, the missing time information is assumed to be all zeros. A timestamp can be assigned to a DATE, TIME, or TIMESTAMP column, a string column, a DATE, TIME, or TIMESTAMP variable, or a string variable. When a timestamp value is assigned to a timestamp with lower precision, the excess fractional seconds are truncated. When a timestamp value is assigned to a timestamp with higher precision, missing digits are assumed to be zeros.

When a datetime value is assigned to a string variable or column, it is converted to its string representation. Leading zeros are not omitted from any part of the date, time, or timestamp. The required length of the target varies depending on the format of the string representation. If the length of the target is greater than required, it is padded on the right with blanks. If the length of the target is less than required, the result depends on the type of datetime value involved and on the type of target.

- If the target is a string column, truncation is not allowed. The following rules apply:

DATE

- The length attribute of the column must be at least 10 if the date format is *ISO, USA, *EUR, or *JIS. If the date format is *YMD, *MDY, or *DMY, the length attribute of the column must be at least 8. If the date format is *JUL, the length of the variable must be at least 6.

TIME

- The length attribute of the column must be at least 8.

TIMESTAMP

- The length attribute of the column must be at least 19 for TIMESTAMP(0) and 20+p for TIMESTAMP(p).

- When the target is a variable, the following rules apply:

DATE

- The length of the variable must be at least 10 if the date format is *ISO, *USA, *EUR, or *JIS. If the date format is *YMD, *MDY, or *DMY, the length of the variable must be at least 8. If the date format is *JUL, the length of the variable must be at least 6.

TIME

- If the *USA format is used, the length of the variable must not be less than 8. This format does not include seconds.
- If the *ISO, *EUR, *JIS, or *HMS time format is used, the length of the variable must not be less than 5. If the length is 5, 6, or 7, the seconds part of the time is omitted from the result, and SQLWARN1 is set to 'W'. In this case, the seconds part of the time is assigned to the indicator variable if one is provided, and, if the length is 6 or 7, blank padding occurs so that the value is a valid string representation of a time.

TIMESTAMP

- The length of the variable must not be less than 19. If the length is between 19 and 31, the timestamp is truncated like a string, causing the omission of one or more digits of fractional seconds. If the length is 20, the trailing decimal point is replaced by a blank so that the value is a valid string representation of a timestamp with a precision of 0.

XML assignments

The following rules apply when the assignment target is XML.

The general rule for XML assignments is that only an XML value can be assigned to an XML column or an XML variable. There are exceptions to this rule as follows:

- **Processing of input XML variables:** This is a special case of the XML assignment rule because the variable is based on a string value. To make the assignment to XML within SQL, the string value is implicitly parsed into an XML value using the setting of the CURRENT IMPLICIT XMLPARSE OPTION special register. This determines whether to preserve or to strip whitespace, unless the variable is an argument of the XMLVALIDATE function which always strips unnecessary whitespace.
- **Assigning strings to input parameter markers of data type XML:** If an input parameter marker has an implicit or explicit data type of XML, the value assigned to that parameter marker could be a character string variable, graphic string variable, or binary string variable. In this case, the string value is implicitly parsed into an XML value using the setting of the CURRENT IMPLICIT XMLPARSE OPTION special register. This determines whether to preserve or to strip whitespace, unless the parameter marker is an argument of the XMLVALIDATE function which always strips unnecessary whitespace.
- **Assigning strings directly to XML columns in data change statements:** If assigning directly to a column of type XML in a data change statement, the assigned expression can also be a character string, a graphic string, or a binary string. In this case, the result of XMLPARSE (DOCUMENT *expression* STRIP WHITESPACE) is assigned to the target column. The supported string data types are defined by the supported arguments for the XMLPARSE function. This exception also applies to SQL parameters of type XML.
- **Assigning XML to strings on retrieval:** If retrieving XML values into variables using a FETCH or SELECT INTO in embedded SQL, the data type of the variable can be CLOB, DBCLOB, or BLOB. The XML value is implicitly serialized to a string encoded in the variable's CCSID. If using other application programming interfaces (such as CLI, JDBC, or .NET), XML values can be retrieved into the character, graphic, or binary string types that are supported by the application programming interface. In all these cases, the XML value is implicitly serialized to a string encoded in the CCSID determined by the QAQQINI file as described in “XML Values” on page 80.

For the FETCH, SELECT INTO, SET, and VALUES INTO statements, character string, graphic string, or binary string values cannot be retrieved into XML variables. For the INSERT, UPDATE, MERGE, SET, VALUES INTO, and CALL statements, values in XML variables cannot be assigned to columns, SQL variables, or SQL parameters of a character, graphic, or binary string data type.

DataLink assignments

The assignment of a value to a DataLink column results in the establishment of a link to a file unless the linkage attributes of the value are empty or the column is defined with NO LINK CONTROL. In cases where a linked value already exists in the column, that file is unlinked. Assigning a null value where a linked value already exists also unlinks the file associated with the old value.

If the application provides the same data location as already exists in the column, the link is retained. There are two reasons that this might be done:

- the comment is being changed
- if the table is placed in link pending state, the links in the table can be reinstated by providing linkage attributes identical to the ones in the column.

A DataLink value may be assigned to a column by using the DLVALUE scalar function. The DLVALUE scalar function creates a new DataLink value which can then be assigned a column. Unless the value contains only a comment or the URL is exactly the same, the act of assignment will link the file.

When assigning a value to a DataLink column, the following error conditions can occur:

- Data Location (URL) format is invalid
- File server is not registered with this database
- Invalid link type specified
- Invalid length of comment or URL

Note that the size of a URL parameter or function result is the same on both input or output and is bound by the length of the DataLink column. However, in some cases the URL value returned has an access token attached. In situations where this is possible, the output location must have sufficient storage space for the access token and the length of the DataLink column. Hence, the actual length of the comment and URL in its fully expanded form provided on input should be restricted to accommodate the output storage space. If the restricted length is exceeded, this error is raised.

When the assignment is also creating a link, the following errors can occur:

- File server not currently available.
- File does not exist.
- Referenced file cannot be accessed for linking.
- File already linked to another column.

Note that this error will be raised even if the link is to a different relational database.

In addition, when the assignment removes an existing link, the following errors can occur:

- File server not currently available.
- File with referential integrity control is not in a correct state according to the Db2 DataLinks File Manager.

A DataLink value may be retrieved from the database through the use of scalar functions (such as DLLINKTYPE and DLURLPATH). The results of these scalar functions can then be assigned to variables.

Note that usually no attempt is made to access the file server at retrieval time.²⁸It is therefore possible that subsequent attempts to access the file server through file system commands might fail.

A warning may be returned when retrieving a DataLink value because the table is in link pending state.

Row ID assignments

A row ID value can only be assigned to a column, parameter, or variable with a row ID data type. For the value of the ROWID column, the column must be defined as GENERATED BY DEFAULT or OVERRIDING SYSTEM VALUE must be specified. A unique constraint is implicitly added to every table that has a ROWID column that guarantees that every ROWID value is unique. The value that is specified for the column must be a valid row ID value that was previously generated by Db2 for z/OS or Db2 for i.

²⁸ It may be necessary to access the file server to determine the prefix name associated with a path. This can be changed at the file server when the mount point of a file system is moved. First access of a file on a server will cause the required values to be retrieved from the file server and cached at the database server for the subsequent retrieval of DataLink values for that file server. An error is returned if the file server cannot be accessed.

Distinct type assignments

The rules that apply to the assignments of distinct types to variables are different than the rules for all other assignments that involve distinct types.

Assignments to variables

The assignment of a distinct type to a variable is based on the source data type of the distinct type. Therefore, the value of a distinct type is assignable to a variable only if the source data type of the distinct type is assignable to the variable.

Example:

Assume that distinct type AGE was created with the following SQL statement:

```
CREATE TYPE AGE AS SMALLINT WITH COMPARISONS
```

When the statement is executed, the following cast functions are also generated:

```
AGE (SMALLINT) RETURNS AGE
AGE (INTEGER) RETURNS AGE
SMALLINT (AGE) RETURNS SMALLINT
```

Next, assume that column STU_AGE was defined in table STUDENTS with distinct type AGE. Now, consider this valid assignment of a student's age to host variable HV_AGE, which has an INTEGER data type:

```
SELECT STU_AGE INTO :HV_AGE FROM STUDENTS WHERE STU_NUMBER = 200
```

The distinct type value is assignable to the host variable HV_AGE because the source data type of the distinct type (SMALLINT) is assignable to the host variable (INTEGER).

Assignments other than to variables

A distinct type can be either the source or target of an assignment. Assignment is based on whether the data type of the value to be assigned is castable to the data type of the target. [“Casting between data types” on page 86](#) shows which casts are supported when a distinct type is involved. Therefore, a distinct type value can be assigned to any target other than a variable when:

- the target of the assignment has the same distinct type, or
- the distinct type is castable to the data type of the target.

Any value can be assigned to a distinct type when:

- the value to be assigned has the same distinct type as the target, or
- the data type of the assigned value is castable to the target distinct type.

Example:

Assume that the source data type for distinct type AGE is SMALLINT:

```
CREATE TYPE AGE AS SMALLINT WITH COMPARISONS
```

Next, assume that two tables TABLE1 and TABLE2 were created with four identical column descriptions:

```
AGECOL    AGE
SMINTCOL  SMALLINT
INTCOL    INTEGER
DECCOL    DEC(6,2)
```

Using the following SQL statement and substituting various values for X and Y to insert values into various columns of TABLE1 from TABLE2, [Table 19 on page 99](#) shows whether the assignments are valid.

```
INSERT INTO TABLE1 (Y) SELECT X FROM TABLE2
```

<i>Table 19. Assessment of various assignments (for example on INSERT)</i>			
TABLE2.X	TABLE1.Y	Valid	Reason
AGECOL	AGECOL	Yes	Source and target are same distinct type
SMINTCOL	AGECOL	Yes	SMALLINT can be cast to AGE (because AGE's source type is SMALLINT)
INTCOL	AGECOL	Yes	INTEGER can be cast to AGE (because AGE's source type is SMALLINT)
DECCOL	AGECOL	No	DECIMAL cannot be cast to AGE
AGECOL	SMINTCOL	Yes	AGE can be cast to its source type SMALLINT
AGECOL	INTCOL	No	AGE cannot be cast to INTEGER
AGECOL	DECCOL	No	AGE cannot be cast to DECIMAL

Array type assignments

For array types, the validity of an assignment to an SQL array variable or parameter is determined according to the following rules:

- If the right hand side of the assignment is an SQL array variable or parameter, the TRIM_ARRAY function, or a CAST expression, then its type must be the same type as the SQL array variable or parameter on the left hand side of the assignment.
- If the right hand side of the assignment is an array constructor or the ARRAY_AGG function, then it is implicitly cast to the type of the SQL array variable or parameter on the left hand side.

Assignments to LOB locators

When a LOB locator is used, it can refer to any string data. If a LOB locator is used for the first fetch of a cursor and the cursor is on a remote server, LOB locators must be used for all subsequent fetches unless the *NOOPTLOB precompile option is used.

Numeric comparisons

Numbers are compared algebraically; that is, with regard to sign. For example, -2 is less than $+1$.

If one number is an integer and the other number is decimal, the comparison is made with a temporary copy of the integer that has been converted to decimal.

When decimal or nonzero scale binary numbers with different scales are compared, the comparison is made with a temporary copy of one of the numbers that has been extended with trailing zeros so that its fractional part has the same number of digits as the other number.

If one number is floating point and the other is integer, decimal, or single-precision floating point, the comparison is made with a temporary copy of the second number converted to a double-precision floating-point number. However, if a single-precision floating-point column is compared to a constant and the constant can be represented by a single-precision floating-point number, the comparison is made with a single-precision form of the constant.

Two floating-point numbers are equal only if the bit configurations of their normalized forms are identical.

If one number is DECFLOAT and the other number is integer, decimal, single precision floating-point, or double precision floating-point, the comparison is made with a temporary copy of the second number converted to DECFLOAT.

If one number is DECFLOAT(16) and the other is DECFLOAT(34), the DECFLOAT(16) value is converted to DECFLOAT(34) before the comparison.

The DECFLOAT data type supports both positive and negative zero. Positive and negative zero have different binary representations, but the equal (=) predicate will return true for comparisons of positive and negative zero.

The DECFLOAT data type allows for multiple bit representations of the same number. For example, 2.00 and 2.0 are two numbers that are numerically equal but have different bit representations. The = (equal) predicate will return true for a comparison of 2.0 = 2.00. Given that 2.0 = 2.00 is true, 2.0 < 2.00 is false. The behavior that is described here holds true for all comparisons of DECFLOAT values (such as for UNION, SELECT DISTINCT, COUNT DISTINCT, basic predicates, IN predicates, MIN, MAX, and so on.) For example:

```
SELECT 2.0 FROM SYSIBM.SYSDUMMY
UNION
SELECT 2.00 FROM SYSIBM.SYSDUMMY
```

yields one row of data. For this query, the value (2.0 or 2.00) that is returned is arbitrary.

The functions COMPARE_DECFLOAT and TOTALORDER can be used to perform comparisons at a binary level. For example, for a comparison of 2.0 <> 2.00. With these functions, decimal floating-point values are compared in the following order: -NaN < -sNaN < -Infinity < -0.10 < -0.100 < -0 < 0 < 0.100 < 0.10 < Infinity < sNaN < NaN

The DECFLOAT data type also supports the specification of positive and negative NaN (quiet and signaling), and positive and negative Infinity. From an SQL perspective, infinity = infinity, NaN = NaN, and sNaN = sNaN.

The DECFLOAT data type also supports the specification of positive and negative NaN (quiet and signaling), and positive and negative infinity.

The following rules are the comparison rules for these special values:

- Infinity compares equal only to infinity of the same sign (positive or negative)
- NaN compares equal only to NaN of the same sign (positive or negative)
- sNaN compares equal only to sNaN of the same sign (positive or negative)

When string and numeric data types are compared, the string is converted to the numeric data type with the same precision and scale, and must contain a valid string representation of a number.

String comparisons

There are two different types of string comparisons.

Binary string comparisons

Binary string comparisons always use a collating sequence of *HEX and the corresponding bytes of each string are compared. Additionally, two binary strings are equal only if the lengths of the two strings are identical. If the strings are equal up to the length of the shorter string length, the shorter string is considered less than the longer string even when the remaining bytes in the longer string are hexadecimal zeros. Note that binary strings cannot be compared to character strings unless the character string is cast to a binary string.

Character and graphic string comparisons

Character and Unicode graphic string comparisons use the collating sequence in effect when the statement is executed for all SBCS data and the single-byte portion of mixed data. If the collating

sequence is *HEX, the corresponding bytes of each string are compared. For all other collating sequences, the corresponding bytes of the weighted value of each string are compared.

If the strings have different lengths, a temporary copy of the shorter string is padded on the right with blanks before comparison. The padding makes each string the same length. The pad character is always a blank, regardless of the collating sequence. For bit data, the pad character is also a blank. For DBCS graphic data, the pad character is a DBCS blank (x'4040'). For Unicode graphic data, the pad character is a UTF-16 blank.²⁹

Two strings are equal if any of the following are true:

- Both strings are empty.
- A *HEX collating sequence is used and all corresponding bytes are equal.
- A collating sequence other than *HEX is used and all corresponding bytes of the weighted value are equal.

An empty string is equal to a blank string. The relationship between two unequal strings is determined by a comparison of the first pair of unequal bytes (or bytes of the weighted value) from the left end of the string. This comparison is made according to the collating sequence in effect when the statement is executed.

In an application that will run in multiple environments, the same collating sequence (which depends on the CCSIDs of the environments) must be used to ensure identical results. The following table illustrates the differences between EBCDIC, ASCII, and the Db2 LUW default collating sequence for United States English by showing a list that is sorted according to each one.

Table 20. Collating Sequence Differences

ASCII and Unicode	EBCDIC	Db2 LUW Default
0000	@@@	0000
9999	co-op	9999
@@@@	coop	@@@@
COOP	piano forte	co-op
PIANO-FORTE	piano-forte	COOP
co-op	COOP	coop
coop	PIANO-FORTE	piano forte
piano forte	0000	PIANO-FORTE
piano-forte	9999	piano-forte

Two varying-length strings with different lengths are equal if they differ only in the number of trailing blanks. In operations that select one value from a set of such values, the value selected is arbitrary. The operations that can involve such an arbitrary selection are DISTINCT, MAX, MIN, UNION, EXCEPT, INTERSECT, and references to a grouping column. See “group-by-clause” on page 763 for more information about the arbitrary selection involved in references to a grouping column.

Conversion rules for comparison:

When two strings are compared, one of the strings is first converted, if necessary, to the coded character set of the other string. Character conversion is necessary only if all of the following are true:

- The CCSIDs of the two strings are different.
- Neither CCSID is 65535.

²⁹ UTF-16 defines a blank character at code point X'0020' and X'3000'. The database manager pads with the blank at code point X'0020'.

- The string selected for conversion is neither null nor empty.
- Conversion between the two CCSIDs is required. For more information, see [“Coded character sets and CCSIDs”](#) on page 32.

If two strings with different encoding schemes are compared, any necessary conversion applies to the string as follows:

Table 21. Selecting the Resulting Encoding Scheme for Character Conversion

First Operand	Second Operand			
	SBCS Data	DBCS Data	Mixed Data	Unicode Graphic Data
SBCS Data	see below	second	second	second
DBCS Data	first	see below	second	second
Mixed Data	first	first	see below	second
Unicode Graphic Data	first	first	first	see below

Otherwise, the string selected for conversion depends on the type of each operand. The following table shows which operand is selected for conversion, given the operand types:

Table 22. Selecting the Operand for Character Conversion

First Operand	Second Operand				
	Column Value	Derived Value	Special Register	Constant	Variable
Column Value	second	second	second	second	second
Derived Value	first	second	second	second	second
Special Register	first	first	second	second	second
Constant	first	first	first	second	second
Variable	first	first	first	first	second

A variable that contains data in a foreign encoding scheme is always effectively converted to the native encoding scheme before it is used in any operation. The above rules are based on the assumption that this conversion has already occurred.

An error is returned if a character of the string cannot be converted or if the conversion between the pair of CCSIDs is not defined. For more information, see [“Coded character sets and CCSIDs”](#) on page 32. A warning occurs if a character of the string is converted to the substitution character.

Datetime comparisons

A DATE, TIME, or TIMESTAMP value can be compared either with another value of the same data type, a datetime constant of the same data type, or with a string representation of that data type. A date value or a string representation of a date can also be compared with a TIMESTAMP, where the missing time information for the date value is assumed to be all zeros. All comparisons are chronological, which means the farther a point in time is from January 1, 0001, the greater the value of that point in time.

Comparisons involving TIME values and string representations of time values always include seconds. If the string representation omits seconds, zero seconds are implied. The time 24:00:00 compares greater than the time 00:00:00.

Comparisons involving TIMESTAMP values are evaluated according to the following rules:

- When comparing timestamp values with different precisions, the higher precision is used for the comparison and any missing digits for fractional seconds are assumed to be zero.
- When comparing a timestamp value with a string representation of a timestamp, the string representation is first converted to `TIMESTAMP(12)`.
- Timestamp comparisons are chronological without regard to representations that might be considered equivalent. Thus, the following predicate is true:

```
TIMESTAMP('1990-02-23-00.00.00') > '1990-02-22-24.00.00'
```

XML comparisons

The XML data type cannot be compared to any data type, including the XML data type.

DataLink comparisons

A `DATALINK` operand cannot be directly compared to any data type. The `DLCOMMENT`, `DLINKTYPE`, `DLURLCOMPLETE`, `DLURLPATH`, `DLURLPATHONLY`, `DLURLSCHEME`, and `DLURLSERVER` scalar functions can be used to extract character string values from a datalink which can then be compared to other strings.

Row ID comparisons

A `ROWID` operand cannot be directly compared to any data type. To compare the bit representation of a `ROWID`, first cast the `ROWID` to a character string.

Distinct type comparisons

A value with a distinct type can be compared only to another value with exactly the same distinct type.

For example, assume that distinct type `YOUTH` and table `CAMP_DB2_ROSTER` table were created with the following SQL statements:

```
CREATE TYPE YOUTH AS INTEGER WITH COMPARISONS
CREATE TABLE CAMP_DB2_ROSTER
(NAME VARCHAR(20),
 ATTENDEE_NUMBER INTEGER NOT NULL,
 AGE YOUTH,
 HIGH_SCHOOL_LEVEL YOUTH)
```

The following comparison is valid because `AGE` and `HIGH_SCHOOL_LEVEL` have the same distinct type:

```
SELECT * FROM CAMP_DB2_ROSTER
WHERE AGE > HIGH_SCHOOL_LEVEL
```

The following comparison is not valid:

```
SELECT * FROM CAMP_DB2_ROSTER
WHERE AGE > ATTENDEE_NUMBER
***INCORRECT***
```

However, `AGE` can be compared to `ATTENDEE_NUMBER` by using a cast function or `CAST` specification to cast between the distinct type and the source type. All of the following comparisons are valid:

```
SELECT * FROM CAMP_DB2_ROSTER
WHERE AGE > YOUTH(ATTENDEE_NUMBER)

SELECT * FROM CAMP_DB2_ROSTER
WHERE AGE > CAST( ATTENDEE_NUMBER AS YOUTH)

SELECT * FROM CAMP_DB2_ROSTER
WHERE INTEGER(AGE) > ATTENDEE_NUMBER

SELECT * FROM CAMP_DB2_ROSTER
WHERE CAST(AGE AS INTEGER) > ATTENDEE_NUMBER
```

Array type comparisons

Comparisons of array type values are not supported.

Elements of arrays can be compared based on the comparison rules for the data type of the elements.

Rules for result data types

The data types of a result are determined by rules which are applied to the operands in an operation. This section explains those rules.

These rules apply to:

- Corresponding columns in UNION, UNION ALL, EXCEPT, or INTERSECT operations
- Result expressions of a CASE expression
- Arguments of the scalar functions COALESCE, IFNULL, MAX, MIN, and VALUE
- Expression values of the IN list of an IN predicate
- Expression values in an ARRAY constructor
- Arguments for the aggregation group ranges in OLAP specifications

For the result data type of expressions that involve the operators /, *, + and -, see [“With arithmetic operators”](#) on page 159. For the result data type of expressions that involve the CONCAT operator, see [“With the concatenation operator”](#) on page 163.

The data type of the result is determined by the data type of the operands. The data types of the first two operands determine an intermediate result data type, this data type and the data type of the next operand determine a new intermediate result data type, and so on. The last intermediate result data type and the data type of the last operand determine the data type of the result. For each pair of data types, the result data type is determined by the sequential application of the rules summarized in the tables that follow.

If neither operand column allows nulls, the result does not allow nulls. Otherwise, the result allows nulls.

If the data type and attributes of any operand column are not the same as those of the result, the operand column values are converted to conform to the data type and attributes of the result. The conversion operation is exactly the same as if the values were assigned to the result. For example,

- If one operand column is CHAR(10), and the other operand column is CHAR(5), the result is CHAR(10), and the values derived from the CHAR(5) column are padded on the right with five blanks.
- If the whole part of a number cannot be preserved then an error is returned.

Numeric operands

Numeric types are compatible with other numeric and character-string and graphic-string data types.

If one operand column is...	And the other operand is...	The data type of the result column is...
SMALLINT	SMALLINT or String	SMALLINT
INTEGER	SMALLINT, INTEGER, or String	INTEGER
BIGINT	SMALLINT, INTEGER, BIGINT, or String	BIGINT
DECIMAL(w,x)	SMALLINT	DECIMAL(p,x) where p = min(mp, x+max(w-x,5)) mp = 31 or 63 (See Note 1)
DECIMAL(w,x)	INTEGER	DECIMAL(p,x) where p = min(mp, x+max(w-x,11)) mp = 31 or 63 (See Note 1)

If one operand column is...	And the other operand is...	The data type of the result column is...
DECIMAL(w,x)	BIGINT	DECIMAL(p,x) where p = min(mp, x+max(w-x,19)) mp = 31 or 63 (See Note 1)
DECIMAL(w,x)	DECIMAL(y,z) or NUMERIC(y,z,)	DECIMAL(p,s) where p = min(mp, max(x,z)+max(w-x,y-z)) s = max(x,z) mp = 31 or 63 (See Note 1)
DECIMAL(w,x)	String	DECIMAL(w,x)
NUMERIC(w,x)	SMALLINT	NUMERIC(p,x) where p = min(mp, x + max(w-x,5)) mp = 31 or 63 (See Note 1)
NUMERIC(w,x)	INTEGER	NUMERIC(p,x) where p = min(mp, x + max(w-x,11)) mp = 31 or 63 (See Note 1)
NUMERIC(w,x)	BIGINT	NUMERIC(p,x) where p = min(mp, x + max(w-x,19)) mp = 31 or 63 (See Note 1)
NUMERIC(w,x)	NUMERIC(y,z)	NUMERIC(p,s) where p = min(mp, max(x,z) + max(w-x, y-z)) s = max(x,z) mp = 31 or 63 (See Note 1)
NUMERIC(w,x)	String	NUMERIC(w,x)
NONZERO SCALE BINARY	NONZERO SCALE BINARY	NONZERO SCALE BINARY (If either operand is nonzero scale binary, both operands must be binary with the same scale.)
REAL	REAL	REAL
REAL	SMALLINT, INTEGER, BIGINT, DECIMAL, NUMERIC, or String	DOUBLE
DOUBLE	SMALLINT, INTEGER, BIGINT, DECIMAL, NUMERIC, REAL, DOUBLE, or String	DOUBLE
DECFLOAT(n)	REAL, DOUBLE, INTEGER, or SMALLINT	DECFLOAT(n)
DECFLOAT(n)	DECIMAL(p<=16,s) or NUMERIC(p<=16,s)	DECFLOAT(n)

If one operand column is...	And the other operand is...	The data type of the result column is...
DECFLOAT(n)	BIGINT, DECIMAL(p>16,s), or NUMERIC(p>16,s)	DECFLOAT(34)
DECFLOAT(n)	DECFLOAT(m)	DECFLOAT(max(n,m))
DECFLOAT(n)	String	DECFLOAT(34)

Notes:

1. The value of mp is 63 if:

- either w or y is greater than 31, or
- a value of 63 was specified for the maximum precision on the DECRESULT parameter of the CRTSQLxxx command, RUNSQLSTM command, or SET OPTION statement

Otherwise, the value of mp is 31.

Character and graphic string operands

Character and graphic strings are compatible with other character and graphic strings when there is a defined conversion between their corresponding CCSIDs. A character string and a graphic string are compatible if the encoding scheme of the graphic-string data type is Unicode and the character-string data type is not bit data.

If one operand column is...	And the other operand is...	The data type of the result column is...
CHAR(x)	CHAR(y)	CHAR(z) where z = max(x,y)
GRAPHIC(x)	CHAR(y) or GRAPHIC(y)	GRAPHIC(z) where z = max(x,y)
VARCHAR(x)	CHAR(y) or VARCHAR(y)	VARCHAR(z) where z = max(x,y)
VARCHAR(x)	GRAPHIC(y)	VARGRAPHIC(z) where z = max(x,y)
VARGRAPHIC(x)	CHAR(y), VARCHAR(y), GRAPHIC(y), or VARGRAPHIC(y)	VARGRAPHIC(z) where z = max(x,y)
CLOB(x)	CHAR(y), VARCHAR(y), or CLOB(y)	CLOB(z) where z = max(x,y)
CLOB(x)	GRAPHIC(y) or VARGRAPHIC(y)	DBCLOB(z) where z = max(x,y)
DBCLOB(x)	CHAR(y), VARCHAR(y), CLOB(y), GRAPHIC(y), VARGRAPHIC(y), or DBCLOB(y)	DBCLOB(z) where z = max(x,y)

When one of the operands has a CCSID of 1208, the length (x or y value) of every operand that does not have a CCSID of 1208 is doubled for determining the result length.

The CCSID of the result graphic string will be derived based on the [“Conversion rules for operations that combine strings”](#) on page 110.

Binary string operands

Binary strings are compatible only with other binary strings or character strings FOR BIT DATA. Other data types can be treated as a binary-string data type by using the BINARY, VARBINARY, or BLOB scalar functions to cast the data type to a binary string.

If one operand column is...	And the other operand is...	The data type of the result column is...
BINARY(x)	BINARY(y) or CHAR(y) FOR BIT DATA	BINARY(z) where $z = \max(x,y)$
VARBINARY(x)	BINARY(y), VARBINARY(y), CHAR(y) FOR BIT DATA, or VARCHAR(y) FOR BIT DATA	VARBINARY(z) where $z = \max(x,y)$
VARCHAR(x) FOR BIT DATA	BINARY(y)	VARBINARY(z) where $z = \max(x,y)$
BLOB(x)	BINARY(y), VARBINARY(y), BLOB(y), CHAR(y) FOR BIT DATA, or VARCHAR(y) FOR BIT DATA	BLOB(z) where $z = \max(x,y)$

Datetime operands

A DATE type is compatible with another DATE type or any character or Unicode graphic string expression that contains a valid string representation of a date. The data type of the result is DATE.

A TIME type is compatible with another TIME type or any character or Unicode graphic string expression that contains a valid string representation of a time. The data type of the result is TIME.

A TIMESTAMP type is compatible with another TIMESTAMP type, a DATE type, or any character or Unicode graphic string expression that contains a valid string representation of a date or a timestamp. The data type of the result is TIMESTAMP.

If one operand column is...	And the other operand is...	The data type of the result column is...
DATE	DATE, CHAR(y), VARCHAR(y), CLOB(y), GRAPHIC(y), VARGRAPHIC(y), or DBCLOB(y)	DATE
TIME	TIME, CHAR(y), VARCHAR(y), CLOB(y), GRAPHIC(y), VARGRAPHIC(y), or DBCLOB(y)	TIME
TIMESTAMP(x)	TIMESTAMP(y)	TIMESTAMP($\max(x,y)$)
TIMESTAMP(x)	DATE, CHAR(y), VARCHAR(y), CLOB(y), GRAPHIC(y), VARGRAPHIC(y), or DBCLOB(y)	TIMESTAMP(x)

DataLink operands

A DataLink is compatible with another DataLink. However, DataLinks with NO LINK CONTROL are only compatible with other DataLinks with NO LINK CONTROL; DataLinks with FILE LINK CONTROL READ PERMISSION FS are only compatible with other DataLinks with FILE LINK CONTROL READ PERMISSION FS; and DataLinks with FILE LINK CONTROL READ PERMISSION DB are only compatible with other

DataLinks with FILE LINK CONTROL READ PERMISSION DB. The data type of the result is DATALINK. The length of the result DATALINK is the largest length of all the data types.

If one operand column is...	And the other operand is...	The data type of the result column is...
------------------------------------	------------------------------------	---

DATALINK(x)	DATALINK(y)	DATALINK(z) where $z = \max(x,y)$
-------------	-------------	-----------------------------------

ROWID operands

A ROWID is compatible with another ROWID. The data type of the result is ROWID.

XML operands

The XML data type is compatible only with another XML data type. The data type of the result is XML.

The result CCSID is the value from the SQL_XML_DATA_CCSID QAQQINI option setting as described in [“XML Values” on page 80](#).

Distinct type operands

A user-defined distinct type is compatible only with the same user-defined distinct type. The data type of the result is the user-defined distinct type.

If one operand column is...	And the other operand is...	The data type of the result column is...
------------------------------------	------------------------------------	---

Distinct Type	Distinct Type	Distinct Type
---------------	---------------	---------------

Conversion rules for operations that combine strings

The operations that combine strings are concatenation, UNION, UNION ALL, EXCEPT, and INTERSECT. (These rules also apply to the MAX, MIN, VALUE, COALESCE, IFNULL, and CONCAT scalar functions and CASE expressions.) In each case, the CCSID of the result is determined at bind time, and the execution of the operation may involve conversion of strings to the coded character set identified by that CCSID.

The CCSID of the result is determined by the CCSIDs of the operands. The CCSIDs of the first two operands determine an intermediate result CCSID, this CCSID and the CCSID of the next operand determine a new intermediate result CCSID, and so on. The last intermediate result CCSID and the CCSID of the last operand determine the CCSID of the result string or column. For each pair of CCSIDs, the result CCSID is determined by the sequential application of the following rules:

- If the CCSIDs are equal, the result is that CCSID.
- If either CCSID is 65535, the result is 65535.³⁰
- If one CCSID denotes data in an encoding scheme different from the other CCSID, the result is determined by the following table:

Table 23. Selecting the Encoding Scheme of the Intermediate Result

First Operand	Second Operand			
	SBCS Data	DBCS Data	Mixed Data	Unicode Graphic Data
SBCS Data	see below	second	second	second
DBCS Data	first	see below	second	second
Mixed Data	first	first	see below	second
Unicode Graphic Data	first	first	first	see below

- Otherwise, the resulting CCSID is determined by the following tables:

Table 24. Selecting the CCSID of the Intermediate Result

First Operand	Second Operand				
	Column Value	Derived Value	Constant	Special Register	Variable
Column Value	first	first	first	first	first
Derived Value	second	first	first	first	first
Constant	second	second	first	first	first
Special Register	second	second	first	first	first
Variable	second	second	second	second	first

A variable containing data in a foreign encoding scheme is effectively converted to the native encoding scheme before it is used in any operation. The above rules are based on the assumption that this conversion has already occurred.

³⁰ If either operand is a CLOB or DBCLOB, the resulting CCSID is the job default CCSID.

Note that an intermediate result is considered to be a derived value operand. For example, assume COLA, COLB, and COLC are columns with CCSIDs 37, 278, and 500, respectively. The result CCSID of COLA CONCAT COLB CONCAT COLC is determined as follows:

1. The result CCSID of COLA CONCAT COLB is first determined to be 37 because both operands are columns, so the CCSID of the first operand is chosen.
2. The result CCSID of “intermediate result” CONCAT COLC is determined to be 500, because the first operand is a derived value and the second operand is a column, so the CCSID of the second operand is chosen.

An operand of concatenation, or the result expression of the CASE expression, or the operands of the IN predicate, or the selected argument of the MAX, MIN, VALUE, COALESCE, IFNULL, or CONCAT scalar function is converted, if necessary, to the coded character set of the result string. Each string of an operand of UNION, UNION ALL, EXCEPT, or INTERSECT is converted, if necessary, to the coded character set of the result column. Character conversion is necessary only if all of the following are true:

- The CCSIDs are different.
- Neither CCSID is 65535.
- The string is neither null nor empty.
- Conversion between the two CCSIDs is required. For more information, see [“Coded character sets and CCSIDs”](#) on page 32.

An error is returned if a character of the string cannot be converted or if the conversion between the pair of CCSIDs is not defined. For more information, see [“Coded character sets and CCSIDs”](#) on page 32. A warning occurs if a character of a string is converted to the substitution character.

Constants

A *constant* (also called a *literal*) specifies a value. Constants are classified as string constants or numeric constants. String constants are further classified as character or graphic. Numeric constants are further classified as integer, floating point, or decimal.

All constants have the attribute NOT NULL. A negative sign in a numeric constant with a value of zero is ignored.

Integer constants

An *integer constant* specifies an integer as a signed or unsigned number with a maximum of 19 digits that does not include a decimal point. The data type of an integer constant is large integer if its value is within the range of a large integer. The data type of an integer constant is big integer if its value is outside the range of a large integer, but within the range of a big integer. A constant that is defined outside the range of big integer values is considered a decimal constant.

Examples

```
64      -15      +100      32767      720176      12345678901
```

In syntax diagrams, the term *integer* is used for a large integer constant that must not include a sign.

Decimal constants

A *decimal constant* specifies a decimal number as a signed or unsigned number that consists of no more than 63 digits and either includes a decimal point or is not within the range of binary integers.

The precision is the total number of digits (including leading and trailing zeros); the scale is the number of digits to the right of the decimal point (including trailing zeros). If the precision of the decimal constant is greater than the largest decimal precision and the scale is not greater than the largest decimal precision, then leading zeroes to the left of the decimal point are eliminated to reduce the precision to the largest decimal precision.

Examples

```
25.5      1000.      -15.      +37589.3333333333
```

Floating-point constants

A *floating-point constant* specifies a double-precision floating-point number as two numbers separated by an E. The first number can include a sign and a decimal point; the second number can include a sign but not a decimal point. The value of the constant is the product of the first number and the power of 10 specified by the second number; it must be within the range of floating-point numbers. The number of characters in the constant must not exceed 24. Excluding leading zeros, the number of digits in the first number must not exceed 17 and the number of digits in the second must not exceed 3.

Examples

```
15E1      2.E5      2.2E-1      +5.E+2
```

Decimal floating-point constants

A *decimal floating-point constant* specifies a decimal floating-point number as two numbers separated by an E. The first number can include a sign and a decimal point; the second number can include a sign but not a decimal point. The value of the constant is the product of the first number and the power of 10 specified by the second number; it must be within the range of DECFLOAT(34). The number of characters

in the constant must not exceed 42. Excluding leading zeros, the number of digits in the first number must not exceed 34 and the number of digits in the second must not exceed 4.

A constant specified as two numbers separated by E is a decimal floating-point constant only if:

- Excluding leading zeros, the number of digits in the first number exceeds 17 (precision).
- The exponent is outside of the range of double floating-point numbers (smaller than -308 or larger than 308).

In addition to numeric constants, the following reserved keywords can be used to specify decimal floating-point special values. These special values are: INFINITY, NAN, and SNAN. INFINITY represents infinity, a number whose magnitude is infinitely large. INFINITY can be preceded by an optional sign. INF can be specified in place of INFINITY. NAN represents Not a Number (NaN) and is sometimes called quiet NaN. It is a value that represents undefined results which does not cause a warning or exception. SNAN represents signaling NaN (sNaN). It is a value that represents undefined results which will cause a warning or exception if used in any operation that is defined in any numerical operation. Both NAN and SNAN can be preceded by an optional sign, but the sign is not significant for arithmetic operations. SNAN can be used in non-numerical operations without causing a warning or exception, for example in the VALUES list of an INSERT or as a constant compared in a predicate.

When one of the special values (INFINITY, INF, NAN, and SNAN) is used in a context where it could be interpreted as an identifier, such as a column name, cast a string constant representing the special value to decimal-floating point.

```
CAST('snan' AS DECFLOAT(34))
CAST('INF' AS DECFLOAT(34))
CAST('Nan' AS DECFLOAT(34))
```

Examples

```
1.8E308      -1.23456789012345678E-2   SNAN      -INFINITY
```

Character-string constants

A *character-string constant* specifies a varying-length character string.

The two forms of character-string constant follow:

- A sequence of characters that starts and ends with a string delimiter. The number of bytes between the string delimiters cannot be greater than 32740. Two consecutive string delimiters are used to represent one string delimiter within the character string. Two consecutive string delimiters that are not contained within a string represent the empty string.
- An X followed by a sequence of characters that starts and ends with a string delimiter. The characters between the string delimiters must be an even number of hexadecimal digits. Blanks between the string delimiters are ignored. The number of hexadecimal digits must not exceed 32762. A hexadecimal digit is a digit or any of the letters A through F (uppercase or lowercase). Under the conventions of hexadecimal notation, each pair of hexadecimal digits represents a character. This form of string constant allows you to specify characters that do not have a keyboard representation.

Character-string constants can contain mixed data. If the job CCSID supports mixed data, a character-string constant is classified as mixed data if it includes a DBCS substring. In all other cases, a character-string constant is classified as SBCS data.

The CCSID assigned to the constant is the CCSID of the SQL statement text containing the constant unless the SQL statement is encoded in Unicode or a foreign encoding scheme (such as ASCII). In this case, the SQL statement text is converted from Unicode or the foreign encoding scheme to the default CCSID of the current server. The CCSID assigned to the constant will be the default CCSID of the current server³¹.

The CCSID of the SQL statement text is defined in the following table.

³¹ If the default CCSID is 65535, the CCSID used will be the value of the DFTCCSID job attribute.

Table 25. CCSID of the SQL statement text for different interfaces

SQL Interface	CCSID of SQL statement text
Embedded SQL	<ul style="list-style-type: none"> For static statements, the CCSID of the source file for the CRTSQLxxx command. For dynamic statements, the CCSID of the variable specified on the PREPARE statement, or if a string constant is specified on the PREPARE statement, the CCSID of the source file for the CRTSQLxxx command.
RUNSQLSTM	The CCSID of the specified source file.
STRSQL and RUNSQL	The default CCSID of the current server.
Call Level Interface (CLI) on the server	<p>Unicode, if SQL_ATTR_UCS2, SQL_ATTR_UTF8, or wide APIs are specified.</p> <p>Otherwise, the default CCSID of the current server. The SQL_ATTR_NON_HEXCCSID environment variable can be used to specify the DFTCCSID job attribute instead.</p>
ODBC on a client using the IBM i Access Family ODBC Driver	<p>Unicode, if UNICODESQL is specified.</p> <p>Otherwise, the default CCSID of the current server. If the default CCSID is 65535, the CCSID used will be the value of the DFTCCSID job attribute.</p>
JDBC or SQLJ on the server using IBM Developer Kit for Java	Unicode
JDBC on a client using the IBM Toolbox for Java	Unicode
OLE DB on a client using the IBM i Access Family OLE DB Provider	Unicode
.ADO .NET on a client using the IBM i Access Family ODO .NET Provider	Unicode

Character-string constants are used to represent constant datetime values in assignments and comparisons. For more information see [“String representations of datetime values”](#) on page 75.

Examples

```
'Peggy' '14.12.1990' '32' 'DON'T CHANGE' '' X'FFFF'
```

Graphic-string constants

There are two types of graphic-string constants: DBCS and Unicode graphic-string constants.

DBCS graphic-string constants

A *graphic-string constant* is a varying-length graphic string. The length of the specified string cannot be greater than 16370. The forms of DBCS graphic-string constants are:

Context	Graphic String Constant	Empty String	Example
All contexts	G ' _s ddbc-string _s ' _I	G ' _s _s ' _I G '' g ' _s _s ' _I g ''	G ' _s 元 氣 _s ' _I
PL/I	_s ' ddbc-string ' G _s _I	_s ' ' G _s _I	_s ' 元 氣 ' G _s _I

R139F000-1

In the normal form, the SQL delimiters and the G is an SBCS character. The SBCS ' is the EBCDIC apostrophe, X'7D'.

In the PL/I form, the apostrophes and the G are DBCS characters. Two consecutive DBCS string delimiters are used to represent one string delimiter within the string. Note that this PL/I form is only valid for static statements embedded in PL/I programs.

A hexadecimal DBCS graphic constant is also supported. The form of the hexadecimal DBCS graphic constant is:

GX'ssss'

In this constant, **ssss** represents a string from 0 to 32760 hexadecimal digits. The number of characters between the string delimiters must be an even multiple of 4. Blanks between the string delimiters are ignored. Each group of 4 digits represents a single DBCS graphic character. The hexadecimal for shift-in and shift-out ('0E'X and '0F'X) are not included in the string.

The CCSID assigned to constants is the DBCS CCSID associated with the CCSID of the source unless the source is encoded in a foreign encoding scheme (such as ASCII). In this case, the CCSID assigned to the constant is the DBCS CCSID associated with the default CCSID of the current server when the SQL statement containing the constant is prepared. If there is no DBCS CCSID associated with the CCSID of the source, the CCSID is 65535.

For information about associated DBCS CCSIDs, see the Use DBCS CCSIDs topic in the IBM i Information Center. For information about the CCSID of the source, see Character String Constants.

Unicode graphic-string constants

There are two types of Unicode graphic-string constants: N and UX. The form of the Unicode graphic constant is:

N'ssss'

In the constant, **ssss** is a string of 16370 characters. The characters are converted from the source CCSID to the Unicode CCSID during processing.

The form of the hexadecimal Unicode graphic constant is:

UX'ssss'

In the constant, **ssss** represents a string from 0 to 32760 hexadecimal digits. The number of characters between the string delimiters must be an even multiple of 4. Blanks between the string delimiters are ignored. Each group of 4 or more digits represents a single Unicode graphic character.

The CCSID of a Unicode graphic-string constant is 13488 (UCS-2). If the standards option is specified, the CCSID is 1200 (UTF-16). For information about the standards option, see [“Standards compliance” on page xix](#).

Binary-string constants

A *binary-string constant* specifies a varying-length binary string.

The two forms of a binary-string constant are:

- A BX followed by a sequence of characters that starts and ends with a string delimiter. The characters between the string delimiters must be an even number of hexadecimal digits. Blanks between the string

delimiters are ignored. The number of hexadecimal digits must not exceed 32740. A hexadecimal digit is a digit or any of the letters A through F (uppercase or lowercase).

- An X followed by a sequence of characters that starts and ends with a string delimiter. The characters between the string delimiters must be an even number of hexadecimal digits. Blanks between the string delimiters are ignored. The number of hexadecimal digits must not exceed 32740. A hexadecimal digit is a digit or any of the letters A through F (uppercase or lowercase).

The CCSID assigned to the constant is 65535.

Note that the syntax of the second form of binary string constant is identical to the second form of a character constant. A constant of this form is only treated as a binary string constant if the standards option is specified. For information on the standards option, see [“Standards compliance”](#) on page xix.

Examples

```
BX'FFFF'  
X'FFFF'
```

Datetime constants

A *datetime constant* specifies a date, time, or timestamp.

Typically, character-string constants are used to represent constant datetime values in assignments and comparisons. For information on string representations of datetime values, see [“String representations of datetime values”](#) on page 75. However, the ANSI/ISO SQL standard form of a datetime constant can be used to specifically denote the constant as a *datetime constant* instead of a string constant.

The format for the three ANSI/ISO SQL standard datetime constants are:

- DATE 'yyyy-mm-dd'

The data type of the value is DATE.

- TIME 'hh:mm:ss'

The data type of the value is TIME.

- TIMESTAMP 'yyyy-mm-dd hh:mm:ss.nnnnnnnnnnn'

The data type of the value is TIMESTAMP(*p*), where *p* is the number of digits of fractional seconds.

Trailing zeros can be truncated or omitted entirely from fractional seconds.

Leading zeros must not be omitted from any part of a standard datetime constant.

Example

```
DATE '2003-09-03'
```

Decimal point

You can specify a *default decimal point*.

The *default decimal point* can be specified:

- To interpret numeric constants
- To determine the decimal point character to use when casting a character string to a number (for example, in the DECFLOAT, DECIMAL, DOUBLE_PRECISION, FLOAT, and REAL scalar functions and the CAST specification)
- To determine the decimal point character to use in the result when casting a number to a string (for example, in the CHAR, VARCHAR, CLOB, GRAPHIC, and VARGRAPHIC scalar functions and the CAST specification)

The default decimal point can be specified through the following interfaces:

Table 26. Default Decimal Point Interfaces

SQL Interface	Specification
Embedded SQL	<p>The *JOB, *PERIOD, *COMMA, or *SYSVAL value in the OPTION parameter is specified on the Create SQL Program (CRTSQLxxx) commands. The SET OPTION statement can also be used to specify the DECMPT parameter within the source of a program containing embedded SQL.</p> <p>(For more information about CRTSQLxxx commands, see Embedded SQL programming.)</p>
Interactive SQL and Run SQL Statements	<p>The DECPNT parameter on the Start SQL (STRSQL) command or by changing the session attributes. The DECMPT parameter on the Run SQL Statements (RUNSQLSTM) command.</p> <p>(For more information about STRSQL and RUNSQLSTM commands, see SQL programming.)</p>
Call Level Interface (CLI) on the server	<p>SQL_ATTR_DECIMAL_SEP environment or connection variables</p> <p>(For more information about CLI, see SQL Call Level Interfaces (ODBC).)</p>
JDBC or SQLJ on the server using IBM IBM Developer Kit for Java	<p>Decimal Separator connection property</p> <p>(For more information about JDBC and SQLJ, see IBM Developer Kit for Java.)</p>
ODBC on a client using the IBM i Access Family ODBC Driver	<p>Decimal Separator in the Advanced Server Options in ODBC Setup</p> <p>(For more information about ODBC, see IBM i Access.)</p>
JDBC on a client using the IBM Toolbox for Java	<p>Format in JDBC Setup</p> <p>(For more information about ODBC, see IBM i Access.)</p> <p>(For more information about the IBM Toolbox for Java, see IBM Toolbox for Java.)</p>

If the comma is the decimal point, the following rules apply:

- A period will also be allowed as a decimal point.
- A comma intended as a separator of numeric constants in a list must be followed by a space.
- A comma intended as a decimal point must not be followed by a space.

Thus, to specify a decimal constant without a fractional part, the trailing comma must be followed by a non-blank character. The non-blank character can be a separator comma, as in:

```
VALUES(9999999999, , 111)
```

Delimiters

*APOST and *QUOTE are mutually exclusive COBOL precompiler options that name the string delimiter within COBOL statements. *APOST names the apostrophe (') as the string delimiter; *QUOTE names the

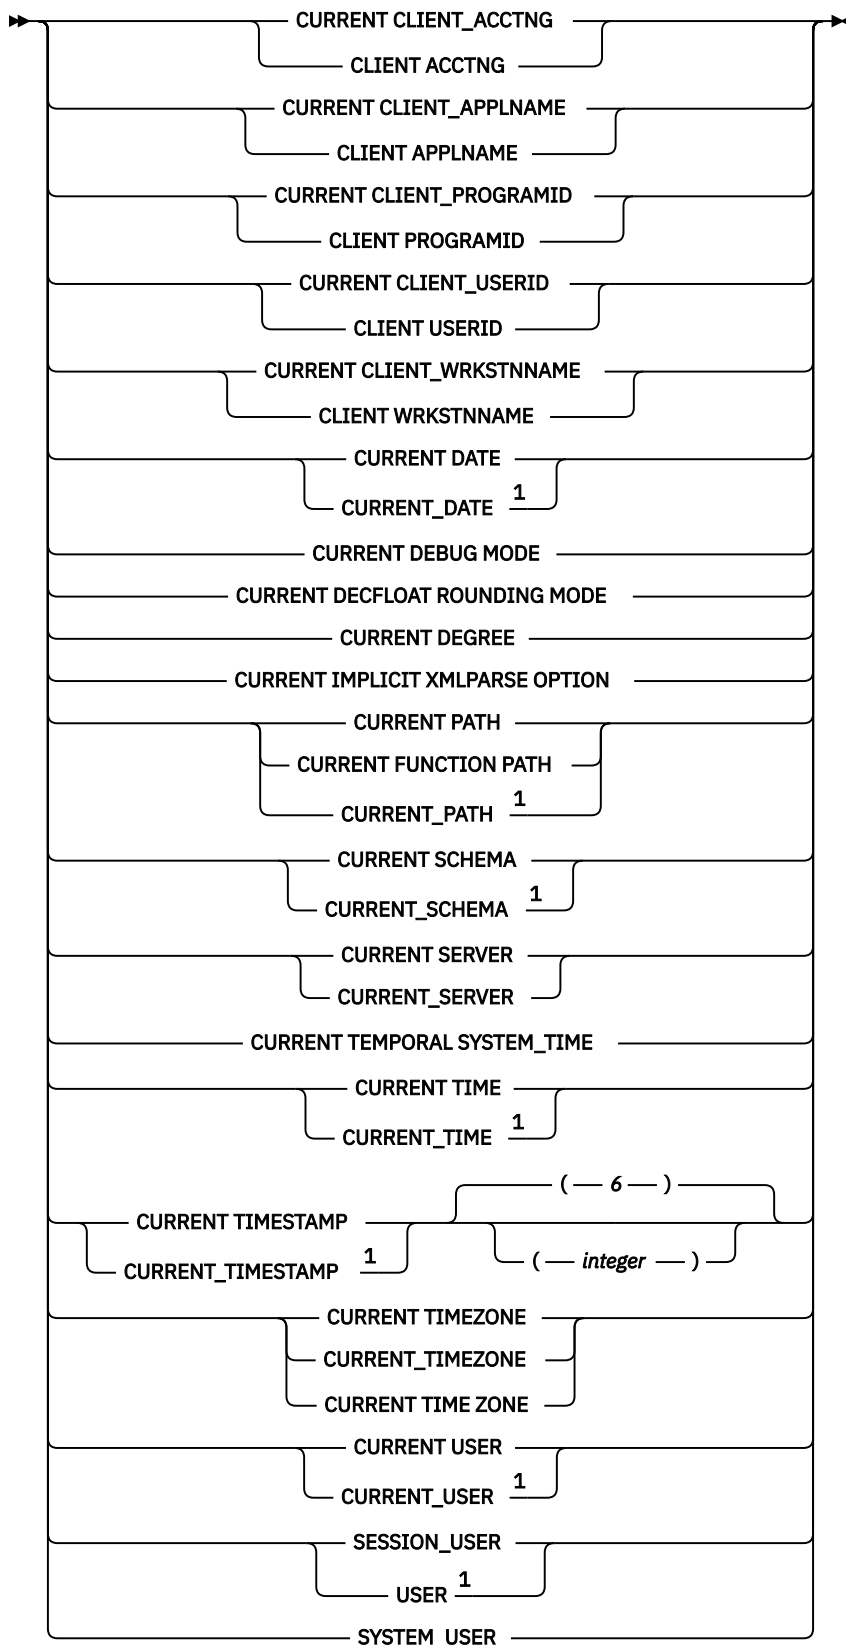

quotation mark ("). *APOST and *QUOTE are mutually exclusive COBOL precompiler options that play a similar role for SQL statements embedded in COBOL programs. *APOST names the apostrophe (') as the SQL string delimiter; with this option, the quotation mark (") is the SQL escape character. *QUOTE names the quotation mark as the SQL string delimiter; with this option, the apostrophe is the SQL escape character. The values of *APOST and *QUOTE are respectively the same as the values of *APOST and *QUOTE.

In host languages other than COBOL, the usages are fixed. The string delimiter for the host language and for static SQL statements is the apostrophe ('); the SQL escape character is the quotation mark (").

Special registers

A *special register* is a storage area that is defined for an application process by database manager and is used to store information that can be referenced in SQL statements. A reference to a special register is a reference to a value provided by the current server. If the value is a string, its CCSID is a default CCSID of the current server.

The special registers can be referenced as follows:

Notes:

¹ The SQL 2003 Core standard uses the form with the underscore.

The value of these special registers, except for CURRENT TEMPORAL SYSTEM_TIME, cannot be null.

CURRENT CLIENT_ACCTNG

The CURRENT CLIENT_ACCTNG special register specifies a VARCHAR(255) value that contains the value of the accounting string from the client information specified for the current connection.

The default value of this register is the empty string. The value of the accounting string can be changed through these interfaces:

- The [Set Client Information \(SQLESETI\)](#) API can change the client special register.
- The SYSPROC.WLM_SET_CLIENT_INFO procedure can change the client special register.
- In CLI, SQLSetConnectAttr() can be used to set the SQL_ATTR_INFO_ACCTSTR connection attribute.
- In ODBC, SQLSetConnectAttr() can be used to set the ODBC_ATTR_INFO_ACCTSTR connection attribute.
- In JDBC, the setClientInfo connection method can be used to set the ClientAccounting connection property.

Example

Get the current value of the accounting string for this connection

```
VALUES CURRENT_CLIENT_ACCTNG  
INTO :ACCT_STRING
```

CURRENT CLIENT_APPLNAME

The CURRENT CLIENT_APPLNAME special register specifies a VARCHAR(255) value that contains the value of the application name from the client information specified for the current connection.

The default value of this register is the empty string. The value of the application name can be changed through these interfaces:

- The Set Client Information (SQLESETI) API can change the client special register.
- The SYSPROC.WLM_SET_CLIENT_INFO procedure can change the client special register.
- In CLI, SQLSetConnectAttr() can be used to set the SQL_ATTR_INFO_APPLNAME connection attribute.
- In ODBC, SQLSetConnectAttr() can be used to set the ODBC_ATTR_INFO_APPLNAME connection attribute.
- In JDBC, the setClientInfo connection method can be used to set the ApplicationName connection property.

Example

Select the departments that are allowed to use the application being used in this connection.

```
SELECT DEPT  
FROM DEPT_APPL_MAP  
WHERE APPL_NAME = CURRENT_CLIENT_APPLNAME
```

CURRENT CLIENT_PROGRAMID

The CURRENT CLIENT_PROGRAMID special register specifies a VARCHAR(255) value that contains the value of the client program ID from the client information specified for the current connection.

The default value of this register is the empty string. The value of the client program ID can be changed through these interfaces:

- The Set Client Information (SQLESETI) API can change the client special register.
- The SYSPROC.WLM_SET_CLIENT_INFO procedure can change the client special register.

- In CLI, `SQLSetConnectAttr()` can be used to set the `SQL_ATTR_INFO_PROGRAMID` connection attribute.
- In ODBC, `SQLSetConnectAttr()` can be used to set the `ODBC_ATTR_INFO_PROGRAMID` connection attribute.
- In JDBC, the `setClientInfo` connection method can be used to set the `ClientProgramID` connection property.

Example

Get the program ID being used for this connection.

```
VALUES CURRENT CLIENT_PROGRAMID
INTO :PGM_ID
```

CURRENT CLIENT_USERID

The `CURRENT CLIENT_USERID` special register specifies a `VARCHAR(255)` value that contains the value of the client user ID from the client information specified for the current connection.

The default value of this register is the empty string. The value of the client user ID can be changed through these interfaces:

- The Set Client Information (`SQLESETI`) API can change the client special register.
- The `SYSPROC.WLM_SET_CLIENT_INFO` procedure can change the client special register.
- In CLI, `SQLSetConnectAttr()` can be used to set the `SQL_ATTR_INFO_USERID` connection attribute.
- In ODBC, `SQLSetConnectAttr()` can be used to set the `ODBC_ATTR_INFO_USERID` connection attribute.
- In JDBC, the `setClientInfo` connection method can be used to set the `ClientUser` connection property.

Example

Find out in which department the current client user ID works.

```
SELECT DEPT
FROM DEPT_USERID_MAP
WHERE USER_ID = CURRENT CLIENT_USERID
```

CURRENT CLIENT_WRKSTNNAME

The `CURRENT CLIENT_WRKSTNNAME` special register specifies a `VARCHAR(255)` value that contains the value of the workstation name from the client information specified for the current connection.

The default value of this register is the empty string. The value of the workstation name can be changed through these interfaces:

- The Set Client Information (`SQLESETI`) API can change the client special register.
- The `SYSPROC.WLM_SET_CLIENT_INFO` procedure can change the client special register.
- In CLI, `SQLSetConnectAttr()` can be used to set the `SQL_ATTR_INFO_WRKSTNNAME` connection attribute.
- In ODBC, `SQLSetConnectAttr()` can be used to set the `ODBC_ATTR_INFO_WRKSTNNAME` connection attribute.
- In JDBC, the `setClientInfo` connection method can be used to set the `ClientHostName` connection property.

Example

Get the workstation name being used for this connection.

```
VALUES CURRENT CLIENT_WRKSTNNAME
INTO :WS_NAME
```

CURRENT DATE

The CURRENT DATE special register specifies a date that is based on a reading of the time-of-day clock when the SQL statement is executed at the current server.

If this special register is used more than once within a single SQL statement, or used with CURRENT TIME, CURRENT TIMESTAMP, or the CURDATE, CURTIME, or NOW scalar functions within a single statement; all values are based on a single clock reading.³²

Example

Using the PROJECT table, set the project end date (PRENDATE) of the MA2111 project (PROJNO) to the current date.

```
UPDATE PROJECT
SET PRENDATE = CURRENT DATE
WHERE PROJNO = 'MA2111'
```

CURRENT DEBUG MODE

The CURRENT DEBUG MODE special register specifies whether SQL or Java procedures should be created or altered so they can be debugged by the Unified Debugger.

Any explicit specification of the DEBUG MODE or the DBGVIEW option in the SET OPTION statement on the CREATE PROCEDURE or ALTER PROCEDURE statement overrides the value in the CURRENT DEBUG MODE special register. CURRENT DEBUG MODE affects static and dynamic SQL statements. The data type of the register is VARCHAR(8). The valid values include:

DISALLOW

Procedures will be created so they cannot be debugged by the Unified Debugger. When the DEBUG MODE attribute of a procedure is DISALLOW, the procedure can be subsequently altered to change the DEBUG MODE attribute.

ALLOW

Procedures will be created so they can be debugged by the Unified Debugger. When the DEBUG MODE attribute of a procedure is ALLOW, the procedure can be subsequently altered to change the DEBUG MODE attribute.

DISABLE

Procedures will be created so they cannot be debugged by the Unified Debugger. When the DEBUG MODE attribute of a procedure is DISABLE, the procedure cannot be subsequently altered to change the DEBUG MODE attribute.

The value can be changed by invoking the SET CURRENT DEBUG MODE statement. For details about this statement, see [“SET CURRENT DEBUG MODE”](#) on page 1495.

The initial value of CURRENT DEBUG MODE is DISALLOW.

Example

The following statement prevents subsequent creates or alters of SQL or Java procedures from being debuggable:

```
SET CURRENT DEBUG MODE = DISALLOW
```

³² LOCALDATE can be specified as a synonym for CURRENT_DATE.

CURRENT DECFLOAT ROUNDING MODE

The CURRENT DECFLOAT ROUNDING MODE special register specifies the rounding mode that is used when DECFLOAT values are manipulated in dynamically prepared SQL statements.

The data type of the register is VARCHAR(128). The rounding modes supported are:

ROUND_CEILING

Round toward +infinity. If all of the discarded digits are zero or if the sign is negative, the result is unchanged other than the removal of the discarded digits. Otherwise, the result coefficient is incremented by one (rounded up).

ROUND_DOWN

Round toward zero (truncation). The discarded digits are ignored.

ROUND_FLOOR

Round toward -infinity. If all of the discarded digits are zero or if the sign is positive, the result is unchanged other than the removal of the discarded digits. Otherwise, the sign is negative and the result coefficient is incremented by one.

ROUND_HALF_DOWN

Round to nearest; if equidistant, round down. If the discarded digits represent greater than half (0.5) of the value of a one in the next left position, then the result coefficient is incremented by one (rounded up). Otherwise, the discarded digits are ignored.

ROUND_HALF_EVEN

Round to nearest; if equidistant, round so that the final digit is even. If the discarded digits represent greater than half (0.5) of the value of a one in the next left position, then the result coefficient is incremented by one (rounded up). If they represent less than half, then the result coefficient is not adjusted (that is, the discarded digits are ignored). Otherwise (they represent exactly half), the result coefficient is unaltered if its rightmost digit is even, or incremented by one (rounded up) if its rightmost digit is odd (to make an even digit).

ROUND_HALF_UP

Round to nearest; if equidistant, round up. If the discarded digits represent greater than or equal to half (0.5) of the value of a one in the next left position, then the result coefficient is incremented by one (rounded up). Otherwise, the discarded digits are ignored.

ROUND_UP

Round away from zero. If all of the discarded digits are zero, the result is unchanged other than the removal of discarded digits. Otherwise, the result coefficient is incremented by one (rounded up).

The initial value of CURRENT DECFLOAT ROUNDING MODE in an activation group is established by the first SQL statement that is executed in the activation group.

- If the first SQL statement in an activation group is executed from an SQL program or SQL package, the CURRENT DECFLOAT ROUNDING MODE special register is set to the value of the DECFLTRND parameter.
- Otherwise, the initial value is ROUND_HALF_EVEN.

The DECFLTRND parameter on the CRTSQLxxx command or SET OPTION is used for static SQL statements.

Example

Set the host variable APPL_ROUND (VARCHAR(128)) to the current rounding mode.

```
SELECT CURRENT DECFLOAT ROUNDING MODE
INTO :APPL_ROUND
FROM SYSIBM.SYSDUMMY1
```

CURRENT DEGREE

The CURRENT DEGREE special register specifies the degree of I/O or Symmetric MultiProcessing (SMP) parallelism for the execution of queries, index creates, index rebuilds, index maintenance, and reorganizes.

CURRENT DEGREE affects static and dynamic SQL statements. The data type of the register is CHAR(5). The valid values include:

1

No parallel processing is allowed.

2 through 32767

Specifies the degree of parallelism that will be used.

ANY

Specifies that the database manager can choose to use any number of tasks for either I/O or SMP parallel processing.

Use of parallel processing and the number of tasks used is determined based on the number of processors available in the system, this job's share of the amount of active memory available in the pool in which the job is run, and whether the expected elapsed time for the operation is limited by CPU processing or I/O resources. The database manager chooses an implementation that minimizes elapsed time based on the job's share of the memory in the pool.

NONE

No parallel processing is allowed.

MAX

The database manager can choose to use any number of tasks for either I/O or SMP parallel processing. MAX is similar to ANY except the database manager assumes that all active memory in the pool can be used.

IO

The CQE optimizer can use parallel I/O methods only. This setting does not require the SMP feature. The SQE optimizer considers I/O parallelism with or without this setting.

The initial value of CURRENT DEGREE is determined by the current degree in effect from the CHGQRYA CL command, PARALLEL_DEGREE parameter in the current query options file (QAQQINI), or the QQRYDEGREE system value.

The value can be changed by invoking the SET CURRENT DEGREE statement. For details about this statement, see [“SET CURRENT DEGREE” on page 1499](#).

Example

The following statement inhibits parallelism:

```
SET CURRENT DEGREE = '1'
```

CURRENT IMPLICIT XMLPARSE OPTION

The CURRENT IMPLICIT XMLPARSE OPTION special register specifies whitespace handling options that are to be used when serialized XML data is implicitly parsed by the Db2 server without validation.

An implicit non-validating parse operation occurs when an SQL statement is processing an XML host variable or an implicitly or explicitly typed XML parameter marker that is not an argument of the XMLVALIDATE function.

The data type of the register is VARCHAR(128). The supported values are:

STRIP WHITESPACE

Whitespace that is in the document to improve readability is removed. The whitespace characters are: blank, carriage return, line feed, and tab. All boundary whitespace (whitespace between elements) is removed.

PRESERVE WHITESPACE

No whitespace is removed.

The initial value of CURRENT IMPLICIT XMLPARSE OPTION is 'STRIP WHITESPACE'.

Example

Set the CURRENT IMPLICIT XMLPARSE OPTION to PRESERVE WHITESPACE.

```
SET CURRENT IMPLICIT XMLPARSE OPTION = PRESERVE WHITESPACE
```

CURRENT PATH

The CURRENT PATH special register specifies the SQL path used to resolve unqualified type names, function names, and procedure names in dynamically prepared SQL statements.

It is also used to resolve unqualified procedure names that are specified as variables in SQL CALL statements (CALL *variable*). The data type is VARCHAR(8843).

The CURRENT PATH special register contains the value of the SQL path, which is a list of one or more schema names. Each schema name is enclosed in delimiters and separated from the following schema by a comma (any delimiters within the string are repeated as they are in any delimited identifier). The delimiters and commas are included in the length of the special register. The maximum number of schema names in the path is 268.

If a schema name has a different system name, the schema name is returned in the CURRENT PATH special register even if the system name was explicitly specified in the SET PATH statement.

For information about when the SQL path is used to resolve unqualified names in both dynamic and static SQL statements and the effect of its value, see [“Unqualified function, procedure, specific name, type, and variables”](#) on page 59.

The initial value of the CURRENT PATH special register in an activation group is established by the first SQL statement that is executed.

- If the first SQL statement in an activation group is executed from an SQL program or SQL package and the SQLPATH parameter was specified on the CRTSQLxxx command, the path is the value specified in the SQLPATH parameter. The SQLPATH value can also be specified using the SET OPTION statement.
- Otherwise,
 - For SQL naming, "QSYS", "QSYS2", "SYSPROC", "SYSIBMADM", "*the value of the run-time authorization ID of the statement*".
 - For system naming, "*LIBL".

The value of the special register can be changed by executing the SET PATH statement. For details about this statement, see [“SET PATH”](#) on page 1531. For portability across the platforms, it is recommended that a SET PATH statement be issued at the beginning of an application.

Example

Set the special register so that schema SMITH is searched before schemas QSYS and QSYS2 (SYSTEM PATH).

```
SET CURRENT PATH SMITH, SYSTEM PATH
```

CURRENT SCHEMA

The CURRENT SCHEMA special register specifies a VARCHAR(128) value that identifies the schema name used to qualify unqualified database object references where applicable in dynamically prepared SQL statements.

CURRENT SCHEMA is not used to qualify names in programs where the DYNDFTCOL has been specified. If DYNDFTCOL is specified in a program, its schema name is used instead of the CURRENT SCHEMA schema name.³³

The initial value of CURRENT SCHEMA is the authorization ID of the current session user.

The value of the special register can be changed by executing the SET SCHEMA statement. For more information, see [“SET SCHEMA” on page 1537](#).

The DFTRDBCOL keyword controls the schema name used to qualify unqualified database object references where applicable for static SQL statements.

Example

Set the schema for object qualification to 'D123'.

```
SET CURRENT SCHEMA = 'D123'
```

CURRENT SERVER

The CURRENT SERVER special register specifies a VARCHAR(18) value that identifies the current application server.

CURRENT SERVER can be changed by the CONNECT (Type 1), CONNECT (Type 2), or SET CONNECTION statements, but only under certain conditions. See the description in [“CONNECT \(type 1\)” on page 962](#), [“CONNECT \(type 2\)” on page 967](#), and [“SET CONNECTION” on page 1492](#).

CURRENT SERVER cannot be specified unless the local relational database is named by adding the entry to the relational database directory using the ADDRDBDIRE or WRKRDBDIRE command.

Example

Set the host variable APPL_SERVE (VARCHAR(18)) to the name of the current server.

```
SELECT CURRENT SERVER  
INTO :APPL_SERVE  
FROM SYSIBM.SYSDUMMY1
```

CURRENT TEMPORAL SYSTEM_TIME

The CURRENT TEMPORAL SYSTEM_TIME special register specifies a TIMESTAMP(12) value that is used in the default SYSTEM_TIME period specification for references to system-period temporal tables.

When a system-period temporal table is referenced and the value in effect for the CURRENT TEMPORAL SYSTEM_TIME special register is not the null value, the following period specification is implicit:

```
FOR SYSTEM_TIME AS OF CURRENT TEMPORAL SYSTEM_TIME
```

The initial value of the special register in a user-defined function, procedure, or trigger is inherited from the invoking application. In other contexts the initial value of the special register is the null value.

The value of this special register can be changed by executing the SET CURRENT TEMPORAL SYSTEM_TIME statement. If the value of the special register is changed within a routine, that new value is not passed back to the invoking application.

³³ For compatibility with Db2 for z/OS, the special register CURRENT SQLID is treated as a synonym for CURRENT SCHEMA.

The setting for the SYSTIME option determines whether references to system-period temporal tables in both static SQL statements and dynamic SQL statements are affected by the value of the CURRENT TEMPORAL SYSTEM_TIME special register. The option can be set to YES or NO.

When the value of the CURRENT TEMPORAL SYSTEM_TIME special register is not null and the SYSTIME option is set to YES, FOR SYSTEM_TIME cannot be explicitly specified in a select-statement.

Examples

For the following examples, assume the table IN_TRAY is a system-period temporal table.

Example 1: Based on the state of the messages in IN_TRAY as of the date specified by the CURRENT TEMPORAL SYSTEM_TIME special register, list the user IDs and subject lines.

```
SELECT SOURCE, SUBJECT
FROM IN_TRAY
```

If the special register is set to a non-null value, the previous statement is equivalent to the following statement:

```
SELECT SOURCE, SUBJECT
FROM IN_TRAY
FOR SYSTEM_TIME AS OF CURRENT TEMPORAL SYSTEM_TIME
```

Example 2: List the user ID and subject line for the messages in IN_TRAY sent before the value specified by the CURRENT TEMPORAL SYSTEM_TIME special register, which has been set to a value of '2011-01-01-00.00.00.000000'.

```
SELECT SOURCE, SUBJECT
FROM IN_TRAY
WHERE RECEIVED < CURRENT TEMPORAL SYSTEM_TIME
```

Assuming that the CURRENT TEMPORAL SYSTEM_TIME special register is set to the null value, the following statement returns the same result.

```
SELECT SOURCE, SUBJECT
FROM IN_TRAY
FOR SYSTEM_TIME AS OF '2011-01-01-00.00.00.000000'
WHERE DATE(RECEIVED) < DATE('2011-01-01-00.00.00.000000')
```

CURRENT TIME

The CURRENT TIME special register specifies a time that is based on a reading of the time-of-day clock when the SQL statement is executed at the current server.

If this special register is used more than once within a single SQL statement, or used with CURRENT DATE, CURRENT TIMESTAMP, or the CURDATE, CURTIME, or NOW scalar functions within a single statement; all values are based on a single clock reading.³⁴

Example

Using the CL_SCHED table, select all the classes (CLASS_CODE) that start (STARTING) later today. Today's classes have a value of 3 in the DAY column.

```
SELECT CLASS_CODE FROM CL_SCHED
WHERE STARTING > CURRENT TIME AND DAY = 3
```

³⁴ LOCALTIME and LOCALTIME(0) can be specified as a synonyms for CURRENT_TIME.

CURRENT TIMESTAMP

The CURRENT TIMESTAMP special register specifies a timestamp that is based on a reading of the time-of-day clock when the SQL statement is executed at the current server.

If this special register is used more than once within a single SQL statement, or used with CURRENT DATE, CURRENT TIME, or the CURDATE, CURTIME, or NOW scalar functions within a single statement; all values are based on a single clock reading.³⁵

If a timestamp with a specific precision is desired, the special register can be referenced as CURRENT TIMESTAMP(*integer*), where *integer* can range from 0 to 12. The default precision is 6.

Example

Insert a row into the IN_TRAY sample table. The value of the RECEIVED column should be a timestamp that indicates when the row was inserted. The values for the other three columns come from the host variables SRC (CHAR(8)), SUB (CHAR(64)), and TXT (VARCHAR(200)).

```
INSERT INTO IN_TRAY
VALUES (CURRENT_TIMESTAMP, :SRC, :SUB, :TXT)
```

CURRENT USER

The CURRENT USER special register specifies the primary authorization ID that is to be used for statement authorization. The data type of the special register is VARCHAR(128).

When multiple authorization IDs have been adopted within a thread, the value of the most recently adopted authorization ID within the thread will be returned.

Example

Find the tables owned by the current statement authorization ID.

```
SELECT TABLE_SCHEMA, TABLE_NAME FROM QSYS2.SYSTABLES
WHERE TABLE_OWNER = CURRENT_USER AND TABLE_TYPE = 'T'
```

CURRENT TIMEZONE

The CURRENT TIMEZONE special register specifies the difference between UTC and local time at the current server.

The difference is represented by a time duration (a decimal number in which the first two digits are the number of hours, the next two digits are the number of minutes, and the last two digits are the number of seconds).³⁶ The number of hours is between -24 and 24 exclusive. Subtracting CURRENT TIMEZONE from a local time converts that local time to UTC.

Example

Using the IN_TRAY table, select all the rows from the table and adjust the value to UTC.

```
SELECT RECEIVED - CURRENT_TIMEZONE, SOURCE,
SUBJECT, NOTE_TEXT FROM IN_TRAY
```

³⁵ LOCALTIMESTAMP and LOCALTIMESTAMP(6) can be specified as a synonym for CURRENT_TIMESTAMP. LOCALTIMESTAMP(*n*) can be specified as a synonym for CURRENT_TIMESTAMP(*n*).

³⁶ Coordinated Universal Time, formerly known as GMT.

SESSION_USER

The SESSION_USER special register specifies the run-time authorization ID at the current server. The data type of the special register is VARCHAR(128).

The initial value of SESSION_USER for a new connection is the same as the value of the SYSTEM_USER special register.

The value can be changed by executing the SET SESSION AUTHORIZATION statement. For more information, see [“SET SESSION AUTHORIZATION” on page 1540](#).

Example

Select all notes from the IN_TRAY table that the user placed there himself.

```
SELECT * FROM IN_TRAY
WHERE SOURCE = SESSION_USER
```

SYSTEM_USER

The SYSTEM_USER special register specifies the authorization ID that connected to the current server. The data type of the special register is VARCHAR(128).

Example

Select all notes from the IN_TRAY table that the user placed there himself.

```
SELECT * FROM IN_TRAY
WHERE SOURCE = SYSTEM_USER
```

USER

The USER special register specifies the run-time authorization ID at the current server. The data type of the special register is VARCHAR(18).

The initial value of USER for a new connection is the same as the value of the SYSTEM_USER special register.

The value can be changed by executing the SET SESSION AUTHORIZATION statement. For more information, see [“SET SESSION AUTHORIZATION” on page 1540](#).

Example

Select all notes from the IN_TRAY table that the user placed there himself.

```
SELECT * FROM IN_TRAY
WHERE SOURCE = USER
```

Column names

The meaning of a column name depends on its context.

A column name can be used to:

- Declare the name of a column, as in a CREATE TABLE statement.
- Identify a column, as in a CREATE INDEX statement.
- Specify values of the column, as in the following contexts:
 - In an *aggregate function*, a column name specifies all values of the column in the group or intermediate result table to which the function is applied. Groups and intermediate result tables are explained under [Chapter 6, “Queries,” on page 735](#). For example, MAX(SALARY) applies the function MAX to all values of the column SALARY in a group.
 - In a *GROUP BY* or *ORDER BY* clause, a column name specifies all values in the intermediate result table to which the clause is applied. For example, ORDER BY DEPT orders an intermediate result table by the values of the column DEPT.
 - In an *expression*, a *search condition*, or a *scalar function*, a column name specifies a value for each row or group to which the construct is applied. For example, when the search condition CODE = 20 is applied to some row, the value specified by the column name CODE is the value of the column CODE in that row.
- Provide a column name for an expression to temporarily rename a column, as in the *correlation-clause* of a *table-reference* in a FROM clause, or in the AS clause in the *select-clause*.

Qualified column names

A qualifier for a column name can be a table name, a view name, an alias name, or a correlation name.

Whether a column name can be qualified depends on its context:

- In the COMMENT and LABEL statements, the column name must be qualified.
- Where the column name specifies values of the column, a column name can be qualified.
- In the *assignment-clause* of an UPDATE statement, it may be qualified.
- In the *column-name-list* of an INSERT statement, it may be qualified.
- In all other contexts, a column name must not be qualified.

Where a qualifier is optional it can serve two purposes. See [“Column name qualifiers to avoid ambiguity” on page 133](#) and [“Column name qualifiers in correlated references” on page 135](#) for details.

Correlation names

A *correlation name* can be defined in the FROM clause of a query and after the target *table-name* or *view-name* in an UPDATE or DELETE statement.

For example, the clause shown below establishes Z as a correlation name for X.MYTABLE:

```
FROM X.MYTABLE Z
```

A correlation name is associated with a table or view only within the context in which it is defined. Hence, the same correlation name can be defined for different purposes in different statements, or in different clauses of the same statement.

As a qualifier, a correlation name can be used to avoid ambiguity or to establish a correlated reference. A correlation name can also be used as a shorter name for a table or view. In the example that is shown above, Z might have been used merely to avoid having to enter X.MYTABLE more than once.

If a correlation name is specified for a table or view, any qualified reference to a column of that instance of the table or view must use the correlation name, rather than the table name or view name. For example,

the reference to EMPLOYEE.PROJECT in the following example is incorrect, because a correlation name has been specified for EMPLOYEE:

```
FROM EMPLOYEE E
WHERE EMPLOYEE . PROJECT= ' ABC '          ***INCORRECT***
```

The qualified reference to PROJECT should instead use the correlation name, “E”, as shown below:

```
FROM EMPLOYEE E
WHERE E . PROJECT= ' ABC '
```

Names specified in a FROM clause are either *exposed* or *non-exposed*. A correlation name is always an exposed name. A table name or view name is said to be *exposed* in that FROM clause if a correlation name is not specified. For example, in the following FROM clause, a correlation name is specified for EMPLOYEE but not for DEPARTMENT, so DEPARTMENT is an exposed name, and EMPLOYEE is not:

```
FROM EMPLOYEE E, DEPARTMENT
```

A table name or view name that is exposed in a FROM clause must not be the same as any other table name or view name exposed in that FROM clause or any correlation name in the FROM clause. The names are compared after qualifying any unqualified table or view names.

The first two FROM clauses shown below are correct, because each one contains no more than one reference to EMPLOYEE that is exposed:

1. Given the FROM clause:

```
FROM EMPLOYEE E1, EMPLOYEE
```

a qualified reference such as EMPLOYEE.PROJECT denotes a column of the second instance of EMPLOYEE in the FROM clause. A qualified reference to the first instance of EMPLOYEE must use the correlation name “E1” (E1.PROJECT).

2. Given the FROM clause:

```
FROM EMPLOYEE, EMPLOYEE E2
```

a qualified reference such as EMPLOYEE.PROJECT denotes a column of the first instance of EMPLOYEE in the FROM clause. A qualified reference to the second instance of EMPLOYEE must use the correlation name “E2” (E2.PROJECT).

3. Given the FROM clause:

```
FROM EMPLOYEE, EMPLOYEE          ***INCORRECT***
```

the two exposed table names included in this clause (EMPLOYEE and EMPLOYEE) are the same, and this is not allowed.

4. Given the following statement:

```
SELECT *
FROM EMPLOYEE E1, EMPLOYEE E2
WHERE EMPLOYEE . PROJECT= ' ABC '          ***INCORRECT***
```

the qualified reference EMPLOYEE.PROJECT is incorrect, because both instances of EMPLOYEE in the FROM clause have correlation names. Instead, references to PROJECT must be qualified with either correlation name (E1.PROJECT or E2.PROJECT).

5. Given the FROM clause:

```
FROM EMPLOYEE, X . EMPLOYEE
```

a reference to a column in the second instance of EMPLOYEE must use X.EMPLOYEE (X.EMPLOYEE.PROJECT). This FROM clause is only valid if the authorization ID of the statement is not X.

A correlation name specified in a FROM clause must not be the same as:

- Any other correlation name in that FROM clause
- Any unqualified table name or view name exposed in the FROM clause
- The second SQL identifier of any qualified table name or view name that is exposed in the FROM clause.

For example, the following FROM clauses are incorrect:

```
FROM EMPLOYEE E, EMPLOYEE E
FROM EMPLOYEE DEPARTMENT, DEPARTMENT      ***INCORRECT***
FROM X.T1, EMPLOYEE T1
```

The following FROM clause is technically correct, though potentially confusing:

```
FROM EMPLOYEE DEPARTMENT, DEPARTMENT EMPLOYEE
```

The use of a correlation name in the FROM clause also allows the option of specifying a list of column names to be associated with the columns of the result table. As with a correlation name, these listed column names become the exposed names of the columns that must be used for references to the columns throughout the query. If a column name list is specified, then the column names of the underlying table become non-exposed.

Given the FROM clause:

```
FROM DEPARTMENT D (NUM, NAME, MGR, ANUM, LOC)
```

a qualified reference such as D.NUM denotes the first column of the DEPARTMENT table that is defined in the table as DEPTNO. A reference to D.DEPTNO using this FROM clause is incorrect since the column name DEPTNO is a non-exposed column name.

If a list of columns is specified, it must consist of as many names as there are columns in the *table-reference*. Each column name must be unique and unqualified.

Column name qualifiers to avoid ambiguity

In the context of a function, a GROUP BY clause, an ORDER BY clause, an expression, or a search condition, a column name refers to values of a column in some target table or view in a DELETE or UPDATE statement or *table-reference* in a FROM clause.

The tables, views, and *table-references*³⁷ that might contain the column are called the *object tables* of the context. Two or more object tables might contain columns with the same name. One reason for qualifying a column name is to designate the object from which the column comes. For information about avoiding ambiguity between SQL parameters and variables and column names, see [“References to SQL parameters and SQL variables” on page 1581](#).

A nested table expression which is preceded by a LATERAL or TABLE keyword will consider *table-references* that precede it in the FROM clause as object tables. The *table-references* that follow the nested table expression are not considered as object tables.

Table designators

A qualifier that designates a specific object table is called a *table designator*. The clause that identifies the object tables also establishes the table designators for them.

For example, the object tables of an expression in a SELECT clause are named in the FROM clause that follows it:

```
SELECT CORZ.COLA, OWNY.MYTABLE.COLA
FROM OWNX.MYTABLE CORZ, OWNY.MYTABLE
```

Table designators in the FROM clause are established as follows:

³⁷ In the case of a *joined-table*, each *table-reference* within the *joined-table* is an object table.

- A name that follows a table or view name is both a correlation name and a table designator. Thus, CORZ is a table designator. CORZ is used to qualify the first column name in the select list.
- In SQL naming, an exposed table or view name is a table designator. Thus, OWNY.MYTABLE is a table designator. OWNY.MYTABLE is used to qualify the second column name in the select list.
- In system naming, the table designator for an exposed table or view name is the unqualified table or view name. In the following example MYTABLE is the table designator for OWNY/MYTABLE.

```
SELECT CORZ.COLA, MYTABLE.COLA
FROM OWNX/MYTABLE CORZ, OWNY/MYTABLE
```

Two or more object tables can be instances of the same table. In this case, distinct correlation names must be used to unambiguously designate the particular instances of the table. In the following FROM clause, X and Y are defined to refer, respectively, to the first and second instances of the table EMPLOYEE:

```
SELECT * FROM EMPLOYEE X,EMPLOYEE Y
```

Avoiding undefined or ambiguous references

When a column name refers to values of a column, it must be possible to resolve that column name to exactly one object table.

The following situations are considered errors:

- No object table contains a column with the specified name. The reference is undefined.
- The column name is qualified by a table designator, but the table designated does not include a column with the specified name. Again the reference is undefined.
- The name is unqualified and more than one object table includes a column with that name. The reference is ambiguous.
- The column name is qualified by a table designator, but the table designated is not unique in the FROM clause and both occurrences of the designated table include the column. The reference is ambiguous.
- The column name is in a nested table expression which is not preceded by the LATERAL or TABLE keyword or a table function or nested table expression that is the right operand of a right outer join, full outer join, or a right exception join and the column name does not refer to a column of a *table-reference* within the nested table expression's fullselect. The reference is undefined.

Avoid ambiguous references by qualifying a column name with a uniquely defined table designator. If the column is contained in several object tables with different names, the object table names can be used as designators. Ambiguous references can also be avoided without the use of the table designator by giving unique names to the columns of one of the object tables using the column name list following the correlation name.

When qualifying a column with the exposed table name form of a table designator, either the qualified or unqualified form of the exposed table name may be used. However, the qualifier used and the table used must be the same after fully qualifying the table name or view name and the table designator.

1. If the default schema is CORPDATA, then:

```
SELECT CORPDATA.EMPLOYEE.WORKDEPT
FROM EMPLOYEE
```

is a valid statement.

2. If the default schema is REGION, then:

```
SELECT CORPDATA.EMPLOYEE.WORKDEPT
FROM EMPLOYEE ***INCORRECT***
```

is invalid, because EMPLOYEE represents the table REGION.EMPLOYEE, but the qualifier for WORKDEPT represents a different table, CORPDATA.EMPLOYEE.

3. If the default schema is REGION, then:

```
SELECT EMPLOYEE.WORKDEPT
FROM CORPDATA.EMPLOYEE          ***INCORRECT***
```

is invalid, because EMPLOYEE in the select list represents the table REGION.EMPLOYEE, but the explicitly qualified table name in the FROM clause represents a different table, CORPDATA.EMPLOYEE. In this case, either omit the table qualifier in the select list, or define a correlation name for the table designator in the FROM clause and use that correlation name as the qualifier for column names in the statement.

Column name qualifiers in correlated references

A *subselect* is a form of a query that can be used as a component of various SQL statements.

Refer to Chapter 6, “Queries,” on page 735 for more information about subselects. A *subquery* is a form of a fullselect that is enclosed within parentheses. For example, a *subquery* can be used in a search condition. A fullselect used in the FROM clause of a query is called a *nested table expression*.

A subquery can include search conditions of its own, and these search conditions can, in turn, include subqueries. Therefore, an SQL statement can contain a hierarchy of subqueries. Those elements of the hierarchy that contain subqueries are said to be at a higher level than the subqueries they contain.

Every element of the hierarchy has a clause that establishes one or more table designators. This is the FROM clause, except in the highest level of an UPDATE or DELETE statement. A search condition, the select list, the join clause, an argument of a table function in a subquery, or a *nested table expression* that is preceded by the LATERAL keyword can reference not only columns of the tables identified by the FROM clause of its own element of the hierarchy, but also columns of tables identified at any level along the path from its own element to the highest level of the hierarchy. A reference to a column of a table identified at a higher level is called a *correlated reference*. A reference to a column of a table identified at the same level from a *nested table expression* through the use of the LATERAL keyword is called *lateral correlation*.

A correlated reference to column C of table T can be of the form C, T.C, or Q.C, if Q is a correlation name defined for T. However, a correlated reference in the form of an unqualified column name is not good practice. The following explanation is based on the assumption that a correlated reference is always in the form of a qualified column name and that the qualifier is a correlation name.

Q.C is a correlated reference only if these three conditions are met:

- Q.C is used in a search condition, select list, join clause, or an argument of a table function in a subquery.
- Q does not designate a table used in the FROM clause of that subquery, select list, join clause, or an argument of a table function in a subquery.
- Q does designate a table used at some higher level.

Q.C refers to column C of the table or view at the level where Q is used as the table designator of that table or view. Because the same table or view can be identified at many levels, unique correlation names are recommended as table designators. If Q is used to designate a table at more than one level, Q.C refers to the lowest level that contains the subquery that includes Q.C.

In the following statement, Q is used as a correlation name for T1 and T2, but Q.C refers to the correlation name associated with T2, because it is the lowest level that contains the subquery that includes Q.C.

```
SELECT *
FROM T1 Q
WHERE A < ALL (SELECT B
               FROM T2 Q
               WHERE B < ANY (SELECT D
                             FROM T3
                             WHERE D = Q.C))
```

Unqualified column names in correlated references

An unqualified column name can also be a correlated reference.

If the column:

- Is used in a search condition of a subquery
- Is not contained in a table used in the FROM clause of that subquery
- Is contained in a table used at some higher level

Unqualified correlated references are not recommended because it makes the SQL statement difficult to understand. The column will be implicitly qualified when the statement is prepared depending on which table the column was found in. Once this implicit qualification is determined it will not change until the statement is re-prepared. When an SQL statement that has an unqualified correlated reference is prepared or executed, a warning is returned (SQLSTATE 01545).

Variables

A *variable* in an SQL statement specifies a value that can be changed when the SQL statement is executed.

There are several types of *variables* used in SQL statements:

global variable

Global variables are either built-in global variables or user-defined global variables. For more information about how to refer to global variables see [“Global variables” on page 137](#).

host variable

Host variables are defined by statements of a host language. For more information about how to refer to host variables see [“References to host variables” on page 139](#).

transition variable

Transition variables are defined in a trigger and refer to either the old or new values of columns. For more information about how to refer to transition variables see [“CREATE TRIGGER” on page 1170](#).

SQL variable

SQL variables are defined by an SQL compound statement in an SQL function, SQL procedure, or trigger. For more information about SQL variables, see [“References to SQL parameters and SQL variables” on page 1581](#).

SQL parameter

SQL parameters are defined in an CREATE FUNCTION (SQL scalar), CREATE FUNCTION (SQL table), or CREATE PROCEDURE (SQL) statement. For more information about SQL parameters, see [“References to SQL parameters and SQL variables” on page 1581](#).

parameter marker

Variables cannot be referenced in dynamic SQL statements. Parameter markers are defined in an SQL descriptor and used instead. For more information about parameter markers, see [Parameter Markers in “PREPARE” on page 1435](#).

Global variables

Global variables are named memory variables that you can access and modify through SQL statements.

The Db2 database management system supports the following types of global variables:

Built-in global variable

A built-in global variable is part of the database management system, and is available to any SQL statement that runs on the database manager. For a list of the built-in global variables and information on these variables, see [Chapter 3, “Built-in global variables,” on page 229](#).

User-defined global variable

A user-defined global variable enables you to share relational data between SQL statements without the need for application logic to support this data transfer.

A user-defined global variable is associated with a specific session³⁸ and contains a value that is specific to that session. A user-defined session global variable is available to any active SQL statement running against the database on which the variable was defined. A user-defined global variable can be associated with more than one session, but its value will be specific to each session. User-defined global variables are defined in the system catalog.

You can control access to global variables through the GRANT (Global Variable Privileges) and REVOKE (Global Variable Privileges) statements.

Global variable names are qualified names. If an unqualified global variable name is the main object of an ALTER, CREATE, COMMENT, DROP, GRANT, or REVOKE statement, the name is implicitly qualified

³⁸ Note that what SQL calls a session equates to an activation group on the IBM i. See [“Application servers” on page 36](#) for details

using the same rules as for qualifying unqualified table names. Otherwise, the SQL path is used for name resolution.

For static SQL statements and SQL routines, global variables are resolved for a statement the first time all table references are resolved. In views, triggers, and other global variables, they are resolved when the object is created. If resolution were to be performed again on any global variable, it could change the behavior if, for example, a new global variable had been added with the same name in a different schema that is also in the SQL path.

Global variables that are referenced in dynamic statements will be resolved when the statement is initially prepared. They will not be resolved again unless the statement needs to be refreshed because a table has changed.

The name of a global variable can be the same as the name of a column in a table or view that is referenced in an SQL statement, as well as the name of an SQL variable or an SQL parameter in an SQL routine. Names that are the same should be explicitly qualified. If the name is not qualified, or it is qualified but is still ambiguous, the following rules describe the precedence of resolution:

- The name is checked to see if it is the name of a column of any existing table or view referenced in the statement at the current server.
- If used in an SQL routine, the name is checked to see if it is the name of an SQL variable, SQL parameter, or transition variable.
- If not found by either of these rules, it is assumed to be a global variable.
- If the SQL_GVAR_BUILD_RULE QAQQINI option is *EXIST and the global variable does not exist at precompile time or when an SQL routine is being created, an error will be issued.

When a global variable is referenced in a trigger, view, routine, or global variable, a dependency on the fully qualified global variable name is recorded for the statement or object. Also, if applicable, the authorization ID being used for the statement is checked for the appropriate privilege on the global variable.

Global variables can be used in any SQL statement that allows a variable. Global variables can be referenced within any expression except in the following situations:

- Check constraints
- Materialized query tables (MQTs)
- Indexes
- A global variable is not allowed if the query specifies:
 - a distributed table,
 - a table with a read trigger, or
 - a logical file built over multiple physical file members.

Authorization: If a global variable is referenced in a statement, the privileges held by the authorization ID of the statement must include at least one of the following:

- For the global variable identified in the statement,
 - The READ privilege on the global variable if the global variable is referenced, and
 - The WRITE privilege on the global variable if the global variable is assigned a value, and
 - The system authority *EXECUTE on the library containing the global variable
- Database administrator authority

The value of a global variable can be changed using the FETCH, SET, SELECT INTO, or VALUES INTO statement. It can also be changed if it is an argument of an OUT or INOUT parameter in a CALL statement.

References to host variables

A *host variable* is a COBOL data item, an RPG field, or a PLI, REXX, C++, C, or Java variable that is referenced in an SQL statement. Host variables are defined by statements of the host language.

Host variables cannot be referenced in dynamic SQL statements; instead, parameter markers must be used. For more information on parameter markers, see “Variables in dynamic SQL” on page 141.

A *host variable* in an SQL statement must identify a host variable described in the program according to the rules for declaring host variables.

All host variables used in an SQL statement should be declared in an SQL declare section in all host languages other than Java, REXX, and RPG. Variables do not have to be declared in REXX. In Java and RPG, there is no declare section, and host variables may be declared throughout the program. No variables may be declared outside an SQL declare section with names identical to variables declared inside an SQL declare section. An SQL declare section begins with BEGIN DECLARE SECTION and ends with END DECLARE SECTION.

For further information about using host variables, see the [Embedded SQL programming](#) topic.

A variable in the INTO clause of a FETCH, a SELECT INTO, a SET variable, a GET DESCRIPTOR, or a VALUES INTO statement identifies a host variable to which a value from a result column is assigned. A variable in the GET DIAGNOSTICS statement identifies a host variable to which a diagnostic value is assigned. A host variable in a CALL or in an EXECUTE statement can be an output argument that is assigned a value after execution of the procedure, an input argument that provides an input value for the procedure, or both an input and output argument. In all other contexts a variable specifies a value to be passed to the database manager from the application program.

Non-Java variable references:

The general form of a *variable* reference in all languages other than Java is:

Each *host-identifier* must be declared in the source program. The first *host-identifier* designates the main variable, and the second *host-identifier* designates the associated indicator variable. An indicator variable must be a small integer. Depending on the operation, the main variable either provides a value to the database manager or is provided a value from the database manager. A given host variable can serve as both an input and an output variable in the same program.

The purposes of an indicator variable are to:

- Specify a non-null value. A 0 (zero), or positive value of the indicator variable specifies that the associated, first, *host-identifier* provides the value of this host variable reference.
- Specify the null value. A negative value of the indicator variable specifies the null value.
- On output, indicate that one of the following numeric conversion errors:
 - Numeric conversion error (underflow or overflow)
 - Arithmetic expression error (division by 0)
 - A numeric value that is not valid

A -2 value of the indicator variable indicates a null result because of one of these warnings.

- On output, indicate one of the following string errors:

- Characters could not be converted
- Mixed data not properly formed

A -2 value of the indicator variable indicates a null result because of one of these warnings.

- On output, indicate one of the following datetime errors:
 - Date or timestamp conversion error (a date or timestamp that is not within the valid range of the dates for the specified format)
 - String representation of the datetime value is not valid
 A -2 value of the indicator variable indicates a null result because of one of these warnings.
- On output, indicate one of the following miscellaneous errors:
 - Argument of SUBSTR scalar function is out of range
 - Argument of a decryption function contains a data type that is not valid.
 A -2 value of the indicator variable indicates a null result because of one of these warnings.
- On output, record the original length of a string if the string is truncated on assignment to a host variable. If the string is truncated and there is no indicator variable, no error condition results.
- On output, record the seconds portion of a time if the time is truncated on assignment to a host variable. If the time is truncated and there is no indicator variable, no error condition results.

For example, if :V1:V2 is used to specify an insert or update value, and if V2 is negative, the value specified is the null value. If V2 is not negative the value specified is the value of V1.

Similarly, if :V1:V2 is specified in a CALL, FETCH, SELECT INTO, or VALUES INTO statement and the value returned is null, V1 is undefined, and V2 is set to a negative value. The negative value is:

- -1 if the value selected was the null value, or
- -2 if the null value was returned due to data mapping errors in the select list of an outer subselect.³⁹

If the value returned is not null, that value is assigned to V1 and V2 is set to zero (unless the assignment to V1 requires string truncation, in which case, V2 is set to the original length of the string). If an assignment requires truncation of the seconds part of time, V2 is set to the number of seconds.

If the second *host-identifier* is omitted, the *host variable* does not have an indicator variable. The value specified by the *host variable* :V1 is always the value of V1, and null values cannot be assigned to the variable. Thus, this form should not be used on output unless the corresponding result column cannot contain null values. If this form is used for an output host variable and the returned value is null, the database manager returns an error at run-time (SQLSTATE 23502).

An indicator variable for an input host variable in an INSERT, MERGE, or UPDATE statement can also be set to some special values to indicate that a target column is to be set to the default value, or to indicate that a value should not be assigned to a target column. These special values are only allowed when extended indicators are enabled. Extended indicators are enabled when the SET OPTION statement specified EXTIND = *YES, the precompile specified OPTION(*EXTIND), or when the WITH EXTENDED INDICATORS prepare attribute or cursor attribute has been specified for the statement.

When extended indicators are enabled, an input indicator variable in an INSERT, MERGE, or UPDATE statement specifies that the target column for the associated host variable is assigned one of the following types of values:

- A non-null value. A 0 (zero) or positive value specifies that the associated *host-identifier* provides the value of this host variable reference.
- NULL. A -1, -2, -3, -4, or -6 value specifies the null value.
- DEFAULT. A -5 value specifies the default value of the target column.
- UNASSIGNED. A -7 value specifies that this host variable is treated as if a value was not specified for assignment to the target column in the statement.

These indicator values can also be used in indicator structures with host structures. When extended indicators are enabled, indicator values other than positive values, zero, and the negative values listed

³⁹ It should be noted that although the null value returned for data mapping errors can be returned on certain scalar functions and for arithmetic expressions, the result column is not considered null capable unless an argument of the arithmetic expression or scalar function is null capable.

previously must not be used. DEFAULT and UNASSIGNED extended indicator values must only be used in contexts where they are supported (INSERT, MERGE, and UPDATE statements). The DEFAULT and UNASSIGNED extended indicator values can only be used for an expression containing a single host parameter or a CAST of a single host parameter that is being assigned to a column. Output indicators are never set to extended indicator values.

When extended indicator variables are enabled, rules for data type validation in assignment and comparison are loosened for host variables where the associated indicator value is negative. Data type assignment and comparison validation rules are not enforced for host variables where the associated indicator value is NULL, DEFAULT, or ASSIGNED.

The unassigned extended indicator value can also be specified in the USING SUBSET clause for OPEN or EXECUTE to remove a host variable from the replacement variable list. Extended indicators do not need to be enabled for these statements to accept the extended indicator value.

An SQL statement that references host variables in C, C++, ILE RPG, and PL/I, must be within the scope of the declaration of those host variables. For host variables referenced in the SELECT statement of a cursor, that rule applies to the OPEN statement rather than to the DECLARE CURSOR statement.

The CCSID of a string host variable is either:

- The CCSID specified in the DECLARE VARIABLE statement, or
- If a DECLARE VARIABLE with a CCSID clause is not specified for the host variable, the default CCSID of the application requester at the time the SQL statement that contains the host variable is executed unless the CCSID is for a foreign encoding scheme other than Unicode (such as ASCII). In this case, the host variable is converted to the default CCSID of the current server.

Java variable references:

The general form of a host variable reference in Java is:

In Java, indicator variables are not used. Instead, instances of a Java class can be set to a null value. Variables defined as Java primitive types cannot be set to a null value.

If IN, OUT, or INOUT is not specified, the default depends on the context in which the variable is used. If the Java variable is used in an INTO clause, OUT is the default. Otherwise, IN is the default. For more information about Java variables, see [IBM Developer Kit for Java](#).

Example

Using the PROJECT table, set the host variable PNAME (VARCHAR(26)) to the project name (PROJNAME), the host variable STAFF (DECIMAL(5,2)) to the mean staffing level (PRSTAFF), and the host variable MAJPROJ (CHAR(6)) to the major project (MAJPROJ) for project (PROJNO) 'IF1000'. Columns PRSTAFF and MAJPROJ may contain null values, so provide indicator variables STAFF_IND (SMALLINT) and MAJPROJ_IND (SMALLINT).

```
SELECT PROJNAME, PRSTAFF, MAJPROJ
  INTO :PNAME, :STAFF :STAFF_IND, :MAJPROJ :MAJPROJ_IND
  FROM PROJECT
  WHERE PROJNO = 'IF1000'
```

Variables in dynamic SQL

In dynamic SQL statements, parameter markers are used instead of variables. A parameter marker is a question mark (?) that represents a position in a dynamic SQL statement where the application will

provide a value; that is, where a variable would be found if the statement string were a static SQL statement.

The following examples shows a static SQL that uses host variables and a dynamic statement that uses parameter markers:

```
INSERT INTO DEPT
VALUES( :HV_DEPTNO, :HV_DEPTNAME, :HV_MGRNO:IND_MGRNO, :HV_ADMRDEPT)

INSERT INTO DEPT
VALUES( ?, ?, ?, ? )
```

For more information about parameter markers, see [Parameter Markers](#), in “PREPARE” on page 1435.

References to LOB or XML variables

You can define regular LOB or XML variables, LOB or XML locator variables, and LOB or XML file reference variables.

Regular LOB or XML variables, LOB or XML locator variables, and LOB or XML file reference variables can be defined in the following host languages:

- C
- C++
- ILE RPG
- ILE COBOL
- PL/I (LOB only)

Where LOBs or XML are allowed, the term *variable* in a syntax diagram can refer to a regular variable, a locator variable, or a file reference variable. Since these variables are not native data types in host programming languages, SQL extensions are used and the precompilers generate the host language constructs necessary to represent each variable.

When it is possible to define a variable that is large enough to hold an entire LOB or XML value and the performance benefit of delaying the transfer of data from the server is not required, a LOB or XML locator is not needed. However, it is often not acceptable to store an entire LOB or XML value in temporary storage due to host language restrictions, storage restrictions, or performance requirements. When storing an entire LOB or XML value at one time is not acceptable, a LOB or XML value can be referred to by a LOB or XML locator and portions of the LOB or XML value can be accessed.

References to LOB or XML locator variables

A LOB or XML *locator variable* is a variable that contains the locator representing a LOB or XML value on the application server.

LOB or XML locator variables can be defined in the following host languages:

- C
- C++
- ILE RPG
- ILE COBOL
- PL/I (LOB only)

See “[Manipulating large objects with locators](#)” on page 73 for information about how locators can be used to manipulate LOB and XML values.

A locator variable in an SQL statement must identify a LOB or XML locator variable described in the program according to the rules for declaring locator variables. This is always indirectly through an SQL statement. For example, in C:

```
static volatile SQL TYPE IS CLOB_LOCATOR *loc1;
```

Like all other variables, a LOB or XML locator variable can have an associated indicator variable. Indicator variables for LOB or XML locator variables behave in the same way as indicator variables for other data types. When a null value is returned from the database, the indicator variable is set and the variable is unchanged. When the indicator variable associated with a LOB or XML locator is null, the value of the referenced LOB or XML is null. This means that a locator can never point to a null value.

If a locator variable does not currently represent any value, an error occurs when the locator variable is referenced.

At transaction commit or any transaction termination, all LOB or XML locators that were acquired by the transaction are released.

It is the application programmer's responsibility to guarantee that any LOB or XML locator is only used in SQL statements that are executed at the same application server that originally generated the LOB or XML locator. For example, assume that a LOB locator is returned from one application server and assigned to a LOB locator variable. If that LOB locator variable is subsequently used in an SQL statement that is executed at a different application server, unpredictable results will occur.

References to LOB or XML file reference variables

A LOB or XML *file reference variable* is used for direct file input and output for a LOB or XML.

A LOB or XML *file reference variable* can be defined in the following host languages:

- C
- C++
- ILE RPG
- ILE COBOL
- PL/I (LOB only)

Since these are not native data types, SQL extensions are used and the precompilers generate the host language constructs necessary to represent each variable.

A file reference variable represents (rather than contains) the file, just as a LOB or XML locator represents, rather than contains, the LOB or XML data. Database queries, updates, and inserts may use file reference variables to store or to retrieve single column values. The file referenced must exist at the application requester.

Like all other variables, a file reference variable can have an associated indicator variable. Indicator variables for file reference variables behave in the same way as indicator variables for other data types. When a null value is returned from the database, the indicator variable is set and the variable is unchanged. When the indicator variable associated with a file reference variable is null, the value of the referenced LOB or XML is null. This means that a file reference variable can never point to a null value.

The length attribute of a file reference variable is assumed to be the maximum length of a LOB or XML.

File reference variables are currently supported in the root (/), QOpenSys, and UDFS file systems. When a file is created, it is given the CCSID of the data that is being written to the file. Currently, mixed CCSIDs are not supported. To use a file created with a file reference variable, the file should be opened in binary mode.

For more information about file reference variables, see the [SQL programming](#) topic collection.

References to XML variables

XML variables are defined in host languages as a type of LOB variable.

Like LOBs, an XML variable can be defined as a string, locator, or file reference variable. It can be treated as CLOB, DBCLOB, or BLOB data. XML-supported CCSIDs can be assigned for CLOB and DBCLOB variables. This value is used to define the encoding of the XML data stored within the LOB variable. An XML variable defined as a BLOB will contain data that is encoded as specified within the data according to the XML 1.0 specification for determining encoding. For example, an XML variable that uses a CLOB storage structure can be defined in C as follows:

SQL TYPE IS XML AS CLOB(10K);

Although the application's XML variable declaration includes a LOB type specification, the variable declarations are considered the XML data type, not the LOB type that is used in the declaration. The application can also use non-XML variables in place of XML variables. For example, when a prepared statement is executed, the application might use a character variable to replace an XML parameter marker in the statement.

Although the XML data type is incompatible with all other data types, both XML and non-XML data types can be used for input to and output from XML data. Applications can use character, Unicode graphic, or binary variables as input or output variables in SQL statements.

Whenever an XML variable is used as input to an SQL statement, the value is implicitly parsed.

Host structures

A *host structure* is a COBOL group, PL/I, C, or C++ structure, or RPG data structure that is referenced in an SQL statement. In Java and REXX, there is no equivalent to a *host structure*.

Host structures are defined by statements of the host language, as explained in the [Embedded SQL programming](#) topic collection. As used here, the term host structure does not include an SQLCA or SQLDA.

The form of a host structure reference is identical to the form of a host variable reference. The reference :S1:S2 is a host structure reference if S1 names a host structure. If S1 designates a host structure, S2 must be either a small integer variable, or an array of small integer variables. S1 is the host structure and S2 is its indicator array.

A host structure can be referenced in any context where a list of host variables can be referenced. A host structure reference is equivalent to a reference to each of the host variables contained within the structure in the order which they are defined in the host language structure declaration. The *n*th variable of the indicator array is the indicator variable for the *n*th variable of the host structure.

In C, for example, if V1, V2, and V3 are declared as variables within the structure S1, the statement:

```
EXEC SQL FETCH CURSOR1 INTO :S1;
```

is equivalent to:

```
EXEC SQL FETCH CURSOR1 INTO :V1, :V2, :V3;
```

If the host structure has *m* more variables than the indicator array, the last *m* variables of the host structure do not have indicator variables. If the host structure has *m* fewer variables than the indicator array, the last *m* variables of the indicator array are ignored. These rules also apply if a reference to a host structure includes an indicator variable or if a reference to a host variable includes an indicator array. If an indicator array or indicator variable is not specified, no variable of the host structure has an indicator variable.

In addition to structure references, individual host variables in the host structure or indicator variables in the indicator array can be referenced by qualified names. The qualified form is a host identifier followed by a period and another host identifier. The first host identifier must name a host structure, and the second host identifier must name a host variable within that host structure.

The general form of a host variable or host structure reference is:

A *host-variable* in an expression must identify a host variable (not a structure) described in the program according to the rules for declaring host variables.

The following C example shows a references to host structure, host indicator array, and a host variable:

```
struct { char empno[7];
        struct
            { short int firstname_len;
              char firstname_text[12];
            } firstname;
        char midint,
        struct
            { short int lastname_len;
              char lastname_text[15];
            } lastname;
        char workdept[4];
    } pemp1;
short ind[14];
short eind
struct { short ind1;
        short ind2;
    } indstr;

.....
strcpy(pemp1.empno, "000220");
.....
EXEC SQL
  SELECT *
  INTO :pemp1:ind
  FROM corpdata.employee
  WHERE empno=:pemp1.empno;
```

In the example above, the following references to host variables and host structures are valid:

```
:pemp1    :pemp1.empno    :pemp1.empno:eind    :pemp1.empno:indstr.ind1
```

For more information about how to refer to host structures in C, C++, COBOL, PL/I, and RPG, see the [Embedded SQL programming topic collection](#).

Host structure arrays

In PL/I, C++, and C, a host structure array is a structure name having a dimension attribute. In COBOL, it is a one-dimensional table. In RPG, it is an occurrence data structure. In ILE RPG, it can also be a data structure with the keyword DIM.

A host structure array can only be referenced in the FETCH statement when using a multiple-row fetch, or in an INSERT statement when using a multiple-row insert. Host structure arrays are defined by statements of the host language, as explained in the [Embedded SQL programming topic collection](#).

The form of a host structure array is identical to the form of a host variable reference. The reference :S1:S2 is a reference to host structure array if S1 names a host structure array. If S1 designates a host structure, S2 must be either a small integer host variable, an array of small integer host variables, or a two dimensional array of small integer host variables. In the following example, S1 is the host structure array and S2 is its indicator array.

```
EXEC SQL FETCH CURSOR1 FOR 5 ROWS
        INTO :S1:S2;
```

The dimension of the host structure and the indicator array must be equal.

If the host structure has m more variables than the indicator array, the last m variables of the host structure do not have indicator variables. If the host structure has m fewer variables than the indicator array, the last m variables of the indicator array are ignored. If an indicator array or variable is not specified, no variable of the host structure array has an indicator variable.

The following diagram specifies the syntax of references to an array of host structures:

Arrays of host structures are not supported in REXX.

Functions

A *function* is an operation denoted by a function name followed by one or more operands that are enclosed in parentheses. It represents a relationship between a set of input values and a set of result values. The input values to a function are called *arguments*. For example, a function can be passed two input arguments that have date and time data types and return a value with a timestamp data type as the result.

Types of functions

There are several ways to classify functions.

One way to classify functions is as built-in, user-defined, or generated user-defined functions for distinct types.

- *Built-in functions* are functions that come with the database manager. These functions provide a single-value result. Built-in functions include operator functions such as "+", aggregate functions such as AVG, and scalar functions such as SUBSTR. For a list of the built-in aggregate and scalar functions and information about these functions, see [Chapter 4, “Built-in functions,” on page 243](#).

The *built-in functions* are part of schema QSYS2.⁴⁰

- *User-defined functions* are functions that are created using the CREATE FUNCTION statement and registered to the database manager in catalog table QSYS2.SYSROUTINES and catalog view QSYS2.SYSFUNCS. For more information, see [“CREATE FUNCTION” on page 975](#). These functions allow users to extend the function of the database manager by adding their own or third party vendor function definitions.

A user-defined function is either an *SQL*, *external*, or *sourced* function. An SQL function is defined to the database using only SQL statements. An external function is defined to the database with a reference to an external program or service program that is executed when the function is invoked. A sourced function is defined to the database with a reference to a built-in function or another user-defined function. Sourced functions can be used to extend built-in aggregate and scalar functions for use on distinct types.

A user-defined function resides in the schema in which it was created. The schema cannot be QSYS, QSYS2, QTEMP, SYSIBM, or SYSPROC.

- *Generated user-defined functions for distinct types* are functions that the database manager automatically generates when a distinct type is created using the CREATE TYPE statement. These functions support casting from the distinct type to the source type and from the source type to the distinct type. The ability to cast between the data types is important because a distinct type is compatible only with itself.

The generated cast functions reside in the same schema as the distinct type for which they were created. The schema cannot be QSYS, QSYS2, QTEMP, SYSIBM, or SYSPROC. For more information about the functions that are generated for a distinct type, see [“CREATE TYPE \(distinct\)” on page 1193](#).

Another way to classify functions is as aggregate, scalar, or table functions, depending on the input data values and result values.

- An *aggregate function* receives a set of values for each argument (such as the values of a column) and returns a single-value result for the set of input values. Aggregate functions are sometimes called *column functions*. Built-in functions and user-defined sourced functions can be aggregate functions.
- A *scalar function* receives a single value for each argument and returns a single-value result. Built-in functions and user-defined functions can be scalar functions. Generated user-defined functions for distinct types are also scalar functions.

⁴⁰ *Built-in functions* are implemented internally by the database manager, so an associated program or service program object does not exist for a *built-in function*. Furthermore, the catalog does not contain information about *built-in functions*. However, *built-in functions* can be treated as if they exist in QSYS2 and a *built-in function* name can be qualified with QSYS2.

- A *table function* returns a table for the set of arguments it receives. Each argument is a single value. A table function can only be referenced in the FROM clause of a subselect. A table function can be defined as an external function or as an SQL function, but a table function cannot be a sourced function.

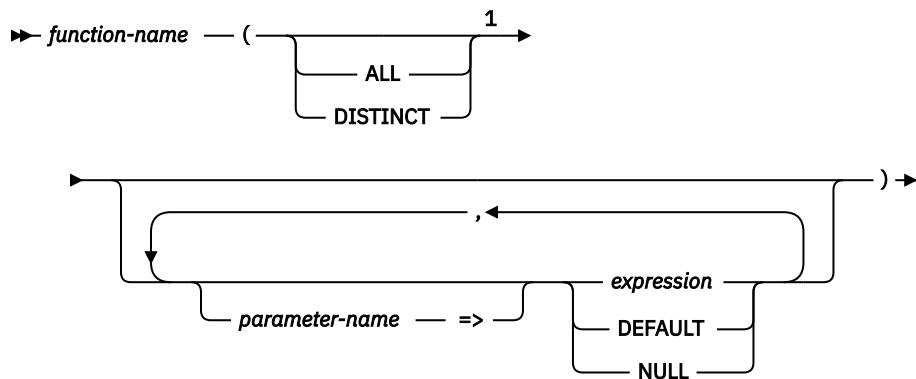

Table functions can be used to apply SQL language processing power to data that is not stored in the database or to allow access to such data as if it were stored in a table. For example, a table function can read a file, get data from the Web, or access a Lotus Notes® database and return a result table.

Function invocation

Each reference to a scalar or aggregate function (either built-in or user-defined) conforms to specific syntax.

The syntax is as follows: ⁴¹

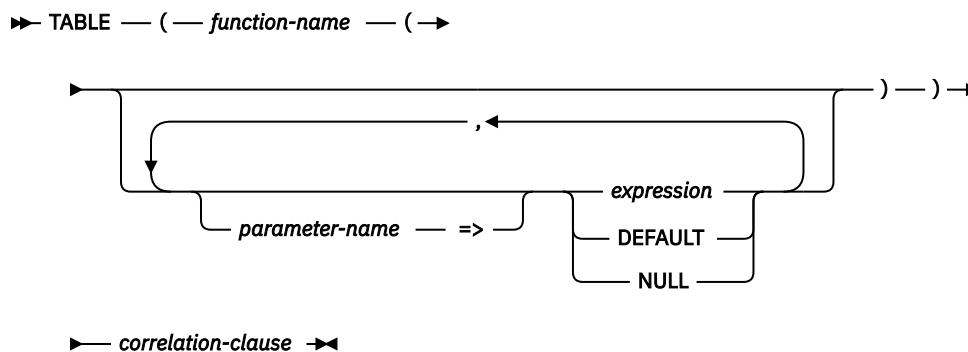

function-invocation

Notes:

- ¹ The ALL or DISTINCT keyword can be specified only for an aggregate function or a user-defined function that is sourced on an aggregate function.

Each reference to a table function conforms to the following syntax:

In the above syntax, *expression* is the same as it is for a scalar or aggregate function. See [“Expressions” on page 158](#) for other rules for *expression*.

An argument is a value passed to a function upon invocation or the specification of DEFAULT. When a function is invoked in SQL, it is passed a list of zero or more arguments. They are positional in that the semantics of an argument are determined by its position in the argument list. A parameter is a formal definition of an input to a function. When a function is defined to the database, either internally (a built-in function) or by a user (a user-defined function), its parameters (zero or more) are specified, and the order

⁴¹ A few functions allow keywords instead of expressions. For example, the CHAR function allows a list of keywords to indicate the desired date format. A few functions use keywords instead of commas in a comma separated list of expressions. For example, the EXTRACT, TRIM, and POSITION functions use keywords.

of their definitions defines their positions and their semantics. Therefore, every parameter is a particular positional input to a function.

On invocation, an argument is assigned to a parameter using either the positional syntax or the named syntax. If using the positional syntax, an argument corresponds to a particular parameter according to its position in the list of arguments. If using the named syntax, an argument corresponds to a particular parameter by the name of the parameter. When an argument is assigned to a parameter using the named syntax, then all the arguments that follow it must also be assigned using the named syntax. The name of a named argument can appear only once in a function invocation. In cases where the data types of the arguments of the function invocation are not a match to the data types of the parameters of the selected function, the arguments are converted to the data type of the parameter at execution time using the same rules as assignment to columns. This includes the case where precision, scale, or length differs between the argument and the parameter. In cases where an argument of the function invocation is the specification of DEFAULT, the actual value used for the argument is the value specified as the default for the corresponding parameter in the function definition. If no default value was defined for the parameter, the null value is used. If an untyped expression (a parameter marker, a NULL keyword, or a DEFAULT keyword) is used as the argument, the data type associated with the argument is determined by the data type of the parameter of the selected function.

For SQL functions that are inlined and external functions, all references to date, time, or timestamp special register values in the argument list and in any default expressions will use one clock reading. For SQL functions that are not inlined, any references to date, time, or timestamp special register values in the argument list will use one clock reading for any default expressions and a separate clock reading for any references in the explicit arguments.

When the function is invoked, the value of each of its parameters is assigned, using storage assignment, to the corresponding parameter of the function. Control is passed to external functions according to the calling conventions of the host language. When execution of a user-defined aggregate or scalar function is complete, the result of the function is assigned, using storage assignment, to the result data type. For details on the assignment rules, see [“Assignments and comparisons”](#) on page 89.

Table functions can be referenced only in the FROM clause of a subselect. For more details on referencing a table function, see the description of the FROM clause in [“table-reference”](#) on page 742.

Function resolution

A function is invoked by its function name, which is implicitly or explicitly qualified with a schema name, followed by parentheses that enclose the arguments to the function.

Within the database, each function is uniquely identified by its function signature, which is its schema name, function name, the number of parameters, and the data types of the parameters. Thus, a schema can contain several functions that have the same name but each of which have a different number of parameters, or parameters with different data types. Or, a function with the same name, number of parameters, and types of parameters can exist in multiple schemas.

- **Overloading a function:** A function name for which there are multiple function instances with the same number of parameters in the same schema is called an overloaded function.
- **Overriding a function:** Functions can be overridden across the schemas of an SQL path, in which case there is more than one function with the same name and the same number of parameters in different schemas of the SQL path. These functions do not necessarily have different parameter data types.

When any function is invoked, the database manager must determine which function to execute. This process is called *function resolution*.

Determining the set of candidate functions:

- Let A be the number of arguments in a function invocation.
- Let P be the number of parameters in a function signature.
- Let N be the number of parameters in a function signature without a defined default.

Candidate functions for resolution of a function invocation are selected based on the following criteria:

- Each candidate function has a matching name and applicable number of parameters. An applicable number of parameters satisfies the condition $N \leq A \leq P$.
- Each parameter of a candidate function that does not have a corresponding argument in the function invocation, specified by either position or name, is defined with a default.
- Each candidate function from a set of one or more schemas has the EXECUTE privilege associated with the authorization ID of the statement invoking the function.

Function resolution is similar for functions that are invoked with a qualified or unqualified function name with the exception that for an unqualified name, the database manager needs to search more than one schema.

- *Qualified function resolution:* When a function is invoked with a function name and a schema name, the database manager only searches the specified schema for candidate functions.

If no candidate function in the schema is found, an error is returned. If a function is selected, its successful use depends on it being invoked in a context in which the returned result is allowed. For example, if the function returns an integer data type where a character data type is required, or returns a table where a table is not allowed, an error is returned.

- *Unqualified function resolution:* When a function is invoked with only a function name, the database manager needs to search more than one schema to resolve the function instance to execute. The SQL path contains the list of schemas to search. For each schema in the SQL path (see [“SQL path” on page 57](#)), the database manager selects candidate functions.

If no candidate function in any schema in the path is found, an error is returned. If a function is selected, its successful use depends on it being invoked in a context in which the returned result is allowed. For example, if the function returns an integer data type where a character data type is required, or returns a table where a table is not allowed, an error is returned.

After the database manager identifies the candidate functions, it selects the candidate with the best fit as the function instance to execute (see [“Determining the best fit” on page 150](#)). If more than one schema contains the function instance with the best fit (the function signatures are identical except for the schema name), the database manager selects the function whose schema is earliest in the SQL path.

Function resolution applies to all functions, including built-in functions. Built-in functions logically exist in schema QSYS2. If schema QSYS2 is not explicitly specified in the SQL path, the schema is implicitly assumed at the front of the path. When an unqualified function name is specified, the SQL path must be set to a list of schemas in the desired search order so that the intended function is selected.

In a CREATE VIEW or CREATE TABLE statement, function resolution occurs at the time the view or materialized query table is created. If another function with the same name is subsequently created, the view or materialized query table is not affected, even if the new function is a better fit than the one chosen at the time the view or materialized table was created. In a CREATE FUNCTION, CREATE PROCEDURE, CREATE TRIGGER, CREATE VARIABLE, CREATE MASK, or CREATE PERMISSION statement, function resolution occurs at the time the function, procedure, trigger, variable, mask, or permission is created. The schema of the function that was chosen is saved in the trigger, variable, mask, and permission. It is also saved in functions and procedures for default expressions. If another function with the same name is subsequently created, the function, procedure, trigger, variable, mask, permission, or routine default is only affected if the new function is a better fit than the one chosen at the time the object was created.

Determining the best fit

There might be more than one function with the same name that is a candidate for execution. In that case, the data types of the parameters, the position of the schema in the SQL path, and the total number of parameters of each function in the set of candidate functions are used to determine if the function meets the best fit requirements. Note that the data type of the result of the function or the type of function (aggregate, scalar, or table) under consideration does not enter into this determination.

If the set of candidate functions contains more than one function and named arguments are used in the function invocation, the ordinal position of the parameter corresponding to a named argument must be the same for all candidate functions.

The term *set of parameters* is used to refer to all of the parameters at the same position in the parameter lists (where such a parameter exists) for the set of candidate functions. The corresponding argument of a parameter is determined based on how the arguments are specified in the function invocation. For positional arguments, the corresponding argument to a parameter is the argument in the same position in the function invocation as the position of the parameter in the parameter list of the candidate function. For named arguments, the corresponding argument to a parameter is the argument with the same name as the parameter. In this case, the order of the arguments in the function invocation is not considered while determining the best fit. If the number of parameters in a candidate function is greater than the number of arguments in the function invocation, each parameter that does not have a corresponding argument is processed as if it does have a corresponding argument that has the DEFAULT keyword as the value.

The following steps are used to determine the function that is the best fit:

- Step 1: Considering arguments that are typed expressions

The database manager determines the function, or set of functions, that meet the best fit requirements for the invocation by comparing the data type of each parameter with the data type of the corresponding argument.

When determining whether the data type of a parameter is the same as the data type of its corresponding argument:

- Synonyms of data types match. For example, DOUBLE and FLOAT are considered to be the same.
- Attributes of a data type such as length, precision, scale, and CCSID are ignored. Therefore, CHAR(8) and CHAR(35) are considered to be the same, as are DECIMAL(11,2), and DECIMAL(4,3).
- The character and graphic types are considered to be the same. For example, the following are considered to be the same type: CHAR and GRAPHIC, VARCHAR and VARGRAPHIC, and CLOB and DBCLOB. CHAR(13) and GRAPHIC(8) are considered to be the same type.

A subset of the candidate functions is obtained by considering only those functions for which the data type of each argument of the function invocation that is not an untyped expression matches or is promotable to the data type of the corresponding parameter of the function instance. If the argument of the function invocation is an untyped expression, the data type of the corresponding parameter can be any data type. The precedence list for the promotion of data types in [“Promotion of data types” on page 84](#) shows the data types that fit (considering promotion) for each data type in best-to-worst order. If this subset is not empty, then the best fit is determined using the [Promotable process](#) on this subset of candidate functions. If this subset is empty, then the best fit is determined using the [Castable process](#) on the original set of candidate functions.

Promotable process

This process determines the best fit only considering whether arguments in the function invocation match or can be promoted to the data type of the corresponding parameter of the function definition. For the subset of candidate functions, the parameter lists are processed from left to right, processing the set of parameters in the first position from the subset of candidate functions before moving on to the set of parameters in the second position, and so on. The following steps are used to eliminate candidate functions from the subset of candidate functions (only considering promotion):

1. If one candidate function has a parameter where the data type of the corresponding argument fits (only considering promotion) the data type of the parameter better than other candidate functions, those candidate functions that do not fit the function invocation equally well are eliminated. The precedence list for the promotion of data types in [“Promotion of data types” on page 84](#) shows the data types that fit (considering promotion) for each data type in best-to-worst order.
2. If the data type of the corresponding argument is an untyped expression, no candidate functions are eliminated.
3. These steps are repeated for the next set of parameters from the remaining candidate functions until there are no more sets of parameters.

Castable process

This process determines the best fit first considering, for each parameter, if the data type of the corresponding argument in the function invocation matches or can be promoted to the data type of the parameter of the function definition. Then, for each set of parameters where no corresponding argument has a data type that was promotable, the database manager considers, for each parameter, if the data type of the corresponding argument can be implicitly cast for function resolution to the data type of the parameter.

For the set of candidate functions, the parameters in the parameter lists are processed from left to right, processing the set of parameters in the first position from all the candidate functions before moving on to the set of parameters in the second position, and so on. The following steps are used to eliminate candidate functions from the set of candidate functions (only considering promotion):

1. If one candidate function has a parameter where the data type of the corresponding argument fits (only considering promotion) the data type of the parameter better than other candidate functions, those candidate functions that do not fit the function invocation equally well are eliminated. The precedence list for the promotion of data types in [“Promotion of data types” on page 84](#) shows the data types that fit (considering promotion) for each data type in best-to-worst order.
2. If the data type for the corresponding argument is not promotable (which includes the case when the corresponding argument is an untyped expression) to the data type of the parameter of any candidate function, no candidate functions are eliminated.
3. These steps are repeated for the next set of parameters from the remaining candidate functions until there are no more sets of parameters.

If at least one set of parameters has no corresponding argument that fit (only considering promotion) and the corresponding argument for the set of parameters has a data type, the database manager compares each such set of parameters from left to right. The following steps are used to eliminate candidate functions from the set of candidate functions (considering implicit casting).

1. If all the data types of the set of parameters for all remaining candidate functions do not belong to the same data type precedence list, as specified in [“Promotion of data types” on page 84](#), an error is returned.
 2. If the data type of the corresponding arguments cannot be implicitly cast to the data type of the parameters, as specified in [“Implicit casting for function resolution” on page 153](#), an error is returned.
 3. If one candidate function has a parameter where the data type of the corresponding argument fits (considering implicit casting) the data type of the parameter better than other candidate functions, those candidate functions that do not fit the function invocation equally well are eliminated. The data type list in [“Implicit casting for function resolution” on page 153](#) shows the data type that fits (considering implicit casting) better.
 4. These steps are repeated for the next set of parameters which has no corresponding argument that fits (only considering promotion) and the corresponding argument for the set of parameters has a data type until there are no more such sets of parameters or an error occurs.
- Step 2: Considering SQL path
If more than one candidate function remains, the database manager selects those candidate functions whose schema is earliest in the SQL path.
 - Step 3: Considering number of arguments in the function invocation
If more than one candidate function remains and if one candidate function has a number of parameters that is less than or equal to the number of parameters of the other candidate functions, those candidate functions that have a greater number of parameters are eliminated.
 - Step 4: Considering arguments that are untyped expressions
If more than one candidate function remains and at least one set of parameters has a corresponding argument that is an untyped expression, the database manager compares each such set of parameters

from left to right. The following steps are used to eliminate candidate functions from the set of candidate functions:

1. If all the data types of the set of parameters for all remaining candidate functions do not belong to the same data type precedence list, as specified in [“Promotion of data types” on page 84](#), an error is returned.
2. If the data type of the parameter of one candidate function is further left in the data type ordering for implicit casting than other candidate functions, those candidate functions where the data type of the parameter is further right in the data type ordering are eliminated. The data type list in [“Implicit casting for function resolution” on page 153](#) shows the data type ordering for implicit casting.

If there are still multiple candidate functions, an error is returned.

Implicit casting for function resolution

Implicit casting for function resolution is not supported for arguments with a user-defined type or an XML, ROWID, or DATALINK data type. It is also not supported for built-in or user-defined cast functions. It is supported for the following cases:

- Any supported cast between built-in types, except for DATE, TIME, and TIMESTAMP to numeric data types. See [Table 16 on page 87](#).
- An untyped argument can be cast to any data type.

Similar to the data type precedence list for promotion, for implicit casting there is an order to the data types that are in the group of related data types. This order is used when performing function resolution that considers implicit casting. [Table 27 on page 153](#) shows the data type ordering for implicit casting for function resolution. The data types are listed in best-to-worst order (note that this is different than the ordering in the data type precedence list for promotion).

Data type group	Data type list for implicit casting for function resolution (in best-to-worst order)
Numeric data types	DECFLOAT, double, real, decimal, BIGINT, INTEGER, SMALLINT
Character and graphic string data types	VARCHAR or VARGRAPHIC, CHAR or GRAPHIC, CLOB or DBCLOB
Binary data types	VARBINARY, BINARY, BLOB, VARCHAR FOR BIT DATA, CHAR FOR BIT DATA
Datetime data types	TIMESTAMP, DATE, TIME

Note:

The lower case types above are defined as follows:

decimal

= DECIMAL(p,s) or NUMERIC(p,s)

real

= REAL or FLOAT(*n*) where *n* is a specification for single precision floating point

double

= DOUBLE, DOUBLE PRECISION, FLOAT or FLOAT(*n*) where *n* is a specification for double precision floating point

Examples

The following are examples of function resolution. (Note that not all required keywords are shown.)

Example 1: This is an example illustrating the SQL path considerations in function resolution. For this example, there are eight ACT functions, in three different schemas, registered as:

```
CREATE FUNCTION AUGUSTUS.ACT (CHAR(5), INT, DOUBLE) SPECIFIC ACT_1 ...
CREATE FUNCTION AUGUSTUS.ACT (INT, INT, DOUBLE) SPECIFIC ACT_2 ...
CREATE FUNCTION AUGUSTUS.ACT (INT, INT, DOUBLE, INT) SPECIFIC ACT_3 ...
CREATE FUNCTION JULIUS.ACT (INT, DOUBLE, DOUBLE) SPECIFIC ACT_4 ...
CREATE FUNCTION JULIUS.ACT (INT, INT, DOUBLE) SPECIFIC ACT_5 ...
CREATE FUNCTION JULIUS.ACT (SMALLINT, INT, DOUBLE) SPECIFIC ACT_6 ...
CREATE FUNCTION JULIUS.ACT (INT, INT, DECFLOAT) SPECIFIC ACT_7 ...
CREATE FUNCTION NERO.ACT (INT, INT, DEC(7,2)) SPECIFIC ACT_8 ...
```

The function reference is as follows (where I1 and I2 are INTEGER columns, and D is a DECIMAL column):

```
SELECT ... ACT(I1, I2, D) ...
```

Assume that the application making this reference has an SQL path established as:

```
"JULIUS", "AUGUSTUS", "CAESAR"
```

Following the function resolution rules:

- The function with specific name ACT_8 is eliminated as a candidate, because the schema NERO is not included in the SQL path.
- The function with specific name ACT_3 is eliminated as a candidate, because it has the wrong number of parameters. ACT_1 and ACT_6 are eliminated because, in both cases, the first argument cannot be promoted to the data type of the first parameter.
- Because there is more than one candidate remaining, the arguments are considered in order.
 - For the first argument, the remaining functions, ACT_2, ACT_4, ACT_5, and ACT_7 are an exact match with the argument type. No functions can be eliminated from consideration; therefore the next argument must be examined.
 - For this second argument, ACT_2, ACT_5, and ACT_7 are exact matches, but ACT_4 is not, so it is eliminated from consideration. The next argument is examined to determine some differentiation among ACT_2, ACT_5, and ACT_7.
 - For the third and last argument, neither ACT_2, ACT_5, nor ACT_7 match the argument type exactly. Although ACT_2 and ACT_5 are equally good, ACT_7 is not as good as the other two because the type DOUBLE is closer to DECIMAL than is DECFLOAT. ACT_7 is eliminated.
- There are two functions remaining, ACT_2 and ACT_5, with identical parameter signatures. The final tie-breaker is to see which function's schema comes first in the SQL path, and on this basis, ACT_5 is the function chosen.

Example 2: This is an example of a situation where function resolution will result in an error since more than one candidate function fits the invocation equally well, but the corresponding parameters for one of the arguments do not belong to the same type precedence list.

For this example, there are only three function in a single schema defined as follows:

```
CREATE FUNCTION CAESAR.ACT (INT, VARCHAR(5), VARCHAR(5)) SPECIFIC ACT_1 ...
CREATE FUNCTION CAESAR.ACT (INT, INT, DATE) SPECIFIC ACT_2 ...
CREATE FUNCTION CAESAR.ACT (INT, INT, DOUBLE) SPECIFIC ACT_3 ...
```

The function reference is as follows (where I1 and I2 are INTEGER columns, and VC is a VARCHAR column):

```
SELECT ... ACT(I1, I2, VC) ...
```

Assume that the application making this reference has an SQL path established as:

```
"CAESAR"
```

Following the function resolution rules:

- Each of the candidate functions is evaluated to determine if the data type of each input argument of the function invocation matches or is promotable to the data type of the corresponding parameter of the function instance:
 - For the first argument, all the candidate functions have an exact match with the parameter type.
 - For the second argument, ACT_1 is eliminated because INTEGER is not promotable to VARCHAR.
 - For the third argument, both ACT_2 and ACT_3 are eliminated since VARCHAR is not promotable to DATE or DOUBLE, so no candidate functions remain.
- Since the subset of candidate functions from above is empty, the candidate functions are considered using the castable process:
 - For the first argument, all the candidate functions have an exact match with the parameter type.
 - For the second argument, ACT_1 is eliminated since INTEGER is not promotable to VARCHAR. ACT_2 and ACT_3 are better candidates.
 - For the third argument, the data type of the corresponding parameters of ACT_2 and ACT_3 do not belong to the same data type precedence list, so an error is returned.

Example 3: This example illustrates a situation where function resolution will succeed using the castable process.

For this example, there are only three function in a single schema defined as follows:

```
CREATE FUNCTION CAESAR.ACT (INT, VARCHAR(5), VARCHAR(5)) SPECIFIC ACT_1 ...
CREATE FUNCTION CAESAR.ACT (INT, INT, DECFLOAT) SPECIFIC ACT_2 ...
CREATE FUNCTION CAESAR.ACT (INT, INT, DOUBLE) SPECIFIC ACT_3 ...
```

The function reference is as follows (where I1 and I2 are INTEGER columns, and VC is a VARCHAR column):

```
SELECT ... ACT(I1, I2, VC) ...
```

Assume that the application making this reference has an SQL path established as:

```
"CAESAR"
```

Following the function resolution rules:

- Each of the candidate functions is evaluated to determine if the data type of each input argument of the function invocation matches or is promotable to the data type of the corresponding parameter of the function instance:
 - For the first argument, all the candidate functions have an exact match with the parameter type.
 - For the second argument, ACT_1 is eliminated because INTEGER is not promotable to VARCHAR.
 - For the third argument, both ACT_2 and ACT_3 are eliminated since VARCHAR is not promotable to DECFLOAT or DOUBLE, so no candidate functions remain.
- Since the subset of candidate functions from above is empty, the candidate functions are considered using the castable process:
 - For the first argument, all the candidate functions have an exact match with the parameter type.
 - For the second argument, ACT_1 is eliminated since INTEGER is not promotable to VARCHAR. ACT_2 and ACT_3 are better candidates.
 - For the third argument, both DECFLOAT and DOUBLE are in the same data type precedence list and VARCHAR can be implicitly cast to both DECFLOAT and DOUBLE. Since DECFLOAT is a better fit for the purpose of implicit casting, ACT_2 is the best fit

Example 4: This example illustrates that during function resolution using the castable process that promotion of later arguments takes precedence over implicit casting.

For this example, there are only three function in a single schema defined as follows:

```
CREATE FUNCTION CAESAR.ACT (INT, INT, VARCHAR(5)) SPECIFIC ACT_1 ...
CREATE FUNCTION CAESAR.ACT (INT, INT, DECFLOAT) SPECIFIC ACT_2 ...
CREATE FUNCTION CAESAR.ACT (INT, INT, DOUBLE) SPECIFIC ACT_3 ...
```

The function reference is as follows (where I1 is an INTEGER columns, VC1 is a VARCHAR column, and C1 is a CHAR column):

```
SELECT ... ACT(I1, VC1, C1) ...
```

Assume that the application making this reference has an SQL path established as:

```
"CAESAR"
```

Following the function resolution rules:

- Each of the candidate functions is evaluated to determine if the data type of each input argument of the function invocation matches or is promotable to the data type of the corresponding parameter of the function instance:
 - For the first argument, all the candidate functions have an exact match with the parameter type.
 - For the second argument, all candidate functions are eliminated since VARCHAR is not promotable to INTEGER, so no candidate functions remain.
- Since the subset of candidate functions from above is empty, the candidate functions are considered using the castable process:
 - For the first argument, all the candidate functions have an exact match with the parameter type.
 - For the second argument, none of the candidate functions have a parameter to which the corresponding argument can be promoted, so no candidate functions are eliminated.
 - Since the third argument can be promoted to the parameter of ACT_1, but not to the parameters of ACT_2 or ACT_3, ACT_1 is the best fit.

Best fit considerations

Once the function is selected, there are still possible reasons why the use of the function may not be permitted. Each function is defined to return a result with a specific data type. If this result data type is not compatible within the context in which the function is invoked, an error will occur.

For example, given functions named STEP defined with different data types as the result:

```
STEP(SMALLINT) RETURNS DATE)
STEP(DOUBLE) RETURNS INTEGER
```

and the following function reference (where S is a SMALLINT column):

```
SELECT ... 3 +STEP(S)
```

then, because there is an exact match on argument type, the first STEP is chosen. An error occurs on the statement because the result type is DATE instead of a numeric type as required for an argument of the addition operator.

In cases where the arguments of the function invocation were not an exact match to the data types of the parameters of the selected function, the arguments are converted to the data type of the parameter at execution using the same rules as assignment to columns (see [“Assignments and comparisons”](#) on page 89). This includes the case where precision, scale, length, or CCSID differs between the argument and the parameter.

An error also occurs in the following examples:

- The function is referenced in the TABLE clause of a FROM clause, but the function selected by the function resolution step is a scalar or aggregate function.

- The function referenced in an SQL statement requires a scalar or aggregate function, but the function selected by the function resolution step is a table function.

Expressions

An expression specifies a value.

Authorization: The use of some of the expressions, such as a *scalar-fullselect*, *sequence-reference*, *function-invocation*, or *cast-specification* may require having the appropriate authorization. For these expressions, the privileges held by the authorization ID of the statement must include the following authorization:

- *global variable*. For information about authorization considerations, see [“Global variables” on page 137](#).
- *scalar-fullselect*. For information about authorization considerations, see [Chapter 6, “Queries,” on page 735](#).
- *sequence-reference*. The authorization to reference the sequence. For information about authorization considerations, see [“Notes” on page 193](#).
- *function-invocation*. The authorization to execute a user-defined function. For information about authorization considerations, see [“Function invocation” on page 148](#).
- *array-element-specification*. The authorization to reference an array type. For information about authorization considerations, see [“GRANT \(type privileges\)” on page 1382](#).
- *cast-specification*. The authorization to reference a user-defined type. For information about authorization considerations, see [“CAST specification” on page 176](#).

operator:

Without operators

If no operators are used, the result of the expression is the specified value.

Example

SALARY	:SALARY	'SALARY'	MAX(SALARY)
--------	---------	----------	-------------

With arithmetic operators

If arithmetic operators are used, the result of the expression is a number derived from the application of the operators to the values of the operands.

If any operand can be null, the result can be null. If any operand has the null value, the result of the expression is the null value.

If one operand of an arithmetic operator is numeric, the other operand can be a string. The string is first converted to the data type of the numeric operand and must contain a valid string representation of a number.

The prefix operator *+* (*unary plus*) does not change its operand. The prefix operator *-* (*unary minus*) reverses the sign of a nonzero non-decimal floating-point operand. The prefix operator *-* (*unary minus*) reverses the sign of all decimal floating-point operands, including zero and special values; that is, signaling and non-signaling NaNs and plus and minus infinity. If the data type of A is small integer, the data type of - A is large integer. The first character of the token following a prefix operator must not be a plus or minus sign.

The *infix operators*, *+*, *-*, ***, */*, and ****, specify addition, subtraction, multiplication, division, and exponentiation, respectively. The value of the second operand of division must not be zero, except if the calculation is performed using decimal floating-point arithmetic and the first operand is infinity or -infinity.

In COBOL, blanks must precede and follow a minus sign to avoid any ambiguity with COBOL host variable names (which allow use of a dash).

The result of an exponentiation (****) operator is a double-precision floating-point number. The result of the other operators depends on the type of the operand.

Operands with a NUMERIC data type are converted to DECIMAL operands prior to performing the arithmetic operation.

Two integer operands

If both operands of an arithmetic operator are integers with zero scale, the operation is performed in binary, and the result is a large integer unless either (or both) operand is a big integer, in which case the result is a big integer. Any remainder of division is lost. The result of an integer arithmetic operation (including *unary minus*) must be within the range of large or big integers. If either integer operand has nonzero scale, it is converted to a decimal operand with the same precision and scale.

Integer and decimal operands

If one operand is an integer with zero scale and the other is decimal, the operation is performed in decimal using a temporary copy of the integer that has been converted to a decimal number with precision and scale 0.

This is defined in the following table:

Operand	Precision of Decimal Copy
Column or variable: big integer	19
Column or variable: large integer	11
Column or variable: small integer	5
Constant (including leading zeros)	Same as the number of digits in the constant

If one operand is an integer with nonzero scale, it is first converted to a decimal operand with the same precision and scale.

Two decimal operands

If both operands are decimal, the operation is performed in decimal. The result of any decimal arithmetic operation is a decimal number with a precision and scale that are dependent on the operation and the precision and scale of the operands. If the operation is addition or subtraction and the operands do not have the same scale, the operation is performed with a temporary copy of one of the operands. The copy of the shorter operand is extended with trailing zeros so that its fractional part has the same number of digits as the longer operand.

Unless specified otherwise, all functions and operations that accept decimal numbers allow a precision of up to 63 digits. The result of a decimal operation must not have a precision greater than 63.

Decimal arithmetic in SQL

The following formulas define the precision and scale of the result of decimal operations in SQL. The symbols p and s denote the precision and scale of the first operand and the symbols p' and s' denote the precision and scale of the second operand.

The symbol mp denotes the maximum precision. The value of mp is 63 if:

- either p or p' is greater than 31, or
- a value of 63 was explicitly specified for the maximum precision.

Otherwise, the value of mp is 31.

The symbol ms denotes the maximum scale. The default value of ms is 31. ms can be explicitly set to any number from 0 to the maximum precision.

The symbol mds denotes the minimum divide scale. The default value of mds is 0, where 0 indicates that no minimum scale is specified. mds can be explicitly set to any number from 1 to $\min(ms, 9)$.

The maximum precision, maximum scale, and minimum divide scale can be explicitly specified on the DECRESULT parameter of the CRTSQLxxx command, RUNSQLSTM command, or SET OPTION statement. They can also be specified in ODBC data sources, JDBC properties, OLE DB properties, .NET properties.

Addition and subtraction

The scale of the result of addition and subtraction is $\max(s, s')$. The precision is $\min(mp, \max(p-s, p'-s') + \max(s, s') + 1)$.

Multiplication

The precision of the result of multiplication is $\min(mp, p+p')$ and the scale is $\min(ms, s+s')$.

Division

The precision of the result of division is $(p-s+s') + \max(mds, \min(ms, mp - (p-s+s')))$. The scale is $\max(mds, \min(ms, mp - (p-s+s')))$. The scale must not be negative.

Floating-point operands

If either operand of an arithmetic operator is floating point and neither operand is decimal floating-point, the operation is performed in floating point. The operands are first converted to double-precision floating-point numbers, if necessary. Thus, if any element of an expression is a floating-point number, the result of the expression is a double-precision floating-point number.

An operation involving a floating-point number and an integer is performed with a temporary copy of the integer converted to double-precision floating point. An operation involving a floating-point number and a decimal number is performed with a temporary copy of the decimal number that has been converted to double-precision floating point. The result of a floating-point operation must be within the range of floating-point numbers.

The order in which floating-point operands (or arguments to functions) are processed can slightly affect results because floating-point operands are approximate representations of real numbers. Since the order in which operands are processed may be implicitly modified by the optimizer (for example, the optimizer may decide what degree of parallelism to use and what access plan to use), an application should not depend on the results being precisely the same each time an SQL statement is executed that uses floating-point operands.

Decimal floating-point operands

If either operand of an arithmetic operator is decimal floating-point, the operation is performed in decimal floating-point.

Integer and DECFLOAT(n) operands

If one operand is a small integer or integer and the other is DECFLOAT, the operation is performed in DECFLOAT(n) using a temporary copy of the integer that has been converted to a DECFLOAT(n) number. If one operand is a big integer and the other is DECFLOAT, then a temporary copy of the big integer is converted to a DECFLOAT(34) number. The rules for two DECFLOAT operands are then applied.

Decimal and DECFLOAT(n) operands

If one operand is a decimal and the other is DECFLOAT, the operation is performed in DECFLOAT using a temporary copy of the decimal number that has been converted to a DECFLOAT number based on the precision of the decimal number. If the decimal number has a precision < 17, the decimal number is converted to DECFLOAT(16). Otherwise, the decimal number is converted to a DECFLOAT(34) number. The rules for two DECFLOAT operands are then applied.

Floating-point and DECFLOAT(n) operands

If one operand is floating-point (real or double) and the other is DECFLOAT, the operation is performed in DECFLOAT(n) using a temporary copy of the floating-point number that has been converted to a DECFLOAT(n) number.

Two DECFLOAT operands

If both operands are DECFLOAT(n), the operation is performed in DECFLOAT(n). If one operand is DECFLOAT(16) and the other is DECFLOAT(34), the operation is performed in DECFLOAT(34).

General arithmetic operation rules for DECFLOAT

The following general rules apply to all arithmetic operations on the DECFLOAT data type.

- Every operation on finite numbers is carried out (as described under the individual operations) as though an exact mathematical result is computed, using integer arithmetic on the coefficient where possible.

If the coefficient of the theoretical exact result has no more than the number of digits that reflect its precision (16 or 34), then (unless there is an underflow or overflow) it is used for the result without change. Otherwise, it is rounded (shortened) to exactly the number of digits that reflect its precision (16 or 34) and the exponent is increased by the number of digits removed.

Rounding uses the DECFLOAT rounding mode. For more information, see [“CURRENT DECFLOAT ROUNDING MODE”](#) on page 124.

If the value of the adjusted exponent of the result is less than E_{\min} , then a subnormal warning is returned.⁴² In this case, the calculated coefficient and exponent form the result, unless the value of the exponent is less than E_{tiny} , in which case the exponent will be set to E_{tiny} , the coefficient is rounded (possibly to zero) to match the adjustment of the exponent, and the sign is unchanged. If this rounding gives an inexact result then an underflow warning is returned.⁴²

If the value of the adjusted exponent of the result is larger than E_{\max} then an overflow warning is returned. In this case, the result may be infinite. It will have the same sign as the theoretical result.

- Arithmetic using the special value Infinity follows the usual rules, where negative Infinity is less than every finite number and positive Infinity is greater than every finite number. Under these rules, an infinite result is always exact. The following arithmetic operations return a warning and result in NaN:⁴²
 - Add +infinity to -infinity during an addition or subtraction operation
 - Multiply 0 or -0 by +infinity or -infinity
 - Divide either +infinity or -infinity by either +infinity or -infinity
- Signaling NaNs always raise a warning or error when used as an operand of an arithmetic operation and NaNs are returned.
- The result of an arithmetic operation which has an operand which is a NaN, is NaN. The sign of the result is copied from the first operand which is a NaN. Whenever the result is a NaN, the sign of the result depends only on the copied operand.
- The sign of the result of a multiplication or division will be negative only if the operands have different signs and neither is a NaN.
- The sign of the result of an addition or subtraction will be negative only if the result is less than zero and neither operand is a NaN.

In some instances, negative zero might be the result from arithmetic operations and numeric functions.

Examples involving special values

```
INFINITY + 1           = INFINITY
INFINITY + INFINITY    = INFINITY
INFINITY + -INFINITY   = NAN           -- warning
NAN + 1                = NAN
NAN + INFINITY         = NAN
1 - INFINITY           = -INFINITY
INFINITY - INFINITY    = NAN           -- warning
-INFINITY - -INFINITY  = NAN           -- warning
-0.0 - 0.0E1          = -0.0
-1.0 * 0.0E1          = -0.0
1.0E1 / 0              = INFINITY
-1.0E5 / 0.0          = -INFINITY
1.0E5 / -0             = -INFINITY
INFINITY / -INFINITY   = NAN           -- warning
INFINITY / 0           = INFINITY     -- warning
```

⁴² The warning is only returned if *YES is specified for the SQL_DECFLOAT_WARNINGS query option.

```
-INFINITY / 0          = -INFINITY  -- warning
-INFINITY / -0         = INFINITY   -- warning
```

Distinct type operands

A distinct type cannot be used with arithmetic operators even if its source data type is numeric. To perform an arithmetic operation, create a function with the arithmetic operator as its source. For example, if there were distinct types INCOME and EXPENSES, both of which had DECIMAL(8,2) data types, then the following user-defined function, REVENUE, could be used to subtract one from the other.

```
CREATE FUNCTION REVENUE ( INCOME, EXPENSES )
  RETURNS DECIMAL(8,2) SOURCE "-" ( DECIMAL, DECIMAL)
```

Alternately, the - (minus) operator could be overloaded using a user-defined function to subtract the new data types.

```
CREATE FUNCTION "-" ( INCOME, EXPENSES )
  RETURNS DECIMAL(8,2) SOURCE "-" ( DECIMAL, DECIMAL)
```

Alternatively, the distinct type can be cast to a built-in type, and the result can be used as an operand of an arithmetic operator.

With the concatenation operator

If the concatenation operator (CONCAT or ||) is used, the result of the expression is a string.

The operands of concatenation must be compatible strings or numeric, date, time, or timestamp data types.⁴³ The operands must not be distinct types. If a numeric, date, time, or timestamp operand is specified, it is CAST to the equivalent character string prior to concatenation. Note that a binary string cannot be concatenated with a character string unless the character string is defined as FOR BIT DATA.

The data type of the result is determined by the data types of the operands. The data type of the result is summarized in the following table:

<i>Table 28. Result Data Types With Concatenation</i>		
If one operand column is ...	And the other operand is ...	The data type of the result column is ...
DBCLOB(x)	CHAR(y)* or VARCHAR(y)* or CLOB(y)* or GRAPHIC(y) or VARGRAPHIC(y) or DBCLOB(y)	DBCLOB(z) where z = MIN(x + y, maximum length of a DBCLOB)
VARGRAPHIC(x)	CHAR(y)* or VARCHAR(y)* or GRAPHIC(y) or VARGRAPHIC(y)	VARGRAPHIC(z) where z = MIN(x + y, maximum length of a VARGRAPHIC)
GRAPHIC(x)	CHAR(y)* mixed data	VARGRAPHIC(z) where z = MIN(x + y, maximum length of a VARGRAPHIC)
GRAPHIC(x)	CHAR(y)* SBCS data or GRAPHIC(y)	GRAPHIC(z) where z = MIN(x + y, maximum length of a GRAPHIC)
CLOB(x)*	GRAPHIC(y) or VARGRAPHIC(y)	DBCLOB(z) where z = MIN(x + y, maximum length of a DBCLOB)
VARCHAR(x)*	GRAPHIC(y)	VARGRAPHIC(z) where z = MIN(x + y, maximum length of a VARGRAPHIC)

⁴³ Using the vertical bar (|) character might inhibit code portability between relational database products. Use the CONCAT operator in place of the || operator. Alternatively, if conformance to SQL 2003 Core standard is of primary importance, use the || operator).

<i>Table 28. Result Data Types With Concatenation (continued)</i>		
If one operand column is ...	And the other operand is ...	The data type of the result column is ...
CLOB(x)	CHAR(y) or VARCHAR(y) or CLOB(y)	CLOB(z) where z = MIN(x + y, maximum length of a CLOB)
VARCHAR(x)	CHAR(y) or VARCHAR(y)	VARCHAR(z) where z = MIN(x + y, maximum length of a VARCHAR)
CHAR(x) mixed data	CHAR(y)	VARCHAR(z) where z = MIN(x + y, maximum length of a VARCHAR)
CHAR(x) SBCS data	CHAR(y)	CHAR(z) where z = MIN(x + y, maximum length of a CHAR)
BLOB(x)	BINARY(y) or VARBINARY(y) or BLOB(y) or CHAR(y) FOR BIT DATA or VARCHAR(y) FOR BIT DATA	BLOB(z) where z = MIN(x + y, maximum length of a BLOB)
VARBINARY(x)	BINARY(y) or VARBINARY(y) or CHAR(y) FOR BIT DATA or VARCHAR(y) FOR BIT DATA	VARBINARY(z) where z = MIN(x + y, maximum length of a VARBINARY)
BINARY(x)	VARCHAR(y) FOR BIT DATA	VARBINARY(z) where z = MIN(x + y, maximum length of a VARBINARY)
BINARY(x)	BINARY(y) or CHAR(y) FOR BIT DATA	BINARY(z) where z = MIN(x + y, maximum length of a BINARY)
Note:		
* Character strings are only allowed when the other operand is a graphic string if the graphic string is Unicode.		

<i>Table 29. Result Encoding Schemes With Concatenation</i>		
If one operand column is ...	And the other operand is ...	The data type of the result column is ...
Unicode data	Unicode data or DBCS or mixed or SBCS data	Unicode data
DBCS data	DBCS data	DBCS data
bit data	mixed or SBCS or bit data	bit data
mixed data	mixed or SBCS data	mixed data
SBCS data	SBCS data	SBCS data

If the sum of the lengths of the operands exceeds the maximum length attribute of the resulting data type:

- The length attribute of the result is the maximum length of the resulting data type.⁴⁴
- If only blanks are truncated no warning or error occurs.
- If non-blanks are truncated, an error occurs.

If either operand can be null, the result can be null, and if either is null, the result is the null value. Otherwise, the result consists of the first operand string followed by the second.

⁴⁴ If the expression is in the select-list, the length attribute may be further reduced in order to fit within the maximum record size. For more information, see [“Maximum row sizes”](#) on page 1164.

With mixed data this result will not have redundant shift codes "at the seam". Thus, if the first operand is a string ending with a "shift-in" character (X'0F'), while the second operand is a character string beginning with a "shift-out" character (X'0E'), these two bytes are eliminated from the result.

The actual length of the result is the sum of the lengths of the operands unless redundant shifts are eliminated; in which case, the actual length is two less than the sum of the lengths of the operands.

The CCSID of the result is determined by the CCSID of the operands as explained under [“Conversion rules for operations that combine strings”](#) on page 110. Note that as a result of these rules:

- If any operand is bit data, the result is bit data.
- If one operand is mixed data and the other is SBCS data, the result is mixed data. However, this does not necessarily mean that the result is well-formed mixed data.

Example

Concatenate the column FIRSTNAME with a blank and the column LASTNAME.

```
FIRSTNAME CONCAT ' ' CONCAT LASTNAME
```

Scalar fullselect

A scalar fullselect as supported in an expression is a fullselect, enclosed in parentheses, that returns a single row consisting of a single column value. If the fullselect does not return a row, the result of the expression is the null value. If the select list element is an expression that is simply a column name, the result column name is based on the name of the column. Otherwise, the result column is unnamed.

See [“fullselect”](#) on page 783 for more information.

A scalar fullselect is not allowed if the query specifies:

- a distributed table,
- a table with a read trigger, or
- a logical file built over multiple physical file members.

If the scalar fullselect is a subselect, it is also referred to as a scalar subselect. See [“subselect”](#) on page 736 for more information.

Datetime operands and durations

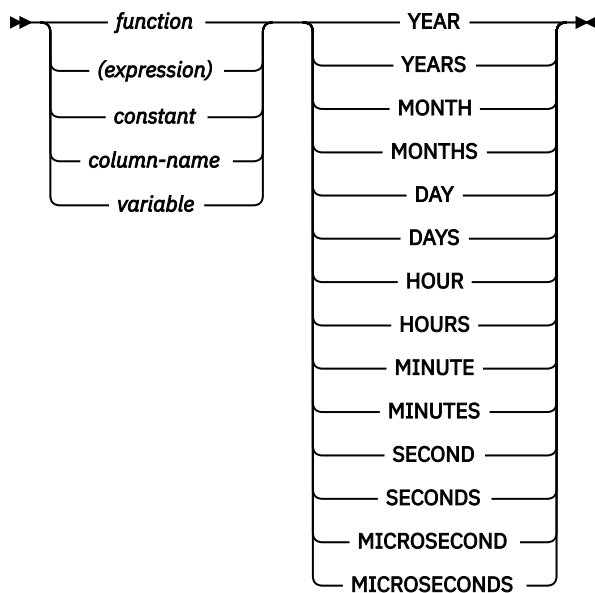

Datetime values can be incremented, decremented, and subtracted. These operations may involve decimal numbers called *durations*. A *duration* is a positive or negative number representing an interval of time.

There are four types of durations:

Labeled durations

The form a labeled duration is as follows:

labeled-duration:

A *labeled duration* represents a specific unit of time as expressed by a number (which can be the result of an expression) followed by one of the seven duration keywords: YEARS, MONTHS, DAYS, HOURS, MINUTES, SECONDS, or MICROSECONDS⁴⁵. The number specified is converted as if it were assigned to a DECIMAL(15,0) number, except for SECONDS which uses DECIMAL(27,12) to allow 0 to 12 digits of fractional seconds to be included. The MICROSECONDS duration returns 6 digits of fractional seconds.

A labeled duration can only be used as an operand of an arithmetic operator in which the other operand is a value of data type DATE, TIME, or TIMESTAMP. Thus, the expression HIREDATE + 2 MONTHS + 14 DAYS is valid whereas the expression HIREDATE + (2 MONTHS + 14 DAYS) is not. In both of these expressions, the labeled durations are 2 MONTHS and 14 DAYS.

Date duration

A *date duration* represents a number of years, months, and days, expressed as a DECIMAL(8,0) number. To be properly interpreted, the number must have the format *yyyymmdd*, where *yyyy* represents the number of years, *mm* the number of months, and *dd* the number of days. The result of subtracting one date value from another, as in the expression HIREDATE - BIRTHDATE, is a date duration.

Time duration

A *time duration* represents a number of hours, minutes, and seconds, expressed as a DECIMAL(6,0) number. To be properly interpreted, the number must have the format *hhmmss* where *hh* represents the number of hours, *mm* the number of minutes, and *ss* the number of seconds. The result of subtracting one time value from another is a time duration.

Timestamp duration

A *timestamp duration* represents a number of years, months, days, hours, minutes, seconds, and fractional seconds, expressed as a DECIMAL(14+s,s) number, where *s* is the number of digits of fractional seconds ranging from 0 to 12. To be properly interpreted, the number must have the format *yyyymmddhhmmss.zzzzzzzzzz*, where *yyyy*, *mm*, *dd*, *hh*, *mm*, *ss*, and *zzzzzzzzzz* represent, respectively, the number of years, months, days, hours, minutes, seconds, and fractional seconds. The result of subtracting one timestamp value from another is a timestamp duration with scale that matches the maximum timestamp precision of the timestamp operands.

⁴⁵ Note that the singular form of these keywords is also acceptable: YEAR, MONTH, DAY, HOUR, MINUTE, SECOND, and MICROSECOND.

Datetime arithmetic in SQL

The only arithmetic operations that can be performed on datetime values are addition and subtraction. If a datetime value is the operand of addition, the other operand must be a duration.

The specific rules governing the use of the addition operator with datetime values follow:

- If one operand is a date, the other operand must be a date duration or labeled duration of years, months, or days.
- If one operand is a time, the other operand must be a time duration or a labeled duration of hours, minutes, or seconds.
- If one operand is a timestamp, the other operand must be a duration. Any type of duration is valid.
- Neither operand of the addition operator can be an untyped parameter marker.

The rules for the use of the subtraction operator on datetime values are not the same as those for addition because a datetime value cannot be subtracted from a duration, and because the operation of subtracting two datetime values is not the same as the operation of subtracting a duration from a datetime value. The specific rules governing the use of the subtraction operator with datetime values follow:

- If the first operand is a date, the second operand must be a date, a timestamp, a date duration, a string representation of a date, a string representation of a timestamp, or a labeled duration of years, months, or days.
- If the second operand is a date, the first operand must be a date, a timestamp, a string representation of a date, or a string representation of a timestamp.
- If the first operand is a time, the second operand must be a time, a time duration, a string representation of a time, or a labeled duration of hours, minutes, or seconds.
- If the second operand is a time, the first operand must be a time, or string representation of a time.
- If the first operand is a timestamp, the second operand must be a date, a timestamp, a string representation of a date, a string representation of a timestamp, or a duration. If the second operand is a string representation of a timestamp, it is implicitly converted to a timestamp with the same precision as the first operand.
- If the second operand is a timestamp, the first operand must be a date, a timestamp, a string representation of a date, or a string representation of a timestamp. If the first operand is a string representation of a timestamp, it is implicitly converted to a timestamp with the same precision as the second operand.
- Neither operand of the subtraction operator can be an untyped parameter marker.

Date arithmetic

Dates can be subtracted, incremented, or decremented.

Subtracting dates

The result of subtracting one date (DATE2) from another (DATE1) is a date duration that specifies the number of years, months, and days between the two dates. The data type of the result is DECIMAL(8,0). If DATE1 is greater than or equal to DATE2, DATE2 is subtracted from DATE1. If DATE1 is less than DATE2, however, DATE1 is subtracted from DATE2, and the sign of the result is made negative. The following procedural description clarifies the steps involved in the operation $RESULT = DATE1 - DATE2$.

If $DAY(DATE2) \leq DAY(DATE1)$
then $DAY(RESULT) = DAY(DATE1) - DAY(DATE2)$.

If $DAY(DATE2) > DAY(DATE1)$
then $DAY(RESULT) = N + DAY(DATE1) - DAY(DATE2)$
where $N =$ the last day of $MONTH(DATE2)$.
 $MONTH(DATE2)$ is then incremented by 1.

If MONTH(​DATE2) <= MONTH(​DATE1)
then MONTH(​RESULT) = MONTH(​DATE1) - MONTH(​DATE2).

If MONTH(​DATE2) > MONTH(​DATE1)
then MONTH(​RESULT) = 12 + MONTH(​DATE1) - MONTH(​DATE2).
YEAR(​DATE2) is then incremented by 1.

YEAR(​RESULT) = YEAR(​DATE1) - YEAR(​DATE2).

For example, the result of DATE('3/15/2000') - '12/31/1999' is 215 (or, a duration of 0 years, 2 months, and 15 days).

Incrementing and decrementing dates

The result of adding a duration to a date, or of subtracting a duration from a date, is itself a date. (For the purposes of this operation, a month denotes the equivalent of a calendar page. Adding months to a date, then, is like turning the pages of a calendar, starting with the page on which the date appears.) The result must fall between the dates January 1, 0001 and December 31, 9999 inclusive.

If a duration of years is added or subtracted, only the year portion of the date is affected. The month is unchanged, as is the day unless the result would be February 29 of a non-leap-year. In this case, the day is changed to 28, an SQLSTATE of '01506' is assigned to the RETURNED_SQLSTATE condition area item in the SQL Diagnostics Area (or SQLWARN6 in the SQLCA is set to 'W') to indicate the end-of-month adjustment.

Similarly, if a duration of months is added or subtracted, only months and, if necessary, years are affected. The day portion of the date is unchanged unless the result would be invalid (September 31, for example). In this case, the day is set to the last day of the month, and SQLWARN6 in the SQLCA is set to 'W' to indicate the end-of-month adjustment.

Adding or subtracting a duration of days will, of course, affect the day portion of the date, and potentially the month and year. Adding a labeled duration of DAYS will not cause an end-of-month adjustment.

Date durations, whether positive or negative, may also be added to and subtracted from dates. As with labeled durations, the result is a valid date, and a warning indicator is set in the SQLCA whenever an end-of-month adjustment is necessary.

When a positive date duration is added to a date, or a negative date duration is subtracted from a date, the date is incremented by the specified number of years, months, and days, in that order. Thus DATE1 + X, where X is a positive DECIMAL(8,0) number, is equivalent to the expression:

- DATE1 + YEAR(X) YEARS + MONTH(X) MONTHS + DAY(X) DAYS

When a positive date duration is subtracted from a date, or a negative date duration is added to a date, the date is decremented by the specified number of days, months, and years, in that order. Thus, DATE1 - X, where X is a positive DECIMAL(8,0) number, is equivalent to the expression:

- DATE1 - DAY(X) DAYS - MONTH(X) MONTHS - YEAR(X) YEARS

Note: If one or more months is added to a given date and then the same number of months is subtracted from the result, the final date is not necessarily the same as the original date.

Also note that logically equivalent expressions may not produce the same result. For example:

- (DATE('2002-01-31') + 1 MONTH) + 1 MONTH will result in a date of 2002-03-28.

does not produce the same result as

- DATE('2002-01-31') + 2 MONTHS will result in a date of 2002-03-31.

The order in which labeled date durations are added to and subtracted from dates can affect the results. For compatibility with the results of adding or subtracting date durations, a specific order must be used. When labeled date durations are added to a date, specify them in the order of YEARS + MONTHS + DAYS. When labeled date durations are subtracted from a date, specify them in the order of DAYS - MONTHS - YEARS. For example, to add one year and one day to a date, specify:

- DATE1 + 1 YEAR + 1 DAY

To subtract one year, one month, and one day from a date, specify:

- DATE1 - 1 DAY - 1 MONTH - 1 YEAR

Time arithmetic

Times can be subtracted, incremented, or decremented.

Subtracting times

The result of subtracting one time (TIME2) from another (TIME1) is a time duration that specifies the number of hours, minutes, and seconds between the two times. The data type of the result is DECIMAL(6,0). If TIME1 is greater than or equal to TIME2, TIME2 is subtracted from TIME1. If TIME1 is less than TIME2, however, TIME1 is subtracted from TIME2, and the sign of the result is made negative. The following procedural description clarifies the steps involved in the operation $RESULT = TIME1 - TIME2$.

If $SECOND(TIME2) \leq SECOND(TIME1)$
then $SECOND(RESULT) = SECOND(TIME1) - SECOND(TIME2)$.

If $SECOND(TIME2) > SECOND(TIME1)$
then $SECOND(RESULT) = 60 + SECOND(TIME1) - SECOND(TIME2)$.
MINUTE(TIME2) is then incremented by 1.

If $MINUTE(TIME2) \leq MINUTE(TIME1)$
then $MINUTE(RESULT) = MINUTE(TIME1) - MINUTE(TIME2)$.

If $MINUTE(TIME2) > MINUTE(TIME1)$
then $MINUTE(RESULT) = 60 + MINUTE(TIME1) - MINUTE(TIME2)$.
HOUR(TIME2) is then incremented by 1.

$HOUR(RESULT) = HOUR(TIME1) - HOUR(TIME2)$.

For example, the result of $TIME('11:02:26') - '00:32:56'$ is 102930 (a duration of 10 hours, 29 minutes, and 30 seconds).

Incrementing and decrementing times

The result of adding a duration to a time, or of subtracting a duration from a time, is itself a time. Any overflow or underflow of hours is discarded, thereby ensuring that the result is always a time. If a duration of hours is added or subtracted, only the hours portion of the time is affected. The minutes and seconds are unchanged.

Similarly, if a duration of minutes is added or subtracted, only minutes and, if necessary, hours are affected. The seconds portion of the time is unchanged.

Adding or subtracting a duration of seconds will, of course, affect the seconds portion of the time, and potentially the minutes and hours.

Time durations, whether positive or negative, also can be added to and subtracted from times. The result is a time that has been incremented or decremented by the specified number of hours, minutes, and seconds, in that order. $TIME1 + X$, where “X” is a DECIMAL(6,0) number, is equivalent to the expression:

```
TIME1 + HOUR(X) HOURS + MINUTE(X) MINUTES + SECOND(X) SECONDS
```

Timestamp arithmetic

Timestamps can be subtracted, incremented, or decremented.

Subtracting timestamps

The result of subtracting one timestamp (TS2) from another (TS1) is a timestamp duration that specifies the number of years, months, days, hours, minutes, seconds, and fractional seconds between the two timestamps. The data type of the result is DECIMAL(14+s,s), where s is the maximum timestamp precision of TS1 and TS2. If TS1 is greater than or equal to TS2, TS2 is subtracted from TS1. If TS1 is less than TS2, however, TS1 is subtracted from TS2 and the sign of the result is made negative. The following procedural description clarifies the steps involved in the operation $RESULT = TS1 - TS2$.

If $SECOND(TS2,s) \leq SECOND(TS1,s)$
then $SECOND(RESULT,s) = SECOND(TS1,s) - SECOND(TS2,s)$.

If $SECOND(TS2,s) > SECOND(TS1,s)$
then $SECOND(RESULT,s) = 60 + SECOND(TS1,s) - SECOND(TS2,s)$
and $MINUTE(TS2)$ is incremented by 1.

The minutes part of the timestamps are subtracted as specified in the rules for subtracting times.

If $HOUR(TS2) \leq HOUR(TS1)$
then $HOUR(RESULT) = HOUR(TS1) - HOUR(TS2)$.

If $HOUR(TS2) > HOUR(TS1)$
then $HOUR(RESULT) = 24 + HOUR(TS1) - HOUR(TS2)$
and $DAY(TS2)$ is incremented by 1.

The date part of the timestamps is subtracted as specified in the rules for subtracting dates.

The result of subtracting a date (D1) from a timestamp (TS1) is the same as subtracting $TIMESTAMP(D1)$ from TS1. Similarly, the result of subtracting one timestamp (TS1) from a date (D2) is the same as subtracting TS1 from $TIMESTAMP(D2)$.

Incrementing and decrementing timestamps

The result of adding a duration to a timestamp, or of subtracting a duration from a timestamp, is itself a timestamp. The precision of the result timestamp matches the precision of the timestamp operand. Date and time arithmetic is performed as previously defined, except that an overflow or underflow of hours is carried into the date part of the result, which must be within the range of valid dates. Fractional seconds overflow into seconds. Thus, subtracting a duration, X, from a timestamp, $TIMESTAMP1$, where X is a DECIMAL(14+s,s) number is equivalent to the expression:

```
TIMESTAMP1 - YEAR(X) YEARS - MONTH(X) MONTHS - DAY(X) DAYS
            - HOUR(X) HOURS - MINUTE(X) MINUTES
            - SECOND(X,s) SECONDS
```

When subtracting a duration with non-zero scale, a labeled duration of MICROSECOND or MICROSECONDS, or a labeled duration of SECOND or SECONDS with a value that includes fractions of a second, the subtraction is performed as if the timestamp value has up to 12 fractional second digits. The resulting value is assigned to a timestamp value with the timestamp precision of the timestamp operand which could result in truncation of fractional second digits.

Precedence of operations

Expressions within parentheses are evaluated first. When the order of evaluation is not specified by parentheses, exponentiation is applied after prefix operators (such as -, unary minus) and before multiplication and division. Multiplication and division are applied before addition and subtraction. Operators at the same precedence level are applied from left to right.

The following table shows the priority of all operators.

Priority	Operators
1	+, - (when used for signed numeric values)
2	**
3	*, /, CONCAT,
4	+, - (when used between two operands)

Example 1:

In this example, the first operation is the addition in (SALARY + BONUS) because it is within parenthesis. The second operation is multiplication because it is at a higher precedence level than the second addition operator and it is to the left of the division operator. The third operation is division because it is at a higher precedence level than the second addition operator. Finally, the remaining addition is performed.

```
1.10 * (SALARY + BONUS) + SALARY / :VAR3
```

↑ ↑ ↑ ↑
2 1 4 3

Example 2:

In this example, the first operation (CONCAT) combines the character strings in the variables YYYYMM and DD into a string representing a date. The second operation (-) then subtracts that date from the date being processed in DATECOL. The result is a date duration that indicates the time elapsed between the two dates.

```
DATECOL - :YYYYMM CONCAT :DD
```

2 1

ARRAY constructor

The ARRAY constructor returns an array specified by a list of expressions or a fullselect.

fullselect

A fullselect that returns a single column. The values returned by the fullselect are the elements of the array. The cardinality of the array is equal to the number of rows returned by the fullselect. An ORDER BY clause in the fullselect can be used to specify the order among the elements of the array; otherwise, the order is undefined. The attributes of the base type of the array are the same as the data type of the result column of the fullselect.

element-expression

An expression defining the value of an element within the array. The cardinality of the array is equal to the number of element expressions. The first *element-expression* is assigned to the array element with array index 1. The second *element-expression* is assigned to the array element with array index 2, and so on. All element expressions must have compatible data types. The attributes of the base type of the array are determined by all the operands as explained in [“Rules for result data types” on page 105](#).

If there is no expression within the brackets, the result is an empty array. The cardinality of an empty array is 0.

An ARRAY constructor can only be specified on the right side of a SET variable or *assignment-statement*.

Examples

- Set the array variable RECENT_CALLS of array type PHONENUMBERS to an array of fixed numbers.

```
SET RECENT_CALLS = ARRAY[9055553907, 4165554213, 4085553678]
```

- Set the array variable DEPT_PHONES of array type PHONENUMBERS to an array of phone numbers retrieved from the DEPARTMENT_INFO table.

```
SET DEPT_PHONES = ARRAY[SELECT DECIMAL(AREA_CODE CONCAT '555' CONCAT EXTENSION,16)
FROM DEPARTMENT_INFO
WHERE DEPTID = 624]
```

ARRAY element specification

The ARRAY element specification returns the element from an array specified by *expression*.

► *array-variable* [*expression*] ◄
└─ CAST (*parameter-marker* AS *array-type*) ─┘

array-variable

Specifies a variable or parameter of type array in an SQL procedure or SQL function.

CAST(*parameter-marker* AS *array-type*)

Specifies the array data type to be used for the parameter marker. The array data type passed for the parameter marker value must match this array data type exactly.

[*expression*]

Specifies the array index of the element that is to be extracted from the array. The array index must return a value that is an exact numeric with zero scale or DECFLOAT. Its value must be between 1 and the cardinality of the array.

The data type of the result is the data type specified for the array on the CREATE TYPE (Array) statement.

If *expression* is null or the array is null, the null value is returned.

CASE expression

CASE expressions allow an expression to be selected based on the evaluation of one or more conditions.

searched-when-clause

simple-when-clause

In general, the value of the *case-expression* is the value of the *result-expression* following the first (leftmost) *when-clause* that evaluates to true. If no *when-clause* evaluates to true and the `ELSE` keyword is present then the result is the value of the `ELSE` *result-expression* or `NULL`. If no *when-clause* evaluates to true and the `ELSE` keyword is not present then the result is `NULL`. Note that when a *when-clause* evaluates to unknown (because of nulls), the *when-clause* is not true and hence is treated the same way as a *when-clause* that evaluates to false.

searched-when-clause

Specifies a *search-condition* that is applied to each row or group of table data presented for evaluation, and the result when that condition is true.

simple-when-clause

Specifies that the value of the *expression* prior to the first `WHEN` keyword is tested for equality with the value of the *expression* that follows each `WHEN` keyword. It also specifies the result when that condition is true.

The data type of the *expression* prior to the first `WHEN` keyword must be compatible with the data types of the *expression* that follows each `WHEN` keyword.

result-expression or NULL

Specifies the value that follows the `THEN` keyword and `ELSE` keywords. There must be at least one *result-expression* in the `CASE` expression with a defined data type. `NULL` cannot be specified for every case.

All *result-expressions* must have compatible data types, where the attributes of the result are determined based on the “[Rules for result data types](#)” on page 105.

search-condition

Specifies a condition that is true, false, or unknown about a row or group of table data.

The *search-condition* must not include a subquery in an `EXISTS` or `IN` predicate.

If a `CASE` expression is used in a select list, the `SET` clause of an `UPDATE` or `MERGE` statement, or the `VALUES` clause of an `INSERT` or `MERGE` statement, and if *simple-when-clause* or *searched-when-clause* references a column for which column access control is activated, the masked value will be used instead of the column value.

There are two scalar functions, `NULLIF` and `COALESCE`, that are specialized to handle a subset of the functionality provided by `CASE`. The following table shows the equivalent expressions using `CASE` or these functions.

Table 30. Equivalent CASE Expressions

CASE Expression	Equivalent Expression
CASE WHEN e1=e2 THEN NULL ELSE e1 END	NULLIF(e1,e2)
CASE WHEN e1 IS NOT NULL THEN e1 ELSE e2 END	COALESCE(e1,e2)
CASE WHEN e1 IS NOT NULL THEN e1 ELSE COALESCE(e2,...,eN) END	COALESCE(e1,e2,...,eN)

Examples

- If the first character of a department number is a division in the organization, then a CASE expression can be used to list the full name of the division to which each employee belongs:

```
SELECT EMPNO, LASTNAME,
CASE SUBSTR(WORKDEPT,1,1)
WHEN 'A' THEN 'Administration'
WHEN 'B' THEN 'Human Resources'
WHEN 'C' THEN 'Accounting'
WHEN 'D' THEN 'Design'
WHEN 'E' THEN 'Operations'
END
FROM EMPLOYEE
```

- The number of years of education are used in the EMPLOYEE table to give the education level. A CASE expression can be used to group these and to show the level of education.

```
SELECT EMPNO, FIRSTNAME, MIDINIT, LASTNAME,
CASE
WHEN EDLEVEL < 15 THEN 'SECONDARY'
WHEN EDLEVEL < 19 THEN 'COLLEGE'
ELSE 'POST GRADUATE'
END
FROM EMPLOYEE
```

- Another interesting example of CASE statement usage is in protecting from division by 0 errors. For example, the following code finds the employees who earn more than 25% of their income from commission, but who are not fully paid on commission:

```
SELECT EMPNO, WORKDEPT, SALARY+COMM
FROM EMPLOYEE
WHERE (CASE WHEN SALARY=0 THEN NULL
ELSE COMM/SALARY
END) > 0.25
```

- The following CASE expressions are equivalent:

```
SELECT LASTNAME,
CASE
WHEN LASTNAME = 'Haas' THEN 'President'
...
ELSE 'Unknown'
END
FROM EMPLOYEE

SELECT LASTNAME,
CASE LASTNAME
WHEN 'Haas' THEN 'President'
...
ELSE 'Unknown'
END
FROM EMPLOYEE
```

CAST specification

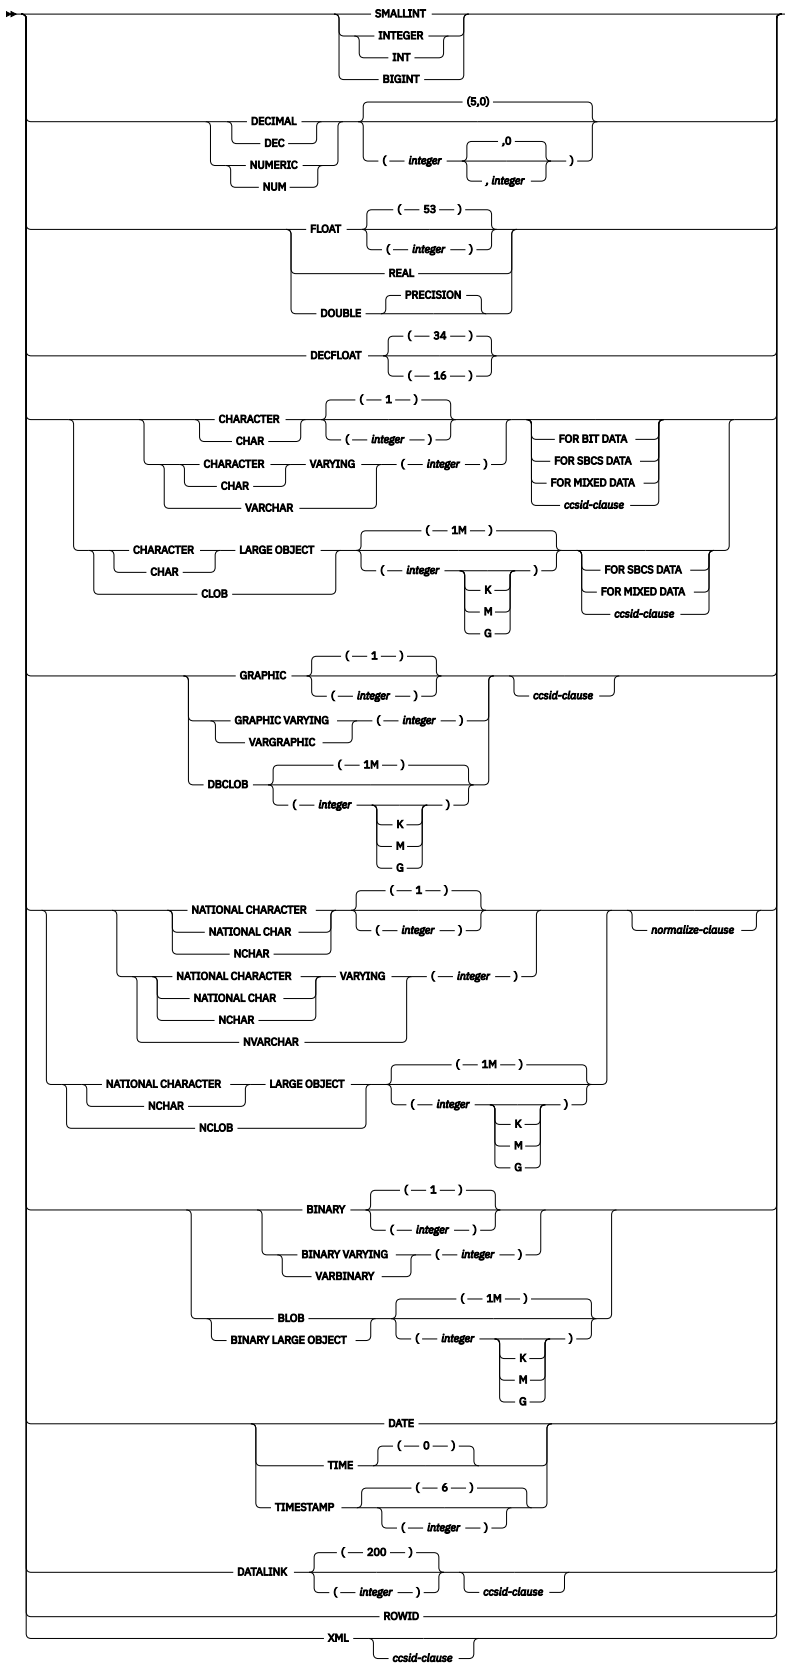

The CAST specification returns the cast operand (the first operand) cast to the type specified by the *data-type*.

data-type

built-in-type

ccsid-clause

normalize-clause

The CAST specification returns the cast operand (the first operand) cast to the type specified by the *data-type*. If the data type of either operand is a distinct type, the privileges held by the authorization ID of the statement must include USAGE authority on the distinct type.

expression

Specifies that the cast operand is an expression other than NULL or a parameter marker. The result is the argument value converted to the specified target data type.

The supported casts are shown in [“Casting between data types” on page 86](#), where the first column represents the data type of the cast operand (source data type) and the data types across the top represent the target data type of the CAST specification. If the cast is not supported, an error is returned.

When casting character or graphic strings to a character or graphic string with a different length, a warning is returned if truncation of other than trailing blanks occurs.

NULL

Specifies that the cast operand is the null value. The result is a null value that has the specified *data-type*.

parameter-marker

A parameter marker (specified as a question mark character) is normally considered an expression, but is documented separately in this case because it has a special meaning. If the cast operand is a *parameter-marker*, the specified *data-type* is considered a promise that the replacement will be assignable to the specified *data-type* (using storage assignment rules, see [“Assignments and comparisons” on page 89](#)). Such a parameter marker is called a *typed parameter marker*. Typed parameter markers will be treated like any other typed value for the purpose of DESCRIBE of a select list or for column assignment.

data-type

Specifies the data type of the result. If the data type is not qualified, the SQL path is used to find the appropriate data type. For more information, see [“Unqualified function, procedure, specific name, type, and variables” on page 59](#). For a description of *data-type*, see [“CREATE TABLE” on page 1115](#). (For portability across operating systems, when specifying a floating-point data type, use REAL or DOUBLE instead of FLOAT.)

Restrictions on the supported data types are based on the specified cast operand.

- For a cast operand that is an *expression*, see [Table 16 on page 87](#) for the target data types that are supported based on the data type of the cast operand.
- For a cast operand that is the keyword NULL, the target data type can be any data type.
- For a cast operand that is a parameter marker, the target data type can be any data type. If the data type is a distinct type, the application that uses the parameter marker will use the source data type of the distinct type. If the data type is an array type, the parameter marker must represent an array with a cardinality less than or equal to the maximum cardinality of the target array data type. The data type of the parameter marker must match the data type of the target array data type exactly.

If the CCSID attribute is not specified, then:

- If the *data-type* is BINARY, VARBINARY, or BLOB, a CCSID of 65535 is used.
- If FOR BIT DATA is specified, a CCSID of 65535 is used.
- If the *expression* is a character string, and the *data-type* is CHAR, VARCHAR, or CLOB:
 - If FOR SBCS DATA is specified,
 - If the CCSID of the *expression* is a Unicode CCSID, then the single-byte CCSID associated with the default CCSID of the job is used.

- Otherwise, the single-byte CCSID associated with the CCSID of the *expression* is used.⁴⁶
- If FOR MIXED DATA is specified,
 - If the CCSID of the *expression* is a Unicode CCSID, then the mixed-byte CCSID associated with the default CCSID of the job is used.
 - Otherwise, the mixed-byte CCSID associated with the CCSID of the *expression* is used.⁴⁶
- Otherwise,
 - If *expression* is SBCS data, the CCSID of the *expression* is used.⁴⁷⁴⁶
 - If *expression* is mixed data and the length attribute of the result is greater than or equal to 4, then the CCSID of the *expression* is used.
 - If *expression* is mixed data that is DBCS-open or DBCS-either and the length attribute of the result is less than 4, the CCSID of the result is the associated SBCS CCSID for the mixed data CCSID.
- If the *expression* is a graphic string or *expression* is a parameter marker, and the *data-type* is CHAR, VARCHAR, or CLOB:
 - If FOR SBCS DATA is specified, the single-byte CCSID associated with the default CCSID of the job is used.
 - If FOR MIXED DATA is specified, the mixed-byte CCSID associated with default CCSID of the job is used.
 - Otherwise,
 - If the default CCSID of the job is SBCS data, the default CCSID of the job is used.
 - If the default CCSID of the job is mixed data and the length attribute of the result is greater than or equal to 4, then the default CCSID of the job is used.
 - If the default CCSID of the job is mixed data that is DBCS-open or DBCS-either and the length attribute of the result is less than 4, the CCSID of the result is the associated SBCS CCSID for the mixed data CCSID.
- If the *expression* is a character string, datetime expression, or parameter marker, and the *data-type* is GRAPHIC, VARGRAPHIC, or DBCLOB, the CCSID 1200 is used.
- If the *expression* is a graphic string, and the *data-type* is GRAPHIC, VARGRAPHIC, or DBCLOB; the CCSID of the *expression* is used.
- If the *data-type* is XML, the CCSID value as specified by the SQL_XML_DATA_CCSID QAQQINI setting is used. See [“XML Values” on page 80](#) for more information.
- Otherwise, the default CCSID of the job is used.

If the CCSID attribute is specified, the data will be converted to that CCSID. If NORMALIZED is specified, the data will be normalized. If FOR MIXED DATA or a mixed CCSID is specified, the result length cannot be less than 4.

For information about which casts between data types are supported and the rules for casting to a data type see [“Casting between data types” on page 86](#).

Examples

- An application is only interested in the integer portion of the SALARY column (defined as DECIMAL(9,2)) from the EMPLOYEE table. The following CAST specification will convert the SALARY column to INTEGER.

```
SELECT EMPNO, CAST(SALARY AS INTEGER)
FROM EMPLOYEE
```

⁴⁶ For XSLTRANSFORM, if the CCSID of the *expression* is 65535, the default CCSID of the job is used.

⁴⁷ If the CCSID of the *expression* is 65535, casting to CLOB is not allowed.

- Assume that two distinct types exist. T_AGE was sourced on SMALLINT and is the data type for the AGE column in the PERSONNEL table. R_YEAR was sourced on INTEGER and is the data type for the RETIRE_YEAR column in the same table. The following UPDATE statement could be prepared.

```
UPDATE PERSONNEL SET RETIRE_YEAR = ?  
WHERE AGE = CAST( ? AS T_AGE )
```

The first parameter is an untyped parameter marker that would have a data type of R_YEAR. An explicit CAST specification is not required in this case because the parameter marker value is assigned to the distinct type.

The second parameter marker is a typed parameter marker that is cast to distinct type T_AGE. An explicit CAST specification is required in this case because the parameter marker value is compared to the distinct type.

OLAP specifications

On-Line Analytical Processing (OLAP) specifications provide the ability to return ranking, row numbering, and other aggregate function information as a scalar value in a query result.

OLAP-specification

ordered-OLAP-specification

lag-function

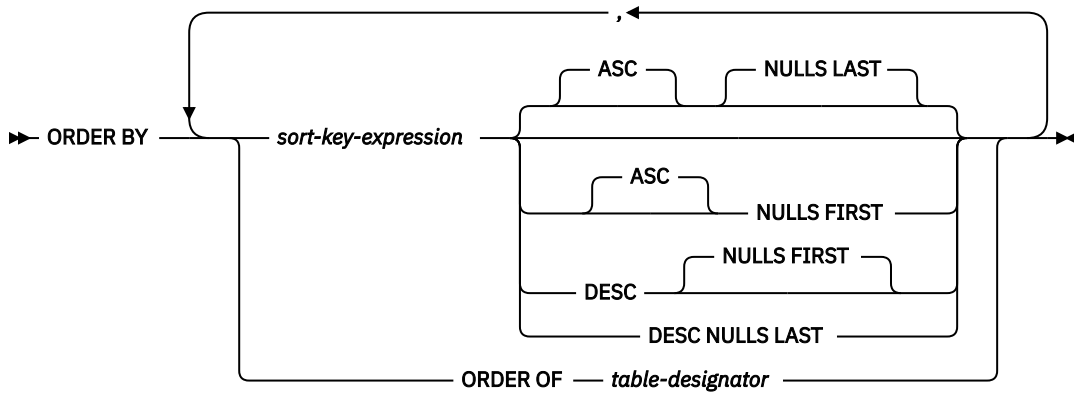

lead-function

window-partition-clause

window-order-clause

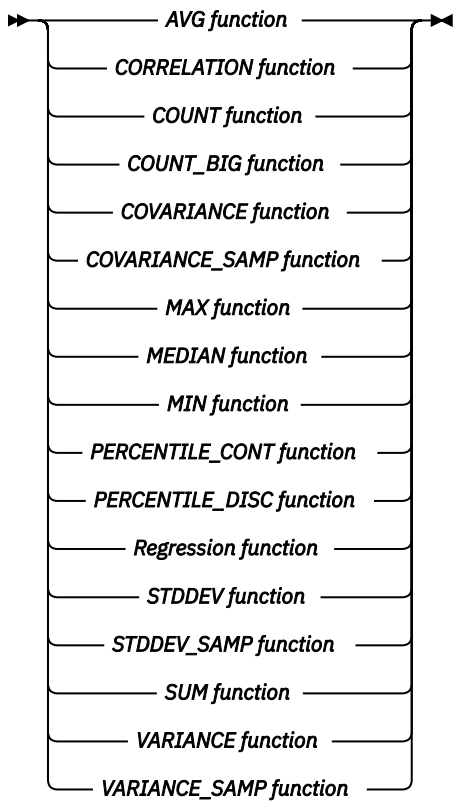

numbering-specification

aggregation-specification

aggregate-function

OLAP-aggregate-function

first-value-function

last-value-function

nth-value-function

ratio-to-report-function

window-aggregation-group-clause

group-start

group-between

group-bound1

group-bound2

group-end

An OLAP specification can be included in an expression in a *select-clause* or the ORDER BY clause of a *select-statement*. The query result to which the OLAP specification is applied is the result table of the innermost subselect that includes the OLAP specification. OLAP specifications are sometimes referred to as *window functions*.

An OLAP specification is not valid in a WHERE, VALUES, GROUP BY, HAVING, or SET clause, or *join-condition* in an ON clause of a joined table. An OLAP specification cannot be used as an argument of an aggregate function in the *select-clause*.

When invoking an OLAP specification, a window is specified that defines the rows over which the function is applied, and in what order.

ordered-OLAP-specification

Specifies OLAP operations that require a *window-order-clause*.

LAG or LEAD

Returns an *expression* value computed using rows prior to or following the current row.

offset must be a positive integer or positive bigint constant. If *offset* is not specified, the value 1 is used.

default-value must be an expression that is castable to the type of *expression*. If *default-value* is not specified, the default value is the null value.

If IGNORE NULLS is specified, all rows where the *expression* value is the null value are not considered in the calculation.

LAG

The LAG function returns the *expression* value for the row at *offset* rows before the current row. If a *window-partition-clause* is specified, *offset* means *offset* rows before the current row and within the current partition.

LEAD

The LEAD function returns the *expression* value for the row at *offset* rows after the current row. If a *window-partition-clause* is specified, *offset* means *offset* rows after the current row and within the current partition.

If *offset* goes beyond the scope of the current partition, the *default-value* is returned.

The data type of the result is the data type of *expression*. The result can be null. If IGNORE NULLS is specified and all values in the window are null, the result is the null value.

RANK or DENSE_RANK

Specifies that the ordinal rank of a row within the window is computed. Rows that are not distinct with respect to the ordering within their window are assigned the same rank. The results of ranking may be defined with or without gaps in the numbers resulting from duplicate values.

The data type of the result is BIGINT. The result cannot be null.

RANK

Specifies that the rank of a row is defined as 1 plus the number of rows that strictly precede the row. Thus, if two or more rows are not distinct with respect to the ordering, then there will be one or more gaps in the sequential rank numbering.

DENSE_RANK

Specifies that the rank of a row is defined as 1 plus the number of preceding rows that are distinct with respect to the ordering. Therefore, there will be no gaps in the sequential rank numbering.

NTILE

Specifies that the quantile rank of a row within the window is computed.

The argument must be castable to a BIGINT. If *expression* does not return a SMALLINT, INTEGER, or BIGINT, it is cast to BIGINT before evaluating the function. It must have a value greater than zero. *expression* must not contain a *scalar-fullselect*, a column reference, or a user-defined function reference.

The result is the quantile rank of the current row. The argument determines the number of quantiles in the result, which is determined by dividing the number of rows in the window by the value of the argument. If the number of rows within the window is not evenly divisible by the argument, each quantile will have a least n rows, and quantiles 1 through m will each have $n+1$ rows.

- r is the number of rows in the window
- q is the value of the argument
- $m = \text{MOD}(r, q)$
- $n = \text{TRUNC}(r, q)$

The data type of the result is SMALLINT, INTEGER, or BIGINT based on the value of the argument. If the argument can be null, the result can be null. If the argument is null, the result is the null value.

CUME_DIST

A cumulative distribution function that determines a percentile ranking for each row, expressed as a decimal fraction ranging from 0 to 1. Given the default ascending order of rows, CUME_DIST computes the number of rows that are ranked lower than or equal to the current row, including the current row, divided by the total number of rows in the partition. If the *window_order_clause* specifies descending order, CUME_DIST computes the number of rows that are ranked higher than or equal to the current row divided by the total number of rows in the partition.

For example, given default ordering, if there are ten rows in the partition and the current row ranks lower than six of those rows, the CUME_DIST result is 0.7 (six rows plus the current row = 7/10). The lowest-ranking row in a partition has a CUME_DIST value of 1.0, assuming default ascending order. If there is a single row in the partition, its CUME_DIST value is also 1.0.

The data type of the result is DECFLOAT(34). The result cannot be null.

PERCENT_RANK

The PERCENT_RANK function is a distribution function that returns a relative percentile rank of a row within an OLAP window, expressed as a value between 0.0 - 1.0. When the number of rows in the OLAP window is greater than 1, the result is computed as follows:

- The RANK of the current row in the OLAP window minus 1 divided by the number of rows in the OLAP window minus 1.

Otherwise, the result is 0.0.

The data type of the result is DECFLOAT(34). The result cannot be null.

numbering-specification

Specifies an OLAP operation that returns sequential numbers for each row.

ROW_NUMBER

Specifies that a sequential row number is computed for the row within the window defined by the ordering, starting with 1 for the first row. If the ORDER BY clause is not specified in the window, the row numbers are assigned to the rows in arbitrary order, as returned by the subselect (not according to any ORDER BY clause in the *select-statement*).

The data type of the result is BIGINT. The result cannot be null.

window-partition-clause

Defines the partition within which the OLAP operation is applied.

PARTITION BY (*partitioning-expression*,...)

Defines the partition within which the OLAP operation is applied. A *partitioning-expression* is an expression used in defining the partitioning of the result set. Each column name referenced in a *partitioning-expression* must unambiguously reference a column of the result table of the subselect that contains the OLAP specification. A *partitioning-expression* cannot include a *scalar-fullselect* or any function that is not deterministic or has an external action.

window-order-clause

Defines the ordering of rows within a partition that is used to determine the value of the OLAP specification. It does not define the ordering of the result table.

ORDER BY (*sort-key-expression*,...)

A *sort-key-expression* is an expression used in defining the ordering of the rows within a window partition. Each column name referenced in a *sort-key-expression* must unambiguously reference a column of the result table of the subselect, including the OLAP specification. A *sort-key-expression* cannot include a *scalar-fullselect* or any function that is not deterministic or that has an external action.

The sum of the length attributes of the *sort-key-expressions* must not exceed 3.5 gigabytes.

ASC

Specifies that the values of the *sort-key-expression* are used in ascending order.

DESC

Specifies that the values of the *sort-key-expression* are used in descending order.

NULLS FIRST

Specifies that the window ordering considers null values before all non-null values in the sort order.

NULLS LAST

Specifies that the window ordering considers null values after all non-null values in the sort order.

ORDER OF *table-designator*

Specifies that the same ordering used in *table-designator* should be applied to the result table of the subselect. There must be a table reference matching *table-designator* in the FROM clause of the subselect that specifies this clause and the table reference must identify a *nested-table-expression* or *common-table-expression*. The subselect (or fullselect) corresponding to the specified *table-designator* must include an ORDER BY clause that is dependent on the data. The ordering that is applied is the same as if the columns of the ORDER BY clause in the nested subselect (or fullselect) were included in the outer subselect (or fullselect), and these columns were specified in place of the ORDER OF clause.

OLAP-aggregate-function

Specifies a function that will compute a single value from the OLAP window.

FIRST_VALUE or LAST_VALUE

Returns the first or last value in an OLAP window.

If IGNORE NULLS is specified, all rows where the *expression* value is the null value are not considered in the calculation.

FIRST_VALUE

The result is the *expression* value for the first row in an OLAP window.

LAST_VALUE

The result is the *expression* value for the last row in an OLAP window.

The data type of the result is the data type of *expression*. The result can be null. If IGNORE NULLS is specified and all values in the window are null, the result is the null value.

NTH_VALUE

Returns the *expression* value for the *n*th row in an OLAP window.

n-expression must be an integer constant or variable with a value greater than zero.

If IGNORE NULLS is specified, all rows where the *expression* value is the null value are not considered in the calculation.

If FROM FIRST is specified, the *n*th value is computed counting forward from the beginning of the OLAP window.

If FROM LAST is specified, the *n*th value is computed counting backward from the end of the OLAP window.

The result is the *n*th value within the OLAP window as determined by *n-expression*.

The data type of the result is the data type of *expression*. The result can be null. If *n-expression* is null, then the result is the null value. If IGNORE NULLS is specified and all values in the window are null, the result is the null value.

FIRST_VALUE(*expression*) is equivalent to NTH_VALUE(*expression*, 1) FROM FIRST.

LAST_VALUE(*expression*) is equivalent to NTH_VALUE(*expression*, 1) FROM LAST.

RATIO_TO_REPORT

Returns the ratio of an argument to the sum of the arguments in an OLAP window. For example, the following functions are equivalent:

```
RATIO_TO_REPORT(expression) OVER (...)
CAST(expression AS DECFLOAT(34)) /
SUM(CAST(expression as DECFLOAT(34))) OVER(...)
```

The argument must be an expression that is castable to DECFLOAT(34). The division is performed using DECFLOAT(34).

The data type of the result is DECFLOAT(34). If the argument can be null, the result can be null; if the argument is null, the result is the null value.

window-aggregation-group-clause

The aggregation group of a given row is a set of rows that is defined in relation to the given row (in the ordering of the rows in the partition of the given row). *window-aggregation-group-clause* specifies the aggregation group. If this clause is not specified and a *window-order-clause* is also not specified, the aggregation group consists of all rows of the window partition. The aggregation group of all rows of the window partition can be explicitly specified using the RANGE or ROWS clauses.

If *window-order-clause* is specified but *window-aggregation-group-clause* is not specified, the window aggregation group consists of all rows that precede a given row of the partition of the given row or all rows that are peers of the given row in the window ordering of the window partition that is defined by the *window-order-clause*

ROW

Specifies that the aggregation group is defined by counting rows.

RANGE

Specifies that the aggregation group is defined by an offset from a sort key.

group-start

Specifies the starting point for the aggregation group. The aggregation group end is the CURRENT ROW. Specifying *group-start* is equivalent to specifying *group-between* as BETWEEN *group-start* AND CURRENT ROW.

group-between

Specifies that the aggregation group start and end based on either ROWS or RANGE.

group-end

Specifies the ending point for the aggregation group. The aggregation group start is the CURRENT ROW. Specifying *group-end* is equivalent to specifying *group-between* as BETWEEN CURRENT ROW AND *group-end*.

UNBOUNDED PRECEDING

Specifies that the entire partition that precedes the current row is included in the aggregation group. This can be specified with either the ROWS or RANGE clauses. Including the entire partition that precedes the current row can also be specified with multiple *sort-key-expressions* in the *window-order-clause*.

UNBOUNDED FOLLOWING

Specifies that the entire partition that follows the current row is included in the aggregation group. This can be specified with either the ROWS or RANGE clauses. Including the entire partition that follows the current row can also be specified with multiple *sort-key-expressions* in the *window-order-clause*.

CURRENT ROW

Specifies that the aggregation group starts or ends based on the current row. If ROWS is specified, the current row is the aggregation group boundary. If RANGE is specified, the aggregation group boundary includes the set of rows with the values specified for the *sort-key-expression* as the current row. This clause cannot be specified in *group-bound-2* if *group-bound-1* specifies *unsigned-constant* FOLLOWING.

***unsigned-constant* PRECEDING**

Specifies either the range or the number of rows that precede the current row. If ROWS is specified, *unsigned-constant* must be zero or a positive integer or positive bigint that indicates a number of rows. If RANGE is specified, the data type of *unsigned-constant* must be comparable to the data type of the *sort-key-expression* of the *window-order-clause*. Only one *sort-key-expression* is allowed, and the data type of *sort-key-expression* must allow subtraction. This clause cannot be specified in *group-bound-2* if *group-bound-1* is CURRENT ROW or *unsigned-constant* FOLLOWING.

***unsigned-constant* FOLLOWING**

Specifies either the range or the number of rows that follow the current row. If ROWS is specified, *unsigned-constant* must be zero or a positive integer or positive bigint that indicates a number of rows. If RANGE is specified, the data type of *unsigned-constant* must be comparable to the data type of the *sort-key-expression* of the *window-order-clause*. Only one *sort-key-expression* is allowed, and the data type of *sort-key-expression* must allow addition.

Notes

Comparisons: Partitioning and ordering are performed in accordance with the comparison rules described in “[Assignments and comparisons](#)” on page 89.

Collating sequence: If a collating sequence other than *HEX is in effect when the statement that contains the OLAP expression is executed, and the *partitioning-expressions* or the *sort-key-expressions* are SBCS data, mixed data, or Unicode data, then the results are determined using the weighted values. The weighted values are derived by applying the collating sequence to the *partitioning-expressions* and the *sort-key-expressions*.

Column masks: If a column that is referenced in the *partitioning-expression* or the *sort-key-expression* of the OLAP specification is defined to have a column mask, the column mask is not applied.

Restrictions: An OLAP specification is not allowed if the query specifies:

- a distributed table,
- a table with a read trigger, or
- a logical file built over multiple physical file members.

Determinism: An OLAP specification is non-deterministic.

Syntax alternatives:

- DENSERANK can be specified in place of DENSE_RANK.
- ROWNUMBER can be specified in place of ROW_NUMBER.
- IGNORE NULLS or RESPECT NULLS can be specified as a *string-constant* final argument to LAG, LEAD, FIRST_VALUE, and LAST_VALUE.

Examples

- Display the ranking of employees, in order by surname, according to their total salary (based on salary plus bonus) that have a total salary more than \$30,000:

```
SELECT EMPNO, LASTNAME, FIRSTNAME, SALARY+BONUS AS TOTAL_SALARY,  
       RANK() OVER (ORDER BY SALARY+BONUS DESC) AS RANK_SALARY  
FROM EMPLOYEE  
WHERE SALARY+BONUS > 30000  
ORDER BY LASTNAME
```

Note that if the result is to be ordered by the ranking, then replace ORDER BY LASTNAME with:

```
ORDER BY RANK_SALARY
```

or:

```
ORDER BY RANK() OVER (ORDER BY SALARY+BONUS DESC)
```

- Rank the departments according to their average total salary:

```
SELECT WORKDEPT, AVG(SALARY+BONUS) AS AVG_TOTAL_SALARY,  
       RANK() OVER (ORDER BY AVG(SALARY+BONUS) DESC) AS RANK_AVG_SAL  
FROM EMPLOYEE  
GROUP BY WORKDEPT  
ORDER BY RANK_AVG_SAL
```

- Rank the employees within a department according to their education level. Having multiple employees with the same rank in the department should not increase the next ranking value:

```
SELECT WORKDEPT, EMPNO, LASTNAME, FIRSTNAME, EDLEVEL,  
       DENSE_RANK() OVER (PARTITION BY WORKDEPT ORDER BY EDLEVEL DESC)  
       AS RANK_EDLEVEL  
FROM EMPLOYEE  
ORDER BY WORKDEPT, LASTNAME
```

- Provide row numbers in the result of a query:

```

SELECT ROW_NUMBER() OVER (ORDER BY WORKDEPT, LASTNAME ) AS NUMBER,
       LASTNAME, SALARY
FROM EMPLOYEE
ORDER BY WORKDEPT, LASTNAME

```

- List the top five wage earners:

```

SELECT EMPNO, LASTNAME, FIRSTNME, TOTAL_SALARY, RANK_SALARY
FROM (SELECT EMPNO, LASTNAME, FIRSTNME, SALARY+BONUS AS TOTAL_SALARY,
            RANK() OVER (ORDER BY SALARY+BONUS DESC) AS RANK_SALARY
      FROM EMPLOYEE) AS RANKED_EMPLOYEE
WHERE RANK_SALARY < 6
ORDER BY RANK_SALARY

```

Note that a nested table expression was used to first compute the result, including the rankings, before the rank could be used in the WHERE clause. A common table expression could also have been used.

- Compute the top 3 stock prices for stock ABC using NTH_VALUE:

```

SELECT Symbol, StockDate, Price,
       FIRST_VALUE(Price) OVER (PARTITION BY Symbol ORDER BY StockDate) AS FIRST_PRICE,
       NTH_VALUE(Price, 2) OVER (PARTITION BY Symbol ORDER BY StockDate) AS SECOND_PRICE,
       NTH_VALUE(Price, 3) OVER (PARTITION BY Symbol ORDER BY StockDate) AS THIRD_PRICE
FROM DailyStockData
WHERE StockDate BETWEEN CURRENT DATE - 1 MONTH AND CURRENT DATE
      AND Symbol = 'ABC'

```

- Compute the quartile rank using NTILE:

```

SELECT proc_id, total_sales,
       NTILE(4) OVER (ORDER BY total_sales DESC) AS Quartile
FROM Sales

```

- Calculate the 30 day moving average for the stocks 'ABC' and 'XYZ' during 2005:

```

WITH V1(SYMBOL, TRADINGDATE, MOVINGAVG30DAY) AS
(
  SELECT SYMBOL, TRADINGDATE,
         AVG(CLOSINGPRICE) OVER (PARTITION BY SYMBOL
                                ORDER BY TRADINGDATE
                                ROWS BETWEEN 29 PRECEDING AND CURRENT ROW)
  FROM DAILYSTOCKDATA
  WHERE SYMBOL IN ('ABC', 'XYZ')
        AND TRADINGDATE BETWEEN DATE('2005-01-01') - 2 MONTHS AND '2005-12-31'
)
SELECT SYMBOL, TRADINGDATE, MOVINGAVG30DAY
FROM V1
WHERE TRADINGDATE BETWEEN '2005-01-01' AND '2005-12-31'
ORDER BY SYMBOL, TRADINGDATE

```

- Display the difference between each employee's salary and the median of the salaries of that employee's department:

```

SELECT EMPNO, WORKDEPT, SALARY,
       SALARY - (MEDIAN(SALARY) OVER (PARTITION BY WORKDEPT))
FROM EMPLOYEE
ORDER BY WORKDEPT

```

- Display the difference between each employee's salary and the 90th percentile of salaries within that employee's department:

```

SELECT EMPNO, WORKDEPT, SALARY,
       SALARY - (PERCENTILE_CONT(0.9) WITHIN GROUP (ORDER BY SALARY)
                OVER (PARTITION BY WORKDEPT))
FROM EMPLOYEE
ORDER BY WORKDEPT

```

- Find the cumulative distribution and the relative percentile rank of each employee's salary within their department.

```

SELECT EMPNO, WORKDEPT, SALARY,
       CAST(CUME_DIST() OVER (PARTITION BY WORKDEPT ORDER BY SALARY) AS DECIMAL(4,3))
       AS CUME_DIST,

```

```
CAST(PERCENT_RANK() OVER (PARTITION BY WORKDEPT ORDER BY SALARY)
     AS DECIMAL(4,3))
AS PERCENT_RANK
FROM EMP
ORDER BY WORKDEPT, SALARY
```

Sequence reference

A sequence is referenced by using the NEXT VALUE and PREVIOUS VALUE expressions specifying the name of the sequence.

sequence-reference

nextval-expression

➤ NEXT VALUE — FOR — *sequence-name* ➤

prevval-expression

➤ PREVIOUS VALUE — FOR — *sequence-name* ➤

A sequence is referenced by using the NEXT VALUE and PREVIOUS VALUE expressions specifying the name of the sequence.

nextval-expression

A NEXT VALUE expression generates and returns the next value for a specified sequence. A new value is generated for a sequence when a NEXT VALUE expression specifies the name of the sequence. However, if there are multiple instances of a NEXT VALUE expression specifying the same sequence name within a query, the sequence value is incremented only once for each row of the result, and all instances of NEXT VALUE return the same value for a row of the result. NEXT VALUE is a non-deterministic expression with external actions since it causes the sequence value to be incremented.

When the next value for the sequence is generated, if the maximum value for an ascending sequence or the minimum value for a descending sequence of the logical range of the sequence is exceeded and the NO CYCLE option is in effect, then an error is returned.

The data type and length attributes of the result of a NEXT VALUE expression are the same as for the specified sequence. The result cannot be null.

prevval-expression

A PREVIOUS VALUE expression returns the most recently generated value for the specified sequence for a previous statement within the current application process. This value can be repeatedly referenced by using PREVIOUS VALUE expressions and specifying the name of the sequence. There may be multiple instances of PREVIOUS VALUE expressions specifying the same sequence name within a single statement and they all return the same value.

A PREVIOUS VALUE expression can be used only if a NEXT VALUE expression specifying the same sequence name has already been referenced in the current application process.

The data type and length attributes of the result of a PREVIOUS VALUE expression are the same as for the specified sequence. The result cannot be null.

sequence-name

Identifies the sequence to be referenced. The *sequence-name* must identify a sequence that exists at the current server.

Notes

Authorization: If a sequence is referenced in a statement, the privileges held by the authorization ID of the statement must include at least one of the following:

- For the sequence identified in the statement,
 - The USAGE privilege on the sequence, and
 - The system authority *EXECUTE on the library containing the sequence
- Database administrator authority

For information about the system authorities corresponding to SQL privileges, see [Corresponding System Authorities When Checking Privileges to a Sequence](#).

Generating values with NEXT VALUE: When a value is generated for a sequence, that value is consumed, and the next time that a value is requested, a new value will be generated. This is true even when the statement containing the NEXT VALUE expression fails or is rolled back.

Scope of PREVIOUS VALUE: The PREVIOUS VALUE value persists until the next value is generated for the sequence in the current session, the sequence is dropped or altered, or the application session ends. The value is unaffected by COMMIT or ROLLBACK statements. The value of PREVIOUS VALUE cannot be directly set and is a result of executing the NEXT VALUE expression for the sequence.

A technique commonly used, especially for performance, is for an application or product to manage a set of connections and route transactions to an arbitrary connection. In these situations, the availability of the PREVIOUS VALUE for a sequence should only be relied on until the end of the transaction.

Use as a Unique Key Value: The same sequence number can be used as a unique key value in two separate tables by referencing the sequence number with a NEXT VALUE expression for the first row (this generates the sequence value), and a PREVIOUS VALUE expression for the other rows (the instance of PREVIOUS VALUE refers to the sequence value most recently generated in the current session), as shown below:

```
INSERT INTO ORDER (ORDERNO, CUSTNO)
VALUES (NEXT VALUE FOR ORDER_SEQ, 123456)

INSERT INTO LINE_ITEM (ORDERNO, PARTNO, QUANTITY)
VALUES (PREVIOUS VALUE FOR ORDER_SEQ, 987654, 1)
```

Allowed use of NEXT VALUE and PREVIOUS VALUE: NEXT VALUE and PREVIOUS VALUE expressions can be specified in the following places:

- Within the *select-clause* of a SELECT statement or SELECT INTO statement as long as the statement does not contain a DISTINCT keyword, a GROUP BY clause, an ORDER BY clause, a UNION keyword, an INTERSECT keyword, or EXCEPT keyword
- Within a VALUES clause of a *fullselect* (NEXT VALUE is not allowed)
- Within a VALUES clause of an INSERT statement
- Within the *select-clause* of the fullselect of an INSERT statement
- Within the SET clause of a searched or positioned UPDATE statement, though NEXT VALUE cannot be specified in the *select-clause* of the subselect of an expression in the SET clause

A PREVIOUS VALUE expression can be specified anywhere within a SET clause of an UPDATE statement, but a NEXT VALUE expression can be specified only in a SET clause if it is not within the *select-clause* of the fullselect of an expression. For example, the following uses of sequence expressions are supported:

```
UPDATE T SET C1 = (SELECT PREVIOUS VALUE FOR S1 FROM T)
UPDATE T SET C1 = PREVIOUS VALUE FOR S1
UPDATE T SET C1 = NEXT VALUE FOR S1
```

The following use of a sequence expression is not supported:

```
UPDATE T SET C1 = (SELECT NEXT VALUE FOR S1 FROM T)
```

- Within an *assignment-statement*, except within the *select-clause* of the fullselect of an expression. The following uses of sequence expressions are supported:

```
SET :ORDERNUM = NEXT VALUE FOR INVOICE
SET :ORDERNUM = PREVIOUS VALUE FOR INVOICE
```

The following use of a sequence expression is not supported:

```
SET :X = (SELECT NEXT VALUE FOR S1 FROM T)
```

```
SET :X = (SELECT PREVIOUS VALUE FOR S1 FROM T)
```

- Within a VALUES or VALUES INTO statement though not within the *select-clause* of the fullselect of an expression
- Within the *SQL-routine-body* of a CREATE PROCEDURE statement
- Within the *SQL-trigger-body* of a CREATE TRIGGER statement (PREVIOUS VALUE is not allowed)
- Within the argument list of a CALL statement.
- Within a default expression for CREATE PROCEDURE or CREATE FUNCTION. A function with a default containing NEXT VALUE or PREVIOUS VALUE can only be used in location where the NEXT VALUE or PREVIOUS VALUE can be specified directly.

Restrictions on the use of NEXT VALUE and PREVIOUS VALUE: NEXT VALUE and PREVIOUS VALUE expressions cannot be specified in the following places:

- Within a materialized query table definition in a CREATE TABLE or ALTER TABLE statement
- Within a CHECK constraint
- Within a view definition
- Within a CREATE INDEX statement
- Within the *SQL-routine-body* of a CREATE FUNCTION statement

In addition, the NEXT VALUE expression cannot be specified in the following places:

- CASE expression
- Parameter list of an aggregate function
- Subquery in a context other than those explicitly allowed
- SELECT statement for which the outer SELECT contains a DISTINCT operator or a GROUP BY clause
- SELECT statement for which the outer SELECT is combined with another SELECT statement using the UNION, INTERSECT, or EXCEPT operator
- SELECT statement that contains an OFFSET clause.
- Join condition of a join
- Nested table expression
- Parameter list of a table function
- *select-clause* of the fullselect of an expression in the SET clause of an UPDATE statement
- WHERE clause of the outermost SELECT statement or a DELETE, or UPDATE statement
- ORDER BY clause of the outermost SELECT statement
- IF, WHILE, DO . . . UNTIL, or CASE statements in an SQL routine

Using sequence expressions with a cursor: Normally, a SELECT NEXT VALUE FOR ORDER_SEQ FROM T1 would produce a result table containing as many generated values from the sequence ORDER_SEQ as the number of rows retrieved from T1. A reference to a NEXT VALUE expression in the SELECT statement of a cursor refers to a value that is generated for a row of the result table. A sequence value is generated for a NEXT VALUE expression each time a row is retrieved.

If blocking is done at a client in a DRDA environment, sequence values may get generated at the Db2 server before the processing of an application's FETCH statement. If the client application does not explicitly FETCH all the rows that have been retrieved from the database, the application will never see all those generated values of the sequence (as many as the rows that were not FETCHed). These values may constitute a gap in the sequence.

A reference to the PREVIOUS VALUE expression in a SELECT statement of a cursor is evaluated at OPEN time. In other words, a reference to the PREVIOUS VALUE expression in the SELECT statement of a cursor refers to the last value generated by this application process for the specified sequence prior to the opening of the cursor. Once evaluated at OPEN time, the value returned by PREVIOUS VALUE within

the body of the cursor will not change from FETCH to FETCH, even if NEXT VALUE is invoked within the body of the cursor. After the cursor is closed, the value of PREVIOUS VALUE will be the last NEXT VALUE generated by the application process.

Syntax alternatives: The keywords NEXTVAL and PREVVAL can be used as alternatives for NEXT VALUE and PREVIOUS VALUE respectively.

Examples

- Assume that there is a table called ORDER, and that a sequence called ORDER_SEQ is created as follows:

```
CREATE SEQUENCE ORDER_SEQ
  START WITH 1
  INCREMENT BY 1
  NO MAXVALUE
  NO CYCLE
  CACHE 24
```

Following are some examples of how to generate an ORDER_SEQ sequence number with a NEXT VALUE expression:

```
INSERT INTO ORDER (ORDERNO, CUSTNO)
  VALUES (NEXT VALUE FOR ORDER_SEQ, 123456)

UPDATE ORDER
  SET ORDERNO = NEXT VALUE FOR ORDER_SEQ
  WHERE CUSTNO = 123456

VALUES NEXT VALUE FOR ORDER
  INTO :HV_SEQ
```

XMLCAST specification

The XMLCAST specification returns the cast operand (the first operand) cast to the XML *data-type*.

data-type

built-in-type

ccsid-clause

normalize-clause

expression

Specifies that the cast operand is an expression other than NULL or a parameter marker. It must have a data type of XML. The result is the argument value converted to the specified XML target data type and CCSID.

NULL

Specifies that the cast operand is the null value. The result is a null value that has the XML data type.

parameter-marker

A parameter marker (specified as a question mark character) is normally considered an expression, but is documented separately in this case because it has a special meaning. If the cast operand is a *parameter-marker*, the XML data type is considered a promise that the replacement will be assignable to the XML data type. Such a parameter marker is called a *typed parameter marker*. Typed parameter markers will be treated like any other typed value for the purpose of DESCRIBE of a select list or for column assignment.

data-type

Specifies the data type of the result. The data type must be XML or a distinct type based on XML.

If the CCSID attribute is not specified, then the CCSID value as specified by the `SQL_XML_DATA_CCSID QAQQINI` setting is used. See “XML Values” on page 80 for more information.

If the CCSID attribute is specified, the data will be converted to that CCSID. If `NORMALIZED` is specified, the data will be normalized.

Example

- Create a null XML value:

```
VALUES(XMLCAST(NULL AS XML))
```

Predicates

A *predicate* specifies a condition that is true, false, or unknown about a given value, row, or group.

The following rules apply to all types of predicates:

- Predicates are evaluated after the expressions that are operands of the predicate.
- All values specified in the same predicate must be compatible.
- The value of a variable may be null (that is, the variable may have a negative indicator variable).
- The CCSID conversion of operands of predicates involving two or more operands are done according to “Conversion rules for comparison:” on page 101.
- Use of a DataLink value is limited to the NULL predicate.

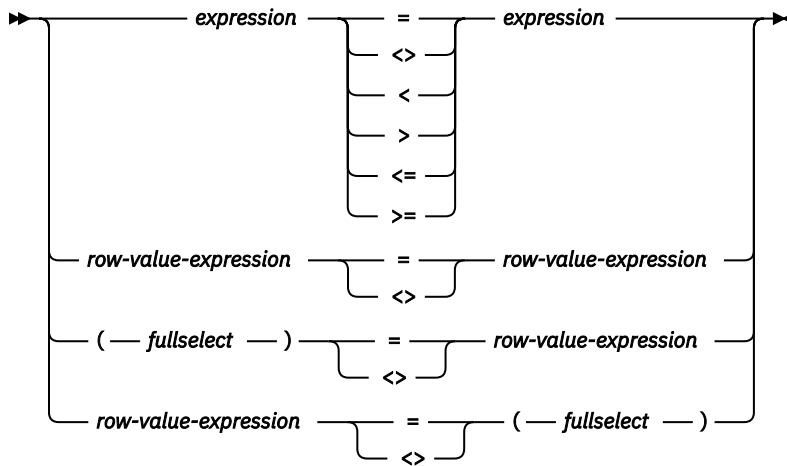

Row-value expression: The operand of several predicates (basic, quantified, and IN) can be a *row-value-expression*:

A *row-value-expression* returns a single row that consists of one or more column values. The values can be specified as a list of expressions. The number of columns that are returned by the *row-value-expression* is equal to the number of expressions that are specified in the list.

Basic predicate

A *basic predicate* compares two values or compares a set of values with another set of values.

Note:

Other comparison operators are also supported.⁴⁸

Notes

When a single *expression* is specified on the left side of the operator, another *expression* must be specified on the right side. The data types of the corresponding expressions must be compatible. The value of the expression on the left side is compared with the value of the expression on the right side. If the value of either operand is null, the result of the predicate is unknown. Otherwise the result is either true or false.

When a *row-value-expression* is specified on the left side of the operator (= or <>) and another *row-value-expression* is specified on the right side of the operator, both *row-value-expressions* must have the same number of value expressions. The data types of the corresponding expressions of the *row-value-expressions* must be compatible. The value of each expression on the left side is compared with the value of its corresponding expression on the right side.

When a *row-value-expression* is specified and a *fullselect* is also specified:

- SELECT * is not allowed in the outermost select lists of the *fullselect*.
- The result table of the *fullselect* must have the same number of columns as the *row-value-expression*. The data types of the corresponding expressions of the *row-value-expression* and the *fullselect* must be compatible. The value of each expression on the left side is compared with the value of its corresponding expression on the right side.

The result of the predicate depends on the operator:

⁴⁸ The following forms of the comparison operators are also supported in basic and quantified predicates: ! =, !<, !>, ¬=, ¬<, and ¬> are supported. All these product-specific forms of the comparison operators are intended only to support existing SQL statements that use these operators and are not recommended for use when writing new SQL statements.

Some keyboards must use the hex values for the not (¬) symbol. The hex value varies and is dependent on the keyboard that is used. A not sign (¬) or the character that must be used in its place in certain countries or regions, can cause parsing errors in statements passed from one database server to another. The problem occurs if the statement undergoes character conversion with certain combinations of source and target CCSIDs. To avoid this problem, substitute an equivalent operator for any operator that includes a not sign. For example, substitute '<>' for '¬=', '<=' for '¬>', and '>=' for '¬<'.

- If the operator is =, the result of the predicate is:
 - True if all pairs of corresponding value expressions evaluate to true.
 - False if any one pair of corresponding value expressions evaluates to false.
 - Otherwise, unknown (that is, if at least one comparison of corresponding value expressions is unknown because of a null value and no pair of corresponding value expressions evaluates to false).
- If the operator is <>, the result of the predicate is:
 - True if any one pair of corresponding value expressions evaluates to false.
 - False if all pairs of corresponding value expressions evaluate to true.
 - Otherwise, unknown (that is, if at least one comparison of corresponding value expressions is unknown because of a null value and no pair of corresponding value expressions evaluates to true).

If the corresponding operands of the predicate are SBCS data, mixed data, or Unicode data, and if the collating sequence in effect at the time the statement is executed is not *HEX, then the comparison of the operands is performed using weighted values for the operands. The weighted values are based on the collating sequence.

For values *x* and *y*:

Predicate	Is true if and only if...
$x = y$	<i>x</i> is equal to <i>y</i>
$x <> y$	<i>x</i> is not equal to <i>y</i>
$x < y$	<i>x</i> is less than <i>y</i>
$x > y$	<i>x</i> is greater than <i>y</i>
$x >= y$	<i>x</i> is greater than or equal to <i>y</i>
$x <= y$	<i>x</i> is less than or equal to <i>y</i>

Examples

Example 1: Four examples of comparison predicates.

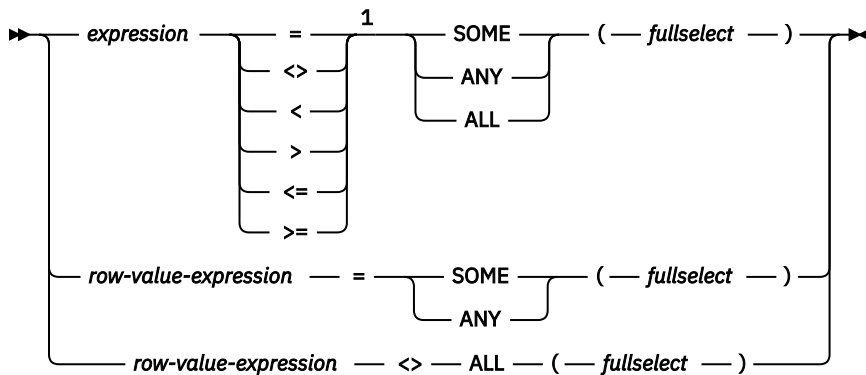

```
EMPNO = '528671'
PRTSTAFF <> :VAR1
SALARY + BONUS + COMM < 20000
SALARY > (SELECT AVG(SALARY)
          FROM EMPLOYEE)
```

Example 2: List the name, first name, and salary of the employee who is responsible for the 'OP1000' project.

```
SELECT LASTNAME, FIRSTNAME, SALARY
FROM EMPLOYEE X
WHERE EMPNO = (SELECT RESPEMP
               FROM PROJA1 Y
               WHERE MAJPROJ = 'OP1000' )
```

Quantified predicate

A *quantified predicate* compares a value or values with a set of values.

Notes:

¹ Other comparison operators are also supported. ⁴⁸

When *expression* is specified, the *fullselect* must return a single result column. The *fullselect* can return any number of values, whether null or not null. The result depends on the operator that is specified:

- When ALL is specified, the result of the predicate is:
 - True if the result of the *fullselect* is empty, or if the specified relationship is true for every value returned by the *fullselect*.
 - False if the specified relationship is false for at least one value returned by the *fullselect*.
 - Unknown if the specified relationship is not false for any values returned by the *fullselect* and at least one comparison is unknown because of a null value.
- When SOME or ANY is specified, the result of the predicate is:
 - True if the specified relationship is true for at least one value returned by the *fullselect*.
 - False if the result of the *fullselect* is empty, or if the specified relationship is false for every value returned by the *fullselect*.
 - Unknown if the specified relationship is not true for any of the values returned by the *fullselect* and at least one comparison is unknown because of a null value.

When *row-value-expression* is specified, the number of result columns returned by the *fullselect* must be the same as the number of value expressions specified by *row-value-expression*. The *fullselect* can return any number of rows of values. The data types of the corresponding expressions of the row value expressions must be compatible. The value of each expression from *row-value-expression* is compared with the value of the corresponding result column from the *fullselect*. `SELECT *` is not allowed in the outermost select lists of the *fullselect*. The value of the predicate depends on the operator that is specified:

- When ALL is specified, the result of the predicate is:
 - True if the result of the *fullselect* is empty or if the specified relationship is true for every row returned by *fullselect*.
 - False if the specified relationship is false for at least one row returned by the *fullselect*.
 - Unknown if the specified relationship is not false for any row returned by the *fullselect* and at least one comparison is unknown because of a null value.
- When SOME or ANY is specified, the result of the predicate is:
 - True if the specified relationship is true for at least one row returned by the *fullselect*.
 - False if the result of the *fullselect* is empty or if the specified relationship is false for every row returned by the *fullselect*.

- Unknown if the specified relationship is not true for any of the rows returned by the fullselect and at least one comparison is unknown because of a null value.

If the corresponding operands of the predicate are SBCS data, mixed data, or Unicode data, and if the collating sequence in effect at the time the statement is executed is not *HEX, then the comparison of the operands is performed using weighted values for the operands. The weighted values are based on the collating sequence.

Examples

Table **TBLA**

```
COLA
-----
 1
 2
 3
 4
null
```

Table **TBLB**

```
COLB
-----
 2
 3
```

Example 1

```
SELECT * FROM TBLA WHERE COLA = ANY(SELECT COLB FROM TBLB)
```

Results in 2,3. The fullselect returns (2,3). COLA in rows 2 and 3 equals at least one of these values.

Example 2

```
SELECT * FROM TBLA WHERE COLA > ANY(SELECT COLB FROM TBLB)
```

Results in 3,4. The fullselect returns (2,3). COLA in rows 3 and 4 is greater than at least one of these values.

Example 3

```
SELECT * FROM TBLA WHERE COLA > ALL(SELECT COLB FROM TBLB)
```

Results in 4. The fullselect returns (2,3). COLA in row 4 is the only one that is greater than both these values.

Example 4

```
SELECT * FROM TBLA WHERE COLA > ALL(SELECT COLB FROM TBLB WHERE COLB<0)
```

Results in 1,2,3,4 and null. The fullselect returns no values. Thus, the result of the predicate is true for all rows in TBLA.

Example 5

```
SELECT * FROM TBLA WHERE COLA > ANY(SELECT COLB FROM TBLB WHERE COLB<0)
```

Results in an empty result table. The fullselect returns no values. Thus, the result of the predicate is false for all rows in TBLA.

BETWEEN predicate

The BETWEEN predicate compares a value with a range of values.

► *expression* — **BETWEEN** — *expression* — **AND** — *expression* ◄

NOT

If the data types of the operands are not the same, all values are converted to the data type that would result by applying the “[Rules for result data types](#)” on page 105.

If the operands of the BETWEEN predicate are strings with different CCSIDs, operands are converted as if the below logically-equivalent search conditions were specified.

The BETWEEN predicate:

```
value1 BETWEEN value2 AND value3
```

is logically equivalent to the search condition:

```
value1 >= value2 AND value1 <= value3
```

The BETWEEN predicate:

```
value1 NOT BETWEEN value2 AND value3
```

is logically equivalent to the search condition:

```
NOT(value1 BETWEEN value2 AND value3)
```

If the operands of the predicate are SBCS data, mixed data, or Unicode data, and if the collating sequence in effect at the time the statement is executed is not *HEX, then the comparison of the operands is performed using weighted values for the operands. The weighted values are based on the collating sequence.

Examples

```
EMPLOYEE.SALARY BETWEEN 20000 AND 40000  
SALARY NOT BETWEEN 20000 + :HV1 AND 40000
```

DISTINCT predicate

The DISTINCT predicate compares a value with another value.

►► *expression* — IS —  — DISTINCT FROM — *expression* ◄◄

When the predicate is IS DISTINCT, the result of the predicate is true if the comparison of the expressions evaluates to true. Otherwise, the result of the predicate is false. The result cannot be unknown.

When the predicate IS NOT DISTINCT FROM, the result of the predicate is true if the comparison of the expressions evaluates to true (null values are considered equal to null values). Otherwise, the result of the predicate is false. The result cannot be unknown.

The DISTINCT predicate:

```
value1 IS NOT DISTINCT FROM value2
```

is logically equivalent to the search condition:

```
( value1 IS NOT NULL AND value2 IS NOT NULL AND value1 = value2 )  
OR  
( value1 IS NULL AND value2 IS NULL )
```

The DISTINCT predicate:

```
value1 IS DISTINCT FROM value2
```

is logically equivalent to the search condition:

```
NOT (value1 IS NOT DISTINCT FROM value2)
```

If the operands of the DISTINCT predicate are strings with different CCSIDs, operands are converted as if the above logically-equivalent search conditions were specified.

If the operands of the predicate are SBCS data, mixed data, or Unicode data, and if the collating sequence in effect at the time the statement is executed is not *HEX, then the comparison of the operands is performed using weighted values for the operands. The weighted values are based on the collating sequence.

Example

Assume that table T1 exists and it has a single column C1, and three rows with the following values for C1: 1, 2, null. The following query produces the following results:

```
SELECT * FROM T1  
WHERE C1 IS DISTINCT FROM :HV:IND
```

C1	:HV:IND	Result
1	2	True
2	2	False
1	Null	True
Null	Null	False

The following query produces the following results:

```
SELECT * FROM T1  
WHERE C1 IS NOT DISTINCT FROM :HV:IND
```

C1	:HV:IND	Result
1	2	False
2	2	True
1	Null	False
Null	Null	True

EXISTS predicate

The EXISTS predicate tests for the existence of certain rows.

► EXISTS — (*fullselect*) ◄

The fullselect may specify any number of columns, and

- The result is true only if the number of rows specified by the fullselect is not zero.
- The result is false only if the number of rows specified by the fullselect is zero.
- The result cannot be unknown.

The values returned by the fullselect are ignored.

Example

```
EXISTS (SELECT *  
        FROM EMPLOYEE WHERE SALARY > 60000)
```

IN predicate

The IN predicate compares a value or values with a set of values.

When *expression1* is specified, the IN predicate compares a value with a set of values. When *fullselect1* is specified, the fullselect must return a single result column, and can return any number of values, whether null or not null. The data type of *expression1* and the data type of the result column of the *fullselect1*, *expression2*, or *expression3* must be compatible. Each variable must identify a structure or variable that is described in accordance with the rule for declaring host structures or variables.

When a *row-value-expression* is specified, the IN predicate compares values with a collection of values.

- SELECT * is not allowed in the outermost select list of *fullselect2*.
- The result table of the *fullselect2* must have the same number of columns as *row-value-expression*. The data types of the corresponding expressions of *row-value-expression* and of its the corresponding result column of *fullselect2* must be compatible. The value of each expression in *row-value-expression* is compared with the value of its corresponding result column of *fullselect2*.

The value of the predicate depends on the operator that is specified:

- When the operator is IN, the result of the predicate is:
 - True if at least one row returned from the *fullselect2* is equal to the *row-value-expression*.
 - False if the result of *fullselect2* is empty or if no row returned from the *fullselect2* is equal to the *row-value-expression*.
 - Otherwise, unknown (that is, if the comparison of *row-value-expression* to the row returned from *fullselect2* evaluates to unknown because of a null value for at least one row returned from *fullselect2* and no row returned from *fullselect2* is equal to the *row-value-expression*).
- When the operator is NOT IN, the result of the predicate is:
 - True if the result of *fullselect2* is empty or if the *row-value-expression* is not equal to any of the rows returned by *fullselect2*.
 - False if the *row-value-expression* is equal to at least one row returned by *fullselect2*.
 - Otherwise, unknown (that is, if the comparison of *row-value-expression* to the row returned from *fullselect2* evaluates to unknown because of a null value for at least one row returned from *fullselect2* and the comparison of *row-value-expression* to the row returned from *fullselect2* is not true for any row returned by *fullselect2*).

An IN predicate is equivalent to other predicates as follows:

IN predicate	Equivalent predicate
expression IN (expression)	expression = expression
expression IN (fullselect)	expression = ANY (fullselect)
expression NOT IN (fullselect)	expression <> ALL (fullselect)

IN predicate

expression **IN** (expression1, expression2, ..., expressionn)

Equivalent predicate

expression **IN (SELECT * FROM R)**

Where T is a table with a single row and R is a temporary table formed by the following fullselect:

```
SELECT expression1 FROM T
UNION
SELECT expression2 FROM T
UNION
.
.
UNION
SELECT expressionn FROM T
```

row-value-expression **IN** (fullselect)

row-value-expression = **SOME** (fullselect)

row-value-expression **IN** (fullselect)

row-value-expression = **ANY** (fullselect)

row-value-expression **NOT IN** (fullselect)

row-value-expression **<> ALL** (fullselect)

If the operands of the IN predicate have different data types or attributes, the rules used to determine the data type for evaluation of the IN predicate are those for UNION, UNION ALL, EXCEPT, and INTERSECT. For a description, see [“Rules for result data types”](#) on page 105.

If the operands of the IN predicate are strings with different CCSIDs, the rules used to determine which operands are converted are those for operations that combine strings. For a description, see [“Conversion rules for operations that combine strings”](#) on page 110.

If the corresponding operands of the predicate are SBCS data, mixed data, or Unicode data, and if the collating sequence in effect at the time the statement is executed is not *HEX, then the comparison of the operands is performed using weighted values for the operands. The weighted values are based on the collating sequence.

Examples

```
DEPTNO IN ('D01', 'B01', 'C01')
```

```
EMPNO IN(SELECT EMPNO FROM EMPLOYEE WHERE WORKDEPT = 'E11')
```

IS JSON predicate

The IS JSON predicate determines whether a value is in a JSON format with the specified attributes.

The result of the IS JSON predicate is true if the *JSON-expression* conforms to the JSON format specified by the item type and the UNIQUE KEYS clause. The result is false if the *JSON-expression* does not conform to the JSON format specified by the item type and the UNIQUE KEYS clause or if *JSON-expression* is the empty string. If NOT is specified, the result is reversed. If the value of *JSON-expression* is null, the result is unknown.

JSON-expression

An expression that returns a value that is a built-in string data type.

FORMAT JSON or FORMAT BSON

Specifies how *JSON-expression* is to be interpreted.

FORMAT JSON

JSON-expression contains JSON data. If *JSON-expression* is binary data, the data is interpreted as UTF-8 or UTF-16. Binary data cannot be encoded using an EBCDIC CCSID.

FORMAT BSON

JSON-expression contains the BSON representation of JSON data. When FORMAT BSON is specified, *JSON-expression* must be a binary string data type.

If the FORMAT clause is not specified and *JSON-expression* is a character or graphic string, *JSON-expression* is treated as JSON. If the FORMAT clause is not specified and *JSON-expression* is a binary string, *JSON-expression* is treated as BSON.

VALUE, ARRAY, OBJECT, or SCALAR

Specifies the type of JSON item to compare with the contents of *JSON-expression*.

VALUE

A valid JSON value of any of the types ARRAY, OBJECT, or SCALAR.

ARRAY

A valid JSON array which is a list of values separated by commas and enclosed in square brackets.

OBJECT

A valid JSON object which is a list of *key:value* pairs separated by commas and enclosed between a left brace and right brace.

SCALAR

A valid JSON value that is not a JSON array or a JSON object. A scalar value can be a character string, a number, or one of the JSON literals: null, true, or false.

WITHOUT UNIQUE KEYS or WITH UNIQUE KEYS

Specifies whether *JSON-expression* is considered to be valid JSON when keys are not unique. This clause is ignored if the JSON item is not a JSON object.

WITHOUT UNIQUE KEYS

A JSON object with keys that are not unique is valid JSON.

WITH UNIQUE KEYS

A JSON object with keys that are not unique is not valid JSON.

Example

- Create a trigger to ensure only a valid JSON object can be inserted into a JSON_DATA column.

```
CREATE TRIGGER VALIDATE_JSON BEFORE INSERT ON T
REFERENCING NEW AS N
FOR EACH ROW
IF N.JSON_DATA IS NOT JSON OBJECT THEN
  SIGNAL SQLSTATE '75007' SET MESSAGE_TEXT = 'Input is not valid JSON';
END IF
```

JSON_EXISTS predicate

The JSON_EXISTS predicate determines whether JSON data contains a JSON value that can be located using the specified *sql-json-path-expression*.

The result of the JSON_EXISTS predicate is true if at least one value can be located in *JSON-expression* using the *sql-json-path-expression*. If *sql-json-path-expression* uses strict mode and an error occurs, the result of the predicate is determined by the ON ERROR clause. The result of the JSON_EXISTS predicate is unknown if *JSON-expression* is the null value.

JSON-expression

An expression that returns a built-in string data type. If it is a character or graphic data type, it must contain correctly formatted JSON data. If it is a binary data type, it is interpreted according to the explicit or implicit FORMAT clause.

FORMAT JSON or FORMAT BSON

Specifies how *JSON-expression* is to be interpreted.

FORMAT JSON

JSON-expression contains JSON data. If *JSON-expression* is binary data, the data is interpreted as UTF-8 or UTF-16. Binary data cannot be encoded using an EBCDIC CCSID.

FORMAT BSON

JSON-expression contains the BSON representation of JSON data. When FORMAT BSON is specified, *JSON-expression* must be a binary string data type.

If the FORMAT clause is not specified and *JSON-expression* is a character or graphic string, *JSON-expression* is treated as JSON. If *JSON-expression* is a binary string, *JSON-expression* is treated as BSON.

sql-json-path-expression

An expression that returns a value that is a built-in character or graphic string data type. The string is interpreted as an SQL/JSON path expression and is used to locate a JSON value within the JSON data specified by *JSON-expression*. For information on the content of an SQL/JSON path expression, see “[sql-json-path-expression](#)” on page 213.

If the value of *sql-json-path-expression* is the empty string, a string of all blanks, or the null value, no value can be located so the result of the predicate is false.

AS path-name

Specifies a name to be used to identify the *sql-json-path-expression*.

FALSE ON ERROR, TRUE ON ERROR, UNKNOWN ON ERROR, or ERROR ON ERROR

Specifies the result of the predicate when an error is encountered.

FALSE ON ERROR

The result is false if an error is encountered. This is the default.

TRUE ON ERROR

The result is true if an error is encountered.

UNKNOWN ON ERROR

The result is unknown if an error is encountered.

ERROR ON ERROR

An error is returned if an error is encountered.

Example

- Return rows for employees who do not have an emergency contact in their JSON_DATA column. COALESCE causes null values to be treated as an empty string. The FALSE ON ERROR clause is used so all rows that do not contain an emergency value will be returned.

```
SELECT empno, lastname FROM employee  
WHERE NOT JSON_EXISTS(COALESCE(json_data, ''), 'strict $.emergency' FALSE ON ERROR);
```

sql-json-path-expression

An SQL/JSON path expression defines access to the elements of a JSON text.

sql-json-accessor-expression

array-specifier

index-value

lax or strict

Specifies the JSON path mode.

lax

Specifies that certain structural errors are tolerated when navigating the current JSON text. These include:

- automatic unnesting of arrays
- automatic wrapping of scalar values to be a one element array if referenced as an array
- specification of nonexistent items, including array index values that are out of range

If an item does not exist, the SQL/JSON path expression returns an empty string which is handled according to the current ON EMPTY clause.

strict

Specifies that an error is reported when the specified path expression cannot be used to navigate the current JSON text. The error is handled according to the current ON ERROR clause.

sql-json-accessor-expression

\$

Specifies the start of the context item to which the rest of the SQL/JSON path expression is applied.

json-path-key-name

Specifies the key name of a *key,value* pair in the JSON text. If the name contains any special characters, it must be delimited with " characters.

*

Specifies that the values for all the keys will be returned as an SQL/JSON sequence.

array-specifier

Specifies a list of one or more array index values to apply to an array. The values can be specified as individual numbers or as ranges. They can be specified in any order and may contain duplicates, but the result will be returned in document order without duplicates. If a range of index values is specified and the from and to values are out of order, in `lax` mode all index values in the range are used; in `strict` mode it is an error.

index-value

Specifies an array index value.

number

An unsigned integer constant representing an array element. The first element of the array has an index of 0.

last

Indicates the last element of the array. This value cannot be specified as the first value in an index range.

last - number

Indicates a position relative to the last element of the array.

Indicates all array elements are to be selected.

Example

- Consider the following text:

```
{ "isbn": "123-456-222", "author": [ { "name": "Jones"}, {"name", "Smith"}]}
```

Here are the results of using various SQL/JSON path expressions to access items in the JSON text.

Path	Value
\$.isbn	"123-456-222"
\$.author[0].name	"Jones"
\$.author[1].name	"Smith"

LIKE predicate

The LIKE predicate searches for strings that have a certain pattern. The pattern is specified by a string in which the underscore and percent sign have special meanings. Trailing blanks in a pattern are a part of the pattern.

If the value of any of the arguments is null, the result of the LIKE predicate is unknown.

The *match-expression*, *pattern-expression*, and *escape-expression* must identify strings or numbers. A numeric argument is cast to a character string before evaluating the predicate. For more information about converting numeric to a character string, see “VARCHAR” on page 623. The values for *match-expression*, *pattern-expression*, and *escape-expression* must either all be binary strings or none can be binary strings. The three arguments can include a mixture of character strings and graphic strings.

None of the expressions can yield a distinct type. However, it can be a function that casts a distinct type to its source type.

If the operands of the predicate are SBCS data, mixed data, or Unicode data, and if the collating sequence in effect at the time the statement is executed is not *HEX, then the comparison of the operands is performed using weighted values for the operands. The weighted values are based on the collating sequence. An ICU collating sequence is not allowed with a LIKE predicate.

With character strings, the terms *character*, *percent sign*, and *underscore* in the following discussion refer to single-byte characters. With graphic strings, the terms refer to double-byte or Unicode characters. With binary strings, the terms refer to the code points of those single-byte characters.

match-expression

An expression that specifies the string that is to be examined to see if it conforms to a certain pattern of characters.

LIKE pattern-expression

An expression that specifies the string that is to be matched.

Simple description: A simple description of the LIKE pattern is as follows:

- The underscore sign (`_`) represents any single character.
- The percent sign (`%`) represents a string of zero or more characters.
- Any other character represents itself.

If the *pattern-expression* needs to include either the underscore or the percent character, the *escape-expression* is used to specify a character to precede either the underscore or percent character in the pattern.

Rigorous description: Let *x* denote a value of *match-expression* and *y* denote the value of *pattern-expression*.

The string *y* is interpreted as a sequence of the minimum number of substring specifiers so each character of *y* is part of exactly one substring specifier. A substring specifier is an underscore, a percent sign, or any nonempty sequence of characters other than an underscore or a percent sign.

The result of the predicate is unknown if *x* or *y* is the null value. Otherwise, the result is either true or false. The result is true if *x* and *y* are both empty strings or if there exists a partitioning of *x* into substrings such that:

- A substring of *x* is a sequence of zero or more contiguous characters and each character of *x* is part of exactly one substring.

- If the *n*th substring specifier is an underscore, the *n*th substring of *x* is any single character.
- If the *n*th substring specifier is a percent sign, the *n*th substring of *x* is any sequence of zero or more characters.
- If the *n*th substring specifier is neither an underscore nor a percent sign, the *n*th substring of *x* is equal to that substring specifier and has the same length as that substring specifier.
- The number of substrings of *x* is the same as the number of substring specifiers.

It follows that if *y* is an empty string and *x* is not an empty string, the result is false. Similarly, it follows that if *x* is an empty string and *y* is not an empty string consisting of other than percent signs, the result is false.

The predicate `x NOT LIKE y` is equivalent to the search condition `NOT(x LIKE y)`.

If necessary, the CCSID of the *match-expression*, *pattern-expression*, and *escape-expression* are converted to the compatible CCSID between the *match-expression* and *pattern-expression*.

Mixed data: If the column is mixed data, the pattern can include both SBCS and DBCS characters. The special characters in the pattern are interpreted as follows:

- An SBCS underscore refers to one SBCS character.
- A DBCS underscore refers to one DBCS character.
- A percent sign (either SBCS or DBCS) refers to any number of characters of any type, either SBCS or DBCS.
- Redundant shifts in *match-expression* and *pattern-expression* are ignored.⁴⁹

Unicode data: For Unicode, the special characters in the pattern are interpreted as follows:

- An SBCS or DBCS underscore refers to one character (a character can be one or more bytes)
- A percent sign (either SBCS or DBCS) refers to a string of zero or more characters (a character can be one or more bytes).

When the LIKE predicate is used with Unicode data, the Unicode percent sign and underscore use the code points indicated in the following table:

Character	UTF-8	UTF-16 or UCS-2
Half-width %	X'25'	X'0025'
Full-width %	X'EFBC85'	X'FF05'
Half-width _	X'5F'	X'005F'
Full-width _	X'EFBCBF'	X'FF3F'

The full-width or half-width % matches zero or more characters. The full-width or half width _ character matches exactly one character. (For EBCDIC data, a full-width _ character matches one DBCS character.)

Binary data: If the column is binary data, the pattern contains bytes. The special bytes in the pattern are interpreted as follows:

- The code point for an SBCS underscore (X'6D') refers to one byte.
- The code point for an SBCS percent (X'6C') refers to any number of bytes.

Parameter marker:

⁴⁹ Redundant shifts are normally ignored. To guarantee that they are ignored, however, specify the IGNORE_LIKE_REDUNDANT_SHIFTS query attribute. See [Database Performance and Query Optimization](#) for information about setting query attributes.

When the pattern specified in a LIKE predicate is a parameter marker, and a fixed-length character variable is used to replace the parameter marker; specify a value for the variable that is the correct length. If a correct length is not specified, the select will not return the intended results.

For example, if the variable is defined as CHAR(10), and the value WYSE% is assigned to that variable, the variable is padded with blanks on assignment. The pattern used is

```
'WYSE%      '
```

This pattern requests the database manager to search for all values that start with WYSE and end with five blank spaces. If you intended to search for only the values that start with 'WYSE' you should assign the value 'WYSE%%%%%%%%%' to the variable.

ESCAPE *escape-expression*

An expression that specifies a character to be used to modify the special meaning of the underscore (`_`) and percent (`%`) characters in the pattern-expression. This allows the LIKE predicate to be used to match values that contain the actual percent and underscore characters. The following rules apply the use of the ESCAPE clause and the *escape-expression*:

- The *escape-expression* must be a string of length 1.⁵⁰
- The *pattern-expression* must not contain the escape character except when followed by the escape character, percent, or underscore.

For example, if '+' is the escape character, any occurrences of '+' other than '++', '+_', or '+%' in the *pattern-expression* is an error.

- The *escape-expression* can be a parameter marker.

The following example shows the effect of successive occurrences of the escape character, which in this case is the plus sign (+).

When the pattern string is...	The actual pattern is...
+%	A percent sign
++%	A plus sign followed by zero or more arbitrary characters
+++%	A plus sign followed by a percent sign

Examples

Example 1

Search for the string 'SYSTEMS' appearing anywhere within the PROJNAME column in the PROJECT table.

```
SELECT PROJNAME
FROM PROJECT
WHERE PROJECT.PROJNAME LIKE '%SYSTEMS%'
```

Example 2

Search for a string with a first character of 'J' that is exactly two characters long in the FIRSTNME column of the EMPLOYEE table.

```
SELECT FIRSTNME
FROM EMPLOYEE
WHERE EMPLOYEE.FIRSTNME LIKE 'J_'
```

Example 3

⁵⁰ If it is NUL-terminated, a C character string variable of length 2 can be specified.

In this example:

```
SELECT *
FROM TABLEY
WHERE C1 LIKE 'AAAA+%BBB%' ESCAPE '+'
```

'+' is the escape character and indicates that the search is for a string that starts with 'AAAA%BBB'. The '+%' is interpreted as a single occurrence of '%' in the pattern.

Example 4

In the following table of EBCDIC examples, assume COL1 is mixed data. The table shows the results when the predicates in the first column are evaluated using the COL1 values from the second column:

Predicates	COL1 Values	Result
WHERE COL1 LIKE 'aaa 0AB%CS1'	'aaa 0ABDZC S1'	True
WHERE COL1 LIKE 'aaa 0AB S1% 0CS1'	'aaa 0AB S1 dzx 0CS1'	True
WHERE COL1 LIKE 'a% 0CS1'	'a 0CS1'	True
	'ax 0CS1'	True
	'ab 0DE S1 fg 0CS1'	True
WHERE COL1 LIKE 'a_0CS1'	'a% 0CS1'	True
	'a 0XC S1'	False
WHERE COL1 LIKE 'a_0__CS1'	'a 0XC S1'	True
	'ax 0CS1'	False
WHERE COL1 LIKE ' 0S1'	Empty string	True
WHERE COL1 LIKE 'ab 0CS1_'	'ab 0CS1 d'	True
	'ab 0S1 0CS1 d'	True

RV3F001-0

Example 5

Assume that a distinct type named ZIP_TYPE with a source data type of CHAR(5) exists and an ADDRZIP column with data type ZIP_TYPE exists in some table TABLEY. The following statement selects the row if the zip code (ADDRZIP) begins with '9555'.

```
SELECT *
FROM TABLEY
WHERE CHAR(ADDRZIP) LIKE '9555%'
```

Example 6

The RESUME column in sample table EMP_RESUME is defined as a CLOB. If the variable LASTNAME has a value of 'JONES', the following statement selects the RESUME column when the string JONES appears anywhere in the column.

```
SELECT RESUME
FROM EMP_RESUME
WHERE RESUME LIKE '%||LASTNAME||%'
```

NULL predicate

The NULL predicate tests for null values.

► *expression* — IS — NOT — NULL ►

The result of a NULL predicate cannot be unknown. If the value of the expression is null, the result is true. If the value is not null, the result is false.

If NOT is specified, the result is reversed.

Syntax alternatives: For compatibility with other SQL dialects, you can use ISNULL as a synonym for IS NULL and NOTNULL as a synonym for IS NOT NULL.

Examples

```
EMPLOYEE.PHONE IS NULL
```

```
SALARY IS NOT NULL
```

REGEXP_LIKE predicate

The REGEXP_LIKE predicate searches for a regular expression pattern in a string.

If the *pattern-expression* is found, the result is true. If the *pattern-expression* is not found, the result is false. If *source-string* and *pattern-expression* are empty strings, the result is true. If *source-string* or *pattern-expression* is the empty string (but not both), the result is false. If the value of any of the arguments is null, the result is unknown.

source-string

An expression that specifies the string in which the search is to take place. The expression must return a value that is a built-in character string, graphic string, numeric, or datetime data type. If the value is not a UTF-16 DBCLOB, it is implicitly cast to a UTF-16 DBCLOB before searching for the regular expression pattern. A character string with the FOR BIT DATA attribute or a binary string is not supported. The length of a string must not be greater than 1 gigabyte.

pattern-expression

An expression that specifies the regular expression string that is the pattern for the search. The expression must return a value that is a built-in character string, graphic string, numeric, or datetime data type. If the value is not a UTF-16 DBCLOB, it is implicitly cast to a UTF-16 DBCLOB before searching for the regular expression pattern. A character string with the FOR BIT DATA attribute or a binary string is not supported. The length of the string must not be greater than 32K.

A valid *pattern-expression* consists of a set of characters and control characters that describe the pattern of the search. For a description of the valid control characters, see [“Regular expression control characters”](#) on page 221.

start

An expression that specifies the position within *source-string* at which the search is to start. The expression must return a value of any built-in numeric, character-string, or graphic-string data type. The argument is cast to INTEGER before searching for the regular expression pattern. For more information about converting to INTEGER, see [“INTEGER or INT”](#) on page 442. The value of the integer must be greater than or equal to 1. If the value of the integer is greater than the actual length of the *source-string*, the result of the predicate is false.

flags

An expression that specifies flags that control aspects of the pattern matching. The expression must return a value that is a built-in character string or graphic string data type. A character string with the FOR BIT DATA attribute or a binary string is not supported. The string can include one or more valid flag values and the combination of flag values must be valid. An empty string is the same as the value 'c'.

For a description of the valid flag characters, see [“Regular expression flag values”](#) on page 220.

Regular expression flag values

The following table describes the supported flag values.

Flag value	Description
c	Specifies that matching is case sensitive. This is the default value if neither 'c' nor 'i' is specified. This value must not be specified with a value of 'i'.

Table 31. Flag Values (continued)

Flag value	Description
i	Specifies that matching is case insensitive. This value must not be specified with a value of 'c'.
m	Specifies that the input data could contain more than one line. By default, the '^' and the '\$' in a pattern will only match the start and the end, respectively, of the input string. If this flag is set, "^" and "\$" will also match at the start and end of each line within the input string.
n	Specifies that the '\n' character in a pattern matches a line terminator in the input string. By default, the '\n' in a pattern will not match a line terminator. A carriage-return and line-feed pair in the input string behaves as a single line terminator, and will match a single "\n" in a pattern.
s	Specifies that the '\n' character in a pattern matches a line terminator in the input string. This is a synonym for the 'n' value.
x	Specifies that white space characters in a pattern are ignored, unless escaped.

Regular expression control characters

The regular expression processing is performed using the International Components for Unicode (ICU) regular expression API on Unicode data with regular expression patterns that use the control characters listed below.

Note that only halfwidth characters are recognized. Any fullwidth characters that correspond to the characters in these tables will not be recognized.

Table 32. Regular Expression Metacharacters

Character	Outside of sets	[Inside sets]	Description
\a	✓	✓	Match a BELL, \u0007
\A	✓		Match at the beginning of the input. Differs from ^ in that \A will not match after a new line within the input.
\b	✓		Match if the current position is a word boundary. Boundaries occur at the transitions between word (\w) and non-word (\W) characters, with combining marks ignored.
\B	✓		Match if the current position is not a word boundary.
\cX	✓	✓	Match a control-X character.
\d	✓	✓	Match any character with the Unicode General Category of Nd (Number, Decimal Digit.)
\D	✓	✓	Match any character that is not a decimal digit.
\e	✓	✓	Match an ESCAPE, \u001B.
\E	✓	✓	Terminates a \Q ... \E quoted sequence.
\f	✓	✓	Match a FORM FEED, \u000C.
\G	✓		Match if the current position is at the end of the previous match.
\n	✓	✓	Match a LINE FEED, \u000A.
\N{UNICODE CHARACTER NAME}	✓	✓	Match the named character.

Table 32. Regular Expression Metacharacters (continued)

Character	Outside of sets	[Inside sets]	Description
\p{UNICODE PROPERTY NAME}	✓	✓	Match any character with the specified Unicode Property.
\P{UNICODE PROPERTY NAME}	✓	✓	Match any character not having the specified Unicode Property.
\Q	✓	✓	Quotes all following characters until \E.
\r	✓	✓	Match a CARRIAGE RETURN, \u000D
\s	✓	✓	Match a white space character. White space is defined as [\t\n\f\r\p{Z}].
\S	✓	✓	Match a non-white space character.
\t	✓	✓	Match a HORIZONTAL TABULATION, \u0009.
\uhhhh	✓	✓	Match the character with the hex value hhhh.
\Uhhhhhhhh	✓	✓	Match the character with the hex value hhhhhhhh. Exactly eight hex digits must be provided, even though the largest Unicode code point is \U0010ffff.
\w	✓	✓	Match a word character. Word characters are [\p{Alphabetic}\p{Mark}\p{Decimal_Number}\p{Connector_Punctuation}\u200c\u200d].
\W	✓	✓	Match a non-word character.
\x{hhhh}	✓	✓	Match the character with hex value hhhh. From one to six hex digits may be supplied.
\xhh	✓	✓	Match the character with two digit hex value hh
\X	✓		Match a Grapheme Cluster
\Z	✓		Match if the current position is at the end of input, but before the final line terminator, if one exists.
\z	✓		Match if the current position is at the end of input.
\n	✓		Back Reference. Match whatever the nth capturing group matched. n must be a number > 1 and < total number of capture groups in the pattern.
\0ooo	✓	✓	Match an Octal character. 'ooo' is from one to three octal digits. 0377 is the largest allowed Octal character. The leading zero is required; it distinguishes Octal constants from back references.
[pattern]	✓	✓	Match any one character from the set.
.	✓		Match any character.
^	✓		Match at the beginning of a line.
\$	✓		Match at the end of a line.
\	✓		Quotes the following character. Characters that must be quoted to be treated as literals are * ? + [() { } ^ \$ \.

Table 32. Regular Expression Metacharacters (continued)

Character	Outside of sets	[Inside sets]	Description
\		✓	Quotes the following character. Characters that must be quoted to be treated as literals are [] \ Characters that may need to be quoted, depending on the context are - &

Table 33. Regular Expression Operators

Operator	Description
	Alternation. A B matches either A or B.
*	Match 0 or more times. Match as many times as possible.
+	Match 1 or more times. Match as many times as possible.
?	Match zero or one times. Prefer one
{n}	Match exactly n times
{n,}	Match at least n times. Match as many times as possible.
{n,m}	Match between n and m times. Match as many times as possible, but not more than m.
*?	Match 0 or more times. Match as few times as possible.
+?	Match 1 or more times. Match as few times as possible.
??	Match zero or one times. Prefer zero.
{n}?	Match exactly n times
{n,}?	Match at least n times, but no more than required for an overall pattern match
{n,m}?	Match between n and m times. Match as few times as possible, but not less than n.
*+	Match 0 or more times. Match as many times as possible when first encountered, do not retry with fewer even if overall match fails (Possessive Match)
++	Match 1 or more times. Possessive match
?+	Match zero or one times. Possessive match
{n}+	Match exactly n times
{n,}+	Match at least n times. Possessive Match.
{n,m}+	Match between n and m times. Possessive Match.
(...)	Capturing parentheses. Range of input that matched the parenthesized subexpression is available after the match.
(?: ...)	Non-capturing parentheses. Groups the included pattern, but does not provide capturing of matching text. Somewhat more efficient than capturing parentheses.
(?> ...)	Atomic-match parentheses. First match of the parenthesized subexpression is the only one tried; if it does not lead to an overall pattern match, back up the search for a match to a position before the "(?>"
(?# ...)	Free-format comment (?# comment).
(?= ...)	Look-ahead assertion. True if the parenthesized pattern matches at the current input position, but does not advance the input position.

Table 33. Regular Expression Operators (continued)

Operator	Description
(?! ...)	Negative look-ahead assertion. True if the parenthesized pattern does not match at the current input position. Does not advance the input position.
(?<= ...)	Look-behind assertion. True if the parenthesized pattern matches text preceding the current input position, with the last character of the match being the input character just before the current position. Does not alter the input position. The length of possible strings matched by the look-behind pattern must not be unbounded (no * or + operators.)
(?<! ...)	Negative Look-behind assertion. True if the parenthesized pattern does not match text preceding the current input position, with the last character of the match being the input character just before the current position. Does not alter the input position. The length of possible strings matched by the look-behind pattern must not be unbounded (no * or + operators.)
(?ismwx-ismwx: ...)	Flag settings. Evaluate the parenthesized expression with the specified flags enabled or disabled.
(?ismwx-ismwx)	Flag settings. Change the flag settings. Changes apply to the portion of the pattern following the setting. For example, (?i) changes to a case insensitive match.

Table 34. Set Expressions (Character Classes)

Example	Description
[abc]	Match any of the characters a, b or c
[^abc]	Negation - match any character except a, b or c
[A-M]	Range - match any character from A to M. The characters to include are determined by Unicode code point ordering.
[\u0000-\U0010ffff]	Range - match all characters.
[\p{Letter}] [\p{General_Category=Letter}] [\p{L}]	Characters with Unicode Category = Letter. All forms shown are equivalent.
[\P{Letter}]	Negated property. (Upper case \P) Match everything except Letters.
[\p{numeric_value=9}]	Match all numbers with a numeric value of 9. Any Unicode Property may be used in set expressions.
[\p{Letter}&&\p{script=cyrillic}]	Logical AND or intersection. Match the set of all Cyrillic letters.
[\p{Letter}-\p{script=latin}]	Subtraction. Match all non-Latin letters.
[[a-z][A-Z][0-9]] [[a-zA-Z0-9]]	Implicit Logical OR or Union of Sets. The examples match ASCII letters and digits. The two forms are equivalent.
[:script=Greek:]	Alternate POSIX-like syntax for properties. Equivalent to \p{script=Greek}

Notes

Prerequisites: In order to use the REGEXP_LIKE predicate, the International Components for Unicode (ICU) option must be installed

Processing: The regular expression processing is done using the International Components for Unicode (ICU) regular expression interface. For more information see, <http://userguide.icu-project.org/strings/regexp>.

If only three arguments are specified, the third argument may be a *start* or *flags* argument. If the third argument is a string, it is interpreted as a *flags* argument. Otherwise, it is interpreted as a *start* argument.

Examples

- *Example 1:* Select the employee number where the last name is spelled LUCCHESSEI, LUCHESSI, or LUCHESEI from the EMPLOYEE table without considering upper or lower case letters.

```
SELECT EMPNO FROM EMPLOYEE
WHERE REGEXP_LIKE(LASTNAME, 'luc+?hes+?i', 'i')
```

The result is 1 row with EMPNO value '000110'.

- *Example 2:* Select any invalid product identifier values from the PRODUCT table. The expected format is 'nnn-*nnn*-nn' where 'n' is a digit from 0 to 9.

```
SELECT PID FROM PRODUCT
WHERE NOT REGEXP_LIKE(pid, '[0-9]{3}-[0-9]{3}-[0-9]{2}')
```

The result is 0 rows because all the product identifiers match the pattern.

Trigger event predicates

A trigger event predicate is used in a triggered action to test the event that activated the trigger. It is only allowed in the triggered action of a CREATE TRIGGER statement.

DELETING

True if the trigger was activated by a delete operation. False otherwise.

INSERTING

True if the trigger was activated by an insert operation. False otherwise.

UPDATING

True if the trigger was activated by an update operation. False otherwise.

Notes

A trigger event predicate can be used anywhere in the triggered action of a CREATE TRIGGER statement.

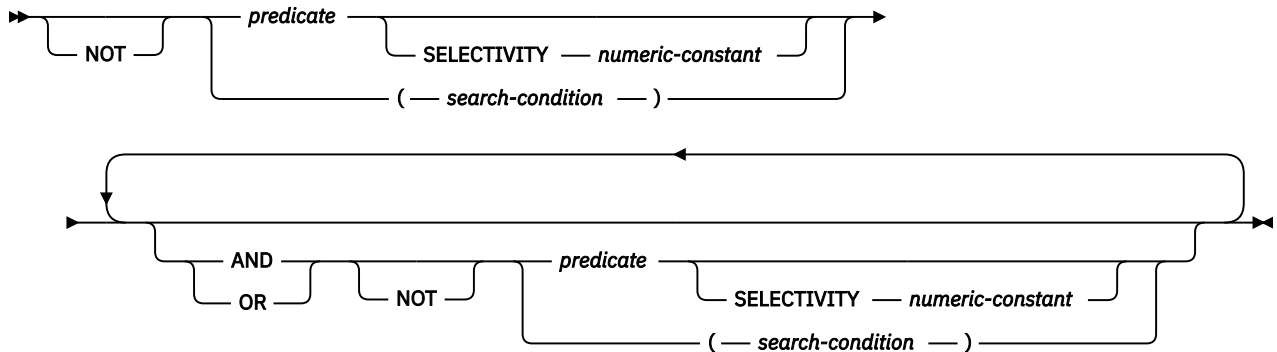

Example

The following trigger, by using trigger event predicates in the routine body, increments the number of employees each time a new person is hired (that is, each time a new row is inserted into the EMPLOYEE table), decrements the number of employees each time an employee leaves the company, and raises an error when an update occurs that would result in a salary increase greater than ten percent of the current salary.

```
CREATE TRIGGER HIRED
AFTER INSERT OR DELETE OR UPDATE OF SALARY ON EMPLOYEE
REFERENCING NEW AS N OLD AS O FOR EACH ROW
BEGIN
  IF INSERTING
    THEN UPDATE COMPANY_STATS SET NBREMP = NBREMP + 1;
  END IF;
  IF DELETING
    THEN UPDATE COMPANY_STATS SET NBREMP = NBREMP - 1;
  END IF;
  IF UPDATING AND (N.SALARY > 1.1 * O.SALARY)
    THEN SIGNAL SQLSTATE '75000' SET MESSAGE_TEXT = 'Salary increase > 10%'
  END IF;
END
```

Search conditions

A *search condition* specifies a condition that is true, false, or unknown about a given row or group.

Description

SELECTIVITY numeric-constant

Specifies the expected selectivity percentage for the predicate. The selectivity value must be a numeric constant in the range from 0 to 1 (inclusive). For example, if you specify 0.01, the predicate is expected to filter out all but one percent of all the rows in the table. An error is returned if the **SELECTIVITY** clause is specified for a trigger event predicate, or if it is used with a *search-condition* that is part of a check constraint or in a **CREATE INDEX** statement.

Some predicates are rewritten during query processing. Since a **SELECTIVITY** clause cannot be properly applied to the rewritten predicates, the following predicates will usually ignore a user-supplied selectivity value:

- **DISTINCT** and **NOT DISTINCT**
- **NOT BETWEEN**
- **EXISTS**
- **IN** with a list of values
- *row-value-expression* compared to *row-value-expression*

The result of a search condition is derived by application of the specified *logical operators* (**AND**, **OR**, **NOT**) to the result of each specified predicate. If logical operators are not specified, the result of the search condition is the result of the specified predicate.

AND and **OR** are defined in the following table in which **P** and **Q** are any predicates:

Table 35. Truth Tables for **AND** and **OR**

P	Q	P AND Q	P OR Q
True	True	True	True
True	False	False	True
True	Unknown	Unknown	True
False	True	False	True
False	False	False	False
False	Unknown	False	Unknown
Unknown	True	Unknown	True
Unknown	False	False	Unknown

Table 35. Truth Tables for AND and OR (continued)

P	Q	P AND Q	P OR Q
Unknown	Unknown	Unknown	Unknown

NOT(true) is false, NOT(false) is true, and NOT(unknown) is unknown.

Search conditions within parentheses are evaluated first. If the order of evaluation is not specified by parentheses, NOT is applied before AND, and AND is applied before OR. The order in which operators at the same precedence level are evaluated is undefined to allow for optimization of search conditions.

Examples

In the examples, the numbers on the second line indicate the order in which the operators are evaluated.

Example 1

Example 2

Chapter 3. Built-in global variables

This chapter contains semantic descriptions, rules, and examples of the use of the built-in global variables.

Built-in global variables are provided with the database manager and are used in SQL statements to retrieve scalar values associated with the variables.

As an example, the ROUTINE_TYPE global variable can be referenced in an SQL statement to retrieve the current routine type.

The authorization ID of any statement that retrieves the value of the global variable is required to have the READ privilege on the global variable and the system authority *EXECUTE on the library containing the global variable.

Example

To access the global variable CLIENT_HOST, run the following query:

```
SELECT SYSIBM.CLIENT_HOST  
FROM SYSIBM.SYSDUMMY1
```

The query returns the host name of the current client.

```
hote11nx93
```

CLIENT_HOST

This global variable contains the host name of the current client, as returned by the system.

This global variable has the following characteristics:

- It is read-only, with values maintained by system.
- The type is VARCHAR(255).
- The schema is SYSIBM.
- The scope of this global variable is session.

If the client connection originated from an application running on the local system, the value of the global variable is NULL. The server obtains the client IP address from the network when the connection is accepted. If the process did not originate from a remote system using TCP/IP, the value of the global variable is NULL.

CLIENT_IPADDR

This global variable contains the IP address of the current client, as returned by the system.

This global variable has the following characteristics:

- It is read-only, with values maintained by system.
- The type is VARCHAR(128).
- The schema is SYSIBM.
- The scope of this global variable is session.

CLIENT_PORT

This global variable contains the port number used by the current client to communicate with the server.

This global variable has the following characteristics:

- It is read-only, with values maintained by system.
- The type is INTEGER.
- The schema is SYSIBM.
- The scope of this global variable is session.

If the client did not connect by using the TCP/IP protocol, the value of the global variable is NULL.

JOB_NAME

This global variable contains the name of the current job.

This global variable has the following characteristics:

- It is read-only, with values maintained by system.
- The type is VARCHAR(28).
- The schema is QSYS2.
- The scope of this global variable is session.

PACKAGE_NAME

This global variable contains the name of the package currently being used for a DRDA connection.

This global variable has the following characteristics:

- It is read-only, with values maintained by system.
- The type is VARCHAR(128).
- The schema is SYSIBM.
- The scope of this global variable is session.

If there is no package currently executing, the value is NULL.

PACKAGE_SCHEMA

This global variable contains the schema name of the package currently being used for a DRDA connection.

This global variable has the following characteristics:

- It is read-only, with values maintained by system.
- The type is VARCHAR(128).
- The schema is SYSIBM.
- The scope of this global variable is session.

If there is no package currently executing, the value is NULL.

PACKAGE_VERSION

This global variable contains the version identifier of the package currently being used for a DRDA connection.

This global variable has the following characteristics:

- It is read-only, with values maintained by system.
- The type is VARCHAR(64).
- The schema is SYSIBM.
- The scope of this global variable is session.

If there is no package currently executing or the current executing package does not have a version identifier, the value is NULL. A package will have a version identifier only when it is created from a server other than Db2 for i.

PROCESS_ID

This global variable contains the process ID of the current job.

This global variable has the following characteristics:

- It is read-only, with values maintained by system.
- The type is INTEGER.
- The schema is QSYS2.
- The scope of this global variable is session.

Example

Review the details for this job.

```
SELECT USER, CURRENT SERVER, QSYS2.JOB_NAME, QSYS2.PROCESS_ID, QSYS2.THREAD_ID  
FROM SYSIBM.SYSDUMMY1
```

ROUTINE_SCHEMA

This global variable contains the schema name of the currently executing routine.

This global variable has the following characteristics:

- It is read-only, with values maintained by system.
- The type is VARCHAR(128).
- The schema is SYSIBM.
- The scope of this global variable is session.

If there is no routine currently executing, the value is NULL.

The value of ROUTINE_SCHEMA global variable is set only for procedures and functions. The value always reflects the schema name of the currently executing routine.

The value is not changed for functions that are inlined. The value remains the same as it was when the inline function was invoked.

ROUTINE_SPECIFIC_NAME

This global variable contains the name of the currently executing routine.

This global variable has the following characteristics:

- It is read-only, with values maintained by system.
- The type is VARCHAR(128).
- The schema is SYSIBM.
- The scope of this global variable is session.

If there is no routine currently executing, the value is NULL.

The value of ROUTINE_SPECIFIC_NAME global variable is set only for procedures and functions. The value always reflects the name of the currently executing routine.

The value is not changed for functions that are inlined. The value remains the same as it was when the inline function was invoked.

ROUTINE_TYPE

This global variable contains the type of the currently executing routine.

This global variable has the following characteristics:

- It is read-only, with values maintained by system.
- The type is CHAR(1).
- The schema is SYSIBM.
- The scope of this global variable is session.

The value of the global variable is 'P' for procedure or 'F' for function. If there is no routine currently executing, the value is NULL.

The value of ROUTINE_TYPE global variable is set only for procedures and functions. The value always reflects the type of the currently executing routine.

The value is not changed for functions that are inlined. The value remains the same as it was when the inline function was invoked.

SERVER_MODE_JOB_NAME

This global variable contains the name of the job that established the SQL server mode connection.

This global variable has the following characteristics:

- It is read-only, with values maintained by system.
- The type is VARCHAR(28).
- The schema is QSYS2.
- The scope of this global variable is session.

If there is no server mode connection, the value is NULL.

THREAD_ID

This global variable contains the thread ID of the current thread.

This global variable has the following characteristics:

- It is read-only, with values maintained by system.
- The type is BIGINT.
- The schema is QSYS2.
- The scope of this global variable is session.

Example

Capture the thread scoped record locks over the SALES table which are held by the current thread.

```
SELECT * FROM QSYS2.RECORD_LOCK_INFO L
WHERE L.TABLE_NAME = 'SALES' AND
      L.JOB_NAME = QSYS2.JOB_NAME AND
      L.THREAD_ID = QSYS2.THREAD_ID
```

Chapter 4. Built-in functions

This chapter contains syntax diagrams, semantic descriptions, rules, and examples of the use of the *built-in functions* listed in the following tables.

For more information about functions, see “Functions” on page 147.

Table 36. Aggregate Functions

Function	Description	Reference
ARRAY_AGG	Aggregates a set of elements into an array.	“ARRAY_AGG” on page 259
AVG	Returns the average of a set of numbers	“AVG” on page 261
CORR or CORRELATION	Returns the coefficient of correlation of a set of number pairs	“CORR or CORRELATION” on page 262
COUNT	Returns the number of rows or values in a set of rows or values	“COUNT” on page 263
COUNT_BIG	Returns the number of rows or values in a set of rows or values (COUNT_BIG is similar to COUNT except that the result can be greater than the maximum value of integer)	“COUNT_BIG” on page 264
COVARIANCE or COVAR	Returns the (population) covariance of a set of number pairs	“COVARIANCE or COVAR” on page 265
COVAR_SAMP or COVARIANCE_SAMP	Returns the unbiased sample covariance (n-1) of a set of number pairs	“COVAR_SAMP or COVARIANCE_SAMP” on page 266
GROUPING	Returns a value that indicates whether a row was generated as a summary row for a grouping set.	“GROUPING” on page 267
JSON_ARRAYAGG	Returns a JSON array containing an array element for each value in a set of JSON or SQL values.	“JSON_ARRAYAGG” on page 268
JSON_OBJECTAGG	Returns a JSON object containing a <i>key:value</i> pair for each specific key and value in a set of SQL values.	“JSON_OBJECTAGG” on page 273
LISTAGG	Aggregates a set of string elements into one string by concatenating the strings.	“LISTAGG” on page 277
MAX	Returns the maximum value in a set of values in a group	“MAX” on page 280
MEDIAN	Returns the median of a set of numbers	“MEDIAN” on page 281
MIN	Returns the minimum value in a set of values in a group	“MIN” on page 282
PERCENTILE_CONT	Returns the value that corresponds to the specified percentile given a sort specification by using a continuous distribution model.	“PERCENTILE_CONT” on page 283
PERCENTILE_DISC	Returns the value that corresponds to the specified percentile given a sort specification by using a discrete distribution model.	“PERCENTILE_DISC” on page 285

Table 36. Aggregate Functions (continued)

Function	Description	Reference
Regression functions	The regression functions support the fitting of an ordinary-least-squares regression line of the form $y = a * x + b$ to a set of number pairs.	“Regression functions” on page 287
STDDEV	Returns the biased standard deviation of a set of numbers	“STDDEV_POP or STDDEV” on page 290
STDDEV_SAMP	Returns the sample standard deviation of a set of numbers	“STDDEV_SAMP” on page 291
SUM	Returns the sum of a set of numbers	“SUM” on page 292
VARIANCE or VAR	Returns the biased variance of a set of numbers	“VAR_POP or VARIANCE or VAR” on page 293
VAR_SAMP or VARIANCE_SAMP	Returns the sample variance of a set of numbers	“VAR_SAMP or VARIANCE_SAMP” on page 294
XMLAGG	Returns an XML sequence containing an item for each non-null value in a set of XML values.	“XMLAGG” on page 295
XMLGROUP	Returns an XML value that is a well-formed XML document.	“XMLGROUP” on page 297

Table 37. Cast Scalar Functions

Function	Description	Reference
BIGINT	Returns a big integer representation of a number	“BIGINT” on page 315
BINARY	Returns a BINARY representation of a string of any type	“BINARY” on page 317
BLOB	Returns a BLOB representation of a string of any type	“BLOB” on page 321
CHAR	Returns a CHARACTER representation of a value	“CHAR” on page 325
CLOB	Returns a CLOB representation of a value	“CLOB” on page 333
DATE	Returns a DATE from a value	“DATE” on page 352
DBCLOB	Returns a DBCLOB representation of a string	“DBCLOB” on page 361
DECFLOAT	Returns a DECFLOAT representation of a number	“DECFLOAT” on page 369
DECIMAL	Returns a DECIMAL representation of a number	“DECIMAL or DEC” on page 374
DOUBLE_PRECISION or DOUBLE	Returns a DOUBLE PRECISION representation of a number	“DOUBLE_PRECISION or DOUBLE” on page 392
FLOAT	Returns a FLOAT representation of a number	“FLOAT” on page 408
GRAPHIC	Returns a GRAPHIC representation of a string	“GRAPHIC” on page 416
INTEGER or INT	Returns an INTEGER representation of a number	“INTEGER or INT” on page 442
REAL	Returns a REAL representation of a number	“REAL” on page 536

Table 37. Cast Scalar Functions (continued)

Function	Description	Reference
ROWID	Returns a Row ID from a value	“ROWID” on page 558
SMALLINT	Returns a SMALLINT representation of a number	“SMALLINT” on page 573
TIME	Returns a TIME from a value	“TIME” on page 589
TIMESTAMP	Returns a TIMESTAMP from a value or a pair of values	“TIMESTAMP” on page 590
TIMESTAMP_ISO	Returns a timestamp value from a datetime value	“TIMESTAMP_ISO” on page 597
TO_CLOB	Returns a CLOB representation of a value	“TO_CLOB” on page 602
VARBINARY	Returns a VARBINARY representation of a string of any type	“VARBINARY” on page 620
VARCHAR	Returns a VARCHAR representative of a value	“VARCHAR” on page 623
VARGRAPHIC	Returns a VARGRAPHIC representation of a value	“VARGRAPHIC” on page 638
ZONED	Returns a zoned decimal representation of a number	“ZONED” on page 683

Table 38. Datalink Scalar Functions

Function	Description	Reference
DLCOMMENT	Returns the comment value from a DataLink value	“DLCOMMENT” on page 383
DLLINKTYPE	Returns the link type value from a DataLink value	“DLLINKTYPE” on page 384
DLURLCOMPLETE	Returns the complete URL value from a DataLink value with a link type of URL	“DLURLCOMPLETE” on page 385
DLURLPATH	Returns the path and file name necessary to access a file within a given server from a DataLink value with a linktype of URL	“DLURLPATH” on page 386
DLURLPATHONLY	Returns the path and file name necessary to access a file within a given server from a DataLink value with a linktype of URL without a file access token	“DLURLPATHONLY” on page 387
DLURLSCHEME	Returns the scheme from a DataLink value with a linktype of URL	“DLURLSCHEME” on page 388
DLURLSERVER	Returns the file server from a DataLink value with a linktype of URL	“DLURLSERVER” on page 389
DLVALUE	Returns a DataLink value	“DLVALUE” on page 390

Table 39. Datetime Scalar Functions

Function	Description	Reference
ADD_MONTHS	Returns a date that represents the date argument plus the number of months argument	“ADD_MONTHS” on page 303
CURDATE	Returns a date based on a reading of the time-of-day clock	“CURDATE” on page 347
CURTIME	Returns a time based on a reading of the time-of-day clock	“CURTIME” on page 348
DAY	Returns the day part of a value	“DAY” on page 354
DAYNAME	Returns the name of the day part of a value	“DAYNAME” on page 355
DAYOFMONTH	Returns an integer that represents the day of the month	“DAYOFMONTH” on page 356
DAYOFWEEK	Returns the day of the week from a value, where 1 is Sunday and 7 is Saturday	“DAYOFWEEK” on page 357
DAYOFWEEK_ISO	Returns the day of the week from a value, where 1 is Monday and 7 is Sunday	“DAYOFWEEK_ISO” on page 358
DAYOFYEAR	Returns the day of the year from a value	“DAYOFYEAR” on page 359
DAYS	Returns an integer representation of a date	“DAYS” on page 360
EXTRACT	Returns a specified portion of a datetime value	“EXTRACT” on page 404
HOUR	Returns the hour part of a value	“HOUR” on page 426
JULIAN_DAY	Returns an integer value representing a number of days from January 1, 4712 B.C. to the date specified in the argument	“JULIAN_DAY” on page 467
LAST_DAY	Returns a date or timestamp that represents the last day of the month of the argument	“LAST_DAY” on page 469
MICROSECOND	Returns the microsecond part of a value	“MICROSECOND” on page 492
MIDNIGHT_SECONDS	Returns an integer value representing the number of seconds between midnight and a specified time value	“MIDNIGHT_SECONDS” on page 493
MINUTE	Returns the minute part of a value	“MINUTE” on page 495
MONTH	Returns the month part of a value	“MONTH” on page 498
MONTHNAME	Returns the name of the month part of a value	“MONTHNAME” on page 499
MONTHS_BETWEEN	Returns an estimate of the number of months between two dates	“MONTHS_BETWEEN” on page 500
NEXT_DAY	Returns a date or timestamp value that represents the first weekday after the day named by the second argument	“NEXT_DAY” on page 514
NOW	Returns a timestamp based on a reading of the time-of-day clock	“NOW” on page 517
QUARTER	Returns an integer that represents the quarter of the year in which a date resides	“QUARTER” on page 532

Table 39. Datetime Scalar Functions (continued)

Function	Description	Reference
ROUND_TIMESTAMP	Returns a timestamp rounded to the specified unit.	“ROUND_TIMESTAMP” on page 555
SECOND	Returns the seconds part of a value	“SECOND” on page 568
TIMESTAMP_FORMAT	Returns a timestamp from a character string representation of a timestamp according to the specified format of the string.	“TIMESTAMP_FORMAT” on page 592
TIMESTAMPDIFF	Returns an estimated number of intervals based on the difference between two timestamps	“TIMESTAMPDIFF” on page 598
TO_DATE	Returns a timestamp from a character string representation of a timestamp according to the specified format of the string.	“TO_DATE” on page 603
TO_TIMESTAMP	Returns a timestamp from a character string representation of a timestamp according to the specified format of the string.	“TO_TIMESTAMP” on page 605
TRUNC_TIMESTAMP	Returns a timestamp truncated to the specified unit.	“TRUNC_TIMESTAMP” on page 614
WEEK	Returns the week of the year from a value, where the week starts with Sunday	“WEEK” on page 646
WEEK_ISO	Returns the week of the year from a value, where the week starts with Monday	“WEEK_ISO” on page 647
YEAR	Returns the year part of a value	“YEAR” on page 682

Table 40. HTTP Scalar Functions

Function	Description	Reference
BASE64_DECODE	Returns a character string that has been Base64 decoded.	“BASE64_DECODE” on page 313
BASE64_ENCODE	Returns the Base64 encoded version of a binary value.	“BASE64_ENCODE” on page 314
HTTP_DELETE	Deletes a text-based resource from the specified URL through an HTTP DELETE request.	“HTTP_DELETE” on page 427
HTTP_GET	Retrieves a text-based resource from the specified URL through an HTTP GET request.	“HTTP_GET” on page 428
HTTP_POST	Updates a text-based resource under the specified URL through an HTTP POST request	“HTTP_POST” on page 433
HTTP_PUT	Retrieves a text-based resource from the specified URL through an HTTP PUT request.	“HTTP_PUT” on page 434
URL_DECODE	Completes URL decoding of the provided text using UTF-8 encoding.	“URL_DECODE” on page 617
URL_ENCODE	Completes URL encoding of the provided text using UTF-8 encoding.	“URL_ENCODE” on page 617

Table 41. JSON Scalar Functions

Function	Description	Reference
BSON_TO_JSON	Converts a string containing formatted BSON data to a character string containing the data formatted as JSON.	“BSON_TO_JSON” on page 322
JSON_ARRAY	Generates a JSON array either by explicitly listing the array elements or by using a query	“JSON_ARRAY” on page 449
JSON_OBJECT	Generates a JSON object using the specified <i>key:value</i> pairs.	“JSON_OBJECT” on page 453
JSON_QUERY	Returns an SQL/JSON value from the specified JSON text by using an SQL/JSON path expression	“JSON_QUERY” on page 457
JSON_TO_BSON	Converts a string containing formatted JSON data to a binary string containing the data formatted as BSON.	“JSON_TO_BSON” on page 462
JSON_VALUE	Returns an SQL scalar value from a JSON text by using an SQL/JSON path expression	“JSON_VALUE” on page 463

Table 42. Miscellaneous Scalar Functions

Function	Description	Reference
ARRAY_MAX_CARDINALITY	Returns a value representing the maximum number of elements an array can contain.	“ARRAY_MAX_CARDINALITY” on page 306
ARRAY_TRIM	Returns a copy of an array from which a number of elements have been removed from the end of the array.	“ARRAY_TRIM” on page 307
CARDINALITY	Returns a value representing the number of elements of an array	“CARDINALITY” on page 323
COALESCE	Returns the first argument that is not null	“COALESCE” on page 338
CONTAINS	Returns an indication of whether a match was found in a text index.	“CONTAINS” on page 341
DATABASE	Returns the current server	“DATABASE” on page 349
GENERATE_UNIQUE	Returns a bit character string that is unique compared to any other execution of the function	“ATAN2” on page 312
GET_BLOB_FROM_FILE	Returns a BLOB locator containing the data from a source stream file or a source physical file member.	“GET_BLOB_FROM_FILE” on page 411
GET_CLOB_FROM_FILE	Returns a CLOB locator containing the data from a source stream file or a source physical file member.	“GET_CLOB_FROM_FILE” on page 412
GET_DBCLOB_FROM_FILE	Returns a DBCLOB locator containing the data from a source stream file or a source physical file member.	“GET_DBCLOB_FROM_FILE” on page 413

Table 42. Miscellaneous Scalar Functions (continued)

Function	Description	Reference
GET_XML_FILE	Returns a BLOB locator containing the data from a source stream file or a source physical file member with the data converted to UTF-8.	“GET_XML_FILE” on page 414
GREATEST	Returns the maximum value in a set of values	“GREATEST” on page 421
HEX	Returns a hexadecimal representation of a value	“HEX” on page 424
IDENTITY_VAL_LOCAL	Returns the most recently assigned value for an identity column	“IDENTITY_VAL_LOCAL” on page 435
IFNULL	Returns the first argument that is not null	“IFNULL” on page 439
INTERPRET	Returns the first operand interpreted as the specified data type.	“INTERPRET” on page 444
LEAST	Returns the minimum value in a set of values	“LEAST” on page 471
LENGTH	Returns the length of a value	“LENGTH” on page 474
MAX	Returns the maximum value in a set of values	“MAX” on page 490
MAX_CARDINALITY	Returns a value representing the maximum number of elements an array can contain.	“MAX_CARDINALITY” on page 491
MIN	Returns the minimum value in a set of values	“MIN” on page 494
NULLIF	Returns a null value if the arguments are equal, otherwise it returns the value of the first argument	“NULLIF” on page 518
NVL	Returns the first argument that is not null	“NVL” on page 519
RAISE_ERROR	Raises an error with the specified SQLSTATE and message text	“RAISE_ERROR” on page 534
RID	Returns the relative record number of a row as BIGINT.	“RID” on page 550
RRN	Returns the relative record number of a row as DECIMAL(15,0)	“RRN” on page 562
SCORE	Returns an indication of how frequently a match was found in a text index.	“SCORE” on page 565
SYS_CONNECT_BY_PATH	Returns a string representing the path from the root row to the current row for hierarchical queries.	“SYS_CONNECT_BY_PATH” on page 761
TABLE_NAME	Returns the unqualified name of the object found for an alias.	“TABLE_NAME” on page 585
TABLE_SCHEMA	Returns the schema name of the object found for an alias.	“TABLE_SCHEMA” on page 586
TRIM_ARRAY	Returns a copy of an array from which a number of elements have been removed from the end of the array.	“TRIM_ARRAY” on page 611
VALUE	Returns the first argument that is not null	“VALUE” on page 619

Table 42. Miscellaneous Scalar Functions (continued)

Function	Description	Reference
VERIFY_GROUP_FOR_USER	Returns an indication of whether a user is in a list of specified profiles.	“VERIFY_GROUP_FOR_USER” on page 644
WRAP	Obfuscates DDL statement text	“WRAP” on page 648

Table 43. MQSeries Scalar Functions

Function	Description	Reference
MQREAD	Returns a message from a specified MQSeries® location (return value of VARCHAR) without removing the message from the queue	“MQREAD” on page 502
MQREADCLOB	Returns a message from a specified MQSeries location (return value of CLOB) without removing the message from the queue	“MQREADCLOB” on page 504
MQRECEIVE	Returns a message from a specified MQSeries location (return value of VARCHAR) with removal of message from the queue	“MQRECEIVE” on page 506
MQRECEIVECLOB	Returns a message from a specified MQSeries location (return value of CLOB) with removal of message from the queue	“MQRECEIVECLOB” on page 508
MQSEND	Sends a message to a specified MQSeries location	“MQSEND” on page 510

Table 44. Numeric Scalar Functions

Function	Description	Reference
ABS or ABSVAL	Returns the absolute value of a number	“ABS or ABSVAL” on page 301
ACOS	Returns the arc cosine of a number, in radians	“ACOS” on page 302
ANTILOG	Returns the anti-logarithm (base 10) of a number	“ANTILOG” on page 305
ASIN	Returns the arc sine of a number, in radians	“ASIN” on page 309
ATAN	Returns the arc tangent of a number, in radians	“ATAN” on page 310
ATANH	Returns the hyperbolic arc tangent of a number, in radians	“ATANH” on page 311
ATAN2	Returns the arc tangent of x and y coordinates as an angle expressed in radians	“ATAN2” on page 312
BITAND, BITANDNOT, BITOR, BITXOR, BITNOT	Return a base 10 value based on a bitwise operation using the two's complement representation of the input arguments	“BITAND, BITANDNOT, BITOR, BITXOR, and BITNOT” on page 318
CEILING	Returns the smallest integer value that is greater than or equal to a number	“CEILING or CEIL” on page 324
COMPARE_DECFLOAT	Returns an indication of how two decimal floating-point values compare	“COMPARE_DECFLOAT” on page 339
COS	Returns the cosine of a number	“COS” on page 344

Table 44. Numeric Scalar Functions (continued)

Function	Description	Reference
COSH	Returns the hyperbolic cosine of a number	“COSH” on page 345
DECFLOAT_FORMAT	Returns a DECFLOAT(34) value that is based on the interpretation of the input string using the specified format.	“DECFLOAT_FORMAT” on page 371
DECFLOAT_SORTKEY	Returns an integer value that can be used to sort decimal floating-point values.	“DECFLOAT_SORTKEY” on page 373
DEGREES	Returns the number of degrees of an angle	“DEGREES” on page 380
DIGITS	Returns a character-string representation of the absolute value of a number	“DIGITS” on page 382
EXP	Returns a value that is the base of the natural logarithm (e) raised to a power specified by the argument	“EXP” on page 403
FLOOR	Returns the largest integer value that is less than or equal to a number	“FLOOR” on page 409
LN	Returns the natural logarithm of a number	“LN” on page 476
LOG10	Returns the common logarithm (base 10) of a number	“LOG10” on page 482
MOD	Returns the remainder of the first argument divided by the second argument	“MOD” on page 496
MULTIPLY_ALT	Multiplies the first argument by the second argument and returns the product	“MULTIPLY_ALT” on page 512
NORMALIZE_DECFLOAT	Returns a decimal floating-point value in its simplest form	“NORMALIZE_DECFLOAT” on page 516
PI	Returns the value of π	“PI” on page 524
POWER or POW	Returns the result of raising the first argument to the power of the second argument	“POWER or POW” on page 529
QUANTIZE	Returns a decimal floating-point value formatted according to a provided value	“QUANTIZE” on page 530
RADIANS	Returns the number of radians for an argument that is expressed in degrees	“RADIANS” on page 533
RANDOM or RAND	Returns a random number	“RANDOM or RAND” on page 535
ROUND	Returns a numeric value that has been rounded to the specified number of decimal places	“ROUND” on page 553
SIGN	Returns the sign of a number	“SIGN” on page 570
SIN	Returns the sine of a number	“SIN” on page 571
SINH	Returns the hyperbolic sine of a number	“SINH” on page 572
SQRT	Returns the square root of a number	“SQRT” on page 576
TAN	Returns the tangent of a number	“TAN” on page 587
TANH	Returns the hyperbolic tangent of a number	“TANH” on page 588

Table 44. Numeric Scalar Functions (continued)

Function	Description	Reference
TO_NUMBER	Returns a DECFLOAT(34) value that is based on the interpretation of the input string using the specified format.	“TO_NUMBER” on page 604
TOTALORDER	Returns an ordering indication for two decimal floating-point values	“TOTALORDER” on page 606
TRUNCATE or TRUNC	Returns a number value that has been truncated at a specified number of decimal places	“TRUNCATE or TRUNC” on page 612

Table 45. Partitioning Scalar Functions

Function	Description	Reference
DATAPARTITIONNAME	Returns the partition name where a row is located	“DATAPARTITIONNAME” on page 350
DATAPARTITIONNUM	Returns the partition number of a row	“DATAPARTITIONNUM” on page 351
DBPARTITIONNAME	Returns the relational database name where a row is located	“DBPARTITIONNAME” on page 367
DBPARTITIONNUM	Returns the node number of a row	“DBPARTITIONNUM” on page 368
HASH	Returns the partition number of a set of values	“HASH” on page 422
HASHED_VALUE	Returns the partition map index number of a row	“HASHED_VALUE” on page 423

Table 46. String Scalar Functions

Function	Description	Reference
ASCII	Returns the ASCII code value of the leftmost character of the argument as an integer	“ASCII” on page 308
BIT_LENGTH	Returns the length of a string expression in bits	“BIT_LENGTH” on page 320
CHARACTER_LENGTH	Returns the length of a string expression	“CHARACTER_LENGTH or CHAR_LENGTH” on page 331
CHR	Returns the EBCDIC character that has the ASCII code value specified by the argument.	“CHR” on page 332
CONCAT	Returns a string that is the concatenation of two strings	“CONCAT” on page 340
DECRYPT_BIT, DECRYPT_BINARY, DECRYPT_CHAR, and DECRYPT_DB	Decrypts an encrypted string	“DECRYPT_BIT, DECRYPT_BINARY, DECRYPT_CHAR and DECRYPT_DB” on page 377
DIFFERENCE	Returns a value representing the difference between the sounds of two strings	“DIFFERENCE” on page 381

Table 46. String Scalar Functions (continued)

Function	Description	Reference
ENCRYPT and ENCRYPT_RC2	Encrypts a string using the RC2 encryption algorithm	“ENCRYPT_RC2 or ENCRPYT” on page 397
ENCRYPT_AES	Encrypts a string using the AES encryption algorithm	“ENCRYPT_AES” on page 394
ENCRYPT_TDES	Encrypts a string using the Triple DES encryption algorithm	“ENCRYPT_TDES” on page 400
GETHINT	Returns a hint from an encrypted string	“GETHINT” on page 415
HEXORAW	Returns a binary string representation of a character string that has been formatted	“HEXORAW” on page 425
INSERT	Returns a string where a substring is deleted and a new string inserted in its place	“INSERT” on page 440
INSTR	Returns the starting position of a string within another string.	“INSTR” on page 448
LAND	Returns a string that is the logical AND of the argument strings	“LAND” on page 468
LCASE	Returns a string in which all the characters have been converted to lowercase characters	“LCASE” on page 470
LEFT	Returns the leftmost characters from the string	“LEFT” on page 472
LNOT	Returns a string that is the logical NOT of the argument string	“LNOT” on page 477
LOCATE	Returns the starting position of one string within another string	“LOCATE” on page 478
LOCATE_IN_STRING	Returns the starting position of a string within another string.	“LOCATE_IN_STRING” on page 480
LOR	Returns a string that is the logical OR of the argument strings	“LOR” on page 483
LOWER	Returns a string in which all the characters have been converted to lowercase characters	“LOWER” on page 484
LPAD	Returns a string that is padded on the left	“LPAD” on page 485
LTRIM	Returns a string in which blanks or hexadecimal zeroes have been removed from the beginning of another string	“LTRIM” on page 488
OCTET_LENGTH	Returns the length of a string expression in octets	“OCTET_LENGTH” on page 520
OVERLAY	Returns a string where a number of characters have been deleted from the original string and a new string inserted into the string.	“OVERLAY” on page 521
POSITION	Returns the starting position of one string within another string	“POSITION” on page 525
POSSTR	Returns the starting position of one string within another string	“POSSTR” on page 527

Table 46. String Scalar Functions (continued)

Function	Description	Reference
REGEXP_COUNT	Returns a returns a count of the number of times that a regular expression pattern is matched in a string	“REGEXP_COUNT” on page 538
REGEXP_INSTR	Returns the starting position or the position after the end of the matched substring.	“REGEXP_INSTR” on page 540
REGEXP_REPLACE	Returns a modified version of the source string where a regular expression pattern is replaced with a replacement string	“REGEXP_REPLACE” on page 542
REGEXP_SUBSTR	Returns an occurrence of a substring of a string that matches the regular expression pattern	“REGEXP_SUBSTR” on page 544
REPEAT	Returns a string composed of another string repeated a number of times	“REPEAT” on page 546
REPLACE	Returns a string where all occurrences of one string are replaced by another string	“REPLACE” on page 548
RIGHT	Returns the rightmost characters from the string	“RIGHT” on page 551
RPAD	Returns a string that is padded on the right	“RPAD” on page 559
RTRIM	Returns a string in which blanks or hexadecimal zeroes have been removed from the end of another string	“RTRIM” on page 563
SOUNDEX	Returns a character code representing the sound of the words in the argument	“SOUNDEX” on page 574
SPACE	Returns a character string that consists of a specified number of blanks	“SPACE” on page 575
STRIP	Removes blanks or another specified character from the end or beginning of a string expression	“STRIP” on page 577
STRLEFT	Returns the leftmost characters from the string	“STRLEFT” on page 578
STRPOS	Returns the starting position of one string within another string	“STRPOS” on page 579
STRRIGHT	Returns the rightmost characters from the string	“STRRIGHT” on page 580
SUBSTR	Returns a substring of a string	“SUBSTR” on page 581
SUBSTRING	Returns a substring of a string	“SUBSTRING” on page 583
TO_CHAR	Returns a character string representation of the first argument using the format indicated by the optional format-string.	“TO_CHAR” on page 601
TRANSLATE	Returns a string in which one or more characters in a string are converted to other characters	“TRANSLATE” on page 607

Table 46. String Scalar Functions (continued)

Function	Description	Reference
TRIM	Removes blanks or another specified character from the beginning, the end, or both the beginning and the end of a string expression	“TRIM” on page 609
UCASE	Returns a string in which all the characters have been converted to uppercase characters	“UCASE” on page 615
UPPER	Returns a string in which all the characters have been converted to uppercase characters	“UPPER” on page 616
VARBINARY_FORMAT	Returns a binary string representation of a character string that has been formatted	“VARBINARY_FORMAT” on page 621
VARCHAR_FORMAT	Returns a character string representation of the first argument using the format indicated by the optional format-string.	“VARCHAR_FORMAT” on page 629
VARCHAR_FORMAT_BINARY	Returns a character string representation of a bit string that has been formatted	“VARCHAR_FORMAT_BINARY” on page 637
XOR	Returns a string that is the logical XOR of the argument strings	“XOR” on page 676

Table 47. XML Scalar Functions

Function	Description	Reference
XMLATTRIBUTES	Constructs XML attributes from the arguments.	“XMLATTRIBUTES” on page 650
XMLCOMMENT	Returns an XML value with the input argument as the content.	“XMLCOMMENT” on page 651
XMLCONCAT	Returns an XML sequence containing the concatenation of a variable number of XML input arguments.	“XMLCONCAT” on page 652
XMLDOCUMENT	Returns an XML value that is a well-formed XML document.	“XMLDOCUMENT” on page 654
XMLELEMENT	Returns an XML value that is an XML element.	“XMLELEMENT” on page 655
XMLFOREST	Returns an XML value that is a sequence of XML elements.	“XMLFOREST” on page 658
XMLNAMESPACES	Constructs namespace declarations from the arguments.	“XMLNAMESPACES” on page 661
XMLPARSE	Returns an XML value by parsing the arguments as an XML document.	“XMLPARSE” on page 663
XMLPI	Returns an XML value with a single processing instruction.	“XMLPI” on page 664
XMLROW	Returns an XML value that is a well-formed XML document.	“XMLROW” on page 665
XMLSERIALIZE	Returns a serialized XML value as the specified data type.	“XMLSERIALIZE” on page 667

Function	Description	Reference
XMLTEXT	Returns an XML value that contains the value of the input argument.	“XMLTEXT” on page 671
XMLVALIDATE	Returns an XML value that has been augmented with information obtained from XML schema validation.	“XMLVALIDATE” on page 672
XSLTRANSFORM	Transforms an XML document into a different data format.	“XSLTRANSFORM” on page 677

Function	Description	Reference
BASE_TABLE	Returns a table with one row containing the table name and schema name for the specified alias name	“BASE_TABLE” on page 687
HTTP_DELETE_VERBOSE	Deletes a text-based resource from the specified URL through an HTTP DELETE request. It returns a one row table that contains the normal HTTP response for the request and the header information returned from the HTTP request.	“HTTP_DELETE_VERBOSE” on page 689
HTTP_GET_VERBOSE	Retrieves a text-based resource from the specified URL through an HTTP GET request. It returns a one row table that contains the normal HTTP response for the request and the header information returned from the HTTP request.	“HTTP_GET_VERBOSE” on page 690
HTTP_POST_VERBOSE	Updates a text-based resource under the specified URL through an HTTP POST request. It returns a one row table that contains the normal HTTP response for the request and the header information returned from the HTTP request.	“HTTP_POST_VERBOSE” on page 692
HTTP_PUT_VERBOSE	Updates a text-based resource under the specified URL through an HTTP PUT request. It returns a one row table that contains the normal HTTP response for the request and the header information returned from the HTTP request.	“HTTP_PUT_VERBOSE” on page 693
JSON_TABLE	Returns a table from the evaluation of SQL/JSON path expressions.	“JSON_TABLE” on page 694
MQREADALL	Returns a table containing the messages and message metadata from a specified MQSeries location with a VARCHAR column and without removing the messages from the queue	“MQREADALL” on page 704
MQREADALLCLOB	Returns a table containing the messages and message metadata from a specified MQSeries location with a CLOB column and without removing the messages from the queue	“MQREADALLCLOB” on page 706

Table 48. Table Functions (continued)

Function	Description	Reference
MQRECEIVEALL	Returns a table containing the messages and message metadata from a specified MQSeries location with a VARCHAR column and with removal of messages from the queue	“MQRECEIVEALL” on page 708
MQRECEIVEALLCLOB	Returns a table containing the messages and message metadata from a specified MQSeries location with a CLOB column and with removal of messages from the queue	“MQRECEIVEALLCLOB” on page 711
XMLTABLE	Returns a table from the evaluation of an XPath expression.	“XMLTABLE” on page 714

Aggregate functions

An aggregate function takes a set of values (like a column of data) and returns a single value result from the set of values.

The following information applies to all aggregate functions other than COUNT(*) and COUNT_BIG(*).

- The argument of an aggregate function is a set of values derived from an expression. The expression may include columns but cannot include another aggregate function. The scope of the set is a group or an intermediate result table as explained in Chapter 6, "Queries".
- If a GROUP BY clause is specified in a query and the intermediate result of the FROM, WHERE, GROUP BY, and HAVING clauses is an empty result table, then the aggregate functions are not applied and the result of the query is an empty table.
- If a GROUP BY clause is not specified in a query and the intermediate result of the FROM, WHERE, and HAVING clauses is an empty result table, then the aggregate functions are applied to the empty result table. For example, the result of the following SELECT statement is applied to an empty result table because department D01 has no employees:

```
SELECT COUNT(DISTINCT JOB)
FROM EMPLOYEE
WHERE WORKDEPT = 'D01'
```

- The keyword DISTINCT is not considered an argument of the function, but rather a specification of an operation that is performed before the function is applied. If DISTINCT is specified, redundant duplicate values are eliminated. If ALL is implicitly or explicitly specified, redundant duplicate values are not eliminated.

When interpreting the DISTINCT clause for decimal floating-point values that are numerically equal, the number of significant digits in the value is not considered. For example, the decimal floating-point number 123.00 is not distinct from the decimal floating-point number 123. The representation of the number returned from the query will be any one of the representations encountered (for example, either 123.00 or 123).

- An aggregate function can be used in a WHERE clause only if that clause is part of a subquery of a HAVING clause and the column name specified in the expression is a correlated reference to a group. If the expression includes more than one column name, each column name must be a correlated reference to the same group.

ARRAY_AGG

The ARRAY_AGG function aggregates a set of elements into an array.

►► ARRAY_AGG ►►

expression

An expression that returns a value that is any data type that can be specified for a CREATE TYPE (Array) statement.

ORDER BY

Specifies the order of the rows from the same grouping set that are processed in the aggregation. If the ORDER BY clause is not specified, or if the ORDER BY clause cannot differentiate the order of the sort key value, the rows in the same grouping set are arbitrarily ordered.

sort-key-expression

Specifies a sort key value that is either a column name or an expression. The data type of the column or expression must not be a DATALINK or XML value.

The ordering of the aggregated elements is based on the values of the sort keys.

The sum of the length attributes of the *sort-key-expressions* must not exceed 3.5 gigabytes.

If a collating sequence other than *HEX is in effect when the statement that contains the ARRAY_AGG function is executed and the *sort-key-expressions* are SBCS data, mixed data, or Unicode data, then the result is obtained by comparing weighted values. The weighted values are derived by applying the collating sequence to the *sort-key-expressions*.

The ARRAY_AGG function can only be specified within an SQL procedure or an SQL function in the following specific contexts:

- The *select-clause* of a SELECT INTO statement
- The *select-clause* of a scalar subquery on the right side of a SET statement

The SELECT that uses ARRAY_AGG cannot contain the DISTINCT clause.

Examples

Assume an array type and a table are created as follows:

```
CREATE TYPE PHONELIST AS DECIMAL(10,0) ARRAY[10]

CREATE TABLE EMPLOYEE (
  ID          INTEGER NOT NULL,
  PRIORITY    INTEGER NOT NULL,
  PHONENUMBER DECIMAL(10,0),
  PRIMARY KEY (ID, PRIORITY) )
```

Create a procedure that uses a SELECT INTO statement to return the prioritized list of contact numbers under which an employee can be reached.

```
CREATE PROCEDURE GETPHONENUMBERS
  (IN EMPID INTEGER,
  OUT NUMBERS PHONELIST)
BEGIN
  SELECT ARRAY_AGG(PHONENUMBER ORDER BY PRIORITY) INTO NUMBERS
  FROM EMPLOYEE
```

```
WHERE ID = EMPID;  
END
```

Create a procedure that uses a SET statement to return the list of an employee's contact numbers in an arbitrary order.

```
CREATE PROCEDURE GETPHONENUMBERS  
  (IN EMPID INTEGER,  
   OUT NUMBERS PHONELIST)  
BEGIN  
  SET NUMBERS =  
    (SELECT ARRAY_AGG(PHONENUMBER)  
     FROM EMPLOYEE  
     WHERE ID = EMPID);  
END
```

AVG

The AVG function returns the average of a set of numbers.

numeric-expression

An expression that returns a value of any built-in numeric, character-string, or graphic-string data type. If the argument is a character-string or graphic-string, it is cast to DECFLOAT(34) before evaluating the function. The sum of the argument values must be within the range of the data type of the result.

The data type of the result is the same as the data type of the argument values, except that:

- The result is DECFLOAT(34) if the argument values are DECFLOAT(16).
- The result is double-precision floating point if the argument values are single-precision floating point.
- The result is large integer if the argument values are small integers.
- The result is decimal if the argument values are decimal or nonzero scale binary with precision p and scale s . The precision of the result is $p-s + \min(ms, mp-p+s)$. The scale of the result is $\min(ms, mp-p+s)$.

For information about the values of p , s , ms , and mp , see [“Decimal arithmetic in SQL” on page 160](#).

The function is applied to the set of values derived from the argument values by the elimination of null values. If DISTINCT is used, duplicate values are eliminated.

The result can be null. If set of values is empty, the result is the null value. Otherwise, the result is the average value of the set.

The order in which the values are aggregated is undefined, but every intermediate result must be within the range of the result data type.

If the type of the result is integer, the fractional part of the average is lost.

Notes

Results involving DECFLOAT special values: If the data type of the argument is decimal floating-point and a special value of sNaN or -sNaN, or both +Infinity and -Infinity are included in the aggregation, an error or warning is returned. Otherwise, if +NaN or -NaN is found, the result is +NaN or -NaN. If +Infinity or -Infinity is found, the result is +Infinity or -Infinity.

Examples

- Using the PROJECT table, set the host variable AVERAGE (DECIMAL(5,2)) to the average staffing level (PRSTAFF) of projects in department (DEPTNO) 'D11'.

```
SELECT AVG(PRSTAFF)
  INTO :AVERAGE
  FROM PROJECT
  WHERE DEPTNO = 'D11'
```

Results in AVERAGE being set to 4.25 (that is, 17/4).

- Using the PROJECT table, set the host variable ANY_CALC to the average of each unique staffing value (PRSTAFF) of projects in department (DEPTNO) 'D11'.

```
SELECT AVG(DISTINCT PRSTAFF)
  INTO :ANY_CALC
  FROM PROJECT
  WHERE DEPTNO = 'D11'
```

Results in ANY_CALC being set to 4.66 (that is, 14/3).

CORR or CORRELATION

The CORRELATION function returns the coefficient of correlation of a set of number pairs.

→ CORR (— *expression1* — , — *expression2* —) →
CORRELATION

expression1

An expression that returns a value of any built-in numeric, character-string, or graphic-string data type. If the argument is a character-string or graphic-string, it is cast to DECFLOAT(34) before evaluating the function.

expression2

An expression that returns a value of any built-in numeric, character-string, or graphic-string data type. If the argument is a character-string or graphic-string, it is cast to DECFLOAT(34) before evaluating the function.

If either argument is decimal floating-point, the result of the function is DECFLOAT(34). Otherwise, the result of the function is a double precision floating-point number. The result can be null. When not null, the result is between -1 and 1.

The function is applied to the set of (*expression1*, *expression2*) pairs derived from the argument values by the elimination of all pairs for which either *expression1* or *expression2* is null.

If the function is applied to an empty set, or if either STDDEV(*expression1*) or STDDEV(*expression2*) is equal to zero, the result is a null value. Otherwise, the result is the correlation coefficient for the value pairs in the set. The result is equivalent to the following:

1. Let *sdexp1* be the result of STDDEV(*expression1*) and let *sdexp2* be the result of STDDEV(*expression2*).
2. The result of CORRELATION(*expression1*, *expression2*) is:

```
COVARIANCE(expression1, expression2) / (sdexp1 * sdexp2)
```

The order in which the values are aggregated is undefined, but every intermediate result must be within the range of the result data type.

Notes

Results involving DECFLOAT special values: If the data type of the argument is decimal floating-point and a special value of sNaN or -sNaN, or both +Infinity and -Infinity are included in the aggregation, an error or warning is returned. Otherwise, if +NaN or -NaN is found, the result is +NaN or -NaN. If +Infinity or -Infinity is found, the result is +Infinity or -Infinity.

Syntax alternatives: CORR should be used for conformance to the SQL standard.

Example

- Using the EMPLOYEE table, set the host variable CORRLN to the correlation between the salary and the bonus for those employees in department 'A00'.

```
SELECT CORRELATION(SALARY, BONUS)
  INTO :CORRLN
  FROM EMPLOYEE
  WHERE WORKDEPT = 'A00';
```

CORRLN is set to 0.9760236077658643 when using the sample table.

COUNT

The COUNT function returns the number of rows or values in a set of rows or values.

expression

The argument values can be of any built-in data type other than a DataLink. XML is not allowed for COUNT (DISTINCT *expression*).

The result of the function is a large integer and it must be within the range of large integers. The result cannot be null. If the table is a distributed table, then the result is DECIMAL(15,0). For more information about distributed tables, see the [DB2 Multisystem](#) topic collection.

The argument of COUNT(*) is a set of rows. The result is the number of rows in the set. A row that includes only null values is included in the count.

The argument of COUNT(*expression*) or COUNT(ALL *expression*) is a set of values. The function is applied to the set derived from the argument values by the elimination of null values. The result is the number of non-null values in the set including duplicates.

The argument of COUNT(DISTINCT *expression*) is a set of values. The function is applied to the set of values derived from the argument values by the elimination of null values and duplicate values. The result is the number of values in the set.

If a collating sequence other than *HEX is in effect when the statement that contains the COUNT(DISTINCT *expression*) is executed and the arguments are SBCS data, mixed data, or Unicode data, then the result is obtained by comparing weighted values for each value in the set. The weighted values are based on the collating sequence.

Examples

- Using the EMPLOYEE table, set the host variable FEMALE (INTEGER) to the number of rows where the value of the SEX column is 'F'.

```
SELECT COUNT(*)
  INTO :FEMALE
  FROM EMPLOYEE
  WHERE SEX = 'F'
```

Results in FEMALE being set to 19.

- Using the EMPLOYEE table, set the host variable FEMALE_IN_DEPT (INTEGER) to the number of departments (WORKDEPT) that have at least one female as a member.

```
SELECT COUNT(DISTINCT WORKDEPT)
  INTO :FEMALE_IN_DEPT
  FROM EMPLOYEE
  WHERE SEX='F'
```

Results in FEMALE_IN_DEPT being set to 6. (There is at least one female in departments A00, C01, D11, D21, E11, and E21.)

COUNT_BIG

The COUNT_BIG function returns the number of rows or values in a set of rows or values. It is similar to COUNT except that the result can be greater than the maximum value of integer.

expression

The argument values can be of any built-in data type other than a DataLink. XML is not allowed for COUNT_BIG(DISTINCT *expression*).

The result of the function is a decimal with precision 31 and scale 0. The result cannot be null.

The argument of COUNT_BIG(*) is a set of rows. The result is the number of rows in the set. A row that includes only null values is included in the count.

The argument of COUNT_BIG(*expression*) is a set of values. The function is applied to the set derived from the argument values by the elimination of null values. The result is the number of values in the set.

If a collating sequence other than *HEX is in effect when the statement that contains the COUNT_BIG(DISTINCT *expression*) is executed and the arguments are SBCS data, mixed data, or Unicode data, then the result is obtained by comparing weighted values for each value in the set. The weighted values are based on the collating sequence.

Examples

- Refer to COUNT examples and substitute COUNT_BIG for occurrences of COUNT. The results are the same except for the data type of the result.
- To count on a specific column, a sourced function must specify the type of the column. In this example, the CREATE FUNCTION statement creates a sourced function that takes any column defined as CHAR, uses COUNT_BIG to perform the counting, and returns the result as a double precision floating-point number. The query shown counts the number of unique departments in the sample employee table.

```
CREATE FUNCTION RICK.COUNT(CHAR(19)) RETURNS DOUBLE
SOURCE QSYS2.COUNT_BIG(CHAR());

SET CURRENT PATH RICK, SYSTEM PATH

SELECT COUNT(DISTINCT WORKDEPT) FROM EMPLOYEE;
```

COVARIANCE or COVAR

The COVARIANCE function returns the (population) covariance of a set of number pairs.

► COVARIANCE (— *expression1* — , — *expression2* —) ◄
COVAR

expression1

An expression that returns a value of any built-in numeric, character-string, or graphic-string data type. If the argument is a character-string or graphic-string, it is cast to DECFLOAT(34) before evaluating the function.

expression2

An expression that returns a value of any built-in numeric, character-string, or graphic-string data type. If the argument is a character-string or graphic-string, it is cast to DECFLOAT(34) before evaluating the function.

If either argument is decimal floating-point, the result of the function is DECFLOAT(34). Otherwise, the result of the function is a double precision floating-point number. The result can be null.

The function is applied to the set of (*expression1*, *expression2*) pairs derived from the argument values by the elimination of all pairs for which either *expression1* or *expression2* is null.

If the function is applied to an empty set, the result is a null value. Otherwise, the result is the covariance for the value pairs in the set. The result is equivalent to the following:

1. Let *avgexp1* be the result of `AVG(expression1)` and let *avgexp2* be the result of `AVG(expression2)`.
2. The result of `COVARIANCE(expression1, expression2)` is:

```
AVG( (expression1 - avgexp1) * (expression2 - avgexp2) )
```

The order in which the values are aggregated is undefined, but every intermediate result must be within the range of the result data type.

Notes

Results involving DECFLOAT special values: If the data type of the argument is decimal floating-point and a special value of sNaN or -sNaN, or both +Infinity and -Infinity are included in the aggregation, an error or warning is returned. Otherwise, if +NaN or -NaN is found, the result is +NaN or -NaN. If +Infinity or -Infinity is found, the result is +Infinity or -Infinity.

Syntax alternatives: COVAR_POP can be specified as a synonym for COVARIANCE.

Example

- Using the EMPLOYEE table, set the host variable COVARNCE to the covariance between the salary and the bonus for those employees in department 'A00'.

```
SELECT COVARIANCE(SALARY, BONUS)
INTO :COVARNCE
FROM EMPLOYEE
WHERE WORKDEPT = 'A00';
```

COVARNCE is set to 1743000.0000 when using the sample table.

COVAR_SAMP or COVARIANCE_SAMP

The COVARIANCE_SAMP function returns the unbiased sample covariance (n-1) of a set of number pairs.

► COVAR_SAMP (— *expression1* — , — *expression2* —) ►
COVARIANCE_SAMP

expression1

An expression that returns a value of any built-in numeric, character-string, or graphic-string data type. If the argument is a character-string or graphic-string, it is cast to DECFLOAT(34) before evaluating the function.

expression2

An expression that returns a value of any built-in numeric, character-string, or graphic-string data type. If the argument is a character-string or graphic-string, it is cast to DECFLOAT(34) before evaluating the function.

If either argument is decimal floating-point, the result of the function is DECFLOAT(34). Otherwise, the result of the function is a double precision floating-point number. The result can be null.

The function is applied to the set of (*expression1*, *expression2*) pairs derived from the argument values by the elimination of all pairs for which either *expression1* or *expression2* is null.

If the function is applied to an empty set or a set with only one row, the result is a null value. Otherwise, the result is the sample covariance for the value pairs in the set. The result is equivalent to the following:

1. Let avgexp1 be the result of AVG(*expression1*) and let avgexp2 be the result of AVG(*expression2*).
2. The result of COVARIANCE_SAMP(*expression1*, *expression2*) is:

```
SUM( (expression1 - avgexp1) * (expression2 - avgexp2) ) /  
  ( COUNT(expression1) - 1 )
```

The order in which the values are aggregated is undefined, but every intermediate result must be within the range of the result data type.

Notes

Results involving DECFLOAT special values: If the data type of the argument is decimal floating-point and a special value of sNaN or -sNaN, or both +Infinity and -Infinity are included in the aggregation, an error or warning is returned. Otherwise, if +NaN or -NaN is found, the result is +NaN or -NaN. If +Infinity or -Infinity is found, the result is +Infinity or -Infinity.

Syntax alternatives: COVAR_SAMP should be used for conformance to the SQL standard.

Example

- Set the host variable COVARNCE_S to the sample covariance between the salary and bonus for those employees in department 'A00' of the EMPLOYEE table. The data type of the host variable COVARNCE_S is double-precision floating point.

```
SELECT COVARIANCE_SAMP(SALARY, BONUS)  
  INTO :COVARNCE_S  
  FROM EMPLOYEE  
  WHERE WORKDEPT = 'A00'
```

COVARNCE_S is set to 2178750.0000 when the sample table is used.

GROUPING

Used in conjunction with grouping-sets and super-groups, the GROUPING aggregate function returns a value that indicates whether a row returned in a GROUP BY answer set is a row generated by a grouping set that excludes the column represented by *expression*.

►► GROUPING — (— *expression* —) ►►

expression

The argument values can be any built-in data type, but must be an item of a GROUP BY clause.

The data type of the result is a small integer. It is set to one of the following values:

- 1** The value of *expression* in the returned row is a null value, and the row was generated by the super-group. This generated row can be used to provide subtotal values for the GROUP BY expression.
- 0** The value is other than the above.

Example

The following query:

```
SELECT SALES_DATE, SALES_PERSON,
       SUM(SALES) AS UNITS_SOLD,
       GROUPING(SALES_DATE) AS DATE_GROUP,
       GROUPING(SALES_PERSON) AS SALES_GROUP
FROM SALES
GROUP BY CUBE( SALES_DATE, SALES_PERSON)
ORDER BY SALES_DATE, SALES_PERSON
```

Results in:

SALES_DATE	SALES_PERSON	UNITS_SOLD	DATE_GROUP	SALES_GROUP
12/31/1995	GOUNOT	1	0	0
12/31/1995	LEE	6	0	0
12/31/1995	LUCCHESSI	1	0	0
12/31/1995	-	8	0	1
03/29/1996	GOUNOT	11	0	0
03/29/1996	LEE	12	0	0
03/29/1996	LUCCHESSI	4	0	0
03/29/1996	-	27	0	1
03/30/1996	GOUNOT	21	0	0
03/30/1996	LEE	21	0	0
03/30/1996	LUCCHESSI	4	0	0
03/30/1996	-	46	0	1
03/31/1996	GOUNOT	3	0	0
03/31/1996	LEE	27	0	0
03/31/1996	LUCCHESSI	1	0	0
03/31/1996	-	31	0	1
04/01/1996	GOUNOT	14	0	0
04/01/1996	LEE	25	0	0
04/01/1996	LUCCHESSI	4	0	0
04/01/1996	-	43	0	1
-	GOUNOT	50	1	0
-	LEE	91	1	0
-	LUCCHESSI	14	1	0
-	-	155	1	1

An application can recognize a SALES_DATE subtotal row by the fact that the value of DATE_GROUP is 0 and the value of SALES_GROUP is 1. A SALES_PERSON subtotal row can be recognized by the fact that the value of DATE_GROUP is 1 and the value of SALES_GROUP is 0. A grand total row can be recognized by the fact that the value of both DATE_GROUP and SALES_GROUP is 1.

JSON_ARRAYAGG

The JSON_ARRAYAGG function returns a JSON array containing an array element for each value in a set of JSON or SQL values.

data-type

ccsid-clause

normalize-clause

JSON-expression

The expression to use to generate a value in the JSON array. The result type of this expression can be any built-in data type except XML, ROWID, or DATALINK. It cannot be CHAR or VARCHAR bit data. It cannot be a user-defined type that is sourced on any of these data types.

FORMAT JSON or FORMAT BSON

Specifies whether *JSON-expression* is already formatted data.

FORMAT JSON

JSON-expression is formatted as JSON data. If *JSON-expression* is a character or graphic string data type, it is treated as JSON data. If *JSON-expression* is a binary string data type, it is interpreted as UTF-8 or UTF-16 data.

FORMAT BSON

JSON-expression is formatted as the BSON representation of JSON data and must be a binary string data type.

If neither **FORMAT JSON** nor **FORMAT BSON** is specified:

- If *JSON-expression* is one of the built-in functions `JSON_ARRAY`, `JSON_OBJECT`, `JSON_QUERY`, `JSON_ARRAYAGG`, or `JSON_OBJECTAGG`, the explicit or implicit **FORMAT** value of the function's **RETURNING** clause determines the format of *JSON-expression*.
- If *JSON-expression* is a binary string type, it is interpreted as **FORMAT BSON**.
- Otherwise, *JSON-expression* is considered unformatted data. If the generated value is not numeric, the result string will be constructed with strings enclosed in quotes and any special characters will be escaped. A numeric value that is not a valid JSON number, such as `INFINITY` or `NAN`, will result in an error.

ORDER BY

Specifies the order of the rows from the same grouping set that are processed in the aggregation. If the **ORDER BY** clause is not specified, or if the **ORDER BY** clause cannot differentiate the order of the sort key value, the rows in the same grouping set are arbitrarily ordered.

sort-key-expression

Specifies a sort key value that is either a column name or an expression. The data type of the column or expression must not be a `DATALINK` or `XML` value..

ASC

Processes the *sort-key-expression* in ascending order. This is the default.

DESC

Processes the *sort-key-expression* in descending order.

The ordering is based on the values of the sort keys, which might or might not be used in *JSON-expression*.

The sum of the length attributes of the *sort-key-expressions* must not exceed 3.5 gigabytes.

If a collating sequence other than `*HEX` is in effect when the statement that contains the `JSON_ARRAYAGG` function is executed and the *sort-key-expressions* are `SBCS` data, mixed data, or Unicode data, then the result is obtained by comparing weighted values. The weighted values are derived by applying the collating sequence to the *sort-key-expressions*.

ABSENT ON NULL or NULL ON NULL

Specifies what to return when an array element produced by *JSON-expression* is the null value.

ABSENT ON NULL

A null array element is not included in the JSON array. This is the default.

NULL ON NULL

A null array element is included in the JSON array.

RETURNING *data-type*

Specifies the format of the result.

data-type

The data type of the result. For CHAR and VARCHAR results, the CCSID cannot be 65535. The default is CLOB(2G) CCSID 1208.

If a CCSID is specified and the *data-type* is GRAPHIC, VARGRAPHIC, or DBCLOB, the CCSID must be a Unicode CCSID.

If the CCSID attribute is not specified, the CCSID is determined as described in [“CAST specification” on page 176](#).

FORMAT JSON

JSON data is returned as a JSON string.

ENCODING UTF8 or ENCODING UTF16

The encoding to use when *data-type* is a binary string type. This clause is only allowed for binary string types. The default for binary strings is UTF8.

The result can be null. If the set of values is empty, the result is the null value.

Example

- Return a JSON array containing all the department numbers.

```
SELECT JSON_ARRAYAGG(deptno) AS deptlist FROM dept;
```

The result is the following JSON array.

```
["A00", "B01", "C01", "D01", "D11", "D21", "E01", "E11", "E21", "F22", "G22", "H22", "I22", "J22"]
```

- Return a JSON array for each department containing a list of employees assigned to that department.

```
SELECT workdept, JSON_ARRAYAGG(lastname ORDER BY lastname) AS dept_employees
FROM emp
WHERE workdept LIKE 'D%'
GROUP BY workdept;
```

The result is the following 2 rows.

DEPTNO	PROJLIST
D11	["ADAMSON", "BROWN", "JOHN", "JONES", "LUTZ", "PIANKA", "SCOUTTEN", "STERN", "WALKER", "YAMAMOTO", "YOSHIMURA"]
D21	["JEFFERSON", "JOHNSON", "MARINO", "MONTEVERDE", "PEREZ", "PULASKI", "SMITH"]

- Return a JSON object that contains a list of departments and employees in each department.

```
SELECT JSON_OBJECT('department number' VALUE deptno,
                  'department name' VALUE deptname,
                  'employee list' VALUE
                    JSON_ARRAYAGG(
                      JSON_OBJECT('last name' VALUE lastname,
                                   'employee id' VALUE empno)
                      ORDER BY lastname))
FROM dept LEFT OUTER JOIN emp ON deptno = workdept
WHERE deptno LIKE 'D%'
GROUP BY deptno, deptname;
```

The result is the following 3 rows.

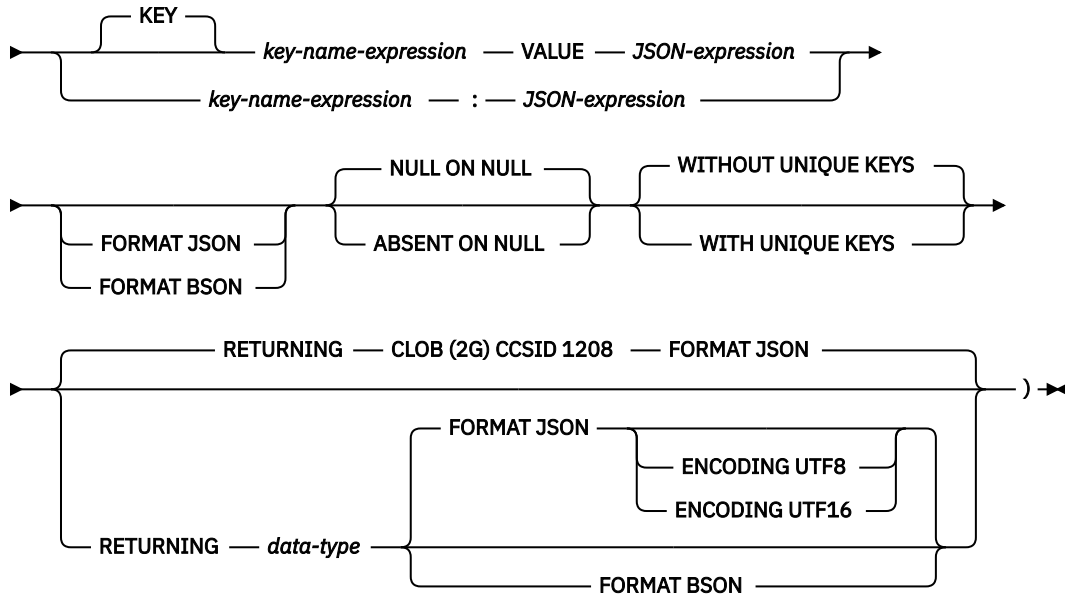

```
{
  "department number": "D11",
  "department name": "MANUFACTURING SYSTEMS",
  "employee list": [
    {"last name": "ADAMSON", "employee id": "000150"},
    {"last name": "BROWN", "employee id": "000200"},
    {"last name": "JOHN", "employee id": "200220"},
    {"last name": "JONES", "employee id": "000210"},
    {"last name": "LUTZ", "employee id": "000220"},
    {"last name": "PIANKA", "employee id": "000160"},
    {"last name": "SCOUTTEN", "employee id": "000180"},
    {"last name": "STERN", "employee id": "000060"},
    {"last name": "WALKER", "employee id": "000190"}
  ]
}
```

```
        {"last name":"YAMAMOTO","employee id":"200170"},
        {"last name":"YOSHIMURA","employee id":"000170"}]}
{"department number":"D21","department name":"ADMINISTRATION SYSTEMS",
  "employee list":[{"last name":"JEFFERSON","employee id":"000150"},
    {"last name":"JOHNSON","employee id":"000150"},
    {"last name":"MARINO","employee id":"000150"},
    {"last name":"MONTEVERDE","employee id":"000150"},
    {"last name":"PEREZ","employee id":"000150"},
    {"last name":"PULASKI","employee id":"000150"},
    {"last name":"SMITH","employee id":"000150"}]}
{"department number":"D01","department name":"DEVELOPMENT CENTER"}
```

JSON_OBJECTAGG

The JSON_OBJECTAGG function returns a JSON object containing a *key:value* pair for each specific key and value in a set of SQL values.

►► JSON_OBJECTAGG — (→

data-type

ccsid-clause

normalize-clause

key-name-expression

The name of the JSON key. The name must not be null. When using the colon form for defining a *key:value* pair, *key-name-expression* must be a character string literal. Otherwise, the result of *key-name-expression* must be a built-in character or graphic string data type. It cannot be CHAR or VARCHAR bit data.

JSON-expression

The expression to use to generate the JSON value associated with *key-name-expression*. The result type of this expression can be any built-in data type except XML, ROWID, or DATALINK. It cannot be CHAR or VARCHAR bit data. It cannot be a user-defined type that is sourced on any of these data types.

FORMAT JSON or FORMAT BSON

Specifies whether *JSON-expression* is already formatted data.

FORMAT JSON

JSON-expression is formatted as JSON data. If *JSON-expression* is a character or graphic string data type, it is treated as JSON data. If *JSON-expression* is a binary string data type, it is interpreted as UTF-8 or UTF-16 data.

FORMAT BSON

JSON-expression is formatted as the BSON representation of JSON data and must be a binary string data type.

If neither FORMAT JSON nor FORMAT BSON is specified:

- If *JSON-expression* is one of the built-in functions JSON_ARRAY, JSON_OBJECT, JSON_QUERY, JSON_ARRAYAGG, or JSON_OBJECTAGG, the explicit or implicit FORMAT value of the function's RETURNING clause determines the format of *JSON-expression*.
- If *JSON-expression* is a binary string type, it is interpreted as FORMAT BSON.
- Otherwise, *JSON-expression* is considered unformatted data. If the generated value is not numeric, the result string will be constructed with strings enclosed in quotes and any special characters will be escaped. A numeric value that is not a valid JSON number, such as INFINITY or NAN, will result in an error.

NULL ON NULL or ABSENT ON NULL

Specifies what to return when *JSON-expression* is the null value.

NULL ON NULL

A null value is returned. This is the default.

ABSENT ON NULL

The *key:value* pair is omitted from the JSON object.

WITHOUT UNIQUE KEYS or WITH UNIQUE KEYS

Specifies whether the key values for the resulting JSON object must be unique.

WITHOUT UNIQUE KEYS

The resulting JSON object will not be checked for duplicate keys. This is the default.

WITH UNIQUE KEYS

The resulting JSON object is required to have unique key values. An error will be issued if duplicate keys are generated.

Generating a JSON object with unique keys is considered the best practice. If *key-name-expression* generates unique key names, omit WITH UNIQUE KEYS to improve performance.

RETURNING data-type

Specifies the format of the result.

data-type

The data type of the result. For CHAR and VARCHAR results, the CCSID cannot be 65535. The default is CLOB(2G) CCSID 1208.

If a CCSID is specified and the *data-type* is GRAPHIC, VARGRAPHIC, or DBCLOB, the CCSID must be a Unicode CCSID.

If the CCSID attribute is not specified, the CCSID is determined as described in [“CAST specification”](#) on page 176.

FORMAT JSON

JSON data is returned as a JSON string.

ENCODING UTF8 or ENCODING UTF16

The encoding to use when *data-type* is a binary string type. This clause is only allowed for binary string types. The default for binary strings is UTF8.

FORMAT BSON

JSON data is returned in BSON format. When FORMAT BSON is specified, *data-type* must be a VARBINARY or BLOB string type.

The result can be null. If the set of values is empty, the result is the null value.

Example

- Return a JSON object containing the manager numbers for each department. If no manager is assigned, omit the department from the result.

```
SELECT JSON_OBJECTAGG(deptno VALUE mgrno ABSENT ON NULL) FROM dept;
```

The result is the following JSON string. Note that the order of entries in the JSON object is not defined.

```
{ "A00": "000010", "B01": "000020", "C01": "000030", "D11": "000060", "D21": "000070",  
  "E01": "000050", "E11": "000090", "E21": "000100" }
```

- Return a JSON object for each department containing a list of projects assigned to that department.

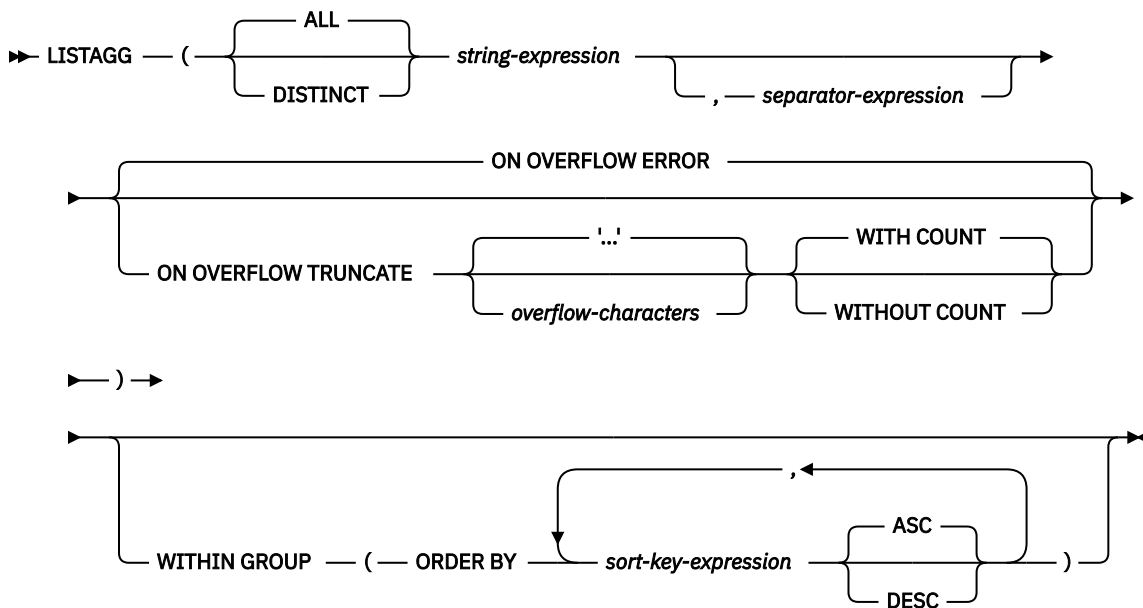

```
SELECT deptno, JSON_OBJECTAGG(projno VALUE projname) AS projlist FROM proj  
WHERE deptno LIKE 'D%'  
GROUP BY deptno;
```

The result is the following 3 rows. Note that the order of entries in the JSON object is not defined.

DEPTNO	PROJLIST
D01	{ "AD3100": "ADMIN SERVICES", "MA2100": "WELD LINE AUTOMATION" }
D11	{ "MA2110": "W L PROGRAMMING", "MA2111": "W L PROGRAM DESIGN", "MA2112": "W L ROBOT DESIGN", "MA2113": "W L PROD CONT PROGS" }
D21	{ "AD3110": "GENERAL ADMIN SYSTEMS", "AD3111": "PAYROLL PROGRAMMING", "AD3112": "PERSONNEL PROGRAMMING", "AD3113": "ACCOUNT PROGRAMMING" }

LISTAGG

The LISTAGG function aggregates a set of string elements into one string by concatenating the strings. Optionally, a separator string can be provided which is inserted between contiguous input strings.

The LISTAGG function aggregates a set of string values for the group into one string by appending the *string-expression* values based on the order specified in the WITHIN GROUP clause.

The function is applied to the set of values that are derived from the first argument by the elimination of null values. If DISTINCT is specified, duplicate *string-expression* values are eliminated. If a separator argument is specified that is not the null value, the separator value is inserted between each pair of non-null *string-expression* values.

string-expression

An expression that specifies the string values to be aggregated. The expression must return a value that is a built-in string, numeric, or datetime data type. If the value is a numeric or datetime data type, it is implicitly cast to VARCHAR before the function is evaluated.

separator-expression

An expression that defines the string that is to be used between non-null *string-expression* values. The expression must return a value that is a built-in string, numeric, or datetime data type. If the value is a numeric or datetime data type, it is implicitly cast to VARCHAR before the function is evaluated. *separator-expression* must not contain a scalar-fullselect, a column reference, or a reference to a function that is not deterministic or external action.

If no *separator-expression* is specified or if *separator-expression* is the null value, there is no separation between *string-expression* values.

ON OVERFLOW ERROR or ON OVERFLOW TRUNCATE

Specifies the behavior if the actual length of the aggregated result string exceeds the result length. The default is ON OVERFLOW ERROR.

ON OVERFLOW ERROR

Indicates an error is returned if the actual length of the result string exceeds the result length.

ON OVERFLOW TRUNCATE

Indicates the aggregated result string will be truncated if the actual length of the result string exceeds the result length. The truncation will occur at the end of a string value. The result string will contain complete entries including a final *separator-expression*, if one is defined.

If *string-expression* is a binary string or a non-Unicode graphic string, this option is not allowed.

'...' or overflow-characters

Indicates a character string constant to be appended to the end of the result string to indicate truncation occurred.

'...'

Indicates that three period characters are appended directly after the last complete entry. This is the default.

overflow-characters

Indicates the character string constant to be appended directly after the last complete entry.

WITH COUNT or WITHOUT COUNT

Indicates whether the number of truncated values is included at the end of the result string. The default is WITH COUNT.

WITH COUNT

The number of values truncated from the string is appended to the end of the result string. It is formatted as a number within parentheses. For example, if 10 entries were truncated, (10) is included at the end of the string.

WITHOUT COUNT

No indication of the number of entries that were truncated is returned.

WITHIN GROUP

Indicates that the aggregation will follow the specified ordering within the grouping set.

If WITHIN GROUP is not specified, the ordering of strings within the result is not deterministic.

ORDER BY

Specifies the order of the rows from the same grouping set that are processed in the aggregation. If the ORDER BY clause is not specified, or if the ORDER BY clause cannot differentiate the order of the sort key value, the rows in the same grouping set are arbitrarily ordered.

sort-key-expression

Specifies a sort key value that is either a column name or an expression. The data type of the column or expression must not be a DATALINK or XML value.

The ordering of the aggregated elements is based on the values of the sort keys.

The sum of the length attributes of the *sort-key-expression* must not exceed 3.5 gigabytes.

ASC

Processes the *sort-key-expression* in ascending order. This is the default.

DESC

Processes the *sort-key-expression* in descending order.

If a collating sequence other than *HEX is in effect when the statement that contains the LISTAGG function is executed and the *sort-key-expressions* are SBCS data, mixed data, or Unicode data, then the result is obtained by comparing weighted values. The weighted values are derived by applying the collating sequence to the *sort-key-expressions*.

The result data type of LISTAGG is based on the data type of *string-expression*

<i>Table 49. Determining the result data type and length</i>	
Data type of <i>string-expression</i>	Result data type and length
CHAR(<i>n</i>) or VARCHAR(<i>n</i>)	VARCHAR(MAX(4000, <i>n</i>))
CLOB(<i>n</i>)	CLOB(1M)
GRAPHIC(<i>n</i>) or VARGRAPHIC(<i>n</i>)	VARGRAPHIC(MAX(2000, <i>n</i>))
DBCLOB(<i>n</i>)	DBCLOB(1M)
BINARY(<i>n</i>) or VARBINARY(<i>n</i>)	VARBINARY(MAX(4000, <i>n</i>))

Table 49. Determining the result data type and length (continued)

Data type of <i>string-expression</i>	Result data type and length
BLOB(<i>n</i>)	BLOB(1M)

The result data type can exceed VARCHAR(4000), VARBINARY(4000), or VARGRAPHIC(2000) if a derived size is used to determine the size of the result. The maximum possible value is the maximum for the result data type. The following example yields a return data type of VARCHAR(10000):

```
LISTAGG(CAST(NAME AS VARCHAR(10000)), ',')
```

If the actual length of the aggregated result string exceeds the result length, the behavior is determined by the ON OVERFLOW clause.

The CCSID of the result is the CCSID of *string-expression*.

If a collating sequence other than *HEX is in effect when the statement that contains the LISTAGG function is executed, and the *sort-key-expressions* are SBCS data, mixed data, or Unicode data, then the result is obtained by comparing the weighted values. The weighted values are derived by applying the collating sequence to the *sort-key-expressions*.

The result can be null. If the function is applied to an empty set or all of the *string-expression* values in the set are null values, the result is the null value.

Rules

- LISTAGG cannot be used as part of an OLAP specification.

Example

- Produce an alphabetical list of comma-separated names, grouped by department.

```
SELECT workdept,
       LISTAGG(lastname, ', ') WITHIN GROUP(ORDER BY lastname)
       AS employees
FROM emp
GROUP BY workdept
```

Generates the following result:

```
WORKDEPT  EMPLOYEES
A00       HAAS, HEMMINGER, LUCCHESSI, O'CONNELL, ORLANDO
B01       THOMPSON
C01       KWAN, NATZ, NICHOLLS, QUINTANA
D11       ADAMSON, BROWN, JOHN, JONES, LUTZ, PIANKA, SCOUTTEN, STERN, WALKER
          YAMAMOTO, YOSHIMURA
D21       JEFFERSON, JOHNSON, MARINO, MONTEVERDE, PEREZ, PULASKI, SMITH
E01       GEYER
E11       HENDERSON, PARKER, SCHNEIDER, SCHWARTZ, SETRIGHT, SMITH, SPRINGER
E21       ALONZO, GOUNOT, LEE, MEHTA, SPENSER, WONG
```

MAX

The MAX aggregate function returns the maximum value in a set of values in a group.

expression

The argument values can be any built-in data type other than a DataLink or XML.

The data type and length attribute of the result are the same as the data type and length attribute of the argument values. When the argument is a string, the result has the same CCSID as the argument.

If a collating sequence other than *HEX is in effect when the statement that contains the MAX function is executed and the arguments are SBCS data, mixed data, or Unicode data, then the result is obtained by comparing weighted values for each value in the set. The weighted values are based on the collating sequence.

The function is applied to the set of values derived from the argument values by the elimination of null values.

The result can be null. If the set of values is empty, the result is a null value. Otherwise, the result is the maximum value in the set.

The specification of DISTINCT has no effect on the result and is not advised.

Notes

Results involving DECFLOAT special values: If the data type of the argument is decimal floating-point and positive or negative Infinity, sNaN, or NaN is found, the maximum value is determined using decimal floating-point ordering rules. See “Numeric comparisons” on page 99. If multiple representations of the same decimal floating-point value are found (for example, 2.00 and 2.0), it is unpredictable which representation will be returned.

Examples

- Using the EMPLOYEE table, set the host variable MAX_SALARY (DECIMAL(7,2)) to the maximum monthly salary (SALARY / 12) value.

```
SELECT MAX(SALARY) /12
INTO :MAX_SALARY
FROM EMPLOYEE
```

Results in MAX_SALARY being set to 4395.83.

- Using the PROJECT table, set the host variable LAST_PROJ (CHAR(24)) to the project name (PROJNAME) that comes last in the sort sequence.

```
SELECT MAX(PROJNAME)
INTO :LAST_PROJ
FROM PROJECT
```

Results in LAST_PROJ being set to 'WELD LINE PLANNING '.

MEDIAN

The MEDIAN function returns the median of a set of numbers.

►► MEDIAN — (— *numeric-expression* —) ◄◄

numeric-expression

An expression that returns a built-in numeric, character-string, or graphic-string data type. If the argument is a character-string or graphic-string, it is cast to DECFLOAT(34) before evaluating the function.

If the argument is DECFLOAT(*n*), the result of the function is DECFLOAT(34). Otherwise, the result of the function is a double precision floating-point number.

The function is applied to the set of values derived from the argument values by the elimination of null values.

The result can be null. If *numeric-expression* is null or the function is applied to the empty set, the result is the null value.

Notes

When used in an OLAP specification, only the *window-partition-clause* can be specified.

Examples

- Calculate the median salary of the employees in department D11 from the EMPLOYEE table.

```
SELECT MEDIAN(SALARY)
FROM EMPLOYEE
WHERE WORKDEPT = 'D11';
```

The result is 24680.00. Department D11 has 11 employees. The middle row of a group of 11 values is the sixth row. The result of MEDIAN over that group is the value of the sixth row, which is 24680.00.

- Calculate the median salary of the employees in department E21 from the EMPLOYEE table.

```
SELECT MEDIAN(SALARY)
FROM EMPLOYEE
WHERE WORKDEPT = 'E21';
```

The result is 24605.00. Department E21 has six employees. Because there are an even number of rows, the MEDIAN is computed by interpolating a value between the middle two rows. The middle two rows are the third row with the value 23840.00 and the fourth row with the value 25370.00. MEDIAN is computed by averaging those two values, which is 24605.00.

MIN

The MIN aggregate function returns the minimum value in a set of values in a group.

expression

The argument values can be any built-in data type other than a DataLink or XML.

The data type and length attribute of the result are the same as the data type and length attribute of the argument values. When the argument is a string, the result has the same CCSID as the argument. The result can be null.

If a collating sequence other than *HEX is in effect when the statement that contains the MIN function is executed and the arguments are SBCS data, mixed data, or Unicode data, then the result is obtained by comparing weighted values for each value in the set.

The function is applied to the set of values derived from the argument values by the elimination of null values.

If the set of values is empty, the result is a null value. Otherwise, the result is the minimum value in the set.

The specification of DISTINCT has no effect on the result and is not advised.

Notes

Results involving DECFLOAT special values: If the data type of the argument is decimal floating-point and positive or negative Infinity, sNaN, or NaN is found, the minimum value is determined using decimal floating-point ordering rules. See “Numeric comparisons” on page 99. If multiple representations of the same decimal floating-point value are found (for example, 2.00 and 2.0), it is unpredictable which representation will be returned.

Examples

- Using the EMPLOYEE table, set the host variable COMM_SPREAD (DECIMAL(7,2)) to the difference between the maximum and minimum commission (COMM) for the members of department (WORKDEPT) 'D11'.

```
SELECT MAX(COMM) - MIN(COMM)
  INTO :COMM_SPREAD
  FROM EMPLOYEE
  WHERE WORKDEPT = 'D11'
```

Results in COMM_SPREAD being set to 1118 (that is, 2580 - 1462).

- Using the PROJECT table, set the host variable FIRST_FINISHED (CHAR(10)) to the estimated ending date (PRENDATE) of the first project scheduled to be completed.

```
SELECT MIN(PRENDATE)
  INTO :FIRST_FINISHED
  FROM PROJECT
```

Results in FIRST_FINISHED being set to '1982-09-15'.

PERCENTILE_CONT

The PERCENTILE_CONT function returns the value that corresponds to the specified percentile given a sort specification by using a continuous distribution model.

►► PERCENTILE_CONT — (— *percentile-expression* —) — WITHIN GROUP — (— ORDER BY ►►

percentile-expression

Specifies the percentile to be calculated by the function. *percentile-expression* must return any built-in numeric, character-string, or graphic-string data type. If the argument is a character-string or graphic-string, it is cast to DECFLOAT(34) before evaluating the function. The value must be between 0 and 1. *percentile-expression* must not contain a *scalar-fullselect*, a column reference, or a user-defined function reference.

WITHIN GROUP

Specifies that the percentile is to be calculated over the rows identified in the group.

sort-expression

Specifies the set of values over which to calculate the percentile as well as the order of the set. *sort-expression* must return a built-in numeric, character string, or graphic string data type. If the *sort-expression* is a character-string or graphic-string, it is cast to DECFLOAT(34) before evaluating the function.

ASC

Specifies that the percentile is to be calculated using values from *sort-expression* in ascending order.

DESC

Specifies that the percentile is to be calculated using values from *sort-expression* in descending order.

The result is the value at the percentile specified by *percentile-expression* over the set of values identified by *sort-expression*. The set of values is treated as a continuous distribution. The calculated percentile is an interpolated value which might not have appeared in the input set. If the data type of *sort-expression* is DECFLOAT(*n*), the result of the function is DECFLOAT(34). Otherwise the data type of the result is double-precision floating point.

The function is applied to the set of values derived from the argument values by the elimination of null values.

The result can be null. If *percentile-expression* is null or if the function is applied to the empty set, the result is the null value.

Notes

When used in an OLAP specification, only the *window-partition-clause* can be specified.

Results involving DECFLOAT special values: If the data type of the argument is decimal floating-point and a special value of sNaN or -sNaN, or both +Infinity and -Infinity are included in the aggregation, an error or warning is returned. Otherwise, if +NaN or -NaN is found, the result is +NaN or -NaN. If +Infinity or -Infinity is found, the result is +Infinity or -Infinity.

Column masks: If a column that is referenced in the *sort-expression* of the PERCENTILE_CONT function is defined to have a column mask, the column mask is not applied.

The result of using PERCENTILE_CONT(0.5) WITHIN GROUP (ORDER BY *sort-expression*) is equivalent to specifying MEDIAN(*sort-expression*).

Examples

- **Example 1:** Calculate the median salary of the employees in department D11.

```
SELECT PERCENTILE_CONT(0.5) WITHIN GROUP (ORDER BY SALARY) FROM EMPLOYEE
WHERE WORKDEPT = 'D11'
```

The result is 24680.00. There are 11 employees in department D11. The middle row of a group of 11 values is the sixth row. Since there are an odd number of rows, PERCENTILE_CONT for the percentile 0.5 returns the value of the sixth row, which is 24680.00.

- **Example 2:** Calculate the median commission of the employees in department E21.

```
SELECT PERCENTILE_CONT(0.5) WITHIN GROUP (ORDER BY COMM) FROM EMPLOYEE
WHERE WORKDEPT = 'E21'
```

The result is 1968.5. Since there are an even number of rows, the PERCENTILE_CONT is computed by interpolating a value between the middle two rows. The middle two rows are row three with value 1907.00 and row four with value 2030.00. PERCENTILE_CONT is computed by averaging those two values, which results in 1968.5.

PERCENTILE_DISC

The PERCENTILE_DISC function returns the value that corresponds to the specified percentile given a sort specification by using a discrete distribution model.

►► PERCENTILE_DISC (— *percentile-expression* —) — WITHIN GROUP — (— ORDER BY ►►

percentile-expression

Specifies the percentile to be calculated by the function. *percentile-expression* must return any built-in numeric, character-string, or graphic-string data type. If the argument is a character-string or graphic-string, it is cast to DECFLOAT(34) before evaluating the function. The value must be between 0 and 1. *percentile-expression* must not contain a *scalar-fullselect*, a column reference, or a user-defined function reference.

WITHIN GROUP

Specifies that the percentile is to be calculated over the rows identified in the group.

sort-expression

Specifies the set of values over which to calculate the percentile as well as the order of the set. *sort-expression* must return a built-in numeric, character string, or graphic string data type.

ASC

Specifies that the percentile is to be calculated using values from *sort-expression* in ascending order.

DESC

Specifies that the percentile is to be calculated using values from *sort-expression* in descending order.

The result is the value at the percentile specified by *percentile-expression* over the set of values identified by *sort-expression*. Each value in the input set is treated as a discrete value. The calculated percentile is always a value that appeared in the input set. The data type of the result is the same as the data type of the result of *sort-expression*.

If a collating sequence other than *HEX is in effect when the statement that contains the PERCENTILE_DISC function is executed, and the *sort-expression* is SBCS data, mixed data, or Unicode data, then the result is determined by comparing the weighted values. The weighted values are derived by applying the collating sequence to the *sort-expression*.

The function is applied to the set of values derived from the argument values by the elimination of null values.

The result can be null. If *percentile-expression* is null or if the function is applied to the empty set, the result is the null value.

Notes

When used in an OLAP specification, only the *window-partition-clause* can be specified.

Results involving DECFLOAT special values: If the data type of the argument is decimal floating-point and a special value of sNaN or -sNaN, or both +Infinity and -Infinity are included in the aggregation, an error or warning is returned. Otherwise, if +NaN or -NaN is found, the result is +NaN or -NaN. If +Infinity or -Infinity is found, the result is +Infinity or -Infinity.

Column masks: If a column that is referenced in the *sort-expression* of the PERCENTILE_DISC function is defined to have a column mask, the column mask is not applied.

Examples

- **Example 1:** Calculate the median salary as a discrete value of the employees in department D11.

```
SELECT PERCENTILE_DISC(0.5) WITHIN GROUP (ORDER BY SALARY)
FROM EMPLOYEE
WHERE WORKDEPT = 'D11'
```

The result is 24680.00. There are 11 employees in department D11. The middle row of a group of 11 values is the sixth row. Since there are an odd number of rows, PERCENTILE_DISC for the percentile 0.5 returns the value of the sixth row, which is 24680.00.

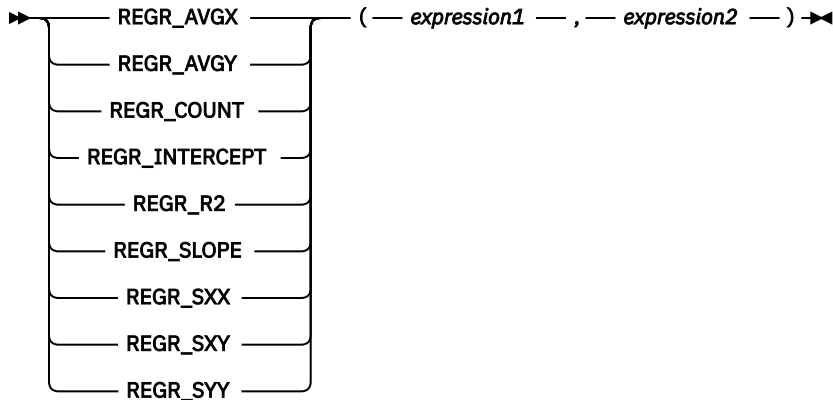

- **Example 2:** Calculate the median commission as a discrete value of the employees in department E21.

```
SELECT PERCENTILE_DISC(0.5) WITHIN GROUP (ORDER BY COMM)
FROM EMPLOYEE
WHERE WORKDEPT = 'E21'
```

The result is 1907.00. Since there are an even number of rows, PERCENTILE_DISC is computed by returning the first of the two middle rows, which is row three with value 1907.00.

Regression functions

The regression functions support the fitting of an ordinary-least-squares regression line of the form $y = a * x + b$ to a set of number pairs. The first element of each pair (*expression1*) is interpreted as a value of the dependent variable (that is, a "y value"). The second element of each pair (*expression2*) is interpreted as a value of the independent variable (that is, an "x value").

expression1

An expression that returns a value of any built-in numeric, character-string, or graphic-string data type. If the argument is a character-string or graphic-string, it is cast to DECFLOAT(34) before evaluating the function.

expression2

An expression that returns a value of any built-in numeric, character-string, or graphic-string data type. If the argument is a character-string or graphic-string, it is cast to DECFLOAT(34) before evaluating the function.

The REGR_COUNT function returns the number of non-null number pairs used to fit the regression line.

The REGR_INTERCEPT function returns the y-intercept of the regression line ("b" in the equation $y = a * x + b$).

The REGR_R2 function returns the coefficient of determination ("R-squared" or "goodness-of-fit") for the regression.

The REGR_SLOPE function returns the slope of the line ("a" in the equation $y = a * x + b$).

The REGR_AVGX, REGR_AVGY, REGR_SXX, REGR_SXY, and REGR_SYY functions return quantities that can be used to compute various diagnostic statistics needed for the evaluation of the quality and statistical validity of the regression model.

The data type of the result of REGR_COUNT is bigint. For the remaining functions, if either argument is DECFLOAT(n), the data type of the result is DECFLOAT(34); otherwise, the data type of the result is double-precision floating-point. If either argument is a special decimal floating-point value, the rules for general arithmetic operations for decimal floating-point apply. See [“General arithmetic operation rules for DECFLOAT” on page 162](#) for more information.

The result can be null. When not null, the result of REGR_R2 is between 0 and 1, and the result of both REGR_SXX and REGR_SYY is non-negative.

Each function is applied to the set of (*expression1*, *expression2*) pairs derived from the argument values by the elimination of all pairs for which either *expression1* or *expression2* is null.

If the set is empty, REGR_COUNT returns zero and the remaining functions return a null value.

If the set is not empty, the functions return results defined as follows:

REGR_COUNT

The number of non-null pairs in the set

REGR_SLOPE

If $VARIANCE(expression2)$ is positive:

```
REGR_SLOPE(expression1,expression2) =  
  COVARIANCE(expression1,expression2)/VARIANCE(expression2)
```

If $VARIANCE(expression2)$ is equal to zero, returns the null value.

REGR_INTERCEPT

If $VARIANCE(expression2)$ is positive:

```
REGR_INTERCEPT(expression1, expression2) =  
  AVG(expression1) - REGR_SLOPE(expression1, expression2) * AVG(expression2)
```

If $VARIANCE(expression2)$ is equal to zero, returns the null value.

REGR_R2

If $VARIANCE(expression2)$ is positive:

- If $VARIANCE(expression1)$ is positive:

```
REGR_R2(expression1, expression2) =  
  POWER(CORRELATION(expression1, expression2), 2)
```

- if $VARIANCE(expression1)$ is equal to zero:

```
REGR_R2(expression1, expression2) = 1
```

If $VARIANCE(expression2)$ is equal to zero, returns the null value.

REGR_AVGX

```
REGR_AVGX(expression1, expression2) = AVG(expression2)
```

REGR_AVGY

```
REGR_AVGY(expression1, expression2) = AVG(expression1)
```

REGR_SXX

```
REGR_SXX(expression1, expression2) =  
  REGR_COUNT(expression1, expression2) * VARIANCE(expression2)
```

REGR_SYY

```
REGR_SYY(expression1, expression2) =  
  REGR_COUNT(expression1, expression2) * VARIANCE(expression1)
```

REGR_SXY

```
REGR_SXY(expression1, expression2) =  
  REGR_COUNT(expression1, expression2) * COVARIANCE(expression1, expression2)
```

The order in which the values are aggregated is undefined, but every intermediate result must be within the range of the result data type.

The usual diagnostic statistics that accompany a linear-regression analysis can be computed in terms of the above functions. For example:

```
Adjusted R2  
  1 - ( (1 - REGR_R2) * ((REGR_COUNT - 1) / (REGR_COUNT - 2)) )  
Standard error  
  SQRT( (REGR_SYY - (POWER(REGR_SXY,2)/REGR_SXX))/(REGR_COUNT-2) )  
Total sum of squares  
  REGR_SYY  
Regression sum of squares  
  POWER(REGR_SXY,2) / REGR_SXX  
Residual sum of squares  
  (Total sum of squares)-(Regression sum of squares)  
t statistic for slope
```

$$t \text{ statistic for } y\text{-intercept} = \frac{\text{REGR_INTERCEPT} / ((\text{Standard error}) * \sqrt{(1/\text{REGR_COUNT}) + (\text{POWER}(\text{REGR_AVGX}, 2) / \text{REGR_SXX}))}}{\text{REGR_SLOPE} * \sqrt{\text{REGR_SXX}}} / (\text{Standard error})$$

Note

Syntax alternatives: REGR_ICPT can be specified as a synonym for REGR_INTERCEPT.

Example

- Using the EMPLOYEE table, compute an ordinary-least-squares regression line that expresses the bonus of an employee in department (WORKDEPT) 'A00' as a linear function of the employee's salary. Set the host variables SLOPE, ICPT, RSQR to the slope, intercept, and coefficient of determination of the regression line, respectively. Also set the host variables AVGSAL and AVGBONUS to the average salary and average bonus, respectively, of the employees in department 'A00', and set the host variable CNT (integer) to the number of employees in department 'A00' for whom both salary and bonus data are available. Store the remaining regression statistics in host variables SXX, SYY, and SXY.

```
SELECT REGR_SLOPE(BONUS, SALARY), REGR_INTERCEPT(BONUS, SALARY),
       REGR_R2(BONUS, SALARY), REGR_COUNT(BONUS, SALARY),
       REGR_AVGX(BONUS, SALARY), REGR_AVGY(BONUS, SALARY),
       REGR_SXX(BONUS, SALARY), REGR_SYY(BONUS, SALARY),
       REGR_SXY(BONUS, SALARY)
INTO  :SLOPE, :ICPT,
      :RSQR, :CNT,
      :AVGSAL, :AVGBONUS,
      :SXX, :SYY,
      :SXY
FROM  EMPLOYEE
WHERE WORKDEPT = 'A00'
```

When using the sample table, the host variables are set to the following approximate values:

```
SLOPE:      0.018363799188747826
ICPT:       69.8388031396513
RSQR:       0.9526220829162935
CNT:        5
AVGSAL:     40850.0
AVGBONUS:   820.0
SXX:        4.74575E8
SYY:        168000.0
SXY:        8715000.0
```

STDDEV_POP or STDDEV

The STDDEV_POP function returns the biased standard deviation ($/n$) of a set of numbers.

The formula used to calculate the biased standard deviation is:

```
STDDEV_POP = SQRT(VAR_POP)
```

where $SQRT(VAR_POP)$ is the square root of the variance.

numeric-expression

An expression that returns a value of any built-in numeric, character-string, or graphic-string data type. If the argument is a character-string or graphic-string, it is cast to DECFLOAT(34) before evaluating the function.

If the argument is DECFLOAT(n), the result of the function is DECFLOAT(34). Otherwise, the data type of the result is double-precision floating point.

The function is applied to the set of values derived from the argument values by the elimination of null values. If DISTINCT is specified, duplicate values are eliminated.

The result can be null. If the set of values is empty, the result is a null value. Otherwise, the result is the standard deviation of the values in the set.

The order in which the values are added is undefined, but every intermediate result must be within the range of the result data type.

Notes

Results involving DECFLOAT special values: If the data type of the argument is decimal floating-point and a special value of sNaN or -sNaN, or both +Infinity and -Infinity are included in the aggregation, an error or warning is returned. Otherwise, if +NaN or -NaN is found, the result is +NaN or -NaN. If +Infinity or -Infinity is found, the result is +Infinity or -Infinity.

Syntax alternatives: STDEV_POP should be used for conformance to the SQL 2003 standard.

Example

- Using the EMPLOYEE table, set the host variable DEV (double-precision floating point) to the standard deviation of the salaries for those employees in department A00.

```
SELECT STDDEV_POP(SALARY)
  INTO :DEV
  FROM EMPLOYEE
  WHERE WORKDEPT = 'A00';
```

Results in DEV being set to approximately 9742.43.

STDDEV_SAMP

The STDDEV_SAMP function returns the sample standard deviation ($\sqrt{n-1}$) of a set of numbers.

The formula used to calculate the sample standard deviation is:

```
STDDEV_SAMP = SQRT(VAR_SAMP)
```

where `SQRT(VAR_SAMP)` is the square root of the sample variance.

numeric-expression

An expression that returns a value of any built-in numeric, character-string, or graphic-string data type. If the argument is a character-string or graphic-string, it is cast to `DECFLOAT(34)` before evaluating the function.

If the argument is `DECFLOAT(n)`, the result of the function is `DECFLOAT(34)`. Otherwise, the data type of the result is double-precision floating point.

The function is applied to the set of values derived from the argument values by the elimination of null values. If `DISTINCT` is specified, duplicate values are eliminated.

The result can be null. If the set of values is empty or contains only one row, the result is a null value. Otherwise, the result is the standard deviation of the values in the set.

The order in which the values are added is undefined, but every intermediate result must be within the range of the result data type.

Notes

Results involving DECFLOAT special values: If the data type of the argument is decimal floating-point and a special value of `sNaN` or `-sNaN`, or both `+Infinity` and `-Infinity` are included in the aggregation, an error or warning is returned. Otherwise, if `+NaN` or `-NaN` is found, the result is `+NaN` or `-NaN`. If `+Infinity` or `-Infinity` is found, the result is `+Infinity` or `-Infinity`.

Example

- Using the `EMPLOYEE` table, set the host variable `DEV` (double-precision floating point) to the sample standard deviation of the salaries for those employees in department `A00`.

```
SELECT STDDEV_SAMP(SALARY)
  INTO :DEV
  FROM EMPLOYEE
  WHERE WORKDEPT = 'A00';
```

Results in `DEV` being set to approximately 10892.37.

SUM

The SUM function returns the sum of a set of numbers.

numeric-expression

An expression that returns a value of any built-in numeric, character-string, or graphic-string data type. If the argument is a character-string or graphic-string, it is cast to DECFLOAT(34) before evaluating the function.

The data type of the result is the same as the data type of the argument values except that the result is:

- DECFLOAT(34) if the argument values are DECFLOAT(16).
- A double-precision floating point if the argument values are single-precision floating point
- A large integer if the argument values are small integers
- A decimal with precision *mp* and scale *s* if the argument values are decimal or nonzero scale binary numbers with precision *p* and scale *s*.

For information about the values of *p*, *s*, and *mp*, see [“Decimal arithmetic in SQL” on page 160](#).

The function is applied to the set of values derived from the argument values by the elimination of null values. If DISTINCT is specified, duplicate values are eliminated.

The order in which the values are added is undefined, but every intermediate result must be within the range of the result data type.

Notes

Results involving DECFLOAT special values: If the data type of the argument is decimal floating-point and a special value of sNaN or -sNaN, or both +Infinity and -Infinity are included in the aggregation, an error is signaled. Otherwise, if +NaN or -NaN is found, the result is +NaN or -NaN. If +Infinity or -Infinity is found, the result is +Infinity or -Infinity.

Example

- Using the EMPLOYEE table, set the host variable JOB_BONUS (DECIMAL(9,2)) to the total bonus (BONUS) paid to clerks (JOB='CLERK').

```
SELECT SUM(BONUS)
INTO :JOB_BONUS
FROM EMPLOYEE
WHERE JOB = 'CLERK'
```

Results in JOB_BONUS being set to 4000.

VAR_POP or VARIANCE or VAR

The VAR_POP function returns the biased variance (/n) of a set of numbers.

The formula used to calculate the biased variance is:

$$\text{VAR_POP} = \text{SUM}(X**2) / \text{COUNT}(X) - (\text{SUM}(X) / \text{COUNT}(X))**2$$

numeric-expression

An expression that returns a value of any built-in numeric, character-string, or graphic-string data type. If the argument is a character-string or graphic-string, it is cast to DECFLOAT(34) before evaluating the function.

If the argument is DECFLOAT(n), the result of the function is DECFLOAT(34). Otherwise, the data type of the result is double-precision floating point.

The function is applied to the set of values derived from the argument values by the elimination of null values. If DISTINCT is specified, duplicate values are eliminated.

The result can be null. If the set of values is empty, the result is a null value. Otherwise, the result is the variance of the values in the set.

The order in which the values are added is undefined, but every intermediate result must be within the range of the result data type.

Notes

Results involving DECFLOAT special values: If the data type of the argument is decimal floating-point and a special value of sNaN or -sNaN, or both +Infinity and -Infinity are included in the aggregation, an error or warning is returned. Otherwise, if +NaN or -NaN is found, the result is +NaN or -NaN. If +Infinity or -Infinity is found, the result is +Infinity or -Infinity.

Syntax alternatives: VAR_POP should be used for conformance to the SQL 2003 standard.

Example

- Using the EMPLOYEE table, set the host variable VARNCE (double-precision floating point) to the variance of the salaries for those employees in department A00.

```
SELECT VAR_POP(SALARY)
  INTO :VARNCE
  FROM EMPLOYEE
  WHERE WORKDEPT = 'A00';
```

Results in VARNCE being set to approximately 94 915 000.

VAR_SAMP or VARIANCE_SAMP

The VAR_SAMP function returns the sample variance ($/n-1$) of a set of numbers.

The formula used to calculate the sample variance is:

$$\text{VAR_SAMP} = (\text{SUM}(X**2) - ((\text{SUM}(X)**2) / (\text{COUNT}(X)))) / (\text{COUNT}(X) - 1)$$

numeric-expression

An expression that returns a value of any built-in numeric, character-string, or graphic-string data type. If the argument is a character-string or graphic-string, it is cast to DECFLOAT(34) before evaluating the function.

If the argument is DECFLOAT(*n*), the result of the function is DECFLOAT(34). Otherwise, the data type of the result is double-precision floating point.

The function is applied to the set of values derived from the argument values by the elimination of null values. If DISTINCT is specified, duplicate values are eliminated.

The result can be null. If the set of values is empty or contains only one row, the result is a null value. Otherwise, the result is the variance of the values in the set.

The order in which the values are added is undefined, but every intermediate result must be within the range of the result data type.

Notes

Results involving DECFLOAT special values: If the data type of the argument is decimal floating-point and a special value of sNaN or -sNaN, or both +Infinity and -Infinity are included in the aggregation, an error or warning is returned. Otherwise, if +NaN or -NaN is found, the result is +NaN or -NaN. If +Infinity or -Infinity is found, the result is +Infinity or -Infinity.

Syntax alternatives: VAR_SAMP should be used for conformance to the SQL 2003 standard.

Example

- Using the EMPLOYEE table, set the host variable VARNCE (double-precision floating point) to the sample variance of the salaries for those employees in department A00.

```
SELECT VAR_SAMP(SALARY)
INTO :VARNCE
FROM EMPLOYEE
WHERE WORKDEPT = 'A00';
```

Results in VARNCE being set to approximately 1 186 437 500.

XMLAGG

The XMLAGG function returns an XML sequence containing an item for each non-null value in a set of XML values.

►► XMLAGG ►►

XML-expression

An expression that returns an XML value.

ORDER BY

Specifies the order of the rows from the same grouping set that are processed in the aggregation. If the ORDER BY clause is not specified, or if the ORDER BY clause cannot differentiate the order of the sort key value, the rows in the same grouping set are arbitrarily ordered.

sort-key-expression

Specifies a sort key value that is either a column name or an expression. The data type of the column or expression must not be a DATALINK or XML value.

The ordering is based on the values of the sort keys, which might or might not be used in *XML-expression*.

The sum of the length attributes of the *sort-key-expressions* must not exceed 3.5 gigabytes.

If a collating sequence other than *HEX is in effect when the statement that contains the XMLAGG function is executed and the *sort-key-expressions* are SBCS data, mixed data, or Unicode data, then the result is obtained by comparing weighted values. The weighted values are derived by applying the collating sequence to the *sort-key-expressions*.

The function is applied to the set of values derived from the argument values by elimination of null values.

The data type of the result is XML. The result can be null. If the set of values is empty, the result is the null value. Otherwise, the result is an XML sequence containing an item for each value in the set.

Example

Note: XMLAGG does not insert blank spaces or new line characters in the output. All example output has been formatted to enhance readability.

- Group employees by their department, generate a "Department" element for each department with its name as the attribute, nest all the "emp" elements for employees in each department, and order the "emp" elements by LASTNAME.

```
SELECT XMLSERIALIZE(XMLDOCUMENT (
    XMLELEMENT(NAME "Department",
        XMLATTRIBUTES(E.WORKDEPT AS "name"),
        XMLAGG(XMLELEMENT ( NAME "emp", E.LASTNAME)
            ORDER BY E.LASTNAME)
        ))
    AS CLOB(200)) AS "dept_list"
FROM EMPLOYEE E
WHERE E.WORKDEPT IN ('C01', 'E21')
GROUP BY WORKDEPT
```

The result of the query would look similar to the following result:

```
dept_list
-----
<Department name="C01">
```

```
<emp>KWAN</emp>
<emp>NICHOLLS</emp>
<emp>QUINTANA</emp>
</Department>
<Department name="E21">
  <emp>GOUNOT</emp>
  <emp>LEE</emp>
  <emp>MEHTA</emp>
  <emp>SPENSER</emp>
</Department>
```

XMLGROUP

The XMLGROUP function returns an XML value that is a well-formed XML document.

Notes:

¹ The same clause must not be specified more than once.

expression

The content of each XML element is specified by an expression. The data type of *expression* must not be ROWID or DATALINK or a distinct type that is based on ROWID or DATALINK. The expression can be any SQL expression. If the expression is not a simple column reference, an element name must be specified. When AS ATTRIBUTES is specified, the data type of *expression* must not be XML or a distinct type that is based on XML.

AS qname-identifier

Specifies the XML element name or attribute name as an SQL identifier. The *qname-identifier* must be of the form of an XML qualified name, or QName. See the W3C XML namespace specifications for more details on valid names. If the name is qualified, the namespace prefix must be declared within the scope. If *qname-identifier* is not specified, *expression* must be a column name. The element name or attribute name is created from the column name using the fully escaped mapping from a column name to a QName.

ORDER BY

Specifies the order of the rows from the same grouping set that are processed in the aggregation. If the ORDER BY clause is not specified, or if the ORDER BY clause cannot differentiate the order of the sort key value, the rows in the same grouping set are arbitrarily ordered.

sort-key-expression

Specifies a sort key value that is either a column name or an expression. The data type of the column or expression must not be a DATALINK or XML value.

The ordering is based on the values of the sort keys, which might or might not be used in *XML-expression*.

OPTION

Specifies additional options for constructing the XML value. If no OPTION clause is specified, the default behavior applies.

ROW row-name

Specifies the name of the element to which each row is mapped. If this option is not specified, the default element name is "row".

ROOT root-name

Specifies the name of the root element. If this option is not specified, the default root element name is "rowset".

AS ATTRIBUTES

Specifies that each expression is mapped to an attribute value with column name or *qname-identifier* serving as the attribute name.

If a collating sequence other than *HEX is in effect when the statement that contains the XMLGROUP function is executed and the *sort-key-expressions* are SBCS data, mixed data, or Unicode data, then the result is obtained by comparing weighted values. The weighted values are derived by applying the collating sequence to the *sort-key-expressions*.

The result of the function is XML. The result can be null. If the set of values is empty, the result is the null value. Otherwise, the result is an XML sequence containing an item for each value in the set.

Notes

The default behavior defines a simple mapping between a result set and an XML value. Some additional notes about function behavior apply:

- By default, each row is transformed into an XML element named "row" and each *expression* is transformed into a nested element with the column name or *qname-identifier* as the element name.
- The null handling behavior is NULL ON NULL. A null value for an expression maps to the absence of the subelement. If all expression values are null, no row element is generated. If no row elements are generated, the function returns the null value.
- The binary encoding scheme for binary and FOR BIT DATA data types is base64Binary encoding.
- The order of the row subelements in the root element will be the same as the order in which the rows are returned in the query result set.

Examples

Note: XMLGROUP does not insert blank spaces or new line characters in the output. All example output has been formatted to enhance readability.

Assume the following table T1 with columns C1 and C2:

C1	C2
1	2
-	2
1	-
-	-

- The following example shows an XMLGROUP query and output fragment with default behavior, using a single top-level element to represent the table:

```
SELECT XMLGROUP(C1, C2) FROM T1
```

Returns the following value for the single result row:

```
<rowset>
<row><C1>1</C1><C2>2</C2></row>
<row><C2>2</C2></row>
<row><C1>1</C1></row>
</rowset>
```

- The following example shows an XMLGROUP query and output fragment with attribute centric mapping. Instead of appearing as nested elements as in the previous example, the data is mapped to element attributes:

```
SELECT XMLGROUP(C1, C2 OPTION AS ATTRIBUTES) FROM T1
```

Returns the following value for the single result row:

```
<rowset>
<row C1="1" C2="2"/>
<row C2="2"/>
<row C1="1"/>
</rowset>
```

- The following example shows an XMLGROUP query and output fragment with the default <rowset> root element replaced by <document> and the default <row> element replaced by <entry>. Columns C1 and C2 are returned as <column1> and <column2> elements, and the return set is ordered by column C1:

```
SELECT XMLGROUP(C1 AS "column1", C2 AS "column2"
ORDER BY C1 OPTION ROW "entry" ROOT "document")
FROM T1
```

Returns the following value for the single result row:

```
<document>
<entry> <column1>1</column1><column2>2</column2></entry>
<entry> <column1>1</column1></entry>
<entry> <column2>2</column2></entry>
</document>
```

Scalar functions

A *scalar function* takes input argument(s) and returns a single value result. A scalar function can be used wherever an expression can be used.

The restrictions on the use of aggregate functions do not apply to scalar functions, because a scalar function is applied to single parameter values rather than to sets of values. The argument of a scalar function can be a function. However, the restrictions that apply to the use of expressions and aggregate functions also apply when an expression or aggregate function is used within a scalar function. For example, the argument of a scalar function can be an aggregate function only if an aggregate function is allowed in the context in which the scalar function is used.

Example

The result of the following SELECT statement has as many rows as there are employees in department D01:

```
SELECT EMPNO, LASTNAME, YEAR(CURRENT DATE - BIRTHDATE)
FROM EMPLOYEE
WHERE WORKDEPT = 'D01'
```

ABS or ABSVAL

The ABS function returns the absolute value of a number.

► `ABS` (`expression`) ◄
 ↳ `ANSVAL` ◀

expression

An expression that returns a value of any built-in numeric, character-string, or graphic-string data type. A string argument is cast to double-precision floating point before evaluating the function. For more information about converting strings to double-precision floating point, see [“DOUBLE_PRECISION or DOUBLE” on page 392](#).

The data type of the result is the same as the data type of the argument values except that the result is:

- A double-precision floating point if the argument values are single-precision floating point
- A large integer if the argument values are small integers
- A decimal with precision *mp* and scale *s* if the argument values are decimal or nonzero scale binary numbers with precision *p* and scale *s*.

Note

Results involving DECFLOAT special values: For decimal floating-point values, the special values are treated as follows:

- ABS(NaN) and ABS(-NaN) return NaN.
- ABS(Infinity) and ABS(-Infinity) return Infinity.
- ABS(sNaN) and ABS(-sNaN) return sNaN.

Example

- Assume the host variable PROFIT is a large integer with a value of -50000.

```
SELECT ABS(:PROFIT)
FROM SYSIBM.SYSDUMMY1
```

Returns the value 50000.

ACOS

The ACOS function returns the arc cosine of the argument as an angle expressed in radians. The ACOS and COS functions are inverse operations.

►► ACOS — (— *expression* —) ►◄

expression

An expression that returns a value of any built-in numeric data type (except for DECFLOAT), character-string, or graphic-string data type. A string argument is cast to double-precision floating point before evaluating the function. For more information about converting strings to double-precision floating point, see [“DOUBLE_PRECISION or DOUBLE” on page 392](#). The value must be greater than or equal to -1 and less than or equal to 1.

The data type of the result is double-precision floating point. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

The result is greater than or equal to 0 and less than or equal to π .

Example

- Assume the host variable ACOSINE is a DECIMAL(10,9) host variable with a value of 0.070737202.

```
SELECT ACOS(:ACOSINE)
FROM SYSIBM.SYSDUMMY1
```

Returns the approximate value 1.49.

ADD_MONTHS

The ADD_MONTHS function returns a date or timestamp that represents *expression* plus *numeric-expression* months.

►► ADD_MONTHS (— *expression* — , — *numeric-expression* —) ►►

expression

An expression that returns a value of one of the following built-in data types: a date, a timestamp, a character string, or a graphic string.

If *expression* is a character or graphic string, its value must be a valid string representation of a date or timestamp. For the valid formats of string representations of dates and timestamps, see [“String representations of datetime values”](#) on page 75.

numeric-expression

An expression that returns a value of a built-in numeric data type with zero scale. A negative numeric value is allowed.

If *expression* is a timestamp, the result of the function is a timestamp with the same precision as *expression*. Otherwise, the result of the function is a date. If either argument can be null, the result can be null; if either argument is null, the result is the null value.

If *expression* is the last day of the month or if the resulting month has fewer days than the day component of *expression*, then the result is the last day of the resulting month. Otherwise, the result has the same day component as *expression*.

Example

- Assume today is January 31, 2000. Set the host variable ADD_MONTH with the last day of January plus 1 month.

```
SET :ADD_MONTH = ADD_MONTHS(LAST_DAY(CURRENT_DATE), 1 )
```

The host variable ADD_MONTH is set with the value representing the end of February, 2000-02-29.

- Assume DATE is a host variable with the value July 27, 1965. Set the host variable ADD_MONTH with the value of that day plus 3 months.

```
SET :ADD_MONTH = ADD_MONTHS(:DATE, 3)
```

The host variable ADD_MONTH is set with the value representing the day plus 3 months, 1965-10-27.

- It is possible to achieve similar results with the ADD_MONTHS function and date arithmetic. The following examples demonstrate the similarities and contrasts.

```
SET :DATEHV = DATE('2000-2-28') + 4 MONTHS
SET :DATEHV ADD_MONTHS('2000-2-28', 4)
```

In both cases, the host variable DATEHV is set with the value '2000-06-28'.

Now consider the same examples but with the date '2000-2-29' as the argument.

```
SET :DATEHV = DATE('2000-2-29') + 4 MONTHS
```

The host variable DATEHV is set with the value '2000-06-29'.

```
SET :DATEHV ADD_MONTHS('2000-2-29', 4)
```

The host variable DATEHV is set with the value '2000-06-30'.

In this case, the ADD_MONTHS function returns the last day of the month, which is June 30, 2000, instead of June 29, 2000. The reason is that February 29 is the last day of the month. So, the ADD_MONTHS function returns the last day of June.

ANTILOG

The ANTILOG function returns the anti-logarithm (base 10) of a number. The ANTILOG and LOG functions are inverse operations.

► ANTILOG (— *expression* —) ◄

expression

An expression that returns a value of any built-in numeric, character-string, or graphic-string data type. A string argument is cast to double-precision floating point before evaluating the function. For more information about converting strings to double-precision floating point, see [“DOUBLE_PRECISION or DOUBLE”](#) on page 392.

If the data type of the argument is DECFLOAT(*n*), the result is DECFLOAT(*n*). Otherwise, the data type of the result is double-precision floating point. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

Note

Results involving DECFLOAT special values: For decimal floating-point values the special values are treated as follows:

- ANTILOG(NaN) returns NaN.
- ANTILOG(-NaN) returns -NaN.
- ANTILOG(Infinity) returns Infinity.
- ANTILOG(-Infinity) returns 0.
- ANTILOG(sNaN) and ANTILOG(-sNaN) return a warning or error.⁵¹

Example

- Assume the host variable ALOG is a DECIMAL(10,9) host variable with a value of 1.499961866.

```
SELECT ANTILOG(:ALOG)
FROM SYSIBM.SYSDUMMY1
```

Returns the approximate value 31.62.

⁵¹ If *YES is specified for the SQL_DECFLOAT_WARNINGS query option, NaN and -NaN are returned respectively with a warning.

ARRAY_MAX_CARDINALITY

The ARRAY_MAX_CARDINALITY function returns a value representing the maximum number of elements an array can contain. This is the cardinality specified on the CREATE TYPE (Array) statement for the user-defined array type.

►► ARRAY_MAX_CARDINALITY (— *array-expression* —) ◄◄

array-expression

The expression can be either an SQL variable or parameter of an array data type, or a cast specification of a parameter marker to an array data type.

The ARRAY_MAX_CARDINALITY function is identical to the MAX_CARDINALITY function. For more information, see [“MAX_CARDINALITY”](#) on page 491 .

ARRAY_TRIM

The ARRAY_TRIM function returns a copy of the array argument from which the specified number of elements have been removed from the end of the array.

►► ARRAY_TRIM (— *array-variable-name* — , ) ◄◄

The ARRAY_TRIM function is identical to the TRIM_ARRAY function. For more information, see [“TRIM_ARRAY” on page 611](#) .

ASCII

The ASCII function returns the ASCII code value of the leftmost character of the argument as an integer.

►► ASCII — (— *expression* —) ►◄

expression

An expression that specifies the string containing the character to evaluate. *expression* must be any built-in numeric or string data type. The first character of the string will be converted to ASCII CCSID 367 for processing by the function.

The result of the function is a large integer. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

Examples

- Return the integer value for the ASCII representation of 'A'.

```
SELECT ASCII('A')
FROM SYSIBM.SYSDUMMY1
```

Returns the value 65.

ASIN

The ASIN function returns the arc sine of the argument as an angle expressed in radians. The ASIN and SIN functions are inverse operations.

►► ASIN — (— *expression* —) ►◄

expression

An expression that returns a value of any built-in numeric data type (except for DECFLOAT), character-string, or graphic-string data type. A string argument is cast to double-precision floating point before evaluating the function. For more information about converting strings to double-precision floating point, see [“DOUBLE_PRECISION or DOUBLE” on page 392](#). The value must be greater than or equal to -1 and less than or equal to 1.

The data type of the result is double-precision floating point. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

The result is greater than or equal to $-\pi/2$ and less than or equal to $\pi/2$.

Example

- Assume the host variable ASINE is a DECIMAL(10,9) host variable with a value of 0.997494987.

```
SELECT ASIN(:ASINE)
FROM SYSIBM.SYSDUMMY1
```

Returns the approximate value 1.50.

ATAN

The ATAN function returns the arc tangent of the argument as an angle expressed in radians. The ATAN and TAN functions are inverse operations.

►► ATAN ((— *expression* —)) ◄◄

expression

An expression that returns a value of any built-in numeric data type (except for DECFLOAT), character-string, or graphic-string data type. A string argument is cast to double-precision floating point before evaluating the function. For more information about converting strings to double-precision floating point, see [“DOUBLE_PRECISION or DOUBLE”](#) on page 392.

The data type of the result is double-precision floating point. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

The result is greater than or equal to $-\pi/2$ and less than or equal to $\pi/2$.

Example

- Assume the host variable ATANGENT is a DECIMAL(10,8) host variable with a value of 14.10141995.

```
SELECT ATAN (: ATANGENT)
FROM SYSIBM.SYSDUMMY1
```

Returns the approximate value 1.50.

ATANH

The ATANH function returns the hyperbolic arc tangent of a number, in radians. The ATANH and TANH functions are inverse operations.

►► ATANH — (— *expression* —) ◄◄

expression

An expression that returns a value of any built-in numeric data type (except for DECFLOAT), character-string, or graphic-string data type. A string argument is cast to double-precision floating point before evaluating the function. For more information about converting strings to double-precision floating point, see [“DOUBLE_PRECISION or DOUBLE” on page 392](#). The value must be greater than -1 and less than 1.

The data type of the result is double-precision floating point. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

Example

- Assume the host variable HATAN is a DECIMAL(10,9) host variable with a value of 0.905148254.

```
SELECT ATANH(:HATAN)
FROM SYSIBM.SYSDUMMY1
```

Returns the approximate value 1.50.

ATAN2

The ATAN2 function returns the arc tangent of x and y coordinates as an angle expressed in radians. The first and second arguments specify the x and y coordinates, respectively.

►► ATAN2 — (— *expression-1* — , — *expression-2* —) ◄◄

expression-1

An expression that returns a value of any built-in numeric data type (except for DECFLOAT), character-string, or graphic-string data type. A string argument is cast to double-precision floating point before evaluating the function. For more information on converting strings to double-precision floating point, see [“DOUBLE_PRECISION or DOUBLE” on page 392](#). If one argument is 0, the other argument must not be 0.

expression-2

An expression that returns a value of any built-in numeric data type (except for DECFLOAT), character-string, or graphic-string data type. A string argument is cast to double-precision floating point before evaluating the function. For more information on converting strings to double-precision floating point, see [“DOUBLE_PRECISION or DOUBLE” on page 392](#). If one argument is 0, the other argument must not be 0.

The data type of the result is double-precision floating point. If any argument can be null, the result can be null; if any argument is null, the result is the null value.

Example

- Assume that host variables HATAN2A and HATAN2B are DOUBLE host variables with values of 1 and 2, respectively.

```
SELECT ATAN2 (:HATAN2A, :HATAN2B)
FROM SYSIBM.SYSDUMMY1
```

Returns a double precision floating-point number with an approximate value of 1.1071487.

BASE64_DECODE

The BASE64_DECODE scalar function returns a character string that has been Base64 decoded. Base64 encoding is widely used to represent binary data as a string.

►► BASE64_DECODE — (— *character-string* —) ►◄

character-string

An expression that returns a character string in CCSID 1208 that is currently Base64 encoded.

The result of the function is a varying length character for bit data string that contains *character-string* after being Base64 decoded.

Example

- Decode a binary string that was originally X'1122334455'. The result is the original value.

```
VALUES QSYS2.BASE64_DECODE('ESIzRFU=');
```

BASE64_ENCODE

The BASE64_ENCODE scalar function returns the Base64 encoded version of a binary value.

►► BASE64_ENCODE — (— *binary-string* —) ◄◄

binary-string

An expression that returns a built-in binary string to be encoded.

The result of the function is a CLOB in CCSID 1208 that contains the bytes of *binary-string* as a Base64-encoded string.

Examples

- Encode a string that contains the value X'1122334455'.

```
VALUES QSYS2.BASE64_ENCODE(X'1122334455');
```

The result is: ESIzRFU=.

- Encode a character string that contains the EBCDIC value 'ABC'.

```
VALUES QSYS2.BASE64_ENCODE('ABC');
```

The result is: wCLD

- Encode a UTF-8 string that contains the value 'ABC'.

```
VALUES QSYS2.BASE64_ENCODE(CAST('ABC' AS VARCHAR(10) CCSID 1208));
```

The result is: QUJD

BIGINT

The BIGINT function returns a big integer representation.

Numeric to Big Integer

►► BIGINT (— *numeric-expression* —) ◄◄

String to Big Integer

►► BIGINT (— *string-expression* —) ◄◄

Datetime to Big Integer

►► BIGINT (— *datetime-expression* —) ◄◄

The BIGINT function returns a big integer representation of:

- A number
- A character or graphic string representation of a decimal number
- A character or graphic string representation of an integer
- A character or graphic string representation of a floating-point number
- A character or graphic string representation of a decimal floating-point number
- A date
- A time
- A timestamp

Numeric to Big Integer

numeric-expression

An expression that returns a numeric value of any built-in numeric data type.

The result is the same number that would occur if the argument were assigned to a big integer column or variable. If the whole part of the argument is not within the range of big integers, an error is returned. The fractional part of the argument is truncated.

String to Big Integer

string-expression

An expression that returns a value that is a character-string or graphic-string representation of a number.

The result is the same number that would result from CAST(*string-expression* AS BIGINT). Leading and trailing blanks are eliminated and the resulting string must conform to the rules for forming a floating-point, decimal floating-point, integer, or decimal constant. If the whole part of the argument is not within the range of big integers, an error is returned. Any fractional part of the argument is truncated.

Datetime to Big Integer

datetime-expression

An expression that is one of the following data types:

- DATE. The result is a BIGINT value representing the date as *yyyymmdd*.
- TIME. The result is a BIGINT value representing the time as *hhmmss*.

- **TIMESTAMP.** The result is a **BIGINT** value representing the timestamp as *yyyymmddhhmmss*. The fractional seconds portion of the timestamp value is not included in the result.

The result of the function is a big integer. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

Note

Syntax alternatives: The **CAST** specification should be used to increase the portability of applications. For more information, see [“CAST specification”](#) on page 176.

Example

- Using the **EMPLOYEE** table, select the **SALARY** column in big integer form for further processing in the application.

```
SELECT BIGINT(SALARY)
FROM EMPLOYEE
```

BINARY

The BINARY function returns a BINARY representation of a string of any type.

►► BINARY — (— *string-expression* — , — *integer* —) ►►

The result of the function is a fixed-length binary string. If the first argument can be null, the result can be null; if the first argument is null, the result is the null value.

string-expression

A *string-expression* whose value must be a built-in character string, graphic string, binary string, or row ID data type.

integer

An integer constant that specifies the length attribute for the resulting binary string. The value must be between 1 and 32766.

If *integer* is not specified:

- If the *string-expression* is the empty string constant, the length attribute of the result is 1.
- Otherwise, the length attribute of the result is the same as the length attribute of the first argument, unless the argument is a graphic string. In this case, the length attribute of the result is twice the length attribute of the argument.

The actual length is the same as the length attribute of the result. If the length of the *string-expression* is less than the length of the result, the result is padded with hexadecimal zeroes up to the length of the result. If the length of the *string-expression* is greater than the length attribute of the result, truncation is performed. A warning (SQLSTATE 01004) is returned unless the first input argument is a character string and all the truncated characters are blanks, or the first input argument is a graphic string and all the truncated characters are double-byte blanks, or the first input argument is a binary string and all the truncated bytes are hexadecimal zeroes.

Note

Syntax alternatives: The CAST specification should be used to increase the portability of applications when the length is specified. For more information, see [“CAST specification”](#) on page 176.

Example

- The following function returns a BINARY for the string 'This is a BINARY'.

```
SELECT BINARY('This is a BINARY')
FROM SYSIBM.SYSDUMMY1
```

BITAND, BITANDNOT, BITOR, BITXOR, and BITNOT

These bitwise functions operate on the "two's complement" representation of the integer value of the input arguments and return the result as a corresponding base 10 integer value in a data type based on the data type of the input arguments.

BITNOT (— expression —)

Function	Description	A bit in the two's complement representation of the result is:
BITAND	Performs a bitwise AND operation.	1 only if the corresponding bits in both arguments are 1.
BITANDNOT	Clears any bit in the first argument that is in the second argument.	Zero if the corresponding bit in the second argument is 1; otherwise, the result is copied from the corresponding bit in the first argument.
BITOR	Performs a bitwise OR operation.	1 unless the corresponding bits in both arguments are zero.
BITXOR	Performs a bitwise exclusive OR operation.	1 unless the corresponding bits in both arguments are the same.
BITNOT	Performs a bitwise NOT operation.	Opposite of the corresponding bit in the argument.

expression

An expression that returns a value of any built-in numeric data type. Arguments of type DECIMAL, REAL, or DOUBLE are cast to DECFLOAT. The value is truncated to a whole number.

The bit manipulation functions can operate on up to 16 bits for SMALLINT, 32 bits for INTEGER, 64 bits for BIGINT, and 113 bits for DECFLOAT. The range of supported DECFLOAT values includes integers from -2^{112} to $2^{112} - 1$, and special values such as NaN or INFINITY are not supported. If the two arguments have different data types, the argument supporting fewer bits is cast to a value with the data type of the argument supporting more bits. This cast impacts the bits that are set for negative values. For example, -1 as a SMALLINT value has 16 bits set to 1, which when cast to an INTEGER value has 32 bits set to 1.

The result of the functions with two arguments has the data type of the argument that is highest in the data type precedence list for promotion. If either argument is DECFLOAT, the data type of the result is DECFLOAT(34). If either argument can be null, the result can be null; if either argument is null, the result is the null value.

The result of the BITNOT function has the same data type as the input argument, except that DECIMAL, REAL, DOUBLE, or DECFLOAT(16) returns DECFLOAT(34). If the argument can be null, the result can be null; if the argument is null, the result is the null value.

Use of the BITXOR function is recommended to toggle bits in a value. Use the BITANDNOT function to clear bits. BITANDNOT(val, pattern) operates more efficiently than BITAND(val, BITNOT(pattern)).

Example

The following examples are based on an ITEM table with a PROPERTIES column of type INTEGER.

- Return all items for which the third property bit is set.

```
SELECT ITEMID FROM ITEM
WHERE BITAND(PROPERTIES, 4) = 4
```

- Return all items for which the fourth or the sixth property bit is set.

```
SELECT ITEMID FROM ITEM
WHERE BITAND(PROPERTIES, 40) <> 0
```

- Clear the twelfth property of the item whose ID is 3412.

```
UPDATE ITEM
SET PROPERTIES = BITANDNOT(PROPERTIES, 2048)
WHERE ITEMID = 3412
```

- Set the fifth property of the item whose ID is 3412.

```
UPDATE ITEM
SET PROPERTIES = BITOR(PROPERTIES, 16)
WHERE ITEMID = 3412
```

- Toggle the eleventh property of the item whose ID is 3412.

```
UPDATE ITEM
SET PROPERTIES = BITXOR(PROPERTIES, 1024)
WHERE ITEMID = 3412
```

- Switch all the bits in a 16-bit value that has only the second bit on.

```
VALUES BITNOT(CAST(2 AS SMALLINT))
```

returns -3 (with a data type of SMALLINT).

BIT_LENGTH

The BIT_LENGTH function returns the length of a string expression in bits.

►► BIT_LENGTH — (— *expression* —) ►►

See [“LENGTH” on page 474](#) , [“CHARACTER_LENGTH or CHAR_LENGTH” on page 331](#) , and [“OCTET_LENGTH” on page 520](#) for similar functions.

expression

An expression that returns a value of any built-in numeric or string data type. A numeric argument is cast to a character string before evaluating the function. For more information about converting numeric to a character string, see [“VARCHAR” on page 623](#).

The result of the function is DECIMAL(31). If the argument can be null, the result can be null; if the argument is null, the result is the null value.

The result is the number of bits (bytes * 8) in the argument. The length of a string includes trailing blanks. The length of a varying-length string is the actual length in bits (bytes * 8), not the maximum length.

Example

- Assume table T1 has a GRAPHIC(10) column called C1.

```
SELECT BIT_LENGTH( C1 )  
FROM T1
```

Returns the value 160.

BLOB

The BLOB function returns a BLOB representation of a string of any type.

►► BLOB (— *string-expression* — , — *integer* —) ◄◄

string-expression

A *string-expression* whose value can be a character string, graphic string, binary string, or row ID.

integer

An integer constant that specifies the length attribute for the resulting binary string. The value must be between 1 and 2 147 483 647.

If *integer* is not specified:

- If the *string-expression* is the empty string constant, the length attribute of the result is 1.
- Otherwise, the length attribute of the result is the same as the length attribute of the first argument, unless the argument is a graphic string. In this case, the length attribute of the result is twice the length attribute of the argument.

The actual length of the result is the minimum of the length attribute of the result and the actual length of the expression (or twice the length of the expression when the input is graphic data). If the length of the *string-expression* is greater than the length attribute of the result, truncation is performed. A warning (SQLSTATE 01004) is returned unless the first input argument is a character string and all the truncated characters are blanks, or the first input argument is a graphic string and all the truncated characters are double-byte blanks, or the first input argument is a binary string and all the truncated bytes are hexadecimal zeroes.

The result of the function is a BLOB. If the first argument can be null, the result can be null; if the first argument is null, the result is the null value.

Note

Syntax alternatives: The CAST specification should be used to increase the portability of applications when the length is specified. For more information, see [“CAST specification”](#) on page 176.

Example

- The following function returns a BLOB for the string 'This is a BLOB'.

```
SELECT BLOB('This is a BLOB')
FROM SYSIBM.SYSDUMMY1
```

- The following function returns a BLOB for the large object that is identified by locator myclob_locator.

```
SELECT BLOB(:myclob_locator)
FROM SYSIBM.SYSDUMMY1
```

- Assume that a table has a BLOB column named TOPOGRAPHIC_MAP and a VARCHAR column named MAP_NAME. Locate any maps that contain the string 'Pellow Island' and return a single binary string with the map name concatenated in front of the actual map. The following function returns a BLOB for the large object that is identified by locator myclob_locator.

```
SELECT BLOB( MAP_NAME CONCAT ': ' CONCAT TOPOGRAPHIC_MAP )
FROM ONTARIO_SERIES_4
WHERE TOPOGRAPHIC_MAP LIKE '%Pellow Island%'
```

BSON_TO_JSON

The `BSON_TO_JSON` function converts a string containing formatted BSON data to a character string containing the data formatted as JSON.

►► `BSON_TO_JSON` — (— *JSON-expression* —) ►►

JSON-expression

Specifies an expression that returns a binary string value. It must contain formatted BSON data.

If *JSON-expression* is a JSON object with a key name of `SYSIBM_ROOT_ARRAY`, the key will be removed and the result will be the key's value.

If *JSON-expression* contains duplicate keys, the duplicate keys are retained in the result JSON string.

The data type of the result is `CLOB(2G)` with a CCSID of 1208.

If the argument can be null, the result can be null; if the argument is null, the result is the null value.

Note

If the outer JSON object's key is `SYSIBM_ROOT_ARRAY`, the key will be removed and the result will be the value of the key.

Example

- Insert a value that contains data formatted as BSON into a column that holds JSON values.

```
INSERT INTO TABLE1 (JSON_COLUMN) VALUES (BSON_TO_JSON(:BSON_DATA));
```

CARDINALITY

The `CARDINALITY` function returns a value representing the number of elements of an array.

►► `CARDINALITY` — (— *array-expression* —) ◄◄

array-expression

The expression can be either an SQL variable or parameter of an array data type, or a cast specification of a parameter marker to an array data type.

The value returned by the `CARDINALITY` function is the highest array index for which the array has an assigned element. This includes elements that have been assigned the null value.

The result of the function is `BIGINT`. The function returns 0 if the array is empty. The result can be null; if the argument is null, the result is the null value.

Example

Assume that array type `PHONENUMBERS` and array variable `RECENT_CALLS` are defined as follows:

```
CREATE TYPE PHONENUMBERS AS INTEGER ARRAY[50];  
DECLARE RECENT_CALLS PHONENUMBERS;
```

`RECENT_CALLS` contains three elements. The following `SET` statement assigns the number of calls that have been stored in the array so far to SQL variable `HOWMANYCALLS`:

```
SET HOWMANYCALLS = CARDINALITY(RECENT_CALLS)
```

After the statement executes, `HOWMANYCALLS` contains 3.

CEILING or CEIL

The CEILING or CEIL function returns the smallest integer value that is greater than or equal to *expression*.

► **CEILING** (*expression*) ►
 CEIL

expression

An expression that returns a value of any built-in numeric, character-string, or graphic-string data type. A string argument is cast to double-precision floating point before evaluating the function. For more information about converting strings to double-precision floating point, see [“DOUBLE_PRECISION or DOUBLE” on page 392](#).

The result of the function has the same data type and length attribute as the argument except that the scale is 0 if the argument is a decimal number. For example, an argument with a data type of DECIMAL(5,5) will result in DECIMAL(5,0).

If the argument can be null, the result can be null; if the argument is null, the result is the null value.

Note

Results involving DECFLOAT special values: For decimal floating-point values, the special values are treated as follows:

- CEILING(NaN) returns NaN.
- CEILING(-NaN) returns -NaN.
- CEILING(Infinity) returns Infinity.
- CEILING(-Infinity) returns -Infinity.
- CEILING(sNaN) and CEILING(-sNaN) return a warning or error.⁵²

Examples

- Find the highest monthly salary for all the employees. Round the result up to the next integer. The SALARY column has a decimal data type

```
SELECT CEIL(MAX(SALARY)/12)
FROM EMPLOYEE
```

This example returns 4396.00 because the highest paid employee is Christine Haas who earns \$52750.00 per year. Her average monthly salary before applying the CEIL function is 4395.83.

- Use CEILING on both positive and negative numbers.

```
SELECT CEILING( 3.5),
       CEILING( 3.1),
       CEILING(-3.1),
       CEILING(-3.5)
FROM SYSIBM.SYSDUMMY1
```

This example returns:

```
04.    04.   -03.   -03.
```

⁵² If *YES is specified for the SQL_DECFLOAT_WARNINGS query option, NaN and -NaN are returned respectively with a warning.

CHAR

The CHAR function returns a fixed-length character-string representation.

Integer to Character

►► CHAR — (— *integer-expression* —) ►►

Decimal to Character

►► CHAR — (— *decimal-expression* — , — *decimal-character* —) ►►

Floating-point to Character

►► CHAR — (— *floating-point-expression* — , — *decimal-character* —) ►►

Decimal floating-point to Character

►► CHAR — (— *decimal-floating-point-expression* — , — *decimal-character* —) ►►

Character to Character

►► CHAR — (— *character-expression* — , — *length* — , — *integer* —) ►►

DEFAULT

Graphic to Character

►► CHAR — (— *graphic-expression* — , — *length* — , — *integer* —) ►►

DEFAULT

Datetime to Character

►► CHAR — (— *datetime-expression* — , — ISO — , — USA — , — EUR — , — JIS — , — LOCAL —) ►►

The CHAR function returns a fixed-length character-string representation of:

- An integer number if the first argument is a SMALLINT, INTEGER, or BIGINT.
- A decimal number if the first argument is a decimal number.
- A double-precision floating-point number if the first argument is a DOUBLE or REAL.
- A decimal floating-point number if the first argument is a DECFLOAT.
- A character string if the first argument is any type of character string.
- A graphic string if the first argument is any type of graphic string.

- A date value if the first argument is a DATE.
- A time value if the first argument is a TIME.
- A timestamp value if the first argument is a TIMESTAMP.
- A row ID value if the first argument is a ROWID.

The result of the function is a fixed-length character string. If the first argument can be null, the result can be null; if the first argument is null, the result is the null value.

Integer to Character

integer-expression

An expression that returns a value that is a built-in integer data type (either SMALLINT, INTEGER, or BIGINT).

The result is the fixed-length character-string representation of the argument in the form of an SQL integer constant. The result consists of n characters that are the significant digits that represent the value of the argument with a preceding minus sign if the argument is negative. The result is left justified.

- If the argument is a small integer:

The length of the result is 6. If the number of characters in the result is less than 6, then the result is padded on the right with blanks.

- If the argument is a large integer:

The length of the result is 11. If the number of characters in the result is less than 11, then the result is padded on the right with blanks.

- If the argument is a big integer:

The length of the result is 20. If the number of characters in the result is less than 20, then the result is padded on the right with blanks.

The CCSID of the result is the default SBCS CCSID at the current server.

Decimal to Character

decimal-expression

An expression that returns a value that is a built-in decimal data type (either DECIMAL or NUMERIC). If a different precision and scale is wanted, the DECIMAL scalar function can be used to make the change.

decimal-character

Specifies the single-byte character constant that is used to delimit the decimal digits in the result character string. The character must be a period or comma. If the second argument is not specified, the decimal point is the default decimal point. For more information, see [“Decimal point” on page 116](#).

The result is a fixed-length character string representation of the argument. The result includes a decimal character and up to p digits, where p is the precision of the *decimal-expression* with a preceding minus sign if the argument is negative. Leading zeros are not returned. Trailing zeros are returned. If the scale of *decimal-expression* is zero, the decimal character is not returned.

The length of the result is $2+p$ where p is the precision of the *decimal-expression*. This means that a positive value will always include one trailing blank.

The CCSID of the result is the default SBCS CCSID at the current server.

Floating-point to Character

floating-point expression

An expression that returns a value that is a built-in floating-point data type (DOUBLE or REAL).

decimal-character

Specifies the single-byte character constant that is used to delimit the decimal digits in the result character string. The character must be a period or comma. If the second argument is not specified, the decimal point is the default decimal point. For more information, see [“Decimal point” on page 116](#).

The result is a fixed-length character-string representation of the argument in the form of a floating-point constant. The length of the result is 24. If the argument is negative, the first character of the result is a minus sign. Otherwise, the first character is a digit or the *decimal-character*. If the argument is zero, the result is 0E0. Otherwise, the result includes the smallest number of characters that can be used to represent the value of the argument such that the mantissa consists of a single digit other than zero followed by a *decimal-character* and a sequence of digits.

If the number of characters in the result is less than 24, then the result is padded on the right with blanks.

The CCSID of the result is the default SBCS CCSID at the current server.

Decimal floating-point to Character

decimal-floating-point expression

An expression that returns a value that is a built-in decimal floating-point data type (DECFLOAT).

decimal-character

Specifies the single-byte character constant that is used to delimit the decimal digits in the result character string. The character must be a period or comma. If the second argument is not specified, the decimal point is the default decimal point. For more information, see [“Decimal point” on page 116](#).

The result is a fixed-length character-string representation of the argument in the form of a decimal floating-point constant.

The length attribute of the result is 42. The actual length of the result is the smallest number of characters that represents the value of the argument, including the sign, digits, and *decimal-character*. Trailing zeros are significant. If the argument is negative, the first character of the result is a minus sign; otherwise, the first character is a digit or the *decimal-character*. If the argument is zero, the result is 0.

If the DECFLOAT value is Infinity, sNaN, or NaN, the strings 'INFINITY', 'SNAN', and 'NAN', respectively, are returned. If the special value is negative, a minus sign will be the first character in the string. The DECFLOAT special value sNaN does not result in an exception when converted to a string.

If the number of characters in the result is less than 42, then the result is padded on the right with blanks.

The CCSID of the result is the default SBCS CCSID at the current server.

Character to Character

character-expression

An expression that returns a value that is a built-in character-string data type.⁵³

length

An integer constant that specifies the length attribute for the resulting fixed length character string. The value must be between 1 and 32766 (32765 if nullable). If the first argument is DBCS-only mixed data, the second argument cannot be less than 4.

If the second argument is not specified or DEFAULT is specified:

- If the *character-expression* is the empty string constant, the length attribute of the result is 1.
- Otherwise, the length attribute of the result is the same as the length attribute of the first argument.

The actual length is the same as the length attribute of the result. If the length of the *character-expression* is less than the length attribute of the result, the result is padded with blanks up to the length of the result. If the length of the *character-expression* is greater than the length attribute of

⁵³ A binary string is also allowed if a CCSID is not specified or if a CCSID of 65535 is explicitly specified.

the result, truncation is performed. A warning (SQLSTATE 01004) is returned unless the truncated characters were all blanks.

integer

An integer constant that specifies the CCSID of the result. It must be a valid SBCS CCSID, mixed data CCSID, or 65535 (bit data). If the third argument is an SBCS CCSID, then the result is SBCS data. If the third argument is a mixed CCSID, then the result is mixed data and the length attribute of the result cannot be less than 4. If the third argument is 65535, then the result is bit data. If the third argument is a SBCS CCSID, then the first argument cannot be a DBCS-either or DBCS-only string.

If the third argument is not specified then:

- If the first argument is SBCS data, then the result is SBCS data. The CCSID of the result is the same as the CCSID of the first argument.
- If the first argument is mixed data and the length attribute of the result is greater than or equal to 4, then the result is mixed data. The CCSID of the result is the same as the CCSID of the first argument.
- If the first argument is mixed data that is DBCS-open or DBCS-either and the length attribute of the result is less than 4, the CCSID of the result is the associated SBCS CCSID for the mixed data CCSID.

Graphic to Character

graphic-expression

An expression that returns a value that is a built-in graphic-string data type. It must not be DBCS-graphic data.

length

An integer constant that specifies the length attribute for the resulting fixed length character string. The value must be between 1 and 32766 (32765 if nullable).

If the second argument is not specified or DEFAULT is specified:

- If the *graphic-expression* is the empty string constant, the length attribute of the result is 1.
- If the result is SBCS data, the result length is n .
- If the result is mixed data, the result length is $(2.5*(n-1)) + 4$.

The actual length is the same as the length attribute of the result. If the length of the *graphic-expression* is less than the length of the result, the result is padded with blanks up to the length of the result. If the length of the *graphic-expression* is greater than the length attribute of the result, truncation is performed. A warning (SQLSTATE 01004) is returned unless the truncated characters were all blanks.

integer

An integer constant that specifies the CCSID of the result. It must be a valid SBCS CCSID or mixed data CCSID. If the third argument is an SBCS CCSID, then the result is SBCS data. If the third argument is a mixed CCSID, then the result is mixed data and the length attribute of the result cannot be less than 4. The third argument cannot be 65535.

If the third argument is not specified, the CCSID of the result is the default CCSID at the current server. If the default CCSID is mixed data and the length attribute of the result is greater than or equal to 4, then the result is mixed data. Otherwise, the result is SBCS data.

Datetime to Character

datetime-expression

An expression that is one of the following three built-in data types

date

The result is the character-string representation of the date in the format specified by the second argument. If the second argument is not specified, the format used is the default date format. If the format is ISO, USA, EUR, or JIS, the length of the result is 10. Otherwise the length of the result is the length of the default date format. For more information see [“String representations of datetime values”](#) on page 75.

time

The result is the character-string representation of the time in the format specified by the second argument. If the second argument is not specified, the format used is the default time format. The length of the result is 8. For more information see [“String representations of datetime values”](#) on page 75.

timestamp

The second argument is not applicable and must not be specified.

The result is the character-string representation of the timestamp. If *datetime-expression* is a `TIMESTAMP(0)`, the length of the result is 19. If the data type of *datetime-expression* is a `TIMESTAMP(n)`, the length of the result is $20+n$. Otherwise the length of the result is 26.

The CCSID of the result is the default SBCS CCSID at the current server.

ISO, EUR, USA, or JIS

Specifies the date or time format of the resulting character string. For more information, see [“String representations of datetime values”](#) on page 75.

LOCAL

Specifies that the date or time format of the resulting character string should come from the `DATFMT`, `DATSEP`, `TIMFMT`, and `TIMSEP` attributes of the job at the current server.

Note

Syntax alternatives: The `CAST` specification should be used to increase the portability of applications when the first argument is a string and the length argument is specified. For more information, see [“CAST specification”](#) on page 176.

Examples

- Assume the column `PRSTDATE` has an internal value equivalent to 1988-12-25. The date format is `*MDY` and the date separator is a slash (/).

```
SELECT CHAR(PRSTDATE, USA)
FROM PROJECT
```

Results in the value '12/25/1988'.

```
SELECT CHAR(PRSTDATE)
FROM PROJECT
```

Results in the value '12/25/88'.

- Assume the column `STARTING` has an internal value equivalent to 17.12.30, the host variable `HOUR_DUR` (`DECIMAL(6,0)`) is a time duration with a value of 050000 (that is, 5 hours).

```
SELECT CHAR(STARTING, USA)
FROM CL_SCHED
```

Results in the value '5:12 PM'.

```
SELECT CHAR(STARTING + :HOUR_DUR, JIS)
FROM CL_SCHED
```

Results in the value '10:12:00'.

- Assume the column `RECEIVED` (timestamp) has an internal value equivalent to the combination of the `PRSTDATE` and `STARTING` columns.

```
SELECT CHAR(RECEIVED)
FROM IN_TRAY
```

Results in the value '1988-12-25-17.12.30.000000'.

- Use the CHAR function to make the type fixed-length character and reduce the length of the displayed results to 10 characters for the LASTNAME column (defined as VARCHAR(15)) of the EMPLOYEE table.

```
SELECT CHAR(LASTNAME, 10)  
FROM EMPLOYEE
```

For rows having a LASTNAME with a length greater than 10 characters (excluding trailing blanks), a warning (SQLSTATE 01004) that the value is truncated is returned.

- Use the CHAR function to return the values for EDLEVEL (defined as SMALLINT) as a fixed length string.

```
SELECT CHAR(EDLEVEL)  
FROM EMPLOYEE
```

An EDLEVEL of 18 would be returned as the CHAR(6) value '18 ' (18 followed by 4 blanks).

- Assume that the same SALARY subtracted from 20000.25 is to be returned with a comma as the decimal character.

```
SELECT CHAR(20000.25 - SALARY, ',')  
FROM EMPLOYEE
```

A SALARY of 21150 returns the value '-1149,75 ' (-1149,75 followed by 3 blanks).

- Assume a host variable, DOUBLE_NUM, has a double precision floating-point data type and a value of -987.654321E-35.

```
SELECT CHAR(:DOUBLE_NUM)  
FROM SYSIBM.SYSDUMMY1
```

Results in the character value '-9.8765432100000002E-33 '.

CHARACTER_LENGTH or CHAR_LENGTH

The CHARACTER_LENGTH or CHAR_LENGTH function returns the length of a string expression.

► CHARACTER_LENGTH (— *expression* —) ◄
CHAR_LENGTH

See [“LENGTH” on page 474](#) for a similar function.

expression

An expression that returns a value of any built-in numeric or string data type. A numeric argument is cast to a character string before evaluating the function. For more information about converting numeric to a character string, see [“VARCHAR” on page 623](#).

The result of the function is a large integer. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

If *expression* is a character string or graphic string, the result is the number of characters in the argument (not the number of bytes). A single character is either an SBCS, DBCS, or multiple-byte character. If *expression* is a binary string, the result is the number of bytes in the argument. The length of strings includes trailing blanks or hexadecimal zeroes. The length of a varying-length string is the actual length, not the maximum length.

Example

- Assume that NAME is a VARCHAR(128) column, encoded in Unicode UTF-8, that contains the value 'Jürgen'.

```
SELECT CHARACTER_LENGTH(NAME), LENGTH(NAME)
FROM T1
WHERE NAME = 'Jürgen'
```

Returns the value 6 for CHARACTER_LENGTH and 7 for LENGTH.

CHR

The CHR function returns the EBCDIC character that has the ASCII code value specified by the argument. If expression is 0, the result is the blank character.

►► CHR — (— *expression* —) ◄◄

expression

An expression that returns a value of a BIGINT, INTEGER, or SMALLINT data type. The value of the argument should be between 0 and 255; otherwise, the return value is null. The value is interpreted as the code point for a character in ASCII CCSID 367.

The result of the function is CHAR(1). The result can be null; if the argument is null, the result is the null value.

The CCSID of the result is the default SBCS CCSID of the current server.

Examples

- Return the EBCDIC character corresponding to the ASCII CCSID 367 code point 65.

```
SELECT CHR(65)
FROM SYSIBM.SYSDUMMY1
```

Returns the value 'A'.

CLOB

The CLOB function returns a character-string representation.

Integer to CLOB

►► CLOB — (— *integer-expression* —) ►►

Decimal to CLOB

►► CLOB — (— *decimal-expression* — , — *decimal-character* —) ►►

Floating-point to CLOB

►► CLOB — (— *floating-point-expression* — , — *decimal-character* —) ►►

Decimal floating-point to CLOB

►► CLOB — (— *decimal-floating-point-expression* — , — *decimal-character* —) ►►

Character to CLOB

►► CLOB — (— *character-expression* — , — *length* — , — *integer* —) ►►

DEFAULT

Graphic to CLOB

►► CLOB — (— *graphic-expression* — , — *length* — , — *integer* —) ►►

DEFAULT

Datetime to CLOB

►► CLOB — (— *datetime-expression* — , — *ISO* — , — *USA* — , — *EUR* — , — *JIS* — , — *LOCAL* —) ►►

The CLOB function returns a character-string representation of:

- An integer number if the first argument is a SMALLINT, INTEGER, or BIGINT
- A decimal number if the first argument is a packed or zoned decimal number
- A double-precision floating-point number if the first argument is a DOUBLE or REAL
- A decimal floating-point number if the first argument is DECFLOAT
- A character string if the first argument is any type of character string
- A graphic string if the first argument is a Unicode graphic string

- A date value if the first argument is a DATE.
- A time value if the first argument is a TIME.
- A timestamp value if the first argument is a TIMESTAMP.

The result of the function is a CLOB. If the first argument can be null, the result can be null; if the first argument is null, the result is the null value.

Integer to CLOB

integer-expression

An expression that returns a value that is a built-in integer data type (either SMALLINT, INTEGER, or BIGINT).

The result is a varying-length character string of the argument in the form of an SQL integer constant. The result consists of n characters that are the significant digits that represent the value of the argument with a preceding minus sign if the argument is negative. The result is left justified.

- If the argument is a small integer, the length attribute of the result is 6.
- If the argument is a large integer, the length attribute of the result is 11.
- If the argument is a big integer, the length attribute of the result is 20.

The actual length of the result is the smallest number of characters that can be used to represent the value of the argument. Leading zeroes are not included. If the argument is negative, the first character of the result is a minus sign. Otherwise, the first character is a digit or the *decimal-character*.

The CCSID of the result is the default SBCS CCSID at the current server.

Decimal to CLOB

decimal-expression

An expression that returns a value that is a built-in decimal data type (either DECIMAL or NUMERIC). If a different precision and scale is wanted, the DECIMAL scalar function can be used to make the change.

decimal-character

Specifies the single-byte character constant that is used to delimit the decimal digits in the result character string. The character must be a period or comma. If the second argument is not specified, the decimal point is the default decimal point. For more information, see [“Decimal point” on page 116](#).

The result is a varying-length character string representation of the argument. The result includes a decimal character and up to p digits, where p is the precision of the *decimal-expression* with a preceding minus sign if the argument is negative. Leading zeros are not returned. Trailing zeros are returned. If the scale of *decimal-expression* is zero, the decimal character is not returned.

The length attribute of the result is $2+p$ where p is the precision of the *decimal-expression*. The actual length of the result is the smallest number of characters that can be used to represent the result, except that trailing characters are included. Leading zeros are not included. If the argument is negative, the result begins with a minus sign. Otherwise, the result begins with a digit or the *decimal-character*.

The CCSID of the result is the default SBCS CCSID at the current server.

Floating-point to CLOB

floating-point expression

An expression that returns a value that is a built-in floating-point data type (DOUBLE or REAL).

decimal-character

Specifies the single-byte character constant that is used to delimit the decimal digits in the result character string. The character must be a period or comma. If the second argument is not specified, the decimal point is the default decimal point. For more information, see [“Decimal point” on page 116](#).

The result is a varying-length character string representation of the argument in the form of a floating-point constant.

The length attribute of the result is 24. The actual length of the result is the smallest number of characters that can represent the value of the argument such that the mantissa consists of a single digit other than zero followed by the *decimal-character* and a sequence of digits. If the argument is negative, the first character of the result is a minus sign; otherwise, the first character is a digit or the *decimal-character*. If the argument is zero, the result is 0E0.

The CCSID of the result is the default SBCS CCSID at the current server.

Decimal floating-point to CLOB

decimal floating-point expression

An expression that returns a value that is a built-in decimal floating-point data type.

decimal-character

Specifies the single-byte character constant that is used to delimit the decimal digits in the result character string. The character must be a period or comma. If the second argument is not specified, the decimal point is the default decimal point. For more information, see [“Decimal point” on page 116](#).

The result is a varying-length character string representation of the argument in the form of a decimal floating-point constant.

The length attribute of the result is 42. The actual length of the result is the smallest number of characters that represents the value of the argument, including the sign, digits, and *decimal-character*. Trailing zeros are significant. If the argument is negative, the first character of the result is a minus sign; otherwise, the first character is a digit or the *decimal-character*. If the argument is zero, the result is 0.

If the DECFLOAT value is Infinity, sNaN, or NaN, the strings 'INFINITY', 'SNAN', and 'NAN', respectively, are returned. If the special value is negative, a minus sign will be the first character in the string. The DECFLOAT special value sNaN does not result in an exception when converted to a string.

The CCSID of the result is the default SBCS CCSID at the current server.

Character to CLOB

character-expression

An expression that returns a value that is a built-in character-string data type.

length

An integer constant that specifies the length attribute for the resulting varying length character string. The value must be between 1 and 2 147 483 647. If the first argument is DBCS-only mixed data, the second argument cannot be less than 4.

If the second argument is not specified or DEFAULT is specified:

- If the *character-expression* is the empty string constant, the length attribute of the result is 1.
- Otherwise, the length attribute of the result is the same as the length attribute of the first argument.

The actual length of the result is the minimum of the length attribute of the result and the actual length of *character-expression*. If the length of the *character-expression* is greater than the length attribute of the result, truncation is performed. A warning (SQLSTATE 01004) is returned unless the truncated characters were all blanks.

integer

An integer constant that specifies the CCSID of the result. It must be a valid SBCS CCSID or mixed data CCSID. If the third argument is an SBCS CCSID, then the result is SBCS data. If the third argument is a mixed CCSID, then the result is mixed data and the length attribute of the result cannot be less than 4. If the third argument is a SBCS CCSID, then the first argument cannot be a DBCS-either or DBCS-only string. The third argument cannot be 65535.

If the third argument is not specified, the first argument must not have a CCSID of 65535:

- If the first argument is bit data, an error is returned.
- If the first argument is SBCS data, then the result is SBCS data. The CCSID of the result is the same as the CCSID of the first argument.
- If the first argument is mixed data and the result length is greater than or equal to 4, then the result is mixed data. The CCSID of the result is the same as the CCSID of the first argument.
- If the first argument is mixed data that is DBCS-open or DBCS-either and the length attribute of the result is less than 4, the CCSID of the result is the associated SBCS CCSID for the mixed data CCSID.

Graphic to CLOB

graphic-expression

An expression that returns a value that is a built-in graphic-string data type. It must not be DBCS-graphic data.

length

An integer constant that specifies the length attribute for the resulting varying length character string. The value must be between 1 and 2 147 483 647. If the result is mixed data, the second argument cannot be less than 4.

If the second argument is not specified or DEFAULT is specified, the length attribute of the result is determined as follows (where n is the length attribute of the first argument):

- If the *graphic-expression* is the empty graphic string constant, the length attribute of the result is 1.
- If the result is SBCS data, the result length is n .
- If the result is mixed data, the result length is $(2.5*(n-1)) + 4$.

The actual length of the result is the minimum of the length attribute of the result and the actual length of *graphic-expression*. If the length of the *graphic-expression* is greater than the length attribute of the result, truncation is performed. A warning (SQLSTATE 01004) is returned unless the truncated characters were all blanks.

integer

An integer constant that specifies the CCSID of the result. It must be a valid SBCS CCSID or mixed data CCSID. If the third argument is an SBCS CCSID, then the result is SBCS data. If the third argument is a mixed CCSID, then the result is mixed data and the length attribute of the result cannot be less than 4. The third argument cannot be 65535.

If the third argument is not specified, the CCSID of the result is the default CCSID at the current server. If the default CCSID is mixed data and the length attribute of the result is greater than or equal to 4, then the result is mixed data. Otherwise, the result is SBCS data.

Datetime to CLOB

datetime-expression

An expression that is one of the following three built-in data types

date

The result is a varying-length character string representation of the date in the format specified by the second argument. If the second argument is not specified, the format used is the default date format. If the format is ISO, USA, EUR, or JIS, the length of the result is 10. Otherwise the length of the result is the length of the default date format. For more information see [“String representations of datetime values” on page 75](#).

time

The result is a varying-length character string representation of the time in the format specified by the second argument. If the second argument is not specified, the format used is the default time format. The length of the result is 8. For more information see [“String representations of datetime values” on page 75](#).

timestamp

The second argument is not applicable and must not be specified.

The result is a varying-length character string representation of the timestamp. If *datetime-expression* is a `TIMESTAMP(0)`, the length of the result is 19. If the data type of *datetime-expression* is a `TIMESTAMP(n)`, the length of the result is 20+n. Otherwise, the length of the result is 26.

The CCSID of the result is the default SBCS CCSID at the current server.

ISO, EUR, USA, or JIS

Specifies the date or time format of the resulting character string. For more information, see [“String representations of datetime values”](#) on page 75.

LOCAL

Specifies that the date or time format of the resulting character string should come from the `DATFMT`, `DATSEP`, `TIMFMT`, and `TIMSEP` attributes of the job at the current server.

Note

Syntax alternatives: `TO_CLOB` is a synonym for `CLOB`.

The `CAST` specification should be used to increase the portability of applications when the first argument is a string and the length attribute is specified. For more information, see [“CAST specification”](#) on page 176.

Example

- The following function returns a CLOB for the string 'This is a CLOB'.

```
SELECT CLOB('This is a CLOB')
FROM SYSIBM.SYSDUMMY1
```

COALESCE

The COALESCE function returns the value of the first non-null expression.

The arguments must be compatible. Character-string arguments are compatible with datetime values. For more information about data type compatibility, see [“Assignments and comparisons”](#) on page 89.

expression-1

An expression that returns a value of any built-in or user-defined data type. ⁵⁴

expression-2

An expression that returns a value of any built-in or user-defined data type. ⁵⁴

The arguments are evaluated in the order in which they are specified, and the result of the function is the first argument that is not null. The result can be null only if all arguments can be null, and the result is null only if all arguments are null.

The selected argument is converted, if necessary, to the attributes of the result. The attributes of the result are determined by all the operands as explained in [“Rules for result data types”](#) on page 105.

Note

Syntax alternatives: NVL and VALUE are synonyms for COALESCE.

Examples

- When selecting all the values from all the rows in the DEPARTMENT table, if the department manager (MGRNO) is missing (that is, null), then return a value of 'ABSENT'.

```
SELECT DEPTNO, DEPTNAME, COALESCE(MGRNO, 'ABSENT'), ADMRDEPT
FROM DEPARTMENT
```

- When selecting the employee number (EMPNO) and salary (SALARY) from all the rows in the EMPLOYEE table, if the salary is missing (that is null), then return a value of zero.

```
SELECT EMPNO, COALESCE(SALARY,0)
FROM EMPLOYEE
```

- When working with several global variables that contain dates, return a non-null date value. When DATE1 is null and DATE2 is not null, DATE2 will be returned. If DATE2 is also null, the value of the CURRENT DATE special register will be returned.

```
VALUES COALESCE(DATE1, DATE2, CURRENT DATE)
```

⁵⁴ This function cannot be used as a source function when creating a user-defined function. Because it accepts any compatible data types as arguments, it is not necessary to create additional signatures to support distinct types.

COMPARE_DECFLOAT

The COMPARE_DECFLOAT function returns an ordering for DECFLOAT values.

►► COMPARE_DECFLOAT (— *expression-1* — , — *expression-2* —) ►►

The COMPARE_DECFLOAT function returns a small integer value that indicates how *expression-1* compares with *expression-2*.

expression-1

An expression that returns a value of any built-in numeric, character-string, or graphic-string data type. If the argument is not DECFLOAT(34), it is logically converted to DECFLOAT(34) for processing.

expression-2

An expression that returns a value of any built-in numeric, character-string, or graphic-string data type. If the argument is not DECFLOAT(34), it is logically converted to DECFLOAT(34) for processing.

The first argument is compared with the second argument and the result is returned according to the following rules.

- If both operands are finite, the comparison is algebraic and follows the rules for DECFLOAT subtraction. If the difference is exactly zero with either sign and with the same number of zeroes to the right of the decimal point, the arguments are equal. If a nonzero difference is positive, the first argument is greater than the second argument. If a nonzero difference is negative, the first argument is less than the second.
- Positive zero and negative zero compare equal.
- Positive Infinity compares equal to positive infinity.
- Positive Infinity compares greater than any finite number.
- Negative Infinity compares equal to negative infinity.
- Negative Infinity compares less than any finite number.
- Numeric comparison is exact. The result is determined for finite operands as if range and precision were unlimited. Overflow or underflow cannot occur.
- If either argument is a NaN or sNaN (positive or negative), the result is unordered.

The result value is set as follows:

0	if the arguments are exactly equal.
1	if <i>expression-1</i> is less than <i>expression-2</i> .
2	if <i>expression-1</i> is greater than <i>expression-2</i> .
3	if the arguments are unordered.

The result of the function is SMALLINT. If either argument can be null, the result can be null; if either argument is null, the result is the null value.

Examples

The following examples demonstrate the values that will be returned when the function is used:

```
COMPARE_DECFLOAT (DECFLOAT(2.17), DECFLOAT(2.17)) = 0
COMPARE_DECFLOAT (DECFLOAT(2.17), DECFLOAT(2.170)) = 2
COMPARE_DECFLOAT (DECFLOAT(2.170), DECFLOAT(2.17)) = 1
COMPARE_DECFLOAT (DECFLOAT(2.17), DECFLOAT(0.0)) = 2
COMPARE_DECFLOAT (INFINITY, INFINITY) = 0
COMPARE_DECFLOAT (INFINITY, -INFINITY) = 2
COMPARE_DECFLOAT (DECFLOAT(-2), INFINITY) = 1
COMPARE_DECFLOAT (NAN, NAN) = 3
COMPARE_DECFLOAT (DECFLOAT(-0.1), SNAN) = 3
```

CONCAT

The CONCAT function combines two arguments.

►► CONCAT — (— *expression-1* — , — *expression-2* —) ►◄

The arguments must be compatible. For more information about data type compatibility, see [“Assignments and comparisons” on page 89](#).

expression-1

An expression that returns a value of any built-in numeric, datetime, or string data type. A numeric or datetime argument is cast to a character string before evaluating the function. For more information about converting numeric or datetime to a character string, see [“VARCHAR” on page 623](#).

expression-2

An expression that returns a value of any built-in numeric, datetime, or string data type. A numeric or datetime argument is cast to a character string before evaluating the function. For more information about converting numeric or datetime to a character string, see [“VARCHAR” on page 623](#).

The result of the function is a string that consists of the first argument string followed by the second. The data type of the result is determined by the data types of the arguments. For more information, see [“With the concatenation operator” on page 163](#). If either argument can be null, the result can be null; if either argument is null, the result is the null value.

Note

Syntax alternatives: The CONCAT function is identical to the CONCAT operator. For more information, see [“With the concatenation operator” on page 163](#).

Example

- Concatenate the column FIRSTNAME with the column LASTNAME.

```
SELECT CONCAT (FIRSTNAME, LASTNAME)
FROM EMPLOYEE
WHERE EMPNO = '000010'
```

Returns the value 'CHRISTINEHAAS'.

CONTAINS

The CONTAINS function searches a text search index using criteria that are specified in a search argument and returns a result about whether or not a match was found.

►► CONTAINS ►►

search-argument-options

Notes:

¹ The same clause must not be specified more than once.

column-name

Specifies a qualified or unqualified name of a column that has a text search index that is to be searched. The column must exist in the table or view that is identified in the FROM clause in the statement and the column of the table, or the column of the underlying base table of the view must have an associated text search index. The underlying expression of the column of a view must be a simple column reference to the column of an underlying table, directly or through another nested view.

search-argument

An expression that returns a character-string data type or graphic-string data type that contains the terms to be searched for. It must not be the empty string or contain all blanks. The actual length of the string must not exceed 32 740 bytes after conversion to Unicode and must not exceed the text search limitations or number of terms as specified in the search argument syntax. For information on *search-argument* syntax, see [Appendix G, “Text search argument syntax,” on page 1989](#).

search-argument-options

A character string or graphic string value that contains the search argument options to use for the search. It must be a constant or a variable.

The options that can be specified as part of the *search-argument-options* are:

QUERYLANGUAGE = value

Specifies the language value. The value can be any of the supported language codes. If QUERYLANGUAGE is not specified, the default is the language value of the text search index that is used when the function is invoked. If the language value of the text search index is AUTO, the default value for QUERYLANGUAGE is en_US. For more information on the query language option, see [“Text search language options” on page 1999](#).

RESULTLIMIT = value

Specifies the maximum number of results that are to be returned from the underlying search engine. The *value* must be an integer from 1 to 2 147 483 647. If RESULTLIMIT is not specified, no result limit is in effect for the query.

CONTAINS may or may not be called for each row of the result table, depending on the plan that the optimizer chooses. If CONTAINS is called once for the query to the underlying search engine, a result set of all of the ROWIDs or primary keys that match are returned from the search engine. This result set is then joined to the table containing the column to identify the result rows. In this case, the RESULTLIMIT value acts like a FETCH FIRST *n* ROWS ONLY from the underlying

text search engine and can be used as an optimization. If CONTAINS is called for each row of the result because the optimizer determines that is the best plan, then the RESULTLIMIT option has no effect.

SYNONYM = OFF or SYNONYMN = ON

Specifies whether to use a synonym dictionary associated with the text search index. The default is OFF.

OFF

Do not use a synonym dictionary.

ON

Use the synonym dictionary associated with the text search index.

If *search-argument-options* is the empty string or the null value, the function is evaluated as if *search-argument-options* were not specified.

The result of the function is a large integer. If *search-argument* can be null, the result can be null; if *search-argument* is null, the result is the null value.

The result is 1 if the column contains a match for the search criteria specified by the *search-argument*. Otherwise, the result is 0. If the column contains the null value, the result is 0.

CONTAINS is a non-deterministic function.

Notes

Prerequisites: In order to use the CONTAINS and SCORE functions, OmniFind Text Search Server for DB2 for i must be installed and started.

Rules: If a view, nested table expression, or common table expression provides a text search column for a CONTAINS or SCORE scalar function and the applicable view, nested table expression, or common table expression has a DISTINCT clause on the outermost SELECT, the SELECT list must contain all the corresponding key fields of the text search index.

If a view, nested table expression, or common table expression provides a text search column for a CONTAINS or SCORE scalar function, the applicable view, nested table expression, or common table expression cannot have a UNION, EXCEPT, or INTERSECT at the outermost SELECT.

If a common table expression provides a text search column for a CONTAINS or SCORE scalar function, the common table expression cannot be subsequently referenced again in the entire query unless that reference does not provide a text search column for a CONTAINS or SCORE scalar function.

CONTAINS and SCORE scalar functions are not allowed if the query specifies:

- a distributed table,
- a table with a read trigger, or
- a logical file built over multiple physical file members.

Examples

- The following statement finds all of the employees who have "COBOL" in their resume. The text search argument is not case-sensitive.

```
SELECT EMPNO
FROM EMP_RESUME
WHERE RESUME_FORMAT = 'ascii'
AND CONTAINS(RESUME, 'cobol') = 1
```

- Find 10 students at random whose online essay contains the phrase "fossil fuel" in Spanish, that is "combustible fósil", to be invited for a radio interview. Since any 10 students can be selected, optimize the query to using RESULTLIMIT to limit the number of results from the search.

```
SELECT FIRSTNAME, LASTNAME
FROM STUDENT_ESSAYS
```

```
WHERE CONTAINS(TERM_PAPER, 'combustible fósil',  
               'QUERYLANGUAGE = es_ES RESULTLIMIT = 10 SYNONYM = ON') = 1
```

- Find the string 'ate' in the COMMENT column. Use a host variable to supply the search argument.

```
char search_arg[100];  
...  
EXEC SQL DECLARE C1 CURSOR FOR  
SELECT CUSTKEY  
FROM CUSTOMERS  
WHERE CONTAINS(COMMENT, :search_arg) = 1  
ORDER BY CUSTKEY;  
strcpy(search_arg, "ate");  
EXEC SQL OPEN C1;
```

COS

The COS function returns the cosine of the argument, where the argument is an angle expressed in radians. The COS and ACOS functions are inverse operations.

►► COS — (— *expression* —) ►◄

expression

An expression that returns a value of any built-in numeric data type (except for DECFLOAT), character-string, or graphic-string data type. A string argument is cast to double-precision floating point before evaluating the function. For more information about converting strings to double-precision floating point, see [“DOUBLE_PRECISION or DOUBLE”](#) on page 392.

The data type of the result is double-precision floating point. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

Example

- Assume the host variable COSINE is a DECIMAL(2,1) host variable with a value of 1.5.

```
SELECT COS (:COSINE)
FROM SYSIBM.SYSDUMMY1
```

Returns the approximate value 0.07.

COSH

The COSH function returns the hyperbolic cosine of the argument, where the argument is an angle expressed in radians.

►► COSH — (— *expression* —) ►◄

expression

An expression that returns a value of any built-in numeric data type (except for DECFLOAT), character-string, or graphic-string data type. A string argument is cast to double-precision floating point before evaluating the function. For more information about converting strings to double-precision floating point, see [“DOUBLE_PRECISION or DOUBLE”](#) on page 392.

The data type of the result is double-precision floating point. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

Example

- Assume the host variable HCOS is a DECIMAL(2,1) host variable with a value of 1.5.

```
SELECT COSH(:HCOS)
FROM SYSIBM.SYSDUMMY1
```

Returns the approximate value 2.35.

COT

The COT function returns the cotangent of the argument, where the argument is an angle expressed in radians.

►► COT — (— *expression* —) ◄◄

expression

An expression that returns a value of any built-in numeric data type (except for DECFLOAT), character-string, or graphic-string data type. A string argument is cast to double-precision floating point before evaluating the function. For more information about converting strings to double-precision floating point, see [“DOUBLE_PRECISION or DOUBLE”](#) on page 392.

The data type of the result is double-precision floating point. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

Example

- Assume the host variable COTAN is a DECIMAL(2,1) host variable with a value of 1.5.

```
SELECT COT(:COTAN)
FROM SYSIBM.SYSDUMMY1
```

Returns the approximate value 0.07.

CURDATE

The CURDATE function returns a date based on a reading of the time-of-day clock when the SQL statement is executed at the current server. The value returned by the CURDATE function is the same as the value returned by the CURRENT DATE special register.

► CURDATE — (—) ◄

The data type of the result is a date. The result cannot be null.

If this function is used more than once within a single SQL statement, or used with the CURTIME or NOW scalar functions or the CURRENT_DATE, CURRENT_TIME, or CURRENT_TIMESTAMP special registers within a single statement, all values are based on a single clock reading.

Note

Syntax alternatives: The CURRENT_DATE special register should be used for maximal portability. For more information, see [“Special registers”](#) on page 119.

Example

- Return the current date based on the time-of-day clock.

```
SELECT CURDATE()  
FROM SYSIBM.SYSDUMMY1
```

CURTIME

The CURTIME function returns a time based on a reading of the time-of-day clock when the SQL statement is executed at the current server. The value returned by the CURTIME function is the same as the value returned by the CURRENT TIME special register.

► CURTIME — (—) ◄

The data type of the result is a time. The result cannot be null.

If this function is used more than once within a single SQL statement, or used with the CURDATE or NOW scalar functions or the CURRENT_DATE, CURRENT_TIME, or CURRENT_TIMESTAMP special registers within a single statement, all values are based on a single clock reading.

Note

Syntax alternatives: The CURRENT_TIME special register should be used for maximal portability. For more information, see [“Special registers”](#) on page 119.

Example

- Return the current time based on the time-of-day clock.

```
SELECT CURTIME()  
FROM SYSIBM.SYSDUMMY1
```

DATABASE

The DATABASE function returns the current server.

►► DATABASE — (—) ◄◄

The result of the function is a VARCHAR(18). The result cannot be null.

The CCSID of the string is the default SBCS CCSID at the current server.

Note

Syntax alternatives: The DATABASE function returns the same result as the CURRENT SERVER special register.

Examples

- Assume that the current server is 'RCHASGMA'.

```
SELECT DATABASE( )  
FROM SYSIBM.SYSDUMMY1
```

Results in a value of 'RCHASGMA'.

DATAPARTITIONNAME

The DATAPARTITIONNAME function returns the partition name of where a row is located. If the argument identifies a non-partitioned table, an empty string is returned.

►► DATAPARTITIONNAME — (— *table-designator* —) ◄◄

For more information about partitions, see the [DB2 Multisystem](#) topic collection.

table-designator

A table designator of the subselect. For more information about table designators, see [“Table designators”](#) on page 133.

In SQL naming, the table name may be qualified. In system naming, the table name cannot be qualified.

The *table-designator* must not identify a *collection-derived-table*, a VALUES clause, a *table-function*, or a *data-change-table-reference*.

If the argument identifies a view, common table expression, or nested table expression, the function returns the partition name of its base table. If the argument identifies a view, common table expression, or nested table expression derived from more than one base table, the function returns the partition name of the first table in the outer subselect of the view, common table expression, or nested table expression.

The argument must not identify a view, common table expression, or nested table expression whose outer fullselect includes an aggregate function, a GROUP BY clause, a HAVING clause, a UNION, INTERSECT, or EXCEPT clause, DISTINCT clause, VALUES clause, or a *table-function*. The DATAPARTITIONNAME function cannot be specified in a SELECT clause if the fullselect contains an aggregate function, a GROUP BY clause, or a HAVING clause.

The data type of the result is VARCHAR(18). The result can be null.

The CCSID of the result is the default CCSID of the current server.

Example

- Join the EMPLOYEE and DEPARTMENT tables, select the employee number (EMPNO) and determine the partition from which each row involved in the join originated.

```
SELECT EMPNO, DATAPARTITIONNAME(X), DATAPARTITIONNAME(Y)
FROM EMPLOYEE X, DEPARTMENT Y
WHERE X.DEPTNO=Y.DEPTNO
```

DATAPARTITIONNUM

The DATAPARTITIONNUM function returns the data partition number of a row. If the argument identifies a non-partitioned table, the value 0 is returned.

►► DATAPARTITIONNUM — (— *table-designator* —) ►◄

For more information about data partitions, see the [DB2 Multisystem](#) topic collection.

table-designator

A table designator of the subselect. For more information about table designators, see “[Table designators](#)” on page 133.

In SQL naming, the table name may be qualified. In system naming, the table name cannot be qualified.

The *table-designator* must not identify a *collection-derived-table*, a VALUES clause, a *table-function*, or a *data-change-table-reference*.

If the argument identifies a view, common table expression, or nested table expression, the function returns the data partition number of its base table. If the argument identifies a view, common table expression, or nested table expression derived from more than one base table, the function returns the data partition number of the first table in the outer subselect of the view, common table expression, or nested table expression.

The argument must not identify a view, common table expression, or nested table expression whose outer fullselect subselect includes an aggregate function, a GROUP BY clause, a HAVING clause, a UNION, INTERSECT, or EXCEPT clause, DISTINCT clause, VALUES clause, or a *table-function*. The DATAPARTITIONNUM function cannot be specified in a SELECT clause if the fullselect contains an aggregate function, a GROUP BY clause, or a HAVING clause.

The data type of the result is a large integer. The result can be null.

Example

- Determine the partition number and employee name for each row in the EMPLOYEE table. If this is a partitioned table, the number of the partition where the row exists is returned.

```
SELECT DATAPARTITIONNUM(EMPLOYEE), LASTNAME  
FROM EMPLOYEE
```

DATE

The DATE function returns a date from a value.

►► DATE — (— *expression* —) ◄◄

expression

An expression that returns a value of one of the following built-in data types: a date, a timestamp, a character string, a graphic string, or any numeric data type.

- If *expression* is a character or graphic string, its value must be one of the following:
 - A valid string representation of a date or timestamp. For the valid formats of string representations of dates and timestamps, see [“String representations of datetime values”](#) on page 75.
 - A string with an actual length of 7 that represents a valid date in the form *yyyynnn*, where *yyyy* are digits denoting a year, and *nnn* are digits between 001 and 366 denoting a day of that year.
- If *expression* is a number, it must be a positive number less than or equal to 3 652 059.

The result of the function is a date. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

The other rules depend on the data type of the argument:

- If the argument is a timestamp:

The result is the date part of the timestamp.
- If the argument is a date:

The result is that date.
- If the argument is a number:

The result is the date that is *n*-1 days after January 1, 0001, where *n* is the integral part of the number.
- If the argument is a character or graphic string:

The result is the date represented by the string or the date part of the timestamp value represented by the string.

Note

Syntax alternatives: The CAST specification should be used to increase the portability of applications when the argument is a date, timestamp, or character string. For more information, see [“CAST specification”](#) on page 176.

Examples

- Assume that the column RECEIVED (TIMESTAMP) has an internal value equivalent to '1988-12-25-17.12.30.000000'.

```
SELECT DATE(RECEIVED)
FROM IN_TRAY
WHERE SOURCE = 'BADAMSON'
```

Results in a date data type with a value of '1988-12-25'.

- The following DATE scalar function applied to an ISO string representation of a date:

```
SELECT DATE('1988-12-25')
FROM SYSIBM.SYSDUMMY1
```

Results in a date data type with a value of '1988-12-25'.

- The following DATE scalar function applied to an EUR string representation of a date:

```
SELECT DATE('25.12.1988')  
FROM SYSIBM.SYSDUMMY1
```

Results in a date data type with a value of '1988-12-25'.

- The following DATE scalar function applied to a positive number:

```
SELECT DATE(35)  
FROM SYSIBM.SYSDUMMY1
```

Results in a date data type with a value of '0001-02-04'.

DAY

The DAY function returns the day part of a value.

►► DAY — (— *expression* —) ◄◄

expression

An *expression* that returns a value of one of the following built-in data types: a date, a timestamp, a character string, a graphic string, or a numeric data type.

- If *expression* is a character or graphic string, its value must be a valid string representation of a date or timestamp. For the valid formats of string representations of dates and timestamps, see [“String representations of datetime values”](#) on page 75.
- If *expression* is a number, it must be a date duration or timestamp duration. For the valid formats of datetime durations, see [“Datetime operands and durations”](#) on page 165.

The result of the function is a large integer. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

The other rules depend on the data type of the argument:

- If the argument is a date, timestamp, or valid character-string representation of a date or timestamp:
The result is the day part of the value, which is an integer between 1 and 31.
- If the argument is a date duration or timestamp duration:
The result is the day part of the value, which is an integer between -99 and 99. A nonzero result has the same sign as the argument.

Examples

- Using the PROJECT table, set the host variable END_DAY (SMALLINT) to the day that the WELD LINE PLANNING project (PROJNAME) is scheduled to stop (PRENDATE).

```
SELECT DAY(PRENDATE)
  INTO :END_DAY
  FROM PROJECT
  WHERE PROJNAME = 'WELD LINE PLANNING'
```

Results in END_DAY being set to 15.

- Return the day part of the difference between two dates:

```
SELECT DAY( DATE('2000-03-15') - DATE('1999-12-31') )
  FROM SYSIBM.SYSDUMMY1
```

Results in the value 15.

DAYNAME

Returns a mixed case character string containing the name of the day (for example, Friday) for the day portion of the argument.

►► DAYNAME — (— *expression* —) ►►

expression

An expression that returns a value of one of the following built-in data types: a date, a timestamp, a character string, or a graphic string.

If *expression* is a character or graphic string, its value must be a valid string representation of a date or timestamp. For the valid formats of string representations of dates and timestamps, see [“String representations of datetime values”](#) on page 75.

The result of the function is VARCHAR(100). If the argument can be null, the result can be null; if the argument is null, the result is the null value.

The CCSID of the result is the default CCSID of the current server.

Note

National language considerations: The name of the day that is returned is based on the language used for messages in the job. This name of the day is retrieved from message CPX9034 in message file QCPFMSG in library *LIBL.

Examples

- Assume that the language used is US English.

```
SELECT DAYNAME( '2003-01-02' )  
FROM SYSIBM.SYSDUMMY1
```

Results in 'Thursday'.

DAYOFMONTH

The DAYOFMONTH function returns an integer between 1 and 31 that represents the day of the month.

►► DAYOFMONTH — (— *expression* —) ►►

expression

An expression that returns a value of one of the following built-in data types: a date, a timestamp, a character string, or a graphic string.

If *expression* is a character or graphic string, its value must be a valid string representation of a date or timestamp. For the valid formats of string representations of dates and timestamps, see [“String representations of datetime values”](#) on page 75.

The result of the function is a large integer. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

Examples

- Using the PROJECT table, set the host variable END_DAY (SMALLINT) to the day that the WELD LINE PLANNING project (PROJNAME) is scheduled to stop (PRENDATE).

```
SELECT DAYOFMONTH(PRENDATE)
INTO :END_DAY
FROM PROJECT
WHERE PROJNAME = 'WELD LINE PLANNING'
```

Results in END_DAY being set to 15.

DAYOFWEEK

The DAYOFWEEK function returns an integer between 1 and 7 that represents the day of the week, where 1 is Sunday and 7 is Saturday.

►► DAYOFWEEK — (— *expression* —) ◄◄

For another alternative, see [“DAYOFWEEK_ISO”](#) on page 358.

expression

An expression that returns a value of one of the following built-in data types: a date, a timestamp, a character string, or a graphic string.

If *expression* is a character or graphic string, its value must be a valid string representation of a date or timestamp. For the valid formats of string representations of dates and timestamps, see [“String representations of datetime values”](#) on page 75.

The result of the function is a large integer. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

Example

- Using the EMPLOYEE table, set the host variable DAY_OF_WEEK (INTEGER) to the day of the week that Christine Haas (EMPNO='000010') started (HIREDATE).

```
SELECT DAYOFWEEK(HIREDATE)
INTO :DAY_OF_WEEK
FROM EMPLOYEE
WHERE EMPNO = '000010'
```

Results in DAY_OF_WEEK being set to 6, which represents Friday.

- The following query returns four values: 1, 2, 1, and 2.

```
SELECT DAYOFWEEK(CAST('10/11/1998' AS DATE)),
DAYOFWEEK(TIMESTAMP('10/12/1998','01.02')),
DAYOFWEEK(CAST(CAST('10/11/1998' AS DATE) AS CHAR(20))),
DAYOFWEEK(CAST(TIMESTAMP('10/12/1998','01.02') AS CHAR(26)))
FROM SYSIBM.SYSDUMMY1
```

DAYOFWEEK_ISO

The DAYOFWEEK_ISO function returns an integer between 1 and 7 that represents the day of the week, where 1 is Monday and 7 is Sunday.

►► DAYOFWEEK_ISO — (— *expression* —) ►►

For another alternative, see [“DAYOFWEEK”](#) on page 357.

expression

An expression that returns a value of one of the following built-in data types: a date, a timestamp, a character string, or a graphic string.

If *expression* is a character or graphic string, its value must be a valid string representation of a date or timestamp. For the valid formats of string representations of dates and timestamps, see [“String representations of datetime values”](#) on page 75.

The result of the function is a large integer. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

Examples

- Using the EMPLOYEE table, set the host variable DAY_OF_WEEK (INTEGER) to the day of the week that Christine Haas (EMPNO='000010') started (HIREDATE).

```
SELECT DAYOFWEEK_ISO(HIREDATE)
INTO :DAY_OF_WEEK
FROM EMPLOYEE
WHERE EMPNO = '000010'
```

Results in DAY_OF_WEEK being set to 5, which represents Friday.

- The following query returns four values: 7, 1, 7, and 1.

```
SELECT DAYOFWEEK_ISO(CAST('10/11/1998' AS DATE)),
DAYOFWEEK_ISO(TIMESTAMP('10/12/1998', '01.02')),
DAYOFWEEK_ISO(CAST(CAST('10/11/1998' AS DATE) AS CHAR(20))),
DAYOFWEEK_ISO(CAST(TIMESTAMP('10/12/1998', '01.02') AS CHAR(26)))
FROM SYSIBM.SYSDUMMY1
```

DAYOFYEAR

The DAYOFYEAR function returns an integer between 1 and 366 that represents the day of the year where 1 is January 1.

►► DAYOFYEAR (— *expression* —) ◄◄

expression

An expression that returns a value of one of the following built-in data types: a date, a timestamp, a character string, or a graphic string.

If *expression* is a character or graphic string, its value must be a valid string representation of a date or timestamp. For the valid formats of string representations of dates and timestamps, see [“String representations of datetime values”](#) on page 75.

The result of the function is a large integer. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

Example

- Using the EMPLOYEE table, set the host variable AVG_DAY_OF_YEAR (INTEGER) to the average of the day of the year that employees started on (HIREDATE).

```
SELECT AVG(DAYOFYEAR(HIREDATE))
INTO :AVG_DAY_OF_YEAR
FROM EMPLOYEE
```

Results in AVG_DAY_OF_YEAR being set to 197.

DAYS

The DAYS function returns an integer representation of a date.

►► DAYS — (— *expression* —) ►►

expression

An expression that returns a value of one of the following built-in data types: a date, a timestamp, a character string, or a graphic string.

If *expression* is a character or graphic string, its value must be a valid string representation of a date or timestamp. For the valid formats of string representations of dates and timestamps, see [“String representations of datetime values”](#) on page 75.

The result of the function is a large integer. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

The result is 1 more than the number of days from January 1, 0001 to *D*, where *D* is the date that would occur if the DATE function were applied to the argument.

Examples

- Using the PROJECT table, set the host variable EDUCATION_DAYS (INTEGER) to the number of elapsed days (PRENDATE - PRSTDATE) estimated for the project (PROJNO) 'IF2000'.

```
SELECT DAYS(PRENDATE) - DAYS(PRSTDATE)
INTO :EDUCATION_DAYS
FROM PROJECT
WHERE PROJNO = 'IF2000'
```

Results in EDUCATION_DAYS being set to 396.

- Using the PROJECT table, set the host variable TOTAL_DAYS (INTEGER) to the sum of elapsed days (PRENDATE - PRSTDATE) estimated for all projects in department (DEPTNO) 'E21'.

```
SELECT SUM(DAYS(PRENDATE) - DAYS(PRSTDATE))
INTO :TOTAL_DAYS
FROM PROJECT
WHERE DEPTNO = 'E21'
```

Results in TOTAL_DAYS being set to 1584.

DBCLOB

The DBCLOB function returns a graphic-string representation.

Integer to DBCLOB

►► DBCLOB (— *integer-expression* —) ►►

Decimal to DBCLOB

►► DBCLOB (— *decimal-expression* — , — *decimal-character* —) ►►

Floating-point to DBCLOB

►► DBCLOB (— *floating-point-expression* — , — *decimal-character* —) ►►

Decimal floating-point to DBCLOB

►► DBCLOB (— *decimal-floating-point-expression* — , — *decimal-character* —) ►►

Character to DBCLOB

►► DBCLOB (— *character-expression* — , — *length* — , — *integer* —) ►►

DEFAULT

Graphic to DBCLOB

►► DBCLOB (— *graphic-expression* — , — *length* — , — *integer* —) ►►

DEFAULT

Datetime to DBCLOB

►► DBCLOB (— *datetime-expression* — , — *ISO* — , — *USA* — , — *EUR* — , — *JIS* — , — *LOCAL* —) ►►

The DBCLOB function returns a graphic-string representation of:

- An integer number if the first argument is a SMALLINT, INTEGER, or BIGINT
- A decimal number if the first argument is a packed or zoned decimal number
- A double-precision floating-point number if the first argument is a DOUBLE or REAL
- A decimal floating-point number if the first argument is a DECFLOAT
- A character string if the first argument is any type of character string
- A graphic string if the first argument is any type of graphic string

- A date value if the first argument is a DATE.
- A time value if the first argument is a TIME.
- A timestamp value if the first argument is a TIMESTAMP.

The result of the function is a DBCLOB. If the first argument can be null, the result can be null; if the first argument is null, the result is the null value.

Integer to DBCLOB

integer-expression

An expression that returns a value that is a built-in integer data type (either SMALLINT, INTEGER, or BIGINT).

The result is a varying-length graphic string of the argument in the form of an SQL integer constant. The result consists of n characters that are the significant digits that represent the value of the argument with a preceding minus sign if the argument is negative. The result is left justified.

- If the argument is a small integer, the length attribute of the result is 6.
- If the argument is a large integer, the length attribute of the result is 11.
- If the argument is a big integer, the length attribute of the result is 20.

The actual length of the result is the smallest number of characters that can be used to represent the value of the argument. Leading zeroes are not included. If the argument is negative, the first character of the result is a minus sign. Otherwise, the first character is a digit or the *decimal-character*.

The CCSID of the result is 1200 (UTF-16).

Decimal to DBCLOB

decimal-expression

An expression that returns a value that is a built-in decimal data type (either DECIMAL or NUMERIC). If a different precision and scale is wanted, the DECIMAL scalar function can be used to make the change.

decimal-character

Specifies the single-byte character constant that is used to delimit the decimal digits in the result character string. The character must be a period or comma. If the second argument is not specified, the decimal point is the default decimal point. For more information, see [“Decimal point” on page 116](#).

The result is a varying-length graphic string representation of the argument. The result includes a decimal character and up to p digits, where p is the precision of the *decimal-expression* with a preceding minus sign if the argument is negative. Leading zeros are not returned. Trailing zeros are returned. If the scale of *decimal-expression* is zero, the decimal character is not returned.

The length attribute of the result is $2+p$ where p is the precision of the *decimal-expression*. The actual length of the result is the smallest number of characters that can be used to represent the result, except that trailing characters are included. Leading zeros are not included. If the argument is negative, the result begins with a minus sign. Otherwise, the result begins with a digit or the *decimal-character*.

The CCSID of the result is 1200 (UTF-16).

Floating-point to DBCLOB

floating-point expression

An expression that returns a value that is a built-in floating-point data type (DOUBLE or REAL).

decimal-character

Specifies the single-byte character constant that is used to delimit the decimal digits in the result character string. The character must be a period or comma. If the second argument is not specified, the decimal point is the default decimal point. For more information, see [“Decimal point” on page 116](#).

The result is a varying-length graphic string representation of the argument in the form of a floating-point constant.

The length attribute of the result is 24. The actual length of the result is the smallest number of characters that can represent the value of the argument such that the mantissa consists of a single digit other than zero followed by the *decimal-character* and a sequence of digits. If the argument is negative, the first character of the result is a minus sign; otherwise, the first character is a digit or the *decimal-character*. If the argument is zero, the result is 0E0.

The CCSID of the result is 1200 (UTF-16).

Decimal floating-point to DBCLOB

decimal floating-point expression

An expression that returns a value that is a built-in decimal floating-point data type.

decimal-character

Specifies the single-byte character constant that is used to delimit the decimal digits in the result character string. The character must be a period or comma. If the second argument is not specified, the decimal point is the default decimal point. For more information, see [“Decimal point” on page 116](#).

The result is a varying-length graphic string representation of the argument in the form of a decimal floating-point constant.

The length attribute of the result is 42. The actual length of the result is the smallest number of characters that represents the value of the argument, including the sign, digits, and *decimal-character*. Trailing zeros are significant. If the argument is negative, the first character of the result is a minus sign; otherwise, the first character is a digit or the *decimal-character*. If the argument is zero, the result is 0.

If the DECFLOAT value is Infinity, sNaN, or NaN, the strings 'INFINITY', 'SNAN', and 'NAN', respectively, are returned. If the special value is negative, a minus sign will be the first character in the string. The DECFLOAT special value sNaN does not result in an exception when converted to a string.

The CCSID of the result is 1200 (UTF-16).

Character to DBCLOB

character-expression

An expression that returns a value that is a built-in character-string data type. It cannot be CHAR or VARCHAR bit data. If the expression is an empty string or the EBCDIC string X'0E0F', the result is an empty string.

length

An integer constant that specifies the length attribute for the resulting varying length character string. The value must be between 1 and 1 073 741 823.

If the second argument is not specified or DEFAULT is specified:

- If the *character-expression* is the empty string constant, the length attribute of the result is 1.
- Otherwise, the length attribute of the result is the same as the length attribute of the first argument.

The actual length of the result is the minimum of the length attribute of the result and the actual length of *character-expression*. If the length of the *character-expression* is greater than the length attribute of the result, truncation is performed. A warning (SQLSTATE 01004) is returned unless the truncated characters were all blanks.

integer

An integer constant that specifies the CCSID for the resulting varying-length graphic string. It must be a DBCS, UTF-16, or UCS-2 CCSID. The CCSID cannot be 65535.

In the following rules, S denotes one of the following:

- If the string expression is a host variable containing data in a foreign encoding scheme, S is the result of the expression after converting the data to a CCSID in a native encoding scheme. (See “Character conversion” on page 28 for more information.)
 - If the string expression is data in a native encoding scheme, S is that string expression.
- If the third argument is not specified and the first argument is character, then the CCSID of the result is determined by a mixed CCSID. Let M denote that mixed CCSID. M is determined as follows:
- If the CCSID of S is a mixed CCSID, M is that CCSID.
 - If the CCSID of S is an SBCS CCSID:
 - If the CCSID of S has an associated mixed CCSID, M is that CCSID.
 - Otherwise the operation is not allowed.

The following table summarizes the result CCSID based on M.

M	Result CCSID	Description	DBCS Substitution Character
930	300	Japanese EBCDIC	X'FEFE'
933	834	Korean EBCDIC	X'FEFE'
935	837	S-Chinese EBCDIC	X'FEFE'
937	835	T-Chinese EBCDIC	X'FEFE'
939	300	Japanese EBCDIC	X'FEFE'
5026	4396	Japanese EBCDIC	X'FEFE'
5035	4396	Japanese EBCDIC	X'FEFE'

If the result is DBCS-graphic data, the equivalence of SBCS and DBCS characters depends on M. Regardless of the CCSID, every double-byte code point in the argument is considered a DBCS character, and every single-byte code point in the argument is considered an SBCS character with the exception of the EBCDIC mixed data shift codes X'0E' and X'0F'.

- If the nth character of the argument is a DBCS character, the nth character of the result is that DBCS character.
- If the nth character of the argument is an SBCS character that has an equivalent DBCS character, the nth character of the result is that equivalent DBCS character.
- If the nth character of the argument is an SBCS character that does not have an equivalent DBCS character, the nth character of the result is the DBCS substitution character.

If the result is Unicode graphic data, each character of the argument determines a character of the result. The nth character of the result is the UTF-16 or UCS-2 equivalent of the nth character of the argument.

Graphic to DBCLOB

graphic-expression

An expression that returns a value that is a built-in graphic-string data type.

length

An integer constant that specifies the length attribute for the resulting varying length character string. The value must be between 1 and 1 073 741 823.

If the second argument is not specified or DEFAULT is specified:

- If the *graphic-expression* is the empty string constant, the length attribute of the result is 1.
- Otherwise, the length attribute of the result is the same as the length attribute of the first argument.

The actual length of the result is the minimum of the length attribute of the result and the actual length of *graphic-expression*. If the length of *graphic-expression* is greater than the length

attribute of the result, truncation is performed. A warning (SQLSTATE 01004) is returned unless the truncated characters were all blanks.

integer

An integer constant that specifies the CCSID for the resulting varying-length graphic string. It must be a DBCS, UTF-16, or UCS-2 CCSID. The CCSID cannot be 65535.

In the following rules, S denotes one of the following:

- If the string expression is a host variable containing data in a foreign encoding scheme, S is the result of the expression after converting the data to a CCSID in a native encoding scheme. (See [“Character conversion”](#) on page 28 for more information.)
- If the string expression is data in a native encoding scheme, S is that string expression.

If the third argument is not specified, then the CCSID of the result is the same as the CCSID of the first argument.

Datetime to DBCLOB

datetime-expression

An expression that is one of the following three built-in data types

date

The result is the varying-length graphic string representation of the date in the format specified by the second argument. If the second argument is not specified, the format used is the default date format. If the format is ISO, USA, EUR, or JIS, the length attribute and actual length of the result is 10. Otherwise the length attribute and actual length of the result is the length of the default date format. For more information see [“String representations of datetime values”](#) on page 75.

time

The result is the varying-length graphic string representation of the time in the format specified by the second argument. If the second argument is not specified, the format used is the default time format. The length attribute and actual length of the result is 8. For more information see [“String representations of datetime values”](#) on page 75.

timestamp

The second argument is not applicable and must not be specified.

The result is the varying-length graphic string representation of the timestamp. If *datetime-expression* is a `TIMESTAMP(0)`, the length attribute and actual length of the result is 19. If the data type of *datetime-expression* is a `TIMESTAMP(n)`, the length attribute and actual length of the result is $20+n$. Otherwise, the length attribute and actual length of the result is 26.

The CCSID of the result is 1200 (UTF-16).

ISO, EUR, USA, or JIS

Specifies the date or time format of the resulting graphic string. For more information, see [“String representations of datetime values”](#) on page 75.

LOCAL

Specifies that the date or time format of the resulting graphic string should come from the `DATFMT`, `DATSEP`, `TIMFMT`, and `TIMSEP` attributes of the job at the current server.

Note

Syntax alternatives: The `CAST` specification should be used to increase the portability of applications when the first argument is a string and the length attribute is specified. For more information, see [“CAST specification”](#) on page 176.

Example

- Using the `EMPLOYEE` table, set the host variable `VAR_DESC` (`VARGRAPHIC(24)`) to the DBCLOB equivalent of the first name (`FIRSTNME`) for employee number (`EMPNO`) '000050'.

```
SELECT DBCLOB(VARGRAPHIC(FIRSTNME))  
INTO :VAR_DESC  
FROM EMPLOYEE  
WHERE EMPNO = '000050'
```

DBPARTITIONNAME

The DBPARTITIONNAME function returns the relational database name (database partition name) of where a row is located. If the argument identifies a non-distributed table, the current server is returned.

►► DBPARTITIONNAME — (— *table-designator* —) ►►

For more information about partitions, see the [DB2 Multisystem](#) topic collection.

table-designator

A table designator of the subselect. For more information about table designators, see [“Table designators”](#) on page 133.

In SQL naming, the table name may be qualified. In system naming, the table name cannot be qualified.

The *table-designator* must not identify a *collection-derived-table*, a VALUES clause, a *table-function*, or a *data-change-table-reference*.

If the argument identifies a view, common table expression, or nested table expression, the function returns the relational database name of its base table. If the argument identifies a view, common table expression, or nested table expression derived from more than one base table, the function returns the partition name of the first table in the outer subselect of the view, common table expression, or nested table expression.

The argument must not identify a view, common table expression, or nested table expression whose outer fullselect includes an aggregate function, a GROUP BY clause, a HAVING clause, a UNION, INTERSECT, or EXCEPT clause, DISTINCT clause, VALUES clause, or a *table-function*. The DBPARTITIONNAME function cannot be specified in a SELECT clause if the fullselect contains an aggregate function, a GROUP BY clause, or a HAVING clause.

The data type of the result is VARCHAR(18). The result can be null.

The CCSID of the result is the default CCSID of the current server.

Note

Syntax alternatives: NODENAME is a synonym for DBPARTITIONNAME.

Example

- Join the EMPLOYEE and DEPARTMENT tables, select the employee number (EMPNO) and determine the node from which each row involved in the join originated.

```
SELECT EMPNO, DBPARTITIONNAME(X), DBPARTITIONNAME(Y)
FROM EMPLOYEE X, DEPARTMENT Y
WHERE X.DEPTNO=Y.DEPTNO
```

DBPARTITIONNUM

The DBPARTITIONNUM function returns the node number (database partition number) of a row.

►► DBPARTITIONNUM — (— *table-designator* —) ◄◄

If the argument identifies a non-distributed table, the value 0 is returned.⁵⁵ For more information about nodes and node numbers, see the [DB2 Multisystem](#) book.

table-designator

A table designator of the subselect. For more information about table designators, see [“Table designators”](#) on page 133.

In SQL naming, the table name may be qualified. In system naming, the table name cannot be qualified.

The *table-designator* must not identify a *collection-derived-table*, a VALUES clause, a *table-function*, or a *data-change-table-reference*.

If the argument identifies a view, common table expression, or nested table expression, the function returns the node number of its base table. If the argument identifies a view, common table expression, or nested table expression derived from more than one base table, the function returns the node number of the first table in the outer subselect of the view, common table expression, or nested table expression.

The argument must not identify a view, common table expression, or nested table expression whose outer fullselect subselect includes an aggregate function, a GROUP BY clause, a HAVING clause, a UNION, INTERSECT, or EXCEPT clause, DISTINCT clause, VALUES clause, or a *table-function*. The DBPARTITIONNUM function cannot be specified in a SELECT clause if the fullselect contains an aggregate function, a GROUP BY clause, or a HAVING clause.

The data type of the result is a large integer. The result can be null.

Note

Syntax alternatives: NODENUMBER is a synonym for DBPARTITIONNUM.

Example

- Determine the node number and employee name for each row in the EMPLOYEE table. If this is a distributed table, the number of the node where the row exists is returned.

```
SELECT DBPARTITIONNUM(EMPLOYEE), LASTNAME
FROM EMPLOYEE
```

⁵⁵ If the argument identifies a DDS created logical file that is based on more than one physical file member, DBPARTITIONNUM will not return 0, but instead will return the underlying physical file member number.

DECFLOAT

The DECFLOAT function returns a decimal floating-point representation of a number or a string representation of a number.

Numeric to DECFLOAT

String to DECFLOAT

The DECFLOAT function returns a decimal floating-point representation of:

- A number
- A character or graphic string representation of a decimal number
- A character or graphic string representation of an integer
- A character or graphic string representation of a floating-point number
- A character or graphic string representation of a decimal floating-point number

Numeric to DECFLOAT

numeric-expression

An expression that returns a value of any built-in numeric data type.

34 or 16

Specifies the number of digits of precision for the result. The default is 34.

The result is the same number that would occur if the first argument were assigned to a decimal floating-point column or variable.

String to DECFLOAT

string-expression

An expression that returns a value that is a character-string or graphic-string representation of a number. Leading and trailing blanks are eliminated and the resulting string folded to uppercase must conform to the rules for forming a floating-point, decimal floating-point, integer, or decimal constant.

34 or 16

Specifies the number of digits of precision for the result. The default is 34.

decimal-character

Specifies the single-byte character constant that is used to delimit the decimal digits in *string-expression* from the whole part of the number. The character must be a period or comma. If *decimal-character* is not specified, the decimal point is the default decimal separator character. For more information, see [“Decimal point” on page 116](#).

The result of the function is a DECFLOAT number with the specified (either implicitly or explicitly) number of digits of precision. If the first argument can be null, the result can be null; if the first argument is null, the result is the null value.

If necessary, the source is rounded to the precision of the target. See [“CURRENT DECFLOAT ROUNDING MODE”](#) on page 124 for more information.

Note

Syntax alternatives: The CAST specification should be used to increase the portability of applications. For more information, see [“CAST specification”](#) on page 176.

Example

- Use the DECFLOAT function in order to force a DECFLOAT data type to be returned in a select-list for the EDLEVEL column (data type = SMALLINT) in the EMPLOYEE table. The EMPNO column should also appear in the *select-clause*.

```
SELECT EMPNO, DECFLOAT(EDLEVEL,16)
FROM EMPLOYEE
```

DECFLOAT_FORMAT

The DECFLOAT_FORMAT function returns a DECFLOAT(34) value that is based on the interpretation of the input string using the specified format.

► DECFLOAT_FORMAT (— *string-expression* — , — *format-string*) ►

string-expression

An expression that returns a built-in character string or graphic string data type. If the value is a graphic data type, it is implicitly cast to VARCHAR before evaluating the function. Leading and trailing blanks are removed from the string. If *format-string* is not specified, the resulting substring must conform to the rules for forming an SQL integer, decimal, floating-point, or decimal floating-point constant and not be greater than 63 characters after stripping leading and trailing blanks. Otherwise, the resulting substring must contain the components of a number that correspond to the format specified by *format-string*.

format-string

An expression that returns a built-in character string or graphic string data type. If the value is a graphic data type, it is implicitly cast to VARCHAR before evaluating the function. *format-string* contains a template of how *string-expression* is to be interpreted for conversion to a DECFLOAT value. *format-string* must contain a valid combination of the listed format elements according to the following rules:

- At least one '0' or '9' format element must be specified.
- A sign format element ('S', 'MI', 'PR') can be specified only one time.
- A decimal point format element can be specified only one time.
- Alphabetic format elements must be specified in upper case.
- A prefix format element can only be specified at the beginning of the format string, before any format elements that are not prefix format elements. When multiple prefix format elements are specified they can be specified in any order.
- A suffix format element can only be specified at the end of the format string, after any format elements that are not suffix format elements. When multiple suffix format elements are specified they can be specified in any order.
- A comma or G format element can be the first format element that is not a prefix format element. There can be any number of comma or G format elements.
- Blanks must not be specified between format elements. Leading and trailing blanks can be specified but are ignored.

Format element	Description
0 or 9	Represents a digit that can be included at the specified location. Both format elements have the same meaning.
S	Prefix: If <i>string-expression</i> represents a negative number, a leading minus sign (–) is expected at the specified location. If <i>string-expression</i> represents a positive number, a leading plus sign (+) or leading blank can be included at the specified location.
\$	Prefix: A leading dollar sign (\$) is expected at the specified location.
MI	Suffix: If <i>string-expression</i> represents a negative number, a trailing minus sign (–) is expected at the specified location. If <i>string-expression</i> represents a positive number, a trailing blank can be included at the specified location.

Format element	Description
PR	Suffix: If <i>string-expression</i> represents a negative number, a leading less than character (<) and a trailing greater than character (>) are expected. If <i>string-expression</i> represents a positive number, a leading blank and a trailing blank can be included.
,	Specifies the expected location of a comma. This comma is used as a group separator.
.	Specifies the expected location of the period. This period is used as a decimal point.
L	Prefix or Suffix: Specifies that the local currency symbol is expected at the specified location. The currency symbol is retrieved from message CPX8416 in message file QCPFMSG in library *LIBL.
D	Specifies that the local decimal point character is expected at the specified location. The decimal character is retrieved from message CPX8416 in message file QCPFMSG in library *LIBL.
G	Specifies that the local group separator character is expected at the specified location. If the local decimal character as retrieved from message CPX8416 in message file QCPFMSG in library *LIBL is a period, the group separator will be a comma. If the local decimal character is a comma, the group separator will be a period.

The result is a DECFLOAT(34). If any argument of the DECFLOAT_FORMAT function can be null, the result can be null; if any argument is null, the result is the null value.

Note

Syntax alternatives: TO_NUMBER is a synonym for DECFLOAT_FORMAT.

Examples

Example	Result
DECFLOAT_FORMAT('123.45')	123.45
DECFLOAT_FORMAT('-123456.78')	-123456.78
DECFLOAT_FORMAT('+123456.78')	123456.78
DECFLOAT_FORMAT('1.23E4')	12300
DECFLOAT_FORMAT('123.4', '9999.99')	123.40
DECFLOAT_FORMAT('001,234', '000,000')	1234
DECFLOAT_FORMAT('1234', '9999MI')	1234
DECFLOAT_FORMAT('1234-', '9999MI')	-1234
DECFLOAT_FORMAT('+1234', 'S9999')	1234
DECFLOAT_FORMAT('-1234', 'S9999')	-1234
DECFLOAT_FORMAT(' 1234', '9999PR')	1234
DECFLOAT_FORMAT('<1234>', '9999PR')	-1234
DECFLOAT_FORMAT('\$123,456.78', '\$999,999.99')	123456.78

DECFLOAT_SORTKEY

The DECFLOAT_SORTKEY function returns a binary value that may be used to sort DECFLOAT values.

►► DECFLOAT_SORTKEY — (— *expression* —) ►◄

The DECFLOAT_SORTKEY function returns a binary value that may be used to sort decimal floating-point values in a manner that is consistent with the IEEE 754R specification on total ordering.

expression

An expression that returns a value of any built-in numeric, character-string, or graphic-string data type.

If the data type of the argument is SMALLINT, INTEGER, REAL, DOUBLE, DECIMAL(p,s) where $p \leq 16$, or NUMERIC(p,s) where $p \leq 16$, then the argument is converted to DECFLOAT(16) for processing. Otherwise, the argument is converted to DECFLOAT(34) for processing.

The result of the function is BINARY(9) if the argument is DECFLOAT(16) or BINARY(17) if the argument is DECFLOAT(34).

If the argument can be null, the result can be null. If the argument is null, the result is the null value.

Example

```
CREATE TABLE T1 (D1 DECFLOAT(16));
INSERT INTO T1 VALUES(2.100);
INSERT INTO T1 VALUES(2.10);
INSERT INTO T1 VALUES(2.1000);
INSERT INTO T1 VALUES(2.1);
```

```
SELECT D1 FROM T1 ORDER BY D1;
```

```
  D1
-----
    2.100
    2.10
    2.1000
    2.1
```

Note that this result set is arbitrary. The ORDER BY has no effect on ordering these values.

```
SELECT D1 FROM T1 ORDER BY DECFLOAT_SORTKEY(D1);
```

```
  D1
-----
    2.1000
    2.100
    2.10
    2.1
```

Note that this result set is ordered according to the IEEE 754R ordering specification.

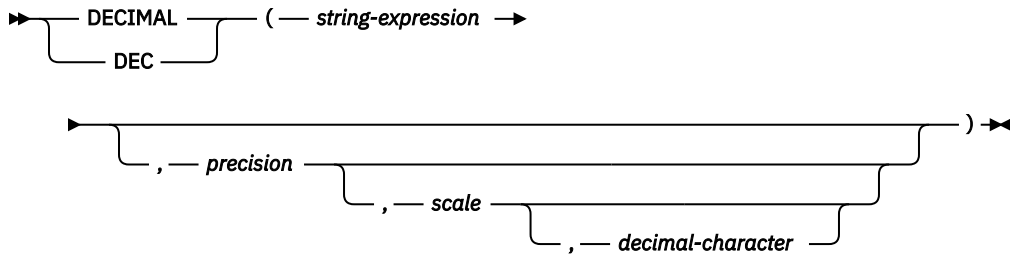

DECIMAL or DEC

The DECIMAL function returns a decimal representation.

Numeric to Decimal

String to Decimal

Datetime to Decimal

The DECIMAL function returns a decimal representation of:

- A number
- A character or graphic string representation of a decimal number
- A character or graphic string representation of an integer
- A character or graphic string representation of a floating-point number
- A character or graphic string representation of a decimal floating-point number
- A date
- A time
- A timestamp

Numeric to Decimal

numeric-expression

An expression that returns a value of any built-in numeric data type.

precision

An integer constant with a value greater than or equal to 1 and less than or equal to 63.

The default for *precision* depends on the data type of the *numeric-expression*:

- 5 for small integer
- 11 for large integer
- 19 for big integer
- 15 for floating point, decimal, numeric, or nonzero scale binary
- 31 for decimal floating point

scale

An integer constant that is greater than or equal to 0 and less than or equal to *precision*. If not specified, the default is 0.

The result is the same number that would occur if the first argument were assigned to a decimal column or variable with a precision of *precision* and a scale of *scale*. An error is returned if the number of significant decimal digits required to represent the whole part of the number is greater than *precision-scale*. If the first argument can be null, the result can be null; if the first argument is null, the result is the null value.

String to Decimal***string-expression***

An expression that returns a character-string or graphic-string representation of a number. Leading and trailing blanks are eliminated and the resulting string must conform to the rules for forming a floating-point, decimal floating-point, integer, or decimal constant.

precision

An integer constant that is greater than or equal to 1 and less than or equal to 63. If not specified, the default is 15.

scale

An integer constant that is greater than or equal to 0 and less than or equal to *precision*. If not specified, the default is 0.

decimal-character

Specifies the single-byte character constant that is used to delimit the decimal digits in *string-expression* from the whole part of the number. The character must be a period or comma. If *decimal-character* is not specified, the decimal point is the default decimal separator character. For more information, see [“Decimal point” on page 116](#).

Digits are truncated from the end if the number of digits to the right of the *decimal-character* is greater than the scale *s*. An error is returned if the number of significant digits to the left of the *decimal-character* (the whole part of the number) in *string-expression* is greater than *precision-scale*. The default decimal separator character is not valid in the substring if the *decimal-character* argument is specified.

Datetime to Decimal***datetime-expression***

An expression that returns a value of type DATE, TIME, or TIMESTAMP

precision

An integer constant that is greater than or equal to 1 and less than or equal to 63 that specifies the precision of the result. If not specified, the default for the precision and scale depends on the data type of *datetime-expression* as follows:

- Precision is 8 and scale is 0 for DATE. The result is a DECIMAL(8,0) value representing the date as *yyyymmdd*.
- Precision is 6 and scale is 0 for a TIME. The result is a DECIMAL(6,0) value representing the time as *hhmmss*.
- Precision is 14+*tp* and scale is *tp* for a TIMESTAMP(*tp*). The result is a DECIMAL(14+*tp*,*tp*) value representing the timestamp as *yyyymmddhhmmss.nnnnnnnnnnnn*.

scale

An integer constant that is greater than or equal to 0 and less than or equal to *precision*. If not specified, the default is 0.

The result is the same number that would result from CAST(*datetime-expression* AS DECIMAL(*precision*,*scale*)). Digits are truncated from the end if the number of digits to the right of the decimal separator character is greater than *scale*. An error is returned if the number of significant digits to the left of the decimal separator character (the whole part of the number) in *datetime-expression* is greater than *precision - scale*.

The result of the function is a decimal number with precision of *precision* and scale of *scale*. If the first argument can be null, the result can be null; if the first argument is null, the result is the null value.

Note

Syntax alternatives: The CAST specification should be used to increase the portability of applications when precision is specified. For more information, see [“CAST specification”](#) on page 176.

Examples

- Use the DECIMAL function in order to force a DECIMAL data type (with a precision of 5 and a scale of 2) to be returned in a select-list for the EDLEVEL column (data type = SMALLINT) in the EMPLOYEE table. The EMPNO column should also appear in the select list.

```
SELECT EMPNO, DECIMAL(EDLEVEL,5,2)
FROM EMPLOYEE
```

- Using the PROJECT table, select all of the starting dates (PRSTDATE) that have been incremented by a duration that is specified in a host variable. Assume the host variable PERIOD is of type INTEGER. Then, in order to use its value as a date duration it must be “cast” as DECIMAL(8,0).

```
SELECT PRSTDATE + DECIMAL(:PERIOD,8)
FROM PROJECT
```

- Assume that updates to the SALARY column are input through a window as a character string using comma as a decimal character (for example, the user inputs 21400,50). Once validated by the application, it is assigned to the host variable newsalary which is defined as CHAR(10).

```
UPDATE STAFF
SET SALARY = DECIMAL(:newsalary, 9, 2, ',')
WHERE ID = :empid
```

The value of SALARY becomes 21400.50.

DECRYPT_BIT, DECRYPT_BINARY, DECRYPT_CHAR and DECRYPT_DB

The DECRYPT_BIT, DECRYPT_BINARY, DECRYPT_CHAR, and DECRYPT_DB functions return a value that is the result of decrypting encrypted data. The password used for decryption is either the *password-string* value or the ENCRYPTION PASSWORD value assigned by the SET ENCRYPTION PASSWORD statement.

The decryption functions can only decrypt values that are encrypted using the ENCRYPT_AES, ENCRYPT_RC2, or ENCRYPT_TDES function.

encrypted-data

An expression that must be a string expression that returns a complete, encrypted data value of a CHAR FOR BIT DATA, VARCHAR FOR BIT DATA, BINARY, VARBINARY, or BLOB built-in data type. The data string must have been encrypted using the ENCRYPT_AES, ENCRYPT_RC2, or ENCRYPT_TDES function.

password-string

An expression that returns a character string value with at least 6 bytes and no more than 127 bytes. The expression must not be a CLOB. This expression must be the same password used to encrypt the data or decryption will result in a different value than was originally encrypted. If the value of the password argument is null or not provided, the data will be decrypted using the ENCRYPTION PASSWORD value, which must have been set using the SET ENCRYPTION PASSWORD statement.

DEFAULT

The data will be decrypted using the ENCRYPTION PASSWORD value, which must have been set using the SET ENCRYPTION PASSWORD statement.

integer

An integer constant that specifies the CCSID of the result. If DECRYPT_BIT or DECRYPT_BINARY is specified, the third argument must not be specified.

If DECRYPT_CHAR is specified, *integer* must be a valid SBCS CCSID or mixed data CCSID. It cannot be 65535 (bit data). If the third argument is an SBCS CCSID, then the result is SBCS data. If the third argument is a mixed CCSID, then the result is mixed data. If the third argument is not specified then the CCSID of the result is the default CCSID of the current server.

If DECRYPT_DB is specified, *integer* must be a valid DBCS CCSID. If the third argument is not specified then the CCSID of the result is the DBCS CCSID associated with the default CCSID of the current server.

The data type of the result is determined by the function specified and the data type of the first argument as shown in the following table. If a cast from the actual type of the encrypted data to the function's result is not supported a warning or error is returned.

Function	Data Type of First Argument	Actual Data Type of Encrypted Data	Result
DECRYPT_BIT	CHAR FOR BIT DATA, VARCHAR FOR BIT DATA, BINARY, or VARBINARY	Character string	VARCHAR FOR BIT DATA

Function	Data Type of First Argument	Actual Data Type of Encrypted Data	Result
DECRYPT_BIT	CHAR FOR BIT DATA, VARCHAR FOR BIT DATA, BINARY, or VARBINARY	Graphic string	Error or Warning **
DECRYPT_BIT	CHAR FOR BIT DATA, VARCHAR FOR BIT DATA, BINARY, or VARBINARY	Binary string	Error or Warning **
DECRYPT_BIT	BLOB	Any string	Error
DECRYPT_BINARY	CHAR FOR BIT DATA, VARCHAR FOR BIT DATA, BINARY, or VARBINARY	Any string	VARBINARY
DECRYPT_BINARY	BLOB	Any string	BLOB
DECRYPT_CHAR	CHAR FOR BIT DATA, VARCHAR FOR BIT DATA, BINARY, or VARBINARY	Character string	VARCHAR
DECRYPT_CHAR	CHAR FOR BIT DATA, VARCHAR FOR BIT DATA, BINARY, or VARBINARY	Unicode graphic string	VARCHAR
DECRYPT_CHAR	CHAR FOR BIT DATA, VARCHAR FOR BIT DATA, BINARY, or VARBINARY	Non-Unicode graphic string	Error or Warning **
DECRYPT_CHAR	CHAR FOR BIT DATA, VARCHAR FOR BIT DATA, BINARY, or VARBINARY	Binary string	Error or Warning **
DECRYPT_CHAR	BLOB	Character string	CLOB
DECRYPT_CHAR	BLOB	Unicode graphic string	CLOB
DECRYPT_CHAR	BLOB	Non-Unicode graphic string	Error or Warning **
DECRYPT_CHAR	BLOB	Binary string	Error or Warning **
DECRYPT_DB	CHAR FOR BIT DATA, VARCHAR FOR BIT DATA, BINARY, or VARBINARY	UTF-8 character string or graphic string	VARGRAPHIC
DECRYPT_DB	CHAR FOR BIT DATA, VARCHAR FOR BIT DATA, BINARY, or VARBINARY	Non-UTF-8 character string	Error or Warning **
DECRYPT_DB	CHAR FOR BIT DATA, VARCHAR FOR BIT DATA, BINARY, or VARBINARY	Binary string	Error or Warning **
DECRYPT_DB	BLOB	UTF-8 character string or graphic string	DBCLOB
DECRYPT_DB	BLOB	Non-UTF-8 character string	Error or Warning **
DECRYPT_DB	BLOB	Binary string	Error or Warning **

Function	Data Type of First Argument	Actual Data Type of Encrypted Data	Result
<p>Note:</p> <p>** If the decryption function is in the select list of an outer subselect, a data mapping warning is returned. Otherwise an error is returned. For more information about data mapping warnings, see “Assignments and comparisons” on page 89.</p>			

If the *encrypted-data* included a hint, the hint is not returned by the function. The length attribute of the result is the length attribute of the data type of *encrypted-data* minus 8 bytes. The actual length of the result is the length of the original string that was encrypted. If the *encrypted-data* includes bytes beyond the encrypted string, these bytes are not returned by the function.

If the argument can be null, the result can be null; if the argument is null, the result is the null value.

If the data is decrypted using a different CCSID than the originally encrypted value, expansion may occur when converting the decrypted value to this CCSID. In such situations, the *encrypted-data* should be cast to a varying-length string with a larger number of bytes.

Note

Password protection: To prevent inadvertent access to the encryption password, do not specify *password-string* as a string constant in the source for a program, procedure, or function. Instead, use the ENCRYPTION PASSWORD special register or a host variable.

When connected to a remote relational database, the specified password itself is sent "in the clear". That is, the password itself is not encrypted. To protect the password in these cases, consider using a communications encryption mechanism such as IPSEC (or SSL if connecting between IBM i products).

Syntax alternatives: For compatibility with previous versions of Db2, DECRYPT_BIN can be specified in place of DECRYPT_BIT.

Examples

- Assume that table EMP1 has a social security column called SSN. This example uses the ENCRYPTION PASSWORD value to hold the encryption password.

```
SET ENCRYPTION PASSWORD = :pw
INSERT INTO EMP1 (SSN) VALUES ENCRYPT_RC2( '289-46-8832' )
SELECT DECRYPT_CHAR( SSN)
FROM EMP1
```

The DECRYPT_CHAR function returns the original value '289-46-8832'.

- This example explicitly passes the encryption password which has been set in variable pw.

```
INSERT INTO EMP1 (SSN) VALUES ENCRYPT_TDES( '289-46-8832', :pw)
SELECT DECRYPT_CHAR( SSN, :pw)
FROM EMP1
```

The DECRYPT_CHAR function returns the original value '289-46-8832'.

DEGREES

The DEGREES function returns the number of degrees of the argument which is an angle expressed in radians.

►► DEGREES (— *expression* —) ◄◄

expression

An expression that returns a value of any built-in numeric, character-string, or graphic-string data type. A string argument is cast to double-precision floating point before evaluating the function. For more information about converting strings to double-precision floating point, see [“DOUBLE_PRECISION or DOUBLE”](#) on page 392.

If the data type of the argument is DECFLOAT(*n*), the result is DECFLOAT(*n*). Otherwise, the data type of the result is double-precision floating point. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

Example

- Assume the host variable RAD is a DECIMAL(4,3) host variable with a value of 3.142.

```
SELECT DEGREES (:RAD)
FROM SYSIBM.SYSDUMMY1
```

Returns the approximate value 180.0.

DIFFERENCE

The DIFFERENCE function returns a value from 0 to 4 representing the difference between the sounds of two strings based on applying the SOUNDEX function to the strings. A value of 4 is the best possible sound match.

► DIFFERENCE (— *expression-1* — , — *expression-2* —) ◄

expression-1

An expression that returns a built-in numeric, character-string, or graphic-string data types, but not CLOBs or DBCLOBs. The arguments cannot be binary strings. A numeric argument is cast to a character string before evaluating the function. For more information about converting numeric to a character string, see [“VARCHAR” on page 623](#).

expression-2

An expression that returns a built-in numeric, character-string, or graphic-string data types, but not CLOBs or DBCLOBs. The arguments cannot be binary strings. A numeric argument is cast to a character string before evaluating the function. For more information about converting numeric to a character string, see [“VARCHAR” on page 623](#).

The data type of the result is INTEGER. If either argument can be null, the result can be null; if either argument is null, the result is the null value.

Examples

- Assume the following statement:

```
SELECT DIFFERENCE('CONSTRAINT', 'CONSTANT'),  
       SOUNDEX('CONSTRAINT'),  
       SOUNDEX('CONSTANT')  
FROM SYSIBM.SYSDUMMY1
```

Returns 4, C523, and C523. Since the two strings return the same SOUNDEX value, the difference is 4 (the highest value possible).

- Assume the following statement:

```
SELECT DIFFERENCE('CONSTRAINT', 'CONTRITE'),  
       SOUNDEX('CONSTRAINT'),  
       SOUNDEX('CONTRITE')  
FROM SYSIBM.SYSDUMMY1
```

Returns 2, C523, and C536. In this case, the two strings return different SOUNDEX values, and hence, a lower difference value.

DIGITS

The DIGITS function returns a character-string representation of the absolute value of a number.

►► DIGITS — (— *expression* —) ►◄

expression

An expression that returns a value of a built-in SMALLINT, INTEGER, BIGINT, DECIMAL, NUMERIC, character-string, or graphic-string data type. A string argument is cast to DECIMAL(63,31) before evaluating the function. For more information about converting strings to decimal, see [“DECIMAL or DEC”](#) on page 374.

If the argument can be null, the result can be null; if the argument is null, the result is the null value.

The result of the function is a fixed-length character string representing the absolute value of the argument without regard to its scale. The result does not include a sign or a decimal point. Instead, it consists exclusively of digits, including, if necessary, leading zeros to fill out the string. The length of the string is:

- 5 if the argument is a small integer with a scale of zero
- 10 if the argument is a large integer with a scale of zero
- 19 if the argument is a big integer
- p if the argument is a decimal (or an integer with a scale greater than zero) with a precision of p

The CCSID of the character string is the default SBCS CCSID at the current server.

Examples

- Assume that a table called TABLEX contains an INTEGER column called INTCOL containing 10-digit numbers. List all combinations of the first four digits contained in column INTCOL.

```
SELECT DISTINCT SUBSTR(DIGITS(INTCOL),1,4)
FROM TABLEX
```

- Assume that COLUMNX has the DECIMAL(6,2) data type, and that one of its values is -6.28.

```
SELECT DIGITS(COLUMNX)
FROM TABLEX
```

Returns the value '000628'.

The result is a string of length six (the precision of the column) with leading zeros padding the string out to this length. Neither sign nor decimal point appear in the result.

DLCOMMENT

The DLCOMMENT function returns the comment value, if it exists, from a DataLink value.

► DLCOMMENT — (— *DataLink-expression* —) ►

DataLink-expression

An expression that results in a value with a built-in DataLink data type.

The result of the function is VARCHAR(254). If the argument can be null, the result can be null; if the argument is null, the result is the null value.

The CCSID of the character string is the same as that of *DataLink-expression*.

Examples

- Prepare a statement to select the date, the description and the comment from the link to the ARTICLES column from the HOCKEY_GOALS table. The rows to be selected are those for goals scored by either of the Richard brothers (Maurice or Henri).

```
stmtvar = "SELECT DATE_OF_GOAL, DESCRIPTION, DLCOMMENT(ARTICLES)
           FROM HOCKEY_GOALS
           WHERE BY_PLAYER = 'Maurice Richard'
           OR BY_PLAYER = 'Henri Richard' ";
EXEC SQL PREPARE HOCKEY_STMT FROM :stmtvar;
```

- Given a DataLink value that was inserted into column COLA of a row in table TBLA using the scalar function:

```
INSERT INTO TBLA
VALUES (DLVALUE('http://dlfs.almaden.ibm.com/x/y/a.b','URL','A comment'))
```

then the following function operating on that value:

```
SELECT DLCOMMENT(COLA)
FROM TBLA
```

Returns the value 'A comment'.

DLLINKTYPE

The DLLINKTYPE function returns the link type value from a DataLink value.

►► DLLINKTYPE — (— *DataLink-expression* —) ◄◄

DataLink-expression

An expression that results in a value with a built-in DataLink data type.

The result of the function is VARCHAR(4). If the argument can be null, the result can be null; if the argument is null, the result is the null value.

The CCSID of the character string is the same as that of *DataLink-expression*.

Examples

- Given a DataLink value that was inserted into column COLA of a row in table TBLA using the scalar function:

```
INSERT INTO TABLA
VALUES( DLVALUE('http://dfs.almaden.ibm.com/x/y/a.b','URL','A comment') )
```

then the following function operating on that value:

```
SELECT DLLINKTYPE(COLA)
FROM TBLA
```

Returns the value 'URL'.

DLURLCOMPLETE

The DLURLCOMPLETE function returns the complete URL value from a DataLink value with a link type of URL. The value is the same as what would be returned by the concatenation of DLURLSCHEME with '://', then DLURLSERVER, and then DLURLPATH. If the DataLink has an attribute of FILE LINK CONTROL and READ PERMISSION DB, the value includes a file access token.

►► DLURLCOMPLETE — (— *DataLink-expression* —) ►►

DataLink-expression

An expression that results in a value with a built-in DataLink data type.

If the argument can be null, the result can be null; if the argument is null, the result is the null value.

The result of the function is a varying-length string. The length attribute depends on the attributes of the DataLink:

- If the DataLink has an attribute of FILE LINK CONTROL and READ PERMISSION DB, the length attribute of the result is the length attribute of the argument plus 19.
- Otherwise, the length attribute of the result is the length attribute of the argument.

If the DataLink value only includes the comment, the result returned is a zero length string.

The CCSID of the character string is the same as that of *DataLink-expression*.

Examples

- Given a DataLink value that was inserted into column COLA (with the attributes of FILE LINK CONTROL and READ PERMISSION DB) of a row in table TBLA using the scalar function:

```
INSERT INTO TABLA
VALUES( DLVALUE('http://dlfs.almaden.ibm.com/x/y/a.b','URL','A comment') )
```

then the following function operating on that value:

```
SELECT DLURLCOMPLETE(COLA)
FROM TBLA
```

Returns the value 'HTTP://DLFS.ALMADEN.IBM.COM/x/y/*****;a.b', where ***** represents the access token.

DLURLPATH

The DLURLPATH function returns the path and file name necessary to access a file within a given server from a DataLink value with a linktype of URL. When appropriate, the value includes a file access token.

►► DLURLPATH — (— *DataLink-expression* —) ►◄

DataLink-expression

An expression that results in a value with a built-in DataLink data type.

If the argument can be null, the result can be null; if the argument is null, the result is the null value.

The result of the function is a varying-length string. The length attribute depends on the attributes of the DataLink:

- If the DataLink has an attribute of FILE LINK CONTROL and READ PERMISSION DB, the length attribute of the result is the length attribute of the argument plus 19.
- Otherwise, the length attribute of the result is the length attribute of the argument.

If the DataLink value only includes the comment, the result returned is a zero length string.

The CCSID of the character string is the same as that of *DataLink-expression*.

Examples

- Given a DataLink value that was inserted into column COLA (with the attributes of FILE LINK CONTROL and READ PERMISSION DB) of a row in table TBLA using the scalar function:

```
INSERT INTO TABLA
VALUES( DLVALUE('http://dlfs.almaden.ibm.com/x/y/a.b','URL','A comment') )
```

then the following function operating on that value:

```
SELECT DLURLPATH(COLA)
FROM TBLA
```

Returns the value '/x/y/*****;a.b', where ***** represents the access token.

DLURLPATHONLY

The DLURLPATHONLY function returns the path and file name necessary to access a file within a given server from a DataLink value with a linktype of URL. The value returned NEVER includes a file access token.

► DLURLPATHONLY — (— *DataLink-expression* —) ►

DataLink-expression

An expression that results in a value with a built-in DataLink data type.

If the argument can be null, the result can be null; if the argument is null, the result is the null value.

The result of the function is a varying-length string with a length attribute of that is equal to the length attribute of the argument.

If the DataLink value only includes the comment, the result returned is a zero length string.

The CCSID of the character string is the same as that of *DataLink-expression*.

Examples

- Given a DataLink value that was inserted into column COLA of a row in table TBLA using the scalar function:

```
INSERT INTO TABLA
VALUES( DLVALUE('http://dlfs.almaden.ibm.com/x/y/a.b','URL','A comment') )
```

then the following function operating on that value:

```
SELECT DLURLPATHONLY(COLA)
FROM TBLA
```

Returns the value '/x/y/a.b'.

DLURLSCHEME

The DLURLSCHEME function returns the scheme from a DataLink value with a linktype of URL. The value will always be in upper case.

►► DLURLSCHEME — (— *DataLink-expression* —) ►◄

DataLink-expression

An expression that results in a value with a built-in DataLink data type.

The result of the function is VARCHAR(20). If the argument can be null, the result can be null; if the argument is null, the result is the null value.

If the DataLink value only includes the comment, the result returned is a zero length string.

The CCSID of the character string is the same as that of *DataLink-expression*.

Examples

- Given a DataLink value that was inserted into column COLA of a row in table TBLA using the scalar function:

```
INSERT INTO TABLA
VALUES( DLVALUE('http://dfs.almaden.ibm.com/x/y/a.b','URL','A comment') )
```

then the following function operating on that value:

```
SELECT DLURLSCHEME(COLA)
FROM TBLA
```

Returns the value 'HTTP'.

DLURLSERVER

The DLURLSERVER function returns the file server from a DataLink value with a linktype of URL. The value will always be in upper case.

►► DLURLSERVER — (— *DataLink-expression* —) ►►

DataLink-expression

An expression that results in a value with a built-in DataLink data type.

If the argument can be null, the result can be null; if the argument is null, the result is the null value.

The result of the function is a varying-length string with a length attribute of that is equal to the length attribute of the argument.

If the DataLink value only includes the comment, the result returned is a zero length string.

The CCSID of the character string is the same as that of *DataLink-expression*.

Examples

- Given a DataLink value that was inserted into column COLA of a row in table TBLA using the scalar function:

```
INSERT INTO TABLA
VALUES( DLVALUE('http://dlfs.almaden.ibm.com/x/y/a.b','URL','A comment') )
```

then the following function operating on that value:

```
SELECT DLURLSERVER(COLA)
FROM TBLA
```

Returns the value 'DLFS.ALMA DEN.IBM.COM'.

DLVALUE

The DLVALUE function returns a DataLink value. When the function is on the right hand side of a SET clause in an UPDATE statement or is in a VALUES clause in an INSERT statement, it usually also creates a link to a file. However, if only a comment is specified (in which case the *data-location* is a zero-length string), the DataLink value is created with empty linkage attributes so there is no file link.

►► DLVALUE (— *data-location* , — *linktype-string* , — *comment-string*) ◄◄

data-location

If the link type is URL, then this is a character string expression that contains a complete URL value. If the expression is not an empty string, it must include the URL scheme and URL server. The actual length of the character string expression must be less than or equal to 32718 characters.

linktype-string

An optional character string expression that specifies the link type of the DataLink value. The only valid value is 'URL'.

comment-string

An optional character string expression that provides a comment or additional location information. The actual length of the character string expression must be less than or equal to 254 characters.

The *comment-string* cannot be the null value. If a *comment-string* is not specified, the *comment-string* is the empty string.

If the first argument can be null, the result can be null; if the first argument is null, the result is the null value.

The result of the function is a DataLink value.

The CCSID of the DataLink is the same as that of *data-location* except in the following cases:

- If the *comment string* is mixed data and *data-location* is not mixed data, the CCSID of the result will be the CCSID of the *comment string*.⁵⁶
- If the *data-location* has a CCSID of bit data (65535), UTF-16 graphic data (1200), UCS-2 graphic data (13488), Turkish data (905 or 1026), or Japanese data (290, 930, or 5026); the CCSID of the result is described in the following table:

CCSID of <i>data-location</i>	CCSID of <i>comment-string</i>	Result CCSID
65535	65535	Job Default CCSID
65535	non-65535	<i>comment-string</i> CCSID (unless the CCSID is 290, 930, 5026, 905, 1026, or 13488 where the CCSID will then be further modified as described in the following rows.)
290	any	4396
930 or 5026	any	939
905 or 1026	any	500
1200	any	500
13488	any	500

⁵⁶ If the CCSID of *comment string* is 5026 or 930, the CCSID of the results will be 939.

When defining a DataLink value using this function, consider the maximum length of the target of the value. For example, if a column is defined as DataLink(200), then the maximum length of the *data-location* plus the comment is 200 bytes.

Examples

- Insert a row into the table. The URL values for the first two links are contained in the variables named url_article and url_snapshot. The variable named url_snapshot_comment contains a comment to accompany the snapshot link. There is, as yet, no link for the movie, only a comment in the variable named url_movie_comment.

```
INSERT INTO HOCKEY_GOALS
VALUES('Maurice Richard',
      'Montreal canadian',
      '?',
      'Boston Bruins',
      '1952-04-24',
      'Winning goal in game 7 of Stanley Cup final',
      DLVALUE(:url_article),
      DLVALUE(:url_snapshot, 'URL', :url_snapshot_comment),
      DLVALUE('', 'URL', :url_movie_comment) )
```

DOUBLE_PRECISION or DOUBLE

The DOUBLE_PRECISION and DOUBLE functions return a floating-point representation.

Numeric to Double

► DOUBLE_PRECISION (— *numeric-expression* —) ◄
DOUBLE

String to Double

► DOUBLE_PRECISION (— *string-expression* —) ◄
DOUBLE

The DOUBLE_PRECISION and DOUBLE functions return a floating-point representation of:

- A number
- A character or graphic string representation of a decimal number
- A character or graphic string representation of an integer
- A character or graphic string representation of a floating-point number
- A character or graphic string representation of a decimal floating-point number

Numeric to Double

numeric-expression

An expression that returns a value of any built-in numeric data type.

The result is the same number that would occur if the expression were assigned to a double-precision floating-point column or variable.

String to Double

string-expression

An expression that returns a value that is a character-string or graphic-string representation of a number.

If the argument is a *string-expression*, the result is the same number that would result from CAST(*string-expression* AS DOUBLE PRECISION). Leading and trailing blanks are eliminated and the resulting string must conform to the rules for forming a floating-point, decimal floating-point, integer, or decimal constant.

The single-byte character constant that must be used to delimit the decimal digits in *string-expression* from the whole part of the number is the default decimal point. For more information, see [“Decimal point”](#) on page 116.

The result of the function is a double-precision floating-point number. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

Note

Syntax alternatives: FLOAT is a synonym for DOUBLE_PRECISION and DOUBLE.

The CAST specification should be used to increase the portability of applications. For more information, see [“CAST specification”](#) on page 176.

Example

- Using the EMPLOYEE table, find the ratio of salary to commission for employees whose commission is not zero. The columns involved (SALARY and COMM) have DECIMAL data types. To eliminate the

possibility of out-of-range results, `DOUBLE_PRECISION` is applied to `SALARY` so that the division is carried out in floating point:

```
SELECT EMPNO, DOUBLE_PRECISION(SALARY)/COMM  
FROM EMPLOYEE  
WHERE COMM > 0
```

ENCRYPT_AES

The ENCRYPT_AES function returns a value that is the result of encrypting *data-string* using the AES encryption algorithm. The password used for decryption is either the *password-string* value or the encryption password value (assigned by the SET ENCRYPTION PASSWORD statement).

►► ENCRYPT_AES (— *data-string* , — *password-string* , — *hint-string*) ◄◄

data-string

An expression that returns the string value to be encrypted. The string expression must be a built-in string data type.

The length attribute for the data type of *data-string* is limited to 24 bytes (or 32 bytes) less than the maximum length of the result data type without a *hint-string* argument and 56 bytes (or 64 bytes) less than the maximum length of the result data type when the *hint-string* argument is specified.

password-string

An expression that returns a character string value with at least 6 bytes and no more than 127 bytes. The expression must not be a CLOB and the CCSID of the expression must not be 65535. The value represents the password used to encrypt the *data-string*. If the value of the password argument is null or not provided, the data will be encrypted using the ENCRYPTION PASSWORD value, which must have been set using the SET ENCRYPTION PASSWORD statement.

hint-string

An expression that returns a character string value with up to 32 bytes that will help data owners remember passwords (For example, 'Ocean' is a hint to remember 'Pacific'). The expression must not be a CLOB and the CCSID of the expression must not be 65535. If a hint value is specified, the hint is embedded into the result and can be retrieved using the GETHINT function. If the *password-string* is specified and this argument is the null value or not provided, no hint will be embedded in the result. If the *password-string* is not specified, the hint may be specified using the SET ENCRYPTION PASSWORD statement.

The data type of the result is determined by the first argument as shown in the following table:

Data Type of the First Argument	Data Type of the Result
BINARY or VARBINARY	VARBINARY
CHAR, VARCHAR, GRAPHIC, or VARGRAPHIC	VARCHAR FOR BIT DATA
BLOB, CLOB, or DBCLOB	BLOB

The length attribute of the result depends on the arguments that are specified:

- When a *password-string* is specified but a *hint-string* is not specified, the length attribute of *data-string* plus 24 plus the number of bytes to a 16 byte boundary.
- Otherwise, the length attribute of *data-string* plus 64 plus the number of bytes to a 16 byte boundary.

The actual length of the result is the sum of :

- The actual length of *data-string* plus a number of bytes to get to a 16 byte boundary.
- The actual length of the hint.

The actual length of the hint is zero if *hint-string* is not specified as a function argument or on the SET ENCRYPTION PASSWORD statement.

- *n*, where *n* (the amount of overhead necessary to encrypt the value) is 24 bytes (or 32 bytes if *data-string* is a LOB or different CCSID values are used for the *data-string*, the password, or the hint).

If the first argument can be null, the result can be null; if the first argument is null, the result is the null value.

Note that the encrypted result is longer than the *data-string* value. Therefore, when assigning encrypted values, ensure that the target is declared with sufficient size to contain the entire encrypted value.

Notes

Password protection: To prevent inadvertent access to the encryption password, do not specify *password-string* as a string constant in the source for a program, procedure, or function. Instead, use the SET ENCRYPTION PASSWORD statement or a host variable.

When connected to a remote relational database, the specified password itself is sent "in the clear". That is, the password itself is not encrypted. To protect the password in these cases, consider using a communications encryption mechanism such as IPSEC (or SSL if connecting between IBM i products).

Encryption algorithm: The internal encryption algorithm used is from the CLiC Toolkit from IBM Research. The 128-bit encryption key is derived from the password using a SHA1 message digest.

Encryption passwords and data: It is the user's responsibility to perform password management. Once the data is encrypted only the password used to encrypt it can be used to decrypt it. Be careful when using CHAR variables to set password values as they may be padded with blanks. The encrypted result may contain a null terminator and other non-printable characters.

Table column definition: When defining columns and distinct types to contain encrypted data:

- The column must be defined with a data type of CHAR FOR BIT DATA, VARCHAR FOR BIT DATA, BINARY, VARBINARY, or BLOB.
- The length attribute of the column must include an additional *n* bytes, where *n* is the overhead necessary to encrypt the data as described above.

Any assignment or cast to a column without one of these data types or with a length shorter than the suggested data length may result in an assignment error or, if the assignment is successful, a failure and lost data when the data is subsequently decrypted. Blanks are valid encrypted data values that may be truncated when stored in a column that is too short.

Some sample column length calculations:

Maximum length of non-encrypted data	6 bytes
Number of bytes to the next 16 byte boundary	10 bytes
Overhead	24 bytes (or 32 bytes)

Encrypted data column length	40 bytes (or 48 bytes)
Maximum length of non-encrypted data	32 bytes
Number of bytes to a 16 byte boundary	0 bytes
Overhead	24 bytes (or 32 bytes)

Encrypted data column length	56 bytes

Administration of encrypted data: Encrypted data can only be decrypted on servers that support the decryption functions that correspond to the ENCRYPT_AES function. Hence, replication of columns with encrypted data should only be done to servers that support the decryption functions.

Example

- Assume that table EMP1 has a social security column called SSN. This example uses the ENCRYPTION PASSWORD value to hold the encryption password.

```
SET ENCRYPTION PASSWORD = 'Ben123'  
INSERT INTO EMP1 (SSN) VALUES ENCRYPT_AES( '289-46-8832' )
```

- This example explicitly passes the encryption password.

```
INSERT INTO EMP1 (SSN) VALUES ENCRYPT_AES( '289-46-8832', 'Ben123' )
```

- The hint 'Ocean' is stored to help the user remember the encryption password 'Pacific'.

```
INSERT INTO EMP1 (SSN) VALUES ENCRYPT_AES( '289-46-8832', 'Pacific', 'Ocean' )
```

ENCRYPT_RC2 or ENCRPYT

The ENCRYPT_RC2 function returns a value that is the result of encrypting *data-string* using the RC2 encryption algorithm. The password used for decryption is either the *password-string* value or the encryption password value (assigned by the SET ENCRYPTION PASSWORD statement).

►► ENCRYPT_RC2 — (— *data-string* — , — *password-string* — , — *hint-string* —) ►►

data-string

An expression that returns the string value to be encrypted. The string expression must be a built-in string data type.

The length attribute for the data type of *data-string* must be less than $m - \text{MOD}(m,8) - n - 1$, where m is the maximum length of the result data type and n is the amount of overhead necessary to encrypt the value.

- If a *hint-string* is not specified, n is 8 bytes.
- If a *hint-string* is specified, n is 40 bytes.

password-string

An expression that returns a character string value with at least 6 bytes and no more than 127 bytes. The expression must not be a CLOB. The value represents the password used to encrypt the *data-string*. If the value of the password argument is null or not provided, the data will be encrypted using the ENCRYPTION PASSWORD value, which must have been set using the SET ENCRYPTION PASSWORD statement.

hint-string

An expression that returns a character string value with up to 32 bytes that will help data owners remember passwords (For example, 'Ocean' is a hint to remember 'Pacific'). The expression must not be a CLOB. If a hint value is specified, the hint is embedded into the result and can be retrieved using the GETHINT function. If the *password-string* is specified and this argument is the null value or not provided, no hint will be embedded in the result. If the *password-string* is not specified, the hint may be specified using the SET ENCRYPTION PASSWORD statement.

The data type of the result is determined by the first argument as shown in the following table:

Data Type of the First Argument	Data Type of the Result
BINARY or VARBINARY	VARBINARY
CHAR, VARCHAR, GRAPHIC, or VARGRAPHIC	VARCHAR FOR BIT DATA
BLOB, CLOB, or DBCLOB	BLOB

The length attribute of the result depends on the arguments that are specified:

- When a *password-string* is specified but a *hint-string* is not specified, the length attribute of *data-string* plus 16 plus the number of bytes to the next 8 byte boundary.⁵⁷
- Otherwise, the length attribute of *data-string* plus 48 plus the number of bytes to the next 8 byte boundary.⁵⁷

The actual length of the result is the sum of :

- The actual length of *data-string* plus a number of bytes to get to the next 8 byte boundary.⁵⁷
- The actual length of the hint.

⁵⁷ Unlike ENCRYPT_TDES and ENCRYPT_AES, 8 bytes are added even if the length of *data-string* is already on an 8 byte boundary.

The actual length of the hint is zero if *hint-string* is not specified as a function argument or on the SET ENCRYPTION PASSWORD statement.

- *n*, where *n* (the amount of overhead necessary to encrypt the value) is 8 bytes (or 16 bytes if *data-string* is a LOB or different CCSID values are used for the *data-string*, the password, or the hint).

If the argument can be null, the result can be null; if the argument is null, the result is the null value.

Note that the encrypted result is longer than the *data-string* value. Therefore, when assigning encrypted values, ensure that the target is declared with sufficient size to contain the entire encrypted value.

Notes

Password protection: To prevent inadvertent access to the encryption password, do not specify *password-string* as a string constant in the source for a program, procedure, or function. Instead, use the SET ENCRYPTION PASSWORD statement or a host variable.

When connected to a remote relational database, the specified password itself is sent "in the clear". That is, the password itself is not encrypted. To protect the password in these cases, consider using a communications encryption mechanism such as IPSEC (or SSL if connecting between IBM i products).

Encryption algorithm: The internal encryption algorithm used is RC2 block cipher with padding, the 128 bit secret key is derived from the password using a MD5 message digest.

Encryption passwords and data: It is the user's responsibility to perform password management. Once the data is encrypted only the password used to encrypt it can be used to decrypt it. Be careful when using CHAR variables to set password values as they may be padded with blanks. The encrypted result may contain a null terminator and other non-printable characters.

Table column definition: When defining columns and distinct types to contain encrypted data:

- The column must be defined with a data type of CHAR FOR BIT DATA, VARCHAR FOR BIT DATA, BINARY, VARBINARY, or BLOB.
- The length attribute of the column must include an additional *n* bytes, where *n* is the overhead necessary to encrypt the data as described above.

Any assignment or cast to a column without one of these data types or with a length shorter than the suggested data length may result in an assignment error or, if the assignment is successful, a failure and lost data when the data is subsequently decrypted. Blanks are valid encrypted data values that may be truncated when stored in a column that is too short.

Some sample column length calculations:

Maximum length of non-encrypted data	6 bytes
Number of bytes to the next 8 byte boundary	2 bytes
Overhead	8 bytes (or 16 bytes)
Encrypted data column length	16 bytes (or 32 bytes)

Maximum length of non-encrypted data	32 bytes
Number of bytes to the next 8 byte boundary	8 bytes
Overhead	8 bytes (or 16 bytes)
Encrypted data column length	48 bytes (or 56 bytes)

Administration of encrypted data: Encrypted data can only be decrypted on servers that support the decryption functions that correspond to the ENCRYPT_RC2 function. Hence, replication of columns with encrypted data should only be done to servers that support the decryption functions.

Syntax alternatives: For compatibility with previous versions of Db2, ENCRYPT can be specified in place of ENCRYPT_RC2.

Example

- Assume that table EMP1 has a social security column called SSN. This example uses the ENCRYPTION PASSWORD value to hold the encryption password.

```
SET ENCRYPTION PASSWORD = 'Ben123'
```

```
INSERT INTO EMP1 (SSN) VALUES ENCRYPT_RC2( '289-46-8832' )
```

- This example explicitly passes the encryption password.

```
INSERT INTO EMP1 (SSN) VALUES ENCRYPT_RC2( '289-46-8832', 'Ben123' )
```

- The hint 'Ocean' is stored to help the user remember the encryption password 'Pacific'.

```
INSERT INTO EMP1 (SSN) VALUES ENCRYPT_RC2( '289-46-8832', 'Pacific', 'Ocean' )
```

ENCRYPT_TDES

The ENCRYPT_TDES function returns a value that is the result of encrypting *data-string* using the Triple DES encryption algorithm. The password used for decryption is either the *password-string* value or the encryption password value (assigned by the SET ENCRYPTION PASSWORD statement).

►► ENCRYPT_TDES (— *data-string* — , — *password-string* — , — *hint-string* —) ►►

data-string

An expression that returns the string value to be encrypted. The string expression must be a built-in string data type.

The length attribute for the data type of *data-string* must be less than $m - \text{MOD}(m,8) - n - 1$, where m is the maximum length of the result data type and n is the amount of overhead necessary to encrypt the value.

password-string

An expression that returns a character string value with at least 6 bytes and no more than 127 bytes. The expression must not be a CLOB and the CCSID of the expression must not be 65535. The value represents the password used to encrypt the *data-string*. If the value of the password argument is null or not provided, the data will be encrypted using the ENCRYPTION PASSWORD value, which must have been set using the SET ENCRYPTION PASSWORD statement.

hint-string

An expression that returns a character string value with up to 32 bytes that will help data owners remember passwords (For example, 'Ocean' is a hint to remember 'Pacific'). The expression must not be a CLOB and the CCSID of the expression must not be 65535. If a hint value is specified, the hint is embedded into the result and can be retrieved using the GETHINT function. If the *password-string* is specified and this argument is the null value or not provided, no hint will be embedded in the result. If the *password-string* is not specified, the hint may be specified using the SET ENCRYPTION PASSWORD statement.

The data type of the result is determined by the first argument as shown in the following table:

Data Type of the First Argument	Data Type of the Result
BINARY or VARBINARY	VARBINARY
CHAR, VARCHAR, GRAPHIC, or VARGRAPHIC	VARCHAR FOR BIT DATA
BLOB, CLOB, or DBCLOB	BLOB

The length attribute of the result depends on the arguments that are specified:

- When a *password-string* is specified but a *hint-string* is not specified, the length attribute of *data-string* plus 24 plus the number of bytes to an 8 byte boundary.
- Otherwise, the length attribute of *data-string* plus 56 plus the number of bytes to an 8 byte boundary.

The actual length of the result is the sum of :

- The actual length of *data-string* plus a number of bytes to get to the an 8 byte boundary.
- The actual length of the hint.

The actual length of the hint is zero if *hint-string* is not specified as a function argument or on the SET ENCRYPTION PASSWORD statement.

- n , where n (the amount of overhead necessary to encrypt the value) is 16 bytes (or 24 bytes if *data-string* is a LOB or different CCSID values are used for the *data-string*, the password, or the hint).

If the argument can be null, the result can be null; if the argument is null, the result is the null value.

Note that the encrypted result is longer than the *data-string* value. Therefore, when assigning encrypted values, ensure that the target is declared with sufficient size to contain the entire encrypted value.

Notes

Password protection: To prevent inadvertent access to the encryption password, do not specify *password-string* as a string constant in the source for a program, procedure, or function. Instead, use the SET ENCRYPTION PASSWORD statement or a host variable.

When connected to a remote relational database, the specified password itself is sent "in the clear". That is, the password itself is not encrypted. To protect the password in these cases, consider using a communications encryption mechanism such as IPSEC (or SSL if connecting between IBM i products).

Encryption algorithm: The internal encryption algorithm used is Triple DES block cipher with padding, the 128 bit secret key is derived from the password using a SHA1 message digest.

Encryption passwords and data: It is the user's responsibility to perform password management. Once the data is encrypted only the password used to encrypt it can be used to decrypt it. Be careful when using CHAR variables to set password values as they may be padded with blanks. The encrypted result may contain a null terminator and other non-printable characters.

Table column definition: When defining columns and distinct types to contain encrypted data:

- The column must be defined with a data type of CHAR FOR BIT DATA, VARCHAR FOR BIT DATA, BINARY, VARBINARY, or BLOB.
- The length attribute of the column must include an additional *n* bytes, where *n* is the overhead necessary to encrypt the data as described above.

Any assignment or cast to a column without one of these data types or with a length shorter than the suggested data length may result in an assignment error or, if the assignment is successful, a failure and lost data when the data is subsequently decrypted. Blanks are valid encrypted data values that may be truncated when stored in a column that is too short.

Some sample column length calculations:

Maximum length of non-encrypted data	6 bytes
Number of bytes to the next 8 byte boundary	2 bytes
Overhead	16 bytes (or 24 bytes)

Encrypted data column length	24 bytes (or 32 bytes)
Maximum length of non-encrypted data	32 bytes
Number of bytes to an 8 byte boundary	0 bytes
Overhead	16 bytes (or 24 bytes)

Encrypted data column length	48 bytes (or 56 bytes)

Administration of encrypted data: Encrypted data can only be decrypted on servers that support the decryption functions that correspond to the ENCRYPT_TDES function. Hence, replication of columns with encrypted data should only be done to servers that support the decryption functions.

Example

- Assume that table EMP1 has a social security column called SSN. This example uses the ENCRYPTION PASSWORD value to hold the encryption password.

```
SET ENCRYPTION PASSWORD = 'Ben123'  
INSERT INTO EMP1 (SSN) VALUES ENCRYPT_TDES( '289-46-8832' )
```

- This example explicitly passes the encryption password.

```
INSERT INTO EMP1 (SSN) VALUES ENCRYPT_TDES( '289-46-8832', 'Ben123' )
```

- The hint 'Ocean' is stored to help the user remember the encryption password 'Pacific'.

```
INSERT INTO EMP1 (SSN) VALUES ENCRYPT_TDES( '289-46-8832', 'Pacific', 'Ocean' )
```

EXP

The EXP function returns a value that is the base of the natural logarithm (e) raised to a power specified by the argument. The EXP and LN functions are inverse operations.

► EXP — (— *expression* —) ◄

expression

An expression that returns a value of any built-in numeric, character-string, or graphic-string data type. A string argument is cast to double-precision floating point before evaluating the function. For more information about converting strings to double-precision floating point, see “DOUBLE_PRECISION or DOUBLE” on page 392.

If the data type of the argument is DECFLOAT(*n*), the result is DECFLOAT(*n*). Otherwise, the data type of the result is double-precision floating point. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

Note

Results involving DECFLOAT special values: For decimal floating-point values the special values are treated as follows:

- EXP(NaN) returns NaN.
- EXP(-NaN) returns -NaN.
- EXP(Infinity) returns Infinity.
- EXP(-Infinity) returns 0.
- EXP(sNaN) and EXP(-sNaN) return a warning or error.⁵⁸

Example

- Assume the host variable E is a DECIMAL(10,9) host variable with a value of 3.453789832.

```
SELECT EXP(:E)
FROM SYSIBM.SYSDUMMY1
```

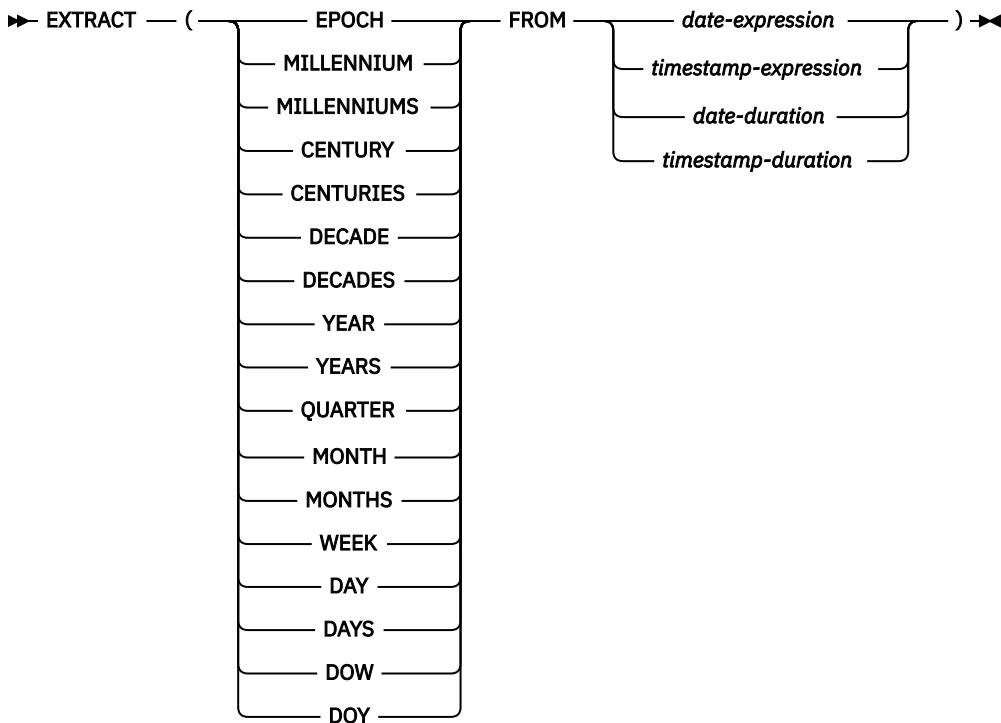

Returns the approximate value 31.62.

⁵⁸ If *YES is specified for the SQL_DECFLOAT_WARNINGS query option, NaN and -NaN are returned respectively with a warning.

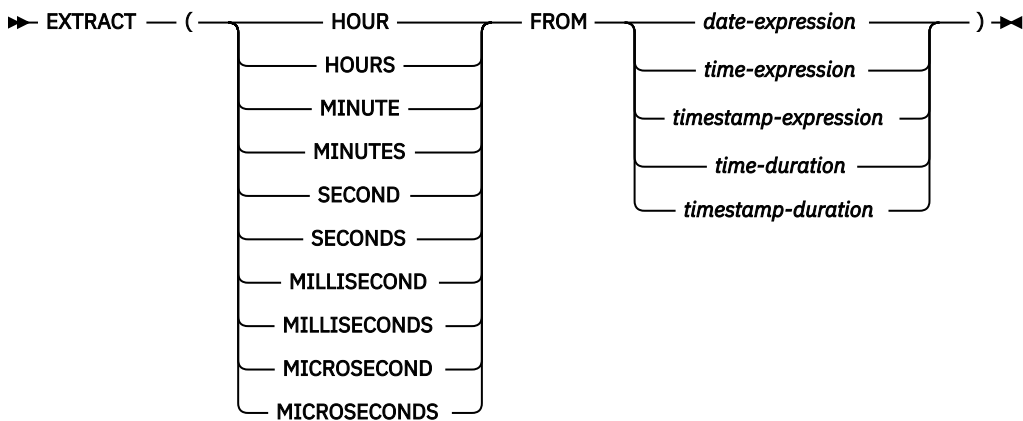

EXTRACT

The EXTRACT function returns a specified portion of a datetime value.

Extract Date Values

Extract Time Values

Extract Date Values

EPOCH

Specifies that the number of seconds since 1970-01-01 00:00:00.00 is returned for the *date-expression* or *timestamp-expression*. The value can be positive or negative. This cannot be specified for a *date-duration* or *timestamp-duration*.

MILLENNIUM or MILLENNIUMS

Specifies that the number of full 1000-year periods represented by the year is returned for the *date-expression*, *timestamp-expression*, *date-duration*, or *timestamp-duration*. For example, 2 is returned for a date between 2000-01-01 and 2999-12-31.

CENTURY or CENTURIES

Specifies that the number of full 100-year periods represented by the year is returned for the *date-expression*, *timestamp-expression*, *date-duration*, or *timestamp-duration*. For example, 20 is returned for a date between 2000-01-01 and 2099-12-31.

DECADE or DECADES

Specifies that the number of full 10-year periods represented by the year is returned for the *date-expression*, *timestamp-expression*, *date-duration*, or *timestamp-duration*. For example, 201 is returned for a date between 2010-01-01 and 2019-12-31.

YEAR or YEARS

Specifies that the year portion of the *date-expression*, *timestamp-expression*, *date-duration*, or *timestamp-duration* is returned. The result is identical to the YEAR scalar function. For more information, see [“YEAR” on page 682](#).

QUARTER

Specifies that the quarter of the year (1 - 4) is returned for the *date-expression* or *timestamp-expression*. The result is identical to the QUARTER scalar function. For more information, see [“QUARTER” on page 532](#). This cannot be specified for a *date-duration* or *timestamp-duration*.

MONTH or MONTHS

Specifies that the month portion of the *date-expression*, *timestamp-expression*, *date-duration*, or *timestamp-duration* is returned. The result is identical to the MONTH scalar function. For more information, see [“MONTH” on page 498](#).

WEEK

Specifies that the number of the week of the year (1 - 53) is returned for the *date-expression* or *timestamp-expression*. The week starts with Monday. The result is identical to the WEEK_ISO scalar function. For more information, see [“WEEK_ISO” on page 647](#). This cannot be specified for a *date-duration* or *timestamp-duration*.

DAY or DAYS

Specifies that the day portion of the *date-expression*, *timestamp-expression*, *date-duration* or *timestamp-duration* is returned. The result is identical to the DAY scalar function. For more information, see [“DAY” on page 354](#).

DOW

Specifies that the day of the week, where 1 represents Sunday and 7 represents Saturday, is returned for the *date-expression* or *timestamp-expression*. The result is identical to the DAYOFWEEK scalar function. For more information, see [“DAYOFWEEK” on page 357](#). This cannot be specified for a *date-duration* or *timestamp-duration*.

DOY

Specifies that the day of the year (1 - 366) is returned for the *date-expression* or *timestamp-expression*. The result is identical to the DAYOFYEAR scalar function. For more information, see [“DAYOFYEAR” on page 359](#). This cannot be specified for a *date-duration* or *timestamp-duration*.

date-expression

An expression that returns the value of either a built-in date, built-in character string, or built-in graphic string data type.

If *date-expression* is a character or graphic string, its value must be a valid character-string or graphic-string representation of a date. For the valid formats of string representations of dates, see [“String representations of datetime values” on page 75](#).

timestamp-expression

An expression that returns the value of either a built-in timestamp, built-in character string, or built-in graphic string data type.

If *timestamp-expression* is a character or graphic string, its value must be a valid character-string or graphic-string representation of a timestamp. For the valid formats of string representations of timestamps, see [“String representations of datetime values” on page 75](#).

date-duration

A date duration expressed as a DECIMAL(8,0) number. For the valid formats of datetime durations, see [“Datetime operands and durations” on page 165](#).

timestamp-duration

A timestamp duration expressed as a DECIMAL(14+s,s) number, where s is the number of digits of fractional seconds ranging from 0 to 12. For the valid formats of datetime durations, see [“Datetime operands and durations”](#) on page 165.

Extract Time Values

HOURL or HOURS

Specifies that the hour portion of the *time-expression*, *timestamp-expression*, *time-duration*, or *timestamp-duration* is returned. Returns 0 for a *date-expression*. The result is identical to the HOUR scalar function. For more information, see [“HOURL”](#) on page 426.

MINUTE or MINUTES

Specifies that the minute portion of the *time-expression*, *timestamp-expression*, *time-duration*, or *timestamp-duration* is returned. Returns 0 for a *date-expression*. The result is identical to the MINUTE scalar function. For more information, see [“MINUTE”](#) on page 495.

SECOND or SECONDS

Specifies that the second portion of the *time-expression*, *timestamp-expression*, *time-duration*, or *timestamp-duration* is returned. Returns 0 for a *date-expression*. The result is identical to:

- SECOND(expression, 6) when the data type of expression is a TIME value, a string representation of a TIME or TIMESTAMP, or a time duration.
- SECOND(expression, s) when the data type of expression is a TIMESTAMP(s) value or a timestamp duration.

For more information, see [“SECOND”](#) on page 568.

MILLISECOND or MILLISECONDS

Specifies the second of the minute, including fractional parts to one thousandth of a second, multiplied by 1000 is returned (0 - 59999) for the *timestamp-expression* or *timestamp-duration*. Returns 0 for a *date-expression*, *time-expression*, or *time-duration*.

MICROSECOND or MICROSECONDS

Specifies the second of the minute, including fractional parts to one millionth of a second, multiplied by 1000000 is returned (0 - 59999999) for the *timestamp-expression* or *timestamp-duration*. Returns 0 for a *date-expression*, *time-expression*, or *time-duration*.

date-expression

An expression that returns the value of either a built-in date, built-in character string, or built-in graphic string data type.

If *date-expression* is a character or graphic string, its value must be a valid character-string or graphic-string representation of a date. If *expression* is a valid string representation of a date, it must be one of the IBM SQL standard formats. For the valid formats of string representations of dates, see [“String representations of datetime values”](#) on page 75.

time-expression

An expression that returns the value of either a built-in time, built-in character string, or built-in graphic string data type.

If *time-expression* is a character or graphic string, its value must be a valid character-string or graphic-string representation of a time. For the valid formats of string representations of times, see [“String representations of datetime values”](#) on page 75.

timestamp-expression

An expression that returns the value of either a built-in timestamp, built-in character string, or built-in graphic string data type.

If *timestamp-expression* is a character or graphic string, its value must be a valid character-string or graphic-string representation of a timestamp. For the valid formats of string representations of timestamps, see [“String representations of datetime values”](#) on page 75.

time-duration

A time duration expressed as a DECIMAL(6,0) number. For the valid formats of datetime durations, see [“Datetime operands and durations”](#) on page 165.

timestamp-duration

A timestamp duration expressed as a DECIMAL(14+s,s) number, where s is the number of digits of fractional seconds ranging from 0 to 12. For the valid formats of datetime durations, see [“Datetime operands and durations”](#) on page 165.

The data type of the result of the function depends on the part of the datetime value that is specified:

- If EPOCH is specified, the data type of result is BIGINT.
- If MILLENNIUM, CENTURY, DECADE, YEAR, QUARTER, MONTH, WEEK, DAY, DOW, DOY, HOUR, MINUTE, MILLISECOND, or MICROSECOND is specified, the data type of the result is INTEGER.
- If SECOND is specified with a `TIMESTAMP(p)` value, the data type of the result is DECIMAL(2+p,p) where p is the fractional seconds precision.
- If SECOND is specified with a TIME value or a string representation of a TIME or TIMESTAMP, the data type of the result is DECIMAL(8,6).

If the argument can be null, the result can be null; if the argument is null, the result is the null value.

Examples

- Assume the column PRSDATE has an internal value equivalent to 1988-12-25.

```
SELECT EXTRACT( MONTH FROM PRSDATE )
FROM PROJECT
```

This statement returns the integer value 12.

- Assume the timestamp global variable GV1 has the value '2007-02-14 12:15:06.123456'.

```
VALUES EXTRACT(MILLISECONDS FROM GV1);
```

This statement returns the integer value 6123.

- Assume the timestamp global variable GV1 has the value '2007-02-14 12:15:06.123456'.

```
VALUES EXTRACT(MICROSECONDS FROM GV1);
```

This statement returns the integer value 6123456.

- Assume the date global variable GV2 has the value '2013-02-14'.

```
VALUES EXTRACT(DECADE FROM GV2);
```

This statement returns the integer value 201.

- Assume the decimal(6,0) global variable GV3 has the value 123020.

```
VALUES EXTRACT(SECONDS FROM GV3);
```

This statement returns the integer value 20.

FLOAT

The FLOAT function returns a floating point representation of a number or string.

Numeric to Float

►► FLOAT (— *numeric-expression* —) ◄◄

String to Float

►► FLOAT (— *string-expression* —) ◄◄

FLOAT is a synonym for the DOUBLE_PRECISION and DOUBLE functions. For more information, see [“DOUBLE_PRECISION or DOUBLE” on page 392.](#)

FLOOR

The FLOOR function returns the largest integer value less than or equal to *expression*.

► FLOOR — (— *expression* —) ►

expression

An expression that returns a value of any built-in numeric, character-string, or graphic-string data type. A string argument is cast to double-precision floating point before evaluating the function. For more information about converting strings to double-precision floating point, see “DOUBLE_PRECISION or DOUBLE” on page 392.

The result of the function has the same data type and length attribute as the argument except that the scale is 0 if the argument is a decimal number. For example, an argument with a data type of DECIMAL(5,5) will result in DECIMAL(5,0).

If the argument can be null, the result can be null; if the argument is null, the result is the null value.

Note

Results involving DECFLOAT special values: For decimal floating-point values, the special values are treated as follows:

- FLOOR(NaN) returns NaN.
- FLOOR(-NaN) returns -NaN.
- FLOOR(Infinity) returns Infinity.
- FLOOR(-Infinity) returns -Infinity.
- FLOOR(sNaN) and FLOOR(-sNaN) returns a warning or error.⁵⁹

Example

- Use the FLOOR function to truncate any digits to the right of the decimal point.

```
SELECT FLOOR(SALARY)
FROM EMPLOYEE
```

- Use FLOOR on both positive and negative numbers.

```
SELECT FLOOR( 3.5),
       FLOOR( 3.1),
       FLOOR(-3.1),
       FLOOR(-3.5)
FROM SYSIBM.SYSDUMMY1
```

This example returns:

```
3.    3.   -4.   -4.
```

respectively.

⁵⁹ If *YES is specified for the SQL_DECFLOAT_WARNINGS query option, NaN and -NaN are returned respectively with a warning.

GENERATE_UNIQUE

The GENERATE_UNIQUE function returns a bit data character string 13 bytes long (CHAR(13) FOR BIT DATA) that is unique compared to any other execution of the same function. The function is defined as non-deterministic

►► GENERATE_UNIQUE — (—) ►►

The result of the function is a unique value that includes the internal form of the Universal Time, Coordinated (UTC) and the system serial number. The result cannot be null.

The result of this function can be used to provide unique values in a table. Each successive value will be greater than the previous value, providing a sequence that can be used within a table. The sequence is based on the time when the function was executed.

This function differs from using the special register CURRENT_TIMESTAMP in that a unique value is generated for each instance of the function in an SQL statement and each row of a multiple row insert statement, an insert statement with a fullselect, or an insert statement in a MERGE statement.

The timestamp value that is part of the result of this function can be determined using the TIMESTAMP function with the result of GENERATE_UNIQUE as an argument.

Examples

- Create a table that includes a column that is unique for each row. Populate this column using the GENERATE_UNIQUE function. Notice that the UNIQUE_ID column is defined as FOR BIT DATA to identify the column as a bit data character string.

```
CREATE TABLE EMP_UPDATE
(UNIQUE_ID CHAR(13) FOR BIT DATA,
 EMPNO CHAR(6),
 TEXT VARCHAR(1000))
INSERT INTO EMP_UPDATE VALUES (GENERATE_UNIQUE(),
                                '000020',
                                'Update entry 1...')
INSERT INTO EMP_UPDATE VALUES (GENERATE_UNIQUE(),
                                '000050',
                                'Update entry 2...')
```

This table will have a unique identifier for each row provided that the UNIQUE_ID column is always set using GENERATE_UNIQUE. This can be done by introducing a trigger on the table.

```
CREATE TRIGGER EMP_UPDATE_UNIQUE
NO CASCADE BEFORE INSERT ON EMP_UPDATE
REFERENCING NEW AS NEW_UPD
FOR EACH ROW MODE DB2SQL
SET NEW_UPD.UNIQUE_ID = GENERATE_UNIQUE()
```

With this trigger, the previous INSERT statements that were used to populate the table can be issued without specifying a value for the UNIQUE_ID column:

```
INSERT INTO EMP_UPDATE(EMPNO, TEXT) VALUES ('000020', 'Update entry 1...')
INSERT INTO EMP_UPDATE(EMPNO, TEXT) VALUES ('000050', 'Update entry 2...')
```

The timestamp (in UTC) for when a row was added to EMP_UPDATE can be returned using:

```
SELECT TIMESTAMP(UNIQUE_ID), EMPNO, TEXT FROM EMP_UPDATE
```

Therefore, the table does not need a timestamp column to record when a row is inserted.

GET_BLOB_FROM_FILE

The GET_BLOB_FROM_FILE function returns the data from a source stream file or a source physical file.

►► GET_BLOB_FROM_FILE (— *string-expression* — , — *integer* —) ►►

string-expression

The argument must be a string expression that specifies a path and file name. The file name may be a name of a source stream file or a source physical file. For a source physical file, the string must be in the form 'library/file(member)'.

integer

An integer constant that specifies how to handle trailing whitespace when the specified file is a source physical file. Valid values are:

- 0 whitespace is returned as it exists in the file
- 1 trailing whitespace (blanks) is removed except for the first trailing blank

If this argument is not specified for a source physical file, the default is 0. If it is specified for a source stream file, it is ignored.

The result of the function is a BLOB locator.

The function will read the file specified by the argument with no CCSID conversion and return it as a BLOB locator. The function must be run under commitment control. The locator will be freed when a COMMIT or ROLLBACK is performed.

Examples

Register an XML schema document in the XSR registry where the XML schema is in a source stream file.

```
CALL XSR_REGISTER ('myschemalib', 'myschema', NULL,  
GET_BLOB_FROM_FILE('/home/XML/MySchema.XSD',0), NULL)
```

GET_CLOB_FROM_FILE

The GET_CLOB_FROM_FILE function returns the data from a source stream file or a source physical file.

► GET_CLOB_FROM_FILE (— *string-expression* — , — *integer* —) ►

string-expression

The argument must be a string expression that specifies a path and file name. The file name may be a name of a source stream file or a source physical file. For a source physical file, the string must be in the form 'library/file(member)'.

integer

An integer constant that specifies how to handle trailing whitespace when the specified file is a source physical file. Valid values are:

- | | |
|---|---|
| 0 | whitespace is returned as it exists in the file |
| 1 | trailing whitespace (blanks) is removed except for the first trailing blank |

If this argument is not specified for a source physical file, the default is 0. If it is specified for a source stream file, it is ignored.

The result of the function is a CLOB locator.

The function will read the file specified by the argument, convert the data to the default job CCSID, and return it as a CLOB locator. The function must be run under commitment control. The locator will be freed when a COMMIT or ROLLBACK is performed.

Examples

Assign the data contained in the source file to host variable HV1. The data will be converted to the default job CCSID and trailing blanks from each line of the source file will be removed.

```
SET :HV1 = GET_CLOB_FROM_FILE('MYLIB/MYFILE(MYMBR)',1)
```

GET_DBCLOB_FROM_FILE

The GET_DBCLOB_FROM_FILE function returns the data from a source stream file or a source physical file.

►► GET_DBCLOB_FROM_FILE (— *string-expression* — , — *integer* —) ◄◄

string-expression

The argument must be a string expression that specifies a path and file name. The file name may be a name of a source stream file or a source physical file. For a source physical file, the string must be in the form 'library/file(member)'.

integer

An integer constant that specifies how to handle trailing whitespace when the specified file is a source physical file. Valid values are:

- | | |
|---|---|
| 0 | whitespace is returned as it exists in the file |
| 1 | trailing whitespace (blanks) is removed except for the first trailing blank |

If this argument is not specified for a source physical file, the default is 0. If it is specified for a source stream file, it is ignored.

The result of the function is a DBCLOB locator.

The function will read the file specified by the argument, convert the data to the double-byte CCSID associated with the default CCSID, and return it as a DBCLOB locator. The function must be run under commitment control. The locator will be freed when a COMMIT or ROLLBACK is performed.

Examples

Assign the data contained in the source stream file to host variable HV1. The data will be converted to the double-byte CCSID associated with the default CCSID.

```
SET :HV1 = GET_DBCLOB_FROM_FILE('/home/XML/MySchema.XSD')
```

GET_XML_FILE

The GET_XML_FILE function returns the data from a source stream file or a source physical file.

►► GET_XML_FILE — (— *string-expression* —) ◄◄

string-expression

The argument must be a string expression that specifies a path and file name. The file name may be a name of a source stream file or a source physical file. For a source physical file, the string must be in the form 'library/file(member)'.

The result of the function is a BLOB locator.

The function will read the file specified by the argument and convert the data to UTF-8. If the file does not contain an XML declaration, one will be added. It will return it as a BLOB locator. The function must be run under commitment control. The locator will be freed when a COMMIT or ROLLBACK is performed.

Examples

Register an XML schema document in the XSR registry where the XML schema is in a source stream file.

```
CALL XSR_REGISTER ('myschemalib', 'myschema', NULL,  
                  GET_XML_FILE('/home/XML/MySchema.XSD'), NULL)
```

GETHINT

The GETHINT function will return the password hint if one is found in the *encrypted-data*. A password hint is a phrase that will help data owners remember passwords (For example, 'Ocean' as a hint to remember 'Pacific').

► GETHINT (— *encrypted-data* —) ◄

encrypted-data

An expression that must be a string expression that returns a complete, encrypted data value of a CHAR FOR BIT DATA, VARCHAR FOR BIT DATA, BINARY, VARBINARY, or BLOB built-in data type. The data string must have been encrypted using the ENCRYPT_RC2 or ENCRYPT_TDES function.

The data type of the result is VARCHAR(32). The actual length of the result is the actual length of the hint that was provided when the data was encrypted.

The result can be null. If the argument is null or if a hint was not added to the *encrypted-data* by the ENCRYPT_RC2 or ENCRYPT_TDES function, the result is the null value.

The CCSID of the result is the default CCSID of the current server.

Example

- The hint 'Ocean' is stored to help the user remember the encryption password 'Pacific'.

```
INSERT INTO EMP1 (SSN) VALUES ENCRYPT_RC2( '289-46-8832', 'Pacific', 'Ocean' )
SELECT GETHINT( SSN )
FROM EMP1
```

The GETHINT function returns the original hint value 'Ocean'.

GRAPHIC

The GRAPHIC function returns a fixed-length graphic-string representation of a string expression.

Integer to Graphic

►► GRAPHIC (— *integer-expression* —) ◄◄

Decimal to GRAPHIC

►► GRAPHIC (— *decimal-expression* — , — *decimal-character* —) ◄◄

Floating-point to GRAPHIC

►► GRAPHIC (— *floating-point-expression* — , — *decimal-character* —) ◄◄

Decimal floating-point to GRAPHIC

►► GRAPHIC (— *decimal-floating-point-expression* — , — *decimal-character* —) ◄◄

Character to Graphic

►► GRAPHIC (— *character-expression* — , — *length* — , — *integer* —) ◄◄

DEFAULT

Graphic to Graphic

►► GRAPHIC (— *graphic-expression* — , — *length* — , — *integer* —) ◄◄

DEFAULT

Datetime to Graphic

►► GRAPHIC (— *datetime-expression* — , — *ISO* — , — *USA* — , — *EUR* — , — *JIS* — , — *LOCAL* —) ◄◄

The GRAPHIC function returns a graphic-string representation of:

- An integer number if the first argument is a SMALLINT, INTEGER, or BIGINT
- A decimal number if the first argument is a packed or zoned decimal number
- A double-precision floating-point number if the first argument is a DOUBLE or REAL
- A decimal floating-point number if the first argument is a DECFLOAT
- A character string if the first argument is any type of character string
- A graphic string if the first argument is any type of graphic string

- A date value if the first argument is a DATE.
- A time value if the first argument is a TIME.
- A timestamp value if the first argument is a TIMESTAMP.

The result of the function is a fixed-length graphic string (GRAPHIC).

If the first argument can be null, the result can be null. If the first argument is null, the result is the null value.

Integer to Graphic

integer-expression

An expression that returns a value that is an integer data type (either SMALLINT, INTEGER, or BIGINT).

The result is a fixed-length graphic string of the argument in the form of an SQL integer constant. The result consists of n characters that are the significant digits that represent the value of the argument with a preceding minus sign if the argument is negative. It is left justified.

- If the argument is a small integer, the length attribute of the result is 6.
- If the argument is a large integer, the length attribute of the result is 11.
- If the argument is a big integer, the length attribute of the result is 20.

The result is the smallest number of characters that can be used to represent the value of the argument. Leading zeroes are not included. If the argument is negative, the first character of the result is a minus sign. Otherwise, the first character is a digit or the *decimal-character*.

The CCSID of the result is 1200 (UTF-16).

Decimal to Graphic

decimal-expression

An expression that returns a value that is a packed or zoned decimal data type (either DECIMAL or NUMERIC). If a different precision and scale is wanted, the DECIMAL scalar function can be used to make the change.

decimal-character

Specifies the single-byte character constant that is used to delimit the decimal digits in the result character string. The character must be a period or comma. If the second argument is not specified, the decimal point is the default decimal point. For more information, see [“Decimal point” on page 116](#).

The result is a fixed-length graphic string representation of the argument. The result includes a decimal character and up to p digits, where p is the precision of the *decimal-expression* with a preceding minus sign if the argument is negative. Leading zeros are not returned. Trailing zeros are returned. If the scale of *decimal-expression* is zero, the decimal character is not returned.

The length attribute of the result is $2+p$ where p is the precision of the *decimal-expression*. The result is the smallest number of characters that can be used to represent the result. Leading zeros are not included. If the argument is negative, the result begins with a minus sign. Otherwise, the result begins with a digit or the *decimal-character*.

The CCSID of the result is 1200 (UTF-16).

Floating-point to Graphic

floating-point expression

An expression that returns a value that is a floating-point data type (DOUBLE or REAL).

decimal-character

Specifies the single-byte character constant that is used to delimit the decimal digits in the result character string. The character must be a period or comma. If the second argument is not specified,

the decimal point is the default decimal point. For more information, see [“Decimal point” on page 116](#).

The result is a fixed-length graphic string representation of the argument in the form of a floating-point constant.

The length attribute of the result is 24. The result is the smallest number of characters that can represent the value of the argument such that the mantissa consists of a single digit other than zero followed by the *decimal-character* and a sequence of digits. If the argument is negative, the first character of the result is a minus sign; otherwise, the first character is a digit or the *decimal-character*. If the argument is zero, the result is 0E0.

The CCSID of the result is 1200 (UTF-16).

Decimal floating-point to Graphic

decimal-floating-point expression

An expression that returns a value that is a built-in decimal floating-point data type.

decimal-character

Specifies the single-byte character constant that is used to delimit the decimal digits in the result character string. The character must be a period or comma. If the second argument is not specified, the decimal point is the default decimal point. For more information, see [“Decimal point” on page 116](#).

The result is a fixed-length graphic string representation of the argument in the form of a floating-point constant.

The length attribute of the result is 42. The actual length of the result is the smallest number of characters that represents the value of the argument, including the sign, digits, and *decimal-character*. Trailing zeros are significant. If the argument is negative, the first character of the result is a minus sign; otherwise, the first character is a digit or the *decimal-character*. If the argument is zero, the result is 0.

If the DECFLOAT value is Infinity, sNaN, or NaN, the strings 'INFINITY', 'SNAN', and 'NAN', respectively, are returned. If the special value is negative, a minus sign will be the first character in the string. The DECFLOAT special value sNaN does not result in an exception when converted to a string.

The CCSID of the result is 1200 (UTF-16).

Character to Graphic

character-expression

An expression that returns a value that is a built-in character-string data type. It cannot be a CHAR or VARCHAR bit data. If the expression is an empty string or the EBCDIC string X'0E0F', the result is a single double-byte blank.

length

An integer constant that specifies the length attribute of the result and must be an integer constant between 1 and 16383 if the first argument is not nullable or between 1 and 16382 if the first argument is nullable. If the length of *character-expression* is less than the length specified, the result is padded with double-byte blanks to the length of the result.

If *length* is not specified, or if DEFAULT is specified, the length attribute of the result is the same as the length attribute of the first argument.

Each character of the argument determines a character of the result. If the length attribute of the resulting fixed-length string is less than the actual length of the first argument, truncation is performed and no warning is returned.

integer

An integer constant that specifies the CCSID of the result. It must be a DBCS, UTF-16, or UCS-2 CCSID. The CCSID cannot be 65535. If the CCSID represents Unicode graphic data, each character of the argument determines a character of the result. The nth character of the result is the UTF-16 or UCS-2 equivalent of the nth character of the argument.

If *integer* is not specified then the CCSID of the result is determined by a mixed CCSID. Let M denote that mixed CCSID.

In the following rules, S denotes one of the following:

- If the string expression is a host variable containing data in a foreign encoding scheme, S is the result of the expression after converting the data to a CCSID in a native encoding scheme. (See “Character conversion” on page 28 for more information.)
- If the string expression is data in a native encoding scheme, S is that string expression.

M is determined as follows:

- If the CCSID of S is a mixed CCSID, M is that CCSID.
- If the CCSID of S is an SBCS CCSID:
 - If the CCSID of S has an associated mixed CCSID, M is that CCSID.
 - Otherwise the operation is not allowed.

The following table summarizes the result CCSID based on M.

M	Result CCSID	Description	DBCS Substitution Character
930	300	Japanese EBCDIC	X'FEFE'
933	834	Korean EBCDIC	X'FEFE'
935	837	S-Chinese EBCDIC	X'FEFE'
937	835	T-Chinese EBCDIC	X'FEFE'
939	300	Japanese EBCDIC	X'FEFE'
5026	4396	Japanese EBCDIC	X'FEFE'
5035	4396	Japanese EBCDIC	X'FEFE'

The equivalence of SBCS and DBCS characters depends on M. Regardless of the CCSID, every double-byte code point in the argument is considered a DBCS character, and every single-byte code point in the argument is considered an SBCS character with the exception of the EBCDIC mixed data shift codes X'0E' and X'0F'.

- If the nth character of the argument is a DBCS character, the nth character of the result is that DBCS character.
- If the nth character of the argument is an SBCS character that has an equivalent DBCS character, the nth character of the result is that equivalent DBCS character.
- If the nth character of the argument is an SBCS character that does not have an equivalent DBCS character, the nth character of the result is the DBCS substitution character.

Graphic to Graphic

graphic-expression

An expression that returns a value of a built-in graphic-string data type.

length

An integer constant that specifies the length attribute of the result and must be an integer constant between 1 and 16383 if the first argument is not nullable or between 1 and 16382 if the first argument is nullable. If the length of *graphic-expression* is less than the length specified, the result is padded with double-byte blanks to the length of the result.

If the second argument is not specified, or if DEFAULT is specified, the length attribute of the result is the same as the length attribute of the first argument.

If the length of the *graphic-expression* is greater than the length attribute of the result, truncation is performed. A warning (SQLSTATE 01004) is returned unless the truncated characters were all blanks.

integer

An integer constant that specifies the CCSID of the result. It must be a DBCS, UTF-16, or UCS-2 CCSID. The CCSID cannot be 65535.

If *integer* is not specified then the CCSID of the result is the CCSID of the first argument.

Datetime to Graphic

datetime-expression

An expression that is one of the following three built-in data types

date

The result is the graphic-string representation of the date in the format specified by the second argument. If the second argument is not specified, the format used is the default date format. If the format is ISO, USA, EUR, or JIS, the length of the result is 10. Otherwise the length of the result is the length of the default date format. For more information see [“String representations of datetime values”](#) on page 75.

time

The result is the graphic-string representation of the time in the format specified by the second argument. If the second argument is not specified, the format used is the default time format. The length of the result is 8. For more information see [“String representations of datetime values”](#) on page 75.

timestamp

The second argument is not applicable and must not be specified.

The result is the graphic-string representation of the timestamp. If *datetime-expression* is a `TIMESTAMP(0)`, the length of the result is 19. If the data type of *datetime-expression* is a `TIMESTAMP(n)`, the length of the result is $20+n$. Otherwise, the length of the result is 26.

The CCSID of the result is 1200 (UTF-16).

ISO, EUR, USA, or JIS

Specifies the date or time format of the resulting graphic string. For more information, see [“String representations of datetime values”](#) on page 75.

LOCAL

Specifies that the date or time format of the resulting graphic string should come from the `DATFMT`, `DATSEP`, `TIMFMT`, and `TIMSEP` attributes of the job at the current server.

Note

Syntax alternatives: The `CAST` specification should be used to increase the portability of applications when the first argument is a string and the length attribute is specified. For more information, see [“CAST specification”](#) on page 176.

Example

- Using the `EMPLOYEE` table, set the host variable `DESC` (`GRAPHIC(24)`) to the `GRAPHIC` equivalent of the first name (`FIRSTNME`) for employee number (`EMPNO`) '000050'.

```
SELECT GRAPHIC( VARGRAPHIC(FIRSTNME))
INTO :DESC
FROM EMPLOYEE
WHERE EMPNO = '000050'
```

GREATEST

The GREATEST scalar function returns the maximum value in a set of values.

► GREATEST (*expression* , *expression*) ◄

The GREATEST function is identical to the MAX function. For more information, see [“MAX” on page 490](#).

HASH

The HASH function returns the partition number of a set of values.

Also see [“HASHED_VALUE”](#) on page 423. For more information about partition numbers, see the [DB2 Multisystem](#) topic collection.

expression

An expression that returns a value of any built-in data type except date, time, timestamp, floating-point, XML, or DataLink values.

The result of the function is a large integer with a value between 0 and 1023.

If any of the arguments are null, the result is zero. The result cannot be null.

Example

- Use the HASH function to determine what the partitions would be if the partitioning key was composed of EMPNO and LASTNAME. This query returns the partition number for every row in EMPLOYEE.

```
SELECT HASH(EMPNO, LASTNAME)
FROM EMPLOYEE
```

HASHED_VALUE

The HASHED_VALUE function returns the partition map index number of a row obtained by applying the hashing function on the partitioning key value of the row.

►► HASHED_VALUE — (— *table-designator* —) ◄◄

Also see the “HASH” on page 422 function. If the argument identifies a non-distributed table, the value 0 is returned. For more information about partition maps and partitioning keys, see the [DB2 Multisystem](#) topic collection.

table-designator

A table designator of the subselect. For more information about table designators, see “[Table designators](#)” on page 133.

In SQL naming, the table name may be qualified. In system naming, the table name cannot be qualified.

The *table-designator* must not identify a *collection-derived-table*, a VALUES clause, a *table-function*, or a *data-change-table-reference*.

If the argument identifies a view, common table expression, or nested table expression, the function returns the partition map index number of its base table. If the argument identifies a view, common table expression, or nested table expression derived from more than one base table, the function returns the partition map index number of the first table in the outer subselect of the view, common table expression, or nested table expression.

The argument must not identify a view, common table expression, or nested table expression whose outer fullselect includes an aggregate function, a GROUP BY clause, a HAVING clause, a UNION, INTERSECT, or EXCEPT clause, DISTINCT clause, VALUES clause, or a *table-function*. The HASHED_VALUE function cannot be specified in a SELECT clause if the fullselect contains an aggregate function, a GROUP BY clause, or a HAVING clause

The data type of the result is a large integer with a value between 0 and 1023. The result can be null.

Note

Syntax alternatives: PARTITION is a synonym for HASHED_VALUE.

Example

- Select the employee number (EMPNO) from the EMPLOYEE table for all rows where the partition map index number is equal to 100.

```
SELECT EMPNO
FROM EMPLOYEE
WHERE HASHED_VALUE(EMPLOYEE) = 100
```

HEX

The HEX function returns a hexadecimal representation of a value.

►► HEX — (— *expression* —) ◄◄

expression

An expression that returns a value of any built-in data type other than a character or binary string with a length attribute greater than 16 336 or a graphic string with a length attribute greater than 8168.

The result of the function is a character string. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

The result is a string of hexadecimal digits, the first two digits represent the first byte of the argument, the next two digits represent the second byte of the argument, and so forth. If the argument is a datetime value, the result is the hexadecimal representation of the internal form of the argument.⁶⁰

If the argument is not a graphic string, the actual length of the result is twice the length of the argument. If the argument is a graphic string, the actual length of the result is four times the length of the argument. If the data type of the result is varying length, the length is limited to the maximum length of the data type. The length of the argument is the value that would be returned if the argument were passed to the LENGTH scalar function. For more information, see “LENGTH” on page 474.

The data type and length attribute of the result depends on the attributes of the argument:

- If the argument is not a string, the result is CHAR with a length attribute that is twice the length of the argument.
- If the argument is a fixed-length character string with a length attribute that is less than one half the maximum length attribute of CHAR, the result is CHAR with a length attribute that is twice the length attribute of the argument. If the argument is a fixed-length graphic string with a length attribute that is less than one fourth the maximum length attribute of CHAR, the result is CHAR with a length attribute that is four times the length attribute of the argument. For more information about the product-specific maximum length, see [Table 129 on page 1645](#).
- Otherwise, the result is VARCHAR whose length attribute depends on the following:
 - If the argument is a character or binary string, the length attribute of the result is the minimum of twice the length attribute of the argument and the maximum length of the data type.
 - If the argument is a graphic string, the length attribute of the result is the minimum of four times the length attribute of the argument and the maximum length of the data type.

The length attribute of the result cannot be greater than the product-specific length attribute of CHAR or VARCHAR. See [Table 129 on page 1645](#) for more information.

The CCSID of the string is the default SBCS CCSID at the current server.

Example

- Use the HEX function to return a hexadecimal representation of the education level for each employee.

```
SELECT FIRSTNAME, MIDINIT, LASTNAME, HEX(EDLEVEL)
FROM EMPLOYEE
```

⁶⁰ This hexadecimal representation for DATE, TIMESTAMP, and NUMERIC data types is different from other database products because the internal form for these data types is different.

HEXTORAW

The HEXTORAW function returns a binary string representation of a character string that has been formatted using a *format-string*.

► HEXTORAW (*expression* , *format-string*) ◄

The HEXTORAW function is identical to VARBINARY_FORMAT except that if the length of *expression* is an odd number of characters, the string is padded on the left with one '0' character. For more information, see [“VARBINARY_FORMAT”](#) on page 621.

HOUR

The HOUR function returns the hour part of a value.

►► HOUR — (— *expression* —) ◄◄

expression

An expression that returns a value of one of the following built-in data types: a date, a time, a timestamp, a character string, a graphic string, or a numeric data type.

- If *expression* is a character or graphic string, its value must be a valid string representation of a datetime value. If *expression* is a valid string representation of a date, it must be in one of the IBM SQL standard formats. For the valid formats of string representations of datetime values, see [“String representations of datetime values”](#) on page 75.
- If the argument is a DATE, it is first converted to a TIMESTAMP(0) value, assuming a time of exactly midnight (00.00.00).
- If *expression* is a number, it must be a time duration or timestamp duration. For the valid formats of datetime durations, see [“Datetime operands and durations”](#) on page 165.

The result of the function is a large integer. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

The other rules depend on the data type of the argument:

- If the argument is a date, time, timestamp, or valid character-string representation of a date, time, or timestamp:

The result is the hour part of the value, which is an integer between 0 and 24.

- If the argument is a time duration or timestamp duration:

The result is the hour part of the value, which is an integer between -99 and 99. A nonzero result has the same sign as the argument.

Example

- Using the CL_SCHED sample table, select all the classes that start in the afternoon.

```
SELECT *  
FROM CL_SCHED  
WHERE HOUR(STARTING) BETWEEN 12 AND 17
```

HTTP_DELETE

The HTTP_DELETE scalar function deletes a text-based resource from the specified URL through an HTTP DELETE request.

► HTTP_DELETE (*url* , *options*) ►

url

An expression that returns a built-in character string or graphic string data type that specifies the URL of the resource being accessed.

The only supported protocols in the URL are *http://* and *https://*. HTTP basic authentication in the form *https://userid:password@* cannot be specified in the URL. Instead, the *basicAuth* option must be used to specify the *userid* and *password* for basic authentication.

options

An expression that returns a built-in character string or graphic string data type. This string must be formatted as a JSON object containing the options, including headers, for the request. See [“HTTP options” on page 428](#) for the list of options.

If no options are provided, the default options are used.

The result of the function is a CLOB(2G) CCSID 1208 containing the response message.

Notes

For more information about using the HTTP functions see [HTTP functions overview](#).

To return the header information from the HTTP request, use the HTTP_DELETE_VERBOSE table function: [“HTTP_DELETE_VERBOSE” on page 689](#)

Example

- Send a HTTP DELETE request to <https://www.example.com/delete> using the certificate store `/home/javaTrustStore/fromJava.KDB` and return the result.

```
VALUES QSYS2.HTTP_DELETE('https://www.example.com/delete',
                        '{"sslCertificateStoreFile":"/home/javaTrustStore/fromJava.KDB"}')
```

HTTP_GET

The HTTP_GET scalar function retrieves a text-based resource from the specified URL through an HTTP GET request.

►► HTTP_GET (— *url* — , — *options* —) ►►

url

An expression that returns a built-in character string or graphic string data type that specifies the URL of the resource being accessed.

The only supported protocols in the URL are *http://* and *https://*. HTTP basic authentication in the form *https://userid:password@* cannot be specified in the URL. Instead, the *basicAuth* option must be used to specify the *userid* and *password* for basic authentication.

options

An expression that returns a built-in character string or graphic string data type. This string must be formatted as a JSON object containing the options, including headers, for the request. See “[HTTP options](#)” on page 428 for the list of options.

If no options are provided, the default options are used.

The result of the function is a CLOB(2G) CCSID 1208 containing the response message.

Notes

For more information about using the HTTP functions see [HTTP functions overview](#).

To return the header information from the HTTP request, use the HTTP_GET_VERBOSE table function: “[HTTP_GET_VERBOSE](#)” on page 690

Example

- Retrieve service information from the IBM PSP website using a certificate store created from a Java certificate store. See [SSL considerations](#) for more information.

```
VALUES QSYS2.HTTP_GET(
    'https://www.ibm.com/support/pages/sites/default/files/inline-files/xmldoc.xml',
    '{ "sslCertificateStoreFile": "/home/javaTrustStore/fromJava.KDB" }');
```

HTTP options

Each HTTP function has a parameter for passing options to be used on the request. These options include the setting of the HTTP headers. This string must be a JSON object in the following format:

```
{ "option": "option-setting", "option": "option-setting" }
```

For example, using the option string

```
{ "header": "User-Agent, IBM i HTTP function" }
```

will cause

```
"User-Agent": "IBM i HTTP function"
```

to be included in the HTTP header sent to the server.

The following options can be set in the JSON object:

Table 52. HTTP options

Option	Possible settings	Default setting	Description
basicAuth	<i>userid,password</i>		<p>Sets the userid and password that will be used for HTTP basic authentication.</p> <p>To prevent exposure of the userid and password, this option is only allowed when the URL begins with <i>https</i>.</p>
connectTimeout	0-2000000	Dependent on TCP/IP system settings	Sets the connect timeout value. If timeout is greater than zero, the value will be used as the maximum time, in seconds, to wait for a connection to complete.
header	<i>headername,headervalue</i>		<p>Sets an HTTP header in the HTTP request with the specified <i>headername</i> and <i>headervalue</i>.</p> <p>This option can be specified multiple times to set multiple headers.</p> <p>A common headers that may be required is the Accept header. This header can be set in the following way: "header": "Accept, *"</p> <p>By default, only the Host and User-Agent HTTP header are set for all requests. The Host is set using the host information in the URL. The User-Agent header defaults to <code>curl/XX.YY</code> where <code>XX.YY</code> are some version numbers. This value was chosen to provide anonymity when accessing web services.</p> <p>If the content-type HTTP header is not set for a POST or PUT operation, the default content type that will be used is: Content-Type: text/xml; charset=UTF-8</p> <p>To correctly use these headers, consult the appropriate Web server and RFC documentation on the use of HTTP request headers. Examples of RFCs are RFC2616 and RFC7231.</p>
ioTimeout	0-2000000	Dependent on TCP/IP system settings	Sets how long to wait for a read request to complete. If timeout is greater than zero, the value will be used as the maximum time, in seconds, to wait for a read request to complete.
proxy	<i>host,port</i>		Sets the HTTP proxy information.
proxyAuth	<i>userid,password</i>		Sets the HTTP proxy authentication information. To prevent exposure of the userid and password, this option is only allowed when the proxySsl option is true.
proxySsl	true false	true	Sets whether a secure (SSL) connection should be used when connecting to the proxy server. A value of true indicates that the transport will connect to the proxy server using a secure channel. A value of false indicates that the transport will connect to the proxy server using an unsecure channel.
redirect	0-2000000	0	Specifies the number of HTTP redirects that will be followed. If the number is greater than zero, HTTP redirects will be followed up to the number specified. If the value is less than one, HTTP redirects will not be followed.
signalErrors	true false	false	Indicates whether an HTTP error should be signaled as an SQLException. This will be seen as SQLSTATE 38501, SQLCODE -443.
sslCertificateStoreFile	<i>file</i>	/QIBM/USERDATA/ICSS/ CERT/SERVER/DEFAULT.KDB	<p>Specifies the name of the certificate store file to be used for the secure session or SSL environment. This parameter is ignored if the sslApplicationID option is set to a value.</p> <p>If SSL communication is to be done by using a path to a keystore file, the user profile the application is running under must have authority to the file.</p> <ul style="list-style-type: none"> Execute (*X) data authority to each directory preceding the stream file being read and Read (*R) data authority to the stream file <p>This option is only used when the URL begins with <i>https</i>.</p>

Table 52. HTTP options (continued)

Option	Possible settings	Default setting	Description
sslCertificateStorePassword	<i>password</i>		Specifies the password for the certificate store file to be used for the secure session or SSL environment. If the option is not passed or is set to the null string, the internal stash file associated with the user profile that is being used to run the application is used as long as the user has authority to the certificate store file and the password has been used one time on the system. This option is ignored if the sslApplicationID option is set to a value. This option is only used when the URL begins with <i>https</i> .
sslCertificateLabel	<i>label</i>		Specifies the label associated with the certificate in the certificate store to be used for the secure session or SSL environment. If the option is not passed or is set to the null string, the default certificate label in the specified certificate store file is used for the SSL environment. This option is ignored if the sslApplicationID option is set to a value. This option is only used when the URL begins with <i>https</i> .
sslTLS11	ENABLE NONE	NONE	Enable or disable the TLS Version 1.1 ciphers. A value of NONE will disable the ciphers; any other value will enable the ciphers. This option is only used when the URL begins with <i>https</i> .
sslTLS12	ENABLE NONE	ENABLE	Enable or disable the TLS Version 1.2 ciphers. A value of NONE will disable the ciphers; any other value will enable the ciphers. This option is only used when the URL begins with <i>https</i> .
sslTLS13	ENABLE NONE	ENABLE	Enable or disable the TLS Version 1.3 ciphers. A value of NONE will disable the ciphers; any other value will enable the ciphers. This option is only used when the URL begins with <i>https</i> .
sslTolerate	true false	false	Tolerate soft validation errors (expired certificate or certificate not in certificate store). Specify a value of true to tolerate soft validation errors, or false to not tolerate soft validation errors. Warning: Enabling this option allows man-in-the-middle attacks to occur and is not recommended. This option is only used when the URL begins with <i>https</i> .
sslApplicationId	<i>id</i>		Application ID to use for the SSL environment. This option is only used when the URL begins with <i>https</i> .
sslDomainName	<i>name</i>	Set using hostname present in https: URL	Fully qualified domain name that will be used as Server Name Indication (SNI) as defined by RFC 6066. This option is only used when the URL begins with <i>https</i> .
sslSniCritical	true false	false	A value of true indicates that the SNI request is critical and thus the server must support the SNI extension. Otherwise, the secure connection will fail if server does not send the extension. A value of false indicates that the server does not need to support the SNI extension. This option is only used when the URL begins with <i>https</i> .

Some of the options can expose sensitive information such as passwords. A number of best practices can be used to prevent the sensitive information from being exposed in the SQL statement text, which may be visible using DBMON. Here are some examples of best practices to protect the password.

1. Use a global variable and concatenate the global values when the SQL Statement is executed.

```
CREATE VARIABLE MYLIB.HTTP_PW VARCHAR(30);
SET MYLIB.HTTP_PW = 'http_pwd';
VALUES QSYS2.HTTP_GET( 'https://www.somesite.com/authorized_info.html',
'{"basicAuth": "userid," CONCAT MYLIB.HTTP_PW CONCAT "}" );
```

2. For interfaces that support a parameter marker, set the password using a parameter marker. Here is an QSHELL example using the JDBC client provided in jt400.jar.

```

java -jar /qibm/proddata/os400/jt400/lib/java6/jt400.jar jdbc:db2:localhost
!PREPARE select QSYS2.HTTP_GET( 'https://www.somesite.com/authorized_info.html',
                                '{"basicAuth":"userid,' CONCAT ? CONCAT '"}' ) from
sysibm.sysdummy1
!setParm 1,http_pwd
!executeQuery

```

3. Store passwords in a table, protected with a column mask.

```

CREATE MYLIB.TABLE PASSWORDS (TYPE VARCHAR(20), PWD_VALUE VARCHAR(100) CCSID 37);

CREATE MASK MYLIB.PASSWORD_MASK ON MYLIB.PASSWORDS
FOR COLUMN PWD_VALUE RETURN
CASE WHEN (VERIFY_GROUP_FOR_USER(SESSION_USER,'<my user id>') = 1)
THEN PWD_VALUE
ELSE 'Sorry' END
ENABLE;

ALTER TABLE MYLIB.PASSWORDS
ACTIVATE COLUMN ACCESS CONTROL;

INSERT INTO MYLIB.PASSWORDS VALUES ('HTTP', 'My secure password');

VALUES QSYS2.HTTP_GET( 'https://www.somesite.com/authorized_info.html',
                        '{"basicAuth":"userid,' CONCAT
                        (SELECT PWD_VALUE FROM MYLIB.PASSWORDS WHERE TYPE = 'HTTP') CONCAT
                        '"}' );

```

HTTP_PATCH

The HTTP_PATCH scalar function updates a text-based resource under the specified URL through an HTTP PATCH request.

►► HTTP_PATCH — (— *url* — , — *request-message* — , — *options* —) ►►

url

An expression that returns a built-in character string or graphic string data type that specifies the URL of the resource being accessed.

The only supported protocols in the URL are *http://* and *https://*. HTTP basic authentication in the form *https://userid:password@* cannot be specified in the URL. Instead, the *basicAuth* option must be used to specify the *userid* and *password* for basic authentication.

request-message

An expression that returns a built-in character string or graphic string data type that specifies the data to update at the specified URL.

options

An expression that returns a built-in character string or graphic string data type. This string must be formatted as a JSON object containing the options, including headers, for the request. See [“HTTP options”](#) on page 428 for the list of options.

If no options are provided, the default options are used.

The result of the function is a CLOB(2G) CCSID 1208 containing the response message.

Notes

For more information about using the HTTP functions see [HTTP functions overview](#).

To return the header information from the HTTP request, use the HTTP_PATCH_VERBOSE table function: [“HTTP_PATCH_VERBOSE”](#) on page 691

Example

- Send a HTTP PATCH request to *https://www.example.com/users* sending 'ABC' and using the certificate store */home/javaTrustStore/fromJava.KDB* and return the result.

```
VALUES QSYS2.HTTP_PATCH('https://www.example.com/users',  
                        'ABC',  
                        '{ "sslCertificateStoreFile": "/home/javaTrustStore/fromJava.KDB" }');
```

HTTP_POST

The HTTP_POST scalar function updates a text-based resource under the specified URL through an HTTP POST request.

► HTTP_POST (url , request-message , options) ◄

url

An expression that returns a built-in character string or graphic string data type that specifies the URL of the resource being accessed.

The only supported protocols in the URL are *http://* and *https://*. HTTP basic authentication in the form *https://userid:password@* cannot be specified in the URL. Instead, the *basicAuth* option must be used to specify the *userid* and *password* for basic authentication.

request-message

An expression that returns a built-in character string or graphic string data type that specifies the data to update at the specified URL.

options

An expression that returns a built-in character string or graphic string data type. This string must be formatted as a JSON object containing the options, including headers, for the request. See [“HTTP options”](#) on page 428 for the list of options.

If no options are provided, the default options are used.

The result of the function is a CLOB(2G) CCSID 1208 containing the response message.

Notes

For more information about using the HTTP functions see [HTTP functions overview](#).

To return the header information from the HTTP request, use the HTTP_POST_VERBOSE table function: [“HTTP_POST_VERBOSE”](#) on page 692

Example

- Send a HTTP POST request to <https://www.example.com/users> sending 'ABC' and using the certificate store `/home/javaTrustStore/fromJava.KDB` and return the result.

```
VALUES QSYS2.HTTP_POST('https://www.example.com/users',
                      'ABC',
                      '{ "sslCertificateStoreFile": "/home/javaTrustStore/fromJava.KDB" }');
```

HTTP_PUT

The HTTP_PUT scalar function retrieves a text-based resource from the specified URL through an HTTP PUT request.

►► HTTP_PUT (— *url* — , — *request-message* — , — *options* —) ◄◄

url

An expression that returns a built-in character string or graphic string data type that specifies the URL of the resource being accessed.

The only supported protocols in the URL are *http://* and *https://*. HTTP basic authentication in the form *https://userid:password@* cannot be specified in the URL. Instead, the *basicAuth* option must be used to specify the *userid* and *password* for basic authentication.

request-message

An expression that returns a built-in character string or graphic string data type that specifies the data to update at the specified URL.

options

An expression that returns a built-in character string or graphic string data type. This string must be formatted as a JSON object containing the options, including headers, for the request. See [“HTTP options”](#) on page 428 for the list of options.

If no options are provided, the default options are used.

The result of the function is a CLOB(2G) CCSID 1208 containing the response message.

Notes

For more information about using the HTTP functions see [HTTP functions overview](#).

To return the header information from the HTTP request, use the HTTP_PUT_VERBOSE table function: [“HTTP_PUT_VERBOSE”](#) on page 693

Example

- Send a HTTP PUT request to *https://www.example.com/users* sending 'ABC' and using the certificate store */home/javaTrustStore/fromJava.KDB* and return the result.

```
VALUES QSYS2.HTTP_PUT('https://www.example.com/users',  
                    'ABC',  
                    '{"sslCertificateStoreFile":"/home/javaTrustStore/fromJava.KDB"}');
```

IDENTITY_VAL_LOCAL

IDENTITY_VAL_LOCAL is a non-deterministic function that returns the most recently assigned value for an identity column.

►► IDENTITY_VAL_LOCAL — (—) ◄◄

The function has no input parameters. The result is a DECIMAL(31,0) regardless of the actual data type of the identity column that the result value corresponds to.

The value returned is the value that was assigned to the identity column of the table identified in the most recent insert operation (specified in either an INSERT statement or a MERGE statement). The insert operation has to be issued at the same level; that is, the value has to be available locally within the level at which it was assigned until replaced by the next assigned value. A new level is initiated when a trigger, function, or stored procedure is invoked. A trigger condition is at the same level as the associated triggered action.

The assigned value can be a value supplied by the user (if the identity column is defined as GENERATED BY DEFAULT) or an identity value that was generated by the database manager.

The result can be null. The result is null if an insert operation has not been issued for a table containing an identity column at the current processing level. This includes invoking the function in a before or after insert trigger.

The result of the IDENTITY_VAL_LOCAL function is not affected by the following statements:

- An insert operation for a table which does not contain an identity column
- An UPDATE statement
- A COMMIT statement
- A ROLLBACK statement

Notes

The following notes explain the behavior of the function when it is invoked in various situations:

Invoking the function within the VALUES clause of an insert operation

Expressions in an insert operation are evaluated before values are assigned to the target columns of the insert operation. Thus, when you invoke IDENTITY_VAL_LOCAL in an insert operation, the value that is used is the most recently assigned value for an identity column from a previous insert operation. The function returns the null value if no such insert operation had been executed within the same level as the invocation of the IDENTITY_VAL_LOCAL function.

Invoking the function following a failed insert operation

The function returns an unpredictable result when it is invoked after the unsuccessful execution of an insert operation for a table with an identity column. The value might be the value that would have been returned from the function had it been invoked before the failed insert operation or the value that would have been assigned had the insert operation succeeded. The actual value returned depends on the point of failure and is therefore unpredictable.

Invoking the function within the SELECT statement of a cursor

Because the results of the IDENTITY_VAL_LOCAL function are not deterministic, the result of an invocation of the IDENTITY_VAL_LOCAL function from within the SELECT statement of a cursor can vary for each FETCH statement.

Invoking the function within a procedure or function default expression

The result of invoking the IDENTITY_VAL_LOCAL function from within the default expression of a procedure or function is undefined; this function should not be used in a default expression.

Invoking the function within the trigger condition of an insert trigger

The result of invoking the IDENTITY_VAL_LOCAL function from within the condition of an insert trigger is the null value.

Invoking the function within a triggered action of an insert trigger

Multiple before or after insert triggers can exist for a table. In such cases, each trigger is processed separately, and identity values generated by SQL statements issued within a triggered action are not available to other triggered actions using the `IDENTITY_VAL_LOCAL` function. This is the case even though the multiple triggered actions are conceptually defined at the same level.

Do not use the `IDENTITY_VAL_LOCAL` function in the triggered action of a before insert trigger. The result of invoking the `IDENTITY_VAL_LOCAL` function from within the triggered action of a before insert trigger is the null value. The value for the identity column of the table for which the trigger is defined cannot be obtained by invoking the `IDENTITY_VAL_LOCAL` function within the triggered action of a before insert trigger. However, the value for the identity column can be obtained in the triggered action by referencing the trigger transition variable for the identity column.

The result of invoking the `IDENTITY_VAL_LOCAL` function in the triggered action of an after insert trigger is the value assigned to an identity column of the table identified in the most recent insert operation invoked in the same triggered action for a table containing an identity column. If an insert operation for a table containing an identity column was not executed within the same triggered action before invoking the `IDENTITY_VAL_LOCAL` function, then the function returns a null value.

Invoking the function following an insert operation with triggered actions

The result of invoking the function after an insert operation that activates triggers is the value actually assigned to the identity column (that is, the value that would be returned on a subsequent `SELECT` statement). This value is not necessarily the value provided in the insert operation or a value generated by the database manager. The assigned value could be a value that was specified in a `SET` transition variable statement within the triggered action of a before insert trigger for a trigger transition variable associated with the identity column.

Scope of `IDENTITY_VAL_LOCAL`

The `IDENTITY_VAL_LOCAL` value persists until the next insert operation in the current session into a table that has an identity column defined on it, or the application session ends. The value is unaffected by `COMMIT` or `ROLLBACK` statements. The `IDENTITY_VAL_LOCAL` value cannot be directly set and is a result of inserting a row into a table.

A technique commonly used, especially for performance, is for an application or product to manage a set of connections and route transactions to an arbitrary connection. In these situations, the availability of the `IDENTITY_VAL_LOCAL` value should only be relied on until the end of the transaction.

Alternative to `IDENTITY_VAL_LOCAL`:

It is recommended that a `SELECT FROM INSERT` be used to obtain the assigned value for an identity column. See [“table-reference” on page 742](#) for more information.

Examples

- Set the variable `IVAR` to the value assigned to the identity column in the `EMPLOYEE` table. The value returned from the function in the `VALUES INTO` statement should be 1.

```
CREATE TABLE EMPLOYEE
(EMPNO INTEGER GENERATED ALWAYS AS IDENTITY,
 NAME CHAR(30),
 SALARY DECIMAL(5,2),
 DEPTNO SMALLINT)

INSERT INTO EMPLOYEE
(NAME, SALARY, DEPTNO)
VALUES('Rupert', 989.99, 50)

VALUES IDENTITY_VAL_LOCAL() INTO :IVAR
```

- Assume two tables, `T1` and `T2`, have an identity column named `C1`. The database manager generates values 1, 2, 3,...for the `C1` column in table `T1`, and values 10, 11, 12,...for the `C1` column in table `T2`.

```
CREATE TABLE T1
(C1 SMALLINT GENERATED ALWAYS AS IDENTITY,
 C2 SMALLINT)
```

```

CREATE TABLE T2
(C1 DECIMAL(15,0) GENERATED BY DEFAULT AS IDENTITY ( START WITH 10 ) ,
C2 SMALLINT)

INSERT INTO T1 ( C2 ) VALUES(5)

INSERT INTO T1 ( C2 ) VALUES(5)

SELECT * FROM T1

```

C1	C2
1	5
2	5

```
VALUES IDENTITY_VAL_LOCAL() INTO :IVAR
```

At this point, the IDENTITY_VAL_LOCAL function would return a value of 2 in IVAR. The following INSERT statement inserts a single row into T2 where column C2 gets a value of 2 from the IDENTITY_VAL_LOCAL function.

```

INSERT INTO T2 ( C2 ) VALUES( IDENTITY_VAL_LOCAL() )

SELECT * FROM T2
WHERE C1 = DECIMAL( IDENTITY_VAL_LOCAL(), 15, 0)

```

C1	C2
10	2

Invoking the IDENTITY_VAL_LOCAL function after this INSERT would result in a value of 10, which is the value generated by the database manager for column C1 of T2. Assume another single row is inserted into T2. For the following INSERT statement, the database manager assigns a value of 13 to identity column C1 and gives C2 a value of 10 from IDENTITY_VAL_LOCAL. Thus, C2 is given the last identity value that was inserted into T2.

```

INSERT INTO T2 ( C2, C1 ) VALUES( IDENTITY_VAL_LOCAL(), 13 )

SELECT * FROM T2
WHERE C1 = DECIMAL( IDENTITY_VAL_LOCAL(), 15, 0)

```

C1	C2
13	10

- The IDENTITY_VAL_LOCAL function can also be invoked in an INSERT statement that both invokes the IDENTITY_VAL_LOCAL function and causes a new value for an identity column to be assigned. The next value to be returned is thus established when the IDENTITY_VAL_LOCAL function is invoked after the INSERT statement completes. For example, consider the following table definition:

```

CREATE TABLE T3
(C1 SMALLINT GENERATED BY DEFAULT AS IDENTITY,
C2 SMALLINT)

```

For the following INSERT statement, specify a value of 25 for the C2 column, and the database manager generates a value of 1 for C1, the identity column. This establishes 1 as the value that will be returned on the next invocation of the IDENTITY_VAL_LOCAL function.

```
INSERT INTO T3 ( C2 ) VALUES( 25 )
```

In the following INSERT statement, the IDENTITY_VAL_LOCAL function is invoked to provide a value for the C2 column. A value of 1 (the identity value assigned to the C1 column of the first row) is assigned to the C2 column, and the database manager generates a value of 2 for C1, the identity column. This

establishes 2 as the value that will be returned on the next invocation of the IDENTITY_VAL_LOCAL function.

```
INSERT INTO T3 ( C2 ) VALUES( IDENTITY_VAL_LOCAL() )
```

In the following INSERT statement, the IDENTITY_VAL_LOCAL function is again invoked to provide a value for the C2 column, and the user provides a value of 11 for C1, the identity column. A value of 2 (the identity value assigned to the C1 column of the second row) is assigned to the C2 column. The assignment of 11 to C1 establishes 11 as the value that will be returned on the next invocation of the IDENTITY_VAL_LOCAL function.

```
INSERT INTO T3 ( C2, C1 ) VALUES( IDENTITY_VAL_LOCAL(), 11 )
```

After the 3 INSERT statements have been processed, table T3 contains the following:

C1	C2
1	25
2	1
11	2

The contents of T3 illustrate that the expressions in the VALUES clause are evaluated before the assignments for the columns of the INSERT statement. Thus, an invocation of an IDENTITY_VAL_LOCAL function invoked from a VALUES clause of an INSERT statement uses the most recently assigned value for an identity column in a previous INSERT statement.

IFNULL

The IFNULL function returns the value of the first non-null expression.

►► IFNULL — (— *expression* — , — *expression* —) ◄◄

The IFNULL function is identical to the COALESCE scalar function with two arguments. For more information, see [“COALESCE”](#) on page 338.

Example

- When selecting the employee number (EMPNO) and salary (SALARY) from all the rows in the EMPLOYEE table, if the salary is missing (that is, null), then return a value of zero.

```
SELECT EMPNO, IFNULL(SALARY, 0)
FROM EMPLOYEE
```

INSERT

Returns a string where *length* characters have been deleted from *source-string* beginning at *start* and where *insert-string* has been inserted into *source-string* beginning at *start*.

►► INSERT — (— *source-string* — , — *start* — , — *length* — , — *insert-string* —) ►►

source-string

An expression that specifies the source string. The *source-string* may be any built-in numeric or string expression. It must be compatible with the *insert-string*. For more information about data type compatibility, see [“Assignments and comparisons” on page 89](#). A numeric argument is cast to a character string before evaluating the function. For more information about converting numeric to a character string, see [“VARCHAR” on page 623](#). The actual length of the string must be greater than zero.

start

An expression that returns a built-in BIGINT, INTEGER, or SMALLINT data type. The integer specifies the starting character within *source-string* where the deletion of characters and the insertion of another string is to begin. The value of the integer must be in the range of 1 to the length of *source-string* plus one.

length

An expression that returns a built-in BIGINT, INTEGER, or SMALLINT data type. The integer specifies the number of characters that are to be deleted from *source-string*, starting at the character position identified by *start*. The value of the integer must be in the range of 0 to the length of *source-string*.

insert-string

An expression that specifies the string to be inserted into *source-string*, starting at the position identified by *start*. The *insert-string* may be any built-in numeric or string expression. It must be compatible with the *source-string*. For more information about data type compatibility, see [“Assignments and comparisons” on page 89](#). A numeric argument is cast to a character string before evaluating the function. For more information about converting numeric to a character string, see [“VARCHAR” on page 623](#). The actual length of the string must be 0 or greater.

The data type of the result of the function depends on the data type of the first and fourth arguments. The result data type is the same as if the two arguments were concatenated except that the result is always a varying-length string. For more information see [“Conversion rules for operations that combine strings” on page 110](#).

The length attribute of the result depends on the arguments:

- If *start* and *length* are constants, the length attribute of the result is:

```
L1 - MIN((L1-V2 + 1), V3) + L4
```

where:

```
L1 is the length attribute of source-string
V2 depends on the encoding schema of source-string:
- If the source-string is UTF-8, the value MIN(L1+1,start*3)
- If the source-string is mixed data, the value MIN(L1+1,(start-1)*2.5+4)
- Otherwise, the value of start
V3 is the value of length
L4 is the length attribute of insert-string
```

- Otherwise, the length attribute of the result is the length attribute of *source-string* plus the length attribute of *insert-string*.

If the length attribute of the result exceeds the maximum for the result data type, an error is returned.

The actual length of the result is:

```
A1 - MIN((A1 - V2 + 1), V3) + A4
```

where:

```
A1 is the actual length of source-string  
V2 is the value of start  
V3 is the value of length  
A4 is the actual length of insert-string
```

If the actual length of the result string exceeds the maximum for the result data type, an error is returned.

If any argument can be null, the result can be null; if any argument is null, the result is the null value.

The CCSID of the result is determined by the CCSID of *source-string* and *insert-string*. The resulting CCSID is the same as if the two arguments were concatenated. For more information, see [“Conversion rules for operations that combine strings” on page 110](#).

Examples

- The following example shows how the string 'INSERTING' can be changed into other strings. The use of the CHAR function limits the length of the resulting string to 10 characters.

```
SELECT INSERT('INSERTING', 4, 2, 'IS'),  
       INSERT('INSERTING', 4, 0, 'IS'),  
       INSERT('INSERTING', 4, 2, '')  
FROM SYSIBM.SYSDUMMY1
```

This example returns 'INSISTING ', 'INSISERTIN', and 'INSTING '.

- The previous example demonstrated how to insert text into the middle of some text. This example shows how to insert text before some text by using 1 as the starting point (*start*).

```
SELECT INSERT('INSERTING', 1, 0, 'XX'),  
       INSERT('INSERTING', 1, 1, 'XX'),  
       INSERT('INSERTING', 1, 2, 'XX'),  
       INSERT('INSERTING', 1, 3, 'XX')  
FROM SYSIBM.SYSDUMMY1
```

This example returns 'XXINSERTIN', 'XXNSERTING', 'XXSERTING ', and 'XXERTING '.

- The following example shows how to insert text after some text. Add 'XX' at the end of string 'ABCABC'. Because the source string is 6 characters long, set the starting position to 7 (one plus the length of the source string).

```
SELECT INSERT('ABCABC', 7, 0, 'XX')  
FROM SYSIBM.SYSDUMMY1
```

This example returns 'ABCABCXX '.

INTEGER or INT

The INTEGER function returns an integer representation.

Numeric to Integer

String to Integer

Date to Integer

Time to Integer

The INTEGER function returns an integer representation of:

- A number
- A character or graphic string representation of a decimal number
- A character or graphic string representation of an integer
- A character or graphic string representation of a floating-point number
- A character or graphic string representation of a decimal floating-point number
- A date
- A time

Numeric to Integer

numeric-expression

An expression that returns a numeric value of any built-in numeric data type.

If the argument is a *numeric-expression*, the result is the same number that would occur if the argument were assigned to a large integer column or variable. If the whole part of the argument is not within the range of integers, an error is returned. The fractional part of the argument is truncated.

String to Integer

string-expression

An expression that returns a value that is a character-string or graphic-string representation of a number.

If the argument is a *string-expression*, the result is the same number that would result from `CAST(string-expression AS INTEGER)`. Leading and trailing blanks are eliminated and the resulting string must conform to the rules for forming a floating-point, decimal floating-point, integer, or decimal constant. If the whole part of the argument is not within the range of integers, an error is returned. Any fractional part of the argument is truncated.

Date to Integer

date-expression

An expression that returns a value of the DATE data type. The result is an INTEGER value representing the date as *yyyymmdd*.

Time to Integer

time-expression

An expression that returns a value of the TIME data type. The result is an INTEGER value representing the time as *hhmmss*.

The result of the function is a large integer. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

Note

Syntax alternatives: The CAST specification should be used to increase the portability of applications. For more information, see [“CAST specification”](#) on page 176.

Example

- Using the EMPLOYEE table, select a list containing salary (SALARY) divided by education level (EDLEVEL). Truncate any decimal in the calculation. The list should also contain the values used in the calculation and the employee number (EMPNO).

```
SELECT INTEGER(SALARY / EDLEVEL), SALARY, EDLEVEL, EMPNO
FROM EMPLOYEE
```

INTERPRET

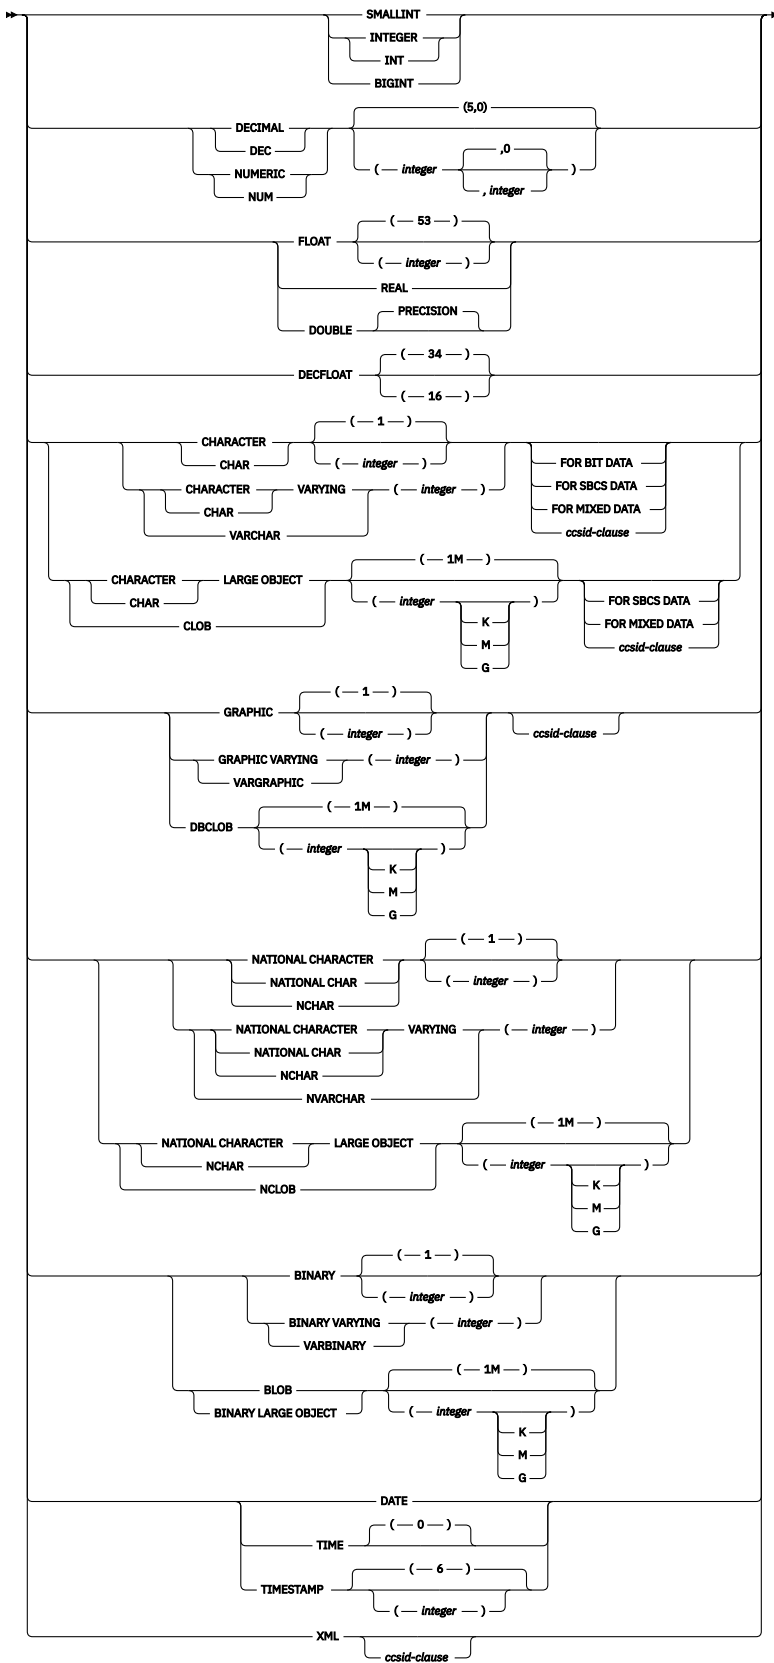

The INTERPRET function returns the first operand interpreted as the specified *data-type*.

►► INTERPRET — (— *expression* — AS — *data-type* —) ◄◄

data-type

►► *built-in-type* ◄◄
 |
 | *distinct-type* ◄◄

built-in-type

ccsid-clause

►► CCSID — *integer* ◄◄

If the argument can be null, the result can be null; if the argument is null, the result is the null value.

string-expression

An expression that returns a built-in binary string or character FOR BIT DATA string that contains the internal IBM i representation of *data-type*. The length of *string-expression* must follow the rules in Table 53 on page 446.

data-type

Specifies the data type of the result. For a description of *data-type*, see “CREATE TABLE” on page 1115.

If the CCSID attribute is not specified for a character or graphic string data type:

- If *data-type* is CHAR, VARCHAR, or CLOB:
 - If FOR BIT DATA is specified, a CCSID of 65535 is used.
 - If FOR MIXED DATA is specified, the mixed-byte CCSID associated with the default CCSID of the job is used.
 - Otherwise, the single-byte CCSID associated with the default CCSID of the job is used.
- If *data-type* is GRAPHIC, VARGRAPHIC, or DBCLOB, CCSID 1200 is used.

Table 53. Data type interpretation rules

Result data type	Required <i>string-expression</i> length in bytes	Other considerations
SMALLINT	2	
INTEGER	4	
BIGINT	8	
DECIMAL(<i>p,s</i>)	(<i>p</i> /2) + 1	
NUMERIC(<i>p,s</i>)	<i>p</i>	
FLOAT (single precision)	4	
FLOAT (double precision)	8	
DECFLOAT(16)	8	
DECFLOAT(34)	16	
CHAR(<i>n</i>)	0 to <i>n</i>	If the length of <i>string-expression</i> is less than <i>n</i> , the result is padded on the right with blanks.
VARCHAR(<i>n</i>)	2 to a maximum of <i>n</i> + 2	The length represented by the first 2 bytes of <i>string-expression</i> cannot exceed <i>n</i> and must not be greater than the length of <i>string-expression</i> - 2.
CLOB(<i>n</i>)	4 to a maximum of <i>n</i> + 4	The length represented by the first 4 bytes of <i>string-expression</i> cannot exceed <i>n</i> and must not be greater than the length of <i>string-expression</i> - 4.
GRAPHIC(<i>n</i>)	0 to 2 <i>n</i>	The length of <i>string-expression</i> must be divisible by 2. If the length of <i>string-expression</i> is less than 2 <i>n</i> , the result is padded on the right with blanks.
VARGRAPHIC(<i>n</i>)	2 to a maximum of 2 <i>n</i> + 2	The length of <i>string-expression</i> must be divisible by 2. The length represented by the first 2 bytes of <i>string-expression</i> cannot exceed <i>n</i> and must not be greater than the length of (<i>string-expression</i> - 2) / 2.
DBCLOB(<i>n</i>)	4 to a maximum of 2 <i>n</i> + 4	The length of <i>string-expression</i> must be divisible by 2. The length represented by the first 4 bytes of <i>string-expression</i> cannot exceed <i>n</i> and must not be greater than the length of (<i>string-expression</i> - 4) / 2.
BINARY(<i>n</i>)	0 to <i>n</i>	If the length of <i>string-expression</i> is less than <i>n</i> , the result is padded on the right with hexadecimal zeros.
VARBINARY(<i>n</i>)	2 to a maximum of <i>n</i> + 2	The length represented by the first 2 bytes of <i>string-expression</i> cannot exceed <i>n</i> and must not be greater than the length of <i>string-expression</i> - 2.
BLOB(<i>n</i>)	4 to a maximum of <i>n</i> + 4	The length represented by the first 4 bytes of <i>string-expression</i> cannot exceed <i>n</i> and must not be greater than the length of <i>string-expression</i> - 4.
DATE	4	
TIME	3	

Table 53. Data type interpretation rules (continued)

Result data type	Required <i>string-expression</i> length in bytes	Other considerations
TIMESTAMP(<i>p</i>)	when <i>p</i> is 0, 19; otherwise 20+ <i>p</i>	
XML	4 to 2G	The length represented by the first 4 bytes of <i>string-expression</i> must not be greater than the length of <i>string-expression</i> - 4.

Example

Table 54.	
Function invocation	Result value
INTERPRET(BX'00000011' AS INTEGER)	17
INTERPRET(BX'12345F' AS DECIMAL(5,2))	123.45
INTERPRET(BX'00258541' AS DATE)	2020-04-05
INTERPRET(BX'616263' AS CHAR(3) CCSID 37)	/ÄÄ
INTERPRET(BX'616263' AS CHAR(3) CCSID 1208)	abc
INTERPRET(BX'0005C1C2C3C4C5' AS VARCHAR(5))	ABCDE
INTERPRET(BX'0003C1C2C3C4C5' AS VARCHAR(5))	ABC
INTERPRET(BX'0007C1C2C3C4C5' AS VARCHAR(7))	Error
INTERPRET(BX'0000003003100320033' AS DBCLOB(3) CCSID 1200)	123

INSTR

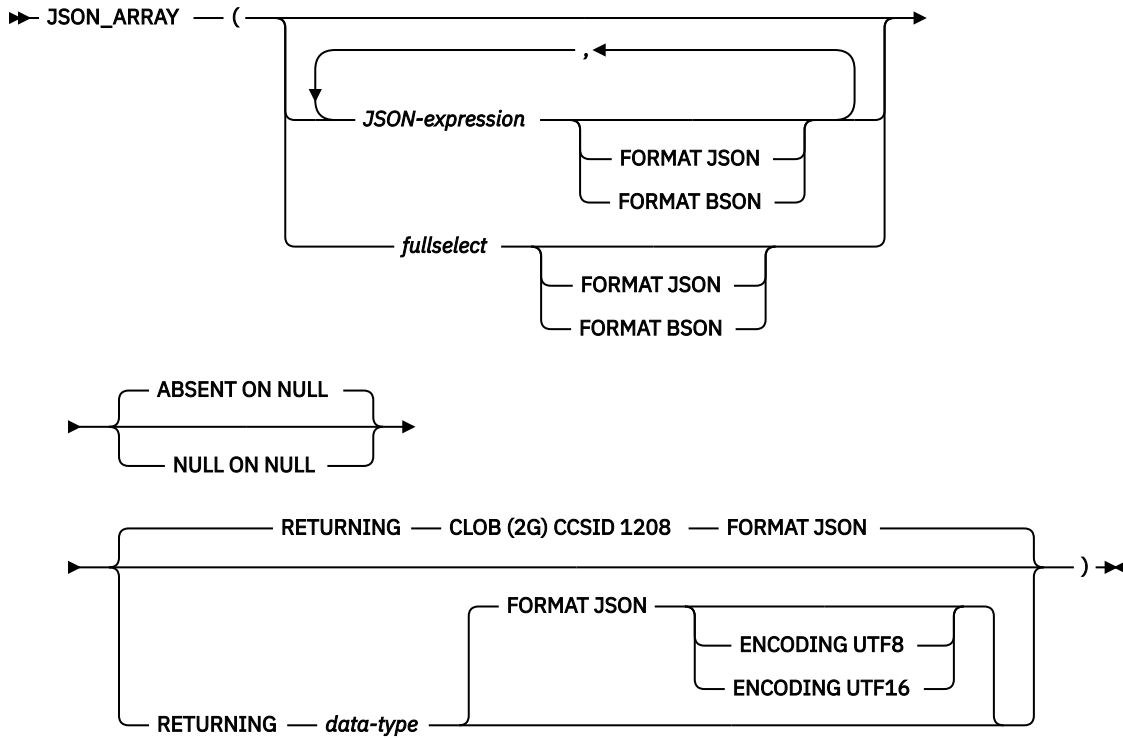

The INSTR function returns the starting position of a string (called the *search-string*) within another string (called the *source-string*). If the *search-string* is not found and neither argument is null, the result is zero. If the *search-string* is found, the result is a number from 1 to the actual length of the *source-string*. If the optional *start* is specified, it indicates the character position in the *source-string* at which the search is to begin.

► INSTR (*source-string* , *search-string* , *start* , *instance*)

The INSTR function is identical to the LOCATE_IN_STRING function. For more information, see [“LOCATE_IN_STRING”](#) on page 480.

JSON_ARRAY

The JSON_ARRAY function generates a JSON array either by explicitly listing the array elements or by using a query. If no *JSON-expression* is provided, the *fullselect* returns no values, or all values are null and ABSENT ON NULL is specified, an empty array is returned.

data-type

ccsid-clause

normalize-clause

JSON-expression

The expression to use to generate a value in the JSON array. The result type of this expression can be any built-in data type except XML, ROWID, or DATALINK. It cannot be CHAR or VARCHAR bit data. It cannot be a user-defined type that is sourced on any of these data types.

fullselect

Specifies a *fullselect* that returns a single column to be used to generate the values in the array. The value of each row is used to generate a value in the JSON array. The result type of this column can be any built-in data type except XML, ROWID, DATALINK, or a user-defined type that is sourced on any of these data types. It cannot be CHAR or VARCHAR bit data.

FORMAT JSON or FORMAT BSON

Specifies whether *JSON-expression* or *fullselect* is already formatted data.

FORMAT JSON

JSON-expression or *fullselect* is formatted as JSON data. If *JSON-expression* or *fullselect* is a character or graphic string data type, it is treated as JSON data. If *JSON-expression* or *fullselect* is a binary string data type, it is interpreted as UTF-8 or UTF-16 data.

FORMAT BSON

JSON-expression or *fullselect* is formatted as the BSON representation of JSON data and must be a binary string data type.

If neither FORMAT JSON nor FORMAT BSON is specified:

- If *JSON-expression* is one of the built-in functions JSON_ARRAY, JSON_OBJECT, JSON_QUERY, JSON_ARRAYAGG, or JSON_OBJECTAGG, the explicit or implicit FORMAT value of the function's RETURNING clause determines the format of *JSON-expression*.
- If *JSON-expression* is a binary string type, it is interpreted as FORMAT BSON.
- Otherwise, *JSON-expression* or *fullselect* is considered unformatted data. If the generated value is not numeric, the result string will be constructed with strings enclosed in quotes and any special characters will be escaped. A numeric value that is not a valid JSON number, such as INFINITY or NAN, will result in an error.

ABSENT ON NULL or NULL ON NULL

Specifies what to return when an array element produced by *JSON-expression* or *fullselect* is the null value.

ABSENT ON NULL

A null array element is not included in the JSON array. This is the default.

NULL ON NULL

A null array element is included in the JSON array.

RETURNING data-type

Specifies the format of the result.

data-type

The data type of the result. For CHAR and VARCHAR results, the CCSID cannot be 65535. The default is CLOB(2G) CCSID 1208.

If a CCSID is specified and the *data-type* is GRAPHIC, VARGRAPHIC, or DBCLOB, the CCSID must be a Unicode CCSID.

If the CCSID attribute is not specified, the CCSID is determined as described in [“CAST specification”](#) on page 176.

FORMAT JSON

JSON data is returned as a JSON string.

ENCODING UTF8 or ENCODING UTF16

The encoding to use when *data-type* is a binary string type. This clause is only allowed for binary string types. The default for binary strings is UTF8.

Examples

- Generate a JSON array containing the values Washington, Jefferson, and Hamilton.

```
VALUES (JSON_ARRAY('Washington', 'Jefferson', 'Hamilton'));
```

The result is the following JSON array:

```
["Washington", "Jefferson", "Hamilton"]
```

- Generate a JSON array that includes all the department numbers.

```
VALUES (JSON_ARRAY((SELECT DEPTNO FROM DEPT  
                      WHERE DEPTNAME LIKE 'BRANCH OFFICE%' )));
```

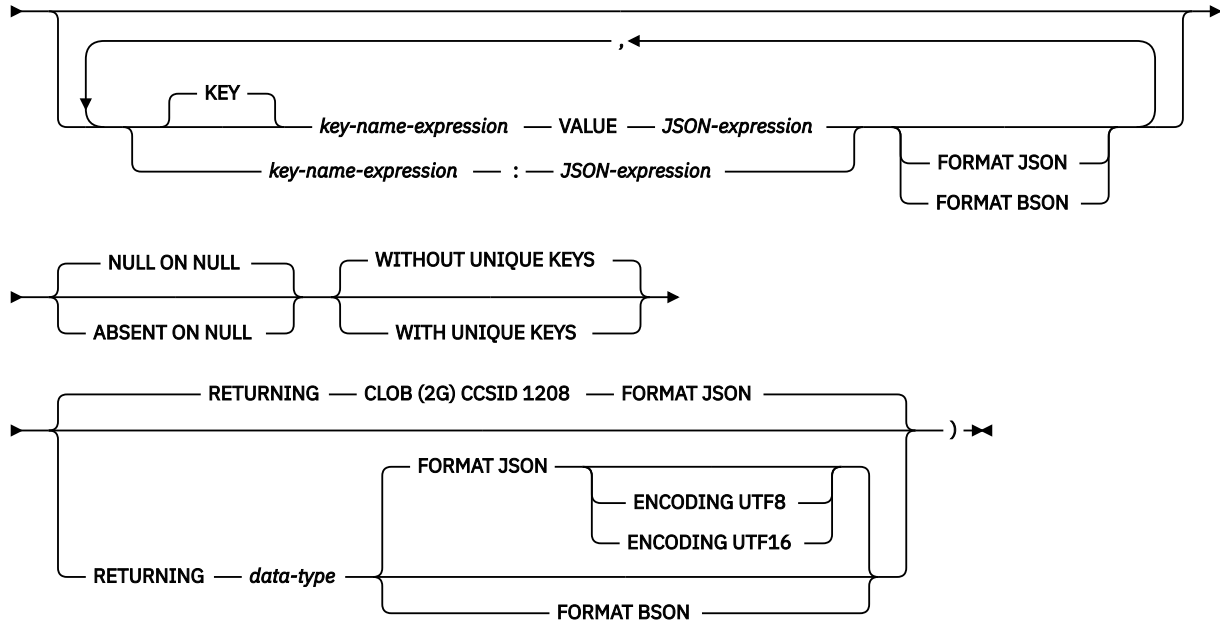

The result is the following JSON array:

```
["F22", "G22", "H22", "I22", "J22"]
```

JSON_OBJECT

The JSON_OBJECT function generates a JSON object using the specified *key:value* pairs. If no *key:value* pairs are provided, an empty object is returned.

►► JSON_OBJECT — (→

data-type

ccsid-clause

normalize-clause

key-name-expression

The name of the JSON key. The name must not be null. When using the colon form for defining a *key:value* pair, *key-name-expression* must be a character string literal. Otherwise, the result of *key-name-expression* must be a built-in character or graphic string data type. It cannot be CHAR or VARCHAR bit data.

JSON-expression

The expression to use to generate the JSON value associated with *key-name-expression*. The result type of this expression can be any built-in data type except XML, ROWID, or DATALINK. It cannot be CHAR or VARCHAR bit data. It cannot be a user-defined type that is sourced on any of these data types.

FORMAT JSON or FORMAT BSON

Specifies whether *JSON-expression* is already formatted data.

FORMAT JSON

JSON-expression is formatted as JSON data. If *JSON-expression* is a character or graphic string data type, it is treated as JSON data. If *JSON-expression* is a binary string data type, it is interpreted as UTF-8 or UTF-16 data.

FORMAT BSON

JSON-expression is formatted as the BSON representation of JSON data and must be a binary string data type.

If neither FORMAT JSON nor FORMAT BSON is specified:

- If *JSON-expression* is one of the built-in functions JSON_ARRAY, JSON_OBJECT, JSON_QUERY, JSON_ARRAYAGG, or JSON_OBJECTAGG, the explicit or implicit FORMAT value of the function's RETURNING clause determines the format of *JSON-expression*.
- If *JSON-expression* is a binary string type, it is interpreted as FORMAT BSON.
- Otherwise, *JSON-expression* is considered unformatted data. If the generated value is not numeric, the result string will be constructed with strings enclosed in quotes and any special characters will be escaped. A numeric value that is not a valid JSON number, such as INFINITY or NAN, will result in an error.

NULL ON NULL or ABSENT ON NULL

Specifies what to return when *JSON-expression* is the null value.

NULL ON NULL

A null value is returned. This is the default.

ABSENT ON NULL

The *key:value* pair is omitted from the JSON object.

WITHOUT UNIQUE KEYS or WITH UNIQUE KEYS

Specifies whether the key values for the resulting JSON object must be unique.

WITHOUT UNIQUE KEYS

The resulting JSON object will not be checked for duplicate keys. This is the default.

WITH UNIQUE KEYS

The resulting JSON object is required to have unique key values. An error will be issued if duplicate keys are generated.

Generating a JSON object with unique keys is considered the best practice. If *key-name-expression* generates unique key names, omit WITH UNIQUE KEYS to improve performance.

RETURNING data-type

Specifies the format of the result.

data-type

The data type of the result. For CHAR and VARCHAR results, the CCSID cannot be 65535. The default is CLOB(2G) CCSID 1208.

If a CCSID is specified and the *data-type* is GRAPHIC, VARGRAPHIC, or DBCLOB, the CCSID must be a Unicode CCSID.

If the CCSID attribute is not specified, the CCSID is determined as described in [“CAST specification”](#) on page 176.

FORMAT JSON

JSON data is returned as a JSON string.

ENCODING UTF8 or ENCODING UTF16

The encoding to use when *data-type* is a binary string type. This clause is only allowed for binary string types. The default for binary strings is UTF8.

FORMAT BSON

JSON data is returned in BSON format. When FORMAT BSON is specified, *data-type* must be a VARBINARY or BLOB string type.

Examples

- Generate a JSON object for a name.

```
VALUES (JSON_OBJECT(KEY 'first' VALUE 'John', KEY 'last' VALUE 'Doe'));
VALUES (JSON_OBJECT('first' : 'John', 'last' : 'Doe'));
```

The result of either of these statements is the following JSON string:

```
{"first": "John", "last": "Doe"}
```

- Generate a JSON object containing the last name, date hired, and salary for the employee with an employee number of '000020'.

```
SELECT JSON_OBJECT(
         'Last name' : LASTNAME,
         'Hire date' : HIREDATE,
         'Salary'   : SALARY)
FROM EMPLOYEE
WHERE EMPNO = '000020';
```

The result of this statement is the following JSON string:

```
{"Last name": "THOMPSON", "Hire date": "1973-10-10", "Salary": 41250.00}
```

JSON_QUERY

The JSON_QUERY function returns an SQL/JSON value from the specified JSON text by using an SQL/JSON path expression.

➤ JSON_QUERY (— *JSON-expression* — , — *sql-json-path-expression* — ➤

data-type

ccsid-clause

normalize-clause

JSON-expression

An expression that returns a value that is a built-in string data type. If a character or graphic value is returned, it must contain correctly formatted JSON data. If it is a binary data type, it is interpreted according to the explicit or implicit **FORMAT** clause.

If *JSON-expression* is a JSON array, it will be implicitly wrapped using a key name of `SYSIBM_ROOT_ARRAY` modifying the *JSON-expression* to be a JSON object. *sql-json-path-expression* is implicitly modified to account for this additional key.

FORMAT JSON or FORMAT BSON

Specifies how *JSON-expression* is to be interpreted.

FORMAT JSON

JSON-expression contains JSON data. If *JSON-expression* is binary data, the data is interpreted as UTF-8 or UTF-16. Binary data cannot be encoded using an EBCDIC CCSID.

FORMAT BSON

JSON-expression contains the BSON representation of JSON data. When **FORMAT BSON** is specified, *JSON-expression* must be a binary string data type.

If the **FORMAT** clause is not specified and *JSON-expression* is a character or graphic string, *JSON-expression* is treated as JSON. If *JSON-expression* is a binary string, *JSON-expression* is treated as BSON.

sql-json-path-expression

An expression that returns a value that is a built-in character or graphic string data type. The string is interpreted as an SQL/JSON path expression and is used to locate a JSON value within the JSON data specified by *JSON-expression*. If more than one value has the same key, one of the JSON values will be selected.

For information on the content of an SQL/JSON path expression, see [“sql-json-path-expression” on page 213](#).

AS path-name

Specifies a name to be used to identify the *sql-json-path-expression*.

RETURNING data-type

Specifies the format of the result.

data-type

The data type of the result. For `CHAR` and `VARCHAR` results, the CCSID cannot be 65535. The default is `CLOB(2G)` CCSID 1208.

If a CCSID is specified and the *data-type* is `GRAPHIC`, `VARGRAPHIC`, or `DBCLOB`, the CCSID must be a Unicode CCSID.

If the CCSID attribute is not specified, the CCSID is determined as described in [“CAST specification” on page 176](#).

FORMAT JSON

JSON data is returned as a JSON string.

ENCODING UTF8 or ENCODING UTF16

The encoding to use when *data-type* is a binary string type. This clause is only allowed for binary string types. The default for binary strings is UTF8.

FORMAT BSON

JSON data is returned in BSON format. When **FORMAT BSON** is specified, *data-type* must be a `VARBINARY` or `BLOB` string type. **FORMAT BSON** can only be used when an SQL/JSON object is returned.

WITHOUT ARRAY WRAPPER or WITH ARRAY WRAPPER

Specifies whether the output value should be wrapped in a JSON array.

WITHOUT ARRAY WRAPPER

The result is not wrapped. This is the default. Using an SQL/JSON path that results in a sequence of two or more SQL/JSON elements results in an error.

WITH UNCONDITIONAL ARRAY WRAPPER

The result is enclosed in square brackets to create a JSON array.

WITH CONDITIONAL ARRAY WRAPPER

The result is enclosed in square brackets to create a JSON array when more than one SQL/JSON element is returned or when a single SQL/JSON element that is not a JSON array or JSON object is returned.

The following table shows how each of these options is applied to the JSON text {a: "10", b: [1, 2]}.

<i>Table 55. Results using each WRAPPER clause</i>		
WRAPPER clause	path value of \$.a	path value of \$.b
WITHOUT ARRAY WRAPPER	"10"	[1,2]
WITH UNCONDITIONAL ARRAY WRAPPER	["10"]	[[1,2]]
WITH CONDITIONAL ARRAY WRAPPER	["10"]	[1,2]

KEEP QUOTES or OMIT QUOTES

Specifies whether the surrounding quotes should be removed when a scalar string is returned.

KEEP QUOTES

Indicates quotes are not removed from scalar strings. This is the default.

OMIT QUOTES

Indicates quotes are removed from scalar strings. When OMIT QUOTES is specified, the WITH ARRAY WRAPPER clause cannot be specified

ON EMPTY

Specifies the behavior when an empty sequence is returned using *sql-json-path-expression*.

NULL ON EMPTY

A null value is returned. This is the default.

ERROR ON EMPTY

An error is returned.

EMPTY ARRAY ON EMPTY

An empty array is returned.

EMPTY OBJECT ON EMPTY

An empty object is returned.

ON ERROR

Specifies the behavior when an error is encountered by JSON_QUERY.

NULL ON ERROR

A null value is returned. This is the default.

ERROR ON ERROR

An error is returned.

EMPTY ARRAY ON ERROR

An empty array is returned.

EMPTY OBJECT ON ERROR

An empty object is returned.

The result can be null. If *JSON-expression* is null, the result is the null value.

Example

- Return the JSON object associated with the name key from a JSON text.

```
VALUES JSON_QUERY('{ "id": "701", "name": { "first": "John", "last": "Doe" } }', '$.name');
```

The result is the following string that represents a JSON object.

```
{ "first": "John", "last": "Doe" }
```

JSON_TO_BSON

The JSON_TO_BSON function converts a string containing formatted JSON data to a binary string containing the data formatted as BSON.

►► JSON_TO_BSON — (— *JSON-expression* —) ►◄

JSON-expression

Specifies an expression that returns a character or graphic string value. It must contain formatted JSON data.

If *JSON-expression* is a JSON array, it will be wrapped using a key name of SYSIBM_ROOT_ARRAY modifying the *JSON-expression* to be a JSON object.

If a JSON object in *JSON-expression* contains duplicate keys, only one of the *key:value* pairs will be included in the result BSON string.

The data type of the result is BLOB(2G).

If the argument can be null, the result can be null; if the argument is null, the result is the null value.

Example

- Read a JSON value from a table and convert it to BSON format.

```
CREATE VARIABLE BSONVAR VARBINARY(2000);  
SELECT JSON_TO_BSON(JSON_COL) INTO BSONVAR FROM TABLE2 WHERE KEY_COLUMN = 27;
```

JSON_VALUE

The JSON_VALUE function returns an SQL scalar value from a JSON text by using an SQL/JSON path expression.

►► JSON_VALUE (— *JSON-expression* — , — *sql-json-path-expression* — ►

data-type

JSON-expression

An expression that returns a value that is a built-in string data type. If a character or graphic value is returned, it must contain correctly formatted JSON data. If it is a binary data type, it is interpreted according to the explicit or implicit `FORMAT` clause.

If *JSON-expression* is a JSON array, it will be implicitly wrapped using a key name of `SYSIBM_ROOT_ARRAY` modifying the *JSON-expression* to be a JSON object. *sql-json-path-expression* is implicitly modified to account for this additional key.

FORMAT JSON or FORMAT BSON

Specifies how *JSON-expression* is to be interpreted.

FORMAT JSON

JSON-expression contains JSON data. If *JSON-expression* is binary data, the data is interpreted as UTF-8 or UTF-16. Binary data cannot be encoded using an EBCDIC CCSID.

FORMAT BSON

JSON-expression contains the BSON representation of JSON data. When `FORMAT BSON` is specified, *JSON-expression* must be a binary string data type.

If the `FORMAT` clause is not specified and *JSON-expression* is a character or graphic string, *JSON-expression* is treated as JSON. If *JSON-expression* is a binary string, *JSON-expression* is treated as BSON.

sql-json-path-expression

An expression that returns a value that is a built-in character or graphic string data type. The string is interpreted as an SQL/JSON path expression and is used to locate a JSON value within the JSON data specified by *JSON-expression*. If more than one value has the same key, one of the JSON values will be selected.

For information on the content of an SQL/JSON path expression, see [“sql-json-path-expression” on page 213](#).

AS path-name

Specifies a name to be used to identify the *sql-json-path-expression*.

RETURNING data-type

Specifies the data type of the result. For `CHAR` and `VARCHAR` results, the CCSID cannot be 65535. Additional rules for result data type conversions are described here: [Table 70 on page 701](#)

The default is `CLOB(2G)` CCSID 1208.

ON EMPTY

Specifies the behavior when an empty sequence is found using *sql-json-path-expression*.

NULL ON EMPTY

A null value is returned. This is the default.

ERROR ON EMPTY

An error is returned.

DEFAULT default-expression ON EMPTY

The value specified by *default-expression* is returned. The expression must be assignment compatible to the result data type.

ON ERROR

Specifies the behavior when an error is encountered by `JSON_VALUE`.

NULL ON ERROR

A null value is returned. This is the default.

ERROR ON ERROR

An error is returned.

DEFAULT *default-expression* ON ERROR

The value specified by *default-expression* is returned. The expression must be assignment compatible to the result data type.

The result can be null. If *JSON-expression* is null, the result is the null value.

Example

- Return a value from a JSON text as an integer.

```
VALUES (JSON_VALUE('{\"id\":\"987\"}', '$.id' RETURNING INTEGER));
```

The result is 987.

- Try to return a value from a JSON text that is an array value. Handle any error by returning a default string.

```
VALUES (JSON_VALUE('{\"friends\":[\"John\",\"Lisa\"]}',  
                  'strict $.friends' DEFAULT 'Not found' ON ERROR));
```

The result is Not found since the value corresponding to the `friends` key is an array, not a scalar value.

JULIAN_DAY

The JULIAN_DAY function returns an integer value representing a number of days from January 1, 4713 B.C. (the start of the Julian date calendar) to the date specified in the argument.

►► JULIAN_DAY — (— *expression* —) ◄◄

expression

An expression that returns a value of one of the following built-in data types: a date, a timestamp, a character string, or a graphic string. If *expression* is a character or graphic string, its value must be a valid string representation of a date or timestamp. For the valid formats of string representations of dates and timestamps, see [“String representations of datetime values”](#) on page 75.

The result of the function is a large integer. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

Note

Julian and Gregorian calendar: The transition from the Julian calendar to the Gregorian calendar on 15 October 1582 is not taken into account by this function.

Examples

- Using sample table EMPLOYEE, set the integer host variable JDAY to the Julian day of the day that Christine Haas (EMPNO = '000010') was employed (HIREDATE = '1965-01-01').

```
SELECT JULIAN_DAY(HIREDATE)
INTO :JDAY
FROM EMPLOYEE
WHERE EMPNO = '000010'
```

The result is that JDAY is set to 2438762.

- Set integer host variable JDAY to the Julian day for January 1, 1998.

```
SELECT JULIAN_DAY('1998-01-01')
INTO :JDAY
FROM SYSIBM.SYSDUMMY1
```

The result is that JDAY is set to 2450815.

LAND

The LAND function returns a string that is the logical 'AND' of the argument strings. This function takes the first argument string, does an AND operation with the next string, and then continues to do AND operations with each successive argument using the previous result. If a character-string argument is shorter than the previous result, it is padded with blanks. If a binary-string argument is shorter than the previous result, it is padded with hexadecimal zeros.

The arguments must be compatible.

expression

An expression that returns a value of any built-in numeric or string data type, but cannot be LOBs. The arguments cannot be mixed data character strings, UTF-8 character strings, or graphic strings. A numeric argument is cast to a character string before evaluating the function. For more information about converting numeric to a character string, see [“VARCHAR” on page 623](#).

The arguments are converted, if necessary, to the attributes of the result. The attributes of the result are determined as follows:

- If all the arguments are fixed-length strings, the result is a fixed-length string of length n , where n is the length of the longest argument.
- If any argument is a varying-length string, the result is a varying-length string with length attribute n , where n is the length attribute of the argument with greatest length attribute. The actual length of the result is m , where m is the actual length of the longest argument.

If an argument can be null, the result can be null; if an argument is null, the result is the null value.

The CCSID of the result is 65535.

Example

- Assume the host variable L1 is a CHARACTER(2) host variable with a value of X'A1B1', host variable L2 is a CHARACTER(3) host variable with a value of X'F0F040', and host variable L3 is a CHARACTER(4) host variable with a value of X'A1B10040'.

```
SELECT LAND(:L1, :L2, :L3)
FROM SYSIBM.SYSDUMMY1
```

Returns the value X'A0B00040'.

LAST_DAY

The LAST_DAY function returns a date or timestamp that represents the last day of the month indicated by *expression*.

►► LAST_DAY — (— *expression* —) ◄◄

expression

An expression that returns a value of one of the following built-in data types: a date, a timestamp, a character string, or a graphic string.

If *expression* is a character or graphic string, its value must be a valid string representation of a date or timestamp. For the valid formats of string representations of dates and timestamps, see [“String representations of datetime values”](#) on page 75.

The result of the function has the same data type as *expression*, unless *expression* is a string in which case the result is DATE. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

Any hours, minutes, seconds, or fractional seconds information included in *expression* is not changed by the function.

Example

- Set the host variable END_OF_MONTH with the last day of the current month.

```
SET :END_OF_MONTH = LAST_DAY(CURRENT_DATE)
```

The host variable END_OF_MONTH is set with the value representing the end of the current month. If the current day is 2000-02-10, then END_OF_MONTH is set to 2000-02-29.

- Set the host variable END_OF_MONTH with the last day of the month in EUR format for the given date.

```
SET :END_OF_MONTH = CHAR(LAST_DAY('1965-07-07'), EUR)
```

The host variable END_OF_MONTH is set with the value '31.07.1965'.

- Assuming that the default date format is ISO,

```
SELECT LAST_DAY('2000-04-24')  
FROM SYSIBM.SYSDUMMY1
```

Returns '2000-04-30' which is the last day of April in 2000.

LCASE

The LCASE function returns a string in which all the characters have been converted to lowercase characters, based on the CCSID of the argument.

►► LCASE (— *expression* —) ◄◄

The LCASE function is identical to the LOWER function. For more information, see [“LOWER” on page 484](#).

LEAST

The LEAST scalar function returns the minimum value in a set of values.

► LEAST (*expression* , *expression*) ◄

The LEAST function is identical to the MIN function. For more information, see [“MIN” on page 494](#).

LEFT

The LEFT function returns the leftmost *integer* characters of *expression*.

►► LEFT (— *expression* — , — *integer* —) ◄◄

If *expression* is a character string, the result is a character string. If *expression* is a graphic string, the result is a graphic string. If *expression* is a binary string, the result is a binary string.

expression

An expression that specifies the string from which the result is derived. The arguments must be expressions that return a value of any built-in numeric, character string, graphic string, or a binary string data type. A numeric argument is cast to a character string before evaluating the function. For more information about converting numeric to a character string, see “VARCHAR” on page 623.

A substring of *expression* is zero or more contiguous characters of *expression*. If *expression* is a character string or graphic string, a single character is either an SBCS, DBCS, or multiple-byte character. If *expression* is a binary string, the result is the number of bytes in the argument.

integer

An expression that returns a built-in integer data type. The integer specifies the length of the result. The value of *integer* must be greater than or equal to 0 and less than or equal to *n*, where *n* is the length attribute of *expression*.

The result of the function is a varying-length string with a length attribute that is the same as the length attribute of *expression* and a data type that depends on the data type of *expression*:

Data type of <i>expression</i>	Data type of the Result
CHAR or VARCHAR	VARCHAR
CLOB	CLOB
GRAPHIC or VARGRAPHIC	VARGRAPHIC
DBCLOB	DBCLOB
BINARY or VARBINARY	VARBINARY
BLOB	BLOB

The actual length of the result is *integer*.

If any argument can be null, the result can be null; if any argument is null, the result is the null value.

The CCSID of the result is the same as that of *expression*.

Note

Syntax alternatives: STRLEFT is a synonym for LEFT.

Example

- Assume the host variable NAME (VARCHAR(50)) has a value of 'KATIE AUSTIN' and the host variable FIRSTNAME_LEN (int) has a value of 5.

```
SELECT LEFT(:NAME, :FIRSTNAME_LEN)
FROM SYSIBM.SYSDUMMY1
```

Returns the value 'KATIE'

- Assume that NAME is a VARCHAR(128) column, encoded in Unicode UTF-8, that contains the value 'Jürgen'.

```
SELECT LEFT(NAME, 2), SUBSTR(NAME, 1, 2)
FROM T1
WHERE NAME = 'Jürgen'
```

Returns the value 'Jü' for LEFT and 'JÊ' for SUBSTR(NAME, 1, 2).

LENGTH

The LENGTH function returns the length of a value.

►► LENGTH — (— *expression* —) ◄◄

See “[CHARACTER_LENGTH or CHAR_LENGTH](#)” on page 331, “[OCTET_LENGTH](#)” on page 520, and “[BIT_LENGTH](#)” on page 320 for similar functions.

expression

An expression that returns a value of any built-in data type.

The result of the function is a large integer. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

The result is the length of the argument. The length of strings includes blanks. The length of a varying-length string is the actual length, not the length attribute.

The length of a graphic string is the number of double-byte characters (the number of bytes divided by 2). The length of all other values is the number of bytes used to represent the value:

- 2 for small integer
- 4 for large integer
- 8 for big integer
- The integral part of $(p/2)+1$ for packed decimal numbers with precision p
- p for zoned decimal numbers with precision p
- 4 for single-precision float
- 8 for double-precision float
- 8 for DECFLOAT(16)
- 16 for DECFLOAT(34)
- The length of the string for strings
- 3 for time
- 4 for date
- $7+((p+1)/2)$ for timestamp(p)
- The actual number of bytes used to store the DataLink value (plus 19 if the DataLink is FILE LINK CONTROL and READ PERMISSION DB) for datalinks
- 26 for row ID

Examples

- Assume the host variable ADDRESS is a varying-length character string with a value of '895 Don Mills Road'.

```
SELECT LENGTH(:ADDRESS)
FROM SYSIBM.SYSDUMMY1
```

Returns the value 18.

- Assume that PRSTDATE is a column of type DATE.

```
SELECT LENGTH(PRSTDATE)
FROM PROJECT
```

Returns the value 4.

- Assume that PRSTDATE is a column of type DATE.

```
SELECT LENGTH(CHAR(PRSTDATE, EUR))  
FROM PROJECT
```

Returns the value 10.

LN

The LN function returns the natural logarithm of a number. The LN and EXP functions are inverse operations.

►► LN — (— *expression* —) ►►

expression

An expression that returns a value of any built-in numeric, character-string, or graphic-string data type. A string argument is cast to double-precision floating point before evaluating the function. For more information about converting strings to double-precision floating point, see [“DOUBLE_PRECISION or DOUBLE” on page 392](#). The value of the argument must be greater than zero.

If the data type of the argument is DECFLOAT(*n*), the result is DECFLOAT(*n*). Otherwise, the data type of the result is double-precision floating point. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

Note

Results involving DECFLOAT special values: For decimal floating-point values the special values are treated as follows:

- LN(NaN) returns NaN. ⁶¹
- LN(-NaN) returns NaN. ⁶¹
- LN(Infinity) returns Infinity.
- LN(-Infinity) returns NaN. ⁶¹
- LN(sNaN) and LN(-sNaN) return a warning or error. ⁶¹
- LN(0) returns -Infinity.
- LN with a negative argument, including -Infinity, returns NaN. ⁶¹

Example

- Assume the host variable NATLOG is a DECIMAL(4,2) host variable with a value of 31.62.

```
SELECT LN(:NATLOG)
FROM SYSIBM.SYSDUMMY1
```

Returns the approximate value 3.45.

⁶¹ If *YES is specified for the SQL_DECFLOAT_WARNINGS query option, NaN is returned with a warning.

LNOT

The LNOT function returns a string that is the logical NOT of the argument string.

►► LNOT — (— *expression* —) ◄◄

expression

An expression that returns a value of any built-in numeric or string data type, but cannot be LOBs.

The arguments cannot be mixed data character strings, UTF-8 character strings, or graphic strings. A numeric argument is cast to a character string before evaluating the function. For more information about converting numeric to a character string, see [“VARCHAR” on page 623](#).

The data type and length attribute of the result is the same as the data type and length attribute of the argument value. If the argument is a varying-length string, the actual length of the result is the same as the actual length of the argument value. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

The CCSID of the result is 65535.

Example

- Assume the host variable L1 is a CHARACTER(2) host variable with a value of X'F0F0'.

```
SELECT LNOT (:L1)
FROM SYSIBM.SYSDUMMY1
```

Returns the value X'0F0F'.

LOCATE

The LOCATE function returns the starting position of the first occurrence of one string (called the *search-string*) within another string (called the *source-string*). If the *search-string* is not found and neither argument is null, the result is zero. If the *search-string* is found, the result is a number from 1 to the actual length of the *source-string*. If the optional *start* is specified, it indicates the character position in the *source-string* at which the search is to begin.

► LOCATE (— *search-string* — , — *source-string* — , — *start* —) ►

search-string

An expression that specifies the string that is to be searched for. *search-string* may be any built-in numeric, datetime, or string expression. It must be compatible with the *source-string*. A numeric or datetime argument is cast to a character string before evaluating the function. For more information about converting numeric and datetime to a character string, see [“VARCHAR” on page 623](#).

source-string

An expression that specifies the source string in which the search is to take place. *source-string* may be any built-in numeric, datetime, or string expression. A numeric or datetime argument is cast to a character string before evaluating the function. For more information about converting numeric and datetime to a character string, see [“VARCHAR” on page 623](#).

start

An expression that specifies the position within *source-string* at which the search is to start. *start* may be any built-in numeric, character string, or graphic string expression. If the value is not of type INTEGER, it is implicitly cast to INTEGER before evaluating the function. The value must be greater than zero.

If *start* is specified, the function is similar to:

```
POSITION( search-string , SUBSTRING(source-string,start) ) + start - 1
```

If *start* is not specified, the function is equivalent to:

```
POSITION( search-string , source-string )
```

For more information, see [“POSITION” on page 525](#).

The result of the function is a large integer. If any of the arguments can be null, the result can be null; if any of the arguments is null, the result is the null value.

The LOCATE function operates on a character basis. Because LOCATE operates on a character-string basis, any shift-in and shift-out characters are not required to be in exactly the same position and their only significance is to indicate which characters are SBCS and which characters are DBCS.

If the CCSID of the *search-string* is different than the CCSID of the *source-string*, it is converted to the CCSID of the *source-string*.

If a collating sequence other than *HEX is in effect when the statement that contains the LOCATE function is executed and the arguments are SBCS data, mixed data, or Unicode data, then the result is obtained by comparing weighted values for each value in the set. The weighted values are based on the collating sequence. An ICU collating sequence table may not be specified with the LOCATE function.

Example

- Select RECEIVED and SUBJECT columns as well as the starting position of the words 'GOOD' within the NOTE_TEXT column for all entries in the IN_TRAY table that contain these words.

```
SELECT RECEIVED, SUBJECT, LOCATE('GOOD', NOTE_TEXT)
FROM IN_TRAY
WHERE LOCATE('GOOD', NOTE_TEXT) <> 0
```

- Assume that NOTE is a VARCHAR(128) column, encoded in Unicode UTF-8, that contains the value 'Jürgen lives on Hegelstraße'. Find the character position of the character 'ß' in the string.

```
SELECT LOCATE( 'ß', NOTE ), POSSTR( NOTE_TEXT, 'ß')  
FROM T1
```

Returns the value 26 for LOCATE and 27 for POSSTR.

At each search position, a match is found when the substring at that position and `CHARACTER_LENGTH(search-string) - 1` values to the right of the search position in *source-string*, is equal to *search-string*.

The result of the function is a large integer. The result is the starting position of the instance of *search-string* within *source-string*. The value is relative to the beginning of the string (regardless of the specification of *start*).

If any argument can be null, the result can be null; if any argument is null, the result is the null value.

The `LOCATE_IN_STRING` function operates on a character basis. Because `LOCATE_IN_STRING` operates on a character-string basis, any shift-in and shift-out characters are not required to be in exactly the same position and their only significance is to indicate which characters are SBCS and which characters are DBCS.

If the `CCSID` of the *search-string* is different than the `CCSID` of the *source-string*, it is converted to the `CCSID` of the *source-string*.

If a collating sequence other than `*HEX` is in effect when the statement that contains the `LOCATE_IN_STRING` function is executed and the arguments are SBCS data, mixed data, or Unicode data, then the result is obtained by comparing weighted values for each value in the set. The weighted values are based on the collating sequence. An ICU collating sequence table may not be specified with the `LOCATE` function.

Syntax alternatives: `INSTR` can be used as a synonym for `LOCATE_IN_STRING`.

Example

- Locate the character 'ß' in the string 'Jürgen lives on Hegelstraße' by searching from the end of the string, and set the host variable `POSITION` with the position within the string.

```
SET :POSITION = LOCATE_IN_STRING('Jürgen lives on Hegelstraße','ß',-1);
```

The value of host variable `POSITION` is set to 26.

- Find the position of an occurrence of the character 'N' in the string 'WINNING' by searching from the start of the string.

```
SELECT LOCATE_IN_STRING('WINNING','N',1,3),
       LOCATE_IN_STRING('WINNING','N',3,2),
       LOCATE_IN_STRING('WINNING','N',3,3)
FROM SYSIBM.SYSDUMMY1;
```

Returns the values:

```
6    4    6
```

- Find the position of an occurrence of the character 'N' in the string 'WINNING' by searching from the end of the string.

```
SELECT LOCATE_IN_STRING('WINNING','N',-1,3),
       LOCATE_IN_STRING('WINNING','N',-3,2),
       LOCATE_IN_STRING('WINNING','N',-3,3)
FROM SYSIBM.SYSDUMMY1;
```

Returns the values:

```
3    3    0
```

LOG10

The LOG10 function returns the common logarithm (base 10) of a number. The LOG10 and ANTILOG functions are inverse operations.

► LOG10 — (— *expression* —) ◄

expression

An expression that returns a value of any built-in numeric, character-string, or graphic-string data type. A string argument is cast to double-precision floating point before evaluating the function. For more information about converting strings to double-precision floating point, see “DOUBLE_PRECISION or DOUBLE” on page 392.

If the data type of the argument is DECFLOAT(*n*), the result is DECFLOAT(*n*). Otherwise, the data type of the result is double-precision floating point. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

Note

Results involving DECFLOAT special values: For decimal floating-point values the special values are treated as follows:

- LOG10(NaN) returns NaN. ⁶²
- LOG10(-NaN) returns NaN. ⁶²
- LOG10(Infinity) returns Infinity.
- LOG10(-Infinity) returns NaN. ⁶²
- LOG10(sNaN) and LOG10(-sNaN) return a warning or error. ⁶²
- LOG10(0) returns -Infinity.
- LOG10 with a negative argument, including -Infinity, returns NaN. ⁶²

Syntax alternatives: LOG is a synonym for LOG10. It is supported only for compatibility with previous Db2 releases. LOG10 should be used instead of LOG because some database managers and applications implement LOG as the natural logarithm of a number instead of the common logarithm of a number.

Example

- Assume the host variable L is a DECIMAL(4,2) host variable with a value of 31.62.

```
SELECT LOG10(:L)
FROM SYSIBM.SYSDUMMY1
```

Returns the approximate value 1.49.

⁶² If *YES is specified for the SQL_DECFLOAT_WARNINGS query option, NaN is returned with a warning.

LOR

The LOR function returns a string that is the logical OR of the argument strings. This function takes the first argument string, does an OR operation with the next string, and then continues to do OR operations for each successive argument using the previous result. If a character-string argument is shorter than the previous result, it is padded with blanks. If a binary-string argument is shorter than the previous result, it is padded with hexadecimal zeros.

The arguments must be compatible.

expression

An expression that returns a value of any built-in numeric or string data type, but cannot be LOBs.

The arguments cannot be mixed data character strings, UTF-8 character strings, or graphic strings. A numeric argument is cast to a character string before evaluating the function. For more information about converting numeric to a character string, see [“VARCHAR” on page 623](#).

The arguments are converted, if necessary, to the attributes of the result. The attributes of the result are determined as follows:

- If all the arguments are fixed-length strings, the result is a fixed-length string of length n , where n is the length of the longest argument.
- If any argument is a varying-length string, the result is a varying-length string with length attribute n , where n is the length attribute of the argument with greatest length attribute. The actual length of the result is m , where m is the actual length of the longest argument.

If an argument can be null, the result can be null; if an argument is null, the result is the null value.

The CCSID of the result is 65535.

Example

- Assume the host variable L1 is a CHARACTER(2) host variable with a value of X'0101', host variable L2 is a CHARACTER(3) host variable with a value of X'F0F000', and host variable L3 is a CHARACTER(4) host variable with a value of X'0000000F'.

```
SELECT LOR(:L1, :L2, :L3)
FROM SYSIBM.SYSDUMMY1
```

Returns the value X'F1F1404F'.

LOWER

The LOWER function returns a string in which all the characters have been converted to lowercase characters, based on the CCSID of the argument. Only SBCS, Unicode graphic characters are converted. The characters A-Z are converted to a-z, and characters with diacritical marks are converted to their lowercase equivalent, if any.

►► LOWER — (— *expression* —) ◄◄

Refer to the [UCS-2 level 1 mapping tables](#) topic in the [Globalization](#) topic collection for a description of the monocasing tables that are used for this translation.

expression

An expression that specifies the string to be converted. *expression* must be any built-in numeric, character, Unicode graphic string. A numeric argument is cast to a character string before evaluating the function. For more information about converting numeric to a character string, see [“VARCHAR” on page 623](#).

The result of the function has the same data type, length attribute, actual length, and CCSID as the argument. If the argument can be null, the result can be null. If the argument is null, the result is the null value.

Note

Syntax alternatives: LCASE is a synonym for LOWER.

Examples

- Ensure that the characters in the value of host variable NAME are lowercase. NAME has a data type of VARCHAR(30) and a value of 'Christine Smith'.

```
SELECT LOWER(:NAME)
FROM SYSIBM.SYSDUMMY1
```

The result is the value 'christine smith'.

LPAD

The LPAD function returns a string composed of *expression* that is padded on the left.

►► LPAD (— *expression* — , — *length* — , — *pad* —) ►►

The LPAD function treats leading or trailing blanks in *expression* as significant. Padding will only occur if the actual length of *expression* is less than *length*, and *pad* is not an empty string.

expression

An expression that specifies the string from which the result is derived.

Expression must be a built-in string, numeric, or datetime data type. A numeric or datetime argument is cast to VARCHAR with a CCSID that is the default SBCS CCSID at the current server before evaluating the function. For more information about converting numeric or datetime to a varying character string, see “VARCHAR” on page 623.

length

An expression that specifies the length of the result. The expression must return a value that is a built-in numeric, character-string, or graphic-string data type. If the data type of the expression is not INTEGER, it is implicitly cast to INTEGER before evaluating the function. The value must be zero or a positive integer that is less than or equal to *n*, where *n* is the maximum length of the result data type. See Appendix A, “SQL limits,” on page 1643 for more information.

If *expression* is a graphic string, *length* indicates the number of DBCS or Unicode graphic characters. If *expression* is a character string, *length* indicates the number of characters where a character may consist of one or more bytes. If *expression* is a binary string, *length* indicates the number of bytes.

pad

An expression that specifies the string with which to pad. The expression must return a value that is a built-in string, numeric, or datetime data type. If the value is a numeric or datetime data type, it is implicitly cast to VARCHAR with a CCSID that is the default SBCS CCSID at the current server before evaluating the function.

If *pad* is not specified, the pad character is set as follows:

- For character and graphic strings, a single-byte, double-byte, UTF-16, or UTF-8 blank character based on the data type and CCSID of *expression*.⁶³
- For binary strings, hexadecimal zeros.

The value for *expression* and the value for *pad* must have compatible data types. If the CCSID of *pad* is different than the CCSID of *expression*, the *pad* value is converted to the CCSID of *expression*. For more information about data type compatibility, see “Assignments and comparisons” on page 89.

The data type of the result depends on the data type of *expression*:

Data type of <i>expression</i>	Data Type of the Result for LPAD
CHAR or VARCHAR or numeric or datetime	VARCHAR
CLOB	CLOB
GRAPHIC or VARGRAPHIC	VARGRAPHIC
DBCLOB	DBCLOB
BINARY or VARBINARY	VARBINARY

⁶³ UTF-16 or UCS-2 defines a blank character at code point X'0020' and X'3000'. The database manager pads with the blank at code point X'0020'. The database manager pads UTF-8 with a blank at code point X'20'

Data type of <i>expression</i>	Data Type of the Result for LPAD
BLOB	BLOB

The length attribute of the result depends on *length*. If *length* is explicitly specified by an integer constant that is greater than zero, the length attribute of the result is *length*. If *length* is explicitly specified by an integer constant that is zero, the length attribute of the result is 1. If *length* is specified as an expression, the length attribute of the result is the minimum of $m+100$ and the maximum length of the result data type, where m is the length attribute of *expression*. See [Appendix A, “SQL limits,” on page 1643](#) for more information.

The actual length of the result is determined from *length*.

- If *length* is 0, the actual length is 0 and the result is the empty result string.
- If *length* is equal to the actual length of *expression*, the actual length is the length of *expression*.
- If *length* is less than the actual length of *expression*, the result is truncated. The actual length is *length* unless the result data type is varying-length mixed data or varying-length Unicode. In this case, only complete characters will be truncated.
 - For Unicode data, the actual length may be $length-1$ to prevent a double-byte character from being split.
 - For mixed data the actual length may be as little as $length-3$ to account for truncation of a double byte character and possibly a “shift-in” character (X'0F') and a “shift-out” character (X'0E').
- If *length* is greater than the actual length of *expression*, the actual length is *length* unless the result data type is varying-length mixed data or varying-length Unicode and *pad* contains double-byte characters. In this case, only complete characters will be padded.
 - For Unicode data, the actual length may be $length-1$ to prevent a double-byte character from being split.
 - For mixed data, the actual length may be may be as little as $length-3$ to account for truncation of a double byte character and possibly a “shift-in” character (X'0F') and a “shift-out” character (X'0E'). Also, this result will not have redundant shift codes “at the seam”. Thus, if the pad is a string ending with a “shift-in” character (X'0F'), and expression begins with a “shift-out” character (X'0E'), these two bytes are eliminated from the result.

If any argument can be null, the result can be null; if any argument is null, the result is the null value.

The CCSID of the result is the same as that of *expression*.

Examples

- *Example 1:* Assume that NAME is a VARCHAR(15) column that contains the values "Chris", "Meg", and "Jeff". The following query will completely pad out a value on the left with periods:

```
SELECT LPAD(NAME,15,'.' ) AS NAME FROM T1;
```

returns:

```
NAME
-----
.....Chris
.....Meg
.....Jeff
```

- *Example 2:* Assume that NAME is a VARCHAR(15) column that contains the values "Chris", "Meg", and "Jeff". The following query will only pad each value to a length of 5:

```
SELECT LPAD(NAME,5,'.' ) AS NAME FROM T1;
```

returns:

```
NAME
-----
Chris
.Meg
.Jeff
```

- *Example 3:* Assume that NAME is a CHAR(15) column containing the values "Chris", "Meg", and "Jeff". The LPAD function does not pad because NAME is a fixed length character field and is blank padded already. However, since the length of the result is 5, the columns are truncated:

```
SELECT LPAD(NAME,5,'.' ) AS NAME FROM T1;
```

returns:

```
NAME
-----
Chris
Meg
Jeff
```

- *Example 4:* Assume that NAME is a VARCHAR(15) column containing the values "Chris", "Meg", and "Jeff". In some cases, a partial instance of the pad specification is returned:

```
SELECT LPAD(NAME,15,'123' ) AS NAME FROM T1;
```

returns:

```
NAME
-----
1231231231Chris
123123123123Meg
12312312312Jeff
```

- *Example 5:* Assume that NAME is a VARCHAR(15) column containing the values "Chris", "Meg", and "Jeff". Note that "Chris" is truncated, "Meg" is padded, and "Jeff" is unchanged:

```
SELECT LPAD(NAME,4,'.' ) AS NAME FROM T1;
```

returns:

```
NAME
----
Chri
.Meg
Jeff
```

LTRIM

The LTRIM function removes any of the specified characters from the beginning of an expression.

► LTRIM (— *string-expression* — , — *trim-expression* —) ►

The LTRIM function removes all of the characters that are contained in *trim-expression* from the beginning of *string-expression*. The collating sequence does not affect the search. If the *string-expression* is defined as FOR BIT DATA or is a binary data type, the search is done by comparing each byte in *trim-expression* to the byte at the beginning of *string-expression*.

string-expression

An expression that returns a value of any built-in numeric, datetime, or string data type. A numeric or datetime argument is cast to a character string before evaluating the function.⁶⁴ For more information about converting numeric or datetime to a character string, see “VARCHAR” on page 623.

trim-expression

An expression that specifies the characters to remove from the beginning of *string-expression*. The expression must return a value of any built-in numeric, datetime, or string data type. A numeric or datetime argument is cast to a character string before evaluating the function.

When *trim-expression* is not specified, the data type of the *string-expression* determines the default value used:

- Hexadecimal zero (X'00') if the argument is a binary string.
- DBCS blank if the argument is a DBCS graphic string.
- UTF-16 or UCS-2 blank if the first argument is a Unicode graphic string.
- UTF-8 blank if the first argument is a UTF-8 character string.
- Otherwise, a SBCS blank.

The value for *string-expression* and the value for *trim-expression* must have compatible data types. For more information about data type compatibility, see “Assignments and comparisons” on page 89. If *string-expression* and *trim-expression* have different CCSIDs, *trim-expression* is converted to the CCSID of *string-expression*.

The data type of the result depends on the data type of *string-expression*:

Data type of <i>string-expression</i>	Data type of the Result
CHAR or VARCHAR	VARCHAR
CLOB	CLOB
GRAPHIC or VARGRAPHIC	VARGRAPHIC
DBCLOB	DBCLOB
BINARY or VARBINARY	VARBINARY
BLOB	BLOB

The length attribute of the result is the same as the length attribute of *string-expression*. The actual length of the result for character or binary strings is the length of *string-expression* minus the number of bytes removed. The actual length of the result for graphic strings is the length of *string-expression* minus the number of graphic characters removed. If all characters are removed, the result is an empty string.

If either argument can be null, the result can be null; if any argument is null, the result is the null value.

The CCSID of the result is the same as that of *string-expression*.

⁶⁴ The LTRIM function with one argument returns the same results as: STRIP(*string-expression*,LEADING)

Examples

- *Example 1:* Use the LTRIM function when the host variable HELLO is defined as CHAR(9) and has a value of

```
' Hello'
```

```
VALUES LTRIM(:HELLO)
```

The result is 'Hello'. When a *trim-expression* is not specified only blanks are removed.

- *Example 2:* Use the LTRIM function to remove individual numbers in the *trim-expression* from the beginning (left side) of the *string-expression*.

```
SELECT LTRIM ('123DEFG123', '321'),  
       LTRIM ('12DEFG123', '321'),  
       LTRIM ('123123222XYZ22', '123'),  
       LTRIM ('12321', '213'),  
       LTRIM ('XYX123', '321')  
FROM SYSIBM.SYSDUMMY1
```

The result is:

```
'DEFG123'  
'DEFG123'  
'XYZ22'  
' (an empty string - all characters removed)  
'XYX123' (no characters removed)
```

The LTRIM function does not remove instances of '1', '2', and '3' on the right side of the string, following characters that are not '1', '2', or '3'.

- *Example 3:* Use the LTRIM function to remove the characters specified in the *trim-expression* from the beginning of the *string-expression*.

```
VALUES LTRIM('...$V..$AR', '$.')
```

The result is 'V..\$AR'. The function stops when it encounters a character not in the *trim-expression*.

- *Example 4:* Use the LTRIM function to remove the characters specified in the *trim-expression* from the beginning of the *string-expression*.

```
VALUES LTRIM('[[ -78]]', '- []')
```

The result is '78]]'. When removing characters and blanks, you must include a blank in the *trim-expression*.

MAX

The MAX scalar function returns the maximum value in a set of values.

The arguments must be compatible. Character-string arguments are compatible with datetime values. The arguments cannot be DataLink or XML values.

expression

An expression that returns the value of any built-in numeric or string data type. If one of the arguments is numeric, then character and graphic string arguments are cast to numeric before evaluating the function.

The result of the function is the largest argument value. The result can be null if at least one argument can be null; the result is the null value if one of the arguments is null.

The selected argument is converted, if necessary, to the attributes of the result. The attributes of the result are determined by all the operands as explained in [“Rules for result data types” on page 105](#).

If a collating sequence other than *HEX is in effect when the statement is executed and the arguments are SBCS data, mixed data, or Unicode data, the weighted values of the strings are compared instead of the actual values. The weighted values are based on the collating sequence.

Note

Syntax alternatives: GREATEST can be specified as a synonym for MAX.

Examples

- Assume the host variable M1 is a DECIMAL(2,1) host variable with a value of 5.5, host variable M2 is a DECIMAL(3,1) host variable with a value of 4.5, and host variable M3 is a DECIMAL(3,2) host variable with a value of 6.25.

```
SELECT MAX(:M1, :M2, :M3)
FROM SYSIBM.SYSDUMMY1
```

Returns the value 6.25.

- Assume the host variable M1 is a CHARACTER(2) host variable with a value of 'AA', host variable M2 is a CHARACTER(3) host variable with a value of 'AA ', and host variable M3 is a CHARACTER(4) host variable with a value of 'AA A'.

```
SELECT MAX(:M1, :M2, :M3)
FROM SYSIBM.SYSDUMMY1
```

Returns the value 'AA A'.

MAX_CARDINALITY

The MAX_CARDINALITY function returns a value representing the maximum number of elements an array can contain. This is the cardinality specified on the CREATE TYPE (Array) statement for the user-defined array type.

►► MAX_CARDINALITY — (— *array-expression* —) ◄◄

array-expression

The expression can be either an SQL variable or parameter of an array data type, or a cast specification of a parameter marker to an array data type.

The result of the function is BIGINT. The result cannot be null.

Note

Syntax alternatives: ARRAY_MAX_CARDINALITY can be specified as a synonym for MAX_CARDINALITY.

Example

Assume that array type PHONENUMBERS and array variable RECENT_CALLS are defined as follows:

```
CREATE TYPE PHONENUMBERS AS INTEGER ARRAY[50];  
DECLARE RECENT_CALLS PHONENUMBERS;
```

The following statement sets LIST_SIZE to the maximum cardinality with which RECENT_CALLS was defined.

```
SET LIST_SIZE = MAX_CARDINALITY(RECENT_CALLS)
```

After the statement executes, LIST_SIZE contains 50.

MICROSECOND

The MICROSECOND function returns the microsecond part of a value.

►► MICROSECOND — (— *expression* —) ◄◄

expression

An *expression* that returns a value of one of the following built-in data types: a date, a time, a timestamp, a character string, a graphic string, or a numeric data type.

- If *expression* is a character or graphic string, its value must be a valid string representation of a datetime value. If *expression* is a valid string representation of a date, it must be in one of the IBM SQL standard formats. For the valid formats of string representations of dates and timestamps, see [“String representations of datetime values”](#) on page 75.
- If the argument is a DATE, it is first converted to a TIMESTAMP(0) value, assuming a time of exactly midnight (00.00.00).
- If *expression* is a number, it must be a timestamp duration. For the valid formats of datetime durations, see [“Datetime operands and durations”](#) on page 165.

The result of the function is a large integer. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

The other rules depend on the data type of the argument:

- If the argument is date, time, or timestamp or a valid character-string representation of a date, time, or timestamp:

The result is an integer that ranges from 0 to 999999.

If the precision of the timestamp exceeds 6, the value is truncated.

- If the argument is a duration:

The result is the microsecond part of the value, which is an integer between -999999 and 999999. A nonzero result has the same sign as the argument.

Example

- Assume a table TABLEA contains two columns, TS1 and TS2, of type TIMESTAMP. Select all rows in which the microseconds portion of TS1 is not zero and the seconds portion of TS1 and TS2 are identical.

```
SELECT *  
FROM TABLEA  
WHERE MICROSECOND(TS1) <> 0 AND SECOND(TS1) = SECOND(TS2)
```

MIDNIGHT_SECONDS

The MIDNIGHT_SECONDS function returns an integer value that is greater than or equal to 0 and less than or equal to 86 400 representing the number of seconds between midnight and the time value specified in the argument.

►► MIDNIGHT_SECONDS — (— *expression* —) ◄◄

expression

An expression that returns a value of one of the following built-in data types: a date, a time, a timestamp, a character string, or a graphic string. Its value must be a valid string representation of a time or timestamp. For the valid formats of string representations of times and timestamps, see [“String representations of datetime values”](#) on page 75.

If the argument is a DATE, it is first converted to a TIMESTAMP(0) value, assuming a time of exactly midnight (00.00.00).

The result of the function is large integer. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

Examples

- Find the number of seconds between midnight and 00:01:00, and midnight and 13:10:10. Assume that host variable XTIME1 has a value of '00:01:00', and that XTIME2 has a value of '13:10:10'.

```
SELECT MIDNIGHT_SECONDS(:XTIME1), MIDNIGHT_SECONDS(:XTIME2)
FROM SYSIBM.SYSDUMMY1
```

This example returns 60 and 47410. Because there are 60 seconds in a minute and 3600 seconds in an hour, 00:01:00 is 60 seconds after midnight ((60 * 1) + 0), and 13:10:10 is 47410 seconds ((3600 * 13) + (60 * 10) + 10).

- Find the number of seconds between midnight and 24:00:00, and midnight and 00:00:00.

```
SELECT MIDNIGHT_SECONDS('24:00:00'), MIDNIGHT_SECONDS('00:00:00')
FROM SYSIBM.SYSDUMMY1
```

This example returns 86400 and 0. Although these two values represent the same point in time, different values are returned.

MIN

The MIN scalar function returns the minimum value in a set of values.

►► MIN (— *expression* — , — *expression* —) ◄◄

The arguments must be compatible. Character-string arguments are compatible with datetime values. The arguments cannot be DataLink or XML values.

expression

An expression that returns a value of any built-in numeric or string data type. If one of the arguments is numeric, then character and graphic string arguments are cast to numeric before evaluating the function.

The result of the function is the minimum argument value. The result can be null if at least one argument can be null; the result is the null value if one of the arguments is null.

The selected argument is converted, if necessary, to the attributes of the result. The attributes of the result are determined by all the operands as explained in [“Rules for result data types” on page 105](#).

If a collating sequence other than *HEX is in effect when the statement is executed and the arguments are SBCS data, mixed data, or Unicode data, the weighted values of the strings are compared instead of the actual values. The weighted values are based on the collating sequence.

Note

Syntax alternatives: LEAST can be specified as a synonym for MIN.

Examples

- Assume the host variable M1 is a DECIMAL(2,1) host variable with a value of 5.5, host variable M2 is a DECIMAL(3,1) host variable with a value of 4.5, and host variable M3 is a DECIMAL(3,2) host variable with a value of 6.25.

```
SELECT MIN (:M1, :M2, :M3)
FROM SYSIBM.SYSDUMMY1
```

Returns the value 4.50.

- Assume the host variable M1 is a CHARACTER(2) host variable with a value of 'AA', host variable M2 is a CHARACTER(3) host variable with a value of 'AAA', and host variable M3 is a CHARACTER(4) host variable with a value of 'AAAA'.

```
SELECT MIN (:M1, :M2, :M3)
FROM SYSIBM.SYSDUMMY1
```

Returns the value 'AA'.

MINUTE

The MINUTE function returns the minute part of a value.

►► MINUTE — (— *expression* —) ►►

expression

An expression that returns a value of one of the following built-in data types: a date, a time, a timestamp, a character string, a graphic string, or a numeric data type.

- If *expression* is a character or graphic string, its value must be a valid string representation of a datetime value. If *expression* is a valid string representation of a date, it must be in one of the IBM SQL standard formats. For the valid formats of string representations of datetime values, see [“String representations of datetime values”](#) on page 75.
- If the argument is a DATE, it is first converted to a TIMESTAMP(0) value, assuming a time of exactly midnight (00.00.00).
- If *expression* is a number, it must be a time duration or timestamp duration. For the valid formats of datetime durations, see [“Datetime operands and durations”](#) on page 165.

The result of the function is a large integer. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

The other rules depend on the data type of the argument:

- If the argument is a date, time, or timestamp, or a valid character-string representation of a date, time, or timestamp:

The result is the minute part of the value, which is an integer between 0 and 59.

- If the argument is a time duration or timestamp duration:

The result is the minute part of the value, which is an integer between -99 and 99. A nonzero result has the same sign as the argument.

Example

- Using the CL_SCHED sample table, select all classes with a duration less than 50 minutes.

```
SELECT *  
FROM CL_SCHED  
WHERE HOUR(ENDING - STARTING) = 0 AND  
MINUTE(ENDING - STARTING) < 50
```

MOD

The MOD function divides the first argument by the second argument and returns the remainder.

►► MOD ((— *expression-1* — , — *expression-2* —))►►

The formula used to calculate the remainder is:

$$\text{MOD}(x,y) = x - (x/y) * y$$

where x/y is the truncated integer result of the division. The result is negative only if first argument is negative.

expression-1

An expression that returns a value of any built-in numeric, character-string, or graphic-string data type. A string argument is cast to double-precision floating point before evaluating the function. For more information about converting strings to double-precision floating point, see [“DOUBLE_PRECISION or DOUBLE” on page 392](#).

expression-2

An expression that returns a value of any built-in numeric, character-string, or graphic-string data type. A string argument is cast to double-precision floating point before evaluating the function. For more information about converting strings to double-precision floating point, see [“DOUBLE_PRECISION or DOUBLE” on page 392](#). *expression-2* cannot be zero unless either argument is decimal floating-point.

If an argument can be null, the result can be null; if an argument is null, the result is the null value.

The attributes of the result are determined as follows:

- If both arguments are large or small integers with zero scale, the data type of the result is large integer.
- If both arguments are integers with zero scale and at least one of the arguments is a big integer, the data type of the result is big integer.
- If one argument is an integer with zero scale and the other is decimal, the result is decimal with the same precision and scale as the decimal argument.
- If both arguments are decimal or integer with scale numbers, the result is decimal. The precision of the result is $\min(p-s, p'-s') + \max(s, s')$, and the scale of the result is $\max(s, s')$, where the symbols p and s denote the precision and scale of the first operand, and the symbols p' and s' denote the precision and scale of the second operand.
- If either argument is floating point and the other operand is not decimal floating-point, the data type of the result is double-precision floating point.

The operation is performed in floating point. If necessary, the operands are first converted to double precision floating-point numbers. For example, an operation that involves a floating-point number and either an integer or a decimal number is performed with a temporary copy of the integer or decimal number that has been converted to double precision floating-point. The result of a floating-point operation must be within the range of floating-point numbers.

- If either argument is decimal floating-point, the data type of the result is DECFLOAT(34). If the argument is a special decimal floating-point value, the general rules for arithmetic operations apply. See [“General arithmetic operation rules for DECFLOAT” on page 162](#) for more information.

If either argument is decimal floating-point and the second operand evaluates to 0, the result is NaN and the invalid operation warning (SQLSTATE 0168D) is issued.⁶⁵ MOD(1, -Infinity) returns the value 1.

⁶⁵ If *YES is specified for the SQL_DECFLOAT_WARNINGS query option, NaN is returned with a warning. Otherwise, a division by zero warning or error is returned.

Examples

- Assume the host variable M1 is an integer host variable with a value of 5, and host variable M2 is an integer host variable with a value of 2.

```
SELECT MOD(:M1, :M2)  
FROM SYSIBM.SYSDUMMY1
```

Returns the value 1.

- Assume the host variable M1 is an integer host variable with a value of 5, and host variable M2 is a DECIMAL(3,2) host variable with a value of 2.20.

```
SELECT MOD(:M1, :M2)  
FROM SYSIBM.SYSDUMMY1
```

Returns the value 0.60.

- Assume the host variable M1 is a DECIMAL(4,2) host variable with a value of 5.50, and host variable M2 is a DECIMAL(4,1) host variable with a value of 2.0.

```
SELECT MOD(:M1, :M2)  
FROM SYSIBM.SYSDUMMY1
```

Returns the value 1.50.

MONTH

The MONTH function returns the month part of a value.

►► MONTH — (— *expression* —) ◄◄

expression

An *expression* that returns a value of one of the following built-in data types: a date, a timestamp, a character string, a graphic string, or a numeric data type.

- If *expression* is a character or graphic string, its value must be a valid string representation of a date or timestamp. For the valid formats of string representations of dates and timestamps, see [“String representations of datetime values”](#) on page 75.
- If *expression* is a number, it must be a date duration or timestamp duration. For the valid formats of datetime durations, see [“Datetime operands and durations”](#) on page 165.

The result of the function is a large integer. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

The other rules depend on the data type of the argument:

- If the argument is a date, a timestamp, or a valid character-string representation of a date or timestamp:
The result is the month part of the value, which is an integer between 1 and 12.
- If the argument is a date duration or timestamp duration:
The result is the month part of the value, which is an integer between -99 and 99. A nonzero result has the same sign as the argument.

Example

- Select all rows from the EMPLOYEE table for people who were born (BIRTHDATE) in DECEMBER.

```
SELECT *  
FROM EMPLOYEE  
WHERE MONTH(BIRTHDATE) = 12
```

MONTHNAME

Returns a mixed case character string containing the name of the month (for example, January) for the month portion of the argument.

►► MONTHNAME — (— *expression* —) ►◄

expression

An expression that returns a value of one of the following built-in data types: a date, a timestamp, a character string, or a graphic string.

If *expression* is a character or graphic string, its value must be a valid string representation of a date or timestamp. For the valid formats of string representations of dates and timestamps, see [“String representations of datetime values”](#) on page 75.

The result of the function is VARCHAR(100). If the argument can be null, the result can be null; if the argument is null, the result is the null value.

The CCSID of the result is the default CCSID of the current server.

Note

National language considerations: The name of the month that is returned is based on the language used for messages in the job. This name of the month is retrieved from message CPX3BC0 in message file QCPFMSG in library *LIBL.

Examples

- Assume that the language used is US English.

```
SELECT MONTHNAME( '2003-01-02' )
FROM SYSIBM.SYSDUMMY1
```

Results in 'January'.

MONTHS_BETWEEN

The MONTHS_BETWEEN function returns an estimate of the number of months between *expression1* and *expression2*.

►► MONTHS_BETWEEN (— *expression1* — , — *expression2* —) ◄◄

expression1

An expression that returns a value of one of the following built-in data types: a date, a timestamp, a character-string, or a graphic-string.

If *expression1* is a character or graphic string, its value must be a valid string representation of a date or timestamp. For the valid formats of string representations of dates and timestamps, see [“String representations of datetime values”](#) on page 75

expression2

An expression that returns a value of one of the following built-in data types: a date, a timestamp, a character-string, or a graphic-string.

If *expression2* is a character or graphic string, its value must be a valid string representation of a date or timestamp. For the valid formats of string representations of dates and timestamps, see [“String representations of datetime values”](#) on page 75

If *expression1* represents a date that is later than *expression2*, then the result is positive. If *expression2* represents a date that is equal to or later than *expression1*, then the result is negative.

- If *expression1* and *expression2* represent dates or timestamps with the same day of the month or the last day of the month, or both arguments represent the last day of their respective months, the result is a the whole number difference based on the year and month values ignoring any time portions of timestamp arguments.
- Otherwise, the whole number part of the result is the difference based on the year and month values. The fractional part of the result is calculated from the remainder based on an assumption that every month has 31 days. If either argument represents a timestamp, the arguments are effectively processed as timestamps with precision 12, and the time portions of these values are also considered when determining the result.

The result of the function is a DECIMAL(31,15). If either argument can be null, the result can be null; if either argument is null, the result is the null value.

Examples

- Calculate the months between two dates:

```
SELECT MONTHS_BETWEEN('2005-01-17', '2005-02-17')
FROM SYSIBM.SYSDUMMY1
```

Returns the value -1.0000000000000000

```
SELECT MONTHS_BETWEEN('2005-02-20', '2005-01-17')
FROM SYSIBM.SYSDUMMY1
```

Returns the value 1.096774193548387

- The following table contains additional examples:

Table 56. Additional examples using MONTHS_BETWEEN

Value for argument e1	Value for argument e2	Value returned by MONTHS_BETWEEN (e1,e2)	Value returned by ROUND(MONTHS_BETWEEN(e1,e2)*31,2)	Comment
2005-02-02	2005-01-01	1.032258064516129	32.00	
2007-11-01-09.00.00 .00000	2007-12-07-14.30.12 .12345	-1.20094538659274 1	-37.23	
2007-12-13-09.40.30 .00000	2007-11-13-08.40.30 .00000	1.0000000000000000	31.00	See Note 1
2007-03-15	2007-02-20	0.838709677419354	26.00	See Note 2
2008-02-29	2008-02-28-12.00.00	0.016129032258064	0.50	
2008-03-29	2008-02-29	1.0000000000000000	31.00	
2008-03-30	2008-02-29	1.032258064516129	32.00	
2008-03-31	2008-02-29	1.0000000000000000	31.00	See Note 3

Note:

1. The time difference is ignored because the day of the month is the same for both values.
2. The result is not 23 because, even though February has 28 days, the assumption is that all months have 31 days.
3. The result is not 33 because both dates are the last day of their respective month, and so the result is only based on the year and month portions.

MQREAD

The MQREAD function returns a message from a specified MQSeries location (return value of VARCHAR) without removing the message from the queue.

The MQREAD function returns a message from the MQSeries location that is specified by *receive-service*, using the quality-of-service policy that is defined in *service-policy*. Performing this operation does not remove the message from the queue that is associated with *receive-service*, but instead returns the message at the beginning of the queue.

receive-service

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be an empty string or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression must refer to a service point that is defined in the SYSIBM.MQSERVICE table. A service point is a logical end-point from where a message is sent or received. Service point definitions include the name of the MQSeries queue manager and queue. For more information about MQSeries Application Messaging, see [SQL Programming](#).

If *receive-service* is not specified or the null value, DB2.DEFAULT.SERVICE is used.

service-policy

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be an empty string or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression must refer to a service policy that is defined in the SYSIBM.MQPOLICY table. A service policy specifies a set of quality-of-service options that are to be applied to this messaging operation. These options include message priority and message persistence. For more information about MQSeries Application Messaging, see [SQL Programming](#).

If *service-policy* is not specified or the null value, DB2.DEFAULT.POLICY is used.

correl-id

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The expression must have an actual length that is no greater than 24 bytes. The value of the expression specifies the correlation identifier that is associated with this message. A correlation identifier is often specified in request-and-reply scenarios to associate requests with replies. The first message with a matching correlation identifier is returned. For more information about MQSeries Application Messaging, see [SQL Programming](#).

A fixed length string with trailing blanks is considered a valid value. However, when the *correl-id* is specified on another request such as MQSEND, the identical *correl-id* must be specified to be recognized as a match. For example, specifying a value of 'test' for *correl-id* on MQRECEIVE does not match a *correl-id* value of 'test ' (with trailing blanks) specified earlier on an MQSEND request.

If *correl-id* is not specified or is an empty string or the null value, a correlation identifier is not used, and the message at the beginning of the queue is returned.

The result of the function is a varying-length string with a length attribute of 32000. The result can be null. If no messages are available to be returned, the result is the null value.

The CCSID of the result is the default CCSID at the current server.

Notes

Prerequisites: In order to use the MQSeries functions, IBM MQSeries for IBM i must be installed, configured, and operational.

Example

- This example reads the message at the head of the queue specified by the default service (DB2.DEFAULT.SERVICE), using the default policy (DB2.DEFAULT.POLICY).

```
SELECT MQREAD ()  
FROM SYSIBM.SYSDUMMY1
```

- This example reads the message at the head of the queue specified by the service "MYSERVICE" using the default policy (DB2.DEFAULT.POLICY).

```
SELECT MQREAD ('MYSERVICE')  
FROM SYSIBM.SYSDUMMY1
```

- This example reads the message at the head of the queue specified by the service "MYSERVICE", and using the policy "MYPOLICY".

```
SELECT MQREAD ('MYSERVICE', 'MYPOLICY')  
FROM SYSIBM.SYSDUMMY1
```

- This example reads the first message with a correlation id that matches '1234' from the head of the queue specified by the service "MYSERVICE" using the policy "MYPOLICY".

```
SELECT MQREAD ('MYSERVICE', 'MYPOLICY', '1234')  
FROM SYSIBM.SYSDUMMY1
```

MQREADCLOB

The MQREADCLOB function returns a message from a specified MQSeries location (return value of CLOB) without removing the message from the queue.

►► MQREADCLOB — (→

The MQREADCLOB function returns a message from the MQSeries location that is specified by *receive-service*, using the quality-of-service policy that is defined in *service-policy*. Performing this operation does not remove the message from the queue that is associated with *receive-service*, but instead returns the message at the beginning of the queue.

receive-service

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be an empty string or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression must refer to a service point that is defined in the SYSIBM.MQSERVICE table. A service point is a logical end-point from where a message is sent or received. Service point definitions include the name of the MQSeries queue manager and queue. For more information about MQSeries Application Messaging, see [SQL Programming](#).

If *receive-service* is not specified or the null value, DB2.DEFAULT.SERVICE is used.

service-policy

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be an empty string or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression must refer to a service policy that is defined in the SYSIBM.MQPOLICY table. A service policy specifies a set of quality-of-service options that are to be applied to this messaging operation. These options include message priority and message persistence. For more information about MQSeries Application Messaging, see [SQL Programming](#).

If *service-policy* is not specified or the null value, DB2.DEFAULT.POLICY is used.

correl-id

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The expression must have an actual length that is no greater than 24 bytes. The value of the expression specifies the correlation identifier that is associated with this message. A correlation identifier is often specified in request-and-reply scenarios to associate requests with replies. The first message with a matching correlation identifier is returned. For more information about MQSeries Application Messaging, see [SQL Programming](#).

A fixed length string with trailing blanks is considered a valid value. However, when the *correl-id* is specified on another request such as MQSEND, the identical *correl-id* must be specified to be recognized as a match. For example, specifying a value of 'test' for *correl-id* on MQRECEIVE does not match a *correl-id* value of 'test ' (with trailing blanks) specified earlier on an MQSEND request.

If *correl-id* is not specified or is an empty string or the null value, a correlation identifier is not used, and the message at the beginning of the queue is returned.

The result of the function is a CLOB with a length attribute of 2 MB. The result can be null. If no messages are available to be returned, the result is the null value.

The CCSID of the result is the default CCSID at the current server.

Notes

Prerequisites: In order to use the MQSeries functions, IBM MQSeries for IBM i must be installed, configured, and operational.

Example

- This example reads the message at the head of the queue specified by the default service (DB2.DEFAULT.SERVICE), using the default policy (DB2.DEFAULT.POLICY).

```
SELECT MQREADCLOB ()  
FROM SYSIBM.SYSDUMMY1
```

- This example reads the message at the head of the queue specified by the service "MYSERVICE" using the default policy (DB2.DEFAULT.POLICY).

```
SELECT MQREADCLOB ('MYSERVICE')  
FROM SYSIBM.SYSDUMMY1
```

- This example reads the message at the head of the queue specified by the service "MYSERVICE", and using the policy "MYPOLICY".

```
SELECT MQREADCLOB ('MYSERVICE', 'MYPOLICY')  
FROM SYSIBM.SYSDUMMY1
```

- This example reads the first message with a correlation id that matches '1234' from the head of the queue specified by the service "MYSERVICE" using the policy "MYPOLICY".

```
SELECT MQREADCLOB ('MYSERVICE', 'MYPOLICY', '1234')  
FROM SYSIBM.SYSDUMMY1
```

MQRECEIVE

The MQRECEIVE function returns a message from a specified MQSeries location (return value of VARCHAR) with removal of the message from the queue.

The MQRECEIVE function returns a message from the MQSeries location that is specified by *receive-service*, using the quality-of-service policy that is defined in *service-policy*. Performing this operation removes the message from the beginning of the queue that is associated with *receive-service*.

receive-service

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be an empty string or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression must refer to a service point that is defined in the SYSIBM.MQSERVICE table. A service point is a logical end-point from where a message is sent or received. Service point definitions include the name of the MQSeries queue manager and queue. For more information about MQSeries Application Messaging, see [SQL Programming](#).

If *receive-service* is not specified or the null value, DB2.DEFAULT.SERVICE is used.

service-policy

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be an empty string or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression must refer to a service policy that is defined in the SYSIBM.MQPOLICY table. A service policy specifies a set of quality-of-service options that are to be applied to this messaging operation. These options include message priority and message persistence. For more information about MQSeries Application Messaging, see [SQL Programming](#).

If *service-policy* is not specified or the null value, DB2.DEFAULT.POLICY is used.

correl-id

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The expression must have an actual length that is no greater than 24 bytes. The value of the expression specifies the correlation identifier that is associated with this message. A correlation identifier is often specified in request-and-reply scenarios to associate requests with replies. The first message with a matching correlation identifier is returned. For more information about MQSeries Application Messaging, see [SQL Programming](#).

A fixed length string with trailing blanks is considered a valid value. However, when the *correl-id* is specified on another request such as MQSEND, the identical *correl-id* must be specified to be recognized as a match. For example, specifying a value of 'test' for *correl-id* on MQRECEIVE does not match a *correl-id* value of 'test ' (with trailing blanks) specified earlier on an MQSEND request.

If *correl-id* is not specified or is an empty string or the null value, a correlation identifier is not used, and the message at the beginning of the queue is returned.

The result of the function is a varying-length string with a length attribute of 32000. The result can be null. If no messages are available to be returned, the result is the null value.

The CCSID of the result is the default CCSID at the current server.

Notes

Prerequisites: In order to use the MQSeries functions, IBM MQSeries for IBM i must be installed, configured, and operational.

Example

- This example receives the message at the head of the queue specified by the default service (DB2.DEFAULT.SERVICE), using the default policy (DB2.DEFAULT.POLICY).

```
SELECT MQRECEIVE ()  
FROM SYSIBM.SYSDUMMY1
```

- This example receives the message at the head of the queue specified by the service "MYSERVICE" using the default policy (DB2.DEFAULT.POLICY).

```
SELECT MQRECEIVE ('MYSERVICE')  
FROM SYSIBM.SYSDUMMY1
```

- This example receives the message at the head of the queue specified by the service "MYSERVICE" using the policy "MYPOLICY".

```
SELECT MQRECEIVE ('MYSERVICE', 'MYPOLICY')  
FROM SYSIBM.SYSDUMMY1
```

- This example receives the first message with a correlation id that matches '1234' from the head of the queue specified by the service "MYSERVICE" using the policy "MYPOLICY".

```
SELECT MQRECEIVE ('MYSERVICE', 'MYPOLICY', '1234')  
FROM SYSIBM.SYSDUMMY1
```

MQRECEIVECLOB

The MQRECEIVECLOB function returns a message from a specified MQSeries location (return value of CLOB) with removal of the message from the queue.

►► MQRECEIVECLOB — (→

The MQRECEIVE function returns a message from the MQSeries location that is specified by *receive-service*, using the quality-of-service policy that is defined in *service-policy*. Performing this operation removes the message from the beginning of the queue that is associated with *receive-service*.

receive-service

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be an empty string or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression must refer to a service point that is defined in the SYSIBM.MQSERVICE table. A service point is a logical end-point from where a message is sent or received. Service point definitions include the name of the MQSeries queue manager and queue. For more information about MQSeries Application Messaging, see [SQL Programming](#).

If *receive-service* is not specified or the null value, DB2.DEFAULT.SERVICE is used.

service-policy

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be an empty string or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression must refer to a service policy that is defined in the SYSIBM.MQPOLICY table. A service policy specifies a set of quality-of-service options that are to be applied to this messaging operation. These options include message priority and message persistence. For more information about MQSeries Application Messaging, see [SQL Programming](#).

If *service-policy* is not specified or the null value, DB2.DEFAULT.POLICY is used.

correl-id

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The expression must have an actual length that is no greater than 24 bytes. The value of the expression specifies the correlation identifier that is associated with this message. A correlation identifier is often specified in request-and-reply scenarios to associate requests with replies. The first message with a matching correlation identifier is returned. For more information about MQSeries Application Messaging, see [SQL Programming](#).

A fixed length string with trailing blanks is considered a valid value. However, when the *correl-id* is specified on another request such as MQSEND, the identical *correl-id* must be specified to be recognized as a match. For example, specifying a value of 'test' for *correl-id* on MQRECEIVE does not match a *correl-id* value of 'test ' (with trailing blanks) specified earlier on an MQSEND request.

If *correl-id* is not specified or is an empty string or the null value, a correlation identifier is not used, and the message at the beginning of the queue is returned.

The result of the function is a CLOB with a length attribute of 2 MB. The result can be null. If no messages are available to be returned, the result is the null value.

The CCSID of the result is the default CCSID at the current server.

Notes

Prerequisites: In order to use the MQSeries functions, IBM MQSeries for IBM i must be installed, configured, and operational.

Example

- This example receives the message at the head of the queue specified by the default service (DB2.DEFAULT.SERVICE), using the default policy (DB2.DEFAULT.POLICY).

```
SELECT MQRECEIVECLOB ()  
FROM SYSIBM.SYSDUMMY1
```

- This example receives the message at the head of the queue specified by the service "MYSERVICE" using the default policy (DB2.DEFAULT.POLICY).

```
SELECT MQRECEIVECLOB ('MYSERVICE')  
FROM SYSIBM.SYSDUMMY1
```

- This example receives the message at the head of the queue specified by the service "MYSERVICE" using the policy "MYPOLICY".

```
SELECT MQRECEIVECLOB ('MYSERVICE', 'MYPOLICY')  
FROM SYSIBM.SYSDUMMY1
```

- This example receives the first message with a correlation id that matches '1234' from the head of the queue specified by the service "MYSERVICE" using the policy "MYPOLICY".

```
SELECT MQRECEIVECLOB ('MYSERVICE', 'MYPOLICY', '1234')  
FROM SYSIBM.SYSDUMMY1
```

MQSEND

The MQSEND function sends a message to a specified MQSeries location.

Notes:

¹ The *correl-id* cannot be specified unless a *send-service* and a *service-policy* are also specified.

The MQSEND function sends the message data that is contained in *msg-data* to the MQSeries location that is specified by *send-service*, using the quality-of-service policy that is defined in *service-policy*. The message is sent using the MQSeries built-in format MQFMT_STRING.

send-service

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be an empty string or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression must refer to a service point that is defined in the SYSIBM.MQSERVICE table. A service point is a logical end-point from where a message is sent or received. Service point definitions include the name of the MQSeries queue manager and queue. For more information about MQSeries Application Messaging, see [SQL Programming](#).

If *send-service* is not specified or the null value, DB2.DEFAULT.SERVICE is used.

service-policy

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be an empty string or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression must refer to a service policy that is defined in the SYSIBM.MQPOLICY table. A service policy specifies a set of quality-of-service options that are to be applied to this messaging operation. These options include message priority and message persistence. For more information about MQSeries Application Messaging, see [SQL Programming](#).

If *service-policy* is not specified or the null value, DB2.DEFAULT.POLICY is used.

msg-data

An expression that returns a value that is a built-in character string data type. If the expression is a CLOB, the value must not be longer than 2 MB. Otherwise, the value must not be longer than 32000 bytes. The value of the expression is the message data that is to be sent via MQSeries. A null value, an empty string, and a fixed length string with trailing blanks are all considered valid values.

correl-id

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The expression must have an actual length that is no greater than 24 bytes. The value of the expression specifies the correlation identifier that is associated with this message. A correlation identifier is often specified in request-and-reply scenarios to associate requests with replies. For more information about MQSeries Application Messaging, see [SQL Programming](#).

A fixed length string with trailing blanks is considered a valid value. However, when the *correl-id* is specified on another request such as MQRECEIVE, the identical *correl-id* must be specified to be recognized as a match. For example, specifying a value of 'test' for *correl-id* on MQSEND does not match a *correl-id* value of 'test ' (with trailing blanks) specified subsequently on an MQRECEIVE request.

If *correl-id* is not specified or is an empty string or the null value, a correlation identifier is not sent.

The result of the function is a varying-length string with a length attribute of 1. The result is nullable, even though a null value is never returned. The result is '1' if the function was successful or '0' if unsuccessful.

The CCSID of the result is the default SBCS CCSID at the current server.

Notes

Prerequisites: In order to use the MQSeries functions, IBM MQSeries for IBM i must be installed, configured, and operational.

Example

- This example sends the string "Testing 123" to the default service (DB2.DEFAULT.SERVICE), using the default policy (DB2.DEFAULT.POLICY), with no correlation identifier.

```
SELECT MQSEND ('Testing 123')
FROM SYSIBM.SYSDUMMY1
```

- This example sends the string "Testing 345" to the service "MYSERVICE", using the policy "MYPOLICY", with no correlation identifier.

```
SELECT MQSEND ('MYSERVICE', 'MYPOLICY', 'Testing 345')
FROM SYSIBM.SYSDUMMY1
```

- This example sends the string "Testing 678" to the service "MYSERVICE", using the policy "MYPOLICY", with correlation identifier "TEST3".

```
SELECT MQSEND ('MYSERVICE', 'MYPOLICY', 'Testing 678', 'TEST3')
FROM SYSIBM.SYSDUMMY1
```

- This example sends the string "Testing 901" to the service "MYSERVICE", using the default policy (DB2.DEFAULT.POLICY), and no correlation identifier.

```
SELECT MQSEND ('MYSERVICE', 'Testing 901')
FROM SYSIBM.SYSDUMMY1
```

MULTIPLY_ALT

The MULTIPLY_ALT scalar function returns the product of the two arguments as a decimal value. It is provided as an alternative to the multiplication operator, especially when the sum of the precisions of the arguments exceeds 63.

►► MULTIPLY_ALT (— *expression-1* — , — *expression-2* —) ◄◄

expression-1

An expression that returns a value of any built-in numeric data type (other than floating-point or decimal floating-point), character-string, or graphic-string data type. A string argument is cast to double-precision floating point before evaluating the function. For more information about converting strings to double-precision floating point, see [“DOUBLE_PRECISION or DOUBLE” on page 392](#).

expression-2

An expression that returns a value of any built-in numeric data type (other than floating-point or decimal floating-point), character-string, or graphic-string data type. A string argument is cast to double-precision floating point before evaluating the function. For more information about converting strings to double-precision floating point, see [“DOUBLE_PRECISION or DOUBLE” on page 392](#).
expression-2 cannot be zero.

The result of the function is a DECIMAL. The precision and scale of the result are determined as follows, using the symbols p and s to denote the precision and scale of the first argument, and the symbols p' and s' to denote the precision and scale of the second argument.

- The precision is $\text{MIN}(mp, p+p')$
- The scale is:
 - 0 if the scale of both arguments is 0
 - $\text{MIN}(ms, s+s')$ if $p+p'$ is less than or equal to mp
 - $\text{MIN}(ms, \text{MAX}(\text{MIN}(3, s+s'), mp-(p-s+p'-s')))$ if $p+p'$ is greater than mp .

For information about the values of p , s , ms , and mp , see [“Decimal arithmetic in SQL” on page 160](#).

If either argument can be null, the result can be null; if either argument is null, the result is the null value.

The MULTIPLY_ALT function is a better choice than the multiplication operator when performing decimal arithmetic where a scale of at least 3 is wanted and the sum of the precisions exceeds 63. In these cases, the internal computation is performed so that overflows are avoided and then assigned to the result type value using truncation for any loss of scale in the final result. Note that the possibility of overflow of the final result is still possible when the scale is 3.

The following table compares the result types using MULTIPLY_ALT and the multiplication operator when the maximum precision is 31 and the maximum scale is 31:

Type of Argument 1	Type of Argument 2	Result using MULTIPLY_ALT	Result using multiplication operator
DECIMAL(31,3)	DECIMAL(15,8)	DECIMAL(31,3)	DECIMAL(31,11)
DECIMAL(26,23)	DECIMAL(10,1)	DECIMAL(31,19)	DECIMAL(31,24)
DECIMAL(18,17)	DECIMAL(20,19)	DECIMAL(31,29)	DECIMAL(31,31)
DECIMAL(16,3)	DECIMAL(17,8)	DECIMAL(31,9)	DECIMAL(31,11)
DECIMAL(26,5)	DECIMAL(11,0)	DECIMAL(31,3)	DECIMAL(31,5)
DECIMAL(21,1)	DECIMAL(15,1)	DECIMAL(31,2)	DECIMAL(31,2)

Examples

- Multiply two values where the data type of the first argument is DECIMAL(26,3) and the data type of the second argument is DECIMAL(9,8). The data type of the result is DECIMAL(31,7).

```
SELECT MULTIPLY_ALT(98765432109876543210987.654, 5.43210987)
FROM SYSIBM.SYSDUMMY1
```

Returns the value 536504678578875294857887.5277415.

Note that the complete product of these two numbers is 536504678578875294857887.52774154498, but the last 4 digits are truncated to match the scale of the result data type. Using the multiplication operator with the same values will cause an arithmetic overflow, since the result data type is DECIMAL(31,11) and the result value has 24 digits left of the decimal, but the result data type only supports 20 digits.

NEXT_DAY

The NEXT_DAY function returns a date or timestamp value that represents the first weekday, named by *string-expression*, that is later than the date *expression*.

►► NEXT_DAY (— *expression* — , — *string-expression* —) ►►

expression

An expression that returns a value of one of the following built-in data types: a date, a timestamp, a character string, or a graphic string.

If *expression* is a character or graphic string, its value must be a valid string representation of a date or timestamp. For the valid formats of string representations of dates and timestamps, see [“String representations of datetime values”](#) on page 75.

string-expression

An expression that returns a built-in character string data type or graphic string data type. The value must compare equal to the full name of a day of the week or compare equal to the abbreviation of a day of the week. For example, in the English language:

Day of Week	Abbreviation
MONDAY	MON
TUESDAY	TUE
WEDNESDAY	WED
THURSDAY	THU
FRIDAY	FRI
SATURDAY	SAT
SUNDAY	SUN

The minimum length of the input value is the length of the abbreviation. Leading and trailing blanks are trimmed from *string-expression*. The resulting value is then folded to uppercase, so the characters in the value may be in any case.

The result of the function has the same data type as *expression*, unless *expression* is a string in which case the result data type is `TIMESTAMP(6)`. If either argument can be null, the result can be null; if either argument is null, the result is the null value.

Any hours, minutes, seconds, or fractional seconds information included in *expression* is not changed by the function. If *expression* is a string representing a date, the time information in the resulting `TIMESTAMP` value is all set to zero.

Note

National language considerations: The values of the days of the week (or abbreviations) in *string-expression* may either be the US English values listed in the table above or the values based on the language used for messages in the job. The non-abbreviated name of the day is retrieved from message CPX9034 in message file QCPFMMSG in library *LIBL. The abbreviated name of the day is retrieved from message CPX9039 in message file QCPFMMSG in library *LIBL.

Applications that need to run in many different language environments may want to consider using US English values since they will always be accepted in the NEXT_DAY function.

Example

- Assuming that the default language for the job is US English, set the host variable NEXTDAY with the date of the Tuesday following April 24, 2000.

```
SET :NEXTDAY = NEXT_DAY(CURRENT_DATE, 'TUESDAY')
```

The host variable NEXTDAY is set with the value of '2000-04-25-00.00.00.000000', assuming that the value of the CURRENT_DATE special register is '2000-04-24'.

- Assuming that the default language for the job is US English, set the host variable NEXTDAY with the date of the first Monday in May, 2000. Assume the host variable DAYHV = 'MON'.

```
SET :NEXTDAY = NEXT_DAY(LAST_DAY(CURRENT_TIMESTAMP), :DAYHV)
```

The host variable NEXTDAY is set with the value of '2000-05-01-12.01.01.123456', assuming that the value of the CURRENT_TIMESTAMP special register is '2000-04-24-12.01.01.123456'.

- Assuming that the default language for the job is US English,

```
SELECT NEXT_DAY('2000-04-24', 'TUESDAY')  
FROM SYSIBM.SYSDUMMY1
```

Returns '2000-04-25-00.00.00.000000', which is the Tuesday following '2000-04-24'.

NORMALIZE_DECFLOAT

The NORMALIZE_DECFLOAT function returns a DECFLOAT value equal to the input argument set to its simplest form.

►► NORMALIZE_DECFLOAT (— *expression* —) ►►

The NORMALIZE_DECFLOAT function returns a decimal floating-point value equal to the input argument set to its simplest form; that is, a non-zero number with trailing zeros in the coefficient has those zeros removed. This may require representing the number in normalized form by dividing the coefficient by the appropriate power of ten and adjusting the exponent accordingly. A zero value has its exponent set to 0.

expression

An expression that returns a value of any built-in numeric, character-string, or graphic-string data type. If the data type of the argument is SMALLINT, INTEGER, REAL, DOUBLE, DECIMAL(p,s) where $p \leq 16$, or NUMERIC(p,s) where $p \leq 16$, then the argument is converted to DECFLOAT(16) for processing. Otherwise, the argument is converted to DECFLOAT(34) for processing.

If the argument is a special value then the general rules for arithmetic operations apply. See [“General arithmetic operation rules for DECFLOAT”](#) on page 162 for more information.

The result of the function is a DECFLOAT(16) value if the data type of *expression* after conversion to decimal floating-point is DECFLOAT(16). Otherwise, the result of the function is a DECFLOAT(34) value. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

Examples

The following examples show the result of using the NORMALIZE_DECFLOAT function on various DECFLOAT values:

```
NORMALIZE_DECFLOAT(DECFLOAT(2.1))           = 2.1
NORMALIZE_DECFLOAT(DECFLOAT(-2.0))          = -2
NORMALIZE_DECFLOAT(DECFLOAT(1.200))         = 1.2
NORMALIZE_DECFLOAT(DECFLOAT(-120))          = -1.2E+2
NORMALIZE_DECFLOAT(DECFLOAT(120.00))        = 1.2E+2
NORMALIZE_DECFLOAT(DECFLOAT(0.00))          = 0
NORMALIZE_DECFLOAT(-NAN)                    = -NAN
NORMALIZE_DECFLOAT(-INFINITY)               = -INFINITY
```

NOW

The NOW function returns a timestamp based on a reading of the time-of-day clock when the SQL statement is executed at the current server.

integer

Specifies the precision of the timestamp. Valid values are 0 to 12, inclusive. If a value is not specified, the default precision of 6 is used.

The value returned by the NOW function is the same as the value returned by the CURRENT_TIMESTAMP special register. If this function is used more than once within a single SQL statement, or used with the CURDATE or CURTIME scalar functions or the CURRENT_DATE, CURRENT_TIME, or CURRENT_TIMESTAMP special registers within a single statement, all values are based on a single clock reading.

The data type of the result is a timestamp with a precision specified by *integer*. The result cannot be null.

Note

Syntax alternatives: The CURRENT_TIMESTAMP special register should be used for maximal portability. For more information, see [“Special registers” on page 119](#).

Example

- Return the current timestamp based on the time-of-day clock.

```
SELECT NOW()  
FROM SYSIBM.SYSDUMMY1
```

NULLIF

The NULLIF function returns a null value if the arguments compare equal, otherwise it returns the value of the first argument.

►► NULLIF (— *expression-1* — , — *expression-2* —) ◄◄

The arguments must be compatible data types.

expression-1

An expression that returns a value of any built-in data type other than a DATALINK or XML or any distinct data type other than a distinct type that is based on a DATALINK or XML.

expression-2

An expression that returns a value of any built-in data type other than a DATALINK or XML or any distinct data type other than a distinct type that is based on a DATALINK or XML .

The attributes of the result are the attributes of the first argument. The result can be null. The result is null if the first argument is null or if both arguments are equal.

The result of using NULLIF(e1,e2) is the same as using the expression

```
CASE WHEN e1=e2 THEN NULL ELSE e1 END
```

Note that when e1=e2 evaluates to unknown (because one or both arguments is NULL), CASE expressions consider this not true. Therefore, in this situation, NULLIF returns the value of the first operand, e1.

Example

- Assume host variables PROFIT, CASH, and LOSSES have DECIMAL data types with the values 4500.00, 500.00, and 5000.00 respectively:

```
SELECT NULLIF (:PROFIT + :CASH, :LOSSES )  
FROM SYSIBM.SYSDUMMY1
```

Returns the null value.

NVL

The NVL function returns the value of the first non-null expression.

► NVL (*expression-1* , *expression-2*) ◄

The NVL function is identical to the COALESCE function. For more information, see [“COALESCE” on page 338](#).

OCTET_LENGTH

The OCTET_LENGTH function returns the length of a string expression in octets (bytes).

►► OCTET_LENGTH — (— *expression* —) ►►

See “LENGTH” on page 474 and “CHARACTER_LENGTH or CHAR_LENGTH” on page 331 for similar functions.

expression

An expression that returns a value of any built-in numeric or string data type. A numeric argument is cast to a character string before evaluating the function. For more information about converting numeric to a character string, see “VARCHAR” on page 623.

The result of the function is DECIMAL(31). If the argument can be null, the result can be null; if the argument is null, the result is the null value.

The result is the number of octets (bytes) in the argument. The length of a string includes trailing blanks. The length of a varying-length string is the actual length in octets (bytes), not the maximum length.

Example

- Assume table T1 has a GRAPHIC(10) column called C1.

```
SELECT OCTET_LENGTH( C1 )  
FROM T1
```

Returns the value 20.

OVERLAY

Returns a string where *length* characters have been deleted from *source-string* beginning at *start* and where *insert-string* has been inserted into *source-string* beginning at *start*.

►► OVERLAY ►►

source-string

An expression that specifies the source string. The *source-string* may be any built-in numeric, string, or datetime expression. It must be compatible with the *insert-string*. For more information about data type compatibility, see “Assignments and comparisons” on page 89. A numeric or datetime argument is cast to VARCHAR with a CCSID that is the default SBCS CCSID at the current server before evaluating the function. For more information about converting numeric or datetime to a varying character string, see “VARCHAR” on page 623. The actual length of the string must be greater than zero.

The OVERLAY function is identical to the INSERT function except that the arguments are in a different order and *length* is optional.

insert-string

An expression that specifies the string to be inserted into *source-string*, starting at the position identified by *start*. The *insert-string* may be any built-in numeric, string, or datetime expression. It must be compatible with the *source-string*. For more information about data type compatibility, see “Assignments and comparisons” on page 89. A numeric or datetime argument is cast to VARCHAR with a CCSID that is the default SBCS CCSID at the current server before evaluating the function. For more information about converting numeric or datetime to a varying character string, see “VARCHAR” on page 623.

start

An expression that returns a value of any built-in numeric, character-string, or graphic-string data type. If value is not of type INTEGER, it is implicitly cast to INTEGER before evaluating the function. The integer specifies the starting character within *source-string* where the deletion of characters and the insertion of another string is to begin. The value of the integer must be in the range of 1 to the length of *source-string* plus one.

length

An expression that returns a value of any built-in numeric, character-string, or graphic-string data type. If value is not of type INTEGER, it is implicitly cast to INTEGER before evaluating the function. The integer specifies the number of characters that are to be deleted from *source-string*, starting at the character position identified by *start*. The value of the integer must be in the range of 0 to the length of *source-string*.

The data type of the result of the function depends on the data type of the first and second arguments. The result data type is the same as if the two arguments were concatenated except that the result is always a varying-length string. For more information see “Conversion rules for operations that combine strings” on page 110.

The length attribute of the result depends on the arguments:

- If *start* and *length* are constants, the length attribute of the result is:

$$L1 - \text{MIN}((L1 - V2 + 1), V3) + L4$$

where:

L1 is the length attribute of source-string
V2 depends on the encoding schema of source-string:
- If the source-string is UTF-8, the value MIN(L1+1,start*3)
- If the source-string is mixed data, the value MIN(L1+1,(start-1)*2.5+4)
- Otherwise, the value of start
V3 is the value of length
L4 is the length attribute of insert-string

- Otherwise, the length attribute of the result is the length attribute of *source-string* plus the length attribute of *insert-string*.

If the length attribute of the result exceeds the maximum for the result data type, an error is returned.

The actual length of the result is:

$$A1 - \text{MIN}((A1 - V2 + 1), V3) + A4$$

where:

A1 is the actual length of source-string
V2 is the value of start
V3 is the value of length
A4 is the actual length of insert-string

If the actual length of the result string exceeds the maximum for the result data type, an error is returned.

If any argument can be null, the result can be null; if any argument is null, the result is the null value.

The CCSID of the result is determined by the CCSID of *source-string* and *insert-string*. The resulting CCSID is the same as if the two arguments were concatenated. For more information, see [“Conversion rules for operations that combine strings”](#) on page 110.

Examples

- The following example shows how the string 'INSERTING' can be changed into other strings. The use of the CHAR function limits the length of the resulting string to 10 characters.

```
SELECT OVERLAY('INSERTING', 'IS', 4, 2),
       OVERLAY('INSERTING', 'IS', 4, 0),
       OVERLAY('INSERTING', '', 4, 2)
FROM SYSIBM.SYSDUMMY1
```

This example returns 'INSISTING', 'INSISERTING', and 'INSTING'.

- The previous example demonstrated how to insert text into the middle of some text. This example shows how to insert text before some text by using 1 as the starting point (*start*).

```
SELECT OVERLAY('INSERTING', 'XX', 1, 0),
       OVERLAY('INSERTING', 'XX', 1, 1),
       OVERLAY('INSERTING', 'XX', 1, 2),
       OVERLAY('INSERTING', 'XX', 1, 3)
FROM SYSIBM.SYSDUMMY1
```

This example returns 'XXINSERTING', 'XXNSERTING', 'XXSERTING', and 'XXERTING'.

- The following example shows how to insert text after some text. Add 'XX' at the end of string 'ABCABC'. Because the source string is 6 characters long, set the starting position to 7 (one plus the length of the source string).

```
SELECT OVERLAY('ABCABC', 'XX', 7, 0)
FROM SYSIBM.SYSDUMMY1
```

This example returns 'ABCABCXX'.

- The following example changes the string 'Hegelstraße' to 'Hegelstrasse'.

```
SELECT OVERLAY('Hegelstraße', 'ss', 10, 1)
FROM SYSIBM.SYSDUMMY1
```

This example returns 'Hegelstrasse'.

- Assume the variable UTF8_VAR is defined as UTF8 and UTF16_VAR is defined as UTF16. Assume both contain Unicode string '&N~AB', where '&' is the musical symbol G clef character, and '~' is the combining tilde character.

```
SELECT OVERLAY(UTF8_VAR, 'C', 1),  
       OVERLAY(UTF8_VAR, 'C', 5),  
       OVERLAY(UTF16_VAR, 'C', 1),  
       OVERLAY(UTF16_VAR, 'C', 5)  
FROM SYSIBM.SYSDUMMY1
```

This example returns 'CN~AB', '&N~AC', 'CN~AB', and '&N~AC'.

PI

Returns the value of π 3.141592653589793. There are no arguments.

►► PI (—) ◄◄

The result of the function is double-precision floating-point. The result cannot be null.

Example

- The following returns the circumference of a circle with diameter 10:

```
SELECT PI()*10  
FROM SYSIBM.SYSDUMMY1
```

POSITION

The POSITION function returns the starting position of the first occurrence of one string (called the *search-string*) within another string (called the *source-string*). If the *search-string* is not found and neither argument is null, the result is zero. If the *search-string* is found, the result is a number from 1 to the actual length of the *source-string*.

► POSITION (— *search-string* — IN — *source-string* —) ►
POSITION (— *search-string* — , — *source-string* —)

See the related functions [“LOCATE” on page 478](#) and [“POSSTR” on page 527](#).

search-string

An expression that specifies the string that is to be searched for. *search-string* can be any built-in numeric, datetime, or string expression. It must be compatible with the *source-string*. A numeric or datetime argument is cast to a character string before evaluating the function. For more information about converting numeric and datetime to a character string, see [“VARCHAR” on page 623](#).

source-string

An expression that specifies the source string in which the search is to take place. *source-string* can be any built-in numeric, datetime, or string expression. A numeric or datetime argument is cast to a character string before evaluating the function. For more information about converting numeric and datetime to a character string, see [“VARCHAR” on page 623](#).

The result of the function is a large integer. If either of the arguments can be null, the result can be null. If either of the arguments is null, the result is the null value.

The POSITION function operates on a character basis. Because POSITION operates on a character-string basis, any shift-in and shift-out characters are not required to be in exactly the same position, and their only significance is to indicate which characters are SBCS and which characters are DBCS.

If the CCSID of the *search-string* is different from the CCSID of the *source-string*, it is converted to the CCSID of the *source-string*. If the CCSID of the *source-string* is mixed data or UTF-8, CCSID conversion to UTF-16 will occur.

If a collating sequence other than *HEX is in effect when the statement that contains the POSITION function is executed and the arguments are SBCS data, mixed data, or Unicode data, then the result is obtained by comparing weighted values for each value in the set. The weighted values are based on the collating sequence. An ICU collating sequence table cannot be specified with the POSITION function.

If the *search-string* has a length of zero, the result returned by the function is 1. Otherwise:

- If the *source-string* has a length of zero, the result returned by the function is 0.
- Otherwise,
 - If the value of *search-string* is equal to an identical length of substring of contiguous positions within the value of *source-string*, then the result returned by the function is the starting position of the first such substring within the *source-string* value.
 - Otherwise, the result returned by the function is 0.⁶⁶

Example

- Select RECEIVED and SUBJECT columns as well as the starting position of the words 'GOOD' within the NOTE_TEXT column for all entries in the IN_TRAY table that contain these words.

```
SELECT RECEIVED, SUBJECT, POSITION('GOOD', NOTE_TEXT)
FROM IN_TRAY
WHERE POSITION('GOOD', NOTE_TEXT) <> 0
```

⁶⁶ This includes the case where the *search-string* is longer than the *source-string*.

- Assume that NOTE is a VARCHAR(128) column, encoded in Unicode UTF-8, that contains the value 'Jürgen lives on Hegelstraße'. Find the character position of the character 'ß' in the string.

```
SELECT POSITION('ß', NOTE), POSSTR( NOTE, 'ß')  
FROM T1
```

Returns the value 26 for POSITION and 27 for POSSTR.

POSSTR

The POSSTR function returns the starting position of the first occurrence of one string (called the *search-string*) within another string (called the *source-string*). If the *search-string* is not found and neither argument is null, the result is zero. If the *search-string* is found, the result is a number from 1 to the actual length of the *source-string*.

►► POSSTR — (— *source-string* — , — *search-string* —) ►◄

See the related functions, [“LOCATE” on page 478](#) and [“POSITION” on page 525](#).

source-string

An expression that specifies the source string in which the search is to take place. *source-string* may be any built-in numeric, datetime, or string expression. A numeric or datetime argument is cast to a character string before evaluating the function. For more information about converting numeric and datetime to a character string, see [“VARCHAR” on page 623](#).

search-string

An expression that specifies the string that is to be searched for. *search-string* may be any built-in numeric, datetime, or string expression. It must be compatible with the *source-string*. A numeric or datetime argument is cast to a character string before evaluating the function. For more information about converting numeric and datetime to a character string, see [“VARCHAR” on page 623](#).

The result of the function is a large integer. If either of the arguments can be null, the result can be null. If either of the arguments is null, the result is the null value.

The POSSTR function accepts mixed data strings. However, POSSTR operates on a strict byte-count basis without regard to single-byte or double-byte characters.⁶⁷ It is recommended that if either the *search-string* or *source-string* contains mixed data, POSITION should be used instead of POSSTR. The POSITION function operates on a character basis. In an EBCDIC encoding scheme, any shift-in and shift-out characters are not required to be in exactly the same position, and their only significance is to indicate which characters are SBCS and which characters are DBCS.

If the CCSID of the *search-string* is different than the CCSID of the *source-string*, it is converted to the CCSID of the *source-string*. If the CCSID of the *source-string* is mixed data or UTF-8, CCSID conversion to UTF-16 will occur.

If a collating sequence other than *HEX is in effect when the statement that contains the POSSTR function is executed and the arguments are SBCS data, mixed data, or Unicode data, then the result is obtained by comparing weighted values for each value in the set. The weighted values are based on the collating sequence. An ICU collating sequence table cannot be specified with the POSSTR function.

If the *search-string* has a length of zero, the result returned by the function is 1. Otherwise:

- if the *source-string* has a length of zero, the result returned by the function is 0.
- Otherwise,
 - If the value of *search-string* is equal to an identical length of substring of contiguous positions within the value of *source-string*, then the result returned by the function is the starting position of the first such substring within the *source-string* value.
 - Otherwise, the result returned by the function is 0.⁶⁸

Note

Syntax alternatives: STRPOS is a synonym for POSSTR.

⁶⁷ For example, in an EBCDIC encoding scheme, if the *source-string* contains mixed data, the *search-string* will only be found if any shift-in and shift-out characters are also found in the *source-string* in exactly the same positions.

⁶⁸ This includes the case where the *search-string* is longer than the *source-string*.

Example

- Select RECEIVED and SUBJECT columns as well as the starting position of the words 'GOOD' within the NOTE_TEXT column for all entries in the IN_TRAY table that contain these words.

```
SELECT RECEIVED, SUBJECT, POSSTR(NOTE_TEXT, 'GOOD')  
FROM IN_TRAY  
WHERE POSSTR(NOTE_TEXT, 'GOOD') <> 0
```

POWER or POW

The POWER or POW function returns the result of raising the first argument to the power of the second argument.

► POWER (— *expression-1* — , — *expression-2* —) ◄
POW

expression-1

An expression that returns a value of any built-in numeric, character-string, or graphic-string data type.⁶⁹ A string argument is cast to double-precision floating point before evaluating the function. For more information about converting strings to double-precision floating point, see “DOUBLE_PRECISION or DOUBLE” on page 392.

expression-2

An expression that returns a value of any built-in numeric data type. If the value of *expression-1* is equal to zero, then *expression-2* must be greater than or equal to zero. If the value of *expression-1* is less than zero, then *expression-2* must be an integer value.

If the data type of the argument is decimal floating-point, the data type of the result is DECFLOAT(34). Otherwise, the result of the function is a double-precision floating-point number. If both arguments are 0, the result is 1. If an argument can be null, the result can be null; if an argument is null, the result is the null value.

Note

Results involving DECFLOAT special values: If either argument is decimal floating-point, both arguments are converted to DECFLOAT(34). For decimal floating-point values the special values are treated as follows:

- If either argument is NaN or -NaN, NaN is returned.⁷⁰
- POWER®(Infinity, any valid second argument) returns Infinity.
- POWER(-Infinity, any valid odd integer value) returns -Infinity.
- POWER(-Infinity, any valid even integer value) returns Infinity.
- POWER(0,Infinity) returns 0.
- POWER(1,Infinity) returns 1.
- POWER(any number greater than 1,Infinity) returns Infinity.
- POWER(any number greater than 0 and less than 1,Infinity) returns 0.
- POWER(any number less than 0,Infinity) returns NaN.⁷⁰
- If either argument is sNaN or -sNaN, a warning or error is returned.⁷⁰

Example

- Assume the host variable HPOWER is an integer with value 3.

```
SELECT POWER(2, :HPOWER)
FROM SYSIBM.SYSDUMMY1
```

Returns the value 8.

⁶⁹ The result of the POWER function is exactly the same as the result of exponentiation: *expression-1* ** *expression-2*.

⁷⁰ If *YES is specified for the SQL_DECFLOAT_WARNINGS query option, NaN is returned with a warning

QUANTIZE

The QUANTIZE function returns a decimal floating-point value that is equal in value (except for any rounding) and sign to *expression-1* and which has an exponent set equal to the exponent in *expression-2*.

►► QUANTIZE (— *expression-1* — , — *expression-2* —) ◄◄

expression-1

An expression that returns a value of any built-in numeric, character-string, or graphic-string data type. If the data type of the argument is not a DECFLOAT value, it is converted to DECFLOAT(34) for processing.

expression-2

An expression that returns a value of any built-in numeric, character-string, or graphic-string data type. If the data type of the argument is not a DECFLOAT value, it is converted to DECFLOAT(34) for processing.

If one argument (after conversion) is DECFLOAT(16) and the other is DECFLOAT(34), the DECFLOAT(16) argument is converted to DECFLOAT(34) before the function is processed.

The coefficient of the result is derived from that of *expression-1*. It is rounded if necessary (if the exponent is being increased), multiplied by a power of ten (if the exponent is being decreased), or remains unchanged (if the exponent is already equal to that of *expression-2*).

If necessary, the rounding mode is used by the QUANTIZE function. See [“CURRENT DECFLOAT ROUNDING MODE”](#) on page 124 for more information.

Unlike other arithmetic operations on the DECFLOAT data type, if the length of the coefficient after the quantize operation would be greater than the precision of the resulting DECFLOAT number, an error occurs. This guarantees that unless there is an error, the exponent of the result of a QUANTIZE function is always equal to that of *expression-2*.

The result of the function is a DECFLOAT(16) value if both arguments are DECFLOAT(16). Otherwise, the result of the function is a DECFLOAT(34) value. If either argument can be null, the result can be null; if either argument is null, the result is the null value

Note

Results involving DECFLOAT special values: Decimal floating-point special values are treated as follows:

- If either argument is NaN and the first argument is not -NaN, then NaN is returned.
- If either argument is sNaN, then a warning or error occurs.⁷¹
- If either argument is -NaN and the first argument is not NaN, then -NaN is returned.
- If either argument is -sNaN, then a warning or error occurs.⁷¹
- If both arguments are Infinity (positive or negative), then Infinity (positive or negative) is returned.
- If one argument is Infinity (positive or negative) and the other argument is not Infinity (positive or negative), then NaN is returned.⁷¹

Examples

The following examples illustrate the value that is returned for the QUANTIZE function given the input DECFLOAT values:

```
QUANTIZE(2.17, 0.001)      ==> 2.170
QUANTIZE(2.17, 0.01)     ==> 2.17
QUANTIZE(2.17, 0.1)      ==> 2.2
QUANTIZE(2.17, 1e+0)     ==> 2
QUANTIZE(2.17, 1e+1)     ==> 0E+1
QUANTIZE(2, Infinity)    ==> NaN (exception)
```

⁷¹ If *YES is specified for the SQL_DECFLOAT_WARNINGS query option, NaN is returned with a warning.

```
QUANTIZE(0, 1e+5)      ==> 0E+5
QUANTIZE(217, 1e-1)   ==> 217.0
QUANTIZE(217, 1e+0)   ==> 217
QUANTIZE(217, 1e+1)   ==> 2.2E+2
QUANTIZE(217, 1e+2)   ==> 2E+2
```

In the following example, the value -0 is returned for the QUANTIZE function. The CHAR function is used to avoid the potential removal of the minus sign by a client program.

```
CHAR(QUANTIZE(-0.1, 1)) ==> -0
```

QUARTER

The QUARTER function returns an integer between 1 and 4 that represents the quarter of the year in which the date resides. For example, any dates in January, February, or March will return the integer 1.

►► QUARTER — (— *expression* —) ►►

expression

An expression that returns a value of one of the following built-in data types: a date, a timestamp, a character string, or a graphic string.

If *expression* is a character or graphic string, its value must be a valid string representation of a date or timestamp. For the valid formats of string representations of dates and timestamps, see [“String representations of datetime values”](#) on page 75.

The result of the function is a large integer. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

Example

- Using the PROJECT table, set the host variable QUART (INTEGER) to the quarter in which project 'PL2100' ended (PRENDATE).

```
SELECT QUARTER(PRENDATE)
INTO :QUART
FROM PROJECT
WHERE PROJNO = 'PL2100'
```

Results in QUART being set to 3.

RADIANS

The RADIANS function returns the number of radians for an argument that is expressed in degrees.

►► RADIANS — (— *expression* —) ◄◄

expression

An expression that returns a value of any built-in numeric, character-string, or graphic-string data type. A string argument is cast to double-precision floating point before evaluating the function. For more information about converting strings to double-precision floating point, see [“DOUBLE_PRECISION or DOUBLE”](#) on page 392.

If the data type of the argument is DECFLOAT(*n*), the result is DECFLOAT(*n*). Otherwise, the data type of the result is double-precision floating point. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

Example

- Assume that host variable HDEG is an INTEGER with a value of 180. The following statement:

```
SELECT RADIANS (:HDEG)
FROM SYSIBM.SYSDUMMY1
```

Returns a double precision floating-point number with an approximate value of 3.1415926536.

RAISE_ERROR

The RAISE_ERROR function causes the statement that invokes the function to return an error with the specified SQLSTATE (along with SQLCODE -438) and diagnostic string.

► RAISE_ERROR — (— *sqlstate* — , — *diagnostic-string* —) ◄

sqlstate

An expression that returns a value of a built-in CHAR or VARCHAR data type with exactly 5 characters. The *sqlstate* value must follow the rules for application-defined SQLSTATES:

- Each character must be from the set of digits ('0' through '9') or nonaccented uppercase letters ('A' through 'Z').
- The SQLSTATE class (first two characters) cannot be '00', '01', or '02' because these are not error classes.

If the SQLSTATE does not conform to these rules, an error is returned.

diagnostic-string

An expression that returns a value of a built-in CHAR or VARCHAR data type and a length up to 1000 bytes that describes the error condition. If the string is longer than 1000 bytes, it is truncated.

If an SQLCA is used, the following actions occur:

- The string is returned in the SQLERRMC field of the SQLCA.
- If the actual length of the string is longer than 70 bytes, it is truncated without a warning.

Since the data type of the result of RAISE_ERROR is undefined, it may only be used where parameter markers are allowed. To use this function in a context where parameter markers are not allowed (such as alone in a select list), you must use a cast specification to give a data type to the null value that is returned.

The RAISE_ERROR function always returns NULL with an undefined data type.

Example

- List employee numbers and education levels as Post Graduate, Graduate and Diploma. If an education level is greater than 20, raise an error.

```
SELECT EMPNO,  
       CASE WHEN EDLEVEL < 16 THEN 'Diploma'  
            WHEN EDLEVEL < 18 THEN 'Graduate'  
            WHEN EDLEVEL < 21 THEN 'Post Graduate'  
            ELSE RAISE_ERROR( '07001',  
                             'EDLEVEL has a value greater than 20' )  
       END  
FROM EMPLOYEE
```

RANDOM or RAND

The RANDOM or RAND function returns a floating point value greater than or equal to 0 and less than or equal to 1.

expression

If an expression is specified, it is used as the seed value. The argument must be an expression that returns a value of a built-in small integer, large integer, character-string, or graphic-string data type. A string argument is cast to integer before evaluating the function. For more information on converting strings to integer, see [“INTEGER or INT” on page 442](#).

The data type of the result is double-precision floating point. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

A specific seed value will produce the same sequence of random numbers for a specific instance of a RAND function in a query each time the query is executed. If a seed value is not specified, a different sequence of random numbers is produced each time the query is executed.

The seed value is used only for the first invocation of an instance of the RAND function within a statement.

RAND is a non-deterministic function.

Example

- Assume that host variable HRAND is an INTEGER with a value of 100. The following statement:

```
SELECT RAND(:HRAND)
FROM SYSIBM.SYSDUMMY1
```

Returns a random floating-point number between 0 and 1, such as the approximate value .0121398.

- To generate values in a numeric interval other than 0 to 1, multiply the RAND function by the size of the wanted interval. For example, to get a random number between 0 and 10, such as the approximate value 5.8731398, multiply the function by 10:

```
SELECT RAND(:HRAND) * 10
FROM SYSIBM.SYSDUMMY1
```

REAL

The REAL function returns a single-precision floating-point representation.

Numeric to Real

►► REAL — (— *numeric-expression* —) ►◄

String to Real

►► REAL — (— *string-expression* —) ►◄

The REAL function returns a single-precision floating-point representation of:

- A number
- A character or graphic string representation of a decimal number
- A character or graphic string representation of an integer
- A character or graphic string representation of a floating-point number
- A character or graphic string representation of a decimal floating-point number

Numeric to Real

numeric-expression

The argument is an expression that returns a value of any built-in numeric data type.

The result is the same number that would occur if the argument were assigned to a single-precision floating-point column or variable. If the numeric value of the argument is not within the range of single-precision floating-point, an error is returned.

String to Real

string-expression

An expression that returns a value that is a character-string or graphic-string representation of a number.

If the argument is a *string-expression*, the result is the same number that would result from CAST(*string-expression* AS REAL). Leading and trailing blanks are eliminated and the resulting string must conform to the rules for forming a floating-point, decimal floating-point, integer, or decimal constant. If the numeric value of the argument is not within the range of single-precision floating-point, an error is returned.

The single-byte character constant that must be used to delimit the decimal digits in *string-expression* from the whole part of the number is the default decimal point. For more information, see [“Decimal point” on page 116](#).

The result of the function is a single-precision floating-point number. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

Note

Syntax alternatives: The CAST specification should be used to increase the portability of applications. For more information, see [“CAST specification” on page 176](#).

Example

- Using the EMPLOYEE table, find the ratio of salary to commission for employees whose commission is not zero. The columns involved (SALARY and COMM) have DECIMAL data types. To eliminate the possibility of out-of-range results, REAL is applied to SALARY so that the division is carried out in floating point:

```
SELECT EMPNO, REAL(SALARY)/COMM  
FROM EMPLOYEE  
WHERE COMM > 0
```

REGEXP_COUNT

The REGEXP_COUNT function returns a count of the number of times that a regular expression pattern is matched in a string.

►► REGEXP_COUNT ((*source-string* , *pattern-expression* , *start*) , *flags*)

source-string

An expression that specifies the string in which the search is to take place. The expression must return a value that is a built-in character string, graphic string, numeric, or datetime data type. If the value is not a UTF-16 DBCLOB, it is implicitly cast to a UTF-16 DBCLOB before searching for the regular expression pattern. A character string with the FOR BIT DATA attribute or a binary string is not supported. The length of a string must not be greater than 1 gigabyte.

pattern-expression

An expression that specifies the regular expression string that is the pattern for the search. The expression must return a value that is a built-in character string, graphic string, numeric, or datetime data type. If the value is not a UTF-16 DBCLOB, it is implicitly cast to a UTF-16 DBCLOB before searching for the regular expression pattern. A character string with the FOR BIT DATA attribute or a binary string is not supported. The length of the string must not be greater than 32K.

A valid *pattern-expression* consists of a set of characters and control characters that describe the pattern of the search. For a description of the valid control characters, see [“Regular expression control characters”](#) on page 221.

start

An expression that specifies the position within *source-string* at which the search is to start. The expression must return a value of any built-in numeric, character-string, or graphic-string data type. The argument is cast to INTEGER before evaluating the function. For more information about converting to INTEGER, see [“INTEGER or INT”](#) on page 442. The value of the integer must be greater than or equal to 1. If the value of the integer is greater than the actual length of the *source-string*, the result is 0.

flags

An expression that specifies flags that control aspects of the pattern matching. The expression must return a value that is a built-in character string or graphic string data type. A character string with the FOR BIT DATA attribute or a binary string is not supported. The string can include one or more valid flag values and the combination of flag values must be valid. An empty string is the same as the value 'c'.

For a description of the valid flag characters, see [“Regular expression flag values”](#) on page 220.

The result of the function is an INTEGER representing the number of occurrences of the *pattern-expression* within the *source-string*. If the *pattern-expression* is not found and no argument is null, the result is 0.

If any argument of the REGEXP_COUNT function can be null, the result can be null. If any argument is null, the result is the null value.

Notes

Prerequisites: In order to use the REGEXP_COUNT function, the International Components for Unicode (ICU) option must be installed

Processing: The regular expression processing is done using the International Components for Unicode (ICU) regular expression interface. For more information see, <http://userguide.icu-project.org/strings/regexp>.

If only three arguments are specified, the third argument may be a *start* or *flags* argument. If the third argument is a string, it is interpreted as a *flags* argument. Otherwise, it is interpreted as a *start* argument.

Syntax Alternatives: REGEXP_MATCH_COUNT is a synonym for REGEXP_COUNT.

Example

- Count the number of times "Steven" or "Stephen" occurs in the string "Steven Jones and Stephen Smith are the best players".

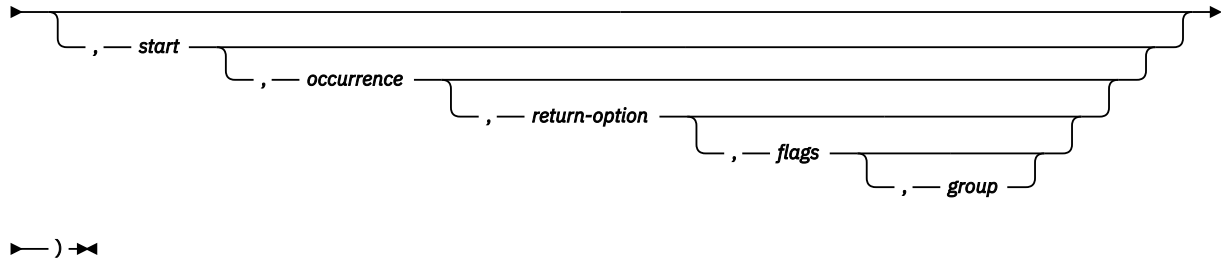

```
SELECT REGEXP_COUNT(  
    'Steven Jones and Stephen Smith are the best players',  
    'Ste(v|ph)en')  
FROM sysibm.sysdummy1
```

The result is 2.

REGEXP_INSTR

The REGEXP_INSTR returns the starting position or the position after the end of the matched substring, depending on the value of the *return_option* argument.

► REGEXP_INSTR (— *source-string* — , — *pattern-expression* — ►

source-string

An expression that specifies the string in which the search is to take place. The expression must return a value that is a built-in character string, graphic string, numeric, or datetime data type. If the value is not a UTF-16 DBCLOB, it is implicitly cast to a UTF-16 DBCLOB before searching for the regular expression pattern. A character string with the FOR BIT DATA attribute or a binary string is not supported. The length of a string must not be greater than 1 gigabyte.

pattern-expression

An expression that specifies the regular expression string that is the pattern for the search. The expression must return a value that is a built-in character string, graphic string, numeric, or datetime data type. If the value is not a UTF-16 DBCLOB, it is implicitly cast to a UTF-16 DBCLOB before searching for the regular expression pattern. A character string with the FOR BIT DATA attribute or a binary string is not supported. The length of the string must not be greater than 32K.

A valid *pattern-expression* consists of a set of characters and control characters that describe the pattern of the search. For a description of the valid control characters, see [“Regular expression control characters”](#) on page 221.

start

An expression that specifies the position within *source-string* at which the search is to start. The expression must return a value of any built-in numeric, character-string, or graphic-string data type. The argument is cast to INTEGER before evaluating the function. For more information about converting to INTEGER, see [“INTEGER or INT”](#) on page 442. The value of the integer must be greater than or equal to 1. If the value of the integer is greater than the actual length of the *source-string*, the result is 0.

occurrence

An expression that specifies which occurrence of the *pattern-expression* within *source-string* to search for. The expression must return a value of any built-in numeric, character-string, or graphic-string data type. The argument is cast to INTEGER before evaluating the function. For more information about converting to INTEGER, see [“INTEGER or INT”](#) on page 442. The value of the integer must be greater than or equal to 1. If *occurrence* is not specified, the default value is 1 which indicates that only the first occurrence of *pattern-expression* is considered.

return-option

An expression that specifies whether to return the starting position or the position after the end of the string that matches the pattern. The expression must return a value of any built-in numeric, character-string, or graphic-string data type. The argument is cast to INTEGER before evaluating the function. For more information about converting to INTEGER, see [“INTEGER or INT”](#) on page 442. The value of the integer must be equal to 0 or 1. A value of 0 returns the starting position of the occurrence. A value of 1 returns the ending position of the occurrence. If *return-option* is not specified, the default value is 0.

flags

An expression that specifies flags that control aspects of the pattern matching. The expression must return a value that is a built-in character string or graphic string data type. A character string with the FOR BIT DATA attribute or a binary string is not supported. The string can include one or more valid flag values and the combination of flag values must be valid. An empty string is the same as the value 'c'.

For a description of the valid flag characters, see [“Regular expression flag values”](#) on page 220.

group

An expression that specifies which capture group of the *pattern-expression* is used to determine the position within *source-string* to return. The expression must return a value of any built-in numeric, character-string, or graphic-string data type. The argument is cast to INTEGER before evaluating the function. For more information about converting to INTEGER, see [“INTEGER or INT”](#) on page 442. The value of the integer must be greater than or equal to 0 and must not be greater than the number of capture groups in the *pattern-expression*. If *group* is not specified, the default is 0 which indicates the entire string that matches the entire pattern is returned.

The result of the function is a large integer. If the *pattern-expression* is found, the result is a number from 1 to *n*, where *n* is the actual length of the *source-string* plus 1. The result value represents the position used to process the function. If the *pattern-expression* is not found and no argument is null, the result is 0.

If any argument of the REGEXP_INSTR function can be null, the result can be null. If any argument is null, the result is the null value.

Notes

Prerequisites: In order to use the REGEXP_INSTR function, the International Components for Unicode (ICU) option must be installed

Processing: The regular expression processing is done using the International Components for Unicode (ICU) regular expression interface. For more information see, <http://userguide.icu-project.org/strings/regexp>.

Examples

- *Example 1:* Find the first occurrence of a 'o' which has a character preceding it.

```
SELECT REGEXP_INSTR('hello to you', '.o',1,1)
FROM sysibm.sysdummy1
```

The result is 4, which is the position of the second 'l' character.

- *Example 2:* Find the second occurrence of a 'o' which has a character preceding it.

```
SELECT REGEXP_INSTR('hello to you', '.o',1,2)
FROM sysibm.sysdummy1
```

The result is 7, which is the position of the character 't'.

- *Example 3:* Find the position after the third occurrence of the first capture group of the regular expression '(o)!' using case insensitive matching.

```
SELECT REGEXP_INSTR('hello to you', '(o).!', 1,3,1,'i',1)
FROM sysibm.sysdummy1
```

The result is 12, which is the position of the character 'u' at the end of the string.

REGEXP_REPLACE

The REGEXP_REPLACE function returns a modified version of the source string where occurrences of the regular expression pattern found in the source string are replaced with the specified replacement string.

►► REGEXP_REPLACE (— *source-string* — , — *pattern-expression* — ►

source-string

An expression that specifies the string in which the search is to take place. The expression must return a value that is a built-in character string, graphic string, numeric, or datetime data type. If the value is not a UTF-16 DBCLOB, it is implicitly cast to a UTF-16 DBCLOB before searching for the regular expression pattern. A character string with the FOR BIT DATA attribute or a binary string is not supported. The length of a string must not be greater than 1 gigabyte.

pattern-expression

An expression that specifies the regular expression string that is the pattern for the search. The expression must return a value that is a built-in character string, graphic string, numeric, or datetime data type. If the value is not a UTF-16 DBCLOB, it is implicitly cast to a UTF-16 DBCLOB before searching for the regular expression pattern. A character string with the FOR BIT DATA attribute or a binary string is not supported. The length of the string must not be greater than 32K.

A valid *pattern-expression* consists of a set of characters and control characters that describe the pattern of the search. For a description of the valid control characters, see [“Regular expression control characters”](#) on page 221.

replacement-string

An expression that specifies the replacement string for matching substrings. The expression must return a value that is a built-in character string, graphic string, numeric, or datetime data type. If the value is not a UTF-16 DBCLOB, it is implicitly cast to a UTF-16 DBCLOB before searching for the regular expression pattern. A character string with the FOR BIT DATA attribute or a binary string is not supported. The length of the string must not be greater than 32K. If *replacement-string* is not specified, the default is the empty string.

The content of the *replacement-string* can include references to capture group text from the search to use in the replacement text. These references are of the form '\$n' or '\n'33, where n is the number of the capture group and 0 represents the entire string that matches the pattern. The value for n must be in the range 0 to 9 and not greater than the number of capture groups in the pattern. For example, either '\$2' or '\2' can be used to refer to the content found in *source-string* for the second capture group specified in *pattern-expression*. If the *replacement-string* must include a literal reference to a '\$' or '\' character, then the '\' character must precede the literal reference so that it appears in the *replacement-string* as '\\$' or '\\'.

start

An expression that specifies the position within *source-string* at which the search is to start. The expression must return a value of any built-in numeric, character-string, or graphic-string data type. The argument is cast to INTEGER before evaluating the function. For more information about converting to INTEGER, see [“INTEGER or INT”](#) on page 442. The value of the integer must be greater than or equal to 1. If the value of the integer is greater than the actual length of the *source-string*, the original string is returned.

occurrence

An expression that specifies which occurrence of the *pattern-expression* within *source-string* to search for and replace. The expression must return a value of any built-in numeric, character-string, or graphic-string data type. The argument is cast to INTEGER before evaluating the function. For more information about converting to INTEGER, see [“INTEGER or INT” on page 442](#). The value of the integer must be greater than or equal to 0. If *occurrence* is not specified, the default value is 0 which indicates that all occurrences of *pattern-expression* in *source-string* are replaced.

flags

An expression that specifies flags that control aspects of the pattern matching. The expression must return a value that is a built-in character string or graphic string data type. A character string with the FOR BIT DATA attribute or a binary string is not supported. The string can include one or more valid flag values and the combination of flag values must be valid. An empty string is the same as the value 'c'.

For a description of the valid flag characters, see [“Regular expression flag values” on page 220](#).

The result of the function is a string. If there are no occurrences of the pattern to be replaced and no argument is null, the original string is returned. The data type of the string is the same as if the first and third arguments were concatenated except that the result is always a varying-length string. For more information, see [“With the concatenation operator” on page 163](#).

The length attribute of the result data type is determined based on the length attributes of the *source-string* and the *replacement-string* using the following calculation: $\text{MIN}(\text{MaxTypeLen}, \text{LAS} + (\text{LAS} + 1) * \text{LAR})$ where MaxTypeLen is the maximum length attribute for the data type of the result, LAS is the length attribute for the data type of *source-string*, and LAR is the length attribute for the data type of *replacement-string*. If *replacement-string* is not specified, the value for LAR is 0. If the actual length of the result string exceeds the maximum for the return data type, an error is returned.

The CCSID of the result is determined by the CCSID of the *source-string* and the *replacement-string*. The resulting CCSID is the same as if the first and third arguments were concatenated. For more information, see [“Rules for result data types” on page 105](#).

If any argument of the REGEXP_REPLACE function can be null, the result can be null. If any argument is null, the result is the null value.

Notes

Prerequisites: In order to use the REGEXP_REPLACE function, the International Components for Unicode (ICU) option must be installed

Processing: The regular expression processing is done using the International Components for Unicode (ICU) regular expression interface. For more information see, <http://userguide.icu-project.org/strings/regexp>.

Example

- Replace the second occurrence of the pattern 'R.d' with 'Orange' using a case sensitive search.

```
SELECT REGEXP_REPLACE(  
  'Red Yellow RED Blue Red Green Blue',  
  'R.d', 'Orange', 1, 2, 'c')  
FROM sysibm.sysdummy1
```

The result is 'Red Yellow RED Blue Orange Green Blue'.

REGEXP_SUBSTR

The REGEXP_SUBSTR function returns one occurrence of a substring of a string that matches the regular expression pattern.

►► REGEXP_SUBSTR (— *source-string* — , — *pattern-expression* →

source-string

An expression that specifies the string in which the search is to take place. The expression must return a value that is a built-in character string, graphic string, numeric, or datetime data type. If the value is not a UTF-16 DBCLOB, it is implicitly cast to a UTF-16 DBCLOB before searching for the regular expression pattern. A character string with the FOR BIT DATA attribute or a binary string is not supported. The length of a string must not be greater than 1 gigabyte.

pattern-expression

An expression that specifies the regular expression string that is the pattern for the search. The expression must return a value that is a built-in character string, graphic string, numeric, or datetime data type. If the value is not a UTF-16 DBCLOB, it is implicitly cast to a UTF-16 DBCLOB before searching for the regular expression pattern. A character string with the FOR BIT DATA attribute or a binary string is not supported. The length of the string must not be greater than 32K.

A valid *pattern-expression* consists of a set of characters and control characters that describe the pattern of the search. For a description of the valid control characters, see [“Regular expression control characters”](#) on page 221.

start

An expression that specifies the position within *source-string* at which the search is to start. The expression must return a value of any built-in numeric, character-string, or graphic-string data type. The argument is cast to INTEGER before evaluating the function. For more information about converting to INTEGER, see [“INTEGER or INT”](#) on page 442. The value of the integer must be greater than or equal to 1. If the value of the integer is greater than the actual length of the *source-string*, the result is the null value.

occurrence

An expression that specifies which occurrence of the *pattern-expression* within *source-string* to search for. The expression must return a value of any built-in numeric, character-string, or graphic-string data type. The argument is cast to INTEGER before evaluating the function. For more information about converting to INTEGER, see [“INTEGER or INT”](#) on page 442. The value of the integer must be greater than or equal to 1. If *occurrence* is not specified, the default value is 1 which indicates that only the first occurrence of *pattern-expression* is considered.

flags

An expression that specifies flags that control aspects of the pattern matching. The expression must return a value that is a built-in character string or graphic string data type. A character string with the FOR BIT DATA attribute or a binary string is not supported. The string can include one or more valid flag values and the combination of flag values must be valid. An empty string is the same as the value 'c'.

For a description of the valid flag characters, see [“Regular expression flag values”](#) on page 220.

group

An expression that specifies which capture group of the *pattern-expression* within *source-string* to return. The expression must return a value of any built-in numeric, character-string, or graphic-string

data type. The argument is cast to INTEGER before evaluating the function. For more information about converting to INTEGER, see “INTEGER or INT” on page 442. The value of the integer must be greater than or equal to 0 and must not be greater than the number of capture groups in the *pattern-expression*. If *group* is not specified, the default is 0 which indicates the entire string that matches the entire pattern is returned.

The result of the function is a string. The data type of the result depends on the data type of *source-string*:

Data type of <i>source-string</i>	Data Type of the Result for REGEXP_SUBSTR
CHAR or VARCHAR or numeric or datetime	VARCHAR
CLOB	CLOB
GRAPHIC or VARGRAPHIC	VARGRAPHIC
DBCLOB	DBCLOB

The length attribute of the result data type is same as the length attribute of the *source-string*. The actual length of the result is the length of the occurrence in the string that matches the *pattern-expression*. If the *pattern-expression* is not found, the result is the null value.

The CCSID of the result is the same as the *source-string*.

If any argument of the REGEXP_SUBSTR function can be null, the result can be null. If any argument is null, the result is the null value.

Notes

Prerequisites: In order to use the REGEXP_SUBSTR function, the International Components for Unicode (ICU) option must be installed

Processing: The regular expression processing is done using the International Components for Unicode (ICU) regular expression interface. For more information see, <http://userguide.icu-project.org/strings/regexp>.

Syntax Alternatives: REGEXP_EXTRACT is a synonym for REGEXP_SUBSTR.

Examples

- *Example 1:* Return the string which matches any character preceding a 'o'.

```
SELECT REGEXP_SUBSTR('hello to you', '.o',1,1)
FROM sysibm.sysdummy1
```

The result is 'lo'.

- *Example 2:* Return the second string occurrence which matches any character preceding a 'o'.

```
SELECT REGEXP_SUBSTR('hello to you', '.o',1,2)
FROM sysibm.sysdummy1
```

The result is 'to'.

- *Example 3:* Return the third string occurrence which matches any character preceding a 'o'.

```
SELECT REGEXP_SUBSTR('hello to you', '.o',1,3)
FROM sysibm.sysdummy1
```

The result is 'yo'.

REPEAT

The REPEAT function returns a string composed of *expression* repeated *integer* times.

►► REPEAT — (— *expression* — , — *integer* —) ◄◄

expression

An expression that specifies the string to be repeated. The string must be a built-in numeric or string expression. A numeric argument is cast to a character string before evaluating the function. For more information on converting numeric to a character string, see “VARCHAR” on page 623.

integer

An expression that returns a built-in BIGINT, INTEGER, or SMALLINT data type whose value is a positive integer or zero. The integer specifies the number of times to repeat the string.

The data type of the result of the function depends on the data type of the first argument:

Data type of <i>expression</i>	Data type of the Result
CHAR or VARCHAR or any numeric type	VARCHAR
CLOB	CLOB
GRAPHIC or VARGRAPHIC	VARGRAPHIC
DBCLOB	DBCLOB
BINARY or VARBINARY	VARBINARY
BLOB	BLOB

If *integer* is a constant, the length attribute of the result is the minimum of the length attribute of *expression* times *integer* and the maximum length of the result data type. Otherwise, the length attribute depends on the data type of the result:

- 1,048,576 for BLOB, CLOB, or DBCLOB
- 4000 for VARCHAR or VARBINARY
- 2000 for VARGRAPHIC

The actual length of the result is the actual length of *expression* times *integer*. If the actual length of the result string exceeds the maximum for the return type, an error is returned.

If either argument can be null, the result can be null; if either argument is null, the result is the null value.

The CCSID of the result is the CCSID of *expression*.⁷²

Examples

- Repeat 'abc' two times to create 'abcabc'.

```
SELECT REPEAT('abc', 2)
FROM SYSIBM.SYSDUMMY1
```

- List the phrase 'REPEAT THIS' five times. Use the CHAR function to limit the output to 60 bytes.

```
SELECT CHAR( REPEAT('REPEAT THIS', 5), 60)
FROM SYSIBM.SYSDUMMY1
```

This example results in 'REPEAT THISREPEAT THISREPEAT THISREPEAT THISREPEAT THISREPEAT THIS '.

⁷² If the value of *expression* is mixed data that is not a properly formed mixed data string, the result will not be a properly formed mixed data string.

- For the following query, the LENGTH function returns a value of 0 because the result of repeating a string zero times is an empty string, which is a zero-length string.

```
SELECT LENGTH( REPEAT('REPEAT THIS', 0) )  
FROM SYSIBM.SYSDUMMY1
```

- For the following query, the LENGTH function returns a value of 0 because the result of repeating an empty string any number of times is an empty string, which is a zero-length string.

```
SELECT LENGTH( REPEAT('', 5) )  
FROM SYSIBM.SYSDUMMY1
```

REPLACE

The REPLACE function replaces all occurrences of *search-string* in *source-string* with *replace-string*. If *search-string* is not found in *source-string*, *source-string* is returned unchanged.

source-string

An expression that specifies the source string. The *source-string* must be a built-in numeric or string expression. A numeric argument is cast to a character string before evaluating the function. For more information about converting numeric to a character string, see [“VARCHAR” on page 623](#).

search-string

An expression that specifies the string to be removed from the source string. The *search-string* must be a built-in numeric or string expression. A numeric argument is cast to a character string before evaluating the function. For more information about converting numeric to a character string, see [“VARCHAR” on page 623](#).

replace-string

An expression that specifies the replacement string. The *replace-string* must be a built-in numeric or string expression. A numeric argument is cast to a character string before evaluating the function. For more information about converting numeric to a character string, see [“VARCHAR” on page 623](#).

If *replace-string* is an empty string or is not specified, nothing replaces the string that is removed from the source string.

source-string, *search-string*, and *replace-string* must be compatible. For more information about data type compatibility, see [“Assignments and comparisons” on page 89](#).

The data type of the result of the function depends on the data type of the arguments. The result data type is the same as if the three arguments were concatenated except that the result is always a varying-length string. For more information see [“Conversion rules for operations that combine strings” on page 110](#).

The length attribute of the result depends on the arguments:

- If *search-string* is variable length, the length attribute of the result is:

$$(L3 * L1)$$

- If the length attribute of *replace-string* is less than or equal to the length attribute of *search-string*, the length attribute of the result is the length attribute of *source-string*
- Otherwise, the length attribute of the result is:

$$(L3 * (L1/L2)) + \text{MOD}(L1, L2)$$

where:

L1 is the length attribute of *source-string*
L2 is the length attribute of *search-string*
L3 is the length attribute of *replace-string*

If the length attribute of the result exceeds the maximum for the result data type, an error is returned.

The actual length of the result is the actual length of *source-string* plus the number of occurrences of *search-string* that exist in *source-string* multiplied by the actual length of *replace-string* minus the actual length of *search-string*. If the actual length of the result string exceeds the maximum for the result data type, an error is returned.

If any argument can be null, the result can be null; if any argument is null, the result is the null value.

The CCSID of the result is determined by the CCSID of *source-string*, *search-string*, and *replace-string*. The resulting CCSID is the same as if the three arguments were concatenated. For more information, see [“Conversion rules for operations that combine strings” on page 110.](#)

Examples

- Replace all occurrences of the character 'N' in the string 'DINING' with 'VID'. Use the CHAR function to limit the output to 10 bytes.

```
SELECT CHAR(REPLACE( 'DINING', 'N', 'VID' ), 10)
FROM SYSIBM.SYSDUMMY1
```

The result is the string 'DIVIDIVIDG'.

- Replace string 'ABC' in the string 'ABCXYZ' with nothing, which is the same as removing 'ABC' from the string.

```
SELECT REPLACE( 'ABCXYZ', 'ABC', '' )
FROM SYSIBM.SYSDUMMY1
```

The result is the string 'XYZ'.

Omitting the third argument returns the same result.

```
SELECT REPLACE( 'ABCXYZ', 'ABC' )
FROM SYSIBM.SYSDUMMY1
```

- Replace string 'ABC' in the string 'ABCCABCC' with 'AB'. This example illustrates that the result can still contain the string that is to be replaced (in this case, 'ABC') because all occurrences of the string to be replaced are identified prior to any replacement.

```
SELECT REPLACE( 'ABCCABCC', 'ABC', 'AB' )
FROM SYSIBM.SYSDUMMY1
```

The result is the string 'ABCABC'.

RID

The RID function returns the relative record number of a row as a BIGINT.

►► RID — (— *table-designator* —) ◄◄

table-designator

A table designator that can be used to qualify a column in the same relative location in the SQL statement as the RID function. For more information about table designators, see [“Table designators” on page 133](#).

In SQL naming, the table name may be qualified. In system naming, the table name cannot be qualified.

The *table-designator* must not identify a *table-function*, a *collection-derived-table*, a VALUES clause, or a *data-change-table-reference*. If the argument identifies a view, common table expression, or nested table expression, its outer subselect must directly or indirectly reference a table.

If the argument identifies a view, common table expression, or nested table expression, the function returns the relative record number of its base table. If the argument identifies a view, common table expression, or nested table expression derived from more than one base table, the function returns the relative record number of the first table in the outer subselect of the view, common table expression, or nested table expression.

If the argument identifies a distributed table, the function returns the relative record number of the row on the node where the row is located. If the argument identifies a partitioned table, the function returns the relative record number of the row in the partition where the row is located. This means that RID will not be unique for each row of a partitioned or distributed table.

The argument must not identify a view, common table expression, or nested table expression whose outer fullselect includes an aggregate function, a GROUP BY clause, a HAVING clause, a UNION, INTERSECT, or EXCEPT clause, a DISTINCT clause, a VALUES clause, or a *table-function*. The RID function cannot be specified in a SELECT clause if the fullselect contains an aggregate function, a GROUP BY clause, or a HAVING clause

The data type of the result is a big integer. The result can be null.

Example

- Return the relative record number and employee name from table EMPLOYEE for those employees in department 20.

```
SELECT RID(EMPLOYEE), LASTNAME
FROM EMPLOYEE
WHERE DEPTNO = 20
```

RIGHT

The RIGHT function returns the rightmost *integer* characters of *expression*.

►► RIGHT — (— *expression* — , — *integer* —) ►►

If *expression* is a character string, the result is a character string. If *expression* is a graphic string, the result is a graphic string. If *expression* is a binary string, the result is a binary string.

expression

An expression that specifies the string from which the result is derived. The string must be a built-in numeric or string expression. A numeric argument is cast to a character string before evaluating the function. For more information on converting numeric to a character string, see “VARCHAR” on page 623.

A substring of *expression* is zero or more contiguous characters of *expression*. If *expression* is a character string or graphic string, a single character is either an SBCS, DBCS, or multiple-byte character. If *expression* is a binary string, the result is the number of bytes in the argument.

integer

An expression that returns a built-in integer data type. The integer specifies the length of the result. *integer* must be greater than or equal to 0 and less than or equal to *n*, where *n* is the length attribute of *expression*.

The result of the function is a varying-length string with a length attribute that is the same as the length attribute of *expression* and a data type that depends on the data type of *expression*:

Data type of <i>expression</i>	Data type of the Result
CHAR or VARCHAR	VARCHAR
CLOB	CLOB
GRAPHIC or VARGRAPHIC	VARGRAPHIC
DBCLOB	DBCLOB
BINARY or VARBINARY	VARBINARY
BLOB	BLOB

The actual length of the result is *integer*.

If any argument can be null, the result can be null; if any argument is null, the result is the null value.

The CCSID of the result is the same as that of *expression*.

Note

Syntax alternatives: STRRIGHT is a synonym for RIGHT.

Example

- Assume that host variable ALPHA has a value of 'ABCDEF'. The following statement:

```
SELECT RIGHT( :ALPHA, 3)
FROM SYSIBM.SYSDUMMY1
```

Returns the value 'DEF', which are the three rightmost characters in ALPHA.

- The following statement returns a zero length string.

```
SELECT RIGHT( 'ABCABC', 0)  
FROM SYSIBM.SYSDUMMY1
```

- Assume that NAME is a VARCHAR(128) column, encoded in Unicode UTF-8, that contains the value 'Jürgen'.

```
SELECT RIGHT(NAME, 5), SUBSTR(NAME, 3, 5)  
FROM T1  
WHERE NAME = 'Jürgen'
```

Returns the value 'ürgen' for RIGHT and an unprintable string (X'BC7267656E') for SUBSTR(NAME, 3, 5).

ROUND

The ROUND function returns *expression-1* rounded to some number of places to the right or left of the decimal point.

expression-1

An expression that returns a value of any built-in numeric, character-string, or graphic-string data type. A string argument is converted to double-precision floating point before evaluating the function. For more information about converting strings to double-precision floating point, see [“DOUBLE_PRECISION or DOUBLE”](#) on page 392.

If *expression-1* is a decimal floating-point data type, the DECFLOAT ROUNDING MODE will not be used. The rounding behavior of ROUND corresponds to a value of ROUND_HALF_UP. If a different rounding behavior is wanted, use the QUANTIZE function.

expression-2

An expression that returns a value of a built-in BIGINT, INTEGER, or SMALLINT data type.

If *expression-2* is positive, *expression-1* is rounded to the *expression-2* number of places to the right of the decimal point.

If *expression-2* is negative, *expression-1* is rounded to $1 +$ (the absolute value of *expression-2*) number of places to the left of the decimal point. If the absolute value of *expression-2* is greater than the number of digits to the left of the decimal point, the result is 0. (For example, ROUND(748.58,-4) returns 0.)

If *expression-2* is not specified, *expression-1* is rounded to zero places to the left of the decimal point.

If *expression-1* is positive, a digit value of 5 is rounded to the next higher positive number. If *expression-1* is negative, a digit value of 5 is rounded to the next lower negative number.

The data type and length attribute of the result are the same as the data type and length attribute of the first argument, except that precision is increased by one if *expression-1* is DECIMAL or NUMERIC and the precision is less than the maximum precision (*mp*). For example, an argument with a data type of DECIMAL(5,2) will result in DECIMAL(6,2). An argument with a data type of DECIMAL(63,2) will result in DECIMAL(63,2).

If either argument can be null, the result can be null. If either argument is null, the result is the null value.

Examples

- Calculate the number 873.726 rounded to 2, 1, 0, -1, -2, -3, and -4 decimal places respectively.

```
SELECT ROUND(873.726, 2),
       ROUND(873.726, 1),
       ROUND(873.726, 0),
       ROUND(873.726, -1),
       ROUND(873.726, -2),
       ROUND(873.726, -3),
       ROUND(873.726, -4)
FROM SYSIBM.SYSDUMMY1
```

Returns the following values, respectively:

```
0873.730  0873.700  0874.000  0870.000  0900.000  1000.000  0000.000
```

- Calculate both positive and negative numbers.

```
SELECT ROUND( 3.5, 0),
       ROUND( 3.1, 0),
```

```
ROUND(-3.1, 0),  
ROUND(-3.5, 0)  
FROM SYSIBM.SYSDUMMY1
```

Returns the following examples, respectively:

```
04.0  03.0  -03.0  -04.0
```

ROUND_TIMESTAMP

The ROUND_TIMESTAMP function returns a timestamp that is the *expression* rounded to the unit specified by the *format-string*. If *format-string* is not specified, *expression* is rounded to the nearest day, as if 'DD' was specified for *format-string*.

expression

An expression that returns a value of one of the following built-in data types: a date, a timestamp, a character-string, or a graphic-string.

If *expression* is a character or graphic string, its value must be a valid string representation of a date or timestamp. It is first converted to a `TIMESTAMP(12)` value. For the valid formats of string representations of dates and timestamps, see [“String representations of datetime values”](#) on page 75.

format-string

An expression that returns a built-in character string data type or graphic string data type. *format-string* contains a template of how *expression* should be rounded. For example, if *format-string* is 'DD', a timestamp that is represented by *expression* is rounded to the nearest day. Leading and trailing blanks are removed from the string, and the resulting substring must be a valid template for a timestamp. The resulting value is then folded to uppercase, so the characters in the value may be in any case. Allowable values for *format-string* are listed in [Table 57 on page 555](#).

The result of the function is a timestamp with a timestamp precision of:

- *p* when the data type of *expression* is `TIMESTAMP(p)`
- 0 when the data type of *expression* is `DATE`
- 6 otherwise.

If either argument can be null, the result can be null; if either argument is null, the result is the null value.

Format model	Rounding or truncating unit	ROUND_TIMESTAMP example	TRUNC_TIMESTAMP example
CC SCC	Century. One greater than the first two digits of a four digit year. For ROUND_TIMESTAMP, rounds up on the 50th year of the century.	Input value: 1897-12-04-12.22.22.00 0000 Result: 1901-01-01-00.00.00.00 0000	Input value: 1897-12-04-12.22.22.00 0000 Result: 1801-01-01-00.00.00.00 0000
YYYY SYYYY YEAR SYEAR YYY YY Y	Year. For ROUND_TIMESTAMP, rounds up on July 1 to January 1st of the next year.	Input value: 1897-12-04-12.22.22.00 0000 Result: 1898-01-01-00.00.00.00 0000	Input value: 1897-12-04-12.22.22.00 0000 Result: 1897-01-01-00.00.00.00 0000

Table 57. ROUND_TIMESTAMP and TRUNC_TIMESTAMP format models (continued)

Format model	Rounding or truncating unit	ROUND_TIMESTAMP example	TRUNC_TIMESTAMP example
IYYY IYY IY I	ISO year. For ROUND_TIMESTAMP, rounds up on July 1 to the first day of the next ISO year. The first day of the ISO year is defined as the Monday of the first ISO week.	Input value: 1897-12-04-12.22.22.00 0000 Result: 1898-01-03-00.00.00.00 0000	Input value: 1897-12-04-12.22.22.00 0000 Result: 1897-01-04-00.00.00.00 0000
Q	Quarter. For ROUND_TIMESTAMP, rounds up on the 16th day of the second month of the quarter.	Input value: 1999-06-04-12.12.30.00 0000 Result: 1999-07-01-00.00.00.00 0000	Input value: 1999-06-04-12.12.30.00 0000 Result: 1999-04-01-00.00.00.00 0000
MONTH MON MM RM	Month. For ROUND_TIMESTAMP, rounds up on the 16th day of the month.	Input value: 1999-06-18-12.12.30.00 0000 Result: 1999-07-01-00.00.00.00 0000	Input value: 1999-06-18-12.12.30.00 0000 Result: 1999-06-01-00.00.00.00 0000
WW	Same day of the week as the first day of the year. For ROUND_TIMESTAMP, rounds up on the 12th hour of the 4th day of the week, with respect to the first day of the year.	Input value: 2000-05-05-12.12.30.00 0000 Result: 2000-05-06-00.00.00.00 0000	Input value: 2000-05-05-12.12.30.00 0000 Result: 2000-04-29-00.00.00.00 0000
IW	Same day of the week as the first day of the ISO year. For ROUND_TIMESTAMP, rounds up on the 12th hour of the 4th day of the week, with respect to the first day of the ISO year.	Input value: 2000-05-05-12.12.30.00 0000 Result: 2000-05-08-00.00.00.00 0000	Input value: 2000-05-05-12.12.30.00 0000 Result: 2000-05-01-00.00.00.00 0000
W	Same day of the week as the first day of the month. For ROUND_TIMESTAMP, rounds up on the 12th hour of the 4th day of the week, with respect to the first day of the month.	Input value: 2000-06-21-12.12.30.00 0000 Result: 2000-06-22-00.00.00.00 0000	Input value: 2000-06-21-12.12.30.00 0000 Result: 2000-06-15-00.00.00.00 0000

Table 57. ROUND_TIMESTAMP and TRUNC_TIMESTAMP format models (continued)

Format model	Rounding or truncating unit	ROUND_TIMESTAMP example	TRUNC_TIMESTAMP example
DDD DD J	Day. For ROUND_TIMESTAMP, rounds up on the 12th hour of the day.	Input value: 2000-05-17-12.59.59.00 0000 Result: 2000-05-18-00.00.00.00 0000	Input value: 2000-05-17-12.59.59.00 0000 Result: 2000-05-17-00.00.00.00 0000
DAY DY D	Starting day of the week. For ROUND_TIMESTAMP, rounds up with respect to the 12th hour of the 4th day of the week. The first day of the week is always Sunday.	Input value: 2000-05-17-12.59.59.00 0000 Result: 2000-05-21-00.00.00.00 0000	Input value: 2000-05-17-12.59.59.00 0000 Result: 2000-05-14-00.00.00.00 0000
HH HH12 HH24	Hour. For ROUND_TIMESTAMP, rounds up at 30 minutes.	Input value: 2000-05-17-23.59.59.00 0000 Result: 2000-05-18-00.00.00.00 0000	Input value: 2000-05-17-23.59.59.00 0000 Result: 2000-05-17-23.00.00.00 0000
MI	Minute. For ROUND_TIMESTAMP, rounds up at 30 seconds.	Input value: 2000-05-17-23.58.45.00 0000 Result: 2000-05-17-23.59.00.00 0000	Input value: 2000-05-17-23.58.45.00 0000 Result: 2000-05-17-23.58.00.00 0000
SS	Second. For ROUND_TIMESTAMP, rounds up at 500000 microseconds.	Input value: 2000-05-17-23.58.45.50 0000 Result: 2000-05-17-23.58.46.00 0000	Input value: 2000-05-17-23.58.45.50 0000 Result: 2000-05-17-23.58.45.00 0000

Note:

The ISO year starts on the first day of the first ISO week of the year. This can be up to three days before January 1st or three days after January 1st. See “WEEK_ISO” on page 647 for details.

Example

- Set the host variable RND_TMSTMP with the current year rounded to the nearest month value.

```
SET :RND_TMSTMP = ROUND_TIMESTAMP('2000-03-18-17.30.00', 'MONTH');
```

Host variable RND_TMSTMP is set with the value 2000-04-01-00.00.00.000000.

ROWID

The ROWID function casts a character string to a row ID.

►► ROWID — (— *string-expression* —) ►◄

string-expression

An expression that returns a character string value. Although the string can contain any value, it is recommended that it contain a ROWID value that was previously generated by Db2 for z/OS or Db2 for i to ensure a valid ROWID value is returned. For example, the function can be used to convert a ROWID value that was cast to a CHAR value back to a ROWID value.

If the actual length of *string-expression* is less than 40, the result is not padded. If the actual length of *string-expression* is greater than 40, the result is truncated. If non-blank characters are truncated, a warning is returned.

The length attribute of the result is 40. The actual length of the result is the length of *string-expression*.

The result of the function is a row ID. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

Note

Syntax alternatives: The CAST specification should be used to increase the portability of applications. For more information, see [“CAST specification”](#) on page 176.

Example

- Assume that table EMPLOYEE contains a ROWID column EMP_ROWID. Also assume that the table contains a row that is identified by a row ID value that is equivalent to X'F0DFD230E3C0D80D81C201AA0A28010000000000203'. Using direct row access, select the employee number for that row.

```
SELECT EMPNO
FROM EMPLOYEE
WHERE EMP_ROWID = ROWID(X'F0DFD230E3C0D80D81C201AA0A28010000000000203')
```

RPAD

The RPAD function returns a string composed of *expression* that is padded on the right.

➤ RPAD (*expression* , *length* , *pad*) ➤

The RPAD function treats leading or trailing blanks in *expression* as significant. Padding will only occur if the actual length of *expression* is less than *length*, and *pad* is not an empty string.

expression

An expression that specifies the string from which the result is derived.

Expression must be a built-in string, numeric, or datetime data type. A numeric or datetime argument is cast to VARCHAR with a CCSID that is the default SBCS CCSID at the current server before evaluating the function. For more information about converting numeric or datetime to a character string, see “VARCHAR” on page 623.

length

An expression that specifies the length of the result. The expression must return a value that is a built-in numeric, character-string, or graphic-string data type. If the data type of the expression is not INTEGER, it is implicitly cast to INTEGER before evaluating the function. The value must be zero or a positive integer that is less than or equal to *n*, where *n* is the maximum length of the result data type. See Appendix A, “SQL limits,” on page 1643 for more information.

If *expression* is a graphic string, *length* indicates the number of DBCS or Unicode graphic characters. If *expression* is a character string, *length* indicates the number of characters where a character may consist of one or more bytes. If *expression* is a binary string, *length* indicates the number of bytes.

pad

An expression that specifies the string with which to pad. The expression must return a value that is a built-in string, numeric, or datetime data type. If the value is a numeric or datetime data type, it is implicitly cast to VARCHAR with a CCSID that is the default SBCS CCSID at the current server before evaluating the function.

If *pad* is not specified, the pad character is set as follows:

- For character and graphic strings, a single-byte, double-byte, UTF-16, or UTF-8 blank character based on the data type and CCSID of *expression*.⁷³
- For binary strings, hexadecimal zeros.

The value for *expression* and the value for *pad* must have compatible data types. If the CCSID of *pad* is different than the CCSID of *expression*, the *pad* value is converted to the CCSID of *expression*. For more information about data type compatibility, see “Assignments and comparisons” on page 89.

The data type of the result depends on the data type of *expression*:

Data type of <i>expression</i>	Data Type of the Result for RPAD
CHAR or VARCHAR or numeric or datetime	VARCHAR
CLOB	CLOB
GRAPHIC or VARGRAPHIC	VARGRAPHIC
DBCLOB	DBCLOB
BINARY or VARBINARY	VARBINARY

⁷³ UTF-16 or UCS-2 defines a blank character at code point X'0020' and X'3000'. The database manager pads with the blank at code point X'0020'. The database manager pads UTF-8 with a blank at code point X'20'

Data type of <i>expression</i>	Data Type of the Result for RPAD
BLOB	BLOB

The length attribute of the result depends on *length*. If *length* is explicitly specified by an integer constant that is greater than zero, the length attribute of the result is *length*. If *length* is explicitly specified by an integer constant that is zero, the length attribute of the result is 1. If *length* is specified as an expression, the length attribute of the result is the minimum of $m+100$ and the maximum length of the result data type, where m is the length attribute of *expression*. See [Appendix A, “SQL limits,” on page 1643](#) for more information.

The actual length of the result is determined from *length*.

- If *length* is 0, the actual length is 0 and the result is the empty result string.
- If *length* is equal to the actual length of *expression*, the actual length is the length of *expression*.
- If *length* is less than the actual length of *expression*, the result is truncated. The actual length is *length* unless the result data type is varying-length mixed data or varying-length Unicode. In this case, only complete characters will be truncated.
 - For Unicode data, the actual length may be $length-1$ to prevent a double-byte character from being split.
 - For mixed data the actual length may be as little as $length-3$ to account for truncation of a double byte character and possibly a “shift-in” character (X'0F') and a “shift-out” character (X'0E').
- If *length* is greater than the actual length of *expression*, the actual length is *length* unless the result data type is varying-length mixed data or varying-length Unicode and *pad* contains double-byte characters. In this case, only complete characters will be padded.
 - For Unicode data, the actual length may be $length-1$ to prevent a double-byte character from being split.
 - For mixed data, the actual length may be may be as little as $length-3$ to account for truncation of a double byte character and possibly a “shift-in” character (X'0F') and a “shift-out” character (X'0E'). Also, this result will not have redundant shift codes “at the seam”. Thus, if the pad is a string ending with a “shift-in” character (X'0F'), and expression begins with a “shift-out” character (X'0E'), these two bytes are eliminated from the result.

If any argument can be null, the result can be null; if any argument is null, the result is the null value.

The CCSID of the result is the same as that of *expression*.

Examples

- *Example 1:* Assume that NAME is a VARCHAR(15) column that contains the values "Chris", "Meg", and "Jeff". The following query will completely pad out a value on the right with periods:

```
SELECT RPAD(NAME,15,'.' ) AS NAME FROM T1;
```

returns:

```
NAME
-----
Chris.....
Meg.....
Jeff.....
```

- *Example 2:* Assume that NAME is a VARCHAR(15) column that contains the values "Chris", "Meg", and "Jeff". The following query will only pad each value to a length of 5:

```
SELECT RPAD(NAME,5,'.' ) AS NAME FROM T1;
```

returns:

```
NAME
-----
Chris
Meg..
Jeff.
```

- *Example 3:* Assume that NAME is a CHAR(15) column containing the values "Chris", "Meg", and "Jeff". Note that the result of RTRIM is a varying length string with the blanks removed

```
SELECT RPAD(RTRIM(NAME),15,'.' ) AS NAME FROM T1;
```

returns:

```
NAME
-----
Chris.....
Meg.....
Jeff.....
```

- *Example 4:* Assume that NAME is a VARCHAR(15) column containing the values "Chris", "Meg", and "Jeff". The following query will completely pad out a value on the right with *pad* (note that in some cases, a partial instance of the pad specification is returned):

```
SELECT RPAD(NAME,15,'123' ) AS NAME FROM T1;
```

returns:

```
NAME
-----
Chris1231231231
Meg123123123123
Jeff12312312312
```

- *Example 5:* Assume that NAME is a VARCHAR(15) column containing the values "Chris", "Meg", and "Jeff". Note that "Chris" is truncated, "Meg" is padded, and "Jeff" is unchanged:

```
SELECT RPAD(NAME,4,'.' ) AS NAME FROM T1;
```

returns:

```
NAME
----
Chri
Meg.
Jeff
```

RRN

The RRN function returns the relative record number of a row.

►► RRN — (— *table-designator* —) ►►

table-designator

A table designator that could be used to qualify a column in the same relative location in the SQL statement as the RRN function. For more information about table designators, see [“Table designators”](#) on page 133.

In SQL naming, the table name may be qualified. In system naming, the table name cannot be qualified.

The *table-designator* must not identify a *collection-derived-table*, a VALUES clause, a *table-function*, or a *data-change-table-reference*. If the argument identifies a view, common table expression, or nested table expression, its outer subselect must directly or indirectly reference a table.

If the argument identifies a view, common table expression, or nested table expression, the function returns the relative record number of its base table. If the argument identifies a view, common table expression, or nested table expression derived from more than one base table, the function returns the relative record number of the first table in the outer subselect of the view, common table expression, or nested table expression.

If the argument identifies a distributed table, the function returns the relative record number of the row on the node where the row is located. If the argument identifies a partitioned table, the function returns the relative record number of the row in the partition where the row is located. This means that RRN will not be unique for each row of a partitioned or distributed table.

The argument must not identify a view, common table expression, or nested table expression whose outer fullselect includes an aggregate function, a GROUP BY clause, a HAVING clause, a UNION, INTERSECT, or EXCEPT clause, a DISTINCT clause, a VALUES clause, or a *table-function*. The RRN function cannot be specified in a SELECT clause if the fullselect contains an aggregate function, a GROUP BY clause, or a HAVING clause.

The data type of the result is a decimal with precision 15 and scale 0. The result can be null.

Example

- Return the relative record number and employee name from table EMPLOYEE for those employees in department 20.

```
SELECT RRN(EMPLOYEE), LASTNAME
FROM EMPLOYEE
WHERE DEPTNO = 20
```

RTRIM

The RTRIM function removes any of the specified characters from the end of an expression.

► RTRIM (— *string-expression* — , — *trim-expression* —) ◄

The RTRIM function removes all of the characters that are contained in *trim-expression* from the end of *string-expression*. The collating sequence does not affect the search. If the *string-expression* is defined as FOR BIT DATA or is a binary data type, the search is done by comparing each byte in *trim-expression* to the byte at the end of *string-expression*.

string-expression

An expression that returns a value of any built-in numeric, datetime, or string data type.⁷⁴ A numeric or datetime argument is cast to a character string before evaluating the function. For more information about converting numeric or datetime to a character string, see “VARCHAR” on page 623.

trim-expression

An expression that specifies the characters to remove from the end of *string-expression*. The expression must return a value of any built-in numeric, datetime, or string data type. A numeric or datetime argument is cast to a character string before evaluating the function.

When *trim-expression* is not specified, the data type of the *string-expression* determines the default value used:

- Hexadecimal zero (X'00') if the argument is a binary string.
- DBCS blank if the argument is a DBCS graphic string.
- UTF-16 or UCS-2 blank if the first argument is a Unicode graphic string.
- UTF-8 blank if the first argument is a UTF-8 character string.
- Otherwise, a SBCS blank.

The value for *string-expression* and the value for *trim-expression* must have compatible data types. For more information about data type compatibility, see “Assignments and comparisons” on page 89. If *string-expression* and *trim-expression* have different CCSIDs, *trim-expression* is converted to the CCSID of *string-expression*.

The data type of the result depends on the data type of *string-expression*:

Data type of <i>string-expression</i>	Data type of the Result
CHAR or VARCHAR	VARCHAR
CLOB	CLOB
GRAPHIC or VARGRAPHIC	VARGRAPHIC
DBCLOB	DBCLOB
BINARY or VARBINARY	VARBINARY
BLOB	BLOB

The length attribute of the result is the same as the length attribute of *string-expression*. The actual length of the result for character or binary strings is the length of *string-expression* minus the number of bytes removed. The actual length of the result for graphic strings is the length of *string-expression* minus the number of graphic characters removed. If all characters are removed, the result is an empty string.

If either argument can be null, the result can be null; if any argument is null, the result is the null value.

The CCSID of the result is the same as that of *string-expression*.

⁷⁴ The RTRIM function returns the same results as: STRIP(*expression*,TRAILING)

Examples

- *Example 1:* Use the RTRIM function when the host variable HELLO is defined as CHAR(9) and has a value of

```
'Hello   '
```

```
VALUES RTRIM(:HELLO)
```

The result is 'Hello '. When a *trim-expression* is not specified only blanks are removed.

- *Example 2:* Use the RTRIM function to remove individual numbers in the *trim-expression* from the end (right side) of the *string-expression*.

```
SELECT RTRIM ('123DEFG123', '321'),  
       RTRIM ('12322XYZ12322222', '123'),  
       RTRIM ('12321', '213'),  
       RTRIM ('123XYX', '321')  
FROM SYSIBM.SYSDUMMY1
```

The result is:

```
'123DEFG'  
'12322XYZ'  
' ' (empty string - all characters removed)  
'123XYX' (no characters removed)
```

The RTRIM function does not remove instances of '1', '2', and '3' on the left side of the string, before characters that are not '1', '2', or '3'.

- *Example 3:* Use the RTRIM function to remove the characters specified in the *trim-expression* from the end of the *string-expression*.

```
VALUES RTRIM('...$VAR$...', '$.')
```

The result is '...\$VAR'.

- *Example 4:* Use the RTRIM function to remove the characters specified in the *trim-expression* from the end of the *string-expression*.

```
VALUES RTRIM('((-78.0) )', '-0. ()')
```

The result is '((-78'. When removing characters and blanks, you must include a blank in the *trim-expression*.

SCORE

The SCORE function searches a text search index using criteria that are specified in a search argument and returns a relevance score that measures how well a document matches the query.

►► SCORE ►►

► (— *column-name* — , — *search-argument* — , — *search-argument-options* —) ►►

search-argument-options

Notes:

¹ The same clause must not be specified more than once.

column-name

Specifies a qualified or unqualified name of a column that has a text search index that is to be searched. The column must exist in the table or view that is identified in the FROM clause in the statement and the column of the table, or the column of the underlying base table of the view must have an associated text search index. The underlying expression of the column of a view must be a simple column reference to the column of an underlying table, either directly or through another nested view.

search-argument

An expression that returns a character-string data type or graphic-string data type that contains the terms to be searched for. It must not be the empty string or contain all blanks. The actual length of the string must not exceed 32 740 bytes after conversion to Unicode and must not exceed the text search limitations or number of terms as specified in the search argument syntax. For information on *search-argument* syntax, see [Appendix G, “Text search argument syntax,” on page 1989](#).

search-argument-options

A character string or graphic string value that specifies the search argument options to use for the search. It must be a constant or a variable.

The options that can be specified as part of the *search-argument-options* are:

QUERYLANGUAGE = value

Specifies the language value. The value can be any of the supported language codes. If QUERYLANGUAGE is not specified, the default is the language value of the text search index that is used when the function is invoked. If the language value of the text search index is AUTO, the default value for QUERYLANGUAGE is en_US. For more information on the query language option, see [“Text search language options” on page 1999](#).

RESULTLIMIT = value

Specifies the maximum number of results that are to be returned from the underlying search engine. The *value* must be an integer from 1 to 2 147 483 647. If RESULTLIMIT is not specified, no result limit is in effect for the query.

SCORE may or may not be called for each row of the result table, depending on the plan that the optimizer chooses. If SCORE is called once for the query to the underlying search engine, a result set of all of the ROWIDs or primary keys that match are returned from the search engine. This result set is then joined to the table containing the column to identify the result rows. In this case, the RESULTLIMIT value acts like a FETCH FIRST *n* ROWS ONLY from the underlying text search

engine and can be used as an optimization. If SCORE is called for each row of the result because the optimizer determines that is the best plan, then the RESULTLIMIT option has no effect.

SYNONYM = OFF or SYNONYM = ON

Specifies whether to use a synonym dictionary associated with the text search index. The default is OFF.

OFF

Do not use a synonym dictionary.

ON

Use the synonym dictionary associated with the text search index.

If *search-argument-options* is the empty string or the null value, the function is evaluated as if *search-argument-options* were not specified.

The result of the function is a double-precision floating-point number. If *search-argument* can be null, the result can be null; if *search-argument* is null, the result is the null value.

The result of SCORE is a value between 0 and 1. The more frequent the column contains a match for the search criteria specified by *search-argument*, the larger the result value. If a match is not found, the result is 0. If the column value is null or *search-argument* contains only blanks or is the empty string, the result is 0.

SCORE is a non-deterministic function.

Notes

Prerequisites: In order to use the CONTAINS and SCORE functions, OmniFind Text Search Server for DB2 for i must be installed and started.

Rules: If a view, nested table expression, or common table expression provides a text search column for a CONTAINS or SCORE scalar function and the applicable view, nested table expression, or common table expression has a DISTINCT clause on the outermost SELECT, the SELECT list must contain all the corresponding key fields of the text search index.

If a view, nested table expression, or common table expression provides a text search column for a CONTAINS or SCORE scalar function, the applicable view, nested table expression, or common table expression cannot have a UNION, EXCEPT, or INTERSECT at the outermost SELECT.

If a common table expression provides a text search column for a CONTAINS or SCORE scalar function, the common table expression cannot be subsequently referenced again in the entire query unless that reference does not provide a text search column for a CONTAINS or SCORE scalar function.

CONTAINS and SCORE scalar functions are not allowed if the query specifies:

- a distributed table,
- a table with a read trigger, or
- a logical file built over multiple physical file members.

Example

- The following statement generates a list of employees in the order of how well their resumes match the query "programmer AND (java OR cobol)", along with a relevance value that is normalized between 0 (zero) and 100.

```
SELECT EMPNO, INTEGER(SCORE(RESUME, 'programmer AND
(java OR cobol)') * 100) AS RELEVANCE
FROM EMP_RESUME
WHERE RESUME_FORMAT = 'ascii'
AND CONTAINS(RESUME, 'programmer AND (java OR cobol)') = 1
ORDER BY RELEVANCE DESC
```

The database manager first evaluates the CONTAINS predicate in the WHERE clause, and therefore, does not evaluate the SCORE function in the SELECT list for every row of the table. In this case, the arguments for SCORE and CONTAINS must be identical.

SECOND

The SECOND function returns the seconds part of a value with optional fractional seconds.

expression

An expression that returns a value of one of the following built-in data types: a date, a time, a timestamp, a character string, a graphic string, or a numeric data type.

- If *expression* is a character or graphic string, its value must be a valid string representation of a datetime value. If *expression* is a valid string representation of a timestamp, it is first converted to a `TIMESTAMP(12)` value. If *expression* is a valid string representation of a date, it must be in one of the IBM SQL standard formats. For the valid formats of string representations of datetime values, see [“String representations of datetime values”](#) on page 75.
- If the argument is a `DATE`, it is first converted to a `TIMESTAMP(0)` value, assuming a time of exactly midnight (00.00.00).
- If *expression* is a number, it must be a time duration or timestamp duration. For the valid formats of datetime durations, see [“Datetime operands and durations”](#) on page 165.

precision-constant

An integer constant representing the number of fractional seconds. The value must be in the range 0 through 12.

The result of the function with a single argument is a large integer. The result of the function with two arguments is `DECIMAL(2+s,s)` where *s* is the value of the *precision-constant*. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

The other rules depend on the data type of the argument:

- If the argument is a date, a time, a timestamp, or a valid character-string representation of a date, time, or timestamp:

If only one argument is specified, the result is the seconds part of the value (0 to 59).

If both arguments are specified, the result is the seconds part of the value (0 to 59) and *precision-constant* digits of the fractional seconds part of the value. If there are no fractional seconds in the value, then zeroes are returned.

- If the argument is a time duration or timestamp duration:

If only one argument is specified, the result is the seconds part of the value (-99 to 99). A nonzero result has the same sign as the argument.

If both arguments are specified, the result is the seconds part of the value (-99 to 99) and *precision-constant* digits of the fractional seconds part of the value. If there are no fractional seconds in the value, then zeroes are returned. A nonzero result has the same sign as the argument.

Examples

- Assume that the host variable `TIME_DUR` (`DECIMAL(6,0)`) has the value 153045.

```
SELECT SECOND(:TIME_DUR)
FROM SYSIBM.SYSDUMMY1
```

Returns the value 45.

- Assume that the column `RECEIVED` (`TIMESTAMP`) has an internal value equivalent to 1988-12-25-17.12.30.000000.

```
SELECT SECOND(RECEIVED)  
FROM IN_TRAY
```

Returns the value 30.

- Get the seconds with fractional seconds from a current timestamp in milliseconds.

```
SELECT SECOND(CURRENT_TIMESTAMP(3), 3)  
FROM SYSIBM.SYSDUMMY1
```

Returns a DECIMAL(5,3) value based on the current timestamp that could be something like 54.321.

SIGN

The SIGN function returns an indicator of the sign of expression.

►► SIGN (— *expression* —) ◄◄

The returned value is:

- 1**
if the argument is less than zero
- 0**
if the argument is DECFLOAT negative zero
- 0**
if the argument is zero
- 1**
if the argument is greater than zero

expression

An expression that returns a value of any built-in numeric, character-string, or graphic-string data type. A string argument is converted to double-precision floating point before evaluating the function. For more information about converting strings to double-precision floating point, see [“DOUBLE_PRECISION or DOUBLE”](#) on page 392.

The result has the same data type and length attribute as the argument, except that precision is increased by one if the argument is DECIMAL or NUMERIC and the scale of the argument is equal to its precision. For example, an argument with a data type of DECIMAL(5,5) will result in DECIMAL(6,5). If the precision is already the maximum precision (*mp*), the scale will be decreased by one. For example, DECIMAL(63,63) will result in DECIMAL(63,62).

If the argument can be null, the result can be null; if the argument is null, the result is the null value.

Example

- Assume that host variable PROFIT is a large integer with a value of 50000.

```
SELECT SIGN(:PROFIT)
FROM EMPLOYEE
```

Returns the value 1.

SIN

The SIN function returns the sine of the argument, where the argument is an angle expressed in radians. The SIN and ASIN functions are inverse operations.

►► SIN — (— *expression* —) ◄◄

expression

An expression that returns a value of any built-in numeric data type (except for DECFLOAT), character-string, or graphic-string data type. A string argument is converted to double-precision floating point before evaluating the function. For more information about converting strings to double-precision floating point, see [“DOUBLE_PRECISION or DOUBLE”](#) on page 392.

The data type of the result is double-precision floating point. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

Example

- Assume the host variable SINE is a decimal (2,1) host variable with a value of 1.5.

```
SELECT SIN(:SINE)
FROM SYSIBM.SYSDUMMY1
```

Returns the approximate value 0.99.

SINH

The SINH function returns the hyperbolic sine of the argument, where the argument is an angle expressed in radians.

►► SINH (— *expression* —) ►►

expression

An expression that returns a value of any built-in numeric data type (except for DECFLOAT), character-string, or graphic-string data type. A string argument is converted to double-precision floating point before evaluating the function. For more information about converting strings to double-precision floating point, see [“DOUBLE_PRECISION or DOUBLE”](#) on page 392.

The data type of the result is double-precision floating point. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

Example

- Assume the host variable HSINE is a decimal (2,1) host variable with a value of 1.5.

```
SELECT SINH (:HSINE)
FROM SYSIBM.SYSDUMMY1
```

Returns the approximate value 2.12.

SMALLINT

The SMALLINT function returns a small integer representation.

Numeric to Smallint

►► SMALLINT — (— *numeric-expression* —) ►◄

String to Smallint

►► SMALLINT — (— *string-expression* —) ►◄

The SMALLINT function returns a small integer representation of

- A number
- A character or graphic string representation of a decimal number
- A character or graphic string representation of an integer
- A character or graphic string representation of a floating-point number
- A character or graphic string representation of a decimal floating-point number

Numeric to Smallint

numeric-expression

An expression that returns a numeric value of any built-in numeric data type.

The result is the same number that would occur if the argument were assigned to a small integer column or variable. If the whole part of the argument is not within the range of small integers, an error is returned. The fractional part of the argument is truncated.

String to Smallint

string-expression

An expression that returns a value that is a character-string or graphic-string representation of a number.

If the argument is a *string-expression*, the result is the same number that would result from `CAST(string-expression AS SMALLINT)`. Leading and trailing blanks are eliminated and the resulting string must conform to the rules for forming a floating-point, decimal floating-point, integer, or decimal constant. If the whole part of the argument is not within the range of small integers, an error is returned. Any fractional part of the argument is truncated.

The result of the function is a small integer. If the argument can be null, the result can be null. If the argument is null, the result is the null value.

Note

Syntax alternatives: The CAST specification should be used to increase the portability of applications. For more information, see [“CAST specification” on page 176](#).

Example

- Using the EMPLOYEE table, select a list containing salary (SALARY) divided by education level (EDLEVEL). Truncate any decimal in the calculation. The list should also contain the values used in the calculation and the employee number (EMPNO).

```
SELECT SMALLINT(SALARY / EDLEVEL), SALARY, EDLEVEL, EMPNO
FROM EMPLOYEE
```

SOUNDEX

The SOUNDEX function returns a 4 character code representing the sound of the words in the argument. The result can be used to compare with the sound of other strings.

►► SOUNDEX — (— *expression* —) ►►

expression

An expression that returns a value of any built-in numeric or string data type, that is not a CLOB or DBCLOB. The argument cannot be a binary string. A numeric argument is cast to a character string before evaluating the function. For more information about converting numeric to a character string, see [“VARCHAR”](#) on page 623.

The data type of the result is CHAR(4). If the argument can be null, the result can be null; if the argument is null, the result is the null value.

The CCSID of the result is the default CCSID of the current server.

The SOUNDEX function is useful for finding strings for which the sound is known but the precise spelling is not. It makes assumptions about the way that letters and combinations of letters sound that can help to search out words with similar sounds. The comparison can be done directly or by passing the strings as arguments to the DIFFERENCE function. For more information, see [“DIFFERENCE”](#) on page 381.

Example

- Using the EMPLOYEE table, find the EMPNO and LASTNAME of the employee with a surname that sounds like 'Loucesy'.

```
SELECT EMPNO, LASTNAME
FROM EMPLOYEE
WHERE SOUNDEX(LASTNAME) = SOUNDEX('Loucesy')
```

Returns the row:

```
000110 LUCCHESI
```

SPACE

The SPACE function returns a character string that consists of the number of SBCS blanks that the argument specifies.

►► SPACE — (— *expression* —) ◄◄

expression

An expression that returns a value of any built-in SMALLINT, INTEGER, BIGINT, character-string, or graphic-string data type. A string argument is converted to integer before evaluating the function. For more information about converting strings to integer, see [“INTEGER or INT” on page 442](#).

The *expression* specifies the number of SBCS blanks for the result, and it must be between 0 and 32740. If *expression* is a constant, it must not be the constant 0.

The result of the function is a varying-length character string (VARCHAR) that contains SBCS data.

If *expression* is a constant, the length attribute of the result is the constant. Otherwise, the length attribute of the result is 4000. The actual length of the result is the value of *expression*. The actual length of the result must not be greater than the length attribute of the result.

If the argument can be null, the result can be null; if the argument is null, the result is the null value.

The CCSID is the default CCSID for SBCS data of the job.

Example

- The following statement returns a character string that consists of 5 blanks.

```
SELECT SPACE(5)
FROM SYSIBM.SYSDUMMY1
```

SQRT

The SQRT function returns the square root of a number.

►► SQRT — (— *expression* —) ►►

expression

An expression that returns a value of any built-in numeric, character-string, or graphic-string data type. A string argument is converted to double-precision floating point before evaluating the function. For more information about converting strings to double-precision floating point, see [“DOUBLE_PRECISION or DOUBLE” on page 392](#). The value of *expression* must be greater than or equal to zero.

If the data type of the argument is DECFLOAT(*n*), the result is DECFLOAT(*n*). Otherwise, the data type of the result is double-precision floating point. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

Note

Results involving DECFLOAT special values: For decimal floating-point values the special values are treated as follows:

- SQRT(NaN) returns NaN. ⁷⁵
- SQRT(-NaN) returns NaN. ⁷⁵
- SQRT(Infinity) returns Infinity.
- SQRT(-Infinity) returns NaN. ⁷⁵
- SQRT(sNaN) and SQRT(-sNaN) return a warning or error. ⁶²

Example

- Assume the host variable SQUARE is a DECIMAL(2,1) host variable with a value of 9.0.

```
SELECT SQRT(:SQUARE)
FROM SYSIBM.SYSDUMMY1
```

Returns the approximate value 3.00.

⁷⁵ If *YES is specified for the SQL_DECFLOAT_WARNINGS query option, NaN is returned with a warning.

STRIP

The STRIP function removes blanks or another specified character from the end, the beginning, or both ends of a string expression.

The STRIP function is identical to the TRIM scalar function. For more information, see [“TRIM” on page 609](#).

STRLEFT

The STRLEFT function returns the leftmost *integer* characters of *expression*.

► STRLEFT (— *expression* — , — *integer* —) ◄

The STRLEFT function is identical to the LEFT function. For more information, see [“LEFT” on page 472](#).

STRPOS

The STRPOS function returns the starting position of the first occurrence of one string (called the *search-string*) within another string (called the *source-string*). If the *search-string* is not found and neither argument is null, the result is zero. If the *search-string* is found, the result is a number from 1 to the actual length of the *source-string*.

►► STRPOS — (— *source-string* — , — *search-string* —) ◄◄

The STRPOS function is identical to the POSSTR function. For more information, see [“POSSTR” on page 527](#).

STRRIGHT

The STRRIGHT function returns the rightmost *integer* characters of *expression*.

►► STRRIGHT (— *expression* — , — *integer* —) ◄◄

The STRRIGHT function is identical to the RIGHT function. For more information, see [“RIGHT” on page 551](#).

SUBSTR

The SUBSTR function returns a substring of a string.

► SUBSTR (*expression* , *start* , *length*) ◄

expression

An expression that specifies the string from which the result is derived.

Expression must be any built-in numeric or string data type. A numeric argument is cast to a character string before evaluating the function. For more information about converting numeric to a character string, see “VARCHAR” on page 623. If *expression* is a character string, the result of the function is a character string. If it is a graphic string, the result of the function is a graphic string. If it is a binary string, the result of the function is a binary string.

A substring of *expression* is zero or more contiguous characters of *expression*. If *expression* is a graphic string, a character is a DBCS or Unicode graphic character. If *expression* is a character string, a character is a byte.⁷⁶ If *expression* is a binary string, a character is a byte.

start

An expression that specifies the position within *expression* of the first character (or byte) of the result. The expression must return a value that is a built-in BIGINT, INTEGER, or SMALLINT data type. A value of 1 indicates that the first character of the result is the first character of *expression*. A negative or zero value indicates a position before the beginning of the string. It may also be greater than the length attribute of *expression*. (The length attribute of a varying-length string is its maximum length.)

length

An expression that specifies the length of the result. If specified, *length* must be an expression that returns a value that is a built-in BIGINT, INTEGER, or SMALLINT data type. The value must be greater than or equal to 0.

If *length* is explicitly specified, *expression* is effectively padded on the right with the necessary number of blank characters so that the specified substring of *expression* always exists. Hexadecimal zeroes are used as the padding character when *expression* is a binary string.

If *expression* is a fixed-length string, omission of *length* is an implicit specification of $\text{LENGTH}(\textit{expression}) - \textit{start} + 1$, which is the number of characters (or bytes) from the *start* character (or byte) to the last character (or byte) of *expression*. If *expression* is a varying-length string, omission of *length* is an implicit specification of zero or $\text{LENGTH}(\textit{expression}) - \textit{start} + 1$, whichever is greater. If the resulting length is zero, the result is the empty string.

The data type of the result depends on the data type of *expression*:

Data type of <i>expression</i>	Data Type of the Result for SUBSTR
CHAR or VARCHAR	CHAR, if: <ul style="list-style-type: none"><i>length</i> is explicitly specified by an integer constant that is greater than zero.<i>length</i> is not explicitly specified, but <i>expression</i> is a fixed-length string and <i>start</i> is an integer constant. VARCHAR, in all other cases
CLOB	CLOB

⁷⁶ The SUBSTR function accepts mixed data strings. However, because SUBSTR operates on a strict byte-count basis, the result will not necessarily be a properly formed mixed data string.

Data type of <i>expression</i>	Data Type of the Result for SUBSTR
GRAPHIC or VARGRAPHIC	GRAPHIC, if: <ul style="list-style-type: none"> • <i>length</i> is explicitly specified by an integer constant that is greater than zero. • <i>length</i> is not explicitly specified, but <i>expression</i> is a fixed-length string and <i>start</i> is an integer constant. VARGRAPHIC, in all other cases.
DBCLOB	DBCLOB
BINARY or VARBINARY	BINARY, if: <ul style="list-style-type: none"> • <i>length</i> is explicitly specified by an integer constant that is greater than zero. • <i>length</i> is not explicitly specified, but <i>expression</i> is a fixed-length string and <i>start</i> is an integer constant. VARBINARY, in all other cases.
BLOB	BLOB

If *expression* is not a LOB, the length attribute of the result depends on *length*, *start*, and the attributes of *expression*.

- If *length* is explicitly specified by an integer constant that is greater than zero, the length attribute of the result is *length*.
- If *length* is not explicitly specified, but *expression* is a fixed-length string and *start* is an integer constant, the length attribute of the result is $\text{LENGTH}(\text{expression}) - \text{start} + 1$.

In all other cases, the length attribute of the result is the same as the length attribute of *expression*. (Remember that if the actual length of *expression* is less than the value for *start*, the actual length of the substring is zero.)

If any argument can be null, the result can be null; if any argument is null, the result is the null value.

The CCSID of the result is the same as that of *expression*.

Examples

- Assume the host variable NAME (VARCHAR(50)) has a value of 'KATIE AUSTIN' and the host variable SURNAME_POS (INTEGER) has a value of 7.

```
SELECT SUBSTR(:NAME, :SURNAME_POS)
FROM SYSIBM.SYSDUMMY1
```

Returns the value 'AUSTIN'.

- Likewise,

```
SELECT SUBSTR(:NAME, :SURNAME_POS, 1)
FROM SYSIBM.SYSDUMMY1
```

Returns the value 'A'.

- Select all rows from the PROJECT table for which the project name (PROJNAME) starts with the word 'OPERATION '.

```
SELECT *
FROM PROJECT
WHERE SUBSTR(PROJNAME,1,10) = 'OPERATION '
```

The space at the end of the constant is necessary to preclude initial words such as 'OPERATIONS'.

SUBSTRING

The SUBSTRING function returns a substring of a string.

expression

An expression that specifies the string from which the result is derived.

Expression must be any built-in numeric or string data type. A numeric argument is cast to a character string before evaluating the function. For more information about converting numeric to a character string, see “VARCHAR” on page 623. If *expression* is a character string, the result of the function is a character string. If it is a graphic string, the result of the function is a graphic string. If it is a binary string, the result of the function is a binary string.

A substring of *expression* is zero or more contiguous characters of *expression*. If *expression* is a graphic string, a character is a DBCS or Unicode graphic character. If *expression* is a character string, a character is a character that may consist of one or more bytes. If *expression* is a binary string, a character is a byte.

start

An expression that specifies the position within *expression* of the first character (or byte) of the result. The expression must return a value that is a built-in BIGINT, INTEGER, or SMALLINT data type. A value of 1 indicates that the first character of the result is the first character of *expression*. A negative or zero value indicates a position before the beginning of the string. It may also be greater than the length attribute of *expression*. (The length attribute of a varying-length string is its maximum length.)

length

An expression that specifies the maximum actual length of the resulting substring. If specified, *length* must be an expression that returns a value that is a built-in BIGINT, INTEGER, or SMALLINT data type. The value must be greater than or equal to 0.

If *length* is explicitly specified, padding is not performed.

If *expression* is a fixed-length string, omission of *length* is an implicit specification of $\text{LENGTH}(\text{expression}) - \text{start} + 1$, which is the number of characters (or bytes) from the *start* character (or byte) to the last character (or byte) of *expression*. If *expression* is a varying-length string, omission of *length* is an implicit specification of zero or $\text{LENGTH}(\text{expression}) - \text{start} + 1$, whichever is greater. If the resulting length is zero, the result is the empty string.

The data type of the result depends on the data type of *expression*:

Data type of <i>expression</i>	Data Type of the Result for SUBSTRING
CHAR or VARCHAR	VARCHAR
CLOB	CLOB
GRAPHIC or VARGRAPHIC	VARGRAPHIC
DBCLOB	DBCLOB
BINARY or VARBINARY	VARBINARY
BLOB	BLOB

The length attribute of the result is the same as the length attribute of *expression*. (Remember that if the actual length of *expression* is less than the value for *start*, the actual length of the substring is zero.)

If any argument can be null, the result can be null; if any argument is null, the result is the null value.
The CCSID of the result is the same as that of *expression*.

Examples

- Select all rows from the PROJECT table for which the project name (PROJNAME) starts with the word 'OPERATION '.

```
SELECT *  
FROM PROJECT  
WHERE SUBSTRING(PROJNAME,1,10) = 'OPERATION '
```

The space at the end of the constant is necessary to preclude initial words such as 'OPERATIONS'.

- Assume that FIRSTNAME is a VARCHAR(12) column, encoded in Unicode UTF-8, in T1. One of its values is the 6-character string 'Jürgen'. When FIRSTNAME has this value:

```
SELECT SUBSTRING(FIRSTNAME, 1,2), SUBSTR(FIRSTNAME, 1,2)  
FROM T1
```

Returns the values 'Jü' (x'4AC3BC') and 'Jô' (x'4AC3').

TABLE_NAME

The TABLE_NAME function returns an unqualified name of the object found for an alias.

►► TABLE_NAME (— *object-name* — — *object-schema* —) ◄◄

The specified *object-name* (and *object-schema*) are used to find an alias by that name.

object-name

A character or graphic string expression that identifies the SQL or system name of the object to be resolved. *object-name* must have an actual length less than 129 characters and may not identify a blank name. This name is case sensitive and must not be delimited.

object-schema

A character or graphic string expression that identifies the SQL or system name of the schema used to qualify *object-name*. *object-schema* must have an actual length less than 129 characters and may not identify a blank name. This name is case sensitive and must not be delimited.

If *object-schema* is not supplied, the default schema is used for the qualifier.

The result of the function is VARCHAR(128). If *object-name* can be null, the result can be null; if *object-name* is null, the result is the null value. If *object-schema* is the null value, the default schema name is used. The result is the character string representing an unqualified name.

The result name is the table name or view name referenced by the alias. If *object-name* is not an alias name, *object-name* is returned.

Example

Get the name of the table referenced by an alias that was created like this:

```
CREATE ALIAS MYLIB2.ALIAS1 FOR MYLIB.EMPLOYEE  
  
VALUES TABLE_NAME('ALIAS1', 'MYLIB2')
```

The result is:

```
EMPLOYEE
```

TAN

The TAN function returns the tangent of the argument, where the argument is an angle expressed in radians. The TAN and ATAN functions are inverse operations.

►► TAN — (— *expression* —) ◄◄

expression

An expression that returns a value of any built-in numeric data type (except for DECFLOAT), character-string, or graphic-string data type. A string argument is converted to double-precision floating point before evaluating the function. For more information about converting strings to double-precision floating point, see [“DOUBLE_PRECISION or DOUBLE”](#) on page 392.

The data type of the result is double-precision floating point. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

Example

- Assume the host variable TANGENT is a DECIMAL(2,1) host variable with a value of 1.5.

```
SELECT TAN (:TANGENT)
FROM SYSIBM.SYSDUMMY1
```

Returns the approximate value 14.10.

TANH

The TANH function returns the hyperbolic tangent of the argument, where the argument is an angle expressed in radians. The TANH and ATANH functions are inverse operations.

►► TANH — (— *expression* —) ►◄

expression

An expression that returns a value of any built-in numeric data type (except for DECFLOAT), character-string, or graphic-string data type. A string argument is converted to double-precision floating point before evaluating the function. For more information about converting strings to double-precision floating point, see [“DOUBLE_PRECISION or DOUBLE”](#) on page 392.

The data type of the result is double-precision floating point. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

Example

- Assume the host variable HTANGENT is a DECIMAL(2,1) host variable with a value of 1.5.

```
SELECT TANH (:HTANGENT)
FROM SYSIBM.SYSDUMMY1
```

Returns the approximate value 0.90.

TIME

The TIME function returns a time from a value.

►► TIME — (— *expression* —) ◄◄

expression

An expression that returns a value of one of the following built-in data types: a date, a time, a timestamp, a character string, or a graphic string.

If *expression* is a character or graphic string, its value must be a valid string representation of a date, time, or timestamp. If *expression* is a valid string representation of a date, it must be one of the IBM SQL standard formats. For the valid formats of string representations of dates, times, and timestamps, see [“String representations of datetime values” on page 75](#).

The result of the function is a time. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

The other rules depend on the data type of the argument:

- If the argument is a date:

The result is midnight.

- If the argument is a time:

The result is that time.

- If the argument is a timestamp:

The result is the time part of the timestamp.

- If the argument is a character or graphic string:

The result is the time represented by the string or the time part of the timestamp value represented by the string.

Note

Syntax alternatives: The CAST specification should be used to increase the portability of applications. For more information, see [“CAST specification” on page 176](#).

Example

- Select all notes from the IN_TRAY sample table that were received at least one hour later in the day (any day) than the current time.

```
SELECT *
FROM IN_TRAY
WHERE TIME(RECEIVED) >= CURRENT TIME + 1 HOUR
```

TIMESTAMP

The `TIMESTAMP` function returns a timestamp from its argument or arguments.

expression-1 and *expression-2*

The rules for the arguments depend on whether a second argument is specified and the data type of the second argument.

- If only *expression-1* is specified:

The argument must be an expression that returns a value of one of the following built-in data types: a date, a timestamp, a character string, or a graphic string. If *expression-1* is a character or graphic string, its value must be one of the following:

- A valid string representation of a date or a timestamp. For the valid formats of string representations of dates and timestamps, see [“String representations of datetime values” on page 75](#).
- A character string with an actual length of 13 that is assumed to be a result from a `GENERATE_UNIQUE` function. For information on `GENERATE_UNIQUE`, see [“GENERATE_UNIQUE” on page 410](#).

- If both arguments are specified:

- If the second argument is *expression-2*:

The first argument must be an expression that returns a value of one of the following built-in data types: a date, a character string, or a graphic string. If *expression-1* is a character or graphic string, its value must be a valid string representation of a date.

expression-2 must be an expression that returns a value of one of the following built-in data types: a time, a character string, or a graphic string. If *expression-2* is a character or graphic string, its value must be a valid string representation of a time. For the valid formats of string representations of dates and times, see [“String representations of datetime values” on page 75](#).

- If the second argument is *precision-constant*:

The first argument must be an expression that returns a value of one of the following built-in data types: a date, a timestamp, a character string, or a graphic string. If *expression-1* is a character or graphic string, its value must be one of the following:

- A valid string representation of a date or timestamp. For the valid formats of string representations of dates and timestamps, see [“String representations of datetime values” on page 75](#).
- A character string with an actual length of 13 that is assumed to be a result from a `GENERATE_UNIQUE` function. For information on `GENERATE_UNIQUE`, see [“GENERATE_UNIQUE” on page 410](#).

precision-constant

An integer constant representing the number of fractional seconds. The value must be in the range 0 through 12.

The result of the function is a timestamp. If either argument can be null, the result can be null; if either argument is null, the result is the null value.

The other rules depend on whether the second argument is specified:

- If both arguments are specified and the second argument is *expression-2*:

The result is a `TIMESTAMP(6)` with the date specified by the first argument and the time specified by the second argument. The fractional seconds part of the timestamp is zero.

- If both arguments are specified and the second argument is *precision-constant*:

The result is a timestamp with the precision specified by the second argument.

- If only one argument is specified and it is a `TIMESTAMP(p)`:

The result is a `TIMESTAMP(p)`.

- If only one argument is specified and it is a `DATE`:

The result is that date with an assumed time of midnight cast to `TIMESTAMP(0)`.

- If only one argument is specified and it is a string:

The result is the `TIMESTAMP(6)` represented by that string. If the argument is a string of length 14, the timestamp has a fractional seconds part of zero.

Note

Syntax alternatives: The `CAST` specification should be used to increase the portability of applications when only one argument is specified. For more information, see [“CAST specification”](#) on page 176.

Examples

- Assume the following date and time values:

```
SELECT TIMESTAMP( DATE('1988-12-25'), TIME('17.12.30') )
FROM SYSIBM.SYSDUMMY1
```

Returns the value '1988-12-25-17.12.30.000000'.

- Convert a timestamp string with 7 digits of fractional seconds to a `TIMESTAMP(9)` value.

```
TIMESTAMP('2007-09-24-15.53.37.2162474', 9)
```

Returns the value '2007-09-24-15.53.37.216247400'.

TIMESTAMP_FORMAT

The `TIMESTAMP_FORMAT` function returns a timestamp that is based on the interpretation of the input string using the specified format.

►► `TIMESTAMP_FORMAT` (— *string-expression* — , — *format-string* — ►►

string-expression

An expression that returns a value of any built-in character string data type or graphic string data type.

The string is interpreted as a date or timestamp using the format specified by *format-string*. The *string-expression* must contain only the components of a date or timestamp that correspond to the format elements specified by *format-string*.

format-string

An expression that returns a built-in character string data type or graphic string data type. *format-string* contains a template of how *string-expression* is to be interpreted as a date or a timestamp value.

A valid *format-string* must contain at least one format element, must not contain multiple specifications for any component of a date or a timestamp, and can contain any combination of the format elements, unless otherwise noted in [Table 58 on page 592](#). For example, *format-string* cannot contain both `YY` and `YYYY`, because they are both used to interpret the year component of *string-expression*. Refer to the table to determine which format elements cannot be specified together.

Two format elements can optionally be separated by one or more of the following separator characters:

- minus sign (-)
- period (.)
- slash (/)
- comma (,)
- apostrophe (')
- semicolon (;)
- colon (:)
- blank ()

Separator characters can also be specified at the start or end of *format-string*. These separator characters can be used in any combination in the format string, for example 'YYYY/MM-DD HH24:MM.SS'. Separator characters specified in a *string-expression* are used to separate components and are not required to match the separator characters specified in the *format-string*.

Table 58. Format elements for the `TIMESTAMP_FORMAT` function

Format element	Related components of a timestamp	Description
AM or PM ^{1, 2}	hour	Meridian indicator (morning or evening) without periods. The meridian indicator is retrieved from message CPX9035 in message file QCPFMSG in library *LIBL.

Table 58. Format elements for the `TIMESTAMP_FORMAT` function (continued)

Format element	Related components of a timestamp	Description
A.M. or P.M. ^{1, 2}	hour	Meridian indicator (morning or evening) with periods. This format element uses the exact strings 'A.M.' or 'P.M.' and is independent of the language used for messages in the job.
DAY, Day, or day ^{1, 3}	none	Name of the day in uppercase, titlecase, or lowercase format. The name of the day is retrieved from message CPX9034 in message file QCPFMSG in library *LIBL.
DY, Dy, or dy ^{1, 3}	none	Abbreviated name of the day in uppercase, titlecase, or lowercase format. The abbreviated name of the day is retrieved from message CPX9039 in message file QCPFMSG in library *LIBL.
D ^{1, 3}	none	Day of week (1-7), where 1 is Sunday.
DD	day	Day of month (01-31).
DDD	month, day	Day of year (001-366).
FF or FF n	fractional seconds	Fractional seconds (0-999999999999). The number n is used to specify the number of digits expected in the <i>string-expression</i> . Valid values for n are 1-12. Specifying FF is equivalent to specifying FF6. When the component in <i>string-expression</i> that corresponds to the FF format element is followed by a separator character or is the last component, the number of digits for the fractional seconds can be less than what is specified by the format element. In this case, zero digits are padded onto the right of the specified digits.
HH	hour	HH behaves the same as HH12.
HH12	hour	Hour of the day (01-12) in 12-hour format. AM is the default meridian indicator.
HH24	hour	Hour of the day (00-24) in 24-hour format.
J	year, month, and day	Julian date (number of days since January 1, 4713 BC).
MI	minute	Minute (00-59).
MM	month	Month (01-12).
MONTH, Month, or month ¹	month	Name of the month in uppercase, titlecase, or lowercase format. The name of the month is retrieved from message CPX3BC0 in message file QCPFMSG in library *LIBL.
MON, Mon, or mon ¹	month	Abbreviated name of the month in uppercase, titlecase, or lowercase format. The name of the month is retrieved from message CPX8601 in message file QCPFMSG in library *LIBL.
NNNNNN	microseconds	Microsecond (same as FF6).
RR ⁴	year	Last 2 digits of the adjusted year (00-99).
RRRR ⁴	year	Four digit adjusted year (0000-9999).
SS	seconds	Seconds (00-59).

Table 58. Format elements for the `TIMESTAMP_FORMAT` function (continued)

Format element	Related components of a timestamp	Description
SSSSS	hours, minutes, and seconds	Seconds since previous midnight (00000-86400).
Y	year	Last digit of the year (0-9). First three digits of the current year are used to determine the full 4-digit year.
YY	year	Last 2 digits of the year (00-99). First two digits of the current year are used to determine the full 4-digit year.
YYY	year	Last three digits of the year (000-999). First digit of the current year is used to determine the full 4-digit year.
YYYY	year	4-digit year (0000-9999).

Notes:

1. Only these exact spellings and case combinations can be used. If this format element is specified in an invalid case combination an error is returned.
2. The AM and PM set of meridian indicators can be used interchangeably in the *format-string*, as can A.M. and P.M. If HH24 is used in the *format-string* along with a meridian indicator, the value of the meridian indicator in the *string-expression* is not used for determining the hour portion of the resulting timestamp.
3. The DAY, Day, day DY, Dy, dy, and D format elements do not contribute to any components of the resulting timestamp. However, a specified value for any of these format elements must be correct for the combination of the year, month, and day components of the resulting timestamp. For example, a value of 'Monday 2008-10-06' for *string-expression* is valid for a value of 'Day YYYY-MM-DD'. However, a value of 'Tuesday 2008-10-06' for *string-expression* would result in an error for the same *format-string*.
4. The RR and RRRR format elements can be used to alter how a specification for a year is to be interpreted by adjusting the value to produce a 2-digit or a 4-digit value depending on the leftmost two digits of the current year according to the following table:

Last two digits of current year	Two digits of year in <i>string-expression</i>	First 2 digits of the year component of date or timestamp
0-50	0-49	First 2 digits of current year
51-99	0-49	First 2 digits of current year + 1
0-50	50-99	First 2 digits of current year - 1
51-99	50-99	First 2 digits of current year

For example, if the current year is 2007, '86' with format 'RR' means 1986, but if the current year is 2052, it means 2086.

The following defaults will be used when a *format-string* does not include a format element for one of the components of a timestamp:

Timestamp component	Default
year	current year, as 4 digits
month	current month, as 2 digits
day	01 (first day of the month)

Timestamp component	Default
hour	00
minute	00
second	00
fractional seconds	a number of zeros matching the timestamp precision of the result

If *string-expression* does not include a value that corresponds to an hour, minute, second, or fractional seconds format element that is specified in the *format-string*, these same defaults are used.

Leading zeros can be specified for any component of the date or timestamp value (for example, month, day, hour, minutes, seconds) that does not have the maximum number of significant digits for the corresponding format element in the *format-string*.

A substring of the *string-expression* representing a component of a date or timestamp (such as year, month, day, hour, minutes, seconds) can include less than the maximum number of digits for that component of the date or timestamp. Any missing digits default to zero. For example, with a format-string of 'YYYY-MM-DD HH24:MI:SS', an input value of '999-3-9 5:7:2' would produce the same result as '0999-03-09 05:07:02'.

precision-constant

An integer constant that specifies the timestamp precision of the result. The value must be in the range 0 to 12. If *precision-constant* is not specified, the timestamp precision defaults to 6.

The result is a timestamp with a precision that is based on *precision-constant*. If either of the first two arguments can be null, the result can be null; if either of the first two arguments is null, the result is the null value.

Notes

Julian and Gregorian calendar: The transition from the Julian calendar to the Gregorian calendar on 15 October 1582 is taken into account by this function.

Syntax alternatives: TO_DATE is a synonym for TIMESTAMP_FORMAT. TO_TIMESTAMP is identical to TIMESTAMP_FORMAT except that if *precision-constant* is not specified, the timestamp precision of the result defaults to 12.

Examples

- Insert a row into the IN_TRAY table with a receiving timestamp that is equal to one second before the beginning of the year 2000 (December 31, 1999 at 23:59:59).

```
INSERT INTO IN_TRAY (RECEIVED)
VALUES (TIMESTAMP_FORMAT('1999-12-31 23:59:59',
'YYYY-MM-DD HH24:MI:SS'))
```

- An application receives strings of date information into a variable called INDATEVAR. This value is not strictly formatted and might include two or four digits for years, and one or two digits for months and days. Date components might be separated with minus sign (-) or slash (/) characters and are expected to be in day, month, and year order. Time information consists of hours (in 24-hour format) and minutes, and is usually separated by a colon. Sample values include '15/12/98 13:48' and '9-3-2004 8:02'. Insert such values into the IN_TRAY table.

```
INSERT INTO IN_TRAY (RECEIVED)
VALUES (TIMESTAMP_FORMAT(:INDATEVAR,
'DD/MM/RRRR HH24:MI'))
```

The use of RRRR in the format allows for 2- and 4-digit year values and assigns missing first two digits based on the current year. If YYYY were used, input values with a 2-digit year would have leading zeros.

The slash separator also allows the minus sign character. Assuming a current year of 2007, resulting timestamps from the sample values are:

```
'15/12/98 13:48' --> 1998-12-15-13.48.00.000000
'9-3-2004 8:02'  --> 2004-03-09-08.02.00.000000
```

- Set the character variable TVAR to the value of ROUTINE_CREATED from QSYS2.SYSPROCS if it is equal to one second before the beginning of the year 2000 ('1999-12-31 23:59:59'). The character string should be interpreted according to the format string provided.

```
SELECT VARCHAR_FORMAT(ROUTINE_CREATED, 'YYYY-MM-DD HH24:MI:SS')
INTO :TVAR
FROM QSYS2.SYSPROCS
WHERE ROUTINE_CREATED =
      TIMESTAMP_FORMAT('1999-12-31 23:59:59', 'YYYY-MM-DD HH24:MI:SS')
```

- Return timestamp values for strings containing meridian indicators:

<i>string-expression</i>	<i>format-expression</i>	Result timestamp value
'2015-10-28 10:29AM'	'YYYY-MM-DD HH12:MIAM'	2015-10-28-10.29.00.000000
'2015-10-28 10:29PM'	'YYYY-MM-DD HH12:MIAM'	2015-10-28-22.29.00.000000
'2015-10-28 10:29AM'	'YYYY-MM-DD HH24:MIAM'	2015-10-28-10.29.00.000000
'2015-10-28 10:29PM'	'YYYY-MM-DD HH24:MIAM'	2015-10-28-10.29.00.000000
'2015-10-28 22:29AM'	'YYYY-MM-DD HH24:MIAM'	2015-10-28-22.29.00.000000
'2015-10-28 22:29PM'	'YYYY-MM-DD HH24:MIAM'	2015-10-28-22.29.00.000000

TIMESTAMP_ISO

Returns a timestamp value based on a date, time, or timestamp argument. If the argument is a date, it inserts zero for the time and fractional seconds part of the timestamp. If the argument is a time, it inserts the value of CURRENT DATE for the date part of the timestamp and zero for the fractional seconds part of the timestamp.

►► **TIMESTAMP_ISO** — (— *expression* —) ◄◄

expression

An *expression* that returns a value of one of the following built-in data types: a timestamp, a date, a time, a character string, or a graphic string.

If *expression* is a character or graphic string, its value must be a valid string representation of a date or timestamp. For the valid formats of string representations of dates and timestamps, see [“String representations of datetime values”](#) on page 75.

If *expression* is a timestamp, the result of the function is a timestamp with the same precision as *expression*. Otherwise, the result of the function is `TIMESTAMP(6)`. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

If *expression* is a time, the function is not deterministic.

Note

Syntax alternatives: The CAST specification should be used to increase the portability of applications. For more information, see [“CAST specification”](#) on page 176.

Example

- Assume the following date value:

```
SELECT TIMESTAMP_ISO( DATE( '1988-12-25' ) )  
FROM SYSIBM.SYSDUMMY1
```

Returns the value '1988-12-25-00.00.00.000000'.

TIMESTAMPDIFF

The TIMESTAMPDIFF function returns an estimated number of intervals of the type defined by the first argument, based on the difference between two timestamps.

►► TIMESTAMPDIFF (— *numeric-expression* — , — *string-expression* —) ►►

numeric-expression

The first argument must be a built-in data type of either INTEGER or SMALLINT. The value specifies the interval that is used to determine the difference between two timestamps. Valid values of the interval follow.

Table 59. Valid values for *numeric-expression* and equivalent intervals that are used to determine the difference between two timestamps

Valid values for <i>numeric-expression</i>	Equivalent intervals
1	Microseconds
2	Seconds
4	Minutes
8	Hours
16	Days
32	Weeks
64	Months
128	Quarters
256	Years

string-expression

string-expression is the result of subtracting two timestamps and converting the result to a string of length 22. If the *string-expression* has more than 6 digits to the right of the decimal point, the string will be truncated to 6 digits. The argument must be an expression that returns a value of a built-in character string or a graphic string.

If a positive or negative sign is present, it is the first character of the string. The following table describes the elements of the character string duration:

Table 60. TIMESTAMPDIFF String Elements

String elements	Valid values	Character position from the decimal point (negative is left)
Years	1-9998 or blank	-14 to -11
Months	0-11 or blank	-10 to -9
Days	0-30 or blank	-8 to -7
Hours	0-24 or blank	-6 to -5
Minutes	0-59 or blank	-4 to -3
Seconds	0-59	-2 to -1
Decimal separator	period	0
Microseconds	000000-999999	1 to 6

The result of the function is an integer with the same sign as *string-expression*. If either argument can be null, the result can be null; if either argument is null, the result is the null value.

The returned value is determined for each interval as indicated by the following table:

<i>Table 61. TIMESTAMPDIFF Computations</i>	
Result interval	Computation using duration elements
Years	years
Quarters	integer value of (months+(years*12))/3
Months	months + (years*12)
Weeks	integer value of ((days+(months*30))/7)+(years*52)
Days	days + (months*30)+(years*365)
Hours	hours + ((days+(months*30)+(years*365))*24)
Minutes (the absolute value of the duration must not exceed 40850913020759.999999)	minutes + (hours+((days+(months*30)+(years*365))*24))*60
Seconds (the absolute value of the duration must be less than 680105031408.000000)	seconds + (minutes+(hours+((days+(months*30)+(years*365))*24))*60
Microseconds (the absolute value of the duration must be less than 3547.483648)	microseconds + (seconds+(minutes*60))*1000000

The following assumptions are used when converting the element values to the requested interval type:

- One year has 365 days.
- One year has 52 weeks.
- One year has 12 months.
- One quarter has 3 months.
- One month has 30 days.
- One week has 7 days.
- One day has 24 hours.
- One hour has 60 minutes.
- One minute has 60 seconds.
- One second has 1000000 microseconds.

The use of these assumptions imply that some result values are an estimate of the interval. Consider the following examples:

- Difference of 1 month where the month has less than 30 days.

```
TIMESTAMPDIFF(16, CHAR(TIMESTAMP('1997-03-01-00.00.00')) - TIMESTAMP('1997-02-01-00.00.00'))
```

The result of the timestamp arithmetic is a duration of 00000100000000.000000, or 1 month. When the TIMESTAMPDIFF function is invoked with 16 for the interval argument (days), the assumption of 30 days in a month is applied and the result is 30.

- Difference of 1 day less than 1 month where the month has less than 30 days.

```
TIMESTAMPDIFF(16, CHAR(TIMESTAMP('1997-03-01-00.00.00') - TIMESTAMP('1997-02-02-00.00.00') ) )
```

The result of the timestamp arithmetic is a duration of 00000027000000.000000, or 27 days. When the `TIMESTAMPDIFF` function is invoked with 16 for the interval argument (days), the result is 27.

- Difference of 1 day less than 1 month where the month has 31 days.

```
TIMESTAMPDIFF(64, CHAR(TIMESTAMP('1997-09-01-00.00.00') - TIMESTAMP('1997-08-02-00.00.00') ) )
```

The result of the timestamp arithmetic is a duration of 00000030000000.000000, or 30 days. When the `TIMESTAMPDIFF` function is invoked with 64 for the interval argument (months), the result is 0. The days portion of the duration is 30, but it is ignored because the interval specified months.

Example

- The following statement estimates the age of employees in months and returns that value as `AGE_IN_MONTHS`:

```
SELECT  
  TIMESTAMPDIFF(64,  
    CAST(CURRENT_TIMESTAMP - CAST(BIRTHDATE AS TIMESTAMP) AS CHAR(22)))  
  AS AGE_IN_MONTHS  
FROM EMPLOYEE
```

TO_CHAR

The TO_CHAR function returns a character string representation of the first argument in the format indicated by the optional *format-string*.

Character to Varchar

►► TO_CHAR (— *string-expression* —) ►◄

Timestamp to Varchar

►► TO_CHAR (— *timestamp-expression* — , — *format-string* —) ►◄

Numeric to Varchar

►► TO_CHAR (— *numeric-expression* — , — *format-string* —) ►◄

The TO_CHAR function is identical to the VARCHAR_FORMAT function. For more information, see [“VARCHAR_FORMAT”](#) on page 629.

TO_CLOB

The TO_CLOB function returns a character-string representation.

Integer to CLOB

►► TO_CLOB (— *integer-expression* —) ►►

Decimal to CLOB

►► TO_CLOB (— *decimal-expression* — , — *decimal-character* —) ►►

Floating-point to CLOB

►► TO_CLOB (— *floating-point-expression* — , — *decimal-character* —) ►►

Decimal floating-point to CLOB

►► TO_CLOB (— *decimal-floating-point-expression* — , — *decimal-character* —) ►►

Character to CLOB

►► TO_CLOB (— *character-expression* — , — *length* — , — *integer* —) ►►

DEFAULT

Graphic to CLOB

►► TO_CLOB (— *graphic-expression* — , — *length* — , — *integer* —) ►►

DEFAULT

Datetime to CLOB

►► TO_CLOB (— *datetime-expression* — , — *ISO* — , — *USA* — , — *EUR* — , — *JIS* — , — *LOCAL* —) ►►

The TO_CLOB function is identical to the CLOB function. For more information, see [“CLOB” on page 333](#).

TO_DATE

The TO_DATE function returns a timestamp that is based on the interpretation of the input string using the specified format.

►► TO_DATE (*string-expression* , *format-string* , *precision-constant*)

The TO_DATE function is identical to the [TIMESTAMP_FORMAT](#) function. For more information, see [“TIMESTAMP_FORMAT”](#) on page 592.

TO_NUMBER

The TO_NUMBER function returns a DECFLOAT(34) value that is based on the interpretation of the input string using the specified format.

►► TO_NUMBER (— *string-expression* — , — *format-string* —) ◄◄

The TO_NUMBER function is identical to the DECFLOAT_FORMAT function. For more information, see [“DECFLOAT_FORMAT” on page 371](#).

TO_TIMESTAMP

The TO_TIMESTAMP function returns a timestamp that is based on the interpretation of the input string using the specified format.

► TO_TIMESTAMP (— *string-expression* — , — *format-string* —) ►

The TO_TIMESTAMP function is identical to TIMESTAMP_FORMAT except that if *precision-constant* is not specified, the timestamp precision of the result defaults to 12. For more information, see [“TIMESTAMP_FORMAT”](#) on page 592.

TOTALORDER

The TOTALORDER function returns an ordering for DECFLOAT values.

►► TOTALORDER (— *expression-1* — , — *expression-2* —) ◄◄

The TOTALORDER function returns a small integer value that indicates how *expression-1* compares with *expression-2*.

expression-1

An expression that returns a value of any built-in numeric, character-string, or graphic-string data type. If the argument is not DECFLOAT(34), it is logically converted to DECFLOAT(34) for processing.

expression-2

An expression that returns a value of any built-in numeric, character-string, or graphic-string data type. If the argument is not DECFLOAT(34), it is logically converted to DECFLOAT(34) for processing.

Numeric comparison is exact, and the result is determined for finite operands as if range and precision were unlimited. Overflow or underflow cannot occur.

TOTALORDER determines ordering based on the total order predicate rules of IEEE 754R, with the following result:

- 1 if the first operand is lower in order compared to the second.
- 0 if both operands have the same order.
- 1 if the first operand is higher in order compared to the second.

The ordering of the special values and finite numbers is as follows:

-NAN<-SNAN<-INFINITY<-0.10<-0.100<-0<0<0.100<0.10<INFINITY<SNAN<NAN

The result of the function is SMALLINT. If either argument can be null, the result can be null; if either argument is null, the result is the null value.

Examples

The following examples show the use of the TOTALORDER function to compare decimal floating-point values:

```
TOTALORDER(-INFINITY, -INFINITY) = 0
TOTALORDER(DECFLOAT(-1.0), DECFLOAT(-1.0)) = 0
TOTALORDER(DECFLOAT(-1.0), DECFLOAT(-1.00)) = -1
TOTALORDER(DECFLOAT(-1.0), DECFLOAT(-0.5)) = -1
TOTALORDER(DECFLOAT(-1.0), DECFLOAT(0.5)) = -1
TOTALORDER(DECFLOAT(-1.0), INFINITY) = -1
TOTALORDER(DECFLOAT(-1.0), SNAN) = -1
TOTALORDER(DECFLOAT(-1.0), NAN) = -1
TOTALORDER(NAN, DECFLOAT(-1.0)) = 1
TOTALORDER(-NAN, -NAN) = 0
TOTALORDER(-SNAN, -SNAN) = 0
TOTALORDER(NAN, NAN) = 0
TOTALORDER(SNAN, SNAN) = 0
```

TRANSLATE

The TRANSLATE function returns a value in which one or more characters in *expression* may have been converted into other characters.

►► TRANSLATE — (— *expression* →

expression

An expression that specifies the string to be converted *expression* must be any built-in numeric or string data type. A numeric argument is cast to a character string before evaluating the function. For more information about converting numeric to a character string, see [“VARCHAR” on page 623](#).

to-string

A string that specifies the characters to which certain characters in *expression* are to be converted. This string is sometimes called the *output translation table*. The string must be any built-in numeric or string constant. A numeric argument is cast to a character string before evaluating the function. For more information about converting numeric to a character string, see [“VARCHAR” on page 623](#). A character string argument must have an actual length that is not greater than 256.

If the actual length of the *to-string* is less than the actual length of the *from-string*, then the *to-string* is padded to the longer length using either the *pad* character if it is specified or a blank if a *pad* character is not specified. If the actual length of the *to-string* is greater than the actual length of the *from-string*, the extra characters in *to-string* are ignored without warning.

from-string

A string that specifies the characters that if found in *expression* are to be converted. This string is sometimes called the *input translation table*. When a character in *from-string* is found, the character in *expression* is converted to the character in *to-string* that is in the corresponding position of the character in *from-string*.

The string must be any built-in numeric or string constant. A numeric argument is cast to a character string before evaluating the function. For more information about converting numeric to a character string, see [“VARCHAR” on page 623](#). A character string argument must have an actual length that is not greater than 256.

If there are duplicate characters in *from-string*, the first one scanning from the left is used and no warning is issued. The default value for *from-string* is a string starting with the character X'00' and ending with the character X'FF' (decimal 255).

pad

A string that specifies the character with which to pad *to-string* if its length is less than *from-string*. The string must be a character string constant with a length of 1. The default is an SBCS blank.

If the first argument is a Unicode graphic or UTF-8 string, no other arguments may be specified.

If only the first argument is specified, the SBCS characters of the argument are converted to uppercase, based on the CCSID of the argument. Only SBCS characters are converted. The characters a-z are converted to A-Z, and characters with diacritical marks are converted to their uppercase equivalent, if any. If the first argument is UTF-16, UCS-2, or UTF-8, the alphabetic UTF-16, UCS-2, or UTF-8 characters are converted to uppercase. Refer to the [UCS-2 level 1 mapping tables](#) topic of the [Globalization](#) topic collection for a description of the monocasing tables that are used for this conversion.

If more than one argument is specified, the result string is built character by character from *expression*, converting characters in *from-string* to the corresponding character in *to-string*. For each character in *expression*, the same character is searched for in *from-string*. If the character is found to be the *n*th

character in *from-string*, the resulting string will contain the *n*th character from *to-string*. If *to-string* is less than *n* characters long, the resulting string will contain the pad character. If the character is not found in *from-string*, it is moved to the result string unconverted.

Conversion is done on a byte basis and, if used improperly, may result in an invalid mixed string. The SRTSEQ attribute does not apply to the TRANSLATE function.

The result of the function has the same data type, length attribute, actual length, and CCSID as the argument. If the first argument can be null, the result can be null. If the argument is null, the result is the null value.

Examples

- Monocase the string 'abcdef'.

```
SELECT TRANSLATE('abcdef')
FROM SYSIBM.SYSDUMMY1
```

Returns the value 'ABCDEF'.

- Monocase the mixed character string.

```
SELECT TRANSLATE('abs0Cs1def')
FROM SYSIBM.SYSDUMMY1
```

Returns the value 'AB^s0C^s1DEF'

- Given that the host variable SITE is a varying-length character string with a value of 'Pivabiska Lake Place'.

```
SELECT TRANSLATE(:SITE, '$', 'L')
FROM SYSIBM.SYSDUMMY1
```

Returns the value 'Pivabiska \$ake Place'.

```
SELECT TRANSLATE(:SITE, '$$', 'L1')
FROM SYSIBM.SYSDUMMY1
```

Returns the value 'Pivabiska \$ake P\$ace'.

```
SELECT TRANSLATE(:SITE, 'pLA', 'Place', '.')
FROM SYSIBM.SYSDUMMY1
```

Returns the value 'pivAbiskA LAk. pLA..'

TRIM

The TRIM function removes blanks or another specified character from the end, from the beginning, or from both of a string expression.

The first argument, if specified, indicates whether characters are removed from the end or beginning of the string. If the first argument is not specified, then the characters are removed from both the end and the beginning of the string.

strip-character

The second argument, if specified, is a single-character constant that indicates the binary, SBCS, or DBCS character that is to be removed. If *expression* is a binary string, the second argument must be a binary string constant. If *expression* is a DBCS graphic or DBCS-only string, the second argument must be a graphic constant consisting of a single DBCS character. If the second argument is not specified then:

- If *expression* is a binary string, then the default strip character is a hexadecimal zero (X'00').
- If *expression* is a DBCS graphic string, then the default strip character is a DBCS blank.
- If *expression* is a Unicode graphic string, then the default strip character is a UTF-16 or UCS-2 blank.
- If *expression* is a UTF-8 character string, then the default strip character is a UTF-8 blank.
- Otherwise, the default strip character is an SBCS blank.

expression

An expression that returns a value of any built-in numeric or string data type. A numeric argument is cast to a character string before evaluating the function. For more information about converting numeric to a character string, see [“VARCHAR” on page 623](#).

The data type of the result depends on the data type of *expression*:

Data type of <i>expression</i>	Data type of the Result
CHAR or VARCHAR	VARCHAR
CLOB	CLOB
GRAPHIC or VARGRAPHIC	VARGRAPHIC
DBCLOB	DBCLOB
BINARY or VARBINARY	VARBINARY
BLOB	BLOB

The length attribute of the result is the same as the length attribute of *expression*. The actual length of the result is the length of the expression minus the number of bytes removed. If all characters are removed, the result is an empty string.

If the first argument can be null, the result can be null; if the first argument is null, the result is the null value.

The CCSID of the result is the same as that of the string.

The SRTSEQ attribute does not apply to the TRIM function.

Examples

- Assume the host variable HELLO of type CHAR(9) has a value of ' Hello '.

```
SELECT TRIM(:HELLO), TRIM( TRAILING FROM :HELLO)
FROM SYSIBM.SYSDUMMY1
```

Results in 'Hello' and ' Hello' respectively.

- Assume the host variable BALANCE of type CHAR(9) has a value of '000345.50'.

```
SELECT TRIM( L '0' FROM :BALANCE )
FROM SYSIBM.SYSDUMMY1
```

Results in: '345.50'

- Assume the string to be stripped contains mixed data.

```
SELECT TRIM( BOTH 'S' 'I' FROM 'S' 'AB C' 'I' )
FROM SYSIBM.SYSDUMMY1
```

Results in: 'S'AB C'I'

TRUNCATE or TRUNC

The TRUNCATE function returns *expression-1* truncated to some number of places to the right or left of the decimal point.

expression-1

An expression that returns a value of any built-in numeric, character-string, or graphic-string data type. A string argument is converted to double-precision floating point before evaluating the function. For more information about converting strings to double-precision floating point, see [“DOUBLE_PRECISION or DOUBLE”](#) on page 392.

If *expression-1* is a decimal floating-point data type, the DECFLOAT ROUNDING MODE will not be used. The rounding behavior of TRUNCATE corresponds to a value of ROUND_DOWN. If a different rounding behavior is wanted, use the QUANTIZE function.

expression-2

An expression that returns a value of a built-in small integer, large integer, or big integer data type. The absolute value of integer specifies the number of places to the right of the decimal point for the result if *expression-2* is not negative, or to the left of the decimal point if *expression-2* is negative.

If *expression-2* is not negative, *expression-1* is truncated to the *expression-2* number of places to the right of the decimal point.

If *expression-2* is negative, *expression-1* is truncated to the absolute value of *expression-2*+1 number of places to the left of the decimal point.

If *expression-2* is not specified, *expression-1* is truncated to zero places to the left of the decimal point.

If the absolute value of *expression-2* is larger than the number of digits to the left of the decimal point, the result is 0. For example, TRUNCATE(748.58,-4) = 0.

The data type and length attribute of the result are the same as the data type and length attribute of the first argument.

If either argument can be null, the result can be null. If either argument is null, the result is the null value.

Examples

- Calculate the average monthly salary for the highest paid employee. Truncate the result to two places to the right of the decimal point.

```
SELECT TRUNCATE(MAX(SALARY/12) , 2)
FROM EMPLOYEE
```

Because the highest paid employee in the sample employee table earns \$52750.00 per year, the example returns the value 4395.83.

- Calculate the number 873.726 truncated to 2, 1, 0, -1, -2, and -3 decimal places respectively.

```
SELECT TRUNCATE(873.726, 2),
       TRUNCATE(873.726, 1),
       TRUNCATE(873.726, 0),
       TRUNCATE(873.726, -1),
       TRUNCATE(873.726, -2),
       TRUNCATE(873.726, -3)
FROM SYSIBM.SYSDUMMY1
```

Returns the following values respectively:

```
0873.720  0873.700  0873.000  0870.000  0800.000  0000.000
```

- Calculate both positive and negative numbers.

```
SELECT TRUNCATE( 3.5, 0),  
       TRUNCATE( 3.1, 0),  
       TRUNCATE(-3.1, 0),  
       TRUNCATE(-3.5, 0)  
FROM SYSIBM.SYSDUMMY1
```

This example returns:

```
3.0  3.0  -3.0  -3.0
```

respectively.

TRUNC_TIMESTAMP

The TRUNC_TIMESTAMP function returns a timestamp that is the *expression* truncated to the unit specified by the *format-string*. If *format-string* is not specified, *expression* is truncated to the nearest day, as if 'DD' was specified for *format-string*.

expression

An expression that returns a value of one of the following built-in data types: a date, a timestamp, a character-string, or a graphic-string.

If *expression* is a character or graphic string, its value must be a valid string representation of a date or timestamp. It is first converted to a `TIMESTAMP(12)` value. For the valid formats of string representations of dates and timestamps, see [“String representations of datetime values”](#) on page 75.

format-string

An expression that returns a built-in character string data type or graphic string data type. *format-string* contains a template of how *expression* should be truncated. For example, if *format-string* is 'DD', a timestamp that is represented by *expression* is truncated to the nearest day. Leading and trailing blanks are removed from the string, and the resulting substring must be a valid template for a timestamp. The resulting value is then folded to uppercase, so the characters in the value may be in any case. Allowable values for *format-string* are listed in [Table 57](#) on page 555.

The result of the function is a timestamp with a timestamp precision of:

- *p* when the data type of *expression* is `TIMESTAMP(p)`
- 0 when the data type of *expression* is `DATE`
- 6 otherwise.

If either argument can be null, the result can be null; if either argument is null, the result is the null value.

Example

- Set the host variable `TRN_TMSTMP` with the current year truncated to the nearest year value.

```
SET :TRN_TMSTMP = TRUNC_TIMESTAMP('2000-03-14-17.30.00', 'YEAR');
```

Host variable `TRN_TMSTMP` is set with the value `2000-01-01-00.00.00.000000`.

UCASE

The UCASE function returns a string in which all the characters have been converted to uppercase characters, based on the CCSID of the argument.

►► UCASE — (— *expression* —) ►◄

The UCASE function is identical to the UPPER function. For more information, see [“UPPER” on page 616](#).

UPPER

The UPPER function returns a string in which all the characters have been converted to uppercase characters, based on the CCSID of the argument. Only SBCS and Unicode graphic characters are converted. The characters a-z are converted to A-Z, and characters with diacritical marks are converted to their uppercase equivalent, if any.

►► UPPER — (— *expression* —) ◄◄

Refer to the [UCS-2 level 1 mapping tables](#) topic of the [Globalization](#) topic collection for a description of the monocasing tables that are used for this translation.

expression

An expression that specifies the string to be converted. *expression* must be any built-in numeric, character, Unicode graphic string. A numeric argument is cast to a character string before evaluating the function. For more information about converting numeric to a character string, see [“VARCHAR” on page 623](#).

The result of the function has the same data type, length attribute, actual length, and CCSID as the argument. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

Note

Syntax alternatives: UCASE is a synonym for UPPER.

Examples

- Uppercase the string 'abcdef' using the UPPER scalar function.

```
SELECT UPPER('abcdef')
FROM SYSIBM.SYSDUMMY1
```

Returns the value 'ABCDEF'.

- Uppercase the mixed character string using the UPPER scalar function.

```
SELECT UPPER('abs0Cs1def')
FROM SYSIBM.SYSDUMMY1
```

Returns the value: 'AB^s0C^s1DEF'

URL_DECODE

The URL_DECODE scalar function completes URL decoding of the provided text using UTF-8 encoding.

►► URL_DECODE — (— *character-string* —) ◄◄

character-string

An expression that returns a built-in character string that is currently encoded.

The result of the function is a varying length character string that contains *character-string* after being decoded.

Example

- Decode the string `https://www.example.com/search?q=IBM+i+Q%26A`

```
VALUES URL_DECODE('https://www.example.com/search?q=IBM+i+Q%26A')
```

Returns

```
https://www.example.com/search?q=IBM i Q&A
```

URL_ENCODE

The URL_ENCODE scalar function completes URL encoding of the provided text using UTF-8 encoding. This is typically used to encode parameter information that is passed as part of the URL.

►► URL_ENCODE — (— *character-string* —) ►►

character-string

An expression that returns a built-in character string that is to be encoded.

The result of the function is a varying length character string that contains *character-string* after being encoded.

Example

- Create a URL that has the parameter encoded for a request to example.com.

```
VALUES 'https://www.example.com/search?q=' CONCAT URL_ENCODE('IBM i Q&A')
```

Returns

```
https://www.example.com/search?q=IBM+i+Q%26A
```

VALUE

The VALUE function returns the value of the first non-null expression.

► VALUE (*expression* , *expression*) ◄

The VALUE function is identical to the COALESCE scalar function. For more information, see [“COALESCE” on page 338](#).

Note

Syntax alternatives: COALESCE should be used for conformance to the SQL 2003 standard.

VARBINARY

The VARBINARY function returns a VARBINARY representation of a string of any type.

►► VARBINARY (— *string-expression* — , — *integer* —) ◄◄

The result of the function is VARBINARY. If the first argument can be null, the result can be null; if the first argument is null, the result is the null value.

string-expression

A *string-expression* whose value can be a character string, graphic string, binary string, or row ID.

integer

An integer constant that specifies the length attribute for the resulting binary string. The value must be between 1 and 32740 (32739 if nullable).

If *integer* is not specified:

- If the *string-expression* is the empty string constant, the length attribute of the result is 1.
- Otherwise, the length attribute of the result is the same as the length attribute of the first argument, unless the argument is a graphic string. In this case, the length attribute of the result is twice the length attribute of the argument.

The actual length of the result is the minimum of the length attribute of the result and the actual length of the expression (or twice the length of the expression when the input is graphic data). If the length of the *string-expression* is greater than the length attribute of the result, truncation is performed. A warning (SQLSTATE 01004) is returned unless the first input argument is a character string and all the truncated characters are blanks, or the first input argument is a graphic string and all the truncated characters are double-byte blanks, or the first input argument is a binary string and all the truncated bytes are hexadecimal zeroes.

Note

Syntax alternatives: The CAST specification should be used to increase the portability of applications when the length is specified. For more information, see [“CAST specification”](#) on page 176.

Example

- The following function returns a VARBINARY for the string 'This is a VARBINARY'.

```
SELECT VARBINARY('This is a VARBINARY')
FROM SYSIBM.SYSDUMMY1
```

VARBINARY_FORMAT

The VARBINARY_FORMAT function returns a binary string representation of a character string that has been formatted using a *format-string*.

► VARBINARY_FORMAT (— *expression* — , — *format-string* —) ►

expression

An expression that returns a value of any built-in numeric, character-string, or graphic-string data type. A numeric or graphic argument is cast to a character string before evaluating the function. For more information about converting numeric or graphic to a character string, see “VARCHAR” on page 623.

All leading and trailing blanks are removed from *expression* before evaluating the function.

If a *format-string* is specified, the length of *expression* must be equal to the length of the *format-string* and the value of *expression* must conform to the template specified by the *format-string*. If a *format-string* is not specified, the value of *expression* (after removing leading and trailing blanks) should be an even number of characters from the ranges '0' to '9', 'a' to 'f', and 'A' to 'F'. If the length is an odd number of characters, the string is padded on the right with one '0' character.

format-string

An expression that returns a built-in character string or graphic string data type. *format-string* contains a template for how the value for *expression* is to be interpreted.

The valid format strings are: 'xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx' and 'XXXXXXXX-XXXX-XXXX-XXXX-XXXXXXXXXXXX' where each 'x' or 'X' corresponds to one hexadecimal digit in the result. If 'X' is specified, the corresponding hexadecimal digit must not be a lower case character. If 'x' is specified, the corresponding hexadecimal digit must not be an upper case character.

The result of the function is a varying-length binary string. The length attribute of the result is half the length attribute of *expression*. If a *format-string* is not specified, the actual length is half the actual length of *expression* (after leading and trailing blanks have been removed and padding to an even number of characters). If a *format-string* is specified, the actual length is half the actual length of the *format-string* (after removing the non-digit separator characters). If either argument can be null, the result can be null; if either argument is null, the result is the null value.

Note

Syntax alternatives: HEXTORAW is a synonym for VARBINARY_FORMAT except that if the length of *expression* is an odd number of characters, the string is padded on the left with one '0' character. VARCHAR_BIT_FORMAT is a synonym for VARBINARY_FORMAT except that the result of the function is a varying-length character string FOR BIT DATA.

Example

- Represent a Universal Unique Identifier in its binary form:

```
VALUES VARBINARY_FORMAT('d83d6360-1818-11db-9804-b622a1ef5492',
                          'xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx')
```

Result returned:

```
BX'D83D6360181811DB9804B622A1EF5492'
```

- Represent a Universal Unique Identifier in its binary form:

```
VALUES VARBINARY_FORMAT('D83D6360-1818-11DB-9804-B622A1EF5492',
                          'XXXXXXXX-XXXX-XXXX-XXXX-XXXXXXXXXXXX')
```

Result returned:

```
BX'D83D6360181811DB9804B622A1EF5492'
```

- Represent a string of hexadecimal characters in binary form:

```
VALUES VARBINARY_FORMAT('ef01abC9')
```

Result returned:

```
BX'EF01ABC9'
```

VARCHAR

The VARCHAR function returns a character-string representation.

Integer to Varchar

➤ VARCHAR (— *integer-expression* —) ➤

Decimal to Varchar

➤ VARCHAR (— *decimal-expression* — , — *decimal-character* —) ➤

Floating-point to Varchar

➤ VARCHAR (— *floating-point-expression* — , — *decimal-character* —) ➤

Decimal floating-point to Varchar

➤ VARCHAR (— *decimal-floating-point-expression* — , — *decimal-character* —) ➤

Character to Varchar

➤ VARCHAR (— *character-expression* — , — *length* — , — *integer* —) ➤

DEFAULT

Graphic to Varchar

➤ VARCHAR (— *graphic-expression* — , — *length* — , — *integer* —) ➤

DEFAULT

Datetime to Varchar

➤ VARCHAR (— *datetime-expression* — , — *ISO* — , — *USA* — , — *EUR* — , — *JIS* — , — *LOCAL* —) ➤

The VARCHAR function returns a character-string representation of:

- An integer number if the first argument is a SMALLINT, INTEGER, or BIGINT.
- A decimal number if the first argument is a packed or zoned decimal number.
- A double-precision floating-point number if the first argument is a DOUBLE or REAL.
- A decimal floating-point number if the first argument is DECFLOAT.
- A character string if the first argument is any type of character string.
- A graphic string if the first argument is any graphic string.

- A date value if the first argument is a DATE.
- A time value if the first argument is a TIME.
- A timestamp value if the first argument is a TIMESTAMP.

The result of the function is a varying-length string. If the first argument can be null, the result can be null; if the first argument is null, the result is the null value.

Integer to Varchar

integer-expression

An expression that returns a value that is an integer data type (either SMALLINT, INTEGER, or BIGINT).

The result is a varying-length character string of the argument in the form of an SQL integer constant. The result consists of n characters that are the significant digits that represent the value of the argument with a preceding minus sign if the argument is negative. It is left justified.

- If the argument is a small integer, the length attribute of the result is 6.
- If the argument is a large integer, the length attribute of the result is 11.
- If the argument is a big integer, the length attribute of the result is 20.

The actual length of the result is the smallest number of characters that can be used to represent the value of the argument. Leading zeroes are not included. If the argument is negative, the first character of the result is a minus sign. Otherwise, the first character is a digit.

The CCSID of the result is the default SBCS CCSID at the current server.

Decimal to Varchar

decimal-expression

An expression that returns a value that is a packed or zoned decimal data type (either DECIMAL or NUMERIC). If a different precision and scale is wanted, the DECIMAL scalar function can be used to make the change.

decimal-character

Specifies the single-byte character constant that is used to delimit the decimal digits in the result character string. The character must be a period or comma. If the second argument is not specified, the decimal point is the default decimal point. For more information, see [“Decimal point” on page 116](#).

The result is a varying-length character string representation of the argument. The result includes a decimal character and up to p digits, where p is the precision of the *decimal-expression* with a preceding minus sign if the argument is negative. Leading zeros are not returned. Trailing zeros are returned. If the scale of *decimal-expression* is zero, the decimal character is not returned.

The length attribute of the result is $2+p$ where p is the precision of the *decimal-expression*. The actual length of the result is the smallest number of characters that can be used to represent the result, except that trailing characters are included. Leading zeros are not included. If the argument is negative, the result begins with a minus sign. Otherwise, the result begins with a digit or the *decimal-character*.

The CCSID of the result is the default SBCS CCSID at the current server.

Floating-point to Varchar

floating-point expression

An expression that returns a value that is a floating-point data type (DOUBLE or REAL).

decimal-character

Specifies the single-byte character constant that is used to delimit the decimal digits in the result character string. The character must be a period or comma. If the second argument is not specified, the decimal point is the default decimal point. For more information, see [“Decimal point” on page 116](#).

The result is a varying-length character string representation of the argument in the form of a floating-point constant.

The length attribute of the result is 24. The actual length of the result is the smallest number of characters that can represent the value of the argument such that the mantissa consists of a single digit other than zero followed by the *decimal-character* and a sequence of digits. If the argument is negative, the first character of the result is a minus sign; otherwise, the first character is a digit or the *decimal-character*. If the argument is zero, the result is 0E0.

The CCSID of the result is the default SBCS CCSID at the current server.

Decimal floating-point to Varchar

decimal-floating-point expression

An expression that returns a value that is a decimal floating-point data type.

decimal-character

Specifies the single-byte character constant that is used to delimit the decimal digits in the result character string. The character must be a period or comma. If the second argument is not specified, the decimal point is the default decimal point. For more information, see [“Decimal point” on page 116](#).

The result is a varying-length character string representation of the argument in the form of a decimal floating-point constant.

The length attribute of the result is 42. The actual length of the result is the smallest number of characters that represents the value of the argument, including the sign, digits, and *decimal-character*. Trailing zeros are significant. If the argument is negative, the first character of the result is a minus sign; otherwise, the first character is a digit or the *decimal-character*. If the argument is zero, the result is 0.

If the DECFLOAT value is Infinity, sNaN, or NaN, the strings 'INFINITY', 'SNAN', and 'NAN', respectively, are returned. If the special value is negative, a minus sign will be the first character in the string. The DECFLOAT special value sNaN does not result in an exception when converted to a string.

The CCSID of the result is the default SBCS CCSID at the current server.

Character to Varchar

character-expression

An expression that returns a value that is a built-in CHAR, VARCHAR, or CLOB data type.⁷⁷

length

An integer constant that specifies the length attribute for the resulting varying length character string. The value must be between 1 and 32740 (32739 if nullable). If the first argument is DBCS-only mixed data, the second argument cannot be less than 4.

If the second argument is not specified or DEFAULT is specified:

- If the *character-expression* is an empty string constant, the length attribute of the result is 1.
- Otherwise, the length attribute of the result is the same as the length attribute of the first argument.

The actual length of the result is the minimum of the length attribute of the result and the actual length of *character-expression*. If the length of the *character-expression* is greater than the length attribute of the result, truncation is performed. A warning (SQLSTATE 01004) is returned unless the truncated characters were all blanks.

integer

An integer constant that specifies the CCSID of the result. It must be a valid SBCS CCSID, mixed data CCSID, or 65535 (bit data). If the third argument is an SBCS CCSID, then the result is SBCS data. If the third argument is a mixed CCSID, then the result is mixed data and the length attribute of the result cannot be less than 4. If the third argument is 65535, then the result is bit data. If the third argument is a SBCS CCSID, then the first argument cannot be a DBCS-either or DBCS-only string.

⁷⁷ A binary string is also allowed if a CCSID is not specified or if a CCSID of 65535 is explicitly specified.

If the third argument is not specified then:

- If the first argument is SBCS data, then the result is SBCS data. The CCSID of the result is the same as the CCSID of the first argument.
- If the first argument is mixed data and the length attribute of the result is greater than or equal to 4, then the result is mixed data. The CCSID of the result is the same as the CCSID of the first argument.
- If the first argument is mixed data that is DBCS-open or DBCS-either and the length attribute of the result is less than 4, the CCSID of the result is the associated SBCS CCSID for the mixed data CCSID.

Graphic to Varchar

graphic-expression

An expression that returns a value that is a GRAPHIC, VARGRAPHIC, and DBCLOB data type. It must not be DBCS-graphic data.

length

An integer constant that specifies the length attribute for the resulting varying length character string. The value must be between 1 and 32740 (32739 if nullable). If the first argument contains DBCS data, the second argument cannot be less than 4.

If the second argument is not specified or DEFAULT is specified, the length attribute of the result is determined as follows (where n is the length attribute of the first argument):

- If the *graphic-expression* is the empty graphic string constant, the length attribute of the result is 1.
- If the result is SBCS data, the result length is n .
- If the result is mixed data, the result length is $(2.5*(n-1)) + 4$.

The actual length of the result is the minimum of the length attribute of the result and the actual length of *graphic-expression*. If the length of the *character-expression* is greater than the length attribute of the result, truncation is performed. A warning (SQLSTATE 01004) is returned unless the truncated characters were all blanks.

integer

An integer constant that specifies the CCSID of the result. It must be a valid SBCS CCSID or mixed data CCSID. If the third argument is an SBCS CCSID, then the result is SBCS data. If the third argument is a mixed CCSID, then the result is mixed data and the length attribute of the result cannot be less than 4. The third argument cannot be 65535.

If the third argument is not specified, the CCSID of the result is the default CCSID at the current server. If the default CCSID is mixed data and the length attribute of the result is greater than or equal to 4, then the result is mixed data. Otherwise, the result is SBCS data.

Datetime to Varchar

datetime-expression

An expression that is one of the following three built-in data types

date

The result is the varying-length character string representation of the date in the format specified by the second argument. If the second argument is not specified, the format used is the default date format. If the format is ISO, USA, EUR, or JIS, the length attribute and actual length of the result is 10. Otherwise the length attribute and actual length of the result is the length of the default date format. For more information see [“String representations of datetime values” on page 75](#).

time

The result is the varying-length character string representation of the time in the format specified by the second argument. If the second argument is not specified, the format used is the default time format. The length attribute and actual length of the result is 8. For more information see [“String representations of datetime values” on page 75](#).

timestamp

The second argument is not applicable and must not be specified.

The result is the varying-length character string representation of the timestamp. If *datetime-expression* is a `TIMESTAMP(0)`, the length attribute and actual length of the result is 19. If the data type of *datetime-expression* is a `TIMESTAMP(n)`, the length attribute and actual length of the result is $20+n$. Otherwise, the length attribute and actual length of the result is 26.

The CCSID of the string is the default SBCS CCSID at the current server.

ISO, EUR, USA, or JIS

Specifies the date or time format of the resulting character string. For more information, see [“String representations of datetime values”](#) on page 75.

LOCAL

Specifies that the date or time format of the resulting character string should come from the `DATFMT`, `DATSEP`, `TIMFMT`, and `TIMSEP` attributes of the job at the current server.

Note

Syntax alternatives: The `CAST` specification should be used to increase the portability of applications when the first argument is a string and the length argument is specified. For more information, see [“CAST specification”](#) on page 176.

Example

- Make `EMPNO` varying-length with a length of 10.

```
SELECT VARCHAR(EMPNO,10)
INTO :VARHV
FROM EMPLOYEE
```

VARCHAR_BIT_FORMAT

The VARCHAR_BIT_FORMAT function returns a character string representation of a character string that has been formatted using a *format-string*.

►► VARCHAR_BIT_FORMAT (*expression* , *format-string*) ◄◄

The VARCHAR_BIT_FORMAT function is identical to VARBINARY_FORMAT except that the result of the function is a varying-length character string FOR BIT DATA. For more information, see [“VARBINARY_FORMAT” on page 621](#).

VARCHAR_FORMAT

The VARCHAR_FORMAT function returns a character string representation of the first argument in the format indicated by the optional *format-string*.

Character to Varchar

➤ VARCHAR_FORMAT (— *string-expression* —) ➤

Timestamp to Varchar

➤ VARCHAR_FORMAT (— *timestamp-expression* — , — *format-string* —) ➤

Numeric to Varchar

➤ VARCHAR_FORMAT (— *numeric-expression* — , — *format-string* —) ➤

If any argument of the VARCHAR_FORMAT function can be null, the result can be null; if any argument is null, the result is the null value.

Character to Varchar

string-expression

An expression that returns a value that is a built-in character-string or graphic-string data type.

If the argument is a character string:

- The length attribute of the result and the actual length are determined as follows:
 - If *string-expression* is an empty string constant, the length attribute of the result is 1.
 - Otherwise, the length attribute and the actual length of the result is the same as the length attribute of *string-expression*.
 - The actual length of the result is the minimum of the length attribute of the result and the actual length of *string-expression*.
- The CCSID of the result is determined as follows:
 - If *string-expression* is SBCS data, then the result is SBCS data. The CCSID of the result is the same as the CCSID of *string-expression*.
 - If *string-expression* is mixed data (DBCS-open, DBCS-only, or DBCS-either), then the result is mixed data. The CCSID of the result is the same as the CCSID of *string-expression*.

If the argument is a graphic string, it must not be DBCS-graphic data.

- The length attribute and the actual length of the result is determined as follows (where *n* is the length attribute of *string-expression*):
 - If *string-expression* is the empty graphic string constant, the length attribute of the result is 1.
 - If the result is SBCS data, the length attribute of the result is *n*.
 - If the result is mixed data, the length attribute of the result is $(2.5*(n-1)) + 4$.
 - The actual length of the result is the minimum of the length attribute of the result and the actual length of *string-expression*.
- The CCSID of the result is the default CCSID at the current server. If the default CCSID is mixed data, then the result is mixed data. If the default CCSID is SBCS data, then the result is SBCS data.

Timestamp to Varchar

timestamp-expression

An expression that returns a value of one of the following built-in data types: a date, a timestamp, a character string, or a graphic string. If the argument is a DATE, it is first converted to a TIMESTAMP(0) value, assuming a time of exactly midnight (00.00.00).

If *timestamp-expression* is a character or graphic string, the value of *timestamp-expression* must be a valid string representation of a date or timestamp. It is first converted to a TIMESTAMP(12) value. For the valid formats of string representations of timestamps, see [“String representations of datetime values”](#) on page 75.

If the argument is a string, the *format-string* argument must also be specified.

format-string

An expression that returns a built-in character string data type or graphic string data type. If the value is not a CHAR or VARCHAR data type, it is implicitly cast to VARCHAR before evaluating the function. *format-string* contains a template of how *timestamp-expression* is to be formatted. The resulting value may contain characters in any case. A valid format is any combination of the formats listed below optionally separated by valid separators. Valid separators are:

- minus sign (-)
- period (.)
- slash (/)
- comma (,)
- apostrophe (')
- semicolon (;)
- colon (:)
- blank ()

Format	Unit
AM or PM ^{1, 2}	Meridian indicator (morning or evening) without periods. The meridian indicator that is returned is based on the language used for messages in the job. This meridian indicator is retrieved from message CPX9035 in message file QCPFMSG in library *LIBL.
A.M. or P.M. ^{1, 2}	Meridian indicator (morning or evening) with periods. This format element uses the exact strings 'A.M.' or 'P.M.' and is independent of the language used for messages in the job.
CC	Century (00-99). If the last two digits of the four digit year are zero, the result is the first two digits of the year. Otherwise, the result is the first two digits of the year plus one.
DAY, Day, or day ^{1, 2}	Name of the day in uppercase, titlecase, or lowercase format. The name of the day that is returned is based on the language used for messages in the job. This name of the day is retrieved from message CPX9034 in message file QCPFMSG in library *LIBL.
DY, Dy, or dy ^{1, 3}	Abbreviated name of the day in uppercase, titlecase, or lowercase format. The abbreviated name of the day is retrieved from message CPX9039 in message file QCPFMSG in library *LIBL.
D ¹	Day of week (1-7), where 1 is Sunday.
DD	Day of month (01-31).
DDD	Day of year (001-366).

Table 62. Format elements for the VARCHAR_FORMAT (Timestamp to VARCHAR) function (continued)

Format	Unit
FF or FF n	Fractional seconds (0-999999999999). The number n is used to specify the number of digits to include in the value returned. Valid values for n are 1-12. The default is 6.
HH	HH behaves the same as HH12.
HH12	Hour of the day (01-12) in 12-hour format.
HH24	Hour of the day (00-24) in 24-hour format.
ID	ISO day of week (1-7), where 1 is Monday and 7 is Sunday
IW	ISO week of year (01-53). The week starts on Monday and includes 7 days. Week 1 is the first week of the year to contain a Thursday, which is equivalent to the first week of the year to contain January 4
I	ISO year (0-9). The last digit of the year based on the ISO week that is returned.
IY	ISO year (00-99). The last two digits of the year based on the ISO week that is returned.
IYY	ISO year (000-999). The last three digits of the year based on the ISO week that is returned.
IYYY	ISO year (0000-9999). The year based on the ISO week that is returned.
J	Julian date (0000000-9999999).
MI	Minute (00-59).
MM	Month (01-12).
MONTH, Month, or month ^{1,3}	Name of the month in uppercase, titlecase, or lowercase format. The name of the month that is returned is based on the language used for messages in the job. This name of the month is retrieved from message CPX3BC0 in message file QCPFMSG in library *LIBL.
MON, Mon, or mon ^{1,3}	Abbreviated name of the month in uppercase, titlecase, or lowercase format. The name of the month that is returned is based on the language used for messages in the job. This name of the month is retrieved from message CPX8601 in message file QCPFMSG in library *LIBL.
MS	Milliseconds (000-999). Same as FF3.
NNNNNN	Microseconds (000000-999999). Same as FF6.
Q	Quarter (1-4).
RR	RR behaves the same as YY.
RRRR	RRRR behaves the same as YYYY.
SS	Seconds (00-59).
SSSSS	Seconds since previous midnight (00000-86400).
US	Microseconds (000000-999999). Same as FF6.
W	Week of month (1-5). Week 1 starts on the first day of the month and ends on the seventh day.
WW	Week of the year (01-53), where week 1 starts on January 1 and ends on January 7.

Table 62. Format elements for the VARCHAR_FORMAT (Timestamp to VARCHAR) function (continued)

Format	Unit
Y	Last digit of the year (0-9).
YY	Last two digits of the year (00-99).
YYY	Last three digits of the year (000-999).
YYYY	Year (0000-9999).

Notes:

1. This format element is case sensitive. In cases where the format elements are ambiguous, the case insensitive format elements will be considered first.
2. The AM and PM set of meridian indicators can be used interchangeably in the *format-string*, as can A.M. and P.M. The result string will contain the appropriate meridian indicator for the actual time value.
3. Only these exact spellings and case combinations can be used. If this format element is specified in an invalid case combination an error is returned.

Examples of valid format strings are:

```
'HH24-MI-SS'
'HH24-MI-SS-NNNNNN'
'YYYY-MM-DD'
'YYYY-MM-DD-HH24-MI-SS'
'YYYY-MM-DD-HH24-MI-SS-NNNNNN'
'FF3.J/Q-YYYY'
```

The result is a representation of *timestamp-expression* in the format specified by *format-string*. *format-string* is interpreted as a series of format elements that can be separated by one or more separator characters. A string of characters in *format-string* is interpreted as the longest format element that matches an element in the previous table. If two format elements are composed of the same character and they are not separated by a separator character, the specification is interpreted, starting from the left, as the longest element that matches an element from the previous table, and continues until matches are found for the remainder of the format string. For example, DDYYYY would be interpreted as DD followed by YYYY, rather than D followed by DY, followed by YYY.

If *format-string* is not specified, *timestamp-expression* is returned as the varying-length character string representation of the timestamp.

The data type of the result is varying-length character or varying-length graphic based on the data type of the *format-string*. The length attribute of the result is the maximum of 255 and the length attribute of the *format-string*. *format-string* also determines the actual length of the result. The actual length must not be greater than the length attribute of the result.

The CCSID of the result is same as the CCSID of the *format-string*. If *format-string* is not specified, the CCSID of the result is the default SBCS CCSID at the current server.

Numeric to Varchar

numeric-expression

An expression that returns a value of any built-in numeric data type. If the argument is not a decimal floating-point value, it is converted to DECFLOAT(34) for processing.

format-string

An expression that returns a built-in character string, graphic string, or numeric data type. If the value is not a CHAR or VARCHAR data type, it is implicitly cast to VARCHAR before evaluating the function. *format-string* contains a template of how *numeric-expression* is to be formatted. A *format-string* must contain a valid combination of the listed format elements according to the following rules:

- A sign format element ('S', 'MI', 'PR') can be specified only one time.
- A decimal point format element can be specified only one time.

- Alphabetic format elements must be specified in upper case.
- A prefix format element can only be specified at the beginning of the format string, before any format elements that are not prefix format elements. When multiple prefix format elements are specified they can be specified in any order.
- A suffix format element can only be specified at the end of the format string, after any format elements that are not suffix format elements. When multiple suffix format elements are specified they can be specified in any order.
- A comma or G format element must not be the first format element that is not a prefix format element. There can be any number of comma or G format elements.
- Blanks must not be specified between format elements. Leading and trailing blanks can be specified but are ignored when formatting the result.

Format element	Description
0	Each 0 represents a significant digit. Leading zeros in a number are displayed as zeros.
9	Each 9 represents a significant digit. Leading zeros in a number are displayed as blanks. Only group separators that have at least one digit to the left of the separator are generated.
S	Prefix: If <i>numeric-expression</i> is a negative number, a leading minus sign (-) is included in the result. If <i>numeric-expression</i> is a positive number, a leading plus sign (+) is included in the result.
\$	Prefix: A leading dollar sign (\$) is included in the result.
MI	Suffix: If <i>numeric-expression</i> is a negative number, a trailing minus sign (-) is included in the result. If <i>numeric-expression</i> is a positive number, a trailing blank is included in the result.
PR	Suffix: If <i>numeric-expression</i> is a negative number, a leading less than character (<) and a trailing greater than character (>) are included in the result. If <i>numeric-expression</i> is a positive number, a leading space and a trailing space are included in the result.
,	Specifies that a comma be included in that location in the result. This comma is used as a group separator.
.	Specifies that a period be included in that location in the result. This period is used as a decimal point.
L	Prefix or Suffix: Specifies that the local currency symbol be included in that location in the result. The currency symbol is retrieved from message CPX8416 in message file QCPFMSG in library *LIBL.
D	Specifies that the local decimal point character be included in that location in the result. The decimal character is retrieved from message CPX8416 in message file QCPFMSG in library *LIBL.
G	Specifies that the local group separator character be included in that location in the result. If the local decimal character as retrieved from message CPX8416 in message file QCPFMSG in library *LIBL is a period, the group separator will be a comma. If the local decimal character is a comma, the group separator will be a period.

If *format-string* is not specified, the function is equivalent to VARCHAR(DECFLOAT(*numeric-expression*)).

The result is a representation of the *numeric-expression* value (which might be rounded) in the format that is specified by *format-string*. Prior to being formatted, the value of *numeric-expression* is rounded by using

the ROUND function if the number of digits to the right of the decimal point is greater than the number of digit format elements ('0' or '9') to the right of the decimal point in *format-string*. *format-string* is applied to this *rounded-input-value* according to the following rules:

- The result does not include any digit characters to the left of the decimal point if all of the following conditions are true:
 - $-1 < \textit{rounded-input-value} < 1$
 - *format-string* does not include a '0' format element to the left of the decimal point
 - *format-string* includes at least one digit format element ('0' or '9') to the right of the decimal point
- The result includes a single 0 character immediately before the implicit or explicit decimal point if all of the following conditions are true:
 - The value of *rounded-input-value* is 0 or -0
 - *format-string* includes only the '9' digit format elements to the left of the implicit or explicit decimal point
 - *format-string* does not include any digit format elements to the right of the decimal point
- If *format-string* includes both '0' and '9' format elements to the left of the decimal point, the position of the first digit format element from the left side of the format string determines the presence of leading blanks or zeroes. All '9' format elements specified after the leftmost '0' format element to the left of the implicit or explicit decimal point are treated the same as if a '0' format element had been specified. For example, the *format-string* value '99099' is the same as the value '99000'.
- If the number of digits to the right of the decimal point in *rounded-input-value* is less than the number of digit format elements to the right of the decimal point in *format-string*, the result includes the number of digit characters to the right of the decimal point that corresponds to the number of digit format elements to the right of the decimal point in *format-string*, padded to the right with zeros.
- If the number of digits to the left of the decimal point in *rounded-input-value* is greater than the number of digit format elements to the left of the decimal point in *format-string*, the result is a string of number sign (#) characters that matches the length that *format-string* produces in the result for valid values.
- If the value of *rounded-input-value* represents any of the positive or negative special values, Infinity, sNaN, or NaN, the string 'INFINITY', 'SNAN', 'NAN', '-INFINITY', '-SNAN', or '-NAN' is returned without using the format that is specified by *format-string*. The decimal floating-point special value sNaN does not result in an exception when converted to a string.
- If *format-string* does not include any of the sign format elements 'S', 'MI', or 'PR', and the value of *rounded-input-value* is negative, a minus sign (–) is included in the result. Otherwise, a blank is included in the resulting string. The minus sign or blank immediately precedes the first digit of the result to the left of the decimal point, or the decimal point if there are no digits to the left of the decimal point.

The result is a string representation of *rounded-input-value*. The data type of the result is varying-length character or varying-length graphic based on the data type of the *format-string*. If a single argument is specified the length attribute is 42. Otherwise the length attribute is 254. The actual length of the result is determined by *format-string*, if specified. Otherwise, the actual length of the result is the smallest number of characters that can represent the value of *rounded-input-value*. If the resulting string exceeds the length attribute of the result, the result will be truncated.

The CCSID of the result is the same as the CCSID of the *format-string*. If *format-string* is not specified, the CCSID of the result is the default SBCS CCSID at the current server.

Note

Syntax alternatives: TO_CHAR is a synonym for VARCHAR_FORMAT.

Examples

Example: Timestamp to VARCHAR

- Set the character variable *TVAR* to a string representation of the timestamp value of RECEIVED from CORPDATA.IN_TRAY, formatted as YYYY-MM-DD HH24:MI:SS.

```
SELECT VARCHAR_FORMAT(RECEIVED, 'YYYY-MM-DD HH24:MI:SS')
INTO :TVAR
FROM CORPDATA.IN_TRAY
WHERE SOURCE = 'CHAAS'
```

Returns the string:

```
1988-12-22 14:07:21
```

Assuming that the value in the RECEIVED column is one second before the beginning of the year 2000 (December 31, 1999 at 23:59:59pm), the following string is returned:

```
1999-12-31 23:59:59
```

The result would be different if HH12 had been specified instead of HH24 in the format string:

```
1999-12-31 11:59:59
```

Example: Timestamp to VARCHAR

- Assume that the variable *TMSTAMP* is defined as a *TIMESTAMP* and has the following value: 2007-03-09-14.07.38.123456. The following examples show several invocations of the function and the resulting string values. The result data type in each case is *VARCHAR(255)*.

Function invocation	Result
<code>VARCHAR_FORMAT(TMSTAMP, 'YYYYMMDDHHMISSFF3')</code>	20070309020738123
<code>VARCHAR_FORMAT(TMSTAMP, 'YYYYMMDDHH24MISS')</code>	20070309140738
<code>VARCHAR_FORMAT(TMSTAMP, 'YYYYMMDDHHMI')</code>	200703090207
<code>VARCHAR_FORMAT(TMSTAMP, 'DD/MM/YY')</code>	09/03/07
<code>VARCHAR_FORMAT(TMSTAMP, 'MM-DD-YYYY')</code>	03-09-2007
<code>VARCHAR_FORMAT(TMSTAMP, 'J')</code>	2454169
<code>VARCHAR_FORMAT(TMSTAMP, 'Q')</code>	1
<code>VARCHAR_FORMAT(TMSTAMP, 'W')</code>	2
<code>VARCHAR_FORMAT(TMSTAMP, 'IW')</code>	10
<code>VARCHAR_FORMAT(TMSTAMP, 'WW')</code>	10
<code>VARCHAR_FORMAT(TMSTAMP, 'Month')</code>	March
<code>VARCHAR_FORMAT(TMSTAMP, 'MONTH')</code>	MARCH
<code>VARCHAR_FORMAT(TMSTAMP, 'MON')</code>	MAR

Example: Timestamp to VARCHAR

- Assume that the variable *DTE* is defined as a *DATE* and has the value of '2007-03-09'. The following examples show several invocations of the function and the resulting string values. The result data type in each case is *VARCHAR(255)*:

Function invocation	Result
<code>VARCHAR_FORMAT(DTE, 'YYYYMMDD')</code>	20070309
<code>VARCHAR_FORMAT(DTE, 'YYYYMMDDHH24MISS')</code>	20070309000000

Example: Timestamp to VARCHAR

- Format the hour of the specified string representation of a timestamp:

```
SELECT
  VARCHAR_FORMAT(TIMESTAMP('1979-04-07-14.00.00.000000'), 'HH'),
  VARCHAR_FORMAT(TIMESTAMP('1979-04-07-14.00.00.000000'), 'HH12'),
  VARCHAR_FORMAT(TIMESTAMP('1979-04-07-14.00.00.000000'), 'HH24'),
  VARCHAR_FORMAT(TIMESTAMP('2000-01-01-00.00.00.000000'), 'HH'),
  VARCHAR_FORMAT(TIMESTAMP('2000-01-01-12.00.00.000000'), 'HH'),
  VARCHAR_FORMAT(TIMESTAMP('2000-01-01-24.00.00.000000'), 'HH'),
  VARCHAR_FORMAT(TIMESTAMP('2000-01-01-00.00.00.000000'), 'HH12'),
  VARCHAR_FORMAT(TIMESTAMP('2000-01-01-12.00.00.000000'), 'HH12'),
  VARCHAR_FORMAT(TIMESTAMP('2000-01-01-24.00.00.000000'), 'HH12'),
  VARCHAR_FORMAT(TIMESTAMP('2000-01-01-00.00.00.000000'), 'HH24'),
  VARCHAR_FORMAT(TIMESTAMP('2000-01-01-12.00.00.000000'), 'HH24')
```

```

VARCHAR_FORMAT(TIMESTAMP('2000-01-01-24.00.00.000000'), 'HH24')
FROM SYSIBM.SYSDUMMY1;

```

The previous SELECT statement returns the following values:

```
'02' '02' '14' '12' '12' '12' '12' '12' '12' '12' '00' '12' '24'
```

Example: Numeric to VARCHAR

- Assume that the variables POSNUM and NEGNUM are defined as DECFLOAT(34) and have the following values: '1234.56' and '-1234.56', respectively. The following examples show several invocations of the function and the resulting string values.

Function invocation	Result
-----	-----
VARCHAR_FORMAT(POSNUM)	'1234.56'
VARCHAR_FORMAT(NEGNUM)	'-1234.56'
VARCHAR_FORMAT(POSNUM, '9999.99')	' 1234.56'
VARCHAR_FORMAT(NEGNUM, '9999.99')	'-1234.56'
VARCHAR_FORMAT(POSNUM, '99999.99')	' 1234.56'
VARCHAR_FORMAT(NEGNUM, '99999.99')	'-1234.56'
VARCHAR_FORMAT(POSNUM, '00000.00')	' 01234.56'
VARCHAR_FORMAT(NEGNUM, '00000.00')	'-01234.56'
VARCHAR_FORMAT(POSNUM, '9999.99MI')	'1234.56 '
VARCHAR_FORMAT(NEGNUM, '9999.99MI')	'1234.56-'
VARCHAR_FORMAT(POSNUM, 'S9999.99')	'+1234.56'
VARCHAR_FORMAT(NEGNUM, 'S9999.99')	'-1234.56'
VARCHAR_FORMAT(POSNUM, '9999.99PR')	' 1234.56 '
VARCHAR_FORMAT(NEGNUM, '9999.99PR')	'<1234.56>'
VARCHAR_FORMAT(POSNUM, '\$\$9,999.99')	'+\$1,234.56'
VARCHAR_FORMAT(NEGNUM, '\$\$9,999.99')	'-\$1,234.56'

VARCHAR_FORMAT_BINARY

The VARCHAR_FORMAT_BINARY function returns a character string representation of a bit string that has been formatted using a *format-string*.

►► VARCHAR_FORMAT_BINARY (— *expression* — , — *format-string* —) ◄◄

expression

An expression that returns a built-in binary string or character FOR BIT DATA string. The length of *expression* must be equal to the number of 'x' or 'X' characters in the *format-string* divided by 2.

format-string

An expression that returns a built-in character string or graphic string data type. *format-string* contains a template for how the value for *expression* is to be formatted.

Valid format strings are: 'xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx' and 'XXXXXXXX-XXXX-XXXX-XXXX-XXXXXXXXXXXX' where each 'x' or 'X' corresponds to one hexadecimal digit from *expression*. If 'x' is specified, the character returned for the corresponding hexadecimal digit will be lower case. Otherwise, the character returned will be upper case.

The result of the function is a varying-length character string with the length attribute and actual length based on the format string. For the two valid format strings, the length attribute and actual length of the result is 36. If either argument can be null, the result can be null; if either argument is null, the result is the null value.

The CCSID of the result is the CCSID of *format-string*.

Note

Syntax alternatives: VARCHAR_FORMAT_BIT is a synonym for VARCHAR_FORMAT_BINARY.

Example

- Represent a Universal Unique Identifier in its formatted form:

```
VALUES VARCHAR_FORMAT_BINARY(BX'd83d6360181811db9804b622a1ef5492',
                              'xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx')
```

Result returned:

```
'd83d6360-1818-11db-9804-b622a1ef5492'
```

- Represent a Universal Unique Identifier in its formatted form:

```
VALUES VARCHAR_FORMAT_BINARY(BX'd83d6360181811db9804b622a1ef5492',
                              'XXXXXXXX-XXXX-XXXX-XXXX-XXXXXXXXXXXX')
```

Result returned:

```
'D83D6360-1818-11DB-9804-B622A1EF5492'
```

VARGRAPHIC

The VARGRAPHIC function returns a graphic-string representation.

LOCAL

The VARGRAPHIC function returns a graphic-string representation of

- An integer number if the first argument is a SMALLINT, INTEGER, or BIGINT.
- A decimal number if the first argument is a packed or zoned decimal number.
- A double-precision floating-point number if the first argument is a DOUBLE or REAL.

- A decimal floating-point number if the first argument is DECFLOAT.
- A character string if the first argument is any type of character string.
- A graphic string if the first argument is a Unicode graphic string.
- A date value if the first argument is a DATE.
- A time value if the first argument is a TIME.
- A timestamp value if the first argument is a TIMESTAMP.

The result of the function is a varying-length graphic string (VARGRAPHIC).

If the first argument can be null, the result can be null. If the first argument is null, the result is the null value. If the first argument is an empty string or the EBCDIC string X'0E0F', the result is an empty string.

Integer to Vargraphic

integer-expression

An expression that returns a value that is an integer data type (either SMALLINT, INTEGER, or BIGINT).

The result is a varying-length graphic string of the argument in the form of an SQL integer constant. The result consists of n characters that are the significant digits that represent the value of the argument with a preceding minus sign if the argument is negative. It is left justified.

- If the argument is a small integer, the length attribute of the result is 6.
- If the argument is a large integer, the length attribute of the result is 11.
- If the argument is a big integer, the length attribute of the result is 20.

The actual length of the result is the smallest number of characters that can be used to represent the value of the argument. Leading zeroes are not included. If the argument is negative, the first character of the result is a minus sign. Otherwise, the first character is a digit or the *decimal-character*.

The CCSID of the result is 1200 (UTF-16).

Decimal to Vargraphic

decimal-expression

An expression that returns a value that is a packed or zoned decimal data type (either DECIMAL or NUMERIC). If a different precision and scale is wanted, the DECIMAL scalar function can be used to make the change.

decimal-character

Specifies the single-byte character constant that is used to delimit the decimal digits in the result character string. The character must be a period or comma. If the second argument is not specified, the decimal point is the default decimal point. For more information, see [“Decimal point” on page 116](#).

The result is a varying-length graphic string representation of the argument. The result includes a decimal character and up to p digits, where p is the precision of the *decimal-expression* with a preceding minus sign if the argument is negative. Leading zeros are not returned. Trailing zeros are returned. If the scale of *decimal-expression* is zero, the decimal character is not returned.

The length attribute of the result is $2+p$ where p is the precision of the *decimal-expression*. The actual length of the result is the smallest number of characters that can be used to represent the result, except that trailing characters are included. Leading zeros are not included. If the argument is negative, the result begins with a minus sign. Otherwise, the result begins with a digit or the *decimal-character*.

The CCSID of the result is 1200 (UTF-16).

Floating-point to Vargraphic

floating-point expression

An expression that returns a value that is a floating-point data type (DOUBLE or REAL).

decimal-character

Specifies the single-byte character constant that is used to delimit the decimal digits in the result character string. The character must be a period or comma. If the second argument is not specified, the decimal point is the default decimal point. For more information, see [“Decimal point” on page 116](#).

The result is a varying-length graphic string representation of the argument in the form of a floating-point constant.

The length attribute of the result is 24. The actual length of the result is the smallest number of characters that can represent the value of the argument such that the mantissa consists of a single digit other than zero followed by the *decimal-character* and a sequence of digits. If the argument is negative, the first character of the result is a minus sign; otherwise, the first character is a digit or the *decimal-character*. If the argument is zero, the result is 0E0.

The CCSID of the result is 1200 (UTF-16).

Decimal floating-point to Vargraphic***decimal-floating-point expression***

An expression that returns a value that is a decimal floating-point data type.

decimal-character

Specifies the single-byte character constant that is used to delimit the decimal digits in the result character string. The character must be a period or comma. If the second argument is not specified, the decimal point is the default decimal point. For more information, see [“Decimal point” on page 116](#).

The result is a varying-length graphic string representation of the argument in the form of a decimal floating-point constant.

The length attribute of the result is 42. The actual length of the result is the smallest number of characters that represents the value of the argument, including the sign, digits, and *decimal-character*. Trailing zeros are significant. If the argument is negative, the first character of the result is a minus sign; otherwise, the first character is a digit or the *decimal-character*. If the argument is zero, the result is 0.

If the DECFLOAT value is Infinity, sNaN, or NaN, the strings 'INFINITY', 'SNAN', and 'NAN', respectively, are returned. If the special value is negative, a minus sign will be the first character in the string. The DECFLOAT special value sNaN does not result in an exception when converted to a string.

The CCSID of the result is 1200 (UTF-16).

Character to Vargraphic***character-expression***

Specifies a character string expression. It cannot be a CHAR or VARCHAR bit data.

length

An integer constant that specifies the length attribute of the result and must be an integer constant between 1 and 16370 if the first argument is not nullable or between 1 and 16369 if the first argument is nullable.

If the second argument is not specified, or if DEFAULT is specified, the length attribute of the result is the same as the length attribute of the first argument, except if the expression is an empty string or the EBCDIC string X'0E0F', the length attribute of the result is 1.

The actual length of the result is the minimum of the length attribute of the result and the actual length of *character-expression*. Each character of the argument determines a character of the result. If the length (in characters) of the *character-expression* is greater than the length attribute of the result, truncation is performed. A warning (SQLSTATE 01004) is returned unless the truncated characters were all blanks.

integer

An integer constant that specifies the CCSID of the result. It must be a DBCS, UTF-16, or UCS-2 CCSID. The CCSID cannot be 65535. If the CCSID represents Unicode graphic data, each character of the argument determines a character of the result. The *n*th character of the result is the UTF-16 or UCS-2 equivalent of the *n*th character of the argument.

If *integer* is not specified then the CCSID of the result is determined by a mixed CCSID. Let *M* denote that mixed CCSID.

In the following rules, *S* denotes one of the following:

- If the string expression is a host variable containing data in a foreign encoding scheme, *S* is the result of the expression after converting the data to a CCSID in a native encoding scheme. (See “Character conversion” on page 28 for more information.)
- If the string expression is data in a native encoding scheme, *S* is that string expression.

M is determined as follows:

- If the CCSID of *S* is 1208 (UTF-8), *M* is 1200 (UTF-16).
- If the CCSID of *S* is a mixed CCSID, *M* is that CCSID.
- If the CCSID of *S* is an SBCS CCSID:
 - If the CCSID of *S* has an associated mixed CCSID, *M* is that CCSID.
 - Otherwise the operation is not allowed.

The following table summarizes the result CCSID based on *M*.

M	Result CCSID	Description	DBCS Substitution Character
930	300	Japanese EBCDIC	X'FEFE'
933	834	Korean EBCDIC	X'FEFE'
935	837	S-Chinese EBCDIC	X'FEFE'
937	835	T-Chinese EBCDIC	X'FEFE'
939	300	Japanese EBCDIC	X'FEFE'
5026	4396	Japanese EBCDIC	X'FEFE'
5035	4396	Japanese EBCDIC	X'FEFE'

The equivalence of SBCS and DBCS characters depends on *M*. Regardless of the CCSID, every double-byte code point in the argument is considered a DBCS character, and every single-byte code point in the argument is considered an SBCS character with the exception of the EBCDIC mixed data shift codes X'0E' and X'0F'.

- If the *n*th character of the argument is a DBCS character, the *n*th character of the result is that DBCS character.
- If the *n*th character of the argument is an SBCS character that has an equivalent DBCS character, the *n*th character of the result is that equivalent DBCS character.
- If the *n*th character of the argument is an SBCS character that does not have an equivalent DBCS character, the *n*th character of the result is the DBCS substitution character.

Graphic to Vargraphic

graphic-expression

An expression that returns a value that is a graphic string.

length

An integer constant that specifies the length attribute of the result and must be an integer constant between 1 and 16370 if the first argument is not nullable or between 1 and 16369 if the first argument is nullable.

If the second argument is not specified, or if DEFAULT is specified, the length attribute of the result is the same as the length attribute of the first argument, except if the expression is an empty string, the length attribute of the result is 1.

The actual length of the result is the minimum of the length attribute of the result and the actual length of *graphic-expression*. Each character of the argument determines a character of the result. If the length (in characters) of the *graphic-expression* is greater than the length attribute of the result, truncation is performed. A warning (SQLSTATE 01004) is returned unless the truncated characters were all blanks.

integer

An integer constant that specifies the CCSID of the result. It must be a DBCS, UTF-16, or UCS-2 CCSID. The CCSID cannot be 65535.

If *integer* is not specified then the CCSID of the result is the CCSID of the first argument.

Datetime to Vargraphic***datetime-expression***

An expression that is one of the following three built-in data types

date

The result is the varying-length graphic string representation of the date in the format specified by the second argument. If the second argument is not specified, the format used is the default date format. If the format is ISO, USA, EUR, or JIS, the length attribute and actual length of the result is 10. Otherwise the length attribute and actual length of the result is the length of the default date format. For more information see [“String representations of datetime values” on page 75](#).

time

The result is the varying-length graphic string representation of the time in the format specified by the second argument. If the second argument is not specified, the format used is the default time format. The length attribute and actual length of the result is 8. For more information see [“String representations of datetime values” on page 75](#).

timestamp

The second argument is not applicable and must not be specified.

The result is the varying-length graphic string representation of the timestamp. If *datetime-expression* is a `TIMESTAMP(0)`, the length attribute and actual length of the result is 19. If the data type of *datetime-expression* is a `TIMESTAMP(n)`, the length attribute and actual length of the result is $20+n$. Otherwise, the length attribute and actual length of the result is 26.

The CCSID of the result is 1200 (UTF-16).

ISO, EUR, USA, or JIS

Specifies the date or time format of the resulting graphic string. For more information, see [“String representations of datetime values” on page 75](#).

LOCAL

Specifies that the date or time format of the resulting graphic string should come from the `DATFMT`, `DATSEP`, `TIMFMT`, and `TIMSEP` attributes of the job at the current server.

Note

Syntax alternatives: The `CAST` specification should be used to increase the portability of applications when the first argument is a string and the length attribute is specified. For more information, see [“CAST specification” on page 176](#).

Example

- Using the EMPLOYEE table, set the host variable VAR_DESC (VARGRAPHIC(24)) to the VARGRAPHIC equivalent of the first name (FIRSTNME) for employee number (EMPNO) '000050'.

```
SELECT VARGRAPHIC(FIRSTNME)
INTO :VAR_DESC
FROM EMPLOYEE
WHERE EMPNO = '000050'
```

VERIFY_GROUP_FOR_USER

The VERIFY_GROUP_FOR_USER function returns a value that indicates whether the specified user is in the list of user profiles or is a member of any of the group user profiles specified by the list of *authorization-id-expression* arguments.

SESSION_USER or USER or CURRENT_USER

Specifies an authorization ID.

authorization-id-expression

An expression that specifies an authorization name. The existence of the authorization name at the current server is not verified. *authorization-id-expression* must return a value of any built-in character-string or graphic-string data type. The value of each *authorization-id-expression* must have a length of at least 1 and be less than or equal to 10.

The result of the function is a large integer. The result cannot be null.

The value of the result is 1 if the authorization ID represented by the first argument is anywhere in the list of *authorization-id-expressions*. Otherwise, the result is 0.

The VERIFY_GROUP_FOR_USER function is deterministic within a connection. It is not deterministic across connections. It can be referenced in a CREATE MASK or CREATE PERMISSION statement to verify access to the data.

Example

Assume that table EMPLOYEE exists and that column level access control is activated for the table. Alex (with QIBM_DB_SECADM authority) created the following column mask to control what information is returned for a social security number depending on who requests the information. The column mask only returns the actual social security number if the session user is a member of the MGR group profile. Otherwise a masked representation of the social security number is returned.

```
CREATE MASK SSN_MASK
ON EMPLOYEE
FOR COLUMN SSN
RETURN
CASE
WHEN VERIFY_GROUP_FOR_USER (SESSION_USER, 'MGR') = 1
THEN SSN
ELSE 'XXX-XX' CONCAT SUBSTR(SSN, 8,4)
END
ENABLE;
```

An ALTER TABLE statement is then issued to activate the column mask on the EMPLOYEE table:

```
ALTER TABLE EMPLOYEE
ACTIVATE COLUMN ACCESS CONTROL;
COMMIT;
```

Assume that Mary is a manager and is a member of the MGR group profile. Mary issues the following statement:

```
SELECT SSN FROM EMPLOYEE WHERE NAME = 'Tom';
```

The SSN_MASK column mask is applied to the SSN column to produce the result table. Since Mary is a member of the MGR group profile, the result table contains Tom's actual social security number.

Later, Mary is no longer a manager and is removed from the MGR group profile. She issues the same query again:

```
SELECT SSN FROM EMPLOYEE WHERE NAME = 'Tom' ;
```

As before, the SSN_MASK column mask is applied to the SSN column to produce the result table. This time the result table contains a masked version of Tom's social security number where only the last 4 digits of the actual number are returned. An 'X' is returned for the other digits.

WEEK

The WEEK function returns an integer between 1 and 54 that represents the week of the year. The week starts with Sunday, and January 1 is always in the first week.

►► WEEK — (— *expression* —) ◄◄

expression

An expression that returns a value of one of the following built-in data types: a date, a timestamp, a character string, or a graphic string.

If *expression* is a character or graphic string, its value must be a valid string representation of a date or timestamp. For the valid formats of string representations of dates and timestamps, see [“String representations of datetime values”](#) on page 75.

The result of the function is a large integer. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

Example

- Using the PROJECT table, set the host variable WEEK (INTEGER) to the week that project ('PL2100') ended.

```
SELECT WEEK(PRENDATE)
INTO :WEEK
FROM PROJECT
WHERE PROJNO = 'PL2100'
```

Results in WEEK being set to 38.

- Assume that table X has a DATE column called DATE_1 with various dates from the list below.

```
SELECT DATE_1, WEEK(DATE_1)
FROM X
```

Results in the following list shows what is returned by the WEEK function for various dates.

1997-12-28	53
1997-12-31	53
1998-01-01	1
1999-01-01	1
1999-01-04	2
1999-12-31	53
2000-01-01	1
2000-01-03	2

WEEK_ISO

The WEEK_ISO function returns an integer between 1 and 53 that represents the week of the year. The week starts with Monday. Week 1 is the first week of the year to contain a Thursday, which is equivalent to the first week containing January 4. Thus, it is possible to have up to 3 days at the beginning of the year appear as the last week of the previous year or to have up to 3 days at the end of a year appear as the first week of the next year.

►► WEEK_ISO — (— *expression* —) ◄◄

expression

An expression that returns a value of one of the following built-in data types: a date, a timestamp, a character string, or a graphic string.

If *expression* is a character or graphic string, its value must be a valid string representation of a date or timestamp. For the valid formats of string representations of dates and timestamps, see [“String representations of datetime values”](#) on page 75.

The result of the function is a large integer. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

Examples

- Using the PROJECT table, set the host variable WEEK (INTEGER) to the week that project ('AD2100') ended.

```
SELECT WEEK_ISO(PRENDATE)
INTO :WEEK
FROM PROJECT
WHERE PROJNO = 'AD3100'
```

Results in WEEK being set to 5.

- Assume that table X has a DATE column called DATE_1 with various dates from the list below.

```
SELECT DATE_1, WEEK_ISO(DATE_1)
FROM X
```

Results in the following:

```
1997-12-28    52
1997-12-31     1
1998-01-01     1
1999-01-01    53
1999-01-04     1
1999-12-31    52
2000-01-01    52
2000-01-03     1
```

WRAP

The WRAP function transforms a readable DDL statement into an obfuscated DDL statement.

►► WRAP — (— *object-definition-string* —) ►►

In an obfuscated DDL statement, the procedural logic and embedded SQL statements are scrambled in such a way that any intellectual property in the logic cannot be easily extracted.

The schema is SYSIBMADM.

object-definition-string

A string of type CLOB or DBCLOB containing a DDL statement. It can be one of the following SQL statements:

- CREATE FUNCTION (SQL scalar)
- CREATE FUNCTION (SQL table)
- CREATE PROCEDURE (SQL)
- CREATE TRIGGER

The result is a string of type CLOB(2M) which contains an encoded version of the input statement. The result cannot be null. The encoding consists of a prefix of the original statement up to and including the routine signature or trigger name, followed by the keyword WRAPPED. This keyword is followed by information about the application server that invoked the function. The information has the form *pppvrrm* where:

- *ppp* identifies the product using the following 3 characters:
 - DSN for Db2 for z/OS
 - QSQ for Db2 for i
 - SQL for Db2 for LUW
- *vv* is a two-digit version identifier, such as '07'
- *rr* is a two-digit release identifier, such as '02'
- *m* is a one-character modification level identifier, such as '0'

For example Db2 for i version 7.3 is identified as 'QSQ07030'.

This application server information is followed by a string of letters (a-z and A-Z), digits (0-9), underscores, and colons.

The encoded DDL statement may be up to one-third longer than the plain text form of the statement. If the result exceeds the maximum length for SQL statements, an error is issued.

Note

The encoding of the statement is meant to obfuscate the content and should not be considered as a form of strong encryption.

Examples

Example 1: Produce an obfuscated version of a function that computes a yearly salary from an hourly wage given a 40 hour work week.

```
VALUES WRAP('CREATE FUNCTION salary(wage DECFLOAT) RETURNS DECFLOAT
            RETURN wage * 40 * 52')
```

The result of this statement would be something of the form:

```
CREATE FUNCTION salary(wage DECFLOAT) WRAPPED QSQ07020 <encoded-suffix>
```

Example 2: Produce an obfuscated version of a trigger that sets a complex default.

```
VALUES WRAP('CREATE OR REPLACE TRIGGER trig1 BEFORE INSERT ON emp  
REFERENCING NEW AS n FOR EACH ROW  
WHEN (n.bonus IS NULL) SET n.bonus = n.salary * .04')
```

The result of this statement would be something of the form:

```
CREATE TRIGGER trig1 WRAPPED QSQ07020 <encoded-suffix>
```

XMLATTRIBUTES

The XMLATTRIBUTES function constructs XML attributes from the arguments.

This function can only be used as an argument of the XMLELEMENT function. The result is an XML sequence containing an XML attribute for each non-null *attribute-value-expression* argument.

attribute-value-expression

An expression whose result is the attribute value. The data type of *attribute-value-expression* must not be ROWID, DATALINK, XML or a distinct type that is based on ROWID, DATALINK, or XML. The expression can be any SQL expression. If the expression is not a simple column reference, an attribute name must be specified.

attribute-name

Specifies an attribute name. The name is an SQL identifier that must be in the form of an XML qualified name, or QName. See the W3C XML namespace specifications for more details on valid names. The attribute name cannot be "xmlns" or prefixed with "xmlns:". A namespace is declared using the function XMLNAMESPACES. Duplicate attribute names, whether implicit or explicit, are not allowed.

If *attribute-name* is not specified, *attribute-value-expression* must be a column name. The attribute name is created from the column name using the fully escaped mapping from a column name to an XML attribute name.

The result of the function is XML. If the result of any *attribute-value-expression* can be null, the result can be null; if the result of every *attribute-value-expression* is null, the result is the null value.

Example

Note: XMLATTRIBUTES does not insert blank spaces or new line characters in the output. All example output has been formatted to enhance readability.

- Produce an element with attributes.

```
SELECT E.EMPNO, XMLELEMENT(  
  NAME "Emp",  
  XMLATTRIBUTES(  
    E.EMPNO, E.FIRSTNAME || ' ' || E.LASTNAME AS "name"  
  )  
  )  
AS "Result"  
FROM EMPLOYEE E  
WHERE E.EDLEVEL = 12
```

This query produces the following result:

```
EMPNO  Result  
000290 <Emp EMPNO="000290" name="JOHN PARKER"/>  
000310 <Emp EMPNO="000310" name="MAUDE SETRIGHT"/>  
200310 <Emp EMPNO="200310" name="MICHELLE SPRINGER"/>
```

XMLCOMMENT

The XMLCOMMENT function returns an XML value with the input argument as the content.

► XMLCOMMENT — (— *string-expression* —) ►

string-expression

An expression that returns a value of any built-in character-string or graphic-string data type. It cannot be CHAR or VARCHAR bit data. The result of *string-expression* is parsed to check for conformance to the content of an XML comment, as specified by the following rules:

- Two adjacent hyphens ('--') must not occur in the string expression.
- The string expression must not end with a hyphen ('-').
- Each character of the string can be any Unicode character, excluding the surrogate blocks, X'FFFE', and X'FFFF'.⁷⁸

If *string-expression* does not conform to the previous rules, an error is returned.

The result of the function is XML. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

Example

- Generate an XML comment.

```
SELECT XMLCOMMENT('This is an XML comment')
FROM SYSIBM.SYSDUMMY1
```

This query produces the following result:

```
<!--This is an XML comment-->
```

⁷⁸ Valid Unicode characters consist of the following Unicode code points: #x9, #xA, #xD, #x20-#xD7FF, #xE000-#xFFFF, #x10000-#x10FFFF.

XMLCONCAT

The XMLCONCAT function returns a sequence containing the concatenation of a variable number of XML input arguments.

► XMLCONCAT ((XML-expression , XML-expression)) ►

XML-expression

An expression that returns an XML value.

The result of the function is an XML sequence that contains the concatenation of the non-null input XML values. Null values in the input are ignored.

The result of the function is XML. The result can be null; if the result of every input value is null, the result is the null value.

Examples

Note: XMLCONCAT does not insert blank spaces or new line characters in the output. All example output has been formatted to enhance readability.

- Concatenate first name and last name elements by using "first" and "last" element names for each employee

```
SELECT XMLSERIALIZE(  
  XMLCONCAT(  
    XMLELEMENT(NAME "first", e.firstnme),  
    XMLELEMENT(NAME "last", e.lastname)  
  ) AS VARCHAR(100) ) AS "result"  
FROM EMPLOYEE E  
WHERE e.lastname = 'SMITH'
```

The result of the query would look similar to the following result:

```
result  
-----  
<first>DANIEL</first><last>SMITH</last>  
<first>PHILIP</first><last>SMITH</last>
```

- Construct a department element for departments A00 and B01 containing a list of employees sorted by first name. Include an introductory comment immediately preceding the department element.

```
SELECT XMLCONCAT(  
  XMLCOMMENT (  
    'Confirm these employees are on track for their product schedule'),  
  XMLELEMENT(  
    NAME "Department",  
    XMLATTRIBUTES( E.WORKDEPT AS "name"),  
    XMLAGG(  
      XMLELEMENT(NAME "emp", E.FIRSTNME)  
      ORDER BY E.FIRSTNME  
    )  
  )  
FROM EMPLOYEE E  
WHERE E.WORKDEPT IN ('A00', 'B01')  
GROUP BY E.WORKDEPT
```

This query produces the following result:

```
<!--Confirm these employees are on track for their product schedule-->  
<Department name="A00">  
<emp>CHRISTINE</emp>  
<emp>SEAN</emp>  
<emp>VINCENZO</emp>  
</Department>  
<!--Confirm these employees are on track for their product schedule-->  
<Department name="B01">
```

```
<emp>MICHAEL</emp>  
</Department>
```

XMLDOCUMENT

The XMLDOCUMENT function returns an XML value.

XML-expression

An expression that returns an XML value.

The result of the function is XML. If the result of *XML-expression* can be null, the result can be null; if every *XML-expression* is null, the result is the null value.

Example

- Insert a constructed document into an XML column.

```
INSERT INTO T1 VALUES(123,
  (SELECT XMLDOCUMENT(
    XMLELEMENT(NAME "Emp",
      E.FIRSTNAME || ' ' || E.LASTNAME,
      XMLCOMMENT('This is just a simple example')
    )
  )
  FROM EMPLOYEE E
  WHERE E.EMPNO = '000120'))
```

XMLELEMENT

The XMLELEMENT function returns an XML value that is an XML element.

Notes:

- 1 The OPTION clause can only be specified if at least one *xmlattributes-function* or *element-content-expression* is specified
- 2 If *element-content-expression* is not specified, EMPTY ON NULL or NULL ON NULL must not be specified.
- 3 The same clause must not be specified more than once.

NAME *element-name*

Specifies the name of an XML element. The name is an SQL identifier that must be in the form of an XML qualified name, or QName. See the W3C XML namespace specifications for more details on valid names. If the name is qualified, the namespace prefix must be declared within the scope.

xmlnamespaces-declaration

Specifies the XML namespace declarations that are the result of the XMLNAMESPACES declaration. The namespaces that are declared are in the scope of the XMLELEMENT function. The namespaces apply to any nested XML functions within the XMLELEMENT function, regardless of whether or not they appear inside another subselect. See [“XMLNAMESPACES” on page 661](#) for more information on declaring XML namespaces.

If *xmlnamespaces-declaration* is not specified, namespace declarations are not associated with the constructed element.

xmlattributes-function

Specifies the XML attributes for the element. The attributes are the result of the XMLATTRIBUTES function. See [“XMLATTRIBUTES” on page 650](#) for more information on construction attributes.

element-content-expression

The content of the generated XML element node is specified by an expression or a list of expressions. The expression can be any SQL expression of any SQL data type except for ROWID or DATALINK. The expression is used to construct the namespace declarations, attributes, and content of the constructed element.

If *element-content-expression* is not specified, an empty string is used as the content for the element and NULL ON NULL or EMPTY ON NULL must not be specified.

OPTION

Specifies additional options for constructing the XML element. This clause has no impact on nested `XMLELEMENT` invocations specified in *element-content-expression*.

EMPTY ON NULL or NULL ON NULL

Specifies whether a null value or an empty element is to be returned if the value of every *element-content-expression* is the null value. This option only affects null handling of element contents, not attribute values. The default is `EMPTY ON NULL`.

EMPTY ON NULL

If the value of each *element-content-expression* is null, an empty element is returned.

NULL ON NULL

If the value of each *element-content-expression* is null, a null value is returned.

XMLBINARY USING BASE64 or XMLBINARY USING HEX

Specifies the assumed encoding of binary input data, character string data with the `FOR BIT DATA` attribute, or a distinct type that is based on one of these types. The encoding applies to element content or attribute values. The default is `XMLBINARY USING BASE64`.

XMLBINARY USING BASE64

Specifies that the assumed encoding is base64 characters, as defined for XML schema type `xs:base64Binary` encoding. The base64 encoding uses a 65-character subset of US-ASCII (10 digits, 26 lowercase characters, 26 uppercase characters, '+', and '/') to represent every six bits of the binary or bit data with one printable character in the subset. These characters are selected so that they are universally representable. Using this method, the size of the encoded data is 33 percent larger than the original binary or bit data.

XMLBINARY USING HEX

Specifies that the assumed encoding is hexadecimal characters, as defined for XML schema type `xs:hexBinary` encoding. The hexadecimal encoding represents each byte (8 bits) with two hexadecimal characters. Using this method, the encoded data is twice the size of the original binary or bit data.

This function takes an element name, an optional collection of namespace declarations, an optional collection of attributes, and zero or more arguments that make up the content of the XML element. The result is an XML sequence containing an XML element node or the null value. If the results of all *element-content-expression* arguments are empty strings, the result is an XML sequence that contains an empty element.

The result of the function is XML. The result can be null; if all the *element-content-expression* argument values are null and the `NULL ON NULL` option is in effect, the result is the null value.

Rules about using namespaces within `XMLELEMENT`: The following rules describe scoping of namespaces:

- The namespaces declared in the `XMLNAMESPACES` declaration are the in-scope namespaces of the element constructed by the `XMLELEMENT` function. If the element is serialized, then each of its in-scope namespaces will be serialized as a namespace attribute unless it is an in-scope namespace of an XML value that includes this element.
- The scope of these namespaces is the lexical scope of the `XMLELEMENT` function, including the element name, the attribute names that are specified in the `XMLATTRIBUTES` function, and all *element-content-expressions*. These are used to resolve the QNames in the scope.
- If an attribute of the constructed element comes from an *element-content-expression*, its namespace might not already be declared as an in-scope namespace of the constructed element. In this case, a new namespace is created for it. If this would result in a conflict, which means that the prefix of the attribute name is already bound to a different URI by an in-scope namespace, Db2 generates a different prefix to be used in the attribute name. A namespace is created for this generated prefix. The name of the generated prefix follows the following pattern: `db2ns-xx`, where `xx` is a pair of characters chosen from the set `[A-Z, a-z, 0-9]`.

Example

Note: XMLEMENT does not insert blank spaces or new line characters in the output. All example output has been formatted to enhance readability.

The following examples use a temporary CANDIDATES employee table:

```
DECLARE GLOBAL TEMPORARY TABLE CANDIDATES
(EMPNO CHAR(6),
 FIRSTNME VARCHAR(12),
 MIDINIT CHAR(1),
 LASTNAME VARCHAR(15),
 WORKDEPT CHAR(4),
 EDLEVEL INT)
INSERT INTO SESSION.CANDIDATES
VALUES('A0001', 'John', 'A', 'Parker', 'X001', 12)
INSERT INTO SESSION.CANDIDATES
VALUES('B0001', NULL, NULL, 'Smith', 'X001', 12)
INSERT INTO SESSION.CANDIDATES
VALUES('B0002', NULL, NULL, NULL, 'X001', NULL)
INSERT INTO SESSION.CANDIDATES
VALUES(NULL, NULL, NULL, NULL, 'X001', NULL)
```

- The following statement used the XMLEMENT function to create an XML element that contains an employee's name. The statement also sets the employee number as an attribute names serial. If there is a null value in the referenced column, the function returns the null value:

```
SELECT E.EMPNO, E.FIRSTNME, E.LASTNAME,
       XMLEMENT(NAME "foo:Emp",
                XMLNAMESPACES('http://www.foo.com' AS "foo"),
                XMLATTRIBUTES(E.EMPNO AS "serial"),
                E.FIRSTNME, E.LASTNAME
                OPTION NULL ON NULL) AS "Result"
FROM SESSION.CANDIDATES E
```

This query produces the following result:

EMPNO	FIRSTNME	LASTNAME	Result
A0001	John	Parker	<foo:Emp xmlns:foo="http://www.foo.com" serial="A0001">JohnParker</foo:Emp>
B0001	(null)	Smith	<foo:Emp xmlns:foo="http://www.foo.com" serial="B0001">Smith</foo:Emp>
B0002	(null)	(null)	(null)
(null)	(null)	(null)	(null)

- The following example is similar to the previous one. However, when there is a null value in the referenced column, an empty element is returned:

```
SELECT E.EMPNO, E.FIRSTNME, E.LASTNAME,
       XMLEMENT(NAME "foo:Emp",
                XMLNAMESPACES('http://www.foo.com' AS "foo"),
                XMLATTRIBUTES(E.EMPNO AS "serial"),
                E.FIRSTNME, E.LASTNAME
                OPTION EMPTY ON NULL) AS "Result"
FROM SESSION.CANDIDATES E
```

This query produces the following result:

EMPNO	FIRSTNME	LASTNAME	Result
A0001	John	Parker	<foo:Emp xmlns:foo="http://www.foo.com" serial="A0001">JohnParker</foo:Emp>
B0001	(null)	Smith	<foo:Emp xmlns:foo="http://www.foo.com" serial="B0001">Smith</foo:Emp>
B0002	(null)	(null)	<foo:Emp xmlns:foo="http://www.foo.com" serial="B0002"></foo:Emp>
(null)	(null)	(null)	<foo:Emp xmlns:foo="http://www.foo.com"></foo:Emp>

XMLFOREST

The XMLFOREST function returns an XML value that is a sequence of XML elements.

Notes:

¹ The same clause must not be specified more than once.

xmlnamespace-declaration

Specifies the XML namespace declarations that are the result of the XMLNAMESPACES declaration. The namespaces that are declared are in the scope of the XMLFOREST function. The namespaces apply to any nested XML functions within the XMLFOREST function, regardless of whether or not they appear inside another subselect. See “XMLNAMESPACES” on page 661 for more information on declaring XML namespaces.

If *xmlnamespace-declaration* is not specified, namespace declarations are not associated with the constructed XML elements.

element-content-expression

Specifies an expression that returns a value that is used for the content of a generated XML element. The data type of the expression must not be ROWID or DATALINK. If the expression is not a simple column reference, *element-name* must be specified.

AS *element-name*

Specifies an identifier that is used for the XML element name.

An XML element name must be an XML qualified name, or QName. See the W3C XML namespace specifications for more details on valid names. If the name is qualified, the namespace prefix must be declared within the scope.

If *element-name* is not specified, *element-content-expression* must be a column name. The element name is created from the column name using the fully escaped mapping from a column name to a QName.

OPTION

Specifies options for the result for NULL values, binary data, and bit data. The options will not be inherited by XMLELEMENT or XMLFOREST functions that appear in *element-content-expression*.

NULL ON NULL or EMPTY ON NULL

Specifies whether a null value or an empty element is to be returned if the value of every *element-content-expression* is the null value. This option only affects null handling of the *element-content-expression* arguments. The default is NULL ON NULL.

NULL ON NULL

If the value of each *element-content-expression* is null, a null value is returned.

EMPTY ON NULL

If the value of each *element-content-expression* is null, an empty element is returned.

XMLBINARY USING BASE64 or XMLBINARY USING HEX

Specifies the assumed encoding of binary input data, character string data with the FOR BIT DATA attribute, ROWID, or a distinct type that is based on one of these types. The encoding applies to element content or attribute values. The default is XMLBINARY USING BASE64.

XMLBINARY USING BASE64

Specifies that the assumed encoding is base64 characters, as defined for XML schema type `xs:base64Binary` encoding. The base64 encoding uses a 65-character subset of US-ASCII (10 digits, 26 lowercase characters, 26 uppercase characters, '+', and '/') to represent every six bits of the binary or bit data with one printable character in the subset. These characters are selected so that they are universally representable. Using this method, the size of the encoded data is 33 percent larger than the original binary or bit data.

XMLBINARY USING HEX

Specifies that the assumed encoding is hexadecimal characters, as defined for XML schema type `xs:hexBinary` encoding. The hexadecimal encoding represents each byte (8 bits) with two hexadecimal characters. Using this method, the encoded data is twice the size of the original binary or bit data.

The result of the function is an XML value. If the result of any *element-content-expression* can be null, the result can be null; if the result of every *element-content-expression* is null and the NULL ON NULL option is in effect, the result is the null value.

The XMLFOREST function can be expressed by using XMLCONCAT and XMLELEMENT. For example, the following two expressions are semantically equivalent.

```
XMLFOREST(xmlnamespaces-declaration, arg1 AS name1, arg2 AS name2, ...)
XMLCONCAT(XMLELEMENT(NAME name1, xmlnamespaces-declaration, arg1),
          XMLELEMENT(NAME name2, xmlnamespaces-declaration, arg2),
          ... )
```

When constructing elements that will be copied as content of another element that defines default namespaces, default namespaces should be explicitly undeclared in the copied element to avoid possible errors that could result from inheriting the default namespace from the new parent element. Predefined namespace prefixes ('`xs`', '`xsi`', '`xml`', '`sqlxml`') must also be declared explicitly when they are used.

Example

Note: XMLFOREST does not insert blank spaces or new line characters in the output. All example output has been formatted to enhance readability.

- Construct a forest of elements with a default namespace.

```
SELECT EMPNO,
       XMLFOREST(XMLNAMESPACES (DEFAULT 'http://hr.org',
                               'http://fed.gov' AS "d"),
                LASTNAME, JOB AS "d:job") AS "Result"
FROM EMPLOYEE WHERE EDLEVEL = 12
```

This query produces the following result:

```
EMPNO Result
000290 <LASTNAME xmlns:"http://hr.org" xmlns:d="http://fed.gov">PARKER
      </LASTNAME>
      <d:job xmlns:"http://hr.org" xmlns:d="http://fed.gov">OPERATOR</d:job>
000310 <LASTNAME xmlns:"http://hr.org" xmlns:d="http://fed.gov">SETRIGHT
      </LASTNAME>
      <d:job xmlns:"http://hr.org" xmlns:d="http://fed.gov">OPERATOR</d:job>
200310 <LASTNAME xmlns:"http://hr.org" xmlns:d="http://fed.gov">SPRINGER
```

```
</LASTNAME>  
<d:job xmlns:"http://hr.org" xmlns:d="http://fed.gov">OPERATOR</d:job>
```

XMLNAMESPACES

The XMLNAMESPACES declaration constructs namespace declarations from the arguments. This declaration can only be used as an argument for the XMLELEMENT and XMLFOREST functions. The result is one or more XML namespace declarations containing in-scope namespaces for each non-null input value.

Notes:

¹ The DEFAULT or NO DEFAULT clause can only be specified one time.

namespace-uri

Specifies an SQL character string constant that contains the namespace name or a universal resource identifier (URI). The character string constant must not be an empty string if it is used with *namespace-prefix*.

AS namespace-prefix

Specifies a namespace prefix. The prefix is an SQL identifier that must be in the form of an XML NCName. See the W3C XML namespace specifications for more details on valid names. The prefix must not be "xml" or "xmlns". The prefix must be unique within the list of namespace declarations.

The following namespace prefixes are pre-defined in SQL/XML: "xml", "xs", "xsd", "xsi", and "sqlxml". Their bindings are:

- xmlns:xml = "http://www.w3.org/XML/1998/namespace"
- xmlns:xs = "http://www.w3.org/2001/XMLSchema"
- xmlns:xsd = "http://www.w3.org/2001/XMLSchema"
- xmlns:xsi = "http://www.w3.org/2001/XMLSchema-instance"
- xmlns:sqlxml = "http://standards.iso.org/iso/9075/2003/sqlxml"

DEFAULT namespace-uri or NO DEFAULT

Specifies whether a default namespace is to be used within the scope of this namespace declaration.

The scope of this namespace declaration is the specified XML element and all XML expressions that are contained in the specified XML element.

DEFAULT namespace-uri

Specifies the default namespace to use within the scope of this namespace declaration. The *namespace-uri* applies for unqualified names in the scope unless it is overridden in a nested scope by another DEFAULT declaration or by a NO DEFAULT declaration.

namespace-uri specifies an SQL character string constant that contains a namespace name or universal resource identifier (URI). The character string constant can be an empty string in the context of the DEFAULT clause.

NO DEFAULT

Specifies that no default namespace is to be used within the scope of this namespace declaration. There is no default namespace in the scope unless the NO DEFAULT clause is overridden in a nested scope by a DEFAULT declaration.

The result of the function is an XML value that is an XML sequence that contains an XML namespace declaration for each specified namespace. The result cannot be null.

Examples

Note: XML processing does not insert blank spaces or new line characters in the output. All example output has been formatted to enhance readability.

- Generate an "employee" element for each employee. The employee element is associated with XML namespace "urn:bo", which is bound to prefix "bo". The element contains attributes for names and a hiredate subelement.

```
SELECT E.EMPNO,  
       XMLSERIALIZE(XMLELEMENT(NAME "bo:employee",  
                               XMLNAMESPACES('urn:bo' AS "bo"),  
                               XMLATTRIBUTES(E.LASTNAME, E.FIRSTNME),  
                               XMLELEMENT(NAME "bo:hiredate", E.HIREDATE))  
       AS CLOB(200))  
FROM EMPLOYEE E WHERE E.EDLEVEL = 12
```

This query produces the following result:

```
00029 <bo:employee xmlns:bo="urn:bo" LASTNAME="PARKER" FIRSTNME="JOHN">  
      <bo:hiredate>1988-05-30</bo:hiredate>  
      </bo:employee>  
00031 <bo:employee xmlns:bo="urn:bo" LASTNAME="SETRIGHT" FIRSTNME="MAUDE">  
      <bo:hiredate>1964-09-12</bo:hiredate>  
      </bo:employee>
```

- Generate two elements for each employee using XMLFOREST. The first "lastname" element is associated with the default namespace "http://hr.org", and the second "job" element is associated with XML namespace "http://fed.gov", which is bound to prefix "d".

```
SELECT EMPNO,  
       XMLSERIALIZE(XMLFOREST(XMLNAMESPACES(DEFAULT 'http://hr.org',  
                                           'http://fed.gov' AS "d"),  
                             LASTNAME, JOB AS "d:job")  
       AS CLOB(200))  
FROM EMPLOYEE WHERE EDLEVEL = 12
```

This query produces the following result:

```
00029 <LASTNAME xmlns="http://hr.org" xmlns:d="http://fed.gov">PARKER  
      </LASTNAME>  
      <d:job xmlns="http://hr.org" xmlns:d="http://fed.gov">  
      OPERATOR</d:job>  
00031 <LASTNAME xmlns="http://hr.org" xmlns:d="http://fed.gov">  
      SETRIGHT</LASTNAME>  
      <d:job xmlns="http://hr.org" xmlns:d="http://fed.gov">  
      OPERATOR</d:job>
```

XMLPARSE

The XMLPARSE function parses the arguments as an XML document and returns an XML value.

DOCUMENT

Specifies that the character string expression to be parsed must evaluate to a well-formed XML document that conforms to XML 1.0.

string-expression

An expression that returns a value that is a built-in character, Unicode graphic, or binary string. If a parameter marker is used, it must be explicitly cast to one of the supported data types.

STRIP WHITESPACE or PRESERVE WHITESPACE

Specifies whether or not whitespace in the input argument is to be preserved. If neither is specified, STRIP WHITESPACE is the default.

STRIP WHITESPACE

Specifies that whitespace characters will be stripped unless the nearest containing element has the attribute `xml:space='preserve'`. The whitespace characters in the CDATA section are also affected by this option.

PRESERVE WHITESPACE

Specifies that all whitespace is to be preserved, even when the nearest containing element has the attribute `xml:space='default'`.

The result of the function is XML. If the result of *string-expression* can be null, the result can be null; if the result of *string-expression* is null, the result is the null value. The CCSID of the result is determined from *string-expression*. If *string-expression* has a CCSID of 65535, the value from the SQL_XML_DATA_CCSID QAQQINI option is used.

The input string may contain an XML declaration that identifies the encoding of the characters in the XML document. The encoding in the XML declaration must match the encoding of the *string-expression*.

Examples

Example 1: Insert an XML document into the EMP table and preserve the whitespace in the original XML document.

```
INSERT INTO EMP (ID, XVALUE) VALUES(1001,  
XMLPARSE(DOCUMENT 'PRESERVE WHITESPACE))
```

XMLPARSE will treat the value for the insert statement as equivalent to the following value:

```
<a xml:space='preserve'> <b> <c>c</c>b </b> </a>
```

Example 2: Insert an XML document into the EMP table and strip the whitespace in the original XML document.

```
INSERT INTO EMP (ID, XVALUE) VALUES(1001,  
XMLPARSE(DOCUMENT 'STRIP WHITESPACE))
```

XMLPARSE will treat the value for the insert statement as equivalent to the following value:

```
<a xml:space='preserve'>  
<b xml:space='default'><c>c</c>b </b>  
</a>
```

XMLPI

The XMLPI function returns an XML value with a single processing instruction.

► XMLPI ((NAME *pi-name* , *string-expression*) ◄

NAME *pi-name*

Specifies the name of a processing instruction. The name is an SQL identifier that must be in the form of an XML NCName. See the W3C XML namespace specifications for more details on valid names. The name must not be "xml" in any case combination.

string-expression

An expression that returns a value that is a built-in character or graphic string. It cannot be CHAR or VARCHAR bit data. The resulting string must conform to the content of an XML processing instruction as specified by the following rules:

- The string must not contain the substring '?>' since this substring terminates a processing instruction
- Each character of the string can be any Unicode character, excluding the surrogate blocks, X'FFFE', and X'FFFF'.⁷⁹

If *string-expression* does not conform to the previous rules, an error is returned.

The resulting string becomes the content of the processing instruction.

The result of the function is XML. If the result of *string-expression* can be null, the result can be null; if the result of *string-expression* is null, the result is the null value. If *string-expression* is an empty string or is not specified, the result is an empty processing instruction.

Example

- Generate an XML processing instruction.

```
SELECT XMLPI(  
  NAME "Instruction", 'Push the red button')  
FROM SYSIBM.SYSDUMMY1
```

This query produces the following result:

```
<?Instruction Push the red button?>
```

- Generate an empty XML processing instruction.

```
SELECT XMLPI(NAME "Warning")  
FROM SYSIBM.SYSDUMMY1
```

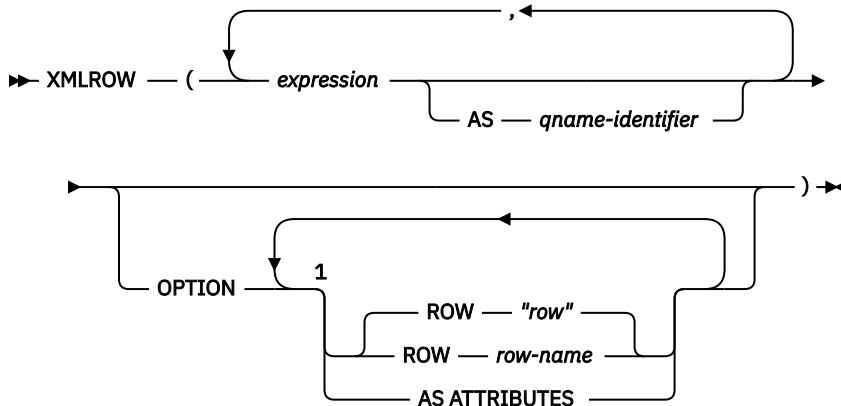

This query produces the following result:

```
<?Warning ?>
```

⁷⁹ Valid Unicode characters consist of the following Unicode code points: #x9, #xA, #xD, #x20-#xD7FF, #xE000-#xFFFF, #x10000-#x10FFFF.

XMLROW

The XMLROW function returns an XML value that is a well-formed XML document.

Notes:

¹ The same clause must not be specified more than once.

expression

The content of each XML element is specified by an expression. The data type of *expression* must not be ROWID or DATALINK or a distinct type that is based on ROWID or DATALINK. When AS ATTRIBUTES is specified, the data type of *expression* must not be XML or a distinct type that is based on XML. The expression can be any SQL expression. If the expression is not a simple column reference, an element name must be specified.

AS qname-identifier

Specifies the XML element name or attribute name as an SQL identifier. The *qname-identifier* must be of the form of an XML qualified name, or QName. See the W3C XML namespace specifications for more details on valid names. If the name is qualified, the namespace prefix must be declared within the scope. If *qname-identifier* is not specified, *expression* must be a column name. The element name or attribute name is created from the column name using the fully escaped mapping from a column name to a QName.

OPTION

Specifies additional options for constructing the XML value. If no OPTION clause is specified, the default behavior applies.

ROW row-name

Specifies the name of the element to which each row is mapped. If this option is not specified, the default element name is "row".

AS ATTRIBUTES

Specifies that each expression is mapped to an attribute value with column name or *qname-identifier* serving as the attribute name. AS ATTRIBUTES cannot be specified if any expression has a result data type of XML.

The result is an XML sequence containing the concatenation of the non-null input XML values.

The result of the function is an XML value. Null values in the input are ignored. If the result of any *expression* can be null, the result can be null; if the result of every *expression* is null, the result is the null value.

Notes

By default, each row in the result set is mapped to an XML value as follows:

- Each row is transformed into an XML element named "row" and each *expression* is transformed into a nested element with the column name or *qname-identifier* as the element name.

- The null handling behavior is NULL ON NULL. A null value for an expression maps to the absence of the subelement. If all expression values are null, the function returns a null value.
- The binary encoding scheme for binary and FOR BIT DATA data types is base64Binary encoding.

Examples

Assume the following table T1 with columns C1 and C2:

C1	C2
1	2
-	2
1	-
-	-

- The following example shows an XMLROW query and output fragment with default behavior, using a sequence of row elements to represent the table:

```
SELECT XMLROW(C1, C2) FROM T1
```

```
<row><C1>1</C1><C2>2</C2></row>
<row><C2>2</C2></row>
<row><C1>1</C1></row>
-
```

- The following example shows an XMLROW query and output fragment with attribute centric mapping. Instead of appearing as nested elements, data is mapped to element attributes:

```
SELECT XMLROW(C1, C2 OPTION AS ATTRIBUTES) FROM T1
```

```
<row C1="1" C2="2"/>
<row C2="2"/>
<row C1="1"/>
-
```

- The following example shows an XMLROW query and output fragment with the default <row> element replaced by <entry>. Columns C1 and C2 are returned as <column1> and <column2> elements, and the total of C1 and C2 is returned inside a <total> element:

```
SELECT XMLROW(C1 AS "column1", C2 AS "column2",
              C1+C2 AS "total" OPTION ROW "entry") FROM T1
```

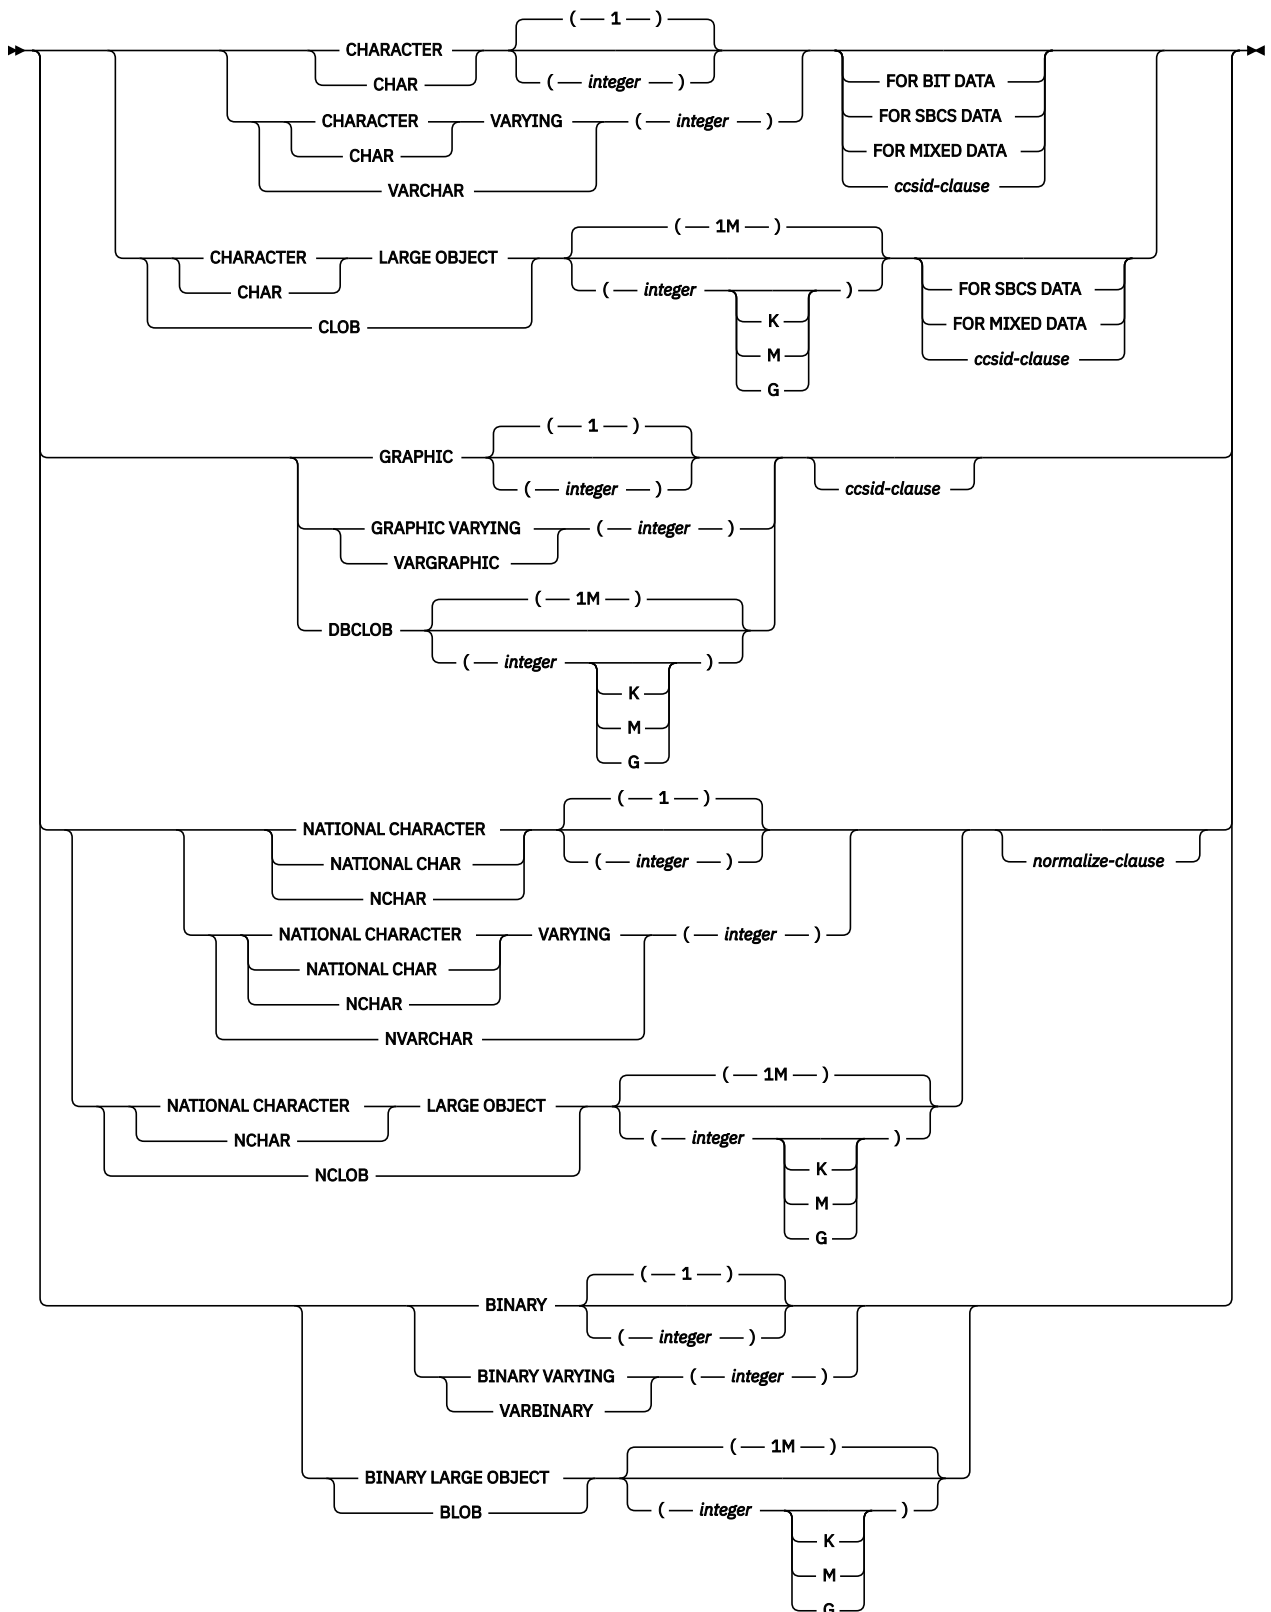

```
<entry><column1>1</column1><column2>2</column2><total>3</total></entry>
<entry><column2>2</column2></entry>
<entry><column1>1</column1></entry>
-
```

XMLSERIALIZE

The XMLSERIALIZE function returns a serialized XML value of the specified data type generated from the *XML-expression* argument.

data-type

Notes:

¹ The same clause must not be specified more than once.

ccsid-clause

normalize-clause

CONTENT

Specifies that any XML value can be specified and the result of the serialization is based on this input value.

XML-expression

An expression that returns a value that is a built-in XML string. This is the input to the serialization process.

AS data-type

Specifies the result type. The implicit or explicit length attribute of the specified result data type must be sufficient to contain the serialized output.

If a `CCSID` is specified and the `data-type` is `GRAPHIC`, `VARGRAPHIC`, or `DBCLOB`, the `CCSID` must be a Unicode `CCSID`.

If the `CCSID` attribute is not specified, the `CCSID` is determined as described in [“CAST specification” on page 176](#).

VERSION '1.0'

Specifies the XML version of the serialized value. The only version supported is '1.0' which must be specified as a string constant.

EXCLUDING XMLDECLARATION or INCLUDING XMLDECLARATION

Specifies whether an XML declaration is included in the result. The default is `EXCLUDING XMLDECLARATION`.

EXCLUDING XMLDECLARATION

Specifies that an XML declaration is not included in the result.

INCLUDING XMLDECLARATION

Specifies that an XML declaration is included in the result. The XML declaration is the string `'<?xml version="1.0" encoding="encoding-name"?'>`, where `encoding-name` matches the `CCSID` of the result data type.

If the result of `XML-expression` can be null, the result can be null; if the result of `XML-expression` is null, the result is the null value.

Examples

Example 1: Serialize into CLOB of UTF-8, the XML value that is returned by the `XMLELEMENT` function, which is a simple XML element with "Emp" as the element name and an employee name as the element content:

```
SELECT e.empno, XMLSERIALIZE(XMLELEMENT(NAME "Emp",
                                     e.firstnme || ' ' || e.lastname)
                           AS CLOB(100) CCSID 1208) AS "result"
FROM employee e WHERE e.lastname = 'SMITH'
```

The result looks similar to the following results:

```
EMPNO    result
-----
000250   <Emp>DANIEL SMITH</Emp>
000300   <Emp>PHILIP SMITH</Emp>
```

Example 2: Serialize into a string of BLOB type, the XML value that is returned by the XMLELEMENT function:

```
SELECT XMLSERIALIZE(XMLELEMENT(NAME "Emp",
                               e.firstnme || ' ' || e.lastname)
                   AS BLOB(1K)
                   VERSION '1.0') AS "result"
FROM employee e WHERE e.empno = '000300'
```

The result looks similar to the following results:

```
result
-----
<Emp>PHILIP SMITH</Emp>
```

Example 3: Serialize into a string of CLOB type, the XML value that is returned by the XMLELEMENT function. Include the XMLDECLARATION:

```
SELECT e.empno, e.firstnme, e.lastname,
       XMLSERIALIZE(XMLELEMENT(NAME "xmp:Emp",
                               XMLNAMESPACES('http://www.xmp.com' as "xmp"),
                               XMLATTRIBUTES(e.empno as "serial"),
                               e.firstnme, e.lastname
                               OPTION NULL ON NULL)
                   AS CLOB(1000) CCSID 1208
                   INCLUDING XMLDECLARATION) AS "Result"
FROM employee e WHERE e.empno = '000300'
```

The result looks similar to the following results:

EMPNO	FIRSTNME	LASTNAME	Result
000300	PHILIP	SMITH	<?xml version="1.0" encoding="UTF-8" ?> <xmp:Emp xmlns:xmp="http://www.xmp.com" serial="000300">PHILIPSMITH</xmp:Emp>

XMLTEXT

The XMLTEXT function returns an XML value that contains the value of *string-expression*.

►► XMLTEXT — (— *string-expression* —) ◄◄

string-expression

An expression that returns a value of a built-in character or graphic string. It cannot be CHAR or VARCHAR bit data.

The result of the function is an XML value. If the result of *string-expression* can be null, the result can be null; if the result of *string-expression* is null, the result is the null value. If the result of *string-expression* is an empty string, the result value is empty text.

Example

- Create a simple XMLTEXT query.

```
VALUES (XMLTEXT ('The stock symbol for Johnson&Johnson is JNJ.'))
```

This query produces the following serialized result:

```
The stock symbol for Johnson&Johnson is JNJ.
```

Note that the '&' sign is mapped to '&' when the text is serialized.

- Use XMLTEXT with XMLAGG to construct mixed content. Suppose that the content of table T is as follows:

SEQNO	PLAINTEXT	EMPHTEXT
1	This query shows how to construct	mixed content
2	using XMLAGG and XMLTEXT. Without	XMLTEXT
3	, XMLAGG will not have text nodes to group with other nodes, therefore, cannot generate	mixed content

```
SELECT XMLELEMENT(NAME "para",
                  XMLAGG(XMLCONCAT(
                              XMLTEXT(PLAINTEXT),
                              XMLELEMENT(
                                  NAME "emphasis", EMPHTEXT))
                          ORDER BY SEQNO), '.') AS "result"
FROM T
```

This query produces the following result:

```
result
-----
<para>This query shows how to construct <emphasis>mixed content</emphasis>
using XMLAGG and XMLTEXT. Without <emphasis>XMLTEXT</emphasis>, XMLAGG
will not have text nodes to group with other nodes, therefore, cannot generate
<emphasis>mixed content</emphasis>.</para>
```

XMLVALIDATE

The XMLVALIDATE function returns a copy of the input XML value augmented with information obtained from XML schema validation, including default values and type annotations.

XML-validate-according-to-clause

►► ACCORDING TO XMLSCHEMA ►►

XML-valid-element-clause

DOCUMENT

Specifies that the XML value resulting from *XML-expression* must be a well-formed XML document that conforms to XML Version 1.0.

XML-expression

An expression that returns a value of data type XML. If *XML-expression* is an XML host variable or an implicitly or explicitly typed parameter marker, the function performs a validating parse that strips ignorable whitespace and the CURRENT IMPLICIT XMLPARSE OPTION setting is not considered.

XML-validate-according-to-clause

Specifies the information that is to be used when validating the input XML value.

ACCORDING TO XMLSCHEMA

Indicates that the XML schema information for validation is explicitly specified. If this clause is not included, the XML schema information must be provided in the content of the *XML-expression* value.

ID XML-schema-name

Specifies an SQL identifier for the XML schema that is to be used for validation. The name, including the implicit or explicit SQL schema qualifier, must uniquely identify an existing XML schema in the XML schema repository at the current server. If no XML schema by this name exists in the implicitly or explicitly specified SQL schema, an error is returned.

URI XML-uri1

Specifies the target namespace URI of the XML schema that is to be used for validation. The value of *XML-uri1* specifies a URI as a character string constant that is not empty. The URI must be the target namespace of a registered XML schema and, if no LOCATION clause is specified, it must uniquely identify the registered XML schema.

NO NAMESPACE

Specifies that the XML schema for validation has no target namespace. The target namespace URI is equivalent to an empty character string that cannot be specified as an explicit target namespace URI.

LOCATION XML-uri2

Specifies the XML schema location URI of the XML schema that is to be used for validation. The value of *XML-uri2* specifies a URI as a character string constant that is not empty. The XML schema location URI, combined with the target namespace URI, must identify a registered XML schema, and there must be only one such XML schema registered.

XML-valid-element-clause

Specifies that the XML value in *XML-expression* must have the specified element name as the root element of the XML document.

NAMESPACE XML-uri3 or NO NAMESPACE

Specifies the target namespace for the element that is to be validated. If neither clause is specified, the specified element is assumed to be in the same namespace as the target namespace of the registered XML schema that is to be used for validation.

NAMESPACE XML-uri3

Specifies the namespace URI for the element that is to be validated. The value of *XML-uri3* specifies a URI as a character string constant that is not empty. This can be used when the registered XML schema that is to be used for validation has more than one namespace.

NO NAMESPACE

Specifies that the element for validation has no target namespace. The target namespace URI is equivalent to an empty character string which cannot be specified as an explicit target namespace URI.

ELEMENT xml-element-name

Specifies the name of a global element in the XML schema that is to be used for validation. The specified element, with implicit or explicit namespace, must match the root element of the value of *XML-expression*.

The result of the function is XML. If the value of *XML-expression* can be null, the result can be null; if the value of *XML-expression* is null, the result is the null value. The CCSID of the result is determined from the *XML-expression*.

The XML validation process is performed on a serialized XML value. Because XMLVALIDATE is invoked with an argument of type XML, this value is automatically serialized prior to validation processing with the following two exceptions:

- If the argument to XMLVALIDATE is an XML host variable or an implicitly or explicitly typed parameter marker, then a validating parse operation is performed on the input value (no implicit non-validating parse is performed and the CURRENT IMPLICIT XMLPARSE OPTION setting is not considered).
- If the argument to XMLVALIDATE is an XMLPARSE invocation using the option PRESERVE WHITESPACE, then the XML parsing and XML validation of the document may be combined into a single validating parse operation.

To validate a document whose root element does not have a namespace, an `xsi:noNamespaceSchemaLocation` attribute must be present on the root element.

Notes

Determining the XML schema: The XML schema can be specified explicitly as part of the XMLVALIDATE invocation or determined from the XML schema information in the input XML value. If the XML schema information is not specified during invocation, the target namespace and the schema location in the input XML value are used to identify the registered schema for validation. If an explicit XML schema is not specified, the input XML value must contain an XML schema information hint. Explicit or implicit XML schema information must identify a registered XML schema, and there must be only one such registered XML schema.

If you do not specify an XML schema document, the database server looks in the input document for an `xsi:schemaLocation` attribute that specifies a namespace and location hint for the XML schema. When there is no target namespace for the XML schema, the `xsi:noNamespaceSchemaLocation` attribute is used to specify a location hint for the XML schema.

xsi:schemaLocation or *xsi:noNamespaceSchemaLocation* attributes are defined by the W3C XML schema specification and are called XML schema hints. An *xsi:schemaLocation* attribute contains one or more pairs of values that help to locate the XML schema document. The first value in each pair is a namespace and the second value is a hint that indicates where to find the XML schema for the namespace. Db2 for i will attempt to match a namespace and location hint to an XML schema, using the primary XML schema document's target namespace and the *schemalocation* parameter that was supplied on the XSR_REGISTER procedure call.

If an XML schema document is specified in the XMLVALIDATE function, it overrides the *xsi:schemaLocation* or *xsi:noNamespaceSchemaLocation* attribute.

If *xsi:schemaLocation* and *xsi:noNamespaceSchemaLocation* attributes are not defined by the XML document, Db2 for i will attempt to locate an XML schema where the target namespace of the primary XSD matches a namespace in the XML document.

Specifying the XML schema explicitly in the XMLVALIDATE function avoids the parsing required to locate the XML schema information hint in the XML value.

XML schema authorization: The XML schema used for validation must be registered in the XML schema repository prior to use. The privileges held by the authorization ID of the statement must include at least one of the following:

- USAGE privilege on the XML schema that is to be used during validation
- Database administrator authority

Examples

- Validate using the XML schema identified by the XML schema hint in the XML instance document.

```
INSERT INTO T1(XMLCOL)
VALUES (XMLVALIDATE(?))
```

Assume that the input parameter marker is bound to an XML value that contains the XML schema information.

```
<po:order
  xmlns:po='http://my.world.com'
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="http://my.world.com/world.xsd" >
  ...
</po:order>
```

Further, assume that the XML schema that is associated with the target namespace "http://my.world.com" and by schemaLocation hint "http://my.world.com/world.xsd" is found in the XML schema repository

Based on these assumptions, the input XML value will be validated according to that XML schema.

- Validate using the XML schema identified by the SQL name PODOCS.WORLDPO

```
INSERT INTO T1(XMLCOL)
VALUES(
  XMLVALIDATE(? ACCORDING TO XMLSCHEMA ID PODOCS.WORLDPO))
```

Assuming that the XML schema that is associated with SQL name PODOC.WORLDPO is found in the XML schema repository, the input XML value will be validated and the type annotated according to that XML schema.

- Validate a specified element of the XML value.

```
INSERT INTO T1(XMLCOL)
VALUES(
  XMLVALIDATE(?
    ACCORDING TO XMLSCHEMA ID F00.WORLDPO
    NAMESPACE 'http://my.world.com/Mary'
    ELEMENT "po"))
```

Assuming that the XML schema that is associated with SQL name FOO.WORLDPO is found in the XML schema repository, the XML schema will be validated against the element "po", whose namespace is "http://my.world.com/Mary".

- XML schema is identified by target namespace and schema location.

```
INSERT INTO T1(XMLCOL)
VALUES(
  XMLVALIDATE(?
    ACCORDING TO XMLSCHEMA URI 'http://my.world.com'
    LOCATION 'http://my.world.com/world.xsd'))
```

Assuming that an XML schema associated with the target namespace "http://my.world.com" and by schemaLocation hint "http://my.world.com/world.xsd" is found in the XML schema repository, the input XML value will be validated according to that XML schema.

XOR

The XOR function returns a string that is the logical XOR of the argument strings. This function takes the first argument string, does an XOR operation with the next string, and then continues to do XOR operations for each successive argument using the previous result. If a character-string argument is shorter than the previous result, it is padded with blanks. If a binary-string argument is shorter than the previous result, it is padded with hexadecimal zeros.

The arguments must be compatible.

expression

An expression that returns a value of any built-in numeric or string data type, but cannot be LOBs. The arguments cannot be mixed data character strings, UTF-8 character strings, or graphic strings. A numeric argument is cast to a character string before evaluating the function. For more information about converting numeric to a character string, see [“VARCHAR” on page 623](#).

The arguments are converted, if necessary, to the attributes of the result. The attributes of the result are determined as follows:

- If all the arguments are fixed-length strings, the result is a fixed-length string of length n , where n is the length of the longest argument.
- If any argument is a varying-length string, the result is a varying-length string with length attribute n , where n is the length attribute of the argument with greatest length attribute. The actual length of the result is m , where m is the actual length of the longest argument.

If an argument can be null, the result can be null; if an argument is null, the result is the null value.

The CCSID of the result is 65535.

Example

- Assume the host variable L1 is a CHARACTER(2) host variable with a value of X'E1E1', host variable L2 is a CHARACTER(3) host variable with a value of X'F0F00', and host variable L3 is a CHARACTER(4) host variable with a value of X'0000000F'.

```
SELECT XOR(:L1, :L2, :L3)
FROM SYSIBM.SYSDUMMY1
```

Returns the value X'1111404F'.

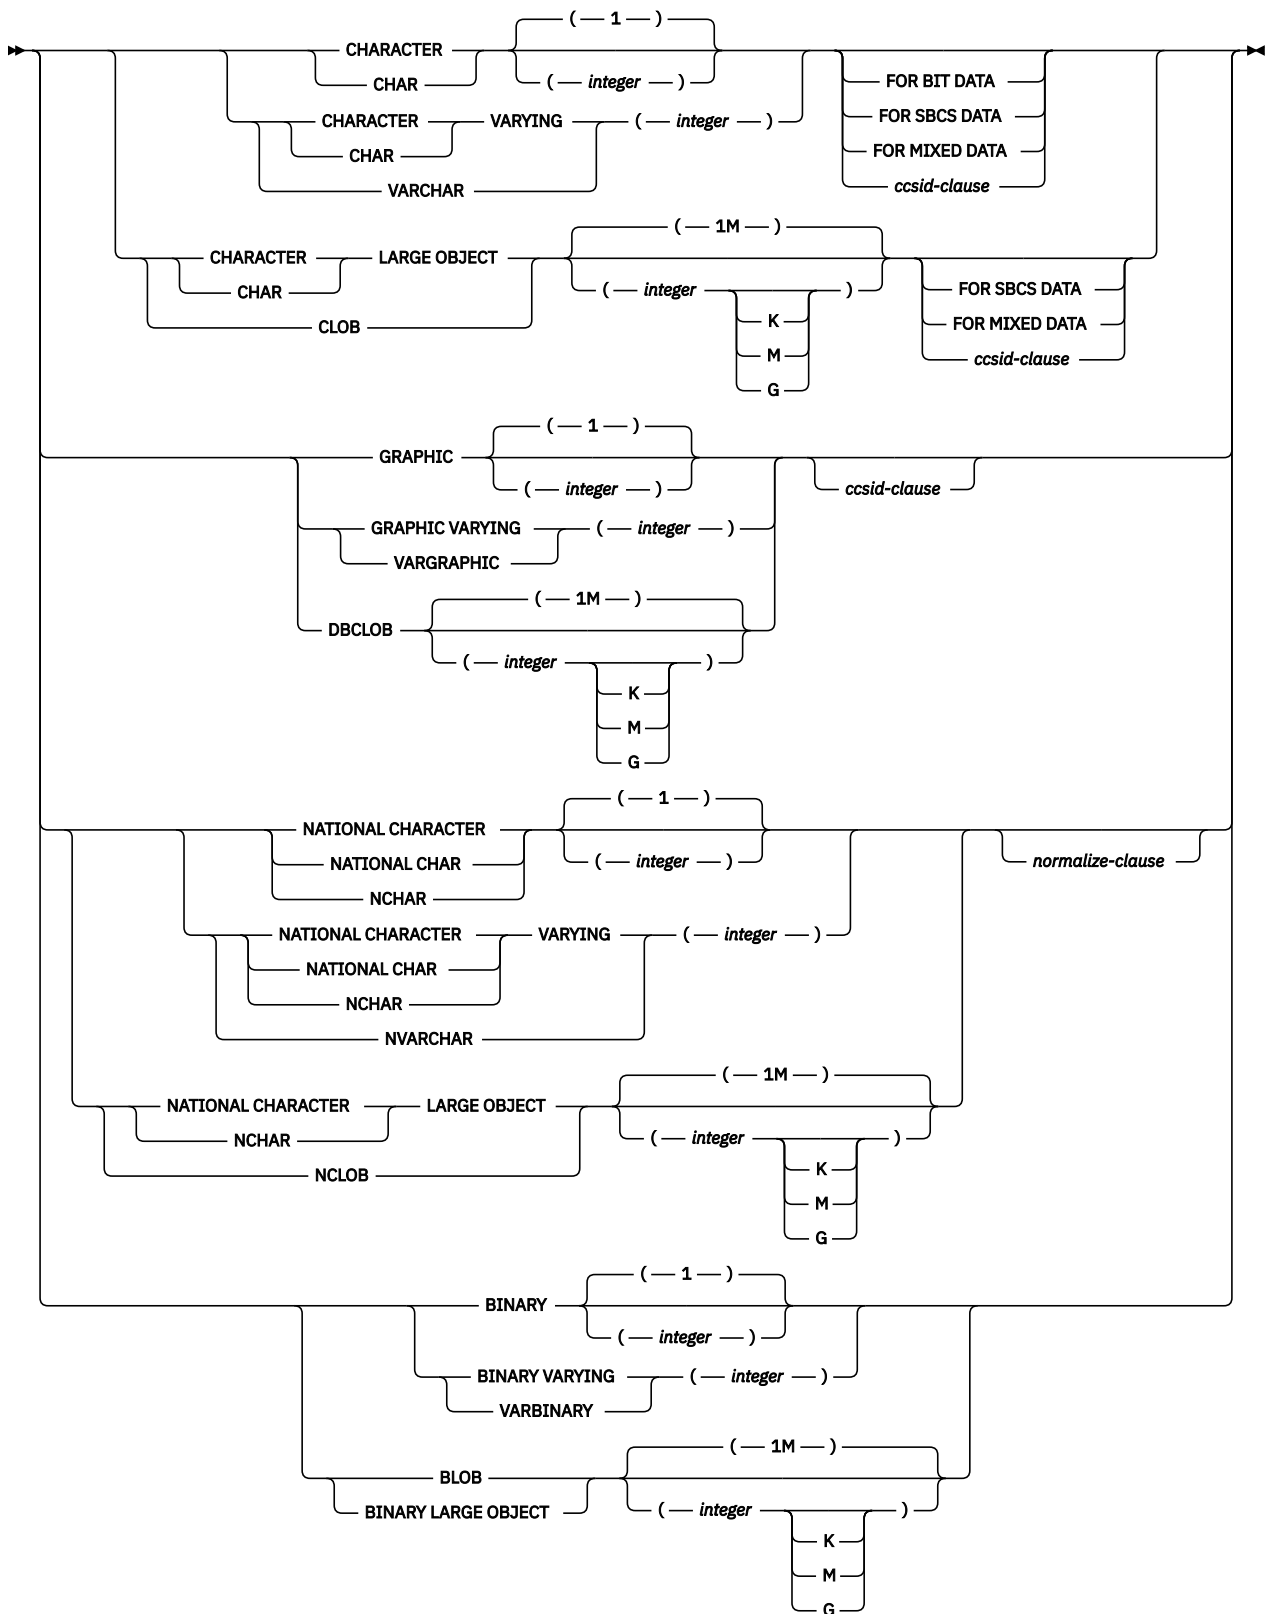

XSLTRANSFORM

The XSLTRANSFORM transforms an XML document into a different data format. The data can be transformed into any form possible for the XSLT processor, including but not limited to XML, HTML, or plain text.

►► XSLTRANSFORM — (— *XML-document* — USING — *xsl-stylesheet* — ►

data-type

ccsid-clause

normalize-clause

Use XSLTRANSFORM to convert XML data into other formats including the conversion of XML documents that conform to one XML schema into documents that conform to another XML schema.

XML-document

A character string, Unicode graphic string, binary string, or XML expression that returns a well-formed XML document. This is the document that is transformed using the XSL style sheet specified in *xsl-stylesheet*.

xsl-stylesheet

A character string, Unicode graphic string, binary string, or XML expression that returns a well-formed XML document. The document is an XSL style sheet that conforms to the XSLT Version 1.10 Recommendation. Style sheets incorporating the `xsl:include` declaration are not supported. This stylesheet is applied to transform the value specified in *xml-document*.

xsl-parameters

A character string, Unicode graphic string, binary string, or XML expression that returns a well-formed XML document. This is a document that provides parameter values to the XSL stylesheet specified in *xsl-stylesheet*. The value of the parameter can be specified as an attribute or as text.

The syntax of the parameter document is as follows:

```
<params xmlns="http://www.ibm.com/XSLTransformParameters">
<param name="..." value="..."/>
<param name="...">enter value here</param> ... </params>
```

Note: The stylesheet document must have `xsl:param` element(s) in it with name attribute values that match the ones specified in the parameter document.

AS data-type

Specifies the result data type. The implicit or explicit length attribute of the specified result data type must be sufficient to contain the transformed output. The default result data type is CLOB(2G).

If a CCSID is specified and the *data-type* is GRAPHIC, VARGRAPHIC, or DBCLOB, the CCSID must be a Unicode CCSID.

If the CCSID attribute is not specified, the CCSID is determined as if the *XML-document* was cast to *data-type* as described in [“CAST specification”](#) on page 176.

The result of the function has the data type specified. CCSID conversion that results in data loss can occur when storing any of the above documents in a character data type.

If either *XML-document* or *xsl-stylesheet* is null, the result is the null value.

Note

Prerequisites: In order to use the XSLTRANSFORM function, the XML Toolkit for IBM i and International Components for Unicode (ICU option) must be installed.

Example

This example illustrates how to use XSLT as a formatting engine. To get set up, first insert the two example documents below into the database.

```
CREATE TABLE XML_TAB (c1 INT, xml_doc CLOB(2M), xsl_doc CLOB(256K));
INSERT INTO XML_TAB VALUES
(1, '<?xml version="1.0"?>
<students xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xsi:noNamespaceSchemaLocation = "/home/steffen/xsd/xslt.xsd">
<student studentID="1" firstName="Steffen" lastName="Siegmund"
age="23" university="Rostock"/>
</students>',
```

```
'<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet version="1.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform">
<xsl:param name="headline"/>
<xsl:param name="showUniversity"/>

  <xsl:template match="students">
    <html>
      <head/>
      <body>
        <h1><xsl:value-of select="$headline"/></h1>
        <table border="1">
          <thead>
            <tr>
              <td width="80">StudentID</td>
              <td width="200">First Name</td>
              <td width="200">Last Name</td>
              <td width="50">Age</td>
              <xsl:choose>
                <xsl:when test="$showUniversity = 'true'">
                  <td width="200">University</td>
                </xsl:when>
              </xsl:choose>
            </tr>
          </thead>
          <xsl:apply-templates/>
        </table>
      </body>
    </html>
  </xsl:template>
  <xsl:template match="student">
    <tr>
      <td><xsl:value-of select="@studentID"/></td>
      <td><xsl:value-of select="@firstName"/></td>
      <td><xsl:value-of select="@lastName"/></td>
      <td><xsl:value-of select="@age"/></td>
      <xsl:choose>
        <xsl:when test="$showUniversity = 'true'">
          <td><xsl:value-of select="@university"/></td>
        </xsl:when>
      </xsl:choose>
    </tr>
  </xsl:template>
</xsl:stylesheet>');
```

Next, call the XSLTRANSFORM function to convert the XML data into HTML and display it.

```
SELECT XSLTRANSFORM (XML_DOC USING XSL_DOC
  WITH '<params xmlns="http://www.ibm.com/XSLTransformParameters"></params>')
FROM XML_TAB;
```

The result is this document:

```
<html>
<head>
<META http-equiv="Content-Type" content="text/html; charset=UTF-8">
</head>
<body>
<h1></h1>
<table border="1">
  <thead>
    <tr>
      <td width="80">StudentID</td>
      <td width="200">First Name</td>
      <td width="200">Last Name</td>
      <td width="50">Age</td>
    </tr>
  </thead>
  <tr>
    <td>1</td>
    <td>Steffen</td>
    <td>Siegmond</td>
    <td>23</td>
  </tr>
</table>
</body>
</html>
```

In this example, the output is HTML and the parameters influence only what HTML is produced and what data is brought over to it. As such it illustrates the use of XSLT as a formatting engine for end-user output.

YEAR

The YEAR function returns the year part of a value.

►► YEAR — (— *expression* —) ◄◄

expression

An *expression* that returns a value of one of the following built-in data types: a date, a timestamp, a character string, a graphic string, or a numeric data type.

- If *expression* is a character or graphic string, its value must be a valid string representation of a date or timestamp. For the valid formats of string representations of dates and timestamps, see [“String representations of datetime values”](#) on page 75.
- If *expression* is a number, it must be a date duration or timestamp duration. For the valid formats of datetime durations, see [“Datetime operands and durations”](#) on page 165.

The result of the function is a large integer. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

The other rules depend on the data type of the argument:

- If the argument is a date or a timestamp or a valid character-string representation of a date or timestamp:

The result is the year part of the value, which is an integer between 1 and 9999.

- If the argument is a date duration or timestamp duration:

The result is the year part of the value, which is an integer between -9999 and 9999. A nonzero result has the same sign as the argument.

Examples

- Select all the projects in the PROJECT table that are scheduled to start (PRSTDATE) and end (PRENDATE) in the same calendar year.

```
SELECT *  
FROM PROJECT  
WHERE YEAR(PRSTDATE) = YEAR(PRENDATE)
```

- Select all the projects in the PROJECT table that are scheduled to take less than one year to complete.

```
SELECT *  
FROM PROJECT  
WHERE YEAR(PRENDATE - PRSTDATE) < 1
```

scale

An integer constant that is greater than or equal to 0 and less than or equal to *precision*. If not specified, the default is 0.

The result is the same number that would occur if the first argument were assigned to a decimal column or variable with a precision of *precision* and a scale of *scale*. An error is returned if the number of significant decimal digits required to represent the whole part of the number is greater than *precision-scale*. If the first argument can be null, the result can be null; if the first argument is null, the result is the null value.

String to Zoned Decimal***string-expression***

An expression that returns a value that is a character-string or graphic-string representation of a number. Leading and trailing blanks are eliminated and the resulting string must conform to the rules for forming a floating-point, decimal floating-point, integer, or decimal constant.

precision

An integer constant that is greater than or equal to 1 and less than or equal to 63. If not specified, the default is 15.

scale

An integer constant that is greater than or equal to 0 and less than or equal to *precision*. If not specified, the default is 0.

decimal-character

Specifies the single-byte character constant that was used to delimit the decimal digits in *string-expression* from the whole part of the number. The character must be a period or comma. If the second argument is not specified, the decimal point is the default decimal separator character. For more information, see [“Decimal point”](#) on page 116.

Digits are truncated from the end if the number of digits to the right of the *decimal-character* is greater than the scale *s*. An error is returned if the number of significant digits to the left of the *decimal-character* (the whole part of the number) in *string-expression* is greater than *precision-scale*. The default decimal separator character is not valid in the substring if the *decimal-character* argument is specified.

Datetime to Zoned Decimal***datetime-expression***

An expression that returns a value of type DATE, TIME, or TIMESTAMP.

precision

An integer constant that is greater than or equal to 1 and less than or equal to 63 that specifies the precision of the result. If not specified, the default for the precision and scale depends on the data type of *datetime-expression* as follows:

- Precision is 8 and scale is 0 for DATE. The result is a NUMERIC(8,0) value representing the date as *yyyymmdd*.
- Precision is 6 and scale is 0 for a TIME. The result is a NUMERIC(6,0) value representing the time as *hhmmss*.
- Precision is 14+*tp* and scale is *tp* for a TIMESTAMP(*tp*). The result is a NUMERIC(14+*tp*,*tp*) value representing the timestamp as *yyyymmddhhmmss.nnnnnnnnnnnn*.

scale

An integer constant that is greater than or equal to 0 and less than or equal to *precision*. If not specified and a *precision* is specified, the default is 0.

The result is the same number that would result from CAST(*datetime-expression* AS NUMERIC(*precision*,*scale*)). Digits are truncated from the end if the number of digits to the right of the decimal separator is greater than the scale *s*. An error is returned if the number of significant digits to the left of the decimal separator (the whole part of the number) in *datetime-expression* is greater than *precision - scale*.

The result of the function is a zoned decimal number with precision of *precision* and scale of *scale*. If the first argument can be null, the result can be null; if the first argument is null, the result is the null value.

Note

Syntax alternatives: The CAST specification should be used to increase the portability of applications when the precision is specified. For more information, see [“CAST specification”](#) on page 176.

Examples

- Assume the host variable Z1 is a decimal host variable with a value of 1.123.

```
SELECT ZONED(:Z1,15,14)
FROM SYSIBM.SYSDUMMY1
```

Returns the value 1.123000000000000.

- Assume the host variable Z1 is a decimal host variable with a value of 1123.

```
SELECT ZONED(:Z1,11,2)
FROM SYSIBM.SYSDUMMY1
```

Returns the value 1123.00.

- Likewise,

```
SELECT ZONED(:Z1,4)
FROM SYSIBM.SYSDUMMY1
```

Returns the value 1123.

Table functions

Table functions return columns of a table and resemble a table created through a CREATE TABLE statement.

A table function can be used only in the FROM clause of an SQL statement. Table functions can be qualified with a schema name.

BASE_TABLE

The BASE_TABLE function returns the object names and schema names of the object found for an alias.

►► BASE_TABLE — (— *object-schema* — , — *object-name* —) ►►

The schema is SYSPROC.

object-schema

A character or graphic string expression that identifies the SQL or system schema name used to qualify the supplied *object-name*. *object-schema* must have an actual length less than 129 characters. A special value of *LIBL may be specified, in which case, the first instance of a file named *object-name* found in the library list will be used. This name is case sensitive and must not be delimited.

object-name

A character or graphic string expression that identifies the SQL or system name of the object to be resolved. *object-name* must have an actual length less than 129 characters. This name is case sensitive and must not be delimited.

If the specified object does not refer to an alias or it is not found, the result of the function is the input object name and schema.

The result of the function is a table containing a single row with the format shown in the following table. All the columns are nullable.

Table 64. Format of the resulting table for BASE_TABLE

Column name	Data type	Contains
BASESCHEMA	VARCHAR(128)	Name of the SQL schema that contains the table or view referenced by the alias. This is <i>object-schema</i> if no alias was found. The name is undelimited and case sensitive.
BASENAME	VARCHAR(128)	Name of the table or view referenced by the alias. This is the <i>object-name</i> if no alias was found. The name is undelimited and case sensitive.
SYSTEM_TABLE_SCHEMA	CHAR(10)	System schema name. This column will contain the NULL value if no alias was found or if the alias references a remote RDB. The name may be delimited and is case sensitive.
SYSTEM_TABLE_NAME	CHAR(10)	System table name. This column will contain the NULL value if no alias was found or if the alias references a remote RDB. The name may be delimited and is case sensitive.
MEMBER_NAME	CHAR(10)	The member name that was identified for a member alias. This column will contain the NULL value if no alias was found or if the alias does not reference a specific member. The name may be delimited and is case sensitive.
RDBNAME	VARCHAR(128)	The RDB if the object is a three-part alias for a remote object. This column will contain the NULL value if no alias was found or there is no RDB is associated with the alias.

The CCSID of the result columns is the default CCSID at the current server.

Example

- The following query will return the base table information for every alias identified in SYSTABLES:

```
SELECT C.BASESCHEMA, C.BASENAME
FROM QSYS2.SYSTABLES A,
LATERAL (
    SELECT * FROM TABLE(SYSPROC.BASE_TABLE(A.TABLE_SCHEMA,A.TABLE_NAME)) AS X)
AS C
WHERE A.TABLE_TYPE='A'
```

HTTP_DELETE_VERBOSE

The HTTP_DELETE_VERBOSE table function deletes a text-based resource from the specified URL through an HTTP DELETE request. It returns a one row table that contains the normal HTTP response for the request and the header information returned from the HTTP request.

► HTTP_DELETE_VERBOSE (— *url* — , — *options* —) ◄

url

An expression that returns a built-in character string or graphic string data type that specifies the URL of the resource being accessed.

The only supported protocols in the URL are *http://* and *https://*. HTTP basic authentication in the form *https://userid:password@* cannot be specified in the URL. Instead, the *basicAuth* option must be used to specify the *userid* and *password* for basic authentication.

options

An expression that returns a built-in character string or graphic string data type. This string must be formatted as a JSON object containing the options, including headers, for the request. See “[HTTP options](#)” on [page 428](#) for the list of options.

If no options are provided, the default options are used.

The result of the function is table containing a single row with the format shown in the following table.

Column name	Data type	Description
RESPONSE_MESSAGE	CLOB(2G) CCSID 1208	The HTTP response for the request.
RESPONSE_HTTP_HEADER	CLOB(2G) CCSID 1208	Header information returned from the HTTP request, formatted as a JSON object.

Notes

For more information about using the HTTP functions see [HTTP functions overview](#).

Example

- Send a HTTP DELETE request to <https://www.example.com/delete> using the certificate store `/home/javaTrustStore/fromJava.KDB`. Return the result and header information.

```
SELECT * FROM TABLE(QSYS2.HTTP_DELETE_VERBOSE(
    'https://www.example.com/delete',
    '{"sslCertificateStoreFile":"/home/javaTrustStore/fromJava.KDB"}');
```

HTTP_PATCH_VERBOSE

The HTTP_PATCH_VERBOSE table function updates a text-based resource under the specified URL through an HTTP PATCH request. It returns a one row table that contains the normal HTTP response for the request and the header information returned from the HTTP request.

► HTTP_PATCH_VERBOSE ((— *url* — , — *request-message* —) , — *options* —) ►

url

An expression that returns a built-in character string or graphic string data type that specifies the URL of the resource being accessed.

The only supported protocols in the URL are *http://* and *https://*. HTTP basic authentication in the form *https://userid:password@* cannot be specified in the URL. Instead, the *basicAuth* option must be used to specify the *userid* and *password* for basic authentication.

request-message

An expression that returns a built-in character string or graphic string data type that specifies the data to update at the specified URL.

options

An expression that returns a built-in character string or graphic string data type. This string must be formatted as a JSON object containing the options, including headers, for the request. See “[HTTP options](#)” on page 428 for the list of options.

If no options are provided, the default options are used.

The result of the function is table containing a single row with the format shown in the following table.

Column name	Data type	Description
RESPONSE_MESSAGE	CLOB(2G) CCSID 1208	The HTTP response for the request.
RESPONSE_HTTP_HEADER	CLOB(2G) CCSID 1208	Header information returned from the HTTP request, formatted as specified by the <i>verboseResponseHeaderFormat</i> option.

Notes

For more information about using the HTTP functions see [HTTP functions overview](#).

Example

- Send a HTTP PATCH request to *https://www.example.com/users* sending 'ABC' and using the certificate store */home/javaTrustStore/fromJava.KDB*. Return the result and header information.

```
SELECT * FROM TABLE(QSYS2.HTTP_PATCH_VERBOSE(  
    'https://www.example.com/users',  
    'ABC',  
    '{"sslCertificateStoreFile":"/home/javaTrustStore/fromJava.KDB"}'));
```

HTTP_POST_VERBOSE

The HTTP_POST_VERBOSE table function updates a text-based resource under the specified URL through an HTTP POST request. It returns a one row table that contains the normal HTTP response for the request and the header information returned from the HTTP request.

► HTTP_POST_VERBOSE ((— *url* — , — *request-message* — , — *options* —) ►

url

An expression that returns a built-in character string or graphic string data type that specifies the URL of the resource being accessed.

The only supported protocols in the URL are *http://* and *https://*. HTTP basic authentication in the form *https://userid:password@* cannot be specified in the URL. Instead, the *basicAuth* option must be used to specify the *userid* and *password* for basic authentication.

request-message

An expression that returns a built-in character string or graphic string data type that specifies the data to update at the specified URL.

options

An expression that returns a built-in character string or graphic string data type. This string must be formatted as a JSON object containing the options, including headers, for the request. See “[HTTP options](#)” on page 428 for the list of options.

If no options are provided, the default options are used.

The result of the function is table containing a single row with the format shown in the following table.

Column name	Data type	Description
RESPONSE_MESSAGE	CLOB(2G) CCSID 1208	The HTTP response for the request.
RESPONSE_HTTP_HEADER	CLOB(2G) CCSID 1208	Header information returned from the HTTP request, formatted as a JSON object.

Notes

For more information about using the HTTP functions see [HTTP functions overview](#).

Example

- Send a HTTP POST request to *https://www.example.com/users* sending 'ABC' and using the certificate store */home/javaTrustStore/fromJava.KDB*. Return the result and header information.

```
SELECT * FROM TABLE(QSYS2.HTTP_POST_VERBOSE (
    'https://www.example.com/users',
    'ABC',
    '{"sslCertificateStoreFile":"/home/javaTrustStore/fromJava.KDB"}');)
```

HTTP_PUT_VERBOSE

The HTTP_PUT_VERBOSE table function updates a text-based resource under the specified URL through an HTTP PUT request. It returns a one row table that contains the normal HTTP response for the request and the header information returned from the HTTP request.

►► HTTP_PUT_VERBOSE ((— *url* — , — *request-message* —) — *options*) ◄◄

url

An expression that returns a built-in character string or graphic string data type that specifies the URL of the resource being accessed.

The only supported protocols in the URL are *http://* and *https://*. HTTP basic authentication in the form *https://userid:password@* cannot be specified in the URL. Instead, the *basicAuth* option must be used to specify the *userid* and *password* for basic authentication.

request-message

An expression that returns a built-in character string or graphic string data type that specifies the data to update at the specified URL.

options

An expression that returns a built-in character string or graphic string data type. This string must be formatted as a JSON object containing the options, including headers, for the request. See “[HTTP options](#)” on page 428 for the list of options.

If no options are provided, the default options are used.

The result of the function is table containing a single row with the format shown in the following table.

Column name	Data type	Description
RESPONSE_MESSAGE	CLOB(2G) CCSID 1208	The HTTP response for the request.
RESPONSE_HTTP_HEADER	CLOB(2G) CCSID 1208	Header information returned from the HTTP request, formatted as a JSON object.

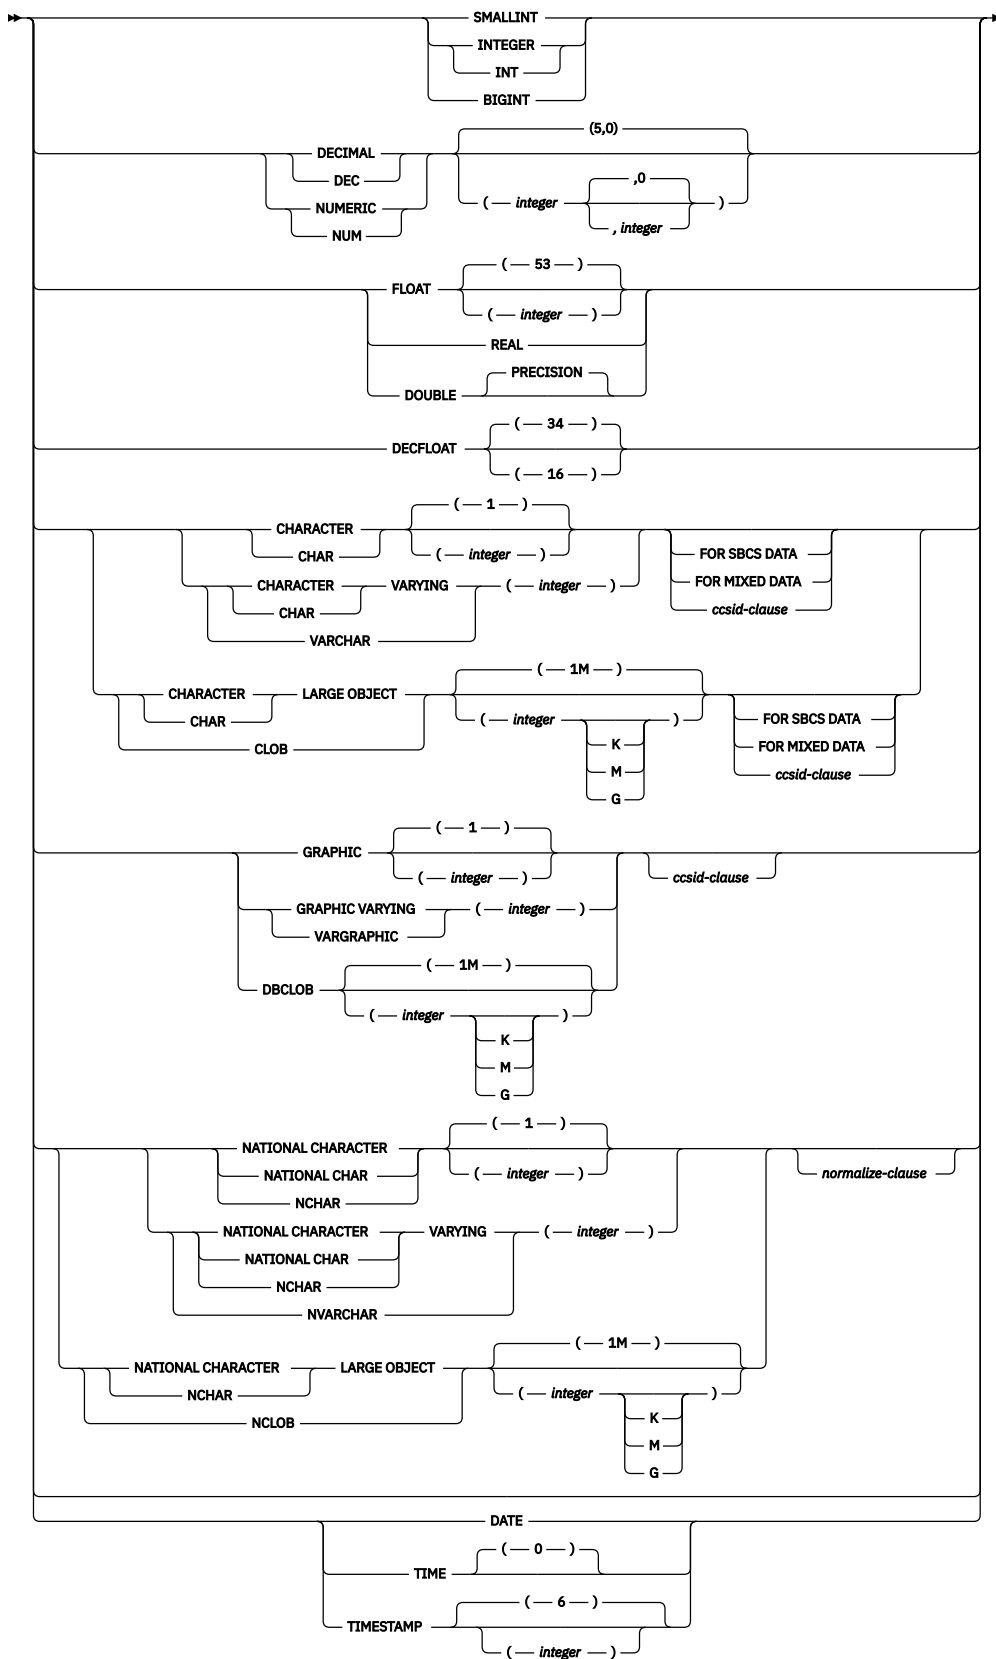

Notes

For more information about using the HTTP functions see [HTTP functions overview](#).

Example

- Send a HTTP PUT request to *https://www.example.com/users* sending 'ABC' and using the certificate store */home/javaTrustStore/fromJava.KDB*. Return the result and header information.

```
SELECT * FROM TABLE(QSYS2.HTTP_PUT_VERBOSE(
    'https://www.example.com/users',
    'ABC',
    '{"sslCertificateStoreFile":"/home/javaTrustStore/fromJava.KDB}'));
```

ccsid-clause

normalize-clause

JSON-expression

Specifies an expression that returns a character, graphic, or binary string value. If a character or graphic value is returned, it must contain a correctly formatted JSON object. If a binary value is returned, it must contain the BSON representation of a JSON object.

The *JSON-expression* specifies the initial context item for the *sql-json-path-expression*, identified within *sql-json-path-expression* as \$.

If *JSON-expression* is a JSON array, it will be implicitly wrapped using a key name of SYSIBM_ROOT_ARRAY modifying the *JSON-expression* to be a JSON object. Any path expressions provided to JSON_TABLE are implicitly modified to account for this additional key.

If *JSON-expression* does not contain correctly formatted data, JSON_TABLE returns an empty table unless a different error behavior is specified with an ON ERROR clause.

FORMAT JSON or FORMAT BSON

Specifies how *JSON-expression* is to be interpreted.

FORMAT JSON

Indicates that *JSON-expression* contains JSON data. If *JSON-expression* is binary data, the data is interpreted as UTF-8 or UTF-16. The binary data cannot be encoded using an EBCDIC CCSID.

FORMAT BSON

Indicates that *JSON-expression* contains the BSON representation of JSON data. When FORMAT BSON is specified, *JSON-expression* must be a binary string data type.

If the FORMAT clause is not specified and *JSON-expression* is a character or graphic string, *JSON-expression* is treated as JSON. If *JSON-expression* is a binary string, *JSON-expression* is treated as BSON.

sql-json-path-expression

Specifies a character or graphic string expression that is interpreted as an SQL/JSON path expression. This expression returns an output sequence where each item in the sequence is used by the column definitions to generate one or more rows in the output table. If the output sequence is empty, the result of JSON_TABLE is an empty table. *sql-json-path-expression* must not be an empty string or a string of all blanks.

For information on the content of an SQL/JSON path expression, see [“sql-json-path-expression” on page 213](#).

AS path-name

Specifies a name to be used to identify the *sql-json-path-expression*.

EMPTY ON ERROR or ERROR ON ERROR

Specifies the desired behavior of JSON_TABLE when a table level error is encountered.

EMPTY ON ERROR

An empty table is returned when a table level error is encountered. This is the default.

ERROR ON ERROR

An error is returned when a table level error is encountered.

COLUMNS

Specifies the output columns of the result table including the column name, data type, and how the column value is computed for each row.

The sum of all the result column lengths cannot exceed 64K bytes. For information on the byte counts of columns according to data type, see [“Maximum row sizes” on page 1164](#). This function can return up to approximately 200 columns, depending on the length of the column name and the length of the column path.

json-table-regular-column-definition

Specifies an output column of the result table including the column name, data type, and an SQL/JSON path expression to extract the value from the sequence item for the row.

column-name

Specifies the name of the column in the result table. The name cannot be qualified and the same name cannot be used for more than one column of the result table.

data-type

Specifies the data type of the column. For CHAR and VARCHAR columns, the CCSID cannot be 65535.

PATH column-path-expression-constant

Specifies a character or graphic string constant that is interpreted as an SQL/JSON path.

The *column-path-expression-constant* specifies an SQL/JSON path expression that determines the column value with respect to an item that is the result of evaluating the SQL/JSON path expression in *sql-json-path-expression*. Given an item from the result of processing the *sql-json-path-expression* as the externally provided context item, the *column-path-expression-constant* is evaluated and returns an output sequence. If a JSON object contains more than one value with the same key, only one of the values for the key will be returned for the output sequence.

The column value is determined based on this output sequence as follows:

- If an empty sequence is returned, the ON EMPTY clause provides the value of the column. If ERROR ON EMPTY is specified, an error is issued.
- If an empty sequence is returned and no ON EMPTY clause is specified, the null value is assigned to the column.
- If a single element sequence is returned and the type of the element is not a JSON array or a JSON object, the value is converted to the *data-type* specified for the column.
- If a single element sequence is returned and the type of the element is a JSON array or a JSON object, an error is returned.
- If a sequence with more than one element is returned, an error is returned.
- If an error occurs, the ON ERROR clause specifies the value of the column.

The value of *column-path-expression-constant* must not be an empty string or a string of all blanks. If the PATH clause is not specified, the *column-path-expression-constant* is defined as '\$.' prepended to the *column-name*.

ON EMPTY

Specifies the behavior when an empty sequence is returned for the column.

NULL ON EMPTY

An SQL null value is returned. This is the default.

ERROR ON EMPTY

An error is returned.

DEFAULT *default-expression* ON EMPTY

The value specified by *default-expression* is returned.

ON ERROR

Specifies the behavior when an error is returned for the column.

NULL ON ERROR

An SQL null value is returned. This is the default.

ERROR ON ERROR

An error is returned.

DEFAULT *default-expression* ON ERROR

The value specified by *default-expression* is returned.

If this clause is not specified:

- If a table level ERROR ON ERROR clause is specified, an error is returned.
- Otherwise, an SQL null value is returned.

json-table-formatted-column-definition

Specifies an output column of the result table including the column name, data type, and an SQL/JSON path expression to extract the value from the sequence item for the row. The extracted value is formatted as a JSON string.

column-name

Specifies the name of the column in the result table. The name cannot be qualified and the same name cannot be used for more than one column of the result table.

data-type

Specifies the data type of the column. The data type must be a character or graphic type. For CHAR and VARCHAR columns, the CCSID cannot be 65535.

FORMAT JSON

Indicates that the retrieved data should be formatted as a JSON string.

PATH *column-path-expression-constant*

Specifies a character or graphic string constant that is interpreted as an SQL/JSON path.

The *column-path-expression-constant* specifies an SQL/JSON path expression that determines the column value with respect to an item that is the result of evaluating the SQL/JSON path expression in *sql-json-path-expression* as well as all the paths specified by prior NESTED PATHs. Given an item from the result of processing the *sql-json-path-expression* as the externally provided context item, the *column-path-expression-constant* is evaluated and returns an output sequence. If a JSON object contains more than one value with the same key, only one of the values for the key will be returned for the output sequence.

The column value is determined based on this output sequence as follows:

- If an empty sequence is returned, the ON EMPTY clause provides the value of the column. If ERROR ON EMPTY is specified, an error is returned.
- If an empty sequence is returned and no ON EMPTY clause is specified, the null value is assigned to the column.
- If an error occurs, the ON ERROR clause specifies the value of the column.

The value for *column-path-expression-constant* must not be an empty string or a string of all blanks. If the PATH clause is not specified, the *column-path-expression-constant* is defined as '\$.' prepended to the *column-name*.

WITHOUT ARRAY WRAPPER or WITH ARRAY WRAPPER

Specifies whether the output value should be wrapped in a JSON array.

WITHOUT ARRAY WRAPPER

Indicates that the result is not wrapped. This is the default. Using an SQL/JSON path that results in a sequence of two or more SQL/JSON elements results in an error.

WITH UNCONDITIONAL ARRAY WRAPPER

Indicates that the result is enclosed in square brackets to create a JSON array.

WITH CONDITIONAL ARRAY WRAPPER

Indicates that the result is enclosed in square brackets to create a JSON array if more than one SQL/JSON element is returned.

KEEP QUOTES or OMIT QUOTES

Specifies whether the surrounding quotes should be removed when a scalar string is returned.

KEEP QUOTES

Indicates quotes are not removed from scalar strings. This is the default.

OMIT QUOTES

Indicates quotes are removed from scalar strings. When OMIT QUOTES is specified, the WITH ARRAY WRAPPER clause cannot be specified

ON EMPTY

Specifies the behavior when an empty sequence is returned for a column.

NULL ON EMPTY

An SQL null value is returned. This is the default.

ERROR ON EMPTY

An error is returned.

EMPTY ARRAY ON EMPTY

An empty JSON array is returned.

EMPTY OBJECT ON EMPTY

An empty JSON object is returned.

ON ERROR

Specifies the behavior when an error is returned for a column.

NULL ON ERROR

An SQL null value is returned.

ERROR ON ERROR

An error is returned.

EMPTY ARRAY ON ERROR

An empty JSON array is returned.

EMPTY OBJECT ON ERROR

An empty JSON object is returned.

If this clause is not specified:

- If a table level ERROR ON ERROR clause is specified, an error is returned.
- Otherwise, an SQL null value is returned.

json-table-ordinality-column-definition

Specifies an ordinality column of the result table.

column-name

Specifies the name of the column in the result table. The name cannot be qualified and the same name cannot be used for more than one column of the result table.

FOR ORDINALITY

Specifies that *column-name* is the ordinality column of the result table for the enclosing nesting level. The data type of this column is BIGINT.

- If the ordinality column is not within a nested column definition, the rows of the result table are numbered sequentially, starting with 1, and the ordinality column contains the sequential number of the current row.
- If the ordinality column is within a nested column definition, the rows produced by the enclosing nested column definition are numbered sequentially, starting with 1, and the ordinality column contains the sequential number of the current row. If the enclosing nested column definition is within an outer nested column definition, the numbering restarts with 1 each time the path expression of the enclosing nested column definition is applied to the result of the outer nested column definition.

json-table-nested-column-definition

Specifies one or more columns that are nested at the current level.

NESTED PATH *nested-path-expression-constant*

Specifies a character or graphic string constant that is interpreted as an SQL/JSON path. The *nested-path-expression-constant* specifies an SQL/JSON path expression that determines the column value with respect to an item that is the result of evaluating the SQL/JSON path expression in *sql-json-path-expression* as well as the *nested-path-expression-constant* from prior NESTED PATHs. Given an item from the result of processing the *sql-json-path-expression* as the externally provided context item and the *nested-path-expression-constant* from prior NESTED PATHs, the *nested-path-expression-constant* is evaluated and is used as the context for the nested columns.

AS nested-path-name

Specifies the name of the current path.

COLUMNS

Specifies the columns to be included in this nesting level.

Table 70. Supported JSON to SQL result column conversions

JSON type	SQL type	Notes®
Number	SMALLINT INTEGER BIGINT	If the source value is beyond the range of the target data type, an overflow error is returned.
Number	DECIMAL NUMERIC	The resulting number value is converted, if necessary, to the precision and scale of the target data type. The necessary number of leading zeros are added or removed. In the fractional part of the number, the necessary number of trailing zeros are added or the necessary number of digits are eliminated. This truncation behavior is similar to the behavior of the cast from DECIMAL to DECIMAL.
Number	FLOAT DOUBLE REAL DECFLOAT	If the source value is beyond the range of the target data type, an overflow error is returned. If the source value contains more significant digits than the precision of the target data type, the source value is rounded to the precision of the target data type.
String or Number	CHAR VARCHAR CLOB GRAPHIC VARGRAPHIC DBCLOB	The resulting value is converted, if necessary, to the CCSID of the target data type using the rules described in “Conversion rules for assignments” on page 94 before it is converted to the target type with a limited length. Truncation occurs if the specified length limit is smaller than the length of the resulting string after CCSID conversion. A warning occurs if any non-blank characters are truncated. If the target type is a fixed-length string (CHAR or GRAPHIC) and the specified length of the target type is greater than the length of the resulting string from CCSID conversion, blanks are padded at the end. This truncation and padding behavior is similar to retrieval assignment of character or graphic strings.
String	DATE	The JSON string is converted to a date value. The JSON string must be in one of the following formats: ISO yyyy-mm-dd USA mm/dd/yyyy EUR dd.mm.yyyy JIS yyyy-mm-dd

Table 70. Supported JSON to SQL result column conversions (continued)

JSON type	SQL type	Notes®
String	TIME	The JSON string is converted to a time value. The JSON string must be in one of the following formats: ISO hh.mm.ss EUR hh.mm.ss JIS hh:mm:ss HMS hh:mm:ss
String	TIMESTAMP	The JSON string is converted to a timestamp value. The JSON string must be in one of the following formats: ISO yyyy-mm-dd hh:mm:ss.nnnnnn IBMSQL yyyy-mm-dd-hh.mm.ss.nnnnnn ISO-8601 yyyy-mm-ddThh:mm:ss.nnnnnn<+/-Offset> If the ISO-8601 timestamp includes an offset, the timestamp is adjusted using that offset. For example, 2021-03-18T03:00:00.0-02:00 is converted to 2021-03-18 05:00:00.000000.
Array or Object	CHAR VARCHAR CLOB GRAPHIC VARGRAPHIC DBCLOB	Must be returned using a FORMAT JSON column. JSON arrays or objects are returned as JSON formatted character strings. The resultant conversion is that same as for string types.
Null	Any	A JSON null value is converted to an SQL null value
Boolean	CHAR VARCHAR CLOB GRAPHIC VARGRAPHIC DBCLOB	A JSON boolean value is converted to either a true or false string and is returned as a string using the conversion rules for JSON strings.

Examples

These examples operate on the following JSON document:

```
{
  "id" : 901,
  "name" : { "first": "John", "last": "Doe" },
  "phones": [ { "type": "home", "number": "555-3762" },
              { "type": "work", "number": "555-8792" } ]
}
```

- List the employee id, first name, last name, and first phone type and number:

```

SELECT U."id", U."first name",U."last name",U."phone type",U."phone number"
FROM EMPLOYEE_TABLE E,
     JSON_TABLE(E.jsondoc,
                'lax $'
                COLUMNS( "id" INTEGER,
                          "first name" VARCHAR(20) PATH 'lax $.name.first',
                          "last name" VARCHAR(20) PATH 'lax $.name.last',
                          "phone type" VARCHAR(20) PATH 'lax $.phones[0].type',
                          "phone number" VARCHAR(20) PATH 'lax $.phones[0].number')
                ) AS U

```

Returns:

id	first name	last name	phone type	phone number
901	John	Doe	home	555-3762

- List the employee id, first name, last name, and all available telephone types and numbers:

```

SELECT U."id", U."first name",U."last name",U."phone type",U."number" AS "phone number"
FROM EMPLOYEE_TABLE E,
     JSON_TABLE(E.jsondoc,
                'lax $'
                COLUMNS( "id" INTEGER,
                          "first name" VARCHAR(20) PATH 'lax $.name.first',
                          "last name" VARCHAR(20) PATH 'lax $.name.last',
                          NESTED PATH 'lax $.phones[*]'
                          COLUMNS (
                              "phone type" VARCHAR(20) PATH 'lax $.type',
                              "number" VARCHAR(20)
                          )
                ) AS U

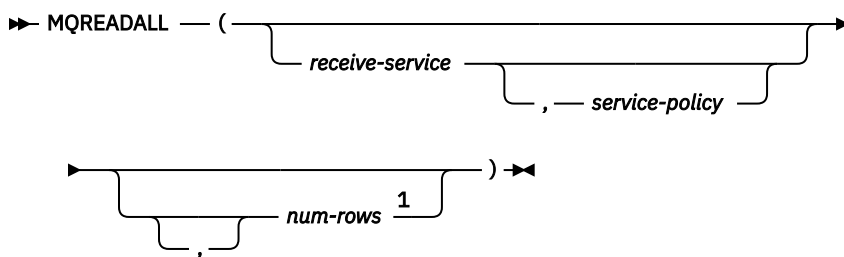

```

Returns:

id	first name	last name	phone type	phone number
901	John	Doe	home	555-3762
901	John	Doe	work	555-8792

MQREADALL

The MQREADALL function returns a table that contains the messages and message metadata from a specified MQSeries location with a VARCHAR column without removing the messages from the queue.

Notes:

¹ The comma is required before *num-rows* when any of the preceding arguments to the function are specified.

The MQREADALL function returns a table containing the messages and message metadata from the MQSeries location that is specified by *receive-service*, using the quality-of-service policy that is defined in *service-policy*. Performing this operation does not remove the messages from the queue that is associated with *receive-service*.

receive-service

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be an empty string or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression must refer to a service point that is defined in the SYSIBM.MQSERVICE table. A service point is a logical end-point from where a message is sent or received. Service point definitions include the name of the MQSeries queue manager and queue. For more information about MQSeries Application Messaging, see [SQL Programming](#).

If *receive-service* is not specified or the null value, DB2.DEFAULT.SERVICE is used.

service-policy

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be an empty string or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression must refer to a service policy that is defined in the SYSIBM.MQPOLICY table. A service policy specifies a set of quality-of-service options that are to be applied to this messaging operation. These options include message priority and message persistence. For more information about MQSeries Application Messaging, see [SQL Programming](#).

If *service-policy* is not specified or the null value, DB2.DEFAULT.POLICY is used.

num-rows

An expression that returns a value that is a SMALLINT or INTEGER data type whose value is a positive integer or zero. The value of the expression specifies the maximum number of messages to return.

If *num-rows* is not specified or the value of expression is zero, all available messages are returned.

The result of the function is a table with the format shown in the following table. All the columns are nullable.

Table 71. Format of the resulting table for MQREADALL

Column name	Data type	Contains
MSG	VARCHAR(32000)	The contents of the MQSeries message
CORRELID	VARCHAR(24)	The correlation ID that is used to relate messages
TOPIC	VARCHAR(40)	Reserved

Table 71. Format of the resulting table for MQREADALL (continued)

Column name	Data type	Contains
QNAME	VARCHAR(48)	The name of the queue from which the message was received
MSGID	VARCHAR(24)	The unique, MQSeries-assigned identifier for the message
MSGFORMAT	VARCHAR(8)	The format of the message, as defined by MQSeries

The CCSID of the result columns, except for CORRELID and MSGID, is the default CCSID at the current server.

Notes

Prerequisites: In order to use the MQSeries functions, IBM MQSeries for IBM i must be installed, configured, and operational.

Example

- This example receives all the messages from the queue specified by the default service (DB2.DEFAULT.SERVICE), using the default policy (DB2.DEFAULT.POLICY). The messages and all the metadata are returned as a table.

```
SELECT *
FROM TABLE (MQREADALL ()) AS T
```

- This example receives all the messages from the head of the queue specified by the service MYSERVICE, using the default policy (DB2.DEFAULT.POLICY). Only the MSG and CORRELID columns are returned.

```
SELECT T.MSG, T.CORRELID
FROM TABLE (MQREADALL ('MYSERVICE')) AS T
```

- This example reads the head of the queue specified by the default service (DB2.DEFAULT.SERVICE), using the default policy (DB2.DEFAULT.POLICY). Only messages with a CORRELID of '1234' are returned. All columns are returned.

```
SELECT *
FROM TABLE (MQREADALL ()) AS T
WHERE T.CORRELID = '1234'
```

- This example receives the first 10 messages from the head of the queue specified by the default service (DB2.DEFAULT.SERVICE), using the default policy (DB2.DEFAULT.POLICY). All columns are returned.

```
SELECT *
FROM TABLE (MQREADALL (10)) AS T
```

MQREADALLCLOB

The MQREADALLCLOB function returns a table that contains the messages and message metadata from a specified MQSeries location with a CLOB column without removing the messages from the queue.

Notes:

¹ The comma is required before *num-rows* when any of the preceding arguments to the function are specified.

The MQREADALLCLOB function returns a table containing the messages and message metadata from the MQSeries location that is specified by *receive-service*, using the quality-of-service policy that is defined in *service-policy*. Performing this operation does not remove the messages from the queue that is associated with *receive-service*.

receive-service

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be an empty string or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression must refer to a service point that is defined in the SYSIBM.MQSERVICE table. A service point is a logical end-point from where a message is sent or received. Service point definitions include the name of the MQSeries queue manager and queue. For more information about MQSeries Application Messaging, see [SQL Programming](#).

If *receive-service* is not specified or the null value, DB2.DEFAULT.SERVICE is used.

service-policy

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be an empty string or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression must refer to a service policy that is defined in the SYSIBM.MQPOLICY table. A service policy specifies a set of quality-of-service options that are to be applied to this messaging operation. These options include message priority and message persistence. For more information about MQSeries Application Messaging, see [SQL Programming](#).

If *service-policy* is not specified or the null value, DB2.DEFAULT.POLICY is used.

num-rows

An expression that returns a value that is a SMALLINT or INTEGER data type whose value is a positive integer or zero. The value of the expression specifies the maximum number of messages to return.

If *num-rows* is not specified or the value of expression is zero, all available messages are returned.

The result of the function is a table with the format shown in the following table. All the columns are nullable.

Table 72. Format of the resulting table for MQREADALLCLOB

Column name	Data type	Contains
MSG	CLOB(2M)	The contents of the MQSeries message
CORRELID	VARCHAR(24)	The correlation ID that is used to relate messages

Table 72. Format of the resulting table for MQREADALLCLOB (continued)

Column name	Data type	Contains
TOPIC	VARCHAR(40)	Reserved
QNAME	VARCHAR(48)	The name of the queue from which the message was received
MSGID	VARCHAR(24)	The unique, MQSeries-assigned identifier for the message
MSGFORMAT	VARCHAR(8)	The format of the message, as defined by MQSeries

The CCSID of the result columns, except for CORRELID and MSGID, is the default CCSID at the current server.

Notes

Prerequisites: In order to use the MQSeries functions, IBM MQSeries for IBM i must be installed, configured, and operational.

Example

- This example receives all the messages from the queue specified by the default service (DB2.DEFAULT.SERVICE), using the default policy (DB2.DEFAULT.POLICY). The messages and all the metadata are returned as a table.

```
SELECT *
FROM TABLE (MQREADALLCLOB ()) AS T
```

- This example receives all the messages from the head of the queue specified by the service MYSERVICE, using the default policy (DB2.DEFAULT.POLICY). Only the MSG and CORRELID columns are returned.

```
SELECT T.MSG, T.CORRELID
FROM TABLE (MQREADALLCLOB ('MYSERVICE')) AS T
```

- This example reads the head of the queue specified by the default service (DB2.DEFAULT.SERVICE), using the default policy (DB2.DEFAULT.POLICY). Only messages with a CORRELID of '1234' are returned. All columns are returned.

```
SELECT *
FROM TABLE (MQREADALLCLOB ()) AS T
WHERE T.CORRELID = '1234'
```

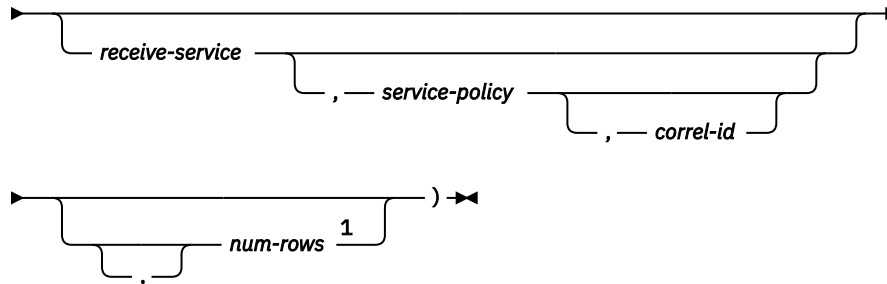

- This example receives the first 10 messages from the head of the queue specified by the default service (DB2.DEFAULT.SERVICE), using the default policy (DB2.DEFAULT.POLICY). All columns are returned.

```
SELECT *
FROM TABLE (MQREADALLCLOB (10)) AS T
```

MQRECEIVEALL

The MQRECEIVEALL function returns a table that contains the messages and message metadata from a specified MQSeries location with a VARCHAR column with removal of the messages from the queue.

►► MQRECEIVEALL — (→

Notes:

¹ The comma is required before *num-rows* when any of the preceding arguments to the function are specified.

The MQRECEIVEALL function returns a table containing the messages and message metadata from the MQSeries location that is specified by *receive-service*, using the quality-of-service policy that is defined in *service-policy*. Performing this operation removes the messages from the queue that is associated with *receive-service*.

receive-service

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be an empty string or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression must refer to a service point that is defined in the SYSIBM.MQSERVICE table. A service point is a logical end-point from where a message is sent or received. Service point definitions include the name of the MQSeries queue manager and queue. For more information about MQSeries Application Messaging, see [SQL Programming](#).

If *receive-service* is not specified or the null value, DB2.DEFAULT.SERVICE is used.

service-policy

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be an empty string or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression must refer to a service policy that is defined in the SYSIBM.MQPOLICY table. A service policy specifies a set of quality-of-service options that are to be applied to this messaging operation. These options include message priority and message persistence. For more information about MQSeries Application Messaging, see [SQL Programming](#).

If *service-policy* is not specified or the null value, DB2.DEFAULT.POLICY is used.

correl-id

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The expression must have an actual length that is no greater than 24 bytes. The value of the expression specifies the correlation identifier that is associated with this message. A correlation identifier is often specified in request-and-reply scenarios to associate requests with replies. The first message with a matching correlation identifier is returned. For more information about MQSeries Application Messaging, see [SQL Programming](#).

A fixed length string with trailing blanks is considered a valid value. However, when the *correl-id* is specified on another request such as MQSEND, the identical *correl-id* must be specified to be recognized as a match. For example, specifying a value of 'test' for *correl-id* on MQRECEIVEALL does not match a *correl-id* value of 'test ' (with trailing blanks) specified earlier on an MQSEND request.

If *correl-id* is not specified or is an empty string or the null value, a correlation identifier is not used, and the message at the beginning of the queue is returned.

num-rows

An expression that returns a value that is a SMALLINT or INTEGER data type whose value is a positive integer or zero. The value of the expression specifies the maximum number of messages to return.

If *num-rows* is not specified or the value of expression is zero, all available messages are returned.

The result of the function is a table with the format shown in the following table. All the columns are nullable.

Table 73. Format of the resulting table for MQRECEIVEALL

Column name	Data type	Contains
MSG	VARCHAR(32000)	The contents of the MQSeries message
CORRELID	VARCHAR(24)	The correlation ID that is used to relate messages
TOPIC	VARCHAR(40)	Reserved
QNAME	VARCHAR(48)	The name of the queue from which the message was received
MSGID	VARCHAR(24)	The unique, MQSeries-assigned identifier for the message
MSGFORMAT	VARCHAR(8)	The format of the message, as defined by MQSeries

The CCSID of the result columns, except for CORRELID and MSGID, is the default CCSID at the current server.

Notes

Prerequisites: In order to use the MQSeries functions, IBM MQSeries for IBM i must be installed, configured, and operational.

Example

- This example receives all the messages from the queue specified by the default service (DB2.DEFAULT.SERVICE), using the default policy (DB2.DEFAULT.POLICY). The messages and all the metadata are returned as a table.

```
SELECT *  
FROM TABLE (MQRECEIVEALL ()) AS T
```

- This example receives all the messages from the head of the queue specified by the service MYSERVICE, using the default policy (DB2.DEFAULT.POLICY). Only the MSG and CORRELID columns are returned.

```
SELECT T.MSG, T.CORRELID  
FROM TABLE (MQRECEIVEALL ('MYSERVICE')) AS T
```

- This example receives all of the message from the head of the queue specified by the service "MYSERVICE", using the policy "MYPOLICY". Only messages with a CORRELID of '1234' are returned. Only the MSG and CORRELID columns are returned.

```
SELECT *  
FROM TABLE (MQRECEIVEALL ('MYSERVICE', 'MYPOLICY', '1234')) AS T
```

- This example receives the first 10 messages from the head of the queue specified by the default service (DB2.DEFAULT.SERVICE), using the default policy (DB2.DEFAULT.POLICY). All columns are returned.

```
SELECT *  
FROM TABLE (MQRECEIVEALL (10)) AS T
```

MQRECEIVEALLCLOB

The MQRECEIVEALLCLOB function returns a table that contains the messages and message metadata from a specified MQSeries location with a CLOB column with removal of the messages from the queue.

►► MQRECEIVEALLCLOB — (→

Notes:

¹ The comma is required before *num-rows* when any of the preceding arguments to the function are specified.

The MQRECEIVEALLCLOB function returns a table containing the messages and message metadata from the MQSeries location that is specified by *receive-service*, using the quality-of-service policy that is defined in *service-policy*. Performing this operation removes the messages from the queue that is associated with *receive-service*.

receive-service

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be an empty string or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression must refer to a service point that is defined in the SYSIBM.MQSERVICE table. A service point is a logical end-point from where a message is sent or received. Service point definitions include the name of the MQSeries queue manager and queue. For more information about MQSeries Application Messaging, see [SQL Programming](#).

If *receive-service* is not specified or the null value, DB2.DEFAULT.SERVICE is used.

service-policy

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be an empty string or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression must refer to a service policy that is defined in the SYSIBM.MQPOLICY table. A service policy specifies a set of quality-of-service options that are to be applied to this messaging operation. These options include message priority and message persistence. For more information about MQSeries Application Messaging, see [SQL Programming](#).

If *service-policy* is not specified or the null value, DB2.DEFAULT.POLICY is used.

correl-id

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The expression must have an actual length that is no greater than 24 bytes. The value of the expression specifies the correlation identifier that is associated with this message. A correlation identifier is often specified in request-and-reply scenarios to associate requests with replies. The first message with a matching correlation identifier is returned. For more information about MQSeries Application Messaging, see [SQL Programming](#).

A fixed length string with trailing blanks is considered a valid value. However, when the *correl-id* is specified on another request such as MQSEND, the identical *correl-id* must be specified to be recognized as a match. For example, specifying a value of 'test' for *correl-id* on MQRECEIVEALLCLOB

does not match a *correl-id* value of 'test ' (with trailing blanks) specified earlier on an MQSEND request.

If *correl-id* is not specified or is an empty string or the null value, a correlation identifier is not used, and the message at the beginning of the queue is returned.

num-rows

An expression that returns a value that is a SMALLINT or INTEGER data type whose value is a positive integer or zero. The value of the expression specifies the maximum number of messages to return.

If *num-rows* is not specified or the value of expression is zero, all available messages are returned.

The result of the function is a table with the format shown in the following table. All the columns are nullable.

Table 74. Format of the resulting table for MQRECEIVEALLCLOB

Column name	Data type	Contains
MSG	CLOB(2M)	The contents of the MQSeries message
CORRELID	VARCHAR(24)	The correlation ID that is used to relate messages
TOPIC	VARCHAR(40)	Reserved
QNAME	VARCHAR(48)	The name of the queue from which the message was received
MSGID	VARCHAR(24)	The unique, MQSeries-assigned identifier for the message
MSGFORMAT	VARCHAR(8)	The format of the message, as defined by MQSeries

The CCSID of the result columns, except for CORRELID and MSGID, is the default CCSID at the current server.

Notes

Prerequisites: In order to use the MQSeries functions, IBM MQSeries for IBM i must be installed, configured, and operational.

Example

- This example receives all the messages from the queue specified by the default service (DB2.DEFAULT.SERVICE), using the default policy (DB2.DEFAULT.POLICY). The messages and all the metadata are returned as a table.

```
SELECT *  
FROM TABLE (MQRECEIVEALLCLOB ()) AS T
```

- This example receives all the messages from the head of the queue specified by the service MYSERVICE, using the default policy (DB2.DEFAULT.POLICY). Only the MSG and CORRELID columns are returned.

```
SELECT T.MSG, T.CORRELID  
FROM TABLE (MQRECEIVEALLCLOB ('MYSERVICE')) AS T
```

- This example receives all of the message from the head of the queue specified by the service "MYSERVICE", using the policy "MYPOLICY". Only messages with a CORRELID of '1234' are returned. Only the MSG and CORRELID columns are returned.

```
SELECT *  
FROM TABLE (MQRECEIVEALLCLOB ('MYSERVICE', 'MYPOLICY', '1234')) AS T
```

- This example receives the first 10 messages from the head of the queue specified by the default service (DB2.DEFAULT.SERVICE), using the default policy (DB2.DEFAULT.POLICY). All columns are returned.

```
SELECT *  
FROM TABLE (MQRECEIVEALLCLOB (10)) AS T
```

XMLTABLE

The XMLTABLE function returns a result table from the evaluation of XPath expressions, possibly using specified input arguments as XPath variables. Each item in the result sequence of the row XPath expression represents a row of the result table.

►► XMLTABLE — (*xmlns-declaration* , *row-xquery-expression-constant* →

row-xquery-argument

xml-table-regular-column-definition

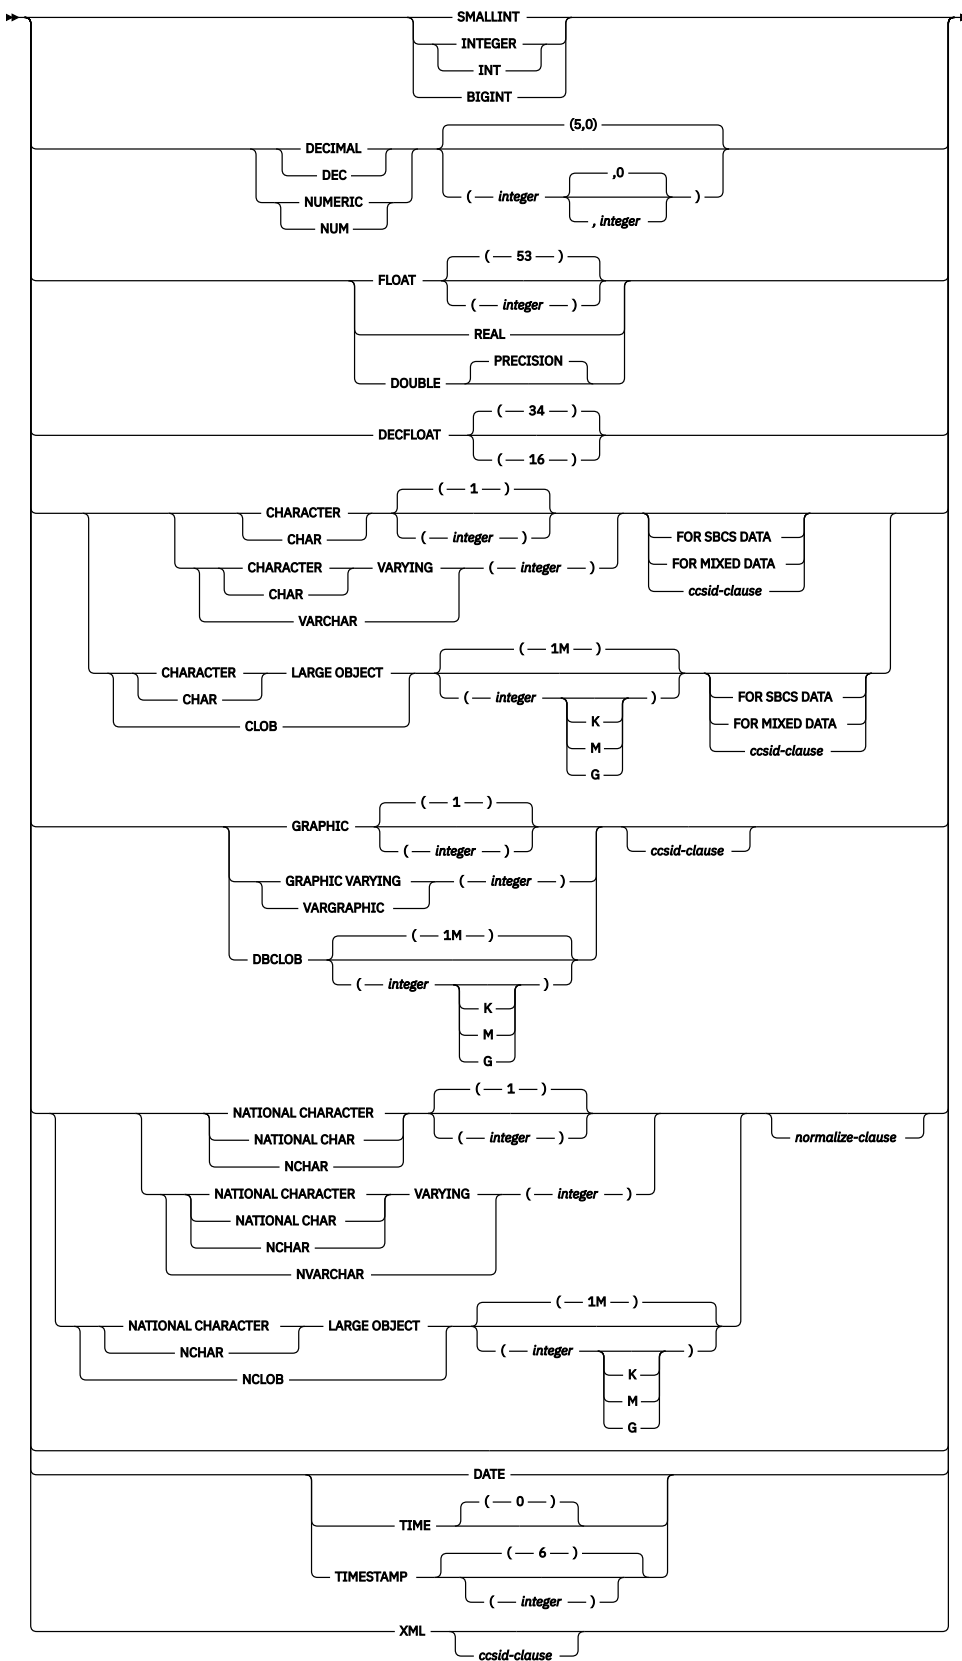

xml-table-ordinality-column-definition

►► *column-name* — FOR ORDINALITY →

Notes:

- ¹ *xquery-context-item-expression* must not be specified more than one time.
- ² The *xml-table-ordinality-column-definition* clause must not be specified more than one time.
- ³ Neither the *default-clause* nor the *PATH* clause can be specified more than one time.

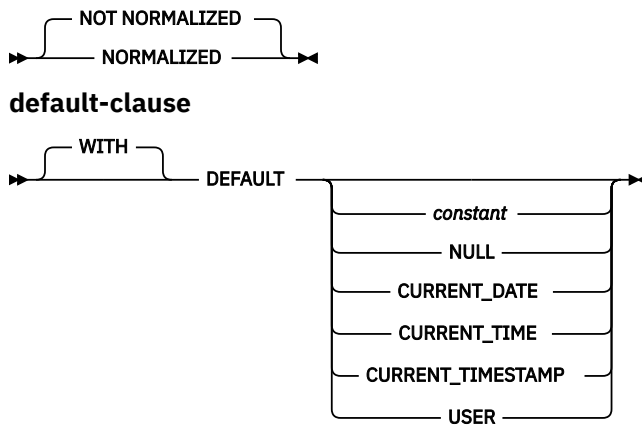

data-type

ccsid-clause

normalize-clause

The function name cannot be specified as a qualified name.

xmlnamespaces-declaration

Specifies one or more XML namespace declarations, using the XMLNAMESPACES function, that become part of the static context of the *row-xquery-expression-constant* and the *column-xquery-expression-constant*. The set of statically known namespaces for XPath expressions which are arguments of XMLTABLE is the combination of the pre-established set of statically known namespaces and the namespace declarations specified in this clause. The XPath prolog within an XPath expression can override these namespaces.

If *xmlnamespaces-declaration* is not specified, only the pre-established set of statically known namespaces apply to the XPath expressions.

row-xquery-expression-constant

Specifies an SQL string constant that is interpreted as an XPath expression using supported XPath language syntax. This expression determines the number of rows in the result table. The expression is evaluated using the optional set of input XML values that is specified in *row-xquery-argument*, and returns an output XPath sequence where one row is generated for each item in the sequence. If the sequence is empty, the result of XMLTABLE is an empty table. *row-xquery-expression-constant* must not be an empty string or a string of all blanks.

PASSING

Specifies input values and the manner in which these values are passed to the XPath expression specified by *row-xquery-expression-constant*.

BY VALUE

Specifies that any XML arguments are passed by value. When XML values are passed by value, the XPath evaluation uses a copy of the XML data. This is the default behavior. Db2 for i binds the XPath variable expression to a document node that represents the XML input value.

This clause has no impact on how non-XML values are passed. Non-XML values always create a copy of the value during the cast to XML.

row-xquery-argument

Specifies an argument that is to be passed to the XPath expression specified by *row-xquery-expression-constant*. *row-xquery-argument* specifies an SQL expression that is evaluated before being passed to the XPath expression.

If the data type of *row-xquery-argument* is not XML, the result of the expression is converted to XML. For *xquery-variable-expression*, a null value is converted to an XML empty sequence.

How *row-xquery-argument* is used in the XPath expression depends on whether the argument is specified as an *xquery-context-item-expression* or an *xquery-variable-expression*.

row-xquery-argument must not contain a NEXT VALUE or PREVIOUS VALUE expression or an OLAP specification.

xquery-context-item-expression

Specifies an SQL expression that returns a value that is XML or that is a type that has a supported conversion to XML.

xquery-context-item-expression specifies the initial context item for the *row-xquery-expression*. The value of the initial context item is the result of *xquery-context-item-expression* after being converted to XML. *xquery-context-item-expression* must not be specified more than one time.

xquery-variable-expression

Specifies an SQL expression whose value is available to the XPath expression specified by *row-xquery-expression-constant* during execution. The expression must return a value that is XML or that is a type that has a supported conversion to XML.

xquery-variable-expression specifies an argument that will be passed to *row-xquery-expression-constant* as an XPath variable. If *xquery-variable-expression* is the null value, the XPath variable is set to an XML empty sequence. The scope of the XPath variables that are created from the PASSING clause is the XPath expression specified by *row-xquery-expression-constant*.

AS identifier

Specifies that the value generated by *xquery-variable-expression* will be passed to *row-xquery-expression-constant* as an XPath variable. The *identifier* is a name that must be in the form of an XML NCName. See the W3C XML namespace specifications for more details on valid names. The leading dollar sign (\$) that precedes variable names in the XPath language must not be included as part of *identifier*. The identifier must not be greater than 128 bytes in length. Two arguments within the same PASSING clause cannot use the same identifier.

BY VALUE

Specifies that *xquery-variable-expression* is passed by value. When XML values are passed by value, the XPath evaluation uses a copy of the XML data. Db2 for i binds the XPath variable expression to a document node that represents the XML input value. If BY VALUE is not specified following *xquery-variable-expression*, XML arguments are passed using the default passing mechanism that is provided through the syntax that follows the PASSING keyword.

This clause is only valid for input values with the XML data type. Non-XML values always create a copy of the value during the cast to XML.

SQL type	XML type	Notes
SMALLINT	xs:integer	
INTEGER	xs:integer	
BIGINT	xs:integer	
DECIMAL NUMERIC	xs:decimal	Decimal numbers with a precision greater than 34 can lose precision during processing.
FLOAT DOUBLE DECFLOAT	xs:double	

Table 75. Supported SQL to XML conversions (continued)

SQL type	XML type	Notes
CHAR VARCHAR CLOB GRAPHIC VARGRAPHIC DBCLOB	xs:string	When character string values are cast to XML values, the resulting xs:string atomic value cannot contain illegal XML characters. If the input character string is not in Unicode, the input characters are converted to Unicode. CHAR and VARCHAR strings cannot have a CCSID of 65535 or be defined for bit data.
DATE	xs:date	The xs:date value will not have a timezone component. For comparisons, the timezone is implicitly assumed to be UTC. If needed, the fn:adjust-timezone() function can be used to explicitly set the timezone.
TIME	xs:time	The xs:time value will not have a timezone component. For comparisons, the timezone is implicitly assumed to be UTC. If needed, the fn:adjust-timezone() function can be used to explicitly set the timezone.
TIMESTAMP	xs:dateTime	The xs:dateTime value will not have a timezone component. For comparisons, the timezone is implicitly assumed to be UTC. If needed, the fn:adjust-timezone() function can be used to explicitly set the timezone.

COLUMNS

Specifies the output columns of the result table including the column name, data type, and how the column value is computed for each row. If this clause is not specified, a single unnamed column of type XML is returned with the value based on the sequence item from evaluating the XPath expression in the *row-xquery-expression* (equivalent to specifying `PATH ' . '`). To reference this result column, a *column-name* must be specified in the *correlation-clause* following the table function.

The sum of all the result column lengths cannot exceed 64K bytes. For information on the byte counts of columns according to data type, see [“Maximum row sizes” on page 1164](#). Assume the number of *row-xquery-arguments* is *N*. There must be no more than 8000-*N* columns.

xml-table-regular-column-definition

Specifies one output column of the result table including the column name, data type, and an XPath expression to extract the value from the sequence item for the row.

column-name

Specifies the name of the column in the result table. The name cannot be qualified and the same name cannot be used for more than one column of the result table.

data-type

Specifies the data type of the column. For CHAR and VARCHAR columns, the CCSID cannot be 65535.

BY VALUE

Specifies that the result column is returned by value. When XML values are returned by value, a copy of the XML data is returned. This is the default behavior. Db2 for i constructs a document node for the XML result when the value is returned from the table function. This clause must not be specified for a column with a data type that is not XML.

default-clause

Specifies a default value for the column. For XMLTABLE result columns, the default is applied when the processing of the XPath expression contained in *column-xquery-expression-constant* returns an empty sequence.

PATH column-xquery-expression-constant

Specifies a string constant that is interpreted as an XPath expression using supported XPath language syntax. The *column-xquery-expression-constant* specifies an XPath expression that determines the column value with respect to an item that is the result of evaluating the XPath expression in *row-xquery-expression-constant*. Given an item from the result of processing the *row-query-expression-constant* as the externally provided context item, the *column-xquery-expression-constant* is evaluated and returns an output sequence. The column value is determined based on this output sequence as follows:

- If an empty sequence is returned, the *default-clause* provides the value of the column.
- If an empty sequence is returned and no *default-clause* was specified, the null value is assigned to the column.
- If a non-empty sequence is returned, the value is converted to the data-type specified for the column. An error could be returned from processing this implicit conversion.

The value for *column-xquery-expression-constant* must not be an empty string or a string of all blanks. If this clause is not specified, the default XPath expression is the *column-name*.

xml-table-ordinality-column-definition

Specifies the ordinality column of the result table.

column-name

Specifies the name of the column in the result table. The name cannot be qualified and the same name cannot be used for more than one column of the result table.

FOR ORDINALITY

Specifies that *column-name* is the ordinality column of the result table. The data type of this column is BIGINT. The value of this column in the result table is the sequential number of the item for the row in the resulting sequence from evaluating the XPath expression in *row-xquery-expression-constant*.

Table 76. Supported XML to SQL result column conversions		
XML type	SQL type	Notes
xs:integer	SMALLINT INTEGER BIGINT	
xs:decimal	DECIMAL NUMERIC	The resulting xs:decimal value is converted, if necessary, to the precision and scale of the target data type. The necessary number of leading zeros is added or removed. In the fractional part of the number, the necessary number of trailing zeros is added or the necessary number of digits is eliminated. This truncation behavior is similar to the behavior of the cast from DECIMAL to DECIMAL. Decimal numbers with a precision greater than 34 can lose precision during processing.

Table 76. Supported XML to SQL result column conversions (continued)

XML type	SQL type	Notes
xs:double	FLOAT DOUBLE REAL DECFLOAT	<p>If the target type is FLOAT, DOUBLE, or REAL and the source XML value after the XPath cast is an xs:double value of INF, -INF, or NaN, an error is returned. If the source value is an xs:double negative zero, the value is converted to positive zero. If the source value is beyond the range of the target data type, an overflow error is returned. If the source value contains more significant digits than the precision of the target data type, the source value is rounded to the precision of the target data type.</p> <p>If the target type is DECFLOAT and the source XML value is an xs:double value of INF, -INF, or NaN, the result will be the corresponding special DECFLOAT values INF, -INF, or NaN. If the source value is an xs:double negative zero, the result is negative zero. If the target type is DECFLOAT(16) and the source value is beyond the range of DECFLOAT(16), an overflow error is returned. If the source value has more than 16 significant digits, the value is rounded according to the ROUNDING mode that is in effect. This rounding behavior is the same as what is used during the cast of DECFLOAT(34) to DECFLOAT(16).</p>
xs:string	CHAR VARCHAR CLOB GRAPHIC VARGRAPHIC DBCLOB	<p>The resulting XML value is converted, if necessary, to the CCSID of the target data type using the rules described in “Conversion rules for assignments” on page 94 before it is converted to the target type with a limited length. Truncation occurs if the specified length limit is smaller than the length of the resulting string after CCSID conversion. A warning occurs if any non-blank characters are truncated. If the target type is a fixed-length string type (CHAR or GRAPHIC) and the specified length of the target type is greater than the length of the resulting string from CCSID conversion, blanks are padded at the end. This truncation and padding behavior is similar to retrieval assignment of character or graphic strings.</p>
xs:date	DATE	<p>The resulting XML value is adjusted to UTC time and the time zone component is removed. The year part of the resulting xs:date value must be in the range of 0001 to 9999.</p>
xs:time	TIME	<p>The resulting XML value is adjusted to UTC time and the time zone component is removed. Any fractional seconds are truncated from the result.</p>
xs:dateTime	TIMESTAMP	<p>The resulting XML value is adjusted to UTC time and the time zone component is removed. The year part of the resulting xs:dateTime value must be in the range of 0001 to 9999. If the target timestamp type has a precision less than 12, the fractional seconds part of the xs:dateTime value is truncated to the target timestamp precision.</p>

The result of the function is a table. If the evaluation of any of the XPath expressions results in an error, then the XMLTABLE function returns the XPath error.

Example

- List as a table result the purchase order items for orders with a status of 'Unshipped'.

```
SELECT U."PO ID", U."Part #", U."Product Name",
       U."Quantity", U."Price", U."Order Date"
FROM PURCHASEORDER P,
     XMLTABLE('$po/PurchaseOrder/itemlist/item' PASSING P.PORDER AS "po"
              COLUMNS "PO ID"           INTEGER    PATH './@PoNum',
                       "Part #"          CHAR(10)   PATH 'partid',
                       "Product Name"    VARCHAR(50) PATH 'name',
                       "Quantity"        INTEGER    PATH 'quantity',
                       "Price"           DECIMAL(9,2) PATH 'price',
                       "Order Date"      DATE       PATH './@OrderDate'
              ) AS U
WHERE P.STATUS = 'Unshipped'
```

Chapter 5. Procedures

This chapter contains syntax diagrams, semantic descriptions, rules, and examples of the use of the system supplied procedures.

CREATE_WRAPPED

The CREATE_WRAPPED procedure transforms a readable DDL statement into an obfuscated DDL statement and then deploys the object in the database.

►► CREATE_WRAPPED — (— *object-definition-string* —) ►►

In an obfuscated DDL statement, the procedural logic and embedded SQL statements are scrambled in such a way that any intellectual property in the logic cannot be easily extracted.

The schema is SYSIBMADM.

object-definition-string

A string of type CLOB containing a DDL statement. It can be one of the following SQL statements:

- CREATE FUNCTION (SQL scalar)
- CREATE FUNCTION (SQL table)
- CREATE PROCEDURE (SQL)
- CREATE TRIGGER

The procedure transforms the input into an obfuscated DDL statement string and then dynamically executes that DDL statement. The encoding consists of a prefix of the original statement up to and including the routine signature or trigger name, followed by the keyword WRAPPED. This keyword is followed by information about the application server that invoked the function. The information has the form *pppvrrm* where:

- *ppp* identifies the product using the following 3 characters:
 - DSN for Db2 for z/OS
 - QSQ for Db2 for i
 - SQL for Db2 for LUW
- *vv* is a two-digit version identifier, such as '07'
- *rr* is a two-digit release identifier, such as '02'
- *m* is a one-character modification level identifier, such as '0'

For example Db2 for i version 7.3 is identified as 'QSQ07030'.

This application server information is followed by a string of letters (a-z and A-Z), digits (0-9), underscores, and colons.

The encoded DDL statement may be up to one-third longer than the plain text form of the statement. If the result exceeds the maximum length for SQL statements, an error is issued.

Note

The encoding of the statement is meant to obfuscate the content and should not be considered as a form of strong encryption.

Examples

Example 1: Produce an obfuscated version of a function that computes a yearly salary from an hourly wage given a 40 hour work week.

```
CALL CREATE_WRAPPED('CREATE FUNCTION salary(wage DECFLOAT)
                    RETURNS DECFLOAT RETURN wage * 40 * 52');

SELECT ROUTINE_DEFINITION FROM QSYS2.SYSROUTINES
       WHERE routine_name = 'SALARY' AND routine_schema = CURRENT SCHEMA;
```

Upon successful completion of the CALL statement, the ROUTINE_DEFINITION column in QSYS2.SYSROUTINES for the row corresponding to routine 'SALARY' would be something of the form:

```
WRAPPED QSQ07020 <encoded-suffix>
```

Example 2: Produce an obfuscated version of a trigger that sets a complex default.

```
CALL CREATE_WRAPPED('CREATE OR REPLACE TRIGGER trig1 BEFORE INSERT ON emp  
REFERENCING NEW AS n FOR EACH ROW  
WHEN (n.bonus IS NULL) SET n.bonus = n.salary * .04');  
  
SELECT ACTION_STATEMENT FROM QSYS2.SYSTRIGGERS  
WHERE trigname = 'TRIG1' AND trigschema = CURRENT SCHEMA;
```

Upon successful completion of the CALL statement, the ACTION_STATEMENT column in QSYS2.SYSTRIGGERS for the row corresponding to trigger 'TRIG1' would be something of the form:

```
WRAPPED QSQ07020 <encoded-suffix>
```

XDBDECOMPXML

The XDBDECOMPXML procedure extracts values from serialized XML data and populates relational tables with the values.

Authorization

The privileges held by the authorization ID of the statement must include the following:

- The following system authorities:
 - The system authority *EXECUTE on the XDBDECOMPXML service program associated with the procedure, and
 - The system authority *EXECUTE on the SYSPROC library.

The privileges held by the authorization ID of the statement must include:

- The INSERT privilege on any tables specified in the annotations, or
- Database administrator authority

Syntax

```
➤ XDBDECOMPXML ( rschema , name , xml doc ,  
                NULL  
                )  
➤ documentid ) ➤  
                NULL
```

Description

The schema is SYSPROC.

The XDBDECOMPXML stored procedure uses an XML schema which contains annotations that indicate which columns and tables should be used to store the decomposed XML values. The referenced XML schema must exist in the XSR and must be enabled for decomposition. You can enable an XML schema for decomposition by using the XSR_COMPLETE stored procedure. If your XML schema references tables that did not exist when you invoked the XSR_COMPLETE stored procedure, Db2 will return an error.

rschema

An input parameter of type VARCHAR(128) that specifies the SQL schema for the XML schema. It must be a valid SQL identifier. The SQL schema is one part of the qualified name used to identify this XML schema in the XSR. (The other part of the name is supplied by the *name* parameter). This parameter can have the NULL value which indicates that *name* is implicitly qualified based on the rules specified in [“Qualification of unqualified object names”](#) on page 57.

If *rschema* is specified, it cannot be QSYS, QSYS2, SYSIBM, SYSPROC, or QTEMP.

name

An input parameter of type VARCHAR(128) that specifies the name of the XML schema. It must be a valid SQL identifier. The complete name for the XML schema for which decomposition is to be performed is *rschema.name*. The XML schema name must already exist and be enabled for decomposition as a result of calling the XSR_COMPLETE stored procedure. This parameter cannot have the NULL value.

xml doc

An input parameter of type BLOB(2G) that points to the XML value that is to be decomposed. This parameter cannot be null.

documentid

An input parameter of type VARCHAR(1024) that contains a string that the caller can use to identify the input XML document. This parameter can be null.

XSR_ADDSCHEMADOC

The XSR_ADDSCHEMADOC stored procedure adds every XML schema other than the primary XML schema document to the XSR.

Authorization

Each XML schema in the XSR can consist on one or more XML schema documents. When an XML schema consists of multiple documents, you need to call XSR_ADDSCHEMADOC for the additional documents.

The privileges held by the authorization ID of the statement must include the following:

- The following system authorities:
 - The system authority *EXECUTE on the service program associated with the procedure,
 - The system authority *EXECUTE on the SYSPROC library,
 - The system authority *EXECUTE on the library containing the *SQLXSR object, and
 - The ALTER privilege for the *SQLXSR object.
- Database administrator authority

The privileges held by the authorization ID of the statement must include at least one of the following:

- For the XSROBJECTCOMPONENTS and XSROBJECTHIERARCHIES catalog tables:
 - The INSERT privilege on the table, and
 - The system authority *EXECUTE on library QSYS2.
- Database administrator authority

The user ID of the caller of the procedure must have the EXECUTE privilege on the XSR_ADDSCHEMADOC stored procedure and must be the definer of the XSR object as recorded in the XSROBJECTS catalog table.

Syntax

```
► XSR_ADDSCHEMADOC ( — rschema — , — name — , — schemalocation — , — content — , →  
    ► — docproperty — ) ►
```

Description

The schema is SYSPROC.

rschema

An input parameter of type VARCHAR(128) that specifies the SQL schema for the XML schema. It must be a valid SQL identifier. The SQL schema is one part of the qualified name used to identify this XML schema in the XSR. (The other part of the name is supplied by the *name* parameter). This parameter can have the NULL value which indicates that *name* is implicitly qualified based on the rules specified in [“Qualification of unqualified object names”](#) on page 57.

If *rschema* is specified, it cannot be QSYS, QSYS2, SYSIBM, SYSPROC, or QTEMP.

name

An input parameter of type VARCHAR(128) that specifies the name of the XML schema. It must be a valid SQL identifier. The complete name for the XML schema is *rschema.name*. The XML schema must already exist as a result of calling the XSR_REGISTER stored procedure and XML schema registration cannot yet be completed. This parameter cannot have the NULL value.

schemalocation

An input parameter of type VARCHAR(1000), which can have the NULL value, that indicates the schema location of the primary XML schema document to which the XML schema document is being

added. This argument is the external name of the XML schema, that is, the primary document can be identified in the XML instance documents with the `xsi:schemaLocation` attribute. The document that references the *schemalocation* must use a valid URI format.

content

An input parameter of type BLOB(30M) that contains the content of the XML schema document being added. This argument cannot have the NULL value; an XML schema document must be supplied. The content of the XML schema document must be encoded in UTF-8.

docproperty

An input parameter of type BLOB(5M) that indicates the properties for the XML schema document being added. This argument can have the NULL value; otherwise, the value is an XML document.

Example

The following example calls the XSR_ADDSCHEMADOC stored procedure:

```
CALL SYSPROC.XSR_ADDSCHEMADOC(  
  'MyLib',  
  'MySchema',  
  'http://myschema/addschema1.xsd',  
  :schema_content,  
  :schema_docproperties)
```

XSR_COMPLETE

The XSR_COMPLETE procedure is the final stored procedure to be called as part of the XML schema registration process, which registers XML schemas with the XSR. An XML schema is not available for validation until the schema registration completes through a call to this stored procedure.

Authorization

The privileges held by the authorization ID of the statement must include the following:

- The following system authorities:
 - The system authority *EXECUTE on the service program associated with the procedure,
 - The system authority *EXECUTE on the SYSPROC library,
 - The system authority *EXECUTE on the library containing the *SQLXSR object, and
 - The ALTER privilege for the *SQLXSR object.
- Database administrator authority

The privileges held by the authorization ID of the statement must include at least one of the following:

- For the XSROBJECTS, XSROBJECTCOMPONENTS, XSROBJECTHIERARCHIES, and XSRANNOTATIONINFO catalog tables:
 - The UPDATE privilege on XSROBJECTS, XSROBJECTCOMPONENTS, and XSROBJECTHIERARCHIES,
 - The INSERT privilege on XSRANNOTATIONINFO, and
 - The system authority *EXECUTE on library QSYS2.
- Database administrator authority

The user ID of the caller of the procedure must have the EXECUTE privilege on the XSR_COMPLETE stored procedure.

Syntax

```
►► XSR_COMPLETE ( ( — rschema — , — name — , — schemaproperties — , ►  
  
    ► — issuedfordecomposition — ) ►◄
```

Description

The schema is SYSPROC.

rschema

An input parameter of type VARCHAR(128) that specifies the SQL schema for the XML schema. It must be a valid SQL identifier. The SQL schema is one part of the qualified name used to identify this XML schema in the XSR. (The other part of the name is supplied by the *name* parameter). This parameter can have the NULL value which indicates that *name* is implicitly qualified based on the rules specified in [“Qualification of unqualified object names”](#) on page 57.

If *rschema* is specified, it cannot be QSYS, QSYS2, SYSIBM, SYSPROC, or QTEMP.

name

An input parameter of type VARCHAR(128) that specifies the name of the XML schema. It must be a valid SQL identifier. The complete name for the XML schema for which a completion check is to be performed is *rschema.name*. The XML schema name must already exist as a result of calling the XSR_REGISTER stored procedure, and XML schema registration cannot yet be completed. This parameter cannot have the NULL value. Rules for valid characters and delimiters that apply to any SQL identifier also apply to this parameter.

schemaproperties

An input parameter of type BLOB(5M) that specifies properties, if any, associated with the XML schema. The values for this parameter is either NULL, if there are no associated properties, or an XML document representing the properties for the XML schema.

issuedfordecomposition

An input parameter of type INTEGER that indicates if an XML schema is to be used for decomposition. If an XML schema is to be used for decomposition, this value should be set to 1; otherwise, it should be set to 0.

Example

The following example calls the XSR_COMPLETE stored procedure:

```
CALL SYSPROC.XSR_COMPLETE(  
    'MyLib',  
    'MySchema',  
    :schemaproperty_host_var,  
    0)
```

XSR_REGISTER

The XSR_REGISTER procedure is the first stored procedure to be called as part of the XML schema registration process, which registers XML schemas with the XML schema repository (XSR).

Authorization

The user that calls this stored procedure is considered the creator of this XML schema. Db2 obtains the namespace attribute from the schema document when XSR_COMPLETE is invoked.

The privileges held by the authorization ID of the statement must include the following:

- The following system authorities:
 - The system authority *EXECUTE on the service program associated with the procedure, and
 - The system authority *EXECUTE on the SYSPROC library.

The privileges held by the authorization ID of the statement must include as least one of the following:

- The privilege to create in the schema
- Database administrator authority

The privileges held by the authorization ID of the statement must include at least one of the following:

- For the XSROBJECTS, XSROBJECTCOMPONENTS, and XSROBJECTHIERARCHIES catalog tables:
 - The INSERT privilege on the table, and
 - The system authority *EXECUTE on library QSYS2.
- Database administrator authority

Syntax

```
► XSR_REGISTER ( ( rschema , name , schemalocation , content ,  
    docproperty ) ►
```

Description

The schema is SYSPROC.

rschema

An input parameter of type VARCHAR(128) that specifies the SQL schema for the XML schema. It must be a valid SQL identifier. The SQL schema is one part of the qualified name used to identify this XML schema in the XSR. (The other part of the name is supplied by the *name* parameter). This parameter can have the NULL value which indicates that *name* is implicitly qualified based on the rules specified in [“Qualification of unqualified object names”](#) on page 57.

If *rschema* is specified, it cannot be QSYS, QSYS2, SYSIBM, SYSPROC, or QTEMP.

name

An input parameter of type VARCHAR(128) that specifies the name of the XML schema. It must be a valid SQL identifier. The complete name for the XML schema is *rschema.name* and should be unique among all objects in the XSR.

schemalocation

An input parameter of type VARCHAR(1000), which can have the NULL value, that indicates the schema location of the primary XML schema document. This parameter is the external name of the XML schema, that is, the primary document can be identified in the XML instance documents with the xsi:schemaLocation attribute.

content

An input parameter of type BLOB(30M) that contains the content of the primary XML schema document. This parameter cannot have the NULL value; an XML schema document must be supplied. The content of the XML schema document must be encoded in UTF-8.

docproperty

An input parameter of type BLOB(5M) that indicates the properties for the primary XML schema document. This parameter can have the NULL value; otherwise, the value is an XML document.

Example

The following example calls the XSR_REGISTER stored procedure:

```
CALL SYSPROC.XSR_REGISTER(  
  'MyLib',  
  'MySchema',  
  'http://myschema/primary.xsd',  
  :content_host_var,  
  :docproperty_host_var)
```

XSR_REMOVE

The XSR_REMOVE procedure is used to remove all components of an XML schema. After the XML schema is removed, you can reuse the name of the removed XML schema when you register a new XML schema.

Authorization

The privileges held by the authorization ID of the statement must include the following:

- The following system authorities:
 - The system authority *EXECUTE on the service program associated with the procedure, and
 - The system authority *EXECUTE on the SYSPROC library.

The privileges held by the authorization ID of the statement must include at least one of the following:

- The following system authorities:
 - The system authority *OBJOPR and *OBJEXIST on the object associated with the XSR object, and
 - The system authority *EXECUTE on the library that contains the XSR object to be dropped, and
 - The DELETE privilege on the XSROBJECTS, XSROBJECTCOMPONENTS, XSROBJECTHIERARCHIES, and XSRANNOTATIONINFO catalog tables, and
 - The system authority *EXECUTE on library QSYS2.
- Database administrator authority

Syntax

► XSR_REMOVE (*rschema* , *name*) ►
 └── NULL ─┘

Description

The schema is SYSPROC.

rschema

An input parameter of type VARCHAR(128) that specifies the SQL schema for the XML schema. It must be a valid SQL identifier. The SQL schema is one part of the qualified name used to identify this XML schema in the XSR. (The other part of the name is supplied by the *name* parameter). This parameter can have the NULL value which indicates that *name* is implicitly qualified based on the rules specified in “Qualification of unqualified object names” on page 57.

If *rschema* is specified, it cannot be QSYS, QSYS2, SYSIBM, SYSPROC, or QTEMP.

name

An input parameter of type VARCHAR(128) that specifies the name of the XML schema. It must be a valid SQL identifier. The complete name for the XML schema that is to be removed is *rschema.name*. The XML schema name must already exist as a result of calling the XSR_REGISTER stored procedure. This parameter cannot have the NULL value.

Example

The following example calls the XSR_REMOVE stored procedure:

```
CALL SYSPROC.XSR_REMOVE(  
    'MyLib',  
    'MySchema')
```

Chapter 6. Queries

A *query* specifies a result table or an intermediate result table. A query is a component of certain SQL statements.

The three forms of a query are the *subselect*, the *fullselect*, and the *select-statement*. There is another SQL statement that can be used to retrieve at most a single row described under [“SELECT INTO” on page 1489](#).

Authorization

For any form of a query, the privileges held by the authorization ID of the statement must include at least one of the following:

- For each table or view identified in the statement,
 - The SELECT privilege on the table or view, and
 - The system authority *EXECUTE on the library containing the table or view
- Database administrator authority

If a query includes a user-defined function, the privileges held by the authorization ID of the statement must include at least one of the following:

- For each user-defined function identified in the statement:
 - The EXECUTE privilege on the function
- Database administrator authority

For information about the system authorities corresponding to SQL privileges, see [Corresponding System Authorities When Checking Privileges to a Table or View](#) or [Corresponding System Authorities When Checking Privileges to a Function or Procedure](#).

If the query references a table that contains active row or column access control and row permissions or column masks are defined for the table, the authorization ID of the statement does not need authority to reference objects that are specified in the definitions of those row permissions or column masks.

subselect

The *subselect* is a component of the *fullselect*.

A subselect specifies a result table derived from the tables or views identified in the FROM clause. The derivation can be described as a sequence of operations in which the result of each operation is input for the next. (This is only a way of describing the subselect. The method used to perform the derivation may be quite different from this description. If portions of the subselect do not actually need to be executed for the correct result to be obtained, they may or may not be executed.)

When a subselect directly or indirectly references a table for which row or column access control is enforced, the rules that are defined in the row permissions or column masks affect how the rows in the result table are derived. Typically those rules are based on the authorization ID of the process.

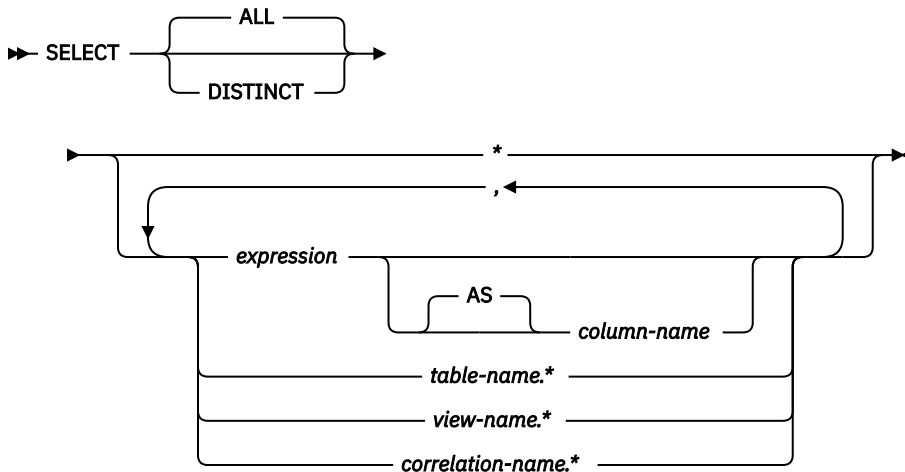

A *scalar-subselect* is a subselect, enclosed in parentheses, that returns a single result row and a single result column. If the result of the subselect is no rows, then the null value is returned. An error is returned if there is more than one row in the result.

The sequence of the (hypothetical) operations is:

1. FROM clause
2. hierarchical-query clause
3. WHERE clause
4. GROUP BY clause
5. HAVING clause
6. SELECT clause
7. ORDER BY clause
8. OFFSET clause
9. FETCH clause

select-clause

The SELECT clause specifies the columns of the final result table.

The column values are produced by the application of the *select list* to R. The select list is the names or expressions specified in the SELECT clause, and R is the result of the previous operation of the subselect. For example, if the only clauses specified are SELECT, FROM, and WHERE, R is the result of that WHERE clause.

ALL

Selects all rows of the final result table and does not eliminate duplicates. This is the default.

DISTINCT

Eliminates all but one of each set of duplicate rows of the final result table. Two rows are duplicates of one another only if each value in the first row is equal to the corresponding value in the second row. (For determining duplicate rows, two null values are considered equal.) The collating sequence is also used for determining distinct values.

DISTINCT is not allowed if the *select-list* contains a DATALINK or XML column, or an expression that returns a value that is the XML data type.

Column access controls do not affect the operation of SELECT DISTINCT. The elimination of duplicated rows is based on the original column values, not the masked values. However, after the application of column masks, the masked values in the final result table might not reflect the uniqueness that is enforced by SELECT DISTINCT.

If a column mask is applied to a column that directly or indirectly derives the result of SELECT DISTINCT, SELECT DISTINCT can return a result that is not deterministic. The following conditions are a few examples of when a result that is not deterministic might be returned:

- The definition of the column mask references other columns of the table to which the column mask is applied.
- The column is referenced in the argument of a built-in scalar function, such as COALESCE, IFNULL, NULLIF, MAX, MIN, LOCATE, etc.
- The column is referenced in the argument of an aggregate function.
- The column is embedded in an expression and the expression contains a function that is not deterministic or has an external action.

Select list notation

*

Represents a list of columns of table R in the order the columns are produced by the FROM clause. Any columns defined with the hidden attribute will not be included. The list of names is established

when the statement containing the SELECT clause is prepared. Therefore, * does not identify any columns that have been added to a table after the statement has been prepared.

* cannot be used in the definition of a row permission or a column mask.

expression

Specifies the values of a result column. Each *column-name* in the *expression* must unambiguously identify a column of R.

column-name or AS column-name

Names or renames the result column. The name must not be qualified and does not have to be unique.

name.*

Represents a list of columns of *name*. Any columns defined with the hidden attribute are not included. The *name* can be a table name, view name, or correlation name, and must designate an exposed table, view, or correlation name in the FROM clause immediately following the SELECT clause. The first name in the list identifies the first column of the table or view, the second name in the list identifies the second column of the table or view, and so on.

The list of names is established when the statement containing the SELECT clause is prepared. Therefore, * does not identify any columns that have been added to a table after the statement has been prepared.

*name.** cannot be used in the definition of a row permission or a column mask.

Normally, when SQL statements are implicitly rebound, the list of names is not reestablished. Therefore, the number of columns returned by the statement does not change. However, there are four cases where the list of names is established again and the number of columns can change:

- When an SQL program or SQL package is saved and then restored on a IBM i product that is not the same release as the system from which it was saved.
- When SQL naming is specified for an SQL program or package and the owner of the program has changed since the SQL program or package was created.
- When an SQL statement is executed for the first time after the install of a more recent release of the IBM i operating system.
- When the SELECT * occurs in the fullselect of an INSERT statement or in a fullselect within a predicate, and a table or view referenced in the fullselect has been deleted and recreated with additional columns.

The number of columns in the result of SELECT is the same as the number of expressions in the operational form of the select list (that is, the list established at prepare time), and cannot exceed 8000. The result of a subquery must be a single expression, unless the subquery is used in the EXISTS predicate.

Applying the select list

The results of applying the select list to R depend on whether GROUP BY or HAVING is used:

If GROUP BY or HAVING is used

- Each *column-name* in the select list must identify a grouping expression, or be specified within an aggregate function, or be a correlated reference:
 - If the grouping expression is a column name, the select list may apply additional operators to the column name. For example, if the grouping expression is column C1, the select list may contain C1+1.
 - If the grouping expression is not a column name, the select list may not apply additional operators to the expression. For example, if the grouping expression is C1+1, the select list may contain C1+1, but not (C1+1)/8.
- The select list is applied to each group of R, and the result contains as many rows as there are groups in R. When the select list is applied to a group of R, that group is the source of the arguments of the aggregate functions in the select list.

- The RRN, RID, DATAPARTITIONNAME, DATAPARTITIONNUM, DBPARTITIONNAME, DBPARTITIONNUM, and HASHED_VALUE functions cannot be specified in the select list.

If neither GROUP BY nor HAVING is used

- The select list must not include any aggregate functions, or each *column-name* must be specified in an aggregate function or be a correlated reference.
- If the select list does not include aggregate functions, it is applied to each row of R and the result contains as many rows as there are rows in R.
- If the select list is a list of aggregate functions, R is the source of the arguments of the functions and the result of applying the select list is one row.

In either case the *n*th column of the result contains the values specified by applying the *n*th expression in the operational form of the select list.

Effect of column masks on result columns: When column masks are enabled, they determine the values in the final result table of an outermost select list. When a column mask is enabled for a column, if the column appears in the outermost select list (either implicitly or explicitly), the column mask is applied to the column to produce the values for the final result table. If the column itself does not appear in the outermost select list, but is included in the output (for example, it appears in a materialized table expression or a view), the masked value is included in the result table of the table expression or view so that it can be used in the final result table.

The enabled column masks do not interfere with the operations of other clauses within the statement, such as the WHERE, GROUP BY, HAVING, SELECT DISTINCT, and ORDER BY clauses.

The rows that are returned in the final result table remain the same, except that the values in the result rows might be masked. As such, if a column with masked values also appears in an ORDER BY clause with a sort-key expression, the order is based on the original column values (the masked values in the final result table might not reflect that order). Similarly, the masked values might not reflect the uniqueness enforced by a SELECT DISTINCT. If the masked column is embedded in an expression, the result of the expression might be different because the column mask is applied to the column before the expression is evaluated. For example, a column mask on column SSN can change the result of the function COUNT(DISTINCT SSN) because the DISTINCT operation is performed on the masked values.

When the definition of a column mask is applied to an SQL statement to mask column values in the final result table, the semantics of the column mask might conflict with certain SQL semantics in the statement. In these situations, the combination of the statement and the column mask might return an error.

See [“ALTER TABLE” on page 869](#) for more information about the application of enabled column masks.

Null attributes of result columns

Result columns allow null values if they are derived from:

- Any aggregate function but COUNT and COUNT_BIG
- Any column that allows null values
- A scalar function or expression with an operand that allows null values
- A host variable that has an indicator variable, an SQL parameter or variable, or in the case of Java, a variable or expression whose type is able to represent a Java null value
- A result of a UNION or INTERSECT if at least one of the corresponding items in the select list is nullable
- An arithmetic expression in the outer select list
- A *scalar-fullselect*
- A user-defined scalar or table function
- A GROUPING SETS *grouping-expression*

Names of result columns

- If the AS clause is specified, the name of the result column is the name specified on the AS clause.
- If the AS clause is not specified and a column list is specified in the correlation clause, the name of the result column is the corresponding name in the correlation column list.
- If neither an AS clause nor a column list in the correlation clause is specified and the result column is derived only from a single column (without any functions or operators), then the result column name is the unqualified name of that column.
- If neither an AS clause nor a column list in the correlation clause is specified and the result column is derived only from a single variable (without any functions or operators), then the result column name is the unqualified name of that variable.
- If neither an AS clause nor a column list in the correlation clause is specified and the result column is derived only from a single pseudo column (without any functions or operators), then the result column name is the name of that pseudo column.
- All other result columns are unnamed.

Data types of result columns

Each column of the result of SELECT acquires a data type from the expression from which it is derived.

When the expression is:	The data type of the result column is:
the name of any numeric column	the same as the data type of the column, with the same precision and scale for decimal columns.
an integer constant	INTEGER or BIGINT (if the value of the constant is outside the range of INTEGER, but within the range of BIGINT).
a decimal or floating-point constant	the same as the data type of the constant, with the same precision and scale for decimal constants.
the name of a DECFLOAT(7) variable	DECFLOAT(16)
the name of any numeric variable	the same as the data type of the variable, with the same precision and scale for decimal variables. If the data type of the variable is not identical to an SQL data type (for example, DISPLAY SIGN LEADING SEPARATE in COBOL), the result column is decimal.
an expression	the same as the data type of the result, with the same precision and scale for decimal results as described under “Expressions” on page 158 .
any function	the data type of the result of the function. For a built-in function, see Chapter 4, “Built-in functions,” on page 243 to determine the data type of the result. For a user-defined function, the data type of the result is what was defined in the CREATE FUNCTION statement for the function.
the name of any string column	the same as the data type of the column, with the same length attribute.
the name of any string variable	the same as the data type of the variable, with a length attribute equal to the length of the variable. If the data type of the variable is not identical to an SQL data type (for example, a NUL-terminated string in C), the result column is a varying-length string.
a character-string constant of length <i>n</i>	VARCHAR(<i>n</i>)

When the expression is:	The data type of the result column is:
a graphic-string constant of length <i>n</i>	VARGRAPHIC(<i>n</i>)
the name of an XML column or variable	XML
the name of a datetime column, or an ILE RPG compiler or an ILE COBOL compiler datetime host variable	the same as the data type of the column or variable.
the name of a distinct type column	the same as the distinct type of the column, with the same length, precision, and scale attributes, if any.
the name of a datalink column	a datalink, with the same length attribute.
the name of a row ID column or a row ID variable	ROWID

from-clause

The FROM clause specifies an intermediate result table.

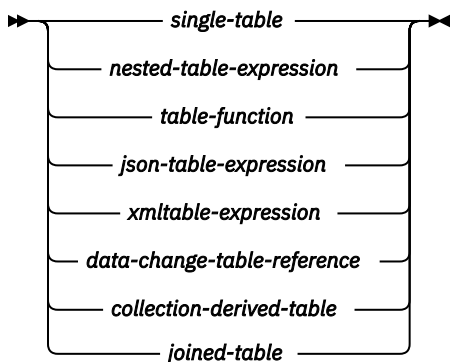

If only one *table-reference* is specified, the intermediate result table is simply the result of that *table-reference*. If more than one *table-reference* is specified in the FROM clause, the intermediate result table consists of all possible combinations of the rows of the specified *table-references* (the Cartesian product). Each row of the result is a row from the first *table-reference* concatenated with a row from the second *table-reference*, concatenated in turn with a row from the third, and so on. The number of rows in the result is the product of the number of rows in all the individual *table-references*.

If *table-reference* has row access controls enforced, *table-reference* has at least one row permission: the default row permission. When there are multiple row permissions defined for a *table-reference*, a row access control search condition is derived by applying the logical OR operator to the search condition in each enabled permission. This derived search condition acts as a filter to the *table-reference* to determine the result table of the *table-reference* that is accessible to the authorization ID of the subselect.

table-reference

A *table-reference* specifies an intermediate result table.

single-table

nested-table-expression

table-function

json-table-expression

xmltable-expression

data-change-table-reference

collection-derived-table

period-specification

correlation-clause

- If a single table or view is identified without a *period-specification*, the intermediate result table is simply that table or view. If a *period-specification* is specified for a *table-name* or *view-name*, the intermediate result table consists of the rows of the temporal table where the period matches the specification.
- A fullselect in parentheses called a *nested table expression*.⁸⁰ If a nested table expression is specified, the result table is the result of that nested table expression. The columns of the result do not need unique names, but a column with a non-unique name cannot be explicitly referenced.
- If a *function-name*, *json-table-expression*, or *xmltable-expression* is specified, the intermediate result table is the set of rows returned by the table function.
- If a *data-change-table-reference* is specified, the intermediate result table is the set of rows inserted by the INSERT statement.
- If a *collection-derived-table* is specified, the intermediate result table is a set of rows from one or more arrays.
- If a *joined-table* is specified, the intermediate result table is the result of one or more join operations. For more information, see “[joined-table](#)” on page 750.

If *table-reference* identifies a distributed table or a table that has a read trigger, the query cannot contain:

- EXCEPT or INTERSECT operations,
- VALUES in a fullselect,
- OLAP specifications,
- recursive common table expressions and CONNECT BY,
- ORDER OF,

⁸⁰ A *nested table expression* is also called a *derived table*.

- scalar fullselects (scalar subselects are supported),
- full outer join,
- LOBs in a GROUP BY,
- grouping sets or super groups,
- ORDER BY or FETCH clause in a subselect,
- OFFSET clause, or FETCH clause with a variable for N rows,
- CORRELATION, COVARIANCE, COVARIANCE_SAMP, LISTAGG, MEDIAN, PERCENTILE_CONT, PERCENTILE_DISC, or Regression aggregate functions,
- VERIFY_GROUP_FOR_USER, LOCATE_IN_STRING, LTRIM or RTRIM with 2 arguments, EXTRACT function with EPOCH,
- BSON_TO_JSON, JSON_ARRAY, JSON_ARRAYAGG, JSON_OBJECT, JSON_OBJECTAGG, JSON_QUERY, JSON_TABLE, JSON_TO_BSON, and JSON_VALUE functions, and the IS JSON and JSON_EXISTS predicates,
- XMLAGG, XMLATTRIBUTES, XMLCOMMENT, XMLCONCAT, XMLDOCUMENT, XMLELEMENT, XMLFOREST, XMLGROUP, XMLNAMESPACES, XMLPI, XMLROW, XMLTABLE, or XMLTEXT functions,
- CONTAINS or SCORE functions,
- default values for user defined functions,
- global variables, or
- references to arrays.

If the CURRENT TEMPORAL SYSTEM_TIME special register is set to a non-null value *CTST*, the value of the SYSTIME option is YES, and *table-name* or *view-name* identifies a system-period temporal table, the table reference is executed as if it contained the following specification with the special register set to the null value:

```
table-name FOR SYSTEM_TIME AS OF CTST
```

or

```
view-name FOR SYSTEM_TIME AS OF CTST
```

The list of names in the FROM clause must conform to these rules:

- Each *table-name* and *view-name* must name an existing table or view at the current server or the *table-identifier* of a common table expression defined preceding the subselect containing the *table-reference*.
- The exposed names must be unique. An exposed name is:
 - A *correlation-name*
 - A *table-name* or *view-name* that is not followed by a *correlation-name*
 - The *table-name* or *view-name* that is the target of the *data-change-table-reference* when the *data-change-table-reference* is not followed by a *correlation-name*

If a *correlation-clause* is not specified for a *nested-table-expression*, *table-function*, *json-table-expression*, *xmltable-expression*, *data-change-table-reference*, or *collection-derived-table*, there is no exposed name for that table reference.

- Each *function-name*, together with the types of its arguments, must resolve to a table function that exists at the current server. An algorithm called function resolution, which is described in [“Function resolution”](#) on page 149, uses the function name and the arguments to determine the exact function to use.
- Each *array-variable-name* must identify an array variable in the SQL routine.

Each *correlation-name* is defined as a designator of the intermediate result table specified by the immediately preceding *table-reference*.

Any qualified reference to a column must use the exposed name. If the same table name or view name is specified twice, at least one specification must be followed by a *correlation-name*. The *correlation-name* is used to qualify references to the columns of the table or view. When a *correlation-name* is specified, column-names can also be specified to give names to the columns of the *table-reference*. If a column list is specified, there must be a name in the column list for each column in the table or view and for each result column in the *nested-table-expression*, *table-function*, *json-table-expression*, *xmltable-expression*, *data-change-table-reference*, or *collection-derived-table*. For more information, see [“Correlation names” on page 131](#). If the *correlation-clause* does not include *column-names*, the exposed column names are determined as follows:

- Column names of the referenced table or view when the *table-reference* is a *table-name* or *view-name*.
- Column names specified in the RETURNS clause of the CREATE FUNCTION statement when the *table-reference* is a *function-name* reference.
- Column names specified in the COLUMNS clause of the *json-table-expression* or *xmltable-expression* when the *table-reference* is a *json-table-expression* or *xmltable-expression*.
- Column names returned by the fullselect when the *table-reference* is a *nested-table-expression*.
- Column names from the target table of the data change statement, along with any defined INCLUDE columns, when the *table-reference* is a *data-change-table-reference*.

In general, *nested-table-expressions*, *table-functions*, and *collection-derived-tables* can be specified in any FROM clause. Columns from the nested table expressions, table functions, and collection derived tables can be referenced in the select list and in the rest of the subselect using the correlation name. The scope of this correlation name is the same as correlation names for other table or view names in the FROM clause. A nested table expression can be used:

- in place of a view to avoid creating the view (when general use of the view is not required)
- when the desired result table is based on variables.

period-specification

Specifies that a period specification applies to the *table-reference*. A query with a *period-specification* is a temporal query. A *period-specification* cannot be specified for a table or view that has a column referenced in a CONTAINS or SCORE built-in function.

The rows of the table reference are derived by application of the period specification. The intermediate result table of a temporal query does not include rows in the associated history table that were added for the ON DELETE ADD EXTRA ROW attribute in the system-period temporal table definition.

The rows of a view reference are derived by application of the period specification to all of the temporal tables that are accessed when computing the result table of the view. If the view does not access any temporal tables, the period specification has no effect on the result table of the view. If a *period-specification* was specified for any of the table references within the view definition, a table reference of that view cannot include a *period-specification*. The definition of the view must not reference an external function with a data access indication other than NO SQL and must not reference an SQL function unless it is an inline function.

If the CURRENT TEMPORAL SYSTEM_TIME special register is set to a value other than the null value, a *period-specification* is not allowed unless the value of the SYSTIME option is NO.

FOR SYSTEM_TIME

Specifies that the SYSTEM_TIME period is used for the period-specification. The table reference must be a view or a system-period temporal table.

AS OF value

Specifies that the *table-reference* includes each row for which the begin value for the specified period is less than or equal to *value* and the end value for the period is greater than *value*. The *table-reference* contains zero rows if *value* is the null value.

value

Specifies an expression that returns a value of a built-in data type. The result of the expression must be comparable to `TIMESTAMP(12)` according to the comparison rules specified in [“Datetime comparisons”](#) on page 102.

The expression must not contain a column reference, a scalar fullselect, or a function that is non-deterministic, external action, or modifies SQL data.

FROM value1 TO value2

Specifies that the *table-reference* includes rows that exist for the period that is specified from *value1* up to *value2*. A row is included in the *table-reference* if the start value for the period in the row is less than *value2* and the end value for the period in the row is greater than *value1*. The *table-reference* contains zero rows if *value1* is greater than or equal to *value2* or if *value1* or *value2* is the null value.

value1 or value2

Specifies an expression that returns a value of a built-in data type. The result of the expression must be comparable to `TIMESTAMP(12)` according to the comparison rules specified in [“Datetime comparisons”](#) on page 102.

The expression must not contain a column reference, a scalar fullselect, or a function that is non-deterministic, external action, or modifies SQL data.

BETWEEN value1 AND value2

Specifies that the *table-reference* includes rows in which the specified period overlaps at any point in time between *value1* and *value2*. A row is included in the *table-reference* if the start value for the period in the row is less than or equal to *value2* and the end value for the period in the row is greater than *value1*. The *table-reference* contains zero rows if *value1* is greater than *value2* or if *value1* or *value2* is the null value. If *value1* = *value2*, the expression is equivalent to `AS OF value1`.

value1 or value2

Specifies an expression that returns a value of a built-in data type. The result of the expression must be comparable to `TIMESTAMP(12)` according to the comparison rules specified in [“Datetime comparisons”](#) on page 102.

The expression must not contain a column reference, a scalar fullselect, or a function that is non-deterministic, external action, or modifies SQL data.

Syntax alternatives:

- `AS OF TIMESTAMP` can be specified in place of `FOR SYSTEM_TIME AS OF`
- `VERSIONS BETWEEN TIMESTAMP` can be specified in place of `FOR SYSTEM_TIME BETWEEN`

json-table-function

Specifies an invocation of the built-in `JSON_TABLE` table function. See [“JSON_TABLE”](#) on page 694 for more information.

xmltable-function

Specifies an invocation of the built-in `XMLTABLE` table function. See [“XMLTABLE”](#) on page 714 for more information.

Data change table reference

A *data-change-table-reference* specifies an intermediate result table that is based on the rows that are directly changed by the `INSERT` statement included in the clause. A *data-change-table-reference* must be the only *table-reference* in the `FROM` clause of the outer fullselect that is used in a select-statement, a `SELECT INTO` statement, a `SET variable` statement, or as the only fullselect in an assignment statement.

The intermediate result table for a *data-change-table-reference* includes all rows that were inserted. All columns of the inserted table may be referenced in the subselect, along with any `INCLUDE` columns defined on the `INSERT` statement. A *data-change-table-reference* has the following restrictions:

- It can appear only in the outer level fullselect.

- The target table or view of the INSERT statement is considered a table or view referenced in the query. Therefore, the authorization ID of the query must be authorized to the table or view as well as having the necessary privileges required by the INSERT.
- A fullselect in the INSERT statement cannot contain correlated references to columns outside the fullselect of the INSERT statement.
- A *data-change-table-reference* in a select-statement makes the cursor READ ONLY. This means that UPDATE WHERE CURRENT OF and DELETE WHERE CURRENT OF cannot be used.
- If the INSERT references a view, the view must be defined using WITH CASCADED CHECK OPTION or could have been defined using WITH CHECK OPTION. In addition, the view cannot have a WHERE clause that contains:
 - a function that modifies SQL data
 - a function that is not deterministic or has external action
- A *data-change-table-reference* clause cannot be specified in a view definition or a materialized query table definition.
- If the target of the SQL data change statement is a view that is defined with an INSTEAD OF INSERT trigger, an error is returned.

If row access control is enforced for the target of the data change statement, the rows in the intermediate result table already satisfy the rules that are specified in the enabled row permissions. If column access control is enforced for the target of the data change statement, the enabled column masks are applied to the outermost select list. See [“select-clause” on page 737](#) for more information.

FINAL TABLE

Specifies that the rows of the intermediate result table represent the set of rows that are inserted by the SQL data change statement as they appear at the completion of the data change statement. If there are AFTER INSERT triggers or referential constraints that result in further changes to the inserted rows of the table that is the target of the data change statement, an error is returned.

NEW TABLE

Specifies that the rows of the intermediate result table represent the set of rows that are changed by the SQL data change statement prior to the application of referential constraints and AFTER triggers. Data in the target table at the completion of the statement might not match the data in the intermediate result table because of additional processing for referential constraints and AFTER triggers.

Collection derived table

A collection derived table can be used to unnest the elements of arrays into rows.

array-expression

An expression that returns an array data type. The expression must be one of the following expressions:

- An SQL variable
- An SQL parameter
- A CAST specification of a parameter marker

Names for the result columns produced by the UNNEST function can be provided as part of the correlation-clause of the collection-derived-table clause.

The result table depends on the input arguments.

- If a single array argument is specified, the result is a single column table with a column data type that matches the array element data type.
- If more than one array is specified, the first array provides the first column in the result table, the second array provides the second column, and so on. The data type of each column matches the data type of the array elements of the corresponding array argument. If WITH ORDINALITY is specified, an extra column of type BIGINT, which contains the position of the elements in the arrays, is appended.

If the cardinalities of the arrays are not identical, the cardinality of the result table is the same as the array with the largest cardinality. The column values in the table are set to the null value for all rows whose array index value is greater than the cardinality of the corresponding array. In other words, if each array is viewed as a table with two columns (one for the subindices and one for the data), then UNNEST performs an OUTER JOIN among the arrays using equality on the subindices as the join predicate.

UNNEST can only be specified within an SQL procedure or SQL function.

Correlated references in table-references

Correlated references can be used in *nested-table-expressions*. The basic rule that applies is that the correlated reference must be from a *table-reference* at a higher level in the hierarchy of subqueries. This hierarchy includes the *table-references* that have already been resolved in the left-to-right processing of the FROM clause. For nested table expressions, the TABLE or LATERAL keyword must appear before the fullselect. For more information see [“References to SQL parameters and SQL variables” on page 1581](#)

A table function can contain one or more correlated references to other tables in the same FROM clause if the referenced tables precede the reference in the left-to-right order of the tables in the FROM clause. The same capability exists for nested table expressions if the optional keyword TABLE or LATERAL is specified. Otherwise, only references to higher levels in the hierarchy of subqueries is allowed.

A nested table expression or table function that contains correlated references to other tables in the same FROM clause:

- Cannot participate in a RIGHT OUTER JOIN, FULL OUTER JOIN, or RIGHT EXCEPTION JOIN
- Can participate in LEFT OUTER JOIN or an INNER JOIN if the referenced tables precede the reference in the left-to-right order of the tables in the FROM clause

If *table-reference* identifies a distributed table or a table that has a read trigger; a nested table expression cannot contain a correlated reference to other tables in the same FROM clause when:

- The nested table expression contains a UNION, EXCEPT, or INTERSECT.
- The nested table expression uses the DISTINCT keyword in the select list.
- The nested table expression contains an ORDER BY and FETCH clause.
- The nested table expression is in the FROM clause of another nested table expression that contains one of these restrictions.

Syntax Alternatives: TABLE can be specified in place of LATERAL.

Example 1

The following example is valid:

```
SELECT D.DEPTNO, D.DEPTNAME, EMPINFO.AVGSAL, EMPINFO.EMPCOUNT
FROM DEPARTMENT D,
     (SELECT AVG(E.SALARY) AS AVGSAL, COUNT (*) AS EMPCOUNT
      FROM EMPLOYEE E
      WHERE E.WORKDEPT =
        (SELECT X.DEPTNO
         FROM DEPARTMENT X
         WHERE X.DEPTNO = E.WORKDEPT ) ) AS EMPINFO
```

The following example is not valid because the reference to D.DEPTNO in the WHERE clause of the *nested-table-expression* attempts to reference a table that is outside the hierarchy of subqueries:

```
SELECT D.DEPTNO, D.DEPTNAME,
       EMPINFO.AVGSAL, EMPINFO.EMPCOUNT
FROM DEPARTMENT D,
     (SELECT AVG(E.SALARY) AS AVGSAL, COUNT (*) AS EMPCOUNT
      FROM EMPLOYEE E
      WHERE E.WORKDEPT = D.DEPTNO ) AS EMPINFO
***INCORRECT***
```

The following example is valid because the reference to D.DEPTNO in the WHERE clause of the *nested-table-expression* references DEPT, which precedes the *nested-table-expression* and the LATERAL keyword was specified:

```
SELECT D.DEPTNO, D.DEPTNAME,
       EMPINFO.AVGSAL, EMPINFO.EMPCOUNT
FROM DEPARTMENT D,
     LATERAL (SELECT AVG(E.SALARY) AS AVGSAL, COUNT (*) AS EMPCOUNT
             FROM EMPLOYEE E
             WHERE E.WORKDEPT = D.DEPTNO ) AS EMPINFO
```

Example 2

The following example of a table function is valid:

```
SELECT t.c1, z.c5
FROM t, TABLE(tf3 (t.c2 ) ) AS z
WHERE t.c3 = z.c4
```

The following example is not valid because the reference to t.c2 is for a table that is to the right of the table function in the FROM clause:

```
SELECT t.c1, z.c5
FROM TABLE(tf6 (t.c2 ) ) AS z, t
WHERE t.c3 = z.c4
***INCORRECT***
```

Example 3

The following example of a table function is valid:

```
SELECT t.c1, z.c5
FROM t, TABLE(tf4 (2 * t.c2 ) ) AS z
WHERE t.c3 = z.c4
```

The following example is not valid because the reference to b.c2 is for the table function that is to the right of the table function containing the reference to b.c2 in the FROM clause:

```
SELECT a.c1, b.c5
FROM TABLE(tf7a (b.c2 ) ) AS z,
     TABLE(tf7b (a.c6 ) ) AS b
WHERE a.c3 = b.c4
***INCORRECT***
```

joined-table

A *joined-table* specifies an intermediate result table that is the result of either an inner, outer, cross, or exception join. The table is derived by applying one of the join operators: INNER, LEFT OUTER, RIGHT OUTER, FULL OUTER, LEFT EXCEPTION, RIGHT EXCEPTION, or CROSS to its operands.

If a join operator is not specified, INNER is implicit. The order in which multiple joins are performed can affect the result. Joins can be nested within other joins. The order of processing for joins is generally from left to right, but based on the position of the required *join-condition* or USING clause. Parentheses are recommended to make the order of nested joins more readable. For example:

```
TB1 LEFT JOIN TB2 ON TB1.C1=TB2.C1
LEFT JOIN TB3 LEFT JOIN TB4 ON TB3.C1=TB4.C1
ON TB1.C1=TB3.C1
```

is the same as

```
(TB1 LEFT JOIN TB2 ON TB1.C1=TB2.C1)
LEFT JOIN (TB3 LEFT JOIN TB4 ON TB3.C1=TB4.C1)
ON TB1.C1=TB3.C1
```

An inner join combines each row of the left table with every row of the right table keeping only the rows where the *join-condition* (or USING clause) is true. Thus, the result table may be missing rows from either or both of the joined tables. Outer joins include the rows produced by the inner join as well as the missing rows, depending on the type of outer join. Exception joins include only the missing rows, depending on the type of exception join.

- A left outer join includes the rows from the left table that were missing from the inner join.
- A right outer join includes the rows from the right table that were missing from the inner join.
- A full outer join includes the rows from both tables that were missing from the inner join.
- A left exception join includes only the rows from the left table that were missing from the inner join.
- A right exception join includes only the rows from the right table that were missing from the inner join.

A joined table can be used in any context in which any form of the SELECT statement is used. A view or a cursor is read-only if its SELECT statement includes a joined table.

Join condition

The *join-condition* is a *search-condition* that must conform to these rules:

- It cannot contain a quantified subquery, IN predicate with a subselect, or EXISTS subquery. It can contain basic predicate subqueries and scalar-fullselects.
- Any column referenced in an expression of the *join-condition* must be a column of one of the operand tables of the associated join (in the scope of the same joined-table clause).
- Each column name must unambiguously identify a column in one of the tables in the *from-clause*.

- Aggregate functions cannot be used in the *expression*.

For any type of join, column references in an expression of the *join-condition* are resolved using the rules for resolution of column name qualifiers specified in “[Column names](#)” on page 131 before any rules about which tables the columns must belong to are applied.

Join USING

The USING clause specifies a shorthand way of defining the join condition. This form is known as a *named-columns-join*.

column-name

Must unambiguously identify a column that exists in both *table-references* of the joined table. The column must not be a DATALINK column.

The result table of the join contains the columns from the USING clause first, then the columns from the first table of the join that were not in the USING clause, followed by the remaining columns from the second table of the join that were not in the USING clause. Any column specified in the USING clause cannot be qualified in the query.

The USING clause is equivalent to a *join-condition* in which each column from the left *table-reference* is compared equal to a column of the same name in the right *table-reference*. For example, assume that TB1 and TB2 have columns C1, C2, ... Cn, D1, D2 *named-columns-join* of the form:

```
TB1 INNER JOIN TB2
      USING (C1, C2, ... Cn)
```

defines a result table that is equivalent to:

```
SELECT TB1.*, TB2.D1, TB2.D2
FROM TB1 INNER JOIN TB2
      ON TB1.C1 = TB2.C1 AND
      TB1.C2 = TB2.C2 AND
      ...
      TB1.Cn = TB2.Cn
```

Join operations

A *join-condition* (or USING clause) specifies pairings of T1 and T2, where T1 and T2 are the left and right operand tables of the JOIN operator of the *join-condition* (or USING clause). For all possible combinations of rows of T1 and T2, a row of T1 is paired with a row of T2 if the *join-condition* (or USING clause) is true. When a row of T1 is joined with a row of T2, a row in the result consists of the values of that row of T1 concatenated with the values of that row of T2. In the case of OUTER joins, the execution might involve the generation of a null row. The null row of a table consists of a null value for each column of the table, regardless of whether the columns allow null values.

INNER JOIN or JOIN

The result of T1 INNER JOIN T2 consists of their paired rows.

Using the INNER JOIN syntax with a *join-condition* (or USING clause) will produce the same result as specifying the join by listing two tables in the FROM clause separated by commas and using the *where-clause* to provide the join condition.

LEFT JOIN or LEFT OUTER JOIN

The result of T1 LEFT OUTER JOIN T2 consists of their paired rows and, for each unpaired row of T1, the concatenation of that row with the null row of T2. All columns derived from T2 allow null values.

RIGHT JOIN or RIGHT OUTER JOIN

The result of T1 RIGHT OUTER JOIN T2 consists of their paired rows and, for each unpaired row of T2, the concatenation of that row with the null row of T1. All columns derived from T1 allow null values.

FULL JOIN or FULL OUTER JOIN

The result of T1 FULL OUTER JOIN T2 consists of their paired rows and, for each unpaired row of T2, the concatenation of that row with the null row of T1 and, for each unpaired row of T1, the

concatenation of that row with the null row of T2. All columns derived from T1 and T2 allow null values.

FULL OUTER JOIN is not allowed if the query specifies:

- a distributed table,
- a table with a read trigger, or
- a logical file built over multiple physical file members.

LEFT EXCEPTION JOIN and EXCEPTION JOIN

The result of T1 LEFT EXCEPTION JOIN T2 consists only of each unpaired row of T1, the concatenation of that row with the null row of T2. All columns derived from T2 allow null values.

RIGHT EXCEPTION JOIN

The result of T1 RIGHT EXCEPTION JOIN T2 consists only of each unpaired row of T2, the concatenation of that row with the null row of T1. All columns derived from T1 allow null values.

CROSS JOIN

The result of T1 CROSS JOIN T2 consists of each row of T1 paired with each row of T2. CROSS JOIN is also known as Cartesian product.

Hierarchical queries

Hierarchical queries are a form of recursive query that provides support for retrieving a hierarchy, such as a bill of materials, from relational data using a CONNECT BY clause.

Connect-by recursion uses the same subquery for the seed (start) and the recursive step (connect). This combination provides a concise method of representing recursions such as bills-of-material, reports-to-chains, or email threads.

Connect-by recursion returns an error if a cycle occurs. A cycle occurs when a row produces itself, either directly or indirectly. Using the optional CONNECT BY NOCYCLE clause, the recursion can be directed to ignore the duplicated row, thus avoiding both the cycle and the error.

subselect

Hierarchical query support includes the following extensions to the subselect.

- The subselect includes a *hierarchical-query-clause*
- The clauses of the subselect are processed in the following sequence:
 1. FROM clause
 2. *hierarchical-query-clause*
 3. WHERE clause
 4. GROUP BY clause
 5. HAVING clause
 6. SELECT clause
 7. ORDER BY clause
 8. OFFSET clause
 9. FETCH clause
- If the subselect includes a *hierarchical-query-clause*, special rules apply for the order of processing the predicates in the WHERE clause. The *search-condition* is factored into predicates along with its AND conditions (conjunction). If a predicate is an implicit join predicate (that is, it references more than one table in the FROM clause), the predicate is applied before the *hierarchical-query-clause*. Any predicate referencing at most one table in the FROM clause is applied to the intermediate result table of the *hierarchical-query-clause*.

A hierarchical query involving joins should be written using explicit joined tables with an ON clause to avoid confusion about the application of WHERE clause predicates.

- The ORDER SIBLINGS BY clause can be specified if the subselect includes a *hierarchical-query-clause*. This clause specifies that the ordering applies only to siblings within the hierarchies.

hierarchical-query-clause

A subselect that includes a *hierarchical-query-clause* is called a hierarchical query.

start-with-clause

▶▶ START WITH — *search-condition* ▶▶

connect-by-clause

▶▶ CONNECT BY — *search-condition* ▶▶
 └─ NOCYCLE ─┘

After establishing a first intermediate result table H_1 , subsequent intermediate result tables H_2 , H_3 , and so forth are generated by joining H_n with R using the *connect-by-clause* as a join condition to produce H_{n+1} . R is the result of the FROM clause of the subselect and any join predicates in the WHERE clause. The process stops when H_{n+1} has yielded an empty result table or when processing has reached the maximum supported depth level of 250. The result table H of the *hierarchical-query-clause* is the UNION ALL of every H_i .

start-with-clause

Specifies the intermediate result table H_1 for the hierarchical query that consists of those rows of R for which the *search-condition* is true. If the *start-with-clause* is not specified, H_1 is the entire intermediate result table R .

connect-by-clause

Produces the intermediate result table H_{n+1} from H_n by joining H_n with R , using the *search-condition*.

If the intermediate result table H_{n+1} would return a row from R for a hierarchical path that is the same as a row from R that is already in that hierarchical path, an error is returned.

NOCYCLE

Specifies that an error is not returned, but the repeated row is not included in the intermediate result table H_{n+1} .

The rules for the *search-condition* in the *start-with-clause* and the *connect-by-clause* are the same as for the *where-clause*.

The unary operator PRIOR is used to distinguish column references to H_n , the last prior recursive step, from column references to R . For example:

```
CONNECT BY MGRID = PRIOR EMPID
```

MGRID is resolved with R , and EMPID is resolved within the previous intermediate result table H_n .

A subselect that is a hierarchical query returns the intermediate result set in a partial order unless that order is destroyed through the use of an explicit ORDER BY clause, a GROUP BY or HAVING clause, or a DISTINCT keyword in the select list. The partial order returns rows, such that rows produced in H_{n+1} for a given hierarchy immediately follow the row in H_n that produced them. The ORDER SIBLINGS BY clause can be used to enforce order within a set of rows produced by the same parent.

A NEXT VALUE expression cannot be specified in:

- The parameter list of a CONNECT_BY_ROOT operator or a SYS_CONNECT_BY_PATH function
- The START WITH or CONNECT BY clauses

Examples

- The following reports-to-chain example illustrates connect-by recursion. The example is based on a table named MY_EMP, which is created and populated with data as follows:

```
CREATE TABLE MY_EMP(  
  EMPID  INTEGER NOT NULL PRIMARY KEY,  
  NAME   VARCHAR(10),  
  SALARY DECIMAL(9, 2),  
  MGRID  INTEGER);  
  
INSERT INTO MY_EMP VALUES ( 1, 'Jones',    30000, 10);  
INSERT INTO MY_EMP VALUES ( 2, 'Hall',     35000, 10);  
INSERT INTO MY_EMP VALUES ( 3, 'Kim',      40000, 10);  
INSERT INTO MY_EMP VALUES ( 4, 'Lindsay',  38000, 10);  
INSERT INTO MY_EMP VALUES ( 5, 'McKeough', 42000, 11);  
INSERT INTO MY_EMP VALUES ( 6, 'Barnes',   41000, 11);  
INSERT INTO MY_EMP VALUES ( 7, 'O'Neil',  36000, 12);  
INSERT INTO MY_EMP VALUES ( 8, 'Smith',    34000, 12);  
INSERT INTO MY_EMP VALUES ( 9, 'Shoeman',  33000, 12);  
INSERT INTO MY_EMP VALUES (10, 'Monroe',   50000, 15);  
INSERT INTO MY_EMP VALUES (11, 'Zander',   52000, 16);  
INSERT INTO MY_EMP VALUES (12, 'Henry',    51000, 16);  
INSERT INTO MY_EMP VALUES (13, 'Aaron',    54000, 15);  
INSERT INTO MY_EMP VALUES (14, 'Scott',    53000, 16);  
INSERT INTO MY_EMP VALUES (15, 'Mills',    70000, 17);  
INSERT INTO MY_EMP VALUES (16, 'Goyal',    80000, 17);  
INSERT INTO MY_EMP VALUES (17, 'Urbassek', 95000, NULL);
```

The following query returns all employees working for Goyal, as well as some additional information, such as the reports-to-chain:

```
1 SELECT NAME,  
2        LEVEL,  
3        SALARY,  
4        CONNECT_BY_ROOT NAME AS ROOT,  
5        SUBSTR(SYS_CONNECT_BY_PATH(NAME, ':'), 1, 25) AS CHAIN  
6 FROM MY_EMP  
7 START WITH NAME = 'Goyal'  
8 CONNECT BY PRIOR EMPID = MGRID  
9 ORDER SIBLINGS BY SALARY;
```

NAME	LEVEL	SALARY	ROOT	CHAIN
Goyal	1	80000.00	Goyal	:Goyal
Henry	2	51000.00	Goyal	:Goyal:Henry
Shoeman	3	33000.00	Goyal	:Goyal:Henry:Shoeman
Smith	3	34000.00	Goyal	:Goyal:Henry:Smith
O'Neil	3	36000.00	Goyal	:Goyal:Henry:O'Neil
Zander	2	52000.00	Goyal	:Goyal:Zander
Barnes	3	41000.00	Goyal	:Goyal:Zander:Barnes
McKeough	3	42000.00	Goyal	:Goyal:Zander:McKeough
Scott	2	53000.00	Goyal	:Goyal:Scott

Lines 7 and 8 comprise the core of the recursion. The optional START WITH clause describes the WHERE clause that is to be used on the source table to seed the recursion. In this case, only the row for employee Goyal is selected. If the START WITH clause is omitted, the entire source table is used to seed the recursion. The CONNECT BY clause describes how, given the existing rows, the next set of rows is to be found. The unary operator PRIOR is used to distinguish values in the previous step from those in the current step. PRIOR identifies EMPID as the employee ID of the previous recursive step, and MGRID as originating from the current recursive step.

LEVEL in line 2 is a pseudo column that describes the current level of recursion.

CONNECT_BY_ROOT is a unary operator that always returns the value of its argument as it was during the first recursive step; that is, the values that are returned by an explicit or implicit START WITH clause.

SYS_CONNECT_BY_PATH() is a binary function that prepends the second argument to the first and then appends the result to the value that it produced in the previous recursive step.

Unless explicitly overridden, connect-by recursion returns a result set in a partial order; that is, the rows that are produced by a recursive step always follow the row that produced them. Siblings at the same level of recursion have no specific order. The ORDER SIBLINGS BY clause in line 9 defines an order for these siblings, which further refines the partial order, potentially into a total order.

- Return the organizational structure of the DEPARTMENT table. Use the level of the department to visualize the hierarchy.

```

SELECT LEVEL, CAST(SPACE((LEVEL - 1) * 4) || '/' || DEPTNAME
AS VARCHAR(40)) AS DEPTNAME
FROM DEPARTMENT
START WITH DEPTNO = 'A00'
CONNECT BY NOCYCLE PRIOR DEPTNO = ADMRDEPT

```

The query returns:

LEVEL	DEPTNAME
1	/SPIFFY COMPUTER SERVICE DIV.
2	/PLANNING
2	/INFORMATION CENTER
2	/DEVELOPMENT CENTER
3	/MANUFACTURING SYSTEMS
3	/ADMINISTRATION SYSTEMS
2	/SUPPORT SERVICES
3	/OPERATIONS
3	/SOFTWARE SUPPORT
3	/BRANCH OFFICE F2
3	/BRANCH OFFICE G2
3	/BRANCH OFFICE H2
3	/BRANCH OFFICE I2
3	/BRANCH OFFICE J2

pseudo columns

A pseudo column is an identifier that shares the same namespace as columns and variables. After regular name resolution for a column has failed, Db2 attempts to match an unqualified identifier to a pseudo column name.

CONNECT_BY_ISCYCLE

CONNECT_BY_ISCYCLE is a pseudo column for use in hierarchical queries. The column returns the value 1 if the row is part of a cycle in the hierarchy; that is, the row has itself as a direct or indirect ancestor given the CONNECT BY clause's *search-condition*. If the row is not part of a cycle, the column returns the value 0.

The data type of the column is SMALLINT and it cannot be null.

CONNECT_BY_ISCYCLE must be specified in the context of a hierarchical query but cannot be specified in the START WITH clause or the CONNECT BY clause, as an argument of the CONNECT_BY_ROOT operator, or as an argument of the SYS_CONNECT_BY_PATH function.

CONNECT_BY_ISLEAF

CONNECT_BY_ISLEAF is a pseudo column for use in hierarchical queries. The column returns the value 1 if the row is a leaf in the hierarchy as defined by the CONNECT BY clause. If the row is not a leaf, the column returns the value 0.

The data type of the column is SMALLINT and it cannot be null.

CONNECT_BY_ISLEAF must be specified in the context of a hierarchical query but cannot be specified in the START WITH clause or the CONNECT BY clause, as an argument of the CONNECT_BY_ROOT operator, or as an argument of the SYS_CONNECT_BY_PATH function.

LEVEL

LEVEL is a pseudo column for use in hierarchical queries. The column returns the recursive step in the hierarchy at which the row was produced. All rows produced by the START WITH clause return the value 1. Rows produced by applying the first iteration of the CONNECT BY clause return 2, and so on.

The data type of the column is INTEGER and it cannot be null.

LEVEL must be specified in the context of a hierarchical query but cannot be specified in the START WITH clause, as an argument of the CONNECT_BY_ROOT operator, or as an argument of the SYS_CONNECT_BY_PATH function.

CONNECT_BY_ROOT

The CONNECT_BY_ROOT unary operator is for use only in hierarchical queries. For every row in the hierarchy, this operator returns the expression for the row's root ancestor.

►► CONNECT_BY_ROOT — *expression* ◄◄

expression

An expression that does not contain a NEXT VALUE expression, a hierarchical query construct (such as the LEVEL pseudocolumn), the SYS_CONNECT_BY_PATH function, or an OLAP specification.

The result data type and length of the operator is the same as the result data type and length of the expression.

A CONNECT_BY_ROOT operator cannot be specified in the START WITH clause or the CONNECT BY clause of a hierarchical query. It cannot be specified as an argument to the SYS_CONNECT_BY_PATH function.

A CONNECT_BY_ROOT operator has a higher precedence than any infix operator. Therefore, to pass an expression with infix operators (such as + or ||) as an argument, parentheses must be used. For example:

```
CONNECT_BY_ROOT FIRSTNME || LASTNAME
```

returns the FIRSTNME value of the root ancestor row concatenated with the LASTNAME value of the actual row in the hierarchy, because this expression is equivalent to:

```
(CONNECT_BY_ROOT FIRSTNME) || LASTNAME
```

rather than:

```
CONNECT_BY_ROOT (FIRSTNME || LASTNAME)
```

Example

- Return the hierarchy of departments and their root departments in the DEPARTMENT table.

```
SELECT CONNECT_BY_ROOT DEPTNAME AS ROOT, DEPTNAME
FROM DEPARTMENT
START WITH DEPTNO IN ('B01', 'C01', 'D01', 'E01')
CONNECT BY PRIOR DEPTNO = ADMRDEPT
```

This query returns:

ROOT	DEPTNAME
-----	-----
PLANNING	PLANNING
INFORMATION CENTER	INFORMATION CENTER
DEVELOPMENT CENTER	DEVELOPMENT CENTER
DEVELOPMENT CENTER	MANUFACTURING SYSTEMS
DEVELOPMENT CENTER	ADMINISTRATION SYSTEMS
SUPPORT SERVICES	SUPPORT SERVICES
SUPPORT SERVICES	OPERATIONS
SUPPORT SERVICES	SOFTWARE SUPPORT

SUPPORT SERVICES	BRANCH OFFICE G2
SUPPORT SERVICES	BRANCH OFFICE H2
SUPPORT SERVICES	BRANCH OFFICE I2
SUPPORT SERVICES	BRANCH OFFICE J2

PRIOR

The PRIOR unary operator is for use only in the CONNECT BY clause of hierarchical queries.

►► PRIOR — *expression* ◀◀

The CONNECT BY clause performs an inner join between the intermediate result table H_n of the hierarchical query and the source result table specified in the FROM clause. All column references to tables that are referenced in the FROM clause, and which are arguments to the PRIOR operator, are considered to be ranging over H_n .

The primary key of the intermediate result table H_n is typically joined to the foreign keys of the source result table to recursively traverse the hierarchy.

```
CONNECT BY PRIOR T.PK = T.FK
```

If the primary key is a composite key, care must be taken to prefix each column with PRIOR:

```
CONNECT BY PRIOR T.PK1 = T.FK1 AND PRIOR T.PK2 = T.FK2
```

expression

An expression that does not contain a NEXT VALUE expression, a hierarchical query construct (such as the LEVEL pseudocolumn), the SYS_CONNECT_BY_PATH function, or an OLAP specification.

The result data type and length of the operator is the same as the result data type and length of the expression.

A PRIOR operator has a higher precedence than any infix operator. Therefore, to pass an expression with infix operators (such as + or ||) as an argument, parentheses must be used. For example:

```
PRIOR FIRSTNME || LASTNAME
```

returns the FIRSTNME value of the prior row concatenated with the LASTNAME value of the actual row in the hierarchy, because this expression is equivalent to:

```
(PRIOR FIRSTNME) || LASTNAME
```

rather than:

```
PRIOR (FIRSTNME || LASTNAME)
```

Example

- Return the hierarchy of departments in the DEPARTMENT table.

```
SELECT LEVEL, DEPTNAME
FROM DEPARTMENT
START WITH DEPTNO = 'A00'
CONNECT BY NOCYCLE PRIOR DEPTNO = ADMRDEPT
```

This query returns:

LEVEL	DEPTNAME
1	SPIFFY COMPUTER SERVICE DIV.
2	PLANNING
2	INFORMATION CENTER
2	DEVELOPMENT CENTER
3	MANUFACTURING SYSTEMS
3	ADMINISTRATION SYSTEMS
2	SUPPORT SERVICES
3	OPERATIONS
3	SOFTWARE SUPPORT
3	BRANCH OFFICE F2
3	BRANCH OFFICE G2
3	BRANCH OFFICE H2

3 BRANCH OFFICE I2
3 BRANCH OFFICE J2

SYS_CONNECT_BY_PATH

The SYS_CONNECT_BY_PATH function is used in hierarchical queries to build a string representing a path from the root row to this row.

► SYS_CONNECT_BY_PATH — (— *string-expression1* — , — *string-expression2* —) ◀

The string for a given row at LEVEL *n* is built as follows:

- Step 1 (using the values of the root row from the first intermediate result table H₁):

```
path1 := string-expression2 || string-expression1
```

- Step *n* (based on the row from the intermediate result table H_{*n*}):

```
pathn := pathn-1 || string-expression2 || string-expression1
```

string-expression1

A character string expression that identifies the row. It must be a built-in character string data type. The expression must not include a NEXT VALUE expression for a sequence, any hierarchical query construct such as the LEVEL pseudocolumn or the CONNECT_BY_ROOT operator, an OLAP specification, or an aggregate function.

string-expression2

A character string expression that serves as a separator. It must be a built-in character string data type. The expression must not include a NEXT VALUE expression for a sequence, any hierarchical query construct such as the LEVEL pseudocolumn or the CONNECT_BY_ROOT operator, an OLAP specification, or an aggregate function.

The result is a CLOB(1M).

The SYS_CONNECT_BY_PATH function must not be used outside of the context of a hierarchical query. It cannot be used in a START WITH clause or a CONNECT BY clause.

Example

- Return the hierarchy of departments in the DEPARTMENT table.

```
SELECT CAST(SYS_CONNECT_BY_PATH(DEPTNAME, '/')
           AS VARCHAR(76)) AS ORG
FROM DEPARTMENT
START WITH DEPTNO = 'A00'
CONNECT BY NOCYCLE PRIOR DEPTNO = ADMRDEPT
```

This query returns:

```
ORG
-----
/SPIFFY COMPUTER SERVICE DIV.
/SPIFFY COMPUTER SERVICE DIV./PLANNING
/SPIFFY COMPUTER SERVICE DIV./INFORMATION CENTER
/SPIFFY COMPUTER SERVICE DIV./DEVELOPMENT CENTER
/SPIFFY COMPUTER SERVICE DIV./DEVELOPMENT CENTER/MANUFACTURING SYSTEMS
/SPIFFY COMPUTER SERVICE DIV./DEVELOPMENT CENTER/ADMINISTRATION SYSTEMS
/SPIFFY COMPUTER SERVICE DIV./SUPPORT SERVICES
/SPIFFY COMPUTER SERVICE DIV./SUPPORT SERVICES/OPERATIONS
/SPIFFY COMPUTER SERVICE DIV./SUPPORT SERVICES/SOFTWARE SUPPORT
/SPIFFY COMPUTER SERVICE DIV./SUPPORT SERVICES/BRANCH OFFICE F2
/SPIFFY COMPUTER SERVICE DIV./SUPPORT SERVICES/BRANCH OFFICE G2
/SPIFFY COMPUTER SERVICE DIV./SUPPORT SERVICES/BRANCH OFFICE H2
/SPIFFY COMPUTER SERVICE DIV./SUPPORT SERVICES/BRANCH OFFICE I2
/SPIFFY COMPUTER SERVICE DIV./SUPPORT SERVICES/BRANCH OFFICE J2
```

where-clause

The WHERE clause specifies an intermediate result table that consists of those rows of R for which the *search-condition* is true. R is the result of the FROM clause of the statement.

►► WHERE — *search-condition* ◄◄

The *search-condition* must conform to the following rules:

- Each *column-name* must unambiguously identify a column of R or be a correlated reference. A *column-name* is a correlated reference if it identifies a column of a table, view, *common-table-expression*, or *nested-table-expression* identified in an outer fullselect.
- An aggregate function must not be specified unless the WHERE clause is specified in a subquery of a HAVING clause and the argument of the function is a correlated reference to a group.

Any subquery in the *search-condition* is effectively executed for each row of R and the results are used in the application of the *search-condition* to the given row of R. A subquery is executed for each row of R if it includes a correlated reference to a column of R. A subquery with no correlated reference is typically executed just once.

If row access controls are enabled for a table and no other row permission is defined, the row access control search condition is the default row permission, $1 = 0$. If only one row permission is defined, the row access control search condition is the search conditions that are specified by that permission. Otherwise, if multiple row permissions are defined for a table, the row access control search condition is derived by application of the logical OR operator to the search conditions that are specified by each row permission. This row access control search condition, as a whole, is connected by application of the logical AND operator to the search conditions specified by the WHERE clause and has the same precedence level as other search conditions in the WHERE clause. This process is repeated for each *table-reference* in the FROM clause of the subselect for which row access controls are enabled.

The row access control search condition acts as a filter to the *table-reference* to determine the results of the *table-reference* that are accessible to the authorization ID of the subselect. Because the order in which operators are evaluated is undefined for operators at the same precedence level, other search conditions in the WHERE clause might be evaluated before the row access control search condition. So, the other search conditions have access to the rows that are restricted by the row permission rules. To ensure that sensitive data is protected, the predicates that reference user-defined functions that are defined with the NOT SECURED option are always evaluated after the row access control search condition.

Column access control does not affect the operation of the WHERE clause.

If a collating sequence other than *HEX is in effect when the statement that contains the WHERE clause is executed and if the *search-condition* contains operands that are SBCS data, mixed data, or Unicode data, then the comparison for those predicates is done using weighted values. The weighted values are derived by applying the collating sequence to the operands of the predicate.

group-by-clause

The GROUP BY clause specifies an intermediate result table that consists of a grouping of the rows of R. R is the result of the previous clause of the subselect.

In its simplest form, a GROUP BY clause contains a *grouping-expression*. A *grouping-expression* is an expression that defines the grouping of R. The following restrictions apply to *grouping-expression*.

- Each column name included in *grouping-expression* must unambiguously identify a column of R.
- The result of *grouping-expression* cannot be a DataLink or XML data type or a distinct type that is based on a DataLink or XML.
- *grouping-expression* cannot include any of the following items:
 - A correlated column
 - A variable
 - An aggregate function
 - Any function that is non-deterministic

More complex forms of the GROUP BY clause include *grouping-sets* and *super-groups*. For a description of these forms, see [“grouping-sets” on page 764](#) and [“super-groups” on page 764](#), respectively.

The result of the GROUP BY clause is a set of groups of rows. In each group of more than one row, all values of each *grouping-expression* are equal, and all rows with the same set of values of the *grouping-expressions* are in the same group. For grouping, all null values for a *grouping-expression* are considered equal.

Because every row of a group contains the same value of any *grouping-expression*, *grouping-expressions* can be used in a search condition in a HAVING clause, in the SELECT clause, or in a *sort-key-expression* of an ORDER BY clause (see [“order-by-clause” on page 777](#) for details). In each case, the reference specifies only one value for each group. The *grouping-expression* specified in these clauses must exactly match the *grouping-expression* in the GROUP BY clause, except that blanks are not significant. For example, a *grouping-expression* of

```
SALARY*.10
```

will match the expression in a *having-clause* of

```
HAVING SALARY*.10
```

but will not match

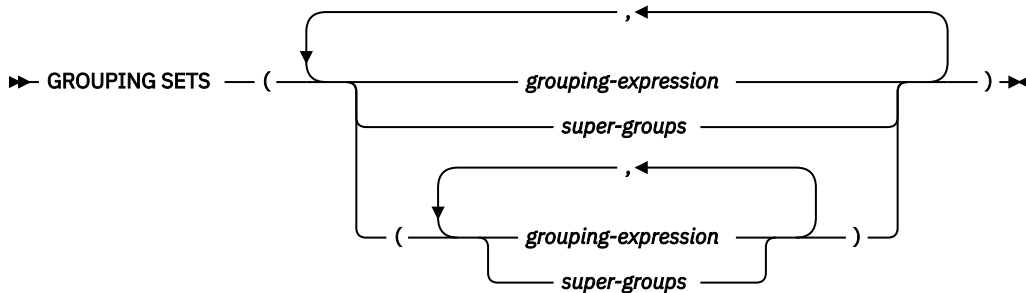

```
HAVING .10 *SALARY  
OR  
HAVING (SALARY*.10)+100
```

If the *grouping-expression* contains varying-length strings with trailing blanks, the values in the group can differ in the number of trailing blanks and may not all have the same length. In that case, a reference to the *grouping-expression* still specifies only one value for each group, but the value for a group is chosen arbitrarily from the available set of values. Thus, the actual length of the result value is unpredictable.

Column access controls do not affect the operation of the GROUP BY clause. The grouping is performed using the original column values.

If a collating sequence other than *HEX is in effect when the statement that contains the GROUP BY clause is executed, and the *grouping-expressions* are SBCS data, mixed data, or Unicode data, then the rows are placed into groups using the weighted values. The weighted values are derived by applying the collating sequence to the *grouping-expressions*. In that case, a reference to the *grouping-expression* still specifies only one value for each group, but the value for a group is chosen arbitrarily from the available set of values. Thus, the actual value of the result is unpredictable.

grouping-sets

A *grouping-sets* specification allows multiple grouping clauses to be specified in a single statement. This can be thought of as the union of two or more groups of rows into a single result set. It is logically equivalent to the union of multiple subselects with the group by clause in each subselect corresponding to one grouping set. A grouping set can be a single element or can be a list of elements delimited by parentheses, where an element is either a *grouping-expression* or a *super-group*. Using grouping sets allows the groups to be computed with a single pass over the base table.

The *grouping-sets* specification allows either a simple *grouping-expression* to be used, or the more complex forms of *super-groups*. For a description of *super-groups*, see [“super-groups”](#) on page 764.

Note that grouping sets are the fundamental building blocks for GROUP BY operations. A simple GROUP BY with a single column can be considered a grouping set with one element. For example:

```
GROUP BY a
```

is the same as

```
GROUP BY GROUPING SETS( (a) )
```

and

```
GROUP BY a, b, c
```

is the same as

```
GROUP BY GROUPING SETS( (a,b,c) )
```

Non-aggregation columns from the select list of the subselect that are excluded from a grouping set will return a null for such columns for each row generated for that grouping set. This reflects the fact that aggregation was done without considering the values for those columns.

If a *table-reference* in the previous clauses of the query identifies a distributed table or a table that has a read trigger; a *grouping-sets* specification is not allowed.

Example C2 through Example C7 illustrate the use of grouping sets.

super-groups

Notes:

¹ Alternate specification when used alone in *group-by-clause* is: *grouping-expression-list* WITH ROLLUP.

² Alternate specification when used alone in *group-by-clause* is: *grouping-expression-list* WITH CUBE.

grouping-expression-list

grand-total

► (—) ◄

ROLLUP (grouping-expression-list)

A *ROLLUP grouping* is an extension to the GROUP BY clause that produces a result set containing *sub-total* rows in addition to the "regular" grouped rows. *Sub-total* rows are "super-aggregate" rows that contain further aggregates whose values are derived by applying the same aggregate functions that were used to obtain the grouped rows. These rows are called sub-total rows because that is their most common use; however, any aggregate function can be used for the aggregation. For instance, MAX and AVG are used in example C8.

A ROLLUP grouping is a series of *grouping-sets*. The general specification of a ROLLUP with *n* elements

```
GROUP BY ROLLUP ( C1, C2, . . . , Cn-1, Cn )
```

is equivalent to

```
GROUP BY GROUPING SETS ( (C1, C2, . . . , Cn-1, Cn),
                          (C1, C2, . . . , Cn-1),
                          . . .
                          (C1, C2),
                          (C1),
                          ( ) )
```

Note that the *n* elements of the ROLLUP translate to *n+1* grouping sets. Note also that the order in which the *grouping-expressions* are specified is significant for ROLLUP. For example:

```
GROUP BY ROLLUP ( a, b )
```

is equivalent to

```
GROUP BY GROUPING SETS ( ( a, b ),
                          ( a ),
                          ( ) )
```

while

```
GROUP BY ROLLUP ( b, a )
```

is equivalent to

```
GROUP BY GROUPING SETS ( (b,a),
                          (b),
                          () )
```

The ORDER BY clause is the only way to guarantee the order of the rows in the result set. Example C3 illustrates the use of ROLLUP.

CUBE (*grouping-expression-list*)

A *CUBE grouping* is an extension to the GROUP BY clause that produces a result set that contains all the rows of a ROLLUP aggregation and, in addition, contains "cross-tabulation" rows. *Cross-tabulation* rows are additional "super-aggregate" rows that are not part of an aggregation with sub-totals. Only 10 expressions are allowed in the *grouping-expression-list*.

Like a ROLLUP, a CUBE grouping can also be thought of as a series of *grouping-sets*. In the case of a CUBE, all permutations of the cubed *grouping-expression-list* are computed along with the grand total. Therefore, the n elements of a CUBE translate to $2^{**} n$ (2 to the power n) grouping-sets. For instance, a specification of

```
GROUP BY CUBE (a,b,c)
```

is equivalent to

```
GROUP BY GROUPING SETS ( (a,b,c),
                          (a,b),
                          (a,c),
                          (b,c),
                          (a),
                          (b),
                          (c),
                          () )
```

Notice that the 3 elements of the CUBE translate to 8 grouping sets.

The order of specification of elements does not matter for CUBE. 'CUBE(DayOfYear, Sales_Person)' and 'CUBE(Sales_Person, DayOfYear) yield the same result sets. The use of the word 'same' applies to content of the result set, not to its order. The ORDER BY clause is the only way to guarantee the order of the rows in the result set. Example C4 illustrates the use of CUBE.

grouping-expression-list

A *grouping-expression-list* is used within a CUBE or ROLLUP grouping to define the number of elements in the CUBE or ROLLUP operation. This is controlled by using parentheses to delimit elements with multiple *grouping-expressions*.

The rules for a *grouping-expression* are described in "group-by-clause" on page 763. For example, suppose that a query is to return the total expenses for the ROLLUP of City within a Province but not within a County. However, the clause

```
GROUP BY ROLLUP (Province, County, City)
```

results in unwanted sub-total rows for the County. In the clause

```
GROUP BY ROLLUP (Province, (County, City))
```

the composite (County, City) forms one element in the ROLLUP and, therefore, a query that uses this clause will yield the wanted result. In other words, the two element ROLLUP

```
GROUP BY ROLLUP (Province, (County, City))
```

generates

```
GROUP BY GROUPING SETS ( (Province, County, City),
                          (Province),
                          () )
```

while the three element ROLLUP generates

```
GROUP BY GROUPING SETS ( (Province, County, City),
                          (Province, County),
```

```
(Province),  
( )
```

Example C2 also uses composite column values.

grand-total

Both CUBE and ROLLUP return a row which is the overall (grand total) aggregation. This may be separately specified with empty parentheses within the GROUPING SETS clause. It may also be specified directly in the GROUP BY clause, although there is no effect on the result of the query. Example C4 uses the grand-total syntax.

Combining grouping sets

This can be used to combine any of the types of GROUP BY clauses. When simple *grouping-expressions* are combined with other groups, they are "appended" to the beginning of the resulting *grouping sets*. When ROLLUP and CUBE expressions are combined, they operate like "multipliers" on the remaining expression, forming additional grouping set entries according to the definition of either ROLLUP or CUBE.

For instance, combining *grouping-expression* elements acts as follows

```
GROUP BY a, ROLLUP (b,c)
```

is equivalent to

```
GROUP BY GROUPING SETS( (a,b,c),  
                          (a,b),  
                          (a) )
```

Or similarly

```
GROUP BY a,b, ROLLUP (c,d)
```

is equivalent to

```
GROUP BY GROUPING SETS( (a,b,c,d),  
                          (a,b,c),  
                          (a,b) )
```

Combining of ROLLUP elements acts as follows:

```
GROUP BY ROLLUP(a), ROLLUP (b,c)
```

is equivalent to

```
GROUP BY GROUPING SETS( (a,b,c),  
                          (a,b),  
                          (a),  
                          (b,c),  
                          (b),  
                          ( ) )
```

Similarly,

```
GROUP BY ROLLUP(a), CUBE (b,c)
```

is equivalent to

```
GROUP BY GROUPING SETS( (a,b,c),  
                          (a,b),  
                          (a,c),  
                          (a),  
                          (b,c),  
                          (b),  
                          (c),  
                          ( ) )
```

Combining of CUBE and ROLLUP elements acts as follows:

```
GROUP BY CUBE(a,b), ROLLUP (c,d)
```

is equivalent to

```
GROUP BY GROUPING SETS( (a,b,c,d),
                          (a,b,c),
                          (a,b),
                          (a,c,d),
                          (a,c),
                          (a),
                          (b,c,d),
                          (b,c),
                          (b),
                          (c,d),
                          (c),
                          () )
```

Like a simple *grouping-expression*, combining grouping sets also eliminates duplicates within each grouping set. For instance,

```
GROUP BY a, ROLLUP (a,b)
```

is equivalent to

```
GROUP BY GROUPING SETS( (a,b),
                          (a) )
```

A more complete example of combining grouping sets is to construct a result set that eliminates certain rows that would be returned for a full CUBE aggregation.

For example, consider the following GROUP BY clause:

```
GROUP BY Region,
        ROLLUP (Sales_Person, WEEK(Sales_Date)),
        CUBE (YEAR(Sales_Date), MONTH(Sales_Date))
```

The column listed immediately to the right of GROUP BY is grouped, those within the parentheses following ROLLUP are rolled up, and those within the parentheses following CUBE are cubed. Thus, the above clause results in a cube of MONTH within YEAR which is then rolled up within WEEK within Sales_Person within the Region aggregation. It does not result in any grand total row or any cross-tabulation rows on Region, Sales_Person, or WEEK(Sales_Date) so produces fewer rows than the clause:

```
GROUP BY ROLLUP (Region, Sales_Person, WEEK(Sales_Date),
                YEAR(Sales_Date), MONTH(Sales_Date))
```

Examples of grouping sets, cube, and rollup

The queries in Example C1 through C4 use a subset of the rows in the SALES table based on the predicate 'WEEK(SALES_DATE) = 13'.

```
SELECT WEEK(SALES_DATE) AS WEEK,
        DAYOFWEEK(SALES_DATE) AS DAY_WEEK,
        SALES_PERSON,
        SALES AS UNITS_SOLD
FROM SALES
WHERE WEEK(SALES_DATE) = 13
```

which results in:

WEEK	DAY_WEEK	SALES_PERSON	UNITS_SOLD
13	6	LUCCHESSI	3
13	6	LUCCHESSI	1
13	6	LEE	2
13	6	LEE	2
13	6	LEE	3

13	6 LEE	5
13	6 GOUNOT	3
13	6 GOUNOT	1
13	6 GOUNOT	7
13	7 LUCCHESSI	1
13	7 LUCCHESSI	2
13	7 LUCCHESSI	1
13	7 LEE	7
13	7 LEE	3
13	7 LEE	7
13	7 LEE	4
13	7 GOUNOT	2
13	7 GOUNOT	18
13	7 GOUNOT	1

Example C1:

Here is a query with a basic GROUP BY over 3 columns:

```
SELECT WEEK(SALES_DATE) AS WEEK,
       DAYOFWEEK(SALES_DATE) AS DAY_WEEK,
       SALES_PERSON,
       SUM(SALES) AS UNITS_SOLD
FROM SALES
WHERE WEEK(SALES_DATE) = 13
GROUP BY WEEK(SALES_DATE), DAYOFWEEK(SALES_DATE), SALES_PERSON
ORDER BY WEEK, DAY_WEEK, SALES_PERSON
```

This results in:

WEEK	DAY_WEEK	SALES_PERSON	UNITS_SOLD
13	6	GOUNOT	11
13	6	LEE	12
13	6	LUCCHESSI	4
13	7	GOUNOT	21
13	7	LEE	21
13	7	LUCCHESSI	4

Example C2:

Produce the result based on two different grouping sets of rows from the SALES table.

```
SELECT WEEK(SALES_DATE) AS WEEK,
       DAYOFWEEK(SALES_DATE) AS DAY_WEEK,
       SALES_PERSON,
       SUM(SALES) AS UNITS_SOLD
FROM SALES
WHERE WEEK(SALES_DATE) = 13
GROUP BY GROUPING SETS( (WEEK(SALES_DATE), SALES_PERSON),
                        (DAYOFWEEK(SALES_DATE), SALES_PERSON) )
ORDER BY WEEK, DAY_WEEK, SALES_PERSON
```

This results in:

WEEK	DAY_WEEK	SALES_PERSON	UNITS_SOLD
13	-	GOUNOT	32
13	-	LEE	33
13	-	LUCCHESSI	8
-	6	GOUNOT	11
-	6	LEE	12
-	6	LUCCHESSI	4
-	7	GOUNOT	21
-	7	LEE	21
-	7	LUCCHESSI	4

The rows with WEEK 13 are from the first grouping set and the other rows are from the second grouping set.

Example C3:

If you use 3 distinct columns involved in the grouping sets of Example C2 and perform a ROLLUP, you can see grouping sets for (WEEK, DAY_WEEK, SALES_PERSON), (WEEK, DAY_WEEK), (WEEK), and grand total.

```
SELECT WEEK(SALES_DATE) AS WEEK,  
       DAYOFWEEK(SALES_DATE) AS DAY_WEEK,  
       SALES_PERSON,  
       SUM(SALES) AS UNITS_SOLD  
FROM SALES  
WHERE WEEK(SALES_DATE) = 13  
GROUP BY ROLLUP( WEEK(SALES_DATE), DAYOFWEEK(SALES_DATE), SALES_PERSON )  
ORDER BY WEEK, DAY_WEEK, SALES_PERSON
```

This results in:

WEEK	DAY_WEEK	SALES_PERSON	UNITS_SOLD
13	6	GOUNOT	11
13	6	LEE	12
13	6	LUCCHESSI	4
13	6	-	27
13	7	GOUNOT	21
13	7	LEE	21
13	7	LUCCHESSI	4
13	7	-	46
13	-	-	73
-	-	-	73

Example C4:

If you run the same query as Example C3 only replace ROLLUP with CUBE, you can see additional grouping sets for (WEEK, SALES_PERSON), (DAY_WEEK, SALES_PERSON), (DAY_WEEK), and (SALES_PERSON) in the result.

```
SELECT WEEK(SALES_DATE) AS WEEK,  
       DAYOFWEEK(SALES_DATE) AS DAY_WEEK,  
       SALES_PERSON,  
       SUM(SALES) AS UNITS_SOLD  
FROM SALES  
WHERE WEEK(SALES_DATE) = 13  
GROUP BY CUBE( WEEK(SALES_DATE), DAYOFWEEK(SALES_DATE), SALES_PERSON )  
ORDER BY WEEK, DAY_WEEK, SALES_PERSON
```

This results in:

WEEK	DAY_WEEK	SALES_PERSON	UNITS_SOLD
13	6	GOUNOT	11
13	6	LEE	12
13	6	LUCCHESSI	4
13	6	-	27
13	7	GOUNOT	21
13	7	LEE	21
13	7	LUCCHESSI	4
13	7	-	46
13	-	GOUNOT	32
13	-	LEE	33
13	-	LUCCHESSI	8
13	-	-	73
-	6	GOUNOT	11
-	6	LEE	12
-	6	LUCCHESSI	4
-	6	-	27
-	7	GOUNOT	21
-	7	LEE	21
-	7	LUCCHESSI	4
-	7	-	46
-	-	GOUNOT	32
-	-	LEE	33
-	-	LUCCHESSI	8
-	-	-	73

Example C5:

Obtain a result set which includes a grand total of selected rows from the SALES table together with a group of rows aggregated by SALES_PERSON and MONTH.

```
SELECT SALES_PERSON,  
       MONTH(SALES_DATE) AS MONTH,  
       SUM(SALES) AS UNITS_SOLD  
FROM SALES  
GROUP BY GROUPING SETS( (SALES_PERSON, MONTH(SALES_DATE)),  
                        ( ) )  
ORDER BY SALES_PERSON, MONTH
```

This results in:

SALES_PERSON	MONTH	UNITS_SOLD
GOUNOT	3	35
GOUNOT	4	14
GOUNOT	12	1
LEE	3	60
LEE	4	25
LEE	12	6
LUCCHESSI	3	9
LUCCHESSI	4	4
LUCCHESSI	12	1
-	-	155

Example C6:

This example shows two simple ROLLUP queries followed by a query which treats the two ROLLUPs as grouping sets in a single result set and specifies row ordering for each column involved in the grouping sets.

Example C6-1:

```
SELECT WEEK(SALES_DATE) AS WEEK,  
       DAYOFWEEK(SALES_DATE) AS DAY_WEEK,  
       SUM(SALES) AS UNITS_SOLD  
FROM SALES  
GROUP BY ROLLUP( WEEK(SALES_DATE), DAYOFWEEK(SALES_DATE) )  
ORDER BY WEEK, DAY_WEEK
```

This results in:

WEEK	DAY_WEEK	UNITS_SOLD
13	6	27
13	7	46
13	-	73
14	1	31
14	2	43
14	-	74
53	1	8
53	-	8
-	-	155

Example C6-2:

```
SELECT MONTH(SALES_DATE) AS MONTH,  
       REGION,  
       SUM(SALES) AS UNITS_SOLD  
FROM SALES  
GROUP BY ROLLUP( MONTH(SALES_DATE), REGION )  
ORDER BY MONTH, REGION
```

This results in:

MONTH	REGION	UNITS_SOLD
3	Manitoba	22

```

3 Ontario-North      8
3 Ontario-South     34
3 Quebec            40
3 -                 104
4 Manitoba          17
4 Ontario-North     1
4 Ontario-South     14
4 Quebec            11
4 -                 43
12 Manitoba         2
12 Ontario-South    4
12 Quebec           2
12 -                8
- -                155

```

Example C6-3:

```

SELECT WEEK(SALES_DATE) AS WEEK,
       DAYOFWEEK(SALES_DATE) AS DAY_WEEK,
       MONTH(SALES_DATE) AS MONTH,
       REGION,
       SUM(SALES) AS UNITS_SOLD
FROM SALES
GROUP BY GROUPING SETS(ROLLUP(WEEK(SALES_DATE), DAYOFWEEK(SALES_DATE) ),
                       ROLLUP( MONTH(SALES_DATE), REGION ) )
ORDER BY WEEK, DAY_WEEK, MONTH, REGION

```

This results in:

WEEK	DAY_WEEK	MONTH	REGION	UNITS_SOLD
13	6	-	-	27
13	7	-	-	46
13	-	-	-	73
14	1	-	-	31
14	2	-	-	43
14	-	-	-	74
53	1	-	-	8
53	-	-	-	8
-	-	3	Manitoba	22
-	-	3	Ontario-North	8
-	-	3	Ontario-South	34
-	-	3	Quebec	40
-	-	3	-	104
-	-	4	Manitoba	17
-	-	4	Ontario-North	1
-	-	4	Ontario-South	14
-	-	4	Quebec	11
-	-	4	-	43
-	-	12	Manitoba	2
-	-	12	Ontario-South	4
-	-	12	Quebec	2
-	-	12	-	8
-	-	-	-	155
-	-	-	-	155

Using the two ROLLUPs as grouping sets causes the result to include duplicate rows. There are even two grand total rows.

Observe how the use of ORDER BY has affected the results:

- In the first grouped set, week 53 has been repositioned to the end
- In the second grouped set, month 12 has now been positioned to the end and the regions now appear in alphabetic order.
- Null values are sorted high.

Example C7:

In queries that perform multiple ROLLUPs in a single pass (such as Example C6-3) you may want to be able to indicate which grouping set produced each row. The following steps demonstrate how to provide a column (called GROUP) which indicates the origin of each row in the result set. By origin means which one of the two grouping sets produced the row in the result set.

Step 1: Introduce a way of generating new data values using a query which selects from a VALUES clause (which is an alternate form of a fullselect). This query shows how a table called X can be derived that has 2 columns, R1 and R2, and one row of data.

```
SELECT R1, R2
FROM (VALUES ('GROUP 1', 'GROUP 2')) AS X(R1, R2)
```

Results in:

```
R1      R2
-----
GROUP 1 GROUP 2
```

Step 2: Form the cross product of this table X with the SALES table. This adds columns R1 and R2 to every row.

```
SELECT R1, R2,
       WEEK(SALES_DATE) AS WEEK,
       DAYOFWEEK(SALES_DATE) AS DAY_WEEK,
       MONTH(SALES_DATE) AS MONTH,
       REGION,
       SALES AS UNITS_SOLD
FROM SALES,
     (VALUES ('GROUP 1', 'GROUP 2')) AS X(R1, R2)
```

Step 3: Now these columns are combined with the grouping sets to include these columns in the rollup analysis.

```
SELECT R1, R2,
       WEEK(SALES_DATE) AS WEEK,
       DAYOFWEEK(SALES_DATE) AS DAY_WEEK,
       MONTH(SALES_DATE) AS MONTH,
       REGION,
       SUM(SALES) AS UNITS_SOLD
FROM SALES,
     (VALUES ('GROUP 1', 'GROUP 2')) AS X(R1, R2)
GROUP BY GROUPING SETS((R1, ROLLUP(WEEK(SALES_DATE), DAYOFWEEK(SALES_DATE))),
                       (R2, ROLLUP(MONTH(SALES_DATE), REGION)))
ORDER BY WEEK, DAY_WEEK, MONTH, REGION
```

This results in:

R1	R2	WEEK	DAY_WEEK	MONTH	REGION	UNITS_SOLD
GROUP 1	-	13	6	-	-	27
GROUP 1	-	13	7	-	-	46
GROUP 1	-	13	-	-	-	73
GROUP 1	-	14	1	-	-	31
GROUP 1	-	14	2	-	-	43
GROUP 1	-	14	-	-	-	74
GROUP 1	-	53	1	-	-	8
GROUP 1	-	53	-	-	-	8
-	GROUP 2	-	-	3	Manitoba	22
-	GROUP 2	-	-	3	Ontario-North	8
-	GROUP 2	-	-	3	Ontario-South	34
-	GROUP 2	-	-	3	Quebec	40
-	GROUP 2	-	-	3	-	104
-	GROUP 2	-	-	4	Manitoba	17
-	GROUP 2	-	-	4	Ontario-North	1
-	GROUP 2	-	-	4	Ontario-South	14
-	GROUP 2	-	-	4	Quebec	11
-	GROUP 2	-	-	4	-	43
-	GROUP 2	-	-	12	Manitoba	2
-	GROUP 2	-	-	12	Ontario-South	4
-	GROUP 2	-	-	12	Quebec	2
-	GROUP 2	-	-	12	-	8
-	GROUP 2	-	-	-	-	155
GROUP 1	-	-	-	-	-	155

Step 4: Notice that because R1 and R2 are used in different grouping sets, whenever R1 is non-null in the result, R2 is null and whenever R2 is non-null in the result, R1 is null. That means you can consolidate

these columns into a single column using the COALESCE function. You can also use this column in the ORDER BY clause to keep the results of the two grouping sets together.

```

SELECT COALESCE(R1, R2) AS GROUP,
       WEEK(SALES_DATE) AS WEEK,
       DAYOFWEEK(SALES_DATE) AS DAY_WEEK,
       MONTH(SALES_DATE) AS MONTH,
       REGION,
       SUM(SALES) AS UNITS_SOLD
FROM SALES,
     (VALUES ('GROUP 1', 'GROUP 2')) AS X(R1, R2)
GROUP BY GROUPING SETS((R1, ROLLUP(WEEK(SALES_DATE), DAYOFWEEK(SALES_DATE))),
                       (R2, ROLLUP(MONTH(SALES_DATE), REGION)))
ORDER BY GROUP, WEEK, DAY_WEEK, MONTH, REGION

```

This results in:

GROUP	WEEK	DAY_WEEK	MONTH	REGION	UNITS_SOLD
GROUP 1		13	6	- -	27
GROUP 1		13	7	- -	46
GROUP 1		13	-	- -	73
GROUP 1		14	1	- -	31
GROUP 1		14	2	- -	43
GROUP 1		14	-	- -	74
GROUP 1		53	1	- -	8
GROUP 1		53	-	- -	8
GROUP 1		-	-	- -	155
GROUP 2		-	-	3 Manitoba	22
GROUP 2		-	-	3 Ontario-North	8
GROUP 2		-	-	3 Ontario-South	34
GROUP 2		-	-	3 Quebec	40
GROUP 2		-	-	3 -	104
GROUP 2		-	-	4 Manitoba	17
GROUP 2		-	-	4 Ontario-North	1
GROUP 2		-	-	4 Ontario-South	14
GROUP 2		-	-	4 Quebec	11
GROUP 2		-	-	4 -	43
GROUP 2		-	-	12 Manitoba	2
GROUP 2		-	-	12 Ontario-South	4
GROUP 2		-	-	12 Quebec	2
GROUP 2		-	-	12 -	8
GROUP 2		-	-	- -	155

Example C8

The following example illustrates the use of various aggregate functions when performing a CUBE. The example also makes use of cast functions and rounding to produce a decimal result with reasonable precision and scale.

```

SELECT MONTH(SALES_DATE) AS MONTH,
       REGION,
       SUM(SALES) AS SALES,
       MAX(SALES) AS BEST_SALE,
       CAST(ROUND(AVG(DECIMAL(SALES)),2) AS DECIMAL(5,2)) AS AVG_UNITS_SOLD
FROM SALES
GROUP BY CUBE (MONTH(SALES_DATE), REGION)
ORDER BY MONTH, REGION

```

This results in:

MONTH	REGION	UNITS_SOLD	BEST_SALE	AVG_UNITS_SOLD
3	Manitoba	22	7	3.14
3	Ontario-North	8	3	2.67
3	Ontario-South	34	14	4.25
3	Quebec	40	18	5.00
3	-	104	18	4.00
4	Manitoba	17	9	5.67
4	Ontario-North	1	1	1.00
4	Ontario-South	14	8	4.67
4	Quebec	11	8	5.50
4	-	43	9	4.78

12	Manitoba	2	2	2.00
12	Ontario-South	4	3	2.00
12	Quebec	2	1	1.00
12	-	8	3	1.60
-	Manitoba	41	9	3.73
-	Ontario-North	9	3	2.25
-	Ontario-South	52	14	4.00
-	Quebec	53	18	4.42
-	-	155	18	3.87

having-clause

The HAVING clause specifies an intermediate result table that consists of those groups of R for which the *search-condition* is true. R is the result of the previous clause of the subselect. If this clause is not GROUP BY, R is considered a single group with no grouping expressions.

► HAVING — *search-condition* ◄

Each expression that contains a *column-name* in the search condition must do one of the following:

- Unambiguously identify a grouping expression of R.
- Be specified within an aggregate function.
- Be a correlated reference. A *column-name* is a correlated reference if it identifies a column of a table, view, common table expression, or nested table expression identified in an outer subselect.

The RRN, RID, DATAPARTITIONNAME, DATAPARTITIONNUM, DBPARTITIONNAME, DBPARTITIONNUM, and HASHED_VALUE functions cannot be specified in the HAVING clause unless it is within an aggregate function. See [“Aggregate functions” on page 258](#) for restrictions that apply to the use of aggregate functions.

A group of R to which the search condition is applied supplies the argument for each aggregate function in the search condition, except for any function whose argument is a correlated reference.

If the search condition contains a subquery, the subquery can be thought of as being executed each time the search condition is applied to a group of R, and the results used in applying the search condition. In actuality, the subquery is executed for each group only if it contains a correlated reference. For an illustration of the difference, see examples 6 and 7 under [“Examples of a subselect” on page 781](#).

A correlated reference to a group of R must either identify a grouping column or be contained within an aggregate function.

When HAVING is used without GROUP BY, any column name in the select list must appear within an aggregate function.

If a collating sequence other than *HEX is in effect when the statement that contains the HAVING clause is executed and if the *search-condition* contains operands that have SBCS data, mixed data, or Unicode data, the comparison for those predicates is done using weighted values. The weighted values are derived by applying the collating sequence to the operands in the predicate.

order-by-clause

The ORDER BY clause specifies an ordering of the rows of the result table.

sort-key

A subselect that contains an ORDER BY clause cannot be specified in the outermost fullselect of a view.

Note: An ORDER BY clause in a subselect does not affect the order of the rows returned by a query. An ORDER BY clause only affects the order of the rows returned if it is specified in the outermost fullselect.

If the subselect is not enclosed within parentheses and is not the outermost fullselect, the ORDER BY clause cannot be specified.

If a single sort specification (one *sort-key* with associated ascending or descending ordering specification) is identified, the rows are ordered by the values of that specification. If more than one sort specification is identified, the rows are ordered by the values of the first identified sort specification, then by the values of the second identified sort specification, and so on.

If the subselect includes a *hierarchical-query-clause*, ORDER SIBLINGS BY can be specified. This specifies that the ordering applies to siblings within the hierarchies only and parent rows are sorted before their child rows.

If a collating sequence other than *HEX is in effect when the statement that contains the ORDER BY clause is executed and if the ORDER BY clause involves sort specifications that are SBCS data, mixed data, or Unicode data, the comparison for those sort specifications is done using weighted values. The weighted values are derived by applying the collating sequence to the values of the sort specifications.

A named column in the select list may be identified by a *sort-key* that is a *integer* or a *column-name*. An unnamed column in the select list may be identified by a *integer* or, in some cases by a *sort-key-expression* that matches the expression in the select list (see details of *sort-key-expression*). “Names of result columns” on page 740 defines when result columns are unnamed. If the fullselect includes a UNION operator, see “fullselect” on page 783 for the rules on named columns in a fullselect.

Ordering is performed in accordance with the comparison rules described in Chapter 2, “Language elements,” on page 43. The null value is higher than all other values. If your ordering specification does not determine a complete ordering, rows with duplicate values of the last identified *sort-key* have an arbitrary order. If the ORDER BY clause is not specified, the rows of the result table have an arbitrary order.

The sum of the length attributes of the *sort-keys* must not exceed 3.5 gigabytes.

column-name

Must unambiguously identify a column of the result table. The column must not be a DATALINK or XML column and must not be the result of the ARRAY_AGG function. The rules for unambiguous column references are the same as in the other clauses of the fullselect. See “Column name qualifiers to avoid ambiguity” on page 133 for more information.

If the fullselect includes a UNION, UNION ALL, EXCEPT, or INTERSECT, the column name cannot be qualified.

The *column-name* may also identify a column name of a table, view, or *nested-table-expression* identified in the FROM clause. This includes columns defined as implicitly hidden. An error occurs if the subselect includes an aggregation in the select list and the *column-name* is not a *grouping-expression*.

integer

Must be greater than 0 and not greater than the number of columns in the result table. The integer *n* identifies the *n*th column of the result table. The identified column must not be a DATALINK or XML column and must not be the result of the ARRAY_AGG function.

sort-key-expression

An expression that is not simply a column name or an unsigned integer constant. The query to which ordering is applied must be a subselect to use this form of *sort-key*.

The *sort-key-expression* cannot contain RRN, RID, DATAPARTITIONNAME, DATAPARTITIONNUM, DBPARTITIONNAME, DBPARTITIONNUM, and HASHED_VALUE scalar functions if the *fullselect* includes a UNION, UNION ALL, EXCEPT, or INTERSECT. The result of the *sort-key-expression* must not be DATALINK or XML.

If the subselect is grouped, the *sort-key-expression* can be an expression in the select list of the subselect or can include an aggregate function, constant, or variable.

ASC

Uses the values of the column in ascending order. This is the default.

DESC

Uses the values of the column in descending order.

ORDER OF *table-designator*

Specifies that the same ordering used in *table-designator* should be applied to the result table of the subselect. There must be a table reference matching *table-designator* in the FROM clause of the subselect that specifies this clause and the table reference must identify a *nested-table-expression* or *common-table-expression*. The ordering that is applied is the same as if the columns of the ORDER BY clause in the *nested-table-expression* or *common-table-expression* were included in the outer subselect (or fullselect), and these columns were specified in place of the ORDER OF clause. If the *nested-table-expression* or *common-table-expression* has no ORDER BY clause, the order is not defined.

ORDER OF is not allowed if the query specifies:

- a distributed table,
- a table with a read trigger, or
- a logical file built over multiple physical file members.

INPUT SEQUENCE

Specifies that the result table reflects the input order of the rows of an INSERT statement. INPUT SEQUENCE ordering can be specified only when an INSERT statement is specified in a *from-clause*. If INPUT SEQUENCE is specified and the input data is not ordered, the INPUT SEQUENCE clause is ignored.

Column access controls do not effect the operation of the ORDER BY clause. The order is based on the original column values. However, after column masks are applied, the masked values in the final result table might not reflect the order of the original column values.

A *sort-key* must not be LOB if the query specifies:

- a distributed table,
- a table with a read trigger, or
- a logical file built over multiple physical file members.

fetch-clause

The *fetch-clause* sets a maximum number of rows that can be retrieved.

The *fetch-clause* sets a maximum number of rows that can be retrieved. It lets the database manager know that the application does not want to retrieve more than *fetch-row-count* rows, regardless of how many rows there are in the intermediate result table. An attempt to fetch beyond *fetch-row-count* rows is handled the same way as normal end of data.

A *fetch-clause* cannot be specified in the outermost fullselect of a view.

Determining a predictable set of rows to retrieve requires the specification of an **ORDER BY** clause with sort keys that uniquely identify the sort order of each row in the intermediate result table. If the intermediate result table includes duplicate sort keys for some rows, the order of the rows is not deterministic. If there is no **ORDER BY** clause, the intermediate result table is not in a deterministic order. If the order of the intermediate result table is not deterministic, the set of rows retrieved is unpredictable. If both the *order-by-clause* and *fetch-clause* are specified, the *fetch-clause* is processed on the ordered data.

fetch-row-count

An expression that specifies the maximum number of rows to retrieve. *fetch-row-count* must not contain a *scalar-fullselect*, a column reference, a table reference, a user-defined function reference, or a built-in scalar function identified as restricted in a check constraint; see [check-constraint](#). If the data type of the expression is not **BIGINT**, the result of the expression is cast to a **BIGINT** value. The value of *fetch-row-count* must be a positive number or zero. It cannot be the null value.

Limiting the result table to a specified number of rows can improve performance. In some cases, the database manager will cease processing the query when it has determined the specified number of rows. If the *offset-clause* is also specified, the database manager will also consider the offset value in determining when to cease processing.

If the fullselect contains an SQL data change statement in the **FROM** clause, all the rows are modified regardless of the limit on the number of rows to fetch.

Row access controls can indirectly affect the **FETCH FIRST** clause because row access controls affect the rows that are accessible to the authorization ID of the subselect.

Notes

Syntax alternatives:

- The keywords **FIRST** and **NEXT** can be used interchangeably. The result is unchanged; however, using the keyword **NEXT** is more readable when the *offset-clause* is used.
- The following are supported for compatibility with SQL used by other database products. These alternatives are non-standard and should not be used.

Alternative syntax	Equivalent syntax
LIMIT <i>x</i>	FETCH FIRST <i>x</i> ROWS ONLY
LIMIT <i>x</i> OFFSET <i>y</i>	OFFSET <i>y</i> ROWS FETCH FIRST <i>x</i> ROWS ONLY
LIMIT <i>y</i> , <i>x</i>	OFFSET <i>y</i> ROWS FETCH FIRST <i>x</i> ROWS ONLY

Examples of a subselect

subselect can be used in many different ways.

Example 1

Select all columns and rows from the EMPLOYEE table.

```
SELECT * FROM EMPLOYEE
```

Example 2

Join the EMPPROJECT and EMPLOYEE tables, select all the columns from the EMPPROJECT table and add the employee's surname (LASTNAME) from the EMPLOYEE table to each row of the result.

```
SELECT EMPPROJECT.*, LASTNAME
FROM EMPPROJECT, EMPLOYEE
WHERE EMPPROJECT.EMPNO = EMPLOYEE.EMPNO
```

Example 3

Join the EMPLOYEE and DEPARTMENT tables, select the employee number (EMPNO), employee surname (LASTNAME), department number (WORKDEPT in the EMPLOYEE table and DEPTNO in the DEPARTMENT table) and department name (DEPTNAME) of all employees who were born (BIRTHDATE) earlier than 1930.

```
SELECT EMPNO, LASTNAME, WORKDEPT, DEPTNAME
FROM EMPLOYEE, DEPARTMENT
WHERE WORKDEPT = DEPTNO
AND YEAR(BIRTHDATE) < 1930
```

This subselect could also be written as follows:

```
SELECT EMPNO, LASTNAME, WORKDEPT, DEPTNAME
FROM EMPLOYEE INNER JOIN DEPARTMENT
ON WORKDEPT = DEPTNO
WHERE YEAR(BIRTHDATE) < 1930
```

Example 4

Select the job (JOB) and the minimum and maximum salaries (SALARY) for each group of rows with the same job code in the EMPLOYEE table, but only for groups with more than one row and with a maximum salary greater than or equal to 27000.

```
SELECT JOB, MIN(SALARY), MAX(SALARY)
FROM EMPLOYEE
GROUP BY JOB
HAVING COUNT(*) > 1 AND MAX(SALARY) >= 27000
```

Example 5

Select all the rows of EMPPROJECT table for employees (EMPNO) in department (WORKDEPT) 'E11'. (Employee department numbers are shown in the EMPLOYEE table.)

```
SELECT * FROM EMPPROJECT
WHERE EMPNO IN (SELECT EMPNO FROM EMPLOYEE
WHERE WORKDEPT = 'E11')
```

Example 6

From the EMPLOYEE table, select the department number (WORKDEPT) and maximum departmental salary (SALARY) for all departments whose maximum salary is less than the average salary for all employees.

```
SELECT WORKDEPT, MAX(SALARY)
FROM EMPLOYEE
GROUP BY WORKDEPT
HAVING MAX(SALARY) < (SELECT AVG(SALARY)
FROM EMPLOYEE)
```

The subquery in the HAVING clause would only be executed once in this example.

Example 7

Using the EMPLOYEE table, select the department number (WORKDEPT) and maximum departmental salary (SALARY) for all departments whose maximum salary is less than the average salary in all other departments.

```
SELECT WORKDEPT, MAX(SALARY)
FROM EMPLOYEE EMP_COR
GROUP BY WORKDEPT
HAVING MAX(SALARY) < (SELECT AVG(SALARY)
FROM EMPLOYEE
WHERE NOT WORKDEPT = EMP_COR.WORKDEPT)
```

In contrast to example 6, the subquery in the HAVING clause would need to be executed for each group.

Example 8

Join the EMPLOYEE and EMPPROJECT tables, select all of the employees and their project numbers. Return even those employees that do not have a project number currently assigned.

```
SELECT EMPLOYEE.EMPNO, PROJNO
FROM EMPLOYEE LEFT OUTER JOIN EMPPROJECT
ON EMPLOYEE.EMPNO = EMPPROJECT.EMPNO
```

Any employee in the EMPLOYEE table that does not have a project number in the EMPPROJECT table will return one row in the result table containing the EMPNO value and the null value in the PROJNO column.

fullselect

The *fullselect* is a component of the *select-statement*, ALTER TABLE statement for the definition of a materialized query table, CREATE TABLE statement, CREATE VIEW statement, DECLARE GLOBAL TEMPORARY TABLE statement, INSERT statement, SET transition-variable statement, SET VARIABLE statement, UPDATE statement, and *assignment-statement*.

values-clause

values-row

A fullselect that is enclosed in parenthesis is called a *subquery*. For example, a *subquery* can be used in a search condition.

A *scalar-fullselect* is a fullselect, enclosed in parentheses, that returns a single result row and a single result column. If the result of the fullselect is no rows, then the null value is returned. An error is returned if there is more than one row in the result.

A *fullselect* specifies a result table. If *UNION*, *EXCEPT*, or *INTERSECT* is not used, the result of the fullselect is the result of the specified subselect or *values-clause*.

values-clause

Derives a result table by specifying the actual values, using expressions, for each column of a row in the result table. Multiple rows may be specified.

NULL can only be used with multiple specifications of *values-row*, and at least one row in the same column must not be *NULL*.

A *values-row* is specified by:

- A single expression for a single column result table or,
- n expressions (or NULL) separated by commas and enclosed in parentheses, where n is the number of columns in the result table.

A multiple row VALUES clause must have the same number of expressions in each *values-row*.

The following are examples of *values-clauses* and their meanings.

VALUES (1), (2), (3)	- 3 rows of 1 column
VALUES 1, 2, 3	- 3 rows of 1 column
VALUES (1, 2, 3)	- 1 row of 3 columns
VALUES (1,21), (2,22), (3,23)	- 3 rows of 2 columns

A *values-clause* that is composed of n specifications of *values-row*, RE_1 to RE_n , where n is greater than 1 is equivalent to:

```
RE1 UNION ALL RE2 ... UNION ALL REn
```

This means that the corresponding expressions of each *values-row* must be comparable. All result columns in a *values-row* are unnamed.

UNION, EXCEPT, or INTERSECT

The set operators UNION, EXCEPT, and INTERSECT correspond to the relational operators union, difference, and intersection. A fullselect specifies a result table. If a set operator is not used, the result of the fullselect is the result of the specified subselect. Otherwise, the result table is derived by combining two other result tables (R1 and R2) subject to the specified set operator.

UNION DISTINCT or UNION ALL

If UNION is specified without the ALL option, the result is the set of all rows in either R1 or R2, with duplicate rows eliminated. In either case, however, each row of the UNION table is either a row from R1 or a row from R2.

EXCEPT DISTINCT

The result consists of all rows that are only in R1, with duplicate rows in the result of this operation eliminated. Each row in the result table of the difference is a row from R1 that does not have a matching row in R2.

INTERSECT DISTINCT

The result consists of all rows that are in both R1 and R2, with the duplicate rows eliminated. Each row in the result table of the intersection is a row that exists in both R1 and R2.

The expression that corresponds to the n th column in R1 and R2 can reference columns with column masks. The n th column of the result of the set operation can be derived from the masked values in R1 or R2.

With DISTINCT, the elimination of the duplicate rows is based on the unmasked values in R1 and R2. Because all rows are from R1 or R2, the output values in the result table of the set operation may vary when one or more of the following conditions occur:

- The expression corresponding to the n th column in R1 references columns with column masks, but the expression corresponding to the n th column in R2 does not, or vice versa.
- The expressions corresponding to the n th column in R1 and R2 reference columns with different column masks.
- The column mask definition references columns that are not the same target column for which the column mask is defined, and those columns are not part of the DISTINCT operation. It is recommended that the column mask definition does not reference other columns from the target table.

For example, a row in R1 is derived from the masked value, and a row in R2 is derived from the unmasked value. If the DISTINCT picks the row for the result table from R1, the masked value is returned. If the DISTINCT picks the row for the result table from R2, the unmasked value is returned.

Rules for columns:

- R1 and R2 must have the same number of columns, and the data type of the *n*th column of R1 must be compatible with the data type of the *n*th column of R2. Character-string values are compatible with datetime values.
- The *n*th column of the result of UNION, UNION ALL, EXCEPT, or INTERSECT is derived from the *n*th columns of R1 and R2. The attributes of the result columns are determined using the rules for result columns.
- If the *n*th column of R1 is named, then the *n*th column of the result table has that result column name. Otherwise, the result column is unnamed.
- If UNION, INTERSECT, or EXCEPT is specified, no column can be a DATALINK or XML column.

For information on the valid combinations of operand columns and the data type of the result column, see “Rules for result data types” on page 105.

EXCEPT and INTERSECT restrictions: VALUES, INTERSECT, and EXCEPT are not allowed if the query specifies one of the following:

- A distributed table
- A table with a read trigger
- A logical file built over multiple physical file members

Duplicate rows: Two rows are duplicates if each value in the first is equal to the corresponding value of the second. (For determining duplicates, two null values are considered equal.)

Operator precedence: UNION, UNION ALL, and INTERSECT are associative set operations. However, when UNION, UNION ALL, EXCEPT, and INTERSECT are used in the same statement, the result depends on the order in which the operations are performed. Operations within parenthesis are performed first. When the order is not specified by parentheses, operations are performed in left-to-right order with the exception that all INTERSECT operations are performed before UNION or EXCEPT operations.

Results of set operators: In the following example, the values of tables R1 and R2 are shown on the left. The other headings listed show the values as a result of various set operations on R1 and R2.

R1	R2	UNION ALL	UNION	EXCEPT	INTERSECT
1	1	1	1	2	1
1	1	1	2	5	3
1	3	1	3		4
2	3	1	4		
2	3	1	5		
2	3	2			
3	4	2			
4		2			
4		3			
5		3			
		3			
		3			
		3			
		4			
		4			
		4			

R1	R2	UNION ALL	UNION	EXCEPT	INTERSECT
		5			

Collating sequence: If a collating sequence other than *HEX is in effect when the statement that contains the UNION, EXCEPT, or INTERSECT keyword is executed and if the result tables contain columns that are SBCS data, mixed data, or Unicode data, the comparison for those columns is done using weighted values. The weighted values are derived by applying the collating sequence to each value.

Examples of a fullselect

Example 1

Select all columns and rows from the EMPLOYEE table.

```
SELECT * FROM EMPLOYEE
```

Example 2

List the employee numbers (EMPNO) of all employees in the EMPLOYEE table whose department number (WORKDEPT) either begins with 'E' or who are assigned to projects in the EMPPROJECT table whose project number (PROJNO) equals 'MA2100', 'MA2110', or 'MA2112'.

```
SELECT EMPNO FROM EMPLOYEE
WHERE WORKDEPT LIKE 'E%'
UNION
SELECT EMPNO FROM EMPPROJECT
WHERE PROJNO IN('MA2100', 'MA2110', 'MA2112')
```

Example 3

Make the same query as in example 2, only use UNION ALL so that no duplicate rows are eliminated.

```
SELECT EMPNO FROM EMPLOYEE
WHERE WORKDEPT LIKE 'E%'
UNION ALL
SELECT EMPNO FROM EMPPROJECT
WHERE PROJNO IN('MA2100', 'MA2110', 'MA2112')
```

Example 4

Make the same query as in example 2, and, in addition, "tag" the rows from the EMPLOYEE table with 'emp' and the rows from the EMPPROJECT table with 'empproject'. Unlike the result from example 2, this query may return the same EMPNO more than once, identifying which table it came from by the associated "tag".

```
SELECT EMPNO, 'emp' FROM EMPLOYEE
WHERE WORKDEPT LIKE 'E%'
UNION
SELECT EMPNO, 'empproject' FROM EMPPROJECT
WHERE PROJNO IN('MA2100', 'MA2110', 'MA2112')
```

Example 5

This example of EXCEPT produces all rows that are in T1 but not in T2, with duplicate rows removed.

```
(SELECT * FROM T1)
EXCEPT DISTINCT
(SELECT * FROM T2)
```

If no NULL values are involved, this example returns the same results as:

```
(SELECT DISTINCT *
FROM T1
WHERE NOT EXISTS (SELECT * FROM T2
WHERE T1.C1 = T2.C1 AND T1.C2 = T2.C2 AND... ) )
```

where C1, C2, and so on represent the columns of T1 and T2.

Example 6

This example of INTERSECT produces all rows that are in both tables T1 and T2, with duplicate rows removed.

```
(SELECT * FROM T1)
INTERSECT DISTINCT
(SELECT * FROM T2)
```

If no NULL values are involved, this example returns the same results as:

```
(SELECT DISTINCT *
FROM T1
WHERE EXISTS (SELECT * FROM T2
WHERE T1.C1 = T2.C1 AND T1.C2 = T2.C2 AND... ) )
```

where C1, C2, and so on represent the columns of T1 and T2.

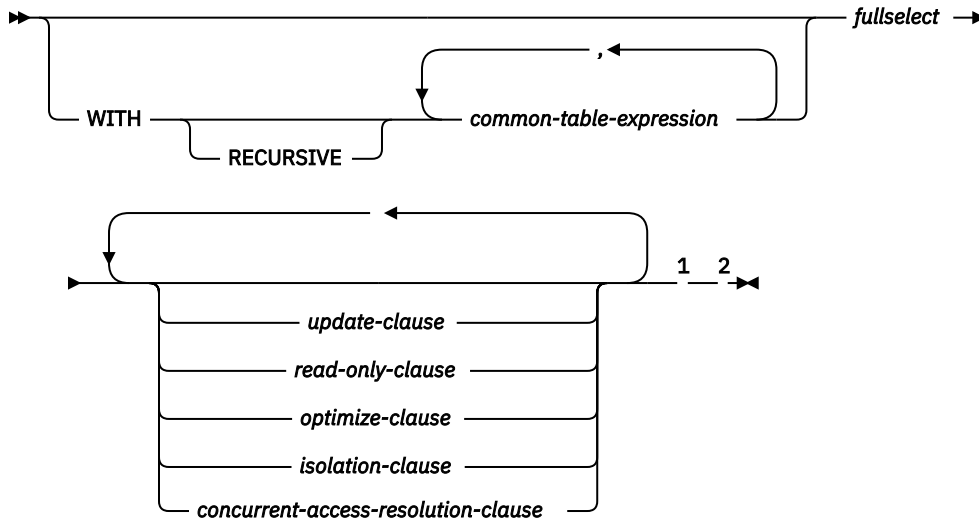

Example 7

Make the same query as in example 3, only include an additional two employees currently not in any table and tag these rows as "new".

```
SELECT EMPNO, 'emp' FROM EMPLOYEE
WHERE WORKDEPT LIKE 'E%'
UNION
SELECT EMPNO, 'empproject' FROM EMPPROJACT
WHERE PROJNO IN('MA2100', 'MA2110', 'MA2112')
UNION
VALUES ('NEWAAA', 'new'), ('NEWBBB', 'new')
```

select-statement

The *select-statement* is the form of a query that can be directly specified in a DECLARE CURSOR or FOR statement, prepared and then referenced in a DECLARE CURSOR statement, or directly specified in an SQLJ assignment clause. It can also be issued interactively. In any case, the table specified by a *select-statement* is the result of the fullselect.

Notes:

- ¹ The *update-clause* and *read-only-clause* cannot both be specified in the same *select-statement*.
- ² Each clause may be specified only once.

RECURSIVE

Indicates that a *common-table-expression* is potentially recursive.

common-table-expression

A *common-table-expression* permits defining a result table with a *table-identifier* that can be specified as a table name in any FROM clause of the fullselect that follows. Multiple common table expressions can be specified following the single WITH keyword. Each common table expression specified can also be referenced by name in the FROM clause of subsequent common table expressions.

search-clause

cycle-clause

If a list of columns is specified, it must consist of as many names as there are columns in the result table of the fullselect. Each *column-name* must be unique and unqualified. If these column names are not specified, the names are derived from the select list of the subselect used to define the common table expression.

The *table-identifier* of a common table expression must be different from any other common table expression *table-identifier* in the same statement. A common table expression *table-identifier* can be specified as a table name in any FROM clause throughout the fullselect. A *table-identifier* of a common table expression overrides any existing table, view, or alias (in the catalog) with the same unqualified name or any *table-identifier* specified for a trigger.

If more than one common table expression is defined in the same statement, cyclic references between the common table expressions are not permitted. A *cyclic reference* occurs when two common table expressions *dt1* and *dt2* are created such that *dt1* refers to *dt2* and *dt2* refers to *dt1*.

The *table name* of a common table expression can only be referenced in the *select-statement*, INSERT statement, or CREATE VIEW statement that defines it.

If a *select-statement*, INSERT statement, or CREATE VIEW statement refers to an unqualified table name, the following rules are applied to determine which table is actually being referenced:

- If the unqualified name corresponds to one or more common table expression names that are specified in the *select-statement*, the name identifies the common table expression that is in the innermost scope.
- If in a CREATE TRIGGER statement and the unqualified name corresponds to a transition table name, the name identifies that transition table.
- Otherwise, the name identifies a persistent table, a temporary table, or a view that is present in the default schema.

A *common-table-expression* can be used:

- In place of a view to avoid creating the view (when general use of the view is not required and positioned UPDATE or DELETE is not used)
- To enable grouping by a column that is derived from a scalar-fullselect or function that is not deterministic
- When the required result table is based on variables
- When the same result table needs to be shared in a *fullselect*
- When the result needs to be derived using recursion

If a *fullselect* of a common table expression contains a reference to itself in a FROM clause, the common table expression is a *recursive table expression*. Queries using recursion are useful in supporting applications such as bill of materials (BOM), reservation systems, and network planning.

The following restrictions must be true of a recursive *common-table-expression*:

- Each fullselect that is part of the recursion cycle must start with SELECT or SELECT ALL. Use of SELECT DISTINCT is not allowed.
- The UNION ALL set operator must be specified.
- A list of *column-names* must be specified following the *table-identifier* of the *common-table-expression*.
- The first *fullselect* of the first union (the initialization *fullselect*) must not include a reference to the *common-table-expression* itself in any FROM clause.
- Each *fullselect* that is part of the recursion cycle must not include any aggregate functions, GROUP BY clauses, or HAVING clauses.
- The FROM clauses of these *fullselects* can include at most one reference to a *common-table-expression* that is part of a recursion cycle.
- The table being defined in the *common-table-expression* cannot be referenced in a subquery of a *fullselect* that defines the *common-table-expression*.
- LEFT OUTER JOIN and FULL OUTER JOIN are not allowed if the *common-table-expression* is the right operand. RIGHT OUTER JOIN and FULL OUTER JOIN are not allowed if the *common-table-expression* is the left operand.
- Each *fullselect* other than the initialization *fullselect* that is part of the recursion cycle must not include an ORDER BY clause.

If a column name of the *common-table-expression* is referred to in the iterative *fullselect*, the attributes of the result columns are determined using the rules for result columns. For more information see [“Rules for result data types”](#) on page 105.

search-clause

The SEARCH clause in the definition of the recursive *common-table-expression* is used to specify the order in which the result rows are to be returned.

SEARCH DEPTH FIRST

Each parent or containing item appears in the result before the items that it contains.

SEARCH BREADTH FIRST

Sibling items are grouped before subordinate items.

BY *column-name*,...

Identifies the columns that associate the parent and child relationship of the recursive query. Each *column-name* must unambiguously identify a column of the parent. The column must not be a DATALINK or XML column. The rules for unambiguous column references are the same as in the other clauses of the fullselect. See [“Column name qualifiers to avoid ambiguity”](#) on page 133 for more information.

The *column-name* must identify a column name of the recursive *common-table-expression*. The *column-name* must not be qualified.

SET *seq-column-name*

Specifies the name of a result column that contains an ordinal number of the current row in the recursive query result. The data type of the *seq-column-name* is BIGINT.

The *seq-column-name* may only be referenced in the ORDER BY clause of the outer fullselect that references the *common-table-expression*. The *seq-column-name* cannot be referenced in the fullselect that defines the *common-table-expression*.

The *seq-column-name* must not be the same as *using-column-name* or *cycle-column-name*.

cycle-clause

The CYCLE clause in the definition of the recursive *common-table-expression* is used to prevent an infinite loop in the recursive query when the parent and child relationship of the data results in a loop.

CYCLE *column-name*,...

Specifies the list of columns that represent the parent/child join relationship values for the recursion. Any new row from the query is first checked for a duplicate value (per these column names) in the existing rows that lead to this row in the recursive query results to determine if there is a cycle.

Each *column-name* must identify a result column of the common table expression. It must not be an XML or DataLink column. The same *column-name* must not be specified more than once.

SET *cycle-column-name*

Specifies the name of a result column that is set based on whether a cycle has been detected in the recursive query:

- If a duplicate row is encountered, indicating that a cycle has been detected in the data, the *cycle-column-name* is set to the TO *constant*.
- If a duplicate row is not encountered, indicating that a cycle has not been detected in the data, the *cycle-column-name* is set to the DEFAULT *constant*.

The data type of the *cycle-column-name* is CHAR(1).

When cyclic data in the row is encountered, the duplicate row is not returned to the recursive query process for further recursion and that child branch of the query is stopped. By specifying the provided *cycle-column-name* is in the result set of the main fullselect, the existence of cyclic data can actually be determined and even corrected if that is wanted.

The *cycle-column-name* must not be the same as *using-column-name* or *seq-column-name*.

The *cycle-column-name* can be referenced in the fullselect that defines the *common-table-expression*.

TO *constant*

Specifies a CHAR(1) constant value to assign to the *cycle-column* if a cycle has been detected in the data. The TO *constant* must not be equal to the DEFAULT *constant*.

DEFAULT *constant*

Specifies a CHAR(1) constant value to assign to the *cycle-column* if a cycle has not been detected in the data. The DEFAULT *constant* must not be equal to the TO *constant*.

USING *using-column-name*

Identifies the temporary results consisting of the columns from the CYCLE column list. The temporary result is used by the database manager to identify duplicate rows in the query result.

The *using-column-name* must not be the same as *cycle-column-name* or *seq-column-name*.

When developing recursive common table expressions, remember that an infinite recursion cycle (loop) can be created. Ensure that recursion cycles will end. This is especially important if the data involved is cyclic. A recursive common table expression is expected to include a predicate that will prevent an infinite loop. The recursive common table expression is expected to include:

- In the iterative *fullselect*, an integer column incremented by a constant.
- A predicate in the WHERE clause of the iterative *fullselect* in the form "counter_col < constant" or "counter_col < :hostvar".

A warning is issued if this syntax is not found in the recursive common table expression.

Recursive common table expressions are not allowed if the query specifies:

- a distributed table,
- a table with a read trigger, or
- a logical file built over multiple physical file members.

Recursion example: bill of materials

Bill of materials (BOM) applications are a common requirement in many business environments. To illustrate the capability of a recursive common table expression for BOM applications, consider a table of parts with associated subparts and the quantity of subparts required by the part.

For this example, create the table as follows:

```
CREATE TABLE PARTLIST
( PART      VARCHAR(8),
  SUBPART   VARCHAR(8),
  QUANTITY  INTEGER )
```

To give query results for this example, assume that the PARTLIST table is populated with the following values:

PART	SUBPART	QUANTITY
00	01	5
00	05	3
01	02	2
01	03	3
01	04	4
01	06	3
02	05	7
02	06	6
03	07	6
04	08	10
04	09	11
05	10	10
05	11	10
06	12	10
06	13	10
07	14	8
07	12	8

Example 1: Single level explosion

The first example is called single level explosion. It answers the question, "What parts are needed to build the part identified by '01'?". The list will include the direct subparts, subparts of the subparts and so on. However, if a part is used multiple times, its subparts are only listed once.

```
WITH RPL (PART, SUBPART, QUANTITY) AS
( SELECT ROOT.PART, ROOT.SUBPART, ROOT.QUANTITY
  FROM PARTLIST ROOT
  WHERE ROOT.PART = '01'
  UNION ALL
  SELECT CHILD.PART, CHILD.SUBPART, CHILD.QUANTITY
  FROM RPL PARENT, PARTLIST CHILD
  WHERE PARENT.SUBPART = CHILD.PART
)
SELECT DISTINCT PART, SUBPART, QUANTITY
FROM RPL
ORDER BY PART, SUBPART, QUANTITY
```

The above query includes a common table expression, identified by the name RPL, that expresses the recursive part of this query. It illustrates the basic elements of a recursive common table expression.

The first operand (fullselect) of the UNION, referred to as the initialization fullselect, gets the direct children of part '01'. The FROM clause of this fullselect refers to the source table and will never refer to itself (RPL in this case). The result of this first fullselect goes into the common table expression RPL (Recursive PARTLIST). As in this example, the UNION must always be a UNION ALL.

The second operand (fullselect) of the UNION uses RPL to compute subparts of subparts by having the FROM clause refer to the common table expression RPL and the source table with a join of a part from the source table (child) to a subpart of the current result contained in RPL (parent). The result goes back to RPL again. The second operand of UNION is then used repeatedly until no more children exist.

The SELECT DISTINCT in the main fullselect of this query ensures the same part/subpart is not listed more than once.

The result of the query is as follows:

PART	SUBPART	QUANTITY
01	02	2
01	03	3
01	04	4
01	06	3
02	05	7
02	06	6
03	07	6
04	08	10
04	09	11
05	10	10
05	11	10
06	12	10
06	13	10
07	12	8
07	14	8

Observe in the result that part '01' goes to '02' which goes to '06' and so on. Further, notice that part '06' is reached twice, once through '01' directly and another time through '02'. In the output, however, its subcomponents are listed only once (this is the result of using a SELECT DISTINCT) as required.

Example 2: Summarized explosion

The second example is a summarized explosion. The question posed here is, what is the total quantity of each part required to build part '01'. The main difference from the single level explosion is the need to aggregate the quantities. The first example indicates the quantity of subparts required for the part whenever it is required. It does not indicate how many of the subparts are needed to build part '01'.

```

WITH RPL (PART, SUBPART, QUANTITY) AS
(
  SELECT ROOT.PART, ROOT.SUBPART, ROOT.QUANTITY
  FROM PARTLIST ROOT
  WHERE ROOT.PART = '01'
  UNION ALL
  SELECT PARENT.PART, CHILD.SUBPART, PARENT.QUANTITY*CHILD.QUANTITY
  FROM RPL PARENT, PARTLIST CHILD
  WHERE PARENT.SUBPART = CHILD.PART
)
SELECT PART, SUBPART, SUM(QUANTITY) AS "Total Qty Used"
FROM RPL
GROUP BY PART, SUBPART
ORDER BY PART, SUBPART

```

In the above query, the select list of the second operand of the UNION in the recursive common table expression, identified by the name RPL, shows the aggregation of the quantity. To find out how much of a subpart is used, the quantity of the parent is multiplied by the quantity per parent of a child. If a part is used multiple times in different places, it requires another final aggregation. This is done by the grouping over the common table expression RPL and using the SUM aggregate function in the select list of the main fullselect.

The result of the query is as follows:

PART	SUBPART	Total Qty Used
01	02	2
01	03	3
01	04	4
01	05	14
01	06	15
01	07	18

01	08	40
01	09	44
01	10	140
01	11	140
01	12	294
01	13	150
01	14	144

Looking at the output, consider the line for subpart '06'. The total quantity used value of 15 is derived from a quantity of 3 directly for part '01' and a quantity of 6 for part '02' which is needed 2 times by part '01'.

Example 3: Controlling depth

The question may come to mind, what happens when there are more levels of parts in the table than you are interested in for your query? That is, how is a query written to answer the question, "What are the first two levels of parts needed to build the part identified by '01'?" For the sake of clarity in the example, the level is included in the result.

```

WITH RPL ( LEVEL, PART, SUBPART, QUANTITY)
  AS ( SELECT 1, ROOT.PART, ROOT.SUBPART, ROOT.QUANTITY
        FROM PARTLIST ROOT
        WHERE ROOT.PART = '01'
        UNION ALL
        SELECT PARENT.LEVEL+1, CHILD.PART, CHILD.SUBPART, CHILD.QUANTITY
        FROM RPL PARENT, PARTLIST CHILD
        WHERE PARENT.SUBPART = CHILD.PART
        AND PARENT.LEVEL < 2
      )
SELECT PART, LEVEL, SUBPART, QUANTITY
FROM RPL

```

This query is similar to example 1. The column LEVEL was introduced to count the levels from the original part. In the initialization fullselect, the value for the LEVEL column is initialized to 1. In the subsequent fullselect, the level from the parent is incremented by 1. Then to control the number of levels in the result, the second fullselect includes the condition that the parent level must be less than 2. This ensures that the second fullselect only processes children to the second level.

The result of the query is:

PART	LEVEL	SUBPART	QUANTITY
01	1	02	2
01	1	03	3
01	1	04	4
01	1	06	3
02	2	05	7
02	2	06	6
03	2	07	6
04	2	08	10
04	2	09	11
06	2	12	10
06	2	13	10

update-clause

The UPDATE clause identifies the columns that can appear as targets in an assignment clause in a subsequent positioned UPDATE statement. Each *column-name* must be unqualified and must identify a column of the table or view identified in the first FROM clause of the fullselect. The clause must not be specified if the result table of the fullselect is read-only.

If an UPDATE clause is specified with a *column-name* list, and extended indicators are not enabled, then *column-name* must be an updatable column.

If the UPDATE clause is specified without *column-name* list, then the implicit *column-name* list is determined as follows:

- If extended indicators are enabled, all the columns of the table or view identified in the first FROM clause of the fullselect.
- Otherwise, all the updatable columns of the table or view identified in the first FROM clause of the fullselect.

If the UPDATE clause is not specified in a *select-statement* and its result table is not *read-only*, then an implicit UPDATE clause will result. The implicit *column-name* list is determined as follows:

- If extended indicators are enabled, all the columns of the table or view identified in the first FROM clause of the fullselect are included.
- Otherwise, all the updatable columns of the table or view identified in the first FROM clause of the fullselect are included.

The UPDATE clause must not be specified if the result table of the fullselect is read-only (for more information see [“DECLARE CURSOR” on page 1215](#)) or if the FOR READ ONLY clause is used.

When the UPDATE clause is used, FETCH operations referencing the cursor acquire an exclusive row lock.

read-only-clause

The READ ONLY clause indicates that the result table is read-only; therefore, the cursor cannot be used for positioned UPDATE and DELETE statements.

►► FOR READ ONLY ◄◄

Some result tables are read-only by nature. (For example, a table based on a read-only view). FOR READ ONLY can still be specified for such tables, but the specification has no effect.

For result tables in which updates and deletes are allowed, specifying FOR READ ONLY can possibly improve the performance of FETCH operations by allowing the database manager to do blocking and avoid exclusive locks. For example, in programs that contain dynamic SQL statements without the FOR READ ONLY or ORDER BY clause, the database manager might open cursors as if the UPDATE clause was specified.

A read-only result table must not be referred to in an UPDATE or DELETE statement, whether it is read-only by nature or specified as FOR READ ONLY.

To guarantee that selected data is not locked by any other job, you can specify the optional syntax of USE AND KEEP EXCLUSIVE LOCKS on the *isolation-clause*. This guarantees that the selected data can later be updated or deleted without incurring a row lock conflict.

Syntax Alternatives: FOR FETCH ONLY can be specified in place of FOR READ ONLY.

optimize-clause

The *optimize-clause* tells the database manager to assume that the program does not intend to retrieve more than *integer* rows from the result table. Without this clause, or with the keyword ALL, the database manager assumes that all rows of the result table are to be retrieved. Optimizing for *integer* rows can improve performance. The database manager will optimize the query based on the specified number of rows.

The clause does not change the result table or the order in which the rows are fetched. Any number of rows can be fetched, but performance can possibly degrade after *integer* fetches.

The value of *integer* must be a positive integer (not zero).

Row access controls indirectly affect the *optimize-clause* because row access controls affect the rows that are accessible to the authorization ID of the subselect.

isolation-clause

The *isolation-clause* specifies an isolation level at which the select statement is executed.

lock-clause

► USE AND KEEP EXCLUSIVE LOCKS ◄

RR

Repeatable Read

USE AND KEEP EXCLUSIVE LOCKS

Exclusive row locks are acquired and held until a COMMIT or ROLLBACK statement is executed.

RS

Read Stability

USE AND KEEP EXCLUSIVE LOCKS

Exclusive row locks are acquired and held until a COMMIT or ROLLBACK statement is executed. The USE AND KEEP EXCLUSIVE LOCKS clause is only allowed in the *isolation-clause* in the following SQL statements:

- DECLARE CURSOR
- FOR
- *select-statement*
- SELECT INTO
- PREPARE in the ATTRIBUTES string

It is not allowed on updatable cursors.

CS

Cursor Stability

KEEP LOCKS

The KEEP LOCKS clause specifies that any read locks acquired will be held for a longer duration. Normally, read locks are released when the next row is read. If the isolation clause is associated with a cursor, the locks will be held until the cursor is closed or until a COMMIT or ROLLBACK statement is executed. Otherwise, the locks will be held until the completion of the SQL statement.

UR

Uncommitted Read

NC

No Commit

If *isolation-clause* is not specified, the default isolation is used with the exception of a default isolation level of uncommitted read. See [“Isolation level” on page 23](#) for a description of how the default is determined.

Exclusive locks: The USE AND KEEP EXCLUSIVE LOCKS clause should be used with caution. If it is specified, the exclusive row locks that are acquired on rows will prevent concurrent access to those rows by other users running COMMIT(*CS), COMMIT(*RS), and COMMIT(*RR) till the end of the unit of work. Concurrent access by users running COMMIT(*NC) or COMMIT(*UR) is not prevented.

Keyword Synonyms: The following keywords are synonyms supported for compatibility to prior releases. These keywords are non-standard and should not be used:

- The keyword NONE can be used as a synonym for NC.
- The keyword CHG can be used as a synonym for UR.
- The keyword ALL can be used as a synonym for RS.

concurrent-access-resolution-clause

The *concurrent-access-resolution-clause* specifies the concurrent access resolution to use for the statement.

SKIP LOCKED DATA

Specifies that the *select-statement*, searched UPDATE statement (including a searched update operation in a MERGE statement), or searched DELETE statement that is prepared in the PREPARE statement will skip rows when incompatible locks are held on the row by other transactions. These rows can belong to any accessed table that is specified in the statement. SKIP LOCKED DATA can be used only when isolation level NC, UR, CS, or RS is in effect.

SKIP LOCKED DATA is ignored if it is specified when the isolation level that is in effect is RR.

USE CURRENTLY COMMITTED

Specifies that the database manager can use the currently committed version of the data for applicable scans when it is in the process of being updated or deleted. Rows in the process of being inserted can be skipped. This clause applies if possible when the isolation level is CS without the KEEP LOCKS clause and is ignored otherwise. Applicable scans include read-only scans.

WAIT FOR OUTCOME

Specifies to wait for the commit or rollback when encountering data in the process of being updated or deleted. Rows encountered that are in the process of being inserted are not skipped. This clause applies if possible when the isolation level is CS or RS. It is ignored when an isolation level of NC, UR, or RR is in effect.

Examples of a select-statement

You can use select-statement in many different ways.

Example 1

Select all columns and rows from the EMPLOYEE table.

```
SELECT * FROM EMPLOYEE
```

Example 2

Select the project name (PROJNAME), start date (PRSTDATE), and end date (PRENDATE) from the PROJECT table. Order the result table by the end date with the most recent dates appearing first.

```
SELECT PROJNAME, PRSTDATE, PRENDATE  
FROM PROJECT  
ORDER BY PRENDATE DESC
```

Example 3

Select the department number (WORKDEPT) and average departmental salary (SALARY) for all departments in the EMPLOYEE table. Arrange the result table in ascending order by average departmental salary.

```
SELECT WORKDEPT, AVG(SALARY)  
FROM EMPLOYEE  
GROUP BY WORKDEPT  
ORDER BY AVGSAL
```

Example 4

Declare a cursor named UP_CUR, to be used in a C program, that updates the start date (PRSTDATE) and the end date (PRENDATE) columns in the PROJECT table. The program must receive both of these values together with the project number (PROJNO) value for each row. The declaration specifies that the access path for the query be optimized for the retrieval of a maximum of 2 rows. Even so, the program can retrieve more than 2 rows from the result table. However, when more than 2 rows are retrieved, performance could possibly degrade.

```
EXEC SQL DECLARE UP_CUR CURSOR FOR  
SELECT PROJNO, PRSTDATE, PRENDATE  
FROM PROJECT  
FOR UPDATE OF PRSTDATE, PRENDATE  
OPTIMIZE FOR 2 ROWS ;
```

Example 5

Select items from a table with an isolation level of Read Stability (RS).

```
SELECT NAME, SALARY  
FROM PAYROLL  
WHERE DEPT = 704  
WITH RS
```

Example 6

This example names the expression SALARY+BONUS+COMM as TOTAL_PAY:

```

SELECT SALARY+BONUS+COMM AS TOTAL_PAY
FROM EMPLOYEE
ORDER BY TOTAL_PAY

```

Example 7

Determine the employee number and salary of sales representatives along with the average salary and head count of their departments. Also, list the average salary of the department with the highest average salary.

Using a common table expression for this case saves the overhead of creating the DINFO view as a regular view. Because of the context of the rest of the fullselect, only the rows for the department of the sales representatives need to be considered by the view.

```

WITH
  DINFO (DEPTNO, AVGSALARY, EMPCOUNT) AS
    (SELECT OTHERS.WORKDEPT, AVG(OTHERS.SALARY), COUNT(*)
     FROM EMPLOYEE OTHERS
     GROUP BY OTHERS.WORKDEPT),
  DINFOMAX AS
    (SELECT MAX(AVGSALARY) AS AVGMAX
     FROM DINFO)
SELECT THIS_EMP.EMPNO, THIS_EMP.SALARY, DINFO.AVGSALARY, DINFO.EMPCOUNT,
       DINFOMAX.AVGMAX
FROM EMPLOYEE THIS_EMP, DINFO, DINFOMAX
WHERE THIS_EMP.JOB = 'SALESREP'
AND THIS_EMP.WORKDEPT = DINFO.DEPTNO

```

Example 8

Find the average charges for each subscriber (SNO) in the state of California during the last Friday of each month in the first quarter of 2000. Group the result according to SNO. Each MONTHnn table has columns for SNO, CHARGES, and DATE. The CUST table has columns for SNO and STATE.

```

SELECT V.SNO, AVG(V.CHARGES)
FROM CUST, LATERAL (
  SELECT SNO, CHARGES, DATE
  FROM MONTH1
  WHERE DATE BETWEEN '01/01/2000' AND '01/31/2000'
  UNION ALL
  SELECT SNO, CHARGES, DATE
  FROM MONTH2
  WHERE DATE BETWEEN '02/01/2000' AND '02/29/2000'
  UNION ALL
  SELECT SNO, CHARGES, DATE
  FROM MONTH3
  WHERE DATE BETWEEN '03/01/2000' AND '03/31/2000'
) AS V (SNO, CHARGES, DATE)
WHERE CUST.SNO=V.SNO
AND CUST.STATE='CA'
AND DATE IN ('01/28/2000', '02/25/2000', '03/31/2000')
GROUP BY V.SNO

```

Chapter 7. Statements

This section contains syntax diagrams, semantic descriptions, rules, and examples of the use of the SQL statements.

The statements are listed in the following table.

SQL Statement	Description	Page
ALTER FUNCTION (external scalar)	Alters the description of an external scalar function	“ALTER FUNCTION (external scalar)” on page 820
ALTER FUNCTION (external table)	Alters the description of an external table function	“ALTER FUNCTION (external table)” on page 825
ALTER FUNCTION (SQL scalar)	Alters the description of an SQL scalar function	“ALTER FUNCTION (SQL scalar)” on page 830
ALTER FUNCTION (SQL table)	Alters the description of an SQL table function	“ALTER FUNCTION (SQL table)” on page 837
ALTER MASK	Alters the state of a mask	“ALTER MASK” on page 845
ALTER PERMISSION	Alters the state of a permission	“ALTER PERMISSION” on page 847
ALTER PROCEDURE (external)	Alters the description of an external procedure	“ALTER PROCEDURE (external)” on page 849
ALTER PROCEDURE (SQL)	Alters the description of an SQL procedure	“ALTER PROCEDURE (SQL)” on page 854
ALTER SEQUENCE	Alters the description of a sequence	“ALTER SEQUENCE” on page 864
ALTER TABLE	Alters the description of a table	“ALTER TABLE” on page 869
ALTER TRIGGER	Alters the description of a trigger	“ALTER TRIGGER” on page 920
COMMENT	Adds or replaces a comment to the description of an object	“COMMENT” on page 940
CREATE ALIAS	Creates an alias	“CREATE ALIAS” on page 971
CREATE FUNCTION	Creates a user-defined function	“CREATE FUNCTION” on page 975
CREATE FUNCTION (external scalar)	Creates an external scalar function	“CREATE FUNCTION (external scalar)” on page 980
CREATE FUNCTION (external table)	Creates an external table function	“CREATE FUNCTION (external table)” on page 1000
CREATE FUNCTION (sourced)	Creates a user-defined function based on another existing scalar or aggregate function	“CREATE FUNCTION (sourced)” on page 1018

Table 77. SQL Schema Statements (continued)

SQL Statement	Description	Page
CREATE FUNCTION (SQL scalar)	Creates an SQL scalar function	“CREATE FUNCTION (SQL scalar)” on page 1028
CREATE FUNCTION (SQL table)	Creates an SQL table function	“CREATE FUNCTION (SQL table)” on page 1042
CREATE INDEX	Creates an index on a table	“CREATE INDEX” on page 1055
CREATE MASK	Creates a column mask for a table	“CREATE MASK” on page 1064
CREATE PERMISSION	Creates a row permission for a table	“CREATE PERMISSION” on page 1070
CREATE PROCEDURE	Creates a procedure.	“CREATE PROCEDURE” on page 1074
CREATE PROCEDURE (external)	Creates an external procedure.	“CREATE PROCEDURE (external)” on page 1075
CREATE PROCEDURE (SQL)	Creates an SQL procedure.	“CREATE PROCEDURE (SQL)” on page 1090
CREATE SCHEMA	Creates a schema and a set of objects in that schema	“CREATE SCHEMA” on page 1103
CREATE SEQUENCE	Creates a sequence	“CREATE SEQUENCE” on page 1108
CREATE TABLE	Creates a table	“CREATE TABLE” on page 1115
CREATE TRIGGER	Creates a trigger	“CREATE TRIGGER” on page 1170
CREATE TYPE	Creates a type	“CREATE TYPE (distinct)” on page 1193
CREATE VARIABLE	Creates a global variable	“CREATE VARIABLE” on page 1200
CREATE VIEW	Creates a view of one or more tables or views	“CREATE VIEW” on page 1206
DROP	Drops an alias, function, index, package, procedure, schema, sequence, table, trigger, type, variable, view, or XSR object.	“DROP” on page 1288
GRANT (function or procedure privileges)	Grants privileges on a function or procedure	“GRANT (function or procedure privileges)” on page 1357
GRANT (variable privileges)	Grants privileges on a global variable	“GRANT (variable privileges)” on page 1385
GRANT (package privileges)	Grants privileges on a package	“GRANT (package privileges)” on page 1365
GRANT (schema privileges)	Grants privileges on a schema	“GRANT (schema privileges)” on page 1368

Table 77. SQL Schema Statements (continued)

SQL Statement	Description	Page
GRANT (sequence privileges)	Grants privileges on a sequence	“GRANT (sequence privileges)” on page 1371
GRANT (table or view privileges)	Grants privileges on a table or view	“GRANT (table or view privileges)” on page 1374
GRANT (type privileges)	Grants privileges on a type	“GRANT (type privileges)” on page 1382
GRANT (XML schema privileges)	Grants privileges on an XML schema	“GRANT (XML schema privileges)” on page 1388
LABEL	Adds or replaces a label to the description of an object	“LABEL” on page 1407
RENAME	Renames a table, view, or index.	“RENAME” on page 1458
REVOKE (function or procedure privileges)	Revokes privileges on a function or procedure	“REVOKE (function or procedure privileges)” on page 1461
REVOKE (variable privileges)	Revokes privileges on a global variable	“REVOKE (variable privileges)” on page 1478
REVOKE (package privileges)	Revokes the privilege to execute statements in a package	“REVOKE (package privileges)” on page 1467
REVOKE (schema privileges)	Revokes privileges on a schema	“REVOKE (schema privileges)” on page 1469
REVOKE (sequence privileges)	Revokes privileges on a sequence	“REVOKE (sequence privileges)” on page 1471
REVOKE (table or view privileges)	Revokes privileges on a table or view	“REVOKE (table or view privileges)” on page 1473
REVOKE (type privileges)	Revokes the privilege to use a type	“REVOKE (type privileges)” on page 1476
REVOKE (XML schema privileges)	Revokes privileges on an XML schema	“REVOKE (XML schema privileges)” on page 1480
TRANSFER OWNERSHIP	Transfers ownership of an object to a different authorization ID	“TRANSFER OWNERSHIP” on page 1555

Table 78. SQL Data Change Statements

SQL Statement	Description	Page
DELETE	Deletes one or more rows from a table	“DELETE” on page 1259
INSERT	Inserts one or more rows into a table	“INSERT” on page 1395
MERGE	Updates a target table using data from a source table	“MERGE” on page 1418
TRUNCATE	Deletes all the rows from a table	“TRUNCATE” on page 1558
UPDATE	Updates the values of one or more columns in one or more rows of a table	“UPDATE” on page 1561

Table 79. SQL Data Statements

SQL Statement	Description	Page
	All SQL data change statements	Table 78 on page 807
ALLOCATE CURSOR	Allocates a cursor for the result set identified by the result set locator variable.	“ALLOCATE CURSOR” on page 817
ASSOCIATE LOCATORS	Gets the result set locator value for each result set returned by a procedure.	“ASSOCIATE LOCATORS” on page 923
CLOSE	Closes a cursor	“CLOSE” on page 938
DECLARE CURSOR	Defines an SQL cursor	“DECLARE CURSOR” on page 1215
FETCH	Positions a cursor on a row of the result table; can also assign values from one or more rows of the result table to variables	“FETCH” on page 1311
FREE LOCATOR	Removes the association between a LOB locator variable and its value	“FREE LOCATOR” on page 1318
HOLD LOCATOR	Allows a LOB locator variable to retain its association with a value beyond a unit of work	“HOLD LOCATOR” on page 1391
LOCK TABLE	Either prevents concurrent processes from changing a table or prevents concurrent processes from using a table	“LOCK TABLE” on page 1416
OPEN	Opens a cursor	“OPEN” on page 1429
REFRESH TABLE	Refreshes the data in a materialized query table	“REFRESH TABLE” on page 1453
SELECT	Executes a query	“SELECT” on page 1488
SELECT INTO	Assigns values to variables	“SELECT INTO” on page 1489
SET transition-variable	Assigns values to a transition variable	“SET transition-variable” on page 1546
SET variable	Assigns values to a variable	“SET variable” on page 1548
VALUES	Executes a query.	“VALUES” on page 1572
VALUES INTO	Specifies a result table of no more than one row and assigns the values to variables.	“VALUES INTO” on page 1573

Table 80. SQL Transaction Statements

SQL Statement	Description	Page
COMMIT	Ends a unit of work and commits the database changes made by that unit of work	“COMMIT” on page 950
RELEASE SAVEPOINT	Releases a savepoint within a unit of work	“RELEASE SAVEPOINT” on page 1457
ROLLBACK	Ends a unit of work and backs out the database changes made by that unit of work or made since the specified savepoint	“ROLLBACK” on page 1482

Table 80. SQL Transaction Statements (continued)

SQL Statement	Description	Page
SAVEPOINT	Sets a savepoint within a unit of work	“SAVEPOINT” on page 1486
SET TRANSACTION	Changes the isolation level for the current unit of work	“SET TRANSACTION” on page 1543

Table 81. SQL Connection Statements

SQL Statement	Description	Page
CONNECT (type 1)	Connects to an application server and establishes the rules for remote unit of work	“CONNECT (type 1)” on page 962
CONNECT (type 2)	Connects to an application server and establishes the rules for application-directed distributed unit of work	“CONNECT (type 2)” on page 967
DISCONNECT	Immediately ends one or more connections	“DISCONNECT” on page 1286
RELEASE (connection)	Places one or more connections in the release-pending state	“RELEASE (connection)” on page 1455
SET CONNECTION	Establishes the application server of the process by identifying one of its existing connections	“SET CONNECTION” on page 1492

Table 82. SQL Dynamic Statements

SQL Statement	Description	Page
ALLOCATE DESCRIPTOR	Allocates an SQL descriptor	“ALLOCATE DESCRIPTOR” on page 818
Compound (dynamic)	Groups other statements together in an executable routine	“compound (dynamic)” on page 953
DEALLOCATE DESCRIPTOR	Deallocates an SQL descriptor	“DEALLOCATE DESCRIPTOR” on page 1214
DESCRIBE	Describes the result columns of a prepared statement	“DESCRIBE” on page 1266
DESCRIBE CURSOR	Describes the cursor.	“DESCRIBE CURSOR” on page 1271
DESCRIBE INPUT	Describes the input parameter markers of a prepared statement	“DESCRIBE INPUT” on page 1273
DESCRIBE PROCEDURE	Describes the result sets returned by a procedure.	“DESCRIBE PROCEDURE” on page 1276
DESCRIBE TABLE	Describes the columns of a table or view	“DESCRIBE TABLE” on page 1282
EXECUTE	Executes a prepared SQL statement	“EXECUTE” on page 1304
EXECUTE IMMEDIATE	Prepares and executes an SQL statement	“EXECUTE IMMEDIATE” on page 1309
GET DESCRIPTOR	Gets information from an SQL descriptor	“GET DESCRIPTOR” on page 1319

Table 82. SQL Dynamic Statements (continued)

SQL Statement	Description	Page
PREPARE	Prepares an SQL statement for execution	“PREPARE” on page 1435
SET DESCRIPTOR	Sets items in an SQL descriptor	“SET DESCRIPTOR” on page 1505

Table 83. SQL Session Statements

SQL Statement	Description	Page
DECLARE GLOBAL TEMPORARY TABLE	Defines a declared temporary table	“DECLARE GLOBAL TEMPORARY TABLE” on page 1223
SET CURRENT DEBUG MODE	Assigns a value to the CURRENT DEBUG MODE special register	“SET CURRENT DEBUG MODE” on page 1495
SET CURRENT DECFLOAT ROUNDING MODE	Assigns a value to the CURRENT DECFLOAT ROUNDING MODE special register	“SET CURRENT DECFLOAT ROUNDING MODE” on page 1497
SET CURRENT DEGREE	Assigns a value to the CURRENT DEGREE special register	“SET CURRENT DEGREE” on page 1499
SET CURRENT IMPLICIT XMLPARSE OPTION	Assigns a value to the CURRENT IMPLICIT XMLPARSE OPTION special register	“SET CURRENT IMPLICIT XMLPARSE OPTION” on page 1502
SET CURRENT TEMPORAL SYSTEM_TIME	Assigns a value to the CURRENT TEMPORAL SYSTEM_TIME special register	“SET CURRENT TEMPORAL SYSTEM_TIME” on page 1504
SET ENCRYPTION PASSWORD	Assigns a value to the default encryption password and default encryption password hint	“SET ENCRYPTION PASSWORD” on page 1510
SET PATH	Assigns a value to the CURRENT PATH special register	“SET PATH” on page 1531
SET SCHEMA	Assigns a value to the CURRENT SCHEMA special register	“SET SCHEMA” on page 1537
SET SESSION AUTHORIZATION	Changes the user of the job and the USER special register	“SET SESSION AUTHORIZATION” on page 1540

Table 84. SQL Embedded Host Language Statements

SQL Statement	Description	Page
BEGIN DECLARE SECTION	Marks the beginning of an SQL declare section	“BEGIN DECLARE SECTION” on page 928
CALL	Calls a procedure	“CALL” on page 930
DECLARE PROCEDURE	Defines an external procedure	“DECLARE PROCEDURE” on page 1244
DECLARE STATEMENT	Declares the names used to identify prepared SQL statements	“DECLARE STATEMENT” on page 1254

Table 84. SQL Embedded Host Language Statements (continued)

SQL Statement	Description	Page
DECLARE VARIABLE	Declares a subtype or normalized other than the default for a host variable	“DECLARE VARIABLE” on page 1256
END DECLARE SECTION	Marks the end of an SQL declare section	“END DECLARE SECTION” on page 1303
GET DIAGNOSTICS	Obtains information about the previously executed SQL statement	“GET DIAGNOSTICS” on page 1332
INCLUDE	Inserts declarations into a source program	“INCLUDE” on page 1393
SET OPTION	Establishes the options for processing SQL statements	“SET OPTION” on page 1512
SET RESULT SETS	Identifies the result sets in a procedure	“SET RESULT SETS” on page 1534
SIGNAL	Signals an error or warning condition	“SIGNAL” on page 1551
TAG	Identifies the branch location for a WHENEVER statement in ILE RPG.	“TAG” on page 1554
WHENEVER	Defines actions to be taken on the basis of SQL return codes	“WHENEVER” on page 1576

Table 85. SQL Control Statements

SQL Statement	Description	Page
assignment-statement	Assigns a value to an output parameter or to a local variable	“assignment-statement” on page 1590
CALL	Calls a procedure	“CALL statement” on page 1593
CASE	Selects an execution path based on multiple conditions	“CASE statement” on page 1595
compound-statement	Groups other statements together in an SQL routine	“compound-statement” on page 1597
FOR	Executes a statement for each row of a table	“FOR statement” on page 1605
GET DIAGNOSTICS	Obtains information about the previously executed SQL statement	“GET DIAGNOSTICS statement” on page 1607
GOTO	Branches to a user-defined label within an SQL routine or trigger	“GOTO statement” on page 1615
IF	Provides conditional execution based on the truth value of a condition	“IF statement” on page 1617
ITERATE	Causes the flow of control to return to the beginning of a labeled loop	“ITERATE statement” on page 1622
LEAVE	Continues execution by leaving a block or loop	“LEAVE statement” on page 1624
LOOP	Repeats the execution of a statement	“LOOP statement” on page 1625

SQL Statement	Description	Page
REPEAT	Repeats the execution of a statement	“REPEAT statement” on page 1628
RESIGNAL	Resignals an error or warning condition	“RESIGNAL statement” on page 1630
RETURN	Returns from a routine	“RETURN statement” on page 1634
SIGNAL	Signals an error or warning condition	“SIGNAL statement” on page 1637
WHILE	Repeats the execution of a statement while a specified condition is true	“WHILE statement” on page 1641

How SQL statements are invoked

The SQL statements described in this chapter are classified as *executable* or *nonexecutable*. The *Invocation* section in the description of each statement indicates whether the statement is executable.

An *executable statement* can be invoked in any of the following ways:

- Embedded in an application program
- Dynamically prepared and executed
- Issued interactively

Note: Statements embedded in REXX or processed using RUNSQLSTM are prepared and executed dynamically.

Depending on the statement, some or all of these methods can be used. The *Invocation* section in the description of each statement tells you which methods can be used.

A *nonexecutable statement* can only be embedded in an application program.

Embedding a statement in an application program

SQL statements can be included in a source program that will be submitted to the precompiler by using the CRTSQLCBL, CRTSQLCBLI, CRTSQLCI, CRTSQLCPPI, CRTSQLPLI, CRTSQLRPG, or CRTSQLRPGI commands. Such statements are said to be *embedded* in the program.

An embedded statement can be placed anywhere in the program where a host language statement is allowed. Each embedded statement must be preceded by a keyword (or keywords) to indicate that the statement is an SQL statement:

- In C, COBOL, PL/I, and RPG, each embedded statement must be preceded by the keywords EXEC and SQL.
- In Java, each embedded statement must be preceded by the keywords #sql.
- In REXX, each embedded statement must be preceded by the keyword EXECSQL.

Executable statements

An executable statement embedded in an application program is executed every time a statement of the host language would be executed if specified in the same place. This means that a statement within a loop is executed every time the loop is executed, and a statement within a conditional construct is executed only when the condition is satisfied.

An embedded statement can contain references to variables. A variable referenced in this way can be used in two ways:

- As input (the current value of the variable is used in the execution of the statement)
- As output (the variable is assigned a new value as a result of executing the statement)

In particular, all references to variables in expressions and predicates are effectively replaced by current values of the variables; that is, the variables are used as input. The treatment of other references is described individually for each statement.

Follow all executable statements with a test of the SQL return state or the SQL return code. Alternatively, the `WHENEVER` statement (which is itself nonexecutable) can be used to change the flow of control immediately after the execution of an embedded statement.

Objects referenced in SQL statements need not exist when the statements are prepared.

Nonexecutable statements

An embedded nonexecutable statement is processed only by the precompiler. The precompiler reports any errors encountered in the statement. The statement is *never* executed, and acts as a no-operation if placed among executable statements of the application program. Therefore, do not follow such statements by a test of an SQL return code.

Dynamic preparation and execution

An application program can dynamically build an SQL statement in the form of a character string placed in a variable. In general, the statement is built from some data available to the program (for example, input from a workstation).

The statement can be prepared for execution using the (embedded) statement `PREPARE` and executed by the (embedded) statement `EXECUTE`. Alternatively, the (embedded) statement `EXECUTE IMMEDIATE` can be used to prepare and execute a statement in one step. In Java, the statement can be prepared for execution by means of the `Statement`, `PreparedStatement`, and `CallableStatement` classes, and executed by means of their respective `execute()` methods.

A statement that is dynamically prepared must not contain references to host variables. Instead, the statement can contain parameter markers. See [“PREPARE” on page 1435](#) for rules concerning the parameter markers. When the prepared statement is executed, the parameter markers are effectively replaced by the current values of the variables specified in the `EXECUTE` statement. See [“EXECUTE” on page 1304](#) for rules concerning this replacement. After a statement is prepared, it can be executed several times with different values of variables. Parameter markers are not allowed in `EXECUTE IMMEDIATE`.

In C, COBOL, PL/I, REXX, and RPG, the successful or unsuccessful execution of the statement is indicated by the values returned in the stand-alone `SQLCODE` or `SQLSTATE` after the `EXECUTE` (or `EXECUTE IMMEDIATE`) statement. The SQL return code should be checked as described above for embedded statements. See the topic [“SQL diagnostic information” on page 814](#) for more information. In Java, the successful or unsuccessful execution of the statement is handled by Java Exceptions.

Static invocation of a select-statement

A *select-statement* can be included as a part of the (nonexecutable) statement `DECLARE CURSOR`.

Such a statement is executed every time the cursor is opened by means of the (embedded) statement `OPEN`. After the cursor is open, the result table can be retrieved one row at a time by successive executions of the `FETCH` statement or multiple rows at a time by using the multiple-row `FETCH` statement.

Used in this way, the *select-statement* can contain references to variables. These references are effectively replaced by the values that the variables have at the moment of executing `OPEN`.

Dynamic invocation of a select-statement

An application program can dynamically build a *select-statement* in the form of a character string placed in a variable.

In general, the statement is built from some data available to the program (for example, a query obtained from a workstation). The statement is then executed every time the cursor is opened by means of the (embedded) statement OPEN. After the cursor is open, the result table can be retrieved one row at a time by successive executions of the FETCH statement or multiple rows at a time by using the multiple-row FETCH statement.

Used in this way, the *select-statement* must not contain references to variables. It can instead contain parameter markers. See [“PREPARE” on page 1435](#) for rules concerning the parameter markers. The parameter markers are effectively replaced by the values of the variables specified in the OPEN statement. See [“OPEN” on page 1429](#) for rules concerning this replacement.

Interactive invocation

A capability for entering SQL statements from a workstation is part of the architecture of the database manager. A statement entered in this way is said to be issued interactively.

A statement issued interactively must be an executable statement that does not contain parameter markers or references to variables, because these make sense only in the context of an application program.

The Db2 for i database provides the Start Structured Query Language (STRSQL) command, the Start Query Manager (STRQM) command, and the Run SQL Script support of System i Navigator for this facility. Other products are also available.

SQL diagnostic information

The database manager uses a diagnostics area to store status information and diagnostic information about the execution of an executable SQL statement. When an SQL statement other than GET DIAGNOSTICS or *compound-statement* is processed, the current diagnostics area is cleared, before processing the SQL statement. As each SQL statement is processed, information about the execution of that SQL statement is recorded in the current diagnostics area as one or more completion conditions or exception conditions.

A completion condition indicates the SQL statement completed successfully, completed with a warning condition, or completed with a not found condition. An exception condition indicates that the statement was not successful. The GET DIAGNOSTICS statement can be used in most languages to return conditions and other information about the previously executed SQL statement from the diagnostics area. For more information, see [“GET DIAGNOSTICS” on page 1332](#). Additionally, the condition information is provided through language specific mechanisms:

- For SQL procedures, SQL functions, and SQL triggers, see [“SQL-procedure-statement” on page 1586](#).
- For host languages, see [“Detecting and processing error and warning conditions in host language applications” on page 814](#).

Detecting and processing error and warning conditions in host language applications

Each host language provides a mechanism for handling diagnostic information:

- In C, COBOL, and PL/I, an application program containing executable SQL statements must provide at least one of the following:
 - A structure named SQLCA.
 - A stand-alone CHAR(5) (CHAR(6) in C) variable named SQLSTATE.
 - A stand-alone integer variable named SQLCODE.

A stand-alone SQLSTATE or SQLCODE must not be declared in a host structure. Both a stand-alone SQLSTATE and SQLCODE may be provided.

An SQLCA can be obtained by using the INCLUDE SQLCA statement. If an SQLCA is provided, neither a stand-alone SQLSTATE or SQLCODE can be provided. The SQLCA includes a character-string variable named SQLSTATE and an integer variable named SQLCODE.

A stand-alone SQLSTATE should be used to conform with the SQL 2003 Core standard.

- In Java, for error conditions, the getSQLState method can be used to get the SQLSTATE and the getErrorCode method can be used to get the SQLCODE.
- In REXX and RPG, an SQLCA is provided automatically.

SQLSTATE

The database manager sets SQLSTATE after each SQL statement (other than GET DIAGNOSTICS or a compound statement) is executed. Thus, application programs can check the execution of SQL statements by testing SQLSTATE instead of SQLCODE.

SQLSTATE provides application programs with common codes for common error conditions. Furthermore, SQLSTATE is designed so that application programs can test for specific errors or classes of errors. The scheme is the same for all database managers and is based on the ISO/ANSI SQL 2003 Core standard. A complete list of SQLSTATE classes and SQLSTATEs associated with each SQLCODE is supplied in the [SQL Messages and Codes](#) topic collection.

SQLCODE

The database manager sets SQLCODE after each SQL statement (other than GET DIAGNOSTICS or a compound statement) is executed. SQLCODE is set as follows:

- If SQLCODE = 0 and SQLWARN0 is blank, execution was successful.
- If SQLCODE = 100, no data was found. For example, a FETCH statement returned no data, because the cursor was positioned after the last row of the result table.
- If SQLCODE > 0 and not = 100, execution was successful with a warning.
- If SQLCODE = 0 and SQLWARN0 = 'W', execution was successful with a warning.
- If SQLCODE < 0, execution was not successful.

A complete listing of Db2 for i SQLCODEs and their corresponding SQLSTATEs is provided in the [SQL Messages and Codes](#) topic collection.

SQL comments

In most host languages, static SQL statements can include host language or SQL comments. In Java and REXX, static SQL statements cannot include host language or SQL comments.

Dynamic SQL statements can include SQL comments.

There are two types of SQL comments:

simple comments

Simple comments are introduced by two consecutive hyphens.

bracketed comments

Bracketed comments are introduced by /* and end with */.

These rules apply to the use of simple comments:

- The two hyphens must be on the same line and must not be separated by a space.
- Simple comments can be started wherever a space is valid (except within a delimiter token or between 'EXEC' and 'SQL').
- Simple comments cannot be continued to the next line.

- In COBOL, the hyphens must be preceded by a space.

These rules apply to the use of bracketed comments:

- The /* must be on the same line and not separated by a space.
- The */ must be on the same line and not separated by a space.
- Bracketed comments can be started wherever a space is valid (except within a delimiter token or between 'EXEC' and 'SQL').
- Bracketed comments can be continued to the next line.
- Bracketed comments can be nested within other bracketed comments.

A comment embedded in an SQL statement that precedes a name (such as a table name) may cause object names in the text saved for a view, trigger, variable, or MQT to not be maintained correctly. Similarly, names in rows of a dependency view (such as SYSTRIGDEP) may not be correctly qualified.

Example 1

This example shows how to include simple comments in a statement:

```
CREATE VIEW PRJ_MAXPER      -- PROJECTS WITH MOST SUPPORT PERSONNEL
AS SELECT PROJNO, PROJNAME -- NUMBER AND NAME OF PROJECT
FROM PROJECT
WHERE DEPTNO = 'E21'      -- SYSTEMS SUPPORT DEPT CODE
AND PRSTAFF > 1
```

Example 2

This example shows how to include bracketed comments in a statement:

```
CREATE VIEW PRJ_MAXPER      /* PROJECTS WITH MOST SUPPORT
                             PERSONNEL */
AS SELECT PROJNO, PROJNAME /* NUMBER AND NAME OF PROJECT */
FROM PROJECT
WHERE DEPTNO = 'E21'      /* SYSTEMS SUPPORT DEPT CODE */
AND PRSTAFF > 1
```

ALLOCATE CURSOR

The ALLOCATE CURSOR statement defines a cursor and associates it with a result set locator variable.

Invocation

This statement can be embedded in an application program. It is an executable statement that can be dynamically prepared. It cannot be issued interactively. It must not be specified in REXX.

Authorization

None required.

Syntax

```
➤ ALLOCATE — cursor-name — CURSOR FOR RESULT SET — rs-locator-variable ➤
```

Description

cursor-name

Names the cursor. The name must not identify a cursor that has already been declared in the source program.

CURSOR FOR RESULT SET *rs-locator-variable*

Specifies a result set locator variable that has been declared in the application program according to the rules for declaring result set locator variables.

The result set locator variable must contain a valid result set locator value as returned by the ASSOCIATE LOCATORS or DESCRIBE PROCEDURE SQL statement. The value of the result set locator variable is used at the time the cursor is allocated. Subsequent changes to the value of the result set locator have no effect on the allocated cursor. The result set locator value must not be the same as a value used for another cursor allocated in the source program.

Rules

- The following rules apply when you use an allocated cursor:
 - You cannot open an allocated cursor with the OPEN statement.
 - You can close an allocated cursor with the CLOSE statement. Closing an allocated cursor closes the associated cursor defined in the stored procedure.
 - You can allocate only one cursor to each result set.
- Allocated cursors follow the same rules as declared cursors in a program with the CLOSQLCSR option. The CLOSQLCSR option can be specified on the CRTSQLxxx command or using the SET OPTION statement.
- A commit operation closes allocated cursors that were declared without the WITH HOLD clause by the procedure including any that are running with a commit level of *NONE.
- Closing an allocated cursor closes the associated cursor in the procedure.

Example

This SQL procedure example defines and associates cursor C1 with the result set locator variable LOC1 and the related result set returned by the SQL procedure:

```
ALLOCATE C1 CURSOR FOR RESULT SET LOC1;
```

ALLOCATE DESCRIPTOR

The ALLOCATE DESCRIPTOR statement allocates an SQL descriptor.

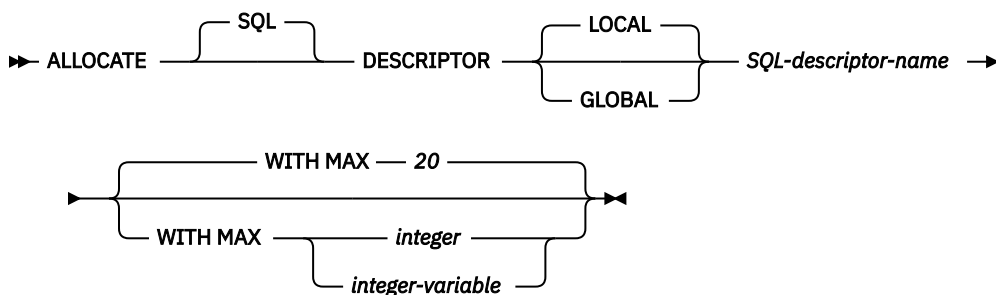

Invocation

This statement can only be embedded in an application program, SQL function, SQL procedure, or trigger. It cannot be issued interactively. It is an executable statement that cannot be dynamically prepared. It must not be specified in REXX.

Authorization

None required.

Syntax

Description

LOCAL

Defines the scope of the name of the descriptor to be local to the program invocation. The descriptor will not be known outside this scope. For example, a program called from another separately compiled program cannot use a descriptor that was allocated by the calling program. The scope of the descriptor is also limited to the thread in which the program that contains the descriptor is running. For example, if the same program is running in two separate threads in the same job, the second thread cannot use a descriptor that was allocated by the first thread.

GLOBAL

Defines the scope of the name of the descriptor to be global to the SQL session. The descriptor will be known to any program that executes using the same database connection.

SQL-descriptor-name

Names the descriptor to allocate. The name must not be the same as a descriptor that already exists with the specified scope.

WITH MAX

The descriptor is allocated to support the specified maximum number of items. If this clause is not specified, the descriptor is allocated with a maximum of 20 items.

integer

Specifies the number of items to allocate. The value of *integer* must be greater than zero and not greater than 8000.

integer-variable

Specifies an integer variable (or decimal or numeric variable with zero scale) that contains the number of items to allocate. It cannot be a global variable. The value of *integer-variable* must be greater than zero and not greater than 8000.

Notes

Descriptor persistence: Local descriptors are implicitly deallocated based on the CLOSQLCSR option:

- For ILE programs, if CLOSQLCSR(*ENDACTGRP) is specified (the default), local descriptors are implicitly deallocated when the activation group ends. If CLOSQLCSR(*ENDMOD) is specified, local descriptors are implicitly deallocated on exit from the module.
- For OPM programs, if CLOSQLCSR(*ENDPGM) is specified (the default), local descriptors are implicitly deallocated when the program ends. If CLOSQLCSR(*ENDSQL) is specified, local descriptors are implicitly deallocated when the first SQL program on the call stack ends. If CLOSQLCSR(*ENDJOB) is specified, local descriptors are implicitly deallocated when the job ends.

Global descriptors are implicitly deallocated when the activation group ends.

Both local and global descriptors can be explicitly deallocated using the DEALLOCATE DESCRIPTOR statement.

Examples

Allocate a descriptor called 'NEWDA' large enough to hold 20 items.

```
EXEC SQL ALLOCATE DESCRIPTOR 'NEWDA'  
WITH MAX 20
```

ALTER FUNCTION (external scalar)

The ALTER FUNCTION (external scalar) statement alters an external scalar function at the current server.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following:

- For the function identified in the statement:
 - The ALTER privilege for the function, and
 - The system authority *EXECUTE on the library containing the function.
- Database administrator authority

If a different external program is specified, the privileges held by the authorization ID of the statement must also include the same privileges required to create a new external scalar function. For more information, see [“CREATE FUNCTION \(external scalar\)”](#) on page 980.

If the SECURED option is specified or if the function is currently secure:

- The authorization ID of the statement must have security administrator authority. See [“Administrative authority”](#) on page 15.

For information about the system authorities corresponding to SQL privileges, see [Corresponding System Authorities When Checking Privileges to a Function or Procedure](#), [Corresponding System Authorities When Checking Privileges to a Table or View](#), and [Corresponding System Authorities When Checking Privileges to a Distinct Type](#).

Syntax

parameter-type

data-type

option-list

Notes:

¹ The clauses in the *option-list* can be specified in any order.

built-in-type

Description

FUNCTION or SPECIFIC FUNCTION

Identifies the function to alter. *function-name* must identify an external scalar function that exists at the current server. It cannot identify a built-in function, a sourced function, or an SQL function. An external table function cannot be altered to be an external scalar function.

The specified function is altered. The owner of the function is preserved. If the external program or service program exists at the time the function is altered, all privileges on the function are preserved.

FUNCTION *function-name*

Identifies the function by its name. The *function-name* must identify exactly one function. The function may have any number of parameters defined for it. If there is more than one function of the specified name in the specified or implicit schema, an error is returned.

FUNCTION *function-name (parameter-type,...)*

Identifies the function by its function signature, which uniquely identifies the function. The *function-name (parameter-type,...)* must identify a function with the specified function signature. The specified parameters must match the data types in the corresponding position that were specified when the function was created. The number of data types, and the logical concatenation of the data types is used to identify the specific function instance which is being altered. Synonyms for data types are considered a match. Parameters that have defaults must be included in this signature.

If *function-name()* is specified, the function identified must have zero parameters.

function-name

Identifies the name of the function.

(parameter-type,...)

Identifies the parameters of the function.

If an unqualified distinct type name is specified, the database manager searches the SQL path to resolve the schema name for the distinct type.

For data types that have a length, precision, or scale attribute, use one of the following:

- Empty parenthesis indicates that the database manager ignores the attribute when determining whether the data types match. For example, DEC() will be considered a match for a parameter of a function defined with a data type of DEC(7,2). However, FLOAT cannot be specified with empty parenthesis because its precision value indicates a specific data type (REAL or DOUBLE).
- If a specific value for a length, precision, or scale attribute is specified, the value must exactly match the value that was specified (implicitly or explicitly) in the CREATE FUNCTION statement. If the data type is FLOAT, the precision does not have to exactly match the value that was specified because matching is based on the data type (REAL or DOUBLE).
- If length, precision, or scale is not explicitly specified, and empty parentheses are not specified, the default attributes of the data type are implied. The implicit length must exactly match the value that was specified (implicitly or explicitly) in the CREATE FUNCTION statement.

Specifying the FOR DATA clause or CCSID clause is optional. Omission of either clause indicates that the database manager ignores the attribute when determining whether the data types match. If either clause is specified, it must match the value that was implicitly or explicitly specified in the CREATE FUNCTION statement.

AS LOCATOR

Specifies that the function is defined to receive a locator for this parameter. If AS LOCATOR is specified, the data type must be LOB or XML or a distinct type based on a LOB or XML.

SPECIFIC FUNCTION *specific-name*

Identifies the function by its specific name. The *specific-name* must identify a specific function that exists at the current server.

ALTER option-list

Indicates that one or more of the options of the function are to be altered. If an option is not specified, the value from the existing function definition is used. See [“CREATE FUNCTION \(external scalar\)”](#) on page 980 for a description of each option.

RESTRICT

Indicates that the function will not be altered if it is referenced by any view, function, procedure, or materialized query table.

Notes

General considerations for defining or replacing functions: See CREATE FUNCTION (external scalar) for general information about defining a function. ALTER FUNCTION (external scalar) allows individual attributes to be altered while preserving the privileges on the function.

Altering a function from NOT SECURED to SECURED: The function is considered secure after the ALTER FUNCTION statement is executed. Db2 treats the SECURED attribute as an assertion that declares that the user has established an audit procedure for all changes to the user-defined function. Db2 assumes that all subsequent ALTER FUNCTION statements are being reviewed through this audit process.

Invoking other user-defined functions in a secure function: When a secure user-defined function is referenced in an SQL data change statement that references a table that is using row access control or column access control, and if the secure user-defined function invokes other user-defined functions, the nested user-defined functions are not validated as secure. If those nested functions can access sensitive data, a user authorized to the Database Security Administrator function of IBM i needs to ensure that those functions are allowed to access that data and should ensure that a change control audit procedure has been established for all changes to those functions.

Syntax alternatives: The following keywords are synonyms supported for compatibility to prior releases. These keywords are non-standard and should not be used:

- The keywords VARIANT and NOT VARIANT can be used as synonyms for NOT DETERMINISTIC and DETERMINISTIC.
- The keywords NULL CALL and NOT NULL CALL can be used as synonyms for CALLED ON NULL INPUT and RETURNS NULL ON NULL INPUT.
- The keywords SIMPLE CALL can be used as a synonym for GENERAL.
- The keyword DB2GENRL may be used as a synonym for DB2GENERAL.
- The value DB2SQL may be used as a synonym for SQL.
- The keywords PARAMETER STYLE in the PARAMETER STYLE clause are optional.
- The keywords IS DETERMINISTIC may be used as a synonym for DETERMINISTIC.

Example

Modify the definition for function MYFUNC to change the name of the external program that will be invoked when the function is invoked. The name of the external program is PROG10B.

```
ALTER FUNCTION MYFUNC  
EXTERNAL NAME PROG10B
```

ALTER FUNCTION (external table)

The ALTER FUNCTION (external table) statement alters an external table function at the current server.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following:

- For the function identified in the statement:
 - The ALTER privilege for the function, and
 - The system authority *EXECUTE on the library containing the function.
- Database administrator authority

If a different external program is specified, the privileges held by the authorization ID of the statement must also include the same privileges required to create a new external table function. For more information, see [“CREATE FUNCTION \(external table\)”](#) on page 1000.

If the SECURED option is specified or if the function is currently secure:

- The authorization ID of the statement must have security administrator authority. See [“Administrative authority”](#) on page 15.

For information about the system authorities corresponding to SQL privileges, see [Corresponding System Authorities When Checking Privileges to a Function or Procedure](#), [Corresponding System Authorities When Checking Privileges to a Table or View](#), and [Corresponding System Authorities When Checking Privileges to a Distinct Type](#).

Syntax

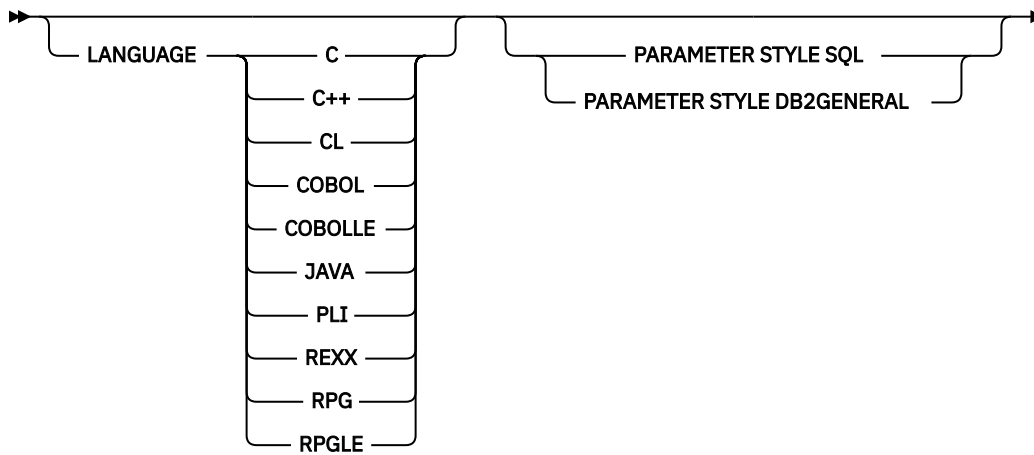

parameter-type

data-type

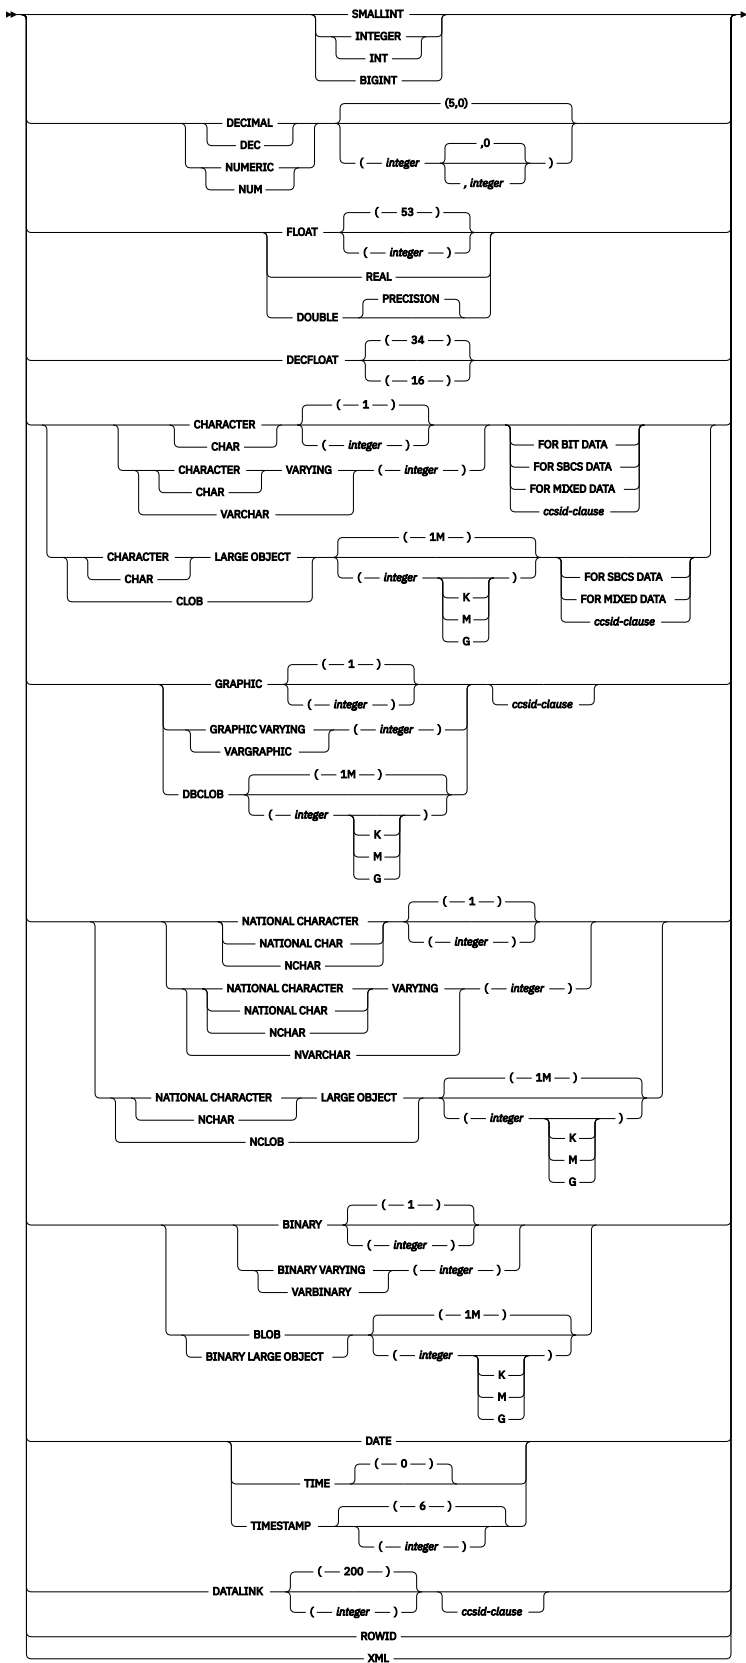

option-list

Notes:

¹ The clauses in the *option-list* can be specified in any order.

built-in-type

ccsid-clause

➤ CCSID — integer ➤

Description

FUNCTION or SPECIFIC FUNCTION

Identifies the function to alter. *function-name* must identify an external table function that exists at the current server. It cannot identify a built-in function, a sourced function, or an SQL function. An external scalar function cannot be altered to be an external table function.

The specified function is altered. The owner of the function is preserved. If the external program or service program exists at the time the function is altered, all privileges on the function are preserved.

FUNCTION *function-name*

Identifies the function by its name. The *function-name* must identify exactly one function. The function may have any number of parameters defined for it. If there is more than one function of the specified name in the specified or implicit schema, an error is returned.

FUNCTION *function-name (parameter-type,...)*

Identifies the function by its function signature, which uniquely identifies the function. The *function-name (parameter-type,...)* must identify a function with the specified function signature. The specified parameters must match the data types in the corresponding position that were specified when the function was created. The number of data types, and the logical concatenation of the data types is used to identify the specific function instance which is being altered. Synonyms for data types are considered a match. Parameters that have defaults must be included in this signature.

If *function-name()* is specified, the function identified must have zero parameters.

function-name

Identifies the name of the function.

(parameter-type,...)

Identifies the parameters of the function.

If an unqualified distinct type name is specified, the database manager searches the SQL path to resolve the schema name for the distinct type.

For data types that have a length, precision, or scale attribute, use one of the following:

- Empty parenthesis indicates that the database manager ignores the attribute when determining whether the data types match. For example, DEC() will be considered a match for a parameter of a function defined with a data type of DEC(7,2). However, FLOAT cannot be specified with empty parenthesis because its precision value indicates a specific data type (REAL or DOUBLE).
- If a specific value for a length, precision, or scale attribute is specified, the value must exactly match the value that was specified (implicitly or explicitly) in the CREATE FUNCTION statement. If the data type is FLOAT, the precision does not have to exactly match the value that was specified because matching is based on the data type (REAL or DOUBLE).
- If length, precision, or scale is not explicitly specified, and empty parentheses are not specified, the default attributes of the data type are implied. The implicit length must exactly match the value that was specified (implicitly or explicitly) in the CREATE FUNCTION statement.

Specifying the FOR DATA clause or CCSID clause is optional. Omission of either clause indicates that the database manager ignores the attribute when determining whether the data types match. If either clause is specified, it must match the value that was implicitly or explicitly specified in the CREATE FUNCTION statement.

AS LOCATOR

Specifies that the function is defined to receive a locator for this parameter. If AS LOCATOR is specified, the data type must be a LOB or XML or a distinct type based on a LOB or XML.

SPECIFIC FUNCTION *specific-name*

Identifies the function by its specific name. The *specific-name* must identify a specific function that exists at the current server.

ALTER option-list

Indicates that one or more of the options of the function are to be altered. If an option is not specified, the value from the existing function definition is used. See [“CREATE FUNCTION \(external table\)”](#) on page 1000 for a description of each option.

RESTRICT

Indicates that the function will not be altered if it is referenced by any view, function, procedure, or materialized query table.

Notes

General considerations for defining or replacing functions: See CREATE FUNCTION (external table) for general information about defining a function. ALTER FUNCTION (external table) allows individual attributes to be altered while preserving the privileges on the function.

Altering a function from NOT SECURED to SECURED: The function is considered secure after the ALTER FUNCTION statement is executed. Db2 treats the SECURED attribute as an assertion that declares that the user has established an audit procedure for all changes to the user-defined function. Db2 assumes that all subsequent ALTER FUNCTION statements are being reviewed through this audit process.

Invoking other user-defined functions in a secure function: When a secure user-defined function is referenced in an SQL data change statement that references a table that is using row access control or column access control, and if the secure user-defined function invokes other user-defined functions, the nested user-defined functions are not validated as secure. If those nested functions can access sensitive data, a user authorized to the Database Security Administrator function of IBM i needs to ensure that those functions are allowed to access that data and should ensure that a change control audit procedure has been established for all changes to those functions.

Syntax alternatives: The following keywords are synonyms supported for compatibility to prior releases. These keywords are non-standard and should not be used:

- The keywords VARIANT and NOT VARIANT can be used as synonyms for NOT DETERMINISTIC and DETERMINISTIC.
- The keywords NULL CALL and NOT NULL CALL can be used as synonyms for CALLED ON NULL INPUT and RETURNS NULL ON NULL INPUT.
- The keyword DB2GENRL may be used as a synonym for DB2GENERAL.
- The value DB2SQL may be used as a synonym for SQL.
- The keywords PARAMETER STYLE in the PARAMETER STYLE clause are optional.
- The keywords IS DETERMINISTIC may be used as a synonym for DETERMINISTIC.

Example

Modify the definition for an external table function to set the estimated cardinality to 10,000.

```
ALTER FUNCTION GET_TABLE  
ALTER CARDINALITY 10000
```

ALTER FUNCTION (SQL scalar)

The ALTER FUNCTION (SQL scalar) statement alters an SQL scalar function at the current server.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following:

- For the function identified in the statement:
 - The ALTER privilege for the function, and
 - The system authority *EXECUTE on the library containing the function.
- Database administrator authority

If a different external program is specified, the privileges held by the authorization ID of the statement must also include the same privileges required to create a new external scalar function. For more information, see [“CREATE FUNCTION \(SQL scalar\)”](#) on page 1028.

If the SECURED option is specified or if the function is currently secure:

- The authorization ID of the statement must have security administrator authority. See [“Administrative authority”](#) on page 15.

For information about the system authorities corresponding to SQL privileges, see [Corresponding System Authorities When Checking Privileges to a Function or Procedure](#), [Corresponding System Authorities When Checking Privileges to a Table or View](#), and [Corresponding System Authorities When Checking Privileges to a Distinct Type](#).

Syntax

parameter-type

data-type1, data-type2, data-type3

routine-specification

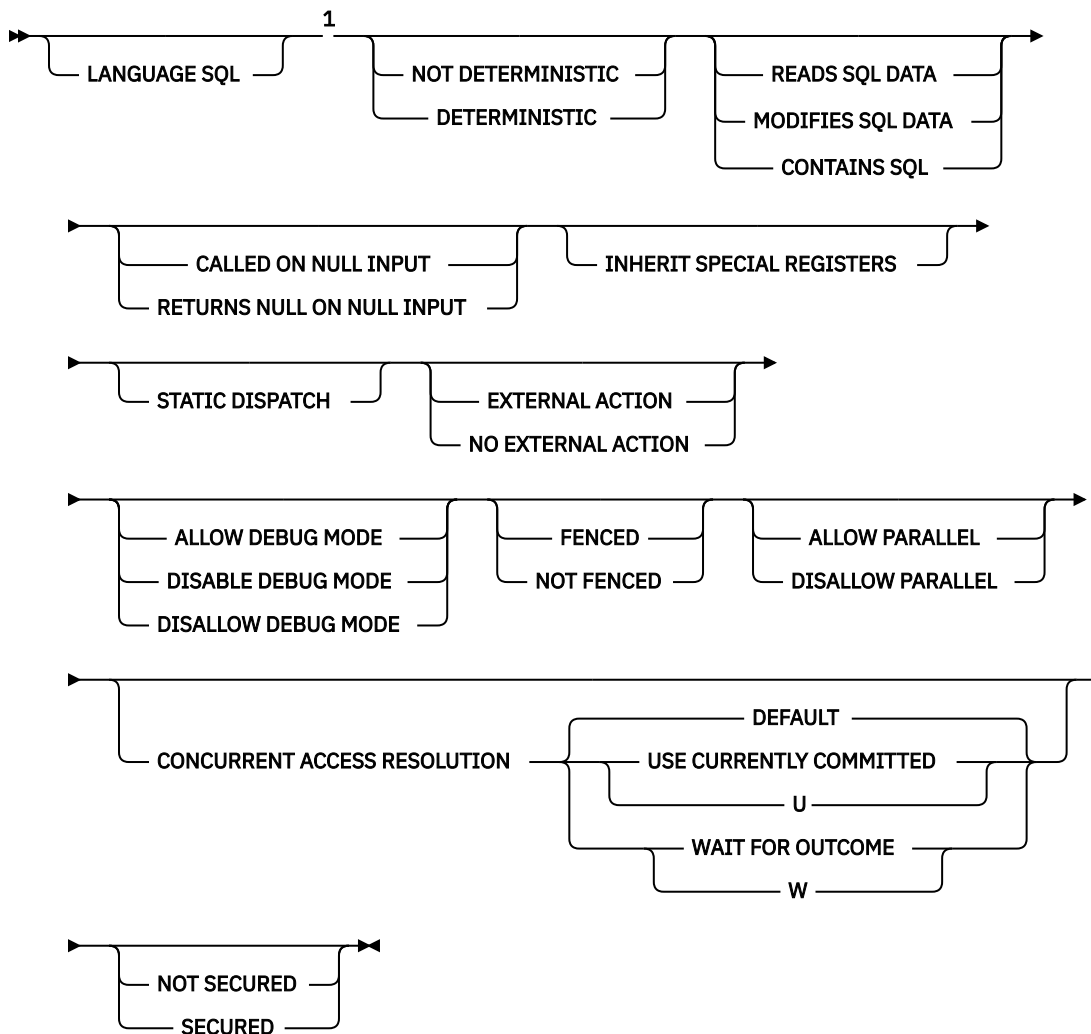

parameter-declaration

SQL-routine-body

option-list

Notes:

¹ The clauses in the *option-list* can be specified in any order.

built-in-type

Description

FUNCTION or SPECIFIC FUNCTION

Identifies the function to alter. *function-name* must identify an SQL scalar function that exists at the current server.

The specified function is altered. The owner of the function and all privileges on the function are preserved.

FUNCTION *function-name*

Identifies the function by its name. The *function-name* must identify exactly one function. The function may have any number of parameters defined for it. If there is more than one function of the specified name in the specified or implicit schema, an error is returned.

FUNCTION *function-name (parameter-type,...)*

Identifies the function by its function signature, which uniquely identifies the function. The *function-name (parameter-type,...)* must identify a function with the specified function signature. The specified parameters must match the data types in the corresponding position that were specified when the function was created. The number of data types, and the logical concatenation of the data types is used to identify the specific function instance which is being altered. Synonyms for data types are considered a match. Parameters that have defaults must be included in this signature.

If *function-name()* is specified, the function identified must have zero parameters.

function-name

Identifies the name of the function.

(parameter-type,...)

Identifies the parameters of the function.

If an unqualified distinct type name is specified, the database manager searches the SQL path to resolve the schema name for the distinct type.

For data types that have a length, precision, or scale attribute, use one of the following:

- Empty parenthesis indicates that the database manager ignores the attribute when determining whether the data types match. For example, DEC() will be considered a match for a parameter of a function defined with a data type of DEC(7,2). However, FLOAT cannot be specified with empty parenthesis because its precision value indicates a specific data type (REAL or DOUBLE).
- If a specific value for a length, precision, or scale attribute is specified, the value must exactly match the value that was specified (implicitly or explicitly) in the CREATE FUNCTION statement. If the data type is FLOAT, the precision does not have to exactly match the value that was specified because matching is based on the data type (REAL or DOUBLE).
- If length, precision, or scale is not explicitly specified, and empty parentheses are not specified, the default attributes of the data type are implied. The implicit length must exactly match the value that was specified (implicitly or explicitly) in the CREATE FUNCTION statement.

Specifying the FOR DATA clause or CCSID clause is optional. Omission of either clause indicates that the database manager ignores the attribute when determining whether the data types match. If either clause is specified, it must match the value that was implicitly or explicitly specified in the CREATE FUNCTION statement.

AS LOCATOR

Specifies that the function is defined to receive a locator for this parameter. If AS LOCATOR is specified, the data type must be a LOB or XML or a distinct type based on a LOB or XML.

SPECIFIC FUNCTION *specific-name*

Identifies the function by its specific name. The *specific-name* must identify a specific function that exists at the current server.

ALTER *option-list*

Indicates that one or more of the options of the function are to be altered. If ALTER FUNCTION ALTER *option-list* is specified and an option is not specified, the value from the existing function definition is used. See [“CREATE FUNCTION \(SQL scalar\)” on page 1028](#) for a description of each option.

REPLACE *routine-specification*

Indicates that the existing function definition, including options and parameters, is to be replaced by those specified in this statement. The values of all options are replaced when a function is replaced. If an option is not specified, the same default is used as when a new SQL scalar function is created, for more information see [“CREATE FUNCTION \(SQL scalar\)” on page 1028](#).

If the routine has a comment or label, they are removed from the routine definition.

RESTRICT

Indicates that the function will not be altered or replaced if it is referenced by any function, materialized query table, procedure, trigger, or view.

(*parameter-declaration,...*)

Specifies the number of parameters of the function, the data type of each parameter, and the name of each parameter.

The maximum number of parameters allowed in an SQL function is 2000.

parameter-name

Names the parameter. The name is used to refer to the parameter within the body of the function. The name cannot be the same as any other *parameter-name* in the parameter list.

data-type3

Specifies the data type of the input parameter. If a CCSID is specified, the parameter will be converted to that CCSID prior to passing it to the function. If a CCSID is not specified, the CCSID is determined by the default CCSID at the current server at the time the function is invoked.

default-clause

Specifies a default value for the parameter. The default can be a constant, a special register, a global variable, an expression, or the keyword NULL. The expression is any expression defined in [“Expressions” on page 158](#), that does not include an aggregate function or column name. If a default value is not specified, the parameter has no default and cannot be omitted on invocation. The maximum length of the expression string is 64K.

The default expression must be assignment compatible to the parameter data type.

Any comma in the default expression that is intended as a separator of numeric constants in a list must be followed by a space.

A default cannot be specified for a parameter of type array.

RETURNS

Specifies the output of the function.

data-type2

Specifies the data type and attributes of the output.

You can specify any built-in data type (except LONG VARCHAR, or LONG VARGRAPHIC) or a distinct type.

If a CCSID is specified and the CCSID of the return data is encoded in a different CCSID, the data is converted to the specified CCSID.

If a CCSID is not specified the return data is converted to the CCSID of the job (or associated graphic CCSID of the job for graphic string return values), if the CCSID of the return data is encoded in a different CCSID. To avoid any potential loss of characters during the conversion, consider explicitly specifying a CCSID that can represent any characters that will be returned from the function. This is especially important if the data type is graphic string data. In this case, consider using CCSID 1200 or 13488 (Unicode graphic string data).

option-list

List of options for the function being altered. These options are the same ones that are listed above under ALTER *option-list*. If a specific option is not specified, the same default that is used when a new function is created is used. For more information see [“CREATE FUNCTION \(SQL scalar\)”](#) on page 1028.

SET OPTION-statement

Specifies the options that will be used to create the function. For example, to create a debuggable function, the following statement could be included:

```
SET OPTION DBGVIEW = *SOURCE
```

For more information, see [“SET OPTION”](#) on page 1512.

The options CNULRQD, COMPILEOPT, NAMING, and SQLCA are not allowed in the ALTER FUNCTION statement. The following options are used when processing default value expressions: ALWCPYDTA, CONACC, DATFMT, DATSEP, DECFLTRND, DECMPT, DECRESULT, DFTRDBCOL, LANGID, SQLCURRULE, SQLPATH, SRTSEQ, TGTRLS, TIMFMT, and TIMSEP.

SQL-routine-body

Specifies a single SQL statement, including a compound statement. See [“SQL control statements”](#) on page 1579 for more information about defining SQL functions.

A call to a procedure that issues a CONNECT, SET CONNECTION, RELEASE, DISCONNECT, COMMIT, ROLLBACK, and SET TRANSACTION statement is not allowed in a function.

The *SQL-routine-body* must contain at least one RETURN statement and a RETURN statement must be executed when the function is called.

ALTER PROCEDURE (SQL), ALTER FUNCTION (SQL scalar), and ALTER FUNCTION (SQL table) with a REPLACE keyword are not allowed in an *SQL-routine-body*.

Notes

General considerations for defining or replacing functions: See CREATE FUNCTION (SQL scalar) for general information about defining a function. ALTER FUNCTION (SQL scalar) allows individual attributes to be altered while preserving the privileges on the function.

Cascaded effects: If REPLACE is specified without RESTRICT and the function signature or result data type is altered, the results from any function, materialized query table, procedure, trigger, or view that references the function may be unpredictable. Any referenced objects should be recreated.

Obfuscated statements: A function that was created using an obfuscated statement can be altered. When the statement is altered the encoded version of the statement that is saved in the catalog is modified and could exceed the maximum length for an SQL statement. If this happens an error will be issued and the alter will fail.

Altering a function from NOT SECURED to SECURED: The function is considered secure after the ALTER FUNCTION statement is executed. Db2 treats the SECURED attribute as an assertion that declares that the user has established an audit procedure for all changes to the user-defined function. Db2 assumes that all subsequent ALTER FUNCTION statements are being reviewed through this audit process.

Invoking other user-defined functions in a secure function: When a secure user-defined function is referenced in an SQL data change statement that references a table that is using row access control or column access control, and if the secure user-defined function invokes other user-defined functions, the nested user-defined functions are not validated as secure. If those nested functions can access sensitive data, a user authorized to the Database Security Administrator function of IBM i needs to ensure that

those functions are allowed to access that data and should ensure that a change control audit procedure has been established for all changes to those functions.

Syntax alternatives: The following keywords are synonyms supported for compatibility to prior releases. These keywords are non-standard and should not be used:

- The keywords VARIANT and NOT VARIANT can be used as synonyms for NOT DETERMINISTIC and DETERMINISTIC.
- The keywords NULL CALL and NOT NULL CALL can be used as synonyms for CALLED ON NULL INPUT and RETURNS NULL ON NULL INPUT.
- The keywords IS DETERMINISTIC may be used as a synonym for DETERMINISTIC.

Example

Modify the definition for an SQL scalar function to indicate that the function is deterministic.

```
ALTER FUNCTION MY_UDF1
DETERMINISTIC
```

ALTER FUNCTION (SQL table)

The ALTER FUNCTION (SQL table) statement alters an SQL table function at the current server.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following:

- For the function identified in the statement:
 - The ALTER privilege for the function, and
 - The system authority *EXECUTE on the library containing the function.
- Database administrator authority

If a different external program is specified, the privileges held by the authorization ID of the statement must also include the same privileges required to create a new external table function. For more information, see [“CREATE FUNCTION \(SQL table\)”](#) on page 1042.

If the SECURED option is specified or if the function is currently secure:

- The authorization ID of the statement must have security administrator authority. See [“Administrative authority”](#) on page 15.

For information about the system authorities corresponding to SQL privileges, see [Corresponding System Authorities When Checking Privileges to a Function or Procedure](#), [Corresponding System Authorities When Checking Privileges to a Table or View](#), and [Corresponding System Authorities When Checking Privileges to a Distinct Type](#).

➤ CCSID — integer ➤

Description

FUNCTION or SPECIFIC FUNCTION

Identifies the function to alter. *function-name* must identify an SQL table function that exists at the current server.

The specified function is altered. The owner of the function and all privileges on the function are preserved.

FUNCTION *function-name*

Identifies the function by its name. The *function-name* must identify exactly one function. The function may have any number of parameters defined for it. If there is more than one function of the specified name in the specified or implicit schema, an error is returned.

FUNCTION *function-name (parameter-type,...)*

Identifies the function by its function signature, which uniquely identifies the function. The *function-name (parameter-type,...)* must identify a function with the specified function signature. The specified parameters must match the data types in the corresponding position that were specified when the function was created. The number of data types, and the logical concatenation of the data types is used to identify the specific function instance which is being altered. Synonyms for data types are considered a match. Parameters that have defaults must be included in this signature.

If *function-name()* is specified, the function identified must have zero parameters.

function-name

Identifies the name of the function.

(parameter-type,...)

Identifies the parameters of the function.

If an unqualified distinct type name is specified, the database manager searches the SQL path to resolve the schema name for the distinct type.

For data types that have a length, precision, or scale attribute, use one of the following:

- Empty parenthesis indicates that the database manager ignores the attribute when determining whether the data types match. For example, DEC() will be considered a match for a parameter of a function defined with a data type of DEC(7,2). However, FLOAT cannot be specified with empty parenthesis because its precision value indicates a specific data type (REAL or DOUBLE).
- If a specific value for a length, precision, or scale attribute is specified, the value must exactly match the value that was specified (implicitly or explicitly) in the CREATE FUNCTION statement. If the data type is FLOAT, the precision does not have to exactly match the value that was specified because matching is based on the data type (REAL or DOUBLE).
- If length, precision, or scale is not explicitly specified, and empty parentheses are not specified, the default attributes of the data type are implied. The implicit length must exactly match the value that was specified (implicitly or explicitly) in the CREATE FUNCTION statement.

Specifying the FOR DATA clause or CCSID clause is optional. Omission of either clause indicates that the database manager ignores the attribute when determining whether the data types match. If either clause is specified, it must match the value that was implicitly or explicitly specified in the CREATE FUNCTION statement.

AS LOCATOR

Specifies that the function is defined to receive a locator for this parameter. If AS LOCATOR is specified, the data type must be a LOB or XML or a distinct type based on a LOB or XML.

SPECIFIC FUNCTION *specific-name*

Identifies the function by its specific name. The *specific-name* must identify a specific function that exists at the current server.

ALTER *option-list*

Indicates that one or more of the options of the function are to be altered. If ALTER FUNCTION ALTER *option-list* is specified and an option is not specified, the value from the existing function definition is used. See [“CREATE FUNCTION \(SQL table\)”](#) on page 1042 for a description of each option.

REPLACE *routine-specification*

Indicates that the existing function definition, including options and parameters, is to be replaced by those specified in this statement. The values of all options are replaced when a function is replaced. If an option is not specified, the same default is used as when a new SQL table function is created, for more information see [“CREATE FUNCTION \(SQL table\)”](#) on page 1042.

If the routine has a comment or label, they are removed from the routine definition.

RESTRICT

Indicates that the function will not be altered or replaced if it is referenced by any function, materialized query table, procedure, trigger, or view.

(*parameter-declaration,...*)

Specifies the number of parameters of the function, the data type of each parameter, and the name of each parameter.

The maximum number of parameters allowed in an SQL function is 2000.

parameter-name

Names the parameter. The name is used to refer to the parameter within the body of the function. The name cannot be the same as any other *parameter-name* in the parameter list.

data-type3

Specifies the data type of the input parameter. If a CCSID is specified, the parameter will be converted to that CCSID prior to passing it to the function. If a CCSID is not specified, the CCSID is determined by the default CCSID at the current server at the time the function is invoked.

default-clause

Specifies a default value for the parameter. The default can be a constant, a special register, a global variable, an expression, or the keyword NULL. The expression is any expression defined in [“Expressions”](#) on page 158, that does not include an aggregate function or column name. If a default value is not specified, the parameter has no default and cannot be omitted on invocation. The maximum length of the expression string is 64K.

The default expression must be assignment compatible to the parameter data type.

Any comma in the default expression that is intended as a separator of numeric constants in a list must be followed by a space.

A default cannot be specified for a parameter of type array.

RETURNS TABLE

Specifies the output table of the function.

Assume the number of parameters is *N*. There must be no more than 2000-*N* columns.

column-name

Specifies the name of a column of the output table. Do not specify the same name more than once.

data-type2

Specifies the data type and attributes of the output.

You can specify any built-in data type (except LONG VARCHAR, or LONG VARGRAPHIC) or a distinct type.

If a CCSID is specified and the CCSID of the return data is encoded in a different CCSID, the data is converted to the specified CCSID.

If a CCSID is not specified the return data is converted to the CCSID of the job (or associated graphic CCSID of the job for graphic string return values), if the CCSID of the return data is

encoded in a different CCSID. To avoid any potential loss of characters during the conversion, consider explicitly specifying a CCSID that can represent any characters that will be returned from the function. This is especially important if the data type is graphic string data. In this case, consider using CCSID 1200 or 13488 (Unicode graphic string data).

option-list

List of options for the function being altered. These options are the same ones that are listed above under ALTER *option-list*. If a specific option is not specified, the same default that is used when a new function is created is used. For more information see [“CREATE FUNCTION \(SQL table\)”](#) on page 1042.

SET OPTION-statement

Specifies the options that will be used to create the function. For example, to create a debuggable function, the following statement could be included:

```
SET OPTION DBGVIEW = *SOURCE
```

For more information, see [“SET OPTION”](#) on page 1512.

The options CNULRQD, COMPILEOPT, NAMING, and SQLCA are not allowed in the ALTER FUNCTION statement. The following options are used when processing default value expressions: ALWCPYDTA, CONACC, DATFMT, DATSEP, DECFLTRND, DECMPT, DECRESULT, DFTRDBCOL, LANGID, SQLCURRULE, SQLPATH, SRTSEQ, TGTRLS, TIMFMT, and TIMSEP.

SQL-routine-body

Specifies a single SQL statement, including a compound statement. See [“SQL control statements”](#) on page 1579 for more information about defining SQL functions.

A call to a procedure that issues a CONNECT, SET CONNECTION, RELEASE, DISCONNECT, COMMIT, ROLLBACK, and SET TRANSACTION statement is not allowed in a function.

The *SQL-routine-body* must contain at least one RETURN statement and a RETURN statement must be executed when the function is called.

ALTER PROCEDURE (SQL), ALTER FUNCTION (SQL scalar), and ALTER FUNCTION (SQL table) with a REPLACE keyword are not allowed in an *SQL-routine-body*.

Notes

General considerations for defining or replacing functions: See CREATE FUNCTION (SQL table) for general information about defining a function. ALTER FUNCTION (SQL table) allows individual attributes to be altered while preserving the privileges on the function.

Cascaded effects: If REPLACE is specified without RESTRICT and the function signature or result data types are altered, the results from any function, materialized query table, procedure, trigger, or view that references the function may be unpredictable. Any referenced objects should be recreated.

Obfuscated statements: A function that was created using an obfuscated statement can be altered. When the statement is altered the encoded version of the statement that is saved in the catalog is modified and could exceed the maximum length for an SQL statement. If this happens an error will be issued and the alter will fail.

Altering a function from NOT SECURED to SECURED: The function is considered secure after the ALTER FUNCTION statement is executed. Db2 treats the SECURED attribute as an assertion that declares that the user has established an audit procedure for all changes to the user-defined function. Db2 assumes that all subsequent ALTER FUNCTION statements are being reviewed through this audit process.

Invoking other user-defined functions in a secure function: When a secure user-defined function is referenced in an SQL data change statement that references a table that is using row access control or column access control, and if the secure user-defined function invokes other user-defined functions, the nested user-defined functions are not validated as secure. If those nested functions can access sensitive data, a user authorized to the Database Security Administrator function of IBM i needs to ensure that those functions are allowed to access that data and should ensure that a change control audit procedure has been established for all changes to those functions.

Syntax alternatives: The following keywords are synonyms supported for compatibility to prior releases. These keywords are non-standard and should not be used:

- The keywords VARIANT and NOT VARIANT can be used as synonyms for NOT DETERMINISTIC and DETERMINISTIC.
- The keywords NULL CALL and NOT NULL CALL can be used as synonyms for CALLED ON NULL INPUT and RETURNS NULL ON NULL INPUT.
- The keywords IS DETERMINISTIC may be used as a synonym for DETERMINISTIC.

Example

Modify the definition for an SQL table function to set the estimated cardinality to 10,000.

```
ALTER FUNCTION GET_TABLE  
ALTER CARDINALITY 10000
```

ALTER MASK

The ALTER MASK statement alters a column mask that exists at the current server.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

The authorization ID of the statement must have security administrator authority. See [“Administrative authority”](#) on page 15.

Syntax

Description

mask-name

Identifies the column mask to be altered. It must identify a column mask that exists at the current server.

ENABLE, DISABLE, or REGENERATE

ENABLE

Specifies that the column mask is to be enabled for column access control. If column access control is not currently activated for the table, the column mask will become effective when column access control is activated for the table. If column access control is currently activated for the table, the column mask becomes effective immediately.

A column mask that gets an error when trying to be enabled cannot be enabled until any errors in the mask definition are resolved. This may require the column mask to be dropped and recreated with a modified definition.

ENABLE is ignored if the column mask is already defined as enabled for column access control.

DISABLE

Specifies that the column mask is to be disabled for column access control. If column access control is not currently activated for the table, the column mask will remain ineffective when column access control is activated for the table. If column access control is currently activated for the table, the column mask becomes ineffective.

DISABLE is ignored if the column mask is already defined as disabled for column access control.

REGENERATE

Specifies that the column mask is to be regenerated. The column mask definition in the catalog is used and existing dependencies and authorizations, if any, are retained. The column mask definition is reevaluated as if the column mask were being created. The user-defined functions that are referenced in the column mask definition must be resolved to the same secure UDFs as were resolved during the column mask creation.

Examples

Example 1: Enable column mask M1.

```
ALTER MASK M1 ENABLE
```

Example 2: Disable column mask M1.

```
ALTER MASK M1 DISABLE
```

Example 3: Regenerate column mask M1.

```
ALTER MASK M1 REGENERATE
```

ALTER PERMISSION

The ALTER PERMISSION statement alters a row permission that exists at the current server.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

The authorization ID of the statement must have security administrator authority. See [“Administrative authority”](#) on page 15.

Syntax

```
➤➤ ALTER PERMISSION — permission-name { ENABLE | DISABLE | REGENERATE }
```

Description

permission-name

Identifies the row permission to be altered. It must identify a row permission that exists at the current server. It cannot be a default permission.

ENABLE, DISABLE, or REGENERATE

ENABLE

Specifies that the row permission is to be enabled for row access control. If row access control is not currently activated for the table, the row permission will become effective when row access control is activated for the table. If row access control is currently activated for the table, the row permission becomes effective immediately.

A row permission that gets an error when trying to be enabled cannot be enabled until any errors in the permission definition are resolved. This may require the row permission to be dropped and recreated with a modified definition.

ENABLE is ignored if the row permission is already defined as enabled for row access control.

DISABLE

Specifies that the row permission is to be disabled for row access control. If row access control is not currently activated for the table, the row permission will remain ineffective when row access control is activated for the table. If row access control is currently activated for the table, the row permission becomes ineffective.

If row access control is currently activated for the table and all row permissions are disabled, a default row permission that allows no access to any row of the table will be used.

DISABLE is ignored if the row permission is already defined as disabled for row access control.

REGENERATE

Specifies that the row permission is to be regenerated. The row permission definition in the catalog is used and existing dependencies and authorizations, if any, are retained. The row permission definition is reevaluated as if the row permission were being created. The user-defined functions that are referenced in the row permission must be resolved to the same secure UDFs as were resolved during the row permission creation.

Examples

Example 1: Enable permission P1.

```
ALTER PERMISSION P1 ENABLE
```

Example 2: Disable permission P1.

```
ALTER PERMISSION P1 DISABLE
```

Example 3: Regenerate permission P1.

```
ALTER PERMISSION P1 REGENERATE
```

ALTER PROCEDURE (external)

The ALTER PROCEDURE (external) statement alters an external procedure at the current server.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following:

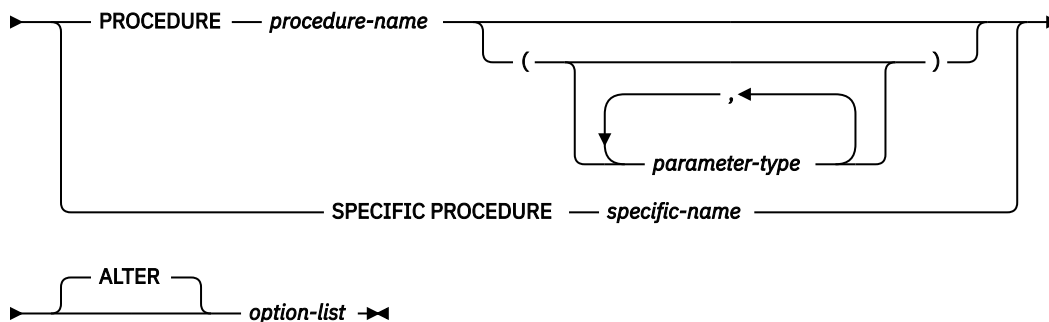

- For the procedure identified in the statement:
 - The ALTER privilege for the procedure, and
 - The system authority *EXECUTE on the library containing the procedure.
- Database administrator authority

If a different external program is specified, the privileges held by the authorization ID of the statement must also include the same privileges required to create a new external procedure. For more information, see “CREATE PROCEDURE (external)” on page 1075.

For information about the system authorities corresponding to SQL privileges, see [Corresponding System Authorities When Checking Privileges to a Function or Procedure](#), [Corresponding System Authorities When Checking Privileges to a Table or View](#), and [Corresponding System Authorities When Checking Privileges to a Distinct Type](#).

Syntax

➤ ALTER ➤

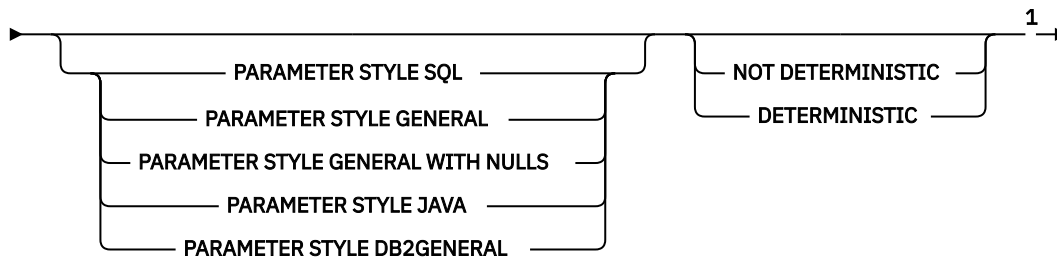

parameter-type

data-type

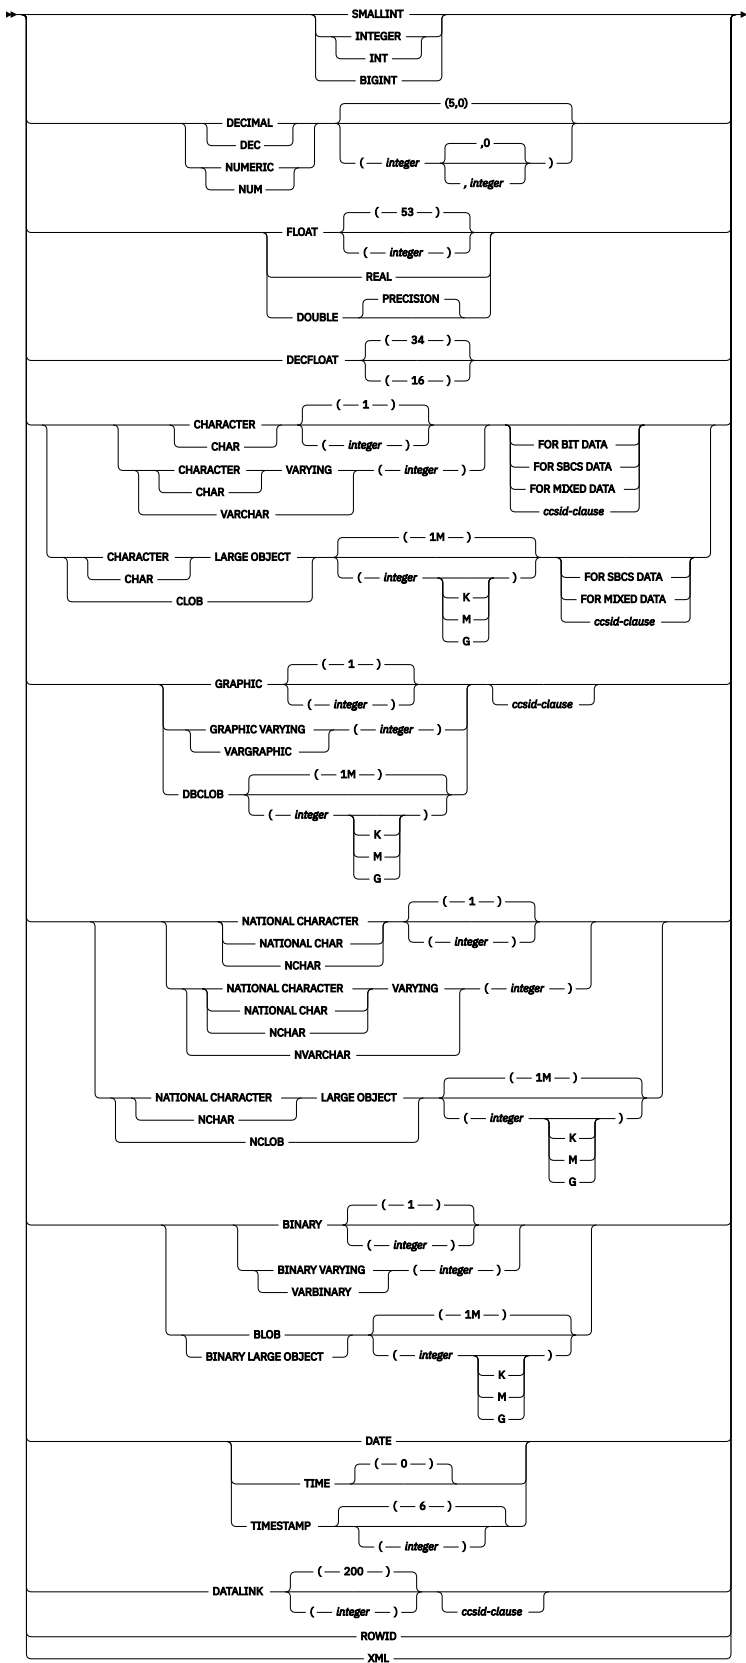

option-list

Notes:

¹ The clauses in the *option-list* can be specified in any order.

built-in-type

ccsid-clause

➤ CCSID — integer ➤

Description

PROCEDURE or SPECIFIC PROCEDURE

Identifies the procedure to alter. *procedure-name* must identify an external procedure that exists at the current server.

The specified procedure is altered. The owner of the procedure is preserved. If the external program or service program exists at the time the procedure is altered, all privileges on the procedure are preserved.

PROCEDURE *procedure-name*

Identifies the procedure by its name. The *procedure-name* must identify exactly one external procedure. The procedure may have any number of parameters defined for it. If there is more than one procedure of the specified name in the specified or implicit schema, an error is returned.

PROCEDURE *procedure-name (parameter-type,...)*

Identifies the procedure by its procedure signature, which uniquely identifies the procedure. The *procedure-name (parameter-type,...)* must identify an external procedure with the specified procedure signature. The specified parameters must match the data types in the corresponding position that were specified when the procedure was created. The number of data types and the logical concatenation of the data types is used to identify the specific procedure instance which is being altered. Synonyms for data types are considered a match. Parameters that have defaults must be included in this signature.

If *procedure-name()* is specified, the procedure identified must have zero parameters.

procedure-name

Identifies the name of the procedure.

(parameter-type,...)

Identifies the parameters of the procedure.

If an unqualified distinct type or array type name is specified, the database manager searches the SQL path to resolve the schema name for the distinct type or array type.

For data types that have a length, precision, or scale attribute, use one of the following:

- Empty parenthesis indicates that the database manager ignores the attribute when determining whether the data types match. For example, DEC() will be considered a match for a parameter of a procedure defined with a data type of DEC(7,2). However, FLOAT cannot be specified with empty parenthesis because its precision value indicates a specific data type (REAL or DOUBLE).
- If a specific value for a length, precision, or scale attribute is specified, the value must exactly match the value that was specified (implicitly or explicitly) in the CREATE PROCEDURE statement. If the data type is FLOAT, the precision does not have to exactly match the value that was specified because matching is based on the data type (REAL or DOUBLE).
- If length, precision, or scale is not explicitly specified, and empty parentheses are not specified, the default attributes of the data type are implied. The implicit length must exactly match the value that was specified (implicitly or explicitly) in the CREATE PROCEDURE statement.

Specifying the FOR DATA clause or CCSID clause is optional. Omission of either clause indicates that the database manager ignores the attribute when determining whether the data types match. If either clause is specified, it must match the value that was implicitly or explicitly specified in the CREATE PROCEDURE statement.

AS LOCATOR

Specifies that the procedure is defined to receive a locator for this parameter. If AS LOCATOR is specified, the data type must be a LOB or XML or a distinct type based on a LOB or XML.

SPECIFIC PROCEDURE *specific-name*

Identifies the procedure by its specific name. The *specific-name* must identify a specific procedure that exists at the current server.

ALTER option-list

Indicates that one or more of the options of the procedure are to be altered. If an option is not specified, the value from the existing procedure definition is used. See [“CREATE PROCEDURE \(external\)”](#) on page 1075 for a description of each option.

Notes

General considerations for defining or changing a procedure: See CREATE PROCEDURE for general information about defining a procedure. ALTER PROCEDURE (external) allows individual attributes to be altered while preserving the privileges on the procedure.

Syntax alternatives: The following keywords are synonyms supported for compatibility to prior releases. These keywords are non-standard and should not be used:

- The keywords VARIANT and NOT VARIANT can be used as synonyms for NOT DETERMINISTIC and DETERMINISTIC.
- The keywords NULL CALL can be used as synonyms for CALLED ON NULL INPUT.
- DYNAMIC RESULT SET, RESULT SETS, and RESULT SET may be used as synonyms for DYNAMIC RESULT SETS.
- The value DB2SQL may be used as a synonym for SQL.

Examples

Modify the definition for procedure MYPROC to change the name of the external program that is invoked when the procedure is called. The name of the external program is PROG10A.

```
ALTER PROCEDURE MYPROC  
EXTERNAL NAME PROG10A
```

ALTER PROCEDURE (SQL)

The ALTER PROCEDURE (SQL) statement alters a procedure at the current server.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following:

- For the procedure identified in the statement:
 - The ALTER privilege for the procedure, and
 - The system authority *EXECUTE on the library containing the procedure.
- Database administrator authority

If a distinct type is referenced in a *parameter-declaration*, the privileges held by the authorization ID of the statement must include at least one of the following:

- For each distinct type identified in the statement:
 - The USAGE privilege on the distinct type, and
 - The system authority *EXECUTE on the library containing the distinct type
- Administrative authority

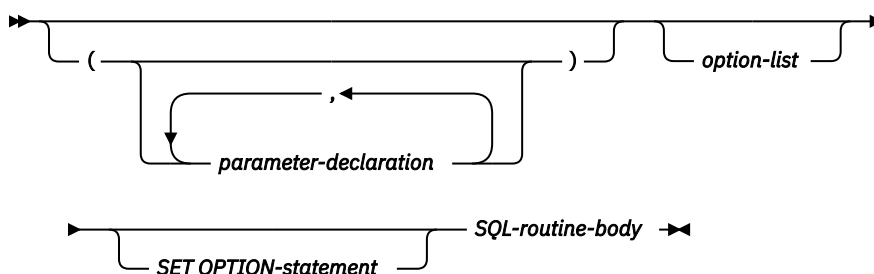

For information about the system authorities corresponding to SQL privileges, see [Corresponding System Authorities When Checking Privileges to a Function or Procedure](#) and [Corresponding System Authorities When Checking Privileges to a Distinct Type](#).

SQL-routine-body

SQL-routine-body (continued)

built-in-type

Description

PROCEDURE or SPECIFIC PROCEDURE

Identifies the procedure to alter. *procedure-name* must identify an SQL procedure that exists at the current server.

The specified procedure is altered. The owner of the procedure and all privileges on the procedure are preserved.

PROCEDURE *procedure-name*

Identifies the procedure by its name. The *procedure-name* must identify exactly one SQL procedure. The procedure may have any number of parameters defined for it. If there is more than one procedure of the specified name in the specified or implicit schema, an error is returned.

PROCEDURE *procedure-name (parameter-type,...)*

Identifies the procedure by its procedure signature, which uniquely identifies the procedure. The *procedure-name (parameter-type,...)* must identify an SQL procedure with the specified procedure signature. The specified parameters must match the data types in the corresponding position that were specified when the procedure was created. The number of data types and the logical concatenation of the data types is used to identify the specific procedure instance which is being altered. Synonyms for data types are considered a match. Parameters that have defaults must be included in this signature.

If *procedure-name()* is specified, the procedure identified must have zero parameters.

procedure-name

Identifies the name of the procedure.

(parameter-type,...)

Identifies the parameters of the procedure.

If an unqualified distinct type or array type name is specified, the database manager searches the SQL path to resolve the schema name for the distinct type or array type.

For data types that have a length, precision, or scale attribute, use one of the following:

- Empty parenthesis indicates that the database manager ignores the attribute when determining whether the data types match. For example, DEC() will be considered a match for a parameter of a procedure defined with a data type of DEC(7,2). However, FLOAT cannot be specified with empty parenthesis because its precision value indicates a specific data type (REAL or DOUBLE).
- If a specific value for a length, precision, or scale attribute is specified, the value must exactly match the value that was specified (implicitly or explicitly) in the CREATE PROCEDURE statement. If the data type is FLOAT, the precision does not have to exactly match the value that was specified because matching is based on the data type (REAL or DOUBLE).
- If length, precision, or scale is not explicitly specified, and empty parentheses are not specified, the default attributes of the data type are implied. The implicit length must exactly match the value that was specified (implicitly or explicitly) in the CREATE PROCEDURE statement.

Specifying the FOR DATA clause or CCSID clause is optional. Omission of either clause indicates that the database manager ignores the attribute when determining whether the data types match. If either clause is specified, it must match the value that was implicitly or explicitly specified in the CREATE PROCEDURE statement.

AS LOCATOR

Specifies that the procedure is defined to receive a locator for this parameter. If AS LOCATOR is specified, the data type must be a LOB or a distinct type based on a LOB.

SPECIFIC PROCEDURE *specific-name*

Identifies the procedure by its specific name. The *specific-name* must identify a specific procedure that exists at the current server.

ALTER *option-list*

Indicates that one or more of the options of the procedure are to be altered. If ALTER PROCEDURE ALTER *option-list* is specified and an option is not specified, the value from the existing procedure definition is used. See [“CREATE PROCEDURE \(SQL\)”](#) on page 1090 for a description of each option.

REPLACE *routine-specification*

Indicates that the existing procedure definition, including options and parameters, is to be replaced by those specified in this statement. The values of all options are replaced when a procedure is replaced. If an option is not specified, the same default is used as when a new SQL procedure is created, for more information see [“CREATE PROCEDURE \(SQL\)”](#) on page 1090.

If the routine has a comment or label, they are removed from the routine definition.

(*parameter-declaration*,...)

Specifies the number of parameters of the procedure, the data type of each parameter, and the name of each parameter. A parameter for a procedure can be used for input only, for output only, or for both input and output.

The maximum number of parameters allowed in an SQL procedure is 2000.

IN

Identifies the parameter as an input parameter to the procedure.

OUT

Identifies the parameter as an output parameter that is returned by the procedure. If the parameter is not set within the procedure, the null value is returned.

INOUT

Identifies the parameter as both an input and output parameter for the procedure. If the parameter is not set within the procedure, its input value is returned. If an INOUT parameter is defined with a default and the default is used when calling the procedure, no value for the parameter is returned.

parameter-name

Names the parameter for use as an SQL variable. The name cannot be the same as any other *parameter-name* for the procedure.

data-type

Specifies the data type of the parameter. If a CCSID is specified, the parameter will be converted to that CCSID prior to passing it to the procedure. If a CCSID is not specified, the CCSID is determined by the default CCSID at the current server at the time the procedure is called.

default-clause

Specifies a default value for the parameter. The default can be a constant, a special register, a global variable, an expression, or the keyword NULL. The expression is any expression defined in [“Expressions”](#) on page 158, that does not include an aggregate function or column name. If a default value is not specified, the parameter has no default and cannot be omitted on invocation. The maximum length of the expression string is 64K.

The default expression must not modify SQL data. The expression must be assignment compatible to the parameter data type. All objects referenced in a default expression must exist when the procedure is created.

Any comma in the default expression that is intended as a separator of numeric constants in a list must be followed by a space.

A default cannot be specified:

- for an OUT parameter.
- for a parameter of type array.

option-list

List of options for the procedure being altered. These options are the same ones that are listed above under ALTER *option-list*. If a specific option is not specified, the same default that is used when a new procedure is created is used. For more information see [“CREATE PROCEDURE \(SQL\)”](#) on page 1090.

SET OPTION-statement

Specifies the options that will be used to create the procedure. For example, to create a debuggable procedure, the following statement could be included:

```
SET OPTION DBGVIEW = *SOURCE
```

For more information, see [“SET OPTION” on page 1512](#).

The options CLOSQLCSR, CNULRQD, COMPILEOPT, NAMING, and SQLCA are not allowed in the ALTER PROCEDURE statement. The following options are used when processing default value expressions: ALWCPYDTA, CONACC, DATFMT, DATSEP, DECFLTRND, DECMPT, DECRESULT, DFTRDBCOL, LANGID, SQLCURRULE, SQLPATH, SRTSEQ, TGTRLS, TIMFMT, and TIMSEP.

SQL-routine-body

Specifies a single SQL statement, including a compound statement. See [“SQL control statements” on page 1579](#) for more information about defining SQL procedures.

CONNECT, SET CONNECTION, RELEASE, DISCONNECT, and SET TRANSACTION statements are not allowed in a procedure that is running on a remote application server. COMMIT and ROLLBACK statements are not allowed in an ATOMIC SQL procedure or in a procedure that is running on a connection to a remote application server.

ALTER PROCEDURE (SQL), ALTER FUNCTION (SQL scalar), and ALTER FUNCTION (SQL table) with a REPLACE keyword are not allowed in an *SQL-routine-body*.

Notes

General considerations for defining or replacing procedures: See CREATE PROCEDURE for general information about defining a procedure. ALTER PROCEDURE (SQL) allows individual attributes or the routine specification to be altered while preserving the privileges on the procedure.

Alter Procedure Replace considerations: When an SQL procedure definition is replaced, SQL creates a temporary source file that will contain C source code with embedded SQL statements. A program object is then created using the CRTPGM command. The SQL options used to create the program are the options that are in effect at the time the ALTER PROCEDURE (SQL) statement is executed. The program is created with ACTGRP(*CALLER).

When an SQL procedure is altered, a new *PGM or *SRVPGM object is created and the procedure's attributes are stored in the created program object. If the *PGM or *SRVPGM object is saved and then restored to this or another system, the catalogs are automatically updated with those attributes.

The specific name is used as the name of the member in the source file and the name of the program object, if it is a valid system name. If the procedure name is not a valid system name, a unique name is generated. If a source file member with the same name already exists, the member is overlaid. If a module or a program with the same name already exists, the objects are not overlaid, and a unique name is generated. The unique names are generated according to the rules for generating system table names.

Target release considerations: When an SQL procedure definition is replaced, the target release will be the current release in which the ALTER statement is executed unless the user explicitly specifies a different target release. The target release can be explicitly specified using the TGTRLS keyword in the SET OPTION statement. If the ALTER is specified in the source for a RUNSQLSTM or CRTSQLxxx command, the TGTRLS keyword can also be specified on the command.

If the procedure definition is not replaced, the target release of the existing procedure will be preserved unless the target release level of the procedure is earlier than the earliest supported release level. In this case, the target release will be changed to the earliest supported release level.

Obfuscated statements: A procedure that was created using an obfuscated statement can be altered. When the statement is altered the encoded version of the statement that is saved in the catalog is modified and could exceed the maximum length for an SQL statement. If this happens an error will be issued and the alter will fail.

Syntax alternatives: The following keywords are synonyms supported for compatibility to prior releases. These keywords are non-standard and should not be used:

- The keywords `VARIANT` and `NOT VARIANT` can be used as synonyms for `NOT DETERMINISTIC` and `DETERMINISTIC`.
- The keywords `NULL CALL` can be used as synonyms for `CALLED ON NULL INPUT`.
- `DYNAMIC RESULT SET`, `RESULT SETS`, and `RESULT SET` may be used as synonyms for `DYNAMIC RESULT SETS`.

Examples

Modify the definition for an SQL procedure so that SQL changes are committed on return from the SQL procedure.

```
ALTER PROCEDURE UPDATE_SALARY_2  
ALTER COMMIT ON RETURN YES
```

ALTER SEQUENCE

The ALTER SEQUENCE statement can be used to change a sequence.

The ALTER SEQUENCE statement can be used to change a sequence in any of these ways:

- Restarting the sequence
- Changing the increment between future sequence values
- Setting or eliminating the minimum or maximum values
- Changing the number of cached sequence numbers
- Changing the attribute that determines whether the sequence can cycle or not
- Changing whether sequence numbers must be generated in order of request

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following:

- For the sequence identified in the statement:
 - The system authority *EXECUTE on the library containing the sequence
 - The ALTER privilege for the sequence
- Database administrator authority

The privileges held by the authorization ID of the statement must include at least one of the following:

- The following system authorities:
 - *USE to the Change Data Area (CHGDTAARA) command
 - *USE to the Retrieve Data Area (RTVDTAARA) command
- Administrative authority

The privileges held by the authorization ID of the statement must include at least one of the following:

- For the SYSSEQOBJECTS catalog table:
 - The UPDATE privilege on the table, and
 - The system authority *EXECUTE on library QSYS2
- Administrative authority

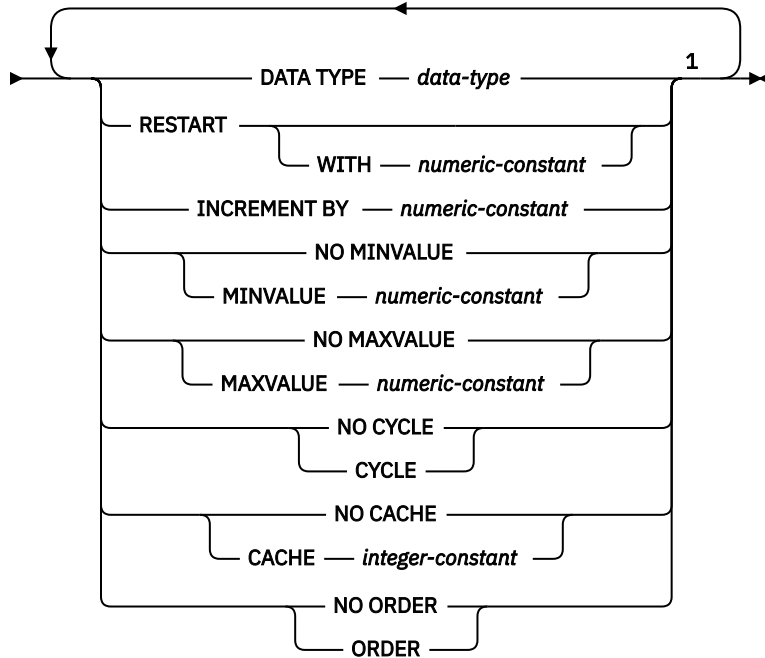

If a distinct type is referenced, the privileges held by the authorization ID of the statement must include at least one of the following:

- For the distinct type identified in the statement:
 - The USAGE privilege on the distinct type, and
 - The system authority *EXECUTE on the library containing the distinct type
- Administrative authority

For information on the system authorities corresponding to SQL privileges, see [Corresponding System Authorities When Checking Privileges to a Sequence](#), [Corresponding System Authorities When Checking Privileges to a Table or View](#), and [Corresponding System Authorities When Checking Privileges to a Distinct Type](#).

Syntax

➤ ALTER SEQUENCE — *sequence-name* ➤

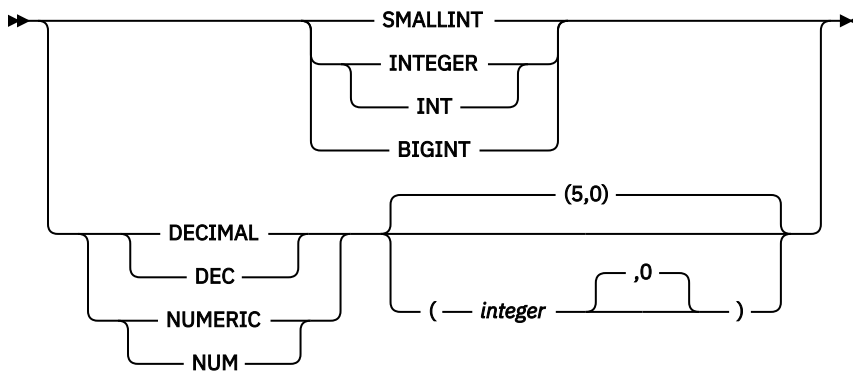

Notes:

¹ The same clause must not be specified more than once.

data-type

built-in-type

Description

sequence-name

Identifies the sequence to be altered. The name must identify a sequence that already exists at the current server.

DATA TYPE *data-type*

Specifies the new data type to be used for the sequence value. The data type can be any exact numeric type (SMALLINT, INTEGER, BIGINT, DECIMAL, or NUMERIC) with a scale of zero, or a user-defined distinct type for which the source type is an exact numeric type with a scale of zero.

Each of the existing START WITH, INCREMENT BY, MINVALUE, and MAXVALUE attributes that are not changed by the ALTER SEQUENCE statement must contain a value that could be assigned to a column of the data type associated with the new data type.

built-in-type

Specifies the new built-in data type used as the basis for the internal representation of the sequence. If the data type is DECIMAL or NUMERIC, the precision must be less than or equal to 63 and the scale must be 0. See [“CREATE TABLE” on page 1115](#) for a more complete description of each built-in data type.

For portability of applications across platforms, use DECIMAL instead of a NUMERIC data type.

distinct-type-name

Specifies that the new data type of the sequence is a distinct type (a user-defined data type). If the source type is DECIMAL or NUMERIC, the precision of the sequence is the precision of the source type of the distinct type. The precision of the source type must be less than or equal to 63 and the scale must be 0. If a distinct type name is specified without a schema name, the distinct type name is resolved by searching the schemas on the SQL path.

RESTART

Restarts the sequence. If *numeric-constant* is not specified, the sequence is restarted at the value specified implicitly or explicitly as the starting value on the CREATE SEQUENCE statement that originally created the sequence.

WITH numeric-constant

Restarts the sequence with the specified value. This value can be any positive or negative value that could be assigned to a column of the data type associated with the sequence, without nonzero digits to the right of the decimal point.

INCREMENT BY *numeric-constant*

Specifies the interval between consecutive values of the sequence. This value can be any positive or negative value that could be assigned to a column of the data type associated with the sequence, and does not exceed the value of a large integer constant, without nonzero digits existing to the right of the decimal point.

If this value is negative, then this is a descending sequence. If this value is 0 or positive, this is an ascending sequence after the ALTER statement.

NO MINVALUE or MINVALUE

Specifies the minimum value at which a descending sequence either cycles or stops generating values, or an ascending sequence cycles to after reaching the maximum value.

NO MINVALUE

For an ascending sequence, the value is the original starting value. For a descending sequence, the value is the minimum value of the data type (and precision, if DECIMAL or NUMERIC) associated with the sequence.

MINVALUE *numeric-constant*

Specifies the numeric constant that is the minimum value that is generated for this sequence. This value can be any positive or negative value that could be assigned to a column of the data type associated with the sequence and without non-zero digits to the right of the decimal point. The value must be less than or equal to the maximum value.

NO MAXVALUE or MAXVALUE

Specifies the maximum value at which an ascending sequence either cycles or stops generating values, or a descending sequence cycles to after reaching the minimum value.

NO MAXVALUE

For an ascending sequence, the value is the maximum value of the data type (and precision, if DECIMAL or NUMERIC) associated with the sequence. For a descending sequence, the value is the original starting value.

MAXVALUE *numeric-constant*

Specifies the numeric constant that is the maximum value that is generated for this sequence. This value can be any positive or negative value that could be assigned to a column of the data

type associated with the sequence and without non-zero digits to the right of the decimal point. The value must be greater than or equal to the minimum value.

CYCLE or NO CYCLE

Specifies whether this sequence should continue to generate values after reaching either the maximum or minimum value of the sequence.

NO CYCLE

Specifies that values will not be generated for the sequence once the maximum or minimum value for the sequence has been reached.

CYCLE

Specifies that values continue to be generated for this sequence after the maximum or minimum value has been reached. If this option is used, after an ascending sequence reaches the maximum value of the sequence, it generates its minimum value. After a descending sequence reaches its minimum value of the sequence, it generates its maximum value. The maximum and minimum values for the sequence determine the range that is used for cycling.

When CYCLE is in effect, duplicate values can be generated for a sequence by the database manager.

CACHE or NO CACHE

Specifies whether to keep some preallocated values in memory. Preallocating and storing values in the cache improves the performance of the NEXT VALUE sequence expression.

CACHE *integer-constant*

Specifies the maximum number of sequence values that are preallocated and kept in memory. Preallocating and storing values in the cache reduces synchronous I/O when values are generated for the sequence.

In certain situations, such as system failure, all cached sequence values that have not been used in committed statements are lost, and thus, will never be used. The value specified for the CACHE option is the maximum number of sequence values that could be lost in these situations.

The minimum value is 2.

NO CACHE

Specifies that values of the sequence are not to be preallocated. It ensures that there is not a loss of values in situations, such as system failure. When this option is specified, the values of the sequence are not stored in the cache. In this case, every request for a new value for the sequence results in synchronous I/O.

NO ORDER or ORDER

Specifies whether the sequence numbers must be generated in order of request.

NO ORDER

Specifies that the sequence numbers do not need to be generated in order of request.

ORDER

Specifies that the sequence numbers are generated in order of request. If ORDER is specified, the performance of the NEXT VALUE sequence expression will be worse than if NO ORDER is specified.

Notes

Altering a sequence:

- Only future sequence numbers are affected by the ALTER SEQUENCE statement.
- All the cached values are lost when a sequence is altered.
- After restarting a sequence or changing it to cycle, it is possible that a generated value will duplicate a value previously generated for that sequence.

Syntax alternatives: The following keywords are synonyms supported for compatibility to prior releases of other Db2 products. These keywords are non-standard and should not be used:

- The keywords NOMINVALUE, NOMAXVALUE, NOCYCLE, NOCACHE, and NOORDER can be used as synonyms for NO MINVALUE, NO MAXVALUE, NO CYCLE, NO CACHE, and NO ORDER.

Examples

A possible reason for specifying RESTART without a numeric value would be to reset the sequence to the START WITH value. In this example, the goal is to generate the numbers from 1 up to the number of rows in a table and then inserting the numbers into a column added to the table using temporary tables.

```
ALTER SEQUENCE ORG_SEQ RESTART  
  
DECLARE GLOBAL TEMPORARY TABLE TEMP_ORG AS  
  (SELECT NEXT VALUE FOR ORG_SEQ, ORG.*  
   FROM ORG) WITH DATA  
  
INSERT INTO TEMP_ORG  
  (SELECT NEXT VALUE FOR ORG_SEQ, ORG.*  
   FROM ORG
```

Another use would be to get results back where all the resulting rows are numbered:

```
ALTER SEQUENCE ORG_SEQ RESTART  
  
SELECT NEXT VALUE FOR ORG_SEQ, ORG.*  
FROM ORG
```

ALTER TABLE

The ALTER TABLE statement alters the definition of a table.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following:

- For the table identified in the statement,
 - The ALTER privilege on the table, and
 - The system authority *EXECUTE on the library containing the table
- Database administrator authority

To define a foreign key, the privileges held by the authorization ID of the statement must include at least one of the following on the parent table:

- The REFERENCES privilege or object management authority for the table
- The REFERENCES privilege on each column of the specified parent key
- Database administrator authority

If a field procedure is defined, the privileges held by the authorization ID of the statement must include at least one of the following:

- The following system authorities:
 - The system authority *EXECUTE on the program, and
 - The system authority *EXECUTE on the library containing the program
- Database administrator authority

If a *select-statement* is specified, the privileges held by the authorization ID of the statement must include at least one of the following on the tables or views specified in these clauses:

- The SELECT privilege for the table or view
- Database administrator authority

If a distinct type is referenced, the privileges held by the authorization ID of the statement must include at least one of the following:

- For each distinct type identified in the statement:
 - The USAGE privilege on the distinct type, and
 - The system authority *EXECUTE on the library containing the distinct type
- Database administrator authority

If an ACTIVATE or DEACTIVATE clause is specified:

- The authorization ID of the statement must have security administrator authority. See [“Administrative authority”](#) on page 15.

To drop a partition from a table that has active row permissions with DELETE ROWS, the privileges held by the authorization ID of the statement must include at least one of the following:

- The system authorities of *OBJOPR and *OBJEXIST on the table
- Database administrator authority

To attach a partition, the privileges held by the authorization ID of the statement must also include at least one of the following:

- For the source table identified in the statement,
 - The SELECT privilege, and
 - The system authority of *OBJEXIST, and
 - The system authority *EXECUTE on the library containing the source table
- Database administrator authority

To detach a partition, the privileges held by the authorization ID of the statement must also include at least one of the following:

- For the source table identified in the statement,
 - The SELECT, DELETE, and ALTER privileges, and
 - The system authority *EXECUTE on the library containing the source table
- Database administrator authority

To detach a partition, the privileges held by the authorization ID of the statement must include at least one of the following:

- The privilege to create in the schema. For more information, see [Privileges necessary to create in a schema](#).
- Database administrator authority

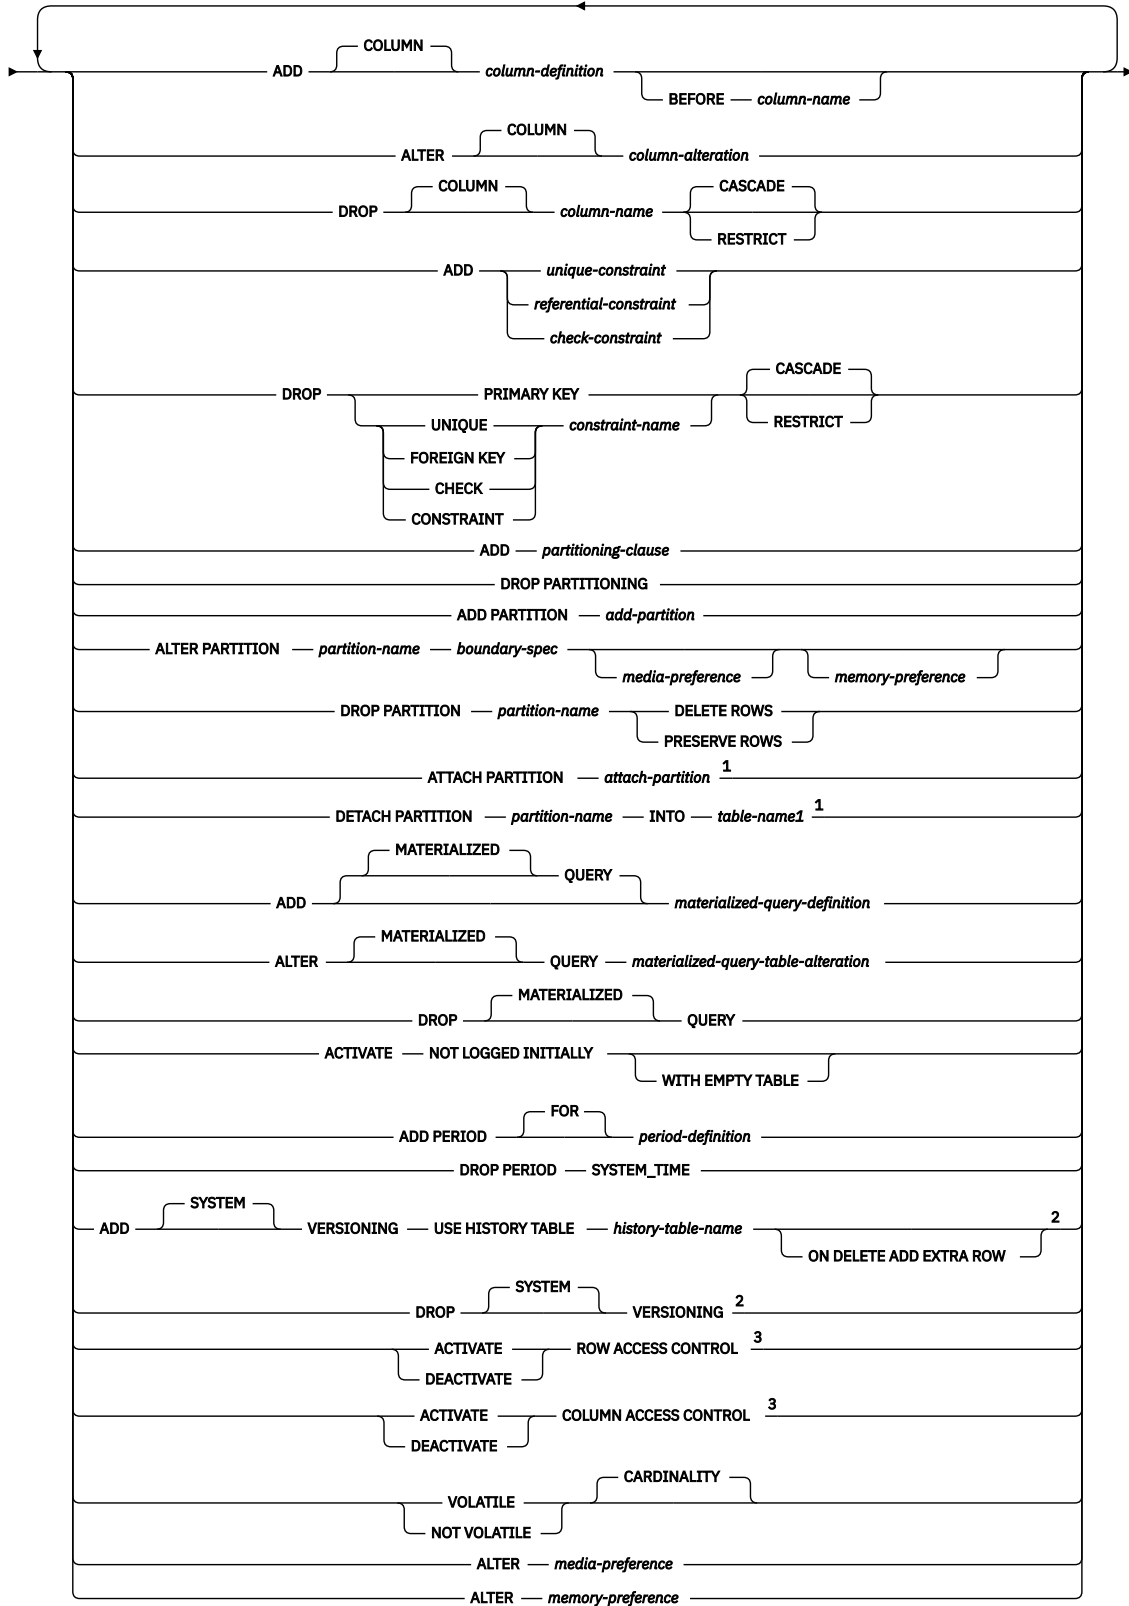

To alter a table to become a system-period temporal table (with the ADD VERSIONING clause), alter a system-period temporal table when one or more of the changes also result in changes to the associated history table, or to DROP VERSIONING, the privileges that are held by the authorization ID of the statement must also include at least one of the following authorities:

- The following system authorities:
 - The ALTER privilege on the history table, and
 - The system authority *EXECUTE on the library containing the history table
- Database administrator authority

For information on the system authorities corresponding to SQL privileges, see [Corresponding System Authorities When Checking Privileges to a Table or View](#) and [Corresponding System Authorities When Checking Privileges to a Distinct Type](#).

Syntax

→ ALTER TABLE — *table-name* →

media-preference

memory-preference

column-definition

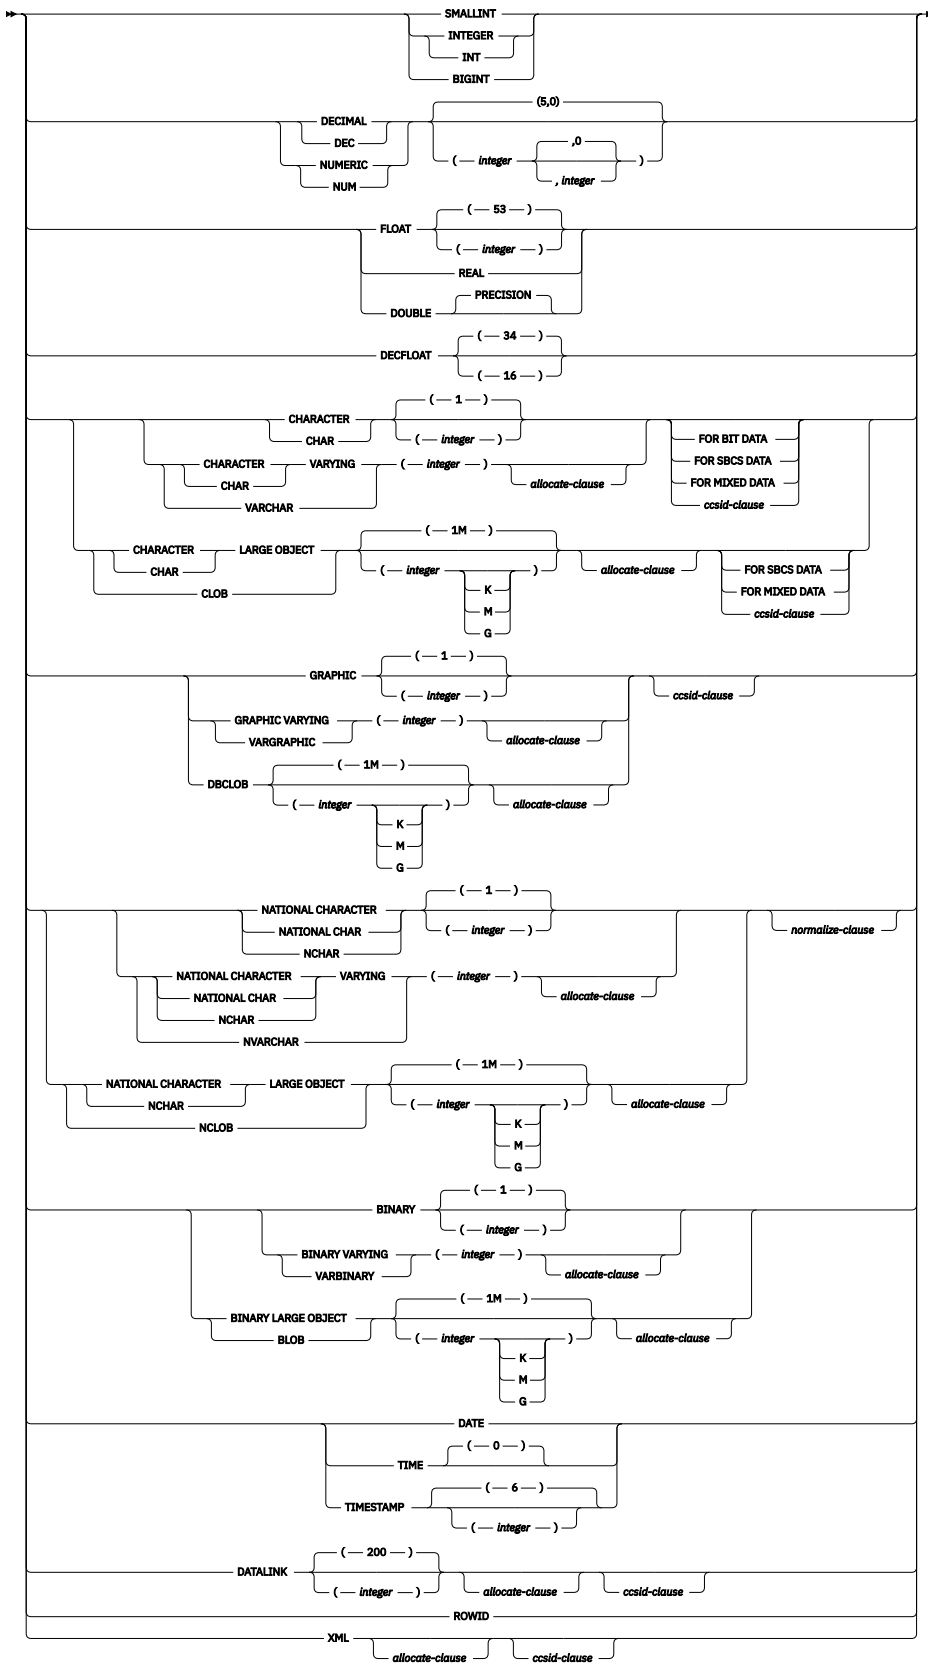

data-type

Notes:

- ¹ ATTACH PARTITION or DETACH PARTITION cannot be specified with any other clause.
- ² ADD VERSIONING or DROP VERSIONING cannot be specified with any other clause.
- ³ If an ACTIVATE or DEACTIVATE clause is specified, clauses other than ACTIVATE or DEACTIVATE are not allowed on the ALTER TABLE statement. Each clause must not be specified more than once.
- ⁴ *data-type* is optional for row change timestamp, row-begin, row-end, and transaction-start-ID columns.
- ⁵ The same clause must not be specified more than once.
- ⁶ The *datalink-options* can only be specified for DATALINKs and distinct types sourced on DATALINKs.

Notes:

- ¹ GENERATED can be specified only if the column has a ROWID data type (or a distinct type that is based on a ROWID data type), or the column is an identity column, or the column is a row change timestamp.
- ² The same clause must not be specified more than once.
- ³ All five *file-link-options* must be specified, but they can be specified in any order.
- ⁴ The same clause must not be specified more than once.
- ⁵ GENERATED can be specified only if the column has a ROWID data type (or a distinct type that is based on a ROWID data type), the column is an identity column, *identity-options* are specified, *as-row-transaction-timestamp-clause* is specified, *as-row-transaction-start-id-clause* is specified, or the column is a row change timestamp.
- ⁶ The ON DELETE and ON UPDATE clauses may be specified in either order.
- ⁷ The same clause must not be specified more than once.
- ⁸ This syntax for a *partition-element* is valid if there is only one *partition-expression* with a numeric or datetime data type.
- ⁹ The same clause must not be specified more than once. MAINTAINED BY USER must be specified.
- ¹⁰ The same clause must not be specified more than once.

Description

table-name

Identifies the table to be altered. The *table-name* must identify a table that exists at the current server. It must not be a view, a catalog table, or a declared temporary table. If *table-name* identifies a materialized query table or a history table, *ADD column-definition*, *ALTER column-alteration*, or *DROP COLUMN* are not allowed. If *table-name* identifies a materialized query table or a temporal table, *ATTACH PARTITION* and *DETACH PARTITION* are not allowed.

ADD COLUMN *column-definition*

Adds a column to the table. The table cannot be a history table. If the table has rows, every value of the column is set to its default value, unless the column is a ROWID column or a generated column. The database manager generates default values for ROWID columns and generated columns. If the table previously had n columns, the ordinality of the new column is $n+1$. The value of $n+1$ must not exceed 8000.

A table can have only one ROWID and one of each type of generated column.

A DataLink column with FILE LINK CONTROL cannot be added to a table that is a dependent in a referential constraint with a delete rule of CASCADE or to a system period temporal table. A ROWID column cannot be added to a system-period temporal table.

Adding a new column must not make the sum of the row buffer byte counts of the columns be greater than 32766 or, if a VARCHAR, VARBINARY, or VARGRAPHIC column is specified, 32740. Additionally, if a LOB or XML column is specified, the sum of the byte counts of the columns must not be greater than 3 758 096 383 at the time of insert or update. For information on the byte counts of columns according to data type, see [“Maximum row sizes” on page 1164](#).

If the table is a system-period temporal table, the column is also added to the associated history table. The following attributes are copied for the column in the history table:

- Column name and system column name
- Data type
- Length, precision, and scale
- FOR BIT DATA, FOR SBCS DATA, FOR MIXED DATA attribute
- CCSID
- Allocate attribute
- Null attribute
- Hidden attribute
- Field procedure

column-name

Names the column to be added to the table. Do not use the same name for more than one column of the table or for a *system-column-name* of the table. A column named SYSTEM_TIME cannot be added to a table that has a period. Do not qualify *column-name*.

FOR COLUMN *system-column-name*

Provides an IBM i name for the column. Do not use the same name for more than one *column-name* or *system-column-name* of the table.

If the *system-column-name* is not specified, and the *column-name* is not a valid *system-column-name*, a system column name is generated. For more information about how system column names are generated, see [“Rules for Column Name Generation” on page 1166](#).

data-type

Specifies the data type of the column. The data type can be a built-in data type or a distinct type.

built-in-type

Specifies a built-in data type. See [“CREATE TABLE” on page 1115](#) for a description of built-in types.

distinct-type-name

Specifies that the data type of a column is a distinct type. The length, precision, and scale of the column are respectively the length, precision, and scale of the source type of the distinct type. If a distinct type name is specified without a schema name, the distinct type name is resolved by searching the schemas on the SQL path.

DEFAULT

Specifies a default value for the column. This clause cannot be specified more than once in the same *column-definition*. DEFAULT cannot be specified for the following types of columns because the system generates default values:

- a ROWID column
- an identity column
- a row change timestamp column
- a row-begin column
- a row-end column
- a transaction-start-ID column
- a generated expression column

For an XML column, the default is NULL unless NOT NULL is specified; in that case there is no default.

If a value is not specified following the DEFAULT keyword or a DEFAULT clause is not specified, then:

- if the column is a generated column, the default depends on the type of generated column. For these values, see “GENERATED” on page 884 keyword.
- if the column is nullable, the default value is the null value.
- if the column is not nullable, the default depends on the data type of the column:

Data type	Default value
Numeric	0
Fixed-length character or graphic string	Blanks
Fixed-length binary string	Hexadecimal zeros
Varying-length string	A string length of 0
Date	For existing rows, a date corresponding to January 1, 0001. For added rows, the current date.
Time	For existing rows, a time corresponding to 0 hours, 0 minutes, and 0 seconds. For added rows, the current time.
Timestamp	For existing rows, a date corresponding to January 1, 0001 and a time corresponding to 0 hours, 0 minutes, 0 seconds, and 0 fractional seconds. For added rows, the current timestamp.
Datalink	A value corresponding to DLVALUE('','URL','')
<i>distinct-type</i>	The default value of the corresponding source type of the distinct type.

Omission of NOT NULL and DEFAULT from a *column-definition* is an implicit specification of DEFAULT NULL.

constant

Specifies the constant as the default for the column. The specified constant must represent a value that could be assigned to the column in accordance with the rules of assignment as described in “Assignments and comparisons” on page 89. A floating-point constant or decimal floating-point constant must not be used for a SMALLINT, INTEGER, BIGINT, DECIMAL, or NUMERIC column. A decimal constant must not contain more digits to the right of the decimal point than the specified scale of the column.

USER

Specifies the value of the USER special register at the time of INSERT or UPDATE as the default value for the column. The data type of the column must be CHAR or VARCHAR with a length

attribute that is greater than or equal to the length attribute of the USER special register. For existing rows, the value is that of the USER special register at the time the ALTER TABLE statement is processed.

NULL

Specifies null as the default for the column. If NOT NULL is specified, DEFAULT NULL must not be specified within the same *column-definition*.

CURRENT_DATE

Specifies the current date as the default for the column. If CURRENT_DATE is specified, the data type of the column must be DATE or a distinct type based on a DATE.

CURRENT_TIME

Specifies the current time as the default for the column. If CURRENT_TIME is specified, the data type of the column must be TIME or a distinct type based on a TIME.

CURRENT_TIMESTAMP or CURRENT_TIMESTAMP(*integer*)

Specifies the current timestamp as the default for the column. If CURRENT_TIMESTAMP is specified, the data type of the column must be TIMESTAMP or a distinct type based on a TIMESTAMP. The timestamp precision of the CURRENT_TIMESTAMP special register used as the default will always match the timestamp precision of the column, regardless of the precision specified for the special register.

cast-function-name

This form of a default value can only be used with columns defined as a distinct type, BINARY, VARBINARY, BLOB, CLOB, DBCLOB, DATE, TIME, or TIMESTAMP data types. The following table describes the allowed uses of these *cast-functions*.

Data Type	Cast Function Name
Distinct type N based on a BINARY, VARBINARY, BLOB, CLOB, or DBCLOB	BINARY, VARBINARY, BLOB, CLOB, or DBCLOB *
Distinct type N based on a DATE, TIME, or TIMESTAMP	N (the user-defined cast function that was generated when N was created) ** or DATE, TIME, or TIMESTAMP *
Distinct type N based on other data types	N (the user-defined cast function that was generated when N was created) **
BINARY, VARBINARY, BLOB, CLOB, or DBCLOB	BINARY, VARBINARY, BLOB, CLOB, or DBCLOB *
DATE, TIME, or TIMESTAMP	DATE, TIME, or TIMESTAMP *
Notes:	
* The name of the function must match the name of the data type (or the source type of the distinct type) with an implicit or explicit schema name of QSYS2.	
** The name of the function must match the name of the distinct type for the column. If qualified with a schema name, it must be the same as the schema name for the distinct type. If not qualified, the schema name from function resolution must be the same as the schema name for the distinct type.	

constant

Specifies a constant as the argument. The constant must conform to the rules of a constant for the source type of the distinct type or for the data type if not a distinct type. For BINARY, VARBINARY, BLOB, CLOB, DBCLOB, DATE, TIME, and TIMESTAMP functions, the constant must be a string constant.

USER

Specifies the value of the USER special register at the time of INSERT or UPDATE as the default value for the column. The data type of the source type of the distinct type of the column must be CHAR or VARCHAR with a length attribute that is greater than or equal to the length attribute of USER. For existing rows, the value is that of the USER special register at the time the ALTER TABLE statement is processed.

CURRENT_DATE

Specifies the current date as the default for the column. If CURRENT_DATE is specified, the data type of the source type of the distinct type of the column must be DATE.

CURRENT_TIME

Specifies the current time as the default for the column. If CURRENT_TIME is specified, the data type of the source type of the distinct type of the column must be TIME.

CURRENT_TIMESTAMP or CURRENT_TIMESTAMP(*integer*)

Specifies the current timestamp as the default for the column. If CURRENT_TIMESTAMP is specified, the data type of the source type of the distinct type of the column must be TIMESTAMP. The timestamp precision of the CURRENT_TIMESTAMP special register used as the default will always match the timestamp precision of the column, regardless of the precision specified for the special register.

If the value specified is not valid, an error is returned.

GENERATED

Specifies that the database manager generates values for the column. GENERATED may be specified if the column is to be considered an identity column (defined with the AS IDENTITY clause), a row change timestamp column, a row-begin column, a row-end column, a transaction-start-ID column, or a generated expression column. It may also be specified if the data type of the column is a ROWID (or a distinct type that is based on a ROWID). Otherwise, it must not be specified. An identity, ROWID, or row change timestamp column cannot be added to a system-period temporal table.

If the column is nullable, the null value is assigned as the value for the column in existing rows. Otherwise, the value for the column in existing rows depends on the type of generated column:

- IDENTITY generates an identity value for each row
- ROW CHANGE TIMESTAMP uses a value that corresponds to the timestamp of the ALTER TABLE statement
- ROW BEGIN uses a date that corresponds to January 1, 0001 and a time that corresponds to 0 hours, 0 minutes, 0 seconds, and 0 fractional seconds
- ROW END uses a date that corresponds to December 30, 9999, and a time that corresponds to 0 hours, 0 minutes, 0 seconds, and 0 fractional seconds
- TRANSACTION START ID uses a date that corresponds to January 1, 0001, and a time that corresponds to 0 hours, 0 minutes, 0 seconds, and 0 fractional seconds
- A generated expression uses 0 for numeric columns, a string with length 0 for varying-length character string columns, and blanks for fixed-length character string columns.

ALWAYS

Specifies that the database manager will always generate a value for the column when a row is inserted or updated and a default value must be generated. ALWAYS is the recommended value.

BY DEFAULT

Specifies that the database manager will generate a value for the column when a row is inserted or updated and a default value must be generated, unless an explicit value is specified.

For a ROWID column, the database manager uses a specified value, but it must be a valid unique row ID value that was previously generated by the database manager or Db2 for i.

For an identity column or row change timestamp column, the database manager inserts or updates a specified value but does not verify that it is a unique value for the column unless the identity column or row change timestamp column has a unique constraint or a unique index that solely specifies the identity column or row change timestamp column.

AS IDENTITY

Specifies that the column is an identity column for the table. A table can have only one identity column. An identity column is not allowed in a distributed table. AS IDENTITY can be specified only if the data type for the column is an exact numeric type with a scale of zero (SMALLINT, INTEGER, BIGINT, DECIMAL or NUMERIC with a scale of zero, or a distinct type based on one of these data types). If a DECIMAL or NUMERIC data type is specified, the precision must not be greater than 31.

An identity column is implicitly NOT NULL. See the AS IDENTITY clause in [“CREATE TABLE”](#) on page 1115 for the descriptions of the identity attributes.

FOR EACH ROW ON UPDATE AS ROW CHANGE TIMESTAMP

Specifies that the column is a timestamp and the values will be generated by the database manager. The database manager generates a value for the column for each row as a row is inserted, and for every row in which any column is updated. The value generated for a row change timestamp column is a timestamp corresponding to the time of the insert or update of the row. If multiple rows are inserted with a single SQL statement, the value for the row change timestamp column may be different for each row to reflect when each row was inserted. The generated value is not guaranteed to be unique.

A table can have only one row change timestamp column. If *data-type* is specified, it must be a TIMESTAMP with a precision of 6 or a distinct type based on a TIMESTAMP with a precision of 6. A row change timestamp column cannot have a DEFAULT clause and must be NOT NULL.

AS ROW BEGIN

Specifies that the column contains timestamp data and that the values are generated by the database manager. The database manager generates a value for the column for each row as the row is inserted, and for every row in which any column is updated. The generated value is a timestamp that corresponds to the start time that is associated with the most recent transaction. If multiple rows are inserted with a single SQL statement, the values for the transaction start timestamp column are the same for each row.

For a system-period temporal table, the database manager ensures uniqueness of the generated values for a row-begin column across transactions. The timestamp value might be adjusted to ensure that rows inserted into an associated history table have the end timestamp value greater than the begin timestamp value. This can happen when a conflicting transaction is updating the same row in the system-period temporal table. The SYSTIME_PERIOD_ADJ QAQQINI option must be set to *ADJUST for this adjustment to the timestamp value to occur. If multiple rows are inserted or updated within a single SQL transaction and an adjustment is not needed, the values for the row-begin column are the same for all the rows and are unique from the values generated for the column for another transaction.

A row-begin column is intended to be used for a system-period temporal table and is required as the first column of a SYSTEM_TIME period. A table can have only one row-begin column. If *data-type* is not specified, the column is defined as a TIMESTAMP(12). If *data-type* is specified, it must be TIMESTAMP(12). The column cannot have a DEFAULT clause and must be defined as NOT NULL. A row-begin column is not updatable.

For existing rows, the value of the column is set to a date that corresponds to January 1, 0001 and a time that corresponds to 0 hours, 0 minutes, 0 seconds, and 0 fractional seconds.

AS ROW END

Specifies that a value for the data type of the column is assigned by the database manager whenever a row is inserted or any column in the row is updated. The assigned value is TIMESTAMP '9999-12-30-00.00.00.000000000000'. For a system-period temporal table, when a row is deleted, the value of the row-end column in the historical row reflects when the row was deleted. If multiple rows are deleted with a single SQL statement, the values for the column in the historical rows are the same.

A row-end column is intended to be used for a system-period temporal table and is required as the second column of a SYSTEM_TIME period. A table can have only one row-end column. If *data-type* is not specified, the column is defined as TIMESTAMP(12). If *data-type* is specified, it must be TIMESTAMP(12). The column cannot have a DEFAULT clause and must be defined as NOT NULL. A row-end column is not updatable.

For existing rows, the value of the column is set to a date that corresponds to December 30, 9999 and a time that corresponds to 0 hours, 0 minutes, 0 seconds, and 0 fractional seconds.

AS TRANSACTION START ID

Specifies that the value is assigned by the database manager whenever a row is inserted into the table or any column in the row is updated. The database manager assigns a unique timestamp value per transaction or the null value. The null value is assigned to the transaction-start-ID column if the column is nullable and if there is a row-begin column in the table for which the value did not need to be adjusted. Otherwise the value is generated. If multiple rows are inserted or updated within a single SQL transaction, the values for the transaction-start-ID column are the same for all the rows and are unique from the values generated for the column for another transaction.

A transaction-start-ID column is intended to be used for a system-period temporal table and is required for a system-period temporal table. A table can have only one transaction-start-ID column. If *data-type* is not specified, the column is defined as `TIMESTAMP(12)`. If *data-type* is specified it must be `TIMESTAMP(12)`. A transaction-start-ID column cannot have a `DEFAULT` clause. A transaction-start-ID column is not updatable.

For existing rows, if the column is nullable, the null value is assigned as the value of the column. Otherwise, the value of the column is set to a timestamp with a date that corresponds to January 1, 0001 and a time that corresponds to 0 hours, 0 minutes, 0 seconds, and 0 fractional seconds.

DATA CHANGE OPERATION

Specifies that the database manager generates a value for each row that is inserted, for every row in which any column is updated, and for all rows deleted from a system-period temporal table when the history table is defined with `ON DELETE ADD EXTRA ROW`. The column will contain one of the following values:

- I** insert operation
- U** update operation
- D** delete operation

If *data-type* is not specified, the column is defined as `CHAR(1)`. If *data-type* is specified it must be `CHAR(1)`. The column cannot have a `DEFAULT` clause or a field procedure.

For existing rows, if the column is nullable, the null value is assigned as the value of the column. Otherwise, the value of the column is set to blank.

special-register

Specifies that the value of a special register is assigned by the database manager for each row that is inserted, for every row in which any column is updated, and for all rows deleted from a system-period temporal table when the history table is defined with `ON DELETE ADD EXTRA ROW`. The value of the special register at the time of the data change statement is used. If multiple rows are changed with a single SQL statement, the value for the column will be the same for all of the rows.

data-type must be defined according to the following table:

Special register	Data type for the column
CURRENT CLIENT_ACCTNG	VARCHAR(255)
CURRENT CLIENT_APPLNAME	VARCHAR(255)
CURRENT CLIENT_PROGRAMID	VARCHAR(255)
CURRENT CLIENT_USERID	VARCHAR(255)
CURRENT CLIENT_WRKSTNNAME	VARCHAR(255)
CURRENT SERVER	VARCHAR(18)
SESSION_USER	VARCHAR(128)

Special register	Data type for the column
USER	VARCHAR(18)

The column cannot have a DEFAULT clause or a field procedure.

For existing rows, if the column is nullable, the null value is assigned as the value of the column. Otherwise, the value of the column is set to a string with length 0.

built-in-global-variable

Specifies that the value of a built-in global variable is assigned by the database manager for each row that is inserted, for every row in which any column is updated, and for all rows deleted from a system-period temporal table when the history table is defined with ON DELETE ADD EXTRA ROW. The value of the built-in global variable at the time of the data change statement is used. If multiple rows are changed with a single SQL statement, the value for the column will be the same for all of the rows.

data-type must be defined according to the following table:

Built-in global variable	Data type for the column
QSYS2.JOB_NAME	VARCHAR(28)
QSYS2.SERVER_MODE_JOB_NAME	VARCHAR(28)
SYSIBM.CLIENT_HOST	VARCHAR(255)
SYSIBM.CLIENT_IPADDR	VARCHAR(128)
SYSIBM.CLIENT_PORT	INTEGER
SYSIBM.PACKAGE_NAME	VARCHAR(128)
SYSIBM.PACKAGE_SCHEMA	VARCHAR(128)
SYSIBM.PACKAGE_VERSION	VARCHAR(64)
SYSIBM.ROUTINE_SCHEMA	VARCHAR(128)
SYSIBM.ROUTINE_SPECIFIC_NAME	VARCHAR(128)
SYSIBM.ROUTINE_TYPE	CHAR(1)

The column cannot have a DEFAULT clause or a field procedure.

For existing rows, if the column is nullable, the null value is assigned as the value of the column. Otherwise, the value of the column is set to 0 for numeric columns, a string with length 0 for varying-length character string columns, and blanks for fixed-length character string columns.

NOT NULL

Prevents the column from containing null values. Omission of NOT NULL implies that the column can contain null values. If NOT NULL is specified in the column definition, then DEFAULT must also be specified unless the column is an identity column. NOT NULL is required for a row change timestamp column, a row-begin column, and a row-end column.

NOT HIDDEN

Indicates the column is included in implicit references to the table in SQL statements. This is the default.

IMPLICITLY HIDDEN

Indicates the column is not visible in SQL statements unless it is referred to explicitly by name. For example, SELECT * does not include any hidden columns in the result. A table must contain at least one column that is not IMPLICITLY HIDDEN.

column-constraint

The *column-constraint* of a *column-definition* provides a shorthand method of defining a constraint composed of a single column. Thus, if a *column-constraint* is specified in the definition of column C,

the effect is the same as if that constraint were specified as a *unique-constraint*, *referential-constraint* or *check-constraint* in which C is the only identified column.

CONSTRAINT *constraint-name*

A *constraint-name* must not be the same as a constraint name that was previously specified in the ALTER TABLE statement and must not identify a constraint that already exists at the current server.

If the clause is not specified, a unique constraint name is generated by the database manager.

PRIMARY KEY

Provides a shorthand method of defining a primary key composed of a single column. Thus, if PRIMARY KEY is specified in the definition of column C, the effect is the same as if the PRIMARY KEY(C) clause is specified as a separate clause.

This clause must not be specified in more than one *column-definition* and must not be specified at all if the UNIQUE clause is specified in the column definition. The column must not be a LOB, DataLink, or XML column. If a sort sequence is specified, the column must not contain a field procedure.

When a primary key is added, a CHECK constraint is implicitly added to enforce the rule that the NULL value is not allowed in the column that makes up the primary key.

UNIQUE

Provides a shorthand method of defining a unique constraint composed of a single column. Thus, if UNIQUE is specified in the definition of column C, the effect is the same as if the UNIQUE (C) clause is specified as a separate clause.

This clause cannot be specified more than once in a column definition and must not be specified if PRIMARY KEY is specified in the *column-definition*. The column must not be a LOB, DataLink, or XML column. If a sort sequence is specified, the column must not contain a field procedure.

references-clause

The *references-clause* of a column-definition provides a shorthand method of defining a foreign key composed of a single column. Thus, if a *references-clause* is specified in the definition of column C, the effect is the same as if that *references-clause* were specified as part of a FOREIGN KEY clause in which C is the only identified column. The *references-clause* is not allowed if the table is a declared global temporary table, a distributed table, or a history table. The column cannot be a row change timestamp column.

CHECK(*check-condition*)

Provides a shorthand method of defining a check constraint whose *check-condition* only references a single column. Thus, if CHECK is specified in the column definition of column C, no columns other than C can be referenced in the *check-condition* of the check constraint. The effect is the same as if the check constraint were specified as a separate clause.

ROWID, XML, or DATALINK with FILE LINK CONTROL columns cannot be referenced in a CHECK constraint. For additional restrictions see, [“ADD check-constraint” on page 895](#).

FIELDPROC

Designates an *external-program-name* as the field procedure exit routine for the column. It must be an ILE program that does not contain SQL. It cannot be a service program.

The field procedure encodes and decodes column values. Before a value is inserted in the column, it is passed to the field procedure for encoding. Before a value from the column is used, it is passed to the field procedure for decoding.

The field procedure is also invoked during the processing of the ALTER TABLE statement. When so invoked, the procedure provides Db2 with the column's field description. The field description defines the data characteristics of the encoded values. By contrast, the information supplied for the column defines the data characteristics of the decoded values.

constant

Specifies a parameter that is passed to the field procedure when it is invoked. A parameter list is optional.

A field procedure cannot be defined for a column that is a ROWID or DATALINK or a distinct type based on a ROWID or DATALINK. The column must not be an identity column, a row change timestamp column, a row-begin column, a row-end column, a transaction-start-ID column, or a generated expression column. The column must not have a default value of CURRENT DATE, CURRENT TIME, CURRENT TIMESTAMP, or USER. The column cannot be referenced in a check condition, unless it is referenced in a NULL predicate. If it is part of a foreign key, the corresponding parent key column must use the same field procedure. See [SQL Programming](#) for more details on how to create a field procedure.

datalink-options

Specifies the options associated with a DATALINK column. See [“CREATE TABLE” on page 1115](#) for a description of *datalink-options*.

BEFORE *column-name*

Identifies the column before which the new column is added. The name must not be qualified and must identify an existing column in the table. If the BEFORE clause is not specified, the column is added at the end of the row.

ALTER COLUMN *column-alteration*

Alters the definition of a column, including the attributes of an existing identity column. Only the attributes specified will be altered. Others will remain unchanged. If the table is a system-period temporal table, the change will be made to the corresponding history table column, except any change to the default value or a generated column attribute such as identity or row change timestamp is not copied.

column-name

Identifies the column to be altered. The name must not be qualified and must identify an existing column in the table. The name must not identify a column that is being added or dropped in the same ALTER TABLE statement.

SET DATA TYPE *data-type*

Specifies the new data type of the column to be altered. The new data type must be compatible with the existing data type of the column. For more information about the compatibility of data types see [“Assignments and comparisons” on page 89](#). The following alters are not allowed:

- Numeric data type to a character-string data type
- Character-string data type to a numeric data type
- Datetime data type to character-string data type
- Datetime data type to a different datetime data type

For an XML column, only the CCSID can be changed.

The specified length, precision, and scale may be larger, smaller, or the same as the existing length, precision, and scale. However, if the new length, precision, or scale is smaller, truncation or numeric conversion errors may occur.

If the specified column has a default value and a new default value is not specified, the existing default value must represent a value that could be assigned to the column in accordance with the rules for assignment as described in [“Assignments and comparisons” on page 89](#).

A row change timestamp column cannot be altered to a timestamp with a precision other than 6.

A row-begin, row-end, or transaction-start-ID column cannot be altered to a timestamp with a precision other than 12.

A generated expression column cannot be altered to a data type and length different than its required definition.

If the table is a system-period temporal table, the column is also changed in the associated history table. If the table is a system-period temporal table, the column cannot be altered in any way that could cause data loss, such as a shorter string length or lower precision.

If the column is specified in a unique, primary, or foreign key, the new sum of the lengths of the columns of the keys must not exceed $32766 \cdot n$, where n is the number of columns specified that allow nulls.

Changing the attributes will cause any existing values in the column to be converted to the new column attributes according to the rules for assignment to a column, except that string values will be truncated.

Altering the data type attributes of a column can affect a row permission or column mask that is defined for the table. When data type attributes of a column change, row permissions and column masks are reevaluated using the new column attributes. If an error is encountered during the reevaluation process, the ALTER statement fails.

If a row permission or a column mask defined on a different table references this column, the row permission or column mask will not be reevaluated until it is used or is the object of an ALTER REGENERATE. A reevaluation error will result in failure of either the regenerate or the statement that first requires use of the column mask or row permission. The row permission or column mask may need to be dropped and recreated to fix the error.

SET default-clause

Specifies the new default value of the column to be altered. The specified default value must represent a value that could be assigned to the column in accordance with the rules for assignment as described in [“Assignments and comparisons”](#) on page 89.

SET GENERATED ALWAYS or GENERATED BY DEFAULT

Specifies that the database manager generates values for the column. GENERATED may be specified if the column is an identity column, row change timestamp column, or the data type of the column is a ROWID (or a distinct type that is based on a ROWID). For a row-begin, row-end, transaction-start-ID column, and generated expression column, only GENERATED ALWAYS is allowed. For other types of columns, GENERATED must not be specified.

AS IDENTITY

Specifies that the column is changed to an identity column for the table. A table can have only one identity column. An identity column is not allowed in a distributed table. AS IDENTITY can be specified only if the data type for the column is an exact numeric type with a scale of zero (SMALLINT, INTEGER, BIGINT, DECIMAL or NUMERIC with a scale of zero, or a distinct type based on one of these data types). If a DECIMAL or NUMERIC data type is specified, the precision must not be greater than 31.

The column must not be nullable. If the column has an explicit default value, the default value is dropped. See the AS IDENTITY clause in [“CREATE TABLE”](#) on page 1115 for the descriptions of the identity attributes.

as-row-transaction-timestamp-clause

Specifies that the column is changed to a row-begin or row-end column for the table. The column must be a `TIMESTAMP(12)`, must not have a default and must not be nullable.

as-row-transaction-start-id-clause

Specifies that the column is changed to a transaction-start-id column for the table. The column must be a `TIMESTAMP(12)` and must not have a default.

SET NOT NULL

Specifies that the column cannot contain null values. All values for this column in existing rows of the table must be not null. If the specified column has a default value and a new default value is not specified, the existing default value must not be NULL. SET NOT NULL is not allowed if the column is identified in the foreign key of a referential constraint with a DELETE rule of SET NULL and no other nullable columns exist in the foreign key.

SET NOT HIDDEN or IMPLICITLY HIDDEN

Specifies the hidden attribute for the column.

NOT HIDDEN

Indicates the column is included in implicit references to the table in SQL statements.

IMPLICITLY HIDDEN

Indicates the column is not visible in SQL statements unless it is referred to explicitly by name. For example, SELECT * does not include any hidden columns in the result. A table must contain at least one column that is not IMPLICITLY HIDDEN.

SET FIELDPROC

Designates an *external-program-name* as the field procedure exit routine for the column. It must be an ILE program that does not contain SQL. It cannot be a service program.

The field procedure encodes and decodes column values. Before a value is inserted in the column, it is passed to the field procedure for encoding. Before a value from the column is used, it is passed to the field procedure for decoding.

The field procedure is also invoked during the processing of the ALTER TABLE statement. When so invoked, the procedure provides Db2 with the column's field description. The field description defines the data characteristics of the encoded values. By contrast, the information supplied for the column defines the data characteristics of the decoded values.

constant

Specifies a parameter that is passed to the field procedure when it is invoked. A parameter list is optional.

A field procedure cannot be defined for a column that is a ROWID or DATALINK or a distinct type based on a ROWID or DATALINK. The column must not be an identity column, a row change timestamp column, a row-begin column, a row-end column, a transaction-start-ID column, or a generated expression column. The column must not have a default value of CURRENT DATE, CURRENT TIME, CURRENT TIMESTAMP, or USER. The nullability attribute of the encoded and decoded form of the field must match. The column cannot be referenced in a check condition, unless it is referenced in a NULL predicate. If it is part of a foreign key, the corresponding parent key column must use the same field procedure. See [SQL Programming](#) topic collection for an example of a field procedure.

DROP DEFAULT

Drops the current default for the column. The specified column:

- must have a default value and must not have NOT NULL as the null attribute, or
- can have a default value of NULL if the default for the column was defined with DEFAULT NULL.

The new default value is the null value.

DROP NOT NULL

Drops the NOT NULL attribute of the column, allowing the column to have the null value. If a default value is not specified or does not already exist, the new default value is the null value. DROP NOT NULL is not allowed if the column is specified in the primary key of the table or is an identity column, row change timestamp column, row-begin column, row-end column, or ROWID.

DROP GENERATED

Drops the generated attribute of the column. The column must be an identity column, a row change timestamp column, a row-begin column, a row-end column, a transaction-start-ID column, or a generated expression column. The generated attribute cannot be dropped for a row-begin column, row-end column, or transaction-start-ID column if versioning is active.

DROP IDENTITY

Drops the identity attributes of the column, making the column a simple numeric data type column. DROP IDENTITY is not allowed if the column is not an identity column.

DROP ROW CHANGE TIMESTAMP

Drops the row change timestamp attribute of the column, making the column a simple timestamp column. DROP ROW CHANGE TIMESTAMP is not allowed if the column is not a row change timestamp column.

DROP FIELDPROC

Drops the field procedure for the column. DROP FIELDPROC is not allowed if the column does not have a field procedure defined.

identity-alteration

Alters the identity attributes of the column. The column must exist in the specified table and must already be defined with the IDENTITY attribute. For a description of the attributes, see [AS IDENTITY](#).

RESTART

Specifies the next value for an identity column. If WITH *numeric-constant* is not specified, the sequence is restarted at the value specified implicitly or explicitly as the starting value when the identity column was originally created. RESTART does not change the original START WITH value.

WITH *numeric-constant*

Specifies that *numeric-constant* will be used as the next value for the column. The *numeric-constant* must be an exact numeric constant that can be any positive or negative value that could be assigned to this column, without nonzero digits existing to the right of the decimal point.

DROP COLUMN

Drops the identified column from the table.

column-name

Identifies the column to be dropped. The column name must not be qualified. The name must identify a column of the specified table. The name must not identify:

- a column that was already added or altered in this ALTER TABLE statement
- the only column of a table
- the last column of the table that is not hidden
- a partition key of a partitioned table or a distributed table
- a column in a system-period temporal table
- a column in a history table
- a column referenced in the definition of a period

When a column is dropped, any column mask defined for that column is dropped. A column referenced in the definition of a row permission or column mask for a different column cannot be dropped.

CASCADE

Specifies that any views, indexes, triggers, or constraints that are dependent on the column being dropped are also dropped. ⁸¹

RESTRICT

Specifies that the column cannot be dropped if any views, indexes, triggers, materialized query tables, or constraints are dependent on the column. ⁸¹

If all the columns referenced in a constraint are dropped in the same ALTER TABLE statement, RESTRICT does not prevent the drop.

ADD unique-constraint

CONSTRAINT *constraint-name*

Names the constraint. A *constraint-name* must not be the same as a constraint name that was previously specified in the ALTER TABLE statement and must not identify a constraint that already exists at the current server. The *constraint-name* must be unique within a schema.

If not specified, a unique constraint name is generated by the database manager.

UNIQUE (*column-name*,...)

Defines a unique constraint composed of the identified columns. Each *column-name* must be an unqualified name that identifies a column of the table. The same column must not be identified more

⁸¹ A trigger is dependent on the column if it is referenced in the UPDATE OF column list or anywhere in the triggered action.

than once. The column must not be a LOB, DATALINK, or XML column. If a sort sequence is specified, the column must not contain a field procedure. The number of identified columns must not exceed 120, and the sum of their lengths must not exceed $32766-n$, where n is the number of columns specified that allow nulls. UNIQUE is not allowed if the table is a history table.

The set of identified columns cannot be the same as the set of columns specified in another UNIQUE constraint or PRIMARY KEY on the table. For example, UNIQUE (A,B) is not allowed if UNIQUE (B,A) or PRIMARY KEY (A,B) already exists on the table. Any existing nonnull values in the set of columns must be unique. Multiple null values are allowed.

If a unique index already exists on the identified columns, that index is designated as a unique constraint index. Otherwise, a unique index is created to support the uniqueness of the unique key. The unique index is created as part of the system physical file, not as a separate system logical file.

PRIMARY KEY (*column-name*,...)

Defines a primary key composed of the identified columns. Each *column-name* must be an unqualified name that identifies a column of the table. The same column must not be identified more than once. The column must not be a LOB, DATALINK, or XML column. If a sort sequence is specified, the column must not contain a field procedure. The number of identified columns must not exceed 120, and the sum of their lengths must not exceed 32766. The table must not already have a primary key. PRIMARY KEY is not allowed if the table is a history table.

The identified columns cannot be the same as the columns specified in another UNIQUE constraint on the table. For example, PRIMARY KEY (A,B) is not allowed if UNIQUE (B,A) already exists on the table. Any existing values in the set of columns must be unique.

When a primary key is added, a CHECK constraint is implicitly added to enforce the rule that the NULL value is not allowed in any of the columns that make up the primary key.

If a unique index already exists on the identified columns, that index is designated as a primary index. Otherwise, a primary index is created to support the uniqueness of the primary key. The unique index is created as part of the system physical file, not a separate system logical file.

ADD referential-constraint

CONSTRAINT *constraint-name*

Names the constraint. A *constraint-name* must not identify a constraint that already exists at the current server.

If not specified, a unique constraint name is generated by the database manager.

FOREIGN KEY

Defines a referential constraint. FOREIGN KEY is not allowed if the table is a declared global temporary table, a distributed table, or a history table.

Let T1 denote the table being altered.

(*column-name*,...)

The foreign key of the referential constraint is composed of the identified columns. Each *column-name* must be an unqualified name that identifies a column of T1. The same column must not be identified more than once. The column must not be a LOB, DATALINK, or XML column and must not be a row change timestamp column. If a sort sequence is specified, the column must not contain a field procedure. The number of the identified columns must not exceed 120, and the sum of their lengths must not exceed $32766-n$, where n is the number of columns specified that allows nulls.

REFERENCES *table-name*

The *table-name* specified in a REFERENCES clause must identify a base table that exists at the current server, but it must not identify a catalog table, a declared temporary table, a distributed table, or a history table. If the parent is a partitioned table, the unique index that enforces the parent unique constraint must be non-partitioned. This table is referred to as the parent table in the constraint relationship.

A referential constraint is a *duplicate* if its foreign key, parent key, and parent table are the same as the foreign key, parent key, and parent table of an existing referential constraint on the table. Duplicate referential constraints are allowed, but not recommended.

Let T2 denote the identified parent table.

(column-name,...)

The parent key of the referential constraint is composed of the identified columns. Each *column-name* must be an unqualified name that identifies a column of T2. The same column must not be identified more than once. The column must not be a LOB, DATALINK, or XML column and must not be a row change timestamp column. If a sort sequence is specified, the column must not contain a field procedure. The number of identified columns must not exceed 120, and the sum of their lengths must not exceed $32766-n$, where n is the number of columns specified that allow nulls.

The list of column names must be identical to the list of column names in the primary key of T2 or a UNIQUE constraint that exists on T2. The names may be specified in any order. For example, if (A,B) is specified, a unique constraint defined as UNIQUE (B,A) would satisfy the requirement. If a column name list is not specified then T2 must have a primary key. Omission of the column name list is an implicit specification of the columns of that primary key.

The specified foreign key must have the same number of columns as the parent key of T2. The description of the n th column of the foreign key and the n th column of the parent key must have identical data types, lengths, CCSIDs, and FIELDPROCs.

Unless the table is empty, the values of the foreign key must be validated before the table can be used. Values of the foreign key are validated during the execution of the ALTER TABLE statement. Therefore, every nonnull value of the foreign key must match some value of the parent key of T2.

The referential constraint specified by the FOREIGN KEY clause defines a relationship in which T2 is the parent and T1 is the dependent.

ON DELETE

Specifies what action is to take place on the dependent tables when a row of the parent table is deleted. There are five possible actions:

- NO ACTION (default)
- RESTRICT
- CASCADE
- SET NULL
- SET DEFAULT

SET NULL must not be specified unless some column of the foreign key allows null values. SET NULL and SET DEFAULT must not be specified if T1 has an update trigger.

CASCADE must not be specified if T1 has a delete trigger.

CASCADE must not be specified if T1 contains a DataLink column with FILE LINK CONTROL.

The delete rule applies when a row of T2 is the object of a DELETE or propagated delete operation and that row has dependents in T1. Let p denote such a row of T2.

- If RESTRICT or NO ACTION is specified, an error occurs and no rows are deleted.
- If CASCADE is specified, the delete operation is propagated to the dependents of p in T1.
- If SET NULL is specified, each nullable column of the foreign key of each dependent of p in T1 is set to null.
- If SET DEFAULT is specified, each column of the foreign key of each dependent of p in T1 is set to its default value.

ON UPDATE

Specifies what action is to take place on the dependent tables when a row of the parent table is updated.

The update rule applies when a row of T2 is the object of an UPDATE or propagated update operation and that row has dependents in T1. Let *p* denote such a row of T2.

- If RESTRICT or NO ACTION is specified, an error occurs and no rows are updated.

ADD check-constraint

CONSTRAINT *constraint-name*

Names the constraint. A *constraint-name* must not identify a constraint that already exists at the current server. The *constraint-name* must be unique within a schema.

If not specified, a unique constraint name is generated by the database manager.

CHECK(*check-condition*)

Defines a check constraint. The *check-condition* must be true or unknown for every row of the table.

The *check-condition* is a *search-condition*, except:

- It can only refer to columns of the table and the column names must not be qualified.
- The result of any expression in the *check-condition* cannot be a ROWID, XML, or DATALINK with FILE LINK CONTROL data type.
- It must not contain any of the following:
 - Subqueries
 - Aggregate functions
 - Variables
 - Global variables
 - Parameter markers
 - *Sequence-references*
 - Complex expressions that contain LOBs (such as concatenation)
 - OLAP specifications
 - ROW CHANGE expressions
 - IS JSON, JSON_EXISTS, or REGEXP_LIKE predicates
 - Special registers
 - Any function that is not deterministic
 - User-defined functions other than functions that were implicitly generated with the creation of a distinct type
 - The following built-in scalar functions:

ATAN2	DLURLPATHONLY	LOCATE_IN_STRING	RPAD
BSON_TO_JSON	DLURLSCHEME	LPAD	SCORE
CARDINALITY	DLURLSERVER	MAX_CARDINALITY	SOUNDEX
CONTAINS	DLVALUE	MONTHNAME	TABLE_NAME
CURDATE	ENCRYPT_AES	MONTHS_BETWEEN	TABLE_SCHEMA
CURTIME	ENCRYPT_RC2	NEXT_DAY	TIMESTAMP_FORMAT
DATAPARTITIONNAME	ENCRYPT_TDES	NOW	TIMESTAMPDIFF
DATAPARTITIONNUM	GENERATE_UNIQUE	OVERLAY	TRUNC_TIMESTAMP
DAYNAME	GETHINT	RAISE_ERROR	VARCHAR_FORMAT
DBPARTITIONNAME	IDENTITY_VAL_LOCAL	RAND	VERIFY_GROUP_FOR_USER
DECRYPT_BINARY	INSERT	REGEXP_COUNT	WEEK_ISO
DECRYPT_BIT	INTERPRET	REGEXP_INSTR	WRAP
DECRYPT_CHAR	JSON_ARRAY	REGEXP_REPLACE	XMLPARSE

DECRYPT_DB	JSON_OBJECT	REGEXP_SUBSTR	XMLVALIDATE
DIFFERENCE	JSON_QUERY	REPEAT	XSLTRANSFORM
DLURLCOMPLETE ¹	JSON_TO_BSON	REPLACE	
DLURLPATH	JSON_VALUE	ROUND_TIMESTAMP	

¹ For DataLinks with an attribute of FILE LINK CONTROL and READ PERMISSION DB.

ON INSERT VIOLATION

Specifies the action to take if the *check-condition* is false for a row being inserted. If this clause is not specified, an error will occur if the *check-condition* is false for an insert.

SET *column-name* = DEFAULT

The default value for *column-name* is inserted into the table instead of the value provided by the insert operation.

column-name must be referenced in the *check-condition*.

ON UPDATE VIOLATION

Specifies the action to take if the *check-condition* is false for a row being updated. If this clause is not specified, an error will occur if the *check-condition* is false for an update.

PRESERVE *column-name*

The current value for *column-name* remains in the table rather than being replaced by the value provided by the update operation.

column-name must be referenced in the *check-condition*.

For more information about search-condition, see [“Search conditions” on page 227](#).

DROP

PRIMARY KEY

Drops the definition of the primary key and all referential constraints in which the primary key is a parent key. The table must have a primary key.

UNIQUE *constraint-name*

Drops the unique constraint *constraint-name* and all referential constraints dependent on this unique constraint. The *constraint-name* must identify a unique constraint on the table. DROP UNIQUE will not drop a PRIMARY KEY unique constraint.

FOREIGN KEY *constraint-name*

Drops the referential constraint *constraint-name*. The *constraint-name* must identify a referential constraint in which the table is a dependent.

CHECK *constraint-name*

Drops the check constraint *constraint-name*. The *constraint-name* must identify a check constraint on the table.

CONSTRAINT *constraint-name*

Drops the constraint *constraint-name*. The *constraint-name* must identify a unique, referential, or check constraint on the table. If the constraint is a PRIMARY KEY or UNIQUE constraint, all referential constraints in which the primary key or unique key is a parent are also dropped.

CASCADE

Specifies for unique constraints that any referential constraints that are dependent on the constraint being dropped are also dropped.

RESTRICT

Specifies for unique constraints that the constraint cannot be dropped if any referential constraints are dependent on the constraint.

ADD partitioning-clause

Changes a non-partitioned table into a partitioned table. If the specified table is a distributed table or already a partitioned table, an error is returned. A DDS-created physical file cannot be partitioned. See [“CREATE TABLE” on page 1115](#) for a description of the *partitioning-clause*.

Changing a non-partitioned table that contains data into a partitioned table will require data movement between the data partitions. When using range partitioning, all existing data in the table must be assignable to the specified range partitions.

DROP PARTITIONING

Changes a partitioned table into a non-partitioned table. If the specified table is already non-partitioned, an error is returned.

Changing a partitioned table that contains data into a non-partitioned table will require data movement between the data partitions.

ADD PARTITION *add-partition*

Adds one or more partitions to a partitioned table. The specified table must be a partitioned table. The number of partitions must not exceed 256.

Changing the number of hash partitions in a partitioned table that contains data will require data movement between the data partitions.

partition-name

Names the partition. A *partition-name* must not identify a data partition that already exists in the table.

If the clause is not specified, a unique partition name is generated by the database manager.

boundary-spec

Specifies the boundaries of a range partition. If the specified table is not a range partitioned table, an error is returned. Both a *starting-clause* and an *ending-clause* must be specified. See [“CREATE TABLE” on page 1115](#) for a description of the *boundary-spec*.

integer HASH PARTITIONS

Specifies the number of hash partitions to be added. If the specified table is not a hash partitioned table, an error is returned.

ALTER PARTITION

Alters the boundaries of a partition of a range partitioned table. If the specified table is not a range partitioned table, an error is returned.

Changing the boundaries of one or more partitions of a table that contains data may require data movement between the data partitions. All existing data in the table must be assignable to the specified range partitions.

partition-name

Specifies the name of the partition to alter. The *partition-name* must identify a data partition that exists in the table.

boundary-spec

Specifies the new boundaries of a range partition. Both a *starting-clause* and an *ending-clause* must be specified. See [“CREATE TABLE” on page 1115](#) for a description of the *boundary-spec*.

DROP PARTITION

Drops a partition of a partitioned table. If the specified table is not a partitioned table, an error is returned. If the last remaining partition of a partitioned table is specified, an error is returned. A partition cannot

be dropped from a system-period temporal table unless the PRESERVE ROWS option is specified or the partition is empty.

partition-name

Specifies the name of the partition to drop. The *partition-name* must identify a data partition that exists in the table.

DELETE ROWS

Specifies that any data in the specified partition will be discarded. All data stored in the partition is dropped from the table without processing any delete triggers.

PRESERVE ROWS

Specifies that any data in the specified partition will be preserved by moving it to the remaining partitions without processing any delete or insert triggers. If the specified table is a range partitioned table, PRESERVE ROWS must not be specified. Dropping a hash partition will require data movement between the remaining data partitions.

ATTACH PARTITION

Attaches another table as a new data partition. The data in the table being attached becomes a new partition of the table being attached to. There is no data movement involved. If the specified target table is not a partitioned table, an error is returned. If the target table already has the maximum number of partitions, an error is returned. If the table is hash partitioned, an error is returned.

If the table being attached has either row level access control or column level access control activated then the table to attach to must have the same controls activated. No row permissions or column masks are automatically carried over from the table being attached to the target table. The column masks and row permissions do not necessarily need to be exactly the same on both tables, although this would be best from a security perspective. But if the table being attached has row level access control activated then the table to attach to must also have row level access control activated. Similarly, if the table being attached has column level access control activated and at least one column mask enabled then the table to attach to must also have column level access control activated and a column mask enabled for the corresponding columns.

partition-name

Names the data partition. The name must not be the same as any other data partition for the table. If this clause is not specified and the source table is partitioned, the partition name of the source table will be used. Otherwise, if this clause is not specified, a unique partition name is generated by the database manager.

boundary-spec

Specifies the boundaries for the new partition. If a *boundary-spec* is not specified:

- The source table must be a partitioned table with a single partition and the *boundary-spec* of that partition will be implicitly used.
- The number of partition keys and the partition key names of the source table must be the same as those of the target table.

The implicit or explicit range must not overlap that of an existing data partition. See [“CREATE TABLE” on page 1115](#) for a description of the *boundary-spec*. If a *boundary-spec* is specified, the data in the source table must conform to the specified range or subsequent SQL operations may be unpredictable.

FROM *table-name1*

Specifies the table that is to be used as the source of data for the new partition. The table must exist in the same relational database as the target table. If the specified table is not a partitioned table, an error is returned. If the table is hash partitioned, an error is returned. The table must not be a view, a materialized query table, a declared global temporary table, a system-period temporal table, a history table, or a system table. The table must not have a NOT LOGGED INITIALLY attribute. The table definition of *table-name1* cannot have multiple partitions, and it must match the altered table in the following ways:

- The number of columns must be the same.

- The data types, attributes, field procedures, generated expressions, default values, and CCSIDs of the columns in the same ordinal position in the table must be the same.
- The nullability characteristic of the columns in the same ordinal position in the table must be the same.
- If the target table has a row change timestamp column, the corresponding column of the source table must be a row change timestamp column.
- For varying length or LOB data types, the ALLOCATE length of columns in the same ordinal position in the table must be the same.

After the data from *table-name1* is successfully attached, an operation equivalent to DROP TABLE *table-name1* CASCADE is performed to remove this table, which no longer has data, from the database.

DETACH PARTITION

Detaches a partition of a partitioned table. If the specified table is not a partitioned table, an error is returned. A new partitioned table named *table-name1* with one partition will be created to contain the detached partition data. *partition-name* cannot be the last remaining partition of the table being altered. The table being altered must not be a system-period temporal table, a parent table of an enforced referential constraint, or use HASH partitioning.

If the source table contains an identity column, the corresponding column in the created table will not be an identity column. All other column attributes from the source table are defined for the corresponding column in the created table. If the source table has constraints, similar constraints are not added to the created table.

When a partition is detached from a table for which either row level access control or column level access control is activated, the new table that is created for the detached data will automatically have row level access control activated to protect the detached data. Direct access to this new table will return no rows until appropriate row permissions are defined for the table or row level access control is deactivated for this table.

Privileges on the source table are not propagated to the created table.

partition-name

Specifies the name of the partition to detach. *partition-name* must identify a data partition that exists in the table.

table-name1

Names the table. The name, including the implicit or explicit qualifier, must not identify an alias, file, index, table, or view that already exists at the current server.

If SQL names were specified, the table will be created in the schema specified by the implicit or explicit qualifier.

If system names were specified, the table will be created in the schema that is specified by the qualifier. If not qualified:

- If the value of the CURRENT SCHEMA special register is *LIBL, the table will be created in the current library (*CURLIB).
- Otherwise, the table will be created in the current schema.

If the specified partitioned table is journaled, the new table will be journaled to the same journal. Otherwise, the new table will not be journaled.

ADD MATERIALIZED QUERY **materialized-query-definition**

Changes a base table to a materialized query table. If the specified table is already a materialized query table or if the table is referenced in another materialized query table, an error is returned.

select-statement

Defines the query on which the table is based. The columns of the existing table must meet the following characteristics:

- The number of columns in the table must be the same as the number of result columns in the *select-statement*.
- The column attributes of each column of the table must be compatible to the column attributes of the corresponding result column in the *select-statement*.

The *select-statement* for a materialized query table must not contain a reference to the table being altered, a view over the table being altered, or another materialized query table. For additional details about specifying *select-statement* for a materialized query table, see [“CREATE TABLE” on page 1115](#).

refreshable-table-options

Specifies the materialized query table options for altering a base table to a materialized query table.

DATA INITIALLY DEFERRED

Specifies that the data in the table is not validated as part of the ALTER TABLE statement. A REFRESH TABLE statement can be used to make sure the data in the materialized query table is the same as the result of the query in which the table is based.

DATA INITIALLY IMMEDIATE

Specifies that the data is inserted in the table from the result of the query as part of processing the ALTER TABLE statement.

REFRESH DEFERRED

Specifies that the data in the table can be refreshed at any time using the REFRESH TABLE statement. The data in the table only reflects the result of the query as a snapshot at the time when the REFRESH TABLE statement is processed or when it was last updated.

MAINTAINED BY USER

Specifies that the materialized query table is maintained by the user. The user can use INSERT, DELETE, UPDATE, or REFRESH TABLE statements on the table.

ENABLE QUERY OPTIMIZATION or DISABLE QUERY OPTIMIZATION

Specifies whether this materialized query table can be used for query optimization.

ENABLE QUERY OPTIMIZATION

The materialized query table can be used for query optimization.

DISABLE QUERY OPTIMIZATION

The materialized query table will not be used for query optimization. The table can still be queried directly.

If row level or column level access control is activated for any table that is directly or indirectly referenced in the *select-statement* and row access control is not activated for the table being altered, row access control is implicitly activated for the altered table. This restricts direct access to the contents of the materialized query table. A query that explicitly references the table will return a warning that there is no data in the table. To provide access to the materialized query table, an appropriate row permission can be created or an ALTER TABLE DEACTIVATE ROW ACCESS CONTROL on the materialized query table can be issued to remove the row level protection if that is appropriate.

ALTER MATERIALIZED QUERY materialized-query-table-alteration

Changes the attributes of a materialized query table. The *table-name* must identify a materialized query table.

select-statement

Defines the query on which the table is based. The columns of the existing table must meet the following characteristics:

- The number of columns in the table must be the same as the number of result columns in the *select-statement*.

- The column attributes of each column of the table must be compatible to the column attributes of the corresponding result column in the *select-statement*.

The *select-statement* for a materialized query table must not contain a reference to the table being altered, a view over the table being altered, or another materialized query table. For additional details about specifying *select-statement* for a materialized query table, see [“CREATE TABLE” on page 1115](#).

refreshable-table-options

Specifies the materialized query table options for altering a base table to a materialized query table.

DATA INITIALLY DEFERRED

Specifies that the data in the table is not refreshed or validated as part of the ALTER TABLE statement. A REFRESH TABLE statement can be used to make sure the data in the materialized query table is the same as the result of the query in which the table is based.

DATA INITIALLY IMMEDIATE

Specifies that the data is inserted in the table from the result of the query as part of processing the ALTER TABLE statement.

REFRESH DEFERRED

Specifies that the data in the table can be refreshed at any time using the REFRESH TABLE statement. The data in the table only reflects the result of the query as a snapshot at the time when the REFRESH TABLE statement is processed or when it was last updated.

MAINTAINED BY USER

Specifies that the materialized query table is maintained by the user. The user can use INSERT, DELETE, UPDATE, or REFRESH TABLE statements on the table.

ENABLE QUERY OPTIMIZATION or DISABLE QUERY OPTIMIZATION

Specifies whether this materialized query table can be used for query optimization.

ENABLE QUERY OPTIMIZATION

The materialized query table can be used for query optimization.

DISABLE QUERY OPTIMIZATION

The materialized query table will not be used for query optimization. The table can still be queried directly.

SET *refreshable-table-alteration*

Changes how the table is maintained or whether the table can be used in query optimization.

MAINTAINED BY USER

Specifies that the materialized query table is maintained by the user. The user can use INSERT, DELETE, UPDATE, or REFRESH TABLE statements on the table.

REFRESH DEFERRED

Specifies that the data in the table can be refreshed at any time using the REFRESH TABLE statement. The data in the table only reflects the result of the query as a snapshot at the time when the REFRESH TABLE statement is processed or when it was last updated.

ENABLE QUERY OPTIMIZATION or DISABLE QUERY OPTIMIZATION

Specifies whether this materialized query table can be used for query optimization.

ENABLE QUERY OPTIMIZATION

The materialized query table can be used for query optimization.

DISABLE QUERY OPTIMIZATION

The materialized query table will not be used for query optimization. The table can still be queried directly.

DROP MATERIALIZED QUERY

Changes a materialized query table so that it is no longer a materialized query table. The table specified by *table-name* must be defined as a materialized query table. The definition of columns are not changed, but the table can no longer be used for query optimization and is no longer valid for use with the REFRESH TABLE statement. Row level access and column level access for the table remain in their current activated or deactivated state.

ACTIVATE NOT LOGGED INITIALLY

Activates the NOT LOGGED INITIALLY attribute of the table for this current unit of work.

Any changes made to the table by INSERT, DELETE, or UPDATE statements in the same unit of work after the table is altered by this statement are not logged (journalled).

At the completion of the current unit of work, the NOT LOGGED INITIALLY attribute is deactivated and all operations that are done on the table in subsequent units of work are logged (journalled).

ACTIVATE NOT LOGGED INITIALLY is not allowed in a transaction if data change operations are pending for *table-name* or cursors are currently open under commit that reference *table-name*.

ACTIVATE NOT LOGGED INITIALLY is not allowed if the table is a system-period temporal table or a history table. It is ignored if the table has a DATALINK column with FILE LINK CONTROL or if running with isolation level No Commit (NC).

WITH EMPTY TABLE

Causes all data currently in the table to be removed. If the unit of work in which this ALTER statement was issued is rolled back, the table data will NOT be returned to its original state. When this action is requested, no DELETE triggers defined on the affected table are fired.

WITH EMPTY TABLE cannot be specified for a materialized query table or for a parent in a referential constraint. WITH EMPTY TABLE is ignored if running with isolation level No Commit (NC).

A DELETE statement without a WHERE clause will typically perform as well or better than ACTIVATE NOT LOGGED INITIALLY WITH EMPTY TABLE and will allow a ROLLBACK to rollback the delete of the rows in the table.

ADD PERIOD FOR *period-definition*

Adds a period definition to the table.

SYSTEM_TIME (*begin-column-name*, *end-column-name*)

Defines a system period with the name SYSTEM_TIME. There must not be a column in the table with the name SYSTEM_TIME. A table can have only one SYSTEM_TIME period. *begin-column-name* must be defined as ROW BEGIN and *end-column-name* must be defined as ROW END

DROP PERIOD SYSTEM_TIME

Drops the SYSTEM_TIME period from the table. The SYSTEM_TIME period cannot be dropped if the table is a system-period temporal table.

ADD VERSIONING USE HISTORY TABLE *history-table-name*

Specifies that the table is a system-period temporal table. The table must not already be defined as a system-period temporal table or a history table. A SYSTEM_TIME period and a transaction-start-ID column must be defined in the table. The table must not be a materialized query table or a distributed table and must not have a ROWID column or a DATALINK column with FILE LINK CONTROL. Neither the table nor the history table can have the NOT LOGGED INITIALLY attribute activated.

Historical versions of the rows in the table are retained by the database manager. An associated history table is used to store the historical rows of the table. The database manager records extra information that indicates when a row was inserted into the table, and when it was updated or deleted. When a row in a system-period temporal table is updated, a previous version of the row is kept. When data in a system-period temporal table is deleted, the old version of the row is inserted as a historical record.

References to the table can include a period specification to indicate which versions of the data are to be returned.

history-table-name

Identifies a history table where historical rows of the system-period temporal table are kept. *history-table-name* must identify a table that exists at the current server, and is not a catalog table, an

existing system-period temporal table, an existing history table, a declared global temporary table, a materialized query table, or a view.

The identified history table must not contain an identity column, row change timestamp column, row-begin column, row-end column, transaction start-ID column, or include a period. It cannot be part of a referential constraint or have a unique or primary key constraint.

Once a table has been defined as a history table, no direct inserts or updates can be performed on the table. Deletes are allowed.

ON DELETE ADD EXTRA ROW

Indicates that when a row is deleted from the system-period temporal table, the deleted row is added to the history table. This additional history row is not returned for a query with a period specification for a system-period temporal table. Values for the row begin, row end, and any generated expression columns are generated when this row is added.

The ON DELETE ADD EXTRA ROW clause is intended to be used when the system-period temporal table contains generated expression columns. The generated expression columns in an extra row contain information about the delete operation that resulted in the extra row in the history table.

The system-period temporal table and the identified history table must be in the same schema and must have the same number and order of columns. The following attributes for the corresponding columns of the two tables must be the same:

- Name and system column name
- Data type
- Length, precision, and scale
- FOR BIT DATA, FOR SBCS DATA, FOR MIXED DATA attribute
- CCSID
- Null attribute
- Hidden attribute
- Field procedure
- Date and time formats and separators
- Sort sequence and language ID

If the history table contains data, ensure that the data accurately represents historical rows. If the data does not accurately represent historical rows, the results of temporal queries might be unexpected.

If row access control or column access control is activated for the system-period temporal table and row access control is not activated on the history table, the database manager automatically activates row access control on the history table and creates a default row permission for the history table.

DROP VERSIONING

Specifies that the table is no longer a system-period temporal table. The table must be a system-period temporal table. Historical data is no longer recorded and maintained for the table. The definition of the columns and data of the table are not changed, but the table is no longer treated as a system-period temporal table. The SYSTEM_TIME period is retained. Subsequent queries that reference the table must not specify a SYSTEM_TIME period specification for the table. The relationship between the system-period temporal table and the associated history table is removed. The history table is not dropped and the contents of the history table are not affected.

ACTIVATE ROW ACCESS CONTROL or DEACTIVATE ROW ACCESS CONTROL

Specifies whether enabled row permissions are to be applied by Db2 to control the set of rows in the table that are accessible.

ACTIVATE ROW ACCESS CONTROL

Specifies to activate row access control for the table. If the table is an alias, row access control is activated for the base table. Row access control cannot be activated for a declared global temporary table or a table in QTEMP.

A default row permission is implicitly created and allows no access to any rows of the table unless an enabled row permission exists that provides access for the authorization IDs or group profiles that are specified in the definition of the permission. A query that references the table before such a row permission exists will return a warning that there is no data in the table.

If a trigger exists for the table, the trigger must be defined with the SECURED attribute and must not be a READ trigger.

The table must not be referenced in the definition of a view if an INSTEAD OF trigger that is defined with the NOT SECURED attribute exists for the view.

When the table is referenced in a data manipulation statement, all enabled row permissions that have been created for the table, including the default row permission, are applied by Db2 to control the set of rows in the table that are accessible. A permission that gets an error when trying to be activated cannot be activated until any errors in the permission definition are resolved. This may require the permission to be dropped and recreated with a modified definition.

If a materialized query table that depends on the table (directly, or indirectly through a view) for which row level access control is being activated and that materialized query table does not already have row level access control activated, row level access control is implicitly activated for the materialized query table. This restricts direct access to the contents of the materialized query table. A query that explicitly references the table before such a row permission is defined will return a warning that there is no data in the table. To provide access to the materialized query table, an appropriate row permission can be created, or an ALTER TABLE DEACTIVATE ROW ACCESS CONTROL on the materialized query table can be issued to remove the row level protection if that is appropriate.

ACTIVATE ROW ACCESS CONTROL is ignored if row access control is already defined as activated for the table.

If the table is a system-period temporal table and row access control is not already activated on the history table, the database manager automatically activates row access control on the history table and creates a default row permission for the history table.

DEACTIVATE ROW ACCESS CONTROL

Specifies to deactivate row access control for the table. When the table is referenced in a data manipulation statement, any enabled row permissions defined on the table are not applied by Db2 to control the set of rows in the table that are accessible.

DEACTIVATE ROW ACCESS CONTROL is ignored if row access control is already defined as not activated for the table.

ACTIVATE COLUMN ACCESS CONTROL or DEACTIVATE COLUMN ACCESS CONTROL

Specifies whether enabled column masks are to be applied by Db2 to mask column values returned from the table.

ACTIVATE COLUMN ACCESS CONTROL

Specifies to activate column access control for the table. If the table is an alias, column access control is activated for the base table.

If a trigger exists for the table, the trigger must be defined with the SECURED attribute and must not be a READ trigger.

The table must not be referenced in the definition of a view if an INSTEAD OF trigger that is defined with the NOT SECURED attribute exists for the view.

The access to the table is not restricted but when the table is referenced in a data manipulation statement, all enabled column masks that have been created for the table are applied by Db2 to mask the values returned for the columns referenced in the final result table of the queries or to determine

the new values used in the data change statements. A column mask that gets an error when trying to be activated cannot be activated until any errors in the mask definition are resolved. This may require the column mask to be dropped and recreated with a modified definition.

If a materialized query table that depends on the table (directly, or indirectly through a view) for which column level access control is being activated and that materialized query table does not already have row level access control activated, row level access control is implicitly activated for the materialized query table. This restricts direct access to the contents of the materialized query table. A query that explicitly references the table before such a row permission is defined will return a warning that there is no data in the table. To provide access to the materialized query table, an appropriate row permission can be created, or an ALTER TABLE DEACTIVATE ROW ACCESS CONTROL on the materialized query table can be issued to remove the row level protection if that is appropriate.

ACTIVATE COLUMN ACCESS CONTROL is ignored if column access control is already defined as activated for the table.

If the table is a system-period temporal table and row access control is not already activated on the history table, the database manager automatically activates row access control on the history table and creates a default row permission for the history table.

DEACTIVATE COLUMN ACCESS CONTROL

Specifies to deactivate column access control for the table. When the table is referenced in a data manipulation statement, any enabled column masks defined on the table are not applied by Db2 to control the values returned for the columns referenced in the final result table of the queries or to determine whether the new values can be used in the data change statements.

DEACTIVATE COLUMN ACCESS CONTROL is ignored if column access control is already defined as not activated for the table.

VOLATILE or NOT VOLATILE

Indicates to the optimizer whether the cardinality of table *table-name* can vary significantly at run time. Volatility applies to the number of rows in the table, not to the table itself. The default is NOT VOLATILE.

VOLATILE

Specifies that the cardinality of *table-name* can vary significantly at run time, from empty to large. To access the table, the optimizer will typically use an index, if possible.

NOT VOLATILE

Specifies that the cardinality of *table-name* is not volatile. Access plans that reference this table will be based on the cardinality of the table at the time the access plan is built.

media-preference

Specifies the preferred storage media for the table or partition.

UNIT ANY

No storage media is preferred. Storage for the table or partition will be allocated from any available storage media. If UNIT ANY is specified on the table, any *media-preference* that is specified on a partition is used. If the table or partition is currently on solid state disk storage, it may be moved asynchronously onto other media, if available.

UNIT SSD

Solid state disk storage media is preferred. Storage for the table or partition may be allocated from solid state disk storage media, if available. If UNIT SSD is specified on the table, any *media-preference* specified on a partition is ignored. If the table or partition is not currently on solid state disk storage, it may be moved asynchronously onto solid state disk storage media, if available.

memory-preference

KEEP IN MEMORY

Specifies whether the data for the table should be brought into a main storage pool when the data is used in a query.

NO

The data will not be brought into a main storage pool.

YES

The data will be brought into a main storage pool.

Notes

Column references: A column can only be referenced *once* in an ADD, ALTER, or DROP COLUMN clause in a single ALTER TABLE statement. However, that same column can be referenced multiple times for adding or dropping constraints in the same ALTER TABLE statement.

Order of operations: The order of operations within an ALTER TABLE statement is:

- drop period
- drop constraints
- drop materialized query table
- drop partition
- drop partitioning
- drop columns for which the RESTRICT option was specified
- alter all other column definitions
 - drop columns for which the CASCADE option was specified
 - alter column drop attributes (for example, DROP DEFAULT)
 - alter column alter attributes
 - alter column add attributes
 - add columns
- alter partition
- add or alter materialized query table
- add partition or add partitioning
- add constraints
- add period

Within each of these stages, the order in which the user specifies the clauses is the order in which they are performed, with one exception. If any columns are being dropped, that operation is logically done before any column definitions are added or altered.

QTEMP considerations: Any views or logical files in another job's QTEMP that are dependent on the table being altered will be dropped as a result of an ALTER TABLE statement. These objects will not be dropped if the alter is changing cardinality, media preference, memory preference, adding or dropping constraints, activating or deactivating row and column access control, or when specifying ACTIVATE NOT LOGGED INITIALLY.

Authority checking: Authority checking is performed only on the table being altered and any object explicitly referenced in the ALTER TABLE statement (such as tables referenced in the fullselect). Other objects may be accessed by the ALTER TABLE statement, but no authority to those objects is required. For example, no authority is required on views that exist on the table being altered, nor on dependent tables that reference the table being altered through a referential constraint.

Backup recommendation: It is strongly recommended that a current backup of the table and dependent views and logical files exist prior to altering a table.

Performance considerations: The following performance considerations apply to an ALTER TABLE statement when adding, altering, or dropping columns from a table:

- The data in the table may be copied.⁸²

Adding and dropping columns require the data to be copied.

Altering a column usually requires the data to be copied. The data does not need to be copied, however, if the alter only includes the following changes:

- The length attribute of a VARCHAR or VARBINARY column is increasing and the current length attribute is greater than 20.
- The length attribute of a VARGRAPHIC column is increasing and the current length attribute is greater than 10.
- The allocated length of a VARCHAR or VARBINARY column is changing and the current and new allocated lengths are both less than or equal to 20.
- The allocated length of a VARGRAPHIC column is changing and the current and new allocated lengths are both less than or equal to 10.
- The CCSID of a column is changing but no conversion is necessary between the old and new CCSID. For example, if one CCSID is 65535, no data conversion is necessary.
- The default value is changing, and the length of the default value is not greater than the current allocated length.
- DROP DEFAULT is specified.
- DROP NOT NULL is specified, but at least one nullable column will still exist in the table after the alter table is complete.

Altering a column that has a field procedure defined might require the field procedure to be run two times.

- Indexes may need to be rebuilt.⁸³

An index does not need to be rebuilt when columns are added to a table or when columns are dropped or altered and those columns are not referenced in the index key.

Altering a column that is used in the key of an index or constraint usually requires the index to be rebuilt. The index does not need to be rebuilt, however, in the following cases:

- The length attribute of a VARCHAR, VARBINARY, or VARGRAPHIC key is increasing.
- The CCSID of a column is changing but no conversion is necessary between the old and new CCSID. For example, if one CCSID is 65535.

Adding a generated column: When you add a row change timestamp column, row-begin column, row-end column, transaction-start-ID column, or generated expression column to an existing table, the initial values are generated during the alter operation.

Considerations for implicitly hidden columns: A column that is defined as implicitly hidden can be explicitly referenced on the ALTER statement. For example, an implicitly hidden column can be altered, can be specified as part of a referential constraint or a check constraint, or a materialized query table definition.

Altering materialized query tables: The isolation level at the time when a base table is first altered to become a materialized query table by the ALTER TABLE statement is the isolation level for the materialized query table.

Altering a table to change it to a materialized query table with query optimization enabled makes the table eligible for use in optimization. Therefore, ensure that the data in the table is accurate. The DATA INITIALLY IMMEDIATE clause can be used to refresh the data when the table is altered.

ATTACH PARTITION effects on dependent views, indexes, and materialized query tables:

- Views and DDS-created logical files on the source table are dropped.
- Views that reference the target table will now include the new partition.

⁸² In cases where enough storage does not exist to make a complete copy, a special copy that only requires approximately 16-32 megabytes of free storage is performed.

⁸³ Any indexes that need to be rebuilt are rebuilt asynchronously by database server jobs.

- DDS-created logical files that referenced all the partitions prior to the attach will now include the new partition.
- Materialized query tables on the source table are dropped.
- Materialized query tables on the target table will be preserved but users will need to refresh the materialized query tables to include the data associated with the new partition.
- Partitioned (non-spanning) indexes on the source table that correspond to partitioned indexes on the target table will be preserved as part of the target table's partitioned index as long as the logical page size of the index is the same. If the logical page size is different, the index over that partition will be dropped.
- Partitioned (non-spanning) indexes on the source table that do not correspond to partitioned indexes on the target table will be dropped.
- Partitioned (non-spanning) indexes on the target table that do not correspond to indexes on the source table will be modified to include the new partition.
- Non-partitioned (spanning) indexes on the target table will be rebuilt to include the new partition.

DETACH PARTITION effects on dependent views, indexes, and materialized query tables:

- Views on the source table will no longer include the detached partition.
- DDS-created logical files that referenced all the partitions prior to the detach will include the remaining partitions.
- Materialized query tables on the source table will be preserved but users will need to refresh the materialized query tables to remove the data associated with the detached partition.
- Any partitioned (non-spanning) index on the source table will be modified to remove the detached partition index.
- Any non-partitioned (spanning) index on the source table will be rebuilt.

Considerations for using row access control and column access control:

Row access control that is activated explicitly: The ACTIVATE ROW ACCESS CONTROL clause is used to activate row access control for a table. When this happens, a default row permission is implicitly created and allows no access to any rows of the table, unless later another enabled row permission exists that provides access for the authorization IDs that are specified in the definition of the permission. The default row permission is always enabled.

When the table is referenced in a data manipulation statement, all enabled row permissions that have been created for the table, including the default row permission, are implicitly applied by Db2 to control which rows in the table are accessible. A row access control search condition is derived by application of the logical OR operator to the search condition in each enabled row permission. This derived search condition acts as a filter to the table before any user specified operations such as predicates, grouping, ordering, etc. are processed. This derived search condition permits the authorization IDs that are specified in the permission definitions to access certain rows in the table. See the description of subselect for information on how the application of enabled row permissions affects the fetch operation. See the data change statements for information on how the application of enabled row permissions affects the data change operation.

Row access control remains enforced until the DEACTIVATE ROW ACCESS CONTROL clause is used to stop enforcing it.

Implicit row permission that is created when row access control is activated for a table: When the ACTIVATE ROW ACCESS CONTROL clause is used to activate row access control for a table, Db2 implicitly creates a default row permission for the table. The default row permission prevents all access to the table. The implicitly created row permission is in the same schema of the base table and has a name in the form of QIBM_DEFAULT_ *system-table-name* _ *system_schema_name*.

The default row permission is always enabled.

The default row permission is dropped when row access control is deactivated or when the table is dropped.

Activating column access control: The `ACTIVATE COLUMN ACCESS CONTROL` clause is used to activate column access control for a table. The access to the table is not restricted but when the table is referenced in a data manipulation statement, all enabled column masks that have been created for the table are applied to mask the column values referenced in the final result table of the query or to determine the new values used in the data change statements.

When column masks are used to mask the column values, they determine the values in the final result table. If a column has a column mask and the column (a simple reference to a column name or embedded in an expression) appears in the outermost select list, the column mask is applied to the column to produce the value for the final result table. If the column does not appear in the outermost select list but it participates in the final result table, for example, it appears in a nested table expression or view, the column mask is applied to the column returned in the result table of the nested table expression or view so that it can be used in the final result table.

The application of column masks does not interfere with the operations of other clauses within the statement such as the `WHERE`, `GROUP BY`, `HAVING`, `SELECT DISTINCT`, and `ORDER BY`. The rows returned in the final result table remain the same, except that the values in the resultant rows might have been masked by the column masks. As such, if the masked column also appears in an `ORDER BY` sort-key, the order is based on the original column values and the masked values in the final result table might not reflect that order. Similarly, the masked values might not reflect the uniqueness enforced by `SELECT DISTINCT`. If the masked column is embedded in an expression, the result of the expression can become different because the column mask is applied on the column before the expression evaluation can take place. For example, applying a column mask on column `SSN` can change the result of aggregate function `COUNT(DISTINCT SSN)` because the `DISTINCT` operation is performed on the masked values. On the other hand, if the expression in a query is the same as the expression used to mask the column value in the column mask definition, the result of the expression in the query might remain unchanged. For example, the expression in the query is `'XXX-XX-' || SUBSTR(SSN, 8, 4)` and the same expression appears in the column mask definition. In this particular example, the user can replace the expression in the query with column `SSN` to avoid the same expression being evaluated twice.

The following are the contexts where the column masks are used by Db2 to mask the column values for the result of a query. Certain restrictions might apply to some contexts. Those restrictions are described in a separate list.

- The outermost `SELECT` clause of a `SELECT` or `SELECT INTO` statement, or if the column does not appear in the outermost select list but it participates in the final result table, the outermost `SELECT` clause of the corresponding nested table expression, common table expression, or view where the column appears.
- The outermost `SELECT` clause that is used to derive the new values for an `INSERT`, `UPDATE`, or `MERGE` statement.
- A scalar-fullselect expression that appears in the outermost `SELECT` clause of the above statements, the right side of a `SET` variable assignment statement, the `VALUES INTO` statement, or the `VALUES` statement.

A column mask is created without knowing all of the contexts in which it might be used. To mask a column value in the final result table, the column mask definition is merged into the statement by Db2. When the column mask definition is brought into the context of the statement, it might conflict with certain SQL semantics in the statement. Therefore, in some situations the combination of the statement and the application of a column mask can return an error. The following describes when the error might be returned:

- If the `FROM` clause in a subselect references a recursive common table expression, and if the result of the recursive common table expression is used to derive the final result table, the column mask cannot be applied to a column that is referenced in the fullselect of the recursive common table expression.
- If a user-defined function is defined with the `NOT SECURED` option, the argument of the function must not reference a column for which a column mask is enabled and column access control is activated for its table. This rule applies to user-defined functions that are referenced anywhere in the statement.

To avoid the above error situations, one of the following actions must be taken:

- modify or remove the above contexts from the statement

- disable the column mask
- drop the column mask, modify the definition, and recreate the column mask
- deactivate column access control for the table

In some situations, if the statement contains a SELECT DISTINCT or a GROUP BY and a column mask is applied to a column that directly or indirectly derives the result of SELECT DISTINCT or GROUP BY, the statement might return a result that is not deterministic. These situations include:

- The column mask definition references other columns from the same table as the column to which the column mask is applied.
- The column is referenced in the argument of built-in scalar functions (such as COALESCE, IFNULL, NULLIF, MAX, MIN, LOCATE).
- The column is referenced in the argument of an aggregate function.
- The column is embedded in an expression and the expression contains a function that is not deterministic or has an external action.

If the column is not nullable, the definition of its column mask will not, most likely, consider a null value for the column. After the column access control is activated for the table, if the table is the null-padded table in an outer join, the value of the column in the final result table might be a null. To ensure that the column mask can mask a null value, if the table is the null-padded table in an outer join, Db2 will add "WHEN target-column IS NULL THEN NULL" as the first WHEN clause to the column mask definition. This forces a null value to always be masked as a null value. For a nullable column, this removes the ability to mask a null value as something else. Example 4 shows this added WHEN clause.

For INSERT, UPDATE, and MERGE, when a column is referenced while deriving the values of a new row, if that column has an enabled column mask, the masked value is used to derive the new values. If the object table also has column access control activated, the column mask that is applied to derive the new values must return the column itself, not a constant or an expression. If the column mask does not mask the column to itself, the new value cannot be used for insert or update and an error is returned. The rules that are used to apply column masks in order to derive the new values follow the same rules described above for the final result table of a query. See the data change statements for how the column masks are used to affect the insertability and updatability.

A column mask can be applied only to a base table column. If a view, nested table expression, or common table expression column is involved in the final result table, the above error situations can occur inside the view, nested table expression, or common table expression.

Column access control does not affect the XMLTABLE built-in function. If the input to the XMLTABLE function is a column with a column mask, the column mask is not applied.

Column access control remains activated until the DEACTIVATE COLUMN ACCESS CONTROL clause is used to stop enforcing it.

Column masks and trigger transition variables: Values for OLD ROW and OLD TABLE transition variables will never contain masked values.

A SET *transition-variable* assignment statement can assign masked data to the variable. If a violation check constraint does not exist for the column, the masked data will be inserted or updated in the column and no error will be issued.

Stop enforcing row or column access control: The DEACTIVATE ROW ACCESS CONTROL clause is used to stop enforcing row access control for a table. The default row permission is dropped. Thereafter, when the table is referenced in a data manipulation statement, explicitly created row permissions are not applied. The table is accessible based on the granted privileges.

The DEACTIVATE COLUMN ACCESS CONTROL clause is used to stop enforcing column access control for a table. Thereafter, when the table is referenced in a data manipulation statement, the column masks are not applied. The unmasked column values are used for the final result table. The explicitly created row permissions or column masks, if any, remain but have no effect.

Secure triggers for row and column access control: Triggers are used for database integrity, and as such a balance between row and column access control (security) and database integrity is needed.

Enabled row permissions and column masks are not applied to the initial values of transition variables and transition tables. Row and column access control enforced for the triggering table is also ignored for any transition variables or transition tables referenced in the trigger body. To ensure there is no security concern for SQL statements in the trigger action to access sensitive data in transition variables and transition tables, the trigger must be created or altered with the SECURED option. If a trigger is not secure, row and column access control cannot be enforced for the triggering table.

Secure user-defined functions for row and column access control: If a row permission or column mask definition references a user-defined function, the function must be altered with the SECURED option because the sensitive data might be passed as arguments to the function.

Db2 considers the SECURED option an assertion that declares the user has established a change control audit procedure for all changes to the user-defined function. It is assumed that such a control audit procedure is in place for all versions of the user-defined function, and that all subsequent ALTER FUNCTION statements or changes to external programs are being reviewed by this audit process.

Database operations where row and column access control is not applicable: Row and column access control must not compromise database integrity. Columns involved in primary keys, unique keys, indexes, check constraints, and referential integrity must not be subject to row and column access control. Column masks can be defined for those columns but they are not applied during the process of key building or constraint or RI enforcement.

Defining a system-period temporal table: A system-period temporal table definition includes the following aspects:

- A system period named SYSTEM_TIME which is defined using a row-begin column and a row-end column. See [“AS ROW BEGIN” on page 885](#), [“AS ROW END” on page 885](#), and [“ADD PERIOD FOR period-definition” on page 902](#)
- A transaction-start-ID column. See [“AS TRANSACTION START ID” on page 886](#)
- A system-period data versioning definition specified on a subsequent ALTER TABLE statement using the ADD VERSIONING clause which includes the name of the associated history table. See [“ADD VERSIONING USE HISTORY TABLE history-table-name” on page 902](#).

Considerations for transaction-start-ID columns: A transaction-start-ID column contains a null value if the column allows null values and there is a row-begin column and the value of the row-begin column is unique from values of row-begin columns generated for other transactions. Given that the column may contain null values, it is recommended that one of the following methods be used when retrieving a value from the column:

- COALESCE (transaction_start_id_col, row_begin_col)
- CASE WHEN transaction_start_id_col IS NOT NULL THEN transaction_start_id_col ELSE row_begin_col END

Considerations for system-period temporal tables and row and column access control: Row and column access control can be defined on both the system-period temporal table and the associated history table.

- When a system-period temporal table is accessed, any row and column access rules defined on the system-period temporal table are applied to all of the rows returned from the system-period temporal table, regardless of whether the rows are stored in the system-period temporal table or the history table. The row and column access rules defined on the history table are not applied.
- When the history table is accessed directly, the row and column access rules defined on the history table are applied.

When a system-period temporal table is defined and row access control or column access control is activated for the system-period temporal table and row access control is not already activated on the history table, the database manager automatically activates row access control on the history table and creates a default row permission for the history table.

Managing a history table: For an authorized user, limited modifications can be made directly to the history table. Rows can be deleted from the table and partitions can be added or dropped.

Read-only cursors and read-only views: The rules that are used to determine a read-only cursor or a read-only view remain unaffected by row and column access control. The effect of application of enabled column masks is not known until run time. Therefore, the data change operation on a writable cursor or a writable view could still fail at run time.

Syntax alternatives: The following syntax is supported for compatibility to prior releases. The syntax is non-standard and should not be used:

- INLINE LENGTH is a synonym for ALLOCATE.
- If an ADD constraint is the first clause of the ALTER TABLE statement, the ADD keyword is optional, but strongly recommended. Otherwise, it is required.
- *constraint-name* (without the CONSTRAINT keyword) may be specified following the FOREIGN KEY keywords in a *referential-constraint*.
- PART is a synonym for PARTITION.
- PARTITION *partition-number* may be specified instead of PARTITION *partition-name*. A *partition-number* must not identify an existing partition of the table or a partition that was previously specified in the ALTER TABLE statement.

If a *partition-number* is not specified, a unique partition number is generated by the database manager.

- VALUES is a synonym for ENDING AT.
- SET MATERIALIZED QUERY AS DEFINITION ONLY is a synonym for DROP MATERIALIZED QUERY.
- SET SUMMARY AS DEFINITION ONLY is a synonym for DROP MATERIALIZED QUERY
- SET MATERIALIZED QUERY AS (*select-statement*) is a synonym for ADD MATERIALIZED QUERY (*select-statement*)
- SET SUMMARY AS (*select-statement*) is a synonym for ADD MATERIALIZED QUERY (*select-statement*)

Cascaded Effects

Adding a column has no cascaded effects to SQL views, materialized query tables, or most logical files. For example, adding a column to a table does not cause the column to be added to any dependent views, even if those views were created with a SELECT * clause.

Adding a column does cause any SQL triggers to be recreated and include the new column.

Dropping or altering a column may cause several cascaded effects. [Table 86 on page 912](#) lists the cascaded effects of dropping a column.

<i>Table 86. Cascaded effects of dropping a column</i>		
Operation	RESTRICT Effect	CASCADE Effect
Drop of a column referenced by a view	The drop of the column is not allowed.	The view and all views dependent on that view are dropped.

⁸⁴ A column will also be added to a logical file that shares its physical file's format when a column is added to that physical file (unless that format is used again in the logical file with another based-on file).

Table 86. Cascaded effects of dropping a column (continued)

Operation	RESTRICT Effect	CASCADE Effect
Drop of a column referenced by a non-view logical file	<p>The drop is allowed, and the column is dropped from the logical file if:</p> <ul style="list-style-type: none"> • The logical file shares a format with the file being altered, and • The dropped column is not used as a key field or in select/omit specifications, and • That format is not used again in the logical file with another based-on file. <p>Otherwise, the drop of the column is not allowed.</p>	<p>The drop is allowed, and the column is dropped from the logical file if:</p> <ul style="list-style-type: none"> • The logical file shares a format with the file being altered, and • The dropped column is not used as a key field or in select or omit specifications, and • That format is not used again in the logical file with another based-on file. <p>Otherwise, the logical file is dropped.</p>
Drop of a column referenced in an index as part of a key, in the WHERE clause, in the INCLUDE clause, or as an explicit or implicit column in the ADD columns clause	<p>The drop of the index is not allowed.</p>	<p>The index is dropped.</p>
Drop of a column referenced in the key of an keyed physical file where the key is not a PRIMARY KEY	<p>The physical file is changed to a non-keyed physical file.</p>	<p>The physical file is changed to a non-keyed physical file.</p>
Drop of a column referenced in a unique constraint	<p>If all the columns referenced in the unique constraint are dropped in the same ALTER COLUMN statement and the unique constraint is not referenced by a referential constraint, the columns and the constraint are dropped. (Hence, the index used to satisfy the constraint is also dropped.) For example, if column A is dropped, and a unique constraint of UNIQUE (A) or PRIMARY KEY (A) exists and no referential constraints reference the unique constraint, the operation is allowed.</p> <p>Otherwise, the drop of the column is not allowed.</p>	<p>The unique constraint is dropped as are any referential constraints that refer to that unique constraint. (Hence, any indexes used by those constraints are also dropped).</p>

Table 86. Cascaded effects of dropping a column (continued)

Operation	RESTRICT Effect	CASCADE Effect
Drop of a column referenced in a referential constraint	If all the columns referenced in the referential constraint are dropped at the same time, the columns and the constraint are dropped. (Hence, the index used by the foreign key is also dropped). For example, if column B is dropped and a referential constraint of FOREIGN KEY (A) exists, the operation is allowed. Otherwise, the drop of the column is not allowed.	The referential constraint is dropped. (Hence, the index used by the foreign key is also dropped).
Drop of a column referenced in an SQL trigger	The drop of the column is not allowed.	The SQL trigger is dropped.
Drop of a column referenced in an MQT	The drop of the column is not allowed.	The MQT is dropped.

Table 87 on page 914 lists the cascaded effects of altering a column. (Alter of a column in the following chart means altering a data type, precision, scale, length, or nullability characteristic.)

Table 87. Cascaded effects of altering a column

Operation	Effect
Alter of a column referenced by a view	The alter is allowed. The views that are dependent on the table will be recreated. The new column attributes will be used when recreating the views.
Alter of a column referenced by a non-view logical file	The alter is allowed. The non-view logical files that are dependent on the table will be recreated. If the logical file shares a format with the file being altered, and that format is not used again in the logical file with another based-on file, the new column attributes will be used when recreating the logical file. Otherwise, the new column attributes will not be used when recreating the logical file. Instead, the current logical file attributes are used.
Alter of a column referenced in the key of an index.	The alter is allowed. (Hence, the index will usually be rebuilt.)
Alter of a column referenced in a unique constraint	The alter is allowed. (Hence, the index will usually be rebuilt.) If the unique constraint is referenced by a referential constraint, the attributes of the foreign keys no longer match the attributes of the unique constraint including the field procedure. The constraint will be placed in a defined and check-pending state.

Table 87. Cascaded effects of altering a column (continued)

Operation	Effect
Alter of a column referenced in a referential constraint	The alter is allowed. <ul style="list-style-type: none"> • If the referential constraint is in the defined but check-pending state, the alter is allowed and an attempt is made to put the constraint in the enabled state. (Hence, the index used to satisfy the unique constraint will usually to be rebuilt.) • If the referential constraint is in the enabled state, the constraint is placed in the defined and check-pending state.
Alter of a column referenced in an SQL trigger	The trigger is recreated.
Alter of a column referenced in an MQT	The MQT is recreated to include the new attributes.

Examples

Example 1: Add a new column named RATING, which is one character long, to the DEPARTMENT table.

```
ALTER TABLE DEPARTMENT
ADD RATING CHAR
```

Example 2: Add a new column named PICTURE_THUMBNAIL to the EMPLOYEE table. Create PICTURE_THUMBNAIL as a BLOB column with a maximum length of 1K characters.

```
ALTER TABLE EMPLOYEE
ADD PICTURE_THUMBNAIL BLOB(1K)
```

Example 3: Assume a new table EQUIPMENT has been created with the following columns:

```
EQUIP_NO
  INT
EQUIP_DESC
  VARCHAR(50)
LOCATION
  VARCHAR(50)
EQUIP_OWNER
  CHAR(3)
```

Add a referential constraint to the EQUIPMENT table so that the owner (EQUIP_OWNER) must be a department number (DEPTNO) that is present in the DEPARTMENT table. If a department is removed from the DEPARTMENT table, the owner (EQUIP_OWNER) values for all equipment owned by that department should become unassigned (or set to null). Give the constraint the name DEPTQUIP.

```
ALTER TABLE EQUIPMENT
FOREIGN KEY DEPTQUIP (EQUIP_OWNER)
REFERENCES DEPARTMENT
ON DELETE SET NULL
```

Change the default value for the EQUIP_OWNER column to 'ABC'.

```
ALTER TABLE EQUIPMENT
ALTER COLUMN EQUIP_OWNER
SET DEFAULT 'ABC'
```

Drop the LOCATION column. Also drop any views, indexes, or constraints that are built on that column.

```
ALTER TABLE EQUIPMENT  
DROP COLUMN LOCATION CASCADE
```

Alter the table so that a new column called SUPPLIER is added, the existing column called LOCATION is dropped, a unique constraint over the new column SUPPLIER is added, and a primary key is built over the existing column EQUIP_NO.

```
ALTER TABLE EQUIPMENT  
ADD COLUMN SUPPLIER INT  
DROP COLUMN LOCATION  
ADD UNIQUE SUPPLIER  
ADD PRIMARY KEY EQUIP_NO
```

Notice that the column EQUIP_DESC is a variable length column. If an allocated length of 25 was specified, the following ALTER TABLE statement would not change that allocated length.

```
ALTER TABLE EQUIPMENT  
ALTER COLUMN EQUIP_DESC  
SET DATA TYPE VARCHAR(60)
```

Example 4: Alter the EMPLOYEE table. Add the check constraint named REVENUE defined so that each employee must make a total of salary and commission greater than \$30,000.

```
ALTER TABLE EMPLOYEE  
ADD CONSTRAINT REVENUE  
CHECK (SALARY + COMM > 30000)
```

Example 5: Alter EMPLOYEE table. Drop the constraint REVENUE which was previously defined.

```
ALTER TABLE EMPLOYEE  
DROP CONSTRAINT REVENUE
```

Example 6: Alter the EMPLOYEE table. Alter the column PHONENO to accept up to 20 characters for a phone number.

```
ALTER TABLE EMPLOYEE  
ALTER COLUMN PHONENO SET DATA TYPE VARCHAR (20)
```

Example 7: Alter the base table TRANSCOUNT to a materialized query table. The result of the *select-statement* must provide a set of columns that match the columns in the existing table (same number of columns and compatible attributes).

```
ALTER TABLE TRANSCOUNT  
ADD MATERIALIZED QUERY  
(SELECT ACCTID, LOCID, YEAR, COUNT(*) AS CNT  
 FROM TRANS  
 GROUP BY ACCTID, LOCID, YEAR )  
DATA INITIALLY DEFERRED  
REFRESH DEFERRED  
MAINTAINED BY USER
```

Example 8: Alter the CUSTOMER table to become a system-period temporal table.

First, add the columns and the period definition that are required to become a system-period temporal table, along with two columns that will be used for tracking identity of row changes:

```
ALTER TABLE CUSTOMER  
ADD COLUMN SYSTEM_START TIMESTAMP(12) NOT NULL GENERATED ALWAYS AS ROW BEGIN  
ADD COLUMN SYSTEM_END TIMESTAMP(12) NOT NULL GENERATED ALWAYS AS ROW END  
ADD COLUMN TRANSACTION_ID TIMESTAMP(12) GENERATED ALWAYS AS TRANSACTION START ID  
ADD COLUMN AUDIT_TYPE_CHANGE CHAR(1) GENERATED ALWAYS AS (DATA CHANGE OPERATION)  
ADD COLUMN AUDIT_USER VARCHAR(128) GENERATED ALWAYS AS (SESSION_USER)  
ADD PERIOD FOR SYSTEM_TIME (SYSTEM_START, SYSTEM_END);
```

Next, create the history table:

```
CREATE TABLE CUSTOMER_HISTORY LIKE CUSTOMER;
```

Finally, define the CUSTOMER table as a system-period temporal table with the CUSTOMER_HISTORY table as the associated history table:

```
ALTER TABLE CUSTOMER ADD VERSIONING USE HISTORY TABLE CUSTOMER_HISTORY
ON DELETE ADD EXTRA ROW;
```

Examples for column access control

Example 1: Based on the data in the CUSTOMER table, the SELECT DISTINCT statement returns one row with the SALARY value 100,000. A column mask, SALARY_MASK, is created to mask the salary value. After column access control is activated for the CUSTOMER table, the column mask is applied to SALARY column. A user with the 'MGR' authorization ID issues a SELECT DISTINCT statement. The SELECT DISTINCT statement still returns one row because the removal of duplicates is based on the unmasked value of the SALARY column, but the value that is returned in that row is based on the masked SALARY value, which can be either 125,000 or 110,000.

The table CUSTOMER contains:

SALARY	COMMISSION	EMPID
100,000	25,000	123456
100,000	10,000	654321

```
CREATE MASK SALARY_MASK ON CUSTOMER
FOR COLUMN SALARY RETURN
CASE WHEN (SESSION_USER = 'MGR')
THEN SALARY + COMMISSION
ELSE SALARY
END
ENABLE;

COMMIT;

ALTER TABLE CUSTOMER
ACTIVATE COLUMN ACCESS CONTROL;

COMMIT;

SELECT DISTINCT SALARY FROM CUSTOMER;
```

Example 2: Based on the data in T1 and T2 tables, the SELECT DISTINCT statement using the COALESCE function returns one row with the T1.C1 value of 1. A column mask, C1_MASK, is created to mask the value of T1.C1. After column access control is activated for table T1, the column mask is applied to column C1 of table T1. A user with the 'EMP' authorization ID issues a SELECT DISTINCT statement. The SELECT DISTINCT statement still returns one row because the removal of duplicates is based on the unmasked value of T1.C1 from the COALESCE function, but the value that is returned in that row is based on the masked value of T1.C1 from the COALESCE function. The returned value can be either 2 or 3.

```
INSERT INTO T1(C1) VALUES(1);
INSERT INTO T1(C1) VALUES(1);

INSERT INTO T2(C1) VALUES(2);
INSERT INTO T2(C1) VALUES(3);

CREATE MASK C1_MASK ON T1
FOR COLUMN C1 RETURN
CASE WHEN (SESSION_USER = 'EMP')
THEN NULL
ELSE C1
END
ENABLE;

COMMIT;

ALTER TABLE T1
ACTIVATE COLUMN ACCESS CONTROL;

COMMIT;
```

```
SELECT DISTINCT COALESCE(T1.C1, T2.C1) FROM T1, T2;
```

Example 3: Based on the data in the CUSTOMER table, the maximum income is the same in the states CA and IL, 50,000, thus, the SELECT DISTINCT statement returns one row. A column mask, INCOME_MASK, is created to mask the income value. After column access control is activated for the CUSTOMER table, the column mask is applied to the INCOME column before the MAX aggregate function is evaluated. However, the INCOME_MASK column mask, masks the income value of 0 as 100,000 in state IL. As a result, the maximum income becomes 100,000 for state IL, but the maximum income is still 50,000 for state CA. X.B is used in a predicate in the SELECT DISTINCT statement, therefore, the original INCOME values and the original results of the MAX(INCOME) function must be preserved. So the SELECT DISTINCT statement still returns one row, but the value in that row might not be deterministic, that is, the value might be 50,000 from the 'CA' row or might be 100,000 from the 'IL' row.

The CUSTOMER table contains:

STATE	INCOME
CA	40,000
CA	50,000
IL	0
IL	10,000
IL	50,000

```
CREATE MASK INCOME_MASK ON CUSTOMER
FOR COLUMN INCOME RETURN
CASE WHEN(INCOME = 0)
THEN 100000
ELSE INCOME
END
ENABLE;

COMMIT;

ALTER TABLE CUSTOMER
ACTIVATE COLUMN ACCESS CONTROL;

COMMIT;

SELECT DISTINCT B FROM
(SELECT STATE, MAX(INCOME) FROM CUSTOMER
GROUP BY STATE)
X(A, B)
WHERE B > 10000;
```

Example 4: The expression INCOME + RAND() is not deterministic because the RAND function is not deterministic. Based on the data in the CUSTOMER table, the SELECT DISTINCT statement will, most likely, return two distinct rows. However, it could return only one row. A column mask, INCOME_MASK, is created to mask the income value. After column access control is activated for the CUSTOMER table, the column mask is applied to the INCOME column, which causes the masked value for both rows to be the same. Because the RAND function is not deterministic, the SELECT DISTINCT statement will, most likely, still return two distinct rows, but it could return only one row. The uncertainty caused by the RAND function causes the result of the SELECT DISTINCT statement to not be deterministic.

The CUSTOMER table contains:

STATE	INCOME
CA	40,000
CA	50,000

```
CREATE MASK INCOME_MASK ON CUSTOMER
FOR COLUMN INCOME RETURN
```

```

CASE WHEN(INCOME = 40,000)
  THEN 50000
  ELSE INCOME
END
ENABLE;

COMMIT;

ALTER TABLE CUSTOMER
  ACTIVATE COLUMN ACCESS CONTROL;

COMMIT;

SELECT DISTINCT A FROM
  (SELECT INCOME + RAND() FROM CUSTOMER)
  X(A)
WHERE A > 10000;

```

Example 5: A column mask, STATE_MASK, is created for the STATE column of the CUSTOMER table to return a value that shows the city name with the state if the city is SJ, SFO, or OKLD. Otherwise the city is not returned, just the state. After column access control is activated for the CUSTOMER table, a SELECT statement which groups results using the STATE column is issued. However, because the CITY column that is referenced in the STATE_MASK column mask is not a grouping column, an error is returned to signify that the STATE_MASK column mask is not appropriate for this statement.

The CUSTOMER table contains:

STATE	CITY	INCOME
CA	SJ	40,000
CA	SC	30,000
CA	SB	60,000
CA	SFO	80,000
CA	OKLD	50,000
CA	SJ	70,000
NY	NY	50,000

```

CREATE MASK STATE_MASK ON CUSTOMER
FOR COLUMN STATE RETURN
CASE WHEN(CITY = 'SJ')
  THEN CITY||', '||STATE
  WHEN(CITY = 'SFO')
  THEN CITY||', '||STATE
  WHEN(CITY = 'OKLD')
  THEN CITY||', '||STATE
  ELSE STATE
END
ENABLE;

COMMIT;

ALTER TABLE CUSTOMER
  ACTIVATE COLUMN ACCESS CONTROL;

COMMIT;

SELECT STATE, AVG(INCOME) FROM CUSTOMER
  GROUP BY STATE
  HAVING STATE = 'CA';

```

ALTER TRIGGER

The ALTER TRIGGER statement changes the description of the trigger at the current server.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

If ENABLE or DISABLE is specified, the privileges held by the authorization ID of the statement must include at least one of the following:

- For the trigger identified in the statement:
 - The system authority *USE on the Change Physical File Trigger (CHGPFTRG) command,
 - The ALTER privilege on the table or view on which the trigger is defined, and
 - The system authority *EXECUTE on the library containing the trigger.
- Database administrator authority

If the SECURED option is specified, or if the NOT SECURED option is specified and the trigger is currently secured:

- The authorization ID of the statement must have security administrator authority. See [“Administrative authority”](#) on page 15.

For information about the system authorities corresponding to SQL privileges, see [Corresponding System Authorities When Checking Privileges to a Table or View](#).

Syntax

Notes:

¹ The same clause must not be specified more than one time.

Description

trigger-name

Identifies the trigger to be altered. The *trigger-name* must identify a trigger that exists at the current server. It can be either an SQL or a native trigger.

SECURED or NOT SECURED

Specifies whether the trigger is considered secure for row and column access control. If row or column access control is active for the triggering table, altering the trigger from SECURED to NOT SECURED will return an error.

SECURED

Specifies that the trigger is considered secure for row access control and column access control.

SECURED must be specified for a trigger whose subject table is using row access control or column access control. SECURED must also be specified for a trigger that is created for a view and one or more of the underlying tables in the view definition is using row access control or column access control.

NOT SECURED

Specifies that the trigger is considered not secure for row access control and column access control.

NOT SECURED must not be specified for a trigger whose subject table is using row access control or column access control. NOT SECURED must also not be specified for a trigger that is created for a view and one or more of the underlying tables in the view definition is using row access control or column access control.

ENABLE or DISABLE

Specifies the state to which the trigger is to be changed.

ENABLE

The trigger will be called during the appropriate data change operations.

DISABLE

The trigger will not be called during the appropriate data change operations.

Notes

Altering a trigger from NOT SECURED to SECURED: The trigger is considered secure after the ALTER TRIGGER statement is executed. Db2 treats the SECURED attribute as an assertion that declares that the user has established an audit procedure for all activities in the trigger body. If a secure trigger references user-defined functions, Db2 assumes those functions are secure without validation. If those functions can access sensitive data, a user with security administrator authority needs to ensure that those functions are allowed to access that data and that an audit procedure is in place for those functions, and that all subsequent ALTER FUNCTION statements are being reviewed through this audit process.

Transition variable values and row and column access control: Row and column access control is not enforced for transition variables and transition tables. If row or column access control is enforced for the triggering table, row permissions and column masks are not applied to the initial values of transition variables and transition tables. Row and column access control enforced for the triggering table is also ignored for transition variables and transition tables that are referenced in the trigger body or are passed as arguments to user-defined functions invoked within the trigger body. To ensure there are no security concerns for SQL statements accessing sensitive data in transition variables and transition tables, the trigger must be created with the SECURED option. If the trigger is not secure, row access control and column access control cannot be enforced for the triggering table.

Example

Example 1: Change the definition of trigger TRIGGER1 to secured:

```
ALTER TRIGGER TRIGGER1  
SECURED
```

Example 2: Change the definition of trigger TRIGGER1 to not secured:

```
ALTER TRIGGER TRIGGER1  
NOT SECURED
```

ASSOCIATE LOCATORS

The ASSOCIATE LOCATORS statement gets the result set locator value for each result set returned by a procedure.

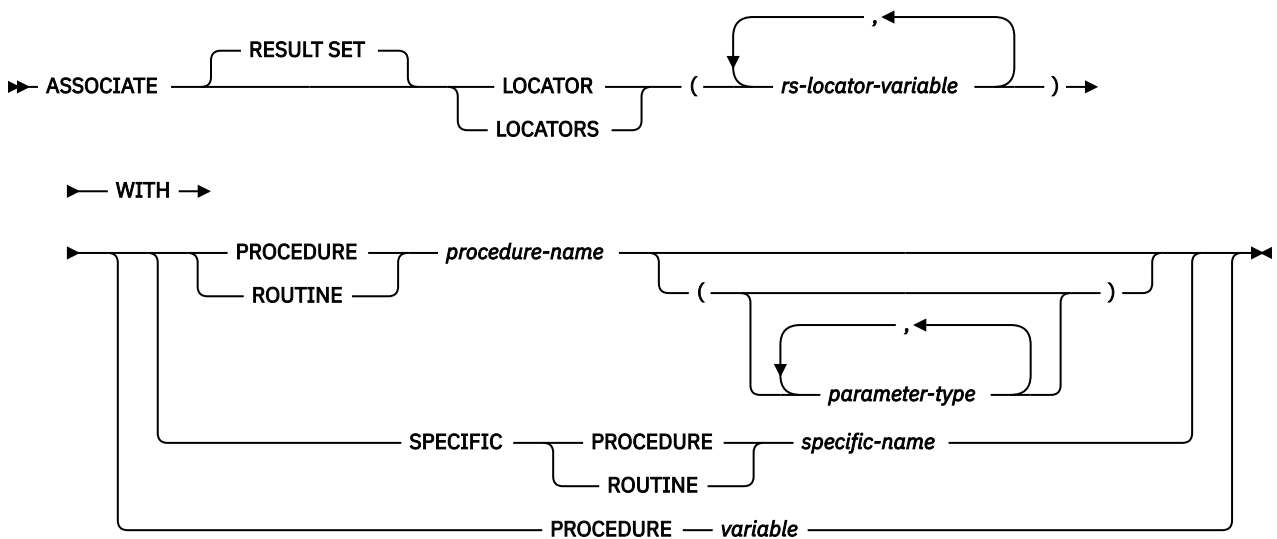

Invocation

This statement can be embedded in an application program. It is an executable statement that can be dynamically prepared. It cannot be issued interactively. It must not be specified in REXX.

Authorization

None required.

Syntax

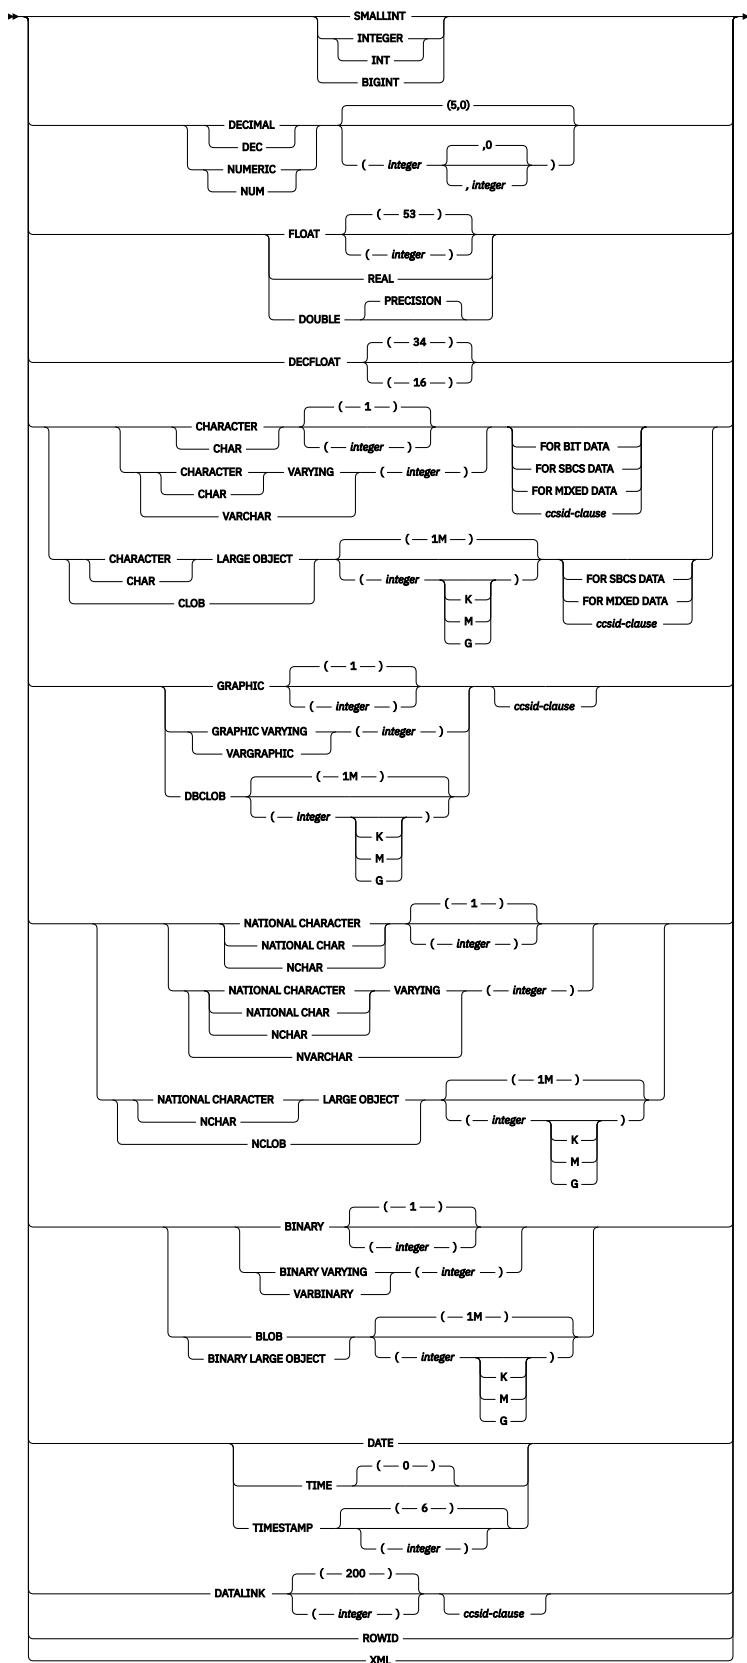

parameter-type

data-type

built-in-type

ccsid-clause

➤ CCSID — *integer* ➤

Description

rs-locator-variable

Identifies a result set locator variable that has been declared according to the rules for declaring result set locator variables.

WITH PROCEDURE *procedure-name* or *variable*

Identifies the procedure that returned one or more result sets. When the ASSOCIATE LOCATORS statement is executed, the procedure name must identify a procedure that the requester has already invoked using the SQL CALL statement.

PROCEDURE or SPECIFIC PROCEDURE

Identifies the procedure. The *procedure-name* must identify a procedure that exists at the current server.

PROCEDURE *procedure-name*

Identifies the procedure by its name. The *procedure-name* must identify exactly one procedure. The procedure may have any number of parameters defined for it. If there is more than one procedure of the specified name in the specified or implicit schema, an error is returned.

PROCEDURE *procedure-name (parameter-type, ...)*

Identifies the procedure by its procedure signature, which uniquely identifies the procedure. The *procedure-name (parameter-type, ...)* must identify a procedure with the specified procedure signature. The specified parameters must match the data types in the corresponding position that were specified when the procedure was created. The number of data types, and the logical concatenation of the data types is used to identify the specific procedure instance which is to be labeled on. Synonyms for data types are considered a match. Parameters that have defaults must be included in this signature.

If *procedure-name ()* is specified, the procedure identified must have zero parameters.

procedure-name

Identifies the name of the procedure.

(parameter-type, ...)

Identifies the parameters of the procedure.

If an unqualified distinct type or array type name is specified, the database manager searches the SQL path to resolve the schema name for the distinct type or array type.

For data types that have a length, precision, or scale attribute, use one of the following:

- Empty parentheses indicate that the database manager ignores the attribute when determining whether the data types match. For example, DEC() will be considered a match for a parameter of a procedure defined with a data type of DEC(7,2). However, FLOAT cannot be specified with empty parenthesis because its parameter value indicates a specific data type (REAL or DOUBLE).
- If a specific value for a length, precision, or scale attribute is specified, the value must exactly match the value that was specified (implicitly or explicitly) in the CREATE PROCEDURE statement. If the data type is FLOAT, the precision does not have to exactly match the value that was specified because matching is based on the data type (REAL or DOUBLE).
- If length, precision, or scale is not explicitly specified, and empty parentheses are not specified, the default attributes of the data type are implied. The implicit length must exactly match the value that was specified (implicitly or explicitly) in the CREATE PROCEDURE statement.

Specifying the FOR DATA clause or CCSID clause is optional. Omission of either clause indicates that the database manager ignores the attribute when determining whether the data types match. If either clause is specified, it must match the value that was implicitly or explicitly specified in the CREATE PROCEDURE statement.

AS LOCATOR

Specifies that the procedure is defined to receive a locator for this parameter. If AS LOCATOR is specified, the data type must be a LOB or XML or a distinct type based on a LOB or XML. If AS LOCATOR is specified, FOR SBCS DATA or FOR MIXED DATA must not be specified.

SPECIFIC PROCEDURE *specific-name*

Identifies the procedure by its specific name. The *specific-name* must identify a specific procedure that exists at the current server.

variable

Specifies a variable that contains a procedure or specific name. If *variable* is specified:

- It must be a character-string variable or Unicode graphic-string variable. It cannot be a global variable.
- It must not be followed by an indicator variable.
- The name that is contained within the variable must be left-justified and must be padded on the right with blanks if its length is less than that of the variable.
- The name must be in uppercase unless it is a delimited name.

If only one procedure with this name has been invoked using the CALL statement, the variable is used as a procedure name. If multiple procedures with this name have been invoked, the variable is used as a specific name.

Notes

Assignment of locator values. If a SET RESULT SETS statement was executed in the procedure, the SET RESULT SETS statement identifies the result sets. The locator values are assigned to the items in the descriptor area or the SQLVAR entries in the SQLDA in the order specified on the SET RESULT SETS statement. If a SET RESULT SETS statement was not executed in the procedure, locator values are assigned to the locator variables in the order that the associated cursors are opened at runtime. Locator values are assigned to the locator variables in the same order that they would be placed in the entries in the SQL descriptor area or the SQLDA as a result of a DESCRIBE PROCEDURE statement.

Locator values are not provided for cursors that are closed when control is returned to the invoking application. If a cursor was closed and later re-opened before returning to the invoking application, the most recently executed OPEN CURSOR statement for the cursor is used to determine the order in which the locator values are returned for the procedure result sets. For example, assume procedure P1 opens three cursors A, B, C, closes cursor B, and then issues another OPEN CURSOR statement for cursor B before returning to the invoking application. The locator values assigned for the following ASSOCIATE LOCATORS statement will be in the order A, C, B.

```
ASSOCIATE RESULT SET LOCATORS (:loc1, :loc2, :loc3) WITH PROCEDURE P1;
```

More than one locator can be associated with a result set. You can issue multiple ASSOCIATE LOCATORS statements for the same procedure with different result set locator variables to associate multiple locators with each result set.

- If the number of result set locator variables specified in the ASSOCIATE LOCATORS statement is less than the number of result sets returned by the procedure, all locator variables specified in the statement are assigned a value and a warning is issued. For example, assume procedure P1 exists and returns four result sets. Each of the following ASSOCIATE LOCATORS statements returns information on the first result set along with a warning that not enough locators were provided to obtain information about all the result sets.

```
CALL P1;
```

```
ASSOCIATE RESULT SET LOCATORS (:loc1) WITH PROCEDURE P1; -> loc1 is assigned a value for first result set, and a warning is returned
```

```
ASSOCIATE RESULT SET LOCATORS (:loc2) WITH PROCEDURE P1; -> loc2 is assigned a value for first result set, and a warning is returned
```

ASSOCIATE RESULT SET LOCATORS (:loc3) WITH PROCEDURE P1; -> loc3 is assigned a value for first result set, and a warning is returned

ASSOCIATE RESULT SET LOCATORS (:loc4) WITH PROCEDURE P1; -> loc4 is assigned a value for first result set, and a warning is returned

- If the number of result set locator variables that are listed in the ASSOCIATE LOCATORS statement is greater than the number of locators returned by the procedure, the extra locator variables are assigned a value of 0.

Multiple calls to the same procedure: When multiple calls to the same procedure are made from the same program, the result sets of earlier invocations are lost unless an ASSOCIATE LOCATOR statement is executed prior to a subsequent CALL to the procedure. The ASSOCIATE LOCATORS statement will refer to the most recent CALL

```
EXEC SQL CALL P1; /* Returns 2 result sets */
EXEC SQL CALL P1; /* Returns 2 result sets, result sets from first invocation are closed */
EXEC SQL ASSOCIATE RESULT SET LOCATORS (:a, :b) WITH PROCEDURE P1; /* Refers to second call */
EXEC SQL CALL P1; /* Returns 2 result sets */
EXEC SQL ASSOCIATE RESULT SET LOCATORS (:c, :d) WITH PROCEDURE P1; /* Refers to third call */

/* The following statements process the result sets from the second call */
EXEC SQL ALLOCATE C1 CURSOR FOR RESULT SET :a;
EXEC SQL ALLOCATE C2 CURSOR FOR RESULT SET :b;
EXEC SQL FETCH C1 INTO :h1;
EXEC SQL CLOSE C1;
EXEC SQL FETCH C2 INTO :h2;
EXEC SQL CLOSE C2;

/* The following statements process the result sets from the third call */
EXEC SQL ALLOCATE C3 CURSOR FOR RESULT SET :c;
EXEC SQL ALLOCATE C4 CURSOR FOR RESULT SET :d;
EXEC SQL FETCH C3 INTO :h1;
EXEC SQL CLOSE C3;
EXEC SQL FETCH C4 INTO :h2;
EXEC SQL CLOSE C4;
```

RETURN TO CLIENT procedures: A result set of a RETURN TO CLIENT procedure becomes associated with the highest procedure on the invocation stack. To associate a locator with such a result set, the procedure name of the highest procedure on the invocation stack must be specified.

Example

Allocate result set locators for procedure P1 which returns 3 result sets

```
ASSOCIATE RESULT SET LOCATORS (:loc11, :loc2, :loc3) WITH PROCEDURE P1;
```

BEGIN DECLARE SECTION

The BEGIN DECLARE SECTION statement marks the beginning of an SQL declare section. An SQL declare section contains declarations of host variables that are eligible to be used as host variables in SQL statements in a program.

Invocation

This statement can only be embedded in an application program. It is not an executable statement. It must not be specified in Java, RPG, or REXX.

Authorization

None required.

Syntax

➤ BEGIN DECLARE SECTION ➤

Description

The BEGIN DECLARE SECTION statement is used to indicate the beginning of an SQL declare section. It can be coded in the application program wherever variable declarations can appear in accordance with the rules of the host language. It cannot be coded in the middle of a host structure declaration. An SQL declare section ends with an END DECLARE SECTION statement, described in [“END DECLARE SECTION” on page 1303](#).

The BEGIN DECLARE SECTION and the END DECLARE SECTION statements must be paired and cannot be nested.

SQL statements should not be included within a declare section, with the exception of the DECLARE VARIABLE and INCLUDE statements.

If SQL declare sections are specified in the program, only the variables declared within the SQL declare sections can be used as host variables. If SQL declare sections are not specified in the program, all variables in the program are eligible for use as host variables.

SQL declare sections should be specified for host languages, other than RPG and REXX, so that the source program conforms to the IBM SQL standard of SQL. SQL declare sections are required for all host variables in C++. The SQL declare section should appear before the first reference to the variable. Host variables are declared without the use of these statements in Java and RPG, and they are not declared at all in REXX.

Variables declared outside an SQL declare section should not have the same name as variables declared within an SQL declare section.

More than one SQL declare section can be specified in the program.

Examples

Example 1: Define the host variables hv_smint (SMALLINT), hv_vchar24 (VARCHAR(24)), and hv_double (DOUBLE) in a C program.

```
EXEC SQL BEGIN DECLARE SECTION;
static short hv_smint;
static struct {
    short hv_vchar24_len;
    char hv_vchar24_value[24];
} hv_vchar24;
static double hv_double;
EXEC SQL END DECLARE SECTION;
```

Example 2: Define the host variables HV-SMINT (smallint), HV-VCHAR24 (varchar(24)), and HV-DEC72 (dec(7,2)) in a COBOL program.

```
WORKING-STORAGE SECTION.  
  EXEC SQL BEGIN DECLARE SECTION END-EXEC.  
01 HV-SMINT          PIC S9(4)          BINARY.  
01 HV-VCHAR24.  
  49 HV-VCHAR24-LENGTH PIC S9(4)          BINARY.  
  49 HV-VCHAR24-VALUE  PIC X(24).  
01 HV-DEC72         PIC S9(5)V9(2)  PACKED-DECIMAL.  
  EXEC SQL END DECLARE SECTION END-EXEC.
```

CALL

The CALL statement calls a procedure.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following:

- If the procedure is an SQL procedure:
 - The EXECUTE privilege on the procedure, and
 - The USAGE privilege on the schema containing the SQL procedure
- If the procedure is a Java external procedure:
 - Read authority (*R) to the integrated file system file that contains the Java class.
 - Read and execute authority (*RX) to all directories that must be accessed in order to find the integrated file system file.
- If the procedure is a REXX external procedure:
 - The system authorities *OBJOPR, *READ, and *EXECUTE on the source file associated with the procedure,
 - The USAGE privilege on the schema containing the source file, and
 - The system authority *USE to the CL command,
- If the procedure is an external procedure, but not a REXX or Java external procedure:
 - The system authority *EXECUTE on the program or service program associated with the procedure, and
 - The USAGE privilege on the schema containing the program or service program associated with the procedure
- Database administrator authority

If a global variable is referenced as an IN or INOUT parameter, the privileges held by the authorization ID for the statement must include at least one of the following:

- The READ privilege on the global variable.
- Database administrator authority

If a global variable is referenced as an OUT or INOUT parameter, the privileges held by the authorization ID for the statement must include at least one of the following:

- The WRITE privilege on the global variable.
- Database administrator authority

For information on the system authorities corresponding to SQL privileges, see [Corresponding System Authorities When Checking Privileges to a Function or Procedure](#).

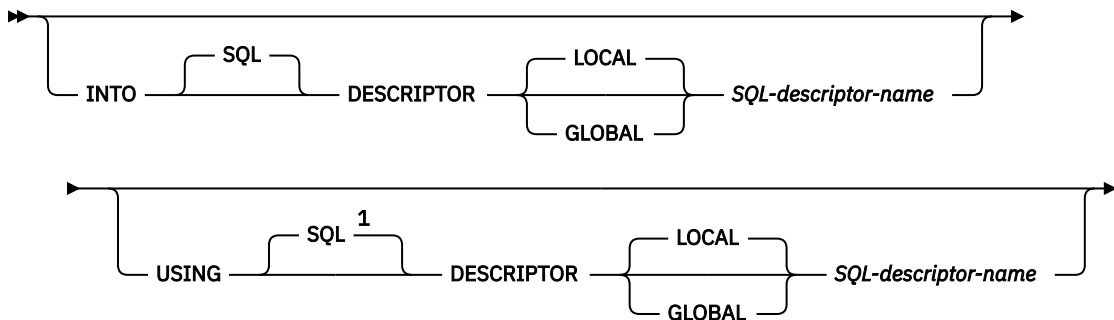

Syntax

argument-list

SQL-descriptors

Notes:

¹ If an SQL descriptor is specified in the USING clause and the INTO clause is not specified, USING DESCRIPTOR is not allowed and USING SQL DESCRIPTOR must be specified.

Description

procedure-name or variable

Identifies the procedure to call by the specified *procedure-name* or the procedure name contained in the *variable*. The identified procedure must exist at the current server.

If a *variable* is specified:

- It must be a character-string variable or Unicode graphic-string. It cannot be a global variable.
- It must not be followed by an indicator variable.
- The procedure name that is contained within the variable must be left-justified and must be padded on the right with blanks if its length is less than that of the variable.
- The name of the procedure must be in uppercase unless the procedure name is a delimited name.

If the procedure name is unqualified, it is implicitly qualified based on the path and number of parameters. For more information see [“Qualification of unqualified object names”](#) on page 57.

If the procedure-name identifies a procedure that was defined by a DECLARE PROCEDURE statement, and the current server is a Db2 for i product, then:

- The DECLARE PROCEDURE statement determines the name of the external program, language, and calling convention.
- The attributes of the parameters of the procedure are defined by the DECLARE PROCEDURE statement.

If there is no DECLARE PROCEDURE and the procedure name identifies a procedure that was defined by a CREATE PROCEDURE statement, and the current server is Db2 for i, then:

- The CREATE PROCEDURE statement determines the name of the external program, language, and calling convention.
- The attributes of the parameters of the procedure are defined by the CREATE PROCEDURE statement.

Otherwise:

- The current server determines the name of the external program, language, and calling convention.
- If the current server is Db2 for i:
 - The external program name is assumed to be the same as the external procedure name.
 - If the program attribute information associated with the program identifies a recognizable language, then that language is used. Otherwise, the language is assumed to be C.
 - The calling convention is assumed to be GENERAL.
- The application requester assumes all parameters that are variables or parameter markers are INOUT. All parameters that are not variables are assumed to be IN.
- The actual attributes of the parameters are determined by the current server.

If the current server is a Db2 for i, the attributes of the parameters will be the same as the attributes of the arguments specified on the CALL statement.⁸⁵

argument-list

Identifies a list of values to be passed as parameters to the procedure. The nth unnamed argument corresponds to the nth parameter in the procedure.

Each parameter defined (using a CREATE PROCEDURE or DECLARE PROCEDURE statement) as OUT must be specified as a variable. A default cannot be specified for an OUT parameter. If a default is used for an INOUT parameter, then the default expression is used to initialize the parameter for input to the procedure. No value is returned for this parameter when the procedure exits.

When a procedure is called, arguments must be specified for all parameters that are not defined to have a default value. When an argument is assigned to a parameter using the named syntax, then all the arguments that follow it must also be assigned using the named syntax.

Any references to date, time, or timestamp special register values in the argument list will use one clock reading for any default expressions and a separate clock reading for any references in the explicit arguments.

If any argument is an array, all other arguments must be literals, special registers, NULL, or DEFAULT.

The application requester assumes all parameters that are variables are INOUT parameters except for Java, where it is assumed all parameters that are variables are IN unless the mode is explicitly specified in the variable reference. All parameters that are not variables are assumed to be input parameters. The actual attributes of the parameters are determined by the current server.

parameter-name

Name of the parameter to which the argument value is assigned. The name must match a parameter name defined for the procedure. Named arguments correspond to the same named parameter regardless of the order in which they are specified in the argument list. When an argument is assigned to a parameter by name, all the arguments that follow it must also be assigned by name.

A named argument must be specified only one time (implicitly or explicitly).

Named arguments are only allowed on a call to a procedure that was defined using a CREATE PROCEDURE statement.

⁸⁵ Note that in the case of decimal constants, leading zeroes are significant when determining the attributes of the argument. Normally, leading zeroes are not significant.

expression

An *expression* of the type described in [“Expressions” on page 158](#), that does not include an aggregate function or column name.

DEFAULT

Specifies the default as defined in the CREATE PROCEDURE statement is used as an argument to the procedure. If no default is defined for the parameter, the NULL value is used.

NULL

Specifies a null value as an argument to the procedure.

SQL-descriptors

If SQL descriptors are specified on CALL, a procedure that has IN and INOUT parameters requires an SQL descriptor to be specified in the USING clause; and a procedure that has OUT or INOUT parameters requires an SQL descriptor to be specified in the INTO clause. If all the parameters of the procedure are INOUT parameters, the same descriptor can be used for both clauses. For more information, see [Multiple SQL descriptors on CALL](#).

INTO

Identifies an SQL descriptor which contains valid descriptions of the output variables to be used with the CALL statement. Before the CALL statement is executed, a descriptor must be allocated using the ALLOCATE DESCRIPTOR statement. The COUNT field in the descriptor header must be set to reflect the number of OUT and INOUT parameters for the procedure. The item information, including TYPE, and where applicable, DATETIME_INTERVAL_CODE, LENGTH, DB2_CCSD, PRECISION, and SCALE, must be set for the variables that are used when processing the statement.

LOCAL

Specifies the scope of the name of the descriptor to be local to program invocation. The information is returned from the descriptor known in this local scope.

GLOBAL

Specifies the scope of the name of the descriptor to be global to the SQL session. The information is returned from the descriptor known to any program that executes using the same database connection.

SQL-descriptor-name

Names the SQL descriptor. The name must identify a descriptor that already exists with the specified scope.

See [“GET DESCRIPTOR” on page 1319](#) for an explanation of the information that is placed in the SQL descriptor.

USING

Identifies an SQL descriptor which contains valid descriptions of the input variables to be used with the CALL statement. Before the CALL statement is executed, a descriptor must be allocated using the ALLOCATE DESCRIPTOR statement. The COUNT field in the descriptor header must be set to reflect the number of IN and INOUT parameters for the procedure. The item information, including TYPE, and where applicable, DATETIME_INTERVAL_CODE, LENGTH, DB2_CCSD, PRECISION, and SCALE, must be set for the variables that are used when processing the statement. The DATA item and when nulls are used, the INDICATOR item, must be set for the input variables.

LOCAL

Specifies the scope of the name of the descriptor to be local to program invocation.

GLOBAL

Specifies the scope of the name of the descriptor to be global to the SQL session.

SQL-descriptor-name

Names the SQL descriptor. The name must identify a descriptor that already exists with the specified scope.

See [“SET DESCRIPTOR” on page 1505](#) for an explanation of the information in the SQL descriptor.

USING DESCRIPTOR *descriptor-name*

Identifies an SQLDA that must contain a valid description of variables.

Before the CALL statement is processed, you must set the following fields in the SQLDA. (The rules for REXX are different. For more information, see the [Embedded SQL Programming](#) topic collection.)

- SQLN to indicate the number of SQLVAR occurrences provided in the SQLDA
- SQLDABC to indicate the number of bytes of storage allocated for the SQLDA
- SQLD to indicate the number of variables used in the SQLDA when processing the statement
- SQLVAR occurrences to indicate the attributes of the variables.

The SQLDA must have enough storage to contain all SQLVAR occurrences. Therefore, the value in SQLDABC must be greater than or equal to $16 + \text{SQLN} * (80)$, where 80 is the length of an SQLVAR occurrence. If LOBs or distinct types are specified, there must be two SQLVAR entries for each parameter marker and SQLN must be set to two times the number of parameter markers.

SQLD must be set to a value greater than or equal to zero and less than or equal to SQLN. It must be the same as the number of parameters in the CALL statement. The *n*th variable described by the SQLDA corresponds to the *n*th parameter marker in the prepared statement. (For a description of an SQLDA, see Appendix D, “SQLDA (SQL descriptor area),” on page 1675.)

Note that RPG/400 does not provide the function for setting pointers. Because the SQLDA uses pointers to locate the appropriate variables, you have to set these pointers outside your RPG/400 application.

The USING DESCRIPTOR clause is not supported for a CALL statement within a Java program.

Notes

Parameter assignments: When the CALL statement is executed, the value of each of its parameters is assigned (using storage assignment rules) to the corresponding parameter of the procedure. A parameter value that is defined to have a default value can be omitted from the argument list when invoking the procedure. Control is passed to the procedure according to the calling conventions of the host language. When execution of the procedure is complete, the value of each parameter of the procedure is assigned (using storage assignment rules for SQL parameters, otherwise using retrieval assignment rules) to the corresponding parameter of the CALL statement defined as OUT or INOUT. For details on the assignment rules, see [“Assignments and comparisons”](#) on page 89.

Global variables: A global variable may be specified and will be modified if used as a parameter that is INOUT or OUT.

Procedure signatures: A procedure is identified by its schema, a procedure name, and the number of parameters. This is called a procedure signature, which must be unique within the database. There can be more than one procedure with the same name in a schema, provided that the number of parameters is different for each procedure.

SQL path: A procedure can be invoked by referring to a qualified name (schema and procedure name), followed by an optional list of arguments enclosed by parentheses. A procedure can also be invoked without the schema name, resulting in a choice of possible procedures in different schemas with the same number of parameters. In this case, the SQL path is used to assist in procedure resolution.

Procedure resolution: For details of how procedure resolution is performed, see [“Procedure resolution”](#) on page 63 .

Cursors and prepared statements in procedures: All cursors opened in the called procedure that are not result set cursors are closed, and all statements prepared in the called procedure are destroyed when the procedure ends. CLOSQLCSR(*ENDACTGRP) can be used to keep cursors open when the procedure ends. For more information, see [“SET OPTION”](#) on page 1512.

Result sets from procedures: There are three ways to return result sets from a procedure:

- If a SET RESULT SETS statement is executed in the procedure, the last SET RESULT SETS statement executed in the procedure identifies the result sets. The result sets are returned in the order specified on the SET RESULT SETS statement.
- If a SET RESULT SETS statement is not executed in the procedure,
 - If no cursors have specified a WITH RETURN clause, each cursor that the procedure opens and leaves open when it returns identifies a result set. The result sets are returned in the order in which the cursors are opened.
 - If any cursors have specified a WITH RETURN clause, each cursor that is defined with the WITH RETURN clause that the procedure opens and leaves open when it returns identifies a result set. The result sets are returned in the order in which the cursors are opened.

When a result set is returned using an open cursor, the rows are returned starting with the current cursor position.

If a cursor result set references an SQL array type, an error will be returned if the array reference would cause incorrect results when processing the result set.

Locks in procedures: All locks that have been acquired in the called procedure are retained until the end of the unit of work.

Errors from procedures: A procedure can return errors (or warnings) using the SQLSTATE like other SQL statements. Applications should be aware of the possible SQLSTATES that can be expected when invoking a procedure. The possible SQLSTATES depend on how the procedure is coded. Procedures may also return SQLSTATES such as those that begin with '38' or '39' if the database manager encounters problems executing the procedure. Applications should therefore be prepared to handle any error SQLSTATE that may result from issuing a CALL statement.

Nesting CALL statements: A program that is executing as a procedure, a user-defined function, or a trigger can issue a CALL statement. When a procedure, user-defined function, or trigger calls a procedure, user-defined function, or trigger, the call is considered to be nested. There is no limit on how many levels procedures and functions can be nested, but triggers can only be nested up to 200 levels deep.

If a procedure returns any query result sets, the result sets are returned to the caller of the procedure. If the SQL CALL statement is nested, the result sets are visible only to the program that is at the previous nesting level. For example, if a client program calls procedure PROCA, which in turn calls procedure PROCB. Only PROCA can access any result sets that PROCB returns; the client program has no access to the query result sets.

When an SQL or an external procedure is called, an attribute is set for SQL data-access that was defined when the procedure was created. The possible values for the attribute are:

NONE
CONTAINS
READS
MODIFIES

If a second procedure is invoked within the execution of the current procedure, an error is issued if:

- The invoked procedure possibly contains SQL and the invoking procedure does not allow SQL
- The invoked procedure reads SQL data and the invoking procedure does not allow reading SQL data
- The invoked procedure modifies SQL data and the invoking procedure does not allow modifying SQL data

REXX procedures: If the external procedure to be called is a REXX procedure, then the procedure must be declared using the CREATE PROCEDURE or DECLARE PROCEDURE statement.

Variables cannot be used in the CALL statement within a REXX procedure. Instead, the CALL must be the object of a PREPARE and EXECUTE using parameter markers.

Multiple SQL descriptors on CALL: If SQL descriptors are specified on CALL and a procedure has IN or INOUT parameters and OUT or INOUT parameters, two descriptors must be specified. The number of

variables that must be allocated in the SQL descriptors depends on how the SQL descriptor attributes are set and the number of each type of parameter.

- If the input SQL descriptor attributes were set using DESCRIBE INPUT and the output SQL descriptor attributes were set using DESCRIBE (OUTPUT), the SQL descriptors will have attributes that match the actual procedure definition at the current server prior to calling the procedure. In this case, the output SQL descriptor will contain one variable for each OUT and INOUT parameter. Likewise, the input SQL descriptor will contain one variable for each IN and INOUT parameter.

This is the recommended technique for specifying multiple SQL descriptors on a CALL statement.

- Otherwise, the actual procedure definition at the current server is unknown prior to calling the procedure, so each parameter is assumed to be INOUT at the time the procedure is called. This means that both SQL descriptors must be specified, and since each parameter is assumed to be INOUT, they must have the same number of variables and the TYPE, DATETIME_INTERVAL_CODE, LENGTH, DB2_CCSID, PRECISION, and SCALE of each variable in the output SQL descriptor must be exactly the same as the corresponding variable in the input SQL descriptor. Otherwise, an error is returned.

If multiple SQL descriptors are specified, the DATA or INDICATOR items associated with any INOUT parameters in the input SQL descriptor may also be modified when the procedure is called. Thus, a SET DESCRIPTOR may be necessary to reset the DATA and INDICATOR items for such an input SQL descriptor prior to its use in another SQL statement.

Examples

Example 1: Call procedure PGM1 and pass two parameters.

```
CALL PGM1 (:hv1, :hv2)
```

Example 2: In C, invoke a procedure called SALARY_PROC using the SQLDA named INOUT_SQLDA.

```
struct sqlda *INOUT_SQLDA;  
/* Setup code for SQLDA variables goes here */  
CALL SALARY_PROC USING DESCRIPTOR :*INOUT_SQLDA;
```

Example 3: A Java procedure is defined in the database using the following statement:

```
CREATE PROCEDURE PARTS_ON_HAND (IN PARTNUM INTEGER,  
                                OUT COST DECIMAL(7,2),  
                                OUT QUANTITY INTEGER)  
LANGUAGE JAVA PARAMETER STYLE JAVA  
EXTERNAL NAME 'parts!onhand';
```

A Java application calls this procedure on the connection context 'ctx' using the following code fragment:

```
...  
int variable1;  
BigDecimal variable2;  
Integer variable3;  
...  
#sql [ctx] {CALL PARTS_ON_HAND(:IN variable1, :OUT variable2, :OUT variable3)};  
...
```

This application code fragment will invoke the Java method *onhand* in class *parts* since the *procedure-name* specified on the CALL statement is found in the database and has the external name 'parts!onhand'.

Example 4: Call procedure PGM2 on relational database BRANCHRDB2 and pass one parameter.

```
CALL BRANCHRDB2.SCHEMA3.PGM2 (:hv1)
```

Example 5: Assume the following procedure exists.

```
CREATE PROCEDURE update_order(  
    IN IN_POID BIGINT,  
    IN IN_CUSTID BIGINT DEFAULT GLOBAL_CUST_ID,
```

```
IN NEW_STATUS VARCHAR(10) DEFAULT NULL,  
IN NEW_ORDERDATE DATE DEFAULT NULL,  
IN NEW_COMMENTS VARCHAR(1000) DEFAULT NULL)...
```

Also assume that the global variable GLOBAL_CUST_ID is set to the value 1002. Call the procedure to change the status of order 5000 for customer 1002 to 'Shipped'. Leave the rest of the order data as it is by allowing the rest of the arguments to default to the null value.

```
CALL update_order (5000, NEW_STATUS => 'Shipped')
```

The customer with ID 1001 has called and indicated that they received their shipment for purchase order 5002 and are satisfied. Update their order.

```
CALL update_order (5002,  
                  IN_CUSTID => 1001,  
                  NEW_STATUS => 'Received',  
                  NEW_COMMENTS => 'Customer satisfied with the order.')
```

CLOSE

The CLOSE statement closes a cursor. If a result table was created when the cursor was opened, that table is destroyed.

Invocation

This statement can only be embedded in an application program. It is an executable statement that cannot be dynamically prepared. It must not be specified in Java.

Authorization

None required. See “[DECLARE CURSOR](#)” on page 1215 for the authorization required to use a cursor.

Syntax

➤ CLOSE — *cursor-name* ➤

Description

cursor-name

Identifies the cursor to be closed. The *cursor-name* must identify a declared cursor as explained in the DECLARE CURSOR statement. When the CLOSE statement is executed, the cursor must be in the open state.

Notes

Implicit cursor close: All cursors in a program are in the closed state when:

- The program is called.
 - If CLOSQLCSR(*ENDPGM) is specified, all cursors are in the closed state each time the program is called.
 - If CLOSQLCSR(*ENDSQL) is specified, all cursors are in the closed state only the first time the program is called as long as one SQL program remains on the call stack.
 - If CLOSQLCSR(*ENDJOB) is specified, all cursors are in the closed state only the first time the program is called in the job.
 - If CLOSQLCSR(*ENDMOD) is specified, all cursors are in the closed state each time the module is initiated.
 - If CLOSQLCSR(*ENDACTGRP) is specified, all cursors are in the closed state the first time the module in the program is initiated within the activation group.
- A program starts a new unit of work by executing a COMMIT or ROLLBACK statement without a HOLD option. Cursors declared with the HOLD option are not closed by a COMMIT statement.

Note: The Db2 for i database manager will open files in order to implement queries. The closing of the files can be separate from the SQL CLOSE statement. For more information, see [SQL Programming](#).

Close cursors for performance: Explicitly closing cursors as soon as possible can improve performance.

Procedure considerations: Special rules apply to cursors within procedures that have not been closed before returning to the calling program. For more information, see “[CALL](#)” on page 930.

Example

In a COBOL program, use the cursor C1 to fetch the values from the first four columns of the EMPPROJACT table a row at a time and put them in the following host variables:

- EMP (CHAR(6))

- PRJ (CHAR(6))
- ACT (SMALLINT)
- TIM (DECIMAL(5,2))

Finally, close the cursor.

```

EXEC SQL BEGIN DECLARE SECTION END-EXEC.
  77 EMP          PIC X(6).
  77 PRJ          PIC X(6).
  77 ACT          PIC S9(4) BINARY.
  77 TIM          PIC S9(3)V9(2) PACKED-DECIMAL.
EXEC SQL END DECLARE SECTION END-EXEC.
.
.
.

EXEC SQL DECLARE C1 CURSOR FOR
      SELECT EMPNO, PROJNO, ACTNO, EMPTIME
      FROM EMPPROJACT          END-EXEC.

EXEC SQL OPEN C1  END-EXEC.

EXEC SQL FETCH C1 INTO :EMP, :PRJ, :ACT, :TIM  END-EXEC.

IF SQLSTATE = '02000'
  PERFORM DATA-NOT-FOUND
ELSE
  PERFORM GET-REST-OF-ACTIVITY UNTIL SQLSTATE IS NOT EQUAL TO '00000'.

EXEC SQL CLOSE C1  END-EXEC.

GET-REST-OF-ACTIVITY
EXEC SQL FETCH C1 INTO :EMP, :PRJ, :ACT, :TIM  END-EXEC.
.
.
.

```

COMMENT

The COMMENT statement adds or replaces comments in the catalog descriptions of various database objects.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

To comment on a table, view, alias, column, type, package, sequence, variable, or XSR object, the privileges held by the authorization ID of the statement must include at least one of the following:

- For the table, view, alias, type, package, sequence, variable, or XSR object in the statement,
 - The ALTER privilege on the table, view, alias, type, package, sequence, variable, or XSR object, and
 - The system authority *EXECUTE on the library that contains the table, view, alias, index, type, package, sequence, variable, or XSR object
- Administrative authority

To comment on a constraint or trigger, the privileges held by the authorization ID of the statement must include at least one of the following:

- For the subject table of the constraint or trigger in the statement:
 - The ALTER privilege on the subject table, and
 - The system authority *EXECUTE on the library that contains the subject table
- Database administrator authority

To comment on an index, the privileges held by the authorization ID of the statement must include at least one of the following:

- For the index identified in the statement,
 - The system authority *OBJALTER on the index, and
 - The system authority *EXECUTE on the library containing the index.
- Administrative authority

To comment on a function, the privileges held by the authorization ID of the statement must include at least one of the following:

- For the SYSPROCS and SYSROUTINES catalog view and table:
 - The UPDATE privilege on SYSROUTINES,
 - The system authority *OBJOPR on SYSPROCS, and
 - The system authority *EXECUTE on library QSYS2
- Administrative authority

To comment on a procedure, the privileges held by the authorization ID of the statement must include at least one of the following:

- For the SYSPROCS and SYSROUTINES catalog view and table:
 - The UPDATE privilege on SYSROUTINES,
 - The system authority *OBJOPR on SYSPROCS, and
 - The system authority *EXECUTE on library QSYS2
- Administrative authority

To comment on a parameter, the privileges held by the authorization ID of the statement must include at least one of the following:

- For the SYSPARMS catalog table:
 - The UPDATE privilege on the table, and
 - The system authority *EXECUTE on library QSYS2
- Administrative authority

To comment on a mask or permission:

- The authorization ID of the statement must be authorized to the Database Security Administrator function of IBM i. See [“Administrative authority” on page 15](#).

To comment on a sequence, the privileges held by the authorization ID of the statement must also include at least one of the following:

- *USE authority to the Change Data Area (CHGDTAARA), CL command
- Administrative authority

To comment on a variable, the privileges held by the authorization ID of the statement must also include at least one of the following:

- For the SYSVARIABLES catalog table:
 - The UPDATE privilege on SYSVARIABLES, and
 - The system authority *EXECUTE on library QSYS2
- Administrative authority

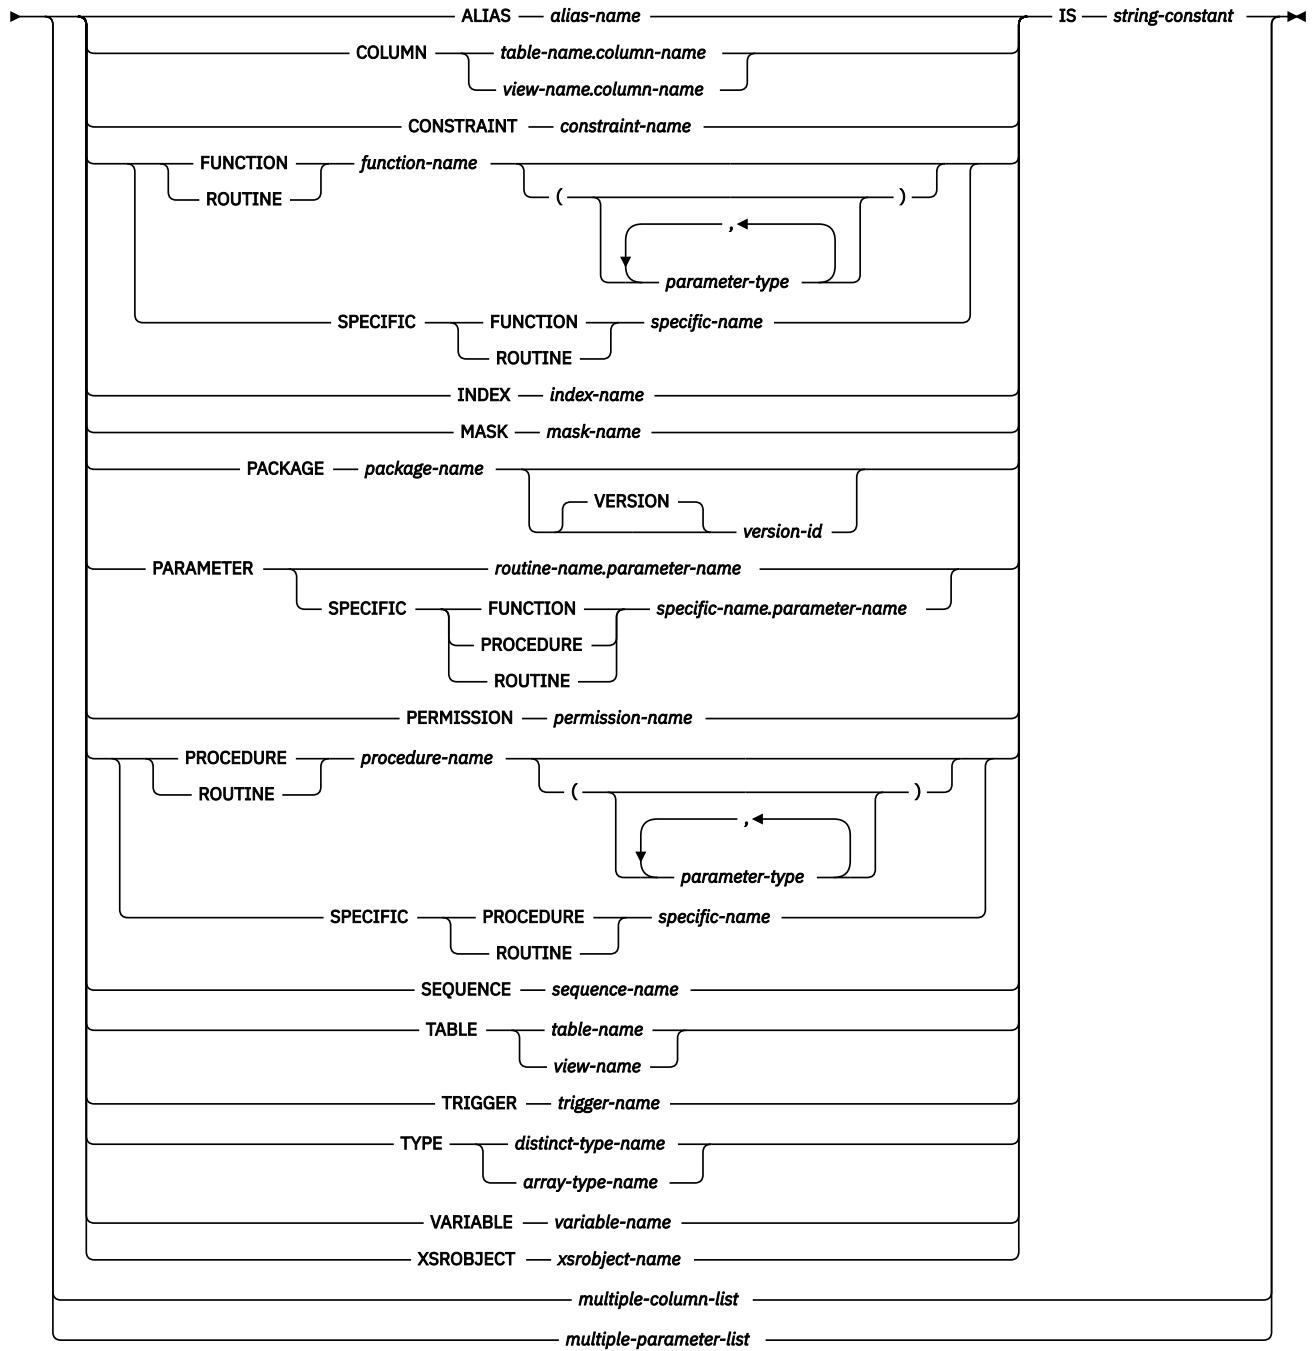

To comment on an XSR object, the privileges held by the authorization ID of the statement must also include at least one of the following:

- For the XSROBJECTS catalog table:
 - The UPDATE privilege on XSROBJECTS, and
 - The system authority *EXECUTE on library QSYS2
- Administrative authority

For information about the system authorities corresponding to SQL privileges, see [Corresponding System Authorities When Checking Privileges to a Table or View](#), [Corresponding System Authorities When Checking Privileges to a User-defined Type](#), [Corresponding System Authorities When Checking Privileges to a Sequence](#), [Corresponding System Authorities When Checking Privileges to a Variable](#), [Corresponding System Authorities When Checking Privileges to a Package](#), and [Corresponding System Authorities When Checking Privileges to an XSR object](#).

Syntax

► COMMENT — ON ►

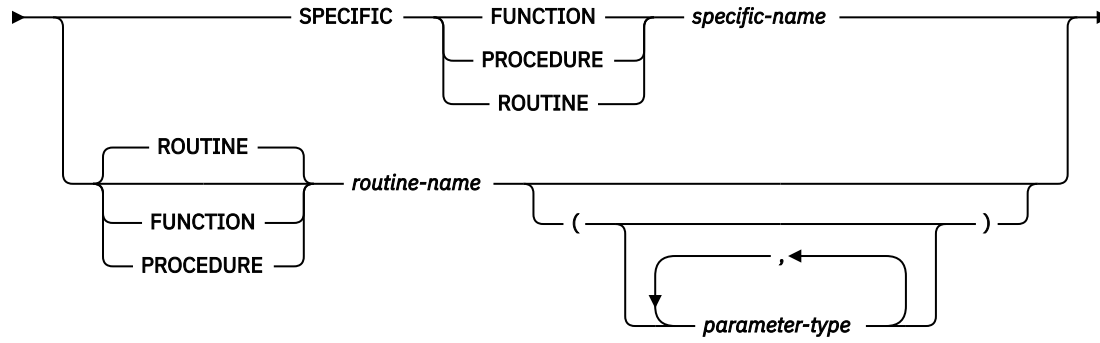

multiple-column-list

multiple-parameter-list

►► PARAMETER →

parameter-type

data-type

built-in-type

Description

ALIAS *alias-name*

Identifies the alias to which the comment applies. The *alias-name* must identify an alias that exists at the current server.

COLUMN

Specifies that a comment will be added to or replaced for a column.

table-name.column-name* or *view-name.column-name

Identifies the column to which the comment applies. The *table-name* or *view-name* must identify a table or view that exists at the current server, but must not identify a declared temporary table. The *column-name* must identify a column of that table or view.

CONSTRAINT

Specifies that a comment will be added to or replaced for a constraint.

constraint-name

Identifies the constraint to which the comment applies. The *constraint-name* must identify a constraint that exists at the current server.

FUNCTION or SPECIFIC FUNCTION

Identifies the function on which the comment applies. The function must exist at the current server and it must be a user-defined function. The function can be identified by its name, function signature, or specific name.

FUNCTION *function-name*

Identifies the function by its name. The *function-name* must identify exactly one function. The function may have any number of parameters defined for it. If there is more than one function of the specified name in the specified or implicit schema, an error is returned.

FUNCTION *function-name (parameter-type, ...)*

Identifies the function by its function signature, which uniquely identifies the function. The *function-name (parameter-type, ...)* must identify a function with the specified function signature. The specified parameters must match the data types in the corresponding position that were specified when the function was created. The number of data types, and the logical concatenation of the data types is used to identify the specific function instance on which to comment. Synonyms for data types are considered a match. Parameters that have defaults must be included in this signature.

If *function-name ()* is specified, the function identified must have zero parameters.

function-name

Identifies the name of the function.

(parameter-type, ...)

Identifies the parameters of the function.

If an unqualified distinct type name is specified, the database manager searches the SQL path to resolve the schema name for the distinct type.

For data types that have a length, precision, or scale attribute, use one of the following:

- Empty parentheses indicate that the database manager ignores the attribute when determining whether the data types match. For example, DEC() will be considered a match for a parameter of a function defined with a data type of DEC(7,2). However, FLOAT cannot be specified with empty parenthesis because its parameter value indicates a specific data type (REAL or DOUBLE).
- If a specific value for a length, precision, or scale attribute is specified, the value must exactly match the value that was specified (implicitly or explicitly) in the CREATE FUNCTION statement. If the data type is FLOAT, the precision does not have to exactly match the value that was specified because matching is based on the data type (REAL or DOUBLE).
- If length, precision, or scale is not explicitly specified, and empty parentheses are not specified, the default attributes of the data type are implied. The implicit length must

exactly match the value that was specified (implicitly or explicitly) in the CREATE FUNCTION statement.

Specifying the FOR DATA clause or CCSID clause is optional. Omission of either clause indicates that the database manager ignores the attribute when determining whether the data types match. If either clause is specified, it must match the value that was implicitly or explicitly specified in the CREATE FUNCTION statement.

AS LOCATOR

Specifies that the function is defined to receive a locator for this parameter. If AS LOCATOR is specified, the data type must be a LOB or XML or a distinct type based on a LOB or XML. If AS LOCATOR is specified, FOR SBCS DATA or FOR MIXED DATA must not be specified.

SPECIFIC FUNCTION *specific-name*

Identifies the function by its specific name. The *specific-name* must identify a specific function that exists at the current server.

INDEX *index-name*

Identifies the index to which the comment applies. The *index-name* must identify an index that exists at the current server.

MASK *mask-name*

Identifies the mask to which the comment applies. The *mask-name* must identify a mask that exists at the current server.

PACKAGE *package-name*

Identifies the package to which the comment applies. The *package-name* must identify a package that exists at the current server.⁸⁶

VERSION *version-id*

version-id is the version identifier that was assigned to the package when it was created. If *version-id* is not specified, a null string is used as the version identifier.

PARAMETER

Specifies that a comment will be added to or replaced for a parameter.

routine-name.parameter-name

Identifies the parameter to which the comment applies. The parameter could be for a procedure or a function. The *routine-name* must identify a procedure or function that exists at the current server, and the *parameter-name* must identify a parameter of that procedure or function.

specific-name.parameter-name

Identifies the parameter to which the comment applies. The parameter could be for a procedure or a function. The *specific-name* must identify a procedure or function that exists at the current server, and the *parameter-name* must identify a parameter of that procedure or function.

PERMISSION *permission-name*

Identifies the permission to which the comment applies. The *permission-name* must identify a permission that exists at the current server.

PROCEDURE or SPECIFIC PROCEDURE

Identifies the procedure to which the comment applies. The *procedure-name* must identify a procedure that exists at the current server.

PROCEDURE *procedure-name*

Identifies the procedure by its name. The *procedure-name* must identify exactly one procedure. The procedure may have any number of parameters defined for it. If there is more than one procedure of the specified name in the specified or implicit schema, an error is returned.

PROCEDURE *procedure-name (parameter-type, ...)*

Identifies the procedure by its procedure signature, which uniquely identifies the procedure. The *procedure-name (parameter-type, ...)* must identify a procedure with the specified procedure signature. The specified parameters must match the data types in the corresponding position that were specified when the procedure was created. The number of data types, and the logical

⁸⁶ If the identified package has a *version-id*, the comment is limited to 176 bytes.

concatenation of the data types is used to identify the specific procedure instance which is to be commented on. Synonyms for data types are considered a match. Parameters that have defaults must be included in this signature.

If *procedure-name ()* is specified, the procedure identified must have zero parameters.

procedure-name

Identifies the name of the procedure.

(parameter-type, ...)

Identifies the parameters of the procedure.

If an unqualified distinct type or array type name is specified, the database manager searches the SQL path to resolve the schema name for the distinct type or array type.

For data types that have a length, precision, or scale attribute, use one of the following:

- Empty parentheses indicate that the database manager ignores the attribute when determining whether the data types match. For example, DEC() will be considered a match for a parameter of a procedure defined with a data type of DEC(7,2). However, FLOAT cannot be specified with empty parenthesis because its parameter value indicates a specific data type (REAL or DOUBLE).
- If a specific value for a length, precision, or scale attribute is specified, the value must exactly match the value that was specified (implicitly or explicitly) in the CREATE PROCEDURE statement. If the data type is FLOAT, the precision does not have to exactly match the value that was specified because matching is based on the data type (REAL or DOUBLE).
- If length, precision, or scale is not explicitly specified, and empty parentheses are not specified, the default attributes of the data type are implied. The implicit length must exactly match the value that was specified (implicitly or explicitly) in the CREATE PROCEDURE statement.

Specifying the FOR DATA clause or CCSID clause is optional. Omission of either clause indicates that the database manager ignores the attribute when determining whether the data types match. If either clause is specified, it must match the value that was implicitly or explicitly specified in the CREATE PROCEDURE statement.

AS LOCATOR

Specifies that the procedure is defined to receive a locator for this parameter. If AS LOCATOR is specified, the data type must be a LOB or XML or a distinct type based on a LOB or XML. If AS LOCATOR is specified, FOR SBCS DATA or FOR MIXED DATA must not be specified.

SPECIFIC PROCEDURE *specific-name*

Identifies the procedure by its specific name. The *specific-name* must identify a specific procedure that exists at the current server.

SEQUENCE *sequence-name*

Identifies the sequence to which the comment applies. The *sequence-name* must identify a sequence that exists at the current server.

TABLE *table-name* or *view-name*

Identifies the table or view to which the comment applies. The *table-name* or *view-name* must identify a table or view that exists at the current server, but must not identify a declared temporary table.

TRIGGER *trigger-name*

Identifies the trigger to which the comment applies. The *trigger-name* must identify a trigger that exists at the current server.

TYPE *distinct-type-name* or *array-type-name*

Identifies the distinct type or array type to which the comment applies. The *distinct-type-name* or *array-type-name* must identify a type that exists at the current server.

VARIABLE *variable-name*

Identifies the variable to which the comment applies. The *variable-name* must identify a variable that exists at the current server.

XSROBJECT *xsobject-name*

Identifies the XSR object to which the comment applies. The *xsobject-name* must identify an XSR object that exists at the current server.

IS

Introduces the comment that to be added or replaced.

string-constant

Can be any character-string constant of up to 2000 characters (500 for a sequence).

multiple-column-list

To comment on more than one column in a table or view, specify the table or view name and then, in parenthesis, a list of the form:

```
(column-name IS string-constant,
 column-name IS string-constant, ... )
```

The column name must not be qualified, each name must identify a column of the specified table or view, and that table or view must exist at the current server.

multiple-parameter-list

To comment on more than one parameter in a procedure or function, specify the procedure name, function name, or specific name, and then, in parenthesis, a list of the form:

```
(parameter-name IS string-constant,
 parameter-name IS string-constant, ... )
```

The parameter name must not be qualified, each name must identify a parameter of the specified procedure or function, and that procedure or function must exist at the current server.

Notes

Syntax alternatives: The following keywords are synonyms supported for compatibility to prior releases. These keywords are non-standard and should not be used:

- The keyword PROGRAM can be used as a synonym for PACKAGE.
- The keywords DATA TYPE or DISTINCT TYPE can be used as a synonym for TYPE.

Examples

Example 1: Insert a comment for the EMPLOYEE table.

```
COMMENT ON TABLE EMPLOYEE
IS 'Reflects first quarter 2000 reorganization'
```

Example 2: Insert a comment for the EMP_VIEW1 view.

```
COMMENT ON TABLE EMP_VIEW1
IS 'View of the EMPLOYEE table without salary information'
```

Example 3: Insert a comment for the EDLEVEL column of the EMPLOYEE table.

```
COMMENT ON COLUMN EMPLOYEE.EDLEVEL
IS 'Highest grade level passed in school'
```

Example 4: Enter comments on two columns in the DEPARTMENT table.

```
COMMENT ON DEPARTMENT
(MGRNO IS 'EMPLOYEE NUMBER OF DEPARTMENT MANAGER',
 ADMRDEPT IS 'DEPARTMENT NUMBER OF ADMINISTERING DEPARTMENT')
```

Example 5: Insert a comment for the PAYROLL package.

```
COMMENT ON PACKAGE PAYROLL  
IS 'This package is used for distributed payroll processing.'
```

COMMIT

The COMMIT statement ends a unit of work and commits the database changes that were made by that unit of work.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

COMMIT is not allowed in a trigger if the trigger program and the triggering program run under the same commitment definition. COMMIT is not allowed in a procedure if the procedure is called on a Distributed Unit of Work connection to a remote application server or if the procedure is defined as ATOMIC. COMMIT is not allowed in a function.

Authorization

None required.

Syntax

Description

The COMMIT statement ends the unit of work in which it is executed and starts a new unit of work. It commits all changes made by SQL schema statements (except DROP SCHEMA) and SQL data change statements during the unit of work. For information about SQL schema statements and SQL data change statements see [Chapter 7, “Statements,” on page 805](#).

Connections in the release-pending state are ended.

WORK

COMMIT WORK has the same effect as COMMIT.

HOLD

Specifies a hold on resources. If specified, currently open cursors are not closed whether they are declared with a HOLD option or not. All resources acquired during the unit of work are held. Locks on specific rows and objects implicitly acquired during the unit of work are released.

All implicitly acquired locks are released; except for object level locks required for the cursors that are not closed.

All locators that are not held are released. For more information about held locators, see [“HOLD LOCATOR” on page 1391](#).

Notes

Recommended coding practices: An explicit COMMIT or ROLLBACK statement should be coded at the end of an application process. Either an implicit commit or rollback operation will be performed at the end of an application process depending on the application environment. Thus, a portable application should explicitly execute a COMMIT or ROLLBACK before execution ends in those environments where explicit COMMIT or ROLLBACK is permitted.

An implicit COMMIT or ROLLBACK may be performed under the following circumstances.

- For the default activation group:

- An implicit COMMIT is not performed when applications that run in the default activation group end. Interactive SQL, Query Manager, and non-ILE programs are examples of programs that run in the default activation group.
- In order to commit work, you must issue a COMMIT.
- For non-default activation groups when the scope of the commitment definition is to the activation group:
 - If the activation group ends normally, the commitment definition is implicitly committed.
 - If the activation group ends abnormally, the commitment definition is implicitly rolled back.
- Regardless of the type of activation group, if the scope of the commitment definition is the job, an implicit commit is never performed.

Effect of commit: Commit without HOLD causes the following to occur:

- Connections in the release-pending state are ended.
- For existing connections:
- all open cursors that were declared with the WITH HOLD clause are preserved and their current position is maintained, although a FETCH statement is required before a Positioned UPDATE or Positioned DELETE statement can be executed.
 - all open cursors that were declared without the WITH HOLD clause including any opened under isolation level NC are closed.
- All LOB locators that are not held are freed. Note that this is true even when the locators are associated with LOB values retrieved via a cursor that has the WITH HOLD property.
 - All locks acquired by the LOCK TABLE statement are released. All implicitly acquired locks are released, except for those required for the cursors that were not closed.

Row lock limit: A unit of work can include the processing of up to 4 million rows, including rows retrieved during a SELECT or FETCH statement⁸⁷, and rows inserted, deleted, or updated as part of INSERT, DELETE, and UPDATE statements.⁸⁸

Unaffected statements: The commit and rollback operations do not affect the DROP SCHEMA statement, and this statement is not, therefore, allowed in an application program that also specifies COMMIT(*CHG), COMMIT(*CS), COMMIT(*ALL), or COMMIT(*RR).

COMMIT Restrictions: A commit or rollback in a user-defined function in a secondary thread is not allowed.

Commitment definition use: The commitment definition used by SQL is determined as follows:

- If the activation group of the program calling SQL is already using an activation group level commitment definition, then SQL uses that commitment definition.
- If the activation group of the program calling SQL is using the job level commitment definition, then SQL uses the job level commitment definition.
- If the activation group of the program calling SQL is not currently using a commitment definition but the job commitment definition is started, then SQL uses the job commitment definition.

⁸⁷ This limit also includes:

- Any rows accessed or changed through files opened under commitment control through high-level language file processing
- Any rows deleted, updated, or inserted as a result of a trigger or CASCADE, SET NULL, or SET DEFAULT referential integrity delete rule.

⁸⁸ Unless you specified COMMIT(*CHG) or COMMIT(*CS), in which case these rows are not included in this total.

- If the activation group of the program calling SQL is not currently using a commitment definition and the job commitment definition is not started, then SQL implicitly starts a commitment definition. SQL uses the Start Commitment Control (STRCMTCTL) command with:
 - A CMTSCOPE(*ACTGRP) parameter
 - A LCKLVL parameter based on the COMMIT option specified on either the CRTSQLxxx, STRSQL, or RUNSQLSTM commands. In REXX, the LCKLVL parameter is based on the commit option in the SET OPTION statement.

Example

In a C program, transfer a certain amount of commission (COMM) from one employee (EMPNO) to another in the EMPLOYEE table. Subtract the amount from one row and add it to the other. Use the COMMIT statement to ensure that no permanent changes are made to the database until both operations are completed successfully.

```
void main ()
{
    EXEC SQL BEGIN DECLARE SECTION;
    decimal(5,2) AMOUNT;
    char FROM_EMPNO[7];
    char TO_EMPNO[7];
    EXEC SQL END DECLARE SECTION;
    EXEC SQL INCLUDE SQLCA;
    EXEC SQL WHENEVER SQLERROR GOTO SQLERR;
    ...
    EXEC SQL UPDATE EMPLOYEE
        SET COMM = COMM - :AMOUNT
        WHERE EMPNO = :FROM_EMPNO;
    EXEC SQL UPDATE EMPLOYEE
        SET COMM = COMM + :AMOUNT
        WHERE EMPNO = :TO_EMPNO;
    FINISHED:
    EXEC SQL COMMIT WORK;
    return;

    SQLERR:
    ...
    EXEC SQL WHENEVER SQLERROR CONTINUE; /* continue if error on rollback */
    EXEC SQL ROLLBACK WORK;
    return;
}
```

compound (dynamic)

A compound (dynamic) statement groups other statements together in an executable routine. A compound statement allows the declaration of SQL variables, cursors, and condition handlers.

Invocation

This statement can be issued interactively. It is an executable statement that can be dynamically prepared. It cannot be embedded in an application program.

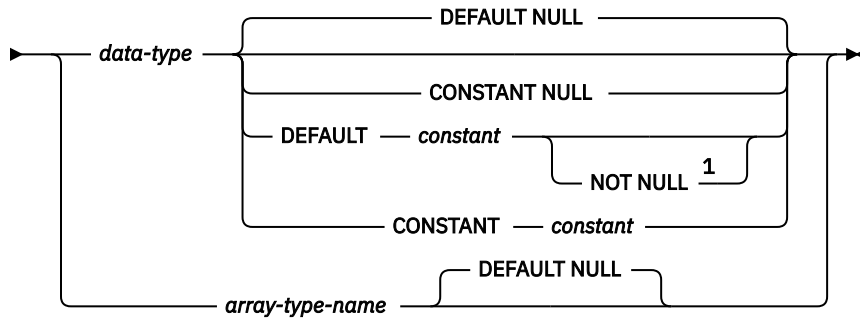

Authorization

The privileges held by the authorization ID of the statement must also include all of the privileges necessary to invoke the SQL statements that are specified in the compound (dynamic) statement.

Syntax

SQL-variable-declaration

SQL-condition-declaration

return-codes-declaration

handler-declaration

specific-condition-value

general-condition-value

data-type

Notes:

- ¹ The DEFAULT and NOT NULL clauses can be specified in either order.
- ² *specific-condition-value* and *general-condition-value* cannot be specified in the same handler declaration.
- ³ The same clause must not be specified more than once.

built-in-type

ccsid-clause

➤ CCSID — *integer* ➤

Description

ATOMIC

ATOMIC indicates that an unhandled exception condition within the compound (dynamic) statement causes the compound statement to be rolled back. If ATOMIC is specified, COMMIT, ROLLBACK (ROLLBACK TO SAVEPOINT may be specified), SET CURRENT DEBUG MODE, SET CURRENT DEGREE, SET CURRENT DECFLOAT ROUNDING MODE, SET CURRENT IMPLICIT XMLPARSE OPTION, SET CURRENT TEMPORAL SYSTEM_TIME, SET PATH, and SET SCHEMA statements cannot be specified in the compound statement.

NOT ATOMIC

NOT ATOMIC indicates that an unhandled exception condition within the compound (dynamic) statement does not cause the compound statement to be rolled back.

SQL-variable-declaration

Declares a variable that is local to the compound (dynamic) statement.

SQL-variable-name

Defines the name of a local SQL variable. The database manager converts all un delimited SQL variable names to uppercase. The name must not be the same as another SQL variable within the same compound (dynamic) statement, excluding any declarations in *compound-statements* nested within the compound (dynamic) statement. Do not name SQL variables the same as a column name. See [“References to SQL parameters and SQL variables” on page 1581](#) for how SQL variable names are resolved when there are columns with the same name involved in a statement. Variable names should not begin with 'SQL'.

data-type

Specifies the data type of the variable. See [“CREATE TABLE” on page 1115](#) for a description of data type.

If the *data-type* is a graphic string data type, consider specifying CCSID 1200 or 13488 to indicate UTF-16 or UCS-2 data. If a CCSID is not specified, the CCSID of the graphic string variable will be the associated DBCS CCSID for the job.

array-type-name

Specifies that the SQL variable is an array as defined with the CREATE TYPE (Array) statement.

DEFAULT constant or NULL

Defines the default for the SQL variable. The specified constant must represent a value that could be assigned to the variable in accordance with the rules of assignment as described in [“Assignments and comparisons” on page 89](#). The variable is initialized when the compound (dynamic) statement is invoked. If a default value is not specified, the SQL variable is initialized to NULL. SQL variables of type XML cannot have a default value specified.

NOT NULL

Prevents the SQL variable from containing the NULL value. Omission of NOT NULL implies that the variable can be null. SQL variables of type XML cannot have NOT NULL specified

CONSTANT constant or NULL

Specifies that the SQL variable has a fixed value that cannot be changed. An SQL variable that is defined using CONSTANT cannot be used as the target of any assignment operation. The specified constant must represent a value that could be assigned to the variable in accordance with the rules of assignment as described in [“Assignments and comparisons” on page 89](#).

SQL-condition-declaration

Declares a condition name and corresponding SQLSTATE value.

SQL-condition-name

Specifies the name of the condition. The condition name must be unique within the compound (dynamic) statement, excluding any declarations in *compound-statements* nested within the compound (dynamic) statement.

FOR SQLSTATE string-constant

Specifies the SQLSTATE associated with this condition. The string constant must be specified as 5 characters. The SQLSTATE class (the first 2 characters) must not be '00'.

return-codes-declaration

Declares special SQL variables called SQLSTATE and SQLCODE that are set for the first condition in the diagnostics area after executing an SQL statement other than GET DIAGNOSTICS or an empty *compound-statement*.

The SQLSTATE and SQLCODE special variables are only intended to be used as a means of obtaining the SQL return codes that resulted from processing the previous SQL statement other than GET DIAGNOSTICS. If there is any intention to use the SQLSTATE and SQLCODE values, save the values immediately to other SQL variables to avoid having the values replaced by the SQL return codes returned after executing the next SQL statement. If a handler is defined that handles an SQLSTATE, you can use an assignment statement to save that SQLSTATE (or the associated SQLCODE) value in another SQL variable, if the assignment is the first statement in the handler.

Assignment to these variables is not prohibited; however, it is not recommended. Assignment to these special variables is ignored by condition handlers. The SQLSTATE and SQLCODE special variables cannot be set to NULL.

DECLARE CURSOR-statement

Declares a cursor in the compound (dynamic) statement. The cursor name must be unique within the compound (dynamic) statement, excluding any declarations in *compound-statements* nested within the compound (dynamic) statement.

A *cursor-name* can only be referenced within the compound (dynamic) statement in which it is declared, including any *compound-statements* nested within the compound (dynamic) statement.

Use an OPEN statement to open the cursor, and a FETCH statement to read rows using the cursor. Any open cursor is closed at the end of the compound (dynamic) statement.

For more information about declaring a cursor, refer to [“DECLARE CURSOR” on page 1215](#).

handler-declaration

Specifies a *handler*, an *SQL-procedure-statement* to execute when an exception or completion condition occurs in the compound (dynamic) statement.

A condition handler declaration cannot reference the same condition value or SQLSTATE value more than once, and cannot reference an SQLSTATE value and a condition name that represent the same SQLSTATE value. For a list of SQLSTATE values as well as more information, see the [SQL messages and codes](#) topic collection.

Furthermore, when two or more condition handlers are declared in a compound (dynamic) statement, no two condition handler declarations may specify the same:

- general condition category or
- specific condition, either as an SQLSTATE value or as a condition name that represents the same value.

A condition handler is active for the set of *SQL-procedure-statements* that follow the *handler-declarations* within the compound (dynamic) statement, including any nested *compound-statements*.

A handler for a condition may exist at several levels of nested compound statements. For example, assume that compound (dynamic) statement *n1* contains another compound statement *n2* which contains another compound statement *n3*. When an exception condition occurs within *n3*, any active handlers within *n3* are first allowed to handle the condition. If no appropriate handler exists in *n3*, then the condition is resignalled to *n2* and the active handlers within *n2* may handle the condition. If no appropriate handler exists in *n2*, then the condition is resignalled to *n1* and the active handlers within *n1* may handle the condition. If no appropriate handler exists in *n1*, the condition is considered unhandled.

There are three types of condition handlers:

CONTINUE

Specifies that after the condition handler is activated and completes successfully, control is returned to the SQL statement following the one that raised the exception. If the error occurs

while executing a comparison as in an IF, CASE, FOR, WHILE, or REPEAT, control returns to the statement following the corresponding END IF, END CASE, END FOR, END WHILE, or END REPEAT.

EXIT

Specifies that after the condition handler is activated and completes successfully, control is returned to the end of the compound (dynamic) statement.

UNDO

Specifies that when the condition handler is activated changes made by the compound (dynamic) statement are rolled back. When the handler completes successfully, control is returned to the end of the compound (dynamic) statement. If UNDO is specified, then ATOMIC must be specified.

The conditions under which the handler is activated are:

SQLSTATE string

Specifies that the handler is invoked when the specific SQLSTATE occurs. The SQLSTATE class (the first 2 characters) must not be '00'.

SQL-condition-name

Specifies that the handler is invoked when the specific SQLSTATE associated with the condition name occurs. The *SQL-condition-name* must be previously defined in a *SQL-condition-declaration*.

SQLEXCEPTION

Specifies that the handler is invoked when an exception condition occurs. An exception condition is represented by an SQLSTATE value where the first two characters are not '00', '01', or '02'.

SQLWARNING

Specifies that the handler is invoked when a warning condition occurs. A warning condition is represented by an SQLSTATE value where the first two characters are '01'.

NOT FOUND

Specifies that the handler is invoked when a NOT FOUND condition occurs. A NOT FOUND condition is represented by an SQLSTATE value where the first two characters are '02'.

SQL-procedure-statement

An SQL statement or SQL control statement as defined in [“SQL-procedure-statement” on page 1586](#). The SET RESULT SETS and SET SESSION AUTHORIZATION SQL statements are not allowed.

Notes

Compound (dynamic) content: See [“SQL control statements” on page 1579](#) for more information on the constructs that can be used in a compound (dynamic) statement.

Nesting compound statements: *Compound-statements* can be nested within a compound (dynamic) statement. Nested compound statements can be used to scope variable definitions, condition names, condition handlers, and cursors to a subset of the statements in the compound (dynamic) statement. This can simplify the processing done for each *SQL-procedure-statement*. Support for nested compound statements enables the use of a compound statement within the declaration of a condition handler.

Compound (dynamic) statement execution: When a compound (dynamic) statement is dynamically prepared and executed, the statements within the compound statement are processed as static statements. A temporary program that embeds the statements for the compound statement is created and then executed. The program name is QTEMP.QCMPDnnnnn, where nnnnn is a unique number for the job.

CURRENT PATH and CURRENT SCHEMA: The current schema and current path apply to the prepared and executed compound (dynamic) statement. Any change to these special registers within the compound statement does not affect subsequent resolution of statements within the same compound statement. For example:

```
SET SCHEMA prodlib;
SET stmt = 'BEGIN SET SCHEMA data1ib; INSERT INTO test_table VALUES(1); END';
PREPARE compound_stmt FROM stmt;
EXECUTE compound_stmt;
```

When the compound statement `compound_stmt` is prepared and executed, the INSERT will resolve to `PRODLIB.TEST_TABLE`, not `DATALIB.TEST_TABLE`.

Most end user SQL script interfaces use dynamic SQL to execute SQL statements. For example, executing the following two statements in IBM i Navigator's Run SQL Scripts is logically equivalent to the above example. The INSERT will resolve to `PRODLIB.TEST_TABLE`, not `DATALIB.TEST_TABLE`.

```
SET SCHEMA prodlib;  
BEGIN  
  SET SCHEMA datalib;  
  INSERT INTO test_table VALUES(1);  
END;
```

Condition handlers: Condition handlers in a compound (dynamic) statement are similar to `WHENEVER` statements used in external SQL application programs. A condition handler can be defined to automatically get control when an exception, warning, or not found condition occurs. The body of a condition handler contains code that is executed when the condition handler is activated. A condition handler can be activated as a result of an exception, warning, or not found condition that is returned by the database manager for the processing of an SQL statement, or the activating condition can be the result of a `SIGNAL` or `RESIGNAL` statement issued within the routine body.

A condition handler is declared within a compound (dynamic) statement, and it is active for the set of *SQL-procedure-statements* that follow all of the condition handler declarations within the compound (dynamic) statement. To be more specific, the scope of a condition handler declaration H is the list of *SQL-procedure-statements* that follows the condition handler declarations contained within the compound (dynamic) statement in which H appears. This means that the scope of H does not include the statements contained in the body of the condition handler H, implying that a condition handler cannot handle conditions that arise inside its own body. Similarly, for any two condition handlers H1 and H2 declared in the same compound (dynamic) statement, H1 will not handle conditions arising in the body of H2, and H2 will not handle conditions arising in the body of H1.

The declaration of a condition handler specifies the condition that activates it, the type of the condition handler (`CONTINUE`, `EXIT`, or `UNDO`), and the handler action. The type of the condition handler determines where control is returned to after successful completion of the handler action.

Condition handler activation: When a condition other than successful completion occurs in the processing of an *SQL-procedure-statement*, if a condition handler that could handle the condition is within scope, one such condition handler will be activated to process the condition.

In a compound (dynamic) statement with nested *compound-statements*, condition handlers that could handle a specific condition may exist at several levels of the nested compound statements. The condition handler that is activated is a condition handler that is declared innermost to the scope in which the condition was encountered. If more than one condition handler at that nesting level could handle the condition, the condition handler that is activated is the most appropriate handler declared in that compound statement.

The most appropriate handler is a handler that is defined in the compound statement which most closely matches the `SQLSTATE` of the exception or completion condition.

For example, if the innermost compound statement declares a specific handler for `SQLSTATE 22001` as well as a handler for `SQLEXCEPTION`, the specific handler for `SQLSTATE 22001` is the most appropriate handler when an `SQLSTATE 22001` is encountered. In this case, the specific handler is activated.

When a condition handler is activated, the condition handler action is executed. If the handler action completes successfully or with an unhandled warning, the diagnostics area is cleared, and the type of the condition handler (`CONTINUE`, `EXIT`, or `UNDO` handler) determines where control is returned. Additionally, the `SQLSTATE` and `SQLCODE` SQL variables are cleared when a handler completes successfully or with an unhandled warning.

If the handler action does not complete successfully, and an appropriate handler exists for the condition encountered in the handler action, that condition handler is activated. Otherwise, the condition encountered within the condition handler is unhandled.

Unhandled conditions: If a condition is encountered and an appropriate handler does not exist for that condition, the condition is unhandled.

- If the unhandled condition is an exception, the compound statement containing the failing statement is terminated with an unhandled exception condition.
- If the unhandled condition is a warning or not found condition, processing continues with the next statement. Note that the processing of the next SQL statement will cause information about the unhandled condition in the diagnostics area to be overwritten, and evidence of the unhandled condition will no longer exist.

Considerations for using SIGNAL or RESIGNAL statements with nested compound statements:

If an *SQL-procedure-statement* specified in the condition handler is either a SIGNAL or RESIGNAL statement with an exception SQLSTATE, the compound (dynamic) statement terminates with the specified exception. This happens even if this condition handler or another condition handler in the same compound (dynamic) statement specifies CONTINUE, since these condition handlers are not in the scope of this exception. If a *compound-statement* is nested in a compound (dynamic) statement, condition handlers in the compound (dynamic) statement may handle the exception from within the *compound-statement* because those condition handlers are within the scope of the exception.

Null values in SQL variables: If the value of an SQL variable is null and it is used in an SQL statement (such as CONNECT or DESCRIBE) that does not allow an indicator variable, an error is returned.

Uncommitted changes: Any uncommitted transactional work is scoped to the activation group of the connection in which the dynamic compound statement is run.

Effect on open cursors: Upon exit from the compound (dynamic) statement for any reason, all open cursors that are declared in that compound statement are closed.

Considerations for SQLSTATE and SQLCODE SQL variables: The compound (dynamic) statement itself does not affect the SQLSTATE and SQLCODE SQL variables. However, SQL statements contained within the compound statement can affect the SQLSTATE and SQLCODE SQL variables. At the end of the compound statement the SQLSTATE and SQLCODE SQL variables reflect the result of the last SQL statement executed within that compound statement that caused a change to the SQLSTATE and SQLCODE SQL variables. If the SQLSTATE and SQLCODE variables were not changed within the compound (dynamic) statement, they contain the same values as when the compound (dynamic) statement was invoked.

CONNECT (type 1)

The CONNECT (type 1) statement connects an activation group within an application process to the identified application server using the rules for remote unit of work. This server is then the current server for the activation group. This type of CONNECT statement is used if RDBCNNMTH(*RUW) was specified on the CRTSQLxxx command.

Differences between the two types of statements are described in “CONNECT (type 1) and CONNECT (type 2) differences” on page 1662. Refer to “Application-directed distributed unit of work” on page 38 for more information about connection states.

Invocation

This statement can only be embedded within an application program or issued interactively. It is an executable statement that cannot be dynamically prepared. It must not be specified in Java or REXX.

CONNECT is not allowed in a trigger or function.

Authorization

The privileges held by the authorization ID of the statement must include communications-level security. (See the section about security in [Distributed Database Programming](#)).

If the application server is Db2 for i, the user profile of the person issuing the statement must also be a valid user profile on the application server system, UNLESS:

- User is specified. In this case, the USER clause must specify a valid user profile on the application server system.
- TCP/IP is used with a server authorization entry for the application server. In this case, the server authorization entry must specify a valid user profile on the application server system.

If a global variable is referenced in a statement, the privileges held by the authorization ID of the statement must include at least one of the following:

- For the global variable identified in the statement,
 - The READ privilege on the global variable, and
 - The system authority *EXECUTE on the library containing the global variable
- Database administrator authority

Syntax

authorization

Description

TO server-name or variable

Identifies the application server by the specified server name or the server name contained in the variable. It can be a global variable if it is qualified with schema name. If a variable is specified:

- It must be a CHAR or VARCHAR host variable.

- It must not be followed by an indicator variable.
- The server name must be left-justified within the variable and must conform to the rules for forming an ordinary identifier.
- If the length of the server name is less than the length of the variable, it must be padded on the right with blanks.

When the CONNECT statement is executed, the specified server name or the server name contained in the variable must identify an application server described in the local directory and the activation group must be in the connectable state.

If the *server-name* is a local relational database and an *authorization-name* is specified, it must be the user of the job. If the specified *authorization-name* is different than the user of the job, an error occurs and the application is left in the unconnected state.

USER *authorization-name* or variable

Identifies the authorization name that will be used to connect to the application server. It can be a global variable if it is qualified with schema name.

If a *variable* is specified,

- It must be a CHAR or VARCHAR host variable.
- It must not be followed by an indicator variable.
- The authorization name must be left-justified within the variable and must conform to the rules of forming an authorization name.
- If the length of the authorization name is less than the length of the variable, it must be padded on the right with blanks.
- The value of the server name must not contain lowercase characters.

USING *password* or variable

Identifies the password that will be used to connect to the application server.

If password is specified as a literal, it must be a character string. The maximum length is 128 characters. It must be left justified. The literal form of the password is not allowed in static SQL or REXX.

If a *variable* is specified,

- It cannot be a global variable.
- It must be a CHAR or VARCHAR host variable.
- It must not be followed by an indicator variable.
- The password must be left-justified within the variable.
- If the length of the password is less than that of the variable, it must be padded on the right with blanks.

RESET

CONNECT RESET is equivalent to CONNECT TO x where x is the local server name.

CONNECT with no operand

This form of the CONNECT statement returns information about the current server and has no effect on connection states, open cursors, prepared statements, or locks. The connection information is returned in the connection information items in the SQL Diagnostics Area (or the SQLCA).

Notes

Successful connection: If the CONNECT statement is successful:

- All open cursors are closed, all prepared statements are destroyed, and all locks are released from the current connection.
- The activation group is disconnected from all current and dormant connections, if any, and connected to the identified application server.

- The name of the application server is placed in the CURRENT SERVER special register.
- Information about the application server is placed in the *connection-information-items* in the SQL Diagnostics Area.
- Information about the application server is also placed in the SQLERRP and SQLERRD(4) fields of the SQLCA. If the application server is an IBM relational database product, the information in the SQLERRP field has the form *pppvrrm*, where:
 - *ppp* identifies the product as follows:
 - ARI for Db2 for VM and VSE
 - DSN for Db2 for z/OS
 - QSQ for Db2 for i
 - SQL for all other Db2 products
 - *vv* is a two-digit version identifier such as '09'
 - *rr* is a two-digit release identifier such as '01'
 - *m* is a one-character modification level such as '0'

For example, if the application server is Version 9 of Db2 for z/OS, the value of SQLERRP is 'DSN09010'.

The SQLERRD(4) field of the SQLCA contains values indicating whether the application server allows committable updates to be performed. For a CONNECT (type 1) statement SQLERRD(4) will always contain the value 1. The value 1 indicates that committable updates can be performed, and the connection:

- Uses an unprotected conversation⁸⁹, or
 - Is a connection to an application requester driver program using the *RUW connection method, or
 - Is a local connection using the *RUW connection method.
- Additional information about the connection is placed in the SQLERRMC field of the SQLCA. Refer to [Appendix C, “SQLCA \(SQL communication area\),” on page 1665](#)

Unsuccessful connection: If the CONNECT statement is unsuccessful, the DB2_MODULE_DETECTING_ERROR condition information item in the SQL Diagnostics Area (or the SQLERRP field of the SQLCA) is set to the name of the module at the application requester that detected the error. Note that the first three characters of the module name identify the product. For example, if the application requester is Db2 LUW the first three characters are 'SQL'.

If the CONNECT statement is unsuccessful because the activation group is not in the connectable state, the connection state of the activation group is unchanged.

If the CONNECT statement is unsuccessful for any other reason:

- The activation group remains in a connectable, but unconnected state
- All open cursors are closed, all prepared statements are destroyed, and all locks are released from all current and dormant connections.

An application in a connectable but unconnected state can only execute the CONNECT or SET CONNECTION statements.

Implicit connect:

- When running in the default activation group, the SQL program implicitly connects to a remote relational database when:
 - The activation group is in a connectable state.
 - The first SQL statement in the first SQL program on the program stack is executed.

⁸⁹ To reduce the possibility of confusion between network connections and SQL connections, in this book the term 'conversation' will be used to apply to network connections over TCP/IP as well as over APPC, even though it formally applies only to APPC connections.

- When running in a non-default activation group, the SQL program implicitly connects to a remote relational database when the first SQL statement in the first SQL program for that activation group is executed.

Note: It is a good practice for the first SQL statement executed by an activation group to be the CONNECT statement.

When APPC is used for connecting to an RDB, implicit connect always sends the *authorization-name* of the application requester job and does not send passwords. If the *authorization-name* of the application server job is different, or if a password must be sent, an explicit connect statement must be used.

When TCP/IP is used for connecting to an RDB, an implicit connect is not bound by the above restrictions. Use of the ADDSVRAUTE and other -SVRAUTE commands allows one to specify, for a given user under which the implicit (or explicit) CONNECT is done, the remote authorization-name and password to be used in connecting to a given RDB.

In order for the password to be stored with the ADDSVRAUTE or CHGSVRAUTE command, the QRETSVRSEC system value must be set to '1' rather than the default of '0'. When using these commands for DRDA connection, it is very important to realize that the value of the RDB name entered into the SERVER parameter must be in UPPER CASE. For more information, see Example 2 under Type 2 CONNECT.

For more information about implicit connect, refer to the [SQL Programming](#) topic collection. Once a connection to a relational database for a user profile is established, the password, if specified, may not be validated again on subsequent connections to the same relational database with the same user profile. Revalidation of the password depends on if the conversation is still active. See the [Distributed Database Programming](#) topic collection for more details.

Connection states: For a description of connection states, see “[Remote unit of work connection management](#)” on page 37. Consecutive CONNECT statements can be executed successfully because CONNECT does not remove the activation group from the connectable state.

A CONNECT to either a current or dormant connection in the application group is executed as follows:

- If the connection identified by the server-name was established using a CONNECT (type 1) statement, then no action is taken. Cursors are not closed, prepared statements are not destroyed, and locks are not released.
- If the connection identified by the server-name was established using a CONNECT (type 2) statement, then the CONNECT statement is executed like any other CONNECT statement.

CONNECT cannot execute successfully when it is preceded by any SQL statement other than CONNECT, COMMIT, DISCONNECT, SET CONNECTION, RELEASE, or ROLLBACK. To avoid an error, execute a commit or rollback operation before a CONNECT statement is executed.

If any previous current or dormant connections were established using protected conversations, then the CONNECT (type 1) statement will fail. Either, a CONNECT (type 2) statement must be used, or the connections using protected conversations must be ended by releasing the connections and successfully committing.

For more information about connecting to a remote relational database and the local directory, see [SQL Programming](#) and the [Distributed Database Programming](#).

SET SESSION AUTHORIZATION: If a SET SESSION AUTHORIZATION statement has been executed in the thread, a CONNECT to the local server will fail unless prior to the connect statement, the SYSTEM_USER value is the same as SESSION_USER.

This includes an implicit connect due to invoking a program that specifies ACTGRP(*NEW).

Examples

Example 1: In a C program, connect to the application server TOROLAB.

```
EXEC SQL CONNECT TO TOROLAB;
```

Example 2: In a C program, connect to an application server whose name is stored in the variable APP_SERVER (VARCHAR(18)). Following a successful connection, copy the product identifier of the application server to the variable PRODUCT.

```
void main ()
{
  char product[9] = " ";
  EXEC SQL BEGIN DECLARE SECTION;
  char APP_SERVER[19];
  char username[11];
  char userpass[129];
  EXEC SQL END DECLARE SECTION;
  EXEC SQL INCLUDE SQLCA;
  strcpy(APP_SERVER, "TOROLAB");
  strcpy(username, "JOE");
  strcpy(userpass, "XYZ1");
  EXEC SQL CONNECT TO :APP_SERVER
          USER :username USING :userpass;
  if (strncmp(SQLSTATE, "00000", 5) )
    { EXEC SQL GET DIAGNOSTICS CONDITION 1
      product = DB2_PRODUCT_ID; }
  ...
  return;
}
```

CONNECT (type 2)

The CONNECT (type 2) statement connects an activation group within an application process to the identified application server using the rules for application directed distributed unit of work. This server is then the current server for the activation group. This type of CONNECT statement is used if RDBCNNMTH(*DUW) was specified on the CRTSQLxxx command.

Differences between the two types of statements are described in “CONNECT (type 1) and CONNECT (type 2) differences” on page 1662. Refer to “Application-directed distributed unit of work” on page 38 for more information about connection states.

Invocation

This statement can only be embedded in an application program or issued interactively. It is an executable statement that cannot be dynamically prepared. It must not be specified in Java or REXX.

CONNECT is not allowed in a trigger or function.

Authorization

The privileges held by the authorization ID of the statement must include communications-level security. (See the section about security in the [Distributed Database Programming topic collection](#).)

If the application server is Db2 for i, the profile ID of the person issuing the statement must also be a valid user profile on the application server system, UNLESS:

- USER is specified. If USER is specified, the USER clause must specify a valid user profile on the application server system.
- TCP/IP is used with a server authorization entry for the application server. If this is the case, the server authorization entry must specify a valid user profile on the application server system.

If a global variable is referenced in a statement, the privileges held by the authorization ID of the statement must include at least one of the following:

- For the global variable identified in the statement,
 - The READ privilege on the global variable, and
 - The system authority *EXECUTE on the library containing the global variable
- Database administrator authority

Syntax

authorization

Description

TO server-name or variable

Identifies the application server by the specified server name or the server name contained in the variable. It can be a global variable if it is qualified with schema name. If a variable is specified:

- It must be a CHAR or VARCHAR host variable.

- It must not be followed by an indicator variable.
- The server name must be left-justified within the variable and must conform to the rules for forming an ordinary identifier.
- If the length of the server name is less than the length of the variable, it must be padded on the right with blanks.
- The value of the server name must not contain lowercase characters.

When the CONNECT statement is executed, the specified server name or the server name contained in the variable must identify an application server described in the local directory.

Let S denote the specified server name or the server name contained in the variable. S must not identify an existing connection of the application process.

USER authorization-name or variable

Identifies the authorization name that will be used to connect to the application server. It can be a global variable if it is qualified with schema name.

If a *variable* is specified:

- It must be a CHAR or VARCHAR host variable.
- It must not be followed by an indicator variable. The authorization name must be left-justified within the variable and must conform to the rules of forming an authorization name.
- If the length of the authorization name is less than the length of the variable, it must be padded on the right with blanks.

USING password or variable

Identifies the password that will be used to connect to the application server.

If password is specified as a literal, it must be a character string. The maximum length is 128 characters. It must be left justified. The literal form of the password is not allowed in static SQL or REXX.

If a *variable* is specified:

- It cannot be a global variable.
- It must be a CHAR or VARCHAR host variable.
- It must not be followed by an indicator variable.
- The password must be left-justified within the variable.
- If the length of the password is less than that of the variable, it must be padded on the right with blanks.

RESET

CONNECT RESET is equivalent to CONNECT TO x where x is the local server name.

CONNECT with no operand

This form of the CONNECT statement returns information about the current server and has no effect on connection states, open cursors, prepared statements, or locks. The connection information is returned in the connection information items in the SQL Diagnostics Area (or the SQLCA).
