The function always returns the same result function each time that the function is invoked with the same input arguments. An example of a deterministic function is a function that calculates the square root of the input. Db2 uses this information to enable the merging of views and table expressions for SELECT and SQL data change statements that refer to this function. DETERMINISTIC is not the default. If applicable, specify DETERMINISTIC to prevent non-optimal access paths from being chosen for SQL statements that refer to this function.

Db2 does not verify that the function program is consistent with the specification of DETERMINISTIC or NOT DETERMINISTIC.

EXTERNAL ACTION or NO EXTERNAL ACTION

Specifies whether the function takes an action that changes the state of an object that Db2 does not manage. An example of an external action is sending a message or writing a record to a file.

EXTERNAL ACTION

The function can take an action that changes the state of an object that Db2 does not manage.

Some SQL statements that invoke functions with external actions can result in incorrect results if parallel tasks execute the function. For example, if the function sends a note for each initial call to it, one note is sent for each parallel task instead of once for the function. Specify the DISALLOW PARALLEL clause for functions that do not work correctly with parallelism.

If you specify EXTERNAL ACTION, then Db2:

- Materializes the views and table expressions in SELECT and SQL data change statements that refer to the function. This materialization can adversely affect the access paths that are chosen for the SQL statements that refer to this function. Do not specify EXTERNAL ACTION if the function does not have an external action.
- Does not move the function from one task control block (TCB) to another between FETCH operations.
- Does not allow another function or stored procedure to use the TCB until the cursor is closed. This is also applicable for cursors declared WITH HOLD.

The only changes to resources made outside of Db2 that are under the control of commit and rollback operations are those changes made under RRS control.

EXTERNAL ACTION must be specified implicitly or explicitly specified if the SQL routine body invokes a function that is defined with EXTERNAL ACTION. EXTERNAL ACTION is the default.

NO EXTERNAL ACTION

The function does not take any action that changes the state of an object that Db2 does not manage. Db2 uses this information to enable the merging of views and table expressions for SELECT and SQL data change statements that refer to this function. If applicable, specify NO EXTERNAL ACTION to prevent non-optimal access paths from being chosen for SQL statements that refer to this function.

Although the scope of global variables are beyond the scope of the routine, global variables can be set in the routine body when NO EXTERNAL ACTION is specified.

Db2 does not verify that the function program is consistent with the specification of EXTERNAL ACTION or NO EXTERNAL ACTION.

READS SQL DATA or CONTAINS SQL

Specifies the classification of SQL statements and nested routines that this routine can execute or invoke. The database manager verifies that the SQL statements issued by the function, and all routines locally invoked by the routine, are consistent with this specification; the verification is not performed when nested remote routines are invoked. For the classification of each statement, see "SQL statement data access classification for routines" on page 2263.

READS SQL DATA

Specifies that the function can execute statements with a data access classification of READS SQL DATA, CONTAINS SQL, or NO SQL. The function cannot execute SQL statements that modify data.

READS SQL DATA is the default.

CONTAINS SQL

Specifies that the function can execute only SQL statements with a data access classification of CONTAINS SQL or NO SQL. The function cannot execute SQL statements that read or modify data.

STATIC DISPATCH

At function resolution time, Db2 chooses a function based on the static (or declared) types of the function parameters. STATIC DISPATCH is the default.

CALLED ON NULL INPUT

Specifies that the function is to be invoked if any, or if all, of the argument values are null. Specifying CALLED ON NULL INPUT means that the body of the function must be coded to test for null argument values.

CALLED ON NULL INPUT is the default.

NOT SECURED or SECURED

Specifies if the function is considered secure for row access control and column access control. The SECURED or NOT SECURED option applies to all future versions of the function.

NOT SECURED

Specifies that the function is not considered secure for row access control and column access control.

NOT SECURED is the default.

When the function is invoked, the arguments of the function must not reference a column for which a column mask is enabled when the table is using active column access control.

SECURED

Specifies that the function is considered secure for row access control and column access control.

The function must be secure when it is referenced in a row permission or a column mask.

SQL-routine-body

Specifies a single RETURN statement. For more information, see "RETURN statement" on page 2230.

If the RETURN statement includes a scalar fullselect, Db2 attempts to define a compiled function. For more information, see "CREATE FUNCTION (compiled SQL scalar)" on page 1423.

To determine what type of SQL scalar function is created, refer to the INLINE column of the SYSIBM.SYSROUTINES catalog table.

WRAPPED *obfuscated-statement-text*

Specifies the encoded definition of the function. A CREATE FUNCTION statement can be encoded using the WRAP scalar function.

WRAPPED must not be specified on a static CREATE statement.

Notes for CREATE FUNCTION (inlined SQL scalar)

Considerations for all types of user-defined functions:

For considerations that apply to all types of user-defined functions, see "CREATE FUNCTION" on page 1419.

Types of SQL scalar functions:

If the syntax of the CREATE FUNCTION statement conforms to the syntax diagrams and descriptions for CREATE FUNCTION (inlined SQL scalar), Db2 defines an inlined function, and a package is not created. When an inlined SQL scalar function is invoked, the *expression* in the RETURN statement of the function is copied (inlined) into the query itself; the function is not invoked. The attributes of an inlined SQL scalar function are described in "CREATE FUNCTION (inlined SQL scalar)" on page 1484.

Otherwise, Db2 attempts to define a compiled function with an associated package. For example, if the RETURN statement contains a scalar fullselect, Db2 attempts to define a compiled function. The attributes of a compiled SQL scalar function are described in "CREATE FUNCTION (compiled SQL scalar)" on page 1423.

To determine what type of SQL scalar function is created, refer to the INLINE column of the SYSIBM.SYSROUTINES catalog table. In the INLINE column, a value of Y indicates that the function is an inlined function, and a value of N indicates that the function is a compiled function.

Considerations for functions defined with MODIFIES SQL DATA:

If a function is specified in a subselect, and the function is defined as MODIFIES SQL DATA, the number of times the function is invoked is invoked will vary depending on the access plan used.

Self-referencing function:

The body of an SQL function (that is, the *expression* or NULL in the RETURN statement in the body of the CREATE FUNCTION statement) cannot contain a recursive invocation of itself or to another function that invokes it, because such a function would not exist to be referenced.

Dependent objects:

An SQL routine is dependent on objects that are referenced in the routine body.

Obfuscated statements:

A CREATE FUNCTION statement can be executed in obfuscated form. In an obfuscated statement, only the function name, parameters, and the WRAPPED keyword are readable. The rest of the statement is encoded in such a way that it is not readable but can be decoded by a database server that supports obfuscated statements. The WRAP scalar function produces obfuscated statements. Any debug options that are specified when the function is created from an obfuscated statement are ignored.

Resolution of object names:

Db2 resolves object names inside the body of the function according to the rules in "Unqualified object name resolution" on page 86 and the type of the object. The name resolution occurs when the function is created.

Referencing date and time special registers:

If an SQL function contains multiple references to any of the date or time special registers, all references return the same value. In addition, this value is the same value that is returned by the retrieving value of the special register in the statement that invoked the function.

Self-referencing function:

The body of an SQL function (that is, the *expression* or NULL in the RETURN clause of the CREATE FUNCTION (inlined SQL scalar) statement) cannot contain a recursive invocation of itself or to another function that invokes it, because such a function would not exist to be referenced.

Dependent objects:

An SQL routine is dependent on objects that are referenced in the routine body.

Alternative syntax and synonyms:

To provide compatibility with previously releases of Db2 or other products in the Db2 family, Db2 supports the following alternative syntax:

- VARIANT as a synonym for NOT DETERMINISTIC
- NOT VARIANT as a synonym for DETERMINISTIC
- NULL CALL as a synonym for CALLED ON NULL INPUT
- TIMEZONE can be specified as an alternative to TIME ZONE.

For an inlined SQL scalar function, the RETURNS clause and the clauses in the *option-list* can be specified in any order.

Examples for CREATE FUNCTION (inlined SQL scalar)

Example 1: Define a scalar function that returns the tangent of a value using existing SIN and COS built-in functions:

```
CREATE FUNCTION TAN (X DOUBLE)
  RETURNS DOUBLE
  LANGUAGE SQL
  CONTAINS SQL
  NO EXTERNAL ACTION
  DETERMINISTIC
  RETURN SIN(X)/COS(X);
```

CREATE FUNCTION (sourced)

This CREATE FUNCTION statement registers a user-defined function that is based on an existing scalar or aggregate function with a database server.

Invocation for CREATE FUNCTION (sourced)

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES RUN behavior is in effect. For more information, see "Authorization IDs and dynamic SQL" on page 94.

Authorization for CREATE FUNCTION (sourced)

The privilege set defined below must include at least one of the following:

- The CREATEIN privilege on the schema
- SYSADM or SYSCTRL authority
- System DBADM
- Installation SYSOPR authority (when the current SQLID of the process is set to SYSINSTL)

The authorization ID that matches the schema name implicitly has the CREATEIN privilege on the schema.

If the authorization ID that is used to create the function has the installation SYSADM authority or the installation SYSOPR authority and if the current SQLID is set to SYSINSTL, the function is identified as system-defined function.

Additional privileges are required for the source function, and other privileges are also needed if the function uses a table as a parameter, or refers to a distinct type. These privileges are:

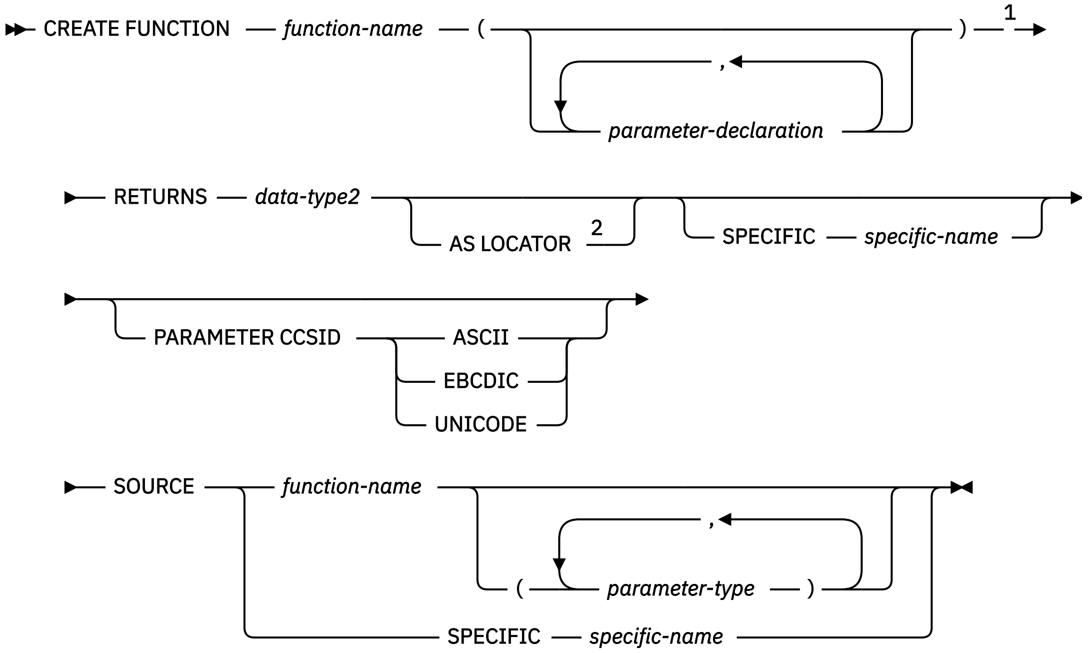
- The EXECUTE privilege for the function that the SOURCE clause references.
- The SELECT privilege on any table that is an input parameter to the function.
- The USAGE privilege on each distinct type that the function references.

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the owner is a role, the implicit schema match does not apply and this role needs to include one of the previously listed conditions.

If the statement is dynamically prepared and is not running in a trusted context for which the ROLE AS OBJECT OWNER clause is specified, the privilege set is the set of privileges that are held by the SQL authorization ID of the process. If the schema name is not the same as the SQL authorization ID of the process, one of the following conditions must be met:

- The privilege set includes SYSADM or SYSCTRL authority.
- The SQL authorization ID of the process has the CREATEIN privilege on the schema.

Syntax for CREATE FUNCTION (sourced)

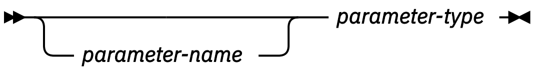


Notes:

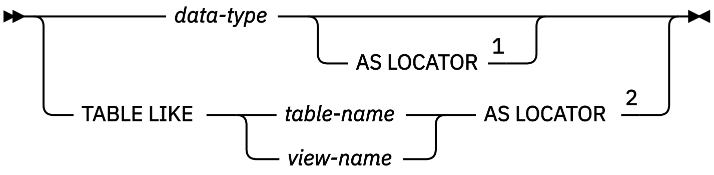
[1] RETURNS, SPECIFIC, and SOURCE can be specified in any order.

[2] AS LOCATOR can be specified only for a LOB data type or a distinct type based on a LOB data type.

parameter-declaration:



parameter-type:



Notes:

[1] AS LOCATOR can be specified only for a LOB data type or a distinct type based on a LOB data type.

[2] The TABLE LIKE name AS LOCATOR clause can only be specified for the parameter list of the function that is being defined.

Description for CREATE FUNCTION (sourced)

function-name

Names the user-defined function. The name is implicitly or explicitly qualified by a schema name. For more information, see "Choosing the schema and function names" and "Determining the uniqueness of functions in a schema" in "CREATE FUNCTION" on page 1419.

(*parameter-declaration,...*)

Specifies the number of input parameters of the function and the data type of each parameter. All of the parameters for a function are input parameters and are nullable. There must be one entry in the list for each parameter that the function expects to receive. Although not required, you can give each parameter a name.

A function can have no parameters. In this case, you must code an empty set of parentheses, for example:

```
CREATE FUNCTION WOOFER()
```

parameter-name

Specifies the name of the input parameter. The name is an SQL identifier, and each name in the parameter list must not be the same as any other name.

data-type

Specifies the data type of the input parameter. The data type can be a built-in data type or a distinct type.

built-in-type

The data type of the input parameter is a built-in data type.

For information on the data types, see built-in-type.

For parameters with a character or graphic data type, the PARAMETER CCSID clause or CCSID clause indicates the encoding scheme of the parameter. If you do not specify either of these clauses, the encoding scheme is the value of field DEF ENCODING SCHEME on installation panel DSNTIPF.

distinct-type-name

The data type of the input parameter is a distinct type. Any length, precision, scale, subtype, or encoding scheme attributes for the parameter are those of the source type of the distinct type.

The implicitly or explicitly specified encoding scheme of all of the parameters with a character or graphic string data type must be the same—either all ASCII, all EBCDIC, or all UNICODE.

Although parameters with a character data type have an implicitly or explicitly specified subtype (BIT, SBCS, or MIXED), the function program can receive character data of any subtype. Therefore, conversion of the input data to the subtype of the parameter might occur when the function is invoked.

Parameters with a datetime data type or a distinct type are passed to the function as a different data type:

- A datetime type parameter is passed as a character data type, and the data is passed in ISO format.

  The encoding scheme for a datetime type parameter is the same as the implicitly or explicitly specified encoding scheme of any character or graphic string parameters. If no character or graphic string parameters are passed, the encoding scheme is the value of field DEF ENCODING SCHEME on installation panel DSNTIPF.
- A distinct type parameter is passed as the source type of the distinct type.

You can specify any built-in data type or distinct type that matches or can be cast to the data type of the corresponding parameter of the source function (the function that is identified in the SOURCE clause). (For information on casting data types, see "Casting between data types" on page 130.) Length, precision, or scale attributes do not have be specified for data types with these attributes. When specifying data types with these attributes, follow these rules:

- An empty set of parentheses can be used to indicate that the length, precision, or scale is the same as the source function.
- If length, precision, or scale is not explicitly specified, and empty parentheses are not specified, the default values are used.

AS LOCATOR

Specifies that a locator to the value of the parameter is passed to the function instead of the actual value. Specify AS LOCATOR only for parameters with a LOB data type or a distinct type based on a LOB data type. Passing locators instead of values can result in fewer bytes being passed to the function, especially when the value of the parameter is very large.

The AS LOCATOR clause has no effect on determining whether data types can be promoted, nor does it affect the function signature, which is used in function resolution.

TABLE LIKE *table-name* or *view-name* AS LOCATOR

Specifies that the parameter is a transition table. However, when the function is invoked, the actual values in the transition table are not passed to the function. A single value is passed instead. This single value is a locator to the table, which the function uses to access the columns of the transition table. A function with a table parameter can only be invoked from the triggered action of a trigger.

The use of TABLE LIKE provides an implicit definition of the transition table. It specifies that the transition table has the same number of columns as the identified table or view. If a table is specified, the transition table includes columns that are defined as implicitly hidden in the table. The columns have the same data type, length, precision, scale, subtype, and encoding scheme as the identified table or view, as they are described in catalog tables SYSCOLUMNS and SYSTABLESPACE. The number of columns and the attributes of those columns are determined at the time the CREATE FUNCTION statement is processed. Any subsequent changes to the number of columns in the table or the attributes of those columns do not affect the parameters of the function.

table-name or *view-name* must identify a table or view that exists at the current server. A view cannot have columns of length 0. The name must not identify a declared temporary table. The table that is identified can contain XML columns; however, the function cannot reference those XML columns. The name does not have to be the same name as the table that is associated with the transition table for the trigger. An unqualified table or view name is implicitly qualified according to the following rules:

- If the CREATE FUNCTION statement is embedded in a program, the implicit qualifier is the authorization ID in the QUALIFIER bind option when the plan or package was created or last rebound. If QUALIFIER was not used, the implicit qualifier is the owner of the plan or package.
- If the CREATE FUNCTION statement is dynamically prepared, the implicit qualifier is the SQL authorization ID in the CURRENT SCHEMA special register.

When the function is invoked, the corresponding columns of the transition table identified by the table locator and the table or view identified in the TABLE LIKE clause must have the same definition. The data type, length, precision, scale, and encoding scheme of these columns must match exactly. The description of the table or view at the time the CREATE FUNCTION statement was executed is used.

Additionally, a character FOR BIT DATA column of the transition table cannot be passed as input for a table parameter for which the corresponding column of the table specified at the definition is not defined as character FOR BIT DATA. (The definition occurs with the CREATE FUNCTION statement.) Likewise, a character column of the transition table that is not FOR BIT DATA cannot be passed as input for a table parameter for which the corresponding column of the table specified at the definition is defined as character FOR BIT DATA.

For more information about using table locators, see Accessing transition tables in a user-defined function or stored procedure (Db2 Application programming and SQL).

RETURNS

Identifies the output of the function.

data-type2

Specifies the data type of the output. The output is nullable.

You can specify any built-in data type or distinct type that can be cast from the data type of the result of the source function. (For information on casting data types, see "Casting between data types" on page 130.)

AS LOCATOR

Specifies that the function returns a locator to the value rather than the actual value. You can specify AS LOCATOR only if the output from the function has a LOB data type or a distinct type based on a LOB data type.

SPECIFIC *specific-name*

Provides a unique name for the function. The name is implicitly or explicitly qualified with a schema name. The name, including the schema name, must not identify the specific name of another function that exists at the current server.

The unqualified form of *specific-name* is an SQL identifier. The qualified form is an SQL identifier (the schema name) followed by a period and an SQL identifier.

If you do not specify a schema name, it is the same as the explicit or implicit schema name of the function name (*function-name*). If you specify a schema name, it must be the same as the explicit or implicit schema name of the function name.

If you do not specify the SPECIFIC clause, the default specific name is the name of the function. However, if the function name does not provide a unique specific name or if the function name is a single asterisk, Db2 generates a specific name in the form of:

```
SQLxxxxxxxxxxxx
```

where `'xxxxxxxxxxxx'` is a string of 12 characters that make the name unique.

The specific name is stored in the SPECIFIC column of the SYSROUTINES catalog table. The specific name can be used to uniquely identify the function in several SQL statements (such as ALTER FUNCTION, COMMENT, DROP, GRANT, and REVOKE) and in Db2 commands (START FUNCTION, STOP FUNCTION, and DISPLAY FUNCTION). However, the function cannot be invoked by its specific name.

PARAMETER CCSID

Indicates whether the encoding scheme for character and graphic string parameters is ASCII, EBCDIC, or UNICODE. The default encoding scheme is the value specified in the CCSID clauses of the parameter list or RETURNS clause, or in the field DEF ENCODING SCHEME on installation panel DSNTIPF.

This clause provides a convenient way to specify the encoding scheme for character and graphic string parameters. If individual CCSID clauses are specified for individual parameters in addition to this PARAMETER CCSID clause, the value specified in *all* of the CCSID clauses must be the same value that is specified in this clause.

This clause also specifies the encoding scheme to be used for system-generated parameters of the routine such as message tokens and DBINFO.

SOURCE

Specifies that the new function is being defined as a sourced function. A *sourced function* is implemented by another function (the *source function*). The source function must be a scalar or aggregate function that exists at the current server, and it must be one of the following types of functions:

- A function that was defined with a CREATE FUNCTION statement
- A cast function that was generated by a CREATE TYPE statement for a distinct type
- A built-in function

If the source function is not a built-in function, the particular function can be identified by its name, function signature, or specific name.

If the source function is a built-in function, the SOURCE clause must include a function signature for the built-in function.

The source function must not be any of the built-in functions (if a particular syntax is shown, only the indicated form cannot be specified):

- ARRAY_AGG
- ARRAY_DELETE
- ARRAY_FIRST
- ARRAY_LAST
- ARRAY_NEXT
- ARRAY_PRIOR
- CARDINALITY
- CHAR(*datetime-expression*, *second-argument*) where *second-argument* is ISO, USA, EUR, JIS, or LOCAL or if CHAR is specified with OCTETS, CODEUNITS16, or CODEUNITS32.
- CHARACTER_LENGTH
- CLOB if OCTETS, CODEUNITS16, or CODEUNITS32 is specified
- COALESCE if a parameter is an array
- COUNT(*)
- COUNT_BIG(*)
- FL 504 CUME_DIST
- FL 504 CUME_DIST (aggregate)
- DBCLOB if OCTETS, CODEUNITS16, or CODEUNITS32 is specified
- DECODE
- DECRYPT_BIT where the second argument is DEFAULT
- DECRYPT_CHAR where the second argument is DEFAULT
- DECRYPT_DB where the second argument is DEFAULT
- DECRYPT_DATAKEY_BIGINT
- DECRYPT_DATAKEY_BIT
- DECRYPT_DATAKEY_CLOB
- DECRYPT_DATAKEY_DBCLOB
- DECRYPT_DATAKEY_DECIMAL
- DECRYPT_DATAKEY_INTEGER
- DECRYPT_DATAKEY_VARCHAR
- DECRYPT_DATAKEY_VARGRAPHIC
- ENCRYPT_DATAKEY
- EXTRACT
- FL 504 FIRST_VALUE
- GETVARIABLE where the second argument is DEFAULT
- FL 502 GRAPHIC if OCTETS, CODEUNITS16, or CODEUNITS32 is specified, or if the first argument is numeric
- IFNULL if a parameter is an array
- INSERT if OCTETS, CODEUNITS16, or CODEUNITS32 is specified
- FL 504 LAG
- FL 504 LAST_VALUE
- FL 504 LEAD

- LEFT if OCTETS, CODEUNITS16, or CODEUNITS32 is specified
- FL 501 LISTAGG
- LOCAL
- LOCATE if OCTETS, CODEUNITS16, or CODEUNITS32 is specified
- MAX
- MAX_CARDINALITY
- MIN
- FL 504 NTH_VALUE
- FL 504 NTILE
- NULLIF
- FL 504 PERCENT_RANK
- FL 504 PERCENT_RANK (aggregate)
- POSITION
- FL 504 RATIO_TO_REPORT
- FL 504 REGEXP_COUNT
- FL 504 REGEXP_INSTR
- FL 504 REGEXP_LIKE
- FL 504 REGEXP_REPLACE
- FL 504 REGEXP_SUBSTR
- RID
- RIGHT if OCTETS, CODEUNITS16, or CODEUNITS32 is specified
- STRIP where multiple arguments are specified
- SUBSTRING
- TRIM where the first argument is BOTH, B, LEADING, L, TRAILING, T, or the first or second argument is FROM
- TRIM_ARRAY
- VARCHAR if OCTETS, CODEUNITS16, or CODEUNITS32 is specified
- FL 502 VARGRAPHIC if OCTETS, CODEUNITS16, or CODEUNITS32 is specified, or if the first argument is numeric.
- XMLAGG
- XMLCONCAT
- XMLELEMENT
- XMLFOREST
- XMLNAMESPACES

If you base the sourced function directly or indirectly on an external scalar function, the sourced function inherits the attributes of the external scalar function. This can involve several layers of sourced functions. For example, assume that function A is sourced on function B, which in turn is sourced on function C. Function C is an external scalar function. Functions A and B inherit all of the attributes that are specified on the EXTERNAL clause of the CREATE FUNCTION statement for function C.

function-name

Identifies the function that is to be used as the source function. The source function can be defined with any number of parameters. If more than one function is defined with the specified name in the specified or implicit schema, an error is returned.

If you specify an unqualified *function-name*, Db2 searches the schemas of the SQL path. Db2 selects the first schema that has only one function with this name on which the user has EXECUTE authority. An error is returned if a function is not found or a schema has more than one function with this name.

function-name (parameter-type,...)

Identifies the function that is to be used as the source function by its function signature, which uniquely identifies the function. The*function-name (parameter-type,...)* must identify a function with the specified signature. The specified parameters must match the data types in the corresponding position that were specified when the function was created. Db2 uses the number of data types and the logical concatenation of the data types to identify the specific function instance. Synonyms for data types are considered a match.

If the function was defined with a table parameter (the LIKE TABLE *name* AS LOCATOR clause was specified in the CREATE FUNCTION statement to indicate that one of the input parameters is a transition table), the function signature cannot be used to uniquely identify the function. Instead, use one of the other syntax variations to identify the function with its function name, if unique, or its specific name.

If *function-name()* is specified, the identified function must have zero parameters.

function-name

Identifies the function name of the source function. If you specify an unqualified name, Db2 searches the schemas of the SQL path. Otherwise, Db2 searches for the function in the specified schema.

parameter-type,...

Identifies the parameters of the function.

If an unqualified distinct type name is specified, Db2 searches the SQL path to resolve the schema name for the distinct type.

Empty parentheses are allowed for some data types that are specified in this context. For data types that have a length, precision, or scale attribute, use one of the following specifications:

- Empty parentheses indicate that Db2 ignores the attribute when determining whether the data types match. For example, DEC() is considered a match for a parameter of a function that is defined with a data type of DEC(7,2). However, FLOAT cannot be specified with empty parentheses because its parameter value indicates a specific data type (REAL or DOUBLE).
- If a specific value for a length, precision, or scale attribute is specified, the value must exactly match the value that was specified (implicitly or explicitly) in the CREATE FUNCTION statement. If the data type is FLOAT, the precision does not need to exactly match the value that was specified because matching is based on the data type (REAL or DOUBLE).
- If length, precision, or scale is not explicitly specified, and empty parentheses are not specified, the default attributes of the data type are implied. The implicit length must exactly match the value that was specified (implicitly or explicitly) in the CREATE FUNCTION statement.

If you omit the FOR *subtype* DATA clause or the CCSID clause for data types with a subtype or encoding scheme attribute, Db2 is to ignore the attribute when determining whether the data types match. An exception to ignoring the attribute is FOR BIT DATA. A character FOR BIT DATA parameter of the new function cannot correspond to a parameter of the source function that is not defined as character FOR BIT DATA. Likewise, a character parameter of the new function that is not FOR BIT DATA cannot correspond to a parameter of the source function that is defined as character FOR BIT DATA.

The number of input parameters in the function that is being created must be the same as the number of parameters in the source function. If the data type of each input parameter is not the same as or castable to the corresponding parameter of the source function, an error occurs. The data type of the final result of the source function must match or be castable to the result of the sourced function.

AS LOCATOR

Specifies that the function is defined to receive a locator for this parameter. If AS LOCATOR is specified, the data type must be a LOB or distinct type that is based on a LOB.

SPECIFIC *specific-name*

Identifies the function to be used as the source function by its specific name.

If you specify an unqualified *specific-name*, Db2 searches the SQL path to locate the schema. Db2 selects the first schema that contains a function with this specific name for which the user has EXECUTE authority. Db2 returns an error if it cannot find a function with the specific name in one of the schemas in the SQL path.

If you specify a qualified *specific-name,* Db2 searches the named schema for the function. Db2 returns an error if it cannot find a function with the specific name.

Notes for CREATE FUNCTION (sourced)

Considerations for all types of user-defined functions:

For considerations that apply to all types of user-defined functions, see "CREATE FUNCTION" on page 1419.

Owner privileges for sourced functions:

For sourced functions, the owner is authorized to execute the function (EXECUTE privilege) in the following cases:

- If the underlying function is a user-defined function, and the owner is authorized with the grant option to execute the underlying function, the privilege on the new function includes the grant option. Otherwise, the owner can execute the new function but cannot grant others the privilege to do so.
- If the underlying function is a built-in function, the owner is authorized with the grant option to execute the underlying built-in function and the privilege on the new function includes the grant option.

For more information, see "GRANT (function or procedure privileges)" on page 1965. For more information about ownership of the object, see "Authorization, privileges, permissions, masks, and object ownership" on page 90.

Rules for creating sourced functions:

Assume that the function that is being created is named NEWF and the source function is named SOURCEF. Consider the following rules when creating a sourced function:

- The unqualified names of the sourced function and source function can be different (NEWF and SOURCEF).
- The number of input parameters for NEWF and SOURCEF must be the same.
- When specifying the input parameters and output for NEWF, you can specify a value for the precision, scale, subtype, or encoding scheme for a data type with any of these attributes or use empty parentheses.

  Empty parentheses, such as VARCHAR(), indicate that the value of the attribute is the same as the attribute for the corresponding parameter of SOURCEF, or that is determined by data type promotion. If you specify any values for the attributes, Db2 checks the values against the corresponding input parameters and returned output of SOURCEF as described next.
- When the CREATE FUNCTION statement is executed, Db2 checks the input parameters of NEWF against those of SOURCEF. The data type of each input parameter of NEWF function must be either the same as, or promotable to, the data type of the corresponding parameter of SOURCEF. (For information on the promotion of data types, see "Casting between data types" on page 130.)

  This checking does not guarantee that an error will not occur when NEWF is invoked. For example, an argument that matches the data type and length or precision attributes of a NEWF parameter might not be promotable if the corresponding SOURCEF parameter has a shorter length or less precision. In general, do not define the parameters of a sourced function with length or precision attributes that are greater than the attributes of the corresponding parameters of the source function.

- When the CREATE FUNCTION statement is executed, Db2 checks the data type identified in the RETURNS clause of NEWF against the data type that SOURCEF returns. The data type that SOURCEF returns must be either the same as, or promotable to, the RETURNS data type of NEWF.

  This checking does not guarantee that an error will not occur when NEWF is invoked. For example, the value of a result that matches the data type and length or precision attributes of those specified for the SOURCEF result might not be promotable if the RETURNS data type of NEWF has a shorter length or less precision. Consider the possible effects of defining the RETURNS data type of a sourced function with length or precision attributes that are less than the attributes defined for the data type returned by source function.

Secure functions:

The sourced user-defined function inherits the SECURED or NOT SECURED attribute from the source function in which only the topmost user-defined function is considered. If the topmost user-defined function is secure, any nested user-defined functions are also considered secure. Db2 does not validate whether those nested user-defined functions are secure. If those nested functions can access sensitive data, the security administrator needs to ensure that those functions are allowed to access sensitive data and should ensure that a change control audit procedure has been established for all changes to those functions.

If the sourced function is defined with the VERIFY_GROUP_FOR_USER or VERIFY_ ROLE_FOR_USER function as its source, the sourced function must specify only two input parameters.

Examples for CREATE FUNCTION (sourced)

Example 1

Assume that you created a distinct type HATSIZE, which you based on the built-in data type INTEGER. You want to have an AVG function to compute the average hat size of different departments. Create a sourced function that is based on built-in function AVG.

```
CREATE FUNCTION AVE (HATSIZE) RETURNS HATSIZE
   SOURCE SYSIBM.AVG (INTEGER);
```

When you created distinct type HATSIZE, two cast functions were generated, which allow HATSIZE to be cast to INTEGER for the argument and INTEGER to be cast to HATSIZE for the result of the function.

Example 2

After Smith registered the external scalar function CENTER in his schema, you decide that you want to use this function, but you want it to accept two INTEGER arguments instead of one INTEGER argument and one FLOAT argument. Create a sourced function that is based on CENTER.

```
CREATE FUNCTION MYCENTER (INTEGER, INTEGER)
   RETURNS FLOAT
   SOURCE SMITH.CENTER (INTEGER, FLOAT);
```

Related concepts

Sourced functions (Db2 Application programming and SQL)

Naming conventions
The rules for forming a name depend on the type of the object designated by the name.

Related tasks

Creating a user-defined function (Db2 Application programming and SQL)

CREATE FUNCTION (SQL table)

The CREATE FUNCTION (SQL table) statement creates an SQL table function at the current server. The function returns a set of rows.

Invocation for CREATE FUNCTION (SQL table)

This statement can only be dynamically prepared only if dynamic rules run behavior is in effect. For more information, see "Authorization IDs and dynamic SQL" on page 94.

Authorization for CREATE FUNCTION (SQL table)

The privilege set that is defined below must include at least one of the following privileges or authorities:

- The CREATEIN privilege on the schema
- SYSADM authority
- SYSCTRL authority
- System DBADM
- Installation SYSOPR authority (when the current SQLID of the process is set to SYSINSTL)

The authorization ID that matches the schema name implicitly has the CREATEIN privilege on the schema.

If the authorization ID that is used to create the function has the installation SYSADM authority or the installation SYSOPR authority and if the current SQLID is set to SYSINSTL, the function is identified as system-defined function.

If a distinct type is referenced (i.e. as the data type of a parameter or SQL variable), the privilege set must also include at least one of the following:

- Ownership of the distinct type
- The USAGE privilege on the distinct type
- SYSADM authority
- SYSDBADM authority

If the function uses a table as a parameter, the privilege set must also include at least one of the following:

- Ownership of the table
- The SELECT privilege on the table
- SYSADM authority

At least one of the following additional privileges is required if the SECURED option is specified

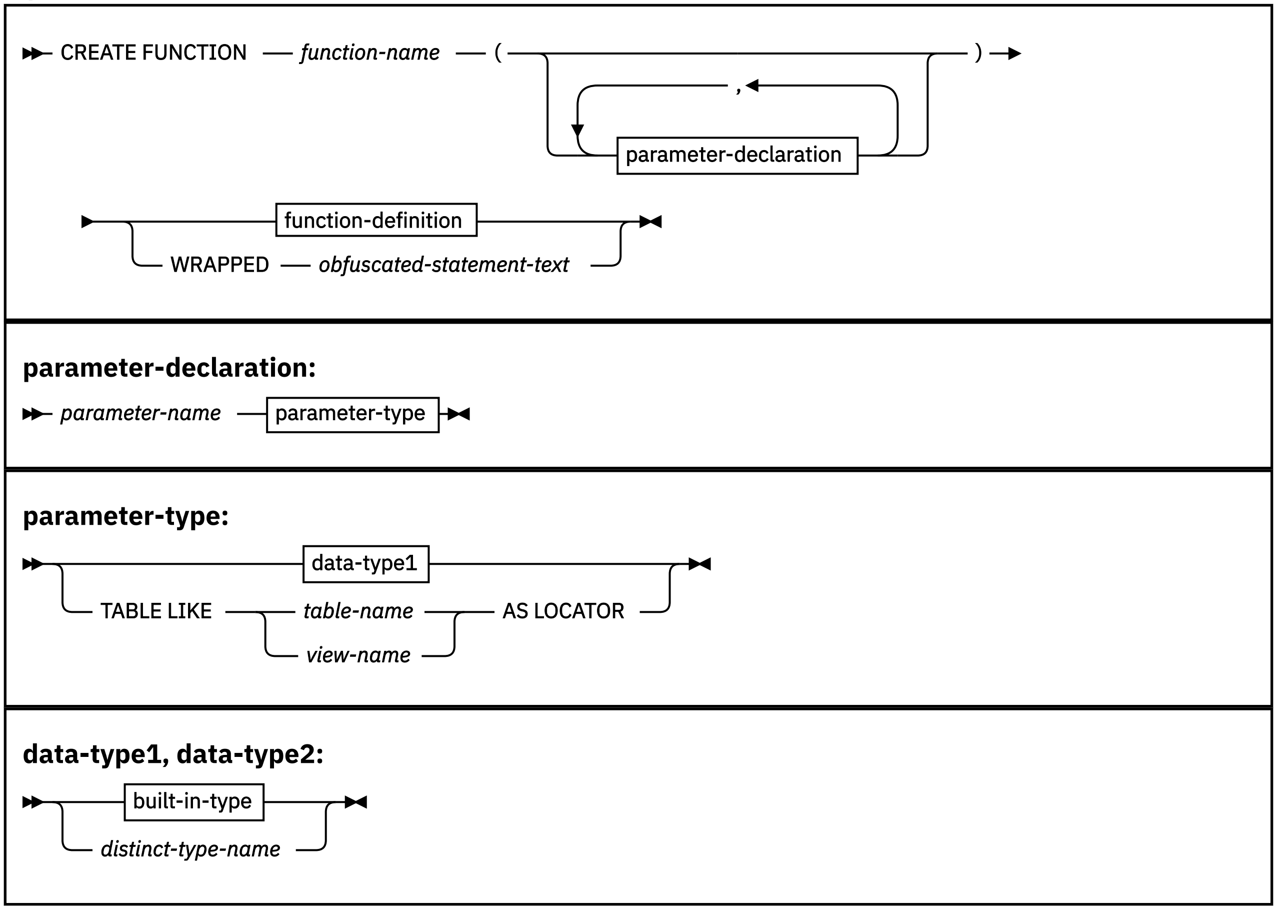
- SECADM authority
- CREATE_SECURE_OBJECT privilege

Privilege set: If the statement is embedded in an application program, the privilege set is the set of privileges that are held by the owner of the plan or package. If the owner is a role, matching of the implicit schema name does not apply and the role must include one of the previously listed privileges or authorities.

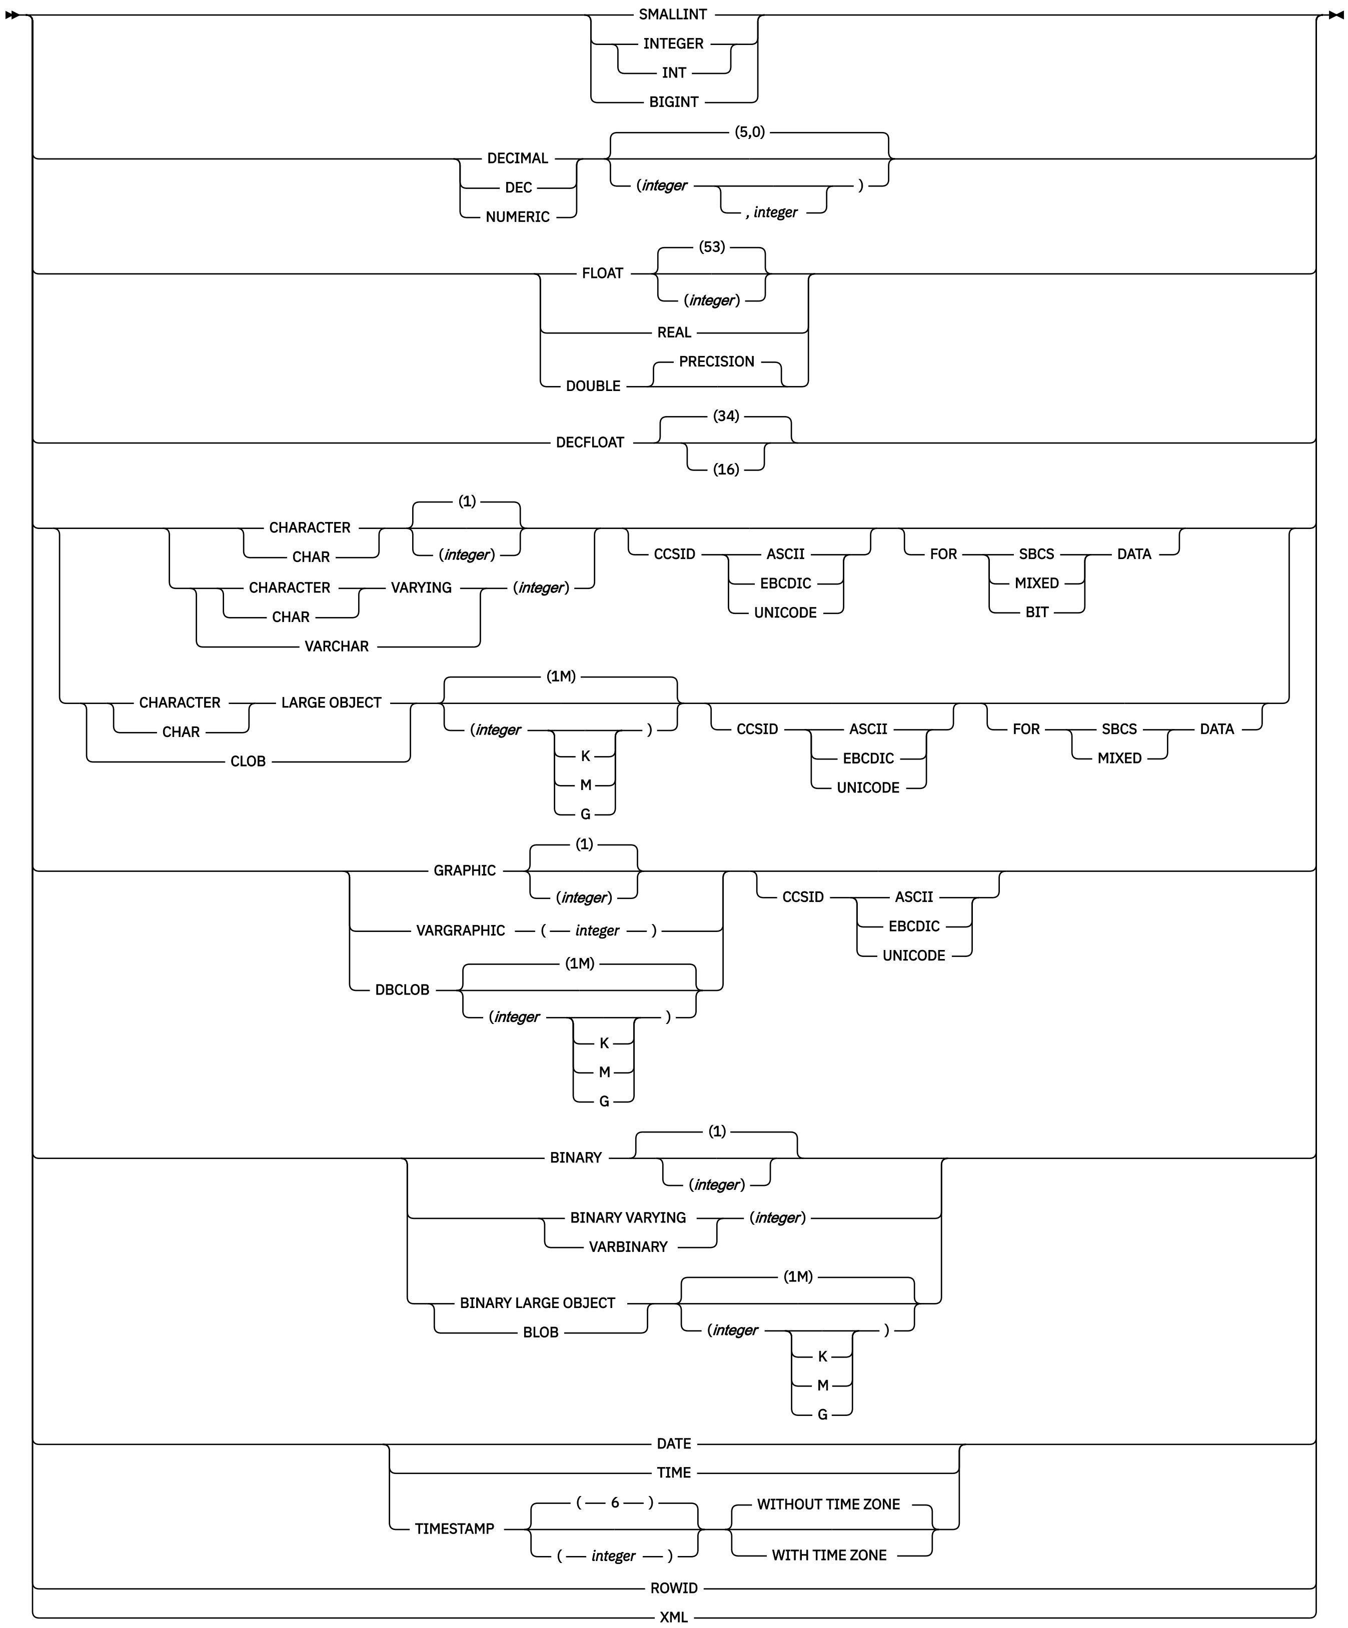
If the statement is dynamically prepared and is not running in a trusted context for which the ROLE AS OBJECT OWNER clause is specified, the privilege set is the set of privileges that are held by the SQL authorization ID of the process. If the schema name is not the same as the SQL authorization ID of the process, one of the following conditions must be met:

- The privilege set includes SYSADM authority
- The privilege set includes SYSCTRL authority
- The SQL authorization ID of the process has the CREATEIN privilege on the schema

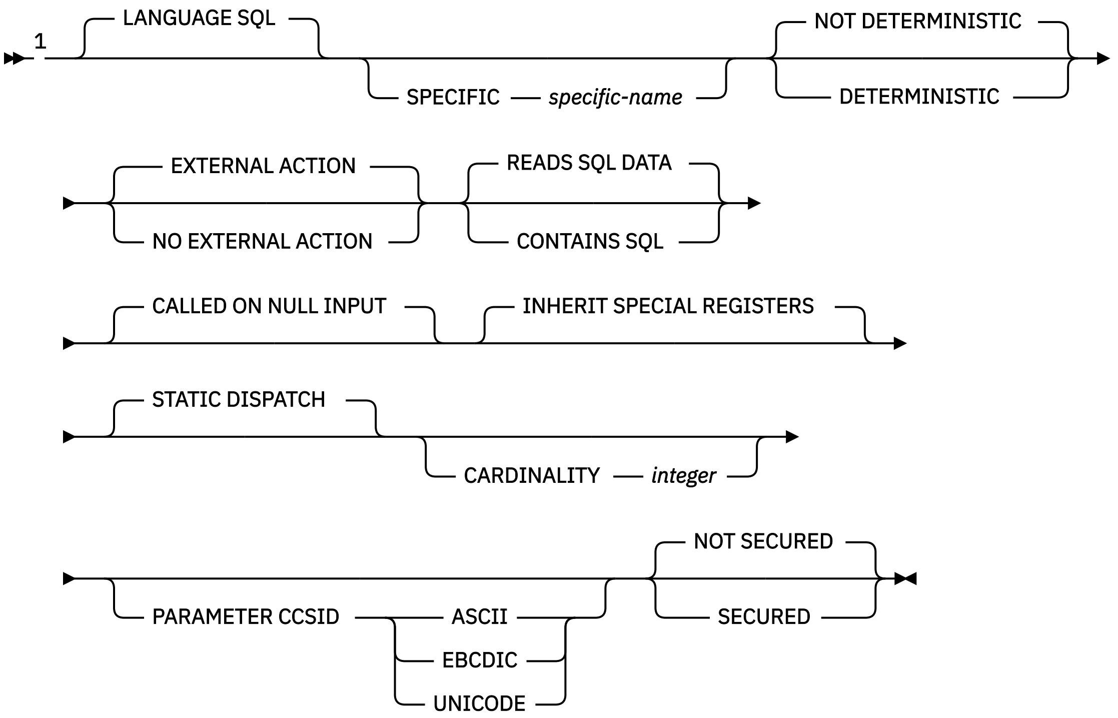
Syntax for CREATE FUNCTION (SQL table)



built-in-type:



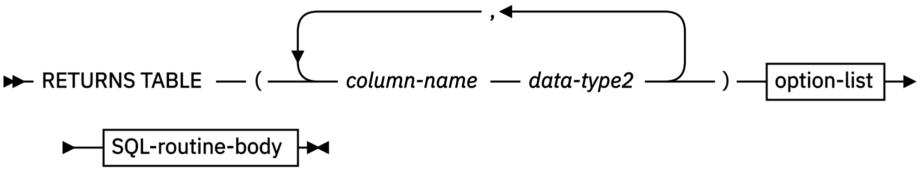
option-list:



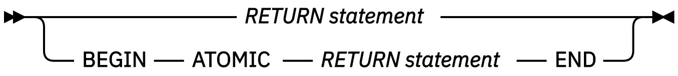
Notes:

[1] The options in the *option-list* can be specified in any order. However, the same clause cannot be specified more than one time.

function-definition



SQL-routine-body:



Description for CREATE FUNCTION (SQL table)

function-name

Names the user-defined function. The name is implicitly or explicitly qualified by a schema name. The combination of the name, the schema name, the number of parameters, and the data type of each parameter (without regard to any length, precision, scale, subtype, or encoding scheme attribute of the data type) must not identify a user-defined function that exists at the current server. For more information, see "Choosing the schema and function names" and "Determining the uniqueness of functions in a schema" in "CREATE FUNCTION" on page 1419.

(*parameter-declaration,...*)

Identifies the number of input parameters of the function, and specifies the name and data type of each parameter. All of the parameters for a function are input parameters and are nullable. There must be one entry in the list for each parameter that the function expects to receive.

parameter-name

Specifies the name of the input parameter. Each name in the parameter list must not be the same as any other name.

data-type1

Specifies the data type of the input parameter. The data type can be a built-in data type or a distinct type.

built-in-type

The data type of the parameter is a built-in data type.

For more information on the data types, including the subtype of character data types (the FOR subtype DATA clause), see built-in types. However, the varying length string data types have different maximum lengths for this statement than for the CREATE TABLE statement. The maximum lengths for parameters (and SQL variables) are as follows:

- VARCHAR or VARBINARY: 32704
- VARGRAPHIC: 16352

For parameters with a character or graphic data type, the PARAMETER CCSID clause or the CCSID clause indicates the encoding scheme of the parameter. If you do not specify either of the CCSID clauses, the encoding scheme is the value of the DEF ENCODING SCHEME field on installation panel DSNTIPF.

Although an input parameter with a character data type has an implicitly or explicitly specified subtype (BIT, SBCS, or MIXED), the value that is actually passed in the input parameter can have any subtype. Therefore, conversion of the input data to the subtype of the parameter might occur when the function is invoked. With ASCII or EBCDIC, an error occurs if mixed data that actually contains DBCS characters is used as the value for an input parameter that is declared with an SBCS subtype.

distinct-type-name

The data type of the parameter is a distinct type. Any length, precision, scale, subtype, or encoding scheme attributes for the parameter are those of the source type for the distinct type.

`TABLE LIKE` ***table-name*** **`AS LOCATOR`**

Specifies that the parameter is a transition table. However, when the function is invoked, the actual values in the transition table are not passed to the function. A single value is passed instead. This value is a locator for the table, which the function uses to access the columns of the transition table. The table that is identified can contain XML columns; however, the function cannot reference those XML columns.

A function with a table parameter can only be invoked from the triggered action of a trigger.

`RETURNS TABLE`

Specifies that the output of the function is a table. The RETURN statement in an SQL table function must return a table result. The parentheses that follow the RETURNS TABLE keyword delimit a list of name and data type pairs of the columns of the output table. All columns of the output table are nullable.

column-name

Specifies the name of the column. The name cannot be qualified, and must be unique within the RETURNS TABLE clause for the function.

data-type2

Specifies the data type and attributes of the column of the output table.

For SQL table functions, the result table of the function might include multiple encoding schemes – similar to what a view definition can include.

`LANGUAGE SQL`

Specifies that the function is written exclusively in SQL.

`SPECIFIC` ***specific-name***

Specifies a unique name for the function.

NOT DETERMINISTIC or DETERMINISTIC

Specifies whether the function returns the same results each time that the function is invoked with the same input arguments. Db2 does not verify that the function program is consistent with the specification of NOT DETERMINISTIC or DETERMINISTIC.

NOT DETERMINISTIC

Specifies that the function might not return the same result table each time that the function is invoked with the same input arguments, even when the referenced data in the database has not changed. The function depends on some state values that might affect the results. When the MATERIALIZE_NODET_SQLTUDF subsystem parameter is set to YES, Db2 disables the merging of SQL table functions that are defined with this option. An example of a table function that is not deterministic is one which references special registers, other functions that are not deterministic, or a sequence in a way that affects the table function's result table. NOT DETERMINISTIC is the default.

DETERMINISTIC

Specifies that the function always returns the same result table each time that the function is invoked with the same input arguments (provided that the referenced data in the database has not changed). Db2 enables the merging of SQL table functions that are defined with this option.

EXTERNAL ACTION or NO EXTERNAL ACTION

Specifies whether the function contains an external action. Db2 does not verify that the function program is consistent with the specification of EXTERNAL ACTION or NO EXTERNAL ACTION.

EXTERNAL ACTION

The function performs some external action (outside the scope of the function program). Thus, the function must be invoked with each successive function invocation. EXTERNAL ACTION must be specified if the function invokes another function that has external actions. EXTERNAL ACTION is the default.

NO EXTERNAL ACTION

The function does not perform any external action. It need not be called with each successive function invocation. Functions that are defined with NO EXTERNAL ACTION might perform better than functions that are defined with EXTERNAL ACTION because the function might not be invoked for each successive function invocation.

Although the scope of global variables are beyond the scope of the routine, global variables can be set in the routine body when NO EXTERNAL ACTION is specified.

READS SQL DATA or CONTAINS SQL

Specifies the classification of SQL statements and nested routines that this routine can execute or invoke. The database manager verifies that the SQL statements issued by the function, and all routines locally invoked by the routine, are consistent with this specification; the verification is not performed when nested remote routines are invoked. For the classification of each statement, see "SQL statement data access classification for routines" on page 2263.

READS SQL DATA

Specifies that the function can execute statements with a data access indication of READS SQL DATA or CONTAINS SQL. The function cannot execute SQL statements that modify data.

READS SQL DATA is the default.

CONTAINS SQL

Specifies that the function can execute only SQL statements with a data access indication of CONTAINS SQL. The function cannot execute statements that read or modify data.

CALLED ON NULL INPUT

Specifies that the function is called regardless of whether any of the input arguments are null, making the function responsible for testing for null argument values. The function can return an empty table, depending on its logic.

CALLED ON NULL INPUT is the default.

INHERIT SPECIAL REGISTERS

Specifies that existing values of special registers are inherited upon entry to the function. INHERIT SPECIAL REGISTERS is the default.

STATIC DISPATCH

At function resolution time, Db2 chooses a function based on the static (or declared) types of the function parameters. STATIC DISPATCH is the default.

CARDINALITY *integer*

Specifies an estimate of the expected number of rows that the function returns. The number is used for optimization purposes. The value of *integer* must be between 0 and 2147483647.

If you do not specify CARDINALITY, Db2 assumes a finite value. The finite value is the same value that Db2 assumes for tables for which the RUNSTATS utility has not gathered statistics.

If a function has an infinite cardinality (the function never returns the end-of-table condition and always returns a row), a query that requires the end-of-table condition to work correctly will need to be interrupted.

PARAMETER CCSID

Specifies the encoding scheme for character and graphic string parameters is ASCII, EBCDIC, or UNICODE. The default encoding scheme is the value that is specifies in the CCSID clauses of the parameter list or RETURNS clause, or in the DEF ENCODING SCHEME field on installation panel DSNTIPF. This clause provides a convenient way to specify the encoding scheme for character and graphic string parameters. If individual CCSID clauses are specified for individual parameters in addition to this PARAMETER CCSID clause, the value specified in all of the CCSID clauses must be the same value that is specified in this clause. This clause also specifies the encoding scheme that is used for system-generated parameters of the routine such as message tokens and DBINFO.

NOT SECURED or SECURED

Specifies if the function is considered secure for row access control and column access control. The SECURED or NOT SECURED option applies to all future versions of the function.

NOT SECURED

Specifies that the function is not considered secure for row access control and column access control.

NOT SECURED is the default.

When the function is invoked, the arguments of the function must not reference a column for which a column mask is enabled when the table is using active column access control.

SECURED

Specifies that the function is considered secure for row access control and column access control.

The function must be secure when it is referenced in a row permission or a column mask.

SQL-routine-body

RETURN-statement

Specifies the return value of the function. A RETURN statement must be specified for an SQL table function.

WRAPPED *obfuscated-statement-text*

Specifies the encoded definition of the function. A CREATE FUNCTION statement can be encoded using the WRAP scalar function.

WRAPPED must not be specified on a static CREATE statement.

ATOMIC

ATOMIC indicates that an unhandled exception condition within the RETURN statement causes the statement to be rolled back.

Notes for CREATE FUNCTION (SQL table)

Considerations for all types of user-defined functions:

For considerations that apply to all types of user-defined functions, see "CREATE FUNCTION" on page 1419.

Self-referencing function:

The body of an SQL function (that is, the *expression* or NULL in the RETURN statement in the body of the CREATE FUNCTION statement) cannot contain a recursive invocation of itself or to another function that invokes it, because such a function would not exist to be referenced.

Dependent objects:

An SQL routine is dependent on objects that are referenced in the routine body.

Obfuscated statements:

A CREATE FUNCTION statement can be executed in obfuscated form. In an obfuscated statement, only the function name, parameters, and the WRAPPED keyword are readable. The rest of the statement is encoded in such a way that it is not readable but can be decoded by a database server that supports obfuscated statements. The WRAP scalar function produces obfuscated statements. Any debug options that are specified when the function is created from an obfuscated statement are ignored.

Resolution of object names:

Db2 resolves object names inside the body of the function according to the rules in "Unqualified object name resolution" on page 86 and the type of the object. The name resolution occurs when the function is created.

Referencing date and time special registers:

If an SQL function contains multiple references to any of the date or time special registers, all references return the same value. In addition, this value is the same value that is returned by the retrieving value of the special register in the statement that invoked the function.

Considerations for columns that are defined with a field procedure:

The body of an SQL table function must not reference a column that is defined with a field procedure, and the RETURNS clause of an SQL table function must not reference a column that is defined with a field procedure. An SQL table function must not be invoked with an expression that is derived from a column that is defined with a field procedure.

Restrictions involving pending definition changes:

The body of an SQL table function must not reference a table that has pending definition changes.

Alternative syntax and synonyms:

To provide compatibility with previously releases of Db2 or other products in the Db2 family, Db2 supports the following alternative syntax:

- VARIANT as a synonym for NOT DETERMINISTIC
- NOT VARIANT as a synonym for DETERMINISTIC
- NULL CALL as a synonym for CALLED ON NULL INPUT

Examples for CREATE FUNCTION (SQL table)

Example 1

Define a table function, JTABLE, to return a table with 3 columns:

```
CREATE FUNCTION JTABLE (COLD_VALUE CHAR(9), T2_FLAG CHAR(1))
    RETURNS TABLE (COLA INT, COLB INT, COLC INT)
    LANGUAGE SQL
    SPECIFIC DEPTINFO
    NOT DETERMINISTIC
    READS SQL DATA
    RETURN
        SELECT A.COLA, B.COLB, B.COLC
            FROM TABLE1 AS A
                LEFT OUTER JOIN
                TABLE2 AS B
            ON A.COL1 = B.COL1 AND T2_FLAG = 'Y'
        WHERE A.COLD = COLD_VALUE;
```

Example 2

Define a table function that returns the employees in a specified department number. The function simply returns the employees for the requested department:

```
CREATE FUNCTION DEPTEMPLOYEES (DEPTNO CHAR(3))
    RETURNS TABLE (EMPNO CHAR(6), LASTNAME VARCHAR(15), FIRSTNAME VARCHAR(12))
    LANGUAGE SQL
    READS SQL DATA
    NO EXTERNAL ACTION
    DETERMINISTIC
    RETURN
        SELECT EMPNO, LASTNAME, FIRSTNME
            FROM YEMP
        WHERE YEMP.WORKDEPT = DEPTEMPLOYEES.DEPTNO;
```

Related concepts

SQL table functions (Db2 Application programming and SQL)

Naming conventions
The rules for forming a name depend on the type of the object designated by the name.

Related tasks

Creating a user-defined function (Db2 Application programming and SQL)

CREATE GLOBAL TEMPORARY TABLE

The CREATE GLOBAL TEMPORARY TABLE statement creates a description of a temporary table at the current server.

Invocation for CREATE GLOBAL TEMPORARY TABLE

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization for CREATE GLOBAL TEMPORARY TABLE

The privilege set that is defined below must include at least one of the following:

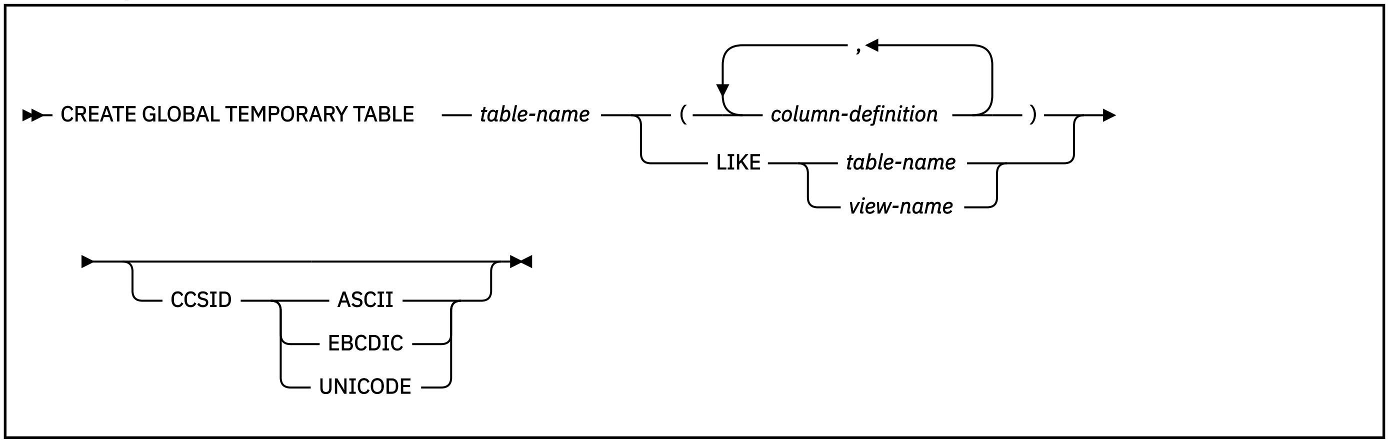
- The CREATETMTAB system privilege
- The CREATETAB database privilege for any database
- DBADM, DBCTRL, or DBMAINT authority for any database
- SYSADM or SYSCTRL authority
- System DBADM
- Installation SYSOPR authority (when the current SQLID of the process is set to SYSINSTL)

However, DBADM, DBCTRL, or DBMAINT authority is not sufficient authority if you are creating a temporary table for someone else and the table qualifier is not your authorization ID.

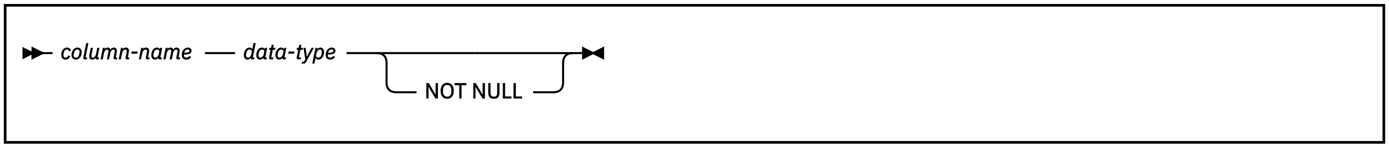
Additional privileges might be required when the data type of a column is a distinct type or the LIKE clause is specified. See the description of *distinct-type* and LIKE for the details.

Privilege set: The privilege set is the same as the privilege set for the CREATE TABLE statement. See information about CREATE TABLE Authorization for details.

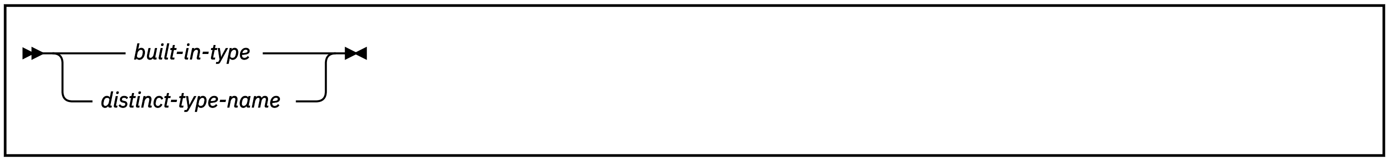
Syntax for CREATE GLOBAL TEMPORARY TABLE



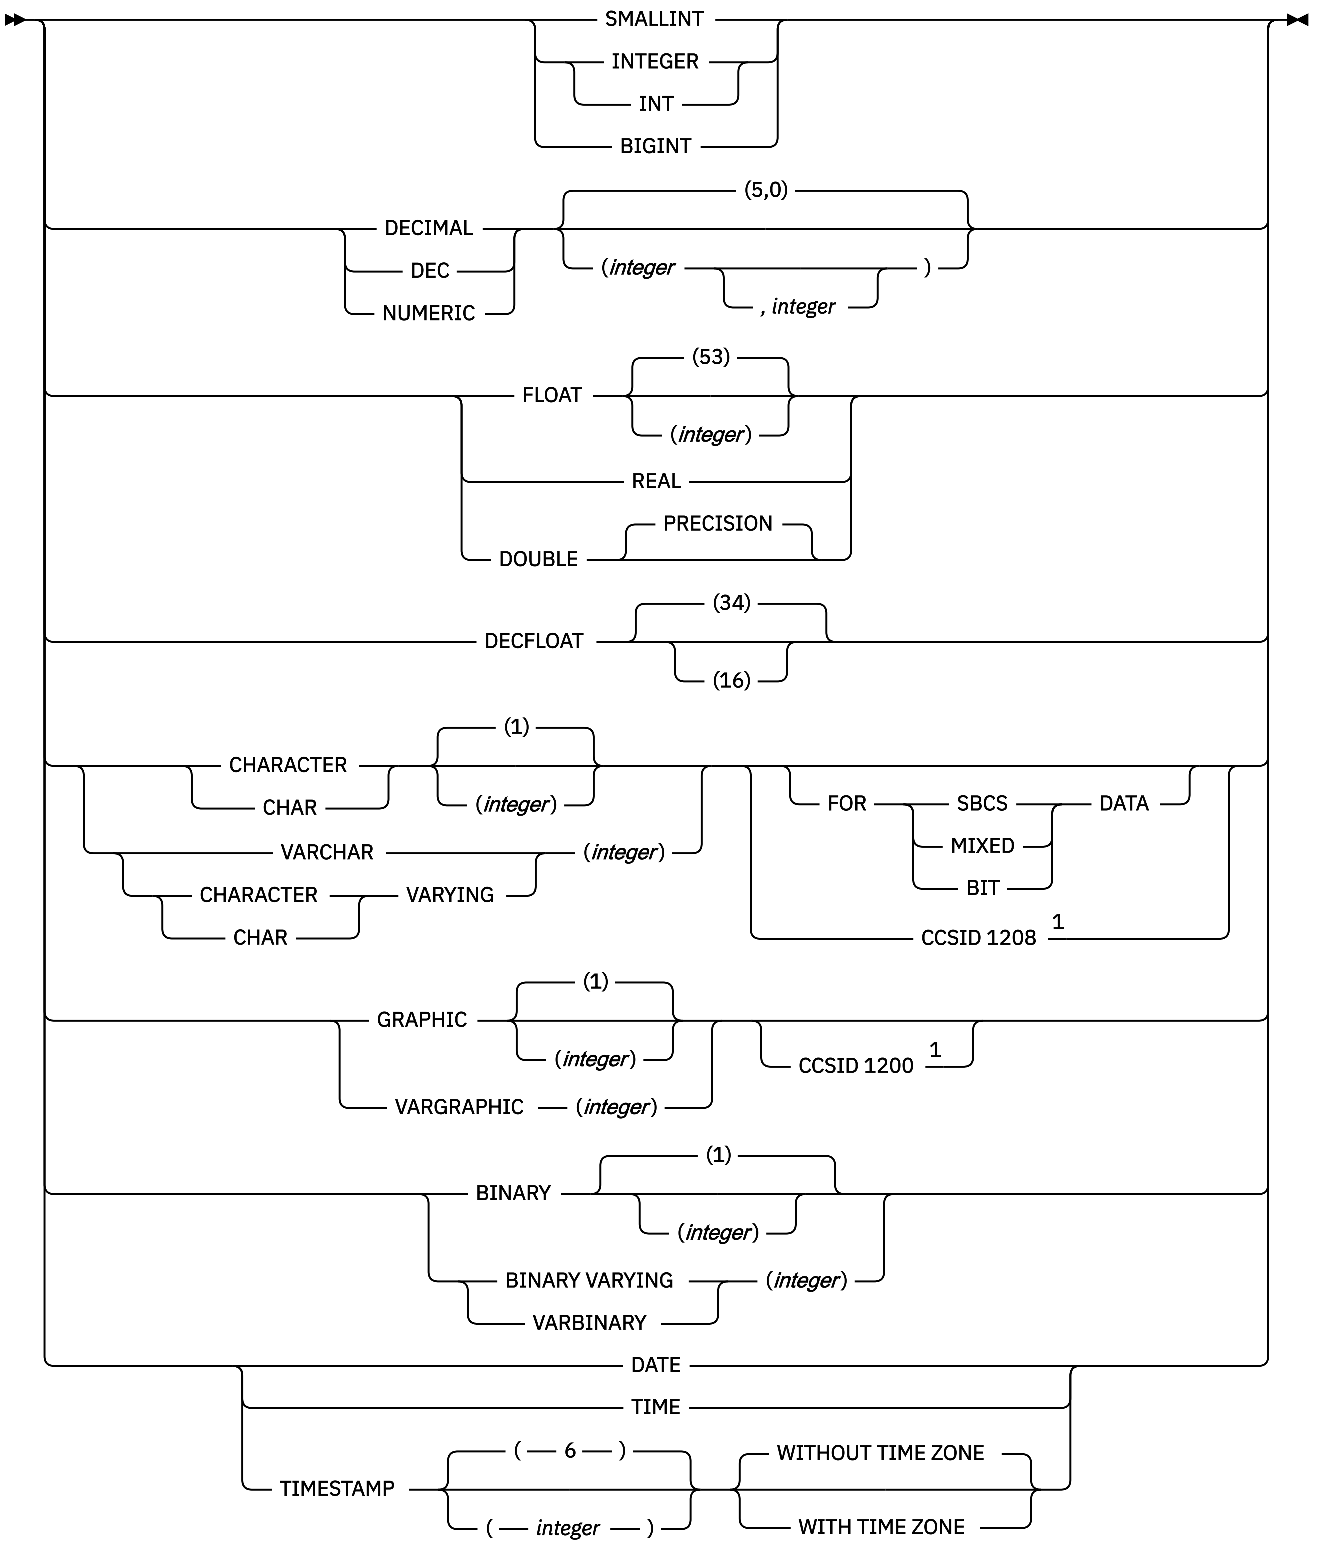
column-definition:



data-type:



built-in-type:



Notes:

[1] The CCSID clause must only be specified for a character string or a graphic string column in an EBCDIC created global temporary table.

Description for CREATE GLOBAL TEMPORARY TABLE

table-name

Names the temporary table. The name, including the implicit or explicit qualifier, must not identify a table, view, alias, synonym, or temporary table that exists at the database server, or a table that exists in the SYSIBM.SYSPENDINGOBJECTS catalog table.

The qualification rules for a temporary table are the same as for other tables.

The owner acquires ALL PRIVILEGES on the table WITH GRANT OPTION and the authority to drop the table.

For more information, see Guidelines for table names (Db2 Administration Guide).

column-definition

Defines the attributes of a column for each instance of the table. The number of columns defined must not exceed 750. The maximum record size must not exceed 32714 bytes. The maximum row size must not exceed 32706 bytes (8 bytes less than the maximum record size).

column-name

Names the column. The name must not be qualified and must not be the same as the name of another column in the table.

data-type

Specifies the data type of the column. The data type can be a built-in data type or a distinct type.

built-in-type

The data type of the column is a built-in data type.

For more information on and the rules that apply to the data types, see built-in-type.

distinct-type

Any distinct type except one that is based on a LOB or ROWID data type. The privilege set must implicitly or explicitly include the USAGE privilege on the distinct type.

NOT NULL

Specifies that the column cannot contain nulls. Omission of NOT NULL indicates that the column can contain nulls.

LIKE *table-name* or *view-name*

Specifies that the columns of the table have exactly the same name and description as the columns of the identified table or view. The name specified after LIKE must identify a table, view, or temporary table that exists at the current server. The identified table must not be an accelerator-only table. A view cannot contain columns of length 0.

The privilege set must implicitly or explicitly include the SELECT privilege on the identified table or view.

This clause is similar to the LIKE clause on CREATE TABLE, but it has the following differences:

- If any column of the identified table or view has an attribute value that is not allowed for a column in a temporary table, that attribute value is ignored. The corresponding column in the new temporary table has the default value for that attribute unless otherwise indicated.
- If any column of the identified table or view allows a default value other than null, that default value is ignored and the corresponding column in the new temporary table has no default value. A default value other than null is not allowed for any column in a temporary table.

CCSID *encoding-scheme*

Specifies the encoding scheme for string data stored in the table.

ASCII

Specifies that the data must be encoded by using the ASCII CCSIDs of the server.

An error occurs if a valid ASCII CCSID has not been specified for the installation.

EBCDIC

Specifies that data must be encoded by using the EBCDIC CCSIDs of the server.

An error occurs if a valid EBCDIC CCSID has not been specified for the installation.

UNICODE
Specifies that data must be encoded by using the CCSIDs of the server for Unicode.

An error occurs if a valid CCSID for Unicode has not been specified for the installation.

Usually, each encoding scheme requires only a single CCSID. Additional CCSIDs are needed when mixed, graphic, or Unicode data is used. An error occurs if CCSIDs have not been defined.

The CCSID clause can be specified for the created temporary table, or for individual columns in the created temporary table. If a CCSID clause is specified for the table, that CCSID specifies the encoding scheme for the table, regardless of whether the LIKE clause is also specified. If a CCSID clause is not specified for the table, the encoding scheme for the table is EBCDIC.

If a CCSID clause is specified for a column, the encoding scheme for the created temporary table must be EBCDIC. If a CCSID clause is not specified for a column, and the LIKE clause is not specified for the table, the CCSID of the column is the same as the CCSID of the table. If the LIKE clause is specified, and the source table that is specified in the LIKE clause is an EBCDIC table with Unicode columns, the columns in the created temporary table that correspond to the Unicode columns in the source table are also Unicode.

Notes for CREATE GLOBAL TEMPORARY TABLE

Owner privileges

The owner of the table has all table privileges (see "GRANT (table or view privileges)" on page 1983) with the ability to grant these privileges to others. For more information about ownership of the object, see "Authorization, privileges, permissions, masks, and object ownership" on page 90.

Instantiation and termination

Let T be a temporary table defined at the current server and let P denote an application process:

- An empty instance of T is created as a result of the first implicit or explicit reference to T in an OPEN, SELECT INTO or SQL data change operation that is executed by any program in P.
- Any program in P can reference T and any reference to T by a program in P is a reference to that instance of T.

  When a commit operation terminates a unit of work in P and no program in P has an open WITH HOLD cursor that is dependent on T, the commit includes the operation DELETE FROM T.
- When a rollback operation terminates a unit of work in P, the rollback includes the operation DELETE FROM T.
- When the connection to the database server at which an instance of T was created terminates, the instance of T is destroyed. However, the definition of T remains. A DROP TABLE statement must be executed to drop the definition of T.

Restrictions and extensions

Let T denote a temporary table:

- Columns of T cannot have default values other than null.
- A column of T cannot have a LOB or ROWID data type (or a distinct type based on one).
- T cannot have unique constraints, referential constraints, or check constraints.
- T cannot be defined as the parent in a referential constraint.
- T cannot be referenced in:
  - A CREATE INDEX statement.
  - A LOCK TABLE statement.
  - As the object of an UPDATE statement in which the object is T or a view of T. However, you can reference T in the WHERE clause of an UPDATE statement (including the update operation of the MERGE statement).

  - Db2 utility commands.

- If T is referenced in the *fullselect* of a CREATE VIEW statement, you cannot specify a WITH CHECK OPTION clause in the CREATE VIEW statement.
- ALTER TABLE T is valid only if the statement is used to add a column to T. Any column that you add to T must have a default value of null.

  When you alter T, any packages that refer to the table are invalidated, and Db2 automatically rebinds the packages the next time they are run.
- DELETE FROM T or a *view of T* is valid only if the statement does not include a WHERE or WHERE CURRENT OF clause. In addition, DELETE FROM *view of T* is valid only if the view was created (CREATE VIEW) without the WHERE clause. A DELETE FROM statement deletes all the rows from the table or view.
- You can refer to T in the FROM clause of any subselect. If you refer to T in the first FROM clause of a *select-statement*, you cannot specify a FOR UPDATE clause.
- You cannot use a DROP DATABASE statement to implicitly drop T. To drop T, reference T in a DROP TABLE statement.
- A temporary table instantiated by an SQL statement using a three-part table name can be accessed by another SQL statement using the same name in the same application process for as long as the Db2 connection which established the instantiation is not terminated.
- GRANT ALL PRIVILEGES ON T is valid, but you cannot grant specific privileges on T.

  Of the ALL privileges, only the ALTER, INSERT, DELETE, and SELECT privileges can actually be used on T.
- REVOKE ALL PRIVILEGES ON T is valid, but you cannot revoke specific privileges from T.
- A COMMIT operation deletes all rows of every temporary table of the application process, but the rows of T are not deleted if any program in the application process has an open WITH HOLD cursor that is dependent on T. In addition, if RELEASE(COMMIT) is in effect and no open WITH HOLD cursors are dependent on T, all logical work files for T are also deleted.
- A ROLLBACK operation deletes all rows and all logical work files of every temporary table of the application process.
- You can reuse threads when using a temporary table, and a logical work file for a temporary table name remains available until deallocation. A new logical work file is not allocated for that temporary table name when the thread is reused.
- You can refer to T in the following statements:

Statement	Statement	Statement
ALTER FUNCTION	CREATE PROCEDURE	DECLARE TABLE
ALTER PROCEDURE	CREATE SYNONYM	DELETE (if it does not include a WHERE clause)
COMMENT	CREATE TABLE LIKE	DROP TABLE
CREATE ALIAS	CREATE VIEW	INSERT
CREATE FUNCTION	DESCRIBE TABLE	LABEL
		SELECT INTO

Alternative syntax and synonyms: For compatibility with previous releases of Db2, you can specify LONG VARCHAR as a synonym for VARCHAR(*integer*) and LONG VARGRAPHIC as a synonym for VARGRAPHIC(*integer*) when defining the data type of a column. However, the use of these synonyms is not encouraged because after the statement is processed, Db2 considers a LONG VARCHAR column to be VARCHAR and a LONG VARGRAPHIC column to be VARGRAPHIC.

Examples for CREATE GLOBAL TEMPORARY TABLE

Example 1: Create a temporary table, CURRENTMAP. Name two columns, CODE and MEANING, both of which cannot contain nulls. CODE contains numeric data and MEANING has character data. Assuming a value of NO for the field MIXED DATA on installation panel DSNTIPF, column MEANING has a subtype of SBCS:

```
CREATE GLOBAL TEMPORARY TABLE CURRENTMAP
     (CODE INTEGER NOT NULL, MEANING VARCHAR(254) NOT NULL);
```

Example 2: Create a temporary table, EMP:

```
CREATE GLOBAL TEMPORARY TABLE EMP
     (TMPDEPTNO   CHAR(3)     NOT NULL,
      TMPDEPTNAME VARCHAR(36) NOT NULL,
      TMPMGRNO    CHAR(6)             ,
      TMPLOCATION CHAR(16)            );
```

CREATE INDEX

The CREATE INDEX statement creates a partitioning index or a secondary index and an index space at the current server. The columns included in the key of the index are columns of a table at the current server.

Invocation for CREATE INDEX

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES RUN behavior is in effect. For more information, see "Authorization IDs and dynamic SQL" on page 94.

Authorization for CREATE INDEX

The privilege set that is defined below must include at least one of the following:

- The INDEX privilege on the table
- Ownership of the table
- DBADM authority for the database that contains the table
- SYSADM or SYSCTRL authority
- System DBADM
- Installation SYSOPR authority (when the current SQLID of the process is set to SYSINSTL)

If the database is implicitly created, the database privileges must be on the implicit database or on DSNDB04.

If the index is created using an expression, the EXECUTE privilege is required on any user-defined function that is invoked in the index expression.

Additional privileges might be required, as explained in the description of the BUFFERPOOL and USING STOGROUP clauses.

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the specified index name includes a qualifier that is not the same as this owner, the privilege set must include SYSADM or SYSCTRL authority, or DBADM or DBCTRL authority for the database.

If ROLE AS OBJECT OWNER is in effect, the schema qualifier must be the same as the role, unless the role has the CREATEIN privilege on the schema, SYSADM authority, or SYSCTRL authority.

If ROLE AS OBJECT OWNER is not in effect, one of the following rules applies:

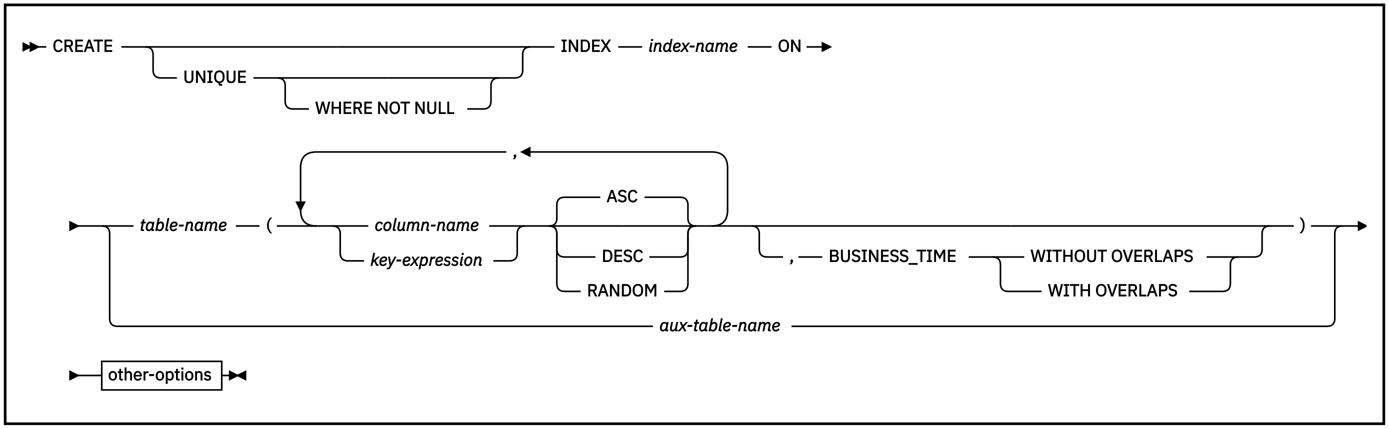
- If the privilege set lacks the CREATIN privilege on the schema, SYSADM authority, or SYSCTRL authority, the schema qualifier (implicit or explicit) must be the same as one of the authorization ids of the process.

- If the privilege set includes SYSADM authority or SYSCTRL authority, the schema qualifier can be any valid schema name.

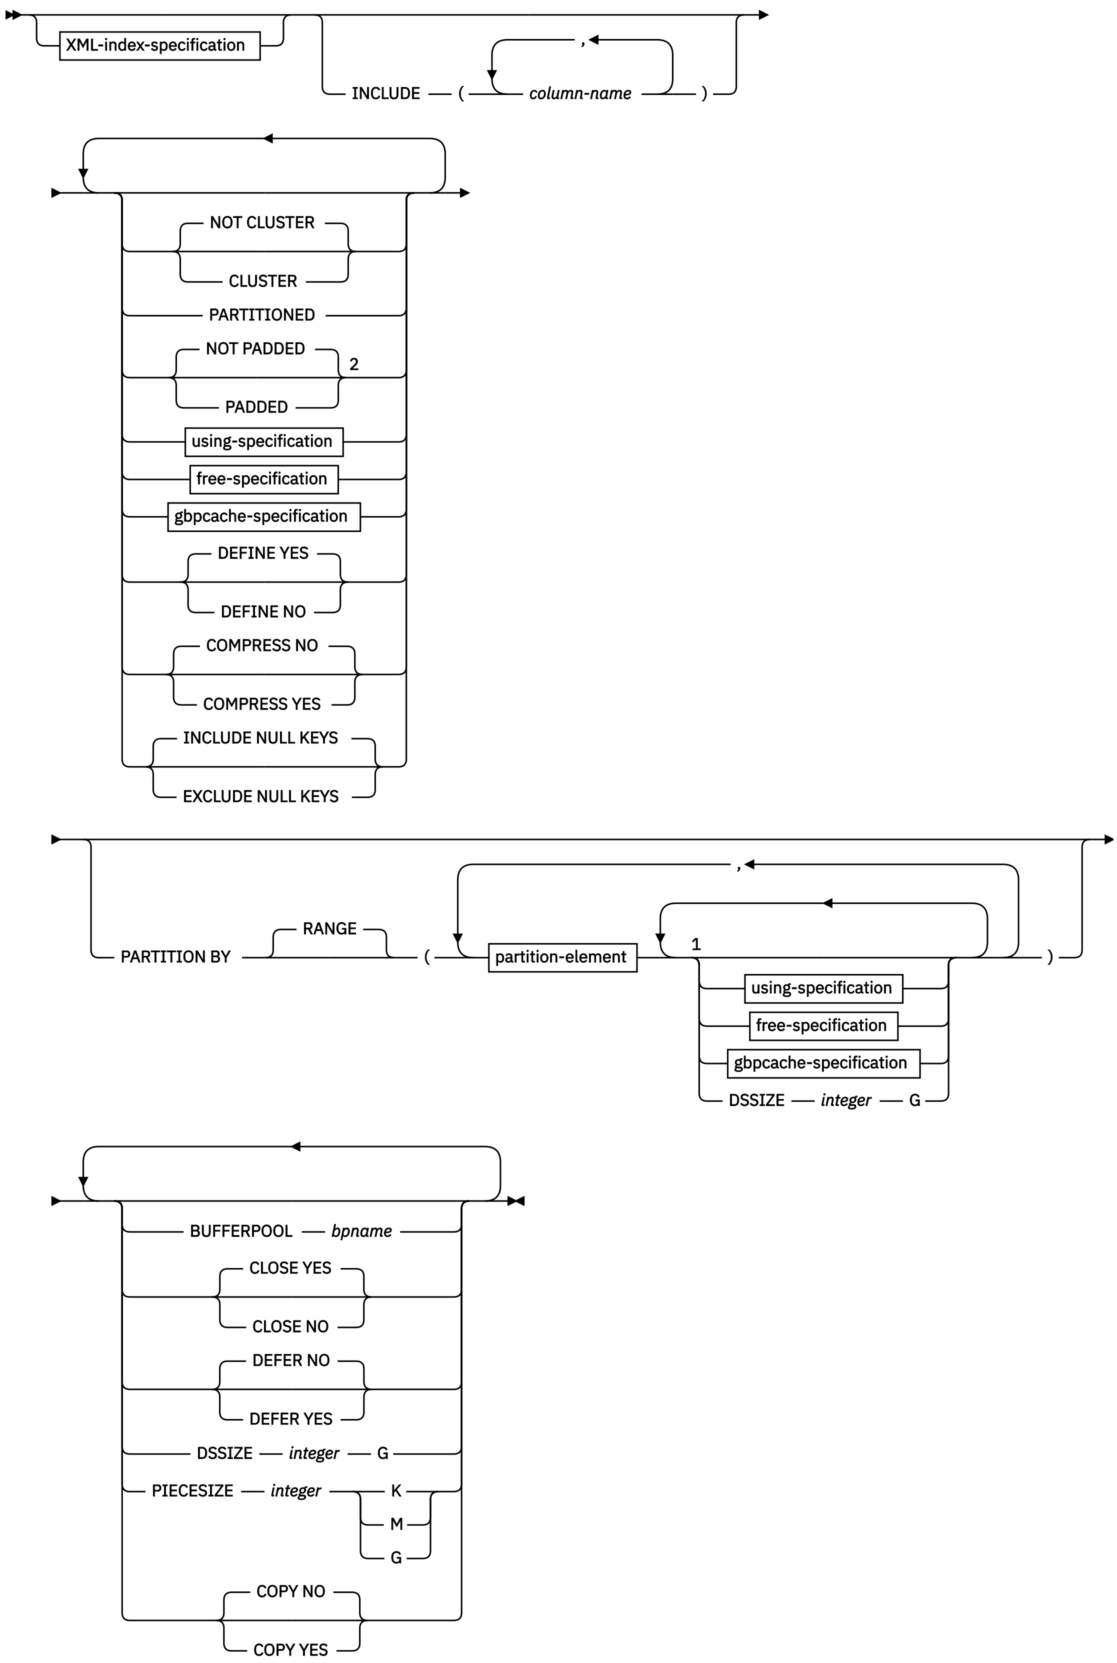
If the statement is dynamically prepared, the privilege set is the privileges that are held by the SQL authorization ID of the process unless the process is within a trusted context and the ROLE AS OBJECT OWNER clause is specified. In that case, the privilege set is the set of privileges that are held by the role that is associated with the primary authorization ID of the process. However, if the specified index name includes a qualifier that is not the same as this authorization ID, the following rules apply:

- If the privilege set includes SYSADM or SYSCTRL authority (or DBADM authority for the database, or DBCTRL authority for the database when creating a table), the schema qualifier can be any valid schema name.
- If the privilege set lacks SYSADM or SYSCTRL authority (or DBADM authority for the database, or DBCTRL authority for the database when creating a table), the schema qualifier is valid only if it is the same as one of the authorization IDs of the process and the privilege set that are held by that authorization ID includes all privileges needed to create the index. This is an exception to the rule that the privilege set is the privileges that are held by the SQL authorization ID of the process.

Syntax for CREATE INDEX



other-options:



Notes:

[1] The same clause must not be specified more than one time.

[2] The value of field PAD INDEXES BY DEFAULT (on installation panel DSNTIPE) determines the default. When the value is NO, NOT PADDED is the default. When the value is YES, PADDED is the default. For more information, see the description of the PADDED or NOT PADDED options.

Description for CREATE INDEX

UNIQUE

Prevents the table from containing two or more rows with the same value of the index key. When UNIQUE is used, all null values for a column are considered equal. For example, if the key is a single column that can contain null values, that column can contain only one null value. The constraint is enforced when rows of the table are updated or new rows are inserted.

The constraint is also checked during the execution of the CREATE INDEX statement. If the table already contains rows with duplicate key values, the index is not created.

UNIQUE WHERE NOT NULL

Prevents the table from containing two or more rows with the same value of the index key where all null values for a column are not considered equal. Multiple null values are allowed. Otherwise, this is identical to UNIQUE.

INDEX *index-name*

Names the index. The name must not identify an index that exists at the current server, or is listed in the SYSIBM.SYSPENDINGOBJECTS catalog table, or is in an accelerator-only table.

The associated index space also has a name. That name appears as a qualifier in the names of data sets defined for the index. If the data sets are managed by the user, the name is the same as the second (or only) part of *index-name*. If this identifier consists of more than eight characters, only the first eight are used. The name of the index space must be unique among the names of the index spaces and table spaces of the database for the identified table. If the data sets are defined by Db2, Db2 derives a unique name.

If the index is an index on a declared temporary table, the qualifier, if explicitly specified, must be SESSION. If the index name is unqualified, Db2 uses SESSION as the implicit qualifier.

For more information, see Index names and guidelines (Db2 Administration Guide).

ON *table-name* or *aux-table-name*

Identifies the table on which the index is created. The name can identify a base table, a materialized query table, a declared temporary table, or an auxiliary table.

table-name

Identifies the base table, materialized query table, or declared temporary table on which the index is created. The name must identify a table that exists at the current server. (The name of a declared temporary table must be qualified with SESSION.)

The name must not identify a clone table. The name must not identify a created temporary table or a table that is implicitly created for an XML column. If the index that is being created is for XML values, the table can contain an XML column, otherwise, the table must not contain an XML column. The name must not identify a catalog table or declared temporary table if the index is created using expressions. The name must not identify an accelerator-only table or a directory table.

If the table has enforced row or column access controls, the row permissions and column masks are not applied during key generation.

column-name,...

Specifies the columns of the index key.

Each *column-name* must identify a column of the table. Do not specify more than 64 columns or the same column more than one time. Do not qualify *column-name*.

Do not specify a column for *column-name* that is defined as follows:

- a LOB column (or a column with a distinct type that is based on a LOB data type)
- a BINARY or VARBINARY column (or a column with a distinct type that is based on a BINARY or VARBINARY data type) when the PARTITION BY RANGE clause is also specified
- a VARBINARY column (or a column with a distinct type that is based on a VARBINARY data type) when the PADDED clause is also specified
- a row change timestamp column when the PARTITION BY RANGE or PARTITIONED clause is also specified.
- a timestamp with time zone column (or a column with a distinct type that is based on the timestamp with time zone data type) when the PARTITION or PARTITION BY RANGE clause is also specified.

A column with an XML type can only be specified if the XMLPATTERN clause is also specified. If the XMLPATTERN clause is specified, only one column can be identified and the column must be an XML type. The resulting index is an XML index.

If the table is an EBCDIC table with Unicode columns, character and graphic columns that are specified for the index key must be all EBCDIC or all Unicode.

The sum of the length attributes of the columns must not be greater than the following limits, where *n* is the number of columns that can contain null values, *m* is the number of varying-length columns, and *d* is the number of DECFLOAT columns in the key:

- 2000 - *n* for a padded, nonpartitioning index
- 2000 - *n* - 2*m* - 3*d* for a nonpadded, nonpartitioning index
- 255 - *n* for a partitioning index (padded or nonpadded)
- 255 - *n* - 2*m*- 3*d* for a nonpadded, partitioning index

key-expression

Specifies an expression that returns a scalar value. An index with a key that includes one or more expressions consisting of more than just a column name is an *expression-based index*. *key-expression* cannot be specified with the GENERATE KEY USING clause or the INCLUDE clause. *key-expression* has the following restrictions:

- Each *key-expression* must contain as least one reference to a column of *table-name*.

  All references to columns of *table-name* must be unqualified. Referenced columns cannot include any FIELDPROCs or a SECURITY LABEL. Referenced columns cannot be implicitly hidden (that is, defined with the IMPLICITLY HIDDEN attribute).
- *key-expression* must not include any of the following:
  - A subquery
  - An aggregate function
  - A function that is not deterministic function
  - A function that has an external action
  - A user-defined function
  - The VERIFY_GROUP_FOR_USER or VERIFY_ROLE_FOR_USER functions
  - A sequence reference
  - A host variable
  - A parameter marker

  - A global variable
  - A special register
  - An expression for which implicit time zone value apply (or example, cast a timestamp to a timestamp with time zone)
  - A CASE expression
  - An OLAP specification
- If *key-expression* invokes a cast function, the privilege set must implicitly include EXECUTE authority on the generated cast functions for the distinct type.
- If *key-expression* invokes the LOWER or UPPER functions, the input *string-expression* cannot be FOR BIT DATA, and the function invocation must contain the *locale-name* argument.
- If *key-expression* invokes the TRANSLATE function, the function invocation must contain the *to-string* argument.
- *key-expression* must not invoke a built-in function with an argument that references a LOB column, unless the function is SUBSTR or JSON_VAL.
- If *key-expression* invokes the SUBSTR function, an argument to the function that references a LOB column can reference only the inline portion of the LOB column.
- If *key-expression* invokes the JSON_VAL function and the first argument is a LOB column, the column must be defined as an inline LOB.
- If *key-expression* invokes the JSON_VAL function, the function invocation must meet the following conditions:
  - The invocation of the JSON_VAL function must be the outermost expression for *key-expression*.
  - If the first argument is a column, that column must be contained in a table in a partition-by-growth table space.
  - The third argument must end with the string ':na', to indicate that the first argument does not contain a JSON array.
- If *key-expression* invokes the JSON_VAL built-in function, the CREATE INDEX statement must not reference any LOB columns other than the LOB column that is the argument to the JSON_VAL function. Such a CREATE INDEX statement can refer only to a single LOB column.
- The same expression cannot be used more than one time in the same index.
- The data type of the result of the expression cannot be a LOB, XML, DECFLOAT, or array value. However, the data type of an intermediate result can be a LOB or DECFLOAT value (or a distinct type that is based on one of these data types), but not an XML value. For an index with a DECFLOAT intermediate result, the rounding mode that was in effect when the index was created should also be in effect when the index is used.
- If a Unicode column in an EBCDIC table is referenced in a *key-expression*, the encoding scheme of the index keys must either be all Unicode or all EBCDIC. Otherwise, the encoding scheme of the result of a *key-expression* must be the same encoding scheme as the table.

The maximum length of the text string of each *key-expression* is 4000 bytes after conversion to UTF-8. The maximum number of *key-expression* in an extended index is 64.

ASC

Puts the index entries in ascending order by the column. ASC cannot be specified with the GENERATE KEY USING clause.

ASC is the default.

DESC

Puts the index entries in descending order by the column. DESC cannot be specified with the GENERATE KEY USING clause or if the ON clause contains *key-expression*.

RANDOM

Index entries are put in a random order by the column. RANDOM cannot be specified in the following cases:

- A varying length column is part of the index key and the index is defined with the NOT PADDED option
- A column of the index key is defined as TIMESTAMP WITH TIME ZONE or DECFLOAT
- The index is an XML index. An XML index is defined with the GENERATE KEY USING clause
- The index is part of the partitioning key
- The index is an expression-based index

BUSINESS_TIME

Specifies that the columns of the BUSINESS_TIME period are automatically added to the end of the index key in the following order:

- The end column of the BUSINESS_TIME period in ascending order
- The start column of the BUSINESS_TIME period in ascending order

BUSINESS_TIME can be specified as the last item in the list. The list must also include at least one *column-name* or *key-expression*. When BUSINESS_TIME is specified, the columns of the BUSINESS_TIME period must not be specified as *column-name* or a *key-expression*, or as columns in the partitioning key.

WITH OR WITHOUT OVERLAPS

Indicates whether multiple rows may exist with the same values for the non-period columns and expressions of the index key for a row, with overlapping time periods.

WITH OVERLAPS

Indicates that multiple rows may exist with the same values for the non-period columns and expressions of the index key for a row, with overlapping time periods. The BUSINESS_TIME WITH OVERLAPS clause is intended for use in defining an index for the foreign key of a temporal referential constraint.

BUSINESS_TIME WITH OVERLAPS must not be specified when UNIQUE is specified for the index definition.

BUSINESS_TIME WITHOUT OVERLAPS must not be specified if the table is defined with a partitioning key that includes any columns of the BUSINESS_TIME period.

WITHOUT OVERLAPS

Indicates that the values for the non-period columns and expressions of the index key for a row must be unique with respect to the time represented by the BUSINESS_TIME period for the row. Db2 enforces that multiple rows do not exist with the same key values for the columns or expressions of the index, with overlapping time periods. The BUSINESS_TIME WITHOUT OVERLAPS clause is intended for use in defining a unique index to enforce a primary key or unique constraint.

BUSINESS_TIME WITHOUT OVERLAPS can only be specified for an index that is defined as UNIQUE.

aux-table-name

Identifies the auxiliary table on which the index is created. The name must identify an auxiliary table that exists at the current server. If the auxiliary table already has an index, do not create another one. An auxiliary table can only have one index.

Do not specify any columns for the index key. The key value is implicitly defined as a unique 19 byte value that is system generated.

If qualified, *table-name* or *aux-table-name* can be a two-part or three-part name. If a three-part name is used, the first part must match the value of the field Db2 LOCATION NAME of installation panel DSNTIPR at the current server. (If the current server is not the local Db2, this name is not necessarily the name in the CURRENT SERVER special register.) Whether the name is two-part or three-part, the authorization ID that qualifies the name is the owner of the index.

The table space that contains the named table must be available to Db2 so that its data sets can be opened. If the table space is EA-enabled, the data sets for the index must be defined to belong to a DFSMS data class that has the extended format and addressability attributes.

GENERATE KEY USING
Along with XMLPATTERN, GENERATE KEY USING is required to generate an XML index.

XMLPATTERN
When an XML column is indexed, only parts of the documents will be indexed. To identify those parts, a path expression that follows the XMLPATTERN clause is specified. Only values of those element, attribute, or text nodes which match the specified pattern are indexed. An XML pattern can be specified using an optional namespace declaration where namespace prefixes are mapped to namespace URIs and by providing a path expression. The path expression is similar to a path expression in XQuery except that the paths that are specified for the XML index can support child axis, self-or-descendant axis, wildcard expressions, or attribute only. The maximum length of an XML pattern text is 4000 bytes after being converted to UTF-8. For more information about XQuery, see Overview of pureXML (Db2 Programming for XML).

prolog
To use qualified names in the *pattern-expression*, namespace prefixes need to be declared. A default namespace can also be declared for use with unqualified names.

declare namespace *NCName=StringLiteral*
The namespace prefix, *NCName*, is mapped to a namespace URI that is identified in *StringLiteral*. Multiple namespaces can be declared, but each namespace prefix must be unique within the list of namespace declarations. *NCName* is an XML name as defined by the XML 1.0 standard. *NCName* cannot include a colon character. The namespace URI cannot be `http://www.w3.org/XML/1998/namespace` or `http://w3.org/2000/xmlns/`.

declare default element namespace *StringLiteral*
Specifies the default namespace URI for unqualified names of elements and types. *StringLiteral* is a namespace URI. If no default element namespace is declared, unqualified names of element and types are in no namespace. Only one default namespace can be declared.

pattern-expression
Pattern-expression is used to identify those nodes in an XML document that are indexed. *Pattern-expression* cannot be an empty or invalid string, and the XQuery expression cannot be nested more than 50 levels. *pattern-expression* cannot be an XQuery updating expression.

/ (forward slash)
Separates path expression steps.

// (double forward slash)
Abbreviated syntax for /descendant-or-self::node()/

. (dot)
Abbreviated syntax for /self::node()/

child::
Specifies children of the context node. child:: is the default if no forward axis is specified.

descendant::
Specifies the descendants of the context node.

self::
Specifies the current context node.

descendant-or-self::
Specifies the context node and the descendents of the context node.

element-name
Identifies an element in an XML document. *element-name* is an XML QName that can have one of the following forms:

nsprefix*:*NCName

nsprefix explicitly specifies a namespace prefix that must be declared.

NCName

An unqualified XML name that uses the default namespace.

*** (an asterisk)**

Indicates any element name. If * is prefixed by attribute:: or @, * indicates any attribute name.

nsprefix*:

Indicates any NCName within the specified namespace.

:*NCName

Indicates a specific XML name in any of the currently declared namespaces.

attribute:: or @

Specifies attributes of the context node.

attribute-name

Identifies an attribute in an XML document. *attribute-name* is an XML QName that can have one of the following forms:

nsprefix*:*NCName

nsprefix explicitly specifies a namespace prefix that must be declared.

NCName

An unqualified XML name that uses the default namespace.

text()

Matches any text node.

`fn:upper-case(.)`

Specifies an element node or an attribute node that identifies the key value for the index for each node that is specified by the context step (the part of *pattern-expression* that is specified prior to fn:upper-case).

The context step of fn:upper-case() must specify an element node or an attribute node. The argument of fn:upper-case() must be a self step. The key values of an XML value index must be specified as the SQL data type VARCHAR. The length of the VARCHAR value can be any value that is allowed in Db2.

`fn:exists()`

Specifies an element node that identifies the key value for the index for each node that is specified by the context step (the part of *pattern-expression* that is specified prior to fn:exists).

The context step of fn:exists() must specify an element node. The argument of fn:exists() must be either a single step of a child element node or an attribute node. The name test part can be a wildcard character for either the namespace prefix or NCName. The key values of an XML value index for an XPath expression that ends with fn:exists() must be specified as the SQL data type VARCHAR(1). The key value will be "T" or "F". "T" implies that fn:exists() evaluates to true and "F" implies that fn:exists() evaluates to false.

AS SQL *data-type*

Specifies that indexed values are stored as an instance of the specified SQL data type. Casting to the specified data type can result in a loss of precision of the values. For example, a loss of precision can occur when an XML integer value is cast to the SQL data type DECFLOAT. If the cast causes a loss of precision, the result will be rounded to the approximate value when it is stored in the index. The cast result cannot be outside of the range that is supported by the SQL data type. If the value cannot be cast to the specified data type, the document is still inserted into the table, but the index entry for that value is not created. No error or warning code is returned.

If the index is unique, the uniqueness is enforced on the value after it is cast to the specified type. Because rounding can occur during the cast to the SQL data type, if a value is cast to the same key value as a document that the table already contains, Db2 will return duplicate key errors at insert time, or fail to create the index.

VARCHAR (*integer*)

The length *integer* is a value in the range 1 - 1000 bytes. If VARCHAR is specified with a length, the specified length is treated as a constraint. If documents are inserted into a table (or exist in the table at create index time) that have nodes with values that are longer than the specified length, the insert or index creation will fail.

DECFLOAT

DECFLOAT can be specified to index numeric values. For the cast to succeed, the string must be a valid XML numeric type. Otherwise the value will be ignored and no insert to the index will occur. The result of the cast cannot be outside of the range that DECFLOAT can represent. Because the XML Schema data type for numeric values allows greater precision than the SQL data type, the result might be rounded to fit into the SQL data type. The DECFLOAT values that are stored in the index are the normalized numeric values.

DATE

The SQL DATE data type values will be normalized to UTC (Coordinated Universal Time) before being stored in the index. For invalid xs:date values, the value will be ignored without being inserted into the index. The XML schema data type for DATE allows for greater precision than the SQL data type. If an out-of-range value is encountered, an error is returned.

TIMESTAMP (12)

The SQL TIMESTAMP data type values will be normalized to UTC (Coordinated Universal Time) before being stored in the index. If the value that is specified in the document does not specify the time zone, Db2 will use the implicit time zone to normalize the value to UTC. For invalid xs:dateTime values, the value will be ignored without being inserted into the index. The XML schema data type for timestamps allows for greater precision than the SQL data type. If an out-of range value is encountered, an error is returned. Only a precision of 12 fractional digits is allowed for an SQL TIMESTAMP index key.

INCLUDE (*column-name*)

Specifies additional columns to append to the set of index key columns of a unique index. Any column that is specified using INCLUDE *column-name* is not used to enforce uniqueness. The included columns might improve performance for some queries using index only access.

The UNIQUE clause must be specified when INCLUDE is specified. Columns that are specified in the INCLUDE clause count towards the limits for the number of columns and the limits on the sum of the length attributes of the columns that are specified in the index. The total number of columns for the index cannot exceed 64.

column-name must be distinct from the columns that are used to enforce uniqueness and from other columns specified in the INCLUDE clause. *column-name* must be unqualified, must identify a column of the specified table, and must not be one of the existing columns of the index. *column-name* must not identify a LOB or DECFLOAT column (or a distinct type that is based on one of those types).

The INCLUDE clause cannot be specified for the following types of indexes:

- A non-unique index
- A partitioning index when index-controlled partitioning is used
- An auxiliary index
- An XML index
- An extended index
- An expression-based index

Columns in the INCLUDE list that are defined as character or graphic string data types must be defined with the same encoding scheme as other key columns with character or graphic string data types.

CLUSTER or NOT CLUSTER

Specifies whether the index is the clustering index for the table. This clause must not be specified for an index on an auxiliary table, or on a table that is defined to use hash organization.

CLUSTER

The index is to be used as the clustering index of the table. CLUSTER cannot be specified if XMLPATTERN or *key-expression* is specified.

NOT CLUSTER

The index is not to be used as the clustering index of the table.

PARTITIONED

Specifies that the index is data partitioned (that is, partitioned according to the partitioning scheme of the underlying data). A partitioned index can be created only on a partitioned table space, not on a partition-by-growth table space. PARTITIONED cannot be specified if XMLPATTERN is specified. The types of partitioned indexes are partitioning and secondary.

An index is considered a partitioning index if the specified index key columns match or comprise a superset of the columns specified in the partitioning key, are in the same order, and have the same ascending or descending attributes.

If PARTITION BY was not specified when the table was created, the CREATE INDEX statement must have the ENDING AT clause specified to define a partitioning index and use index-controlled partitioning. This index is created as a partitioned index even if the PARTITIONED keyword is not specified. When a partitioning index is created, if both the PARTITIONED and ENDING AT keywords are omitted, the index will be non-partitioned. If PARTITIONED is specified, the USING specification with PRIQTY and SECQTY specifications are optional. If these space parameters are not specified, default values are used.

A secondary index is any index defined on a partitioned table space that does not meet the definition of the partitioning index. For partitioned secondary indexes (data-partitioned secondary indexes), the ENDING AT clause is not allowed because the partitioning scheme of the index is predetermined by that of the underlying data. UNIQUE and UNIQUE WHERE NOT NULL are allowed only if the columns in the index are a superset of the partitioning columns. All of the index columns must be specified in a *table-name*(*column-name*) clause, and not in an INCLUDE clause. If a partitioned secondary index is created on a table that uses index-controlled partitioning, the table is converted to use table-controlled partitioning.

Index-controlled partitioning cannot be used if the PREVENT_NEW_IXCTRL_PART subsystem parameter is set to YES.

For more information, see PREVENT_NEW_IXCTRL_PART in macro DSN6SPRM (Db2 Installation and Migration).

NOT PADDED or PADDED

Specifies how varying-length string columns are to be stored in the index. If the index contains no varying-length columns, this option is ignored, and a warning message is returned. Indexes that do not have varying-length string columns are always created as physically padded indexes.

NOT PADDED

Specifies that varying-length string columns are not to be padded to their maximum length in the index. The length information for a varying-length column is stored with the key.

NOT PADDED is ignored and has no effect if the index is being created on an auxiliary table. Indexes on auxiliary tables are always padded.

PADDED

Specifies that varying-length string columns within the index are always padded with the default pad character to their maximum length. PADDED cannot be specified if XMLPATTERN is specified. PADDED cannot be specified for indexes that are defined on VARBINARY columns.

When the index contains at least one varying-length column, the default for the option depends on the value of field PAD INDEXES BY DEFAULT on installation panel DSNTIPE:

- When the value of this field is NO, new indexes are not padded unless PADDED is specified.
- When the value of this field is YES, new indexes are padded unless NOT PADDED is specified.

USING (for non-partitioned indexes)

For non-partitioned indexes, the USING clause indicates whether the data sets for the index are to be managed by the user or managed by Db2. If Db2 definition is specified, the clause also gives space allocation parameters (PRIQTY and SECQTY) and an erase rule (ERASE).

If you omit USING, the data sets Db2 manages on volumes listed in the default storage group of the database that is associated with the table. The default storage group for the database must exist. With no USING clause, PRIQTY, SECQTY, and ERASE assume their default values.

VCAT *catalog-name*

Specifies that the first data set for the index is managed by the user, and that following data sets, if needed, are also managed by the user.

The data sets are VSAM linear data sets cataloged in the integrated catalog facility catalog that *catalog-name* identifies. For more information about *catalog-name* values, see "Naming conventions" on page 79.

More than one Db2 subsystem can share the integrated catalog facility catalogs with the current server. To avoid the chance of those subsystems attempting to assign the same name to different data sets, specify a *catalog-name* value that is not used by the other Db2 subsystems.

Do not specify VCAT in any of the following circumstances:

- For an index on a declared temporary table.
- If the table space is partition-by-growth, and the table space is not part of the Db2 catalog.

STOGROUP *stogroup-name*

Specifies that Db2 will define and manage the data sets for the index. Each data set will be defined on a volume listed in the identified storage group. The values specified (or the defaults) for PRIQTY and SECQTY determine the primary and secondary allocations for the data set. If PRIQTY+118×SECQTY is 2 gigabytes or greater, more than one data set could eventually be used, but only the first is defined during execution of this statement.

To use USING STOGROUP, the privilege set must include one of the following, except when creating an index on a declare global temporary table if *stogroup-name* matches the default storage group of the work file database:

- SYSADM authority
- SYSCTRL authority
- The USE privilege for that storage group

Moreover, *stogroup-name* must identify a storage group that exists at the current server and includes in its description at least one volume serial number. The description can indicate that the choice of volumes will be left to Storage Management Subsystem (SMS). Each volume specified in the storage group must be accessible to z/OS for dynamic allocation of the data set, and all these volumes must be of the same device type.

The integrated catalog facility catalog used for the storage group must **not** contain an entry for the first data set of the index. If the catalog is password protected, the description of the storage group must include a valid password.

The storage group supplies the data set name. The first level qualifier is also the name of, or an alias for, the integrated catalog facility catalog on which the data set is to be cataloged. The naming convention for the data set is the same as if the data set is managed by the user.

PRIQTY *integer*

Specifies the minimum primary space allocation for a Db2-managed data set. *integer* must be a positive integer, or -1. When you specify PRIQTY with a positive integer value, the primary space allocation is at least *n* kilobytes, where *n* is:

12

If *integer* is greater than 0 and less than 12.

integer
If *integer* is between 12 and 4194304.

2097152
If both of the following conditions are true:

- *integer* is greater than 2097152.
- The index is a non-partitioned index on a table space that is not defined with the LARGE or DSSIZE attribute.

4194304
If *integer* is greater than 4194304.

If you do not specify PRIQTY, or you specify a PRIQTY value of -1, Db2 uses a default value for the primary space allocation. For information on how Db2 determines the default value, see Rules for primary and secondary space allocation.

If you specify PRIQTY, and do not specify a value of -1, Db2 specifies the primary space allocation to access method services using the smallest multiple of 4KB not less than *n*. The allocated space can be greater than the amount of space requested by Db2. For example, it could be the smallest number of tracks that will accommodate the space requested. To more closely estimate the actual amount of storage, see DEFINE CLUSTER command (DFSMS Access Method Services for Catalogs).

When determining a suitable value for PRIQTY, be aware that two of the pages of the primary space could be used by Db2 for purposes other than storing index entries.

SECQTY *integer*
Specifies the minimum secondary space allocation for a Db2-managed data set. *integer* must be a positive integer, 0, or -1. If you do not specify SECQTY, or specify a SECQTY value of -1, Db2 uses a formula to determine a value. For information on the actual value that is used for secondary space allocation, whether you specify a value or not, see Rules for primary and secondary space allocation.

If you specify SECQTY, and do not specify a value of -1, Db2 specifies the secondary space allocation to access method services using the smallest multiple of 4KB not less than *integer*. The allocated space can be greater than the amount of space requested by Db2. For example, it could be the smallest number of tracks that will accommodate the space requested. To more closely estimate the actual amount of storage, see DEFINE CLUSTER command (DFSMS Access Method Services for Catalogs).

ERASE
Indicates whether the Db2-managed data sets are to be erased when they are deleted during the execution of a utility or an SQL statement that drops the index.

NO
Does not erase the data sets. Operations involving data set deletion will perform better than ERASE YES. However, the data is still accessible, though not through Db2. This is the default.

YES
Erases the data sets. As a security measure, Db2 overwrites all data in the data sets with zeros before they are deleted.

USING (partitioned indexes)
If the index is partitioned, there is a PARTITION clause for each partition. Within a PARTITION clause, a USING clause is optional. If a USING clause is present, it applies to that partition in the same way that a USING clause for a secondary index applies to the entire index.

When a USING specification is absent from a PARTITION clause, the USING clause parameters for the partition depend on whether a USING clause is specified before the PARTITION clauses.

- If the USING clause is specified, it applies to every PARTITION clause that does not include a USING clause.

- If the USING clause is not specified, the following defaults apply to the partition:
  - Data sets are managed by Db2.
  - The default storage group for the database is used. If the USING clause for the index space is omitted, the default storage group for database must exist.
  - Default values of -1 are used for both PRIQTY and SECQTY.
  - A value of NO is used for ERASE.

VCAT *catalog-name*

Specifies a user-managed data set with a name that starts with the specified catalog name. The identified integrated catalog facility catalog must already contain an entry for the *n*th data set of the index, where *n* is the partition number.

The data sets are VSAM linear data sets cataloged in the integrated catalog facility catalog that *catalog-name* identifies. For more information about *catalog-name* values, see "Naming conventions" on page 79.

More than one Db2 subsystem can share the integrated catalog facility catalogs with the current server. To avoid the chance of those subsystems attempting to assign the same name to different data sets, specify a *catalog-name* value that is not used by the other Db2 subsystems.

Db2 assumes one and only one data set for each partition.

STOGROUP *stogroup-name*

If USING STOGROUP is used, explicitly or by default, for a partition *n*, Db2 defines the data set for the partition during the execution of the CREATE INDEX statement, using space from the named storage group. The privilege set must include SYSADM authority, SYSCTRL authority, or the USE privilege for that storage group. The integrated catalog facility catalog used for the storage group must NOT contain an entry for the *n*th data set of the index.

stogroup-name must identify a storage group that exists at the current server and the privilege set must include one of the following privileges or authorities, except when creating an index on a declare global temporary table if *stogroup-name* matches the default storage group of the work file database:

- SYSADM authority
- SYSCTRL authority
- USE privilege for the storage group

If you omit PRIQTY, SECQTY, or ERASE from a USING STOGROUP clause for some partition, their values are given by the next USING STOGROUP clause that governs that partition: either a USING clause that is not in any PARTITION clause, or a default USING clause. Db2 assumes one and only one data set for each partition.

FREEPAGE *integer*

Specifies how often to leave a page of free space when index entries are created as the result of executing a Db2 utility or when creating an index for a table with existing rows. One free page is left for every *integer* pages. The value of *integer* can range 0 - 255. The default is 0, leaving no free pages.

Do not specify FREEPAGE for an index on a declared temporary table.

PCTFREE *integer*

Determines the percentage of free space to leave in each nonleaf page and leaf page when entries are added to the index or index partition as the result of executing a Db2 utility or when creating an index for a table with existing rows. The first entry in a page is loaded without restriction. When additional entries are placed in a nonleaf or leaf page, the percentage of free space is at least as great as *integer*.

The value of *integer* can range from 0 to 99, however, if a value greater than 10 is specified, only 10 percent of free space will be left in nonleaf pages. The default is 10.

Do not specify PCTFREE for an index on a declared temporary table.

If the index is partitioned , the values of FREEPAGE and PCTFREE for a particular partition are given by the first of these choices that applies:

- The values of FREEPAGE and PCTFREE given in the PARTITION clause for that partition. Do not use more than one *free-specification* in any PARTITION clause.
- The values given in a *free-specification* that is not in any PARTITION clause.
- The default values FREEPAGE 0 and PCTFREE 10.

GBPCACHE

In a data sharing environment, specifies what index pages are written to the group buffer pool. In a non-data-sharing environment, the option is ignored unless the index is on a declared temporary table. Do not specify GBPCACHE for an index on a declared temporary table in either environment (data sharing or non-data-sharing).

CHANGED

Specifies that updated pages are written to the group buffer pool, when there is inter-Db2 R/W interest on the index or partition. When there is no inter-Db2 R/W interest, the group buffer pool is not used. Inter-Db2 R/W interest exists when more than one member in the data sharing group has the index or partition open, and at least one member has it open for update. GBPCACHE CHANGED is the default.

If the index is in a group buffer pool that is defined as GBPCACHE(NO), CHANGED is ignored and no pages are written to the group buffer pool.

ALL

Indicates that pages are written to the group buffer pool as they are read in from DASD.

Exception: In the case of a single updating Db2 subsystem when no other Db2 subsystems have any interest in the page set, no pages are written to the group buffer pool.

If the index is in a group buffer pool that is defined as GBPCACHE(NO), ALL is ignored and no pages are written to the group buffer pool.

NONE

Indicates that no pages are written to the group buffer pool. Db2 uses the group buffer pool only for cross-invalidation.

If the index is partitioned, the value of GBPCACHE for a particular partition is given by the first of these choices that applies:

1. The value of GBPCACHE given in the PARTITION clause for that partition. Do not use more than one *gbpcache-specification* in any PARTITION clause.
2. The value given in a *gbpcache-specification* that is not in any PARTITION clause.
3. GBPCACHE CHANGED is the default value.

DEFINE

Specifies when the underlying data sets for the index are physically created. The SPACE column in catalog table SYSINDEXPART is used to record the status of the data sets (undefined or allocated). If the DEFINE keyword is not specified, the define attribute is inherited from the current state of the base table space.

YES

The data sets are created when the index is created (the CREATE INDEX statement is executed).

NO

The data sets are not created until data is inserted into the index.

DEFINE NO is applicable only for Db2-managed data sets (USING STOGROUP is specified). Use DEFINE NO especially when performance of the CREATE INDEX statement is important or DASD resource is constrained.

Do not use DEFINE NO on an index if you use a program outside of Db2 to propagate data into a table on which that index is defined. If you use DEFINE NO on an index of a table and data is then propagated into the table from a program that is outside of Db2, the index space data sets are allocated, but the Db2 catalog will not reflect this fact. As a result, Db2 treats the data sets for the index space as if they have not yet been allocated. The resulting inconsistency causes Db2 to deny application programs access to the data until the inconsistency is resolved.

DEFINE NO is ignored for user-managed data sets (USING VCAT is specified). DEFINE NO is also ignored if the index is being created on a table that is not empty.

Do not specify DEFINE NO if the index is created on a base table that is involved in a clone relationship.

Do not specify DEFINE NO for an index on a declared temporary table.

COMPRESS NO or COMPRESS YES

Specifies whether compression for index data will be used. If the index is partitioned, the clause will apply to all partitions.

COMPRESS NO

Specifies that no index compression will be used.

COMPRESS NO is the default.

COMPRESS YES

Specifies that index compression will be used. The buffer pool that is used to create the index must be 8K, 16K, or 32K in size. The physical page size on disk will be 4K. The index compression will take place immediately.

Index compression is recommended for applications that do sequential insert operations with few or no delete operations. Random inserts and deletes can adversely effect compression. Index compress is also recommended for applications where the indexes are created primarily for scan operations.

INCLUDE NULL KEYS or EXCLUDE NULL KEYS

Specifies whether an index entry will be created when every key column contains the NULL value.

INCLUDE NULL KEYS

Specifies that an index entry will be created when every key column contains the NULL value.

INCLUDE NULL KEYS is the default.

EXCLUDE NULL KEYS

Specifies that no index entry will be created when every key column contains the NULL value. If any key column is not null the index entry will be created.

EXCLUDE NULL KEYS must not be specified with the following:

- UNIQUE
- BUSINESS_TIME WITHOUT OVERLAPS
- *XML-index-specification*
- *key-expression*
- INCLUDE (*column-name*)

EXCLUDE NULL KEYS must also not be specified if any of the columns that are identified by *column-name* are defined as NOT NULL, or if the index is defined as a partitioning index for use with index-controlled partitioning.

PARTITION BY RANGE

Specifies the partitioning index for the table, which determines the partitioning scheme for the data in the table.

PARTITION BY RANGE should only be specified if the table space is partitioned and the partitioning schema has not already been established.

PARTITION BY RANGE must not be specified if the index is an extended index, is defined with the BUSINESS_TIME WITHOUT OVERLAPS, or if the table is in a universal table space (ranged-partitioned or partition-by-growth table space).

partition-element

Specifies the range for each partition.

PARTITION *integer*

A PARTITION clause specifies the highest value of the index key in one partition of a partitioning index. In this context, highest means highest in the sorting sequences of the index columns. In a column defined as *ascending* (ASC), highest and lowest have their usual meanings. In a column defined as *descending* (DESC), the lowest actual value is highest in the sorting sequence.

If you use CLUSTER, and the table is contained in a partitioned table space, you must use exactly one PARTITION clause for each partition (defined with NUMPARTS on CREATE TABLESPACE). If there are *p* partitions, the value of *integer* must range from 1 through *p*.

The length of the highest value of a partition (also called the limit key) is the same as the length of the partitioning index.

ENDING AT(*constant*, MAXVALUE, or MINVALUE...)

Specifies that this is the partitioning index and indicates how the data will be partitioned. The table space is marked complete after this partitioning index is created. You must use at least one value (*constant*, MAXVALUE, or MINVALUE) after ENDING AT in each PARTITION clause. You can use as many as there are columns in the key. The concatenation of all the values is the highest value of the key in the corresponding partition of the index unless the VALUES statement was already specified when the table or previous index was created.

constant

Specifies a constant value with a data type that must conform to the rules for assigning that value to the column. If a string constant is longer or shorter than required by the length attribute of its column, the constant is either truncated or padded on the right to the required length. If the column is ascending, the padding character is X'FF'. If the column is descending, the padding character is X'00'. The precision and scale of a decimal constant must not be greater than the precision and scale of its corresponding column. A hexadecimal string constant (GX) cannot be specified.

MAXVALUE

Specifies a value greater than the maximum value for the limit key of a partition boundary (that is, all X'FF' regardless of whether the column is ascending or descending). If all of the columns in the partitioning key are ascending, a constant or the MINVALUE clause cannot be specified following MAXVALUE. After MAXVALUE is specified, all subsequent columns must be MAXVALUE.

MINVALUE

Specifies a value that is smaller than the minimum value for the limit key of a partition boundary (that is, all X'00' regardless of whether the column is ascending or descending). If all of the columns in the partitioning key are descending, a constant or the MAXVALUE clause cannot be specified following MAXVALUE. After MINVALUE is specified, all subsequent columns must be MINVALUE.

The key values are subject to the following rules:

- The first value corresponds to the first column of the key, the second value to the second column, and so on. Using fewer values than there are columns in the key has the same effect as using the highest or lowest values for the omitted columns, depending on whether they are ascending or descending.
- If a key includes a ROWID column or a column with a distinct type that is based on a ROWID data type, 17 bytes of the constant that is specified for the corresponding ROWID column are considered.
- The highest value of the key in any partition must be lower than the highest value of the key in the next partition.
- If the concatenation of all the values exceeds 255 bytes, only the first 255 bytes are considered.

- The highest value of the key in the last partition depends on how the table space is defined. For table spaces that are created without the LARGE or DSSIZE options, the values that you specify after VALUES are not enforced. The highest value of the key that can be placed in the table is the highest possible value of the key.

  For large partitioned table space, the values you specify are enforced. The value specified for the last partition is the highest value of the key that can be placed in the table. Any key values greater than the value that is specified for the last partition are out of range.

ENDING AT can be specified only if the ENDING AT clause was not specified on a previous CREATE or ALTER TABLE statement for the underlying table.

INCLUSIVE

Specifies that the specified range values are included in the data partition.

BUFFERPOOL *bpname*

Identifies the buffer pool that is to be used for the index. The privilege set must include SYSADM or SYSCTRL authority or the USE privilege for the buffer pool, except when creating an index on a declare global temporary table and *bpname* matches the default index buffer pool of the work file database.

The *bpname* must identify an activated 4KB, 8KB, 16KB, or 32KB buffer pool.

A buffer pool with a smaller size should be chosen for indexes with random insert patterns. A buffer pool with a larger size should be chosen for indexes with sequential insert patterns.

For more details about *bpname*, see "Naming conventions" on page 79. For a description of active and inactive buffer pools, see Controlling Db2 databases and buffer pools (Db2 Administration Guide).

CLOSE

Specifies whether or not the data set is eligible to be closed when the index is not being used and the limit on the number of open data sets is reached.

YES

Eligible for closing. This is the default unless the index is on a declared temporary table.

NO

Not eligible for closing.

If the limit on the number of open data sets is reached and there are no page sets that specify CLOSE YES to close, page sets that specify CLOSE NO will be closed.

For an index on a declared temporary table, Db2 uses CLOSE NO regardless of the value specified.

DEFER

Indicates whether the index is built during the execution of the CREATE INDEX statement. Regardless of the option specified, the description of the index and its index space is added to the catalog. If the table is determined to be empty and DEFER YES is specified, the index is neither built nor placed in a rebuild-pending status. For more information about using DEFER, see Index names and guidelines (Db2 Administration Guide). Do not specify DEFER for an index on a declared temporary table or an auxiliary table.

NO

The index is built. This is the default.

YES

The index is not built. If the table is populated, the index is placed in a rebuild-pending status and a warning message is issued; the index must be rebuilt by the REBUILD INDEX utility.

DSSIZE *integer* G

Specifies the maximum size for each partition of a partitioned index. Any integer 1 - 1024 can be specified (for example, 1G – 1024G). This keyword is not valid on nonpartitioned secondary indexes. You can only specify DSSIZE on CREATE INDEX if the index is on a table space with relative page numbers.

To specify a value greater than 4G, the data sets for the table space must be associated with a DFSMS data class that has been specified with extended format and extended addressability.

If the index is a partitioned index using relative page numbering, the value of DSSIZE for a particular partition is given by the first of these choices that applies:

- The value of DSSIZE given in the PARTITION clause for that partition.
- The value given by a DSSIZE keyword that is not in any PARTITION clause.
- The default value is inherited from the base table space.

PIECESIZE *integer*

Specifies the maximum addressability of each data set for a non-partitioned index. The subsequent keyword K, M, or G, indicates the units of the value that is specified in *integer*.

K

Indicates that the *integer* value is to be multiplied by 1024 to specify the maximum data set size in bytes. *integer* must be a power of two between 1 and 268435456.

M

Indicates that the *integer* value is to be multiplied by 1048576 to specify the maximum data set size in bytes. *integer* must be a power of two between 1 and 262144.

G

Indicates that the *integer* value is to be multiplied by 1073741824 to specify the maximum data set size in bytes. *integer* must be a power of two between 1 and 256.

integer can be separated from K, M, or G by 0 or more spaces.*integer*

The following table shows the valid values for the data set size, which depend on the size of the table space.

Table 196. Valid values of PIECESIZE clause

K units	M units	G units	Size attribute of table space
256K			
512 K			
1024 K	1 M		
2048 K	2 M		
4096 K	4 M		
8192 K	8 M		
16384 K	16 M		
32768 K	32 M		
65536 K	64 M		
131072 K	128 M		
262144 K	256 M		
524288 K	512 M		
1048576 K	1024 M	1 G	
2097152 K	2048 M	2 G	
4194304 K	4096 M	4 G	LARGE, DSSIZE 4 G (or greater)
8388608 K	8192 M	8 G	DSSIZE 8 G (or greater)
16777216 K	16384 M	16 G	DSSIZE 16 G (or greater)
33554432 K	32768 M	32 G	DSSIZE 32 G (or greater)
67108864 K	65536 M	64 G	DSSIZE 64 G (or greater)

Table 196. Valid values of PIECESIZE clause (continued)

K units	M units	G units	Size attribute of table space
134217728 K	131072 M	128 G	DSSIZE 128 G (or greater)
268435456 K	262144 M	256 G	DSSIZE 256 G

PIECESIZE has no effect on primary and secondary space allocation as it is only a specification of the maximum amount of data that a data set can hold and not the actual allocation of storage.

If you change the PIECESIZE value with the ALTER INDEX statement, the index is put into REBUILD-pending status.

See the following for additional information:

- Number of pieces and maximum piece size for non-partitioned indexes and data-partitioned secondary indexes
- Choosing a value for PIECESIZE

COPY

Indicates whether the COPY utility is allowed for the index. Do not specify COPY for an index on a declared temporary table.

NO

Does not allow full image or concurrent copies or the use of the RECOVER utility on the index. NO is the default.

YES

Allows full image or concurrent copies and the use of the RECOVER utility on the index.

Notes for CREATE INDEX

Owner privileges:

The owner of the table has all table privileges (see "GRANT (table or view privileges)" on page 1983) with the ability to grant these privileges to others. For more information about ownership of the object, see "Authorization, privileges, permissions, masks, and object ownership" on page 90.

Effects of the DEFER clause:

If DEFER NO is implicitly or explicitly specified, the CREATE INDEX statement cannot be executed while a Db2 utility has control of the table space that contains the identified table.

If the identified table already contains data and if the index build is not deferred, CREATE INDEX creates the index entries for it. If the table does not yet contain data, CREATE INDEX creates a description of the index; the index entries are created when data is inserted into the table.

Errors evaluating the expressions for an index:

Errors that occur during the evaluation of an expression for an index are returned when the expression is evaluated. This can occur on an SQL data change statement, SELECT from an SQL data change statement, or the REBUILD INDEX utility. For example, the evaluation of the expression `10 / column_1` returns an error if the value in *column_1* is 0. The error is returned during CREATE INDEX processing if the table is not empty and contains a row with a value of zero in *column_1*, otherwise the error is returned during the processing of the insert or update operation when a row with a value of zero in *column_1* is inserted or updated.

Result length of expressions that return a string type:

If the result data type of *key-expression* is a string type and the result length cannot be calculated at bind time, the length is set to the maximum allowable length of that data type or the largest length that Db2 can estimate. In this case, the CREATE INDEX statement can fail because the total key length might exceed the limit of an index key.

For example, the result length of the expression `REPEAT('A', CEIL(1.1))` is VARCHAR(32767) and the result length of the expression `SUBSTR(DESCRIPTION,1,INTEGER(1.2))` is the length of the DESCRIPTION column. Therefore, a CREATE INDEX statement that uses any of these expressions as a *key-expression* might not be created because the total key length might exceed the limit of an index key.

Use of ASC or DESC on key columns:

There are no restrictions on the use of ASC or DESC for the columns of a parent key or foreign key. An index on a foreign key does not have to have the same ascending and descending attributes as the index of the corresponding parent key.

EBCDIC, ASCII, and UNICODE encoding schemes for an index:

In general, an index has the same encoding scheme as its associated table. However, if an index on an EBCDIC table consists of only Unicode columns, the encoding scheme of the index is Unicode.

Maximum partition size of a partitioned index

The size of a partitioned index depends on whether the corresponding partitioned table space is created with or without the LARGE or DSSIZE keywords, and on the number of partitions.

The following table provides information about partitioned indexes on table spaces that are created without the LARGE or DSSIZE keywords and with 64 or fewer partitions.

Table 197. Maximum number of pieces and the default size of a partitioned index on a partitioned table space that is created without the LARGE or DSSIZE clauses and with a NUMPARTS value of less than or equal to 64

Definition of partitioned table space (non-large)	Maximum number of pieces for a partitioned index	Default size of a partitioned index, per data set
NUMPARTS <= 16	16	4G
NUMPARTS >= 17 but NUMPARTS <= 32	32	2G
NUMPARTS >= 33	64	1G

The following table shows information about partitioned indexes on table spaces that are created with the LARGE or DSSIZE keywords and with more than 64 partitions.

Table 198. Maximum number of pieces and the default partitioned index size for a partitioned table space that is created with the LARGE or DSSIZE clauses or with a NUMPARTS value of greater than 64

Definition of partitioned table space (large)	Maximum number of pieces for a partitioned index	Default index piece size for a partitioned index
One or more of the following conditions are true: • **LARGE clause - specified** • **NUMPARTS greater than 64 but less than 256**	Maximum number of partitions in the partitioned table space	4G
One or more of the following conditions are true: • **DSSIZE clause - specified** • **NUMPARTS greater than or equal to 256**	Maximum number of partitions in the partitioned table space	`MIN(table space DSSIZE, 2^32/ (Maximum number of partitions in the table space) * index page size)`

To calculate the maximum data set size for a partitioned index, you need to first calculate the maximum number of partitions in the table space by using the following formula:

```
MIN(4096, 2^32/ (table space DSSIZE / table space page size))
```

After you calculate the maximum number of partitions in the table space, you can calculate the maximum data set size for a partitioned index with the following formula, using the number of partitions that you calculated above:

```
MIN(table space DSSIZE, 2^32/
(Maximum number of partitions in the table space) * index page size)
```

For an index that is defined with COMPRESS YES, *index page size* is always 4096 (4KB).

For example, suppose that a table space and an index on that table space have the following characteristics:

- DSSIZE: 64 GB
- Page size: 32 KB
- Index page size: 4 KB
- Maximum number of partitions: 2048

Given those characteristics, you can begin by calculating the maximum number of partitions in the table space:

```
MIN(4096, 2^32/ (64GB / 32KB)) = 2048
```

You can then use the value of 2048 to calculate the maximum data set size for the partitioned index:

```
MIN(64 GB, 2^32/ 2048 * 4KB)
= MIN(64GB, 8GB)
= 8GB
```

Number of pieces and maximum piece size for non-partitioned indexes

The largest amount of data that an index can hold is the maximum number of pieces for the index times the maximum amount of data that a piece can hold.

For a non-partitioned index, the maximum amount of data that an index can hold is defined by using the PIECESIZE parameter.

The default piece size for an index is as follows:

- 2 GB (PIECESIZE 2 G) for indexes of table spaces created without the LARGE or DSSIZE option
- 4 GB (PIECESIZE 4 G) for indexes of table spaces created with the LARGE or DSSIZE option
- 4 GB (PIECESIZE 4 G) for auxiliary indexes

The following tables list the maximum number of pieces and the default index piece size for various table spaces.

Table 199. Maximum number of pieces and the default index piece size for a partitioned table space that is created without the LARGE or DSSIZE clauses and has a NUMPART value of less than or equal to 64

Definition of partitioned table space (non-large), NUMPART value	Maximum number of pieces in a non-partitioned index	Default index piece size for a non-partitioned index
NUMPARTS <= 16	32	2G
NUMPARTS >= 17 **but** **NUMPARTS <= 32**	32	2G
NUMPARTS >= 33	32	2G

Table 200. Maximum number of pieces and the default index piece size for a partitioned table space that is created with the LARGE or DSSIZE clauses or has a NUMPARTS value of greater than or equal to 65

Definition of partitioned table space (large)	Maximum number of pieces for a non-partitioned index	Default index piece size for a non-partitioned index
• **LARGE clause - specified** • **DSSIZE clause - not specified**	`MIN(4096, 2^32/(x/y))` - see "1" on page 1544	4G
• **LARGE clause - not specified** • **DSSIZE clause - not specified** • **NUMPARTS clause - greater than 64 but less than 256**	`MIN(4096, 2^32/(x/y))` - see "1" on page 1544	4G
• **LARGE clause - not specified** • **DSSIZE clause - specified or NUMPARTS clause - greater than or equal to 256**	`MIN(4096, 2^32/(x/y))` - see "1" on page 1544	4G

Note:

1. For a non-partitioned index, the formula `MIN(4096, 2^32 / (x / y))`, determines the maximum number of pieces for the non-partitioned index, where *x* and *y* have the following values:

   x is the piece size of the index (stored in the PIECESIZE column of the SYSIBM.SYSINDEXES catalog table)

   y is the page size of the index (stored in the PGSIZE column of the SYSIBM.SYSINDEXES catalog table)

Table 201. Maximum number of pieces and the default index piece size for a non-partitioned table space

Type of non-partitioned table space	Maximum number of pieces	Default index piece size
non-segmented table space	32	2G
segmented table space	32	2G
LOB, auxiliary, or XML table space	32	4G

Choosing a value for PIECESIZE:

To choose a value for PIECESIZE, divide the size of the non-partitioned index by the number of data sets that you want. For example, to ensure that you have five data sets for the non-partitioned index, and your index is 10MB (and not likely to grow much), specify PIECESIZE 2 M. If your non-partitioned index is likely to grow, choose a larger value.

Remember that 32 data sets is the limit if the underlying table space is not defined as LARGE or with a DSSIZE parameter and that the limit is 4096 for objects with greater than 254 parts. For a non-partitioned index on a table space that is defined as LARGE or with a DSSIZE parameter, the maximum is MIN(4096, 2^{32} / (*index piece size*/*index page size*)).

Keep the PIECESIZE value in mind when you are choosing values for primary and secondary quantities. Ideally, the value of your primary quantity plus the secondary quantities should be evenly divisible into PIECESIZE.

Dropping an index:

Partitioning indexes can be dropped. If the table space is using index-controlled partitioning, the table space is converted to table-controlled partitioning. Secondary indexes that are not indexes on auxiliary tables can be dropped simply by dropping the indexes. An empty index on an auxiliary table can be explicitly dropped; a populated index can be dropped only by dropping other objects. For details, see Dropping an index on an auxiliary table and an auxiliary table"Dropping an index on a base table and auxiliary table" in “DROP” on page 1881.

If the index is a unique index that enforces a primary key, unique key, or referential constraint, the constraint must be dropped before the index is dropped. See “DROP” on page 1881.

Unique indexes and enforcement of UNIQUE or PRIMARY KEY specifications for a table:

A table requires a unique index (that is not defined as UNIQUE WHERE NOT NULL) if you use the UNIQUE or PRIMARY KEY clause in the CREATE or ALTER TABLE statements, or if there is a ROWID column that is defined as GENERATED BY DEFAULT. Db2 implicitly creates those unique indexes if the table space is explicitly created and the CREATE or ALTER TABLE statement is processed by the schema processor or if the table space is implicitly created; otherwise, you must explicitly create them. If any of the unique indexes that must be explicitly defined do not exist, the definition of the table is incomplete, and the following rules apply:

- Let K denote a key for which a required unique index does not exist and let *n* denote the number of unique indexes that remain to be created before the definition of the table is complete. (For a new table that has no indexes, K is its primary key or any of the keys defined in the CREATE or ALTER TABLE statement as UNIQUE and *n* is the number of such keys. After the definition of a table is complete, an index cannot be dropped if it is enforcing a primary key or unique key.)
- The creation of the unique index reduces *n* by one if the index key is identical to K. The keys are identical only if they have the same columns in the same order.
- If *n* is now zero, the creation of the index completes the definition of the table.
- If K is a primary key, the description of the index indicates that it is a primary index. If K is not a primary key, the description of the index indicates that it enforces the uniqueness of a key defined as UNIQUE in the CREATE or ALTER TABLE statement.

A unique index cannot be created on a materialized query table.

Unique indexes and XML columns:

If the index is an XML index on a unique XML column, the uniqueness applies to values of the specified pattern across all documents of that column, and the uniqueness is enforced on the value after the value is cast to the specified SQL data type. Because the data type conversion might result in a loss of precision and normalization, multiple values that appear unique in the XML document might still result in duplicate errors. If the index is defined using an expression, the uniqueness is enforced against the values that are stored in the index, not against the original values of the columns. The `WHERE NOT NULL` specification is ignored with a warning if XMLPATTERN is also specified, and the index is treated as if `UNIQUE` had been specified.

Defining an XML index using an XPath pattern-expression that includes functions:

An XPath *pattern-expression* that includes functions (including fn:exists() or fn:upper-case()) will have two parts. The first part is referred to as the *context step* and specifies the XPath of the element node or attribute node for which an index entry will be created (the element or attributes NodeID will be included in the index). The context step follows the same syntax as the XPath *pattern-expression* for an XML index, except that for fn:exists() it has to specify an element node, and for fn:upper-case() it has to specify an element node or an attribute node.

The second part is referred to as the *function expression step* and specifies the fn:exists() or fn:upper-case() XPath function. The function expression step is the right-most part of an XPath *pattern-expression*. For each node specified by the context step, the function expression step specifies the key value for the index. For example, in the XPath *pattern-expression* `/purchaseOrder/items/item/fn:exists(shipDate)`, the context step is `/purchaseOrder/items/item`, and the function expression step is `fn:exists(shipDate)`.

Use of PARTITIONED keyword:

When a partitioned index is created and no additional keywords are specified, the index is non-partitioned. If the keyword PARTITIONED is specified, the index is partitioned. If PARTITION BY RANGE is specified, the index is both data-partitioned and key-partitioned because it is defined on the partitioning columns of the table. Any index on a partitioned table space that does not meet the definition of a partitioning index is a secondary index. When a secondary index is created and no additional keywords are specified, the secondary index is non-partitioned (NPSI). If the keyword PARTITIONED is specified, the index is a data-partitioned secondary index (DPSI).

Creating a partitioning index for a table created without partition boundaries:

When a table is created without specifying partition boundaries using the ENDING AT clause, the table is incomplete until a partitioning index is created. The first index that is created for a table must specify both the PARTITION and the ENDING AT clauses.

When the PARTITION clause is specified while creating an index, either the PARTITIONED clause, or the ENDING AT clause must also be specified.

Considerations for tables that are involved in a clone relationship:

If an index is created on a base table that is involved in a clone relationship, an index with the same name is also created on the clone table. The index on the clone table will be placed in rebuild-pending status unless the clone table is empty when the index is created.

Considerations for tables that contain a row change timestamp column:

To create an index that refers to a row change timestamp column in the table, values must already exist in the column for all rows. Values are stored in row change timestamp columns whenever a row is inserted or updated in the table. If the row change timestamp column is added to an existing table that contains rows, the values for the row change timestamp column is not materialized and stored at the time of the ALTER TABLE statement. Values are materialized for these rows when they are updated, or when a REORG or a LOAD REPLACE utility is run on the table or table space.

Restriction on table spaces when there are pending changes to the definition:

A CREATE INDEX statement is not allowed if there are pending changes to the definition of the table space or to any objects in the table space. In addition, an index that references an expression cannot be created on a table where the inline length of a LOB column has been changed and the table space has not been reorganized.

Effects of DEFINE NO and INCLUDE NULL KEYS or EXCLUDE NULL KEYS:

When INCLUDE NULL KEYS is specified (implicitly or explicitly) with DEFINE NO and the table that is being indexed is populated, a warning is returned, the index is created, and the data set is defined. When EXCLUDE NULL KEYS is specified, it is possible that the data set will not be defined if the all rows for the table that is being indexed contain the NULL value for all key columns. The index will be empty after the CREATE INDEX statement. However, if DEFINE NO is specified with EXCLUDE NULL KEYS a warning is returned.

Creating indexes on Db2 catalog tables:

For details on creating indexes on catalog tables, see "SQL statements allowed on the catalog" on page 2727.

EA-enabled index data sets:

If an index is created for an EA-enabled table space, the data sets for the index must be set up to belong to a DFSMS data class that has the extended format and extended addressability attributes.

Alternative syntax and synonyms:

To provide compatibility with previous releases of Db2 or other products in the Db2 family, Db2 supports the following keywords when creating a partitioned index:

- PART *integer* VALUES as an alternative syntax for `PARTITION` *integer* `ENDING`. The `PARTITION BY RANGE` keyword that precedes the *partition-element* clause is optional.

Although these keywords are supported as alternatives, they are not the preferred syntax.

User-defined indexes on catalog tables:

If you issue CREATE INDEX for an index on a catalog table, and you specify the USING clause, Db2 ignores that clause. Instead, Db2 defines and manages the index data sets. The data sets are defined in the same SMS environment that is used for the catalog data sets with default space attributes.

Temporal referential constraints:

An index is required for the foreign key of a temporal referential constraint. The index must be defined in one of the following ways:

- Specify the BUSINESS_TIME WITH OVERLAPS clause after the columns and key expressions.
- Specify the end column of the BUSINESS_TIME period, followed by the begin column of the BUSINESS_TIME period as the last two keys of the index. ASC must be used for each of these columns.

When a temporal referential constraint is defined for a table, the first index that is created that meets the criteria for an index on the foreign key, is recorded as a dependency for the constraint. An index used for the foreign key of a temporal referential constraint cannot be dropped. A column cannot be added to an index used for a temporal referential constraint.

Examples for CREATE INDEX

Example 1

Create a unique index, named DSN8C10.XDEPT1, on table DSN8C10.DEPT. Index entries are to be in ascending order by the single column DEPTNO. Db2 is to define the data sets for the index, using storage group DSN8G120. Each data set should hold 1 megabyte of data at most. Use 512 kilobytes as the primary space allocation for each data set and 64 kilobytes as the secondary space allocation. These specifications enable each data set to be extended up to 8 times before a new data set is used—512KB + (8*64KB)= 1024KB. Make the index padded.

The data sets can be closed when no one is using the index and do not need to be erased if the index is dropped.

```
    CREATE UNIQUE INDEX DSN8C10.XDEPT1
      ON DSN8C10.DEPT
        (DEPTNO ASC)
      PADDED
      USING STOGROUP DSN8G120
        PRIQTY 512
        SECQTY 64
        ERASE NO
      BUFFERPOOL BP1
      CLOSE YES
      PIECESIZE 1 M;
```

For the above example, the underlying data sets for the index will be created immediately, which is the default (DEFINE YES). Assuming that table DSN8C10.DEPT is empty, if you wanted to defer the creation of the data sets until data is first inserted into the index, you would specify DEFINE NO instead of accepting the default behavior. Specifying PADDED ensures that the varying-length character string columns in the index are padded with blanks.

Example 2

Create a cluster index, named XEMP2, on table EMP in database DSN8C10. Put the entries in ascending order by column EMPNO. Let Db2 define the data sets for each partition using storage group DSN8G120. Make the primary space allocation be 36 kilobytes, and allow Db2 to use the default value for SECQTY, which for this example is 12 kilobytes (3 times 4KB). If the index is dropped, the data sets need not be erased.

There are to be 4 partitions, with index entries divided among them as follows:

Partition 1: entries up to H99
Partition 2: entries above H99 up to P99
Partition 3: entries above P99 up to Z99

Partition 4: entries above Z99

Associate the index with buffer pool BP1 and allow the data sets to be closed when no one is using the index. Enable the use of the COPY utility for full image or concurrent copies and the RECOVER utility.

```
    CREATE INDEX DSN8C10.XEMP2
      ON DSN8C10.EMP
        (EMPNO ASC)
      USING STOGROUP DSN8G120
        PRIQTY 36
        ERASE NO
        CLUSTER
        PARTITION BY RANGE
        (PARTITION 1 ENDING AT('H99'),
         PARTITION 2 ENDING AT('P99'),
         PARTITION 3 ENDING AT('Z99'),
         PARTITION 4 ENDING AT('999'))
      BUFFERPOOL BP1
      CLOSE YES
      COPY YES;
```

Example 3

Create a secondary index, named DSN8C10.XDEPT1, on table DSN8C10.DEPT. Put the entries in ascending order by column DEPTNO. Assume that the data sets are managed by the user with catalog name DSNCAT and each data set is to hold 1GB of data, at most, before the next data set is used.

```
  CREATE UNIQUE INDEX DSN8C10.XDEPT1
    ON DSN8C10.DEPT
      (DEPTNO ASC)
    USING VCAT DSNCAT
    PIECESIZE 1048576 K;
```

Example 4

Assume that a column named EMP_PHOTO with a data type of BLOB(110K) was added to the sample employee table for each employee's photo and auxiliary table EMP_PHOTO_ATAB was created in LOB table space DSN8D12A.PHOTOLTS to store the BLOB data for the column. Create an index named XPHOTO on the auxiliary table. The data sets are to be user-managed with catalog name DSNCAT.

```
  CREATE UNIQUE INDEX DSN8C10.XPHOTO
     ON DSN8C10.EMP_PHOTO_ATAB
     USING VCAT DSNCAT
     COPY YES;
```

In this example, no columns are specified for the key because auxiliary indexes have implicitly generated keys.

Related concepts

Implementing Db2 indexes (Db2 Administration Guide)

Naming conventions
The rules for forming a name depend on the type of the object designated by the name.

CREATE LOB TABLESPACE

The CREATE LOB TABLESPACE statement defines a large object (LOB) table space at the current server. If your data for a table does not fit entirely within a data page, you can define one or more columns as LOB columns. Each LOB column must have an associated auxiliary table in a LOB table space. If the table space for the base table is partitioned, an associated auxiliary table in a LOB table space is required for each LOB column, for each partition of the table space for the base table.

Do not use this statement if Db2 implicitly creates the LOB table space. For more information, see LOB table space implicit creation (Db2 Administration Guide).

For information about explicitly creating an auxiliary table, which defines the relationship between the LOB column of the base table and a LOB table space, see “CREATE AUXILIARY TABLE” on page 1413.

For information about creating table spaces other than LOB table spaces, see "CREATE TABLESPACE" on page 1713.

Invocation for CREATE LOB TABLESPACE

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES RUN behavior is in effect. For more information, see "Authorization IDs and dynamic SQL" on page 94.

Authorization for CREATE LOB TABLESPACE

The privilege set that is defined below must include at least one of the following:

- The CREATETS privilege for the database
- DBADM, DBCTRL, or DBMAINT authority for the database
- SYSADM or SYSCTRL authority
- System DBADM
- Installation SYSOPR authority (when the current SQLID of the process is set to SYSINSTL)

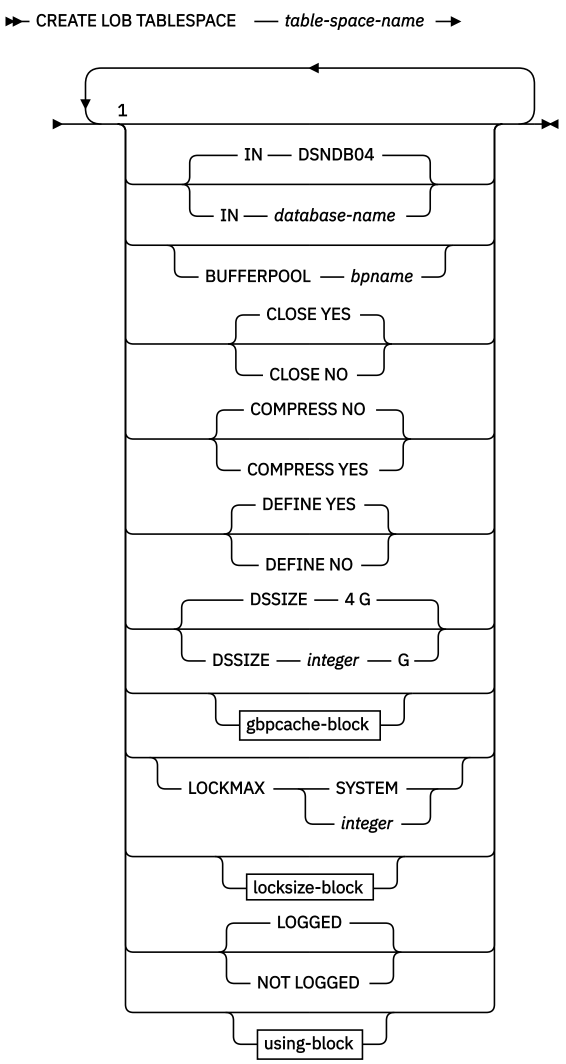
If the database is implicitly created, the database privileges must be on the implicit database or on DSNDB04.

Additional privileges might be required, as explained in the description of the BUFFERPOOL and USING STOGROUP clauses.

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the application is bound in a trusted context with the ROLE AS OBJECT OWNER clause specified, a role is the owner. Otherwise, an authorization ID is the owner.

If the statement is dynamically prepared, the privilege set is the privileges that are held by the SQL authorization ID of the process unless the process is within a trusted context and the ROLE AS OBJECT OWNER clause is specified. In that case, the privileges set is the privileges that are held by the role that is associated with the primary authorization ID of the process.

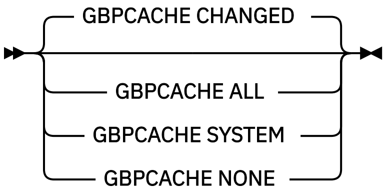
Syntax for CREATE LOB TABLESPACE



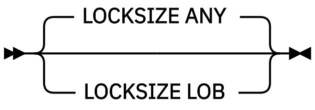
Notes:

[1] The same clause must not be specified more than one time.

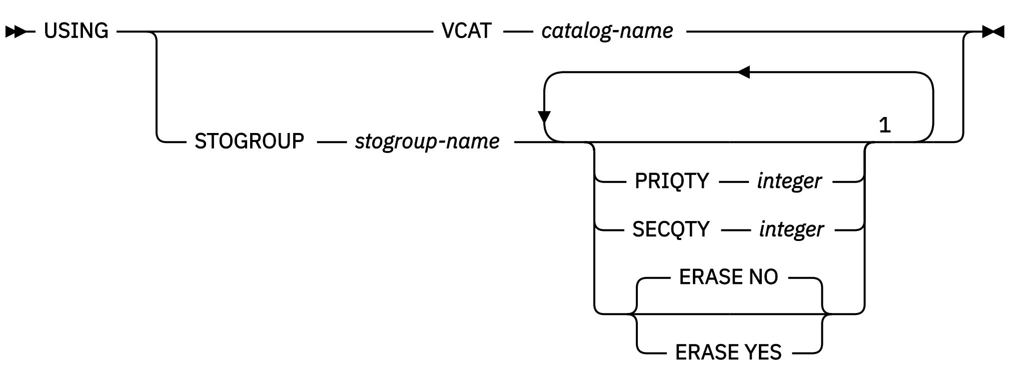
gbpcache-block:



locksize-block:



using-block:



Notes:

[1] The same clause must not be specified more than one time.

table-space-name
Names the table space. The name, qualified with the *database-name* implicitly or explicitly specified by the IN clause, must not identify a table space, index space, or LOB table space that exists at the current server, or that exists in the SYSPENDINGOBJECTS catalog table.

IN *database-name*
Specifies the database in which the table space is created. The LOB table space must be in the same database as its associated base table space. *database-name* must identify a database that exists at the current server and must not specify the following:

- DSNDB06
- A work file database
- A TEMP database
- An implicitly created database

DSNDB04 is the default.

BUFFERPOOL *bpname*
Identifies the buffer pool to be used for the table space and determines the page size of the table space. For 4KB, 8KB, 16KB and 32KB page buffer pools, the page sizes are 4 KB, 8 KB, 16 KB, and 32 KB, respectively. The *bpname* must identify an activated buffer pool, and the privilege set must include SYSADM or SYSCTRL authority, or the USE privilege on the buffer pool.

If you do not specify the BUFFERPOOL clause, the default buffer pool is the buffer pool that is specified in the DEFAULT BUFFER POOL FOR USER LOB DATA field on installation panel DSNTIP1.

See "Naming conventions" on page 79 for more details about *bpname*. See -ALTER BUFFERPOOL (Db2) (Db2 Commands) for a description of active and inactive buffer pools.

CLOSE
When the limit on the number of open data sets is reached, specifies the priority in which data sets are closed.

YES
Eligible for closing before CLOSE NO data sets. CLOSE YES is the default value.

NO
Eligible for closing after all eligible CLOSE YES data sets are closed.

COMPRESS
Specifies whether data compression applies to the LOB data in the table space.

The following conditions are required for LOB compression in Db2 for z/OS:

- Db2 12 must be at function level 500 or higher.

- The zEDC hardware and software must be available and configured in the z/OS system. For more information, see Requirements for zEnterprise Data Compression.

  In data sharing, system performance can degrade dramatically if a member accesses compressed LOB data and the zEDC hardware and software are not configured in z/OS.
- The LOB table space must be associated with a base table that is in a universal table space.
- The total length of the entire LOB must be larger than the defined data page size, otherwise the LOB is not compressed.

For more information, see Compressing LOB data (Db2 Performance).

YES
Specifies data compression. The LOB data is not compressed until the LOAD or REORG utility is run on the table in the table space, or until an insert operation is performed through the insert operation.

NO
Specifies no data compression for the table space.

DEFINE
Specifies when the underlying data sets for the table space are physically created.

YES
The data sets are allocated when the table space is created (when the CREATE LOB TABLESPACE statement is executed). YES is the default.

NO
The data sets are not allocated until data is inserted into the table space. DEFINE NO is applicable only for Db2-managed data sets (USING STOGROUP is specified). DEFINE NO is ignored for user-managed data sets (USING VCAT is specified). Db2 uses the SPACE column in catalog table SYSTABLEPART to record the status of the data sets (undefined or allocated).

DEFINE NO is not recommended if you intend to use any tools outside of Db2 to manipulate data, such as to load data, because data sets might then exist when Db2 does not expect them to exist. When Db2 encounters this inconsistent state, applications will receive an error.

For table spaces that are created with DEFINE NO, point-in-time recover will not work before data sets exist and before a recovery copy exists.

DSSIZE *integer* G

Specifies the maximum size of each data set in *integer* gigabytes for each data set in the LOB table space.

If DSSIZE is not specified, the default value is 4 G. The maximum number of data sets is 254.

To specify a value greater than 4 G, the data sets for the table space must be associated with a DFSMS data class that has been specified with extended format and extended addressability.

For a description of the maximum size of a LOB table space (or the maximum size of LOB data for each column of a base table), see LOB table spaces (Db2 Administration Guide).

GBPCACHE
In a data sharing environment, specifies what pages of the table space are written to the group buffer pool. In a non-data-sharing environment, you can specify GBPCACHE, but it is ignored.

CHANGED
When there is inter-Db2 R/W interest on the table space, updated pages are written to the group buffer pool. When there is no inter-Db2 R/W interest, the group buffer pool is not used. Inter-Db2 R/W interest exists when more than one member in the data sharing group has the table space open, and at least one member has it open for update. GBPCACHE CHANGED is the default.

Recommendation: Use the GBPCACHE CHANGED option. Due to the usage patterns of LOBs, the use of GBPCACHE CHANGED can help avoid excessive and synchronous writes to disk and to the group buffer pool.

If the table space is in a group buffer pool that is defined to be used only for cross-invalidation (GBPCACHE NO), CHANGED is ignored and no pages are cached to the group buffer pool.

ALL

Indicates that pages are to be cached in the group buffer pool as they are read in from DASD.

Exception: In the case of a single updating Db2 member when no other Db2 member has any interest in the page set, no pages are cached in the group buffer pool.

If the table space is in a group buffer pool that is defined to be used only for cross-invalidation (GBPCACHE NO), ALL is ignored and no pages are cached to the group buffer pool.

SYSTEM

Indicates that only changed system pages within the LOB table space are to be cached to the group buffer pool. A system page is a space map page or any other page that does not contain actual data values.

NONE

Indicates that no pages are to be cached to the group buffer pool. Db2 uses the group buffer pool only for cross-invalidation.

LOCKMAX

Specifies the maximum number of locks an application process can hold simultaneously in the table space. If a program requests more than that number, locks are escalated. The locks are released and the intent lock on the table space is promoted to S or X mode.

integer

Specifies the number of locks allowed before escalating, in the range 0 - 2147483647.

Zero (0) indicates that the number of locks on the table space are not counted and escalation does not occur.

SYSTEM

FL 507 Specifies that Db2 determines the maximum number of locks that a program can hold simultaneously in the table space from the SYSIBMADM.MAX_LOCKS_PER_TABLESPACE built-in global variable.

For more information see “MAX_LOCKS_PER_TABLESPACE” on page 331.

The following table summarizes the results of specifying a LOCKSIZE value while omitting LOCKMAX.

LOCKSIZE	Resultant LOCKMAX
ANY	SYSTEM
TABLESPACE, LOB	0

If the lock size is TABLESPACE, LOCKMAX must be omitted, or its value must be 0.

LOCKSIZE

Specifies the size of locks used within the table space and, in some cases, also the threshold at which lock escalation occurs.

ANY

Specifies that Db2 can use any lock size.

FL 507 In most cases, Db2 uses LOCKSIZE LOB LOCKMAX SYSTEM for LOB table spaces. However, when the number of locks acquired for the table space exceeds the maximum number of locks allowed for a table space (the value of the SYSIBMADM.MAX_LOCKS_PER_TABLESPACE built-in global variable), the LOB locks are released and locking is set at the next higher level. For more information, see “MAX_LOCKS_PER_TABLESPACE” on page 331.

If the table space is implicitly created, Db2 uses LOCKSIZE ANY.

TABLESPACE

Specifies table space locks.

LOB

Specifies LOB locks.

LOGGED or NOT LOGGED

Specifies whether changes that are made to the data in the specified table space are recorded in the log. This setting applies to all indexes of the table. Auxiliary indexes inherit the logging attribute from the associated base table space.

LOGGED

Specifies that changes that are made to the data in the specified table space are recorded in the log.

LOGGED is the default.

NOT LOGGED

Specifies that changes that are made to data in the specified table space are not recorded in the log.

NOT LOGGED prevents undo and redo information from being recorded in the log; however, control information for the specified table space will continue to be recorded in the log.

USING block

If you omit USING, the default storage group of the database must exist. The USING clause indicates whether the data set for the table space is defined by you or by Db2. If Db2 is to define the data set, the clause also gives space allocation parameters and an erase rule.

If you omit USING, Db2 defines the data sets using the default storage group of the database and the defaults for PRIQTY, SECQTY, and ERASE.

VCAT *catalog-name*

Specifies that the first data set for the table space is managed by the user, and following data sets, if needed, are also managed by the user.

The data sets are VSAM linear data sets cataloged in the integrated catalog facility catalog that *catalog-name* identifies. For more information about *catalog-name* values, see "Naming conventions" on page 79.

More than one Db2 subsystem can share the integrated catalog facility catalogs with the current server. To avoid the chance of those subsystems attempting to assign the same name to different data sets, specify a *catalog-name* value that is not used by the other Db2 subsystems.

STOGROUP *stogroup-name*

Specifies that Db2 will define and manage the data sets for the table space. Each data set will be defined on a volume of the identified storage group. The values specified (or the defaults) for PRIQTY and SECQTY determine the primary and secondary allocations for the data set. The storage group supplies the name of a volume for the data set and the first-level qualifier for the data set name. The first-level qualifier is also the name of, or an alias[31] for, the integrated catalog facility catalog on which the data set is to be cataloged. The naming conventions for the data set are the same as if the data set is managed by the user. As was mentioned above for VCAT, the first-level qualifier could cause naming conflicts if the local Db2 can share integrated catalog facility catalogs with other Db2 subsystems.

stogroup-name must identify a storage group that exists at the current server. SYSADM or SYSCTRL authority, or the USE privilege on the storage group, is required.

The description of the storage group must include at least one volume serial number, or it must indicate that the choice of volumes is left to Storage Management Subsystem (SMS). If volume serial numbers appear in the description, each must identify a volume that is accessible to z/OS for dynamic allocation of the data set, and all identified volumes must be of the same device type.

The integrated catalog facility catalog used for the storage group must not contain an entry for the first data set of the table space. If the integrated catalog facility catalog is password protected, the description of the storage group must include a valid password.

[31] The alias of an integrated catalog facility catalog.

PRIQTY *integer*

Specifies the minimum primary space allocation for a Db2-managed data set. *integer* must be a positive integer, or -1. In general, when you specify PRIQTY with a positive integer value, the primary space allocation is at least *n* kilobytes, where *n* is the value of *integer*. However, the following exceptions exist:

- For 4KB page sizes, if *integer* is greater than 0 and less than 200, *n* is 200.
- For 8KB page sizes, if *integer* is greater than 0 and less than 400, *n* is 400.
- For 16KB page sizes, if *integer* is greater than 0 and less than 800, *n* is 800.
- For 32KB page sizes, if *integer* is greater than 0 and less than 1600, *n* is 1600.
- For any page size, if *integer* is greater than 67108864, *n* is 67108864.

If you do not specify PRIQTY, or specify PRIQTY with a value of -1, Db2 uses a default value for the primary space allocation; for information on how Db2 determines the default value, see Rules for primary and secondary space allocation (Introduction to Db2 for z/OS).

If you specify PRIQTY, and do not specify a value of -1, Db2 specifies the primary space allocation to access method services using the smallest multiple of *p* KB not less than *n*, where *p* is the page size of the table space. The allocated space can be greater than the amount of space requested by Db2. For example, it could be the smallest number of tracks that will accommodate the request. The amount of storage space requested must be available on some volume in the storage group based on VSAM space allocation restrictions. Otherwise, the primary space allocation will fail. To more closely estimate the actual amount of storage, see DEFINE CLUSTER command (DFSMS Access Method Services for Catalogs).

Executing this statement causes only one data set to be created. However, you might have more data than this one data set can hold. Db2 automatically defines more data sets when they are needed. Regardless of the value in PRIQTY, when a data set reaches its maximum size, Db2 creates a new one. To enable a data set to reach its maximum size without running out of extents, it is recommended that you allow Db2 to automatically choose the value of the secondary space allocations for extents.

If you do choose to explicitly specify SECQTY, to avoid wasting space, use the following formula to make sure that PRIQTY and its associated secondary extent values do not exceed the maximum size of the data set:

```
PRIQTY + (number of extents * SECQTY) <= DSSIZE (implicit or explicit)
```

SECQTY *integer*

Specifies the minimum secondary space allocation for a Db2-managed data set. *integer* must be a positive integer, 0, or -1. If you do not specify SECQTY, or specify SECQTY with a value of -1, Db2 uses a formula to determine a value. For information on the actual value that is used for secondary space allocation, whether you specify a value or not, see Rules for primary and secondary space allocation (Introduction to Db2 for z/OS).

If you specify SECQTY, and do not specify a value of -1, Db2 specifies the secondary space allocation to access method services using the smallest multiple of *p* KB not less than *integer*, where *p* is the page size of the table space. The allocated space can be greater than the amount of space requested by Db2. For example, it could be the smallest number of tracks that will accommodate the request. To more closely estimate the actual amount of storage, see DEFINE CLUSTER command (DFSMS Access Method Services for Catalogs).

ERASE

Indicates whether the Db2-managed data sets for the table space are to be erased when they are deleted during the execution of a utility or an SQL statement that drops the table space.

NO

Does not erase the data sets. Operations involving data set deletion will perform better than ERASE YES. However, the data is still accessible, though not through Db2. This is the default.

YES

Erases the data sets. As a security measure, Db2 overwrites all data in the data sets with zeros before they are deleted.

Notes for CREATE LOB TABLESPACE

Rules for primary and secondary space allocation

You can specify the primary and secondary space allocation or let Db2 choose them. Having Db2 choose the values, especially the secondary space quantity, increases the possibility of reaching the maximum data set size before running out of extents. For more information, see Rules for primary and secondary space allocation (Introduction to Db2 for z/OS).

Determining the number of LOB table spaces to create

For partitioned tables, each partition of the base table requires a separate LOB table space, auxiliary table, and auxiliary index for each LOB column.

Alternative syntax and synonyms

db2z_addpartition

For compatibility with previous Db2 releases or function levels, the following keywords are supported:

- When specifying the logging attributes for a table space, you can specify LOG YES as a synonym for LOGGED, and you can specify LOG NO as a synonym for NOT LOGGED.

Although these keywords are supported as alternatives, they are not the preferred syntax.

Example for CREATE LOB TABLESPACE

Assume that a column named EMP_PHOTO with a data type of BLOB(110K) has been added to the sample employee table for each employee's photo. Create LOB table space PHOTOLTS in database DSN8D12A for the auxiliary table that will hold the BLOB data.

Let Db2 define the data sets for the table space, using storage group DSN8G120. For each data set, the primary space allocation is 3200 kilobytes, and the secondary space allocation is 1600 kilobytes. The data sets do not need to be erased before they are deleted. (Because ERASE NO is the default, the clause does not have to be explicitly specified to get that behavior.)

```
CREATE LOB TABLESPACE PHOTOLTS
  IN DSN8D12A
  USING STOGROUP DSN8G120
    PRIQTY 3200
    SECQTY 1600
  LOCKSIZE LOB
  BUFFERPOOL BP16K0
  GBPCACHE SYSTEM
  NOT LOGGED
  CLOSE NO;
```

Storing LOB data in Db2 tables (Db2 Application programming and SQL)

Creating large objects (Introduction to Db2 for z/OS)

Related reference

CREATE AUXILIARY TABLE

The CREATE AUXILIARY TABLE statement creates an auxiliary table at the current server for storing LOB data.

CREATE MASK

The CREATE MASK statement creates a column mask at the current server. A *column mask* is used for column access control and specifies the value that should be returned for a specified column.

Invocation for CREATE MASK

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES RUN behavior is in effect. For more information, see "Authorization IDs and dynamic SQL" on page 94.

Authorization for CREATE MASK

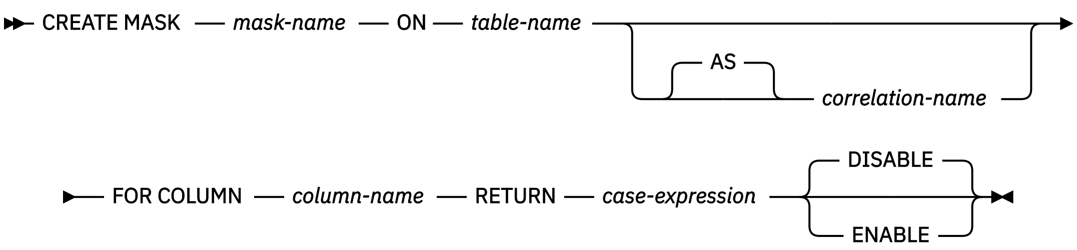
The privilege set that is defined below must include the following authority:

SECADM authority

SECADM authority can create a column mask in any schema. Additional privileges are not needed to reference other objects in the mask definition. For example, the SELECT privilege is not needed query a table, and the EXECUTE privilege is not needed to invoke a user-defined function.

Privilege set: If the statement is embedded in an application program, the privilege set is the set of privileges that are held by the owner of the package. If the statement is dynamically prepared, the privilege set is the set of privileges that are held by the SQL authorization ID of the process. However, if the process is running in a trusted context that is defined with the ROLE AS OBJECT OWNER AND QUALIFIER clause, the privilege set is the set of privileges that are held by the role that is in effect.

Syntax for CREATE MASK



Description for CREATE MASK

mask-name
Specifies the names the column mask. The name, including the implicit or explicit qualifier, must not identify a column mask or a row permission that already exists at the current server.

ON *table-name*
Identifies the table for which the column mask is created. The name must identify a table that exists at the current server. It must not identify any of the following objects:

- An auxiliary table
- A created or declared temporary table
- A view
- A catalog table
- An alias
- A synonym

- A materialized query table or table that is directly or indirectly referenced in the definition of a materialized query table
- A table that was implicitly created for an XML column
- A table that contains a period
- A history table
- An accelerator-only table
- An archive-enabled table
- An archive table

correlation-name

Specifies a correlation name that can be used within *case-expression* to designate the table. For information about *correlation-name*, see "Correlation names" on page 219.

FOR COLUMN *column-name*

Identifies the column to which the mask applies. *column-name* must be an unqualified name that identifies a column of the specified table. A mask must not already exist for the column. The column must not be:

- a LOB column or a distinct type column that is based on a LOB
- an XML column
- defined with a FIELDPROC

RETURN *case-expression*

Specifies a CASE expression that determines the value that is returned for the column. The result of the CASE expression is returned in place of the column value in a row. The result data type, null attribute, data length, subtype, encoding scheme, and CCSID of the CASE expression must be identical to those attributes of the column that is specified by *column-name*. If the data type of *column-name* is a user-defined data type, the result data type of the CASE expression must be the same user-defined type. The CASE expression must not reference any of the following objects:

- A remote object
- The table for which the column mask is being defined
- A created global temporary table or a declared global temporary table
- An auxiliary table
- A table that was implicitly created for an XML column
- A column that is defined with a FIELDPROC
- A LOB column or a distinct type column that is based on a LOB
- An XML column
- A select list notation `*` or *`name`*`.*` in the SELECT clause
- A table function
- A collection-derived table (UNNEST)
- A user-defined function that is defined as not secure
- A function that is not deterministic or that has an external action or is defined with the MODIFIES SQL DATA option
- An aggregate function, unless it is specified in a subquery
- A built-in table function
- An XMLTABLE table function
- An XMLEXISTS predicate
- An OLAP specification
- A ROW CHANGE expression
- A sequence reference

- A host variable, SQL variable, SQL parameter, or trigger transition variable
- A parameter marker
- A table reference that contains a period specification
- A view that includes any of the preceding restrictions in its definition
- An accelerator-only table

The encoding scheme of the table is used to evaluate the CASE expression. Tables and language elements that require multiple encoding scheme evaluation, other than EBCDIC tables with Unicode columns, must not be referenced in the CASE expression. See Determining the encoding scheme and CCSID of a string (Introduction to Db2 for z/OS) for language elements that require multiple evaluation.

If the CASE expression references tables for which row or column access control is active, access controls for those tables are not cascaded.

DISABLE or ENABLE
Specifies that the column mask is to be enabled or disabled for column access control.

DISABLE
Specifies that the column mask is to be disabled for column access control. The column mask will remain disabled regardless of whether column access control is activated for the table.

`DISABLE` is the default.

ENABLE
Specifies that the column mask is to be enabled for column access control. If column access control is not currently active for the table, the column mask will become enabled when column access control is activated for the table. If column access control is currently active for the table, the column mask becomes enabled immediately and all packages and statements in the dynamic statement cache that reference the table are invalidated. For more information, see Changes that invalidate packages (Db2 Application programming and SQL).

Notes for CREATE MASK

How column masks affect queries:
The application of enabled column masks does not interfere with the operations of other clauses within the statement such as the WHERE, GROUP BY, HAVING, SELECT DISTINCT, or ORDER BY. The rows that are returned in the final result table remain the same, except that the values in the resulting rows might have been masked by the column masks. As such, if the masked column also appears in an ORDER BY clause with a *sort-key* expression, the order is based on the original values of the column and the masked values in the final result table might not reflect that order. Similarly, the masked values might not reflect the uniqueness enforced by a SELECT DISTINCT statement. If the masked column is embedded in an expression, the result of the expression might become different because the column mask is applied on the column before the expression evaluation can take place. For example, a column mask on column SSN might change the result of the aggregate function `COUNT(DISTINCT SSN)` because the DISTINCT operation is performed on the unmasked values.

Conflicts between the definition of a column mask and SQL:
A column mask is created as a stand alone object, without knowing all of the contexts in which it might be used. To mask the value of a column in the final result table, the definition of the column mask is merged into a query by Db2. When the definition of the column mask is brought into the context of the statement, it might conflict with certain SQL semantics in the statement. Therefore, in some situations, the combination of the statement and the application of the column mask can return an error. When this happens, either the statement needs to be modified or the column mask must be dropped or re-created with a different definition. See "ALTER TABLE" on page 1227 for those situations in which a bind time error might be issued for the statement.

Column masks and null columns:
If the column is not nullable, the definition of its column mask will not, most likely, consider a null value for the column. After the column access control is activated for the table, if the table is the

null-padded table in an outer join, the value of he column in the final result table might be a null. To ensure that the column mask can mask a null value, if the table is the null-padded table in an outer join, Db2 will add "`WHEN` *target-column* `IS NULL THEN NULL`" as the first WHEN clause to the column mask definition. This forces a null value to always be masked as a null value. For a nullable column, this removes the ability to mask a null value as something else. Example 5 shows this added WHEN clause.

Column mask values for SQL data change statements

When columns are used to derive new values for an INSERT, UPDATE, MERGE, or a SET *transition-variable* assignment statement, the original values of the column, not the masked values, are used to derive the new values. If the columns have column masks, those column masks are applied to ensure that the evaluation of the access control rules at run time masks the column to itself, not to a constant or an expression. This is to ensure that the masked values are the same as the original column values. If a column mask does not mask the column to itself, the existing row is not updated or the new row is not inserted and an error is returned at run time. The rules that are used to apply column masks in order to derive the new values follow the same rules for the final result table of a query.

Column masks that are created before column access control is activated:

The CREATE MASK statement is an independent statement that can be used to create a column access control mask before column access control is activated for a table. The only requirement is that the table and the columns exist before the mask is created. Multiple column masks can be created for a table but a column can have one mask only.

The definition of a mask is stored in the Db2 catalog. Dependency on the table for which the mask is being created and dependencies on other objects referenced in the definition are recorded. No package or dynamic cached statement is invalidated. A column mask can be created as enabled or disabled for column access control. An enabled column mask does not take effect until the ALTER TABLE statement with the ACTIVATE COLUMN ACCESS CONTROL clause is used to activate column access control for the table. SECADM authority is required to issue such an ALTER TABLE statement. A disabled column mask remains ineffective even when column access control is activated for the table. The ALTER MASK statement can be used to alter between ENABLE and DISABLE.

After column access control is activated for a table, when the table is referenced in a data manipulation statement, all enabled column masks that have been created for the table are implicitly applied by Db2 to mask the values returned for the columns referenced in the final result table of the queries or to determine the new values used in the data change statements.

Tip: To avoid multiple invalidations of packages and dynamic cached statements that reference the table, creating column masks before activating column access control for a table .

Column masks that are created after column access control is activated:

The enabled column masks become effective as soon as they are committed. All the packages and dynamic cached statements that reference the table are invalidated. Thereafter, when the table is referenced in a data manipulation statement, all enabled column masks are implicitly applied by Db2 to the statement. Any disabled column mask remains ineffective even when column access control is activated for the table.

No cascaded effect when column or row access control enforced tables are referenced in column mask definitions:

A column mask definition may reference tables and columns that are currently enforced by row or column access control. Access control from those tables and columns are ignored when the table for which the column mask is being created is referenced in a data manipulation statement.

Multiple column masks and row permissions sharing the same environment variables:

Multiple column masks and row permissions can be created for a table. They must use the same set of environment variables. The set of environment variables is determined when the first column mask or row permission is created for the table.

The catalog table SYSENVIRONMENT contains the list of environment variables. The following table shows which environment variable must be the same among the multiple column masks and row permissions.

Table 202. Environment Variables in SYSIBM.SYSENVIRONMENT

Environment variables shown as SYSENVIRONMENT columns	Description	Static create statement	Dynamic create statement	Must be the same among multiple column masks and row permissions?
ENVID	Internal identifier of the environment	Assigned by Db2	Assigned by Db2	Yes
CURRENT_SCHEMA	The qualifier used to qualify unqualified objects such as tables, views. etc.	Package owner	Value of CURRENT_SCHEMA special register	Yes
PATHSCHEMAS	The schema path used to qualify unqualified object such as user-defined functions and CAST functions for user-defined data types.	PATH bind option	Value of CURRENT_PATH special register	Yes
APPLICATION_ ENCODING_ CCSID	The CCSID of the application environment	ENCODING bind option	CURRENT APPLICATION ENCODING SCHEME special register	Yes
ORIGINAL_ ENCODING_ CCSID	The original CCSID of the statement text string	CCSID(n) pre-compiler option or EBCDIC CCSID on DSNTIPF installation panel	CCSID based on DEF ENCODING SCHEME on DSNTIPF installation panel	Yes
DECIMAL_POINT	The decimal point indicator	COMMA or PERIOD precompiler option or DECIMAL POINT IS on DSNTIPF installation panelv	DECIMAL POINT IS on DSNTIPF installation panel	Yes
MIN_DIVIDE_SCALE	The minimum divide scale	MINIMUM DIVIDE SCALE on DSNTIP4 installation panel	MINIMUM DIVIDE SCALE on DSNTIP4 installation panelv	Yesv
STRING_DELIMITER	The string delimiter that is used in COBOL string constants	APOST precompiler option or STRING DELIMITER on DSNTIPF installation panel	STRING DELIMITER on DSNTIPF installation panel	No
SQL_ STRING_ DELIMITER	The SQL string delimiter that is used in constants	APOSTSQL pre-compiler option or SQL STRING DELIMITER on DSNTIPF installation panel	SQL STRING DELIMITER on DSNTIPF installation panel	Yes
MIXED_DATA	Uses mixed DBCS data	MIXED DATA on DSNTIPF installation panel	MIXED DATA on DSNTIPF installation panel	Yes

Table 202. Environment Variables in SYSIBM.SYSENVIRONMENT (continued)

Environment variables shown as SYSENVIRONMENT columns	Description	Static create statement	Dynamic create statement	Must be the same among multiple column masks and row permissions?
DECIMAL_ ARITHMETIC	The rules that are to be used for CURRENT PRECISION and when both operands in a decimal operation have a precision of 15 or less.	DEC(15) or DEC(31) precompiler option or DECIMAL ARITHMETIC on DSNTIP4 installation panel	DECIMAL ARITHMETIC on DSNTIP4 installation panel	Yes
DATE_FORMAT	The date format	DATE pre-compiler option or DATE FORMAT on DSNTIP4 installation panel	DATE FORMAT on DSNTIP4 installation panel	Yes
TIME_FORMAT	The time format	TIME pre-compiler option or TIME FORMAT on DSNTIP4 installation panel	TIME FORMAT on DSNTIP4 installation panel	Yes
FLOAT_FORMAT	The floating point format	FLOAT (S390 | IEEE) pre-compiler option or default of FLOAT S390	Default of FLOAT S390	No
HOST_LANGUAGE	The host language	HOST pre-compiler option or LANGUAGE DEFAULT on DSNTIPF installation panel	LANGUAGE DEFAULT on DSNTIPF installation panel	No
CHARSET	The character set	CCSID(n) pre-compiler option or EBCDIC CCSID on DSNTIPF installation panel	EBCDIC CCSID on DSNTIPF installation panel	No
FOLD	FOLD is only applicable when HOST_LANGUAGE is C or CPP. Otherwise FOLD is blank.	HOST(C(FOL D) precompiler option or default of NO FOLD	default of NO FOLD	No
ROUNDING	The rounding mode that is used when arithmetic and casting operations are performed on DECFLOAT data.	ROUNDING bind option	CURRENT DECFLOAT ROUNDING MODE special register	Yes

Table 202. Environment Variables in SYSIBM.SYSENVIRONMENT (continued)

Environment variables shown as SYSENVIRONMENT columns	Description	Static create statement	Dynamic create statement	Must be the same among multiple column masks and row permissions?
Note: In a data sharing environment, if a separate DSNHDECP module is provided for each member of the group, the DSNHDECP settings for each environment variable should be the same in all members of the data sharing group, otherwise an error might be issued when multiple column masks or row permissions are created.				

Ordinary SQL identifiers specified in a static CREATE MASK statement in a COBOL application:
If the CREATE MASK statement is a static statement in a COBOL application, the ordinary SQL identifiers used in the column mask definition must not follow the rules for naming COBOL words. They must follow the rules for naming "Identifiers in SQL" on page 77. For example, the COBOL word 1ST-TIME is not allowed as an ordinary SQL identifier in a column mask definition; change it to FIRST_TIME or put it in the delimiters.

Encoding scheme and CCSIDs of the data manipulation statement after column masks are applied:
The encoding scheme and CCSIDs of the data manipulation statement are not affected by the column masks that are implicitly applied by Db2 for the column access control. For a target table or a referenced table that is not an EBCDIC table with Unicode columns, the column mask definition is evaluated using its table's encoding scheme and CCSIDs. For a target table or a referenced table that is an EBCDIC table with Unicode columns, the column mask definition is evaluated using the rules for multiple encoding schemes.

Consideration for Db2 limits:
If the data manipulation statement already approaches some Db2 limits in the statement, it should be noted that the more enabled column masks and enabled row permissions are created, the more likely they would impact some limits. For example, they may cause the statement to exceed the maximum total length (32600 bytes) of columns of a query operation requiring sort and evaluating aggregate functions (MULTIPLE DISTINCT and GROUP BY). This is because the enabled column mask and enabled row permission definitions are implicitly merged into the statement when the table is referenced in a data manipulation statement. See "Limits in Db2 for z/OS" in SQL Reference for the limits of a statement.

Restrictions involving pending definition changes:
CREATE MASK is not allowed if the mask is defined on a table or references a table that has pending definition changes.

Examples for CREATE MASK

In the following examples, the data type of column SSN is VARCHAR(11).

Example 1
After column access control is activated for table EMPLOYEE, Paul from the payroll department can see the social security number of the employee whose employee number is 123456. Mary who is a manager can see the last four characters only of the social security number. Peter who is neither cannot see the social security number.

```
CREATE MASK SSN_MASK ON EMPLOYEE
   FOR COLUMN SSN RETURN
     CASE
          WHEN (VERIFY_GROUP_FOR_USER(SESSION_USER,'PAYROLL') = 1)
                  THEN SSN
          WHEN (VERIFY_GROUP_FOR_USER(SESSION_USER,'MGR') = 1)
           THEN 'XXX-XX-' || SUBSTR(SSN,8,4)
          ELSE NULL
     END
   ENABLE;
```

```
COMMIT;

ALTER TABLE EMPLOYEE
    ACTIVATE COLUMN ACCESS CONTROL;

COMMIT;

SELECT SSN FROM EMPLOYEE
    WHERE EMPNO = 123456;
```

Example 2

In the SELECT statement, column SSN is embedded in an expression that is the same as the expression used in the column mask SSN_MASK. After column access control is activated for table EMPLOYEE, the column mask SSN_MASK is applied to column SSN in the SELECT statement. For this particular expression, the SELECT statement produces the same result as before column access control is activated for all users. The user can replace the expression in the SELECT statement with column SSN to avoid the same expression gets evaluated twice.

```
CREATE MASK SSN_MASK ON EMPLOYEE
    FOR COLUMN SSN RETURN
      CASE
           WHEN (1 = 1)
            THEN 'XXX-XX-' || SUBSTR(SSN,8,4)
           ELSE NULL
      END
    ENABLE;

COMMIT;

ALTER TABLE EMPLOYEE
    ACTIVATE COLUMN ACCESS CONTROL;

COMMIT;

SELECT 'XXX-XX-' || SUBSTR(SSN,8,4) FROM EMPLOYEE
    WHERE EMPNO = 123456;
```

Example 3

A state government conducted a survey for the library usage of the households in each city. Fifty households in each city were sampled in the survey. Each household was given an option, opt-in or opt-out, whether to show their usage in any reports generated from the result of the survey.

A SELECT statement is used to generate a report to show the average hours used by households in each city. Column mask CITY_MASK is created to mask the city name based on the opt-in or opt-out information chosen by the sampled households. However, after column access control is activated for table LIBRARY_ USAGE, the SELECT statement receives a bind time error. This is because column mask CITY_MASK references another column LIBRARY_OPT and LIBRARY_OPT does not identify a grouping column.

```
CREATE MASK CITY_MASK ON LIBRARY_USAGE
    FOR COLUMN CITY RETURN
      CASE
           WHEN (LIBRARY_OPT = 'OPT-IN')
            THEN CITY
           ELSE ' '
      END
    ENABLE;

COMMIT;

ALTER TABLE LIBRARY_USAGE
   ACTIVATE COLUMN ACCESS CONTROL;

COMMIT;

SELECT CITY, AVG(LIBRARY_TIME) FROM LIBRARY_USAGE
   GROUP BY CITY;
```

Example 4

Employee with EMPNO 123456 earns bonus $8000 and salary $80000 in May. When the manager retrieves his salary, the manager receives his salary, not the null value. This is because of no cascaded effect when column mask SALARY_MASK references column BONUS for which column mask BONUS_MASK is defined.

```
CREATE MASK SALARY_MASK ON EMPLOYEE
   FOR COLUMN SALARY RETURN
       CASE
            WHEN (BONUS < 10000)
             THEN SALARY
            ELSE NULL
       END
   ENABLE;

COMMIT;

CREATE MASK BONUS_MASK ON EMPLOYEE
   FOR COLUMN BONUS RETURN
       CASE
            WHEN (BONUS > 5000)
             THEN NULL
            ELSE BONUS
       END
   ENABLE;

COMMIT;

ALTER TABLE EMPLOYEE
    ACTIVATE COLUMN ACCESS CONTROL;

COMMIT;

SELECT SALARY FROM EMPLOYEE
    WHERE EMPNO = 123456;
```

Example 5

This example shows Db2 adds "WHEN target-column IS NULL THEN NULL" as the first WHEN clause to the column mask definition then merges the column mask definition into the statement.

```
CREATE EMPLOYEE (EMPID INT,
                 DEPTID CHAR(8),
                 SALARY DEC(9,2) NOT NULL,
                 BONUS DEC(9,2));

CREATE MASK SALARY_MASK ON EMPLOYEE
    FOR COLUMN SALARY RETURN
       CASE
            WHEN SALARY < 10000
             THEN CAST(SALARY*2 AS DEC(9,2))
            ELSE COALESCE(CAST(SALARY/2 AS DEC(9,2)), BONUS)
       END
    ENABLE;

COMMIT;

CREATE MASK BONUS_MASK ON EMPLOYEE
    FOR COLUMN BONUS RETURN
      CASE
          WHEN BONUS > 1000
           THEN BONUS
          ELSE NULL
      END
    ENABLE;

COMMIT;

ALTER TABLE EMPLOYEE
    ACTIVATE COLUMN ACCESS CONTROL;

COMMIT;

SELECT SALARY FROM DEPT
    LEFT JOIN EMPLOYEE ON DEPTNO = DEPTID;

/* When SALARY_MASK is merged into the above statement,
 * 'WHEN SALARY IS NULL THEN NULL' is added as the
 * first WHEN clause, as follows:
 */

SELECT CASE WHEN SALARY IS NULL THEN NULL
            WHEN SALARY < 10000 THEN CAST(SALARY*2 AS DEC(9,2))
```

```
             ELSE COALESCE(CAST(SALARY/2 AS DEC(9,2)), BONUS)
        END SALARY
        FROM DEPT
          LEFT JOIN EMPLOYEE ON DEPTNO = DEPTID;
```

Creating column masks (Managing Security)

CREATE PERMISSION

The CREATE PERMISSION statement creates a row permission for row access control at the current server.

Invocation for CREATE PERMISSION

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES RUN behavior is in effect. For more information, see “Authorization IDs and dynamic SQL” on page 94.

Authorization for CREATE PERMISSION

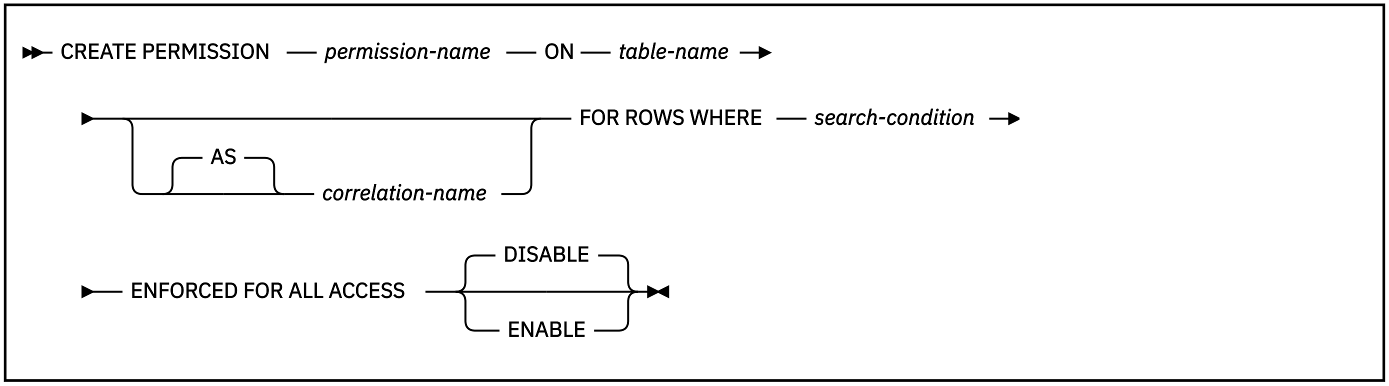
The privilege set that is defined below must include the following authority:

- SECADM authority

SECADM authority can create a row permission in any schema. Additional privileges are not needed to reference other objects in the permission definition. For example, the SELECT privilege is not needed to retrieve from a table, and the EXECUTE privilege is not needed to invoke a user-defined function.

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the package. If the statement is dynamically prepared, the privilege set is the set of privileges that are held by the SQL authorization ID of the process. However, if it is running in a trusted context defined with the ROLE AS OBJECT OWNER AND QUALIFIER clause, the privilege set is the set of privileges that are held by the role in effect.

Syntax for CREATE PERMISSION



Description for CREATE PERMISSION

permission-name

Names the row permission for row access control. The name, including the implicit or explicit qualifier, must not identify a row permission or a column mask that already exists at the current server

ON ***table-name***

Identifies the table on which the row permission is created. The name must identify a table that exists at the current server. It must not identify any of the following objects:

- An auxiliary table
- A created or declared temporary table
- A view
- A catalog table
- An alias
- A synonym
- A materialized query table or table that is directly or indirectly referenced in the definition of a materialized query table
- A table that was implicitly created for an XML column
- A table that contains a period
- A history table
- An accelerator-only table
- An archive-enabled table
- An archive table
- A table that has a security label column.

correlation-name

Can be used within *search-condition* to designate the table. For the explanation of *correlation-name*, see "Correlation names" on page 219.

FOR ROWS WHERE

Indicates that a row permission is created. A row permission specifies a search condition under which rows of the table can be accessed.

search-condition

Specifies a condition that can be true, false, or unknown for a row of the table. *search-condition* follows the same rules that are used by the search condition in a WHERE clause of a subselect. In addition, the search condition must not reference any of the following objects:

- A remote object
- The table for which the row permission is being defined
- A table that has a security label column
- A created global temporary table or a declared global temporary table
- An auxiliary table
- A table that was implicitly created for an XML column
- A collection-derived table (UNNEST)
- A table function
- A host variable, SQL variable, SQL parameter, or trigger transition variable
- A user-defined function that is defined as not secure
- A function that is not deterministic or that has an external action or is defined with the MODIFIES SQL DATA option
- A parameter marker
- A column that is defined with a FIELDPROC
- A LOB column or a distinct type column that is based on a LOB
- An XML column
- An XMLEXISTS predicate
- An OLAP specification

- A ROW CHANGE expression
- A sequence reference
- A select list notation * or *name*.* in the SELECT clause
- A table reference that contains a period specification
- A view that includes any of the preceding restrictions in its definition

The encoding scheme of the table is used to evaluate the *search-condition*. Tables and language elements that require multiple encoding scheme evaluation, other than EBCDIC tables with Unicode columns, must not be referenced in the *search-condition*. See Determining the encoding scheme and CCSID of a string (Introduction to Db2 for z/OS) for those language elements.

If the *search-condition* references tables for which row or column access control is activated, access control from those tables is not cascaded.

ENFORCED FOR ALL ACCESS
Specifies that the row permission applies to all references of the table. If row access control is activated for the table, when the table is referenced in a data manipulation statement, Db2 implicitly applies the row permission to control the access of the table. If the reference of the table is for a fetch operation such as SELECT, the application of the row permission determines what set of rows can be retrieved by the user who requested the fetch operation. If the reference of the table is for a data change operation such as INSERT, the application of the row permission determines whether all rows to be changed are insertable or updatable by the user who requested the data change operation.

DISABLE or ENABLE
Specifies that the row permission is to be enabled or disabled for row access control.

DISABLE
Specifies that the row permission is to be disabled for row access control. The row permission will remain ineffective regardless the row access control is activated for the table or not.

DISABLE is the default.

ENABLE
Specifies that the row permission is to be enabled for row access control. If row access control is not currently activated for the table, the row permission will become effective when row access control is activated for the table. If row access control is currently activated for the table, the row permission becomes effective immediately and all packages and dynamic cached statements that reference the table are invalidated. For more information, see Changes that invalidate packages (Db2 Application programming and SQL).

Notes for CREATE PERMISSION

How row permission are applied and how they affect certain statements:
See the ALTER TABLE statement with the ACTIVATE ROW ACCESS CONTROL clause for information on how to activate row access control and how row permissions are applied. See the description of subselect for information on how the application of row permissions affects the fetch operation. See the data change statements for information on how the application of row permissions affects the data change operation.

Row permissions that are created before row access control is activated for a table:
The CREATE PERMISSION statement is an independent statement that can be used to create a row permission before row access control is activated for a table. The only requirement is that the table and the columns exist before the permission is created. Multiple row permissions can be created for a table.

The definition of the row permission is stored in the Db2 catalog. Dependency on the table for which the permission is being created and dependencies on other objects referenced in the definition are recorded. No package or dynamic cached statement is invalidated. A row permission can be created as enabled or disabled for row access control. An enabled row permission does not take effect until the ALTER TABLE statement with the ACTIVATE ROW ACCESS CONTROL clause is used to activate row access control for the table. A disabled row permission remains ineffective even when row access control is activated for the table. The ALTER PERMISSION statement can be used to alter between ENABLE and DISABLE.

After row access control is activated for a table, when the table is referenced in a data manipulation statement, all enabled row permissions that are defined for the table are implicitly applied by Db2 to control access to the table.

Tip: Create row permissions before activating row access control for a table to avoid multiple invalidations of packages and dynamic cached statements that reference the table.

Row permissions that are created after row access control is activated for a table:

An enabled row permission becomes effective as soon as it is committed. All the packages and dynamic cached statements that reference the table are invalidated. Thereafter, when the table is referenced in a data manipulation statement, all enabled row permissions are implicitly applied to the statement. Any disabled row permission remains ineffective even when row access control is activated for the table.

No cascaded effect when row or column access control enforced tables are referenced in row permission definitions:

A row permission definition may reference tables and columns that are currently enforced by row or column access control. Access control from those tables are ignored when the table for which the row permission is being created is referenced in a data manipulation statement.

Multiple column masks and row permissions sharing the same environment variables:

Multiple column masks and row permissions can be created for a table. They must use the same set of environment variables. The set of environment variables is determined when the first column mask or row permission is created for the table.

The catalog table SYSENVIRONMENT contains the list of environment variables. The following table shows which environment variable must be the same among the multiple column masks and row permissions.

Table 203. Environment Variables in SYSIBM.SYSENVIRONMENT

Environment variables shown as SYSENVIRONMENT columns	Description	Static create statement	Dynamic create statement	Must be the same among multiple column masks and row permissions?
ENVID	Internal identifier of the environment	Assigned by Db2	Assigned by Db2	Yes
CURRENT_SCHEMA	The qualifier used to qualify unqualified objects such as tables, views. etc.	Package owner	Value of CURRENT_SCHEMA special register	Yes
PATHSCHEMAS	The schema path used to qualify unqualified object such as user-defined functions and CAST functions for user-defined data types.	PATH bind option	Value of CURRENT_PATH special register	Yes
APPLICATION_ ENCODING_ CCSID	The CCSID of the application environment	ENCODING bind option	CURRENT APPLICATION ENCODING SCHEME special register	Yes

Table 203. Environment Variables in SYSIBM.SYSENVIRONMENT (continued)

Environment variables shown as SYSENVIRONMENT columns	Description	Static create statement	Dynamic create statement	Must be the same among multiple column masks and row permissions?
ORIGINAL_ ENCODING_ CCSID	The original CCSID of the statement text string	CCSID(n) pre-compiler option or EBCDIC CCSID on DSNTIPF installation panel	CCSID based on DEF ENCODING SCHEME on DSNTIPF installation panel	Yes
DECIMAL_POINT	The decimal point indicator	COMMA or PERIOD precompiler option or DECIMAL POINT IS on DSNTIPF installation panelv	DECIMAL POINT IS on DSNTIPF installation panel	Yes
MIN_DIVIDE_SCALE	The minimum divide scale	MINIMUM DIVIDE SCALE on DSNTIP4 installation panel	MINIMUM DIVIDE SCALE on DSNTIP4 installation panelv	Yesv
STRING_DELIMITER	The string delimiter that is used in COBOL string constants	APOST precompiler option or STRING DELIMITER on DSNTIPF installation panel	STRING DELIMITER on DSNTIPF installation panel	No
SQL_ STRING_ DELIMITER	The SQL string delimiter that is used in constants	APOSTSQL pre-compiler option or SQL STRING DELIMITER on DSNTIPF installation panel	SQL STRING DELIMITER on DSNTIPF installation panel	Yes
MIXED_DATA	Uses mixed DBCS data	MIXED DATA on DSNTIPF installation panel	MIXED DATA on DSNTIPF installation panel	Yes
DECIMAL_ ARITHMETIC	The rules that are to be used for CURRENT PRECISION and when both operands in a decimal operation have a precision of 15 or less.	DEC(15) or DEC(31) precompiler option or DECIMAL ARITHMETIC on DSNTIP4 installation panel	DECIMAL ARITHMETIC on DSNTIP4 installation panel	Yes
DATE_FORMAT	The date format	DATE pre-compiler option or DATE FORMAT on DSNTIP4 installation panel	DATE FORMAT on DSNTIP4 installation panel	Yes
TIME_FORMAT	The time format	TIME pre-compiler option or TIME FORMAT on DSNTIP4 installation panel	TIME FORMAT on DSNTIP4 installation panel	Yes

Table 203. Environment Variables in SYSIBM.SYSENVIRONMENT (continued)

Environment variables shown as SYSENVIRONMENT columns	Description	Static create statement	Dynamic create statement	Must be the same among multiple column masks and row permissions?
FLOAT_FORMAT	The floating point format	FLOAT (S390 | IEEE) pre-compiler option or default of FLOAT S390	Default of FLOAT S390	No
HOST_LANGUAGE	The host language	HOST pre-compiler option or LANGUAGE DEFAULT on DSNTIPF installation panel	LANGUAGE DEFAULT on DSNTIPF installation panel	No
CHARSET	The character set	CCSID(n) pre-compiler option or EBCDIC CCSID on DSNTIPF installation panel	EBCDIC CCSID on DSNTIPF installation panel	No
FOLD	FOLD is only applicable when HOST_LANGUAGE is C or CPP. Otherwise FOLD is blank.	HOST(C(FOL D) precompiler option or default of NO FOLD	default of NO FOLD	No
ROUNDING	The rounding mode that is used when arithmetic and casting operations are performed on DECFLOAT data.	ROUNDING bind option	CURRENT DECFLOAT ROUNDING MODE special register	Yes

Note: In a data sharing environment, if a separate DSNHDECP module is provided for each member of the group, the DSNHDECP settings for each environment variable should be the same in all members of the data sharing group, otherwise an error might be issued when multiple column masks or row permissions are created.

Ordinary SQL identifiers specified in a static CREATE PERMISSION statement in a COBOL application:

If the CREATE PERMISSION statement is a static statement in a COBOL application, the ordinary SQL identifiers used in the row permission definition must not follow the rules for naming COBOL words (DSNH20474, reason code 14). They must follow the rules for naming SQL identifiers as described in the topic “SQL identifiers” in Db2 SQL Reference. For example, the COBOL word 1ST-TIME is not allowed as an ordinary SQL identifier in a row permission definition; change it to FIRST_TIME or put it in the delimiters.

Encoding scheme and CCSIDs of the data manipulation statement after row permissions are applied:

The encoding scheme and CCSIDs of the data manipulation statement are not affected by the row permissions that are implicitly applied by Db2 for the row access control. For a target table or a referenced table that is not an EBCDIC table with Unicode columns, the row permission definition is evaluated using its table's encoding scheme and CCSIDs. For a target table or a referenced table that is an EBCDIC table with Unicode columns, the row permission definition is evaluated using the rules for multiple encoding schemes.

Consideration for Db2 limits:

If the data manipulation statement already approaches some Db2 limits in the statement, it should be noted that the more enabled row permissions and enabled column masks are created, the more likely they would impact some limits. For example, they may cause the statement to exceed the maximum total length (32600 bytes) of columns of a query operation requiring sort and evaluating aggregate functions (MULTIPLE DISTINCT and GROUP BY). This is because the enabled column mask and enabled row permission definitions are implicitly merged into the statement when the table is referenced in a data manipulation statement. See "Limits in Db2 for z/OS" in SQL Reference for the limits of a statement.

Restrictions involving pending definition changes:

CREATE PERMISSION is not allowed if the permission is defined on a table or references a table that has pending definition changes.

Examples for CREATE PERMISSION

Example 1

Secure user-defined function ACCOUNTING_UDF in row permission SALARY_ROW_ACCESS processes the sensitive data in column SALARY. After row access control is activated for table EMPLOYEE, Accountant Paul retrieves the salary of employee with EMPNO 123456 who is making $100,000 a year. Paul may or may not see the row depending on the output value from user-defined function ACCOUNTING_UDF.

```
CREATE PERMISSION SALARY_ROW_ACCESS ON EMPLOYEE
   FOR ROWS WHERE VERIFY_GROUP_FOR_USER(SESSION_USER,'MGR','ACCOUNTING') = 1
            AND
            ACCOUNTING_UDF(SALARY) < 120000
   ENFORCED FOR ALL ACCESS
   ENABLE;

COMMIT;

ALTER TABLE EMPLOYEE
    ACTIVATE ROW ACCESS CONTROL;

COMMIT;

SELECT SALARY FROM EMPLOYEE
   WHERE EMPNO = 123456;
```

Example 2

The tellers in a bank can only access customers from their branch. All tellers have secondary authorization ID TELLER. The customer service representatives are allowed to access all customers of the bank. All customer service representatives have secondary authorization ID CSR. A row permission is created for each group of personnel in the bank accordingly to the access rule defined by SECADM authority. After row access control is activated for table CUSTOMER, in the SELECT statement the search conditions of both row permissions are merged into the statement and they are combined with the logic OR operator to control the set of rows accessible by each group.

```
CREATE PERMISSION TELLER_ROW_ACCESS ON CUSTOMER
   FOR ROWS WHERE VERIFY_GROUP_FOR_USER(SESSION_USER,'TELLER') = 1
            AND
            BRANCH = (SELECT HOME_BRANCH FROM INTERNAL_INFO
                         WHERE EMP_ID = SESSION_USER)
    ENFORCED FOR ALL ACCESS
    ENABLE;

COMMIT;

CREATE PERMISSION CSR_ROW_ACCESS ON CUSTOMER
   FOR ROWS WHERE VERIFY_GROUP_FOR_USER(SESSION_USER,'CSR') = 1
   ENFORCED FOR ALL ACCESS
   ENABLE;

COMMIT;

ALTER TABLE CUSTOMER
   ACTIVATE ROW ACCESS CONTROL;
```

```
COMMIT;

SELECT * FROM CUSTOMER;
```

Row permission (Managing Security)

Naming conventions
The rules for forming a name depend on the type of the object designated by the name.

Related tasks

Creating row permissions (Managing Security)

CREATE PROCEDURE

The CREATE PROCEDURE statement registers a stored procedure with a database server. You can register the following types of procedures with this statement, each of which is described separately.

You can create the following types of stored procedures:

Native SQL procedures

The procedure body is written exclusively in SQL statements, including SQL procedural language (SQL PL) statements. The procedure body is contained and specified in the procedure definition along with various attributes of the procedure. A package is generated for a native SQL procedure. It contains the procedure body, including control statements. It might sometimes also include statements generated by Db2. Each time that the procedure is invoked, the package executes one or more times.

All SQL procedures that are created with a CREATE PROCEDURE statement that does not specify the FENCED or EXTERNAL options are native SQL procedures. More capabilities are supported for native SQL procedures, they usually perform better than external SQL procedures, and no associated C program is generated for them.

See "CREATE PROCEDURE (SQL - native)" on page 1602.

External stored procedures

The procedure body is an external program that is written in a programming language such as C, C++, COBOL, or Java and it can contain SQL statements. The source code for an external stored procedure is separate from the procedure definition and is bound into a package. The name of the external executable is specified as part of the procedure definition along with various attributes of the procedure. All programs must be designed to run using Language Environment. Your COBOL and C++ stored procedures can contain object-oriented extensions. Each time that the stored procedure is invoked, the logic in the procedure controls whether the package executes and how many times.

For more information, see Creating external stored procedures (Db2 Application programming and SQL).

See "CREATE PROCEDURE (external)" on page 1575.

External SQL procedures (deprecated)

The procedure body is written exclusively in SQL statements, including SQL procedural language (SQL PL) statements. The procedure body is specified in the procedure definition along with various attributes of the procedure. A C program and an associated package are generated for an external SQL procedure. It contains the procedure body, including control statements. It might sometimes also include statements generated by Db2.Each time that the procedure is invoked, the package executes one or more times.

Native SQL procedures are more fully supported, easier to maintain, and typically perform better than external SQL procedures, which are deprecated.

See "CREATE PROCEDURE (SQL - external) (deprecated)" on page 1592.

Notes for ALL procedure types

Owner privileges

The owner is authorized to call the procedure (EXECUTE privilege) and grant others the privilege to call the procedure. See "GRANT (function or procedure privileges)" on page 1965. For more information about ownership of the object, see "Authorization, privileges, permissions, masks, and object ownership" on page 90.

Defining the parameters

The input parameters for the procedure are specified as a list within parentheses.

A procedure can have no input parameters. In this case, an empty set of parentheses can be specified or omitted, for example:

```
CREATE PROCEDURE ASSEMBLY_PARTS()
```

or

```
CREATE PROCEDURE ASSEMBLY_PARTS
```

Choosing data types for parameters:

When you choose the data types of the parameters for your stored procedure, consider the rules of promotion that can affect the values of the parameters. (See "Promotion of data types" on page 128). For example, a constant that is one of the input arguments to the stored procedure might have a built-in data type that is different from the data type that the procedure expects, and more significantly, might not be promotable to that expected data type. Based on the rules of promotion, using the following data types for parameters is recommended:

- INTEGER instead of SMALLINT
- DOUBLE instead of REAL
- VARCHAR instead of CHAR
- VARGRAPHIC instead of GRAPHIC
- VARBINARY instead of BINARY

For portability of functions across platforms that are not Db2 for z/OS, do not use the following data types, which might have different representations on different platforms:

- FLOAT. Use DOUBLE or REAL instead.
- NUMERIC. Use DECIMAL instead.

Specifying the encoding scheme for parameters

The encoding scheme of all of the parameters with a character or graphic string data type (both input and output parameters) must be the same—either all ASCII, all EBCDIC, or all UNICODE. If you specify the encoding scheme on the individual parameters, instead of using the PARAMETER CCSID to specify it for all parameters at once or allowing the encoding scheme to default to the system value, ensure that they all agree.

Specifying AS LOCATOR for a parameter

Passing a locator instead of a value can result in fewer bytes being passed in or out of the procedure. This can be useful when the value of the parameter is very large. The AS LOCATOR clause specifies that a locator to the value of the parameter is passed instead of the actual value. Specify AS LOCATOR only for parameters with a LOB data type or a distinct type that is based on a LOB data type.

AS LOCATOR cannot be specified for SQL procedures.

Accessing result sets from nested stored procedures

A stored procedure, user-defined function, or trigger cannot call a stored procedure that is defined with the COMMIT ON RETURN clause.

Special registers in procedures

The settings of the special registers of the caller are inherited by the procedure when called and restored upon return to the caller. Special registers may be changed within a procedure, but these changes do not affect the caller.

Global variables in procedures

The content of global variables that are referenced in routines is inherited from the caller. Global variables can be modified in stored procedures, except when the stored procedure is called by a trigger or a function.

If the procedure contains references to global variables, the level of SQL data access must be at least CONTAINS SQL. If the procedure contains SQL statements that modify global variables, the level of SQL data access must be MODIFIES SQL DATA.

Procedures (Introduction to Db2 for z/OS)

Related tasks

Creating stored procedures (Db2 Application programming and SQL)

CREATE PROCEDURE (external)

The CREATE PROCEDURE statement defines an external stored procedure at the current server.

Invocation for CREATE PROCEDURE (external)

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES RUN behavior is in effect. For more information, see "Authorization IDs and dynamic SQL" on page 94.

Authorization for CREATE PROCEDURE (external)

To create a new procedure in the implicit or explicit schema, the privilege set that is defined below must include at least one of the following:

- The CREATEIN privilege on the schema
- SYSADM or SYSCTRL authority
- System DBADM
- Installation SYSOPR authority (when the current SQLID of the process is set to SYSINSTL)

The authorization ID that matches the schema name implicitly has the CREATEIN privilege on the schema.

FL 507To replace a procedure, the privilege set that is defined below must include at least one of the following:

- Ownership of the procedure
- Both the DROPIN and CREATEIN privileges on the schema
- System DBADM authority
- SYSCTRL authority
- SYSADM authority
- Installation SYSOPR authority (when the current SQLID of the process is set to SYSINSTL)

If the authorization ID that is used to create the procedure has the installation SYSADM authority or the installation SYSOPR authority and if the current SQLID is set to SYSINSTL, the procedure is identified as system-defined procedure.

When LANGUAGE is JAVA and a *jar-name* is specified in the EXTERNAL NAME clause, the privilege set must include USAGE on the JAR file, the Java archive file.

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the owner is a role, the implicit schema match does not apply and this role needs to include one of the previously listed conditions.

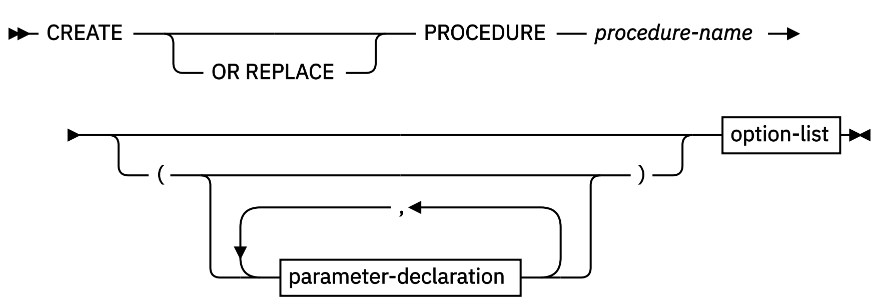
If the statement is dynamically prepared and is not running in a trusted context for which the ROLE AS OBJECT OWNER clause is specified, the privilege set is the set of privileges that are held by the SQL authorization ID of the process. If the schema name is not the same as the SQL authorization ID of the process, one of the following conditions must be met:

- The privilege set includes SYSADM or SYSCTRL authority.
- The SQL authorization ID of the process has the CREATEIN privilege on the schema.

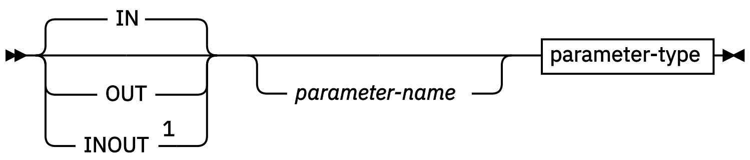
The authorization ID that is used to create the stored procedure must have authority to define programs that run in the specified WLM environment. For more information, see Managing authorizations for creation of stored procedures in WLM environments (Managing Security).

Also, if the stored procedure uses a user-defined type as a parameter, this authorization ID must have the USAGE privilege on each parameter that is defined as a user-defined type.

Syntax for CREATE PROCEDURE (external)



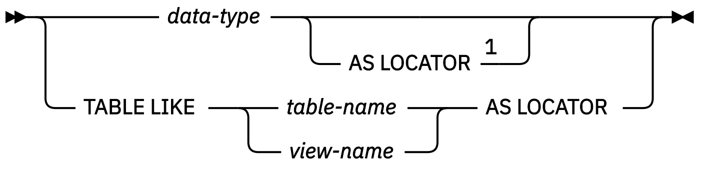
parameter-declaration:



Notes:

[1] For a REXX stored procedure, only one parameter can have type OUT or INOUT. That parameter must be declared last.

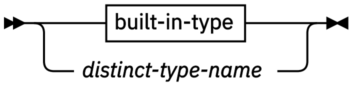
parameter-type:



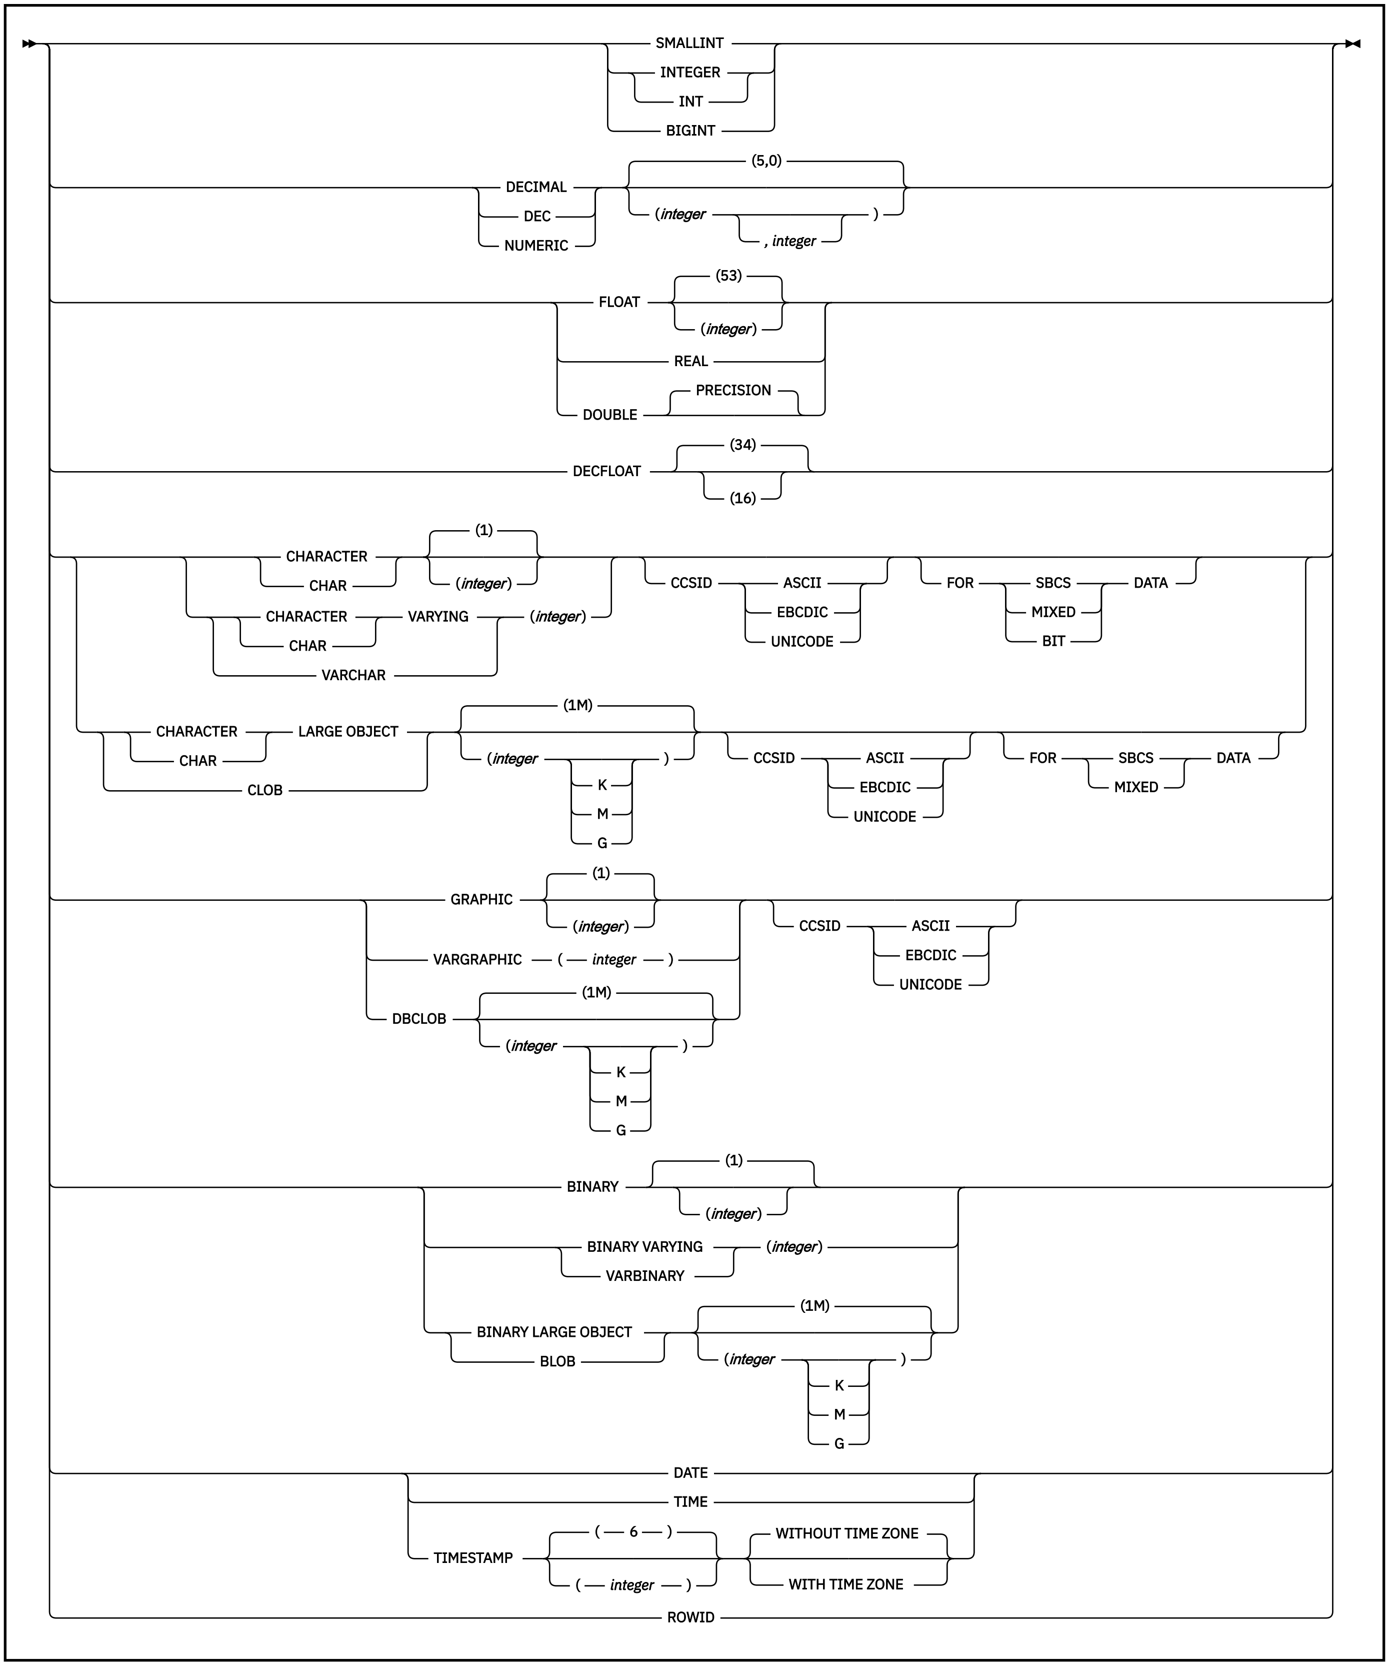
Notes:

[1] AS LOCATOR can be specified only for a LOB data type or a distinct type based on a LOB data type.

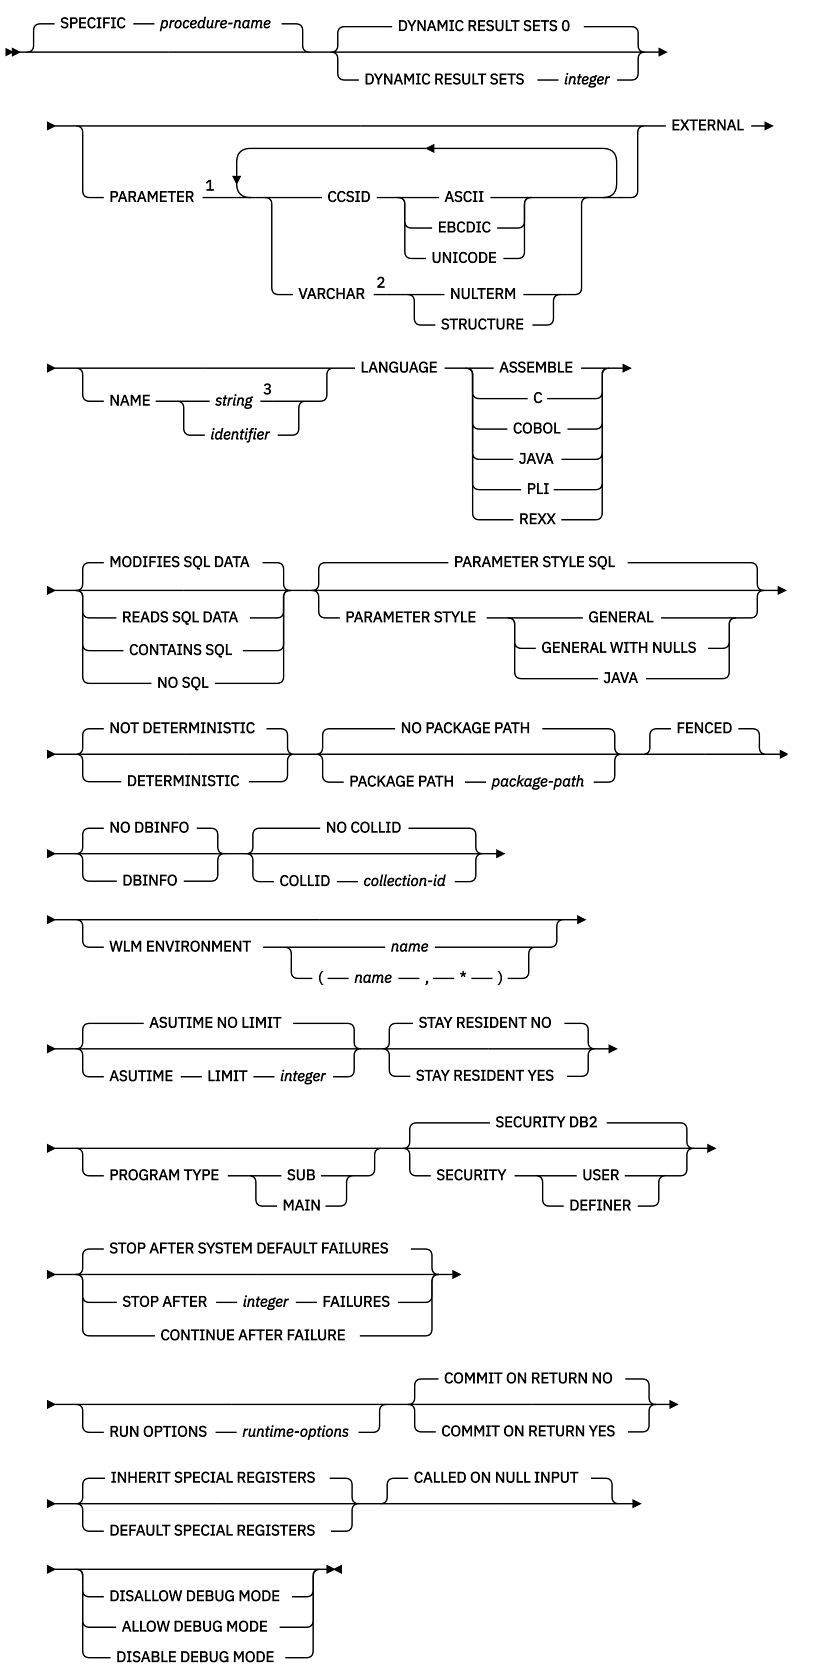
data-type:



built-in-type:



option-list: (The options can be specified in any order.)



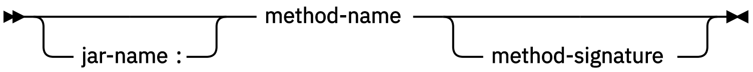
Notes:

[1] The same clause must not be specified more than one time.

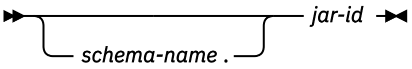
[2] The VARCHAR clause can only be specified is LANGUAGE C is specified.

[3] With LANGUAGE JAVA, use a valid *external-java-routine-name*.

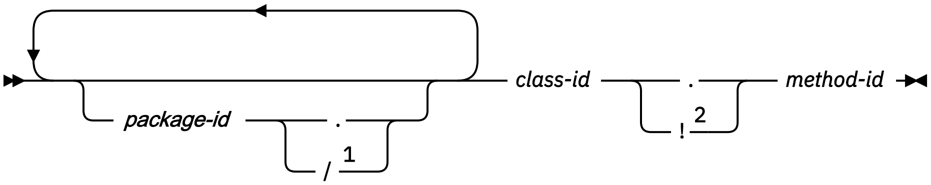
external-java-routine-name



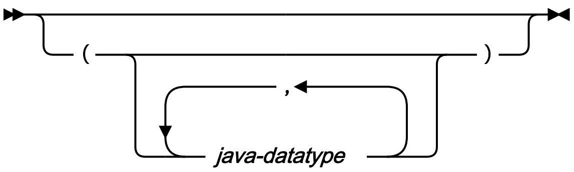
jar-name



method-name



method-signature



Notes:

[1] The slash (/) is supported for compatibility with previous releases of Db2 for z/OS.
[2] The exclamation point (!) is supported for compatibility with other products in the Db2 family.

Description for CREATE PROCEDURE (external)

OR REPLACE

FL 507Specifies that if the procedure exists at the current server, the existing definition is replaced. This option is ignored if a definition for the procedure does not exist at the current server. If a procedure exists with the specified name, the existing procedure must be an external procedure.

If the procedure exists, the procedure is replaced. The existing definition is dropped before the new definition is replaced in the catalog, with the exception that privileges that were granted on the procedure are not affected. The procedure is recreated as follows:

- Any existing comment is discarded
- The definition of the procedure can change
- The timestamp that is associated with the procedure definition is updated
- The owner of the procedure can change
- System default values are used for options that are not explicitly specified, even if those options were explicitly specified when the procedure that is being replaced was originally defined

To replace an existing procedure, one of the following conditions must be met:

- the SPECIFIC clause must be specified with the procedure name
- the signature of the new procedure definition must match the signature of the existing procedure definition, except for parameter names

procedure-name

Names the stored procedure. The name, including the implicit or explicit qualifier, must not identify an existing stored procedure at the current server unless the OR REPLACE clause is specified.

The name cannot be a single asterisk, even if you specify it as a delimited identifier ("*").

The schema name can be 'SYSTOOLS' or 'SYSFUN' if the privilege set includes the SYSADM or SYSCTRL privilege. Otherwise, the schema name must not begin with 'SYS' unless the schema name is 'SYSADM', 'SYSIBMADM', or 'SYSPROC'.

(parameter-declaration,...)

Specifies the number of parameters of the stored procedure and the data type of each parameter, and optionally, the name of each parameter. A parameter for a stored procedure can be used only for input, only for output, or for both input and output. If an error is returned by the procedure, OUT parameters are undefined and INOUT parameters are unchanged.

All parameters are nullable except for numeric parameters in Java procedures, where numeric parameters, other than the DECIMAL types are not nullable in order to conform to the SQL/JRT standard.

IN

Identifies the parameter as an input parameter to the procedure. The value of the parameter on entry to the procedure is the value that is returned to the calling SQL application, even if changes are made to the parameter within the procedure.

IN is the default.

OUT

Identifies the parameter as an output parameter that is returned by the stored procedure.

INOUT

Identifies the parameter as both an input and output parameter for the stored procedure.

parameter-name

Names the parameter for use as an SQL variable. The name cannot be the same as any other *parameter-name* for the procedure.

data-type

Specifies the data type of the parameter. The data type can be a built-in data type or a user-defined type.

If you specify the name of a user-defined type without a schema name, Db2 resolves the user-defined type by searching the schemas in the SQL path.

built-in-type

The data type of the parameter is a built-in data type.

For more information on the data types, see built-in-type.

For parameters with a character or graphic data type, the PARAMETER CCSID clause or CCSID clause indicates the encoding scheme of the parameter. If you do not specify either of these clauses, the encoding scheme is the value of field DEF ENCODING SCHEME on installation panel DSNTIPF.

distinct-type-name

The data type of the input parameter is a distinct type. Any length, precision, scale, subtype, or encoding scheme attributes for the parameter are those of the source type of the distinct type.

Although an input parameter with a character data type has an implicitly or explicitly specified subtype (BIT, SBCS, or MIXED), the value that is actually passed in the input argument on the CALL statement can have any subtype. Therefore, conversion of the input data to the subtype of the parameter might occur when the procedure is called. With ASCII or EBCDIC, an error occurs if mixed data that actually contains DBCS characters is used as the value for an input parameter that is declared with an SBCS subtype.

Parameters with a datetime data type or a distinct type are passed to the function as a different data type:

- A datetime type parameter is passed as a character data type, and the data is passed in ISO format.

  The encoding scheme for a datetime type parameter is the same as the implicitly or explicitly specified encoding scheme of any character or graphic string parameters. If no character or graphic string parameters are passed, the encoding scheme is the value of field DEF ENCODING SCHEME on installation panel DSNTIPF.
- A distinct type parameter is passed as the source type of the distinct type.

AS LOCATOR

Specifies that a locator to the value of the parameter is passed to the procedure instead of the actual value. Specify AS LOCATOR only for parameters with a LOB data type or a distinct type based on a LOB data type. Passing locators instead of values can result in fewer bytes being passed to the procedure, especially when the value of the parameter is very large.

The AS LOCATOR clause has no effect on determining whether data types can be promoted.

TABLE LIKE *table-name* or *view-name* AS LOCATOR

Specifies that the parameter is a transition table. However, when the procedure is called, the actual values in the transition table are not passed to the stored procedure. A single value is passed instead. This single value is a locator to the table, which the procedure uses to access the columns of the transition table. A procedure with a table parameter can only be invoked from the triggered action of a trigger.

The use of TABLE LIKE provides an implicit definition of the transition table. It specifies that the transition table has the same number of columns as the identified table or view. If a table is specified, the transition table includes columns that are defined as implicitly hidden in the table. The columns have the same data type, length, precision, scale, subtype, and encoding scheme as the identified table or view, as they are described in catalog tables SYSCOLUMNS and SYSTABLESPACES. The number of columns and the attributes of those columns are determined at the time the CREATE PROCEDURE statement is processed. Any subsequent changes to the number of columns in the table or the attributes of those columns do not affect the parameters of the procedure.

table-name or *view-name* must identify a table or view that exists at the current server. The name must not identify a declared temporary table. The table that is identified can contain XML columns; however, the procedure cannot reference those XML columns. The name does not have to be the same name as the table that is associated with the transition table for the trigger. An unqualified table or view name is implicitly qualified according to the following rules:

- If the CREATE PROCEDURE statement is embedded in a program, the implicit qualifier is the authorization ID in the QUALIFIER bind option when the plan or package was created or last rebound. If QUALIFIER was not used, the implicit qualifier is the owner of the plan or package.
- If the CREATE PROCEDURE statement is dynamically prepared, the implicit qualifier is the SQL authorization ID in the CURRENT SCHEMA special register.

When the procedure is called, the corresponding columns of the transition table identified by the table locator and the table or view identified in the TABLE LIKE clause must have the same definition. The data type, length, precision, scale, and encoding scheme of these columns must match exactly. The description of the table or view at the time the CREATE PROCEDURE statement was executed is used.

Additionally, a character FOR BIT DATA column of the transition table cannot be passed as input for a table parameter for which the corresponding column of the table specified at the definition is not defined as character FOR BIT DATA. (The definition occurs with the CREATE PROCEDURE statement.) Likewise, a character column of the transition table that is not FOR BIT DATA cannot be passed as input for a table parameter for which the corresponding column of the table specified at the definition is defined as character FOR BIT DATA.

For more information about using table locators, see Accessing transition tables in a user-defined function or stored procedure (Db2 Application programming and SQL).

SPECIFIC *procedure-name*

FL 507Specifies the procedure name as the specific name for the procedure. The name must be the same as the procedure name.

If you do not specify a schema name, the schema name is the same as the explicit or implicit schema name of the procedure name (*procedure-name*). If you specify a schema name, it must be the same as the explicit or implicit schema name of the procedure name.

If you do not specify the SPECIFIC clause, the specific name is the name of the procedure.

Specify the SPECIFIC clause when replacing an existing procedure in the following situations.

- The parameter list of the existing procedure includes a table parameter
- The CREATE statement specifies changes to the parameter list other than parameter names

FENCED

Specifies that the procedure runs in an external address space.

DYNAMIC RESULT SETS *integer*

Specifies the maximum number of query result sets that the stored procedure can return. The default is DYNAMIC RESULT SETS 0, which indicates that there are no result sets. The value must be between 0 and 32767.

ALLOW DEBUG MODE, DISALLOW DEBUG MODE, or DISABLE DEBUG MODE

Specifies whether the procedure can be run in debugging mode. When DYNAMICRULES run behavior is in effect, the default is determined by using the value of the CURRENT DEBUG MODE special register. Otherwise the default is DISALLOW DEBUG MODE.

Do not specify this option unless LANGUAGE JAVA is in effect.

ALLOW DEBUG MODE

Specifies that the JAVA procedure can be run in debugging mode.

DISALLOW DEBUG MODE

Specifies that the JAVA procedure cannot be run in debugging mode.

You can use an ALTER PROCEDURE statement to change this option to ALLOW DEBUG MODE.

DISABLE DEBUG MODE

Specifies that the JAVA procedure can never be run in debugging mode.

The procedure cannot be changed to specify ALLOW DEBUG MODE or DISALLOW DEBUG MODE once the procedure has been created or altered using DISABLE DEBUG MODE. To change this option, you must drop and re-create the procedure using the option that you want.

PARAMETER CCSID or PARAMETER VARCHAR

Specifies the encoding scheme for string parameters, and in the case of LANGUAGE C, specifies the representation of variable length string parameters.

CCSID

Indicates whether the encoding scheme for character or graphic string parameters is ASCII, EBCDIC, or UNICODE. The default encoding scheme is the value specified in the CCSID clauses of the parameter list or in the field DEF ENCODING SCHEME on installation panel DSNTIPF.

This clause provides a convenient way to specify the encoding scheme for character or graphic string parameters. If individual CCSID clauses are specified for individual parameters in addition to this PARAMETER CCSID clause, the value specified in *all* of the CCSID clauses must be the same value that is specified in this clause.

This clause also specifies the encoding scheme to be used for system-generated parameters of the routine such as message tokens and DBINFO.

VARCHAR

Specifies that the representation of the values of varying length character string-parameters for procedures that specify LANGUAGE C.

This option can only be specified if LANGUAGE C is also specified.

NULTERM

Specifies that variable length character string parameters are represented in a NUL-terminated string form.

STRUCTURE

Specifies that variable length character string parameters are represented in a VARCHAR structure form.

Using the PARAMETER VARCHAR clause, there is no way to specify the VARCHAR form of an individual parameter as these is with PARAMETER CCSID. The PARAMETER VARCHAR clause only applies to parameters in the parameter list of a procedure and in the RETURNS clause. It does not apply to system-generated parameters of the routine such as message tokens and DBINFO.

In a data sharing environment, you should not specify the PARAMETER VARCHAR clause until all members of the data sharing group support the clause. If some group members support this clause and others do not, and PARAMETER VARCHAR is specified in an external routine, the routine will encounter different parameter forms depending on which group member invokes the routine.

EXTERNAL

Specifies that the CREATE PROCEDURE statement is being used to define a new procedure that is based on code written in an external programming language. If the NAME clause is not specified, 'NAME *procedure-name*' is assumed. The NAME clause is required for a LANGUAGE JAVA procedure because the default name is not valid for a Java procedure. In some cases, the default name will not be valid. To avoid invalid names, specify the NAME clause for the following types of procedures:

- A procedure that is defined as LANGUAGE JAVA
- A procedure that has a name that is greater than 8 bytes in length, contains an underscore, or does not conform to the rules for an ordinary identifier.

NAME *string* or *identifier*

Identifies the user-written code that implements the stored procedure.

If LANGUAGE is JAVA, *string* must be specified and enclosed in single quotation marks, with no extraneous blanks within the single quotation marks. It must specify a valid *external-java-routine-name*. If multiple *string*s are specified, the total length of all of them must not be greater than 1305 bytes and they must be separated by a space or a line break.

An *external-java-routine-name* contains the following parts:

jar-name

Identifies the name given to the JAR file when it was installed in the database. The name contains *jar-id*, which can optionally be qualified with a schema. Examples are "myJar" and "mySchema.myJar." The unqualified *jar-id* is implicitly qualified with a schema name according to the following rules:

- If the statement is embedded in a program, the schema name is the authorization ID in the QUALIFIER bind option when the package or plan was created or last rebound. If the QUALIFIER was not specified, the schema name is the owner of the package or plan.
- If the statement is dynamically prepared, the schema name is the SQL authorization ID in the CURRENT SCHEMA special register.

If *jar-name* is specified, it must exist when the CREATE PROCEDURE statement is processed. Do not specify a *jar-name* for a JAVA procedure for which NO SQL is also specified.

If *jar-name* is not specified, the procedure is loaded from the class file directly instead of being loaded from a JAR file. Db2 searches the directories in the CLASSPATH associated with the WLM Environment. Environmental variables for Java routines are specified in a data set identified in a JAVAENV DD card on the JCL used to start the address space for a WLM-managed stored procedure.

method-name

Identifies the name of the method and must not be longer than 254 bytes. Its package, class, and method ID's are specific to Java and as such are not limited to 18 bytes. In addition, the rules for what these can contain are not necessarily the same as the rules for an SQL ordinary identifier.

package-id

Identifies a package. The concatenated list of *package-ids* identifies the package that the class identifier is part of. If the class is part of a package, the method name must include the complete package prefix, such as "myPacks.StoredProcs." The Java virtual machine looks in the directory "/myPacks/StoredProcs/" for the classes.

class-id

Identifies the class identifier of the Java object.

method-id

Identifies the method identifier with the Java class to be invoked.

method-signature

Identifies a list of zero or more Java data types for the parameter list and must not be longer than 1024 bytes. Specify the *method-signature* if the procedure involves any input or output parameters that can be NULL. When the stored procedure being created is called, Db2 searches for a Java method with the exact *method-signature*. The number of *java-datatype* elements specified indicates how many parameters that the Java method must have.

A Java procedure can have no parameters. In this case, you code an empty set of parentheses for *method-signature*. If a Java *method-signature* is not specified, Db2 searches for a Java method with a signature derived from the default JDBC types associated with the SQL types specified in the parameter list of the CREATE PROCEDURE statement.

For other values of LANGUAGE, the value must conform to the naming conventions for MVS load modules: the value must be less than or equal to 8 bytes, and it must conform to the rules for an ordinary identifier with the exception that it must not contain an underscore.

LANGUAGE

This mandatory clause is used to specify the language interface convention to which the procedure body is written. All programs must be designed to run in the server's environment. Assembler, C, COBOL, and PL/I programs must be designed to run in IBM's Language Environment.

ASSEMBLE

The stored procedure is written in Assembler.

C

The stored procedure is written in C or C++.

COBOL

The stored procedure is written in COBOL, including the OO-COBOL language extensions.

JAVA

The stored procedure is written in Java and is executed in the Java Virtual Machine. When LANGUAGE JAVA is specified, the EXTERNAL NAME clause must be specified with a valid *external-java-routine-name* and PARAMETER STYLE must be specified with JAVA. The procedure must be a public static method of the specified Java class.

Do not specify LANGUAGE JAVA when DBINFO, PROGRAM TYPE MAIN, or RUN OPTIONS is specified.

PLI

The stored procedure is written in PL/I.

REXX

The stored procedure is written in REXX. Do not specify LANGUAGE REXX when PARAMETER STYLE SQL is in effect. When REXX is specified, the procedure must use PARAMETER STYLE GENERAL or GENERAL WITH NULLS.

MODIFIES SQL DATA, READS SQL DATA, CONTAINS SQL, or NO SQL

Specifies the classification of SQL statements and nested routines that this routine can execute or invoke. The database manager verifies that the SQL statements issued by the procedure, and all routines locally invoked by the routine, are consistent with this specification; the verification is not performed when nested remote routines are invoked. For the classification of each statement, see "SQL statement data access classification for routines" on page 2263.

MODIFIES SQL DATA

Specifies that the procedure can execute any SQL statement except statements that are not supported in procedures.

READS SQL DATA

Specifies that the procedure can execute statements with a data access indication of READS SQL DATA, CONTAINS SQL, or NO SQL. The procedure cannot execute SQL statements that modify data.

CONTAINS SQL

Specifies that the procedure can execute only SQL statements with an access indication of CONTAINS SQL or NO SQL. The procedure cannot execute statements that read or modify data.

NO SQL

Specifies that the procedure can execute only SQL statements with a data access classification of NO SQL. Do not specify NO SQL for a JAVA procedure that uses a JAR file.

PARAMETER STYLE

Identifies the linkage convention used to pass parameters to and return values from the stored procedure. All of the linkage conventions provide arguments to the stored procedure that contain the parameters specified on the CALL statement. Some of the linkage conventions pass additional arguments to the stored procedure that provide more information to the stored procedure. For more information on linkage conventions, see Linkage conventions for external stored procedures (Db2 Application programming and SQL).

SQL

Specifies that, in addition to the parameters on the CALL statement, several additional parameters are passed to the stored procedure. The following parameters are passed:

- The first *n* parameters that are specified on the CREATE PROCEDURE statement.
- *n* parameters for indicator variables for the parameters.
- The SQLSTATE to be returned.
- The qualified name of the stored procedure.
- The specific name of the stored procedure.
- The SQL diagnostic string to be returned to Db2.
- If DBINFO is specified, the DBINFO structure.

PARAMETER STYLE SQL is the default. Do not specify PARAMETER STYLE SQL when LANGUAGE REXX or LANGUAGE JAVA is in effect.

GENERAL

Specifies that the stored procedure uses a parameter passing mechanism where the stored procedure receives only the parameters specified on the CALL statement. Arguments to procedures defined with this parameter style cannot be null.

GENERAL WITH NULLS

Specifies that, in addition to the parameters on the CALL statement as specified in GENERAL, another argument is also passed to the stored procedure. The additional argument contains an indicator array with an element for each of the parameters on the CALL statement. In C, this is an array of short INTS. The indicator array enables the stored procedure to accept or return null parameter values.

JAVA

Specifies that the stored procedure uses a parameter passing convention that conforms to the Java and SQLJ Routines specifications. PARAMETER JAVA can be specified only if LANGUAGE is JAVA. JAVA must be specified for PARAMETER STYLE when LANGUAGE is JAVA.

INOUT and OUT parameters are passed as single-entry arrays. The INOUT and OUT parameters are declared in the Java method as single-element arrays of the Java type.

For REXX stored procedures (LANGUAGE REXX), GENERAL and GENERAL WITH NULLS are the only valid values for PARAMETER STYLE; therefore, specify one of these values and do not allow PARAMETER STYLE to default to SQL.

DETERMINISTIC or NOT DETERMINISTIC

Specifies whether the stored procedure returns the same results each time the stored procedure is called with the same IN and INOUT arguments.

DETERMINISTIC

The stored procedure always returns the same results each time the stored procedure is called with the same IN and INOUT arguments, if the referenced data in the database has not changed.

NOT DETERMINISTIC

The stored procedure might not return the same result each time the procedure is called with the same IN and INOUT arguments, even when the referenced data in the database has not changed. NOT DETERMINISTIC is the default.

Db2 does not verify that the stored procedure code is consistent with the specification of DETERMINISTIC or NOT DETERMINISTIC.

NO PACKAGE PATH or PACKAGE PATH *package-path*

Specifies the package path to use when the procedure is run. This is the list of the possible package collections into which the DBRM this is associated with the procedure is bound.

NO PACKAGE PATH

Specifies that the list of package collections for the procedure is the same as the list of package collection IDs for the calling program. If the calling program does not use a package, Db2 resolves the package by using the CURRENT PACKAGE PATH special register, the CURRENT PACKAGESET special register, or the PKLIST bind option (in this order). For information about how Db2 uses these three items, see Binding an application plan (Db2 Application programming and SQL).

PACKAGE PATH *package-path*

Specifies a list of package collections, in the same format as the SET CURRENT PACKAGE PATH special register.

If the COLLID clause is specified with PACKAGE PATH, the COLLID clause is ignored when the routine is invoked.

The *package-path* value that is provided when the procedure is created is checked when the CALL statement is prepared. If *package-path* contains SESSION_USER (or USER), PATH, or PACKAGE PATH, an error is returned when the *package-path* value is checked.

NO DBINFO or DBINFO

Specifies whether additional status information is passed to the stored procedure when it is invoked.

NO DBINFO

Additional information is not passed. NO DBINFO is the default.

DBINFO

An additional argument is passed when the stored procedure is invoked. The argument is a structure that contains information such as the name of the current server, the application run time authorization ID and identification of the version and release of the database manager that invoked the procedure. For details about the argument and its structure, see DBINFO structure (Db2 Application programming and SQL).

DBINFO can be specified only if PARAMETER STYLE SQL is specified.

NO COLLID or COLLID *collection-id*

Identifies the package collection that is to be used when the stored procedure is executed. This is the package collection into which the DBRM that is associated with the stored procedure is bound.

NO COLLID

The package collection for the stored procedure is the same as the package collection of the calling program. If the invoking program does not use a package, Db2 resolves the package by using the CURRENT PACKAGE PATH special register, the CURRENT PACKAGESET special register, or the PKLIST bind option (in this order). For details about how Db2 uses these three items, see the information on package resolution in Binding an application plan (Db2 Application programming and SQL).

NO COLLID is the default.

COLLID *collection-id*

The package collection for the stored procedure is the one specified.

For REXX stored procedures, *collection-id* can be DSNREXRR, DSNREXRS, DSNREXCR, or DSNREXCS.

For Java stored procedures that meet these conditions, you need to run the DB2Binder utility with the -collection option to bind the driver packages into the collection that is specified by the COLLID value:

- The COLLID value is different from the collection into which the IBM Data Server Driver for JDBC and SQLJ packages are bound.
- *jar-name* is specified in the EXTERNAL NAME clause.

For more information, see the following topics:

- Specifying the package collection that Db2 uses for applications (Db2 Application programming and SQL)
- DB2Binder utility (Db2 Application Programming for Java)

WLM ENVIRONMENT

Identifies the WLM (workload manager) environment in which the stored procedure is to run when the Db2 stored procedure address space is WLM-established. The *name* of the WLM environment is an SQL identifier.

If you do not specify WLM ENVIRONMENT, the stored procedure runs in the default WLM-established stored procedure address space specified at installation time.

name

The WLM environment in which the stored procedure must run. If another stored procedure or a user-defined function calls the stored procedure and that calling routine is running in an address space that is not associated with the specified WLM environment, Db2 routes the stored procedure request to a different address space.

(name,*)

When an SQL application program directly calls a stored procedure, the WLM environment in which the stored procedure runs.

If another stored procedure or a user-defined function calls the stored procedure, the stored procedure runs in the same WLM environment that the calling routine uses.

You must have appropriate authority for the WLM environment.

ASUTIME

Specifies the total amount of processor time, in CPU service units, that a single invocation of a stored procedure can run. The value is unrelated to the ASUTIME column of the resource limit specification table. This option is ignored if LANGUAGE JAVA is specified.

When you are debugging a stored procedure, setting a limit can be helpful in case the stored procedure gets caught in a loop. For information on service units, see z/OS MVS Initialization and Tuning Guide.

NO LIMIT

There is no limit on the service units. NO LIMIT is the default.

LIMIT *integer*

The limit on the number of CPU service units is a positive *integer* in the range 1 - 2147483647. If the procedure uses more service units than the specified value, Db2 cancels the procedure. The CPU cycles that are consumed by parallel tasks in a procedure do not contribute towards the specified ASUTIME LIMIT.

STAY RESIDENT

Specifies whether the stored procedure load module is to remain resident in memory when the stored procedure ends. This option is ignored if LANGUAGE JAVA is specified.

NO

The load module is deleted from memory after the stored procedure ends. NO is the default.

YES

The load module remains resident in memory after the stored procedure ends.

PROGRAM TYPE

Specifies whether the stored procedure runs as a main routine or a subroutine.

SUB

The stored procedure runs as a subroutine. With LANGUAGE JAVA, PROGRAM TYPE SUB is the only valid option.

MAIN

The stored procedure runs as a main routine. With LANGUAGE REXX, PROGRAM TYPE MAIN is always in effect.

The default for PROGRAM TYPE is:

- MAIN with LANGUAGE REXX
- SUB with LANGUAGE JAVA
- For other languages, the default depends on the value of the CURRENT RULES special register:
  - MAIN when the value is Db2
  - SUB when the value is STD

SECURITY

Specifies how the stored procedure interacts with an external security product, such as RACF, to control access to non-SQL resources.

Db2

The stored procedure does not require a special external security environment. If the stored procedure accesses resources that an external security product protects, the access is performed using the authorization ID associated with the stored procedure address space. Db2 is the default.

USER

An external security environment should be established for the stored procedure. If the stored procedure accesses resources that the external security product protects, the access is performed using the authorization ID of the user who invoked the stored procedure.

DEFINER

An external security environment should be established for the stored procedure. If the stored procedure accesses resources that the external security product protects, the access is performed using the authorization ID of the owner of the stored procedure.

STOP AFTER SYSTEM DEFAULT FAILURES, STOP AFTER *nn* FAILURES, or CONTINUE AFTER FAILURE

Specifies whether the routine is to be put in a stopped state after some number of failures.

STOP AFTER SYSTEM DEFAULT FAILURES

Specifies that this routine should be placed in a stopped state after the number of failures indicated by the value of field MAX ABEND COUNT on installation panel DSNTIPX. This is the default.

STOP AFTER *nn* FAILURES

Specifies that this routine should be placed in a stopped state after *nn* failures. The value *nn* can be an integer from 1 to 32767.

CONTINUE AFTER FAILURE

Specifies that this routine should not be placed in a stopped state after any failure.

RUN OPTIONS *runtime-options*

Specifies the Language Environment run time options to be used for the stored procedure. For a REXX stored procedure, specifies the Language Environment run time options to be passed to the REXX language interface to Db2. You must specify *runtime-options* as a character string that is no longer than 254 bytes. If you do not specify RUN OPTIONS or pass an empty string, Db2 does not pass any run time options to Language Environment, and Language Environment uses its installation defaults.

Do not specify RUN OPTIONS when LANGUAGE JAVA is in effect.

For a description of the Language Environment run time options, see Language Environment Programming Reference (z/OS Language Environment Programming Reference).

COMMIT ON RETURN

Indicates whether Db2 commits the transaction immediately on return from the stored procedure.

NO

Db2 does not issue a commit when the stored procedure returns. NO is the default.

YES

Db2 issues a commit when the stored procedure returns if the following statements are true:

- The SQLCODE that is returned by the CALL statement is not negative.
- The stored procedure is not in a must abort state.

The commit operation includes the work that is performed by the calling application process and the stored procedure.

If the stored procedure returns result sets, the cursors that are associated with the result sets must have been defined as WITH HOLD to be usable after the commit.

INHERIT SPECIAL REGISTERS or DEFAULT SPECIAL REGISTERS

Specifies how special registers are set on entry to the routine. The default is INHERIT SPECIAL REGISTERS.

INHERIT SPECIAL REGISTERS

Specifies that the values of special registers are inherited according to the rules listed in the table for characteristics of special registers in a stored procedure in “Special registers in a user-defined function or a stored procedure” on page 215.

DEFAULT SPECIAL REGISTERS

Specifies that special registers are initialized to the default values, as indicated by the rules in the table for characteristics of special registers in a stored procedure in “Special registers in a user-defined function or a stored procedure” on page 215.

CALLED ON NULL INPUT

Specifies that the procedure is to be called even if any or all argument values are null, which means that the procedure must be coded to test for null argument values. The procedure can return null or nonnull values. CALLED ON NULL INPUT is the default.

Notes for CREATE PROCEDURE (external)

Considerations for all types of procedures

For considerations that apply to all types of procedures, see “CREATE PROCEDURE” on page 1573.

Character string representation considerations

The PARAMETER VARCHAR clause is specific to external procedures because of the native use of NUL-terminated strings in C. VARCHAR structure representation is useful when character string data is known to contain embedded NUL-terminators. It is also useful when it cannot be guaranteed that character string data does not contain embedded NUL-terminators.

PARAMETER VARCHAR does not apply to fixed length character strings, VARCHAR FOR BIT DATA, CLOB, DBCLOB, or implicitly generated parameters. The clause does not apply to VARCHAR FOR BIT DATA because BIT DATA can contain X'00' characters, and its value representation starts with length information. It does not apply to LOB data because a LOB value representation starts with length information.

PARAMETER VARCHAR does not apply to optional parameters that are implicitly provided to an external procedure. For example, a CREATE PROCEDURE statement for LANGUAGE C must also specify PARAMETER STYLE SQL, which returns an SQLSTATE NUL-terminated character string; that SQLSTATE will not be represented in VARCHAR structured form. Likewise, none of the parameters that represent the qualified name of the procedure, the specific name of the procedure, or the SQL diagnostic string that is returned to the database manager will be represented in VARCHAR structured form.

Environment for running stored procedures

You can use the WLM ENVIRONMENT clause to identify the address space in which a stored procedure is to run. Using different WLM environments lets you isolate one group of programs from another. For example, you might choose to isolate programs based on security requirements and place all payroll applications in one WLM environment because those applications deal with sensitive data, such as employee salaries.

Regardless of where the stored procedure is to run, Db2 invokes RACF to determine whether you have appropriate authorization. You must have authorization to issue CREATE PROCEDURE statements that refer to the specified WLM environment or the Db2-established stored procedure address space. For example, the following RACF command authorizes Db2 user DB2USER1 to define stored procedures on Db2 subsystem DB2A that run in the WLM environment named PAYROLL.

```
PERMIT  DB2A.WLMENV.PAYROLL  CLASS(DSNR) ID(DB2USER1)  ACCESS(READ)
```

Alternative syntax and synonyms

To provide compatibility with previous releases of Db2 or other products in the Db2 family, Db2 supports the following alternative syntax:

- RESULT SET as a synonym for DYNAMIC RESULT SET
- RESULT SETS as a synonym for DYNAMIC RESULT SETS
- STANDARD CALL as a synonym for DB2SQL
- SIMPLE CALL as a synonym for GENERAL
- SIMPLE CALL WITH NULLS as a synonym for GENERAL WITH NULLS
- VARIANT as a synonym for NOT DETERMINISTIC
- NOT VARIANT as a synonym for DETERMINISTIC
- NULL CALL as a synonym for CALLED ON NULL INPUT
- PARAMETER STYLE DB2SQL as a synonym for PARAMETER STYLE SQL

Examples for CREATE PROCEDURE (external)

Example 1

Create the definition for a stored procedure that is written in COBOL. The procedure accepts an assembly part number and returns the number of parts that make up the assembly, the total part cost, and a result set. The result set lists the part numbers, quantity, and unit cost of each part. Assume that the input parameter cannot contain a null value and that the procedure is to run in a WLM environment called PARTSA.

```
CREATE PROCEDURE SYSPROC.MYPROC(IN INT, OUT INT, OUT DECIMAL(7,2))
       LANGUAGE COBOL
       EXTERNAL NAME MYMODULE
```

```
          PARAMETER STYLE GENERAL
          WLM ENVIRONMENT PARTSA
          DYNAMIC RESULT SETS 1;
```

Example 2

Create the definition for the stored procedure described in Example 1, except use the linkage convention that passes more information than the parameter specified on the CALL statement. Specify Language Environment run time options HEAP, BELOW, ALL31, and STACK.

```
   CREATE PROCEDURE SYSPROC.MYPROC(IN INT, OUT INT, OUT DECIMAL(7,2))
          LANGUAGE COBOL
          EXTERNAL NAME MYMODULE
          PARAMETER STYLE SQL
          WLM ENVIRONMENT PARTSA
          DYNAMIC RESULT SETS 1
          RUN OPTIONS 'HEAP(,,ANY),BELOW(4K,,),ALL31(ON),STACK(,,ANY,)';
```

Example 3

Create the procedure definition for a stored procedure, written in Java, that is passed a part number and returns the cost of the part and the quantity that is currently available.

```
   CREATE PROCEDURE PARTS_ON_HAND(IN PARTNUM INT,
                                  OUT COST DECIMAL(7,2),
                                  OUT QUANTITY INT)
          LANGUAGE JAVA
          EXTERNAL NAME 'PARTS.ONHAND'
          PARAMETER STYLE JAVA;
```

Related concepts

Procedures (Introduction to Db2 for z/OS)

Naming conventions
The rules for forming a name depend on the type of the object designated by the name.

Related tasks

Implementing Db2 stored procedures (Stored procedures provided by Db2)

CREATE PROCEDURE (SQL - external) (deprecated)

The CREATE PROCEDURE statement defines an external SQL procedure at the current server and specifies the source statements for the procedure. This is the only type of SQL procedure that is available for versions of Db2 prior to DB2 9.

Deprecated function: External SQL procedures are deprecated and not as fully supported as native SQL procedures. For best results, create native SQL procedures instead. For more information, see Creating native SQL procedures (Db2 Application programming and SQL) and Migrating an external SQL procedure to a native SQL procedure (Db2 Application programming and SQL).

For information about the SQL control statements that are supported in external SQL procedures, refer to Appendix D, “SQL control statements for external SQL procedures,” on page 2267.

Invocation for CREATE PROCEDURE (SQL - external)

This statement can only be dynamically prepared, but the DYNAMICRULES run behavior must be specified implicitly or explicitly. It is intended to be processed using one of the following methods:

- JCL
- The Db2 for z/OS SQL procedure processor (DSNTPSMP) (IBM Optim™ Development Studio uses this method.)

Issuing the CREATE PROCEDURE statement from another context will result in an incomplete procedure definition even though the statement processing returns without error. For more information on preparing SQL procedures for execution, see Creating external SQL procedures (deprecated) (Db2 Application programming and SQL).

Authorization for CREATE PROCEDURE (SQL - external)

The privilege set that is defined below must include at least one of the following:

- The CREATEIN privilege on the schema
- SYSADM or SYSCTRL authority
- System DBADM
- Installation SYSOPR authority (when the current SQLID of the process is set to SYSINSTL)

The authorization ID that matches the schema name implicitly has the CREATEIN privilege on the schema.

If the authorization ID that is used to create the procedure has the installation SYSADM authority or the installation SYSOPR authority and if the current SQLID is set to SYSINSTL, the procedure is identified as system-defined procedure.

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the owner is a role, the implicit schema match does not apply and this role needs to include one of the previously listed conditions.

If the statement is dynamically prepared and is not running in a trusted context for which the ROLE AS OBJECT OWNER clause is specified, the privilege set is the set of privileges that are held by the SQL authorization ID of the process. If the schema name is not the same as the SQL authorization ID of the process, one of the following conditions must be met:

- The privilege set includes SYSADM or SYSCTRL authority.
- The SQL authorization ID of the process has the CREATEIN privilege on the schema.

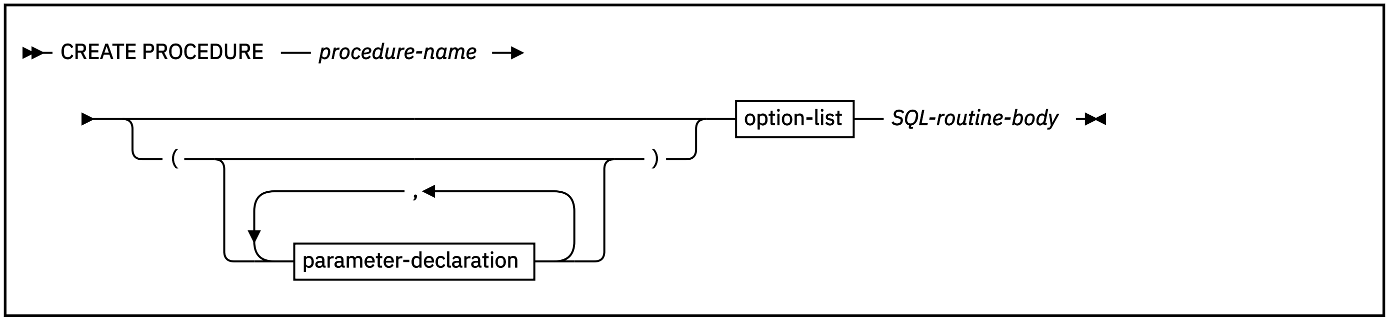
The authorization ID that is used to create the stored procedure must have authority to create programs that are to be run in the specified WLM environment.

The owner of the procedure is determined by how the CREATE PROCEDURE statement is invoked:

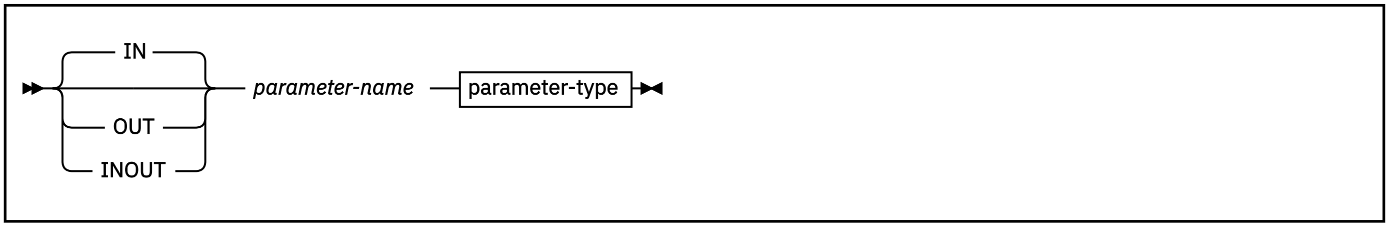
- If the statement is embedded in a program, the owner is the authorization ID of the owner of the plan or package.
- If the statement is dynamically prepared, the owner is the SQL authorization ID in the CURRENT SQLID special register.

The owner is implicitly given the EXECUTE privilege with the GRANT option for the procedure.

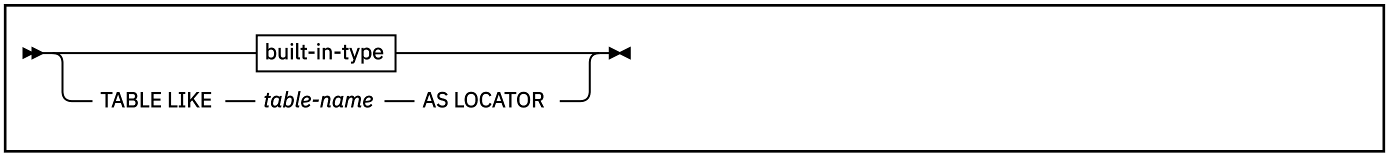
Syntax for CREATE PROCEDURE (SQL - external)



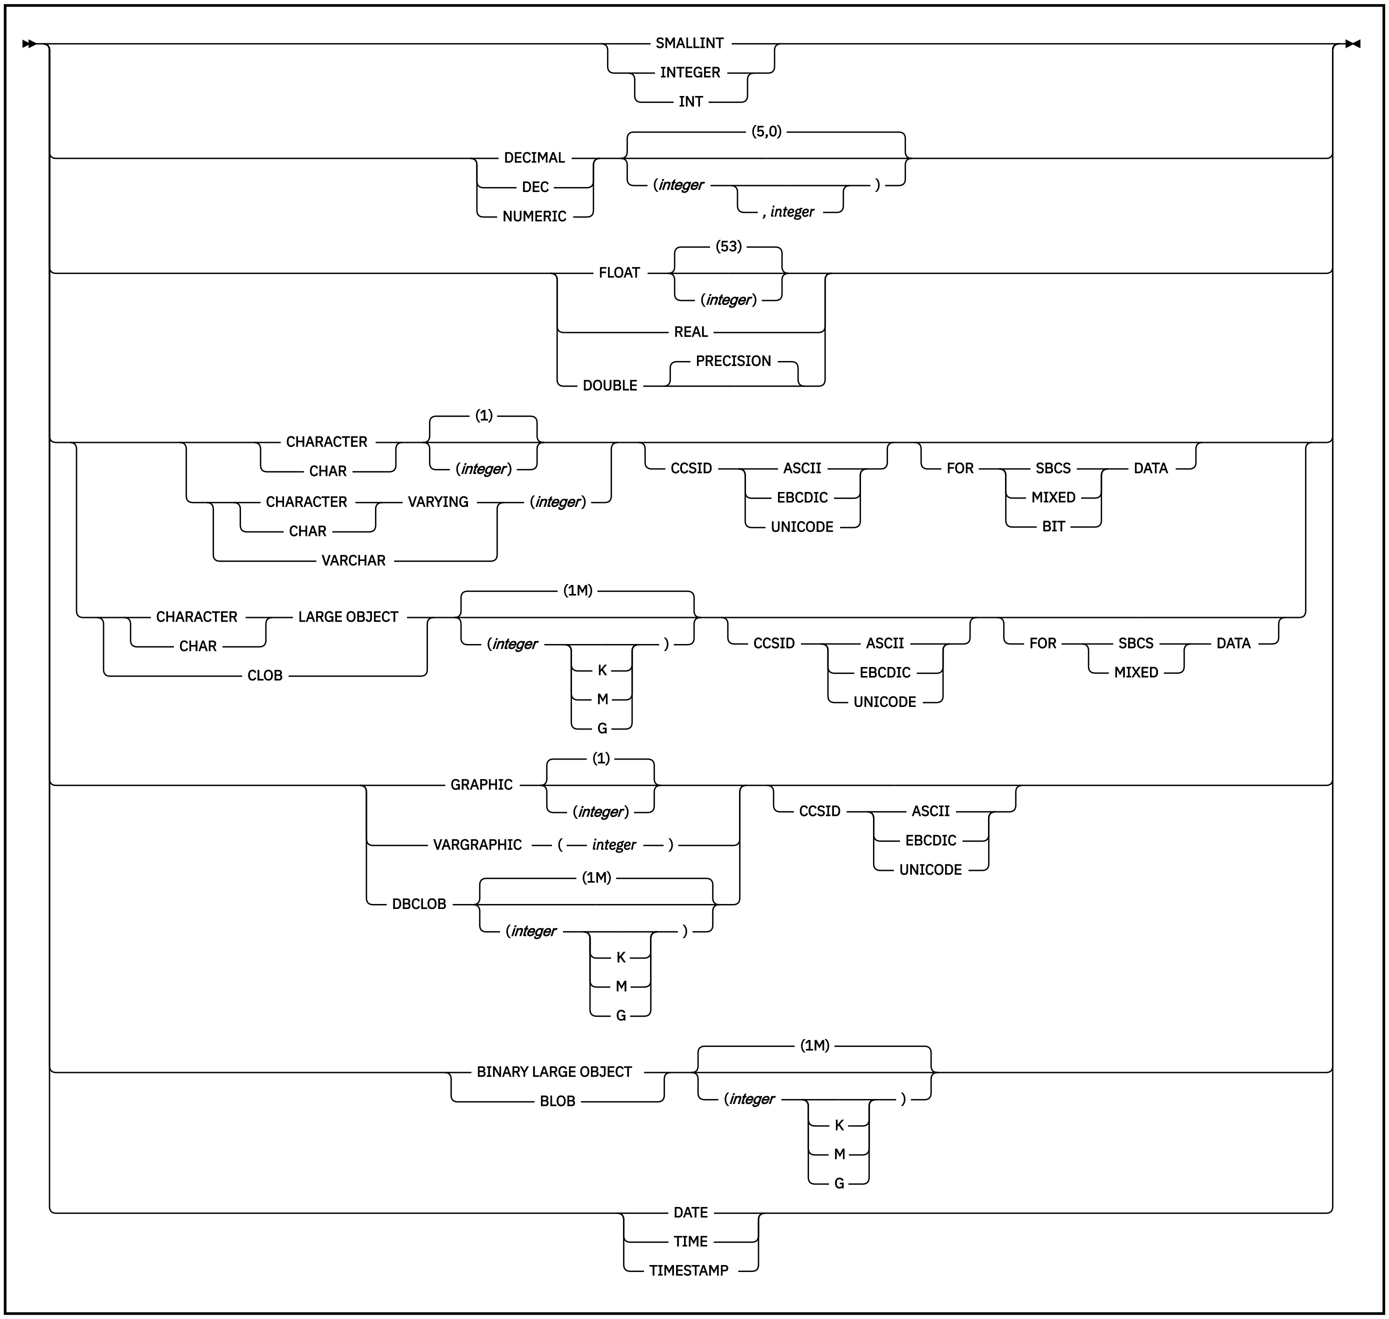
parameter-declaration:



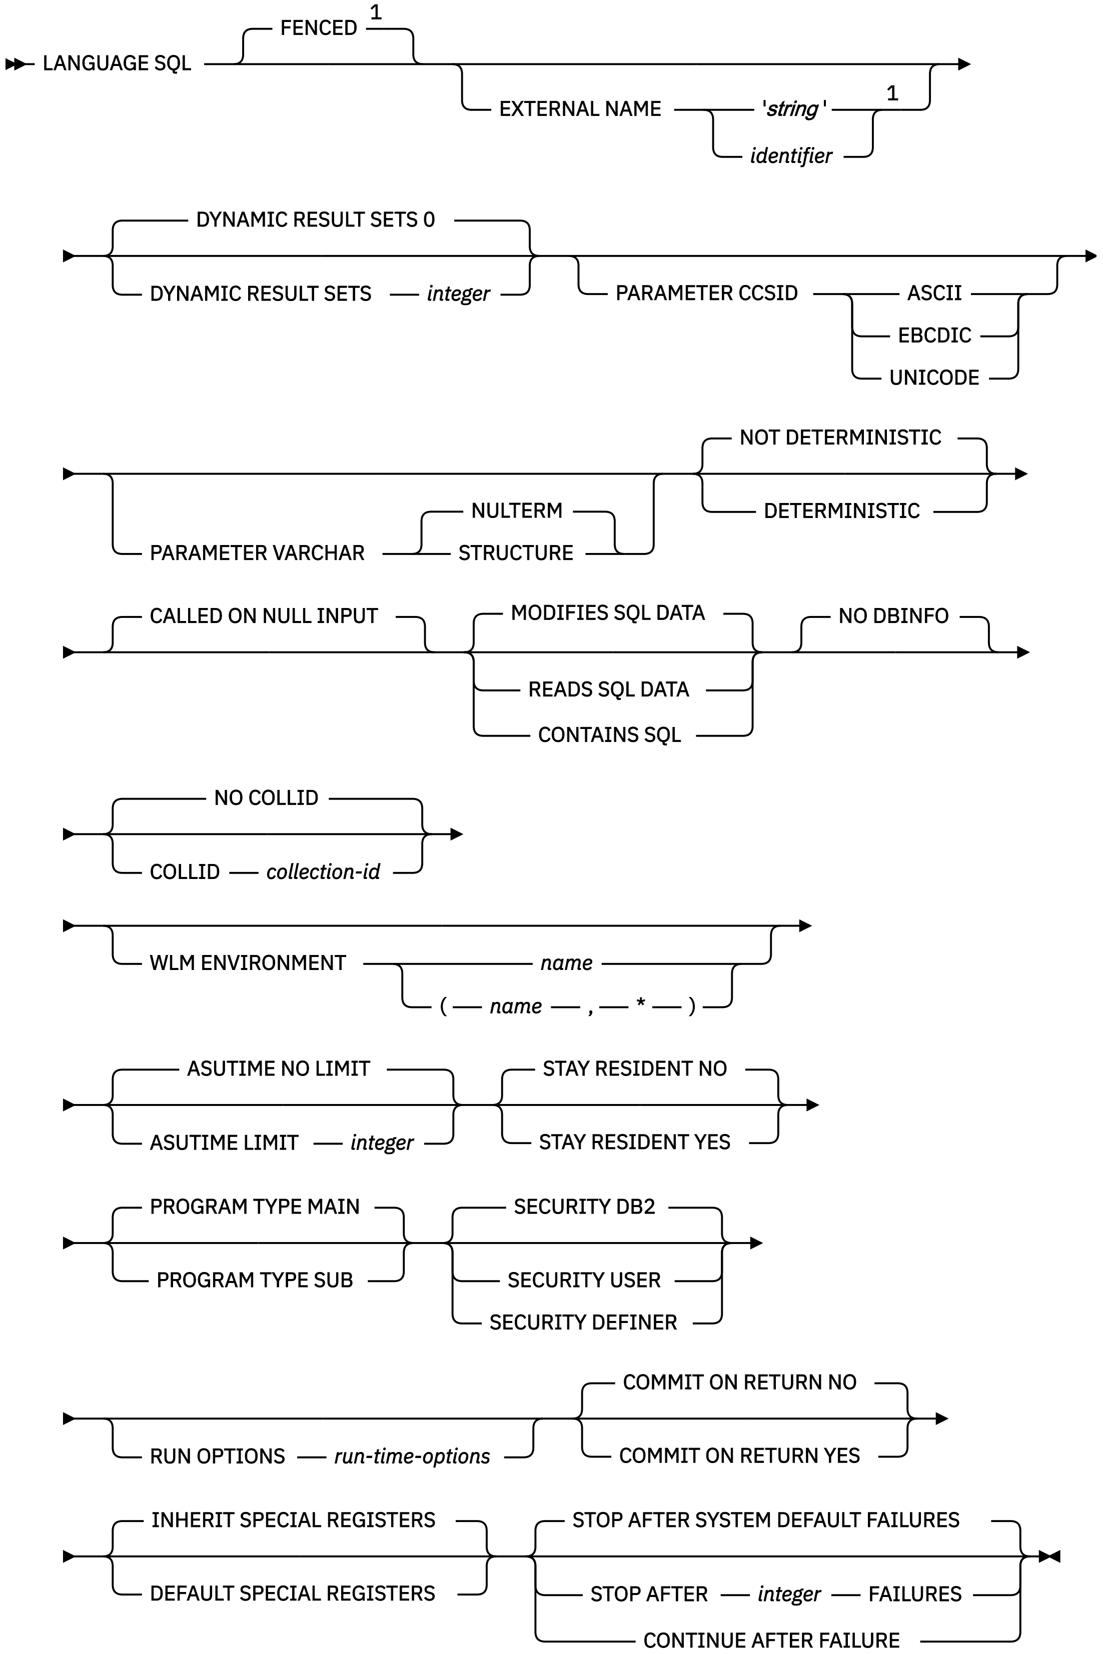
parameter-type:



built-in-type:



option-list: (The options can be specified in any order, but each option can be specified only one time)



Notes:

[1] Either the FENCED or EXTERNAL NAME clause must be specified to indicate that the definition is for an external SQL procedure.

Description for CREATE PROCEDURE (SQL - external)

procedure-name

Names the procedure. The name, including the implicit or explicit qualifier, must not identify an existing stored procedure at the current server.

The schema name can be 'SYSTOOLS' or 'SYSFUN' if the privilege set includes the SYSADM or SYSCTRL privilege. Otherwise, the schema name must not begin with 'SYS' unless the schema name is 'SYSADM', 'SYSIBMADM', or 'SYSPROC'.

(*parameter-declaration,...*)

Specifies the number of parameters of the procedure, the data type of each parameter, and the name of each parameter. A parameter for a procedure can be used only for input, only for output, or for both input and output. If an error is returned by the procedure, OUT parameters are undefined, and INOUT parameters are unchanged. All of the parameters are nullable.

IN

Identifies the parameter as an input parameter to the procedure. The value of the parameter on entry to the procedure is the value that is returned to the calling SQL application, even if changes are made to the parameter within the procedure.

IN is the default.

OUT

Identifies the parameter as an output parameter that is returned by the procedure. If the parameter is not set within the procedure, the null value is returned.

INOUT

Identifies the parameter as both an input and output parameter for the procedure. If the parameter is not set within the procedure, its input value is returned.

parameter-name

Names the parameter for use as an SQL variable. *parameter-name* is an SQL identifier and must not be a delimited identifier that includes lowercase letters or special characters. A parameter name cannot be the same as the name of any other parameter for this version of the procedure.

parameter-type

Specifies the data type of the parameter.

built-in-type

The data type of the parameter is a built-in data type.

For more information on the data types, including the subtype of character data types (the FOR *subtype* DATA clause), see built-in-type. For external SQL procedures, the maximum limit for VARCHAR is 32767 and for VARGRAPHIC is 16382.

For parameters with a character or graphic data type, the PARAMETER CCSID clause or CCSID clause indicates the encoding scheme of the parameter. If you do not specify either of these clauses, the encoding scheme is the value of field DEF ENCODING SCHEME on installation panel DSNTIPF.

Although an input parameter with a character data type has an implicitly or explicitly specified subtype (BIT, SBCS, or MIXED), the value that is actually passed in the input parameter can have any subtype. Therefore, conversion of the input data to the subtype of the parameter might occur when the procedure is called. With ASCII or EBCDIC, an error occurs if mixed data that actually contains DBCS characters is used as the value for an input parameter that is declared with an SBCS subtype.

A parameter with a datetime data type is passed to the SQL procedure as a character data type, and the data is passed in ISO format.

The encoding scheme for a datetime type parameter is determined as follows:

- If there are one or more parameters with a character or graphic data type, the encoding scheme of the datetime type parameter is the same as the encoding scheme of the character or graphic parameters.

- Otherwise, the encoding scheme is the value of field DEF ENCODING SCHEME on installation panel DSNTIPF.

TABLE LIKE *table-name* AS LOCATOR

Specifies that the parameter is a transition table. However, when the procedure is called, the actual values in the transition table are not passed to the procedure. A single value is passed instead. This single value is a locator to the table, which the procedure uses to access the columns of the transition table. A procedure with a table parameter can only be invoked from the triggered action of a trigger.

The transition table includes columns that are defined as implicitly hidden in the table. The table that is identified can contain XML columns; however, the procedure cannot reference those XML columns.

For more information about the TABLE LIKE clause, see TABLE LIKE. For more information about using table locators, see Accessing transition tables in a user-defined function or stored procedure (Db2 Application programming and SQL).

LANGUAGE

Specifies the application programming language in which the procedure is written.

SQL

The procedure is written in Db2 SQL procedural language.

FENCED

Specifies that the procedure runs in an external address space. FENCED also specifies that the SQL procedure program is an MVS load module with an external name.

DYNAMIC RESULT SETS *integer*

Specifies the maximum number of query result sets that the procedure can return. The default is DYNAMIC RESULT SETS 0, which indicates that the procedure can return no result sets. The value of *integer* must be between 0 and 32767.

PARAMETER CCSID

Indicates whether the encoding scheme for character and graphic string parameters is ASCII, EBCDIC, or UNICODE. The default encoding scheme is the value that is specified in the CCSID clauses of the parameter list or in the field DEF ENCODING SCHEME on installation panel DSNTIPF.

This clause provides a convenient way to specify the encoding scheme for character and graphic string parameters. If individual CCSID clauses are specified for individual parameters in addition to this PARAMETER CCSID clause, the value that is specified in *all* of the CCSID clauses must be the same value that is specified in this clause.

This clause also specifies the encoding scheme that is to be used for system-generated parameters of the routine such as message tokens and DBINFO.

PARAMETER VARCHAR

Specifies that the representation of the values of varying length character string-parameters for procedures that specify LANGUAGE C.

NULTERM

Specifies that variable length character string parameters are represented in a NUL-terminated string form.

NULTERM is the default.

STRUCTURE

Specifies that variable length character string parameters are represented in a VARCHAR structure form.

The PARAMETER VARCHAR clause only applies to parameters in the parameter list of a procedure and in the RETURNS clause. It does not apply to system-generated parameters of the routine such as message tokens and DBINFO.

In a data sharing environment, you should not specify the PARAMETER VARCHAR clause until all members of the data sharing group support the clause. If some group members support this clause and others do not, and PARAMETER VARCHAR is specified, the routine will encounter different parameter forms depending on which group member invokes the routine.

EXTERNAL NAME *'string'* or *identifier*

Specifies the name of the MVS load module for the program that runs when the procedure name is specified in an SQL CALL statement. The value must conform to the naming conventions for MVS load modules: the value must be less than or equal to 8 bytes, and it must conform to the rules for an ordinary identifier with the exception that it must not contain an underscore.

EXTERNAL NAME *procedure-name* is the default. In some cases, the default name will not be valid. To avoid an invalid name, specify EXTERNAL NAME for a procedure that has a name that is greater than 8 bytes in length, contains an underscore, or does not conform to the rules for an ordinary identifier.

NOT DETERMINISTIC or DETERMINISTIC

Specifies whether the procedure returns the same results each time the procedure is called with the same IN and INOUT arguments.

NOT DETERMINISTIC

The procedure might not return the same result each time the procedure is called with the same IN and INOUT arguments, even when the referenced data in the database has not changed.

NOT DETERMINISTIC is the default.

DETERMINISTIC

The procedure always returns the same results each time the stored procedure is called with the same IN and INOUT arguments, if the referenced data in the database has not changed.

Db2 does not verify that the procedure code is consistent with the specification of DETERMINISTIC or NOT DETERMINISTIC.

CALLED ON NULL INPUT

Specifies that the procedure is to be called even if any or all argument values are null, which means that the procedure must be coded to test for null argument values. The procedure can return null or non-null values.

CALLED ON NULL INPUT is the default.

MODIFIES SQL DATA, READS SQL DATA, or CONTAINS SQL

Specifies the classification of SQL statements and nested routines that this routine can execute or invoke. The database manager verifies that the SQL statements issued by the procedure, and all routines locally invoked by the routine, are consistent with this specification; the verification is not performed when nested remote routines are invoked. For the classification of each statement, see "SQL statement data access classification for routines" on page 2263.

MODIFIES SQL DATA

Specifies that the procedure can execute any SQL statement except statements that are not supported in procedures.

MODIFIES SQL DATA is the default.

READS SQL DATA

Specifies that the procedure can execute statements with a data access indication of READS SQL DATA or CONTAINS SQL. The procedure cannot execute SQL statements that modify data.

CONTAINS SQL

Specifies that the procedure can execute only SQL statements with a data access indication of CONTAINS SQL. The procedure cannot execute statements that read or modify data.

NO DBINFO

Specifies that no additional status information that is known by Db2 is passed to the procedure when it is invoked.

NO COLLID or COLLID *collection-id*

Identifies the package collection that is to be used when the procedure is executed. This is the package collection into which the DBRM that is associated with the procedure is bound.

NO COLLID

Specifies that the package collection for the procedure is the same as the package collection of the calling program. If the invoking program does not use a package, Db2 resolves the package by using the CURRENT PACKAGE PATH special register, the CURRENT PACKAGESET special register, or the PKLIST bind option (in this order). For details about how Db2 uses these three items, see the information on package resolution in Binding an application plan (Db2 Application programming and SQL).

NO COLLID is the default.

COLLID *collection-id*

Specifies the package collection for the procedure.

WLM ENVIRONMENT *name* or (*name*,*)

Identifies the WLM (workload manager) environment in which the stored procedure is to run when the Db2 stored procedure address space is WLM-established. The *name* of the WLM environment is an SQL identifier.

If you do not specify WLM ENVIRONMENT, the procedure runs in the default WLM-established stored procedure address space that is specified at installation time.

name

The WLM environment in which the procedure must run. If another procedure or a user-defined function calls the procedure and that calling routine is running in an address space that is not associated with the specified WLM environment, Db2 routes the procedure request to a different address space.

(name,*)

When an SQL application program directly calls a procedure, *name* specifies the WLM environment in which the procedure runs.

If another procedure or a user-defined function calls the stored procedure, the procedure runs in the same WLM environment that the calling routine uses.

You must have appropriate authority for the WLM environment.

ASUTIME

Specifies the total amount of processor time, in CPU service units, that a single invocation of a procedure can run. The value is unrelated to the ASUTIME column of the resource limit specification table.

When you are debugging a procedure, setting a limit can be helpful in case the procedure gets caught in a loop. For information on service units, see z/OS MVS Initialization and Tuning Guide.

NO LIMIT

There is no limit on the number of CPU service units that the procedure can run.

NO LIMIT is the default.

LIMIT *integer*

The limit on the number of CPU service units is a positive *integer* in the range 1 - 2147483647. If the procedure uses more service units than the specified value, Db2 cancels the procedure. The CPU cycles that are consumed by parallel tasks in a procedure do not contribute towards the specified ASUTIME LIMIT.

STAY RESIDENT

Specifies whether the load module for the procedure remains resident in memory when the procedure ends.

NO

The load module is deleted from memory after the procedure ends.

NO is the default.

YES

The load module remains resident in memory after the procedure ends.

PROGRAM TYPE

Specifies whether the procedure runs as a main routine or a subroutine.

MAIN

The procedure runs as a main routine.

MAIN is the default.

SUB

The procedure runs as a subroutine.

SECURITY

Specifies how the procedure interacts with an external security product, such as RACF, to control access to non-SQL resources.

Db2

The procedure does not require a special external security environment. If the procedure accesses resources that an external security product protects, the access is performed using the authorization ID that is associated with the address space in which the procedure runs.

Db2 is the default.

USER

An external security environment should be established for the procedure. If the procedure accesses resources that the external security product protects, the access is performed using the authorization ID of the user who invoked the procedure.

DEFINER

An external security environment should be established for the procedure. If the procedure accesses resources that the external security product protects, the access is performed using the authorization ID of the owner of the procedure.

RUN OPTIONS *run-time-options*

Specifies the Language Environment run time options that are to be used for the procedure. You must specify *run-time-options* as a character string that is no longer than 254 bytes. If you do not specify RUN OPTIONS or pass an empty string, Db2 does not pass any run time options to Language Environment, and Language Environment uses its installation defaults.

For a description of the Language Environment run time options, see Language Environment Programming Reference (z/OS Language Environment Programming Reference).

COMMIT ON RETURN

Indicates whether Db2 commits the transaction immediately on return from the procedure.

NO

Db2 does not issue a commit when the procedure returns.

NO is the default.

YES

Db2 issues a commit when the procedure returns if the following statements are true:

- A positive SQLCODE is returned by the CALL statement.
- The procedure is not in a must abort state.

The commit operation includes the work that is performed by the calling application process and the procedure.

If the procedure returns result sets, the cursors that are associated with the result sets must have been defined as WITH HOLD to be usable after the commit.

INHERIT SPECIAL REGISTERS or DEFAULT SPECIAL REGISTERS

Specifies how special registers are set on entry to the routine.

INHERIT SPECIAL REGISTERS

Specifies that the values of special registers are inherited, according to the rules that are listed in the table for characteristics of special registers in a procedure in Table 47 on page 215.

INHERIT SPECIAL REGISTERS is the default.

DEFAULT SPECIAL REGISTERS

Specifies that special registers are initialized to the default values, as indicated by the rules in the table for characteristics of special registers in a procedure in Table 47 on page 215.

STOP AFTER SYSTEM DEFAULT FAILURES, STOP AFTER *nn* FAILURES, or CONTINUE AFTER FAILURE

Specifies the routine is stopped after failures.

STOP AFTER SYSTEM DEFAULT FAILURES

Specifies that this routine should be placed in a stopped state after the number of failures indicated by the value of field MAX ABEND COUNT on installation panel DSNTIPX.

STOP AFTER SYSTEM DEFAULT FAILURES is the default.

STOP AFTER *nn* FAILURES

Specifies that this routine should be placed in a stopped state after *nn* failures. The value *nn* can be an integer from 1 to 32767.

CONTINUE AFTER FAILURE

Specifies that this routine should not be placed in a stopped state after any failure.

SQL-routine-body

Specifies the statements that define the body of the SQL procedure. For information on the SQL control statements that are supported in external SQL procedures, see Appendix D, "SQL control statements for external SQL procedures," on page 2267.

Notes for CREATE PROCEDURE (SQL - external)

Considerations for all types of procedures

For considerations that apply to all types of procedures, see "CREATE PROCEDURE" on page 1573.

Alternative syntax and synonyms

To provide compatibility with previous releases of Db2 or other products in the Db2 family, Db2 supports the following alternative syntax:

- RESULT SET and RESULT SETS as synonyms for DYNAMIC RESULT SETS
- VARIANT as a synonym for NOT DETERMINISTIC
- NOT VARIANT as a synonym for DETERMINISTIC

Examples for CREATE PROCEDURE (SQL - external)

Example 1

Create the definition for an SQL procedure. The procedure accepts an employee number and a multiplier for a pay raise as input. The following tasks are performed in the procedure body:

- Calculate the employee's new salary.
- Update the employee table with the new salary value.

```
CREATE PROCEDURE UPDATESALARY
 (IN EMPLOYEE_NUMBER CHAR(10),
 IN RATE DECIMAL(6,2))
 LANGUAGE SQL
 FENCED
 EXTERNAL NAME 'USALARY1'
 MODIFIES SQL DATA
  UPDATE EMP
  SET SALARY = SALARY * RATE
  WHERE EMPNO = EMPLOYEE_NUMBER
```

Example 2

Create the definition for the SQL procedure described in example 1, but specify that the procedure has these characteristics:

- The procedure runs in a WLM environment called PARTSA.
- The same input always produces the same output.
- SQL work is committed on return to the caller.
- The Language Environment run time options to be used when the SQL procedure executes are 'MSGFILE(OUTFILE),RPTSTG(ON),RPTOPTS(ON)'.

```
CREATE PROCEDURE UPDATESALARY
 (IN EMPLOYEE_NUMBER CHAR(10),
 IN RATE DECIMAL(6,2))
 LANGUAGE SQL
 FENCED
 EXTERNAL NAME 'USALARY2'
 MODIFIES SQL DATA
 WLM ENVIRONMENT PARTSA
 DETERMINISTIC
 RUN OPTIONS 'MSGFILE(OUTFILE),RPTSTG(ON),RPTOPTS(ON)'
 COMMIT ON RETURN YES
   UPDATE EMP
   SET SALARY = SALARY * RATE
   WHERE EMPNO = EMPLOYEE_NUMBER
```

For more examples of SQL procedures, see Appendix D, "SQL control statements for external SQL procedures," on page 2267.

Related concepts

Procedures (Introduction to Db2 for z/OS)

Naming conventions
The rules for forming a name depend on the type of the object designated by the name.

Related tasks

Migrating an external SQL procedure to a native SQL procedure (Db2 Application programming and SQL)

Creating external SQL procedures (deprecated) (Db2 Application programming and SQL)

CREATE PROCEDURE (SQL - native)

The CREATE PROCEDURE statement defines an SQL procedure, or a version of a procedure, at the current server and specifies the source statements for the procedure.

FL 507

If the OR REPLACE clause is specified and the procedure already exists:

- If the VERSION clause is not specified, the procedure definition is replaced.
- If the VERSION clause is specified and the identified version exists, the version is replaced. Otherwise the version is added to the procedure definition.

Native SQL procedures can contain SQL control statements. For information about the SQL control statements that are supported in native SQL procedures, refer to Chapter 8, "SQL procedural language (SQL PL)," on page 2197.

Invocation for CREATE PROCEDURE (SQL - native)

This statement can only be dynamically prepared, and the DYNAMICRULES run behavior must be specified implicitly or explicitly.

Authorization for CREATE PROCEDURE (SQL - native)

To create a new procedure in the implicit or explicit schema, the privilege set that is defined below must include at least one of the following:

- The CREATIN privilege on the schema
- System DBADM authority
- SYSCTRL authority

- SYSADM authority
- Installation SYSOPR authority (when the current SQLID of the process is set to SYSINSTL)

The authorization ID that matches the schema name implicitly has the CREATEIN privilege on the schema.

FL 507To replace a procedure, the privilege set that is defined below must include at least one of the following:

- Ownership of the procedure
- Both the DROPIN and CREATEIN privilege on the schema
- System DBADM authority
- SYSCTRL authority
- SYSADM authority
- Installation SYSOPR authority (when the current SQLID of the process is set to SYSINSTL)

FL 507To add or replace a version of a procedure, the privilege set that is defined below must include at least one of the following:

- Ownership of the procedure
- The ALTERIN privilege on the schema
- System DBADM authority
- SYSCTRL authority
- SYSADM authority
- Installation SYSOPR authority (when the current SQLID of the process is set to SYSINSTL)

If a user-defined type is referenced (as the data type of a parameter or SQL variable), the privilege set must also include at least one of the following privileges or authorities:

- Ownership of the user-defined type
- The USAGE privilege on the user-defined type
- System DBADM authority
- DATAACCESS authority
- SYSADM authority

If the procedure uses a table as a parameter, the privilege set must also include at least one of the following privileges or authorities:

- Ownership of the table
- The SELECT privilege on the table
- DATAACCESS authority
- SYSADM authority

If you specify the WLM ENVIRONMENT FOR DEBUG MODE clause, RACF or an external security product is invoked to check the required authority for defining programs in the WLM environment. If the WLM environment access is protected in RACF, the privilege set must include the required authority.

To create or replace a procedure, or add or replace a version of a procedure, the privilege set must include the required authorization to add a new package or a new version of an existing package depending on the value of the BIND NEW PACKAGE field on installation panel DSNTIPP, or the privilege set must include SYSADM or SYSCTRL or system DBADM authority. The owner of the procedure package must have the privileges that are required to execute the statements in *SQL-routine-body*.

If the SECURED option is specified, at least one of the following privileges is required:

- SECADM authority
- CREATE_SECURE_OBJECT privilege

If the SEPARATE SECURITY subsystem parameter is set to NO, SYSADM authority has implicit SECADM authority.

Additional authorization might be required on the SYSDUMMY*x* tables depending on the content of the procedure definition. For more information, see SYSDUMMYx tables (Introduction to Db2 for z/OS).

If the authorization ID that is used to create the procedure has the installation SYSADM authority or the installation SYSOPR authority and if the current SQLID is set to SYSINSTL, the procedure is identified as system-defined procedure.

Privilege set:

The privilege set is the privileges that are held by the SQL authorization ID of the process unless the process is within a trusted context and the ROLE AS OBJECT OWNER clause is specified. In that case, the privileges set is the privileges that are held by the role that is associated with the primary authorization ID of the process.

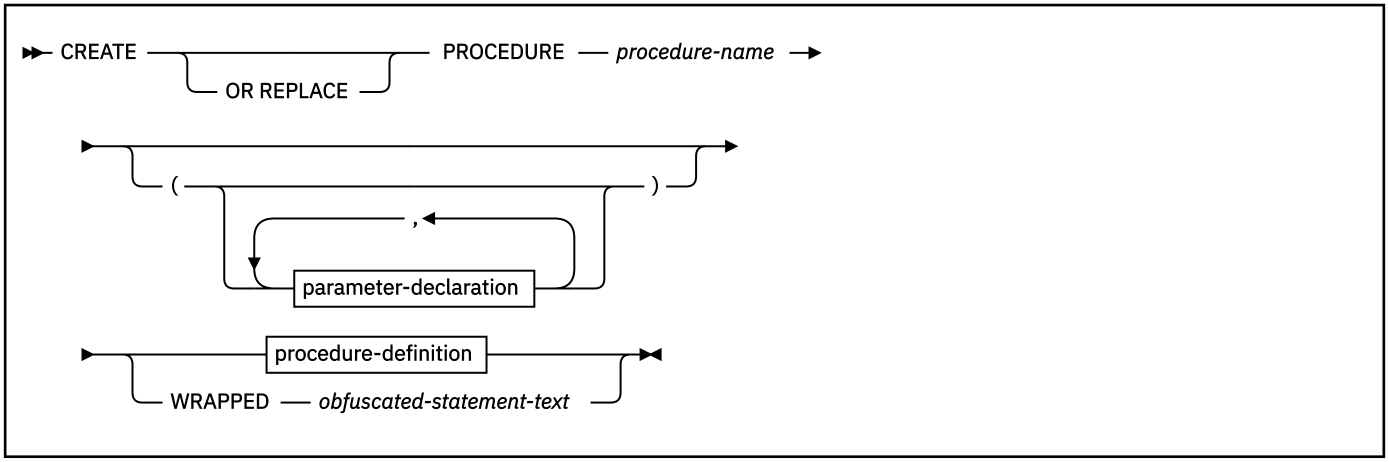
When a CREATE PROCEDURE statement is issued in a trusted context that has the ROLE AS OBJECT OWNER clause, the package owner is determined as follows:

- If the PACKAGE OWNER option is not specified, the role associated with the binder becomes the package owner.
- If the PACKAGE OWNER option is specified, the role specified in the PACKAGE OWNER option becomes the package owner. In a trusted context, the specified PACKAGE OWNER must be a role.

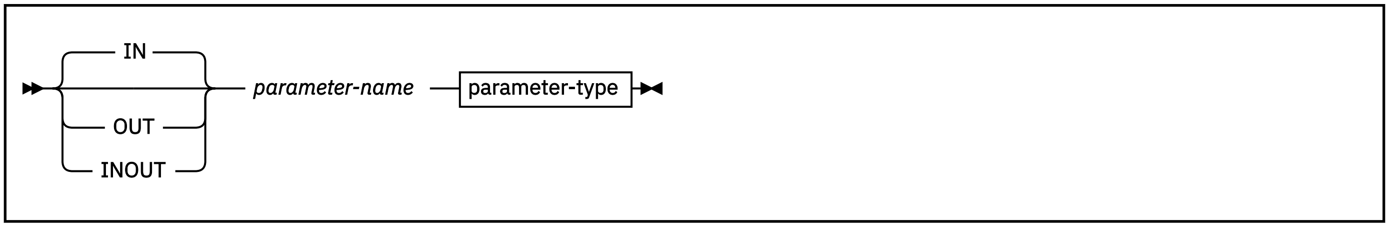
Otherwise, the package owner is determined as follows:

- If the PACKAGE OWNER option is not specified, the procedure owner becomes the package owner.
- If the PACKAGE OWNER option is specified, the *authorization-name* specified in the PACKAGE OWNER option becomes the package owner.

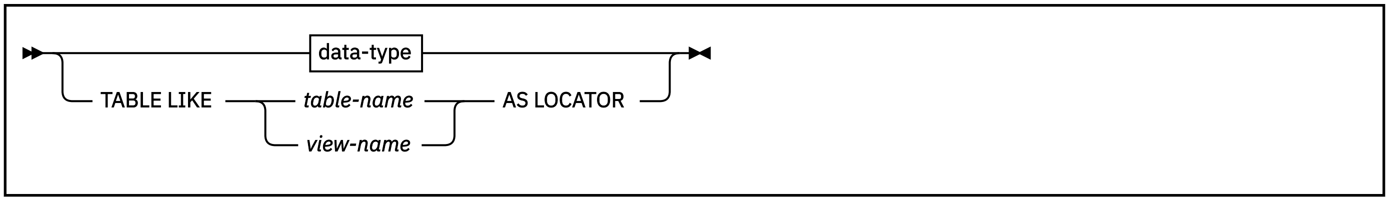
Syntax for CREATE PROCEDURE (SQL - native)



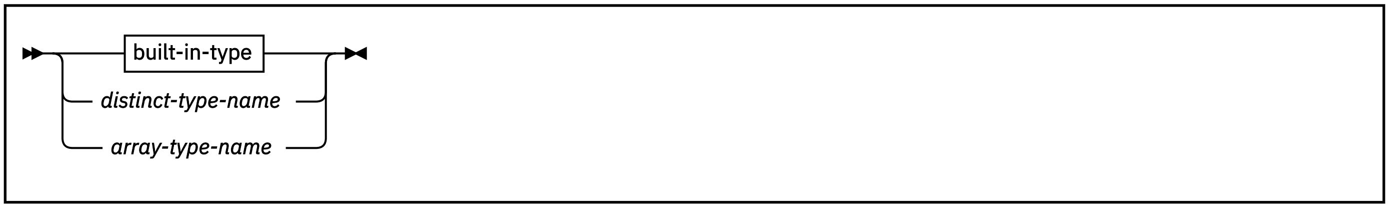
parameter-declaration:



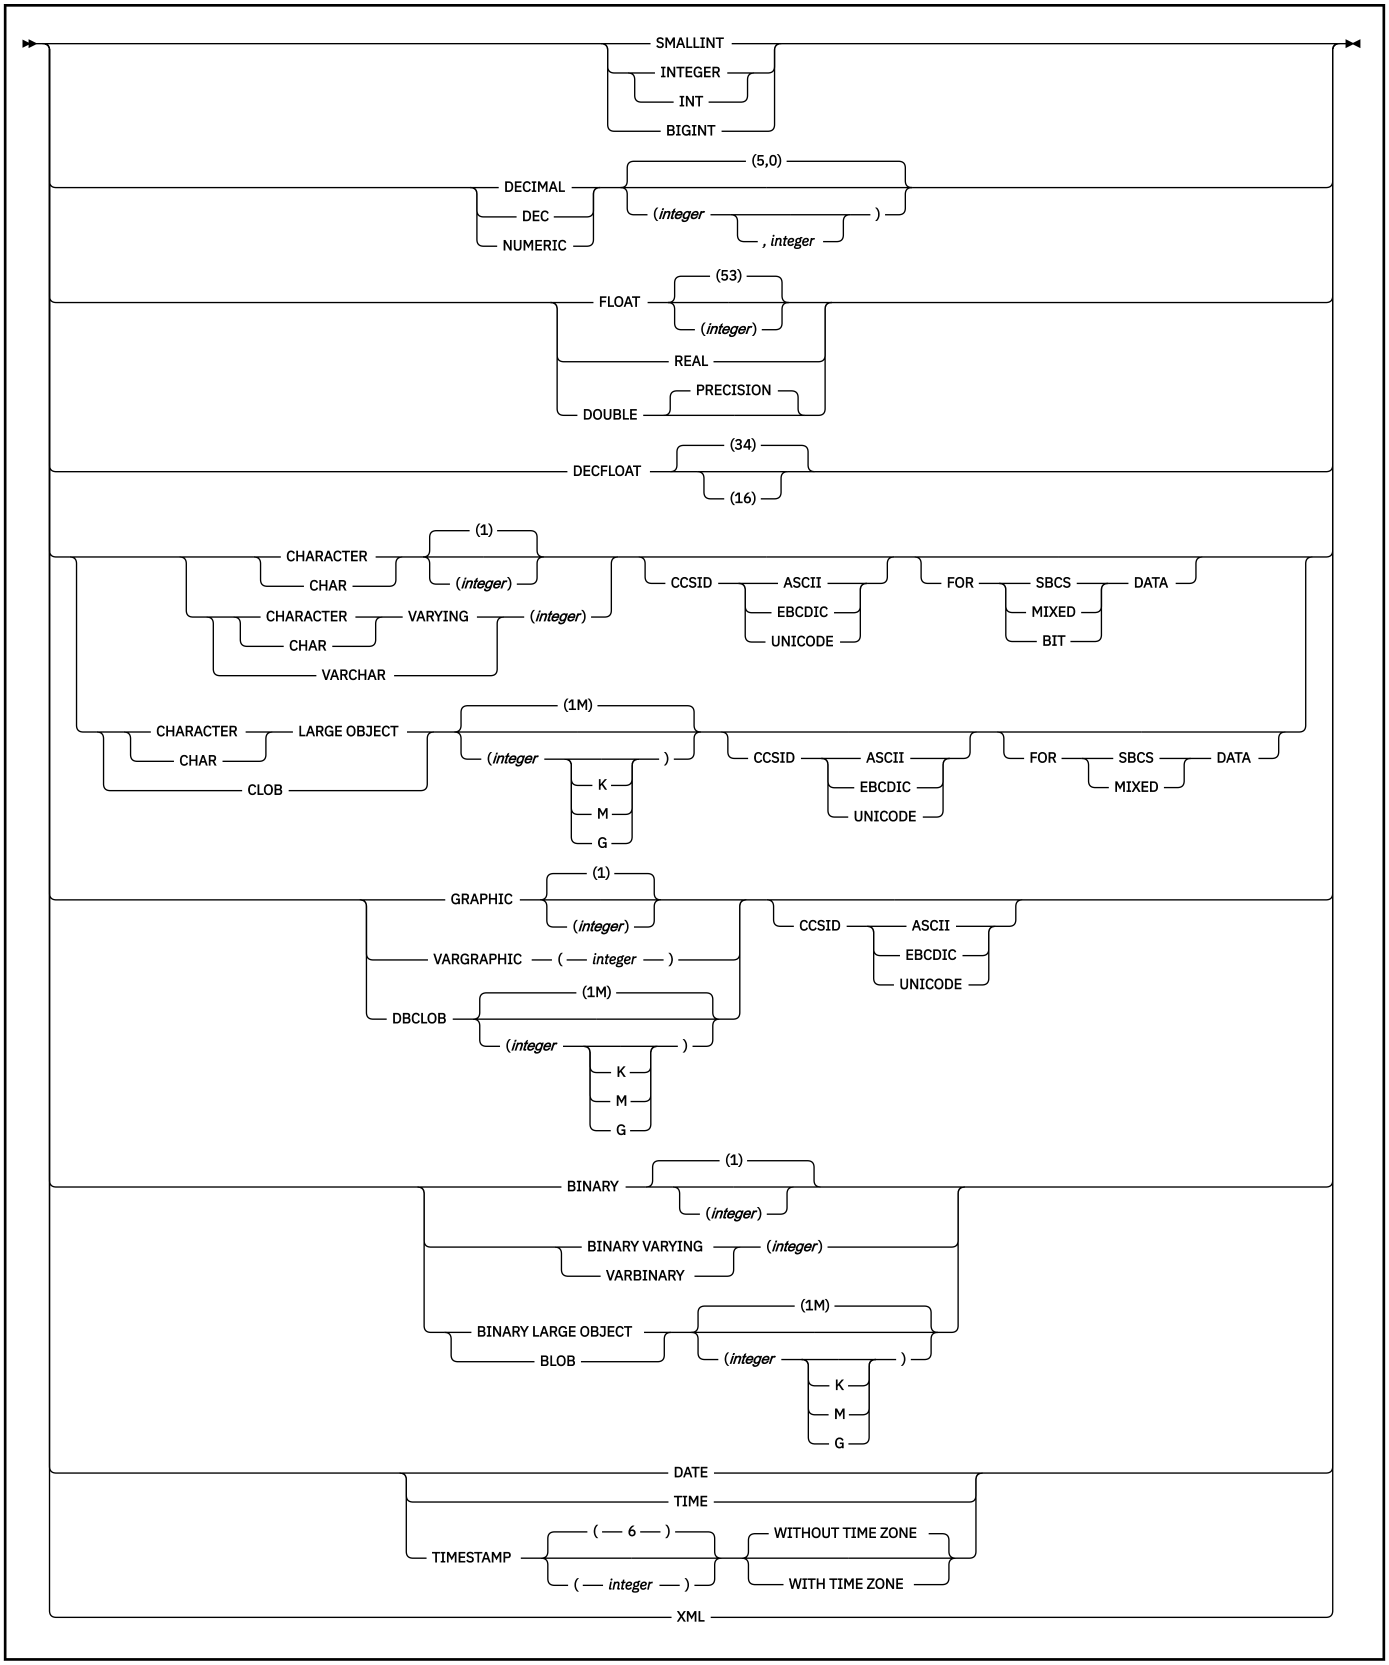
parameter-type:



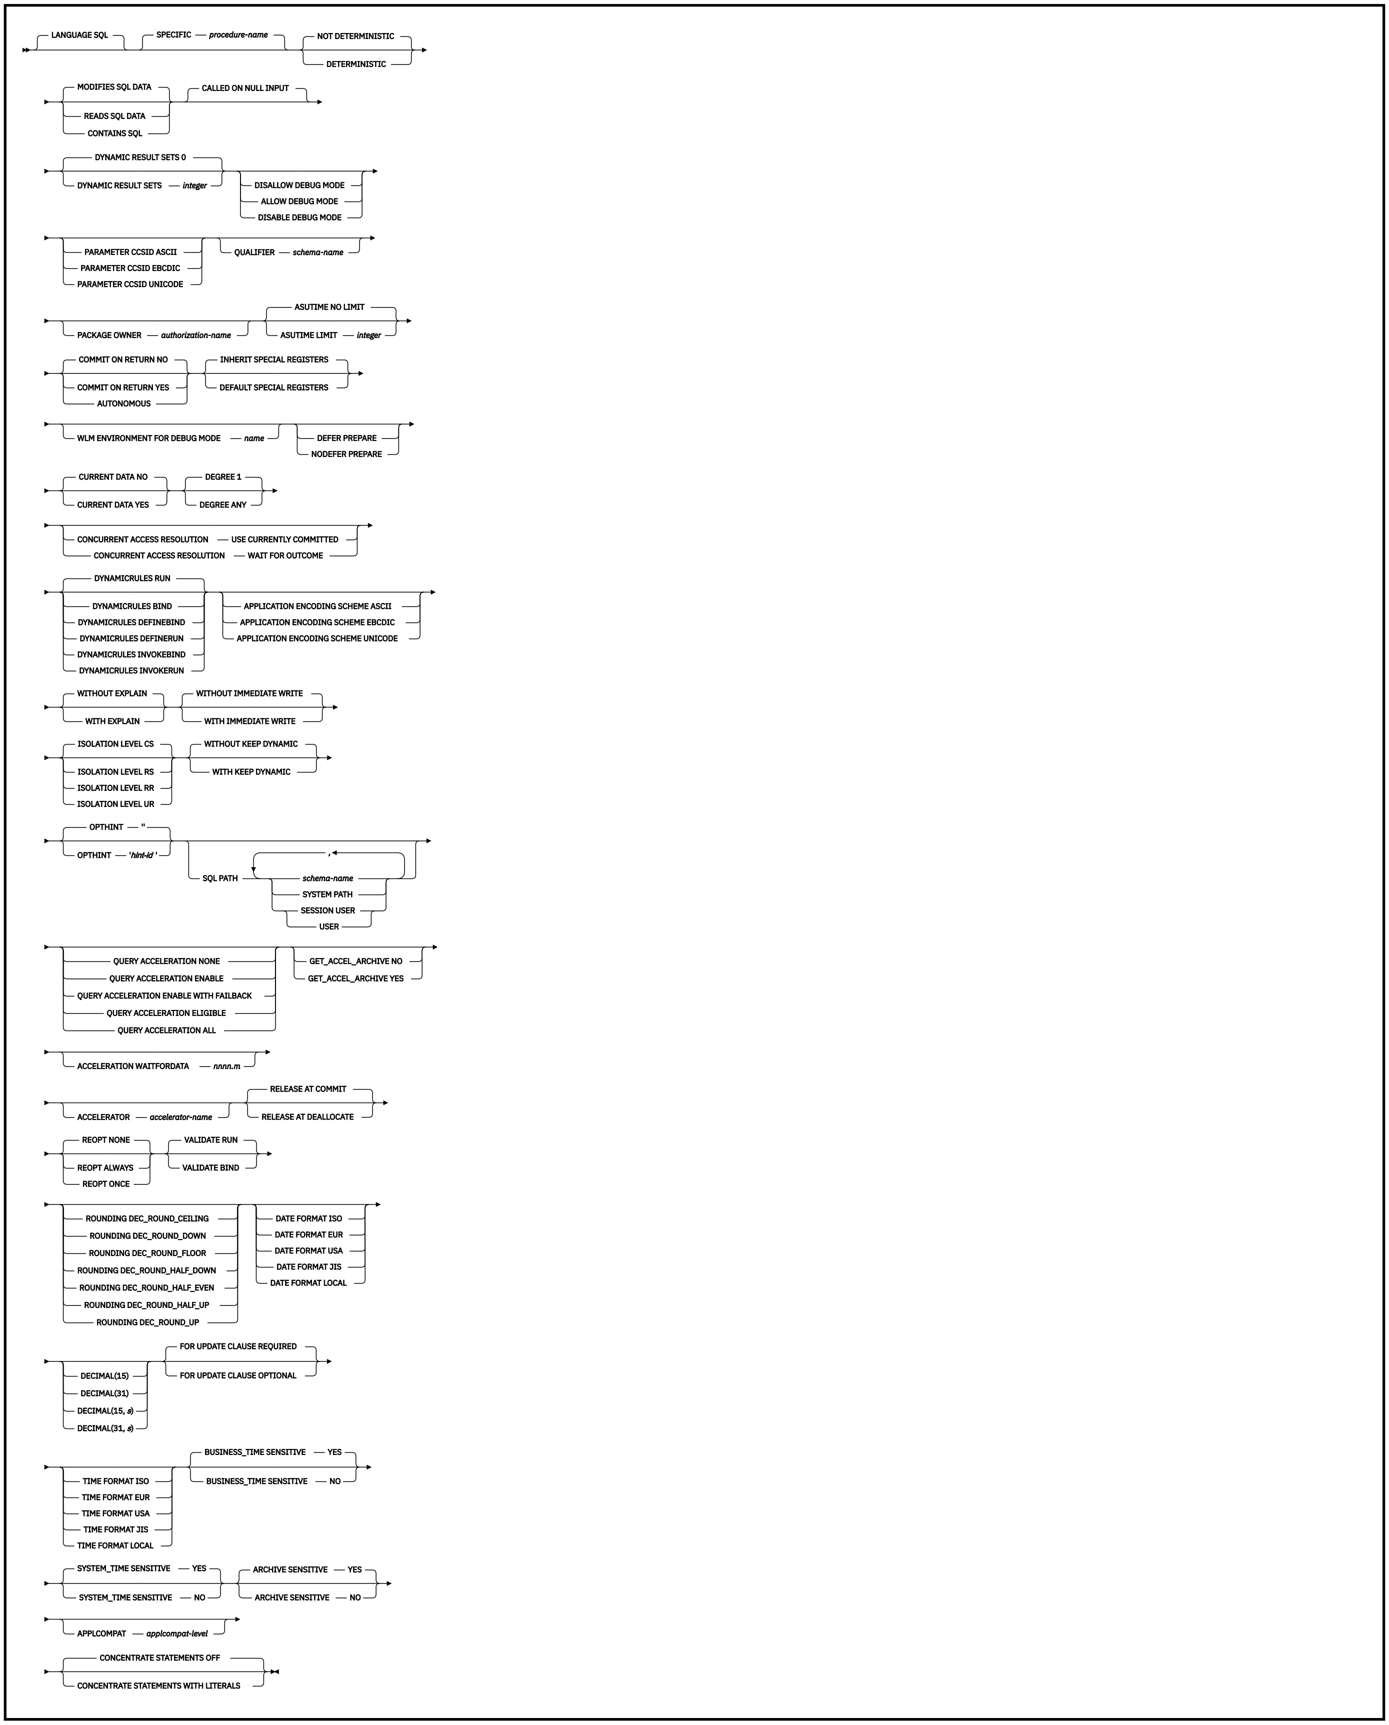
data-type:



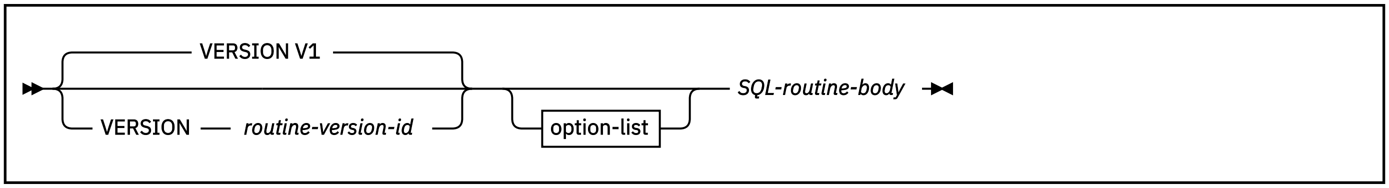
built-in-type:



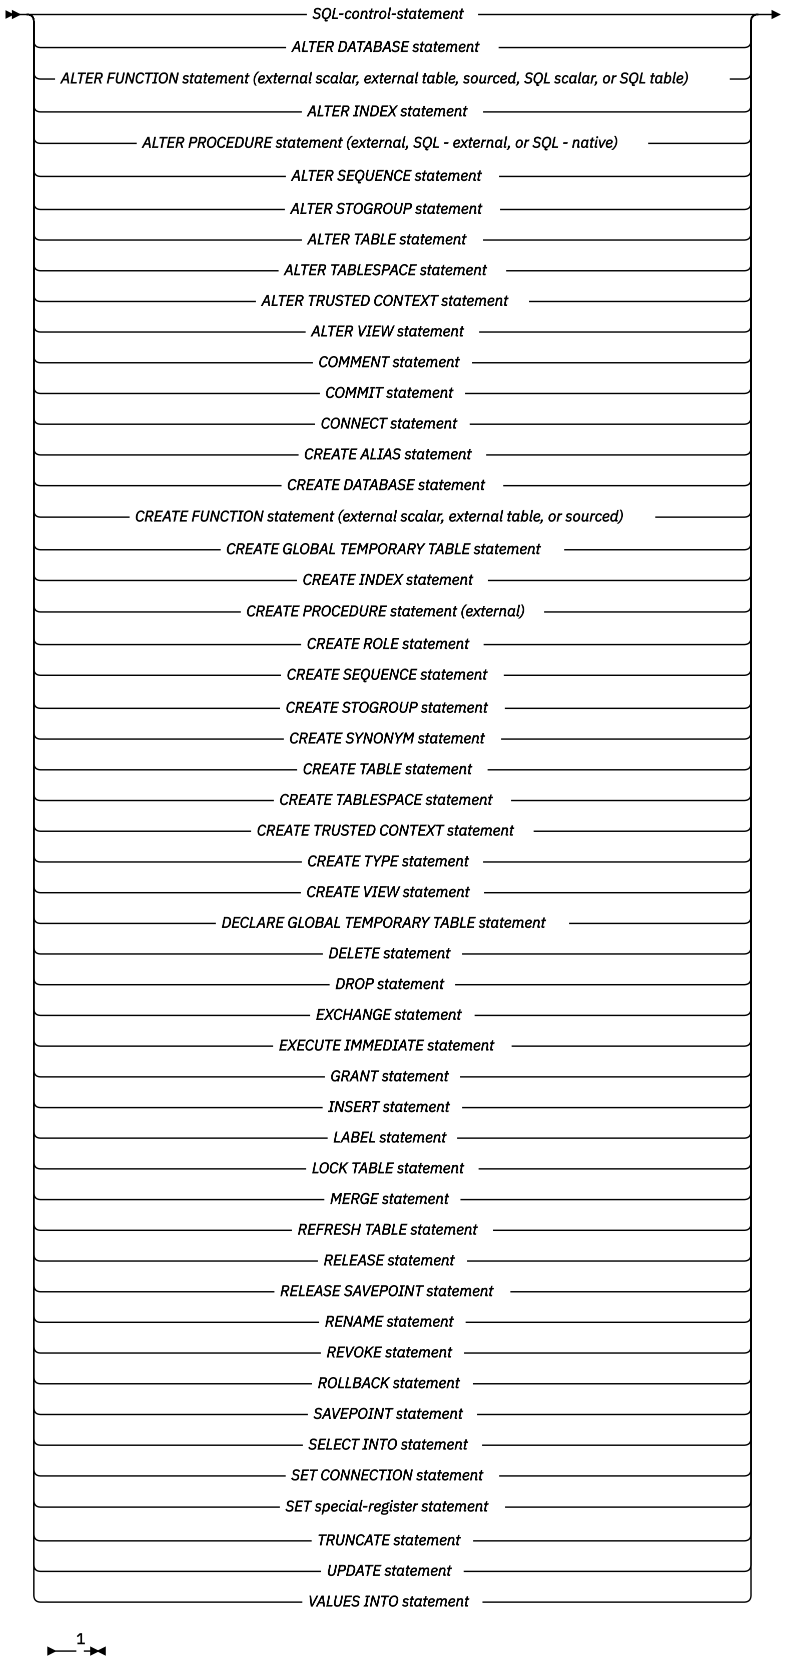
option-list: (The options can be specified in any order, but each one can only be specified one time.)



procedure-definition:



SQL-routine-body:



Notes:

[1] An ALTER FUNCTION statement (SQL scalar) or an ALTER PROCEDURE statement (SQL native) with an ADD VERSION or REPLACE clause are not allowed in an *SQL-routine-body*.

Description for CREATE PROCEDURE (SQL - native)

OR REPLACE

FL 507

Specifies that if the procedure exists at the current server, the existing definition is replaced, or that a version of the procedure is added or replaced. This option is ignored if a definition for the procedure does not exist at the current server. If a procedure exists with the specified name, the existing procedure must be a native SQL procedure.

If the procedure does not yet exist and the VERSION keyword is not specified, the procedure is created with the initial version of the procedure (V1).

If the procedure exists and the VERSION keyword is not specified, the procedure is replaced. The existing definition is dropped before the new definition is replaced in the catalog with the exception that the privileges that were granted on the procedure are not affected. The procedure is re-created as follows:

- Any existing comments are discarded
- The definition of the procedure can change
- The timestamp that is associated with the procedure definition is updated
- The owner of the procedure can change
- System default values are used for options that are not explicitly specified, even if those options were explicitly specified when the procedure that is being replaced was originally defined.

To replace an existing procedure, the procedure must not be defined with more than a single version, or with a single version for which the version id is other than V1. Additionally, one of the following conditions must be met:

- The SPECIFIC clause must be specified with the procedure name
- The signature of the new definition must match the signature of the existing procedure definition, except for parameter names

If the procedure exists with the specified version of the procedure, and the VERSION keyword is specified, the version is replaced in the catalog as if an ALTER PROCEDURE statement had been issued with the REPLACE VERSION clause. The procedure owner is not changed. Binding the replaced version of the procedure might result in a new access path even if the routine body is not changed.

When you replace a version of a procedure, the data types, CCSID specifications, and character data attributes (FOR BIT/SBCS/MIXED DATA) of the parameters must be the same as the attributes of the corresponding parameters for the currently active version of the procedure. The parameter list must not include a table parameter. For options that are not explicitly specified, the system default values for those options are used, even if those options were explicitly specified when the version of the procedure that is being replaced was originally defined. This is not the case for versions of the procedure that specified DISABLE DEBUG MODE. If DISABLE DEBUG MODE is specified for a version of a procedure, the option cannot be changed using a CREATE statement with the OR REPLACE clause.

If the procedure exists but version *routine-version-id* does not exist, and the VERSION keyword is specified, the specified version is created. *routine-version-id* is the version identifier for the new version of the procedure. The new version is defined as if an ALTER PROCEDURE statement had been issued with an ADD VERSION clause. The procedure owner is not changed. When a procedure definition is replaced, any existing comments in the catalog for that definition of the procedure are removed.

When you add a new version of a procedure, the data types, CCSID specifications, and character data attributes (FOR BIT/SBCS/MIXED DATA) of the parameters must be the same as the attributes of the corresponding parameters for the currently active version of the procedure. The parameter list must not include a table parameter. The parameter names can differ from the other versions of the procedure. For options that are not explicitly specified, the system default values are used.

procedure-name

FL 507

Names the procedure. The name, including the implicit or explicit schema name, must not identify a procedure that exists at the current server. However, you can specify an existing procedure name when the OR REPLACE keyword is also specified.

The name must not identify an existing wrapped procedure if the CREATE statement adds or replaces a version of that procedure.

The schema name can be 'SYSTOOLS' or 'SYSFUN' if the privilege set includes the SYSADM or SYSCTRL privilege. Otherwise, the schema name must not begin with 'SYS' unless the schema name is 'SYSADM', 'SYSIBMADM', or 'SYSPROC'.

(*parameter-declaration,...*)

Specifies the number of parameters of the procedure, the data type and usage of each parameter, and the name of each parameter for the version of the procedure that is being defined. The number of parameters and the specified data type and usage of each parameter must match the data types in the corresponding position of the parameter for all other versions of this procedure. Synonyms for data types are considered to be a match. All parameters are nullable.

IN, OUT, and INOUT specify the usage of the parameter. The usage of the parameters must match the implicit or explicit usage of the parameters of other versions of the same procedure.

IN

Identifies the parameter as an input parameter to the procedure. The value of the parameter on entry to the procedure is the value that is returned to the calling SQL application, even if changes are made to the parameter within the procedure.

IN is the default.

OUT

Identifies the parameter as an output parameter that is returned by the procedure. If the parameter is not set within the procedure, the null value is returned.

INOUT

Identifies the parameter as both an input and output parameter for the procedure. If the parameter is not set within the procedure, its input value is returned.

parameter-name

Names the parameter for use as an SQL variable. A parameter name cannot be the same as the name of any other parameter for this version of the procedure. The name of the parameter in this version of the procedure can be different than the name of the corresponding parameter for other versions of this procedure.

built-in-type

The data type of the parameter is a built-in data type.

For more information on the data types, including the subtype of character data types (the FOR *subtype* DATA clause), see "*built-in-type*" in “CREATE TABLE” on page 1645. However, the varying length string data types have different maximum lengths than for the CREATE TABLE statement. The maximum lengths for parameters (and SQL variables) are as follows: 32704 for VARCHAR or VARBINARY, and 16352 for VARGRAPHIC.

For parameters with a character or graphic data type, the PARAMETER CCSID clause or CCSID clause indicates the encoding scheme of the parameter. If you do not specify either of these clauses, the encoding scheme is the value of field DEF ENCODING SCHEME on installation panel DSNTIPF.

Although an input parameter with a character data type has an implicitly or explicitly specified subtype (BIT, SBCS, or MIXED), the value that is actually passed in the input parameter can have any subtype. Therefore, conversion of the input data to the subtype of the parameter might occur when the procedure is called. With ASCII or EBCDIC, an error occurs if mixed data that actually contains DBCS characters is used as the value for an input parameter that is declared with an SBCS subtype.

Parameters with a datetime data type or a distinct type are passed to the function as a different data type:

- A datetime type parameter is passed as a character data type, and the data is passed in ISO format. The encoding scheme for a datetime type parameter is the same as the implicitly or explicitly specified encoding scheme of any character or graphic string parameters. If no character or graphic string parameters are passed, the encoding scheme is the value of field DEF ENCODING SCHEME on installation panel DSNTIPF.
- A distinct type parameter is passed as the source type of the distinct type.

AS LOCATOR

Specifies that a locator to the value of the parameter is passed to the procedure instead of the actual value. Specify AS LOCATOR only for parameters with a LOB data type or a distinct type based on a LOB data type. Passing locators instead of values can result in fewer bytes being passed to the procedure, especially when the value of the parameter is very large.

The AS LOCATOR clause has no effect on determining whether data types can be promoted.

distinct-type-name

The data type of the input parameter is a distinct type. Any length, precision, scale, subtype, or encoding scheme attributes for the parameter are those of the source type of the distinct type. The distinct type must not be based on a LOB data type.

array-type-name

The data type of the input parameter is a user-defined array type.

If you specify *array-type-name* without a schema name, Db2 resolves the array type by searching the schemas in the SQL path.

TABLE LIKE *table-name* AS LOCATOR

Specifies that the parameter is a transition table. However, when the procedure is called, the actual values in the transition table are not passed to the procedure. A single value is passed instead. This single value is a locator to the table, which the procedure uses to access the columns of the transition table. The table that is identified can contain XML columns; however, the procedure cannot reference those XML columns. A procedure with a table parameter can only be invoked from the triggered action of a trigger.

The TABLE LIKE clause must not be specified when the CREATE statement adds or replaces a version of an existing procedure.

VERSION *routine-version-id*

Specifies the version identifier for the version of the procedure that is to be defined. See "Naming conventions" on page 79 for information about specifying *routine-version-id*. You can use an ALTER PROCEDURE statement with the ADD VERSION clause or the BIND DEPLOY command to create additional versions of the procedure.

V1 is the default version identifier.

Important: Do not create additional versions of procedures that are supplied with Db2 by specifying the VERSION keyword. Only versions that are supplied with Db2 are supported. Additional versions of such routines cause the installation and configuration of the supplied routines to fail.

LANGUAGE SQL

Specifies that the procedure is written in the Db2 SQL procedural language.

SPECIFIC *procedure-name*

FL 507

Specifies the procedure name as the specific name for the procedure. The name must be the same as the procedure name.

If you do not specify a schema name, it is the same as the explicit or implicit schema name of the procedure name (*procedure-name*). If you specify a schema name, it must be the same as the explicit or implicit schema name of the procedure name.

If you do not specify the SPECIFIC clause, the specific name is the name of the procedure. The specific name is stored in the SPECIFIC column of the SYSROUTINES catalog table.

Specify the SPECIFIC clause when replacing an existing procedure in the following situations:

- The parameter list of the existing procedure includes a table parameter.
- The CREATE statement specifies changes to the parameter list other than for parameter names.

DETERMINISTIC or NOT DETERMINISTIC

Specifies whether the procedure returns the same results each time it is called with the same IN and INOUT arguments.

DETERMINISTIC

The procedure always returns the same results each time it is called with the same IN and INOUT arguments if the data that is referenced in the database has not changed.

NOT DETERMINISTIC

The procedure might not return the same result each time it is called with the same IN and INOUT arguments, even when the data that is referenced in the database has not changed.

NOT DETERMINISTIC is the default.

Db2 does not verify that the procedure code is consistent with the specification of DETERMINISTIC or NOT DETERMINISTIC.

MODIFIES SQL DATA, READS SQL DATA, or CONTAINS SQL

Specifies the classification of SQL statements and nested routines that this routine can execute or invoke. The database manager verifies that the SQL statements issued by the procedure, and all routines locally invoked by the routine, are consistent with this specification; the verification is not performed when nested remote routines are invoked. For the classification of each statement, see "SQL statement data access classification for routines" on page 2263.

MODIFIES SQL DATA

Specifies that the procedure can execute any SQL statement except statements that are not supported in procedures.

MODIFIES SQL DATA is the default.

READS SQL DATA

Specifies that the procedure can execute statements with a data access indication of READS SQL DATA or CONTAINS SQL. The procedure cannot execute SQL statements that modify data.

CONTAINS SQL

Specifies that the procedure can execute only SQL statements with a data access indication of CONTAINS SQL. The procedure cannot execute statements that read or modify data.

CALLED ON NULL INPUT

Specifies that the procedure will be called if any, or even if all parameter values are null.

DYNAMIC RESULT SETS *integer*

Specifies the maximum number of query result sets that the procedure can return. The default is DYNAMIC RESULT SETS 0, which indicates that there are no result sets. The value must be between 0 and 32767.

`ALLOW DEBUG MODE`, `DISALLOW DEBUG MODE`, or `DISABLE DEBUG MODE`

Specifies whether this version of the routine can be run in debugging mode. The default is determined using the value of the CURRENT DEBUG MODE special register.

`ALLOW DEBUG MODE`

Specifies that this version of the routine can be run in debugging mode. When this version of the routine is invoked and debugging is attempted, a WLM environment must be available.

`DISALLOW DEBUG MODE`

Specifies that this version of the routine cannot be run in debugging mode.

You can use an ALTER statement to change this option to ALLOW DEBUG MODE for this initial version of the routine.

DISABLE DEBUG MODE

Specifies that this version of the routine can never be run in debugging mode.

This version of the routine cannot be changed to specify ALLOW DEBUG MODE or DISALLOW DEBUG MODE after this version of the routine has been created or altered to use DISABLE DEBUG MODE. To change this option, drop the routine and create it again using the option that you want. An alternative to dropping and recreating the routine is to create a version of the routine that uses the option that you want and making that version the active version.

When DISABLE DEBUG MODE is in effect, the WLM ENVIRONMENT FOR DEBUG MODE is ignored.

PARAMETER CCSID

Indicates whether the encoding scheme for character or graphic string parameters is ASCII, EBCDIC, or UNICODE. The default encoding scheme is the value that is specified in the CCSID clauses of the parameter list, or in the field DEF ENCODING SCHEME on installation panel DSNTIPF.

This clause provides a convenient way to specify the encoding scheme for character or graphic string parameters. If individual CCSID clauses are specified for individual parameters in addition to this PARAMETER CCSID clause, the value that is specified in all of the CCSID clauses must be the same value that is specified in this clause.

If the data type for a parameter is a user-defined distinct type that is defined as a character or graphic type string, the CCSID of the distinct type must be the same as the value that is specified in this clause.

If the data type for a parameter is a user-defined array type that is defined with character or graphic string array elements, or a character string array index, the CCSID of these array attributes must be the same as the value that is specified in this clause.

This clause also specifies the encoding scheme that will be used for system-generated parameters of the routine.

QUALIFIER *schema-name*

Specifies the implicit qualifier that is used for unqualified object names that are referenced in the procedure body. For information about how the default for this option is determined, see "Unqualified alias, index, JAR file, mask, permission, sequence, table, trigger, and view names" on page 86.

PACKAGE OWNER *authorization-name*

Specifies the owner of the package that is associated with the version of the routine. The SQL authorization ID of the process is the default value.

ASUTIME

Specifies the total amount of processor time, in CPU service units, that a single invocation of a routine can run. The value is unrelated to the ASUTIME column of the resource limit specification table.

When you are debugging a routine, setting a limit can be helpful in case the routine gets caught in a loop. For information on service units, see z/OS MVS Initialization and Tuning Guide.

NO LIMIT

Specifies that there is no limit on the service units.

NO LIMIT is the default.

LIMIT *integer*

The limit on the number of CPU service units is a positive *integer* in the range 1 - 2 147 483 647. If the procedure uses more service units than the specified value, Db2 cancels the procedure. The CPU cycles that are consumed by parallel tasks in a procedure do not contribute towards the specified ASUTIME LIMIT.

COMMIT ON RETURN NO, COMMIT ON RETURN YES, or AUTONOMOUS

Indicates whether Db2 commits the transaction immediately on return from the procedure.

COMMIT ON RETURN NO

Db2 does not issue a commit when the procedure returns. NO is the default.

COMMIT ON RETURN YES,

Db2 issues a commit when the procedure returns if the following statements are true:

- The SQLCODE that is returned by the CALL statement is not negative.
- The procedure is not in a must-abort state.

The commit operation includes the work that is performed by the calling application process and by the procedure.

If the procedure returns result sets, the cursors that are associated with the result sets must have been defined as WITH HOLD to be usable after the commit.

AUTONOMOUS

Db2 executes the SQL procedure in a unit of work that is independent from the calling application. When this option is specified the procedure follows the rules of the COMMIT ON RETURN YES option before returning to the calling application. However, it does not commit changes in the calling application. When autonomous is specified:

- DYNAMIC RESULT SETS 0 must be in effect.
- Stored procedure parameters must not be defined as:
  - A LOB type
  - The XML data type
  - A distinct data type that is based on a LOB or XML value
  - An array type that is defined with array elements that are a LOB type

A value must not be assigned to a global variable when an autonomous procedure is executing.

INHERIT SPECIAL REGISTERS or DEFAULT SPECIAL REGISTERS

Specifies how special registers are set on entry to the routine.

INHERIT SPECIAL REGISTERS

Specifies that the values of special registers are inherited, according to the rules that are listed in the table for characteristics of special registers in a routine in Table 47 on page 215.

INHERIT SPECIAL REGISTERS is the default.

DEFAULT SPECIAL REGISTERS

Specifies that special registers are initialized to the default values, as indicated by the rules in the table for characteristics of special registers in a routine in Table 47 on page 215.

WLM ENVIRONMENT FOR DEBUG MODE *name*

Specifies the WLM (workload manager) application environment that is used by Db2 when debugging the routine. The *name* of the WLM environment is an SQL identifier.

If you do not specify WLM ENVIRONMENT FOR DEBUG MODE, Db2 uses the default WLM-established stored procedure address space specified at installation time.

You must have the appropriate authority for the WLM application environment.

The WLM ENVIRONMENT FOR DEBUG MODE value is ignored when DISABLE DEBUG MODE is in effect.

DEFER PREPARE or NODEFER PREPARE

Specifies whether to defer preparation of dynamic SQL statements that refer to remote objects, or to prepare them immediately.

The default depends on the value in effect for the REOPT option. If REOPT NONE is in effect, the default is inherited from the plan at run time. Otherwise, the default is DEFER PREPARE.

DEFER PREPARE

Specifies that the preparation of dynamic SQL statements that refer to remote objects will be deferred.

For considerations for distributed processing, see DEFER and NODEFER bind options (Db2 Commands).

NODEFER PREPARE

Specifies that the preparation of dynamic SQL statements that refer to remote objects will not be deferred.

CURRENT DATA YES or CURRENT DATA NO

Specifies whether to require data currency for read-only and ambiguous cursors when the isolation level of cursor stability is in effect. CURRENT DATA also determines whether block fetch can be used for distributed, ambiguous cursors.

CURRENT DATA YES

Specifies that data currency is required for read-only and ambiguous cursors. Db2 acquired page or row locks to ensure data currency. Block fetch is ignored for distributed, ambiguous cursors.

CURRENT DATA NO

Specifies that data currency is not required for read-only and ambiguous cursors. Block fetch is allowed for distributed, ambiguous cursors. Use of CURRENT DATA NO is not recommended if the routine attempts to dynamically prepare and execute a DELETE WHERE CURRENT OF statement against an ambiguous cursor after that cursor is opened. You receive a negative SQLCODE if your routine attempts to use a DELETE WHERE CURRENT OF statement for any of the following cursors:

- A cursor that is using block fetch
- A cursor that is using query parallelism
- A cursor that is positioned on a row that is modified by this or another application process

CURRENT DATA NO is the default.

DEGREE

Specifies whether to attempt to run a query using parallel processing to maximize performance.

1

Specifies that parallel processing should not be used.

1 is the default.

ANY

Specifies that parallel processing can be used.

CONCURRENT ACCESS RESOLUTION

Specifies the whether processing uses only committed data or whether it will wait for commit or rollback of data that is in the process of being updated.

WAIT FOR OUTCOME

Specifies that processing will wait for the commit or rollback of data that is in the process of being updated.

USE CURRENTLY COMMITTED

Specifies that processing use the currently committed version of the data when data that is in the process of being updated is encountered. USE CURRENTLY COMMITTED is applicable on scans that access tables that are defined in universal table spaces with row or page level lock size.

When there is lock contention between a read transaction and an insert transaction, USE CURRENTLY COMMITTED is applicable to scans with isolation level CS or RS. Applicable scans include intent read scans for read-only and ambiguous queries and for updatable cursors. USE CURRENTLY COMMITTED is also applicable to scans initiated from WHERE predicates of UPDATE or DELETE statements and the subselect of INSERT statements.

When there is lock contention is between a read transaction and a delete transaction, USE CURRENTLY COMMITTED is applicable to scans with isolation level CS and when CURRENT DATA NO is specified.

DYNAMICRULES

Specifies the values that apply, at run time, for the following dynamic SQL attributes:

- The authorization ID that is used to check authorization
- The qualifier that is used for unqualified objects

- The source for application programming options that Db2 uses to parse and semantically verify dynamic SQL statements

DYNAMICRULES also specifies whether dynamic SQL statements can include GRANT, REVOKE, ALTER, CREATE, DROP, and RENAME statements.

In addition to the value of the DYNAMICRULES clause, the run time environment of a routine controls how dynamic SQL statements behave at run time. The combination of the DYNAMICRULES value and the run time environment determines the value for the dynamic SQL attributes. That set of attribute values is called the dynamic SQL statement behavior. The following values can be specified:

RUN
Specifies that dynamic SQL statements are to be processed using run behavior.

RUN is the default.

BIND
Specifies that dynamic SQL statements are to be processed using bind behavior.

DEFINEBIND
Specifies that dynamic SQL statements are to be processed using either define behavior or bind behavior.

DEFINERUN
Specifies that dynamic SQL statements are to be processed using either define behavior or run behavior.

INVOKEBIND
Specifies that dynamic SQL statements are to be processed using either invoke behavior or bind behavior.

INVOKERUN
Specifies that dynamic SQL statements are to be processed using either invoke behavior or run behavior.

See For information on the effects of these options, see "Authorization IDs and dynamic SQL" on page 94.

APPLICATION ENCODING SCHEME
Specifies the default encoding scheme for SQL variables in static SQL statements in the routine body. The value is used for defining an SQL variable in a compound statement if the CCSID clause is not specified as part of the data type, and the PARAMETER CCSID routine option is not specified.

ASCII
Specifies that the data is encoded using the ASCII CCSIDs of the server.

EBCDIC
Specifies that the data is encoded using the EBCDIC CCSIDs of the server.

UNICODE
Specifies that the data is encoded using the Unicode CCSIDs of the server.

See the ENCODING bind option in ENCODING bind option (Db2 Commands) for information about how the default for this option is determined.

WITH EXPLAIN or WITHOUT EXPLAIN
Specifies whether information will be provided about how SQL statements in the routine will execute.

WITHOUT EXPLAIN
Specifies that information will not be provided about how SQL statements in the routine will execute.

You can get EXPLAIN output for a statement that is embedded in a routine that is specified using WITHOUT EXPLAIN by embedding the SQL statement EXPLAIN in the routine body. Otherwise, the value of the EXPLAIN option applies to all explainable SQL statements in the routine body, and to the fullselect portion of any DECLARE CURSOR statements.

WITHOUT EXPLAIN is the default.

WITH EXPLAIN

Specifies that information will be provided about how SQL statements in the routine will execute. Information is inserted into the table *owner*.PLAN_TABLE. *owner* is the authorization ID of the owner of the routine. Alternatively, the authorization ID of the owner of the routine can have an alias as *owner*.PLAN_TABLE that points to the base table, PLAN_TABLE. *owner* must also have the appropriate SELECT and INSERT privileges on that table. WITH EXPLAIN does not obtain information for statements that access remote objects. PLAN_TABLE must have a base table and can have multiple aliases with the same table name, PLAN_TABLE, but have different schema qualifiers. It cannot be a view or a synonym and should exist before the CREATE statement is processed. In all inserts to *owner*.PLAN_TABLE, the value of QUERYNO is the statement number that is assigned by Db2.

The WITH EXPLAIN option also populates two optional tables, if they exist: DSN_STATEMNT_TABLE and DSN_FUNCTION_TABLE. DSN_STATEMNT_TABLE contains an estimate of the processing cost for an SQL statement and DSN_FUNCTION_TABLE contains information about function resolution. For more information, see EXPLAIN tables (Db2 Performance).

For more information about the EXPLAIN statement, including a description of the tables that are populated by the WITH EXPLAIN option, see "EXPLAIN" on page 1912.

WITH IMMEDIATE WRITE or WITHOUT IMMEDIATE WRITE

Specifies whether immediate writes are to be done for updates that are made to group buffer pool dependent page sets or partitions. This option is only applicable for data sharing environments. The IMMEDWRITE subsystem parameter has no affect of this option. IMMEDWRITE bind option (Db2 Commands) shows the implied hierarchy of the IMMEDWRITE bind option (which is similar to this routine option) as it affects run time.

WITHOUT IMMEDIATE WRITE

Specifies that normal write activity is performed. Updated pages that are group buffer pool dependent are written at or before phase one of commit or at the end of abort for transactions that have been rolled back.

WITHOUT IMMEDIATE WRITE is the default.

WITH IMMEDIATE WRITE

Specifies that updated pages that are group buffer pool dependent are immediately written as soon as the buffer update completes. Updated pages are written immediately even if the buffer is updated during forward progress or during the rollback of a transaction. WITH IMMEDIATE WRITE might impact performance.

ISOLATION LEVEL RR, RS, CS, or UR

Specifies how far to isolate the routine from the effects of other running applications. For information about isolation levels, see Choosing an ISOLATION option (Db2 Performance).

RR

Specifies repeatable read.

RS

Specifies read stability.

CS

Specifies cursor stability. CS is the default.

UR

Specifies uncommitted read.

WITH KEEP DYNAMIC or WITHOUT KEEP DYNAMIC

Specifies whether Db2 keeps dynamic SQL statements after commit points.

WITHOUT KEEP DYNAMIC

Specifies that Db2 does not keep dynamic SQL statements after commit points.

WITHOUT KEEP DYNAMIC is the default.

WITH KEEP DYNAMIC

Specifies that Db2 keeps dynamic SQL statements after commit points. If you specify WITH KEEP DYNAMIC, the application does not need to prepare an SQL statement after every commit point. Db2 keeps the dynamic SQL statement until one of the following occurs:

- The application process ends
- A rollback operations occurs
- The application executes an explicit PREPARE statement with the same statement identifier as the dynamic SQL statement

If you specify WITH KEEP DYNAMIC, and the dynamic statement cache is active, the Db2 subsystem keeps a copy of the prepared statement in the cache. If the dynamic statement cache is not active, the subsystem keeps only the SQL statement string past a commit point. If the application executes an OPEN, EXECUTE, or DESCRIBE operation for that statement, the statement is implicitly prepared.

If you specify WITH KEEP DYNAMIC, DDF server threads that are used to execute procedures or packages that have this option in effect will remain active. Active DDF server threads are subject to idle thread timeout. For more information see IDLE THREAD TIMEOUT field (IDTHTOIN subsystem parameter) (Db2 Installation and Migration).

If you specify WITH KEEP DYNAMIC, you must not specify REOPT ALWAYS. WITH KEEP DYNAMIC and REOPT ALWAYS are mutually exclusive. However, you can specify WITH KEEP DYNAMIC and REOPT ONCE.

Use WITH KEEP DYNAMIC to improve performance if your DRDA client application uses a cursor that is defined as WITH HOLD. The Db2 subsystem automatically closes a held cursor when there are no more rows to retrieve, which eliminates an extra network message.

OPTHINT '*hint-id*'

Specifies whether query optimization hints are used for static SQL statements that are contained within the body of the routine.

hint-id is a character string of up to 128 bytes in length, which is used by the Db2 subsystem when searching the PLAN_TABLE for rows to use as input. The default value is an empty string (''), which indicates that the Db2 subsystem does not use optimization hints for static SQL statements.

Optimization hints are only used if optimization hints are enabled for your system. For more information, see OPTIMIZATION HINTS field (OPTHINTS subsystem parameter) (Db2 Installation and Migration).

SQL PATH

Specifies the SQL path that Db2 uses to resolve unqualified user-defined type, function, and procedure names in static SQL statements in the procedure body.

This option does not apply to dynamic SQL statements in the procedure body. Db2 uses the CURRENT PATH special register value to resolve unqualified user-defined type, function, and procedure names in dynamic SQL statements.

The default value for SQL PATH is "SYSIBM", "SYSFUN", "SYSPROC", "SYSIBMADM", and the value of the QUALIFIER option, which is the qualifier for the procedure that is the target of the statement.

Schemas "SYSIBM", "SYSFUN", "SYSPROC", "SYSIBMADM" do not need to be explicitly specified. If any of these schemas is not explicitly specified, it is implicitly assumed at the beginning the SQL path.

Db2 calculates the length by taking each *schema-name* specified and removing any trailing blanks from it, adding two delimiters around it, and adding one comma after each schema name except for the last one. The length of the resulting string cannot exceed the length of the CURRENT SCHEMA special register. If you do not specify the "SYSIBM", "SYSFUN", "SYSPROC", "SYSIBMADM", schemas, they are not included in the length of the SQL path. If the total length of the SQL path exceeds the length of the CURRENT PATH special register, Db2 returns an error for the CREATE statement.

For more information, see the following related topics:

- “SQL path” on page 85
- PATH bind option (Db2 Commands)
- “CURRENT PATH special register” on page 200
- “CURRENT SCHEMA special register” on page 206

schema-name

Specifies a schema. Db2 does not validate that the specified schema actually exists when the CREATE statement is processed.

SYSPUBLIC must not be specified for the SQL path.

schema-name-list

Specifies a comma separated list of schema names. The same schema name should not appear more than one time in the list of schema names. The number of schema names that you can specify is limited by the maximum length of the resulting SQL path.

SYSPUBLIC must not be specified for the SQL path.

SYSTEM PATH

Specifies the schema names "SYSIBM", "SYSFUN", "SYSPROC", "SYSIBMADM".

SESSION_USER or USER

Specifies the value of the SESSION_USER or USER special register, which represents a maximum 8 byte (in EBCDIC) *schema-name*. At the time the CREATE statement is processed, this length is included in the total length of the list of schema names that is specified for the PATH bind option.

RELEASE AT

Specifies when to release resources that the procedure uses: either at each commit point or when the procedure terminates.

COMMIT

Specifies that resources will be released at each commit point.

COMMIT is the default.

DEALLOCATE

Specifies that resources will be released only when the thread terminates. DEALLOCATE has no effect on dynamic SQL statements, which always use RELEASE AT COMMIT, with this exception: When you use the RELEASE AT DEALLOCATE clause and the WITH KEEP DYNAMIC clause, and the subsystem is installed with a value of YES for the field CACHE DYNAMIC SQL on installation panel DSNTIP8, the RELEASE AT DEALLOCATE option is honored for dynamic SELECT and data change statements.

Locks that are acquired for dynamic statements are held unit one of the following events occurs:

- The application process ends.
- The application process issues a PREPARE statement with the same statement identifier. (Locks are released at the next commit point).
- The statement is removed from the dynamic statement cache because the statement has not been used. (Locks are released at the next commit point).
- An object that the statement is dependent on is dropped or altered, or a privilege that the statement needs is revoked. (Locks are released at the next commit point).

RELEASE AT DEALLOCATE can increase the package or plan size because additional items become resident in the package or plan.

For more information, see Choosing a RELEASE option (Db2 Performance).

REOPT

Specifies if Db2 will determine the access path at run time by using the values of SQL variables or SQL parameters, parameter markers, and special registers.

NONE

Specifies that Db2 does not determine the access path at run time by using the values of SQL variables or SQL parameters, parameter markers, and special registers.

NONE is the default.

ALWAYS

Specifies that Db2 always determines the access path at run time each time an SQL statement is run. Do not specify REOPT ALWAYS with the WITH KEEP DYNAMIC or NODEFER PREPARE clauses.

ONCE

Specifies that Db2 determine the access path for any dynamic SQL statements only once, at the first time the statement is opened. This access path is used until the prepared statement is invalidated or removed from the dynamic statement cache and need to be prepared again.

QUERY ACCELERATION

Specifies whether a static SQL query is bound for acceleration, and if so, with what behavior.

NONE

Specifies that no static SQL query in the application is bound for acceleration or will be accelerated when the application is run.

ENABLE

Specifies that a static SQL query is bound for acceleration if it satisfies the acceleration criteria, including the cost and heuristics criteria. The query is routed to an accelerator when the application runs. Otherwise, if the static query does not satisfy the acceleration criteria, the query is bound for execution in Db2.

If an error condition, such as one of the following examples, occurs while executing the accelerated static query when the application is run, Db2 fails the static query and returns a negative SQL code to the application:

- A failure occurs while running the static query on the accelerator.
- The accelerator returns an error for the query.
- The accelerator is not started and Db2 cannot route the static query to the accelerator for execution.

ENABLE WITH FAILBACK

Results in the same behavior as ENABLE, except if one of the error conditions occurs on the first OPEN of the accelerated static query when the application is run. In this case, instead of failing the static query and returning a negative SQL code to the application, Db2 performs a temporary *statement-level* incremental bind of the query and runs the query in Db2. The application does not see the acceleration failure. Failback to Db2 is not possible after the application does a successful OPEN for the query on the accelerator.

ELIGIBLE

Specifies that a static SQL query is bound for acceleration if the query meets the basic acceleration criteria, regardless of the cost or heuristics criteria. The query is routed to the accelerator when the application runs.

Like the behavior for ENABLE, if an error condition occurs while executing the accelerated static query when the application is run, Db2 fails the static query and returns a negative SQL code to the application.

ALL

Specifies that all of the static SQL queries in the application are to be bound for acceleration and routed to the accelerator when the application runs. If Db2 determines that a static query cannot be bound to run on the accelerator and the query references a user base table or view, the BIND or REBIND PACKAGE operation fails with an error message for that query. (A failure exception is made for declared global temporary tables (DGTTs) and created global temporary tables and (CGTTs) because these tables cannot be accelerated.)

Like the behavior for ENABLE, if an error condition occurs while executing the accelerated static query when the application is run, Db2 fails the static query and returns a negative SQL code to the application.

This bind option does not apply to a *fullselect* or WITH *common-table-expression* that is specified in a RETURN statement for the routine, or in a SET *host-variable-assignment* that is used in the routine. The queries that are specified in these cases cannot be accelerated.

GET_ACCEL_ARCHIVE

Specifies whether a static SQL query that is bound for acceleration retrieves archived data on the accelerator, instead of active data.

NO

Specifies that no static SQL query is bound to retrieve archived data from the accelerator. If the static query also is not bound for acceleration, the query is bound to run in Db2.

If the static query is bound for acceleration because the QUERYACCELERATION bind option was specified, the query is routed to the accelerator when the application runs; however, the query does not retrieve any archived data.

YES

Specifies that if all of the following criteria are met, the query is bound for acceleration and retrieves the archived data on the accelerator when the application runs:

- The QUERYACCELERATION bind option is also specified.
- The static SQL query references an accelerated table that has partitioned data archived on an accelerator.
- The static query satisfies the acceleration criteria that is specified by the QUERYACCELERATION bind option.

If the static query does not satisfy the acceleration criteria that is specified by the QUERYACCELERATION bind option, the BIND or REBIND PACKAGE operation fails with an error message for that query.

This bind option does not apply to a *fullselect* or WITH *common-table-expression* that is specified in a RETURN statement for the routine, or in a SET *host-variable-assignment* that is used in the routine. The queries that are specified in these cases cannot be accelerated.

ACCELERATION WAITFORDATA

Specifies the maximum amount of time, if any, that an accelerator will delay a query while the accelerator waits for the replication of committed Db2 data changes that occurred prior to Db2 running the query.

For static accelerated queries, you must also set the QUERYACCELERATION bind option for this function or procedure to a valid value other than NONE to request that static queries be accelerated. If the QUERYACCELERATION bind option value is set to NONE, the ACCELERATIONWAITFORDATA bind option is accepted and the package is bound with the option value; however, the option will not apply to static SQL queries because no static queries will be accelerated.

For dynamic accelerated queries, specifying the ACCELERATION WAITFORDATA bind option also initializes the CURRENT QUERY ACCELERATION WAITFORDATA special register, which is used for the dynamic queries in the Db2 function or procedure if the function or procedure option DEFAULT SPECIAL REGISTERS is also used. Initializing CURRENT QUERY ACCELERATION WAITFORDATA to a value greater than 0 specifies that Db2 and the accelerator will apply WAITFORDATA delay behavior and restrictions to all dynamic SQL queries to be accelerated from the Db2 function or procedure. The CURRENT QUERY ACCELERATION special register must also have a valid value other than NONE to request that dynamic queries be accelerated.

nnnn.m

Specifies a DECIMAL(5,1) numeric-constant value that specifies the maximum number of seconds that the accelerator will delay a query while the accelerator waits for the replication of committed Db2 data changes that occurred prior to Db2 running the query.

You can specify a value in the range of 0.0 - 3600.0 seconds. For example, a value of 20.0 represents 20.0 seconds (or 20000 milliseconds), and a value of 30.5 represents 30.5 seconds (or 30500 milliseconds). The maximum value of 3600.0 means they the query is delayed for 3600 seconds.

You can also specify the value as an INTEGER numeric-constant value ranging from 0 - 3600 seconds, which Db2 will convert to a DECIMAL(5,1) value.

Important: When a non-zero value is specified for the ACCELERATIONWAITFORDATA bind option, Db2 and the accelerator will apply other WAITFORDATA delay behaviors, restrictions, and requirements to all queries that will be accelerated from the application package. These behaviors, restrictions, and requirements can cause queries that were formerly accelerated successfully to no longer be accelerated or to fail. See "SET CURRENT QUERY ACCELERATION WAITFORDATA" on page 2143 for more information about WAITFORDATA behaviors, restrictions, and requirements.

ACCELERATOR

Specifies an accelerator server that, if enabled and available, Db2 will consider as the preferred accelerator for eligible SQL queries before sending the queries to other accelerator servers. If the specified accelerator server is not enabled or available, Db2 will send the queries to other available accelerator servers.

VALIDATE RUN or VALIDATE BIND

Specifies whether to recheck, at run time, errors of the type "OBJECT NOT FOUND" and "NOT AUTHORIZED" that are found during bind or rebind. The option has no effect if all objects and needed privileges exist.

VALIDATE RUN

Specifies that if needed objects or privileges do not exist when the CREATE statement is processed, warning messages are returned, but the CREATE statement succeeds. The Db2 subsystem rechecks for the objects and privileges at run time for those SQL statements that failed the checks during processing of the CREATE statement. The authorization checks the use of the authorization ID of the owner of the routine.

VALIDATE RUN is the default.

VALIDATE BIND

Specifies that if needed objects or privileges do not exist at the time the CREATE statement is processed, an error is issued and the CREATE statement fails.

ROUNDING

Specifies the rounding mode for manipulation of DECFLOAT data. The default value is taken from the DEFAULT DECIMAL FLOATING POINT ROUNDING MODE in DECP.

DEC_ROUND_CEILING

Specifies numbers are rounded towards positive infinity.

DEC_ROUND_DOWN

Specifies numbers are rounded towards 0 (truncation).

DEC_ROUND_FLOOR

Specifies numbers are rounded towards negative infinity.

DEC_ROUND_HALF_DOWN

Specifies numbers are rounded to nearest; if equidistant, round down.

DEC_ROUND_HALF_EVEN

Specifies numbers are rounded to nearest; if equidistant, round so that the final digit is even.

DEC_ROUND_HALF_UP

Specifies numbers are rounded to nearest; if equidistant, round up.

DEC_ROUND_UP

Specifies numbers are rounded away from 0.

DATE FORMAT ISO, EUR, USA, JIS, or LOCAL

Specifies the date format for result values that are string representations of date or time values. For more information, see "String representations of datetime values" on page 120.

The default format is specified in the DATE FORMAT field of installation panel DSNTIP4 of the system where the routine is defined. You cannot use the LOCAL option unless you have a date exit routine.

DECIMAL(15), DECIMAL(31), DECIMAL(15,*s*), or DECIMAL(31,*s*)

Specifies the maximum precision that is to be used for decimal arithmetic operations. For more information see "Arithmetic with two decimal operands" on page 250. The default format is specified in the DECIMAL ARITHMETIC field of installation panel DSNTIPF of the system where the routine is defined. If the form *pp.s* is specified, *s* must be a number between 1 and 9. *s* represents the minimum scale that is to be used for division.

FOR UPDATE CLAUSE OPTIONAL or FOR UPDATE CLAUSE REQUIRED

Specifies whether the FOR UPDATE clause is required for a DECLARE CURSOR statement if the cursor is to be used to perform positioned updates.

FOR UPDATE CLAUSE REQUIRED

Specifies that a FOR UPDATE clause must be specified as part of the cursor definition if the cursor will be used to make positioned updates.

FOR UPDATE CLAUSE REQUIRED is the default.

FOR UPDATE CLAUSE OPTIONAL

Specifies that the FOR UPDATE clause does not need to be specified in order for a cursor to be used for positioned updates. The routine body can include positioned UPDATE statements that update columns that the user is authorized to update.

The FOR UPDATE clause with no column list applies to static or dynamic SQL statements. Even if you do not use this clause, you can specify FOR UPDATE OF with a column list to restrict updates to only the columns that are identified in the FOR UPDATE clause and to specify the acquisition of update locks.

TIME FORMAT ISO, EUR, USA, JIS, or LOCAL

Specifies the time format for result values that are string representations of date or time values. For more information, see "String representations of datetime values" on page 120.

The default format is specified in the TIME FORMAT field of installation panel DSNTIP4 of the system where the routine is defined. You cannot use the LOCAL option unless you have a date exit routine.

BUSINESS_TIME SENSITIVE

Determines whether references to application-period temporal tables in both static and dynamic SQL statements are affected by the value of the CURRENT TEMPORAL BUSINESS_TIME special register.

YES

References to application-period temporal tables are affected by the value of the CURRENT TEMPORAL BUSINESS_TIME special register. YES is the default value.

NO

References to application-period temporal tables are not affected by the value of the CURRENT TEMPORAL BUSINESS_TIME special register.

For more information, see ."CURRENT TEMPORAL BUSINESS_TIME special register" on page 207

SYSTEM_TIME SENSITIVE

Determines whether references to system-period temporal tables in both static and dynamic SQL statements are affected by the value of the CURRENT TEMPORAL SYSTEM_TIME special register.

YES

References to system-period temporal tables are affected by the value of the CURRENT TEMPORAL SYSTEM_TIME special register. YES is the default value.

NO

References to system-period temporal tables are not affected by the value of the CURRENT TEMPORAL SYSTEM_TIME special register.

For more information, see "CURRENT TEMPORAL SYSTEM_TIME special register" on page 209.

ARCHIVE SENSITIVE

Determines whether references to archive-enabled tables in SQL statements are affected by the value of the SYSIBMADM.GET_ARCHIVE built-in global variable.

YES

References to archive-enabled tables are affected by the value of the SYSIBMADM.GET_ARCHIVE built-in global variable. YES is the default value.

NO

References to archive-enabled tables are not affected by the value of the SYSIBMADM.GET_ARCHIVE built-in global variable.

For related information, see "GET_ARCHIVE" on page 330

APPLCOMPAT *applcompat-level*

Specifies the application compatibility level behavior for static SQL statements in the procedure body. If this option is not specified, the behavior is determined by the APPLCOMPAT subsystem parameter.

The following *applcompat-level* values can be specified:

V*vv*R*r*M*mmm*

Compatibility with the behavior of the identified Db2 function level. For example, V12R1M510 specifies compatibility with the highest available Db2 12 function level. The equivalent function level or higher must be activated.

For the new capabilities that become available in each application compatibility level, see:

- SQL changes in Db2 13 application compatibility levels
- SQL changes in Db2 12 application compatibility levels

Tip: Extra program preparation steps might be required to increase the application compatibility level for applications that use data server clients or drivers to access Db2 for z/OS. For more information, see Setting application compatibility levels for data server clients and drivers (Db2 Application programming and SQL).

V12R1

Compatibility with the behavior of Db2 12 function level 500. This value has the same result as specifying V12R1M500.

V11R1

Compatibility with the behavior of Db2 11 new-function mode. After migration to Db2 12, this value has the same result as specifying V12R1M100. For more information, see V11R1 application compatibility level (Db2 Application programming and SQL)

V10R1

Compatibility with the behavior of DB2 10 new-function mode. For more information, see V10R1 application compatibility level (Db2 Application programming and SQL).

CONCENTRATE STATEMENTS OFF or CONCENTRATE STATEMENTS WITH LITERALS

Specifies whether each dynamic SQL statement in the routine that specifies literal constants will be cached as a separate unique statement entry in the dynamic statement cache, instead of sharing an existing statement in the cache. Dynamic SQL statements are eligible to share an existing statement in the cache if the new statement meets all of the conditions for sharing a cached version of the same dynamic statement, except that the new statement specifies one or more literal constants that are different than the cached statement.

CONCENTRATE STATEMENTS OFF

Specifies that each dynamic SQL statement that specifies literal constants will be cached as a unique statement entry if it specifies one or more constants that are different than the cached version of the same dynamic statement. CONCENTRATE STATEMENTS OFF is the default dynamic statement caching behavior.

CONCENTRATE STATEMENTS WITH LITERALS

Specifies that each dynamic SQL statement that specifies literal constants will share a cached version of the same dynamic statement that is also prepared using the CONCENTRATE STATEMENTS WITH LITERALS option, if the new dynamic statement meets all of the conditions for sharing the cached statement, and the constants that are specified can be reused in place of the constants in the cached statement.

SQL-routine-body

Specifies the statements that define the body of the SQL procedure. For information on the SQL control statements that are supported in native SQL procedures, see Chapter 8, "SQL procedural language (SQL PL)," on page 2197. If an *SQL-procedure-statement* is the only statement in the procedure body, the statement must not end with a semicolon.

WRAPPED *obfuscated-statement-text*

Specifies the encoded definition of the function. A CREATE PROCEDURE statement can be encoded using the WRAP scalar function.

WRAPPED must not be specified on a static CREATE statement, or a CREATE statement that adds or replaces a version of an existing procedure.

Notes for CREATE PROCEDURE (SQL - native)

Considerations for all types of procedures

For considerations that apply to all types of procedures, see "CREATE PROCEDURE" on page 1573.

Error handling in SQL procedures

You should consider the possible exceptions that can occur for each SQL statement in the body of a procedure. Any exception SQLSTATE that is not handled within the procedure using a handler within a compound statement results in the exception SQLSTATE being returned to the caller of the procedure.

Versions of a procedure

FL 507The CREATE PROCEDURE statement for an SQL procedure defines the initial version of the procedure. You can define an additional version using the ADD VERSION clause of the ALTER PROCEDURE statement, or the CREATE PROCEDURE statement with the OR REPLACE clause and the VERSION clause when the procedure already exists. You can replace a version using the REPLACE VERSION clause of the ALTER PROCEDURE, or the CREATE PROCEDURE statement with the OR REPLACE clause and the VERSION clause when the procedure version already exists.

The data types, CCSID specifications and character data attributes (FOR BIT/SBCS/MIXED DATA) of the parameters must be the same as the attributes of the corresponding parameters for the currently active version of the procedure, unless the OR REPLACE is specified and the VERSION keyword is not specified.

Important: Do not create additional versions of procedures that are supplied with Db2 by specifying the VERSION keyword. Only versions that are supplied with Db2 are supported. Additional versions of such routines cause the installation and configuration of the supplied routines to fail.

Considerations for an existing procedure that is defined using a TABLE LIKE name AS LOCATOR clause

FL 507If an existing native SQL procedure is defined with a table parameter (the TABLE LIKE *name* AS LOCATOR clause was specified in the original CREATE PROCEDURE statement to indicate that one of the parameters is a transition table), the procedure cannot be changed with a CREATE PROCEDURE statement to add or replace a version of the procedure. In this case, the procedure must be dropped and re-created.

Characteristics of the package that is generated for a procedure

The package that is associated with the first version of a procedure is named as follows:

- *location* is set to the value of the CURRENT SERVER special register
- *collection-id* (schema) for the package is the same as the schema qualifier of the procedure.
- *package-id* is the same as the specific name of the procedure
- *version-id* is the same as the version identifier for the initial version of the procedure.

If you want to change the *collection-id* for the name of the package, you need to make a copy of the package.

The package is generated using the bind options that correspond to the implicitly or explicitly specified procedure options. For more information, see the table in "Correspondence of procedure options to BIND options" on page 1627. In addition to the corresponding bind options, the package is generated using the following bind options:

- DBPROTOCOL(DRDA)
- FLAG(1)
- SQLERROR(NOPACKAGE)
- ENABLE(*)

Correspondence of procedure options to BIND options

The following table lists the corresponding bind command options for specific CREATE PROCEDURE and ALTER PROCEDURE options. For more information about the bind options, see BIND and REBIND options for packages, plans, and services (Db2 Commands).

Correspondence of procedure options to bind options

CREATE PROCEDURE or ALTER PROCEDURE option	Bind commands option
ACCELERATION WAITFORDATA *nnnn.m*	ACCELERATIONWAITFORDATA(*nnnn.m*)
ACCELERATOR *accelerator-name*	ACCELERATOR(*accelerator-name*)

WITH KEEPDYNAMIC	KEEPDYNAMIC(YES)
WITHOUT KEEPDYNAMIC	KEEPDYNAMIC(NO)

Application compatibility level considerations for procedure objects

The application compatibility level controls the adoption and use of new capabilities and enhancements. When an object is created or altered, two separate application compatibility levels are used: one to process the definition of the object, and the other for processing the SQL statements in the object body:

Object definition	The CURRENT APPLICATION COMPATIBILITY special register value is used to process the object definition, except for statements in the object body This application compatibility level is stored in the SYSENVIRONMENT.APPLCOMPAT column. You can use the environment ID value in the catalog definition of the object to locate the SYSENVIRONMENT row with the matching ENVID value. This application compatibility level can be changed when the object is regenerated.
Statements in the object body	The application compatibility level that is implicitly or explicitly specified with the APPLCOMPAT option of the CREATE or ALTER statement is used to process statements in the object body. This application compatibility level is stored in the SYSPACKAGE.APPLCOMPAT column for the package associated with the object definition.

Considerations for SQL processor programs

SQL processor programs, such as SPUFI, the command line processor, and DSNTEP2, might not correctly parse SQL statements that end with semicolons in the routine body of a CREATE PROCEDURE statement. These processor programs accept multiple SQL statements as input, with each statement separated with a terminator character. Processor programs that use a semicolon as the SQL statement terminator can truncate a CREATE PROCEDURE statement with embedded semicolons and pass only a portion of it to Db2. Therefore, you might need to change the SQL terminator character for these processor programs. For more information, see Setting the SQL terminator character in a SPUFI input data set (Db2 Application programming and SQL), and SQLTERM in DSNTEP2 and DSNTEP4 sample programs (Db2 Application programming and SQL).

Identifier resolution

See Chapter 8, "SQL procedural language (SQL PL)," on page 2197 for information on how names are resolved to columns, variables, or SQL parameters within an SQL routine.

If duplicate names are used for columns, variables, and parameters, qualify the duplicate names by using the table designator for columns, the routine name for parameters, the label name for SQL variables, and the schema name for global variables.

Lines within the SQL procedure definition

When an SQL procedure is created, information is retained on lines in the CREATE statement. Lines are determined by the presence of the new line control character.

In an SQL procedure, a *new line control character* is a special character that is used for a new line. The new line control characters for an SQL procedure include:

- Line feed
- New line

- Carriage return
- Carriage return, followed by a line feed
- Carriage return, followed by a new line

For more information about control characters, see Tokens.

Stored procedures with a parameter that is defined as an array type

A procedure that is defined with a parameter that is an array type, other than an array global variable, can be invoked only from within an SQL PL context, or from a Java application program that uses IBM Data Server Driver for JDBC and SQLJ type 4 connectivity, unless the corresponding argument in the CALL statement is an array global variable. If the corresponding argument in the CALL statement is an array global variable, the procedure can be invoked outside an SQL PL context.

Obfuscated statements

A CREATE PROCEDURE statement for a native SQL procedure can be executed in obfuscated form. In an obfuscated statement, only the procedure name, parameters, and the WRAPPED keyword are readable. The rest of the statement is encoded in such a way that it is not readable but can be decoded by a database server that supports obfuscated statements. The WRAP scalar function produces obfuscated statements. Any debug options that are specified when the function is created from an obfuscated statement are ignored.

Compatibilities

For compatibility with previous versions of Db2, the following clauses can be specified, but they will be ignored and a warning will be issued:

- STAY RESIDENT
- PROGRAM TYPE
- RUN OPTIONS
- NO DBINFO
- COLLID or NOCOLLID
- SECURITY
- PARAMETER STYLE GENERAL WITH NULLS
- STOP AFTER SYSTEM DEFAULT FAILURES
- STOP AFTER *nn* FAILURES
- CONTINUE AFTER FAILURES
- PARAMETER VARCHAR

If the FENCED or EXTERNAL clause is specified, an external SQL procedure will be generated. See "CREATE PROCEDURE (SQL - external) (deprecated)" on page 1592 for more information.

If WLM ENVIRONMENT is specified without the FOR DEBUG MODE keywords, and error is returned. If WLM ENVIRONMENT is specified for a native SQL procedure, WLM ENVIRONMENT FOR DEBUG MODE must be specified.

Alternative syntax and synonyms

To provide compatibility with previous releases of Db2 or other products in the Db2 family, Db2 supports the following alternative syntax:

- RESULT SET and RESULT SETS as synonyms for DYNAMIC RESULT SETS
- VARIANT as a synonym for NOT DETERMINISTIC
- NOT VARIANT as a synonym for DETERMINISTIC
- NULL CALL as a synonym for CALLED ON NULL

Examples for CREATE PROCEDURE (SQL - native)

Example 1

Create the definition for an SQL procedure. The procedure accepts an employee number and a multiplier for a pay raise as input. The following tasks are performed in the procedure body:

- Calculate the employee's new salary.
- Update the employee table with the new salary value.

```
CREATE PROCEDURE UPDATE_SALARY_1
 (IN EMPLOYEE_NUMBER CHAR(10),
 IN RATE DECIMAL(6,2))
 LANGUAGE SQL
 MODIFIES SQL DATA
  UPDATE EMP
  SET SALARY = SALARY * RATE
  WHERE EMPNO = EMPLOYEE_NUMBER
```

Example 2

Create the definition for the SQL procedure described in example 1, but specify that the procedure has these characteristics:

- The same input always produces the same output.
- SQL work is committed on return to the caller.

```
CREATE PROCEDURE UPDATE_SALARY_1
 (IN EMPLOYEE_NUMBER CHAR(10),
 IN RATE DECIMAL(6,2))
 LANGUAGE SQL
 MODIFIES SQL DATA
 DETERMINISTIC
 COMMIT ON RETURN YES
   UPDATE EMP
   SET SALARY = SALARY * RATE
   WHERE EMPNO = EMPLOYEE_NUMBER
```

Example 3:

Create the definition for an SQL procedure that uses arrays as IN and OUT parameters. The procedure is named GETWEEKENDS. It accepts an array of DATE values as input, and returns an array that contains only the dates that fall on a Saturday or Sunday. For example, if the input dates are a Saturday, a Friday, and a Sunday, the procedure returns only the dates that fall on Saturday and Sunday.

Suppose that the following user-defined array type has been defined:

```
CREATE TYPE DATEARRAY AS DATE ARRAY[100];
```

After the array type is created, any references to it need to specify the fully qualified user-defined array type name. Otherwise, the schema for the type needs to be in the CURRENT PATH.

Suppose that the SQL procedure is defined like this:

```
CREATE PROCEDURE GETWEEKENDS(IN MYDATES DATEARRAY, OUT WEEKENDS DATEARRAY)
 BEGIN
  -- ARRAY INDEX VARIABLES
  DECLARE DATEINDEX, WEEKENDINDEX INT DEFAULT 1;
  -- VARIABLE TO STORE THE ARRAY LENGTH OF MYDATES,
  -- INITIALIZED USING THE CARDINALITY FUNCTION.
  DECLARE DATESCOUNT INT;
  SET DATESCOUNT = CARDINALITY(MYDATES);
  -- FOR EACH DATE IN MYDATES, IF THE DATE IS A SUNDAY OR SATURDAY,
  -- ADD IT TO THE OUTPUT ARRAY NAMED "WEEKENDS"
  WHILE DATEINDEX <= DATESCOUNT DO
   IF DAYOFWEEK(MYDATES[DATEINDEX]) IN (1, 7) THEN
    SET WEEKENDS[WEEKENDINDEX] = MYDATES[DATEINDEX];
    SET WEEKENDINDEX = WEEKENDINDEX + 1;
   END IF;
   SET DATEINDEX = DATEINDEX + 1;
  END WHILE;
 END
```

Also suppose that input array MYDATES contains the following content:

```
['2012-04-28', '2012-02-10','2012-03-18']
```

After the procedure returns, output array WEEKENDS contains the following content:

```
['2012-04-28', '2012-03-18']
```

Example 4

Create the definition for an SQL procedure that uses arrays as OUT parameters. The procedure is named GET_PHONES. It returns an array that contains phone numbers for employee 1775. If more than five phone numbers exist for the employee, an error is returned because the array is defined for only five elements.

Suppose that the following user-defined array type and table have been defined:

```
CREATE TYPE PHONELIST AS DECIMAL(10, 0) ARRAY[5];
CREATE TABLE EMP_PHONES(ID INTEGER, PHONENUMBER DECIMAL(10,0));
```

The SQL procedure is defined like this:

```
CREATE PROCEDURE GET_PHONES(OUT EPHONES PHONELIST)
 BEGIN
  SELECT ARRAY_AGG(PHONENUMBER)
   INTO EPHONES
   FROM EMP_PHONES
   WHERE ID = 1775;
 END
```

For more examples of SQL procedures, see Chapter 8, “SQL procedural language (SQL PL),” on page 2197.

Related concepts

Procedures (Introduction to Db2 for z/OS)

Naming conventions
The rules for forming a name depend on the type of the object designated by the name.

CREATE ROLE

The CREATE ROLE statement creates a role at the current server.

Invocation for CREATE ROLE

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES RUN behavior is in effect. For more information, see “Authorization IDs and dynamic SQL” on page 94.

Authorization for CREATE ROLE

The privilege set that is defined below must include at least one of the following authorities:

- SYSADM authority
- SYSCTRL authority
- SECADM

Privilege set: If the statement is embedded in an application program, the privilege set is the set of privileges that are held by the owner of the plan or package.

If the statement is dynamically prepared, the privilege set is the set of privileges that are held by the SQL authorization ID of the process or by the role that is associated with the primary authorization ID, if the statement is run in a trusted context and the ROLE AS OBJECT OWNER clause is specified.

Syntax for CREATE ROLE

```
►► CREATE ROLE ── role-name ─►◄
```

Description for CREATE ROLE

role-name
Names the role. The name must not identify a role that exists at the current server. The name must not begin with the characters 'SYS' and must not be 'DBADM', ‘NONE', 'NULL', 'PUBLIC', or 'SECADM'.

Examples for CREATE ROLE

The following statement creates a role named TELLER.

```
CREATE ROLE TELLER;
```

Related concepts
Roles in a trusted context (Managing Security)
Managing access through authorization IDs and roles (Managing Security)
Naming conventions
The rules for forming a name depend on the type of the object designated by the name.

CREATE SEQUENCE

The CREATE SEQUENCE statement creates a sequence at the current server.

Invocation for CREATE SEQUENCE

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES RUN behavior is in effect. For more information, see “Authorization IDs and dynamic SQL” on page 94.

Authorization for CREATE SEQUENCE

The privilege set that is defined below must include at least one of the following:

- The CREATEIN privilege on the schema
- SYSADM or SYSCTRL authority
- System DBADM
- Installation SYSOPR authority (when the current SQLID of the process is set to SYSINSTL)

The authorization ID that matches the schema name implicitly has the CREATEIN privilege on the schema.

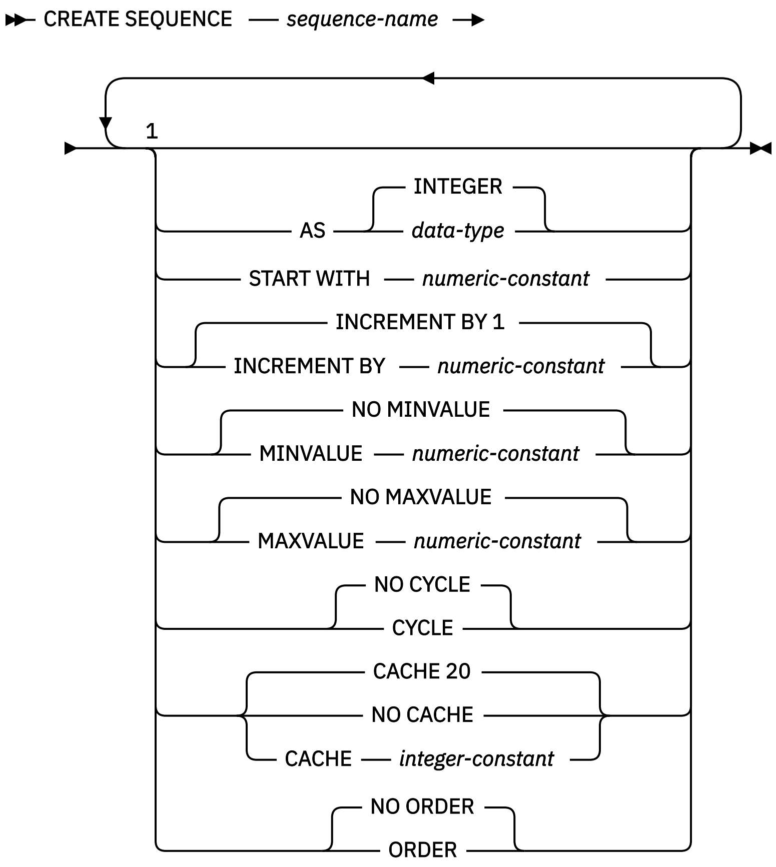
Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the of the owner of the plan or package. If the application is bound in a trusted context with the ROLE AS OBJECT OWNER clause specified, a role is the owner. Otherwise, an authorization ID is the owner.

If the statement is dynamically prepared, the privilege set is the privileges that are held by the SQL authorization ID of the process unless the process is within a trusted context and the ROLE AS OBJECT

OWNER clause is specified. In that case, the privileges set is the privileges that are held by the role that is associated with the primary authorization ID of the process.

If the data type of the sequence is a distinct type, the privilege set must include the USAGE privilege on the distinct type.

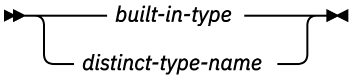
Syntax for CREATE SEQUENCE



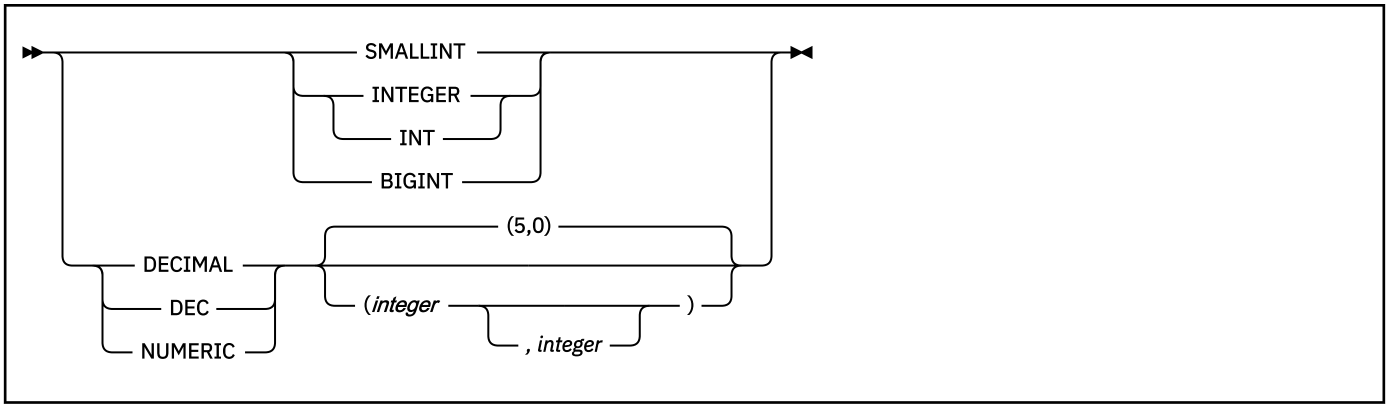
Notes:

[1] The same clause must not be specified more than once. Separator commas can be specified between sequence attributes when a sequence is defined.

data-type:



built-in-type:



Description for CREATE SEQUENCE

sequence-name
Names the sequence. The name, including the implicit or explicit qualifiers, must not identify an existing sequence at the current server, including the sequence names that are generated by Db2.

The schema name must not begin with 'SYS' unless the schema name is 'SYSADM'.

AS *data-type*
Specifies the data type to be used for the sequence value. The data type can be any exact numeric data type (SMALLINT, INTEGER, BIGINT, or DECIMAL with a scale of zero), or a user-defined distinct type for which the source type is an exact numeric data type with a scale of zero. The default, when AS is not specified, is INTEGER. If DECIMAL is specified, the default is DECIMAL(5,0).

START WITH *numeric-constant*
Specifies the first value for the sequence. The value can be any positive or negative value that could be assigned to the a column of the data type that is associated with the sequence without non-zero digits existing to the right of the decimal point.

If the START WITH clause is not explicitly specified with a value, the default is the MINVALUE for ascending sequences and MAXVALUE for descending sequences.

This value is not necessarily the value that a sequence would cycle to after reaching the maximum or minimum value of the sequence. The START WITH clause can be used to start a sequence outside the range that is used for cycles. The range used for cycles is defined by MINVALUE and MAXVALUE.

INCREMENT BY *numeric-constant*
Specifies the interval between consecutive values of the sequence. The value can be any positive or negative value (including 0) that could be assigned to a column of the data type that is associated with the sequence without any non-zero digits existing to the right of the decimal point. The default is 1.

If INCREMENT BY is positive, the sequence ascends. If INCREMENT BY is negative, the sequence descends. If INCREMENT is 0, the sequence is treated as an ascending sequence.

The absolute value of INCREMENT BY can be greater than the difference between MAXVALUE and MINVALUE.

MINVALUE or NO MINVALUE
Specifies the minimum value at which a descending sequence either cycles or stops generating values or an ascending sequence cycles to after reaching the maximum value. The default is NO MINVALUE.

MINVALUE *numeric-constant*
Specifies the minimum end of the range of values for the sequence. The last value that is generated for a cycle of a descending sequence will be equal to or greater than this value. MINVALUE is the value to which an ascending sequence cycles to after reaching the maximum value.

The value can be any positive or negative value that could be assigned to the a column of the data type that is associated with the sequence without non-zero digits existing to the right of the decimal point. The value must be less than or equal to the maximum value.

For the effects of defining MINVALUE and MAXVALUE with the same value, see "Defining a constant sequence" on page 1638.

NO MINVALUE

Specifies that the minimum end point of the range of values for the sequence has not been specified explicitly. In such a case, the default value for MINVALUE becomes one of the following:

- For an ascending sequence, the value is the START WITH value or 1 if START WITH is not specified.
- For a descending sequence, the value is the minimum value of the data type that is associated with the sequence.

MAXVALUE or NO MAXVALUE

Specifies the maximum value at which an ascending sequence either cycles or stops generating values or an descending sequence cycles to after reaching the minimum value. The default is NO MAXVALUE.

MAXVALUE *numeric-constant*

Specifies the maximum end of the range of values for the sequence. The last value that is generated for a cycle of an ascending sequence will be less than or equal to this value. MAXVALUE is the value to which a descending sequence cycles to after reaching the minimum value.

The value can be any positive or negative value that could be assigned to the a column of the data type that is associated with the sequence without non-zero digits existing to the right of the decimal point. The value must be greater than or equal to the minimum value.

For the effects of defining MAXVALUE and MINVALUE with the same value, see "Defining a constant sequence" on page 1638.

NO MAXVALUE

Specifies the maximum end point of the range of values for the sequence has not been specified explicitly. In such a case, the default value for MAXVALUE becomes one of the following:

- For an ascending sequence, the value is the maximum value of the data type that is associated with the sequence.
- For a descending sequence, the value is the START WITH value or -1 if START WITH is not specified.

To find the maximum possible value for a given data type, see Appendix A, "Limits in Db2 for z/OS," on page 2237.

CYCLE or NO CYCLE

Specifies whether or not the sequence should continue to generate values after reaching either its maximum or minimum value. The boundary of the sequence can be reached either with the next value landing exactly on the boundary condition or by overshooting it. The default is NO CYCLE.

CYCLE

Specifies that the sequence continue to generate values after either the maximum or minimum value has been reached. If this option is used, after an ascending sequence reaches its maximum value, it generates its minimum value. After a descending sequence reaches its minimum value, it generates its maximum value. The maximum and minimum values for the sequence defined by the MINVALUE and MAXVALUE options determine the range that is used for cycling.

When CYCLE is in effect, duplicate values can be generated by the sequence. When a sequence is defined with CYCLE, any application conversion tools for converting applications from other vendor platforms to Db2 should also explicitly specify MINVALUE, MAXVALUE, and START WITH values.

NO CYCLE

Specifies that the sequence cannot generate more values once the maximum or minimum value for the sequence has been reached. The NO CYCLE option (the default) can be altered to CYCLE at any time during the life of the sequence.

When the next value is being generated for a sequence if the maximum value (for an ascending sequence) or the minimum value (for a descending sequence) of the logical range of the sequence is exceeded and the NO CYCLE option is in effect, an error occurs.

CACHE or NO CACHE

Specifies whether or not to keep some preallocated values in memory for faster access. This is a performance and tuning option.

CACHE *integer-constant*

Specifies the maximum number of values of the sequence that Db2 can preallocate and keep in memory. Preallocating values in the cache reduces synchronous I/O when values are generated for the sequence. The actual number of values that Db2 caches is always the lesser of the number in effect for the CACHE option and the number of remaining values within the logical range. Thus, the CACHE value is essentially an upper limit for the size of the cache.

The minimum value is 2. The default is CACHE 20.

In a non-data sharing environment, if the system is shut down (either normally or through a system failure), all cached sequence values that have not been used in committed statements are lost (that is, they will never be used). The value specified for the CACHE option is the maximum number of sequence values that could be lost when the system is shut down.

In a data sharing environment, you can use the CACHE and NO ORDER options to allow multiple Db2 members to cache sequence values simultaneously.

NO CACHE

Specifies that values of the sequence are not to be preallocated. This option ensures that there is not a loss of values in the case of a system failure. When NO CACHE is specified, the values of the sequence are not stored in the cache. In this case, every request for a new value for the sequence results in synchronous I/O to the log.

ORDER or NO ORDER

Specifies whether the sequence numbers must be generated in order of request. The default is NO ORDER.

ORDER

Specifies that the sequence numbers are generated in order of request.

In a non-data sharing environment, there is no guarantee that values are assigned in order across the entire server unless NO CACHE is also specified. ORDER applies only to a single-application process.

In a data sharing environment, if ORDER is specified, NO CACHE is implicitly set, even if CACHE *integer-constant* is specified.

NO ORDER

Specifies that the sequence numbers do not need to be generated in order of request.

In a data sharing environment, if the NO ORDER and CACHE *integer-constant* options are in effect, multiple caches can be active simultaneously, and the requests for next value assignments from different Db2 members might not result in the assignment of values in strict numeric order. For example, if members DB2A and DB2B are using the same sequence, and DB2A gets the cache values 1 to 20 and DB2B gets the cache values 21 to 40, the actual order of values assigned would be 1, 21, 2 if DB2A requested the next value first, then DB2B requested, and then DB2A again requested. Therefore, to guarantee that sequence numbers are generated in strict numeric order among multiple Db2 members using the same sequence concurrently, specify the ORDER option.

Notes for CREATE SEQUENCE

Owner privileges

The owner is authorized to change (ALTER privilege) or use (USAGE privilege) the sequence and grant others these privileges. See "GRANT (sequence privileges)" on page 1974. For more information about ownership of the object see "Authorization, privileges, permissions, masks, and object ownership" on page 90.

Relationship of MINVALUE and MAXVALUE

MINVALUE must not be greater than MAXVALUE. Although MINVALUE is typically less than MAXVALUE, MINVALUE can equal MAXVALUE. If START WITH were the same value as MINVALUE and MAXVALUE, the sequence would be constant. The request for the next value in a constant sequence appears to have no effect because all of the values that are generated by the sequence are in fact the same value.

Defining sequences that cycle

When you define a sequence, you can choose to have it cycle automatically or not when the maximum or minimum value for the sequence has been reached.

- Implicitly or explicitly defining a sequence with NO CYCLE causes the sequence to not cycle automatically after the boundary is reached. However, you can use the ALTER SEQUENCE statement to cycle the sequence manually. ALTER SEQUENCE allows you to restart or extend the sequence, which causes sequence values to continue to be generated.
- Explicitly defining a sequence with CYCLE causes the sequence to cycle automatically after the boundary is reached. Sequence values continue to be generated after the sequence cycles.

  When a sequence is defined to cycle automatically, the maximum or minimum value that is generated for a sequence might not be the actual MAXVALUE or MINVALUE value that is specified if the increment is a value other than 1 or -1. For example, the sequence defined with START WITH=1, INCREMENT=2, MAXVALUE=10 will generate a maximum value of 9, and will not generate the value 10.

  When a sequence is defined with CYCLE, any application conversion tools (for converting applications from other vendor platforms to Db2) should also explicitly specify MINVALUE, MAXVALUE, and START WITH.

Defining a constant sequence

You can define a sequence such that it always returns the same (or a constant) value. To create a constant sequence, use either of these techniques when defining the sequence:

- Specify an INCREMENT value of zero and a START WITH value that does not exceed MAXVALUE. Use this option in most cases, and especially if the constant sequence is used often, such as for transaction workloads.
- Specify the same value for START WITH, MINVALUE, and MAXVALUE, and specify CYCLE. This option requires more log write activity and can result in longer wait times, especially if the sequence is used often.

A constant sequence can be used as a numeric global variable. You can use ALTER SEQUENCE to adjust the values that are generated for a constant sequence.

Consumed values of a sequence

After Db2 generates a value for a sequence, that value can be said to be "consumed" regardless of whether or not that value is used by the application or not. The value is not reused within the current cycle. A consumed value might not be used when the statement that caused the value to be generated fails for some reason or is rolled back after the value was generated. Generated but unused values can constitute gaps in a sequence.

Gaps in a sequence

Consecutive values in a sequence differ by the constant INCREMENT BY value specified for the sequence. However, gaps can occur in the values that are assigned to a sequence object by Db2.

The following situations are some examples of how gaps can be introduced in the sequence values:

- A transaction has advanced the sequence and then rolls back.
- The SQL statement leading to the generation of the next value fails after the value was generated.
- The NEXT VALUE expression is used in the SELECT statement of a cursor in a DRDA environment where the client uses block-fetch and not all retrieved rows are fetched by the application.
- The sequence is altered and then the alteration is rolled back.

- The sequence (or an identity column table) is dropped and then the drop is rolled back.
- The SYSIBM.SYSSEQ table space is stopped or closed for any reason (including when DSMAX is reached)
- The Db2 subsystem is stopped or goes down

Values of such gaps are not available for the current cycle, unless the sequence is altered and restarted in a specific way to make them available.

A sequence is incremented independently of a transaction. Thus, a given transaction increments the sequence two times might see a gap in the two numbers that it receives if other transactions concurrently increment the same sequence. Most applications can tolerate these instances as these are not really gaps.

Duplicate sequence values

It is possible the duplicate values can be generated for a sequence. Duplicate values are most likely to occur when a sequence is defined with the CYCLE option, is defined as a constant sequence, or is altered. For example, the following situations could cause duplicate sequence values:

- A sequence is defined with the attributes START WITH=2, INCREMENT BY 2, MINVALUE=2, MAXVALUE=10, and CYCLE.
- The ALTER SEQUENCE statement is used to restart the sequence with a value that has already been generated.
- The ALTER SEQUENCE statement is used to reverse the ascending direction of a sequence by changing the INCREMENT BY value from a positive to a negative.

Using sequences

A sequence can be referenced using a *sequence-reference*. A sequence reference can appear in most places that an expression can appear. A sequence reference can specify whether the value to be returned is a newly generated value or the previously generated value. A NEXT VALUE sequence expression is used to generate a new value. A PREVIOUS VALUE sequence expression is used to obtain the last assigned value of a sequence. For more information, see "Sequence reference" on page 291.

Alternative syntax and synonyms

To provide compatibility with previous releases of Db2 or other products in the Db2 family, Db2 supports the following keywords:

- NOMINVALUE (single key word) as a synonym for NO MINVALUE
- NOMAXVALUE (single key word) as a synonym for NO MAXVALUE
- NOCYCLE (single key word) as a synonym for NO CYCLE
- NOCACHE (single key word) as a synonym for NO CACHE
- NOORDER (single key word) as a synonym for NO ORDER

Examples for CREATE SEQUENCE

Example 1

Create a sequence names "org_seq" that starts at 1 increments by 1, does not cycle, and caches 24 values at a time:

```
CREATE SEQUENCE ORDER_SEQ
   START WITH 1
   INCREMENT BY 1
   NO MAXVALUE
   NO CYCLE
   CACHE 24;
```

INCREMENT 1, NO MAXVALUE, and NO CYCLE are defaults and do not need to be specified.

Example 2

The following example shows how to create and use a sequence named "order_seq" in a table named "orders":

```
CREATE SEQUENCE ORDER_SEQ
   START WITH 1
   INCREMENT BY 1
   NO MAXVALUE
   NO CYCLE
   CACHE 20;
  INSERT INTO ORDERS (ORDERNO, CUSTNO)
    VALUES (NEXT VALUE FOR ORDER_SEQ, 123456);
```

or to update the orders:

```
UPDATE ORDERS
   SET ORDERNO = NEXT VALUE FOR ORDER_SEQ
   WHERE CUSTNO = 123456;
```

Example 3

The following example shows how to use the same sequence number as a unique key value in two separate tables by referencing the sequence number with a NEXT VALUE expression for the first row to generate the sequence value and with a PREVIOUS VALUE expression for the other rows to refer to the sequence value most recently generated.

```
INSERT INTO ORDERS (ORDERNO, CUSTNO)
   VALUES (NEXT VALUE FOR ORDER_SEQ, 123456);
   INSERT INTO LINE_ITEMS (ORDERNO, PARTNO, QUANTITY)
     VALUES (PREVIOUS VALUE FOR ORDER_SEQ, 987654, 100);
```

If NEXT VALUE is invoked in the same statement as the PREVIOUS VALUE, then regardless of their order in the statement, PREVIOUS VALUE returns the previous (unincremented) value and NEXT VALUE returns the next value.

Sequences (Introduction to Db2 for z/OS)

Sequence objects (Db2 Application programming and SQL)

Naming conventions

The rules for forming a name depend on the type of the object designated by the name.

CREATE STOGROUP

The CREATE STOGROUP statement creates a storage group at the current server. Storage from the identified volumes can later be allocated for table spaces and index spaces.

Invocation for CREATE STOGROUP

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES RUN behavior is in effect. For more information, see "Authorization IDs and dynamic SQL" on page 94.

Authorization for CREATE STOGROUP

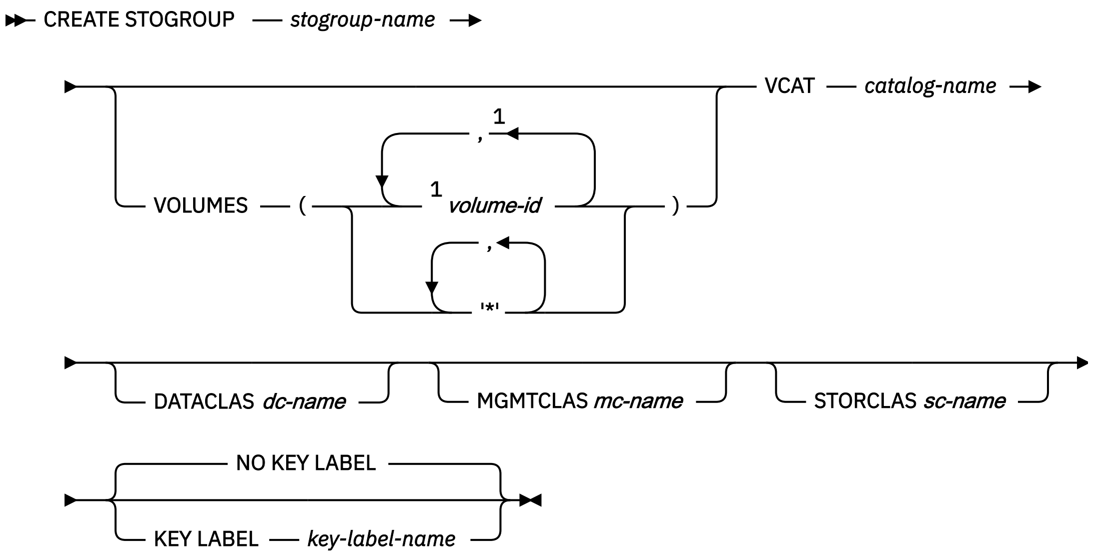
The privilege set that is defined below must include at least one of the following:

- The CREATESG privilege
- SYSADM or SYSCTRL authority
- Installation SYSOPR authority (when the current SQLID of the process is set to SYSINSTL)

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the of the owner of the plan or package. If the application is bound in a trusted context with the ROLE AS OBJECT OWNER clause specified, a role is the owner. Otherwise, an authorization ID is the owner.

If the statement is dynamically prepared, the privilege set is the privileges that are held by the SQL authorization ID of the process unless the process is within a trusted context and the ROLE AS OBJECT OWNER clause is specified. In that case, the privileges set is the privileges that are held by the role that is associated with the primary authorization ID of the process.

Syntax for CREATE STOGROUP



Notes:

[1] The same *volume-id* must not be specified more than once.

Description for CREATE STOGROUP

stogroup-name

Names the storage group. The name must not identify a storage group that exists at the current server.

VOLUMES(*volume-id,...*) or VOLUMES(*'*',...*)

Defines the volumes of the storage group. Each *volume-id* is a volume serial number of a storage volume. The volume serial number can have a maximum of six characters and is specified as an identifier or a string constant.

If the data set that is associated with the storage group is not managed by Storage Management Subsystem (SMS), VOLUMES must be specified. Asterisks are recognized only by SMS. SMS usage is recommended, rather than using Db2 to allocate data to specific volumes. Having Db2 select the volume requires non-SMS usage or assigning an SMS Storage Class with guaranteed space. However, because guaranteed space reduces the benefits of SMS allocation, it is not recommended. If one or more of the DATACLAS, MGMTCLAS, or STORCLAS clauses are specified, VOLUMES can be omitted. If the VOLUMES clause is omitted, the volume selection is controlled by SMS.

If you do choose to use specific volume assignments, additional manual space management must be performed. Free space must be managed for each individual volume to prevent failures during the initial allocation and extension. This process generally requires more time for space management and results in more space shortages. Guaranteed space should be used only where the space needs are relatively small and do not change.

VCAT *catalog-name*

Identifies the integrated catalog facility catalog for the storage group. The designated catalog is the one in which entries are placed for the data sets created by Db2 with the aid of the storage group, for associated table or index spaces or for their partitions. For each such space or partition, association is made through a USING clause in a CREATE TABLESPACE, CREATE INDEX, ALTER TABLESPACE, or ALTER INDEX statement. For more on the association, see the descriptions of those statements.

The data sets are VSAM linear data sets cataloged in the integrated catalog facility catalog that *catalog-name* identifies. For more information about *catalog-name* values, see "Naming conventions" on page 79.

More than one Db2 subsystem can share the integrated catalog facility catalogs with the current server. To avoid the chance of those subsystems attempting to assign the same name to different data sets, specify a *catalog-name* value that is not used by the other Db2 subsystems.

DATACLAS *dc-name*
Identifies the name of the SMS data class to associate with the Db2 storage group. The SMS data class name must be from 1-8 characters in length. The SMS storage administrator defines the data class that can be used. DATACLAS must not be specified more than one time.

MGMTCLAS *mc-name*
Identifies the name of the SMS management class to associate with the Db2 storage group. The SMS management class name must be from 1-8 characters in length. The SMS storage administrator defines the management class that can be used. MGMTCLAS must not be specified more than one time.

STORCLAS *sc-name*
Identifies the name of the SMS storage class to associate with the Db2 storage group. The SMS storage class name must be from 1-8 characters in length. The SMS storage administrator defines the storage class that can be used. STORCLAS must not be specified more than one time.

FL 502 KEY LABEL *key-label-name* or NO KEY LABEL
Specifies whether a key label is specified at the storage group level for encryption.

KEY LABEL *key-label-name*
Specifies the key label that is used to encrypt any data set allocated for the table spaces and index spaces using the storage group.

The key label must be defined in ICSF. The Db2 address space RACF user ID or group must be permitted access to the key label in RACF.

The key label can be overridden when the data set is allocated. For details about the order of precedence, see Notes.

NO KEY LABEL
Indicates that there is no key label specified at the storage group level for encryption.

Notes for CREATE STOGROUP

Device types
When the storage group is used at run time, an error can occur if the volumes in the storage group are of different device types, or if a volume is not available to z/OS for dynamic allocation of data sets.

When a storage group is used to extend a data set, all volumes in the storage group must be of the same device type as the volumes used when the data set was defined. Otherwise, an extend failure occurs if an attempt is made to extend the data set.

Number of volumes
There is no specific limit on the number of volumes that can be defined for a storage group. However, the maximum number of volumes that can be managed for a storage group is 133.

z/OS imposes a limit on the number of volumes that can be allocated per data set (currently, 59 volumes). For the latest information on that restriction, see *z/OS DFSMS Access Method Services for Catalogs*.

Storage group owner
If the statement is embedded in an application program, the owner of the plan or package is the owner of the storage group. If the statement is dynamically prepared, the SQL authorization ID of the

process is the owner of the storage group. The owner has the privilege of altering and dropping the storage group.

Specifying volume IDs

A new storage group must have either specific volume IDs or non-specific volume IDs. You cannot create a storage group that contains a mixture of specific and non-specific volume IDs.

Verifying the existence of volumes and classes

When processing the VOLUMES, DATACLAS, MGMTCLAS, or STORCLAS clauses, Db2 does not check the existence of the volumes or classes or determine the types of devices that are identified or if SMS is active. Later, when the storage group allocates data sets, the list of volumes is passed to Data Facilities (DFSMSdfp) in the physical order of the rows in the SYSIBM.SYSVOLUMES catalog table. For more information, see Implementing Db2 storage groups (Db2 Administration Guide).

Key label requirement

To use a key label for encryption, the VSAM data sets for the page sets need to be associated with an SMS Data Class that has extended format capability (EF enabled).

Determining a key label for base table space and associated objects

When a key label is specified at the table level, Db2 provides the key label to DFSMS to encrypt all the table spaces and index spaces associated with the table. This includes base table space, auxiliary table spaces, XML table spaces, index spaces, and clone table space, regardless of whether the base table space or associated objects are explicitly or implicitly created. Db2 does not enforce any key label relationship between the base table and an associated history or archive table. The key label for the archive and the history tables has to be set independent of the base table. If there is no key label specified at the table level, Db2 will provide the key label to DFSMS specified for the storage group.

When Db2 calls DFSMS to allocate the dataset for table space or index space, DFSMS uses its order of precedence to determine the key label and can override the key label specified by Db2.

DFSMS order of precedence:

- RACF data set profile
- JCL, dynamic allocation, TSO ALLOCATE
- SMS data class construct

If the security administrator has specified a key label for the RACF data set profile, that key label takes precedence over the Db2 provided key label. The REPORT utility can be run to determine the key label used for encryption.

Examples for CREATE STOGROUP

Example 1

Create storage group, DSN8G120, of volumes ABC005 and DEF008. DSNCAT is the integrated catalog facility catalog name.

```
CREATE STOGROUP DSN8G120
  VOLUMES (ABC005,DEF008)
  VCAT DSNCAT;
```

Example 2

Create storage group DSNCG100 with key label, STG01KLABEL.

```
CREATE STOGROUP DSNCG100
  VOLUMES (ABC001,DEF003) VCAT DSNCAT
  KEY LABEL STG01KLABEL;
```

Db2 storage groups (Introduction to Db2 for z/OS)

Naming conventions

The rules for forming a name depend on the type of the object designated by the name.

Related tasks

Creating Db2 storage groups (Db2 Administration Guide)

CREATE SYNONYM (unsupported)

The CREATE SYNONYM statement is unsupported in application compatibility level V12R1M504 and higher. Use CREATE ALIAS statements instead.

Unsupported function: FL 504 Beginning in Db2 12, packages bound with APPLCOMPAT(V12R1M504) or higher cannot issue CREATE SYNONYM statements. Although there are some differences, you can use aliases instead. Unlike synonyms, aliases behave the same for all Db2 family products. For more information about aliases, see Aliases (Introduction to Db2 for z/OS) and "CREATE ALIAS" on page 1410. Existing synonyms remain supported, but support might be removed in the future.

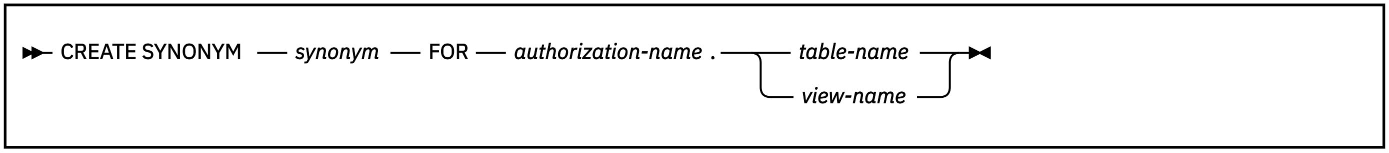
Invocation for CREATE SYNONYM

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES RUN behavior is in effect. For more information, see "Authorization IDs and dynamic SQL" on page 94.

Authorization for CREATE SYNONYM

None required.

Syntax for CREATE SYNONYM



Description for CREATE SYNONYM

synonym

Names the synonym. The name must not identify a synonym, table, view, or alias that exists at the current server and that is owned by the owner of the synonym that is being created and must not identify a table that exists in the SYSIBM.SYSPENDINGOBJECTS catalog table. The unqualified name must not be the same as an existing synonym.

FOR *authorization-name.table-name* or *authorization-name.view-name*

Identifies the object to which the synonym applies. The name must consist of two parts and must identify a table, view, or alias that exists at the current server. If a table is identified, it must not be an auxiliary table or a declared temporary table. If an alias is identified, it must be an alias for a table or view at the current server and the synonym is defined for that table or view. The name must not identify a table that was implicitly created for an XML column, or an accelerator-only table.

Notes for CREATE SYNONYM

Owner privileges: There are no specific privileges on a synonym.

The owner of the synonym is determined as follows:

- If the CURRENT SCHEMA special register contains a value that is not the same as the CURRENT SQLID special register, the owner of the synonym is the value of the CURRENT SCHEMA special register.
- Otherwise, the owner of the schema is the value of the CURRENT SQLID special register.

For more information about ownership of an object, see "Authorization, privileges, permissions, masks, and object ownership" on page 90.

If an alias is used to denote the table or view, the name of that table or view, not the alias, is recorded in the catalog as the definition of the synonym. That severs the connection between the synonym and alias, and even if the alias is dropped and redefined, the synonym is still in effect and names the original table or view.

Example for CREATE SYNONYM

Define DEPT as a synonym for the table DSN8C10.DEPT.

```
   CREATE SYNONYM DEPT
     FOR DSN8C10.DEPT;
```

CREATE TABLE

The CREATE TABLE statement defines a table. The definition must include its name and the names and attributes of its columns. The definition can include other attributes of the table, such as its primary key and its table space.

Invocation for CREATE TABLE

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES RUN behavior is in effect. For more information, see "Authorization IDs and dynamic SQL" on page 94.

Authorization for CREATE TABLE

The privilege set that is defined below must include at least one of the following:

- The CREATETAB privilege for the database explicitly specified by the IN clause.

  If the IN clause is not specified, the CREATETAB privilege on database DSNDB04 is required.
- DBADM, DBCTRL, or DBMAINT authority for the database explicitly specified by the IN clause. If the IN clause is not specified, DBADM, DBCTRL, or DBMAINT authority for database DSNDB04 is required.
- SYSADM or SYSCTRL authority
- System DBADM
- Installation SYSOPR authority (when the current SQLID of the process is set to SYSINSTL)

If the table space is created implicitly, the privilege set that is defined below must include at least one of the following:

- The CREATETS privilege for the database explicitly specified by the IN clause.

  If the IN clause is not specified, the CREATETS privilege on database DSNDB04 is required.
- DBADM, DBCTRL, or DBMAINT authority for the database explicitly specified by the IN clause. If the IN clause is not specified, DBADM, DBCTRL, or DBMAINT authority for database DSNDB04 is required.
- SYSADM or SYSCTRL authority
- Installation SYSOPR authority (when the current SQLID of the process is set to SYSINSTL)

The privilege set must also have the USE privilege for the following objects:

- For the table space if one is specified in the IN clause
- For the default buffer pool and default storage group of the database if a database is specified in the IN clause

If you specify a table space name, you must also have the SYSADM or SYSCTRL authority or the DBADM authority for the database.

For tables that are created in an implicit database, the database authority must be held on DSNDB04.

Additional privileges might be required in the following conditions:

- The clause IN, LIKE or FOREIGN KEY is specified.
- The data type of a column is a distinct type.
- The table space is implicitly created.
- A *fullselect* is specified.
- A column is defined as a security label column.

Privilege set: See the description of the appropriate clauses for details about these privileges.

If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the package.

If the application is bound in a trusted context with the ROLE AS OBJECT OWNER clause specified:

- A role is the owner of the table that is being created
- The privilege set is the set of privileges that are held by that role
- The schema qualifier (implicit or explicit) must be the same as the role, unless the role has the CREATEIN privilege on the schema, or SYSADM, SYSCTRL, or system DBADM authority

Otherwise, an authorization ID is the owner of the package, and the following rules apply:

- If the privilege set lacks the CREATEIN privilege on the schema, SYSADM authority, SYSCTRL authority, and System DBADM authority, the schema qualifier (implicit or explicit) must be the same as the authorization ID of the owner of the package.
- If the privilege set lacks SYSADM authority, SYSCTRL authority, and System DBADM authority, and the table is explicitly qualified, the authorization ID that is the same as the schema name must have all the necessary privileges to create the table, and that authorization ID is the owner of the table. Otherwise, the authorization ID of the owner of the package must have all the necessary privileges to create the table, and that authorization ID is the owner of the table.
- If the privilege set includes SYSADM authority, SYSCTRL authority, or system DBADM authority, the schema qualifier (implicit or explicit) can be any schema name. However, if the table is explicitly qualified, the authorization ID that is the same as the schema name is the owner of the table. Otherwise, the authorization ID of the owner of the package is the owner of the table.
- If the privilege set includes DBADM authority and DBCTRL authority for the database, the schema qualifier (implicit or explicit) can be any schema name. However, if the table is explicitly qualified, the authorization ID that is the same as the schema name is the owner of the table. Otherwise, the authorization ID of the owner of the package is the owner of the table.

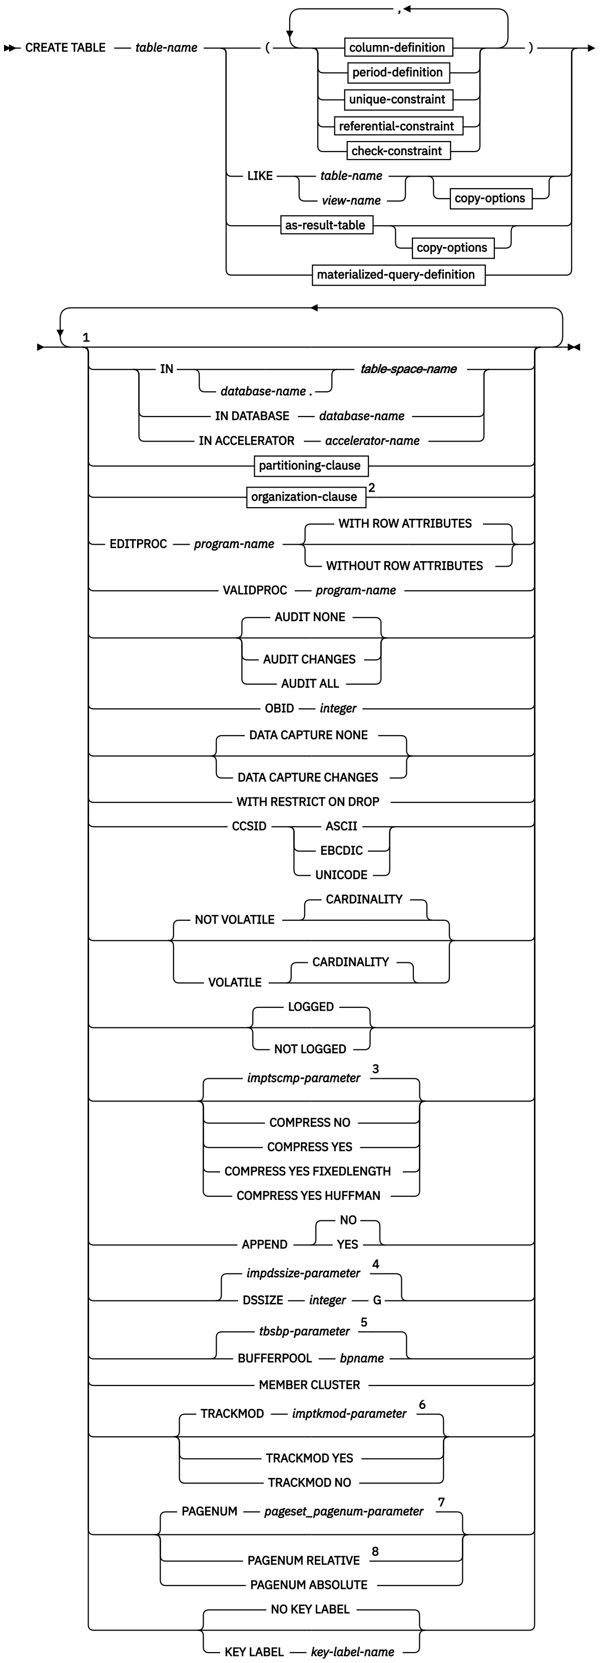
If the statement is dynamically prepared, the privilege set is the privileges that are held by the SQL authorization ID of the process unless the process is within a trusted context and the ROLE AS OBJECT OWNER clause is in effect. When ROLE AS OBJECT OWNER is in effect, the privileges set is the privileges that are held by the role that is associated with the primary authorization ID of the process, and the owner of the table is that role. The schema qualifier (implicit or explicit) must be the same as that role, unless the role has CREATEIN privilege on the schema, or SYSADM authority, SYSCTRL authority, or System DBADM authority.

For the case where the SQL authorization ID of the process holds the privileges, the following rules apply:

- If the privilege set lacks CREATEIN privilege on the schema, SYSADM authority, SYSCTRL authority, and System DBADM authority, the schema qualifier must be the same as one of the authorization IDs of the process.
- If the privilege set lacks SYSADM authority, SYSCTRL authority, and System DBADM authority, and the table is explicitly qualified, then the authorization ID that is the same as the schema name must have all the necessary privileges to create the table, and that authorization ID is the owner of the table. Otherwise, the SQL authorization ID of the process must include all privileges that are needed to create the table, and that authorization ID is the owner of the table.
- If the privilege set includes SYSADM authority, SYSCTRL authority, or System DBADM authority, the schema qualifier can be any schema name. However, if the table is explicitly qualified, then the

authorization ID that is the same as the schema name is the owner of the table. Otherwise, the SQL authorization ID of the process is the owner of the table.

Syntax for CREATE TABLE



Notes:

[1] The same clause must not be specified more than once.

[2] FL 504 Hash-organized tables are deprecated. Beginning in Db2 12, packages bound with APPLCOMPAT(V12R1M504) or higher cannot create hash-organized tables or alter existing tables to use hash-organization. Existing hash organized tables remain supported, but they are likely to be unsupported in the future.

[3] The IMPTSCMP subsystem parameter specifies the default value. See USE DATA COMPRESSION field (IMPTSCMP subsystem parameter) (Db2 Installation and Migration).

[4] The IMPDSSIZE subsystem parameter specifies the default value. See IMPDSSIZE in macro DSN6SYSP (Db2 Installation and Migration).

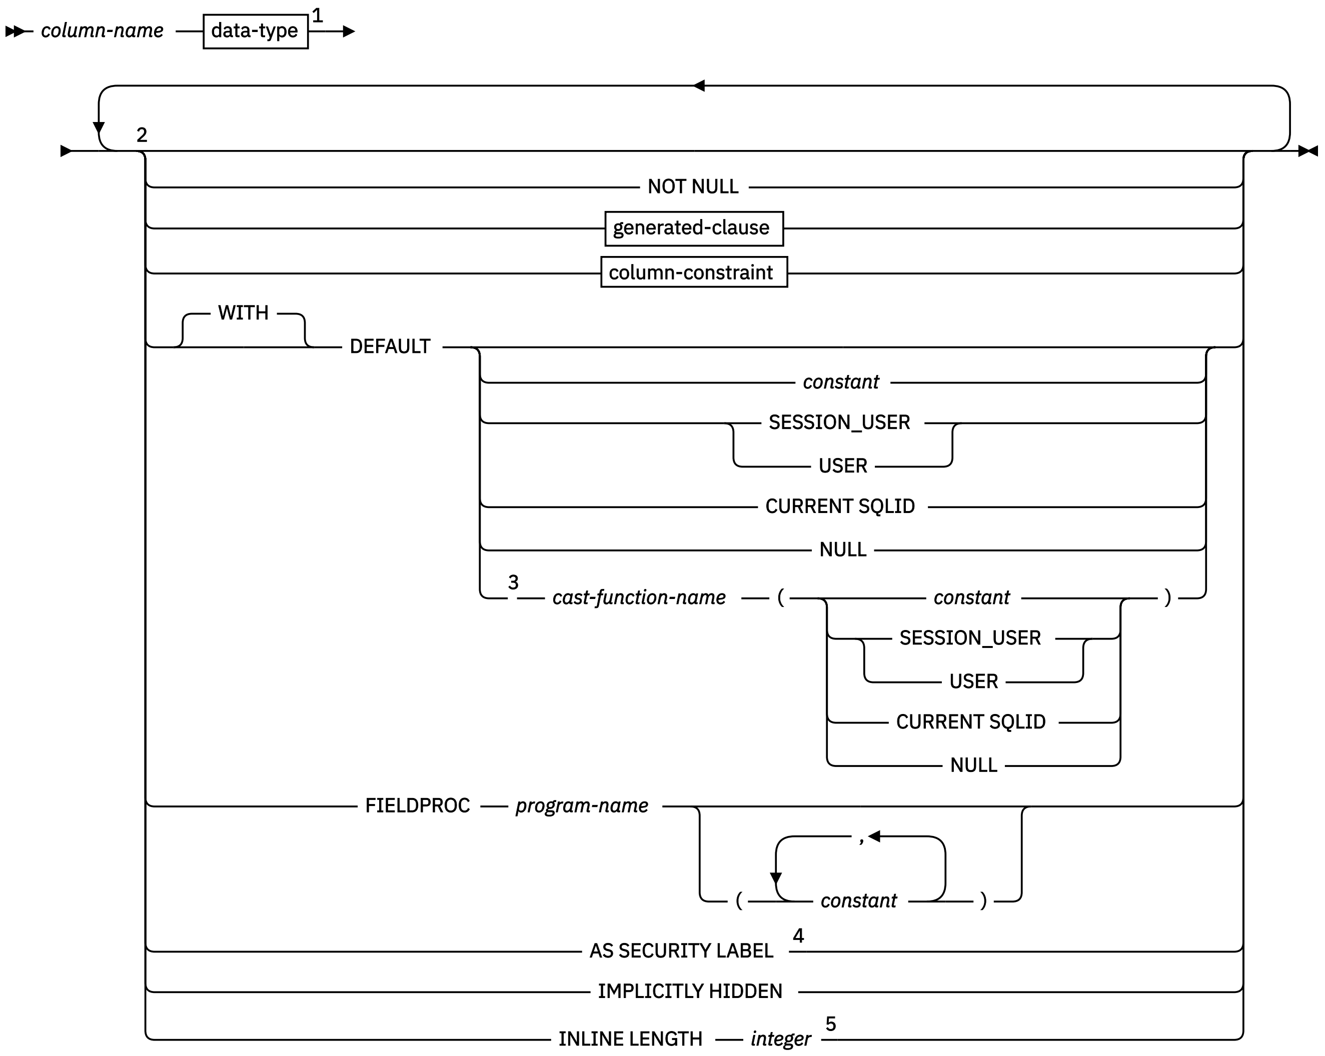
[5] The TBSBPOOL, TBSBP8K, TBSBP16K, or TBSBP32K subsystem parameter determines the default value. See DSNTIP2: Buffer pool sizes panel 2 (Db2 Installation and Migration).

[6] The IMPTKMOD subsystem parameter specifies the default value. See IMPTKMOD in macro DSN6SYSP (Db2 Installation and Migration).

[7] See PAGE SET PAGE NUMBERING field (PAGESET_PAGENUM subsystem parameter) (Db2 Installation and Migration).

[8] PAGENUM RELATIVE is allowed only if a partitioning clause is specified.

column-definition:



Notes:

[1] Data type is optional if *as-row-change-timestamp-clause* is specified

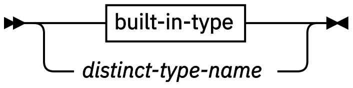
[2] The same clause must not be specified more than one time.

[3] The *cast-function-name* form of the DEFAULT value can only be used with a column that is defined as a distinct type.

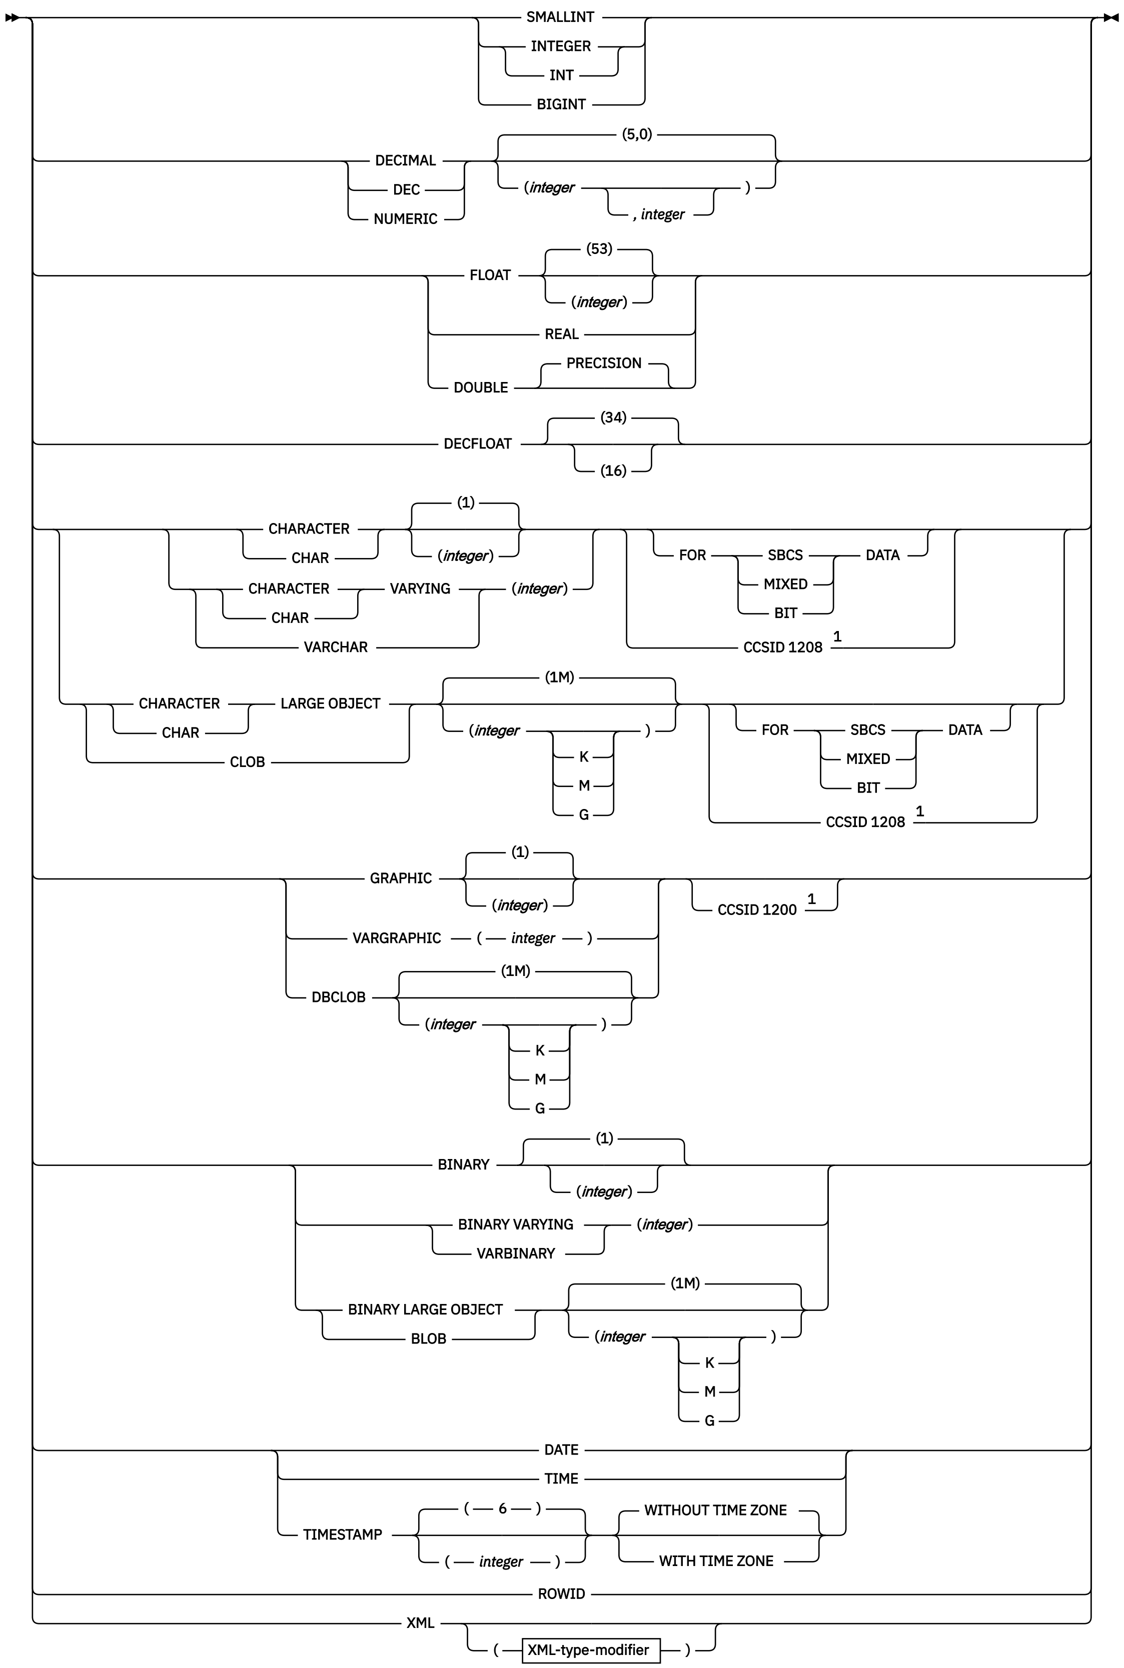
[4] AS SECURITY LABEL can be specified only for a CHAR(8) data type and requires that the NOT NULL and WITH DEFAULT clauses be specified.

[5] INLINE LENGTH only applies to a column with a LOB data type or a distinct type that is based on a LOB data type.

data-type:



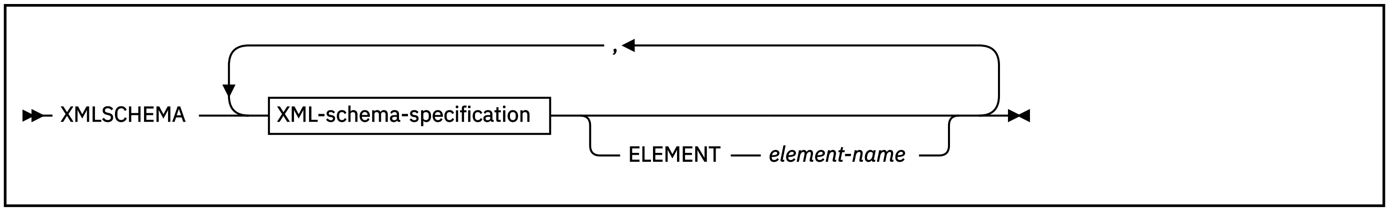
built-in-type:



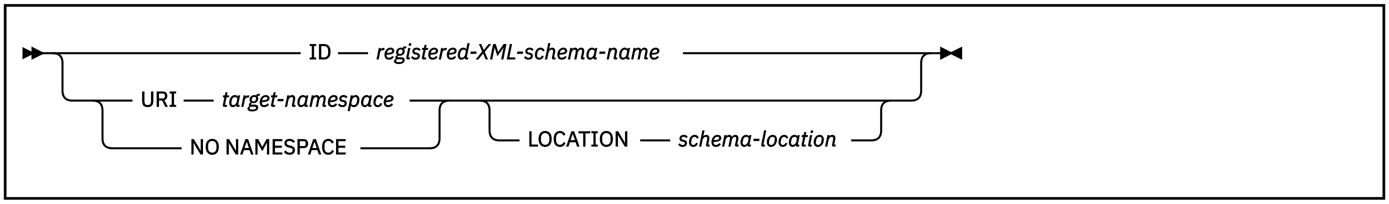
Notes:

[1] The CCSID clause must only be specified for a character string or graphic string column in an EBCDIC table. The CCSID clause must not be specified with *non-deterministic-expression*.

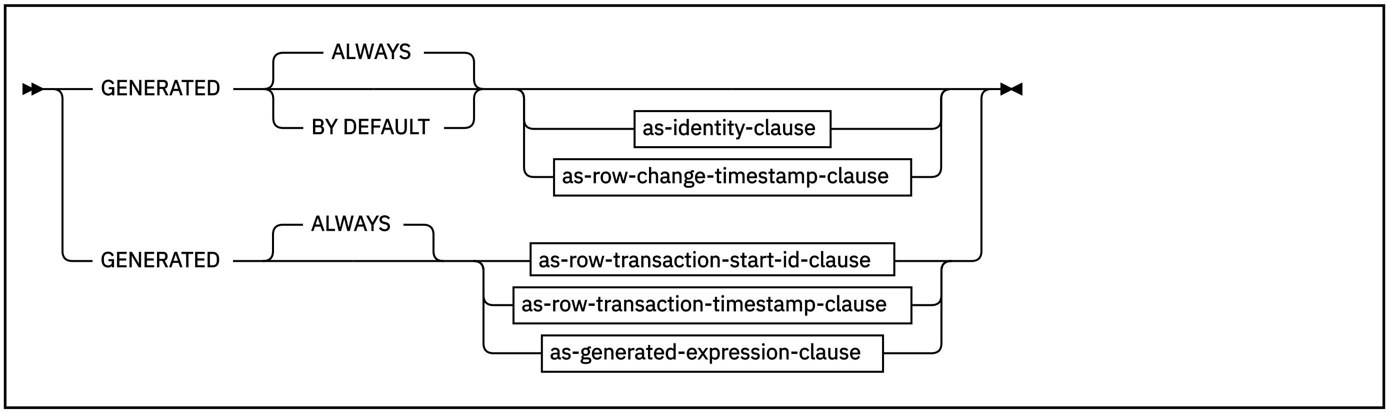
XML-type-modifier:



XML-schema-specification:

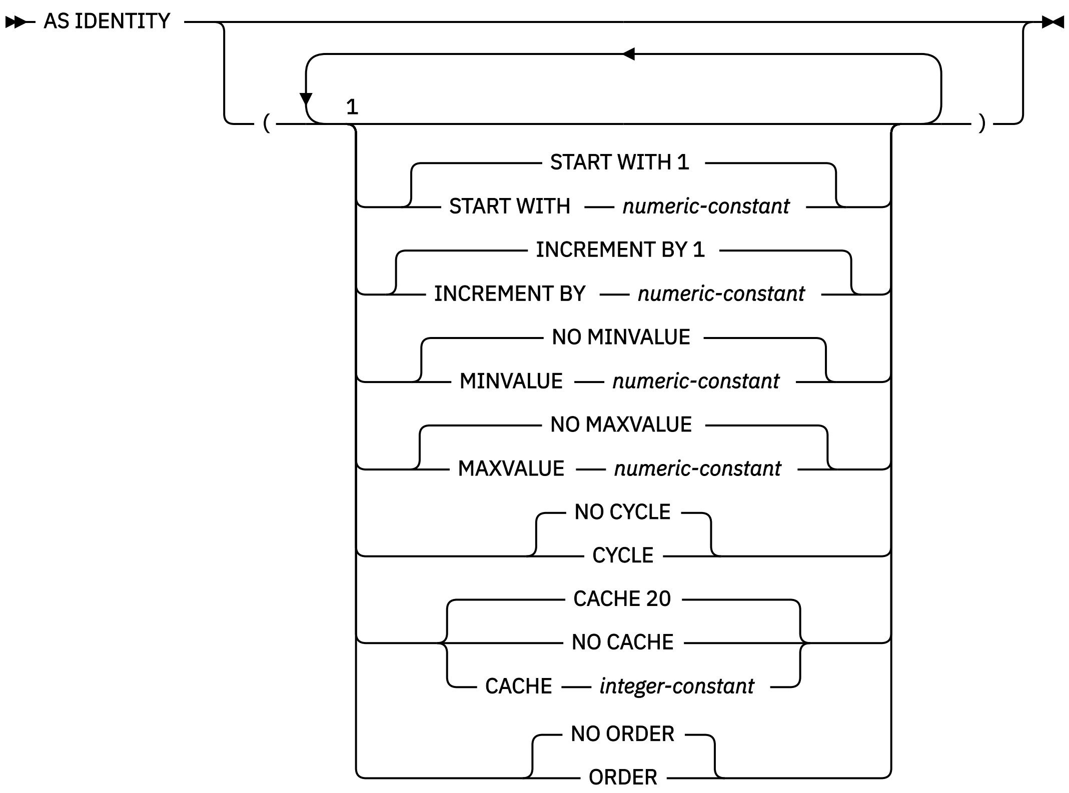


generated-clause:



GENERATED
ALWAYS
BY DEFAULT
as-identity-clause
as-row-change-timestamp-clause
GENERATED
ALWAYS
as-row-transaction-start-id-clause
as-row-transaction-timestamp-clause
as-generated-expression-clause

as-identity-clause:



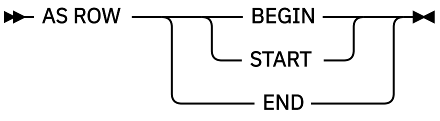
Notes:

[1] Separator commas can be specified between attributes when an identity column is defined.

as-row-change-timestamp-clause:

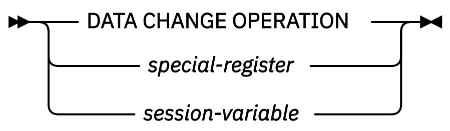
as-row-transaction-start-id-clause:

as-row-transaction-timestamp-clause:

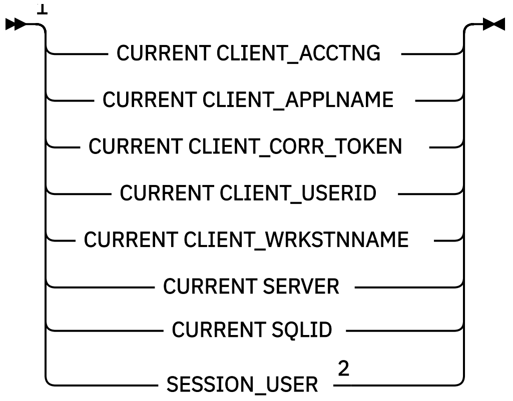


as-generated-expression-clause:

non-deterministic-expression:



special-register:

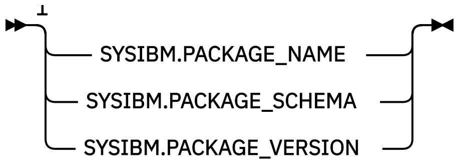


Notes:

[1] This definition of special register is specific to this context, as part of *non-deterministic-expression*.

[2] USER can be specified as a synonym for SESSION_USER.

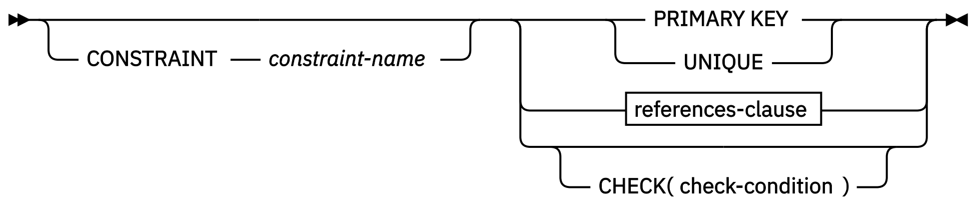
session-variable:



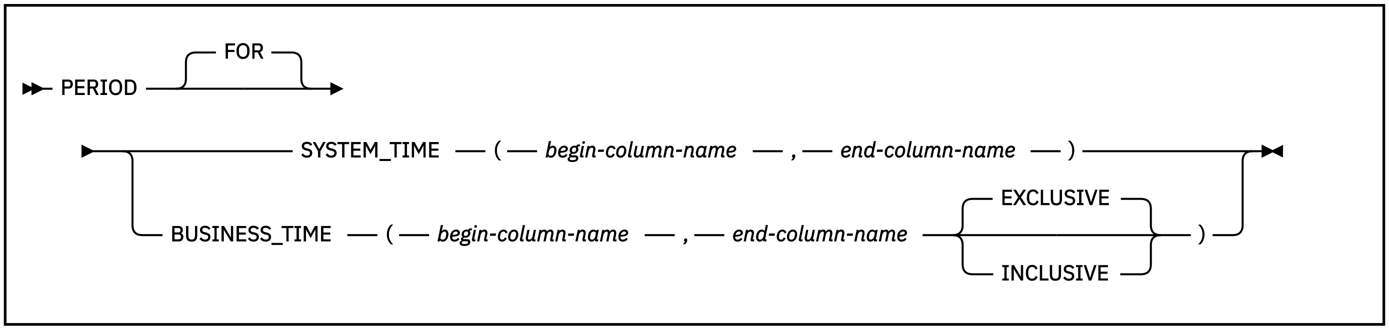
Notes:

[1] This definition of session variable is specific to this context, as part of *non-deterministic-expression*.

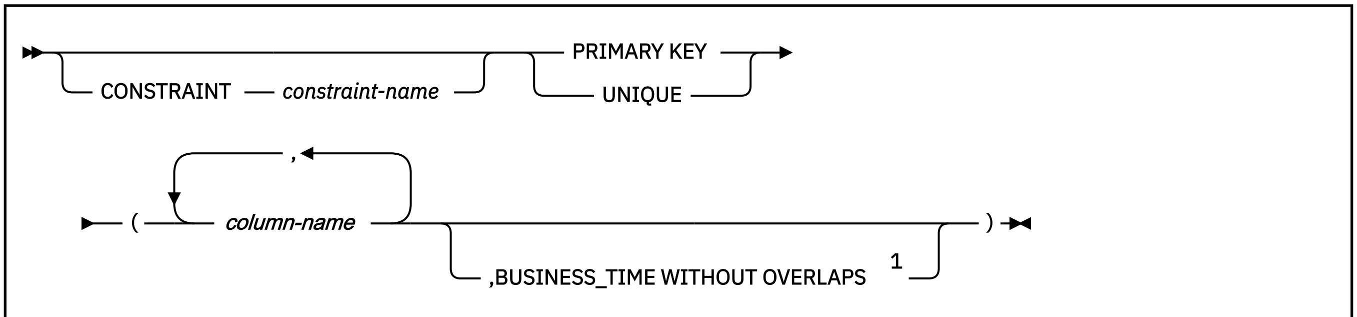
column-constraint:



period-definition:



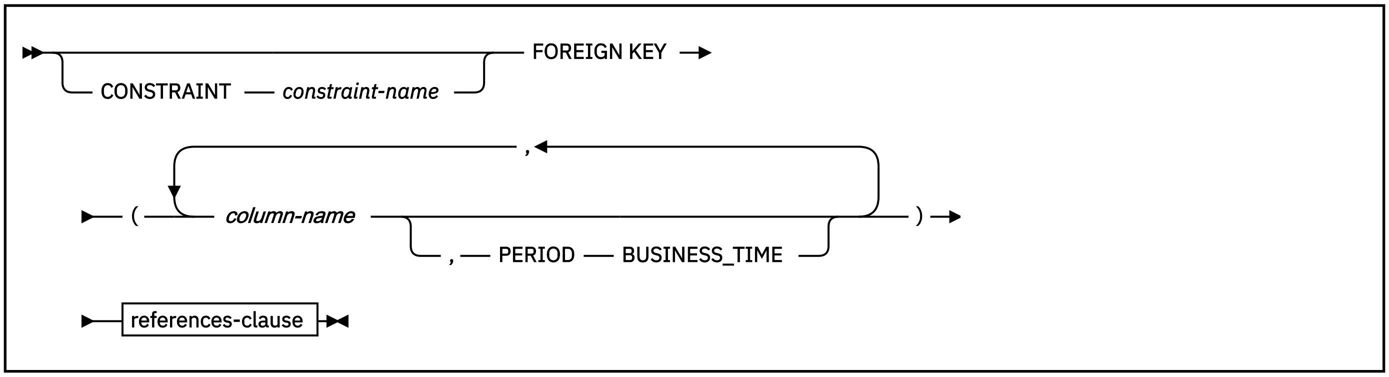
unique-constraint:



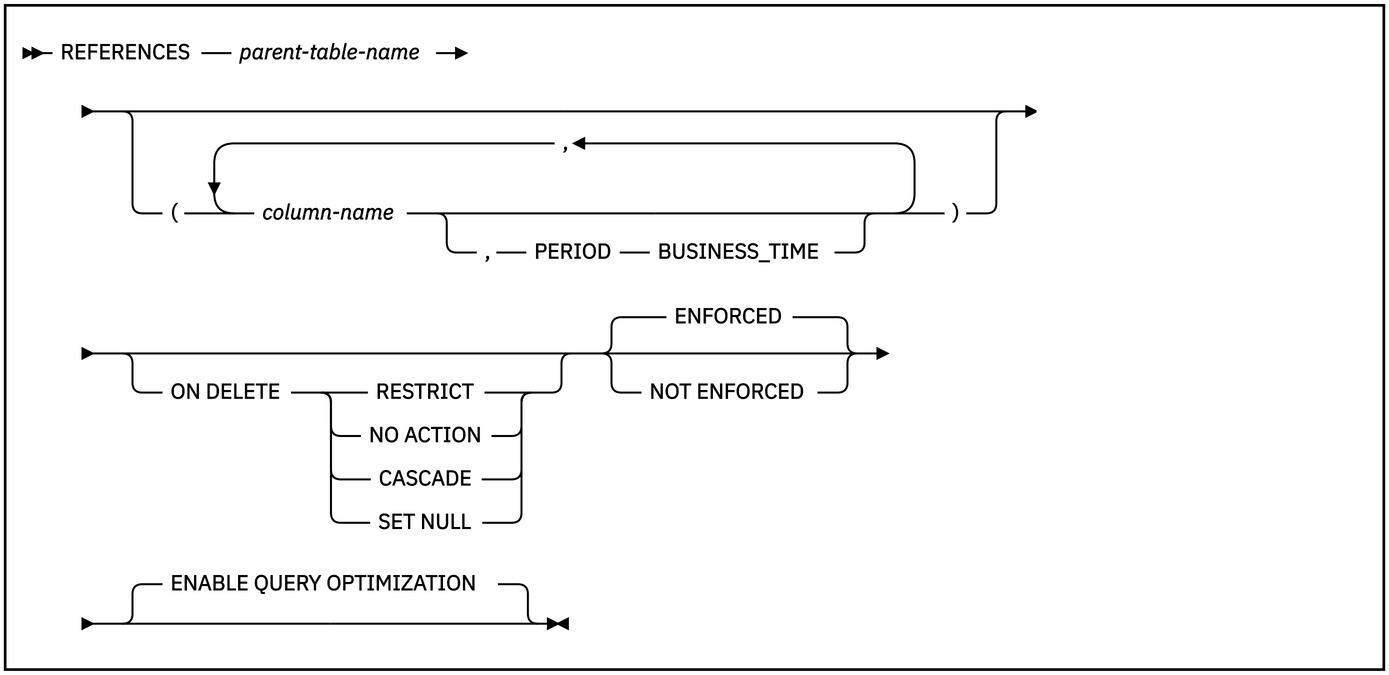
Notes:

[1] If BUSINESS_TIME WITHOUT OVERLAPS is specified, the BUSINESS_TIME period will not overlap in time periods for the same *column-name* values.

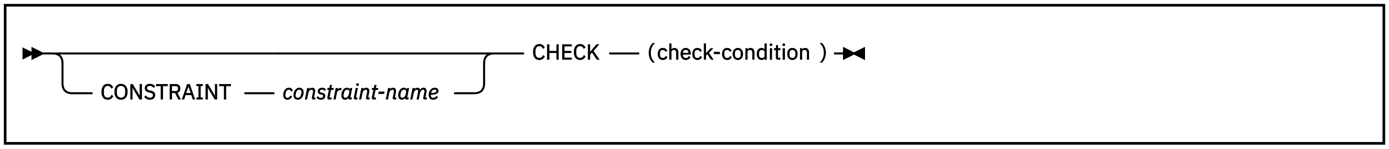
referential-constraint:



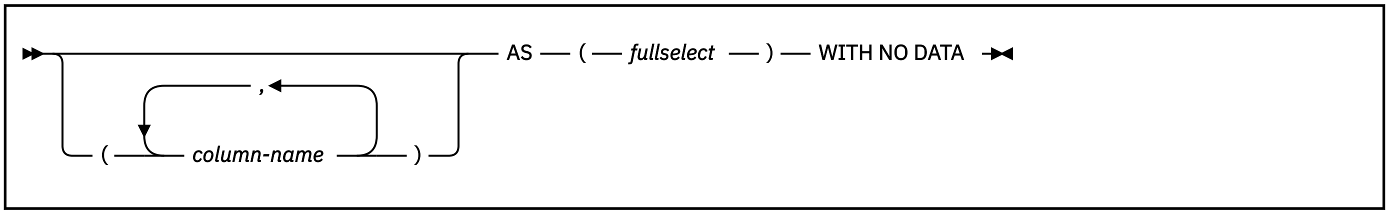
references-clause:



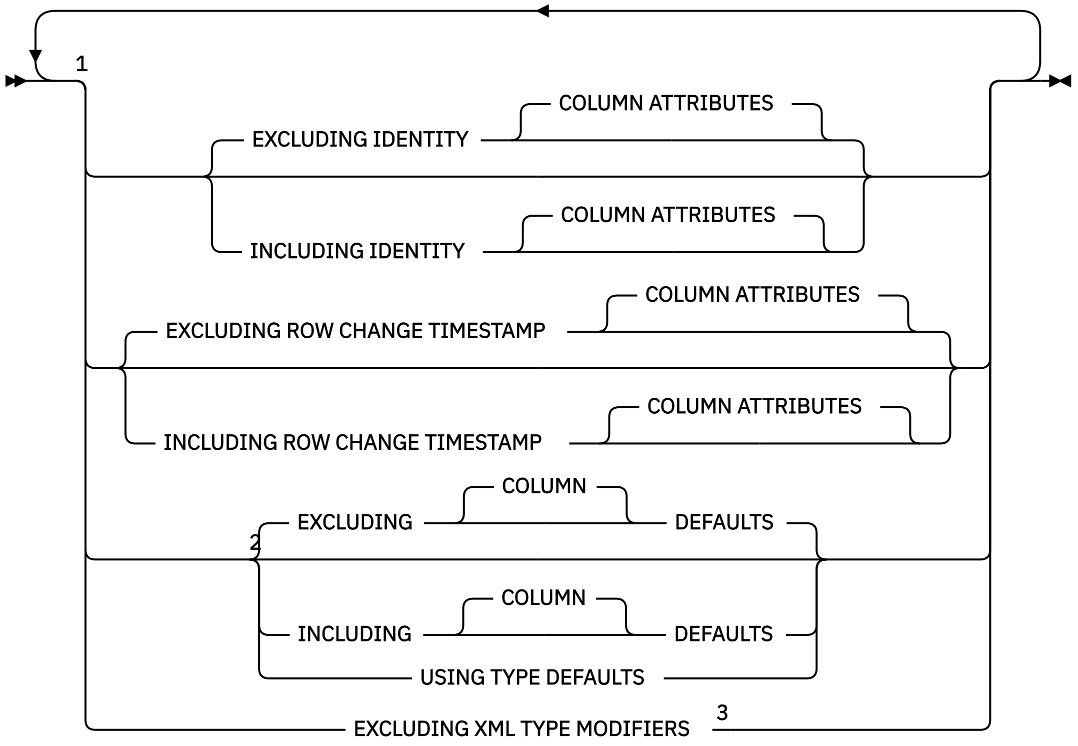
check-constraint:



as-result-table:



copy-options:



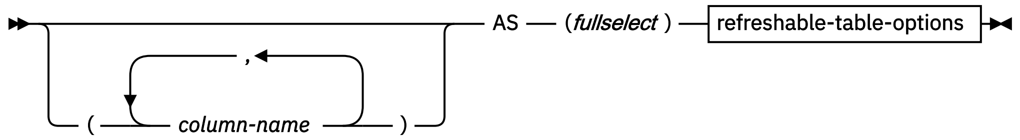
Notes:

[1] These clauses can be specified in any order and must not be specified more than one time.

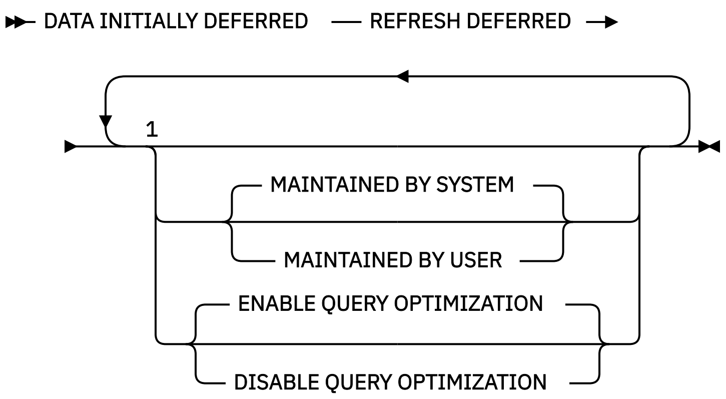
[2] EXCLUDING COLUMN DEFAULTS, INCLUDING COLUMN DEFAULTS, and USING TYPE DEFAULTS must not be specified with the LIKE clause.

[3] EXCLUDING XML TYPE MODIFIERS must be specified with the LIKE clause if the identified table has an XML type modifier and none of the XML columns of the new table has an XML type modifier. EXCLUDING XML TYPE MODIFIERS is not supported when a view is identified in a LIKE clause and the view contains XML columns.

materialized-query-definition



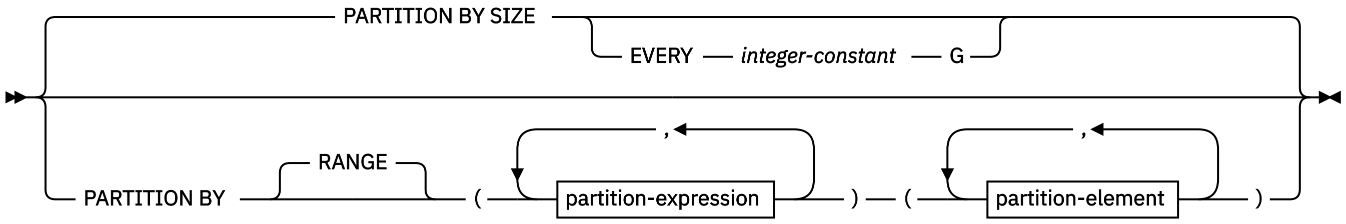
refreshable-table-options:



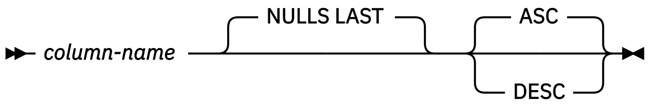
Notes:

[1] The same clause must not be specified more than one time.

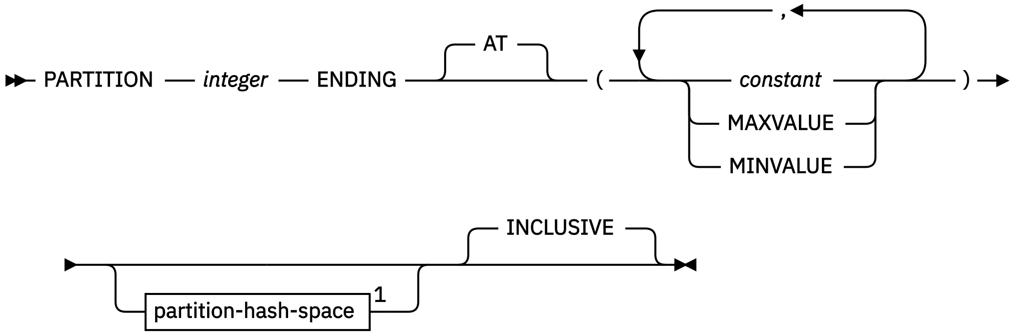
partitioning-clause:



partition-expression:



partition-element:



Notes:

[1] FL 504 Hash-organized tables are deprecated. Beginning in Db2 12, packages bound with APPLCOMPAT(V12R1M504) or higher cannot create hash-organized tables or alter existing tables to use hash-organization. Existing hash organized tables remain supported, but they are likely to be unsupported in the future.

Description for CREATE TABLE

table-name
Names the table. The name, including the implicit or explicit qualifier, must not identify a table, view, alias, or synonym that exists at the current server or a table that exists in the SYSIBM.SYSPENDINGOBJECTS catalog table. The unqualified name must not be the same as an existing synonym.

If the name is qualified, the name can be a two-part or three-part name. If a three-part name is used, the first part must match the value of field Db2LOCATION NAME on installation panel DSNTIPR at the current server. (If the current server is not the local Db2, this name is not necessarily the name in the CURRENT SERVER special register.)

For more information, see Guidelines for table names (Db2 Administration Guide).

FL 502 KEY LABEL *key-label-name* or NO KEY LABEL
Specifies whether key label is specified at the table level for encryption. The *table-name* must identify a table that resides in a universal table space, or a partitioned (non-UTS) table space. If you specify a *table-space-name* using the IN clause, a subsequent REORG of the table space is required for the key label value to take effect.

KEY LABEL *key-label-name*
Specifies the default key label that is used to encrypt all the table spaces and index spaces associated with the table. This includes base table spaces, auxiliary table spaces, XML table spaces, index spaces, and clone table spaces, regardless of whether they are explicitly or implicitly created. Users must set the key label for archive or history tables independently.

The data set must be Db2-managed for all the table spaces and index spaces associated with the table.

The *table-name* must not identify one of the following:

- An accelerator-only table.
- An auxiliary table.

The key label must be defined in ICSF. Db2 address space RACF user ID or group must be permitted access to the key label in RACF.

The key label can be inherited or overridden when the data set is allocated. For details about the order of precedence, see Notes®.

NO KEY LABEL
Indicates that there is no key label specified at the table level for encryption.

column-definition

column-name
Names a column of the table. For a dependent table, up to 749 columns can be named. For a table that is not a dependent, this number is 750. Do not qualify *column-name* and do not use the same name for more than one column of the table.

built-in-type
Specifies the data type of the column as one of the following built-in data types, and for character string data types, specifies the subtype. For more information about defining a table with a LOB column (CLOB, BLOB, or DBCLOB), see Creating a table with LOB columns.

If IN ACCELERATOR is specified, not all data types are supported. For example, DECFLOAT, LOB, ROWID, TIMESTAMP WITH TIME ZONE, and XML are not supported. The *IBM Db2 Analytics Accelerator for z/OS: Stored Procedures Reference* has a complete list of supported data types.

SMALLINT
For a small integer.

INTEGER or INT
For a large integer.

BIGINT
For a big integer.

DECIMAL(*integer,integer*) or DEC(*integer,integer*)
DECIMAL(*integer*) or DEC(*integer*)
DECIMAL or DEC
For a decimal number. The first integer is the precision of the number. That is, the total number of digits, which can range from 1 to 31. The second integer is the scale of the number. That is, the number of digits to the right of the decimal point, which can range from 0 to the precision of the number.

You can use DECIMAL(*p*) for DECIMAL(*p*,0) and DECIMAL for DECIMAL(5,0).

You can also use the word NUMERIC instead of DECIMAL. For example, NUMERIC(8) is equivalent to DECIMAL(8). Unlike DECIMAL, NUMERIC has no allowable abbreviation.

DECFLOAT(*integer*)
For a decimal floating-point number. The value of *integer* must be either 16 or 34 and represents the number of significant digits that can be stored. If *integer* is omitted, the DECFLOAT column will be capable of representing 34 significant digits.

FLOAT(*integer*)
FLOAT
For a floating-point number. If *integer* is between 1 and 21 inclusive, the format is single precision floating-point. If the integer is between 22 and 53 inclusive, the format is double precision floating-point.

You can use DOUBLE PRECISION or FLOAT for FLOAT(53).

REAL
For single precision floating-point.

DOUBLE or DOUBLE PRECISION
For double precision floating-point

CHARACTER(*integer*) or CHAR(*integer*)
CHARACTER or CHAR
For a fixed-length character string of length *integer*, which can range 1–255. If the length specification is omitted, a length of 1 character is assumed.

CCSID 1208
Specifies that the column is a Unicode column encoded in UTF-8. This clause must not be specified for an ASCII or Unicode table.

VARCHAR(*integer*), CHAR VARYING(*integer*), or CHARACTER VARYING(*integer*)
For a varying-length character string of maximum length *integer*, which can range from 1 to the maximum record size minus 10 bytes. See Table 208 on page 1702 to determine the maximum record size.

CCSID 1208
Specifies that the column is a Unicode column encoded in UTF-8. This clause must not be specified for an ASCII or Unicode table.

FOR *subtype* DATA
Specifies a subtype for a character string column, which is a column with a data type of CHAR, VARCHAR, or CLOB. Do not use the FOR *subtype* DATA clause with columns of any other data type (including any distinct type). *subtype* can be one of the following:

SBCS
Column holds single-byte data.

MIXED
Column holds mixed data. Do not specify MIXED if the value of field MIXED DATA on installation panel DSNTIPF is NO unless the CCSID UNICODE clause is also specified, or the table is being created in a Unicode table space or database.

BIT

Column holds BIT data. Do not specify BIT for a CLOB column.

Only character strings are valid when subtype is BIT.

If you do not specify the FOR *subtype* DATA clause, the column is defined with a default subtype. For ASCII or EBCDIC data:

- The default is SBCS when the value of field MIXED DATA on installation panel DSNTIPF is NO.
- The default is MIXED when the value is YES.

For Unicode data, the default subtype is MIXED.

A security label column is always considered SBCS data, regardless of the encoding scheme of the table.

CLOB(*integer* [K|M|G]), CHAR LARGE OBJECT(*integer* [K|M|G]), or CHARACTER LARGE OBJECT(*integer* [K|M|G])
CLOB, CHAR LARGE OBJECT, or CHARACTER LARGE OBJECT

For a character large object (CLOB) string of the specified maximum length in bytes. The maximum length must be in the range 1–2147483647. A CLOB column has a varying-length. It cannot be referenced in certain contexts regardless of its maximum length. For more information, see "Restrictions using LOBs" on page 117.

When *integer* is not specified, the default length is 1M. The maximum value that can be specified for *integer* depends on whether a units indicator is also specified as shown in the following list.

integer

The maximum value for *integer* is 2147483647. The maximum length of the string is *integer*.

***integer* K**

The maximum value for *integer* is 2097152. The maximum length is 1024 times *integer*.

***integer* M**

The maximum value for *integer* is 2048. The maximum length is 1,048,576 times *integer*.

***integer* G**

The maximum value for *integer* is 2. The maximum length is 1,073,741,824 times *integer*.

integer can be separated from K, M, or G by 0 or more spaces.

If you specify a value that evaluates to 2 gigabytes (2,147,483,648), Db2 uses a value that is one byte less, or 2147483647.

CCSID 1208

Specifies that the column is a Unicode column encoded in UTF-8. This clause must not be specified for an ASCII or Unicode table.

GRAPHIC(*integer*)
GRAPHIC

For a fixed-length graphic string of length *integer*, which can range 1–127. If the length specification is omitted, a length of 1 character is assumed.

CCSID 1200

Specifies that the column is a Unicode column encoded in UTF-16. This clause must not be specified for an ASCII or Unicode table.

VARGRAPHIC(*integer*)

For a varying-length graphic string of maximum length *integer*, which must range from 1 to *n*/2, where *n* is the maximum row size minus 2 bytes.

CCSID 1200

Specifies that the column is a Unicode column encoded in UTF-16. This clause must not be specified for an ASCII or Unicode table.

DBCLOB(*integer* [K|M|G])
DBCLOB

For a double-byte character large object (DBCLOB) string of the specified maximum length in double-byte characters. The maximum length must be in the range of 1–1,073,741,823. A DBCLOB column has a varying-length. It cannot be referenced in certain contexts regardless of its maximum length. For more information, see "Restrictions using LOBs" on page 117.

When *integer* is not specified, the default length is 1M. The meaning of *integer* K|M|G is similar to CLOB. The difference is that the number specified is the number of double-byte characters.

integer can be separated from K, M, or G by 0 or more spaces.

CCSID 1200

Specifies that the column is a Unicode column encoded in UTF-16. This clause must not be specified for an ASCII or Unicode table.

BINARY(*integer*)

A fixed-length binary string of length *integer*. The *integer* can range 1–255. If the length specification is omitted, a length of 1 byte is assumed.

BINARY VARYING(*integer*) or VARBINARY(*integer*)

A varying-length binary string of maximum length *integer*, which can range 1–32704. The length is limited by the page size of the table space.

BLOB (*integer* [K|M|G] or BINARY LARGE OBJECT(*integer* [K|M|G])
BLOB or BINARY LARGE OBJECT

For a binary large object (BLOB) string of the specified maximum length in bytes. The maximum length must be in the range of 1–2147483647. A BLOB column has a varying-length. It cannot be referenced in certain contexts regardless of its maximum length. For more information, see "Restrictions using LOBs" on page 117.

When *integer* is not specified, the default length is 1M. The meaning of *integer* K|M|G is the same as for CLOB.

integer can be separated from K, M, or G by 0 or more spaces.

DATE

For a date.

TIME

For a time.

TIMESTAMP(*integer*) WITHOUT TIME ZONE

For a timestamp. *integer* specifies the optional timestamp precision attribute and must be in the range 0–12. The timestamp precision denotes the number of fractional second digits that are included in the timestamp. The default is 6.

TIMESTAMP(*integer*) WITH TIME ZONE

For a timestamp with time zone. *integer* specifies the optional timestamp precision attribute and must be in the range 0–12. The timestamp precision denotes the number of fractional second digits that are included in the timestamp. The default is 6.

ROWID

For a row ID type.

A table can contain at most two ROWID columns. If it contains two, one column is implicitly generated by Db2 and the other column is explicitly defined as a ROWID without the IMPLICITLY HIDDEN attribute. The values in a ROWID column are unique for every row in the table and cannot be updated. You must specify NOT NULL with ROWID.

XML

For an XML document. Only well-formed XML documents can be inserted into an XML column.

If the XML column is the first XML column that you create for the table, a BIGINT DOCID column is implicitly created and is used to store a unique document identifier for the XML columns of a row.

XMLSCHEMA

Specifies one or more XML schemas that are used to validate the XML value. The same XML schema can not be specified more than one time.

If the XML value has already been validated, for example, the XML value is the result of the DSN_XMLVALIDATE function or from an XML column with a type modifier, and the XML schema against which the XML value is validated is one of the schemas specified in the *XML-type-modifier*, Db2 accepts the XML value without revalidation.

XML-schema-specification

Specifies one XML schema. The XML schema can be identified by using either the *registered-XML-schema-name* or the schema's target namespace followed by an optional schema location. Any XML schema that is referenced in this clause must be registered in the XML schema repository prior to use.

ID ***registered-XML-schema-name***

Identifies an XML schema by using its *registered-XML-schema-name*. The name must uniquely identify an existing XML schema in the XML schema repository at the current server. If no XML schema by this name exists, an error is returned.

The schema qualifier must be SYSXSR.

URI ***target-namespace***

Specifies the target namespace URI of the XML schema. The value for the target-namespace URI is a character string constant which is not empty. The URI must be the target namespace of a registered XML schema and, if no LOCATION clause is specified, it must uniquely identify the registered XML schema.

NO NAMESPACE

Specifies that the XML schema has no target namespace. There must be a registered XML schema that has no target namespace. If no LOCATION clause is specified, there must be only one such registered XML schema.

LOCATION ***schema-location***

Specifies the XML schema location URI of the XML schema. The value of *schema-location* is a character string constant that is not empty. The schema location URI, combined with the target namespace URI, must identify a registered XML schema.

ELEMENT ***element-name***

Specifies the name of the global element declaration. *element-name* must match the local name of the root element node in the instance XML document. The namespace name of the root element node must be the same as the target namespace URI.

distinct-type-name

Specifies the data type of the column is a distinct type (a user-defined data type). The length, precision, and scale of the column are respectively the length, precision, and scale of the source type of the distinct type. The privilege set must implicitly or explicitly include the USAGE privilege on the distinct type.

The encoding scheme of the distinct type must be the same as the encoding scheme of the table. The subtype for the distinct type, if it has the attribute, is the subtype with which the distinct type was created.

If the column is to be used in the definition of the foreign key of a referential constraint, the data type of the corresponding column of the parent key must have the same distinct type.

NOT NULL

Prevents the column from containing null values. Omission of NOT NULL implies that the column can contain null values.

column-constraint

The *column-constraint* of a *column-definition* provides a shorthand method of defining a constraint composed of a single column. Thus, if a *column-constraint* is specified in the definition of column C, the effect is the same as if that constraint were specified as a *unique-constraint*, *referential-constraint*, or *check-constraint* in which C is the only identified column.

CONSTRAINT *constraint-name*

Names the constraint. If a constraint name is not specified, a unique constraint name is generated. If the name is specified, it must be different from the names of any referential, check, primary key, or unique key constraints previously specified on the table.

PRIMARY KEY

Provides a shorthand method of defining a primary key composed of a single column. Thus, if PRIMARY KEY is specified in the definition of column C, the effect is the same as if the PRIMARY KEY(C) clause is specified as a separate clause.

The NOT NULL clause must be specified with this clause. PRIMARY KEY cannot be specified more than one time in a column definition, and must not be specified if the UNIQUE clause is specified in the definition. This clause must also not be specified if the definition is for one of the following types of columns:

- a LOB column
- a ROWID column
- a distinct type column that is based on a LOB or ROWID data type
- an XML column
- a row change timestamp column
- a column in an accelerator-only table

The table is marked as unavailable until its primary index is explicitly created unless the CREATE TABLE statement is processed by the schema processor or the table space that contains the table is implicitly created. In that case, Db2 implicitly creates an index to enforce the uniqueness of the primary key and the table definition is considered complete. (For more information about implicitly created indexes, see Implicitly created indexes.)

UNIQUE

Provides a shorthand method of defining a unique key composed of a single column. Thus, if UNIQUE is specified in the definition of column C, the effect is the same as if the UNIQUE(C) clause is specified as a separate clause.

The NOT NULL clause must be specified with this clause. UNIQUE cannot be specified more than one time in a column definition and must not be specified if the PRIMARY KEY clause is specified in the column definition or if the definition is for one of the following types of columns:

- a LOB column
- a ROWID column
- a distinct type column that is based on a LOB or ROWID data type
- an XML column
- a row change timestamp column
- a column in an accelerator-only table

The table is marked as unavailable until all the required indexes are explicitly created unless the CREATE TABLE statement is processed by the schema processor or the table space that contains the table is implicitly created. In that case, Db2 implicitly creates the indexes that are required for the unique keys and the table definition is considered complete. (For more information about implicitly created indexes, see Implicitly created indexes.)

references-clause

The *references-clause* of a *column-definition* provides a shorthand method of defining a foreign key composed of a single column. Thus, if *references-clause* is specified in the definition of column C, the effect is the same as if the *references-clause* were specified as part of a FOREIGN KEY clause in which C is the only identified column.

Do not specify *references-clause* in the definition of the following types of columns because these types of columns cannot be a foreign key:

- a LOB column

- a ROWID column
- a DECFLOAT column
- a distinct type column that is based on a LOB, ROWID, or DECFLOAT data type
- an XML column
- a row change timestamp column
- a security label column

CHECK *(check-condition)*
CHECK *(check-condition)* provides a shorthand method of defining a check constraint that applies to a single column. For conformance with the SQL standard, if CHECK is specified in the column definition of column C, no columns other than C should be referenced in the check condition of the check constraint. The effect is the same as if the check condition were specified as a separate clause.

DEFAULT
Specifies the default value that is assigned to the column in the absence of a value specified on an insert or update operation or LOAD. DEFAULT must not be specified more than one time in the same *column-definition*. Do not specify DEFAULT for the following types of columns because Db2 generates default values:

- An identity column (a column that is defined AS IDENTITY)
- A ROWID column (or a distinct type that is based on a ROWID)
- A row change timestamp column
- A row-begin column
- A row-end column
- A *transaction-start-id* column
- An XML column

If IN ACCELERATOR is specified, do not specify DEFAULT for a column.

Do not specify a value after the DEFAULT keyword for a security label column. Db2 provides the default value for a security label column.

If a value is not specified after DEFAULT, the default value depends on the data type of the column, as follows:

Data Type
Default Value

Numeric
0

Big integer
0

Fixed-length character string
Blanks

Fixed-length graphic string
Blanks

Fixed-length binary string
Hexadecimal zeros

Varying-length string
A string of length 0

Inline BLOB
Hexadecimal zeros

Inline CLOB
Blanks

Inline DBCLOB
Blanks

Date
CURRENT DATE

Time
CURRENT TIME

TIMESTAMP(*integer*) WITHOUT TIME ZONE
CURRENT TIMESTAMP(*p*) WITHOUT TIME ZONE where *p* is the corresponding timestamp precision.

TIMESTAMP(*integer*) WITH TIME ZONE
CURRENT TIMESTAMP(*p*) WITH TIME ZONE where *p* is the corresponding timestamp precision.

If the column is defined as timestamp with time zone the default value must include a time zone.

Distinct type
The default of the source data type

A default value other than the one that is listed above can be specified in one of the following forms:

- WITH DEFAULT for a default value of an empty string
- DEFAULT NULL for a default value of null

Omission of NOT NULL and DEFAULT from a *column-definition*, for a column other than an identity column, is an implicit specification of DEFAULT NULL. For an identity column, it is an implicit specification of NOT NULL, and Db2 generates default values.

constant
Specifies a constant as the default value for the column. The value of the constant must conform to the rules for assigning that value to the column.

A character or graphic string constant must be short enough so that its UTF-8 representation requires no more than 1536. A hexadecimal graphic string constant (GX) cannot be specified.

In addition, the length of the constant value cannot be greater than the INLINE LENGTH attribute for LOB columns.

SESSION_USER or USER
Specifies the value of the SESSION_USER (USER) special register at the time of an SQL data change statement or LOAD as the default value for the column. If SESSION_USER is specified, the data type of the column must be a character string with a length attribute greater than or equal to 8 characters when the value is expressed in CCSID 37. If the data type of the column is an inline CLOB, the INLINE LENGTH attribute must be greater than or equal to 8 characters when the value is expressed as CCSID 37.

CURRENT SQLID
Specifies the value of the SQL authorization ID of the process at the time of an insert or update operation or LOAD as the default value for the column. If CURRENT SQLID is specified, the data type of the column must be a character string with a length attribute greater than or equal to the length attribute of the CURRENT SQLID special register. If the data type of the column is an inline CLOB, the INLINE LENGTH attribute must be greater than or equal to the length attribute of the CURRENT SQLID special register.

NULL
Specifies null as the default value for the column. If NOT NULL is specified, DEFAULT NULL must not be specified with the same *column-definition*.

cast-function-name
The name of the cast function that matches the name of the distinct type for the column. A cast function can only be specified if the data type of the column is a distinct type.

The schema name of the cast function, whether it is explicitly specified or implicitly resolved through function resolution, must be the same as the explicitly or implicitly specified schema name of the distinct type.

constant
Specifies a constant as the argument. The constant must conform to the rules of a constant for the source type of the distinct type. The length of the constant cannot be greater than the INLINE LENGTH attribute for LOB columns.

SESSION_USER or USER
Specifies the value of the SESSION_USER (USER) special register at the time a row is inserted as the default for the column. The source type of the distinct type of the column must be a CHAR, VARCHAR, or inline CLOB with a length attribute (inline length attribute for CLOB) that is greater than or equal to the length attribute of the SESSION_USER special register.

CURRENT SQLID
Specifies the value of the CURRENT SQLID special register at the time a row is inserted as the default for the column. The source type of the distinct type of the column must be a CHAR, VARCHAR, or inline CLOB with a length attribute (or inline length attribute for CLOB) that is greater than or equal to the length attribute of the CURRENT SQLID special register.

NULL
Specifies the NULL value as the argument.

In a given column definition:

- DEFAULT and FIELDPROC cannot both be specified.
- NOT NULL and DEFAULT NULL cannot both be specified.

Table 204 on page 1666 summarizes the effect of specifying the various combinations of the NOT NULL and DEFAULT clauses on the CREATE TABLE statement *column-description* clause.

Table 204. Effect of specifying combinations of the NOT NULL and DEFAULT clauses

If NOT NULL is:	And DEFAULT is:	The effect is:
Specified[1]	Omitted	An error occurs if a value is not provided for the column on an insert or update operation or LOAD.
	Specified without an operand	The system defined nonnull default value is used.
	constant	The specified constant is used as the default value.
	SESSION_USER	The value of the SESSION_USER special register at the time of an insert or update operation or LOAD is used as the default value.
	CURRENT SQLID	The SQL authorization ID of the process at the time of an insert or update operation or LOAD is used as the default value.
	NULL	An error occurs during the execution of CREATE TABLE.

Table 204. Effect of specifying combinations of the NOT NULL and DEFAULT clauses (continued)

If NOT NULL is:	And DEFAULT is:	The effect is:
Omitted	Omitted	Equivalent to an implicit specification of DEFAULT NULL.
	Specified without an operand	The system defined nonnull default value is used.
	constant	The specified constant is used as the default value.
	SESSION_USER	The value of the SESSION_USER special register at execution time is used as the default value.
	CURRENT SQLID	The SQL authorization ID of the process is used as the default value.
	NULL	Null is used as the default value.

Note: The table does not apply to a column with a ROWID data type or to an identity column.

GENERATED

Specifies that Db2 generates values for the column. GENERATED must be specified if the column is to be considered one of the following types of columns:

- An identity column
- A row change timestamp column.
- A ROWID column
- A row-begin column
- A row-end column
- A *transaction-start-id* column
- A generated expression column

GENERATED must only be specified for these types of columns. GENERATED must not be specified with *default-clause* in a column definition.

GENERATED must not be specified if the column definition references global variables.

ALWAYS

Specifies that Db2 always generates a value for the column when a row is inserted or updated and a default value must be generated. ALWAYS is the default and recommended value.

BY DEFAULT

Specifies that Db2 will generate a value for the column when a row is inserted or updated and a default value must be generated, unless an explicit value is specified.

For a row change timestamp column, Db2 inserts or updates a specified value but does not verify that the value is unique for the column unless the row change timestamp column has a unique constraint or a unique index that specifies only the row change timestamp column.

For a ROWID column, Db2 uses a specified value only if it is a valid row ID value that was previously generated by Db2 and the column has a unique, single-column index. Until this index is created on the ROWID column, the SQL insert or update operation and the LOAD utility cannot be used to add rows to the table. If the table space is explicitly created and the value of the CURRENT RULES special register is 'STD' when the CREATE TABLE statement is processed, or if the table space is implicitly created, Db2 implicitly creates the index on the ROWID column. The name of this index is 'I' followed by the first ten characters of the column name followed by seven randomly generated characters. If the column name is less than ten characters, Db2 adds underscore characters to the end of the name until it has ten characters. The implicitly created index has the COPY NO attribute.

For an identity column, Db2 inserts a specified value but does not verify that it a unique value for the column unless the identity column has a unique, single-column index.

BY DEFAULT is the recommended value only when you are using data propagation.

FOR EACH ROW ON UPDATE AS ROW CHANGE TIMESTAMP

Specifies that the column is a timestamp column for the table. Db2 generates a value for the column for each row as the row is inserted, and for any row in which any column is updated. The value that is generated for a row change timestamp column is a timestamp that corresponds to the insert or update time of the row. If multiple rows are inserted or updated with a single statement, the value for the row change timestamp column might be different for each row.

A table can only have one row change timestamp column.

If *data-type* is specified, it must be TIMESTAMP WITHOUT TIME ZONE with a precision of 6.

A row change timestamp column cannot have a DEFAULT clause. NOT NULL must be specified for a row change timestamp column.

AS TRANSACTION START ID

Specifies that the value is assigned by Db2 whenever a row is inserted into the table or any column in the row is updated. Db2 assigns a unique timestamp value per transaction or the null value. The null value is assigned to the transaction-start-ID column if the column is nullable. Otherwise, the value is generated using the time-of-day clock during execution of the first data change statement in the transaction that requires a value to be assigned to a row-begin column or transaction-start-ID column in the table, or when a row in a system-period temporal table is deleted. If multiple rows are inserted or updated within a single SQL transaction, the values for the transaction-start-ID column are the same for all the rows and are unique from the values that are generated for the column for another transaction.

A transaction-start-ID column is required for a system-period temporal table.

A table can have only one transaction-start-ID column. If a data type is not specified, the column is defined as TIMESTAMP(12) WITHOUT TIME ZONE. If a data type is specified, it must be TIMESTAMP(12) WITHOUT TIME ZONE or TIMESTAMP(12) WITH TIME ZONE. If the column is defined as TIMESTAMP WITH TIME ZONE, the values are stored in UTC, with a time zone of +00:00. A transaction-start-ID column cannot have a DEFAULT clause. A transaction-start-ID column is not updatable.

A value for a transaction-start-ID column is composed of a TIMESTAMP(9) value that is unique per transaction per data sharing member followed by 3 digits that indicate the data sharing member number.

AS ROW BEGIN

Specifies that a timestamp value is assigned to the column whenever a row is inserted or any column in the row is updated. If the value of the SYSIBM.TEMPORAL_LOGICAL_TRANSACTION_TIME built-in global variable at the time of the insert or update is null, the value is generated using a reading of the time-of-day clock during execution of the first data change statement in the unit of work that requires a value to be assigned to a row-begin column or transaction-start-ID column in a table, or a row in a system-period temporal table is deleted. Otherwise, the row-begin column is assigned the value of the SYSIBM.TEMPORAL_LOGICAL_TRANSACTION_TIME built-in global variable at the time of the insert or update.

A *row-begin* column is intended to be used for a system-period temporal table.

A table can have only one column defined as AS ROW BEGIN. If a data type is specified, it must be TIMESTAMP(12) WITHOUT TIME ZONE or TIMESTAMP(12) WITH TIME ZONE. If the column is defined as TIMESTAMP(12) WITH TIME ZONE, the values are stored in UTC, with a time zone of +00:00. If no data type is specified, the column is defined as TIMESTAMP(12) WITHOUT TIME

ZONE. A column defined as a row-begin column cannot have a DEFAULT clause, and must be defined as NOT NULL.

A row-begin column is not updatable.

A value for a row-begin column is composed of a TIMESTAMP(9) value that is unique per transaction per data sharing member followed by 3 digits that indicate the data sharing member number.

AS ROW END

Specifies that a value for the data type of the column is assigned by Db2 whenever a row is inserted or any column in the row is updated. The value that is assigned for a TIMESTAMP WITHOUT TIME ZONE column is the TIMESTAMP value '9999-12-30-00.00.00.000000000000'. The value that is assigned for a TIMESTAMP WITH TIME ZONE column is the TIMESTAMP value '9999-12-30-00.00.00.000000000000 +00:00'.

A row-end column is required as the second column of a SYSTEM_TIME period.

A table can have only one row-end column. If a data type is not specified, the column is defined as TIMESTAMP(12) WITHOUT TIME ZONE. If a data type is specified, it must be TIMESTAMP(12) WITHOUT TIME ZONE or TIMESTAMP(12) WITH TIME ZONE. If the column is defined as TIMESTAMP WITH TIME ZONE, the values are stored in UTC, with a time zone of +00:00. A row-end column cannot have a DEFAULT clause and must be defined as NOT NULL. A row-end column is not updatable.

as-generated-expression-clause

Specifies that values for the column are generated by Db2. The generated value is assigned to the column whenever a row is inserted, or any column in the row is updated.

DATA CHANGE OPERATION

Specifies that the database manager generates one of the following values, depending on the specified expression:

I

Insert operation.

U

Update operation.

D

Delete operation.

A table can have only one DATA CHANGE OPERATION column. The column must be defined as CHAR(1). The column cannot have a DEFAULT clause and must not be defined as NOT NULL.

The column is a non-deterministic generated expression column.

Do not specify any of the following clauses for the column:

- CCSID 1200
- CCSID 1208
- FIELDPROC

special-register

Specifies the value of the special register. The column is to contain the value of the special register at the time of the data change statement that assigns the value to the column. If multiple rows are inserted or updated with a single SQL statement, the value for the column is the same for all of the rows.

special-register must be one of the following special registers, and the column must use the required data type.

Table 205. Possible special register values for non-deterministic generated expression columns

Special register	Data type for the column
CURRENT CLIENT_ACCTNG	VARCHAR(255)
CURRENT CLIENT_APPLNAME	VARCHAR(255)
CURRENT CLIENT_CORR_TOKEN	VARCHAR(255)
CURRENT CLIENT_USERID	VARCHAR(255)
CURRENT CLIENT_WRKSTNNAME	VARCHAR(255)
CURRENT SERVER	CHAR(16)
CURRENT SQLID	VARCHAR(*n*) where *n* ≥ 8
SESSION_USER or USER	VARCHAR(128)

The column cannot have a DEFAULT clause and must not be defined as NOT NULL.

The column is a non-deterministic generated expression column.

Do not specify any of the following clauses for the column:

- CCSID 1200
- CCSID 1208
- FIELDPROC

For more information, see "Special registers" on page 177.

session-variable

Specifies the value of a built-in session variable. The fully qualified name of the session variable must be specified. The value of the session variable is obtained from the GETVARIABLE function at the time of the data change operation that assigns the value to the column. If multiple rows are changed with a single SQL statement, the value for the column is the same for all of the rows.

session-variable must be one of the following session variables, and the column must use the required data type.

Table 206. Possible session variable values for non-deterministic generated expression columns

Session variable	Data type for the column
SYSIBM.PACKAGE_NAME	VARCHAR(128)
SYSIBM.PACKAGE_SCHEMA	VARCHAR(128)
SYSIBM.PACKAGE_VERSION	VARCHAR(122)

The column cannot have a DEFAULT clause and must not be defined as NOT NULL.

The column is a non-deterministic generated expression column.

Do not specify any of the following clauses for the column:

- CCSID 1200
- CCSID 1208
- FIELDPROC

For more information, see "Built-in session variables" on page 336.

AS IDENTITY

Specifies that the column is an identity column for the table. A table can have only one identity column. AS IDENTITY can be specified only if the data type for the column is an exact numeric type with a scale of zero (SMALLINT, INTEGER, BIGINT, DECIMAL with a scale of zero, or a distinct type based on one of these types).

An identity column is implicitly NOT NULL. An identity column cannot have a WITH DEFAULT clause.

Defining a column AS IDENTITY does not necessarily ensure the uniqueness of the values. To ensure uniqueness of the values, define a unique, single-column index on the identity column.

If IN ACCELERATOR is specified, AS IDENTITY must not be specified.

START WITH *numeric-constant*

Specifies the first value that is generated for the identity column. The value can be any positive or negative value that could be assigned to the column without non-zero digits existing to the right of the decimal point.

If a value is not explicitly specified when the identity column is defined, the default is the MINVALUE for an ascending identity column and the MAXVALUE for a descending identity column. This value is not necessarily the value that would be cycled to after reaching the maximum or minimum value for the identity column. The range used for cycles is defined by MINVALUE and MAXVALUE. MAXVALUE and MINVALUE do not constrain the numeric-constant value. That is, the START WITH clause can be used to start the generation of values outside the range that is used for cycles. However, the next generated value after the specified START WITH value is MINVALUE for an ascending identity column or MAXVALUE for a descending identity column.

INCREMENT BY *numeric-constant*

Specifies the interval between consecutive values of the identity column. The value can be any positive or negative value (including 0) that does not exceed the value of a large integer constant, and could be assigned to the column without any non-zero digits existing to the right of the decimal point.

If this value is negative, the values for the identity column descend. If this value is 0 or positive, the values for the identity column ascend. The default is 1.

MINVALUE or NO MINVALUE

Specifies the minimum value at which a descending identity column either cycles or stops generating values or an ascending identity column cycles to after reaching the maximum value.

NO MINVALUE

Specifies that the minimum end point of the range of values for the identity column has not be set. In such a case, the default value for MINVALUE becomes one of the following:

- For an ascending identity column, the value is the START WITH value or 1 if START WITH is not specified.
- For a descending identity column, the value is the minimum value of the data type of the column.

The default is NO MINVALUE.

MINVALUE *numeric-constant*

Specifies the numeric constant that is the minimum value that is generated for this identity column. This value can be any positive or negative value that could be assigned to this column without non-zero digits existing to the right of the decimal point. The value must be less than or equal to the maximum value.

MAXVALUE or NO MAXVALUE

Specifies the maximum value at which an ascending identity column either cycles or stops generating values or a descending identity column cycles to after reaching the minimum value.

NO MAXVALUE

Specifies that the minimum end point of the range of values for the identity column has not be set. In such a case, the default value for MAXVALUE becomes one of the following:

- For an ascending identity column, the value is the maximum value of the data type associated with the column.
- For a descending identity column, the value is the START WITH value -1 if START WITH is not specified.

The default is NO MAXVALUE.

MAXVALUE *numeric-constant*

Specifies the numeric constant that is the maximum value that is generated for this identity column. This value can be any positive or negative value that could be assigned to this column without non-zero digits existing to the right of the decimal point. The value must be greater than or equal to the minimum value.

CYCLE or NO CYCLE

Specifies whether this identity column should continue to generate values after reaching either its maximum or minimum value. The default is NO CYCLE.

NO CYCLE

Specifies that values will not be generated for the identity column after the maximum or minimum value has been reached.

CYCLE

Specifies that values continue to be generated for the identity column after the maximum or minimum value has been reached. If this option is used, after an ascending identity column reaches the maximum value, it generates its minimum value. After a descending identity column reaches its minimum value, it generates its maximum value. The maximum and minimum values for the identity column determine the range that is used for cycling.

When CYCLE is in effect, duplicate values can be generated by Db2 for an identity column. However, if a unique index exists on the identity column and a non-unique value is generated for it, an error occurs.

CACHE *integer-constant* or NO CACHE

Specifies whether to keep some preallocated values in memory. Preallocating and storing values in the cache improves the performance of inserting rows into a table. The default is CACHE 20.

In a non-data sharing environment, if the system is shut down (either normally or through a system failure), all cached sequence values that have not been used in committed statements are lost (that is, they will never be used). The value specified for the CACHE option is the maximum number of sequence values that could be lost when the system is shut down.

In a data sharing environment, you can use the CACHE and NO ORDER options to allow multiple Db2 members to cache sequence values simultaneously.

NO CACHE

Specifies that values for the identity column and sequences are not preallocated and stored in the cache, ensuring that values will not be lost in the case of a system failure. In this case, every request for a new value for the identity column or sequence results in synchronous I/O.

In a data sharing environment, use NO CACHE if you need to guarantee that the identity column and sequence values are generated in the order in which they are requested.

CACHE *integer-constant*

Specifies the maximum number of values of the identity column sequence that Db2 can preallocate and keep in memory.

During a Db2 shutdown, all cached identity column values and sequence values that are yet to be assigned will be lost and will not be used. Therefore, the value that is specified for CACHE also represents the maximum number of identity column values and sequence values that will be lost during a Db2 shutdown.

The minimum value is 2.

In a data sharing environment, you can use the CACHE and NO ORDER options to allow multiple Db2 members to cache sequence values simultaneously.

ORDER or NO ORDER

Specifies whether the identity column values must be generated in order of request. The default is NO ORDER.

In a non-data sharing environment, there is no guarantee that values are assigned in order across the entire server unless NO CACHE is also specified. ORDER applies only to a single-application process.

In a data sharing environment, if ORDER is specified, NO CACHE is implicitly set, even if CACHE integer-constant is specified.

NO ORDER

Specifies that the values do not need to be generated in order of request.

ORDER

Specifies that the values are generated in order of request. Specifying ORDER might disable the caching of values. ORDER applies only to a single-application process.

In a data sharing environment, if the CACHE and NO ORDER options are in effect, multiple caches can be active simultaneously, and the requests for identity values from different Db2 members might not result in the assignment of values in strict numeric order. For example, if members DB2A and DB2B are using the identity column, and DB2A gets the cache values 1 to 20 and DB2B gets the cache values 21 to 40, the actual order of values assigned would be 1,21,2 if DB2A requested a value first, then DB2B requested, and then DB2A again requested. Therefore, to guarantee that identity values are generated in strict numeric order among multiple Db2 members using the same identity column, specify the ORDER option.

FIELDPROC *program-name*

Designates *program-name* as the field procedure exit routine for the column. A field procedure can be specified only for a column with a length attribute that is not greater than 255 bytes. FIELDPROC can only be specified for columns that are a built-in character string or graphic string data types. The column must not be one of the following:

- a LOB column
- a security label column
- a row change timestamp column
- a column with the TIMESTAMP WITH TIME ZONE data type
- a Unicode column in an EBCDIC table
- a column in an accelerator-only table

The field procedure encodes and decodes column values: before a value is inserted in the column, it is passed to the field procedure for encoding. Before a value from the column is used by a program, it is passed to the field procedure for decoding. A field procedure could be used, for example, to alter the sorting sequence of values entered in the column.

The field procedure is also invoked during the processing of the CREATE TABLE statement. When so invoked, the procedure provides Db2 with the column's *field description*. The field description defines the data characteristics of the encoded values. By contrast, the information you supply for the column in the CREATE TABLE statement defines the data characteristics of the decoded values.

For more information, see:

Field procedures (Db2 Administration Guide)
"String comparisons" on page 157

constant

Is a parameter that is passed to the field procedure when it is invoked. A parameter list is optional. The *n*th parameter specified in the FIELDPROC clause on CREATE TABLE corresponds to the *n*th parameter of the specified field procedure. The maximum length of the parameter list is 254 bytes, including commas but excluding insignificant blanks and the delimiting parentheses.

If you omit FIELDPROC, the column has no field procedure.

AS SECURITY LABEL

Specifies that the column will contain security label values. This also indicates that the table is defined with multilevel security with row level granularity. A table can have only one security label column. A security label column cannot be defined for an accelerator-only table. To define a table with a security label column, the primary authorization ID of the statement must have a valid security label, and the RACF SECLABEL class must be active. In addition, the following conditions are also required:

- The data type of the column must be CHAR(8).
- The subtype of the column must be SBCS.
- The column must be defined with the NOT NULL and WITH DEFAULT clauses.
- The column must be an EBCDIC column.
- The WITH DEFAULT clause must not specify a default value (Db2 determines the default value)
- No field procedures, check constraints, or referential constraints are defined on the column.
- No edit procedure for the table can be defined with row attribute sensitivity.

For information about using multilevel security, see Multilevel security (Managing Security).

IMPLICITLY HIDDEN

Specifies that the column is not visible in the result for SQL statements unless you explicitly refer to the column by name. For example, assuming that the table T1 includes a column that is defined with the IMPLICITLY HIDDEN clause, the result of a SELECT * would not include the implicitly hidden column. However, the result of a SELECT statement that explicitly refers to the name of the implicitly hidden column would include that column in the result table.

IMPLICITLY HIDDEN must not be specified for a column that is defined as a ROWID, or a distinct type that is based on a ROWID. IMPLICITLY HIDDEN must not be specified for all columns of a table. If IN ACCELERATOR is specified, IMPLICITLY HIDDEN must not be specified.

INLINE LENGTH *integer*

Specifies the maximum length of the inline portion of a LOB column value. The inline portion is the portion that is stored in the base table space. INLINE LENGTH cannot be specified if the column is not a LOB column (or a distinct type that is based on a LOB), if the table is not in a universal table space, or if the table is an accelerator-only table.

For BLOB and CLOB columns, *integer* specifies the maximum number of bytes that are stored in the base table space for the column. *integer* must be between 0 and 32680 (inclusive) for a BLOB or CLOB column.

For a DBCLOB column, *integer* specifies the maximum number of double-byte characters that are stored in the table space for the column. *integer* must be between 0 and 16340 (inclusive) for a DBCLOB column.

If INLINE LENGTH is specified, the value of *integer* cannot be greater than the maximum length of the LOB column.

If the INLINE LENGTH clause is not specified, the maximum length of the LOB column depends on the following conditions:

- If a distinct type is not used or the distinct type that is used has been created without the INLINE LENGTH attribute, the LOB column will use the value of the LOB INLINE LENGTH parameter on installation panel DSNTIPD as the default inline length when the value of LOB INLINE LENGTH does not exceed the maximum length of the LOB column. If the value of LOB INLINE LENGTH exceeds the maximum length of the LOB column, the maximum length is the inline length of this LOB column.

- If a distinct type that has been created with the INLINE LENGTH attribute is used, the LOB column inherits the inline length from the distinct type.

Regardless of how the length is determined, the inline length of the LOB cannot be greater than its maximum length.

period-definition

PERIOD FOR

Defines a period for the table. *begin-column-name* must not be the same as *end-column-name*. The data type, length, precision, and scale for *begin-column-name* must be the same as for *end-column-name*.

If IN ACCELERATOR is specified, PERIOD must not be specified.

SYSTEM_TIME (*begin-column-name*,*end-column-name*)

Defines a system period with the name SYSTEM_TIME. There must not be a column in the table with the name SYSTEM_TIME. A table can have only one SYSTEM_TIME period. *begin-column-name* must be defined as AS ROW BEGIN and *end-column-name* must be defined as AS ROW END.

BUSINESS_TIME (*begin-column-name*,*end-column-name*)

Defines an application period with the name BUSINESS_TIME. There must not be a column in the table with the name BUSINESS_TIME. A table can have only one BUSINESS_TIME period. *begin-column-name* and *end-column-name* must be defined as DATE or TIMESTAMP(6) WITHOUT TIME ZONE, and the columns must be defined as NOT NULL. *begin-column-name* and *end-column-name* must not identify a column that is defined with a GENERATED clause.

An implicit check constraint is generated to ensure the relationship of the value of *end-column-name* to the value of *begin-column-name* as follows:

- For an inclusive-exclusive BUSINESS_TIME period, the value of *end-column-name* is greater than the value of *begin-column-name*.
- For an inclusive-inclusive BUSINESS_TIME period, the value of *end-column-name* is greater than or equal to the value of *begin-column-name*.

The name of the implicitly created check constraint is DB2_GENERATED_CHECK_CONSTRAINT_FOR_BUSINESS_TIME, and that name must not be defined as the name of an existing check constraint.

begin-column-name

Identifies the column that records the beginning of the period of time in which a row is valid. The name must identify a column that exists in the table and must not be the same as a column that is used in the definition of another period for the table. *begin-column-name* must not be the same as *end-column-name*. The data type and precision for *begin-column-name* must be the same as for *end-column-name*.

For a SYSTEM_TIME period, *begin-column-name* must be defined as AS ROW BEGIN.

For a BUSINESS_TIME period, the column must not be defined with a GENERATED clause.

end-column-name

Identifies the column that records the end of the period of time in which a row is valid. In the history table that is associated with a system-period temporal table, the history table column that corresponds to *end-column-name* in the system-period temporal table is set to reflect the deletion of the row. The name must identify a column that exists in the table and must not be the same as a column that is used in the definition of another period for the table.

For a SYSTEM_TIME period, *end-column-name* must be defined as AS ROW END.

For a BUSINESS_TIME period, the column must not be defined with a GENERATED clause.

EXCLUSIVE

Specifies that the value of the end column is not included in the period. The BUSINESS_TIME period is defined as inclusive-exclusive.

INCLUSIVE
Specifies that the value of the end column is included in the period. The BUSINESS_TIME period is defined as inclusive-inclusive.

unique-constraint

CONSTRAINT *constraint-name*
Names the constraint. If a constraint name is not specified, a unique constraint name is generated. If a name is specified, it must be different from the names of any referential, check, primary key, or unique key constraints previously specified on the table.

PRIMARY KEY(*column-name,...*)
Defines a primary key composed of the identified columns. The clause must not be specified more than one time and the same column must not be identified more than one time. The identified columns must be defined as NOT NULL. Each *column-name* must be an unqualified name that identifies a column of the table except for the following types of columns:

- a LOB column
- a ROWID column
- a distinct type column that is based on a LOB or ROWID data type
- an XML column
- a row change timestamp column
- a column in an accelerator-only table

All character and graphic string columns in the key must use the same encoding scheme.

The number of identified columns must not exceed 64. In addition, the sum of the length attributes of the columns must not be greater than 2000 - *n* - 2*m* - 3*d*, where *m* is the number of varying-length columns and *d* is the number of DECFLOAT columns in the key.

The table is marked as unavailable until its primary index is explicitly created unless the table space is explicitly created and the CREATE TABLE statement is processed by the schema processor, or the table space is implicitly created. In that case, Db2 implicitly creates an index to enforce the uniqueness of the primary key and the table definition is considered complete. (For more information about implicitly created indexes, see Implicitly created indexes.)

BUSINESS_TIME WITHOUT OVERLAPS can be specified as the last item in the list. If BUSINESS_TIME WITHOUT OVERLAPS is specified, the list must include at least one *column-name* or *key-expression*. When WITHOUT OVERLAPS is specified, the values for the rest of the specified keys are unique with respect to the time for the BUSINESS_TIME period. When BUSINESS_TIME WITHOUT OVERLAPS is specified, the columns of the BUSINESS_TIME period must not be specified as part of the constraint. The specification of BUSINESS_TIME WITHOUT OVERLAPS adds the following to the constraint:

- The end column of the BUSINESS_TIME period in ascending order
- The begin column of the BUSINESS_TIME period in ascending order

UNIQUE(*column-name,...*)
Defines a unique key composed of the identified columns. Each *column-name* must be an unqualified name that identifies a column of the table. Each identified column must be defined as NOT NULL. The same column must not be identified more than one time. The following types of columns cannot be identified:

- a LOB column
- a ROWID column
- a distinct type column that is based on a LOB or ROWID data type
- an XML column
- a row change timestamp column
- a column in an accelerator-only table

The number of identified columns must not exceed 64. In addition, the sum of the length attributes of the columns must not be greater than 2000 - *n* - 2*m* - 3*d*, where *m* is the number of varying-length columns and *d* is the number of DECFLOAT columns in the key.

All character and graphic string columns in the key must use the same encoding scheme.

A unique key is a duplicate if it is the same as the primary key or a previously defined unique key. The specification of a duplicate unique key is ignored with a warning.

The table is marked as unavailable until all the required indexes are explicitly created unless the table space is explicitly created and the CREATE TABLE statement is processed by the schema processor, or the table space is implicitly created. In these cases, Db2 implicitly creates the indexes that are required for the unique keys and the table definition is considered complete. (For more information about implicitly created indexes, see Implicitly created indexes.)

BUSINESS_TIME WITHOUT OVERLAPS can be specified as the last item in the list. If BUSINESS_TIME WITHOUT OVERLAPS is specified, the list must include at least one *column-name* or *key-expression*. When WITHOUT OVERLAPS is specified, the values for the rest of the specified keys are unique with respect to the time for the BUSINESS_TIME period. When BUSINESS_TIME WITHOUT OVERLAPS is specified, the columns of the BUSINESS_TIME period must not be specified as part of the constraint. The specification of BUSINESS_TIME WITHOUT OVERLAPS adds the following to the constraint:

- The end column of the BUSINESS_TIME period in ascending order
- The begin column of the BUSINESS_TIME period in ascending order

referential-constraint

CONSTRAINT *constraint-name*

Names the referential constraint. If a constraint name is not specified, a unique constraint name is generated. If a name is specified, it must be different from the names of any referential, check, primary key, or unique key constraints previously specified on the table.

FOREIGN KEY (*column-name,...*) references-clause

Each specification of the FOREIGN KEY clause defines a referential constraint. The table being created is the child table for the referential constraint.

The foreign key of the referential constraint is composed of the identified columns, and the columns of the BUSINESS_TIME period if the clause PERIOD BUSINESS_TIME is specified. Each *column-name* must be an unqualified name that identifies a column of the table. The same column must not be identified more than one time. If PERIOD BUSINESS_TIME is specified, the columns of the BUSINESS_TIME period must not be specified as part of the constraint.The column cannot be any of the following types of columns:

- a LOB column
- a ROWID column
- a DECFLOAT column
- an XML column
- a row change timestamp column
- a security label column
- a column in an accelerator-only table

The number of identified columns, and the columns of the BUSINESS_TIME period if the clause PERIOD BUSINESS_TIME is specified, must not exceed 64, including columns of the BUSINESS_TIME period if PERIOD BUSINESS_TIME is specified. The sum of the column length attributes must not exceed 255 minus the number of columns that allow null values. The referential constraint is a duplicate if the FOREIGN KEY and parent table are the same as the FOREIGN KEY and parent table of a previously defined referential constraint. The specification of a duplicate referential constraint is ignored with a warning. An exception is that a duplicate referential constraint is not allowed if the definition of the constraint includes the PERIOD BUSINESS_TIME clause.

REFERENCES *parent-table-name (column-name,...)*

The table name that is specified after REFERENCES is the parent table for the referential constraint. *parent-table-name* must identify a table that exists at the current server[33]. The table name must not identify one of the following tables:

- A catalog table
- A directory table
- A declared global temporary table
- A history table
- An archive table

In the following discussion, let T2 denote an identified table and let T1 denote the table that you are creating (T1 and T2 cannot be the same table[33]).

T2 must have a unique index. The privilege set must include the ALTER or REFERENCES privilege on the parent table, or the REFERENCES privilege on the columns of the nominated parent key, including the columns of the BUSINESS_TIME period if the PERIOD BUSINESS_TIME clause is specified..

The parent key of the referential constraint is composed of the identified columns, or columns of the BUSINESS_TIME period if PERIOD BUSINESS_TIME is specified. Each *column-name* must be an unqualified name that identifies a column of T2. The same column must not be identified more than one time. If PERIOD BUSINESS_TIME is specified, the columns of the BUSINESS_TIME period must not be specified as part of the constraint. The identified column cannot be any of the following types of columns:

- a LOB column
- a ROWID column
- a DECFLOAT column
- an XML column
- a row change timestamp column
- a security label column

The list of column names in the parent key must match the list of column names in a primary key or unique key in the parent table T2. The column names must be specified in the same order as in the primary key or unique key. If PERIOD BUSINESS_TIME was specified for the primary key or unique key of the parent table T2, then PERIOD BUSINESS_TIME must also be specified for the foreign key clause for T1. If any of the referenced columns in T2 has a non-numeric data type, T2 and T1 must use the same encoding scheme, unless T2 is a Unicode table, and T1 is an EBCDIC table with Unicode key columns. In that case, for each character or graphic string column in T1, the CCSID must be the same as the corresponding column in T2.

If a list of column names is not specified, T2 must have a primary key. Omission of a list of column names is an implicit specification of the columns of the primary key for T2.

The specified foreign key must have the same number of columns as the parent key of T2 and, except for their names, default values, null attributes and check constraints, the description of the *n*th column of the foreign key must be identical to the description of the *n*th column of the nominated parent key. If the foreign key includes a column defined as a distinct type, the corresponding column of the nominated parent key must be the same distinct type. If a column of the foreign key has a field procedure, the corresponding column of the nominated parent key must have the same field procedure and an identical field description. A *field description* is a description of the encoded value as it is stored in the database for a column that has been defined to have an associated field procedure.

If PERIOD BUSINESS_TIME is specified in the FOREIGN KEY clause, then PERIOD BUSINESS_TIME must also be specified in the REFERENCES clause. If PERIOD BUSINESS_TIME is not specified in the

[33] This restriction is relaxed when the statement is processed by the schema processor and the other table is created within the same CREATE SCHEMA.

FOREIGN KEY clause, then PERIOD BUSINESS_TIME must also not be specified in the REFERENCES clause.

If the PERIOD BUSINESS_TIME clause is specified, T2 must not be defined as part of a referential cycle. T1 and T2 must not be the same table, and T1 must not be a descendent, directly or indirectly, of another table that is a descendent of T2.

The table space that contains T1 must be available to Db2. If T1 is populated, its table space is placed in a check pending status. A table in a segmented table space is populated if the table is not empty. A table in a table space that is not segmented is considered populated if the table space has ever contained any records.

The referential constraint that is specified by a FOREIGN KEY clause defines a relationship in which T2 is the parent and T1 is the dependent. A description of the referential constraint is recorded in the catalog.

PERIOD BUSINESS_TIME

Specifies that the BUSINESS_TIME period is considered part of the referential constraint. When PERIOD BUSINESS_TIME is specified, the values for the rest of the specified columns are unique with respect to the specified point of time.

PERIOD BUSINESS_TIME can be specified as the last key expression. If PERIOD BUSINESS_TIME is not the last key expression, an error is returned. If PERIOD BUSINESS_TIME is specified, the columns of the BUSINESS_TIME period must not be specified as part of the constraint.

When PERIOD BUSINESS_TIME is specified, the following columns are implicitly added to the end of the constraint:

- The end column of the BUSINESS_TIME period.
- The start column of the BUSINESS_TIME period.

The PERIOD BUSINESS_TIME clause specifies that there must not be a row in the child table for which the period of time represented by the BUSINESS_TIME period values for that row is not contained in the BUSINESS_TIME period of a corresponding row in the parent table. Furthermore, it is not necessary that there be exactly one corresponding row in the parent table where the BUSINESS_TIME period contains the BUSINESS_TIME period of the child row. As long as the BUSINESS_TIME period of a row in the child table is contained in the union of the BUSINESS_TIME periods of two or more contiguous matching rows in the parent table, the referential constraint is considered satisfied.

When the FOREIGN KEY clause specifies the PERIOD BUSINESS_TIME clause, the following conditions apply:

- The corresponding REFERENCES clause must also specify the PERIOD BUSINESS_TIME clause.
- A unique index with the BUSINESS_TIME WITHOUT OVERLAPS clause must be defined on the table. The table is marked as unavailable until the index is created.
- A unique index must be defined on the parent table with the BUSINESS_TIME WITHOUT OVERLAPS clause.

ON DELETE RESTRICT must be, implicitly or explicitly, specified when PERIOD BUSINESS_TIME is also specified.

ON DELETE

The delete rule of the relationship is determined by the ON DELETE clause. For more on the concepts used here, see Referential constraints (Introduction to Db2 for z/OS).

SET NULL must not be specified unless some column of the foreign key allows null values. The default value for the rule depends on the value of the CURRENT RULES special register when the CREATE TABLE statement is processed. If the value of the register is 'Db2', the delete rule defaults to RESTRICT; if the value is 'STD', the delete rule defaults to NO ACTION.

The delete rule applies when a row of T2 is the object of a DELETE or propagated delete operation and that row has dependents in T1. Let *p* denote such a row of T2. Then:

- If RESTRICT or NO ACTION is specified, an error occurs and no rows are deleted.

- If CASCADE is specified, the delete operation is propagated to the dependents of *p* in T1.
- If SET NULL is specified, each nullable column of the foreign key of each dependent of *p* in T1 is set to null.

Let T3 denote a table identified in another FOREIGN KEY clause (if any) of the CREATE TABLE statement. The delete rules of the relationships involving T2 and T3 must be the same and must not be SET NULL if:

- T2 and T3 are the same table.
- T2 is a descendent of T3 and the deletion of rows from T3 cascades to T2.
- T2 and T3 are both descendents of the same table and the deletion of rows from that table cascades to both T2 and T3.

ENFORCED or NOT ENFORCED

Indicates whether or not the referential constraint is enforced by Db2 during normal operations, such as insert, update, or delete.

ENFORCED

Specifies that the referential constraint is enforced by the Db2 during normal operations (such as insert, update, or delete) and that it is guaranteed to be correct. This is the default.

NOT ENFORCED

Specifies that the referential constraint is not enforced by Db2 during normal operations, such as insert, update, or delete. This option should only be used when the data that is stored in the table is verified to conform to the constraint by some other method than relying on the database manager.

ENABLE QUERY OPTIMIZATION

Specifies that the constraint can be used for query optimization. Db2 uses the information in query optimization using materialized query tables with the assumption that the constraint is correct. This is the default.

check-constraint

CONSTRAINT *constraint-name*

Names the check constraint. The constraint name must be different from the names of any referential, check, primary key, or unique key constraints previously specified on the table.

If *constraint-name* is not specified, a unique constraint name is derived from the name of the first column in the *check-condition* specified in the definition of the check constraint.

CHECK (*check-condition*)

Defines a check constraint. At any time, the *check-condition* must be true or unknown for every row of the table. A *check-condition* can evaluate to unknown if a column that is an operand of the predicate is null. A *check-condition* that evaluates to unknown does not violate the check constraint. A *check-condition* is a search condition, with the following restrictions:

- It can refer only to columns of table *table-name*.
- The columns cannot be the following types of columns:
  - LOB columns
  - ROWID columns
  - DECFLOAT columns
  - distinct type columns that are based on LOB, ROWID, and DECFLOAT data types
  - XML columns
  - security label columns
  - columns in an accelerator-only table
- It can be up to 3800 bytes long, not including redundant blanks.
- It must not contain any of the following:

  - Subselects
  - Built-in or user-defined functions
  - CAST specifications
  - Cast functions other than those created when the distinct type was created
  - Host variables
  - Parameter markers
  - Special registers
  - Global variables
  - Columns that include a field procedure
  - CASE expressions
  - ROW CHANGE expressions
  - Row-value expressions
  - DISTINCT predicates
  - GX constants (hexadecimal graphic string constants)
  - Sequence references
  - OLAP specifications
- It must not result in CCSID conversion.
- If a *check-condition* refers to a LOB column (including a distinct type that is based on a LOB), the reference must occur within a LIKE predicate.
- The AND and OR logical operators can be used between predicates. The NOT logical operator cannot be used with the following predicates: NOT BETWEEN, NOT IN, NOT LIKE, or IS NOT NULL.
- The first operand of every predicate must be the column name of a column in the table.
- The second operand in the *check-condition* must be either a constant or the name of a column in the table.
  - If the second operand of a predicate is a constant, and if the constant is:
    - A floating-point number, then the column data type must be floating point.
    - A decimal number, then the column data type must be either floating point or decimal.
    - An integer number, then the column data type must not be a small integer.
    - A small integer number, then the column data type must be small integer.
    - A decimal constant, then its precision must not be larger than the precision of the column.
  - If the second operand of a predicate is a column, then both columns of the predicate must have:
    - The same data type.
    - Identical descriptions with the exception that the specification of the NOT NULL and DEFAULT clauses for the columns can be different, and that string columns with the same data type can have different length attributes.

LIKE

table-name* or *view-name

Specifies that the columns of the table have exactly the same name and description as the columns of the identified table or view.

The name that is specified after LIKE must identify a table or view that exists at the current server or a declared temporary table. A view cannot contain columns of length 0.

LIKE must not reference an accelerator-only table or be used with the IN ACCELERATOR clause.

The privilege set must implicitly or explicitly include the SELECT privilege on the identified table or view. If the identified table or view contains a column with a distinct type, the USAGE privilege on the distinct type is also needed. An identified table must not be an auxiliary table or a clone table. An identified view must not include a column that is an explicitly defined ROWID column (including a distinct type that is based on a ROWID), an identity column, or a row change timestamp column.

The use of LIKE is an implicit definition of *n* columns, where *n* is the number of columns in the identified table (including implicitly hidden columns) or view. A column of the new table that corresponds to an implicitly hidden column in the existing table will also be defined as implicitly hidden. The implicit definition includes all attributes of the *n* columns as they are described in SYSCOLUMNS with the following exceptions:

- When a table is identified in the LIKE clause and a column in the table has a field procedure, the corresponding column of the new table has the same field procedure and the field description. However, the field procedure is not invoked during the execution of the CREATE TABLE statement. When a view is identified in the LIKE clause, none of the columns of the new table will have a field procedure. This is true even in the case that a column of a base table underlying the view has a field procedure defined.
- When a table is identified in the LIKE clause and a column in the table is an identity column, the corresponding column of the new table inherits only the data type of the identity column; none of the identity attributes of the column are inherited unless the INCLUDING IDENTITY clause is specified.
- When a table is identified in the LIKE clause and a column in the table is a security label column, the corresponding column of the new table inherits only the data type of the security label column; none of the security label attributes of the column are inherited.
- When a table that contains a ROWID column is identified in the LIKE clause, the corresponding column of the new table inherits the ROWID column, regardless of whether the column has the IMPLICITLY HIDDEN attribute.
- When a table is identified in the LIKE clause and the table contains a row change timestamp column, a transaction-start-ID column, a row-begin column, or a row-end column, the corresponding column of the new table inherits only the data type of the original column. The new column is not considered a generated column.
- When a table is identified in the LIKE clause and a column in the table is a generated expression column, the corresponding column of the new table inherits only the data type of the original column. The new column is not considered a generated column.
- When a table is identified in the LIKE clause and the table contains an inline LOB column, the corresponding columns of the new table will inherit the inline attribute if the table is in an universal table space. Otherwise, the inline attribute of the table identified in the LIKE clause is ignored.
- When a view is identified in the LIKE clause, the default value that is associated with the corresponding column of the new table depends on the column of the underlying base table for the view. If the column of the base table does not have a default, the new column does not have a default. If the column of the base table has a default, the default of the new column is:

  - Null if the column of the underlying base table allows nulls.
  - The default for the data type of the underlying base table if the underlying base table does not allow nulls.

  The above defaults are chosen regardless of the current default of the base table column. The existence of an INSTEAD OF trigger does not affect the inheritance of default values.
- When a table that uses table-controlled partitioning is identified in the LIKE clause, the new table does not inherit partitioning scheme of that table. You can add these partition boundaries by specifying ALTER TABLE with the ADD PARTITION BY RANGE clause.
- The CCSID of the column is determined by the implicit or explicit CCSID clause. For more information, see the CCSID clause.

  An exception is a Unicode column in an EBCDIC table, which inherits the CCSID of the column in the existing table.

- When a table is identified in the LIKE clause and the table includes a period definition, the new table does not inherit the period. definition.
- When the table that is identified in the LIKE clause is a system-period temporal table, the new table is not a system-period temporal table.
- When the table that is identified in the LIKE clause has row access controls or column access controls activated, the new table does not inherit the row access controls or the column access controls.

The implicit definition does not include any other attributes of the identified table or view. For example, the new table does not have a primary key or foreign key. The table is created in the table space implicitly or explicitly specified by the IN clause, and the table has any other optional clause only if the optional clause is specified.

copy-options

copy-options

Specifies whether identity column attributes, row change timestamp attributes, and column defaults are inherited from the definition of the source of the result table.

EXCLUDING IDENTITY COLUMN ATTRIBUTES or INCLUDING IDENTITY COLUMN ATTRIBUTES

Specifies whether identity column attributes are inherited from the definition of the source of the result table.

EXCLUDING IDENTITY COLUMN ATTRIBUTES

Specifies that identity column attributes are not inherited from the definition of the source of the result table. This is the default.

INCLUDING IDENTITY COLUMN ATTRIBUTES

Specifies that, if available, identity column attributes (such as START WITH, INCREMENT BY, and CACHE values) are inherited from the definition of the source table. These attributes can be inherited if the element of the corresponding column in the table, view, or *fullselect* is the name of a column of a table or the name of a column of a view that directly or indirectly maps to the column name of a base table with the identity attribute. In other cases, the columns of the new temporary table do not inherit the identity attributes. The columns of the new table do not inherit the identity attributes in the following cases:

- The select list of the *fullselect* includes multiple instances of an identity column name (that is, selecting the same column more than one time).
- The select list of the *fullselect* includes multiple identity columns (that is, it involves a join).
- The identity column is included in an expression in the select list.
- The *fullselect* includes a set operation.

EXCLUDING ROW CHANGE TIMESTAMP COLUMN ATTRIBUTES or INCLUDING ROW CHANGE TIMESTAMP COLUMN ATTRIBUTES

Specifies whether row change timestamp column attributes are inherited from the definition of the source of the result table.

EXCLUDING ROW CHANGE TIMESTAMP COLUMN ATTRIBUTES

Specifies that row change timestamp column attributes are not inherited from the source result table definition. This is the default.

INCLUDING ROW CHANGE TIMESTAMP COLUMN ATTRIBUTES

Specifies that, if available, row change timestamp column attributes are inherited from the definition of the source table. These attributes can be inherited if the element of the corresponding column in the table, view, or *fullselect* is the name of a column of a table or the name of a column of a view that directly or indirectly maps to the column name of a base table defined as a row change timestamp column. In other cases, the columns of the new temporary table do not inherit the row change timestamp column attributes. The columns of the new table do not inherit the row change timestamp attributes in the following cases:

- The select list of the *fullselect* includes multiple instances of a row change timestamp column name (that is, selecting the same column more than one time).
- The select list of the *fullselect* includes multiple row change timestamp column names (that is, it involves a join).
- The row change timestamp column is included in an expression in the select list.
- The *fullselect* includes a set operation (such as union).

EXCLUDING COLUMN DEFAULTS, INCLUDING COLUMN DEFAULTS, or USING TYPE DEFAULTS

Specifies whether column defaults are inherited from the source result table definition. EXCLUDING COLUMN DEFAULTS, INCLUDING COLUMN DEFAULTS, and USING TYPE DEFAULTS must not be specified if the LIKE clause is specified.

EXCLUDING COLUMN DEFAULTS

Specifies that the column defaults are not inherited from the definition of the source table. The default values of the column of the new table are either null or there are no default values. If the column can be null, the default is the null value. If the column cannot be null, there is no default value, and an error occurs if a value is not provided for a column on an insert or update operation, or LOAD for the new table.

INCLUDING COLUMN DEFAULTS

Specifies that column defaults for each updatable column of the definition of the source table are inherited. Columns that are not updatable do not have a default defined in the corresponding column of the created table. The existence of an INSTEAD OF trigger for a view does not affect the inheritance of default values.

USING TYPE DEFAULTS

Specifies that the default values for the table depend on data type of the columns that result from *fullselect*, as follows:

Data type	Default value
Numeric	0
Fixed-length character string	Blanks
Fixed-length graphic string	Blanks
Fixed-length binary string	Hexadecimal zeros
Varying-length string	A string of length 0
Fixed-length char or fixed-length graphic	A string of blanks
Fixed-length binary	Hexadecimal zeros
Date	CURRENT DATE
Time	CURRENT TIME
Timestamp(*integer*) without time zone	CURRENT TIMESTAMP(*p*) WITHOUT TIME ZONE where *p* is the corresponding timestamp precision.
Timestamp(*integer*) with time zone	CURRENT TIMESTAMP(*p*) WITH TIME ZONE where *p* is the corresponding timestamp precision.

as-result-table

as-result-table

Specifies that the column definitions of the table are based on the result of the *fullselect*.

column-name

Names the columns in the table. If a list of column names is specified, it must consist of as many names as there are columns in the result table of the *fullselect*. Each *column-name* must be unique and unqualified. If a list of column names is not specified, the columns of the table inherit the names of the columns of the result table of the *fullselect*.

A list of column names must be specified if the result table of the *fullselect* has duplicate column names or an unnamed column. An unnamed column is a column derived from a constant, function, expression, or set operation that is not named using the AS clause.

AS *(fullselect)*

Specifies that the table definition is based on the column definitions from the result of the *fullselect*. The use of AS *(fullselect)* is an implicit definition of *n* columns for the table, where *n* is the number of columns that would result from the *fullselect*. The columns of the new table are defined by the columns that result from the *fullselect*. Every select list element must have a unique name. The AS clause can be used in the *select-clause* to provide unique names.

The implicit definition includes the column name, data type, length, precision, scale, and nullability characteristic of each of the result columns of *fullselect*. The length of each column must not be 0. Other column attributes, such as DEFAULT and IDENTITY, are not inherited from the *fullselect*. A column of the new table that corresponds to an implicitly hidden column of a base table referenced in the *fullselect* is not considered hidden in the new table. The generated column attributes are not inherited from the *fullselect*. That is, a new column of the table is not considered as a generated column. A FIELDPROC is inherited for a column if the corresponding select item of the *fullselect* is a column that can be mapped to a column of a base table or a view. The new table contains a security label column if only one table in the *fullselect* contains a security label column and the primary authorization ID of the statement has a valid security label.

The outermost SELECT list of the *fullselect* must not reference data that is encoded with different encoding schemes. An exception is that the outermost SELECT list can contain a mixture of EBCDIC and Unicode columns. In this case, the new table is an EBCDIC table with one or more Unicode columns.

The implicit definition does not include any other attributes of the identified table or view. For example, the new table does not have a primary key or foreign key. The table is created in the table space implicitly or explicitly specified by the IN clause, and the table has any other optional clause only if the optional clause is specified.

If IN ACCELERATOR is specified, AS (*fullselect*) cannot be specified.

The owner of the table being created must have the SELECT privilege on the tables or views referenced in the fullselect, or the privilege set must include SYSADM or DBADM authority for the database in which the tables of the fullselect reside. Having SELECT privilege means that the owner has at least one of the following authorizations.

- Ownership of the tables or views referenced in the fullselect
- The SELECT privilege on the tables and views referenced in the fullselect
- SYSADM authority
- DBADM authority for the database in which the tables of the fullselect reside

Additional privileges might be necessary for accessing other objects that are referenced in the fullselect.

The fullselect must not:

- Result in a column having a ROWID, BLOB, CLOB, DBCLOB, or XML data type or a distinct type based on these data types.
- Include multiple security label columns.

- Include a PREVIOUS VALUE or a NEXT VALUE expression.
- Refer to host variables or include parameter markers.
- Include an SQL data change statement in the FROM clause.
- In the outermost SELECT, reference a combination of ASCII and EBCDIC data, or a combination of ASCII and Unicode data.
- Result in a column that is an array.
- Reference a remote object.
- Reference an accelerator-only table.

WITH NO DATA

Specifies that the query is used only to define the attributes of the new table. The table is not populated using the results of the *fullselect* and the REFRESH TABLE statement cannot be used.

If the tables that are specified in the *fullselect* use row access controls or column access controls, the row access controls and the column access controls are not defined for the new table.

materialized-query-definition

materialized-query-definition

Specifies that the column definitions of the materialized query table are based on the result of a *fullselect*. If *materialized-query-table-options* are specified, the REFRESH TABLE statement can be used to populate the table with the results of the *fullselect*.

column-name

Names the columns in the table. If a list of column names is specified, it must consist of as many names as there are columns in the result table of the fullselect. Each *column-name* must be unique and unqualified. If a list of column names is not specified, the columns of the table inherit the names of the columns of the result table of the *fullselect*.

A list of column names must be specified if the result table of the *fullselect* has duplicate column names or an unnamed column. An unnamed column is a column derived from a constant, function, expression, or set operation that is not named using the AS clause of the select list.

AS *(fullselect)*

Specifies that the table definition is based on the column definitions from the result of the *fullselect*. The use of AS *(fullselect)* is an implicit definition of *n* columns for the table, where *n* is the number of columns that would result from the *fullselect*. The columns of the new table are defined by the columns that result from the *fullselect*. Every select list element must have a unique name. The AS clause can be used in the *select-clause* to provide unique names.

The implicit definition includes the column name, data type, length, precision, scale, and nullability characteristic of each of the result columns of *fullselect*. The length of each column must not be a 0. Other column attributes, such as DEFAULT, IDENTITY, and unique constraints, are not inherited from the *fullselect*. A column of the new table that corresponds to an implicitly hidden column of a base table referenced in the *fullselect* is not considered hidden in the new table. The generated column attributes are not inherited from the *fullselect*. That is, the new column of the materialized query table is not considered as a generated column. A FIELDPROC is inherited for a column if the corresponding select item of the *fullselect* is a column that can be directly mapped to a column of a base table or a view in the FROM clause of the *fullselect*. The materialized query table contains a security label column if only one table in the *fullselect* contains a security label column and the primary authorization ID of the statement has a valid security label.

The outermost SELECT list of the fullselect can include result columns that are defined as EBCDIC columns and result columns that are defined as Unicode columns. In this case, the materialized query table is an EBCDIC table with one or more Unicode columns.

Authorization for creating materialized query tables

The owner of the table being created must have the SELECT privilege on the tables or views referenced in the fullselect, or the privilege set must include SYSADM or DBADM authority for the database in which the tables of the fullselect reside. Having SELECT privilege means that the owner has at least one of the following authorizations:

- Ownership of the tables or views referenced in the fullselect
- The SELECT privilege on the tables and views referenced in the fullselect
- SYSADM authority
- DBADM authority for the database in which the tables of the fullselect reside

Additional privileges might be necessary for accessing other objects that are referenced in the fullselect.

The rules for establishing the qualifiers for names used in the fullselect are the same as the rules used to establish the qualifiers for *table-name*.

The following restrictions apply when creating materialized query tables. When *fullselect* does not satisfy the restrictions, an error occurs:

- The length of each result column of the fullselect must not be 0.
- The fullselect cannot contain a column of a LOB or XML data type.
- No more than one table in the fullselect can contain a security label column.
- The fullselect must not contain a period specification.
- The outermost SELECT list must not reference data that is encoded with a combination of ASCII and EBCDIC CCSID sets, or a combination of ASCII and Unicode CCSID sets.
- The object that is specified in the FROM clause of the fullselect cannot be a view with columns of length 0.
- The fullselect cannot contain a reference to a created global temporary table, a declared global temporary table, an accelerator-only table, a directory table, or another materialized query table.
- If IN ACCELERATOR is specified, *materialized-query-definition* cannot be specified.
- The fullselect cannot directly or indirectly reference a base table that has been activated for the row or column access control or a base table for which a row permission or a column mask has been defined.
- The fullselect must not refer to host variables or include parameter markers.
- The fullselect must not refer to global variables.
- The fullselect must not include the following built-in functions: LISTAGG, PERCENTILE_CONT, or PERCENTILE_DISC.

Additional restrictions when ENABLE QUERY OPTIMIZATION is in effect:

- The fullselect must be a subselect.
- The subselect cannot include the following:
  - A special register
  - A scalar fullselect
  - A row change timestamp column
  - A ROW CHANGE expression
  - An expression for which implicit time zone values apply (for example, cast a timestamp to a timestamp with time zone)
  - The RAND built-in function
  - The RID built-in function
  - A user-defined scalar or table function that is not deterministic or that has external actions
  - Any predicates that include a subquery
  - A *row-value-expression* in a predicate

  - A join using the INNER JOIN syntax, or an outer join
  - A lateral correlation
  - A nested table expression or view that requires temporary materialization
  - A direct or indirect reference to a table that uses activated row or column access controls, or a table for which row or column access controls have been defined.
  - A FETCH FIRST clause
  - A reference to a global variable
  - A collection-derived table (UNNEST)
  - A GROUPING SETS or *super-groups* clause
- If a table with a security label is referenced, the security label column must be referenced in the outer select list of the subselect.
- If the subselect references a view, the fullselect in the view definition must satisfy all other restrictions.

refreshable-table-options

Specifies the options for a refreshable materialized query table. The ORDER BY clause is allowed, but it is used only by REFRESH. The ORDER BY clause can improve the locality of reference of data in the materialized query table.

DATA INITIALLY DEFERRED

Specifies that the data is not inserted into the materialized query table when it is created. Use the REFRESH TABLE statement to populate the materialized query table, or use the INSERT statement to insert data into a user-maintained materialized query table.

REFRESH DEFERRED

Specifies that the data in the table can be refreshed at any time using the REFRESH TABLE statement. The data in the table only reflects the result of the query as a snapshot at the time when the REFRESH TABLE statement is processed or when it was last updated for a user-maintained materialized query table.

MAINTAINED BY SYSTEM or MAINTAINED BY USER

Specifies how the data in the materialized query table is maintained.

MAINTAINED BY SYSTEM

Specifies that the materialized query table is maintained by the system. Only the REFRESH statement is allowed on the table. This is the default.

MAINTAINED BY USER

Specifies that the materialized query table is maintained by the user, who can use the LOAD utility, an SQL data change statement, a SELECT from data change statement, or REFRESH TABLE SQL statements on the table.

ENABLE QUERY OPTIMIZATION or DISABLE QUERY OPTIMIZATION

Specifies whether this materialized query table can be used for optimization.

ENABLE QUERY OPTIMIZATION

Specifies that the materialized query table can be used for query optimization. If the fullselect specified does not satisfy the restrictions for query optimization, an error occurs.

ENABLE QUERY OPTIMIZATION is the default.

The fullselect must not contain a period specification.

DISABLE QUERY OPTIMIZATION

Specifies that the materialized query table cannot be used for query optimization. The table can still be queried directly.

IN

IN *database-name.table-space-name* or IN DATABASE *database-name*

Identifies the database and table space in which the table is created. Both forms are optional.

If you specify *database-name* and *table-space-name*, the database must be described in the catalog on the current server. The database must not be DSNDB06 or a work file database. The table space must belong to the database that you specify.

If you specify *database-name* but not *table-space-name*, a table space is implicitly created in *database-name*. The name of the table space is derived from the name of the table. The buffer pool that is used is the default buffer pool for user data that is specified on installation panel DSNTIP1.

If you specify a table space but not a database, the database that contains the table space is used.

If you do not specify the IN clause, a database is implicitly created with the name DSN*xxxxx*, where *xxxxx* is a five-digit number. A table space is also implicitly created.

If you specify *table-space-name*, the table space cannot be one of the following table spaces:

- A table space that was created implicitly
- A partitioned table space that already contains a table
- A LOB table space
- An XML table space
- FL 504 A non-UTS table space

If you specify a partitioned table space, you cannot load or use the table until its partitioned scheme is created.

You cannot specify a name in the format of an implicitly created database name, which is DSN*xxxxx*, where *xxxxx* is a five-digit number..

If you specify *table-space-name*, but you do not specify *database-name*, or you do not specify the IN clause, users who have the authority to create table spaces or tables in database DSNDB04 have authority to create tables and table spaces in the implicitly created database.

If you do not specify *table-space-name*, the privilege set must have: SYSADM or SYSCTRL authority; DBADM, DBCTRL, or DBMAINT authority for the database; or the CREATETS privilege for the database. You must also have the USE privilege for the default buffer pool in the database and default storage group.

For implicitly created table spaces, Db2 selects the buffer pool as described in Implicitly defined table spaces (Db2 Administration Guide).

IN ACCELERATOR *accelerator-name*

Specifies that the table is an accelerator-only table. *accelerator-name* identifies the accelerator in which the table will be defined.

FL 509 You can specify an alias (logical name) for *accelerator-name*. For more information, see Using an alias for an accelerator (Db2 Performance). To create a high availability accelerator-only table, specify a location alias that represents multiple accelerators to define the table in all accelerators that are associated with the location alias.

If you specify an accelerator-only table, the table and the data of the table exists only in the accelerator, not in Db2. However, the table and column definition of the accelerator-only table are contained in Db2 catalog tables.

partitioning-clause block

PARTITION BY SIZE or PARTITION BY RANGE

Specifies the partitioning scheme for the table. For more information, see Partitioning data in Db2 tables (Db2 Administration Guide).

PARTITION BY SIZE

Specifies that the table is created in a partition-by-growth table space. If the IN clause specifies a *table-space-name*, it must identify a partition-by-growth table space. If the IN clause does not specify an existing table space name and the PARTITION BY clause is not specified, PARTITION BY SIZE is the default.

If IN ACCELERATOR is specified, PARTITION BY SIZE must not be specified.

EVERY *integer* G

Specifies that the table is to be partitioned by growth, every *integer* G bytes. *integer* must not be greater than 256. If the IN clause identifies a table space, *integer* must be the same as the DSSIZE value that is in effect for the table space that will contain the table.

integer can be separated from G by 0 or more spaces.

PARTITION BY RANGE

Specifies the range partitioning scheme for the table (the columns that are used to partition the data). When this clause is specified, the table space is complete, and it is not necessary to create a partitioned index on the table. If this clause is used, the ENDING AT clause cannot be used on a subsequent CREATE INDEX statement for this table.

PARTITION BY RANGE must not be specified for a table that is created in a partition-by-growth table space. If IN ACCELERATOR is specified, PARTITION BY RANGE must not be specified.

partition-expression

Specifies the key data over which the range is defined to determine the target data partition of the data.

column-name

Specifies the columns of the key. Each *column-name* must identify a column of the table. Do not specify more than 64 columns or the same column more than one time. The sum of length attributes of the columns must not be greater than 255 - *n*, where *n* is the number of columns that can contain null values. Do not specify a qualified column name.

A timestamp with time zone column (or a column with a distinct type that is based on the timestamp with time zone data type) can only be specified as the last column in a partitioning key.

Do not specify a column for *column-name* if the column is defined as follows:

- a LOB column (or a column with a distinct type that is based on a LOB data type)
- a BINARY column (or a column with a distinct type that is based on a BINARY data type)
- a VARBINARY column (or a column with a distinct type that is based on a VARBINARY data type)
- a DECFLOAT column (or a column with a distinct type that is based on a DECFLOAT data type)
- an XML column

All character and graphic string columns in the key must be defined with the same encoding scheme.

NULLS LAST

Specifies that null values are treated as positive infinity for purposes of comparison.

ASC

Puts the entries in ascending order by the column. ASC is the default.

DESC

Puts the entries in descending order by the column.

partition-element

Specifies ranges for a data partitioning key and the table space where rows of the table in the range will be stored.

PARTITION *integer*

integer is the physical number of a partition in the table space. A PARTITION clause must be specified for every partition of the table space. In this context, highest means highest in the sorting sequences of the columns. In a column defined as ascending (ASC), highest and lowest have their usual meanings. In a column defined as descending (DESC), the lowest actual value is highest in the sorting sequence.

ENDING AT (*constant*, MAXVALUE, or MINVALUE, ...)

Defines the limit key for a partition boundary. Specify at least one value (*constant*, MAXVALUE, or MINVALUE) after ENDING AT in each PARTITION clause. You can use as many values as there are columns in the key. The concatenation of all values is the highest value of the key for ascending and the lowest for descending.

constant

Specifies a constant value with a data type that must conform to the rules for assigning that value to the column. If a string constant is longer or shorter than required by the length attribute of its column, the constant is either truncated or padded on the right to the required length. If the column is ascending, the padding character is X'FF'. If the column is descending, the padding character is X'00'. The precision and scale of a decimal constant must not be greater than the precision and scale of its corresponding column. A hexadecimal string constant (GX) cannot be specified.

MAXVALUE

Specifies a value greater than the maximum value for the limit key of a partition boundary (that is, all X'FF' regardless of whether the column is ascending or descending). If all of the columns in the partitioning key are ascending, a constant or the MINVALUE clause cannot be specified following MAXVALUE. After MAXVALUE is specified, all subsequent columns must be MAXVALUE.

MINVALUE

Specifies a value that is smaller than the minimum value for the limit key of a partition boundary (that is, all X'00' regardless of whether the column is ascending or descending). If all of the columns in the partitioning key are descending, a constant or the MAXVALUE clause cannot be specified following MINVALUE. After MINVALUE is specified, all subsequent columns must be MINVALUE.

The key values are subject to the following rules:

- The first value corresponds to the first column of the key, the second value to the second column, and so on. Using fewer values than there are columns in the key has the same effect as using the highest or lowest values for the omitted columns, depending on whether they are ascending or descending.
- The highest value of the key in any partition must be lower than the highest value of the key in the next partition for ascending cases.
- The values specified for the last partition are enforced. The value specified for the last partition is the highest value of the key that can be placed in the table. Any key values greater than the value specified for the last partition are out of range.
- If the concatenation of all the values exceeds 255 bytes, only the first 255 bytes are considered.
- If a key includes a ROWID column or a column with a distinct type that is based on a ROWID data type, 17 bytes of the constant that is specified for the corresponding ROWID column are considered.
- If a null value is specified for the partitioning key and the key is ascending, an error is returned unless MAXVALUE is specified. If the key is descending, an error is returned unless MINVALUE is specified.

partition-hash-space

See partition-hash-space.

INCLUSIVE

Specifies that the specified range values are included in the data partition.

organization-clause

See organization-clause.

Other options

EDITPROC *program-name*

Identifies the user-written code that implements the edit procedure for the table. The edit procedure must exist at the current server. The procedure is invoked during the execution of an SQL data change statement or LOAD and all row retrieval operations on the table.

An edit routine receives an entire table row, and can transform that row in any way. Also, it receives a transformed row and must change the row back to its original form.

For information on writing an EDITPROC exit routine, see Edit procedures (Db2 Administration Guide).

WITH ROW ATTRIBUTES

Specifies that the edit procedure parameter list contains an address for the description of a row. WITH ROW ATTRIBUTES must not be specified for a table with an identity, LOB, XML, ROWID, or SECURITY LABEL column. WITH ROW ATTRIBUTES is the default. When WITH ROW ATTRIBUTES is specified, the column names in the table must not be longer than 18 EBCDIC SBCS characters in length.

WITHOUT ROW ATTRIBUTES

Specifies that the description of the row is not provided to the edit procedure. On entry to the edit procedure, the address for the row description in the parameter list contains a value of zero.

VALIDPROC *program-name*

Designates *program-name* as the validation exit routine for the table. Writing a validation exit routine is described in Validation routines (Db2 Administration Guide).

The validation routine can inhibit a load, insert, update, or delete operation on any row of the table: before the operation takes place, the procedure is passed the row. The values that are represented by any LOB or XML columns in the table are not passed to the validation routine. On an insert or update operation, if the table has a security label column and the user does not have write-down privilege, the user's security label value is passed to the validation routine as the value of the column. After examining the row, the procedure returns a value that indicates whether the operation should proceed. A typical use is to impose restrictions on the values that can appear in various columns. If IN ACCELERATOR is specified, VALIDPROC must not be specified.

A table can have only one validation procedure at a time. In an ALTER TABLE statement, you can designate a replacement procedure or discontinue the use of a validation procedure.

If you omit VALIDPROC, the table has no validation routine.

AUDIT

Identifies the types of access to this table that causes auditing to be performed. For information about audit trace classes, see Types of Db2 traces (Db2 Performance) and -START TRACE (Db2) (Db2 Commands).

If a materialized query table is refreshed with the REFRESH TABLE statement, the auditing also occurs during the REFRESH TABLE operation. AUDIT works as usual for LOAD and SQL data change operations on a user-maintained materialized query table.

NONE

Specifies that no auditing is to be done when this table is accessed. This is the default.

CHANGES

Specifies that auditing is to be done when the table is accessed during the first insert, update, or delete operation. However, the auditing is done only if the appropriate audit trace class is active.

ALL

Specifies that auditing is to be done when the table is accessed during the first operation of any kind performed by a utility or application process. However, the auditing is done only if the appropriate audit trace class is active and the access is not performed with COPY, RECOVER, REPAIR, LOAD with a dummy input data set, or any stand-alone utility.

If the table is subsequently altered with an ALTER TABLE statement, the ALTER TABLE statement is audited for successful and failed attempts in the following cases, if the appropriate audit trace class is active:

- AUDIT attribute is changed to NONE, CHANGES, or ALL on an audited or non-audited table.
- AUDIT CHANGES or AUDIT ALL is in effect.

If IN ACCELERATOR is specified, AUDIT NONE, CHANGES, and ALL must not be specified.

OBID *integer*
Identifies the OBID to be used for this table. An OBID is the identifier for an object's internal descriptor. The integer must be greater than 1 and must not identify an existing or previously used OBID of the database. If you omit OBID, Db2 generates a value.

The following statement retrieves the value of OBID:

```
SELECT OBID
  FROM SYSIBM.SYSTABLES
  WHERE CREATOR = 'ccc' AND NAME = 'nnn';
```

Here, *nnn* is the table name and *ccc* is the creator of the table.

DATA CAPTURE
Specifies whether the logging of the following actions on the table includes additional information to support data replication processing:

- SQL data change operations
- Adding columns (using the ADD COLUMN clause)
- Changing columns (using the ALTER COLUMN clause)

For more information, see Altering a table to capture changed data (Db2 Administration Guide).

If a materialized query table is refreshed with the REFRESH TABLE statement, the logging of the augmented information occurs during the REFRESH TABLE operation. DATA CAPTURE works as usual for insert, update, and delete operations on a user-maintained materialized query table.

A table with data that is stored only in an accelerator-only table cannot be defined with this attribute.

NONE
Do not record additional information to the log. This is the default.

CHANGES
Write additional data about SQL updates to the log. Information about the values that are represented by any LOB or XML columns is not available. Do not specify DATA CAPTURE CHANGES for tables that reside in table spaces that specify NOT LOGGED.

WITH RESTRICT ON DROP
Indicates that the table can be dropped only by using REPAIR DBD DROP. In addition, the database and table space that contain the table can be dropped only by using REPAIR DBD DROP.

The WITH RESTRICT ON DROP clause can be removed using the ALTER TABLE statement with the DROP RESTRICT ON DROP clause. After the WITH RESTRICT ON DROP clause is removed from the definition of the table, the table, the database, and the containing table space can be dropped using the DROP statement.

CCSID *encoding-scheme*
Specifies the encoding scheme for string data stored in the table. If the IN clause is specified with a table space, the value must agree with the encoding scheme that is already in use for the specified table space. The specific CCSIDs for SBCS, mixed, and graphic data are determined by the table space or database specified in the IN clause. If the IN clause is not specified, the value specified is used for the table being created as well as for the table space that Db2 implicitly creates. The specific CCSIDs for SBCS, mixed, and graphic data are determined by the default CCSIDs for the server for the specified encoding scheme. The valid values are ASCII, EBCDIC, and UNICODE.

If IN ACCELERATOR is specified, a Unicode column cannot be defined in an EBCDIC table and a column cannot be defined as ASCII mixed or graphic. *IBM Db2 Analytics Accelerator for z/OS: Stored Procedures Reference* contains a complete description of encoding schemes allowed in an accelerator.

If the CCSID clause is not specified, the encoding scheme for the table depends on the IN clause:

- If the IN clause is specified, the encoding scheme already in use for the table space or database specified in the IN clause is used.
- If the IN clause is not specified, the encoding scheme of the new table is the same as the scheme for the table that is specified in the LIKE clause.

If CCSID EBCDIC is explicitly or implicitly specified, and any columns in the table are defined with the CCSID 1208 or CCSID 1200 clause, CCSID EBCDIC represents the default encoding scheme for character or graphic columns that do not include the CCSID 1208 or CCSID 1200 clause.

If the CCSID clause is specified for a materialized query table:

- If the encoding scheme in the CCSID clause is ASCII or Unicode, or if the encoding scheme in the CCSID clause is EBCDIC and the result table of the fullselect contains no Unicode columns, the encoding scheme specified in the clause must be the same as the scheme for the result CCSID of the fullselect. The CCSID must also be the same as the CCSID of the table space for the table being created.
- If the encoding scheme in the CCSID clause is EBCDIC, and the result table of the fullselect contains Unicode columns, the encoding scheme of the table space for the table must be EBCDIC.

VOLATILE or NOT VOLATILE

Specifies how Db2 chooses to access the table.

VOLATILE

Specifies that Db2 uses index access to the table whenever possible for SQL operations. However, be aware that list prefetch and certain other optimization techniques might be disabled when VOLATILE is used.

One instance in which you might want to use VOLATILE is for a table whose size can vary greatly. If statistics are taken when the table is empty or has only a few rows, those statistics might not be appropriate when the table has many rows.

Another instance in which you might want to use VOLATILE is for a table that contains groups of rows, as defined by the primary key on the table. All but the last column of the primary key of such a table indicate the group to which a given row belongs. The last column of the primary key is the sequence number indicating the order in which the rows are to be read from the group. VOLATILE maximizes concurrency of operations on rows within each group, since rows are usually accessed in the same order for each operation. If IN ACCELERATOR is specified, VOLATILE must not be specified. For this usage, the primary index must be the only index that is defined on the table, and list prefetch is disabled to ensure the sequence in which the rows are locked.

NOT VOLATILE

Specifies that SQL access to this table should be based on the current statistics. NOT VOLATILE is the default.

CARDINALITY

An optional keyword that currently has no effect, but that is provided for Db2 family compatibility.

LOGGED or NOT LOGGED

Specifies whether changes that are made to the data in an implicitly created table space are recorded in the log. This parameter applies to an implicitly created table space and to all indexes of this table. XML table spaces and indexes associated with the XML table spaces inherit the logging attribute from the associated base table space. Auxiliary indexes also inherit the logging attribute from the associated base table space.

Do not specify LOGGED or NOT LOGGED if the table space name is specified by using the IN *table-space-name* clause or if the IN ACCELERATOR clause is specified.

LOGGED

Specifies that changes that are made to the data in an implicitly created table space are recorded in the log.

LOGGED is the default.

NOT LOGGED

Specifies that changes that are made to data in an implicitly created table space are not recorded in the log.

NOT LOGGED prevents undo and redo information from being recorded in the log. However, control information for an implicitly created table space will continue to be recorded in the log.

COMPRESS YES or COMPRESS NO

Specifies whether data compression applies to the rows of any implicitly created table space. The IMPTSCMP subsystem parameter specifies the default value. See USE DATA COMPRESSION field (IMPTSCMP subsystem parameter) (Db2 Installation and Migration).

If the IN *table-space-name* clause or the IN ACCELERATOR clause is specified, COMPRESS must not be specified.

YES

FL 509Specifies that data compression applies to the rows of the implicitly created table space. The rows are not compressed until the LOAD or REORG utility is run on the table in the implicitly created table space, or the total row data size reaches the compression data threshold while an insert operation is performed.

If a keyword for the compression algorithm is not specified, the default compression algorithm is used. The data compression algorithm is determined by the TS_COMPRESSION_TYPE subsystem parameter.

If a keyword for the compression algorithm is specified:

- LOB table spaces that are implicitly created for LOB columns in this table are defined as if COMPRESS YES is specified without a compression algorithm. LOB compression is managed by zEnterprise data compression (zEDC) hardware if available.
- XML table spaces that are implicitly created for XML columns in this table inherit the COMPRESS attribute.

FIXEDLENGTH

FL 509 Specified the fixed-length data compression algorithm.

HUFFMAN

FL 509 Specifies the Huffman data compression algorithm. See Using Huffman compression to compress your data (Db2 Performance) for requirements to enable Huffman compression.

NO

Specifies that data compression is not used for the rows of the implicitly created table space. Inserted and updated rows are not subject to data compression.

APPEND NO or APPEND YES

Specifies whether append processing is used for the table. The APPEND clause must not be specified for a table that is created in a work file table space.

NO

Specifies that append processing is not used for the table. For insert and LOAD operations, Db2 will attempt to place data rows in a well clustered manner with respect to the value in the row's cluster key column.

NO is the default.

YES

Specifies that data rows are to be placed into the table by disregarding the clustering during insert and LOAD operations.

DSSIZE *integer* G

Specifies the maximum size for an implicitly created partition-by-growth or partition-by-range table space. This value is only applied to an implicitly created base table space, not to any associated implicitly created XML or LOB table spaces.

Do not specify DSSIZE *integer* G if any of the following conditions are true:

- The table space name is specified by using the IN *table-space-name* clause.
- The PARTITION BY clause includes the EVERY *integer-constant* G clause.
- The statement contains an accelerator-only table.

The IMPDSSIZE subsystem parameter specifies the default value. See IMPDSSIZE in macro DSN6SYSP (Db2 Installation and Migration).

For more detailed information about the DSSIZE clause, refer to "CREATE TABLESPACE" on page 1713.

integer can be separated from G by 0 or more spaces.

BUFFERPOOL *bpname*

Specifies the buffer pool be use for an implicitly created table space and determines the page size of the table space. For 4KB, 8KB, 16KB and 32KB page buffer pools, the page sizes are 4 KB, 8 KB, 16 KB, and 32 KB, respectively.

bpname must identify an activated buffer pool. The privilege set must include SYSADM authority, SYSCTRL authority, or the USE privilege on the buffer pool.

Do not specify BUFFERPOOL *bpname* if the table space name is specified by using the IN *table-space-name* clause or the IN ACCELERATOR clause is specified.

If you do not specify the BUFFERPOOL clause, Db2 selects the buffer pool as described in Implicitly defined table spaces (Db2 Administration Guide).

Refer to "Naming conventions" on page 79 for more information about *bpname*.

MEMBER CLUSTER

Specifies that data that is inserted by an insert operation is not clustered by the implicit clustering index (the first index) or the explicit clustering index. Db2 places the data in an implicitly created table space based on available space.

Do not specify MEMBER CLUSTER if the table space name is specified by using the IN *table-space-name* clause or if IN ACCELERATOR clause is specified.

TRACKMOD YES or TRACKMOD NO

Specifies whether Db2 tracks modified pages in the space map pages of an implicitly created table space. The IMPTKMOD subsystem parameter specifies the default value. See IMPTKMOD in macro DSN6SYSP (Db2 Installation and Migration).

Do not specify TRACKMOD YES or TRACKMOD NO if the table space name is specified by using the IN *table-space-name* clause or if using the IN ACCELERATOR clause.

TRACKMOD YES

Changed pages are tracked in the space map pages to help improve performance of incremental image copies.

TRACKMOD NO

Changed pages are not tracked in the space map pages. Db2 uses the LRSN value in each page to determine whether a page has been changed.

PAGENUM

Identifies the type of page numbering that is used when you create a partition-by-range table space. This value is applied to an implicitly created base table space. The PAGESET_PAGENUM subsystem parameter specifies the default PAGENUM value. See PAGE SET PAGE NUMBERING field (PAGESET_PAGENUM subsystem parameter) (Db2 Installation and Migration).

RELATIVE

Indicates that internal page numbering is kept as a 4-byte value without a partition number. The page number is a relative page from the start of the partition, and the partition number is kept only in the header page.

ABSOLUTE

Indicates that internal page numbering is kept as a 4-byte value that includes a partition number and page number. Distinguishing which bits represent the partition and which represent the page number requires a shift value. The shift value is LOG base 2 (DSSIZE/(page size)).

Notes for CREATE TABLE

Owner privileges

The owner of the table has all table privileges (see "GRANT (table or view privileges)" on page 1983) with the ability to grant these privileges to others. For more information about ownership of the object, see "Authorization, privileges, permissions, masks, and object ownership" on page 90.

Table design

Designing tables is part of the process of database design. For more information, see Db2 database design (Introduction to Db2 for z/OS) .

If the IN DATABASE clause is specified without a table space name

If you specify IN DATABASE (either explicitly or by default), but do not specify a table space, a table space is implicitly created in the specified database. The name of the table space is derived from the table name. The qualifier of the table space is the same as the qualifier of the table. The owner of the table space is SYSIBM.

For more information, see Implicitly defined table spaces (Db2 Administration Guide).

If the IN clause is not specified

If you do not specify the IN clause, the Db2 implicitly creates a table space as described previously, but the Db2 also chooses a database. Db2 creates a name in the form of DSN*nnnnn*, where *nnnnn* is between 00001 and the maximum value of the sequence SYSIBM.DSNSEQ_IMPLICITDB, which has a default of 10000, inclusive. The owner of the database is SYSIBM.

- If DSN*nnnnn* already exists and is an implicitly created database, the Db2 subsystem creates the table in that database.
- If DSN*nnnnn* does not exist, the Db2 subsystem creates a database with the name DSN*nnnnn*.

If DSN*nnnnn* cannot be created because of a deadlock, timeout, or resource unavailable condition, the Db2 subsystem increments *nnnnn* by one and tries the resultant database name. If the Db2 subsystem reaches the maximum value of the sequence SYSIBM.DSNSEQ_IMPLICITDB, and the corresponding database name is not available, the Db2 subsystem sets *nnnnn* to 00001 and tries the resultant database name. If the Db2 subsystem attempts to create the table a number of times that is equal to the maximum value of the sequence SYSIBM.DSNSEQ_IMPLICITDB without success, an error occurs.

System objects for implicitly created table spaces

If a table space is implicitly created, all of the following required system objects are also implicitly created:

- The enforcing primary key index
- The enforcing unique key index
- Any necessary LOB table spaces, auxiliary table spaces, and auxiliary indexes
- The ROWID index (if the ROWID column is defined as GENERATED BY DEFAULT)

When Db2 implicitly creates a base table space for a table with LOB columns that can have inline LOBs, Db2 creates the base table space in reordered row format, regardless of the value of the RRF subsystem parameter.

The attributes of an implicitly created table space can be changed by using the "ALTER TABLESPACE" on page 1316 statement.

Creating a table in a segmented (non-UTS) table space (deprecated)

A table cannot be created in a segmented table space if any of the following conditions are true:

- FL 504 The effective application compatibility of the CREATE TABLE statement is V12R1M504 or higher.
- The available space in the data set is less than the segment size specified for the table space, and
- The data set cannot be extended.

Deprecated function: FL 504 Non-UTS table spaces for base tables are deprecated. CREATE TABLESPACE statements that run at application compatibility level V12R1M504 or higher always create a partition-by-growth or partition-by-range table space, and CREATE TABLE statements that specify a non-UTS table space (including existing multi-table segmented table spaces) return an error. However, you can use a lower application compatibility level to create table spaces of the deprecated types if needed, such as for recovery situations. For instructions, see Creating non-UTS table spaces (deprecated) (Db2 Administration Guide).

Creating a table with graphic and mixed data columns

You cannot create an ASCII or EBCDIC table with a GRAPHIC, VARGRAPHIC, or DBCLOB column or a CHAR, VARCHAR, or CLOB column defined as FOR MIXED DATA when the setting for installation option MIXED DATA is NO, unless the table is EBCDIC, and the columns are Unicode.

Creating a table with distinct type columns based on LOB, ROWID, and DECFLOAT columns

Because a distinct type is subject to the same restrictions as its source type, all the syntactic rules that apply to LOB columns (CLOB, DBCLOB, and BLOB), ROWID columns, and DECFLOAT columns apply to distinct type columns that are based on LOBs, row IDs, and DECFLOATs. For example, a table cannot have both an explicitly defined ROWID column and a column with a distinct type that is based on a row ID.

Tables with inline LOB columns

If the page size is exceeded for a table in a universal table space, Db2 recalculates the record size using 0 as the inline length for LOB columns that do not specify the INLINE LENGTH clause. A record size of 0 is used in the recalculation even if the LOB_INLINE_LENGTH subsystem parameter value is greater than 0. After the recalculation, if the page size is still exceeded, the CREATE TABLE statement returns an error.

You cannot create a table with an inline LOB column in a table space that has basic row format.

Creating a table with LOB columns

A table with a LOB column (CLOB, DBCLOB, or BLOB) must also have a ROWID column, one or more auxiliary tables, and indexes on the auxiliary tables. In many situations, Db2 can implicitly create the required objects for you. For more information, see "ROWID columns for tables with LOB columns" on page 1698 and "Auxiliary tables and indexes for LOB columns" on page 1699.

ROWID columns for tables with LOB columns

When you create the table without explicitly defining a ROWID column, Db2 implicitly generates a ROWID column for you. This column is called an *implicitly hidden ROWID column*. The implicitly hidden ROWID column has the following attributes:

- Db2 creates the column with a name of DB2_GENERATED_ROWID_FOR_LOBS*nn*.

  Db2 appends *nn* only if the column name already exists in the table, replacing *nn* with 00 and incrementing by 1 until the name is unique within the row.
- Defines the column as GENERATED ALWAYS.
- Appends the implicitly hidden ROWID column to the end of the row after all the other explicitly defined columns.

For example, assume that Db2 generated an implicitly hidden ROWID column named DB2_GENERATED_ROWID_FOR_LOBS for table MYTABLE. The result table for a SELECT * statement for table MYTABLE would not contain that ROWID column. However, the result table for SELECT COL1, DB2_GENERATED_ROWID_FOR_LOBS would include the implicitly hidden ROWID column.

If the MIXED DATA subsystem parameter is set to YES, and a lowercase or mixed case hexadecimal constant is specified as the default value for a LOB column, the CREATE TABLE statement returns an error.

Auxiliary tables and indexes for LOB columns

The definition of a table that contains a LOB column is marked incomplete until an auxiliary table is created in a LOB table space for each LOB column in the base table and an index is created on each auxiliary table. The auxiliary table stores the actual values of a LOB column. For each LOB column in a partitioned table space, one auxiliary table and related index must be defined for each partition of the base table space.

Db2 sometimes implicitly creates the LOB table space, auxiliary table, and index on the auxiliary table for each LOB column in a table or partition. For more information, see LOB table space implicit creation (Db2 Administration Guide).

If Db2 does not implicitly create the LOB table spaces, auxiliary tables, and indexes on the auxiliary tables, you must create these objects by issuing CREATE TABLESPACE, CREATE AUXILIARY TABLE, and CREATE INDEX statements. For more information, see Creating LOB table spaces, auxiliary tables, and auxiliary indexes explicitly (Db2 Administration Guide).

Creating a table with an XML column

If the table has XML columns, the underlying XML table space is implicitly created with the same PAGENUM attribute as the base table space. The DSSIZE is inherited from the base table space for a base table in the partition-by-growth (PBG) table space.

The following table shows the DSSIZE for an implicitly created XML table space for a base table in a partition-by-range (PBR) or range-partitioned (non-UTS) table space. For partition-by-range (PBR) table spaces with relative page numbering, Db2 also rounds the DSSIZE up to the nearest power of two before using the following table.

Table 207. Default DSSIZE for XML table spaces, given the base table space DSSIZE and buffer-pool page size

Base table space DSSIZE	4KB base page size	8KB base page size	16KB base page size	32KB base page size
1–4 GB	4G B	4 GB	4 GB	4 GB
5–8 GB	32 GB	16 GB	16 GB	16 GB
9–16 GB	64 GB	32 GB	16 GB	16 GB
17–32 GB	64 GB	64 GB	32 GB	16 GB
33–64 GB	64 GB	64 GB	64 GB	32 GB
65–128 GB	256 GB	256 GB	128 GB	64 GB
129–256 GB	256 GB	256 GB	256 GB	128 GB
257–512 GB	512 GB	512 GB	512 GB	256 GB
513-1024 GB	1024 GB	1024 GB	1024 GB	512 GB

For more information, see XML table space implicit creation (Db2 Administration Guide).

Naming convention for implicitly created XML objects

Implicitly created XML table spaces names will be X*yyynnnn*, where *yyy* is derived from the first three bytes of the base table name (if the name is shorter than 3, *yyy* is padded with X). *nnnn* is a numeric string that will start at 0000 and be incremented by 1 until a unique number is found.

Implicitly created XML table names will be X*yyyyyyyyyyyyyyyyyynnn*, where *yyyyyyyyyyyyyyyyyy* is the first 18 UTF-8 bytes of the base table name or of the entire name if it is less than 18. *nnn* will only be appended if the name already exists in the table. If the name already exists, *nnn* will be replaced with 000 and will be incremented by 1 until the name is unique.

Implicitly created document ID index names will be I_DOCID*yyyyyyyyyyyyyyyyyynnn*, where *yyyyyyyyyyyyyyyyyy* is the first 18 UTF-8 bytes of the base table name or the entire name if it is less than 18. *nnn* will only be appended if the index already exists in the table. If the index already exists, *nnn* will be replaced with 000 and will be incremented by 1 until the name is unique.

Implicitly created node ID index names will be I_NODEID*yyyyyyyyyyyyyyyyyynnn*, where *yyyyyyyyyyyyyyyyyy* is the first 18 UTF-8 bytes of the XML table name or the entire name if it is less than 18. *nnn* will only be appended if the index already exists in the table. If the index already exists, *nnn* will be replaced with 000 and will be incremented by 1 until the name is unique.

Creating a table with an identity column

When a table has an identity column, Db2 can automatically generate sequential numeric values for the column as rows are inserted into the table. Thus, identity columns are ideal for primary keys. Identity columns and ROWID columns are similar in that both types of columns contain values that Db2 generates. ROWID columns are used in large object (LOB) table spaces and can be useful in direct-row access. ROWID columns contain values of the ROWID data type, which returns a 40-byte VARCHAR value that is not regularly ascending or descending. ROWID data values are therefore not well suited to many application uses, such as generating employee numbers or product numbers. For data that is not LOB data and that does not require direct-row access, identity columns are usually a better approach, because identity columns contain existing numeric data types and can be used in a wide variety of uses for which ROWID values would not be suitable.

When a table is recovered to a point-in-time, it is possible that a large gap in the generated values for the identity column might result. For example, assume a table has an identity column that has an incremental value of 1 and that the last generated value at time T1 was 100 and Db2 subsequently generates values up to 1000. Now, assume that the table space is recovered back to time T1. The generated value of the identity column for the next row that is inserted after the recovery completes will be 1001, leaving a gap from 100 to 1001 in the values of the identity column.

If you want to ensure that an identity column has unique values, create a unique index on the column.

Creating a table with a LONG VARCHAR or LONG VARGRAPHIC column

Although the syntax LONG VARCHAR and LONG VARGRAPHIC is allowed for compatibility with previous releases of Db2, its use is not encouraged. VARCHAR(*integer*) and VARGRAPHIC(*integer*) is the recommended syntax, because after the CREATE TABLE statement is processed, Db2 considers a LONG VARCHAR column to be VARCHAR and a LONG VARGRAPHIC column to be VARGRAPHIC.

When a column is defined using the LONG VARCHAR or LONG VARGRAPHIC syntax, Db2 determines the length attribute of the column. You can use the following information, which is provided for existing applications that require the use of the LONG VARCHAR or LONGVARGRAPHIC syntax, to calculate the byte count and the character count of the column.

To calculate the byte count, use this formula:

2*(INTEGER((INTEGER((*m*-*i*-*k*)/*j*))/2))

Where:

m

Is the maximum row size (8 less than the maximum record size)

i

Is the sum of the byte counts of all columns in the table that are not LONG VARCHAR or LONG VARGRAPHIC

j

is the number of LONG VARCHAR and LONG VARGRAPHIC columns in the table

k

k is the number of LONG VARCHAR and LONG VARGRAPHIC columns that allow nulls

To find the character count:

1. Find the byte count.
2. Subtract 2.

3. If the data type is LONG VARGRAPHIC, divide the result by 2. If the result is not an integer, drop the fractional part.

Defining a system-period temporal table

A system-period temporal table definition includes the following:

- A system period named SYSTEM_TIME which is defined using a row-begin column and a row-end column.
- A transaction-start-ID column.
- A system-period data versioning definition which includes the name of the associated history table, which is specified in a subsequent ALTER TABLE statement.

To ensure that the history table cannot be implicitly dropped when a system-period temporal table is dropped, use the WITH RESTRICT ON DROP clause in the definition of the history table.

Defining an application-period temporal table

An application-period temporal table definition includes an application period named BUSINESS_TIME. The application period is defined using a begin timestamp column and an end timestamp column.

Data change operations on an application-period temporal table might result in an automatic insert of one or two additional rows when a row is updated or deleted. When an update or delete of a row in an application-period temporal table is specified for a portion of the period that is represented by that row, the row is updated or deleted and one or two rows are automatically inserted to represent the portion of the row that is not changed. New values are generated for each generated column in an application-period temporal table for each row that is automatically inserted as a result of an update or delete operation on the table. If a generated column is defined as part of a unique or primary key, parent key in a referential constraint, or unique index, it is possible that an automatic insert will violate a constraint or index, in which case an error is returned.

Bitemporal tables

A table that is defined for system-period data versioning and contains a BUSINESS_TIME period is referred to as a bitemporal table.

Considerations for transaction-start-ID columns

A transaction-start-ID column contains a null value if the column allows null values. A row-begin column which is unique from other row-begin column values that are generated for other transactions exists with the transaction-start-ID column. Given that the column might contain null values, consider using one of the following methods when retrieving a value from the column:

```
COALESCE ( transaction_start_id_col, row_begin_col)
CASE WHEN transaction_start_id_col IS NOT NULL
    THEN transaction_start_id_col
        ELSE row_begin_col
END
```

Implicitly created indexes

When the PRIMARY KEY or UNIQUE clause is used in the CREATE TABLE statement and the CREATE TABLE statement is processed by the schema processor or the table space that contains the table is implicitly created, Db2 implicitly creates the unique indexes used to enforce the uniqueness of the primary or unique keys.

When a ROWID column is defined as GENERATED BY DEFAULT in the CREATE TABLE statement, and the CREATE TABLE statement is processed by SET CURRENT RULES = 'STD' or the table space that contains the table is implicitly created, Db2 implicitly creates the unique indexes used to enforce the uniqueness of the ROWID column.

The privilege set must include the USE privilege of the buffer pool.

Each index is created as if the following CREATE INDEX statement were issued:

```
CREATE UNIQUE INDEX xxx ON table-name (column1,...)
```

Where:

- *xxx* is the name of the index that Db2 generates.
- *table-name* is the name of the table specified in the CREATE TABLE statement.
- *(column1,...)* is the list of column names that were specified in the UNIQUE or PRIMARY KEY clause of the CREATE TABLE statement, or the column is a ROWID column that is defined as GENERATED BY DEFAULT.

For more information about the schema processor, see Creating a schema by using the schema processor (Db2 Administration Guide).

In addition, if A table space that contains the table is implicitly created, Db2 will check the DEFINE DATA SET subsystem parameter to determine whether to define the underlying data set for the index space of the implicitly created index on the base table.

If DEFINE DATA SET is NO, the index is created as if the following CREATE INDEX statement is issued:

```
CREATE UNIQUE INDEX xxx ON table-name (column1,...) DEFINE NO
```

Maximum record size

The maximum record size of a table depends on the page size of the table space and whether the EDITPROC clause is specified, as shown in Table 208 on page 1702..

The initial page size of the table space is the size of its buffer, which is determined by the BUFFERPOOL clause that was explicitly or implicitly specified when the table space was created. When the record size reaches 90 percent of the maximum record size for the page size of the table space, the next largest page size is automatically used.

Table 208. Maximum record size, in bytes

	Page Size = 4KB	**Page Size = 8KB**	**Page Size = 16KB**	**Page Size = 32KB**
Table without EDITPROC=YES	4056	8138	16330	32714
Table with EDITPROC=YES	4046	8128	16320	32704

The maximum record size corresponds to the maximum length of a VARCHAR column if that column is the only column in the table.

If the table space that contains the table is implicitly created, the proper buffer pool size is chosen according to the actual record size. If the record size reaches 90% of the maximum record size for the page size of the table space, the next largest page size will be used. Table 209 on page 1702 shows 90% of the maximum record size:

Table 209. 90% of Maximum record size, in bytes

	Page Size = 4KB	**Page Size = 8KB**	**Page Size = 16KB**	**Page Size = 32KB**
Table without EDITPROC=YES	3650	7324	14697	29443
Table with EDITPROC=YES	3641	7315	14688	29434

A row in a table with PAGENUM RELATIVE or in a table space with PAGENUM RELATIVE must have a minimum data size of 3 bytes. Rows with data that compresses to less than 3 bytes, will not be compressed when stored in the table.

Byte counts

The sum of the byte counts of the columns must not exceed the maximum row size of the table. The maximum row size is eight less than the maximum record size.

For columns that do not allow null values, Table 210 on page 1703 gives the byte counts of columns by data type. For columns that allow null values, the byte count is one more than shown in the table.

Table 210. Byte counts of columns by data type

Data Type	Byte Count
INTEGER	4
SMALLINT	2
BIGINT	8
FLOAT(*n*)	If *n* is between 1 and 21, the byte count is 4. If *n* is between 22 and 53, the byte count is 8.
DECIMAL	INTEGER(*p*/2)+1, where *p* is the precision
DECFLOAT(16)	9
DECFLOAT(34)	17
CHAR(*n*)	*n*
VARCHAR(*n*)	*n*+2
CLOB	6
Inline CLOB	6 + inline byte count
GRAPHIC(*n*)	2*n*
VARGRAPHIC(*n*)	2*n*+2
DBCLOB	6
Inline DBCLOB	6 + (inline char count * 2)
BINARY(*n*)	*n*
VARBINARY(*n*)	*n*+2
BLOB	6
Inline BLOB	6 + inline byte count
DATE	4
TIME	3
TIMESTAMP(*p*) WITHOUT TIME ZONE	INTEGER((*p*+1)/2) + 7 where *p* is the precision
TIMESTAMP(*p*) WITH TIME ZONE	INTEGER((*p*+1)/2) + 9 where *p* is the precision
ROWID	19
distinct type	The length of the source data type upon which the distinct type was based
XML	6 - If column cannot contain multiple versions of an XML document. 14 - If column can contain multiple versions of an XML document.

For more information, see How Db2 uses XML versions (Db2 Programming for XML).

Creating a materialized query table

If the fullselect in the CREATE TABLE statement contains a SELECT *, the select list of the subselect is determined at the time the materialized query table is created. In addition, any references to user-defined functions are resolved at the same time. The isolation level at the time when the CREATE TABLE statement is executed is the isolation level for the materialized query table. After a materialized query table is created, the REFRESH_TIME column of the row for the table in the SYSIBM.SYSVIEWS catalog table contains the default timestamp.

The owner of a materialized query table has all the table privileges with the grant option on the table irrespective of whether the owner has the necessary privileges on the base tables, views, functions, and sequences.

No unique constraints or unique indexes can be created for materialized query tables. Thus, a materialized query table cannot be a parent table in a referential constraint.

When you are creating user-maintained materialized query tables, you should create the materialized query table with query optimization disabled and then enable the table for query optimization after it is populated. Otherwise, Db2 might rewrite queries to use the empty materialized query table, and you will not get accurate results.

Considerations for implicitly hidden columns

A column that is defined as implicitly hidden is not part of the result table of a query that specifies * in a SELECT list. However, an implicitly hidden column can be explicitly referenced in a query. For example, an implicitly hidden column can be referenced in the SELECT list or in a predicate in a query. Additionally, an implicitly hidden column can be explicitly referenced in a COMMENT, CREATE INDEX statement, ALTER TABLE statement, INSERT statement, MERGE statement, UPDATE statement, or RENAME statement. An implicitly hidden column can be referenced in a referential constraint. A REFERENCES clause that does not contain a column list refers implicitly to the primary key of the parent table. It is possible that the primary key of the parent table includes a column defined as implicitly hidden. Such a referential constraint is allowed.

If the SELECT list of the fullselect of a materialized query definition explicitly refers to an implicitly hidden column, that column will be part of the materialized query table.

If the SELECT list of the fullselect of a view definition (CREATE VIEW statement) explicitly refers to an implicitly hidden column, that column will be part of the view, however the view column is not considered 'hidden'.

Restrictions on field procedures, edit procedures, and validation exit procedures

Field procedures, edit procedures, and validation exit procedures cannot be used on tables that have column names that are larger than 18 EBCDIC bytes. If you have tables that have field procedures or validation exit procedures and you add a column where the column name is larger than 18 bytes, the field procedures and validation exit procedures for the table will be invalidated.

Consider using triggers to replace the functionality on field procedures, edit procedures, and validation exit procedures on tables where the column names are larger than 18 EBCDIC bytes.

Restrictions on certain SQL statements in the same unit of work as CREATE TABLE

- A CREATE TABLE statement that contains a PARTITION BY clause should not be followed in the same unit of work by SQL statements that change data.
- A CREATE TABLE statement that contains an IN ACCELERATOR clause should be issued in a separate unit of work from other SQL statements.

Creating a table while a utility runs

You cannot use CREATE TABLE while a Db2 utility has control of the table space implicitly or explicitly specified by the IN clause.

Restrictions involving pending definition changes

A CREATE TABLE statement is not allowed if there are pending changes to the definition of the table space, if the CREATE TABLE statement specifies a FOREIGN KEY clause that reference a column for which there are pending definition changes, or if the CREATE TABLE statement specifies a materialized query table definition that references a table for which there are pending definition changes.

Key label requirement

To use a key label for encryption, the VSAM data sets for the page sets need to be associated with an SMS Data Class that has extended format capability (EF enabled).

Determining a key label for base table space and associated objects

When a key label is specified at the table level, Db2 provides the key label to DFSMS to encrypt all the table spaces and index spaces associated with the table. This includes base table space, auxiliary table spaces, XML table spaces, index spaces, and clone table space, regardless of whether the base table space or associated objects are explicitly or implicitly created. Db2 does not enforce any key label relationship between the base table and an associated history or archive table. The key label for the archive and the history tables has to be set independent of the base table. If there is no key label specified at the table level, Db2 will provide the key label to DFSMS specified for the storage group.

When Db2 calls DFSMS to allocate the dataset for table space or index space, DFSMS uses its order of precedence to determine the key label and can override the key label specified by Db2.

DFSMS order of precedence:

- RACF data set profile
- JCL, dynamic allocation, TSO ALLOCATE
- SMS data class construct

If the security administrator has specified a key label for the RACF data set profile, that key label takes precedence over the Db2 provided key label. The REPORT utility can be run to determine the key label used for encryption.

Description of key label in effect in DB2

Table 211. Example scenarios for a partition-by-growth table space, that describe the key label in effect in DB2. This is the key label provided to DFSMS during allocation of data set for table spaces and index spaces.

Scenarios	Catalog key label value	Key label provided to DFSMS during data set allocation
Create storage group, SG01 with key label, SGKL01.	SYSSTOGROUP record - KEY LABEL: SGKL01	
Create table space, TBSP01 using storage group, SG01 – Creates Partition 1		SGKL01
Create table, TB01 in table space, TBSP01 with key label, TBKL01	SYSTABLESPACE record for TBSP01 / SYSTABLES record for TBKL01 – KEY LABEL: TBKL01	
REORG TABLESPACE TBSP01 – Reorgs Partition 1		TBKL01
Create index, IX01 on table, TB01 creates index space	SYSINDEXES record for IX01 – KEY LABEL: TBKL01	TBKL01
Insert data into TB01 – Creates Partition 2		TBKL01
Alter table, TB01 to specify NO KEY LABEL	SYSTABLESPACE record for TBSP01 / SYSTABLES record for TBKL01 / SYSINDEXES record for IX01 – KEY LABEL: Empty string	
Insert data into TB01 – Creates partition 3		SGKL01

Table 211. Example scenarios for a partition-by-growth table space, that describe the key label in effect in DB2. This is the key label provided to DFSMS during allocation of data set for table spaces and index spaces. (continued)

Scenarios	Catalog key label value	Key label provided to DFSMS during data set allocation
REORG TABLESPACE TBSP01 with REUSE option – Resets and reuses DB2-managed data sets. No change to key label		

Key label considerations

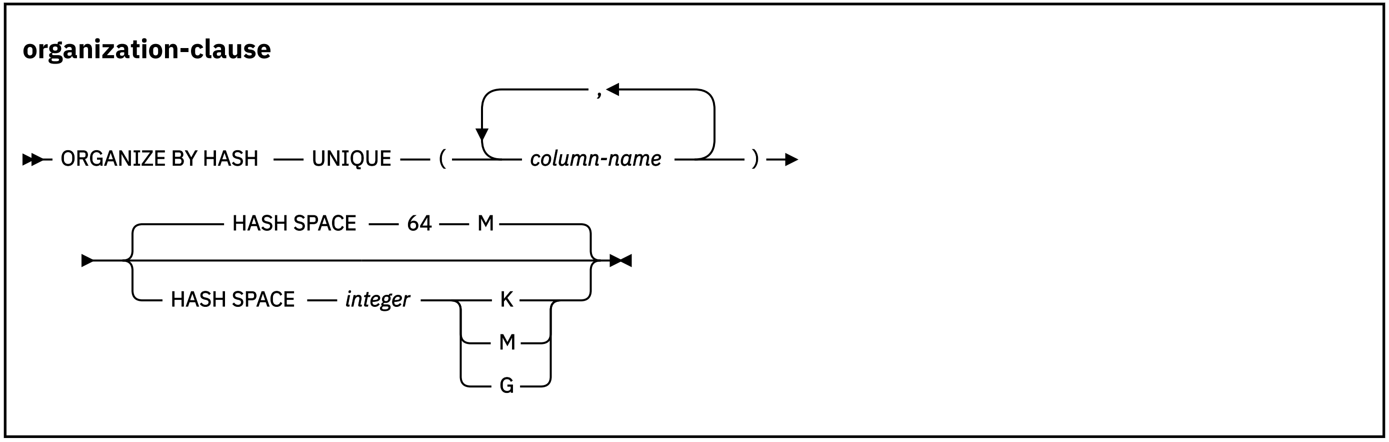
If the last table is dropped from a segmented table space, the table space and its underlying data set will remain. If key label is in effect, the KEYLABEL column for the table space's SYSTABLESPACE record will be cleared. If a new table is created in this table space, it will be encrypted with the previous key label. If the table has to be created as unencrypted, execute the REORG TABLESPACE utility for the table space.

If a table space is explicitly created with the DEFINE YES option and a table with a key label is defined in that table space, then the data sets associated with the table space will not be encrypted. A subsequent REORG is necessary to encrypt the data sets. Users that want immediate encryption of the data sets associated with the table space must to define table spaces with the DEFINE NO option.

Syntax and descriptions for hash organization (deprecated)

Deprecated function: FL 504 Hash-organized tables are deprecated. Beginning in Db2 12, packages bound with APPLCOMPAT(V12R1M504) or higher cannot create hash-organized tables or alter existing tables to use hash-organization. Existing hash organized tables remain supported, but they are likely to be unsupported in the future.

organization-clause



ORGANIZE BY HASH

Specifies that a hash is to be used for the data organization of the table.

If PARTITION BY RANGE is specified, and the IN clause specifies a table space, the table space must be a partition by range universal table space, and cannot be a table space with PAGENUM RELATIVE.

If PARTITION BY RANGE is not specified, and an IN clause is specified, the IN clause must identify a partition-by-growth table space.

ORGANIZE BY HASH must not be specified if the table is defined with APPEND YES.

ORGANIZE BY HASH must not be specified if the table is using basic row format.

If IN ACCELERATOR is specified, ORGANIZE BY HASH must not be specified.

UNIQUE

Specifies that Db2 enforces uniqueness of the hash key columns, preventing the table from containing two or more rows with the same value of the hash key.

(*column-name*,...)

The list of column names defines the hash key that is used to determine where a row will be placed. Each *column-name* must be an unqualified name that identifies a column of the table. The same column must not be specified more than once and the specified columns must be defined as NOT NULL. The number of specified columns must not exceed 64, and the sum of their length attributes must not exceed 255. A specified column cannot be any of the following types:

- a LOB column
- a DECFLOAT column
- a XML column
- a distinct type column that is based on one of the preceding data types

All character and graphic string columns in the key must use the same encoding scheme.

If PARTITION BY RANGE is also specified, the list of column names must specify all of the column names that are specified in *partition-expression* for the table, and must specify the column names in the same order as *partition-expression*. If the ORGANIZE BY clause contains more columns than *partition-expression*, *partition-expression* determines the partition number.

HASH SPACE *integer*K|M|G

Specifies the amount of fixed hash space to preallocate for the table. If the table is partitioned by range, this is the space for each partition.

The default is 64M for a table in a partition-by-growth table space or 64M for each partition of a partition-by-range table space.

K

Indicates that the *integer* value is multiplied by 1024 to specify the hash space size in bytes. The *integer* value must be between 256 and 268,435,456.

M

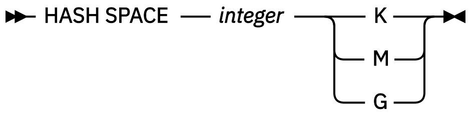
Indicates that the *integer* value is multiplied by 1,048,576 to specify the hash space size in bytes. The *integer* value must be between 1 and 262,144.

G

Indicates that the *integer* value is to be multiplied by 1,073,741,824 to specify the hash space size in bytes. The *integer* value must be between 1 and 256 for a partition by range table and must be between 1 and 131,072 for a non-partitioned table.

If a value greater than 4G is specified, the data sets for the table space are associated with a DFSMS data class that has been specified with extended format and extended addressability.

partition-hash-space



HASH SPACE *integer*K|M|G

Specifies the amount of fixed hash space to preallocate for the partition that is associated with the *partition-element*. If HASH SPACE is omitted from the partition element, the HASH SPACE value from the ORGANIZE BY clause is used. If IN ACCELERATOR is specified, HASH SPACE must not be specified.

If HASH SPACE is not specified, each partition will use the HASH SPACE value specified in *organization-clause*.

The HASH SPACE keyword in *partition-element* must only be specified if *organization-clause* is also specified.

K
Indicates that the *integer* value is multiplied by 1024 to specify the hash space size in bytes. The *integer* value must be between 256 and 268,435,456.

M
Indicates that the *integer* value is multiplied by 1,048,576 to specify the hash space size in bytes. The *integer* value must be between 1 and 262,144.

G
Indicates that the *integer* value is to be multiplied by 1,073,741,824 to specify the hash space size in bytes. The *integer* value must be between 1 and 256 for a partition by range table and must be between 1 and 131,072 for a non-partitioned table.

If a value greater than 4G is specified, the data sets for the table space are associated with a DFSMS data class that has been specified with extended format and extended addressability.

Notes for hash organization (deprecated)

Deprecated function: FL 504 Hash-organized tables are deprecated. Beginning in Db2 12, packages bound with APPLCOMPAT(V12R1M504) or higher cannot create hash-organized tables or alter existing tables to use hash-organization. Existing hash organized tables remain supported, but they are likely to be unsupported in the future.

If the IN clause is not specified with ORGANIZE BY HASH
If you do not specify IN DATABASE (either explicitly or by default), Db2 will use the default DSSIZE of 4G for each partition for a partition-by-range table space or use the value that is specified in the partitioning clause. The hash space value that is specified on CREATE TABLE will be validated, per part, to ensure that the specified DSSIZE is adequate. If the DSSIZE is not adequate, an error will be returned.

If the maximum number of partitions needed for the specified hash space is more than the maximum number of partitions allowed, Db2 to will return an error.

If the selected buffer pool is not available, a error will be returned.

Creating a table with hash organization and LOB columns
If the table space is a partition-by-growth table space, Db2 will preallocate as many partitions as needed depending on the value specified for HASH SPACE. If Db2 needs to implicitly create the LOB object in a new partition, the privilege set for the implicitly created LOB objects must include the USE privilege on the buffer pool for the LOB table space.

Hash space and Db2 page size
If the specified hash space is less than or equal to 64 MB (the Db2 default), Db2 will add extra space for Db2 system pages. If the specified hash space is greater than 64 MB, Db2 will use part of the hash space for Db2 system pages. The amount of space needed for Db2 system pages depends on SEGSIZE and PAGESIZE. The larger the SEGSIZE and/or PAGESIZE becomes, the larger the requirement for Db2 system pages. Db2 can reserve up to 5 MB for system pages for the highest SEGSIZE value (64) and PAGESIZE value (32K).

Hash space and DSSIZE
Depending on certain table space characteristics, Db2 needs to reserve space for the hash overflow area. Therefore, the amount of hash space cannot be equal to the DSSIZE value. The maximum amount of hash space that can be specified is approximately 20% less than the DSSIZE value. Db2 returns an error if the amount of hash space is too large. If the amount of hash space is too large, specify a larger value of DSSIZE, or decrease the amount of hash space.

Specifying APPEND for hash-organized tables
Append processing is not applicable to tables with hash organization since there is no key clustering in hash organization. For insert operations into tables with hash organization, Db2 will use the internal hash algorithm to determine the location of the row.

Maximum record size for hash-organized tables

For hash-organized tables, the maximum record size on whether the EDITPROC clause is specified, as shown in Table 212 on page 1709.

The initial page size of the table space is the size of its buffer, which is determined by the BUFFERPOOL clause that was explicitly or implicitly specified when the table space was created. When the record size reaches 90 percent of the maximum record size for the page size of the table space, the next largest page size is automatically used.

Table 212. Maximum record size, in bytes for hash organized tables

	Page Size = 4KB	Page Size = 8KB	Page Size = 16KB	Page Size = 32KB
Hash table (hash home page)	3817	7899	16091	32475
Hash table with EDITPROC=YES (hash home page)	3807	7889	16081	32465

The maximum record size corresponds to the maximum length of a VARCHAR column if that column is the only column in the table.

If the table space that contains the table is implicitly created, the proper buffer pool size is chosen according to the actual record size.

A row in a table with PAGENUM RELATIVE or in a table space with PAGENUM RELATIVE must have a minimum data size of 3 bytes. Rows with data that compresses to less than 3 bytes, will not be compressed when stored in the table.

Restrictions for tables with hash organization

Tables that use hash organization are subject to the following restrictions:

- A table that is defined to use hash organization cannot be created in a LOB table space or XML table space.
- ORGANIZE BY HASH must not be specified if the table space is defined with the MEMBER CLUSTER clause.
- The MAXROWS clause is applicable only to the hash overflow area of the table space for tables with hash organization. The fixed hash area of each page will contain as many rows as it can hold, up to a maximum of 255.
- The ORGANIZE BY HASH UNIQUE (*column-list*) clause is required when specifying HASH SPACE *integer* K|M|G in the *partition-element*. The *organization-clause* applies to the entire table and the *partition-element* clause applies at the partition level.
- Db2 automatically creates a hash overflow index when a table is created with hash organization.

Alternative syntax and synonyms

To provide compatibility with previous releases of Db2 or other products in the Db2 family, Db2 supports the following clauses:

- NOCACHE (single clause) as a synonym for NO CACHE
- NOCYCLE (single clause) as a synonym for NO CYCLE
- NOMINVALUE (single clause) as a synonym for NO MINVALUE
- NOMAXVALUE (single clause) as a synonym for NO MAXVALUE
- NOORDER (single clause) as a synonym for NO ORDER
- PART *integer* VALUES can be specified as an alternative to PARTITION *integer* ENDING AT.
- VALUES as a synonym for ENDING AT
- DEFINITION ONLY as a synonym for WITH NO DATA

- SUMMARY between CREATE and TABLE
- TIMEZONE can be specified as an alternative to TIME ZONE.

Examples for CREATE TABLE

Example 1

Create a table named DSN8C10.DEPT in the table space DSN8S12D of the database DSN8D12A. Name the five columns DEPTNO, DEPTNAME, MGRNO, ADMRDEPT, and LOCATION, allowing only MGRNO and LOCATION to contain nulls, and designating DEPTNO as the only column in the primary key. All five columns hold character string data. Assuming a value of NO for the field MIXED DATA on installation panel DSNTIPF, all five columns have the subtype SBCS.

```
CREATE TABLE DSN8C10.DEPT
  (DEPTNO   CHAR(3)     NOT NULL,
   DEPTNAME VARCHAR(36) NOT NULL,
   MGRNO    CHAR(6)             ,
   ADMRDEPT CHAR(3)     NOT NULL,
   LOCATION CHAR(16)            ,
   PRIMARY KEY(DEPTNO)          )
  IN DSN8D12A.DSN8S12D;
```

Example 2

Create a table named DSN8C10.PROJ in an implicitly created table space of the database DSN8D12A. Assign the table a validation procedure named DSN8EAPR.

```
CREATE TABLE DSN8C10.PROJ
  (PROJNO   CHAR(6)      NOT NULL,
   PROJNAME VARCHAR(24)  NOT NULL,
   DEPTNO   CHAR(3)      NOT NULL,
   RESPEMP  CHAR(6)      NOT NULL,
   PRSTAFF  DECIMAL(5,2)         ,
   PRSTDATE DATE                 ,
   PRENDATE DATE                 ,
   MAJPROJ  CHAR(6)      NOT NULL)
  IN DATABASE DSN8D12A
  VALIDPROC DSN8EAPR;
```

Example 3

Assume that table PROJECT has a non-primary unique key that consists of columns DEPTNO and RESPEMP (the department number and employee responsible for a project). Create a project activity table named ACTIVITY with a foreign key on that unique key.

```
CREATE TABLE ACTIVITY
  (PROJNO   CHAR(6)      NOT NULL,
   ACTNO    SMALLINT     NOT NULL,
   ACTDEPT  CHAR(3)      NOT NULL,
   ACTOWNER CHAR(6)      NOT NULL,
   ACSTAFF  DECIMAL(5,2)         ,
   ACSTDATE DATE         NOT NULL,
   ACENDATE DATE                 ,
   FOREIGN KEY (ACTDEPT,ACTOWNER)
      REFERENCES PROJECT (DEPTNO,RESPEMP) ON DELETE RESTRICT)
  IN DSN8D12A.DSN8S12D;
```

Example 4

Create an employee photo and resume table EMP_PHOTO_RESUME that complements the sample employee table. The table contains a photo and resume for each employee. Put the table in table space DSN8D12A.DSN8S12E. Let Db2 always generate the values for the ROWID column.

```
CREATE TABLE DSN8C10.EMP_PHOTO_RESUME
  (EMPNO      CHAR(6)     NOT NULL,
   EMP_ROWID  ROWID NOT NULL GENERATED ALWAYS,
   EMP_PHOTO  BLOB(110K),
   RESUME     CLOB(5K),
   PRIMARY KEY (EMPNO))
```

```
     IN DSN8D12A.DSN8S12E
     CCSID EBCDIC;
```

Example 5

Create an EMPLOYEE table with an identity column named EMPNO. Define the identity column so that Db2 will always generate the values for the column. Use the default value, which is 1, for the first value that should be assigned and for the incremental difference between the subsequently generated consecutive numbers.

```
   CREATE TABLE EMPLOYEE
     (EMPNO      INTEGER GENERATED ALWAYS AS IDENTITY,
      ID         SMALLINT,
      NAME       CHAR(30),
      SALARY     DECIMAL(5,2),
      DEPTNO     SMALLINT)
     IN DSN8D12A.DSN8S12D;
```

Example 6

Assume a very large transaction table named TRANS contains one row for each transaction processed by a company. The table is defined with many columns. Create a materialized query table for the TRANS table that contain daily summary data for the date and amount of a transaction.

```
   CREATE TABLE STRANS AS
     (SELECT YEAR AS SYEAR, MONTH AS SMONTH, DAY AS SDAY, SUM(AMOUNT) AS SSUM
      FROM TRANS
      GROUP BY YEAR, MONTH, DAY)
      DATA INITIALLY DEFERRED REFRESH DEFERRED;
```

Example 7

The following example creates a table in a partition-by-growth table space and includes the APPEND option:

```
  CREATE TABLE TS01TB
       (C1 SMALLINT,
        C2 DECIMAL(9,2),
        C3 CHAR(4))
    APPEND YES
    IN TS01DB.TS01TS;
```

Example 8

The following example creates a table in a partition-by-growth table space where the table space is implicitly created:

```
  CREATE TABLE TS02TB
       (C1 SMALLINT,
        C2 DECIMAL(9,2),
        C3 CHAR(4))
     PARTITION BY SIZE EVERY 4G
     IN DATABASE DSNDB04;
```

Example 9

Create a table, EMP_INFO, that contains a phone number and address for each employee. Include a row change timestamp column in the table to track the modification of employee information:

```
  CREATE TABLE EMP_INFO
       (EMPNO CHAR(6) NOT NULL,
        EMP_INFOCHANGE NOT NULL
           GENERATED ALWAYS FOR EACH ROW ON UPDATE
           AS ROW CHANGE TIMESTAMP,
        EMP_ADDRESS VARCHAR(300),
        EMP_PHONENO CHAR(4),
        PRIMARY KEY (EMPNO));
```

Example 10

Create a table, TB01, that uses a range partitioning scheme with a segment size of 4 and 4 partitions.

```
CREATE TABLE TB01 (
   ACCT_NUM         INTEGER,
   CUST_LAST_NM     CHAR(15),
   LAST_ACTIVITY_DT VARCHAR(25),
   COL2             CHAR(10),
   COL3             CHAR(25),
   COL4             CHAR(25),
   COL5             CHAR(25),
   COL6             CHAR(55),
   STATE            CHAR(55))
 IN DBB.TS01

  PARTITION BY (ACCT_NUM)
   (PARTITION 1 ENDING AT (199),
    PARTITION 2 ENDING AT (299),
    PARTITION 3 ENDING AT (399),
    PARTITION 4 ENDING AT (MAXVALUE));
```

Example 11

Create a table, policy_info, that uses a SYSTEM_TIME period and create a history table, hist_policy_info. Then issue an ALTER TABLE statement to associate the policy_info table with the hist_policy_info table.

```
CREATE TABLE policy_info
    (policy_id CHAR(10) NOT NULL,
     coverage INT NOT NULL,
     sys_start TIMESTAMP(12) NOT NULL GENERATED ALWAYS AS ROW BEGIN,
     sys_end TIMESTAMP(12) NOT NULL GENERATED ALWAYS AS ROW END,
     create_id TIMESTAMP(12) GENERATED ALWAYS AS TRANSACTION START ID,
     PERIOD SYSTEM_TIME(sys_start,sys_end));
```

```
CREATE TABLE hist_policy_info
    (policy_id CHAR(10) NOT NULL,
     coverage INT NOT NULL,
     sys_start TIMESTAMP(12) NOT NULL,
     sys_end TIMESTAMP(12) NOT NULL,
     create_id TIMESTAMP(12));
```

```
ALTER TABLE policy_info
    ADD VERSIONING USE HISTORY TABLE hist_policy_info;
```

Example 12

Create a table, policy_info, that uses a BUSINESS_TIME period.

```
CREATE TABLE policy_info
    (policy_id CHAR(4) NOT NULL,
     coverage INT NOT NULL,
     bus_start DATE NOT NULL,
     bus_end DATE NOT NULL,
     PERIOD BUSINESS_TIME(bus_start, bus_end));
```

Example 13

Create a table, policy_info, that uses both a SYSTEM_TIME period and a BUSINESS_TIME period to keep historical rows and track a user-specified time period. A table that specifies both a SYSTEM_TIME period and a BUSINESS_TIME period is sometimes referred to as a *bitemporal table*. To enable retention of historical rows, a history table, hist_policy_info, also needs to be created and associated (using the ALTER TABLE statement) with the policy_info table.

```
CREATE TABLE policy_info
    (policy_id CHAR(4) NOT NULL,
    coverage INT NOT NULL,
    bus_start DATE NOT NULL,
    bus_end DATE NOT NULL,
    sys_start TIMESTAMP(12) NOT NULL GENERATED ALWAYS AS ROW BEGIN,
    sys_end TIMESTAMP(12) NOT NULL GENERATED ALWAYS AS ROW END,
    create_id TIMESTAMP(12) GENERATED ALWAYS AS TRANSACTION START ID,
    PERIOD BUSINESS_TIME(bus_start, bus_end),
    PERIOD SYSTEM_TIME(sys_start, sys_end));
```

```
CREATE TABLE hist_policy_info
    (policy_id CHAR(4) NOT NULL,
    coverage INT NOT NULL,
    bus_start DATE NOT NULL,
    bus_end DATE NOT NULL,
    sys_start TIMESTAMP(12) NOT NULL,
    sys_end TIMESTAMP(12) NOT NULL),
    create_id TIMESTAMP(12);
```

```
ALTER TABLE policy_info
    ADD VERSIONING USE HISTORY TABLE hist_policy_info;
```

Example 14: Create table EMPLOYEE.PERSONAL with key label EMPKEYLABEL.

```
CREATE TABLE EMPLOYEE.PERSONAL
    (DEPTNO CHAR(3) NOT NULL,
     DEPTNAME VARCHAR(36) NOT NULL,
     MGRNO CHAR(6) ,
     ADMRDEPT CHAR(3) NOT NULL,
     LOCATION CHAR(16) ,
     PRIMARY KEY(DEPTNO) )
     IN DSN8D12A.DSN8S12D
     KEY LABEL EMPKEYLABEL;
```

Related concepts

Types of accelerator tables (Db2 Performance)

Unicode columns in EBCDIC tables
A single encoding scheme is used for all character and character string data in a table. An exception is that an EBCDIC table can contain one or more Unicode columns in addition to EBCDIC string columns.

Unicode support in Db2 (Db2 Installation and Migration)

Naming conventions
The rules for forming a name depend on the type of the object designated by the name.

Conditions that prevent query routing to an accelerator

CREATE TABLESPACE

The CREATE TABLESPACE statement defines a table space at the current server. The type of table space depends on the keywords specified.

FL 504Depending on the keywords specified, the result is a partition-by-range or partition-by-growth table space.

For information about the rules and restrictions for creating table spaces in work file databases, see Table spaces in a work file database.

For information about creating large object (LOB) table spaces, see "CREATE LOB TABLESPACE" on page 1548.

Db2 creates XML table spaces implicitly when you create or alter tables to add XML columns. For more information, see XML table space implicit creation (Db2 Administration Guide).

Invocation for CREATE TABLESPACE

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES RUN behavior is in effect. For more information, see "Authorization IDs and dynamic SQL" on page 94.

Authorization for CREATE TABLESPACE

The privilege set that is defined below must include at least one of the following:

- The CREATETS privilege for the database
- DBADM, DBCTRL, or DBMAINT authority for the database
- SYSADM or SYSCTRL authority
- System DBADM
- Installation SYSOPR authority (when the current SQLID of the process is set to SYSINSTL)

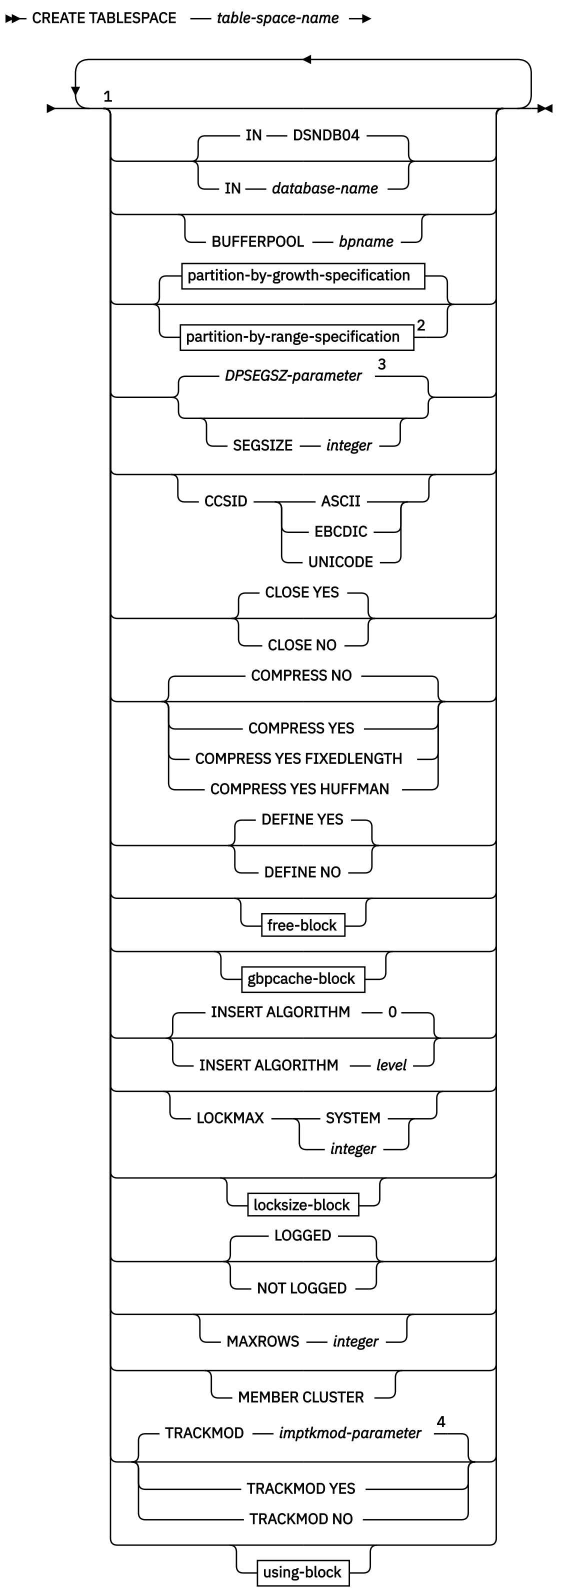
If the database is implicitly created, the database privileges must be on the implicit database or on DSNDB04.

Additional privileges might be required, as explained in the description of the BUFFERPOOL and USING STOGROUP clauses.

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the of the owner of the plan or package. If the application is bound in a trusted context with the ROLE AS OBJECT OWNER clause specified, a role is the owner. Otherwise, an authorization ID is the owner.

If the statement is dynamically prepared, the privilege set is the privileges that are held by the SQL authorization ID of the process unless the process is within a trusted context and the ROLE AS OBJECT OWNER clause is specified. In that case, the privileges set is the privileges that are held by the role that is associated with the primary authorization ID of the process.

Syntax for CREATE TABLESPACE



Notes:

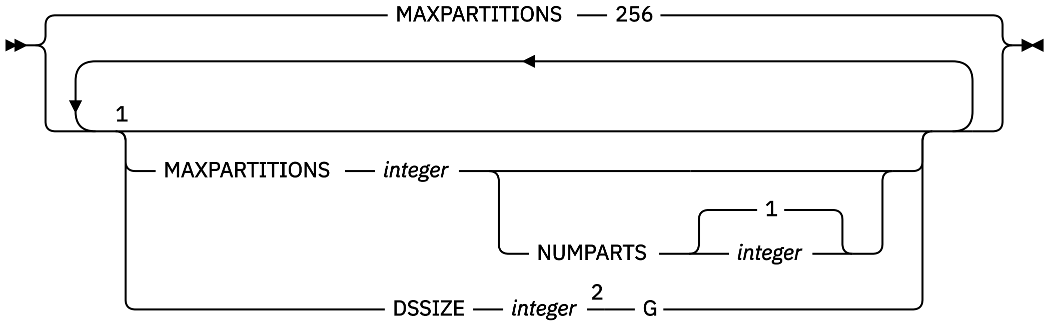
[1] The same clause must not be specified more than one time.

[2] FL 504 If the CREATE TABLESPACE statement runs at application compatibility level V12R1M503 or lower, you can use deprecated specifications to create non-UTS segmented or partitioned table spaces. See Creating non-UTS table spaces (deprecated) (Db2 Administration Guide).

[3] The default SEGSIZE value is controlled by the DPSEGSZ subsystem parameter.

[4] *imptkmod-parameter* is the IMPTKMOD subsystem parameter value. For more information, see IMPTKMOD in macro DSN6SYSP (Db2 Installation and Migration).

partition-by-growth-specification:

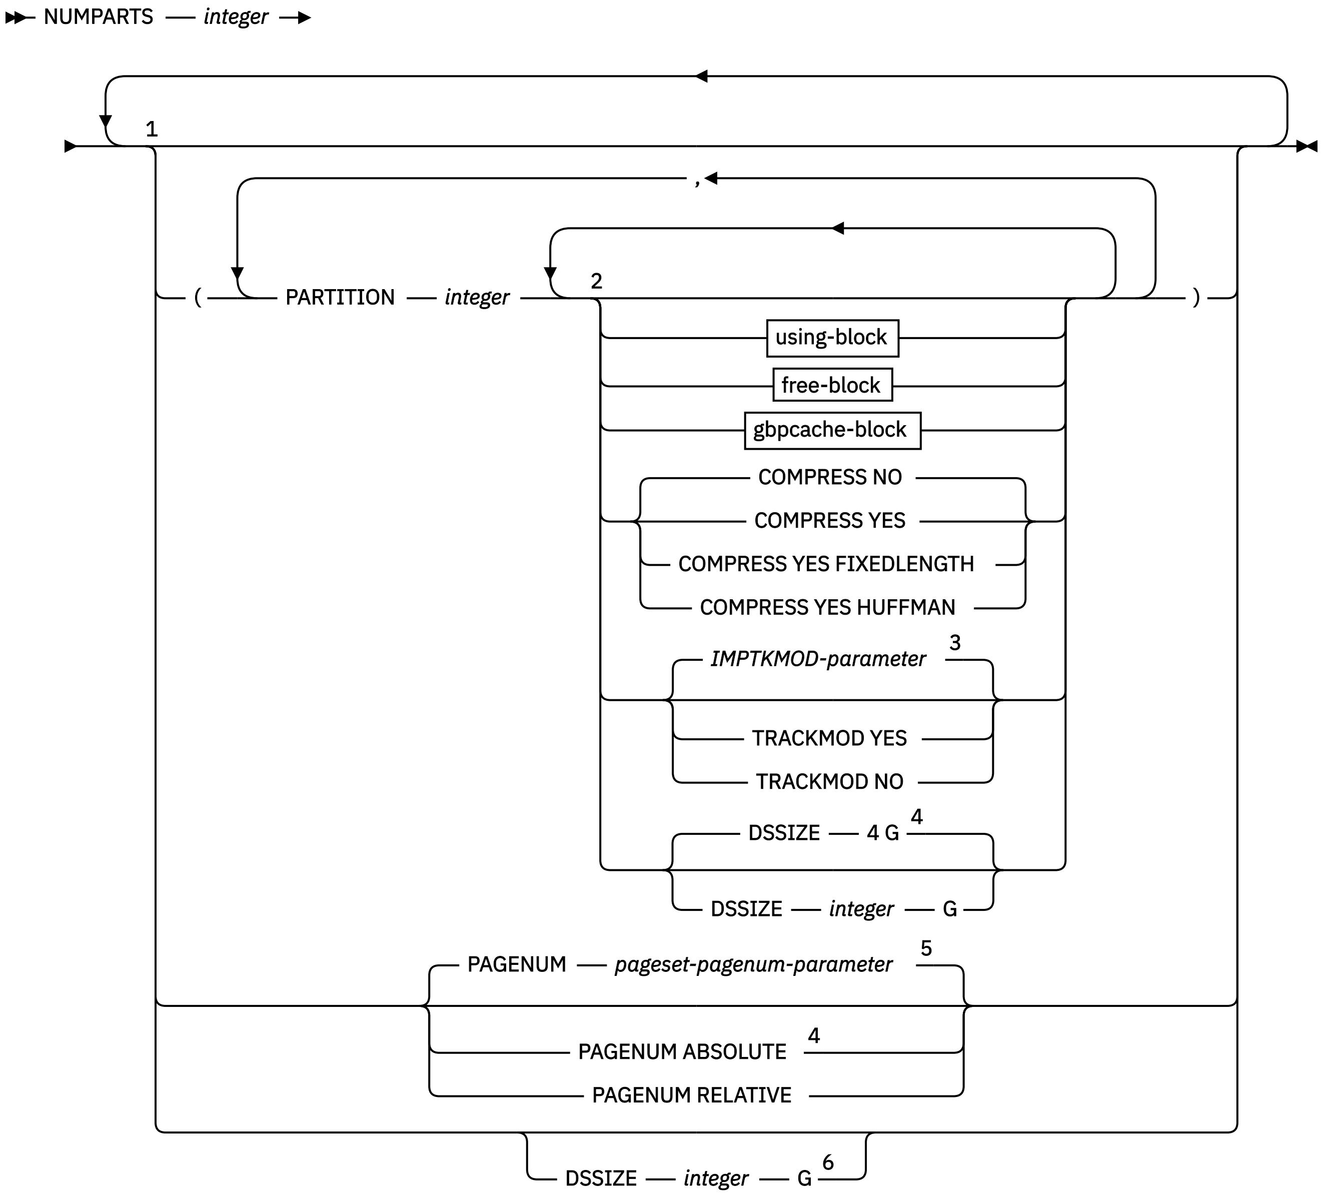


Notes:

[1] The same clause must not be specified more than one time.

[2] Specify a power-of-two integer in the range 1–256, or accept a default based on the MAXPARTITIONS value and the buffer pool page size. See Table 214 on page 1720.

partition-by-range-specification:



Notes:

[1] Group multiple PARTITION clauses. Other clauses must not be specified more than one time.

[2] The same clause must not be specified more than one time.

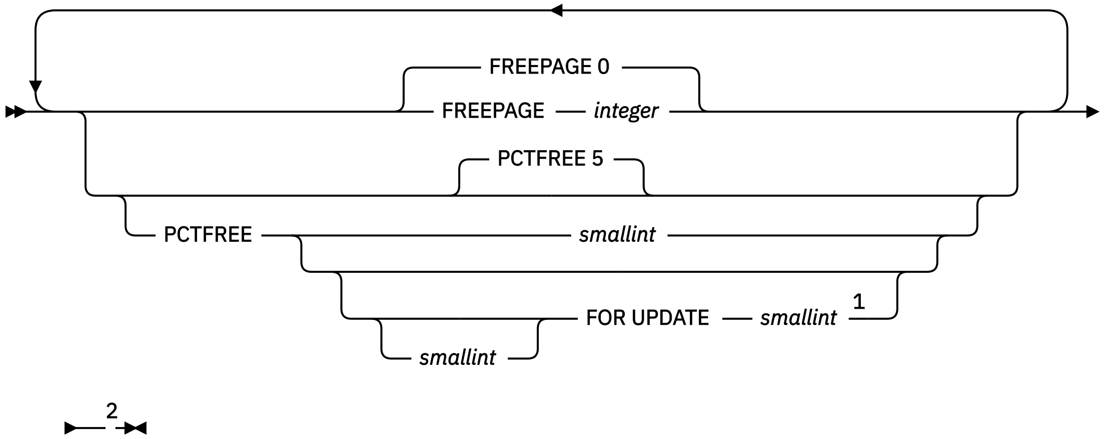
[3] The IMPTKMOD subsystem parameter specified the default TRACKMOD option. For more information, see IMPTKMOD in macro DSN6SYSP (Db2 Installation and Migration).

[4] DSSIZE at the partition level can be specified only if PAGENUM RELATIVE is in effect.

[5] The default for PAGESET_PAGENUM is ABSOLUTE. See PAGE SET PAGE NUMBERING field (PAGESET_PAGENUM subsystem parameter) (Db2 Installation and Migration)

[6] If PAGENUM RELATIVE is used, specify any integer in the range 1–1024, or accept the default value 4G. If absolute page numbers are used, specify a power-of-two integer in the range 1–256, or accept the default value based on the NUMPARTS value and the buffer pool page size. See Table 215 on page 1722.

free-block:

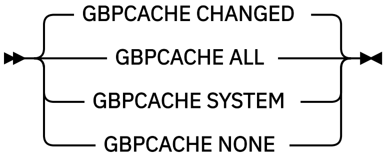


Notes:

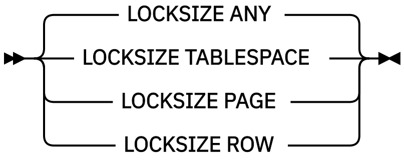
[1] The default PCTFREE value is controlled by the PCTFREE_UPD subsystem parameter.

[2] The same clause must not be specified more than one time.

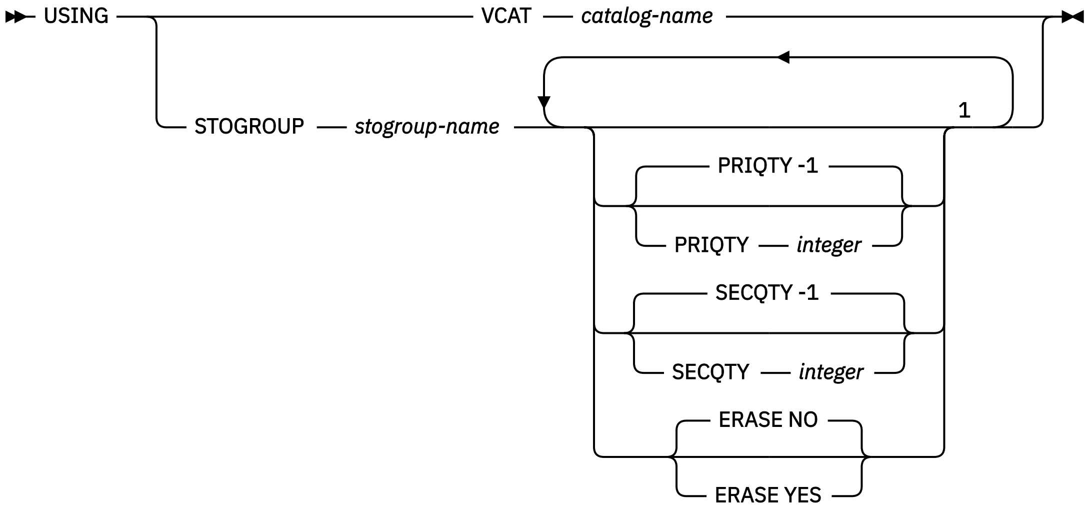
gbpcache-block:



locksize-block:



using-block:



Notes:

[1] The same clause must not be specified more than one time.

Description for CREATE TABLESPACE

table-space-name

Names the table space. The name, qualified with the *database-name* implicitly or explicitly specified by the IN clause, must not identify a table space, index space, or LOB table space that exists at the current server or that exists in the SYSPENDINGOBJECTS catalog table.

A table space that is for declared temporary tables must be in the work file database. PUBLIC implicitly receives the USE privilege (without GRANT authority) on any table space created in the work file database. This implicit privilege is not recorded in the Db2 catalog, and it cannot be revoked.

IN *database-name*

Specifies the database in which the table space is created. *database-name* must identify a database that exists at the current server and must not specify the following:

- DSNDB06
- A TEMP database
- An implicitly created database

If the table space is for declared temporary tables or static scrollable cursors, the name of the work file database must be specified.

FL 504 If *database-name* identifies a work file database, the table space must be a partition-by-growth table space.

DSNDB04 is the default.

BUFFERPOOL *bpname*

Identifies the buffer pool to be used for the table space and determines the page size of the table space. For 4KB, 8KB, 16KB and 32KB page buffer pools, the page sizes are 4 KB, 8 KB, 16 KB, and 32 KB, respectively. The *bpname* must identify an activated buffer pool, and the privilege set must include SYSADM or SYSCTRL authority, or the USE privilege on the buffer pool. If the table space is to be created in a work file database, you can specify neither 8KB buffer pools nor 16KB buffer pools.

If you do not specify the BUFFERPOOL clause, the default buffer pool of the database is used.

See "Naming conventions" on page 79 for more details about *bpname*. See -ALTER BUFFERPOOL (Db2) (Db2 Commands) for a description of active and inactive buffer pools.

The buffer pool page size affects the number of partitions that can be used. For more information, see "Maximum number of partitions and table space size " on page 1731.

partition-by-growth-specification

Specifies the creation of a partition-by-growth table space. FL 504 If partition-by-growth-specification and partition-by-range-specification are both omitted, a partition-by-growth table space is created with MAXPARTITIONS 256. For a summary of clauses that control the table space type to create, see Table space types.

MAXPARTITIONS *integer*

Specifies that the table space is a partition-by-growth table space.

integer specifies the maximum number of partitions to which the table space can grow. *integer* must be in the range of 1–4096, depending on the corresponding value of the DSSIZE clause. The following table shows the maximum value for MAXPARTITIONS in relation to the page size or DSSIZE value for the table space.

Table 213. Maximum MAXPARTITIONS value for a given page size and DSSIZE value

DSSIZE value	4K page size	8K page size	16K page size	32K page size
1–4 G	4096	4096	4096	4096
8 G	2048	4096	4096	4096
16 G	1024	2048	4096	4096
32 G	512	1024	2048	4096
64 G	254	512	1024	2048
128 G	128	256	512	1024
256 G	64	128	256	512

For more information, see "Maximum number of partitions and table space size " on page 1731.

The schema definition for the first partition is always created, and the NUMPARTS value, if specified, controls the number of partition schema definitions to initially create and allocate data sets for. The data sets for additional partitions are not allocated until they are needed.

Although the physical data sets are not defined based on the MAXPARTITIONS value, storage and CPU overhead is possible. If an increase in the number of partitions is expected by using the MAXPARTITONS clause, be aware that specifying a value larger than necessary, such as 4096 (the maximum value), as a default for all partition-by-growth table spaces can cause larger than expected storage requests.

NUMPARTS *integer*

If specified with MAXPARTITIONS, the *integer* value specifies the number of partition schema definitions to initially create. Data sets are also allocated for this many partitions, unless DEFINE NO is specified. *integer* must be a value in the range 1–4096 inclusive and must be less than or equal to the value that is specified for the MAXPARTITIONS clause.

If MAXPARTITIONS is not specified, see the NUMPARTS clause description in "partition-by-range-specification" on page 1721.

DSSIZE *integer* G

Specifies the data set size in *integer* gigabytes for partitions in the table space. Each partition occupies one data set, so the data set size is also the maximum size of the partitions.

When DSSIZE is specified for a partition-by-growth table space, it must be a power-of-two integer in the range 1–256 G (1, 2, 4, 8, 16, 32, 64, 128, or 256).

integer can be separated from G by 0 or more spaces.

FL 504 If the MAXPARTITIONS clause is omitted, the default value for DSSIZE is 4G for any page size. Otherwise, the default value for DSSIZE depends on the buffer pool page size and the specified MAXPARTITIONS value as shown in the following table.

Table 214. DSSIZE defaults for partition-by-growth table spaces

Page size	MAXPARTITIONS value	DSSIZE default value
Any	1–254	4 G
4K	255–4096	4 G
8K	255–4096	8 G
16K	255–4096	16 G
32K	255–4096	32 G

For any DSSIZE value greater than 4 G, the data sets for the table space must be associated with a DFSMS data class that is specified with extended format and extended addressability.

The DSSIZE value affects the number of partitions that can be used. For more information, see "Maximum number of partitions and table space size " on page 1731.

partition-by-range-specification

FL 504 Specifies the creation of a partition-by-range table space. For a summary of clauses that control the table space type to create, see Table space types.

NUMPARTS *integer*

If specified without MAXPARTITIONS, indicates that a partition-by-range table space is created. The *integer* value specifies the number of partitions schema definitions to create. Data sets are also allocated for this many partitions, unless DEFINE NO is also specified. *integer* must be a value in the range 1–4096 inclusive.

If MAXPARTITIONS is also specified, see the NUMPARTS clause description in "partition-by-growth-specification" on page 1719.

For table spaces created with PAGENUM RELATIVE, the maximum number of partitions is 4096. For table spaces with PAGENUM ABSOLUTE, the maximum number of partitions depends on the buffer pool page size and DSSIZE. The total table space size depends on the number of partitions and DSSIZE. For more information, see "Maximum number of partitions and table space size " on page 1731.

PARTITION *integer*

Specifies the partition to which the following partition-level clauses apply. *integer* can range from 1 to the number of partitions given by NUMPARTS.

You can specify the PARTITION clause as many times as needed. If you use the same partition number more than once, only the last specification for that partition is used.

DSSIZE *integer* G

When specified in a PARTITION clause for a partition-by-range table space, which is supported only when PAGENUM RELATIVE is specified for the table space, specifies the data set size in *integer* gigabytes for the partition identified by PARTITION *integer*. Each partition occupies one data set, so the data set size is also the maximum size of the partition. The `integer` G value can be any value 1–1024G. The default value is 4G.

integer can be separated from G by 0 or more spaces.

PAGENUM

Identifies the type of page numbering that is used when you create a partition-by-range table space. The PAGESET_PAGENUM subsystem parameter specifies the default PAGENUM value. The default for PAGESET_PAGENUM is ABSOLUTE. See PAGE SET PAGE NUMBERING field (PAGESET_PAGENUM subsystem parameter) (Db2 Installation and Migration).

RELATIVE

Indicates that internal page numbering is kept as a 4-byte value without a partition number. The page number is a relative page from the start of the partition, and the partition number is kept only in the header page. When PAGENUM RELATIVE is specified, the data sets for the table space must be associated with a DFSMS data class that is specified with extended format and extended addressability.

ABSOLUTE

Indicates that internal page numbering is kept as a 4-byte value that includes a partition number and page number. Distinguishing which bits represent the partition and which represent the page number requires a shift value. The shift value is LOG base 2 (*DSSIZE*/(*page-size*)).

DSSIZE *integer* G

Specifies the data set size in *integer* gigabytes for partitions in the table space. Each partition occupies one data set, so the data set size is also the maximum size of the partitions.

When DSSIZE is specified at the table-space level for a partition-by-range table space with PAGENUM RELATIVE, it can specify any integer value in the range 1–1024 G, and the default value is 4 G.

integer can be separated from G by 0 or more spaces.

If absolute page numbers are used, the DSSIZE value must be a power-of-two integer in the range 1–256 G (1, 2, 4, 8, 16, 32, 64, 128, or 256), and the default value depends on the NUMPARTS value and the buffer pool page size, as shown in the following table.

integer can be separated from G by 0 or more spaces.

Table 215. DSSIZE defaults for partition-by-range table spaces with absolute page numbering

Page size	NUMPARTS value	DSSIZE default value
Any	1–16	4 G
Any	17–32	2 G
Any	33–64	1 G
Any	65–254	4 G
4K	255–4096	4 G
8K	255–4096	8 G
16K	255–4096	16 G
32K	255–4096	32 G

The DSSIZE value affects the number of partitions that can be used. For more information , see "Maximum number of partitions and table space size " on page 1731.

For any DSSIZE value greater than 4 G, the data sets for the table space must be associated with a DFSMS data class that is specified with extended format and extended addressability.

SEGSIZE *integer*

Specifies the size in pages for each segment of the table space. The *integer* value must be a multiple of 4, in the range 4–64.

If SEGSIZE is not specified, the default SEGSIZE value is controlled by the DPSEGSZ subsystem parameter. SEGSIZE 32 is used if the DPSEGSZ value is 0. Otherwise the SEGSIZE value is the DPSEGSZ value.

However, the DPSEGSZ value has no effect for a table space created in a work file database, and SEGSIZE 16 is used.

CCSID *encoding-scheme*

Specifies the encoding scheme for a table in the table space.

If you do not specify a CCSID when it is allowed, the default is the encoding scheme of the database in which the table space resides, except for table spaces in database DSNDB04; for table spaces in DSNDB04, the default is the value of field DEF ENCODING SCHEME on installation panel DSNTIPF.

ASCII

Specifies that the data is encoded using ASCII CCSIDs. If the database in which the table space is to reside is already defined as ASCII, the ASCII CCSIDs associated with that database are used. Otherwise, the default ASCII CCSIDs of the server are used.

EBCDIC

Specifies that the data is encoded using EBCDIC CCSIDs. If the database in which the table space is to reside is already defined as EBCDIC, the EBCDIC CCSIDs associated with that database are used. Otherwise, the default EBCDIC CCSIDs of the server are used.

An EBCDIC table in the table space can include Unicode columns.

UNICODE

Specifies that the data is encoded using the UNICODE CCSIDs of the server.

Usually, each encoding scheme requires only a single CCSID. Additional CCSIDs are needed when mixed, graphic, or Unicode data is used.

All data stored within a table space must use the same encoding scheme unless the table space is in a work file database.

CLOSE

When the limit on the number of open data sets is reached, specifies the priority in which data sets are closed.

YES

Eligible for closing before CLOSE NO data sets. CLOSE YES is the default value, unless the table space is in a work file database.

NO

Eligible for closing after all eligible CLOSE YES data sets are closed.

COMPRESS

Specifies whether data compression applies to the rows of the table space or a partition in the table space.

For partitioned table spaces, the COMPRESS attribute for a partition is determined from the first of the following conditions that apply to the CREATE statement:

- The value specified in the COMPRESS clause in the PARTITION clause for that partition
- The value specified in the COMPRESS clause that is not in any PARTITION clause
- Otherwise, COMPRESS NO is the default for the partition

For more information about data compression, see Compressing your data (Db2 Performance).

YES

FL 509 Specifies that data compression is used for the table space or partition. The rows are not compressed until the LOAD or REORG utility is run on a table in the table space or on a partition, or until the total row data size reaches the compression data threshold while an insert operation is performed.

If a keyword for the compression algorithm is not specified, the default compression algorithm is used. The data compression algorithm is determined by the TS_COMPRESSION_TYPE subsystem parameter.

If a keyword for the compression algorithm is specified:

- LOB table spaces that are implicitly created for LOB columns in this table space are defined as if COMPRESS YES has been specified without a compression algorithm. LOB compression is managed by zEDC hardware if available.
- XML table spaces that are implicitly created for XML columns in this table space inherit the compression attribute.

FIXEDLENGTH

FL 509 Specified the fixed-length data compression algorithm.

HUFFMAN

FL 509 Specifies the Huffman data compression algorithm. See Using Huffman compression to compress your data (Db2 Performance) for requirements to enable Huffman compression.

NO

Specifies no data compression for the table space or partition. Inserted rows are not compressed.

DEFINE

Specifies when the underlying data sets for the table space are physically allocated.

YES

The data sets are created when the table space is created (the CREATE TABLESPACE statement is executed). YES is the default.

NO

The data sets are not created until data is inserted into the table space. DEFINE NO is applicable only for Db2-managed data sets (USING STOGROUP is specified). DEFINE NO is ignored for user-managed data sets (USING VCAT is specified). Db2 uses the SPACE column in catalog table SYSTABLEPART to record the status of the data sets (undefined or allocated).

DEFINE NO is not recommended if you intend to use any tools outside of Db2 to manipulate data, such as to load data, because data sets might then exist when Db2 does not expect them to exist. When Db2 encounters this inconsistent state, applications will receive an error.

For table spaces that are created with DEFINE NO, point-in-time recover will not work before data sets exist and before a recovery copy exists.

free-block

Specifies how to leave free space when the table space is loaded or reorganized.

FREEPAGE *integer*

Specifies how often to leave a page of free space when the table space or partition is loaded or reorganized. You must specify an integer in the range 0–255. If you specify 0, no pages are left as free space. Otherwise, one free page is left after every *n* pages, where *n* is the specified *integer* value. The number of pages left must be less than the segment size. If the integer you specify is not less than the segment size, *n* is one less than the segment size.

The default is FREEPAGE 0, leaving no free pages.

For more information, see:

Reserving free space in table spaces (Db2 Performance)
Reserving free spaces for indexes (Db2 Performance)

PCTFREE *smallint*

Indicates what percentage of each page to leave as free space when the table is loaded or reorganized. *smallint* is in the range 0–99. The first record on each page is loaded without restriction. When additional records are loaded, at least *smallint* percent of free space is left on each page.

The default is PCTFREE 5, which means that 5% of the space on each page is reserved as free space.

FOR UPDATE *smallint*

Specifies the percentage of space to reserve as free space on each page, for use by subsequent update operations. The *smallint* value is an integer in the range -1 to 99. FOR UPDATE -1 specifies that 5% of free space is reserved initially, and the amount of free space is calculated automatically based on certain real-time statistics values. The first record on each page is always loaded without restriction.

An update operation might use more space, if it is available, than is specified by the PCTFREE or PCTFREE FOR UPDATE options.

The default FOR UPDATE value is controlled by the PCTFREE_UPD subsystem parameter.

The value is recorded in the PCTFREE_UPD column of the SYSIBM.SYSTABLEPART catalog table.

The sum of the values for PCTFREE *smallint* and FOR UPDATE *smallint* must be less than or equal to 99.

For more information, see:

Reserving free space in table spaces (Db2 Performance)
Reserving free spaces for indexes (Db2 Performance)

gbpcache-block

In a data sharing environment, specifies which pages of the table space or partition are written to the group buffer pool. In a non-data-sharing environment, you can specify GBPCACHE for a table space, but it is ignored. However, do not specify GBPCACHE for a table space in a work file database in either environment (data sharing or non-data-sharing).

GBPCACHE

Specifies pages of the table space or partition are written to the group buffer pool.

CHANGED

When there is inter-Db2 R/W interest on the table space or partition, updated pages are written to the group buffer pool. When there is no inter-Db2 R/W interest, the group buffer pool is not used. Inter-Db2 R/W interest exists when more than one member in the data sharing group has the table space or partition open, and at least one member has it open for update. GBPCACHE CHANGED is the default.

If the table space is in a group buffer pool that is defined to be used only for cross-invalidation (GBPCACHE NO), CHANGED is ignored and no pages are cached to the group buffer pool.

ALL

Indicates that pages are to be cached in the group buffer pool as they are read in from DASD.

Exception: In the case of a single updating Db2 when no other DB2s have any interest in the page set, no pages are cached in the group buffer pool.

If the table space is in a group buffer pool that is defined to be used only for cross-invalidation (GBPCACHE NO), ALL is ignored and no pages are cached to the group buffer pool.

NONE

Indicates that no pages are to be cached to the group buffer pool. Db2 uses the group buffer pool only for cross-invalidation.

If you specify NONE, the table space or partition must not be in recover pending status and must be in the stopped state when the CREATE TABLESPACE statement is executed.

The value of GBPCACHE for a particular partition is determined by the first of these choices that applies:

1. The GBPCACHE specified in the PARTITION clause for the partition. Do not use more than one *gbpcache-block* in any PARTITION clause.
2. The value specified in a *gbpcache-block* for the table space.
3. The default value CHANGED.

INSERT ALGORITHM *level*

Specifies the algorithm that is used when rows are inserted into tables in this table space. The insert algorithm level is used only where applicable when MEMBER CLUSTER is specified. The default value is 0.

0

Specifies that the insert algorithm level is determined by the DEFAULT_INSERT_ALGORITHM subsystem parameter at the time a row is inserted.

1

Specifies that the basic insert algorithm is used.

2

Specifies that insert algorithm 2 is used.

LOCKMAX

Specifies the maximum number of page or row locks an application process can hold simultaneously in the table space. If a program requests more than that number, locks are escalated. The page or row locks are released and the intent lock on the table space is promoted to S or X mode.

integer

Specifies the number of locks allowed before escalating, in the range 0–2147483647.

Zero (0) indicates that the number of locks on the table or table space are not counted and escalation does not occur.

SYSTEM

FL 507 Specifies that Db2 determines the maximum number of locks that a program can hold simultaneously in the table space from the SYSIBMADM.MAX_LOCKS_PER_TABLESPACE built-in global variable.

For more information see "MAX_LOCKS_PER_TABLESPACE" on page 331.

The following table summarizes the results of specifying a LOCKSIZE value while omitting LOCKMAX.

LOCKSIZE	Resultant LOCKMAX
ANY	SYSTEM
TABLESPACE, PAGE, ROW	0

If the lock size is TABLESPACE, LOCKMAX must be omitted, or its operand must be 0.

locksize-block

Specifies the size of locks used for the table space, and thresholds for lock escalation in some cases.

LOCKSIZE

Specifies the size of locks used within the table space and, in some cases, also the threshold at which lock escalation occurs.

ANY

Specifies that Db2 can use any lock size.

FL 507In most cases, Db2 uses LOCKSIZE PAGE LOCKMAX SYSTEM. However, when the number of locks acquired for the table space exceeds the maximum number of locks allowed for a table space (the value of the SYSIBMADM.MAX_LOCKS_PER_TABLESPACE built-in global variable), the page locks are released and partition level locks are used. For more information see "MAX_LOCKS_PER_TABLESPACE" on page 331.

TABLESPACE

Specifies table space locks.

PAGE

Specifies page locks.

ROW

Specifies row locks.

LOGGED or NOT LOGGED

Specifies whether changes that are made to the data in the specified table space are recorded in the log. LOGGED and NOT LOGGED cannot be specified for table spaces in database DSNDB06, which contains the Db2 catalog. This setting applies to the table that is created in the specified table space and to all indexes of the table. XML table spaces and their indexes inherit the logging attribute from the associated base table space. Auxiliary indexes also inherit the logging attribute from the associated base table space.

LOGGED

Specifies that changes that are made to the data in the specified table space are recorded in the log.

LOGGED is the default.

NOT LOGGED

Specifies that changes that are made to data in the specified table space are not recorded in the log.

NOT LOGGED prevents undo and redo information from being recorded in the log; however, control information for the specified table space will continue to be recorded in the log.

MAXROWS *integer*

Specifies the maximum number of rows that Db2 will consider placing on each data page. The integer can range from 1 through 255. This value is considered for insert operations, LOAD, and REORG. For LOAD and REORG, the PCTFREE specification is considered before MAXROWS; therefore, fewer rows might be stored than the value you specify for MAXROWS.

If you do not specify MAXROWS, the default number of rows is 255.

MEMBER CLUSTER

Specifies that data inserted by an insert operation is not clustered by the implicit clustering index (the first index) or the explicit clustering index. Instead, Db2 chooses where to locate the data in the table space based on available space.

TRACKMOD

Specifies whether Db2 tracks modified pages in the space map pages.

YES

Db2 tracks changed pages in the space map pages to improve the performance of incremental image copy.

NO

Db2 does not track changed pages in the space map pages. It uses the LRSN value in each page to determine whether a page has been changed.

The TRACKMOD clause can be specified for each partition, or for the table space. If the TRACKMOD value is not specified for a partition, the TRACKMOD value for the table space is used. If the TRACKMOD value for the table space is not specified, the default value specified by the IMPTKMOD subsystem parameter is used. For more information, see IMPTKMOD in macro DSN6SYSP (Db2 Installation and Migration).

using-block

Specifies whether Db2 or the user manages the data sets for the table space or its partitions. The USING clause can be specified for each partition or for the table space. If the USING clause is not specified for a partition, the USING clause specified for the table space is used. If the USING clause is not specified for the table space, the storage group of the database is used, with the normal defaults for PRIQTY, SECQTY, and ERASE. If the USING clause for the table space is omitted, the default storage group for database must exist.

VCAT *catalog-name*

Indicates that the data set for the partition is managed by the user using the naming conventions set forth in Data set naming conventions (Db2 Administration Guide). As was true for the nonpartitioned case, *catalog-name* identifies the catalog for the data set and supplies the first-level qualifier for the data set name.

One or more Db2 subsystems could share integrated catalog facility catalogs with the current server. To avoid the chance of having one of those subsystems attempt to assign the same name to different data sets, select a value for *catalog-name* that is not used by the other Db2 subsystems.

USING VCAT must not be specified for a partition-by-growth table space.

Db2 assumes one and only one data set for each partition.

STOGROUP *stogroup-name*

Indicates that Db2 will create a data set for the partition with the aid of a storage group named *stogroup-name*. The data set is defined during the execution of this statement. Db2 assumes one and only one data set for each partition.

The *stogroup-name* must identify a storage group that exists at the current server and the privilege set must include SYSADM authority, SYSCTRL authority, or the USE privilege for the storage group. The integrated catalog facility catalog used for the storage group must not contain an entry for that data set.

When USING STOGROUP is specified for a partition, the defaults for PRIQTY, SECQTY, and ERASE are the values specified in the USING STOGROUP clause that is not in any PARTITION clause. If that USING STOGROUP clause is not specified, the defaults are those specified in the description of PRIQTY, SECQTY, and ERASE.

PRIQTY *integer*

Specifies the minimum primary space allocation for a Db2-managed data set. *integer* must be a positive integer, or -1. In general, when you specify PRIQTY with a positive integer value, the primary space allocation is at least *n* kilobytes, where *n* is the value of *integer*. However, the following exceptions exist:

- For 4KB page sizes, if *integer* is greater than 0 and less than 200, *n* is 200.
- For 8KB page sizes, if *integer* is greater than 0 and less than 400, *n* is 400.
- For 16KB page sizes, if *integer* is greater than 0 and less than 800, *n* is 800.
- For 32KB page sizes, if *integer* is greater than 0 and less than 1600, *n* is 1600.
- For any page size, if *integer* is greater than 67108864, *n* is 67108864.

If you do not specify PRIQTY, or specify PRIQTY with a value of -1, Db2 uses a default value for the primary space allocation; for information on how Db2 determines the default value, see Rules for primary and secondary space allocation (Introduction to Db2 for z/OS).

If you specify PRIQTY, and do not specify a value of -1, Db2 specifies the primary space allocation to access method services using the smallest multiple of *p* KB not less than *n*, where *p* is the page size of the table space. The allocated space can be greater than the amount of space requested by Db2. For example, it could be the smallest number of tracks that will accommodate the request. The amount of storage space requested must be available on some volume in the storage group based on VSAM space allocation restrictions. Otherwise, the primary space allocation will fail. To more closely estimate the actual amount of storage, see DEFINE CLUSTER command (DFSMS Access Method Services for Catalogs).

Executing this statement causes only one data set to be created. However, you might have more data than this one data set can hold. Db2 automatically defines more data sets when they are needed. Regardless of the value in PRIQTY, when a data set reaches its maximum size, Db2 creates a new one. To enable a data set to reach its maximum size without running out of extents, it is recommended that you allow Db2 to automatically choose the value of the secondary space allocations for extents.

If you do choose to explicitly specify SECQTY, to avoid wasting space, use the following formula to make sure that PRIQTY and its associated secondary extent values do not exceed the maximum size of the data set:

```
PRIQTY + (number of extents * SECQTY) <= DSSIZE (implicit or explicit)
```

SECQTY *integer*

Specifies the minimum secondary space allocation for a Db2-managed data set. *integer* must be a positive integer, 0, or -1. If you do not specify SECQTY, or specify SECQTY with a value of -1, Db2 uses a formula to determine a value. For information on the actual value that is used for secondary space allocation, whether you specify a value or not, see Rules for primary and secondary space allocation (Introduction to Db2 for z/OS).

If you specify SECQTY, and do not specify a value of -1, Db2 specifies the secondary space allocation to access method services using the smallest multiple of *p* KB not less than *integer*, where *p* is the page size of the table space. The allocated space can be greater than the amount of space requested by Db2. For example, it could be the smallest number of tracks that will accommodate the request. To more closely estimate the actual amount of storage, see DEFINE CLUSTER command (DFSMS Access Method Services for Catalogs).

ERASE

Indicates whether the Db2-managed data sets for the table space are to be erased when they are deleted during the execution of a utility or an SQL statement that drops the table space.

NO

Does not erase the data sets. Operations involving data set deletion will perform better than ERASE YES. However, the data is still accessible, though not through Db2. This is the default.

YES

Erases the data sets. As a security measure, Db2 overwrites all data in the data sets with zeros before they are deleted.

Notes for CREATE TABLESPACE

Table space types

FL 504 In application compatibility level V12R1M504 and higher, the type of partitioning of the resulting table space depends on whether the CREATE TABLESPACE statement specifies the MAXPARTITIONS clause and NUMPARTS clauses, as shown in the following table. If the CREATE TABLESPACE statement specifies the NUMPARTS clause but no MAXPARTITIONS clause, the result is a partition-by-range table space table space. Otherwise, the result is a partition-by-growth table space.

However, below application compatibility level V12R1M504, deprecated table space types including segmented (non-UTS) and partitioned (non-UTS) table spaces can be created. In such cases, the type of table space created depends on the SEGSIZE, MAXPARTITIONS, and NUMPARTS clauses that the CREATE TABLESPACE statement specifies.

Table 216. CREATE TABLESPACE clauses for specifying table space types, by application compatibility level.

Table space type	APPLCOMPAT(V12R1M504) and higher	APPLCOMPAT(V12R1M503) and lower
Partition-by-growth	Any of the following combinations: - MAXPARTITIONS and NUMPARTS - MAXPARTITIONS - Omit both	Any of the following combinations: - MAXPARTITIONS and NUMPARTS - MAXPARTITIONS and SEGSIZE *n*“1” on page 1730 - MAXPARTITIONS
Partition-by-range	NUMPARTS only	NUMPARTS and SEGSIZE *n*“1” on page 1730
Segmented (non-UTS)	Not supported“2” on page 1730	One of the following combinations: - SEGSIZE *n*“1” on page 1730 - Omit MAXPARTITIONS, NUMPARTS, and SEGSIZE
Partitioned (non-UTS)	Not supported“2” on page 1730	NUMPARTS and SEGSIZE 0

Table 216. CREATE TABLESPACE clauses for specifying table space types, by application compatibility level. (continued)

Table space type	APPLCOMPAT(V12R1M504) and higher	APPLCOMPAT(V12R1M503) and lower

Notes:

1. Where *n* is a non-zero value. The DPSEGSZ subsystem parameter determines the default value. For more information, see DEFAULT PARTITION SEGSIZE field (DPSEGSZ subsystem parameter) (Db2 Installation and Migration).
2. FL 504 Non-UTS table spaces for base tables are deprecated. CREATE TABLESPACE statements that run at application compatibility level V12R1M504 or higher always create a partition-by-growth or partition-by-range table space, and CREATE TABLE statements that specify a non-UTS table space (including existing multi-table segmented table spaces) return an error. However, you can use a lower application compatibility level to create table spaces of the deprecated types if needed, such as for recovery situations. For instructions, see Creating non-UTS table spaces (deprecated) (Db2 Administration Guide).

DSSIZE value greater than 4 G

For any DSSIZE value greater than 4 G, the data sets for the table space must be associated with a DFSMS data class that is specified with extended format and extended addressability.

FL 504 XML table spaces

If a partition-by-growth table space contains an XML column, the corresponding XML table space is a partition-by-growth table space that grows independently of the base table space. If a partition-by-range table space contains an XML column, the corresponding XML table space is a partition-by-range table space that is data partitioned. That is, it is partitioned according to the partitioning scheme of the base table data.

Applications that use currently committed access with table spaces that specify LOCKSIZE PAGE

To ensure that readers of data in a table space that is defined with LOCKSIZE PAGE can always access currently committed data, set MAXROWS to 8 or less. If MAXROWS is greater than 8, readers might need to wait for insert or delete operations on tables in the table space to commit before the readers can access rows in the tables.

For more information, see Accessing currently committed data to avoid lock contention (Db2 Performance).

Table spaces in a work file database

FL 504A table space in a work file database is always a partition-by-growth table space.

The following restrictions apply to table spaces created in a work file database:

- They can be created for another member only if both the executing Db2 subsystem and the other member can access the work file data sets. That is required whether the data sets are user-managed or in a Db2 storage group.
- They cannot use 8 KB or 16 KB page sizes. (The buffer pool in which you define the table space determines the page size. For example, a table space that is defined in a 4 KB buffer pool has 4 KB page sizes.)
- When you create a table space in a work file database, the following clauses are not allowed:

  CCSID
  COMPRESS
  CLOSE YES
  DEFINE NO
  FREEPAGE
  GBPCACHE
  LARGE
  LOCKPART
  LOCKSIZE

LOGGED
MAXROWS
MEMBER CLUSTER
NOT LOGGED
PAGENUM
PCTFREE
SEGSIZE (SEGSIZE 16 is always used)
TRACKMOD

Table spaces for declared temporary tables

Declared temporary tables and sensitive static scrollable cursors must reside in table spaces in the work file database. At least one table space with a 32 KB page size must exist in the work file database before a declared temporary table can be defined and used or before sensitive static scrollable cursors are opened.

Table spaces in the work file database are shared by work files, created and declared global temporary tables and sensitive static scrollable cursor result tables. You cannot specify which table space is to be used for any specific object.

Table space row formats

All newly created table spaces use re-ordered row format.

Rules for primary and secondary space allocation

You can specify the primary and secondary space allocation or let Db2 choose them. Having Db2 choose the values, especially the secondary space quantity, increases the possibility of reaching the maximum data set size before running out of extents. For more information, see Rules for primary and secondary space allocation (Introduction to Db2 for z/OS).

Maximum number of partitions and table space size

For partition-by-range table spaces created with relative page numbering, the maximum number of partitions is 4096. For partition-by-range table spaces with absolute page numbering or partition-by growth table spaces, the following tables show how the maximum number of partitions and the total table space size depend on the buffer pool page size and DSSIZE value, with 5-byte extended addressability (EA) storage."1" on page 1733

4 KB page size

Table 217. Maximum number of partitions and table space size by DSSIZE, with 4 KB page size

DSSIZE	Maximum number of partitions	Total table space size
1G	4096	4 TB
2G	4096	8 TB
4G	4096	16 TB
8G	2048	16 TB
16G	1024	16 TB
32G	512	16 TB
64G	256	16 TB
128G	128	16 TB
256G	64	16 TB

8 KB page size

Table 218. Maximum number of partitions and table space size by DSSIZE, with 8 KB page size

DSSIZE	Maximum number of partitions	Total table space size
1G	4096	4TB
2G	4096	8TB
4G	4096	16TB
8G	4096	32TB
16G	2048	32TB
32G	1024	32TB
64G	512	32TB
128G	256	32TB
256G	128	32TB

16 KB page size

Table 219. Maximum number of partitions and table space size by DSSIZE, with 16 KB page size

DSSIZE	Maximum number of partitions	Total table space size
1G	4096	4 TB
2G	4096	8 TB
4G	4096	16 TB
8G	4096	32 TB
16G	4096	64 TB
32G	2048	64 TB
64G	1024	64 TB
128G	512	64 TB
256G	256	64 TB

32 KB page size

Table 220. Maximum number of partitions and table space size by DSSIZE, with 32 KB page size

DSSIZE	Maximum number of partitions	Total table space size
1G	4096	4 TB
2G	4096	8 TB
4G	4096	16 TB
8G	4096	32 TB
16G	4096	64 TB
32G	4096	128 TB
64G	2048	128 TB

Table 220. Maximum number of partitions and table space size by DSSIZE, with 32 KB page size (continued)

DSSIZE	Maximum number of partitions	Total table space size
128G	1024	128 TB
256G	512	128 TB

Notes:

1. For 5-byte non-EA storage, the maximum values for 4 KB page size are DSSIZE 4 G, 4096 partitions, and 16 TB for total table space.

Alternative syntax and synonyms

For compatibility with previous Db2 releases or function levels, the following keywords are supported:

- You can specify the LOCKPART clause, but it has no effect. Db2 treats all table spaces as if they were defined as LOCKPART YES. LOCKPART YES specifies the use of selective partition locking. When all the conditions for selective partition locking are met, Db2 locks only the partitions that are accessed. When the conditions for selective partition locking are not met, Db2 locks every partition of the table space.

  LOCKSIZE TABLESPACE and LOCKPART YES are mutually exclusive.
- When creating a partitioned table space, you can specify PART as a synonym for PARTITION.
- When specifying the logging attributes for a table space, you can specify LOG YES as a synonym for LOGGED, and you can specify LOG NO as a synonym for NOT LOGGED.
- DSSIZE is the preferred clause for specifying the partition size, however you can specify the CREATE LARGE TABLESPACE when creating partitioned table spaces.
- FL 504 If neither MAXPARTITIONS nor NUMPARTS is specified, you can specify LOCKSIZE TABLE as a synonym for LOCKSIZE TABLESPACE.

Although these keywords are supported as alternatives, they are not the preferred syntax.

Examples for CREATE TABLESPACE

Example 1: using a storage group for a partition-by-growth table space

Create a table space DSN8S12D in database DSN8D12A. Let Db2 define the data sets, using storage group DSN8G120. The primary space allocation is 52 kilobytes; the secondary, 20 kilobytes. The data sets need not be erased before they are deleted.

Locking on tables in the space is to take place at the page level. Associate the table space with buffer pool BP1. The data sets can be closed when no one is using the table space.

```
CREATE TABLESPACE DSN8S12D
  IN DSN8D12A
  USING STOGROUP DSN8G120
    PRIQTY 52
    SECQTY 20
    ERASE NO
  LOCKSIZE PAGE
  BUFFERPOOL BP1
  CLOSE YES;
```

For the above example, the underlying data sets for the table space will be created immediately, which is the default (DEFINE YES). If you want to defer the creation of the data sets until data is first inserted into the table space, you would specify DEFINE NO instead of accepting the default behavior.

FL 504Because the CREATE TABLESPACE statement omits the NUMPARTS and MAXPARTITIONS clauses, the resulting table spaces is a partition-by-growth table space.

Example 2: partition options for a partition-by-range table space

Assume that a large query database application uses a table space to record historical sales data for marketing statistics. Create large table space SALESHX in database DSN8D12A for the application. Create it with 82 partitions, specifying that the data in partitions 80 through 82 is to be compressed.

Let Db2 define the data sets for all the partitions in the table space, using storage group DSN8G120. For each data set, the primary space allocation is 4000 kilobytes, and the secondary space allocation is 130 kilobytes. Except for the data set for partition 82, the data sets do not need to be erased before they are deleted.

Locking on the table is to take place at the page level. There can only be one table in a partitioned table space. Associate the table space with buffer pool BP1. The data sets cannot be closed when no one is using the table space. If there are no CLOSE YES data sets to close, Db2 might close the CLOSE NO data sets when the DSMAX is reached.

```
CREATE TABLESPACE SALESHX
  IN DSN8D12A
  USING STOGROUP DSN8G120
    PRIQTY 4000
    SECQTY 130
    ERASE NO
  NUMPARTS 82
  (PARTITION 80
    COMPRESS YES,
   PARTITION 81
    COMPRESS YES,
   PARTITION 82
    COMPRESS YES
    USING STOGROUP DSN8G120
    ERASE YES)
  LOCKSIZE PAGE
  BUFFERPOOL BP1
  CLOSE NO;
```

FL 504 Because the CREATE TABLESPACE statement specifies a NUMPARTS clause and no MAXPARTITIONS clause, a partition-by-range table space is created.

Example 3: partition-by-range table space

The following example creates a partition-by-range table space, TS1, in database DSN8D12A using storage group DSN8G120. The table space has 16 pages per segment and has 55 partitions. It specifies LOCKSIZE ANY.

```
CREATE TABLESPACE TS1
  IN DSN8D12A
  USING STOGROUP DSN8G120
  NUMPARTS 55
  SEGSIZE 16
  LOCKSIZE ANY;
```

Example 4: partition-by-range table space

The following example creates a partition-by-range table space, TS2, in database DSN8D12A using storage group DSN8G120. The table space has 64 pages per segment and has seven defer-defined partitions, where every other partition is compressed.

```
CREATE TABLESPACE TS2
  IN DSN8D12A
  USING STOGROUP DSN8G120
  NUMPARTS 7
  (
   PARTITION 1 COMPRESS YES,
   PARTITION 3 COMPRESS YES,
   PARTITION 5 COMPRESS YES,
   PARTITION 7 COMPRESS YES
  )
  SEGSIZE 64
  DEFINE NO;
```

Example 5: partition-by-growth table space

The following example creates a partition-by-growth table space that has a maximum size of 2 GB for each partition, four pages per segment with a maximum of 24 partitions for the table space.

```
CREATE TABLESPACE TS01TS IN TS01DB USING STOGROUP SG1
  DSSIZE 2G
  MAXPARTITIONS 24
  LOCKSIZE ANY
  SEGSIZE 4;
```

Implementing Db2 table spaces (Db2 Administration Guide)

CREATE TRIGGER (advanced)

The CREATE TRIGGER (advanced) statement defines an advanced trigger in a schema and builds a trigger package at the current server. Each time that the trigger activates, the trigger package executes one or more times.

For a description of the differences between basic and advanced triggers, see Triggers (Introduction to Db2 for z/OS).

Invocation for CREATE TRIGGER (advanced)

This statement can be issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES RUN behavior is in effect. For more information, see "Authorization IDs and dynamic SQL" on page 94.

Authorization for CREATE TRIGGER (advanced)

To create a new trigger in the implicit or explicit schema, the privilege set that is defined below must include at least one of the following:

- The CREATEIN privilege on the schema
- System DBADM authority
- SYSCTRL authority
- SYSADM authority
- Installation SYSOPR authority (when the current SQLID of the process is set to SYSINSTL)

To replace a trigger, the privilege set that is defined below must include at least one of the following:

- Ownership of the trigger
- DATAACCESS authority and DROPIN and CREATEIN privilege on the schema
- SYSADM authority

Additionally, to create or replace an existing trigger for a table, the privilege set that is defined below must include at least one of the following:

- The TRIGGER privilege on the table on which the trigger is defined
- The ALTER privilege on the table on which the trigger is defined
- DBADM authority on the database that contains the table
- System DBADM authority
- SYSCTRL authority

- SYSADM authority
- Installation SYSOPR authority (when the current SQLID of the process is set to SYSINSTL)

If the database is implicitly created, the database privileges must be on the implicit database or on DSNDB04.

Additionally, to create or replace an existing trigger for a view, the privilege set that is defined below must include at least one of the following:

- Ownership of the view on which the trigger is defined
- System DBADM authority
- SYSCTRL authority
- SYSADM authority

To add or replace a version of an existing trigger, the privilege set that is defined below must include at least one of the following:

- Ownership of the trigger
- DATAACCESS authority and ALTERIN on the schema
- SYSADM authority

Additional privileges might be needed for the following:

- To execute the body of the trigger, the owner of the trigger must have SYSADM authority, or each of the following:
  - The SELECT privilege on the table on which the trigger is defined
  - The SELECT privilege on any table or view that is referenced in the *search-condition* of the *triggered-action*
  - The privileges that are required to execute the statements in *SQL-trigger-body*
- If the SECURED option is specified, either SECADM authority or the CREATE_SECURE_OBJECT privilege is needed.

  Note: If the SEPARATE SECURITY subsystem parameter is set to NO, SYSADM authority has implicit SECADM authority.
- If the WLM ENVIRONMENT FOR DEBUG MODE clause is specified, RACF or an external security product is invoked to check the required authority for defining programs in the WLM environment. If the WLM environment access is protected in RACF, the user that issued the CREATE statement must have the required authority. For more information, see Managing authorizations for creation of stored procedures in WLM environments (Managing Security).
- Additional authorization might be required on the SYSDUMMYx tables depending on the content of the trigger definition. See SYSDUMMYx tables.

Privilege set: The privilege set is the privileges that are held by the SQL authorization ID of the process unless the process is within a trusted context and the ROLE AS OBJECT OWNER clause is specified. In that case, the privilege set is the privileges that are held by the role that is associated with the primary authorization ID of the process and the owner is that role.

Description for CREATE TRIGGER (advanced)

OR REPLACE

Specifies to replace or change the definition for the trigger, if one exists at the current server. This option is ignored if a definition for the trigger does not exist at the current server.

If the VERSION keyword is not specified, and the trigger does not yet exist, the trigger is created with the initial version of the trigger (V1).

If the VERSION keyword is not specified, and the trigger exists:

- The existing trigger must not be defined with more than a single version or with a single version for which the version id is not V1.
- Otherwise, the only version that currently exists is V1 (or the trigger is a basic trigger), the trigger is recreated as follows:
  - The existing definition is effectively dropped before the definition is replaced in the catalog.
  - Any existing comment is discarded.
  - The definition of the trigger (including the object owner and target table or view name) can change.
  - The timestamp associated with the trigger definition is updated.
  - The create time of the trigger is changed and the activation order of the trigger is not maintained.

If the VERSION keyword is specified and the specified version of the trigger exists, the version is effectively replaced in the catalog as if the ALTER TRIGGER statement had been issued with the REPLACE VERSION clause. *The trigger owner is not changed.* The create time of the trigger is not changed, and the statement does not affect the order of trigger execution.

When you replace a version of a trigger, the following trigger attributes must be the same as the corresponding attributes for the currently active version of the trigger: *trigger-activation-time, trigger-event,* table or view name, and *trigger-granularity*. The content of the REFERENCING clause can differ from the other versions of the trigger. For options that are not explicitly specified, the system default values for those options are used, even if those options were explicitly specified for the version of the trigger that is being replaced. This is not the case for versions of the trigger that specified DISABLE DEBUG MODE. If DISABLE DEBUG MODE is specified for a version of a trigger, the option cannot be changed using the REPLACE clause.

If the VERSION keyword is specified and the specified version of the trigger does not exist, the version is defined as if the ALTER TRIGGER statement had been issued with an ADD VERSION clause. *The trigger owner is not changed.* The create time of the trigger is not changed, and the statement does not affect the order of trigger execution.

When you add a new version of a trigger, the following trigger attributes must be the same as the corresponding attributes for the currently active version of the trigger: *trigger-activation-time, trigger-event,* table or view name, and *trigger-granularity*. The content of the REFERENCING clause can differ from the other versions of the trigger. For options that are not explicitly specified, the system default values for those options are used.

trigger-name

Names the trigger. The name, including the implicit or explicit schema name, must not identify a trigger that exists at the current server. However, specifying the name of an existing trigger is allowed in the following situations:

- When the OR REPLACE clause is specified to replace an existing trigger
- When the VERSION clause is specified to add or replace a version of an existing trigger

The name is also used to create the trigger package; therefore, if OR REPLACE is not specified, the name must also not identify a package that is already described in the catalog. The schema name becomes the *collection-id* of the trigger package. Although *trigger-name* can be specified as an ordinary or delimited identifier, the name should conform to the rules for an ordinary identifier. Refer to The implicitly created trigger package for additional information.

The schema name can be 'SYSTOOLS' if the privilege set includes the SYSCTRL privilege. Otherwise, the schema name must not begin with 'SYS' unless the schema name is 'SYSADM', 'SYSIBMADM', or 'SYSPROC'.

VERSION *trigger-version-id*
Specifies the version identifier for the version of the trigger that is to be defined or replaced. See "Naming conventions" on page 79 for information about specifying *trigger-version-id*. You can use an ALTER TRIGGER statement with the ADD VERSION clause or the CREATE TRIGGER statement with the OR REPLACE clause to create additional versions of the trigger. V1 is the default version identifier. See Versions of a trigger for more information about the use of versions for triggers.

trigger-activation-time

NO CASCADE
NO CASCADE is allowed for compatibility with prior releases and other products.

BEFORE
Specifies that the trigger is a before trigger. Db2 executes the triggered action before it applies any changes caused by an insert, delete, or update operation on the subject table. It also specifies that the triggered action does not activate other triggers because the triggered action of a before trigger cannot contain any updates, REFRESH TABLE, or TRUNCATE SQL statements.

BEFORE must not be specified when *view-name* is also specified. FOR EACH ROW must be specified for a BEFORE trigger.

AFTER
Specifies that the trigger is an after trigger. Db2 executes the triggered action after it applies any changes caused by an insert, delete, or update operation on the subject table. AFTER must not be specified if *view-name* is also specified.

INSTEAD OF
Specifies that the trigger is an instead of trigger. The associated triggered action replaces the action against the subject view. Only one INSTEAD OF trigger is allowed for each type of operation on a given subject view. Db2 executes the *triggered-action* instead of the insert, update, or delete operation on the subject view.

INSTEAD OF must not be specified when *table-name* is also specified. The WHEN clause can not be specified for an INSTEAD OF trigger. FOR EACH ROW must be specified for an INSTEAD OF trigger.

ON *table-name*
Identifies the subject table of the BEFORE or AFTER trigger definition. The name must identify a base table that exists at the current server. It must not identify a materialized query table, a clone table, a temporary table, an auxiliary table, an alias, a synonym, a real-time statistics table, an accelerator-only table, a catalog table, or a directory table.

ON *view-name*
Identifies the subject view of the INSTEAD OF trigger definition. The name must identify a view that exists at the current server.

view-name must not specify a view where any of the following conditions are true:

- The view is defined with the WITH CASCADED CHECK option (a symmetric view)
- The view on which a symmetric view has been defined
- The view references data that is encoded with different encoding schemes or CCSID values
- The view has a column that is a ROWID column
- The view has a column that is based on an underlying column of any of the following types:
  - A LOB, XML, or ROWID column
  - An identity column
  - A security label column
  - A row change timestamp column

- A row-begin column
- A row-end column
- A transaction start ID column

- The view has columns that have field procedures
- All of the underlying tables of the view are catalog tables
- All of the underlying tables of the view are created global temporary tables
- All of the underlying tables of the view are clone tables
- The view has other views that are dependent on it

REFERENCING

Specifies the correlation names for the transition variables and the table names for the transition tables. For the rows in the subject table that are modified by the triggering SQL operation (insert, delete, or update), a correlation name identifies the columns of a specific row. *table-identifiers* identify the complete set of affected rows. Transition variables with XML types cannot be referenced inside of a trigger. If the column of a transition table is referenced, the data type of the column cannot be XML.

Each row that is affected by the triggering SQL operation is available to the triggered action by qualifying column names with *correlation-names* that are specified as follows:

OLD ROW AS *correlation-name*

Specifies the correlation name that identifies the transition variables containing the values in the row prior to the triggering SQL operation.

NEW ROW AS *correlation-name*

Specifies the correlation name that identifies the transition variables containing the values in the row as modified by the triggering SQL operation and by any assignment statement in a before trigger that has already been executed.

If OLD and NEW are both specified, a reference to a transition variable must be qualified with the associated correlation name.

The complete set of rows that are affected by the triggering operation is available as a transition table to the triggered action. Specify a *table-identifier* to refer to the transition table as follows:

OLD_TABLE AS *table-identifier*

Specifies the name of a temporary table that identifies the values in the complete set of rows that are modified rows by the triggering SQL operation prior to any actual changes.

NEW_TABLE AS *table-identifier*

Specifies the name of a temporary table that identifies the values in the complete set of rows as modified by the triggering SQL operation and by any assignment statement in a before trigger that has already been executed.

Only one OLD and one NEW *correlation-name* can be specified for a trigger. Only one OLD_TABLE and one NEW_TABLE *table-identifier* can be specified for a trigger. All of the *correlation-names* and *table-identifiers* must be unique from one another.

Table 221 on page 1743 summarizes the allowable combinations of transition variables and transition tables that you can specify for the various trigger types. The OLD *correlation-name* and the OLD_TABLE *table-identifier* are valid only if the triggering event is either a delete operation or an update operation. For a delete operation, the OLD *correlation-name* captures the values of the columns in the deleted row, and the OLD_TABLE *table-identifier* captures the values in the set of deleted rows. For an update operation, the OLD *correlation-name* captures the values of the columns of a row before the update operation, and the OLD_TABLE *table-identifier* captures the values in the set of rows before the update operation.

The NEW *correlation-name* and the NEW_TABLE *table-identifier* are valid only if the triggering event is either an insert operation or an update operation. For both operations, the NEW *correlation-name* captures the values of the columns in the inserted or updated row and the NEW_TABLE *table-identifier* captures the values in the set of inserted or updated rows. For BEFORE triggers, the values of the updated rows include the changes from any assignment statements in the triggered action of BEFORE triggers.

Table 221. Allowable combinations of attributes in a trigger definition

Granularity	Activation time	Triggering SQL operation	Transition variables allowed"1" on page 1743	Transition tables allowed"1" on page 1743
FOR EACH ROW	BEFORE	DELETE	OLD	None
		INSERT	NEW	None
		UPDATE	OLD, NEW	None
	AFTER	DELETE	OLD	OLD_TABLE
		INSERT	NEW	NEW_TABLE
		UPDATE	OLD, NEW	OLD_TABLE, NEW_TABLE
	INSTEAD OF	DELETE	OLD	OLD_TABLE
		INSERT	NEW	NEW_TABLE
		UPDATE	OLD, NEW	OLD_TABLE, NEW_TABLE
FOR EACH STATEMENT	AFTER	DELETE	None	OLD_TABLE
		INSERT	None	NEW_TABLE
		UPDATE	None	OLD_TABLE, NEW_TABLE

Note:

1. If a transition table or variable is referenced where it is not allowed, an error is returned.

A transition variable that has a character data type inherits the subtype and CCSID of the column of the subject table. During the execution of the triggered action, the transition variables are treated like host variables. Therefore, character conversion might occur. However, unlike a host variable, a transition variable can have the bit data attribute, and character conversion never occurs for bit data. A transition variable is considered to be bit data if the column of the table to which it corresponds is bit data.

You cannot modify a transition table; transition tables are read-only. Although a transition table does not inherit any edit or validation procedures from the subject table, it does inherit the encoding scheme and field procedures of the subject table.

The scope of each *correlation-name* and each *table-identifier* is the entire trigger definition.

trigger-granularity

FOR EACH ROW or FOR EACH STATEMENT
Specifies the conditions for which Db2 executes the triggered action.

FOR EACH ROW
Specifies that Db2 executes the triggered action for each row of the subject table that the triggering SQL operation modifies. If the triggering SQL operation does not modify any rows, the triggered action is not executed..

FOR EACH STATEMENT

Specifies that Db2 executes the triggered action only one time for the triggering operation. Even if the triggering operation does not modify or delete any rows, the triggered action is executed one time.

FOR EACH STATEMENT must not be specified for a BEFORE or INSTEAD OF trigger.

FOR EACH ROW or FOR EACH STATEMENT

Specifies the conditions for which Db2 executes the triggered action.

FOR EACH ROW

Specifies that Db2 executes the triggered action for each row of the subject table that the triggering SQL operation modifies. If the triggering SQL operation does not modify any rows, the triggered action is not executed.

FOR EACH STATEMENT

Specifies that Db2 executes the triggered action only one time for the triggering operation. Even if the triggering operation does not modify or delete any rows, the triggered action is executed one time.

FOR EACH STATEMENT must not be specified for a BEFORE or INSTEAD OF trigger.

ALLOW DEBUG MODE, DISALLOW DEBUG MODE, or DISABLE DEBUG MODE

Specifies whether this version of the trigger can be run in debugging mode. The default is determined using the value of the CURRENT DEBUG MODE special register.

ALLOW DEBUG MODE

Specifies that this version of the trigger can be run in debugging mode. When ALLOW DEBUG MODE is in effect, a WLM environment must be available. If you do not specify WLM ENVIRONMENT FOR DEBUG MODE, Db2 uses the default WLM-established stored procedure address space specified at installation time.

DISALLOW DEBUG MODE

Specifies that this version of the trigger cannot be run in debugging mode. You can use an ALTER statement to change this option to ALLOW DEBUG MODE for the initial version of the trigger. When DISALLOW DEBUG MODE is in effect, a WLM environment must be available. If you do not specify WLM ENVIRONMENT FOR DEBUG MODE, Db2 uses the default WLM-established stored procedure address space specified at installation time.

DISABLE DEBUG MODE

Specifies that this version of the trigger can never be run in debugging mode.

This version of the trigger cannot be changed to specify ALLOW DEBUG MODE or DISALLOW DEBUG MODE after this version of the trigger has been created or altered to use DISABLE DEBUG MODE. To change this option, drop the trigger, and create it again using the option that you want. An alternative to dropping and recreating the trigger is to create a version of the trigger that uses the option that you want, and making that version the active version.

When DISABLE DEBUG MODE is in effect, WLM ENVIRONMENT FOR DEBUG MODE is ignored.

QUALIFIER *schema-name*

Specifies the implicit qualifier that is used for unqualified object names that are referenced in the trigger body. For information about how the default for this option is determined, see "Unqualified alias, index, JAR file, mask, permission, sequence, table, trigger, and view names" on page 86.

ASUTIME

Specifies the total amount of processor time, in CPU service units, that a single invocation of this version of the trigger can run. The value is unrelated to the ASUTIME column of the resource limit specification table.

When you are debugging a trigger, setting a limit can be helpful in case the trigger gets caught in a loop. For information on service units, see z/OS MVS Initialization and Tuning Guide.

NO LIMIT

Specifies that there is no limit on the service units.

NO LIMIT is the default.

LIMIT *integer*

The limit on the number of CPU service units is a positive *integer* in the range 1 - 2147483647. If the trigger uses more service units than the specified value, Db2 cancels the trigger. The CPU cycles that are consumed by parallel tasks in a trigger do not contribute towards the specified ASUTIME LIMIT.

WLM ENVIRONMENT FOR DEBUG MODE *name*

Specifies the WLM (workload manager) application environment that is used by Db2 when debugging the trigger. The *name* of the WLM environment is an SQL identifier.

If you do not specify WLM ENVIRONMENT FOR DEBUG MODE, Db2 uses the default WLM-established stored procedure address space specified at installation time.

You must have the appropriate authority for the WLM application environment.

The WLM ENVIRONMENT FOR DEBUG MODE value is ignored when DISABLE DEBUG MODE is in effect.

CURRENT DATA YES or CURRENT DATA NO

Specifies whether to require data currency for read-only and ambiguous cursors when the isolation level of cursor stability is in effect. CURRENT DATA also determines whether block fetch can be used for distributed, ambiguous cursors.

CURRENT DATA YES

Specifies that data currency is required for read-only and ambiguous cursors. Db2 acquires page or row locks to ensure data currency. Block fetch is ignored for distributed, ambiguous cursors.

CURRENT DATA NO

Specifies that data currency is not required for read-only and ambiguous cursors. Block fetch is allowed for distributed, ambiguous cursors. Use of CURRENT DATA NO is not recommended if the trigger attempts to dynamically prepare and execute a DELETE WHERE CURRENT OF statement against an ambiguous cursor after that cursor is opened. You receive an error if your trigger attempts to use a DELETE WHERE CURRENT OF statement for any of the following cursors:

- A cursor that is using block fetch
- A cursor that is using query parallelism
- A cursor that is positioned on a row that is modified by this or another application process

CURRENT DATA NO is the default.

`CONCURRENT ACCESS RESOLUTION`

Specifies the whether processing uses only committed data or whether it will wait for commit or rollback of data that is in the process of being updated.

`WAIT FOR OUTCOME`

Specifies that processing will wait for the commit or rollback of data that is in the process of being updated.

`USE CURRENTLY COMMITTED`

Specifies that processing use the currently committed version of the data when data that is in the process of being updated is encountered. `USE CURRENTLY COMMITTED` is applicable on scans that access tables that are defined in universal table spaces with row or page level lock size.

When there is lock contention between a read transaction and an insert transaction, `USE CURRENTLY COMMITTED` is applicable to scans with isolation level CS or RS. Applicable scans include intent read scans for read-only and ambiguous queries and for updatable cursors. `USE CURRENTLY COMMITTED` is also applicable to scans initiated from WHERE predicates of UPDATE or DELETE statements and the subselect of INSERT statements.

When there is lock contention is between a read transaction and a delete transaction, `USE CURRENTLY COMMITTED` is applicable to scans with isolation level CS and when CURRENT DATA NO is specified.

DYNAMICRULES

Specifies the values that apply, at run time, for the following dynamic SQL attributes:

- The authorization ID that is used to check authorization
- The qualifier that is used for unqualified objects
- The source for application programming options that Db2 uses to parse and semantically verify dynamic SQL statements

In the context of a trigger, DYNAMICRULES also specifies whether dynamic SQL statements can include ALTER, CREATE, and DROP statements.

In addition to the value of the DYNAMICRULES clause, the run time environment of a trigger controls how dynamic SQL statements behave at run time. The combination of the DYNAMICRULES value and the run time environment determines the value for the dynamic SQL attributes. That set of attribute values is called the dynamic SQL statement behavior. The following values can be specified:

RUN

Specifies that dynamic SQL statements are to be processed using run behavior.

RUN is the default.

BIND

Specifies that dynamic SQL statements are to be processed using bind behavior.

See "Authorization IDs and dynamic SQL" on page 94 for information on the effects of these options.

APPLICATION ENCODING SCHEME

Specifies the default encoding scheme for SQL variables in static SQL statements in the trigger body. The value is used for defining an SQL variable in a compound statement if the CCSID clause is not specified as part of the data type.

ASCII

Specifies that the data is encoded using the ASCII CCSIDs of the server.

EBCDIC

Specifies that the data is encoded using the EBCDIC CCSIDs of the server.

UNICODE

Specifies that the data is encoded using the Unicode CCSIDs of the server.

See ENCODING bind option (Db2 Commands) for information about how the default for this option is determined.

WITH EXPLAIN or WITHOUT EXPLAIN

Specifies whether information will be provided about how SQL statements in the trigger will execute.

WITHOUT EXPLAIN

Specifies that information will not be provided about how SQL statements in the trigger will execute.

You can get EXPLAIN output for a statement that is embedded in a trigger that is specified using WITHOUT EXPLAIN by embedding the SQL statement EXPLAIN in the trigger body. Otherwise, the value of the EXPLAIN option applies to all explainable SQL statements in the trigger body, and to the fullselect portion of any DECLARE CURSOR statements.

WITHOUT EXPLAIN is the default.

WITH EXPLAIN

Specifies that information will be provided about how SQL statements in the trigger will execute. Information is inserted into the table *owner*. PLAN_TABLE. *owner* is the authorization ID of the owner of the trigger. Alternatively, the authorization ID of the owner of the trigger can have an alias as *owner*.PLAN_TABLE that points to the base table, PLAN_TABLE. *owner* must also have the appropriate SELECT and INSERT privileges on that table. PLAN_TABLE must have a base table and can have multiple aliases with the same table name, PLAN_TABLE, but have different schema qualifiers. It cannot be a view or a synonym and should exist before the CREATE statement is processed. In all inserts to *owner*.PLAN_TABLE, the value of QUERYNO is the statement number that is assigned by Db2.

The WITH EXPLAIN option also populates two optional tables, if they exist: DSN_STATEMNT_TABLE and DSN_FUNCTION_TABLE. DSN_STATEMNT_TABLE contains an estimate of the processing cost for an SQL statement. See Estimating the cost of SQL statements (Db2 Performance) for more information. DSN_FUNCTION_TABLE contains information about function resolution. See Checking how Db2 resolves functions by using DSN_FUNCTION_TABLE (Db2 Application programming and SQL) for more information.

For more information about the EXPLAIN statement, including a description of the tables that are populated by the WITH EXPLAIN option, see "EXPLAIN" on page 1912.

WITH IMMEDIATE WRITE or WITHOUT IMMEDIATE WRITE

Specifies whether immediate writes are to be done for updates that are made to group buffer pool dependent page sets or partitions. This option is only applicable for data sharing environments. The IMMEDWRITE subsystem parameter has no affect of this option. IMMEDWRITE bind option (Db2 Commands) shows the implied hierarchy of the IMMEDWRITE bind option (which is similar to this trigger option) as it affects run time.

WITHOUT IMMEDIATE WRITE

Specifies that normal write activity is performed. Updated pages that are group buffer pool dependent are written at or before phase one of commit or at the end of abort for transactions that have been rolled back.

WITHOUT IMMEDIATE WRITE is the default.

WITH IMMEDIATE WRITE

Specifies that updated pages that are group buffer pool dependent are immediately written as soon as the buffer update completes. Updated pages are written immediately even if the buffer is updated during forward progress or during the rollback of a transaction. WITH IMMEDIATE WRITE might impact performance.

ISOLATION LEVEL RR, RS, CS, or UR

Specifies how far to isolate the trigger from the effects of other running applications. For information about isolation levels, see Choosing an ISOLATION option (Db2 Performance).

RR

Specifies repeatable read.

RS

Specifies read stability.

CS

Specifies cursor stability. CS is the default.

UR

Specifies uncommitted read.

OPTHINT *string-constant*

Specifies whether query optimization hints are used for static SQL statements that are contained within the body of the trigger.

string-constant is a character string of up to 128 bytes in length, which is used by the Db2 subsystem when searching the PLAN_TABLE for rows to use as input. The default value is an empty string, which indicates that the Db2 subsystem does not use optimization hints for static SQL statements.

Optimization hints are only used if optimization hints are enabled for your system. See Preparing to influence access paths (Db2 Performance) for information about enabling optimization hints.

SQL PATH

Specifies the SQL path that Db2 uses to resolve unqualified user-defined types, functions, and procedure names in the body of the trigger. The default value is "SYSIBM", "SYSFUN", "SYSPROC", "SYSIBMADM", and the value of the QUALIFIER option.

Schemas "SYSIBM", "SYSFUN", "SYSPROC", "SYSIBMADM" do not need to be explicitly specified. If any of these schemas is not explicitly specified, it is implicitly assumed at the beginning the SQL path, in the order listed.

Db2 calculates the length by taking each *schema-name* specified and removing any trailing blanks from it, adding two delimiters around it, and adding one comma after each schema name, except for the last one. The length of the resulting string cannot exceed the length of the CURRENT SCHEMA special register. If you do not specify the "SYSIBM", "SYSFUN", "SYSPROC", "SYSIBMADM", schemas, they are not included in the length of the SQL path. If the total length of the SQL path exceeds the length of the CURRENT PATH special register, Db2 returns an error.

For more information, see:

“SQL path” on page 85
“CURRENT SCHEMA special register” on page 206
“CURRENT PATH special register” on page 200

schema-name

Identifies a schema. Db2 does not verify that the schema exists when the CREATE statement is processed. The same schema name should not appear more than once in the list of schema names.

SYSPUBLIC must not be specified for the SQL path.

SYSTEM PATH

Specifies the schema names "SYSIBM", "SYSFUN", "SYSPROC", "SYSIBMADM".

SESSION_USER or USER

Specifies the value of the SESSION_USER or USER special register, which represents a maximum 8-byte (in EBCDIC) *schema-name*. At the time the CREATE statement is processed, this length is included in the total length of the list of schema names that is specified for the SQL PATH option.

If you specify SESSION_USER (or USER) in a list of schema names, do not use delimiters around the SESSION_USER (or USER) keyword.

RELEASE AT

Specifies when to release resources that the trigger uses: either at each commit point or when the trigger terminates.

COMMIT

Specifies that resources will be released at each commit point.

COMMIT is the default.

DEALLOCATE

Specifies that resources will be released only when the thread terminates. DEALLOCATE has no effect on dynamic SQL statements, which always use RELEASE AT COMMIT, with this exception: When you use the RELEASE AT DEALLOCATE clause and the WITH KEEP DYNAMIC clause, and the subsystem is installed with a value of YES for the field CACHE DYNAMIC SQL on installation panel DSNTIP8, the RELEASE AT DEALLOCATE option is honored for dynamic SELECT and data change statements.

Locks that are acquired for dynamic statements are held unit one of the following events occurs:

- The application process ends.
- The application process issues a PREPARE statement with the same statement identifier. (Locks are released at the next commit point).
- The statement is removed from the dynamic statement cache because the statement has not been used. (Locks are released at the next commit point.)
- An object that the statement is dependent on is dropped or altered, or a privilege that the statement needs is revoked. (Locks are released at the next commit point.)

RELEASE AT DEALLOCATE can increase the package or plan size because additional items become resident in the package or plan.

For more information, see Choosing a RELEASE option (Db2 Performance).

ROUNDING

Specifies the rounding mode for manipulation of DECFLOAT data. The default value is taken from the DEFAULT DECIMAL FLOATING POINT ROUNDING MODE in the application programming defaults module.

DEC_ROUND_CEILING

Specifies numbers are rounded towards positive infinity.

DEC_ROUND_DOWN

Specifies numbers are rounded towards 0 (truncation).

DEC_ROUND_FLOOR

Specifies numbers are rounded towards negative infinity.

DEC_ROUND_HALF_DOWN

Specifies numbers are rounded to nearest; if equidistant, round down.

DEC_ROUND_HALF_EVEN

Specifies numbers are rounded to nearest; if equidistant, round so that the final digit is even.

DEC_ROUND_HALF_UP

Specifies numbers are rounded to nearest; if equidistant, round up.

DEC_ROUND_UP

Specifies numbers are rounded away from 0.

DATE FORMAT ISO, EUR, USA, JIS, or LOCAL

Specifies the date format for result values that are string representations of date or time values. See "String representations of datetime values" on page 120 for more information.

The default format is specified in the DATE FORMAT field of installation panel DSNTIP4 of the system where the routine is defined. You cannot use the LOCAL option unless you have a date exit routine.

DECIMAL(15), DECIMAL(31), DECIMAL(15,*s*), or DECIMAL(31,*s*)

Specifies the maximum precision that is to be used for decimal arithmetic operations. See "Arithmetic with two decimal operands" on page 250 for more information. The default format is specified in the DECIMAL ARITHMETIC field of installation panel DSNTIPF of the system where the routine is defined. If the form *pp.s* is specified, *s* must be a number between 1 and 9. *s* represents the minimum scale that is to be used for division.

TIME FORMAT ISO, EUR, USA, JIS, or LOCAL

Specifies the time format for result values that are string representations of date or time values. See "String representations of datetime values" on page 120 for more information.

The default format is specified in the TIME FORMAT field of installation panel DSNTIP4 of the system where the routine is defined. You cannot use the LOCAL option unless you have a date exit routine.

FOR UPDATE CLAUSE OPTIONAL or FOR UPDATE CLAUSE REQUIRED

Specifies whether the FOR UPDATE clause is required for a DECLARE CURSOR statement if the cursor is to be used to perform positioned updates.

FOR UPDATE CLAUSE REQUIRED

Specifies that a FOR UPDATE clause must be specified as part of the cursor definition if the cursor will be used to make positioned updates.

FOR UPDATE CLAUSE REQUIRED is the default.

FOR UPDATE CLAUSE OPTIONAL

Specifies that the FOR UPDATE clause does not need to be specified in order for a cursor to be used for positioned updates. The trigger body can include positioned UPDATE statements that update columns that the user is authorized to update.

The FOR UPDATE clause with no column list applies to static or dynamic SQL statements. Even if you do not use this clause, you can specify FOR UPDATE OF with a column list to restrict updates to only the columns that are identified in the FOR UPDATE clause and to specify the acquisition of update locks.

NOT SECURED or SECURED

Specifies whether the trigger is considered secure. NOT SECURED is the default.

SECURED

Specifies the trigger is considered secure.

SECURED must be specified for a trigger if its subject table is using row access control or column access control. SECURED must also be specified for a trigger that is created for a view and one or more of the underlying tables in the view definition is using row access control or column access control.

NOT SECURED

Specifies the trigger is considered not secure.

NOT SECURED must not be specified for a trigger whose subject table is using row access control or column access control. NOT SECURED must also not be specified for a trigger that is created for a view and one or more of the underlying tables in the view definition is using row access control or column access control.

BUSINESS_TIME SENSITIVE

Determines whether references to application-period temporal tables in both static and dynamic SQL statements are affected by the value of the CURRENT TEMPORAL BUSINESS_TIME special register.

YES

References to application-period temporal tables are affected by the value of the CURRENT TEMPORAL BUSINESS_TIME special register. YES is the default value.

NO

References to application-period temporal tables are not affected by the value of the CURRENT TEMPORAL BUSINESS_TIME special register.

For more information, see "CURRENT TEMPORAL BUSINESS_TIME special register" on page 207.

SYSTEM_TIME SENSITIVE

Determines whether references to system-period temporal tables in both static and dynamic SQL statements are affected by the value of the CURRENT TEMPORAL SYSTEM_TIME special register.

YES

References to system-period temporal tables are affected by the value of the CURRENT TEMPORAL SYSTEM_TIME special register. YES is the default value.

NO

References to system-period temporal tables are not affected by the value of the CURRENT TEMPORAL SYSTEM_TIME special register.

For more information, see "CURRENT TEMPORAL SYSTEM_TIME special register" on page 209.

ARCHIVE SENSITIVE

Determines whether references to archive-enabled tables in SQL statements are affected by the value of the SYSIBMADM.GET_ARCHIVE built-in global variable.

YES

References to archive-enabled tables are affected by the value of the SYSIBMADM.GET_ARCHIVE built-in global variable. YES is the default value.

NO

References to archive-enabled tables are not affected by the value of the SYSIBMADM.GET_ARCHIVE built-in global variable.

For related information, see "GET_ARCHIVE" on page 330.

APPLCOMPAT *applcompat-level*

Specifies the application compatibility level behavior for static SQL statements in the trigger body. The default value is V12R1M500. The following *applcompat-level* values can be specified:

V*vv*R*r*M*mmm*

Compatibility with the behavior of the identified Db2 function level. For example, V12R1M510 specifies compatibility with the highest available Db2 12 function level. The equivalent function level or higher must be activated.

For the new capabilities that become available in each application compatibility level, see:

- SQL changes in Db2 13 application compatibility levels
- SQL changes in Db2 12 application compatibility levels

Tip: Extra program preparation steps might be required to increase the application compatibility level for applications that use data server clients or drivers to access Db2 for z/OS. For more information, see Setting application compatibility levels for data server clients and drivers (Db2 Application programming and SQL).

V12R1

Compatibility with the behavior of Db2 12 function level 500. This value has the same result as specifying V12R1M500.

Values such as V11R1 and V10R1 for compatibility with previous Db2 releases are not supported for triggers.

For more information, see APPLCOMPAT bind option (Db2 Commands) and APPL COMPAT LEVEL field (APPLCOMPAT subsystem parameter) (Db2 Installation and Migration)

CONCENTRATE STATEMENTS OFF or CONCENTRATE STATEMENTS WITH LITERALS

Specifies whether a dynamic SQL statement that specifies literal constants will be cached as a separate unique statement entry in the dynamic statement cache instead of sharing an existing statement in the cache. Dynamic SQL statements are eligible to share an existing statement in the cache if the new statement meets all of the conditions for sharing a cached version of the same dynamic statement except that the new statement specifies one or more literal constants that are different than the cached statement.

CONCENTRATE STATEMENTS OFF

Specifies that the dynamic SQL statement that specifies literal constants will be cached as a unique statement entry if it specifies one or more constants that are different than the cached version of the same dynamic statement. CONCENTRATE STATEMENTS OFF is the default dynamic statement caching behavior.

CONCENTRATE STATEMENTS WITH LITERALS

Specifies that the dynamic SQL statement that specifies literal constants will share a cached version of the same dynamic statement that is also prepared using the CONCENTRATE STATEMENTS WITH LITERALS option if the new dynamic statement meets all of the conditions for sharing the cached statement and the constants that are specified can be reused in place of the constants in the cached statement.

trigger-event

Specifies that the triggered action that is associated with the trigger is to be executed when the trigger event is applied to the subject table or view.

INSERT

Specifies that the trigger is an insert trigger. Db2 executes the triggered action whenever there is an insert operation on the subject table. However, if the insert trigger is defined on any explain table, and the insert operation was caused by Db2 adding a row to the table, the triggered action is not executed.

DELETE

Specifies that the trigger is a delete trigger. Db2 executes the triggered action whenever there is a delete operation on the subject table.

UPDATE

Specifies that the trigger is an update trigger. Db2 executes the triggered action whenever there is an update operation on the subject table.

If you do not specify a list of column names, an update operation on any column of the subject table, including columns that are subsequently added with the ALTER TABLE statement, activates the triggered action.

OF *column-name,...*

Each *column-name* that you specify must be a column of the subject table and must appear in the list only once. An update operation on any of the listed columns activates the triggered action.

UPDATE OF *column-name* cannot be specified for an INSTEAD OF trigger.

triggered-action

Specifies the action to be performed when the trigger is activated. The *triggered-action* is composed of one or more SQL statements and an optional condition that controls whether the statements are executed.

WHEN (*search-condition*)

Specifies a condition that evaluates to true, false, or unknown. The triggered SQL statements are executed only if the *search-condition* evaluates to true. If the WHEN clause is omitted, the associated SQL statements are always executed.

The WHEN clause must not be specified for an INSTEAD OF trigger.

SQL-trigger-body

Specifies a single *SQL-control-statement*, including a compound statement, or *triggered-SQL-statement* that is to be executed for the *triggered-action*. See Chapter 8, “SQL procedural language (SQL PL),” on page 2197 for more information about defining SQL triggers.

SQL-control-statement

Specifies an SQL control statement, which can include nested control statements and other SQL statements specified in the syntax diagram for “SQL-procedure-statement (SQL PL)” on page 2202. The statements that can be specified for *SQL-procedure-statement* are subject to the syntax notes relating to triggers.

triggered-SQL-statement

Specifies an SQL statement that is the only statement in a trigger body.

.

Only certain SQL statements can be specified in the *SQL-trigger-body*.

The trigger body must not contain a statement that is not supported.

- A statement in the trigger body must not refer to host variables, undefined transition variables, or declared temporary tables.
- A statement in the trigger body must only refer to a table or view that is at the current server.
- A statement in the trigger body must only invoke a stored procedure or user-defined function that is at the current server. An invoked routine can, however, access a server other than the current server.
- A statement in the trigger body must not modify a column that is part of a BUSINESS_TIME period.
- The trigger body must not, directly or indirectly, issue a CALL statement for a procedure that contains one of the following statements:
  - COMMIT
  - CONNECT
  - RELEASE *connection*

    - RELEASE SAVEPOINT
    - ROLLBACK (without TO SAVEPOINT)
    - SAVEPOINT
    - SET CONNECTION
- The trigger body must not, directly or indirectly, issue a CALL statement for a procedure that is defined with the COMMIT ON RETURN option.
- If the trigger is a before trigger:
    - The trigger body must not contain a DELETE, INSERT, MERGE, REFRESH TABLE, TRUNCATE, UPDATE statement, or SELECT FROM *data-change-statement*.
    - The trigger body must not, directly or indirectly, invoke a routine containing one of the following statements:
        - ALTER
        - COMMENT
        - CREATE
        - DECLARE GLOBAL TEMPORARY TABLE
        - DELETE
        - DROP
        - EXCHANGE
        - GRANT
        - INSERT
        - LABEL
        - LOCK TABLE
        - MERGE
        - REFRESH TABLE
        - RENAME
        - REVOKE
        - TRUNCATE
        - UPDATE

A CREATE TRIGGER statement (or ALTER TRIGGER statement) cannot contain a hexadecimal graphic string (GX) constant.

The triggered action can refer to the values in the set of affected rows. This action is supported through the use of transition variables and transition tables.

All tables, views, aliases, sequences, roles, user-defined data types, user-defined functions, and procedures referenced in the *triggered-action* must exist at the current server when the trigger is created, or the version of the trigger is defined. The table or view that an alias refers to must also exist when the trigger is created, or the version of the trigger is defined.

WRAPPED *obfuscated-statement-text*

Specifies the encoded definition of the trigger. A CREATE TRIGGER statement can be encoded using the WRAP scalar function.

WRAPPED must not be specified on a static CREATE statement.

Notes for CREATE TRIGGER (advanced)

Owner privileges:

When an INSTEAD OF trigger is defined, the associated privilege (INSERT, UPDATE, or DELETE on the view) is given to the owner of the view. The owner is granted the privilege with the ability to grant that privilege to others. For more information about ownership of an object, see "Authorization, privileges, permissions, masks, and object ownership" on page 90.

Execution authorization:
The user executing the triggering SQL operation does not need authority to execute a *SQL-trigger-body*. An *SQL-trigger-body* executes using the authority of the owner of the trigger.

Activating a trigger:
Only insert, delete, or update operations can activate a trigger. The activation of a trigger might cause trigger cascading.*Trigger cascading* is the result of the activation of one trigger that executes SQL statements that cause the activation of other triggers or even the same trigger again. The triggered actions might also cause updates as a result of the original modification, which can result in the activation of additional triggers. With trigger cascading, a significant chain of triggers might be activated, causing a significant change to the database as a result of a single insert, delete, or update operation. The number of levels of nested trigger cascading is limited to 16.

Loading a table with the LOAD utility does not activate any triggers that are defined for the table if the SHRLEVEL NONE option is specified or accepted as the default. If the LOAD statement includes the SHRLEVEL CHANGE option, triggers are activated when loading a table with the LOAD utility.

Adding triggers to enforce constraints:
Adding a trigger on a table that already has rows in it will not cause the *triggered-action* to be executed. Thus, if the trigger is designed to enforce constraints on the data in the table, the data in the existing rows might not satisfy those constraints.

Multiple triggers:
Multiple triggers that have the same activation time and triggering event can be defined on a table. The triggers are activated in the order in which they were created. For example, the trigger that was created first is executed first; the trigger that was created second is executed second. If the OR REPLACE option is used to replace an existing trigger, the create time is changed and therefore might affect the order of trigger execution.

Transition variables and transition tables:
The *triggered-action* can refer to the values in the set of affected rows. This action is supported through the use of transition variables and transition tables.

A transition variable has the same name and data type as the corresponding column of the table that the trigger is defined on, and is nullable. A transition variable contains the value of a column in an affected row. A transition variable is qualified by a correlation name that identifies whether the reference is to the old value (before the update) or the new value (after the update). A transition variable can be referenced in the search condition, or in an SQL statement in the trigger body, wherever a variable would be allowed if the reference was made outside the body of a trigger. A new transition variable can be assigned a value in a before update or insert trigger. The values of the updated rows include the changes from any assignments to transition variables in the *triggered-action* of a before trigger.

A transition table contains the complete set of affected rows: either the old values (before the update) or the new values (after the update). A transition table is read-only, and can be referenced in the *triggered-action* of an after or instead of trigger. A column of a transition table has the same name, data type, and null attribute as the corresponding column of the table that the trigger is defined on. A transition table is referenced using an associated table identifier that allows the complete set of affected rows to be treated as a table. A transition table can be referenced in a search condition, or in an SQL statement in the trigger body, wherever a table would be allowed if the reference was made outside the body of a trigger. In addition, a transition table can be passed as an argument to a user-defined function or procedure, specifying the TABLE keyword before the table identifier for the transition table. When the function or procedure is invoked, a table locator is passed for the transition table.

Considerations for table-locator-reference elements:
table-locator-reference must not be specified in the body of a trigger.

Considerations for implicitly hidden columns:

In the body of a trigger, a transition variable that corresponds to an implicitly hidden column can be referenced. A transition table, that corresponds to a table with an implicitly hidden column, includes that column as part of the transition table. Likewise, a transition variable will exist for the column that is defined as implicitly hidden. A transition variable that corresponds to an implicitly hidden column can be referenced in the body of a trigger.

Lines within the advanced trigger definition:

When an advanced trigger is created, information is retained on lines in the CREATE statement. Lines are determined by the presence of the new line control character.

In an advanced trigger, a *new line control character* is a special character that is used for a new line. The new line control characters for an advanced trigger include:

- Line feed
- New line
- Carriage return
- Carriage return, followed by a line feed
- Carriage return, followed by a new line

For more information about control characters, see "Control characters" on page 76.

Identifier resolution:

See SQL control statements for SQL routines for information on how names are resolved to columns, SQL variables, transition variables, or global variables in the trigger body.

If non-unique names are used for columns, SQL variables, transition variables, or global variables, qualify the non-unique names by using the table designator for columns, the label name for SQL variables, correlation name for transition variables, and schema for global variables.

Considerations for transition variables in AFTER and INSTEAD OF triggers:

Transition variables cannot be modified in an AFTER or INSTEAD OF trigger.

Considerations for INSTEAD OF triggers:

The addition of an INSTEAD OF trigger for a view affects the read-only characteristic of the view. If a read-only view has a dependency relationship with an INSTEAD OF trigger, the type of operation that is defined for the INSTEAD OF trigger defines whether the view is deletable, insertable, or updatable.

The creation of an INSTEAD OF trigger causes dependent packages, plans, and statements in the dynamic statement cache to be marked invalid if the view definition is not read-only.

The initial values for new transition variables or new transition table columns that are visible in an INSTEAD OF INSERT trigger are set as follows:

- If a value is explicitly specified for a column in the insert operation, the corresponding new transition variable is that explicitly specified value.
- If a value is not explicitly specified for a column in the insert operation or the DEFAULT clause is specified, the corresponding new transition variable is:
  - the default value of the underlying table column if the view column is updatable (without the INSTEAD OF trigger)
  - otherwise, the null value

  If a view column is not nullable and does not have a default, the value must be explicitly specified in the insert operation.

The initial values for new transition variables that are visible in an INSTEAD OF UPDATE trigger are set as follows:

- If a value is explicitly specified for a column in the update operation, the corresponding new transition variable is that explicitly specified value
- If the DEFAULT clause is explicitly specified for a column in the update operation, the corresponding new transition variable is:

  - the default value of the underlying table column if the view column is updatable (without the INSTEAD OF trigger)
  - otherwise, the null value

  If a view column is not nullable and does not have a default, the value must be explicitly specified in the update operation.

- Otherwise, the corresponding new transition variable is the existing value of the column in the row.

Considerations for a MERGE statement:
The MERGE statement can execute insert, delete, and update operations. The applicable triggers are activated for the MERGE statement for the data change operations that are executed.

Considerations for triggers that are defined on tables that contain XML columns:
Although a trigger can be defined on a table that contains an XML column:

- An XML column cannot be referenced with a transition variable in the trigger body. An *SQL-procedure-statement* cannot reference a transition variable that is an XML data type.
- An XML column of a transition table cannot be referenced in the trigger body. An *SQL-procedure-statement* cannot reference a column in a transition table that is an XML data type.

Creating a trigger with the SECURED option:
Typically, the security administrator will examine the data that is accessed by a trigger, ensure that it is secure, and grant the CREATE_SECURE_OBJECT privilege to someone who requires the privileges to create a secured trigger. After the trigger is created, the security administrator will revoke the CREATE_SECURE_OBJECT privilege from the owner of the trigger.

The trigger is considered secure after the CREATE TRIGGER statement is executed. Db2 treats the SECURED attribute as an assertion that declares that the user has established an audit procedure for all activities in the trigger body. If a secure trigger references user-defined functions, Db2 assumes those functions are secure without validation. If those functions can access sensitive data, the user with SECADM authority needs to ensure that those functions are allowed to access that data and that an audit procedure is in place for all versions of those functions, and that all subsequent ALTER FUNCTION statements or changes to external packages are being reviewed by this audit process.

A trigger must be secure if its subject table is using row access control or column access control. SECURED must also be specified for a trigger that is created for a view and one or more of the underlying tables in the view definition is using row access control or column access control.

Creating a trigger with the NOT SECURED option:
The CREATE TRIGGER statement returns an error if the subject table of the trigger is using row access control or column access control, or if the trigger is for a view and one or more of the underlying tables in the view definition is using row access control or column access control.

Row and column access control that is not enforced for transition variables and transition tables:
If row access control or column access control is enforced for the subject table of the trigger, row permissions and column masks are not applied to the initial values of transition variables and transition tables. Row access control and column access control is enforced for the triggering table, but is ignored for transition variables and transition tables that are referenced in the body of the trigger body or are passed as arguments to user-defined functions that are invoked in the body of the trigger. To ensure that there are no security concerns for SQL statements accessing sensitive data in transition variables and transition tables in the trigger action, the trigger must be created with the SECURED option. If a trigger is not secure, the CREATE TRIGGER statement returns an error.

Versions of a trigger:
The CREATE TRIGGER statement defines the initial version of the trigger. Only one version of the trigger is considered to be the active version of the trigger. You can define additional versions using the ADD VERSION clause of the ALTER TRIGGER statement, or the CREATE TRIGGER statement with the OR REPLACE clause and the VERSION clause where the trigger already exists. You can replace a version using the REPLACE VERSION clause of the ALTER PROCEDURE statement, or the CREATE PROCEDURE statement with the OR REPLACE clause and the VERSION clause, when the procedure version already exists. For all versions of a trigger, the following trigger attributes must be the same:

trigger-activation-time, trigger-event, table or view name, and *trigger-granularity*. The content of the REFERENCING clause can differ for each version of the trigger.

Restrictions involving pending definition changes:
CREATE TRIGGER is not allowed if the trigger is defined on a table for which there are pending definition changes.

Considerations for the special plan, statement, and function tables for EXPLAIN:
You can create a trigger on PLAN_TABLE, DSN_STATEMNT_TABLE, or DSN_FUNCTION_TABLE. However, insert triggers that are defined on these tables are not activated when Db2 adds rows to the tables.

Dependent objects:
A trigger is dependent on the triggering table or view and objects that are referenced in the trigger body.

Adding a column to a subject table or a table referenced in the *triggered-action*:
If a column is added to the subject table after triggers have been defined, the following rules apply:

- If the trigger is an update trigger that was defined without an explicit list of column names, an update to the new column activates the trigger.
- If the subject table is referenced in the *triggered-action*, the new column is not accessible to the SQL statements until the trigger package is rebound.
- The OLD_TABLE and the NEW_TABLE transition tables contain the new column, but the column cannot be referenced unless the trigger is re-created. If the transition tables are passed to a user-defined function or a stored procedure, the user-defined function or stored procedure must be re-created with the new definition of the table (that is, the function or procedure must be dropped and re-created), and the package for the user-defined function or stored procedure must be rebound.

If a column is added to any table that is referenced in the *triggered-action*, the new column is not accessible to the SQL statements until the trigger package is rebound.

Altering the attributes of a column that the triggered action references:
If a column is altered in the table on which the trigger is defined (the subject table), the alter is processed, and the dependent trigger packages are invalidated.

Renaming the table for which the trigger is defined, or tables referenced in the *triggered-action*:
You cannot rename a table for which a trigger is defined (the subject table). Except for the subject table, you can rename any table to which the SQL statements in the triggered action refer. After renaming such a table, drop the trigger and then re-create the trigger so that it refers to the renamed table.

Dropping the table or view for which a trigger is defined:
If the table or view that a trigger is defined on is dropped, the trigger is also dropped.

Effects of dropping or revoking privileges on an object referenced in the *triggered-action*:
Dropping an object that is referenced in the body of a trigger, or revoking a privilege to an object referenced in the body of a trigger, may result in the following:

- Dropping any table, view, alias, or index that is referenced or used within the SQL statements in the triggered action causes the trigger and its package to be invalidated.
- Dropping a synonym that is referenced does not have any effect on the trigger or its package.
- Dropping a user-defined function that is referenced by the SQL statements in the triggered action is not allowed. An error occurs.
- Dropping a sequence that is referenced by the SQL statements in the triggered action is not allowed. An error occurs.
- Revoking a privilege on which the trigger depends causes the trigger and its package to be invalidated. If the appropriate privilege does not exist when the trigger package is rebound, the SQL statement that references the object fails.

Error handling in triggers:

A trigger can return errors, like other SQL statements. Applications need to account for the possible errors that can be expected when a trigger is invoked. Any exception SQLSTATE that is not handled within the trigger body (using a handler) results in the return of the exception SQLSTATE to the statement that caused the trigger to be activated. For example, if a SIGNAL statement (RESIGNAL statement or RAISE_ERROR function) raises a non-severe error in the *SQL-trigger-body*, and the condition is not handled within the trigger body, SQLCODE -438 and the corresponding SQLSTATE are returned. Other non-severe errors are returned with SQLCODE -723 and SQLSTATE 09000. Severe errors that occur during the execution of triggered SQL statements are returned with SQLCODE -901, -906, -911, or -913, and the corresponding SQLSTATE. Warnings are not returned.

Triggers and global variables:

The content of a global variable that is referenced by a trigger is inherited from the triggering SQL operation (delete, insert, or update).

Special registers:

The values of the special registers that are used in the trigger body are determined when the trigger is activated. The value of the CURRENT PACKAGESET special register is set to the schema name of the trigger, and the values of the other special registers are inherited from the triggering SQL operation (insert, update, or delete). Special register values are saved when a trigger is activated and are restored on return from the trigger. The CURRENT DATE, CURRENT TIME, and CURRENT TIMESTAMP special registers are not restored on return from the trigger.

Result sets for stored procedures:

If a trigger invokes a stored procedure that returns result sets, the application that activated the trigger cannot access those result sets.

Transaction isolation:

All of the statements in the *SQL-trigger-body* run under the isolation level that is in effect for the trigger.

Limiting processor time:

The Db2 resource limit facility allows you to specify the maximum amount of processor time for a dynamic, manipulative SQL statement such as SELECT or SQL data change statements. The execution of a trigger is counted as part of the triggering SQL statement. The ASUTIME trigger option can be used to specify such a limit.

Errors binding triggers:

When a CREATE TRIGGER statement is bound, the SQL statements within the triggered action might not be fully parsed. Syntax errors in those statements might not be caught until the CREATE TRIGGER statement is executed.

Characteristics of the package that is generated for a trigger:

The package that is associated with the trigger is named as follows:

- *location* is set to the value of the CURRENT SERVER special register.
- *collection-id* (schema) for the package is the same as the schema qualifier of the trigger.
- *package-id* is the same as the name of the trigger.

The package is generated using the bind options that correspond to the implicitly or explicitly specified trigger options. See Table 191 on page 1356 for more information. In addition to the corresponding bind options, the package is generated using the following bind options:

- FLAG(I)
- SQLERROR(NOPACKAGE)
- ENABLE(*)
- VALIDATE(BIND)

A trigger package becomes invalid if an object or privilege on which it depends is dropped or revoked. The next time that the trigger is activated, Db2 attempts to rebind the invalid trigger package. If the automatic rebind is unsuccessful, the trigger package remains invalid.

You cannot create another package from the trigger package, such as with the BIND COPY command. The only way to drop a trigger package is to drop the trigger or the subject table or view. Dropping the trigger drops the trigger package; dropping the subject table or view drops the trigger and the trigger package.

Each time that the trigger activates, the trigger package executes one or more times.

Considerations for SQL processor programs:

SQL processor programs, such as SPUFI, the command line processor, and DSNTEP2, might not correctly parse SQL statements in the triggered action that are ended with semicolons. These processor programs accept multiple SQL statements, each separated with a terminator character, as input. Processor programs that use a semicolon as the SQL statement terminator can truncate a CREATE TRIGGER statement with embedded semicolons and pass only a portion of it to Db2. Therefore, you might need to change the SQL terminator character for these processor programs. For information on changing the terminator character for SPUFI and DSNTEP2, see Setting the SQL terminator character in a SPUFI input data set (Db2 Application programming and SQL) and DSNTEP2 and DSNTEP4 sample programs (Db2 Application programming and SQL).

Application compatibility level considerations for trigger objects

The application compatibility level controls the adoption and use of new capabilities and enhancements. When an object is created or altered, two separate application compatibility levels are used: one to process the definition of the object, and the other for processing the SQL statements in the object body:

Object definition	The CURRENT APPLICATION COMPATIBILITY special register value is used to process the object definition, except for statements in the object body This application compatibility level is stored in the SYSENVIRONMENT.APPLCOMPAT column. You can use the environment ID value in the catalog definition of the object to locate the SYSENVIRONMENT row with the matching ENVID value. This application compatibility level can be changed when the object is regenerated.
Statements in the object body	The application compatibility level that is implicitly or explicitly specified with the APPLCOMPAT option of the CREATE or ALTER statement is used to process statements in the object body. This application compatibility level is stored in the SYSPACKAGE.APPLCOMPAT column for the package associated with the object definition.

Alternative syntax and synonyms:

To provide compatibility with previous releases of Db2 or other products in the Db2 family, Db2 supports the following keywords:

- OLD TABLE as a synonym for OLD_TABLE
- NEW TABLE as a synonym for NEW_TABLE

Obfuscated statements:

A CREATE TRIGGER statement can be executed in obfuscated form. In an obfuscated statement, only the trigger name and the WRAPPED keyword are readable. The rest of the statement is encoded in such a way that it is not readable but can be decoded by a database server that supports obfuscated statements. The WRAP scalar function produces obfuscated statements. Any debug options that are specified when the trigger is created from an obfuscated statement are ignored.

Examples for CREATE TRIGGER (advanced)

Example 1

Create two triggers that track the number of employees that a company manages. The subject table is the EMPLOYEE table, and the triggers increment and decrement a column with the total number of employees in the COMPANY_STATS table. The tables have these columns:

EMPLOYEE table: ID, NAME, ADDRESS, and POSITION
COMPANY_STATS table: NBEMP, NBPRODUCT, and REVENUE

This example shows the use of transition variables in a row trigger to maintain summary data in another table.

Create the first trigger, NEW_HIRE, so that it increments the number of employees each time a new person is hired; that is, each time a new row is inserted into the EMPLOYEE table, increase the value of column NBEMP in table COMPANY_STATS by 1.

```
CREATE TRIGGER NEW_HIRE
   AFTER INSERT ON EMPLOYEE
   FOR EACH ROW
   BEGIN ATOMIC
     UPDATE COMPANY_STATS SET NBEMP = NBEMP + 1;
   END
```

Create the second trigger, FORM_EMP, so that it decrements the number of employees each time an employee leaves the company; that is, each time a row is deleted from the table EMPLOYEE, decrease the value of column NBEMP in table COMPANY_STATS by 1.

```
CREATE TRIGGER FORM_EMP
   AFTER DELETE ON EMPLOYEE
   FOR EACH ROW
   BEGIN ATOMIC
     UPDATE COMPANY_STATS SET NBEMP = NBEMP - 1;
   END
```

Example 2

Create a trigger, REORDER, that invokes user-defined function ISSUE_SHIP_REQUEST to issue a shipping request whenever a parts record is updated and the on-hand quantity for the affected part is less than 10% of its maximum stocked quantity. User-defined function ISSUE_SHIP_REQUEST orders a quantity of the part that is equal to the part's maximum stocked quantity minus its on-hand quantity; ensures that the request is sent to the appropriate supplier, and returns the quantity ordered.

The parts records are in the PARTS table. Although the table has more columns, the trigger is activated only when columns ON_HAND and MAX_STOCKED are updated.

```
CREATE TRIGGER REORDER
    AFTER UPDATE OF ON_HAND, MAX_STOCKED ON PARTS
    REFERENCING NEW AS NROW
    FOR EACH ROW
    WHEN (NROW.ON_HAND < 0.10 * NROW.MAX_STOCKED)
    BEGIN ATOMIC
      DECLARE QTY_ORDERED INTEGER;

      VALUES(ISSUE_SHIP_REQUEST(NROW.MAX_STOCKED - NROW.ON_HAND, NROW.PARTNO))
        INTO QTY_ORDERED;
    END
```

Example 3

Repeat the scenario in Example 2 except use a SELECT INTO statement instead of a VALUES INTO statement to invoke the user-defined function. This example also shows how to define the trigger as a statement trigger instead of a row trigger. For each row in the transition table that evaluates to true for the WHERE clause, a shipping request is issued for the part.

```
CREATE TRIGGER REORDER
    AFTER UPDATE OF ON_HAND, MAX_STOCKED ON PARTS
    REFERENCING NEW_TABLE AS NTABLE
    FOR EACH STATEMENT
      BEGIN ATOMIC
        DECLARE QTY_ORDERED INTEGER;
        SELECT ISSUE_SHIP_REQUEST(MAX_STOCKED - ON_HAND, PARTNO)
          FROM NTABLE
        WHERE (ON_HAND < 0.10 * MAX_STOCKED)
          INTO QTY_ORDERED;
    END
```

Example 4

Assume that table EMPLOYEE contains column SALARY. Create a trigger, SAL_ADJ, that prevents an update to an employee's salary that exceeds 20% and signals such an error. Have the error that is returned with an SQLSTATE of '75001' and a description. This example shows that the SIGNAL statement is useful for restricting changes that violate business rules.

```
CREATE TRIGGER SAL_ADJ
  AFTER UPDATE OF SALARY ON EMPLOYEE
  REFERENCING OLD AS OLD_EMP
              NEW AS NEW_EMP
  FOR EACH ROW
  WHEN (NEW_EMP.SALARY > (OLD_EMP.SALARY * 1.20))
    BEGIN ATOMIC
      SIGNAL SQLSTATE '75001' ('Invalid Salary Increase - Exceeds 20
    END
```

Example 5

Assume that the following statements create a table, WEATHER (which stores temperature values in Fahrenheit), and a view, CELSIUS_WEATHER for users who prefer to work in Celsius instead of Fahrenheit:

```
CREATE TABLE WEATHER
   (CITY VARCHAR(25),
    TEMPF DECIMAL(5,2));
CREATE VIEW CELSIUS_WEATHER (CITY, TEMPC) AS
   SELECT CITY, (TEMPF-32)/1.8
   FROM WEATHER;
```

The following INSTEAD OF trigger is used on the CELSIUS_WEATHER view to convert Celsius values to Fahrenheit values and then insert the Fahrenheit value into the WEATHER table:

```
CREATE TRIGGER CW_INSERT INSTEAD OF INSERT
   ON CELSIUS_WEATHER
   REFERENCING NEW AS NEWCW
   FOR EACH ROW
     BEGIN ATOMIC
        INSERT INTO WEATHER VALUES
          (NEWCW.CITY,
           1.8*NEWCW.TEMPC+32)
     END;
```

Example 6

Create a before update trigger, STOCK_STATUS, using logic to record and track changes to stock prices.

Assume that the database contains two tables, CURRENTQUOTE and QUOTEHISTORY. CURRENTQUOTE has columns SYMBOL, QUOTE, and STATUS. QUOTEHISTORY has columns SYMBOL, QUOTE, and QUOTE_TIMESTAMP.

When the QUOTE column of CURRENTQUOTE is updated, the new quote must be copied, with a timestamp, to the QUOTEHISTORY table. Also, the STATUS column of CURRENTQUOTE must be updated to reflect whether the stock is:

1	Rising in value
2	At a new high for the year
3	Dropping in value
4	At a new low for the year
5	Steady in value

CREATE TRIGGER statements that accomplish these tasks are as follows:

Trigger STOCK_STATUS sets the status:

```
CREATE TRIGGER STOCK_STATUS
 NO CASCADE BEFORE UPDATE OF QUOTE ON CURRENTQUOTE
 REFERENCING NEW AS NEWQUOTE
 OLD AS OLDQUOTE
 FOR EACH ROW
  BEGIN ATOMIC
   SET NEWQUOTE.STATUS = CASE
   WHEN NEWQUOTE.QUOTE >
    (SELECT MAX(QUOTE)
    FROM QUOTEHISTORY
    WHERE SYMBOL = NEWQUOTE.SYMBOL
    AND YEAR(QUOTE_TIMESTAMP) = YEAR(CURRENT DATE) )
   THEN 'High'
   WHEN NEWQUOTE.QUOTE <
    (SELECT MIN(QUOTE)
    FROM QUOTEHISTORY
    WHERE SYMBOL = NEWQUOTE.SYMBOL
    AND YEAR(QUOTE_TIMESTAMP) = YEAR(CURRENT DATE) )
   THEN 'Low'
   WHEN NEWQUOTE.QUOTE > OLDQUOTE.QUOTE THEN 'Rising'
   WHEN NEWQUOTE.QUOTE < OLDQUOTE.QUOTE THEN 'Dropping'
   WHEN NEWQUOTE.QUOTE = OLDQUOTE.QUOTE THEN 'Steady'
  END;
END
```

Trigger RECORD_HISTORY records changes in the QUOTEHISTORY table:

```
CREATE TRIGGER RECORD_HISTORY
 AFTER UPDATE OF QUOTE ON CURRENTQUOTE
 REFERENCING NEW AS NEWQUOTE FOR EACH ROW
 BEGIN ATOMIC
  INSERT INTO QUOTEHISTORY VALUES (NEWQUOTE.SYMBOL,
  NEWQUOTE.QUOTE,
  CURRENT TIMESTAMP);
 END
```

Example 7

Create a before insert trigger, NEW_HIRED, that uses logic to illustrate the different scopes of a transition variable as compared to an SQL variable that is declared within the trigger body. Suppose that an EMPLOYEE table is defined as follows:

```
CREATE TABLE EMPLOYEE (EMPNO CHAR(6),
 FIRSTNAME VARCHAR(32),
 WORKDEPT CHAR(5),
 NUM INTEGER)#
```

In the trigger NEW_HIRED, the correlation name for the transition variables for the new values is XYZ, and XYZ is also the label for a compound statement in which an SQL variable is defined. The table has a column named NUM, and the SQL variable is also named NUM. The reference to XYZ.NUM in the assignment statement refers to the SQL variable because that is the definition with the most local scope to the assignment statement.

```
CREATE TRIGGER NEW_HIRED
 BEFORE INSERT ON EMPLOYEE
 REFERENCING NEW AS XYZ
 FOR EACH ROW
  XYZ: BEGIN
   DECLARE NUM INTEGER;
   SET XYZ.NUM = XYZ.NUM + 1;
  END XYZ#
```

Suppose that the following INSERT statement is issued:

```
INSERT INTO EMPLOYEE VALUES ('000001', 'RICK', 'DPT01', 10)#
```

The values in the table are the same as the values that were originally specified in the VALUES clause for the INSERT statement. This means that the NUM transition variable is not affected by the assignment statement. The references to XYZ.NUM in the assignment statement resolve to the SQL variable NUM, rather than the transition variable NUM.

Issue the following SELECT statement to see the results after the INSERT statement runs:

```
SELECT * FROM EMPLOYEE#
```

The results are:

EMPNO	FIRSTNAME	WORKDEPT	NUM
000001	RICK	DPT01	10

Example 8

Create a BEFORE INSERT trigger using logic to enforce the rule that a class ends one hour after it begins if the ending time is not provided upon INSERT into CLASS_SCHED. Define the trigger to enforce an additional restriction that a class cannot end beyond 9 pm.

```
CREATE TRIGGER VALIDATE_SCHED
 BEFORE INSERT ON CLASS_SCHED
 REFERENCING NEW AS N
 FOR EACH ROW
  WHEN (N.ENDING IS NULL OR N.ENDING > '21:00')
   VS: BEGIN
    -- SUPPLY DEFAULT VALUE FOR ENDING TIME IF NULL
    IF (N.ENDING IS NULL) THEN
     SET N.ENDING = N.STARTING + 1 HOUR;
    END IF;
    -- ENSURE THAT CLASS DOES NOT END BEYOND 9PM
    IF (N.ENDING > '21:00') THEN
     SIGNAL SQLSTATE '80000'
      SET MESSAGE_TEXT = 'CLASS ENDING TIME IS BEYOND 9 PM';
    END IF;
   END VS
```

Example 9: Change the trigger VALIDATE_SCHED to change the restriction so that classes cannot end beyond 7 PM. The OR REPLACE clause is added to the original CREATE TRIGGER statement, and the rule is changed to check for the ending time (N.ENDING > '19:00'). The CREATE TRIGGER statement replaces the existing definition of the trigger with the updated definition.

```
CREATE OR REPLACE TRIGGER VALIDATE_SCHED
 BEFORE INSERT ON CLASSES
 REFERENCING NEW AS N
 FOR EACH ROW
 -- TRIGGER WHEN CLAUSE
  WHEN (N.ENDING IS NULL OR N.ENDING > '19:00')
   VS: BEGIN
    -- SUPPLY DEFAULT VALUE FOR ENDING TIME IF NULL
    IF (N.ENDING IS NULL) THEN
     SET N.ENDING = N.STARTING + 1 HOUR;
    END IF;
    -- ENSURE THAT CLASS DOES NOT END BEYOND 7 PM
    IF (N.ENDING > '19:00') THEN
     SIGNAL SQLSTATE '80000'
      SET MESSAGE_TEXT = 'CLASS ENDING TIME IS BEYOND 7 PM';
    END IF;
   END VS
```

Related concepts

Triggers (Introduction to Db2 for z/OS)

Naming conventions
The rules for forming a name depend on the type of the object designated by the name.

Related tasks

Creating a trigger (Db2 Application programming and SQL)

Converting existing triggers to support advanced capabilities (Db2 Application programming and SQL)

CREATE TRIGGER (basic)

The CREATE TRIGGER (basic) statement defines a basic trigger in a schema and builds a trigger package at the current server. Each time that the trigger activates, the trigger package executes one or more times.

For a description of the differences between basic and advanced triggers, see Triggers (Introduction to Db2 for z/OS).

Invocation for CREATE TRIGGER (basic)

The statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES RUN behavior is in effect. For more information, see "Authorization IDs and dynamic SQL" on page 94.

Authorization for CREATE TRIGGER (basic)

The privilege set that is defined below must include at least one of the following:

- The CREATEIN privilege on the schema
- SYSADM or SYSCTRL authority
- System DBADM
- Installation SYSOPR authority (when the current SQLID of the process is set to SYSINSTL)

In defining a trigger on a table, the privilege set that is defined below must include SYSADM authority or each of the following:

- The SELECT privilege on the table on which the trigger is defined, if the REFERENCING clause is included in the trigger definition
- The SELECT privilege on any table or view in the *search-condition* of the *triggered-action*
- The necessary privileges to invoke the triggered SQL statements in the triggered action
- The authorization to define a trigger on the table, which must include at least one of the following:
  - The TRIGGER privilege on the table on which the trigger is defined
  - The ALTER privilege on the table on which the trigger is defined
  - DBADM authority on the database that contains the table
  - SYSCTRL authority
  - Installation SYSOPR authority (when the current SQLID of the process is set to SYSINSTL)
  - System DBADM authority

  If the database is implicitly created, the database privileges must be on the implicit database or on DSNDB04.

In defining a trigger on a view, the privilege set that is defined below must include SYSADM authority or each of the following:

- The SELECT privilege on the view on which the trigger is defined, if the REFERENCING clause is included in the trigger definition
- The SELECT privilege on any table or view in the *search-condition* of the *triggered-action*
- The necessary privileges to invoke the triggered SQL statements in the triggered action
- The authorization to define a trigger on the view, which must include at least one of the following:
  - Ownership of the view on which the trigger is defined
  - SYSCTRL authority
  - System DBADM authority

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the owner is a role, the implicit schema match does not apply and this role needs to include one of the previously listed conditions.

If the statement is dynamically prepared and is not running in a trusted context for which the ROLE AS OBJECT OWNER clause is specified, the privilege set is the set of privileges that are held by the SQL authorization ID of the process. The specified trigger name can include a schema name (a qualifier). If the schema name is not the same as the SQL authorization ID of the process, one of the following conditions must be met:

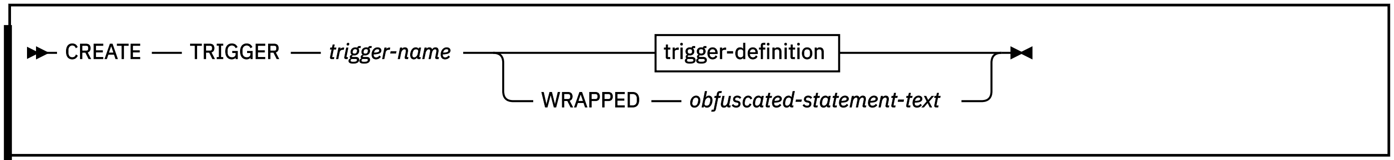
- The privilege set includes SYSADM or SYSCTRL authority.
- The SQL authorization ID of the process has the CREATEIN privilege on the schema.

If the SECURED option is specified, at least one of the following privileges is required:

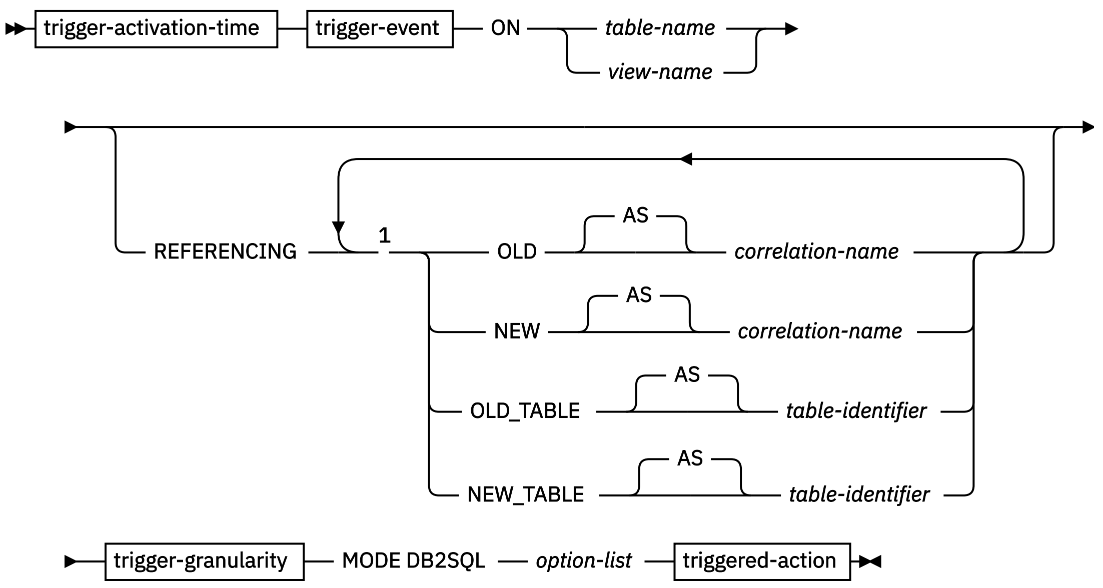
- SECADM authority
- CREATE_SECURE_OBJECT privilege

Note: If the SEPARATE SECURITY subsystem parameter is set to NO, SYSADM authority has implicit SECADM authority.

Syntax for CREATE TRIGGER (basic)



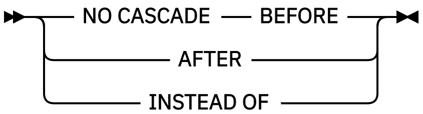
trigger-definition



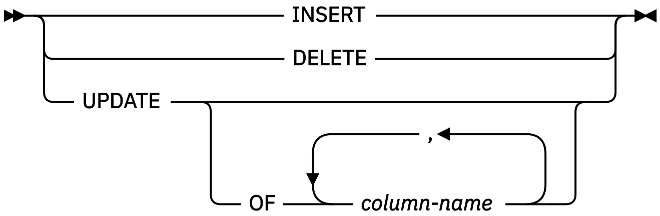
Notes:

[1] The same clause must not be specified more than one time.

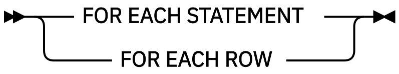
trigger-activation-time



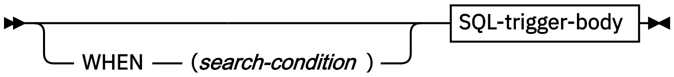
trigger-event



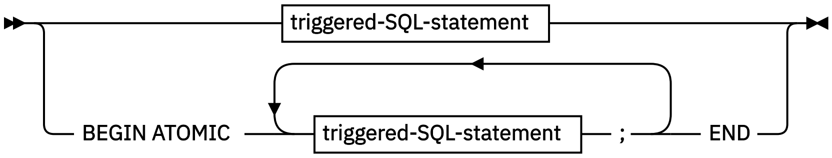
trigger-granularity



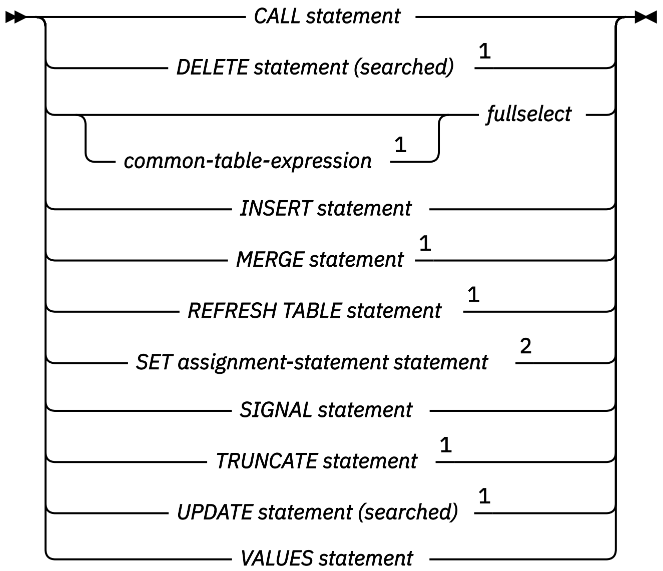
triggered-action



SQL-trigger-body



triggered-SQL-statement:



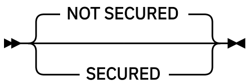
CALL statement
DELETE statement (searched) 1
common-table-expression 1
fullselect
INSERT statement
MERGE statement 1
REFRESH TABLE statement 1
SET assignment-statement statement 2
SIGNAL statement
TRUNCATE statement 1
UPDATE statement (searched) 1
VALUES statement

Notes:

[1] The statement is not allowed in an *SQL-trigger-body* for a BEFORE trigger.

[2] The target of a SET-assignment-statement statement must be a transition variable.

option-list:



Description for CREATE TRIGGER (basic)

trigger-name

Names the trigger. The name, including the implicit or explicit schema name, must not identify a trigger that exists at the current server.

The name is also used to create the trigger package; therefore, the name must also not identify a package that is already described in the catalog. The schema name becomes the collection-id of the trigger package. Although *trigger-name* can be specified as an ordinary or delimited identifier, the name should conform to the rules for an ordinary identifier. Refer to The implicitly created trigger package for additional information.

The schema name can be 'SYSTOOLS' if the privilege set includes the SYSCTRL privilege. Otherwise, the schema name must not begin with 'SYS' unless the schema name is 'SYSADM', 'SYSIBMADM', or 'SYSPROC'.

NO CASCADE BEFORE

Specifies that the trigger is a before trigger. Db2 executes the triggered action before it applies any changes caused by an insert, delete, or update operation on the subject table. It also specifies that the triggered action does not activate other triggers because the triggered action of a before trigger cannot contain any updates, REFRESH TABLE, or TRUNCATE SQL statements.

BEFORE must not be specified when *view-name* is also specified. FOR EACH ROW must be specified for a BEFORE trigger.

AFTER

Specifies that the trigger is an after trigger. Db2 executes the triggered action after it applies any changes caused by an insert, delete, or update operation on the subject table. AFTER must not be specified if *view-name* is also specified.

INSTEAD OF

Specifies that the trigger is an instead of trigger. The associated triggered action replaces the action against the subject view. Only one INSTEAD OF trigger is allowed for each type of operation on a given subject view. Db2 executes the *triggered-action* instead of the insert, update, or delete operation on the subject view.

INSTEAD OF must not be specified when *table-name* is also specified. The WHEN clause can not be specified for an INSTEAD OF trigger. FOR EACH STATEMENT must not be specified for an INSTEAD OF trigger.

In the view definition, the non-numeric columns of the outermost SELECT list of the fullselect must use the same encoding scheme.

ON *table-name*

Identifies the subject table of the BEFORE or AFTER trigger definition. The name must identify a base table that exists at the current server. It must not identify a materialized query table, a clone table, a temporary table, an auxiliary table, an alias, a synonym, a real-time statistics table, an accelerator-only table, a catalog table, or a directory table.

ON *view-name*

Identifies the subject view of the INSTEAD OF trigger definition. The name must identify a view that exists at the current server.

view-name must not specify a view where any of the following conditions are true:

- The view is defined with the WITH CASCADED CHECK option (a symmetric view)
- The view on which a symmetric view has been defined
- The view references data that is encoded with different encoding schemes or CCSID values
- The view has a column that is a ROWID column
- The view has a column that is based on an underlying column of any of the following types:
  - A LOB, XML, or ROWID column
  - An identity column
  - A security label column
  - A row change timestamp column
  - A row-begin column
  - A row-end column
  - A transaction start ID column
- The view has columns that have field procedures
- All of the underlying tables of the view are catalog tables
- All of the underlying tables of the view are created global temporary tables
- All of the underlying tables of the view are clone tables
- The view has other views that are dependent on it

REFERENCING

Specifies the correlation names for the transition variables and the table names for the transition tables. For the rows in the subject table that are modified by the triggering SQL operation (insert, delete, or update), a correlation name identifies the columns of a specific row. *table-identifiers* identify the complete set of affected rows. Transition variables with XML types cannot be referenced inside of a trigger. If the column of a transition table is referenced, the data type of the column cannot be XML.

Each row that is affected by the triggering SQL operation is available to the triggered action by qualifying column names with *correlation-names* that are specified as follows:

OLD AS *correlation-name*

Specifies the correlation name that identifies the values in the row prior to the triggering SQL operation.

NEW AS *correlation-name*

Specifies the correlation name that identifies the values in the row as modified by the triggering SQL operation and by any assignment statement in a before trigger that has already been executed.

The complete set of rows that are affected by the triggering operation is available to the triggered action by using *table-identifiers* that are specified as follows:

OLD_TABLE AS *table-identifier*

Specifies the name of a temporary table that identifies the values in the complete set of rows that are modified rows by the triggering SQL operation prior to any actual changes.

NEW_TABLE AS *table-identifier*

Specifies the name of a temporary table that identifies the values in the complete set of rows as modified by the triggering SQL operation and by any assignment statement in a before trigger that has already been executed.

Only one OLD and one NEW *correlation-name* can be specified for a trigger. Only one OLD_TABLE and one NEW_TABLE *table-identifier* can be specified for a trigger. All of the *correlation-names* and *table-identifiers* must be unique from one another.

Table 222 on page 1770 summarizes the allowable combinations of transition variables and transition tables that you can specify for the various trigger types. The OLD *correlation-name* and the OLD_TABLE *table-identifier* are valid only if the triggering event is either a delete operation or an update operation. For a delete operation, the OLD *correlation-name* captures the values of the columns in the deleted row, and the OLD_TABLE *table-identifier* captures the values in the set of deleted rows. For an update operation, the OLD *correlation-name* captures the values of the columns of a row before the update operation, and the OLD_TABLE *table-identifier* captures the values in the set of updated rows.

The NEW *correlation-name* and the NEW_TABLE *table-identifier* are valid only if the triggering event is either an insert operation or an update operation. For both operations, the NEW *correlation-name* captures the values of the columns in the inserted or updated row and the NEW_TABLE *table-identifier* captures the values in the set of inserted or updated rows. For BEFORE triggers, the values of the updated rows include the changes from any assignment statements in the triggered action of BEFORE triggers.

Table 222. Allowable combinations of attributes in a trigger definition

Granularity	Activation time	Triggering SQL operation	Transition variables allowed“1” on page 1770	Transition tables allowed“1” on page 1770
FOR EACH ROW	BEFORE	DELETE	OLD	None
		INSERT	NEW	None
		UPDATE	OLD, NEW	None
	AFTER	DELETE	OLD	OLD_TABLE
		INSERT	NEW	NEW_TABLE
		UPDATE	OLD, NEW	OLD_TABLE, NEW_TABLE
	INSTEAD OF	DELETE	OLD	OLD_TABLE
		INSERT	NEW	NEW_TABLE
		UPDATE	OLD, NEW	OLD_TABLE, NEW_TABLE
FOR EACH STATEMENT	AFTER	DELETE	None	OLD_TABLE
		INSERT	None	NEW_TABLE
		UPDATE	None	OLD_TABLE, NEW_TABLE

Note:

1. If a transition table or variable is referenced where it is not allowed, an error is returned.

A transition variable that has a character data type inherits the subtype and CCSID of the column of the subject table. During the execution of the triggered action, the transition variables are treated like host variables. Therefore, character conversion might occur. However, unlike a host variable, a transition variable can have the bit data attribute, and character conversion never occurs for bit data. A transition variable is considered to be bit data if the column of the table to which it corresponds is bit data.

You cannot modify a transition table; transition tables are read-only. Although a transition table does not inherit any edit or validation procedures from the subject table, it does inherit the encoding scheme and field procedures of the subject table.

The scope of each *correlation-name* and each *table-identifier* is the entire trigger definition.

trigger-granularity

FOR EACH ROW or FOR EACH STATEMENT
Specifies the conditions for which Db2 executes the triggered action.

FOR EACH ROW
Specifies that Db2 executes the triggered action for each row of the subject table that the triggering SQL operation modifies. If the triggering SQL operation does not modify any rows, the triggered action is not executed..

FOR EACH STATEMENT
Specifies that Db2 executes the triggered action only one time for the triggering operation. Even if the triggering operation does not modify or delete any rows, the triggered action is executed one time.

FOR EACH STATEMENT must not be specified for a BEFORE or INSTEAD OF trigger.

MODE DB2SQL

Indicates that a basic trigger is to be created.

NOT SECURED or SECURED

Specifies whether the trigger is considered secure. NOT SECURED is the default.

SECURED

Specifies the trigger is considered secure.

SECURED must be specified for a trigger if its subject table is using row access control or column access control. SECURED must also be specified for a trigger that is created for a view and one or more of the underlying tables in the view definition is using row access control or column access control.

NOT SECURED

Specifies the trigger is considered not secure.

NOT SECURED must not be specified for a trigger whose subject table is using row access control or column access control. NOT SECURED must also not be specified for a trigger that is created for a view and one or more of the underlying tables in the view definition is using row access control or column access control.

trigger-event

Specifies that the triggered action that is associated with the trigger is to be executed when the trigger event is applied to the subject table or view.

INSERT

Specifies that the trigger is an insert trigger. Db2 executes the triggered action whenever there is an insert operation on the subject table. However, if the insert trigger is defined on any explain table, and the insert operation was caused by Db2 adding a row to the table, the triggered action is not to be executed.

DELETE

Specifies that the trigger is a delete trigger. Db2 executes the triggered action whenever there is a delete operation on the subject table.

UPDATE

Specifies that the trigger is an update trigger. Db2 executes the triggered action whenever there is an update operation on the subject table.

If you do not specify a list of column names, an update operation on any column of the subject table, including columns that are subsequently added with the ALTER TABLE statement, activates the triggered action.

OF *column-name,...*

Each *column-name* that you specify must be a column of the subject table and must appear in the list only once. An update operation on any of the listed columns activates the triggered action.

UPDATE OF *column-name* cannot be specified for an INSTEAD OF trigger.

triggered-action

Specifies the action to be performed when the trigger is activated. The *triggered-action* is composed of one or more SQL statements and an optional condition that controls whether the statements are executed.

WHEN (*search-condition*)

Specifies a condition that evaluates to true, false, or unknown. The triggered SQL statements are executed only if the *search-condition* evaluates to true. If the WHEN clause is omitted, the associated SQL statements are always executed.

The WHEN clause must not be specified for an INSTEAD OF trigger.

SQL-trigger-body

Specifies the SQL statements that are to be executed for the triggered action. Only certain SQL statements can be specified in the SQL-trigger-body.

triggered-SQL-statement
Specifies the SQL statements that can be specified as the only statement in a trigger body.

BEGIN ATOMIC *triggered-SQL-statement,...* END
Specifies a list of SQL statements that are to be executed for the triggered action. The statements are executed in the order in which they are specified.

Only certain SQL statements can be specified in the *SQL-trigger-body*.

The trigger body must not contain a statement that is not supported. Table 223 on page 1772 shows the list of allowable SQL statements, which differs depending on whether the trigger is being defined as BEFORE, AFTER, or INSTEAD OF. An 'X' in the table indicates that the statement is valid.

Table 223. Allowable SQL statements

	Trigger activation time		
SQL statement	**BEFORE**	**AFTER**	**INSTEAD OF**
CALL	X	X	X
DELETE (searched)		X	X
fullselect	X	X	X
INSERT		X	X
MERGE		X	X
REFRESH TABLE		X	X
SET transition variable	X		
SIGNAL	X	X	X
TRUNCATE		X	X
UPDATE (serached)		X	X
VALUES	X	X	X

The statements in the triggered action have these restrictions:

- They must not refer to host variables, parameter markers, undefined transition variables, or declared temporary tables.
- They must only refer to a table or view that is at the current server.
- They must only invoke a stored procedure or user-defined function that is at the current server. An invoked routine can, however, access a server other than the current server.
- They must not contain a fullselect that refers to the subject table if the trigger is defined as BEFORE.
- They must not modify a column that is part of a BUSINESS_TIME period.
- If the trigger is a before trigger:
  - The trigger body must not contain a DELETE, INSERT, MERGE, REFRESH TABLE, TRUNCATE, UPDATE statement, or SELECT FROM *data-change-statement*, and must not reference a procedure or function that is defined as MODIFIES SQL DATA.
  - The trigger body must not, directly or indirectly, issue a CALL statement for a procedure containing one of the following statements:
    - ALTER
    - COMMENT
    - CREATE
    - DELETE
    - DROP

- EXCHANGE
- GRANT
- LABEL
- LOCK TABLE
- MERGE
- REFRESH TABLE
- RENAME
- REVOKE
- TRUNCATE
- UPDATE

A CREATE TRIGGER statement cannot contain a hexadecimal graphic string (GX) constant.

The triggered action can refer to the values in the set of affected rows. This action is supported through the use of transition variables and transition tables.

All tables, views, aliases, sequences, roles, user-defined data types, user-defined functions, and procedures referenced in the *triggered-action* must exist at the current server when the version of the trigger is defined. The table or view that an alias refers to must also exist when the version of the trigger is defined.

WRAPPED *obfuscated-statement-text*

Specifies the encoded definition of the trigger. A CREATE TRIGGER statement can be encoded using the WRAP scalar function.

WRAPPED must not be specified on a static CREATE statement.

Notes for CREATE TRIGGER (basic)

Owner privileges:

When an INSTEAD OF trigger is defined, the associated privilege (INSERT, UPDATE, or DELETE on the view) is given to the owner of the view. The owner is granted the privilege with the ability to grant that privilege to others. For more information about ownership of an object, see "Authorization, privileges, permissions, masks, and object ownership" on page 90.

Execution authorization:

The user executing the triggering SQL operation does not need authority to execute a *SQL-trigger-body*. An *SQL-trigger-body* executes using the authority of the owner of the trigger.

Activating a trigger:

Only insert, delete, or update operations can activate a trigger. The activation of a trigger might cause trigger cascading.*Trigger cascading* is the result of the activation of one trigger that executes SQL statements that cause the activation of other triggers or even the same trigger again. The triggered actions might also cause updates as a result of the original modification, which can result in the activation of additional triggers. With trigger cascading, a significant chain of triggers might be activated, causing a significant change to the database as a result of a single insert, delete, or update operation.

Loading a table with the LOAD utility does not activate any triggers that are defined for the table if the SHRLEVEL NONE option is specified or accepted as the default. If the LOAD statement includes the SHRLEVEL CHANGE option, triggers are activated when loading a table with the LOAD utility.

Adding triggers to enforce constraints:

Adding a trigger on a table that already has rows in it will not cause the *triggered-action* to be executed. Thus, if the trigger is designed to enforce constraints on the data in the table, the data in the existing rows might not satisfy those constraints.

Multiple triggers:
Multiple triggers that have the same triggering SQL operation and activation time can be defined on a table. The triggers are activated in the order in which they were created. For example, the trigger that was created first is executed first; the trigger that was created second is executed second.

Transition variables and transition tables:
The *triggered-action* can refer to the values in the set of affected rows. This action is supported through the use of transition variables and transition tables.

A transition variable has the same name, data type, and nullability attribute as the corresponding column of the table that the trigger is defined on. A transition variable contains the value of a column in an affected row. A transition variable is qualified by a correlation name that identifies whether the reference is to the old value (before the update) or the new value (after the update). A transition variable can be referenced in the search condition, or in an SQL statement in the trigger body, wherever a variable would be allowed if the reference was made outside the body of a trigger. A new transition variable can be assigned a value in a before update or insert trigger. The values of the updated rows include the changes from any assignments to transition variables in the *triggered-action* of a before trigger.

A transition table contains the complete set of affected rows: either the old values (before the update) or the new values (after the update). A transition table is read-only, and can be referenced in the *triggered-action* of an after or instead of trigger. A column of a transition table has the same name, data type, and null attribute as the corresponding column of the table that the trigger is defined on. A transition table is referenced using an associated table identifier that allows the complete set of affected rows to be treated as a table. A transition table can be referenced in a search condition, or in an SQL statement in the trigger body, wherever a table would be allowed if the reference was made outside the body of a trigger. In addition, a transition table can be passed as an argument to a user-defined function or procedure, specifying the TABLE keyword before the table identifier for the transition table. When the function or procedure is invoked, a table locator is passed for the transition table.

A transition variable or transition table is not affected after being returned from a procedure invoked from within a triggered action regardless of whether the corresponding parameter was defined in the CREATE PROCEDURE statement as IN, INOUT, or OUT.

Considerations for *table-locator-reference* elements:
table-locator-reference must not be specified in the body of a trigger.

Considerations for implicitly hidden columns:
In the body of a trigger, a transition variable that corresponds to an implicitly hidden column can be referenced. A transition table, that corresponds to a table with an implicitly hidden column, includes that column as part of the transition table. Likewise, a transition variable will exist for the column that is defined as implicitly hidden. A transition variable that corresponds to an implicitly hidden column can be referenced in the body of a trigger.

Identifier resolution:
Names that are the same should be explicitly qualified. Qualifying a name clearly indicates whether the name refers to a column, a transition variable, or a global variable. If the name is not qualified or is qualified but is still ambiguous, the following rules describe how the name is resolved. If correlation names are specified for both old and new transition variables, a reference to a transition variable must be qualified with the associated correlation name. The name is resolved by checking for a match in the following order:

- If the tables and views specified in the trigger body exist at the time the trigger is created, the name is first checked as a column name at the current server. If the name is found as a column name, but the privilege set that is used to issue the CREATE statement does not have the proper authority to access the table or view, an error is returned.
- If the name is not found as a column, the name is checked as a transition variable name.
- If the name is not found as a transition variable, the name is checked as a global variable.
- If the name is still not resolved, an error is returned.

Considerations for transition variables in AFTER and INSTEAD OF triggers:

Transition variables cannot be modified in an AFTER or INSTEAD OF trigger.

Invalidation of packages:

This statement might invalidate all packages that depend on target objects, and sometimes other related objects through cascading effects, depending on the clauses and keywords specified and other factors. For more information, see Changes that invalidate packages (Db2 Application programming and SQL).

Invalidation of cached dynamic SQL statements:

This statement might invalidate cached dynamic SQL statements that depend on target objects, and sometimes other related objects through cascading effects. For more information, see Invalidation of cached dynamic statements (Db2 Performance).

Considerations for INSTEAD OF triggers:

The addition of an INSTEAD OF trigger for a view affects the read only characteristic of the view. If a read-only view has a dependency relationship with an INSTEAD OF trigger, the type of operation that is defined for the INSTEAD OF trigger defines whether the view is deletable, insertable, or updatable.

The creation of an INSTEAD OF trigger causes dependent packages, plans, and statements in the dynamic statement cache to be marked invalid if the view definition is not read-only.

The initial values for new transition variables or new transition table columns that are visible in an INSTEAD OF INSERT trigger are set as follows:

- If a value is explicitly specified for a column in the insert operation, the corresponding new transition variable is that explicitly specified value.
- If a value is not explicitly specified for a column in the insert operation or the DEFAULT clause is specified, the corresponding new transition variable is:
  - the default value of the underlying table column if the view column is updatable (without the INSTEAD OF trigger)
  - otherwise, the null value

  If a view column is not nullable and does not have a default, the value must be explicitly specified in the insert operation.

The initial values for new transition variables that are visible in an INSTEAD OF UPDATE trigger are set as follows:

- If a value is explicitly specified for a column in the update operation, the corresponding new transition variable is that explicitly specified value
- If the DEFAULT clause is explicitly specified for a column in the update operation, the corresponding new transition variable is:
  - the default value of the underlying table column if the view column is updatable (without the INSTEAD OF trigger)
  - otherwise, the null value

  If a view column is not nullable and does not have a default, the value must be explicitly specified in the update operation.
- Otherwise, the corresponding new transition variable is the existing value of the column in the row.

Considerations for a MERGE statement:

The MERGE statement can execute insert, delete, and update operations. The applicable triggers are activated for the MERGE statement for the data change operations that are executed.

Considerations for triggers that are defined on tables that contain XML columns:

Although a trigger can be defined on a table that contains an XML column:

- An XML column cannot be referenced with a trigger transition variable in the trigger body.
- An XML column of a transition table cannot be referenced in the trigger body.

Creating a trigger with the SECURED option:

Typically, the security administrator will examine the data that is accessed by a trigger, ensure that it is secure, and grant the CREATE_SECURE_OBJECT privilege to someone who requires the privileges to create a secured trigger. After the trigger is created, the security administrator will revoke the CREATE_SECURE_OBJECT privilege from the owner of the trigger.

The trigger is considered secure after the CREATE TRIGGER statement is executed. Db2 treats the SECURED attribute as an assertion that declares that the user has established an audit procedure for all activities in the trigger body. If a secure trigger references user-defined functions, Db2 assumes those functions are secure without validation. If those functions can access sensitive data, the user with SECADM authority needs to ensure that those functions are allowed to access that data and that an audit procedure is in place for all versions of those functions, and that all subsequent ALTER FUNCTION statements or changes to external packages are being reviewed by this audit process.

A trigger must be secure if its subject table is using row access control or column access control. SECURED must also be specified for a trigger that is created for a view and one or more of the underlying tables in the view definition is using row access control or column access control.

Creating a trigger with the NOT SECURED option:

The CREATE TRIGGER statement returns an error if the subject table of the trigger is using row access control or column access control, or if the trigger is for a view and one or more of the underlying tables in the view definition is using row access control or column access control.

Row and column access control that is not enforced for transition variables and transition tables:

If row access control or column access control is enforced for the subject table of the trigger, row permissions and column masks are not applied to the initial values of transition variables and transition tables. Row access control and column access control is enforced for the triggering table, but is ignored for transition variables and transition tables that are referenced in the body of the trigger body or are passed as arguments to user-defined functions that are invoked in the body of the trigger. To ensure that there are no security concerns for SQL statements accessing sensitive data in transition variables and transition tables in the trigger action, the trigger must be created with the SECURED option. If a trigger is not secure, the CREATE TRIGGER statement returns an error.

Restrictions involving pending definition changes:

CREATE TRIGGER is not allowed if the trigger is defined on a table for which there are pending definition changes.

Considerations for the special plan, statement, and function tables for EXPLAIN:

You can create a trigger on PLAN_TABLE, DSN_STATEMNT_TABLE, or DSN_FUNCTION_TABLE. However, insert triggers that are defined on these tables are not activated when Db2 adds rows to the tables.

Dependent objects:

A trigger is dependent on the triggering table and objects that are referenced in the trigger body.

Adding a column to a subject table or a table referenced in the *triggered-action*:

If a column is added to the subject table after triggers have been defined, the following rules apply:

- If the trigger is an update trigger that was defined without an explicit list of column names, an update to the new column activates the trigger.
- If the subject table is referenced in the *triggered-action*, the new column is not accessible to the SQL statements until the trigger package is rebound.
- The OLD_TABLE and the NEW_TABLE transition tables contain the new column, but the column cannot be referenced unless the trigger is re-created. If the transition tables are passed to a user-defined function or a stored procedure, the user-defined function or stored procedure must be re-created with the new definition of the table (that is, the function or procedure must be dropped and re-created), and the package for the user-defined function or stored procedure must be rebound.

If a column is added to any table that is referenced in the *triggered-action*, the new column is not accessible to the SQL statements until the trigger package is rebound.

Dropping a column from a subject table or a table referenced in the *triggered-action*:
A column cannot be dropped from a table for which a trigger is defined.

Altering the attributes of a column that the triggered action references:
If a column is altered in the table on which the trigger is defined (the subject table), the alter is processed, and the dependent trigger packages are invalidated.

Renaming the table for which the trigger is defined, or tables referenced in the *triggered-action*:
You cannot rename a table for which a trigger is defined (the subject table). Except for the subject table, you can rename any table to which the SQL statements in the triggered action refer. After renaming such a table, drop the trigger and then re-create the trigger so that it refers to the renamed table.

Dropping the table or view for which a trigger is defined:
If the table or view that a trigger is defined on is dropped, the trigger is also dropped.

Effects of dropping or revoking privileges on an object referenced in the *triggered-action*:
Dropping an object that is referenced in the body of a trigger, or revoking a privilege to an object that is referenced in the body of a trigger, might have the following results:

- Dropping any table, view, alias, or index that is referenced or used within the SQL statements in the triggered action causes the trigger and its package to be invalidated.
- Dropping a synonym that is referenced does not have any effect on the trigger or its package.
- Dropping a user-defined function that is referenced by the SQL statements in the triggered action is not allowed. An error occurs.
- Dropping a sequence that is referenced by the SQL statements in the triggered action is not allowed. An error occurs.
- Revoking a privilege on which the trigger depends causes the trigger and its package to be invalidated. If the appropriate privilege does not exist when the trigger package is rebound, the SQL statement that references the object fails.

Error handling in triggers:
A trigger can return errors, like other SQL statements. Applications need to account for the possible errors that can be expected when a trigger is invoked.

Triggers and global variables:
The content of a global variable that is referenced by a trigger is inherited from the triggering SQL operation (delete, insert, or update).

Special registers:
The values of the special registers that are used in the trigger body are determined when the trigger is activated. The value of the CURRENT PACKAGESET special register is set to the schema name of the trigger, and the values of the other special registers are inherited from the triggering SQL operation (insert, update, or delete). Special register values are saved when a trigger is activated and are restored on return from the trigger. The CURRENT DATE, CURRENT TIME, and CURRENT TIMESTAMP special registers are not restored on return from the trigger.

Result sets for stored procedures:
If a trigger invokes a stored procedure that returns result sets, the application that activated the trigger cannot access those result sets.

Transaction isolation:
All of the statements in the *SQL-trigger-body* run under the isolation level that is in effect for the trigger.

Limiting processor time:
The Db2 resource limit facility allows you to specify the maximum amount of processor time for a dynamic, manipulative SQL statement such as SELECT or SQL data change statements. The execution of a trigger is counted as part of the triggering SQL statement.

Errors binding triggers:
When a CREATE TRIGGER statement is bound, the SQL statements within the triggered action might not be fully parsed. Syntax errors in those statements might not be caught until the CREATE TRIGGER statement is executed.

Characteristics of the package that is generated for a trigger:

The package that is associated with the trigger is named as follows:

- *location* is set to the value of the CURRENT SERVER special register.
- *collection-id* (schema) for the package is the same as the schema qualifier of the trigger.
- *package-id* is the same as the name of the trigger.
- *version-id* is an empty string.

Db2 creates the trigger package with the following initial attributes (some of these attributes can be modified using the REBIND TRIGGER PACKAGE command):

- ACTION(ADD)
- ARCHIVESENSITIVE(YES)
- BUSTIMESENSITIVE(YES)
- CURRENTDATA(NO)
- DBPROTOCOL(DRDA)
- DEGREE(1)
- DESCSTAT(value from the DESCSTAT subsystem parameter)
- DYNAMICRULES(BIND)
- ENABLE(*)
- ENCODING(0)
- EXPLAIN(NO)
- FLAG(I)
- ISOLATION(CS)
- REOPT(NONE)
- NODEFER(PREPARE)
- OPTHINT
- OWNER(authorization ID) or ROLE
- PATH(path)
- RELEASE(COMMIT)
- ROUNDING(value from the CURRENT DECFLOAT ROUNDING MODE special register)
- SQLERROR(NOPACKAGE)
- SYSTIMESENSITIVE(YES)
- QUALIFIER(authorization ID)
- VALIDATE(BIND)

The values of OWNER, QUALIFIER, and PATH are set depending on whether the CREATE TRIGGER statement is embedded in a program or issued interactively. If the statement is embedded in a program, OWNER and QUALIFIER are the owner and qualifier of the package or plan. PATH is the value from the PATH bind option. If the statement is issued interactively, both OWNER and QUALIFIER are the SQL authorization ID. PATH is the value in the CURRENT PATH special register.

Multiple versions of a trigger package are not allowed. Use the REBIND TRIGGER PACKAGE command to explicitly rebind the basic trigger package. To specify the name of a trigger package for the bind commands, the trigger name must conform to the rules for an ordinary identifier.

A trigger package becomes invalid if an object or privilege on which it depends is dropped or revoked. The next time that the trigger is activated, Db2 attempts to rebind the invalid trigger package. If the automatic rebind is unsuccessful, the trigger package remains invalid.

You cannot create another package from the trigger package, such as with the BIND COPY command. The only way to drop a trigger package is to drop the trigger or the subject table. Dropping the trigger drops the trigger package; dropping the subject table drops the trigger and the trigger package.

Each time that the trigger activates, the trigger package executes one or more times.

Considerations for SQL processor programs:
SQL processor programs, such as SPUFI, the command line processor, and DSNTEP2, might not correctly parse SQL statements in the triggered action that are ended with semicolons. These processor programs accept multiple SQL statements, each separated with a terminator character, as input. Processor programs that use a semicolon as the SQL statement terminator can truncate a CREATE TRIGGER statement with embedded semicolons and pass only a portion of it to Db2. Therefore, you might need to change the SQL terminator character for these processor programs. For information on changing the terminator character for SPUFI and DSNTEP2, see Setting the SQL terminator character in a SPUFI input data set (Db2 Application programming and SQL) and DSNTEP2 and DSNTEP4 sample programs (Db2 Application programming and SQL).

Application compatibility level:
The SQL statements in the trigger body must conform to the behavior specified by the application compatibility option in effect. The application compatibility value used to process the trigger is recorded in the APPLCOMPAT column of the SYSIBM.SYSPACKAGE catalog table.

Alternative syntax and synonyms:
To provide compatibility with previous releases of Db2 or other products in the Db2 family, Db2 supports the following keywords:

- OLD TABLE as a synonym for OLD_TABLE
- NEW TABLE as a synonym for NEW_TABLE

Obfuscated statements:
A CREATE TRIGGER statement can be executed in obfuscated form. In an obfuscated statement, only the trigger name and the WRAPPED keyword are readable. The rest of the statement is encoded in such a way that it is not readable but can be decoded by a database server that supports obfuscated statements. The WRAP scalar function produces obfuscated statements. Any debug options that are specified when the trigger is created from an obfuscated statement are ignored.

Examples for CREATE TRIGGER (basic)

Example 1

Create two triggers that track the number of employees that a company manages. The subject table is the EMPLOYEE table, and the triggers increment and decrement a column with the total number of employees in the COMPANY_STATS table. The tables have these columns:

EMPLOYEE table: ID, NAME, ADDRESS, and POSITION
COMPANY_STATS table: NBEMP, NBPRODUCT, and REVENUE

This example shows the use of transition variables in a row trigger to maintain summary data in another table.

Create the first trigger, NEW_HIRE, so that it increments the number of employees each time a new person is hired; that is, each time a new row is inserted into the EMPLOYEE table, increase the value of column NBEMP in table COMPANY_STATS by 1.

```
CREATE TRIGGER NEW_HIRE
   AFTER INSERT ON EMPLOYEE
   FOR EACH ROW MODE DB2SQL
   BEGIN ATOMIC
     UPDATE COMPANY_STATS SET NBEMP = NBEMP + 1;
   END
```

Create the second trigger, FORM_EMP, so that it decrements the number of employees each time an employee leaves the company; that is, each time a row is deleted from the table EMPLOYEE, decrease the value of column NBEMP in table COMPANY_STATS by 1.

```
   CREATE TRIGGER FORM_EMP
      AFTER DELETE ON EMPLOYEE
      FOR EACH ROW MODE DB2SQL
      BEGIN ATOMIC
        UPDATE COMPANY_STATS SET NBEMP = NBEMP - 1;
      END
```

Example 2

Create a trigger, REORDER, that invokes user-defined function ISSUE_SHIP_REQUEST to issue a shipping request whenever a parts record is updated and the on-hand quantity for the affected part is less than 10% of its maximum stocked quantity. User-defined function ISSUE_SHIP_REQUEST orders a quantity of the part that is equal to the part's maximum stocked quantity minus its on-hand quantity; the function also ensures that the request is sent to the appropriate supplier.

The parts records are in the PARTS table. Although the table has more columns, the trigger is activated only when columns ON_HAND and MAX_STOCKED are updated.

```
 CREATE TRIGGER REORDER
     AFTER UPDATE OF ON_HAND, MAX_STOCKED ON PARTS
     REFERENCING NEW AS NROW
     FOR EACH ROW
     MODE DB2SQL
     WHEN (NROW.ON_HAND < 0.10 * NROW.MAX_STOCKED)
     BEGIN ATOMIC
       VALUES(ISSUE_SHIP_REQUEST(NROW.MAX_STOCKED - NROW.ON_HAND, NROW.PARTNO));
     END
```

Example 3

Repeat the scenario in *Example 2* except use a fullselect instead of a VALUES statement to invoke the user-defined function. This example also shows how to define the trigger as a statement trigger instead of a row trigger. For each row in the transition table that evaluates to true for the WHERE clause, a shipping request is issued for the part.

```
 CREATE TRIGGER REORDER
     AFTER UPDATE OF ON_HAND, MAX_STOCKED ON PARTS
     REFERENCING NEW_TABLE AS NTABLE
     FOR EACH STATEMENT MODE DB2SQL
       BEGIN ATOMIC
         SELECT ISSUE_SHIP_REQUEST(MAX_STOCKED - ON_HAND, PARTNO)
           FROM NTABLE
         WHERE (ON_HAND < 0.10 * MAX_STOCKED);
     END
```

Example 4

Assume that table EMPLOYEE contains column SALARY. Create a trigger, SAL_ADJ, that prevents an update to an employee's salary that exceeds 20% and signals such an error. Have the error that is returned with an SQLSTATE of '75001' and a description. This example shows that the SIGNAL statement is useful for restricting changes that violate business rules.

```
   CREATE TRIGGER SAL_ADJ
     AFTER UPDATE OF SALARY ON EMPLOYEE
     REFERENCING OLD AS OLD_EMP
                 NEW AS NEW_EMP
     FOR EACH ROW MODE DB2SQL
     WHEN (NEW_EMP.SALARY > (OLD_EMP.SALARY * 1.20))
       BEGIN ATOMIC
         SIGNAL SQLSTATE '75001' ('Invalid Salary Increase - Exceeds 20');
       END
```

Example 5

Assume that the following statements create a table, WEATHER (which stores temperature values in Fahrenheit), and a view, CELSIUS_WEATHER for users who prefer to work in Celsius instead of Fahrenheit:

```
   CREATE TABLE WEATHER
      (CITY VARCHAR(25),
       TEMPF DECIMAL(5,2));
   CREATE VIEW CELSIUS_WEATHER (CITY, TEMPC) AS
      SELECT CITY, (TEMPF-32)/1.8
      FROM WEATHER;
```

The following INSTEAD OF trigger is used on the CELSIUS_WEATHER view to convert Celsius values to Fahrenheit values and then insert the Fahrenheit value into the WEATHER table:

```
   CREATE TRIGGER CW_INSERT INSTEAD OF INSERT
      ON CELSIUS_WEATHER
      REFERENCING NEW AS NEWCW
      FOR EACH ROW MODE DB2SQL
        BEGIN ATOMIC
           INSERT INTO WEATHER VALUES
             (NEWCW.CITY,
              1.8*NEWCW.TEMPC+32);
        END
```

Example 6

Consider an application that records and tracks changes to stock prices. The database contains two tables, CURRENTQUOTE and QUOTEHISTORY. CURRENTQUOTE has columns SYMBOL, QUOTE, and STATUS. QUOTEHISTORY has columns SYMBOL, QUOTE, and QUOTE_TIMESTAMP.

When the QUOTE column of CURRENTQUOTE is updated, the new quote must be copied, with a timestamp, to the QUOTEHISTORY table. Also, the STATUS column of CURRENTQUOTE must be updated to reflect whether the stock is:

1	Rising in value
2	At a new high for the year
3	Dropping in value
4	At a new low for the year
5	Steady in value

CREATE TRIGGER statements that accomplish these tasks are as follows:

Trigger STOCK_STATUS sets the status:

```
CREATE TRIGGER STOCK_STATUS
 NO CASCADE BEFORE UPDATE OF QUOTE ON CURRENTQUOTE
 REFERENCING NEW AS NEWQUOTE
 OLD AS OLDQUOTE
 FOR EACH ROW MODE DB2SQL
  BEGIN ATOMIC
   SET NEWQUOTE.STATUS = CASE
   WHEN NEWQUOTE.QUOTE >
    (SELECT MAX(QUOTE)
    FROM QUOTEHISTORY
    WHERE SYMBOL = NEWQUOTE.SYMBOL
    AND YEAR(QUOTE_TIMESTAMP) = YEAR(CURRENT DATE) )
   THEN 'High'
   WHEN NEWQUOTE.QUOTE <
    (SELECT MIN(QUOTE)
    FROM QUOTEHISTORY
    WHERE SYMBOL = NEWQUOTE.SYMBOL
    AND YEAR(QUOTE_TIMESTAMP) = YEAR(CURRENT DATE) )
   THEN 'Low'
   WHEN NEWQUOTE.QUOTE > OLDQUOTE.QUOTE THEN 'Rising'
   WHEN NEWQUOTE.QUOTE < OLDQUOTE.QUOTE THEN 'Dropping'
   WHEN NEWQUOTE.QUOTE = OLDQUOTE.QUOTE THEN 'Steady'
  END;
END
```

Trigger RECORD_HISTORY records changes in the QUOTEHISTORY table:

```
CREATE TRIGGER RECORD_HISTORY
 AFTER UPDATE OF QUOTE ON CURRENTQUOTE
 REFERENCING NEW AS NEWQUOTE FOR EACH ROW MODE DB2SQL
```

```
BEGIN ATOMIC
 INSERT INTO QUOTEHISTORY VALUES (NEWQUOTE.SYMBOL,
 NEWQUOTE.QUOTE,
 CURRENT TIMESTAMP);
END
```

Triggers (Introduction to Db2 for z/OS)

Naming conventions
The rules for forming a name depend on the type of the object designated by the name.

Related tasks

Creating a trigger (Db2 Application programming and SQL)

CREATE TRUSTED CONTEXT

The CREATE TRUSTED CONTEXT statement defines a trusted context at the current server.

Invocation for CREATE TRUSTED CONTEXT

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

Authorization for CREATE TRUSTED CONTEXT

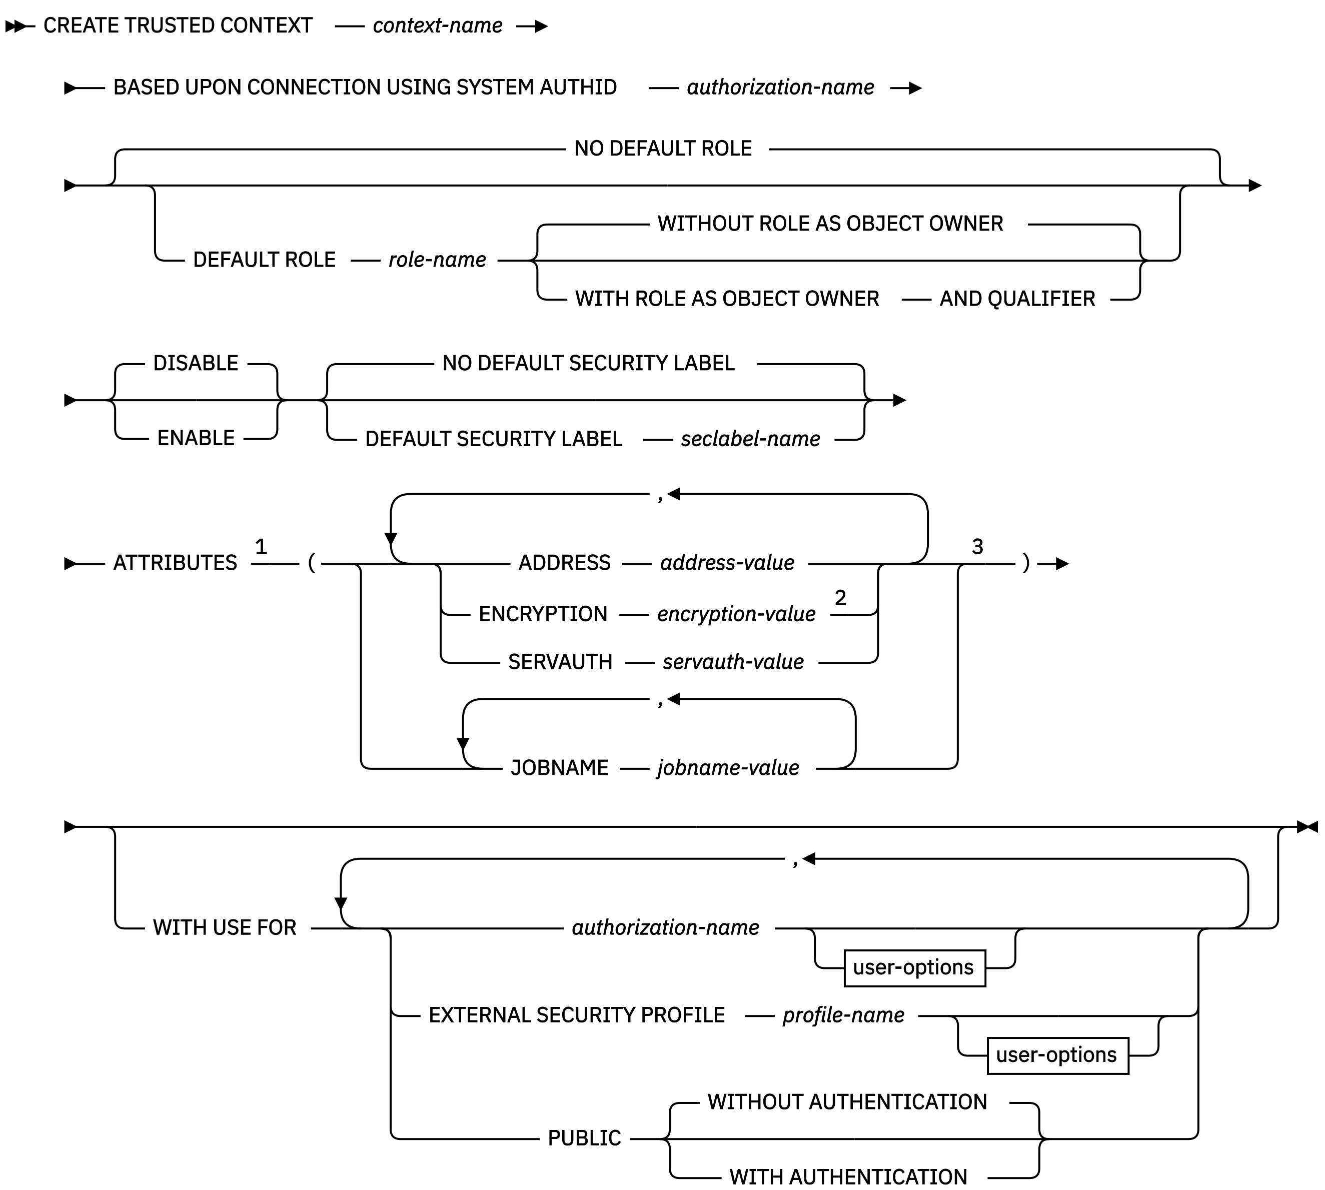
The privilege set that is defined below must include at least one of the following:

- SYSADM authority
- SECADM authority

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the application is bound in a trusted context with the ROLE AS OBJECT OWNER clause specified, a role is the owner. Otherwise, an authorization ID is the owner.

If the statement is dynamically prepared, the privilege set is the privileges that are held by the SQL authorization ID of the process unless the process is within a trusted context and the ROLE AS OBJECT OWNER clause is specified. In that case, the privileges set is the privileges that are held by the role that is associated with the primary authorization ID of the process.

Syntax for CREATE TRUSTED CONTEXT



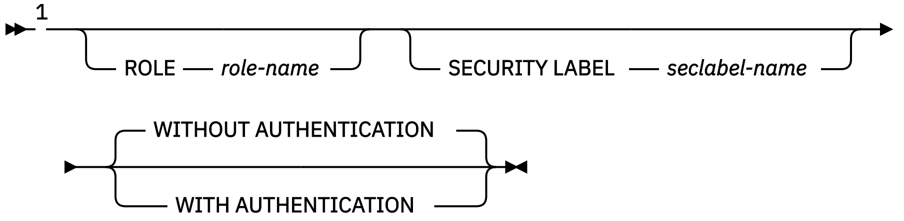
Notes:

[1] This clause and the clauses that follow can be specified in any order. Each clause must not be specified more than one time.

[2] ENCRYPTION must not be specified more than one time.

[3] Each pair of attribute name and corresponding value must be unique.

user-options:



Notes:

[1] These clauses can be specified in any order. Each clause must not be specified more than one time.

Description for CREATE TRUSTED CONTEXT

context-name

Names the trusted context. The name must not identify a trusted context that exists at the current server.

BASED UPON CONNECTION USING SYSTEM AUTHID *authorization-name*

Specifies that the context is a connection that is established by the authorization ID that is specified by *authorization-name*. The system authorization ID is the primary authorization ID. For a remote connection, it is derived from the system user ID that is provided by an external entity, such as a middleware server. For a local connection, the system authorization ID is derived depending on the sources, as specified in Table 224 on page 1784.

Table 224. System authorization ID for a local connection

Source of local connection	System authorization ID
Started task (RRSAF)	USER parameter on JOB statement or RACF USER.
TSO	TSO logon ID
BATCH	USER parameter on JOB statement

authorization-name must not be associated with an existing trusted context.

NO DEFAULT ROLE or DEFAULT ROLE *role-name*

Specifies whether a default role is associated with a trusted connection that is based on the specified trusted context.

NO DEFAULT ROLE

Specifies that the trusted context does not have a default role. The authorization ID of the process is the owner of any object that is created using a trusted connection that is based on this trusted context. That authorization ID must possess all of the privileges that are necessary to create that object.

NO DEFAULT ROLE is the default.

DEFAULT ROLE *role-name*

Specifies that *role-name* is the role for the trusted context. *role-name* must identify a role that exists at the current server. This role is used with the user in a trusted connection that is based on the specified trusted context when the user does not have a user-specified role that is defined as part of the definition of this trusted context.

WITHOUT ROLE AS OBJECT OWNER or WITH ROLE AS OBJECT OWNER AND QUALIFIER

Specifies whether a role is used as the owner of objects that are created using a trusted connection that is based on the specified trusted context.

WITHOUT ROLE AS OBJECT OWNER

Specifies that a role is not used as the owner of the objects that are created using a trusted connection that is based on the specified trusted context. The authorization ID of the process is the owner of any object that is the created using a trusted connection that is based on this trusted context. That authorization ID must possess all of the privileges that are necessary to create the object.

WITHOUT ROLE AS OBJECT OWNER is the default.

WITH ROLE AS OBJECT OWNER AND QUALIFIER

Specifies that the context assigned role is the owner of the objects that are created using a trusted connection that is based on this trusted context and that role must possess all of the privileges that are necessary to create the object. The context assigned role is the role that is defined for the user within this trusted context, if one is defined. Otherwise, the role is the default role that is associated with the trusted context. The role is also used as the grantor for any GRANT statements that are issued, and the revoker for any REVOKE statement that are issued using a trusted connection that is based on this trusted context.

AND QUALIFIER
Specifies that *role-name* will be used as the default for the CURRENT SCHEMA special register. The *role-name* will also be included in the SQL PATH (in place of CURRENT SQLID).

When `WITH ROLE AS OBJECT OWNER AND QUALIFIER` is not specified, there is no change to the default for the CURRENT SCHEMA special register and the SQL PATH.

DISABLE or ENABLE
Specifies whether the trusted context is created in the enabled or disabled state.

DISABLE
Specified that the trusted context is disabled when it is created. A trusted context that is disabled is not considered when a trusted connection is established. DISABLE is the default.

ENABLE
Specifies that the trusted context is enabled when it is created.

NO DEFAULT SECURITY LABEL or DEFAULT SECURITY LABEL *seclabel-name*
Specifies whether the trusted connection has a default security label.

NO DEFAULT SECURITY LABEL
Specifies that the trusted context does not have a default security label.

DEFAULT SECURITY LABEL *seclabel-name*
Specifies that *seclabel-name* is the default security label for the trusted context and is the security label that is used for multilevel security verification. *seclabel-name* must identify one of the RACF SECLABEL values that is defined for the SYSTEM AUTHID. This security label is used for a trusted connection that is based on the specified trusted context when the user does not have a specific security label defined as part of the definition of this trusted context. In this case, *seclabel-name* must also identify one of the RACF SECLABEL values that is defined for the user.

ATTRIBUTES
Specifies a list of one or more connection trust attributes that are used to define the trusted context.

ADDRESS *address-value*
Specifies the actual communication address that is used by the connection to communicate with the database manager. The protocol supported is only for TCP/IP. The ADDRESS attribute can be specified multiple times, but each *address-value* must be unique.

When establishing a trusted connection, if multiple values are defined for the ADDRESS attribute for a trusted context, a candidate connection is considered to match this attribute if the address that is used by a connection matches any of the defined values for the ADDRESS attribute of the trusted context.

address-value specifies a string constant that contains the value that is associated with the ADDRESS trust attribute. *address-value* must be an IPv4 address, an IPv6 address, or a secure domain name with a length no greater than 254 bytes. No validation of *address-value* is done at the time the CREATE TRUSTED CONTEXT statement is processed. *address-value* must be left justified within the string constant.

- An IPv4 address is represented as a dotted decimal address. An example of an IPv4 address is 9.112.46.111
- An IPv6 address is represented as a colon hexadecimal address. An example of an IPv6 address is 2001:0DB8:0000:0000:0008:0800:200C:417A. This address can also be express in a compressed form as 2001:DB8::8:800:200C:417A.
- A domain name is converted to an IP address by the domain name server where a resulting IPv4 or IPv6 address is determined. An example of a domain name is www.ibm.com. The gethostbyname socket call is used to resolve the domain name.

ENCRYPTION ***encryption-value***

Specifies the minimum level of encryption of the data stream (network encryption).

encryption-value specifies a string constant that contains the value that is associated with the ENCRYPTION trust attribute. *encryption-value* must be left justified within the string constant. ENCRYPTION must not be specified more than one time in the statement. *encryption-value* must be one of the following:

- NONE, which specifies that no specific level of encryption is required.
- LOW, which specifies that a minimum of light encryption is required. LOW corresponds to 64-bit DRDA encryption.
- HIGH, which specifies that strong encryption is required. HIGH corresponds to SSL encryption.

The following table summarizes when a trusted context can be used depending on the encryption that is used by the existing connection. If the trusted context cannot be used for the connection, a warning is returned.

Table 225. Summary of when trusted context can be used by an existing connection

Encryption that is used by the existing connection	Value of the ENCRYPTION clause for the trusted context	Can the trusted context be used for the connection?
No encryption	NONE	Yes
No encryption	LOW	No
No encryption	HIGH	No
Low encryption (64-bit)	NONE	Yes
Low encryption (64-bit)	LOW	Yes
Low encryption (64-bit)	HIGH	No
High encryption (128-bit)	NONE	Yes
High encryption (128-bit)	LOW	Yes
High encryption (128-bit)	HIGH	Yes

JOBNAME ***jobname-value***

Specifies the z/OS job name or started task name (depending on the source of the address space) for local applications. The JOBNAME attribute can be specified multiple times, but each *jobname-value* must be unique.

jobname-value specifies a string constant that contains the value that is associated with the JOBNAME trust attribute. *jobname-value* is an EBCDIC 8 byte value that specifies the job name or the started task name. The value must be left justified within the string constant. The last character in the name can be a wildcard character (*) if the first character is an alphabetic character. If the job name ends with a wildcard, any job names that begin with the specified characters are considered for establishing the trusted connection.

The following table lists possible values for the job name depending on the source of the address space.

Table 226. Job name for local connection

Source of the address space	Job name
RRSAF	Job name or started task name
TSO	TSO logon ID
BATCH	Job name on JOB statement

SERVAUTH *servauth-value*

Specifies the name of a resource in the RACF SERVAUTH class. This resource is the network access security zone name that contains the IP address of the connection that is used to communicate with Db2. The SERVAUTH attribute can be specified multiple times but each *servauth-value* must be unique.

servauth-value specifies a string constant that contains the value that is associated with the SERVAUTH trust attribute. *servauth-value* is an EBCDIC 64 byte RACF SERVAUTH CLASS resource name. *servauth-value* must be left justified in the string constant. No validation of *servauth-value* is done at the time the CREATE TRUSTED CONTEXT statement is processed.

WITH USE FOR

Specifies who can use a trusted connection that is based on the specified trusted context.

authorization-name

Specifies that the trusted connection can be used by the specified *authorization-name*. This is the Db2 primary authorization ID. The *authorization-name* must not be specified more than one time in the WITH USE FOR clause.

ROLE *role-name*

Specifies that *role-name* is the role that is used when a trusted connection is used by the specified *authorization-name*. The *role-name* must identify a role that exists at the current server. The role that is explicitly specified for the user overrides any default role that is associated with the trusted context.

SECURITY LABEL *seclabel-name*

Specifies that *seclabel-name* is the security label to use for multilevel security verification when the trusted connection is used by the specified *authorization-name*. The *seclabel-name* must be one of the RACF SECLABEL values that is defined for the user. The security label that is explicitly specified for the user overrides any default security label that is associated with the trusted context.

WITHOUT AUTHENTICATION or WITH AUTHENTICATION

Specifies whether use of the trusted connection requires authentication of the user.

WITHOUT AUTHENTICATION

Specifies that use of a trusted connection by the user does not require authentication. WITHOUT AUTHENTICATION is the default.

WITH AUTHENTICATION

Specifies that use of a trusted connection requires the authentication token with the authorization ID to authenticate the user. If a trusted connection is established locally, the authentication token is the password that is provided by the CONNECT statement with the USER and USING clauses. If the trusted connection is established from a remote client, the authentication token can be one of the following tokens:

- password
- RACF Passticket
- Kerberos token

EXTERNAL SECURITY PROFILE *profile-name*

Specifies that the trusted connection can be used by the Db2 primary authorization IDs that are permitted to use the specified *profile-name* in RACF. *profile-name* must not be specified more than one time in the WITH USE FOR clause. If an authorization ID is permitted to use more than one specified *profile-name*, the role that is specified for *profile-name* can be associated with the process if the user authentication satisfies the AUTHENTICATION definition. This role can hold additional privileges that are available to the process.

ROLE *role-name*

Specifies that *role-name* is the role that is used when a trusted connection is used by any authorization ID permitted to use the specified *profile-name* in RACF. The *role-name* must identify a role that exists at the current server. The role that is explicitly specified for the profile overrides any default role that is associated with the trusted context.

SECURITY LABEL *seclabel-name*

Specifies that *seclabel-name* is the security label to use for multilevel security verification when the trusted connection is used by any authorization ID that is permitted to use the specified *profile-name* in RACF. The *seclabel-name* must be one of the RACF SECLABEL values that is defined for the user. The security label that is explicitly specified for the profile overrides any default security label that is associated with the trusted context.

WITHOUT AUTHENTICATION or WITH AUTHENTICATION

Specifies whether use of the trusted connection requires authentication of the user.

WITHOUT AUTHENTICATION

Specifies that use of a trusted connection by the user does not require authentication. WITHOUT AUTHENTICATION is the default.

WITH AUTHENTICATION

Specifies that use of a trusted connection requires the authentication token with the authorization ID to authenticate the user. If a trusted connection is established locally, the authentication token is the password that is provided by the CONNECT statement with the USER and USING clauses. If the trusted connection is established from a remote client, the authentication token can be one of the following tokens:

- password
- RACF Passticket
- Kerberos token

PUBLIC

Specifies that a trusted connection that is based on the specified trusted context can be used by any user. All users that are using a trusted connection that is defined with PUBLIC use the privileges that are associated with the default role for the associated trusted context. If the default role is not defined for the trusted context, there is no role associated with the users that use a trusted connection that is based on the specified trusted context.

If the default security label for the trusted context is defined, all users that are using the trusted context must have the security label defined as one of the RACF SECLABEL values for the user. The default security label is used for multilevel security verification with all users that are using the trusted context.

WITHOUT AUTHENTICATION or WITH AUTHENTICATION

Specifies whether use of the trusted connection requires authentication of the user.

WITHOUT AUTHENTICATION

Specifies that use of a trusted connection by the user does not require authentication. WITHOUT AUTHENTICATION is the default.

WITH AUTHENTICATION

Specifies that use of a trusted connection requires the authentication token with the authorization ID to authenticate the user. If a trusted connection is established locally, the authentication token is the password that is provided by the CONNECT statement with the USER and USING clauses. If the trusted connection is established from a remote client, the authentication token can be one of the following tokens:

- password
- RACF Passticket
- Kerberos token

Notes for CREATE TRUSTED CONTEXT

Owner privileges: There are no specific privileges on a trusted context.

Requirement for trusted connections: If you set field 1 (RESTART or DEFER) to DEFER and set field 2 (objects to restart or defer) to ALL in installation panel DSNTIPS, you cannot use trusted connections.

Order of precedence for users of a trusted connection: The specifications for a user are determined in the following order of precedence:

- *authorization-name*
- `EXTERNAL SECURITY PROFILE` *profile-name*
- `PUBLIC`

For example, assume that a trusted context is defined with use for JOE WITH AUTHENTICATION, EXTERNAL SECURITY PROFILE SPROFILE WITHOUT AUTHENTICATION, and PUBLIC WITH AUTHENTICATION. Users JOE and SAM are permitted to use the RACF PROFILE SPROFILE. If the trusted connection is used by JOE, authentication is required. If the trusted connection is used by SAM, authentication is not required. However, if user SALLY uses the trusted connection, authentication is required.

User-clause SYSTEM AUTHID considerations: If the *authorization-name* that is specified in the SYSTEM AUTHID clause is the same as the *authorization-name* that is specified in the user-clause *authorization-name*, the role or the security label that is specified for *authorization-name* takes precedence over the default value. The value that is specified for the *profile-name*, is permitted to use the profile. If the authorization name that is specified in the SYSTEM AUTHID clause is permitted to use one of the profile names and is not defined in *authorization-name*, the role or the security label that is specified for that *profile-name* takes precedence over the default value.

If authentication is required for SYSTEM AUTHID, either by specification of the AUTHENTICATION clause in the *user-clause* or by setting the value of the TCP/IP Already Verified subsystem parameter to NO, the authentication requirement takes precedence when establishing a remote trusted connection. For example, if *authorization-name* is the same as the authorization name that is specified for SYSTEM AUTHID and the WITHOUT AUTHENTICATION clause is specified, but the TCP/IP Already Verified subsystem parameter is set to NO, an authentication token is required for SYSTEM AUTHID when the remote trusted connection is established. If *authorization-name* is the SYSTEM AUTHID and the WITH AUTHENTICATION clause is specified, but the TCP/IP Already Verified subsystem parameter is set to YES, an authentication token is still required for SYSTEM AUTHID.

Specifying a role in the definition of a trusted context: The definition of a trusted context can designate a role for a specific authorization ID, and a default role for use for an authorization ID for which a specific role has not been specified in the definition of the trusted context. This role can be used with a trusted connection that is based on the trusted context, but it does not make the role available outside of a trusted connection that is based on the trusted context. When an SQL statement that is not a CREATE, GRANT, or REVOKE statement is issued using a trusted connection, the privileges that are held by a role that is in effect for the authorization ID within the definition of the associated trusted context are considered in addition to other privileges that are directly held by the authorization ID of the statement. The CREATE, GRANT, and REVOKE statements only consider the privileges of the role that is in effect for the trusted connection, or the authorization ID of the statement if a role is not in effect for the trusted connection. If ROLE AS OBJECT OWNER is in effect for a trusted connection, the role that is in effect for the authorization ID for the trusted connection becomes the owner of any object that is created while using the trusted connection.

When a newly created trusted context takes effect: The newly created trusted context takes effect after the CREATE TRUSTED CONTEXT statement is committed. If the CREATE TRUSTED CONTEXT statement results in an error or is rolled back, no trusted context is created.

Examples for CREATE TRUSTED CONTEXT

Example 1: The following statement creates a trusted context called CTX1, which is based on a connection and can only be used by users JOE and SAM. Authentication information is required for JOE to use the trusted connection. The trusted context specifies a default role called CTXROLE. However, when

JOE uses the trusted connection, the default role is overridden by the user role, ROLE1. When SAM uses the trusted connection, SAM uses the default role. CTX1 is enabled when it is created.

```
    CREATE TRUSTED CONTEXT CTX1
        BASED UPON CONNECTION USING SYSTEM AUTHID ADMF001
        ATTRIBUTES (ADDRESS '9.30.131.203',
                    ENCRYPTION 'LOW')
        DEFAULT ROLE CTXROLE
        ENABLE
        WITH USE FOR SAM, JOE ROLE ROLE1 WITH AUTHENTICATION;
```

Example 2: The following statement creates a trusted context, CTX2, for a started task, WASPROD. CTX2 is based on a connection, can be used by user SALLY, specifies a default role CTXROLE, and is enabled when it is created. SALLY uses the default role that is associated with the trusted context.

```
    CREATE TRUSTED CONTEXT CTX2
         BASED UPON CONNECTION USING SYSTEM AUTHID ADMF002
         ATTRIBUTES (JOBNAME 'WASPROD')
         DEFAULT ROLE CTXROLE WITH ROLE AS OBJECT OWNER AND QUALIFIER
         ENABLE
         WITH USE FOR SALLY;
```

CREATE TYPE

The CREATE TYPE statement defines a user-defined data type at the current server.

The following types of user-defined data types can be defined:

Array
A user-defined data type that is an ordinary array or an associative array. The elements of an array type are based on one of the built-in data types. See "CREATE TYPE (array)" on page 1790.

Distinct
A user-defined data type that shares a common representation with one of the built-in data types. Functions that cast between the user-defined distinct type and the source built-in data type are generated when the user-defined distinct type is created. Optionally, support for comparison operations to use with the user-defined distinct type can be generated when the user-defined distinct type is created. See "CREATE TYPE (distinct)" on page 1796.

Related concepts

Distinct types (Db2 Application programming and SQL)

Arrays in SQL statements (Db2 Application programming and SQL)

CREATE TYPE (array)

The CREATE TYPE (array) statement defines an array type at the current server. An array type is a user-defined data type that is an ordinary array or an associative array. The elements of an array type are based on one of the built-in data types.

Invocation for CREATE TYPE (array)

This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared only if DYNAMICRULES RUN behavior is in effect. For more information, see "Authorization IDs and dynamic SQL" on page 94.

Authorization for CREATE TYPE (array)

The privilege set that is defined below must include at least one of the following:

- The CREATEIN privilege on the schema
- SYSADM or SYSCTRL authority
- System DBADM

- Installation SYSOPR authority (when the current SQLID of the process is set to SYSINSTL)

The authorization ID that matches the schema name implicitly has the CREATEIN privilege on the schema.

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package.

If the statement is running under a trusted context for which the ROLE AS OBJECT OWNER clause is specified, the owner is a role. The implicit schema match does not apply, and this role needs to include one of the previously listed conditions.

If the statement is dynamically prepared and is not running in a trusted context for which the ROLE AS OBJECT OWNER clause is specified, the privilege set is the set of privileges that are held by the SQL authorization ID of the process. The specified distinct type name can include a schema name (a qualifier). If the schema name is not the same as the SQL authorization ID of the process, one of the following conditions must be met:

- The privilege set includes SYSADM or SYSCTRL authority.
- The SQL authorization ID of the process has the CREATEIN privilege on the schema.

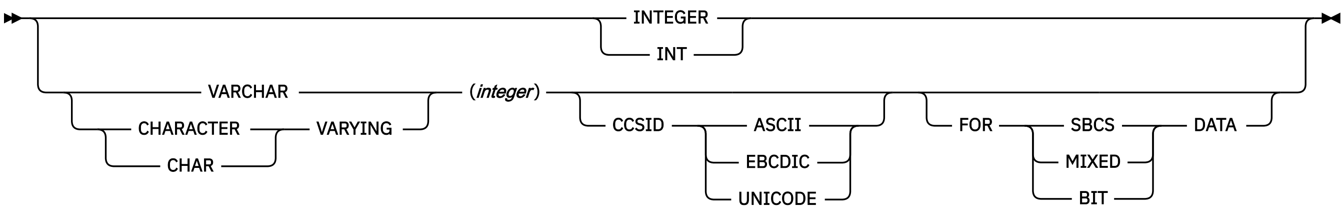
data-type2:



Description for CREATE TYPE (array)

array-type-name

Names the array type. The name, including the implicit or explicit qualifier, must not identify any other built-in or user-defined type that exists at the current server.

The unqualified form of *array-type-name* must not be any of the following system-reserved keywords, even if you specify them as delimited identifiers:

```
ALL                     LIKE                     UNIQUE
AND                     MATCH                    UNKNOWN
ANY                     NOT                      =
BETWEEN                 NULL                     =
DISTINCT                ONLY                     <
EXCEPT                  OR                       <=
EXISTS                  OVERLAPS                 <
FALSE                   SIMILAR                  >
FOR                     SOME                     >=
FROM                    TABLE                    >
IN                      TRUE                     <>
IS                      TYPE
```

The schema name can be 'SYSTOOLS' if the privilege set includes the SYSADM or SYSCTRL privilege. Otherwise, the schema name must not begin with 'SYS' unless the schema name is 'SYSADM'.

built-in-type

Specifies the built-in data type of the array elements. The data type must not be ROWID or XML. For more information on built-in data types, see built-in-type in CREATE TABLE.

CCSID ASCII, EBCDIC, or UNICODE in a *built-in-type* specification

If the data type is a character or graphic string and a CCSID clause is not specified for *built-in-type*, the default CCSID for *built-in-type* is determined as follows:

- If *data-type2* is a character string data type with an explicit CCSID clause, that same CCSID value is used for *built-in-type*.
- If *data-type2* is a character string data type without an explicit CCSID clause, the CCSID for *built-in-type* is determined from the encoding scheme that is indicated by the value of field DEF ENCODING SCHEME on installation panel DSNTIPF.

If a CCSID clause is specified for *built-in-type* and for *data-type2*, the CCSID values must be the same.

FOR SBCS, MIXED, or BIT DATA in a *built-in-type* specification

Specifies a subtype for a character string data type (VARCHAR). Do not use this clause with any other data type.

SBCS

Single-byte data.

MIXED

Mixed data. Do not specify MIXED if the value of field MIXED DATA on installation panel DSNTIPF is NO unless the CCSID UNICODE clause is also specified.

BIT

Bit data.

If you do not specify the FOR SBCS DATA, FOR MIXED DATA, or FOR BIT DATA clause, the default value is determined as follows:

- For ASCII or EBCDIC data:

- The default is SBCS when the value of field MIXED DATA on installation panel DSNTIPF is NO.
  - The default is MIXED when the value is YES.
- For Unicode data, the default subtype is MIXED.

ARRAY[*integer-constant*]

Specifies that the type is an ordinary array with a maximum cardinality of *integer-constant*. The value must be an integer that is greater than 0 and less than or equal to the largest positive integer value (2147483647). The default is 2147483647. Each varying-length string array element is allocated as its maximum length.

The cardinality of an array value is determined by the highest element position that is assigned to the array value. The maximum cardinality of an array is limited by the total amount of memory that is available to Db2 applications. Therefore, although an array with a large cardinality can be created, not all elements might be available for use. An attempt to assign a value to an array element when there is not enough memory results in an error.

ARRAY[*data-type2*]

Specifies that the type is an associative array that is indexed by values of data type *data-type2*. The data type must be the INTEGER or VARCHAR data type. The value that is specified as the index during assignment of a value to an array element must be assignable to a value of *data-type2*.

The cardinality of an array value is determined by the number of unique index values that are used when during assignment of array elements.

CCSID ASCII, EBCDIC, or UNICODE in a *data-type2* specification

If the data type is a character string, and a CCSID clause is not specified for *data-type2*, the default CCSID is determined as follows:

- If *built-in-type* is a character string data type with an explicit CCSID clause, that same CCSID value is used for *data-type2*.
- If *built-in-type* is a character string data type without an explicit CCSID clause, the CCSID for *data-type2* is determined from the encoding scheme that is indicated by the value of field DEF ENCODING SCHEME on installation panel DSNTIPF.

If a CCSID clause is specified for *built-in-type* and for *data-type2*, the CCSID values must be the same.

FOR SBCS, MIXED, or BIT DATA in a *data-type2* specification

Specifies a subtype for a character string data type (VARCHAR). Do not use this clause with any other data type.

SBCS

Single-byte data.

MIXED

Mixed data. Do not specify MIXED if the value of field MIXED DATA on installation panel DSNTIPF is NO unless the CCSID UNICODE clause is also specified.

BIT

Bit data.

If you do not specify the FOR SBCS DATA, FOR MIXED DATA, or FOR BIT DATA clause, the default value is determined as follows:

- For ASCII or EBCDIC data:
  - The default is SBCS when the value of field MIXED DATA on installation panel DSNTIPF is NO.
  - The default is MIXED when the value is YES.
- For Unicode data, the default subtype is MIXED.

Notes for CREATE TYPE (array)

Array type usage: A user-defined array type can only be used as the data type of:

- An SQL variable

- A global variable
- A parameter or RETURNS *data-type* of an SQL scalar function
- A parameter of a native SQL procedure
- The target data type for a CAST specification

Generated cast functions: The successful execution of the CREATE TYPE (array) statement causes the Db2 database manager to generate cast functions for the user-defined array type. Those cast functions are recorded in the Db2 catalog. The unqualified names of the two cast functions are ARRAY and the name of the array type. A generated cast function cannot be explicitly dropped. The cast functions that are generated for an array type are implicitly dropped when the array type is dropped with the DROP statement.

Examples for CREATE TYPE (array)

Example 1

Create an ordinary array user-defined type named PHONENUMBERS, with a maximum of 50 elements. The elements are of the DECIMAL(10,0) data type.

```
CREATE TYPE PHONENUMBERS AS DECIMAL(10,0) ARRAY[50];
```

Example 2

Create an ordinary array user-defined type named NUMBERS, in the schema GENERIC. You do not know the maximum number of elements, so you use the default value. The elements are of the DECFLOAT(34) data type.

```
CREATE TYPE GENERIC.NUMBERS AS DECFLOAT(34) ARRAY[];
```

Example 3

Create an associative array user-defined type named PERSONAL_PHONENUMBERS. The elements are of the DECIMAL(16, 0) data type. The array type is indexed by strings such as 'Home', 'Work', or 'Cell', so the index data type must be VARCHAR.

```
CREATE TYPE PERSONAL_PHONENUMBERS AS DECIMAL(16,0) ARRAY[VARCHAR(8)];
```

Example 4

Create an associative array user-defined type named CAPITALSARRAY. The elements are capital cities. The index values are province, territory, or country names, so the index data type must be VARCHAR.

```
CREATE TYPE CAPITALSARRAY AS VARCHAR(30) ARRAY[VARCHAR(20)];
```

Example 5

Create an associative array user-defined type named PRODUCTS. The elements are product descriptions of up to 40 characters. The index values are product numbers, which have the INTEGER data type.

```
CREATE TYPE PRODUCTS AS VARCHAR(40) ARRAY[INTEGER];
```

Related concepts

Arrays in SQL statements (Db2 Application programming and SQL)

Example of using arrays in an SQL procedure (Db2 Application programming and SQL)

Naming conventions

The rules for forming a name depend on the type of the object designated by the name.

CREATE TYPE (distinct)

The CREATE TYPE (distinct) statement defines a distinct type, which is a data type that a user defines. A distinct type must be based on one of the built-in data types.

Successful execution of the statement also generates:

- A function to cast between the distinct type and its source type
- A function to cast between the source type and its distinct type
- As appropriate, support for the use of comparison operators with the distinct type

Invocation for CREATE TYPE (distinct)

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES RUN behavior is in effect. For more information, see "Authorization IDs and dynamic SQL" on page 94.

Authorization for CREATE TYPE (distinct)

The privilege set that is defined below must include at least one of the following:

- The CREATEIN privilege on the schema
- SYSADM or SYSCTRL authority
- System DBADM
- Installation SYSOPR authority (when the current SQLID of the process is set to SYSINSTL)

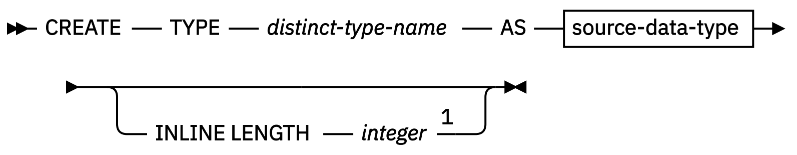
The authorization ID that matches the schema name implicitly has the CREATEIN privilege on the schema.

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the owner is a role, the implicit schema match does not apply and this role needs to include one of the previously listed conditions.

If the statement is dynamically prepared and is not running in a trusted context for which the ROLE AS OBJECT OWNER clause is specified, the privilege set is the set of privileges that are held by the SQL authorization ID of the process. The specified distinct type name can include a schema name (a qualifier). If the schema name is not the same as the SQL authorization ID of the process, one of the following conditions must be met:

- The privilege set includes SYSADM or SYSCTRL authority.
- The SQL authorization ID of the process has the CREATEIN privilege on the schema.

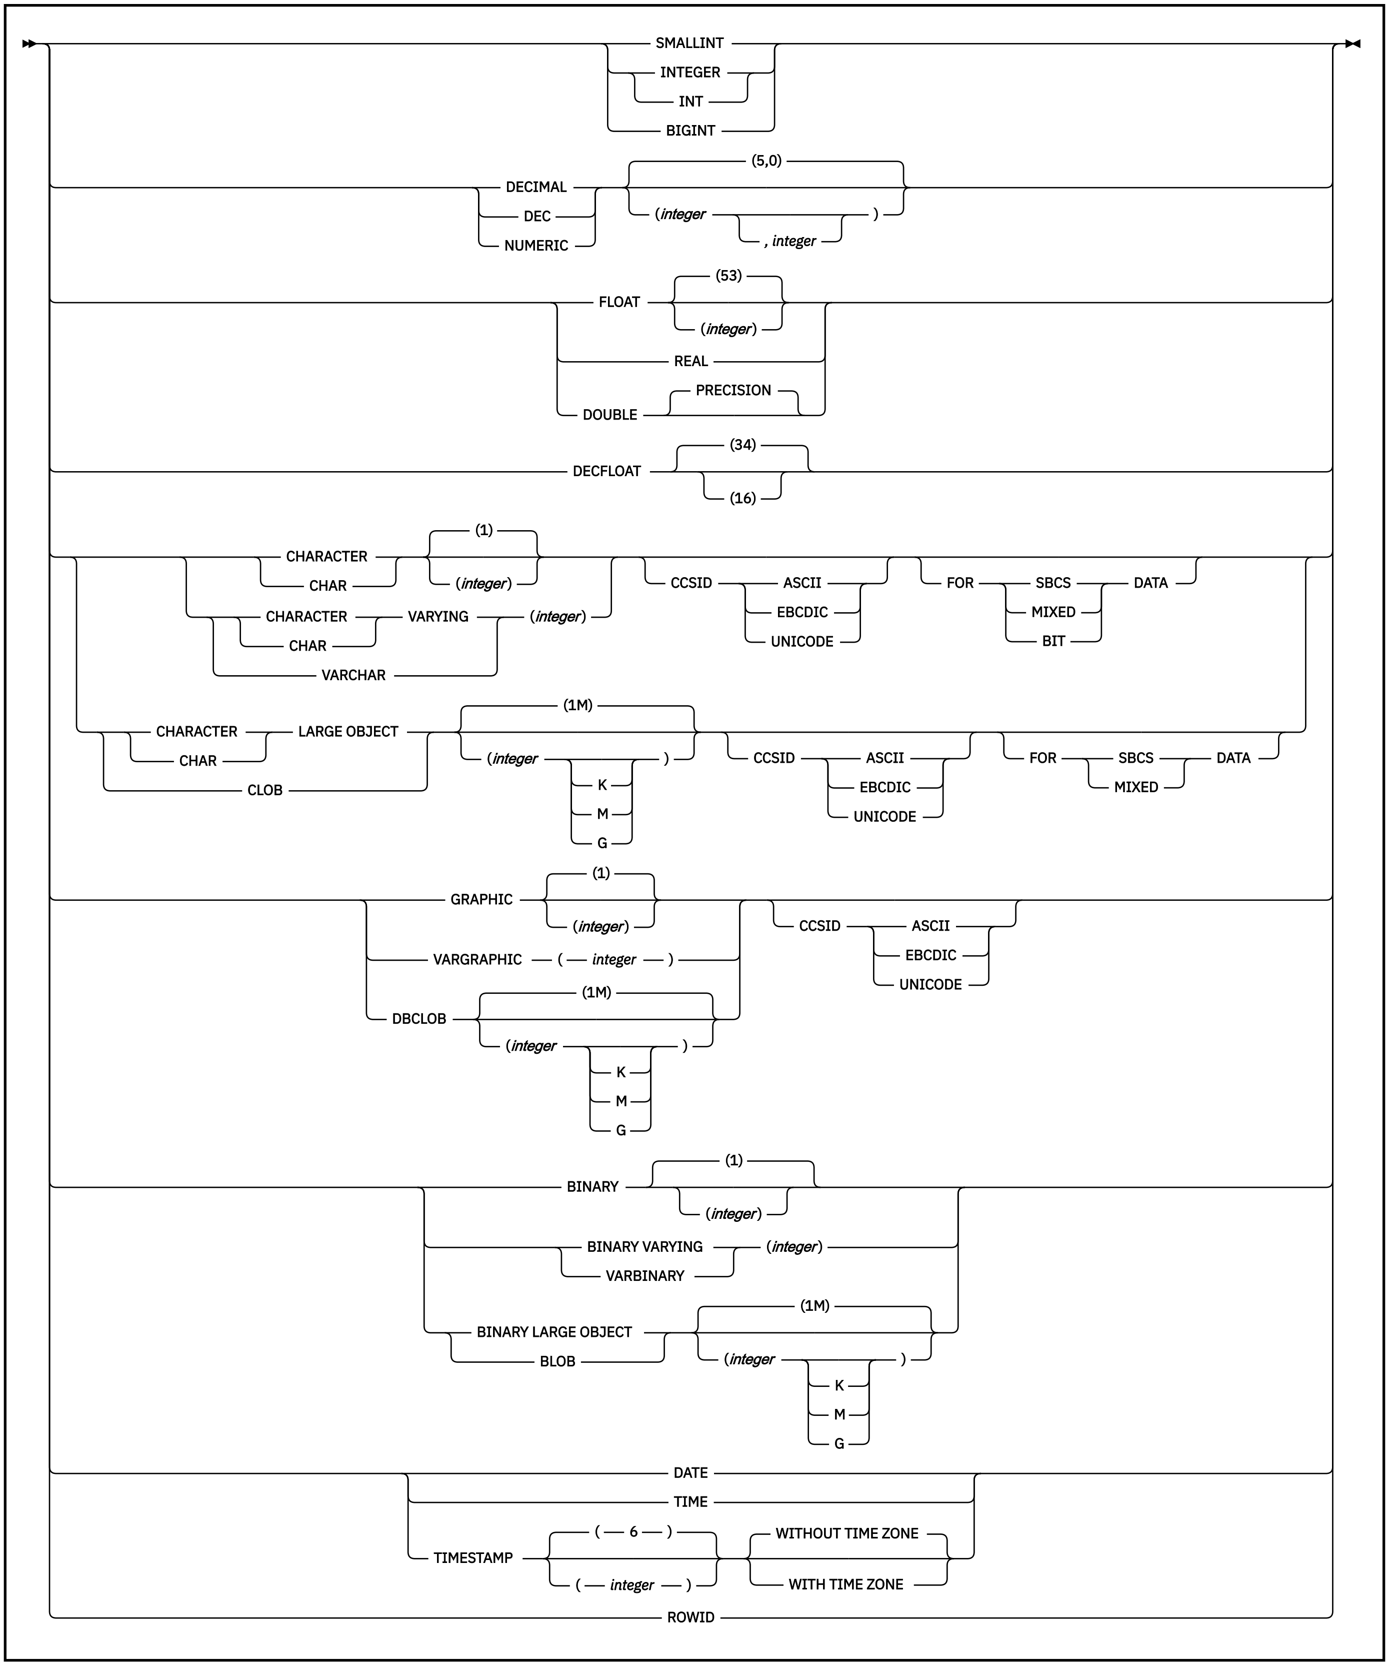
Syntax for CREATE TYPE (distinct)



Notes:

[1] INLINE LENGTH can only be specified when *source-data-type* is a LOB data type.

source-data-type



Description for CREATE TYPE (distinct)

distinct-type-name

Names the distinct type. The name, including the implicit or explicit qualifier, must not identify a distinct type that exists at the current server.

- The unqualified form of *distinct-type-name* must not be the name of a built-in data type, BOOLEAN, or any of following system-reserved keywords even if you specify them as delimited identifiers:

```
ALL                     LIKE                    UNIQUE
AND                     MATCH                   UNKNOWN
ANY                     NOT                     =
BETWEEN                 NULL                    ¬=
DISTINCT                ONLY                    <
EXCEPT                  OR                      <=
EXISTS                  OVERLAPS                ¬<
FALSE                   SIMILAR                 >
FOR                     SOME                    >=
FROM                    TABLE                   ¬>
IN                      TRUE                    <>
IS                      TYPE
```

- The qualified form of *distinct-type-name* is an SQL identifier (the schema name) followed by a period and an SQL identifier.

The schema name can be 'SYSTOOLS' if the privilege set includes the SYSADM or SYSCTRL privilege. Otherwise, the schema name must not begin with 'SYS' unless the schema name is 'SYSADM'.

source-data-type

Specifies the data type that is used as the basis for the internal representation of the distinct type. The data type must be a built-in data type. For more information on built-in data types, see built-in-type.

If the distinct type is based on a character or graphic string data type, the FOR clause indicates the subtype. If you do not specify the FOR clause, the distinct type is defined with the default subtype. For ASCII or EBCDIC data, the default is SBCS when the value of field MIXED DATA on installation panel DSNTIPF is NO. The default is MIXED when the value is YES. For UNICODE character data, the default subtype is mixed.

If the distinct type is based on a string data type, the CCSID clause indicates whether the encoding scheme of the data is ASCII, EBCDIC or UNICODE. If you do not specify CCSID ASCII, CCSID EBCDIC, or UNICODE, the encoding scheme is the value of field DEF ENCODING SCHEME on installation panel DSNTIPF.

INLINE LENGTH *integer*

Specifies the default inline length for columns that reference the distinct type. INLINE LENGTH can only be specified when *source-data-type* is a LOB data type. Only columns in a table that is in a universal table space can inherit the specified inline length for the distinct type. If the table is not in a universal table space, the specified inline length is ignored.

Where *source-data-type* is BLOB and CLOB, *integer* specifies the maximum number of bytes that are stored in the base table space for columns that reference this distinct type. *integer* must be between 0 and 32680 (inclusive) for a BLOB or CLOB *source-data-type*.

Where *source-data-type* is DBCLOB, *integer* specifies the maximum number of double-byte characters that are stored in the table space for columns that reference the distinct type. *integer* must be between 0 and 16340 (inclusive) for a DBCLOB *source-data-type*.

If INLINE LENGTH is specified with a value of 0 for *integer*, any column that references the distinct type will not have an inline length unless the CREATE TABLE or ALTER TABLE ADD statement specifies an inline length for the column.

If INLINE LENGTH is not specified, any column that reference the distinct type takes its default vale from the value of the LOB INLINE LENGTH parameter on installation panel DSNTIPD.

integer cannot be greater than the maximum length of the distinct type.

Notes for CREATE TYPE (distinct)

Owner privileges:

The owner of the distinct type is authorized to define columns, parameters, or variables with the distinct type (USAGE privilege) with the ability to grant these privileges to others. See "GRANT (type or

JAR file privileges)" on page 1986. The owner is also authorized to invoke the generated cast function (EXECUTE privilege; see "GRANT (function or procedure privileges)" on page 1965). The owner is given the USAGE and EXECUTE privileges with the GRANT option. For more information about ownership of the object, see "Authorization, privileges, permissions, masks, and object ownership" on page 90.

Base data types with DBCS or mixed data:

When the implicit or explicit encoding scheme is ASCII or EBCDIC and the base data type is graphic or a character type is MIXED DATA, then the value of field FOR MIXED DATA on installation panel DSNTIPF must be YES; otherwise, an error occurs.

Generated cast functions:

The successful execution of the CREATE TYPE (distinct) statement causes Db2 to generate the following cast functions:

- A function to convert from the distinct type to its base data type
- A function to convert from the base data type to the distinct type
- A function to cast from a data type *A* to distinct type *DT*, where *A* is promotable to the base data type *S* of distinct type *DT*

  For some base data types, Db2 supports an additional function to convert from:

  – INTEGER to the distinct type if the source type is SMALLINT

  – VARCHAR to the distinct type if the source type is CHAR

  – VARGRAPHIC to the distinct type if the source type is GRAPHIC

  – VARBINARY to the distinct type if the source type is BINARY

  – DOUBLE to the distinct type if the source type is REAL

The cast functions are created as if the following statements were executed:

```
CREATE FUNCTION source-type-name (distinct-type-name)
   RETURNS source-type-name …
CREATE FUNCTION distinct-type-name (source-type-name)
   RETURNS distinct-type-name …
```

In cases in which a length, precision, or scale is specified for the base type in the CREATE TYPE statement, the unqualified name of the cast function that converts from the distinct type to the base type is the name of the base data type. The data type of the value that the cast function returns includes any length, precision, or scale values that were specified for the base data type on the CREATE TYPE statement. (See Table 227 on page 1800 for details.)

For example, assume that a distinct type named T_SHOESIZE is created with the following statement:

```
CREATE TYPE CLAIRE.T_SHOESIZE AS VARCHAR(2)
```

When the statement is executed, Db2 also generates the following cast functions. VARCHAR converts from the distinct type to the source type, and T_SHOESIZE converts from the source type to the distinct type.

```
FUNCTION CLAIRE.VARCHAR (CLAIRE.T_SHOESIZE) RETURNS SYSIBM.VARCHAR (2)
FUNCTION CLAIRE.T_SHOESIZE (SYSIBM.VARCHAR (2)) RETURNS CLAIRE.T_SHOESIZE
```

Notice that function VARCHAR returns a value with a data type of VARCHAR(2) and that function T_SHOESIZE has an input parameter with a data type of VARCHAR(2).

The schema of the generated cast functions is the same as the schema of the distinct type. No other function with the same name and function signature must already exist in the database.

In the preceding example, if T_SHOESIZE was based on a SMALLINT, CHAR, or GRAPHIC data type instead of a VARCHAR data type, another cast function would have been generated in addition to the two functions to cast between the distinct type and the base data type. For example, assume that T_SHOESIZE is created with this statement:

```
CREATE TYPE CLAIRE.T_SHOESIZE AS CHAR(2)
```

When the statement is executed, Db2 generates these cast functions:

```
FUNCTION CLAIRE.CHAR (CLAIRE.T_SHOESIZE) RETURNS SYSIBM.CHAR (2)
   FUNCTION CLAIRE.T_SHOESIZE (SYSIBM.CHAR (2)) RETURNS CLAIRE.T_SHOESIZE
   FUNCTION CLAIRE.T_SHOESIZE (SYSIBM.VARCHAR (2)) RETURNS CLAIRE.T_SHOESIZE
```

Notice that the third function enables the casting of a VARCHAR(2) to T_SHOESIZE. This additional function is created to enable casting a constant, such as 'AB', directly to the distinct type. Without the additional function, you would have to first cast 'AB', which has a data type of VARCHAR, to a data type of CHAR and then cast it to the distinct type.

You cannot explicitly drop a generated cast function. The cast functions that are generated for a distinct type are implicitly dropped when the distinct type is dropped with the DROP statement.

For each built-in data type that can be the base data type for a distinct type, the following table gives the names of the generated cast functions, the data types of the input parameters, and the data types of the values that the functions returns.

Table 227. CAST functions on distinct types

Source type name	Function name	Parameter-type	Return-type
SMALLINT	*distinct-type-name*	SMALLINT	*distinct-type-name*
	distinct-type-name	INTEGER	*distinct-type-name*
	SMALLINT	*distinct-type-name*	SMALLINT
INTEGER	*distinct-type-name*	INTEGER	*distinct-type-name*
	INTEGER	*distinct-type-name*	INTEGER
BIGINT	*distinct-type-name*	BIGINT	*distinct-type-name*
	BIGINT	*distinct-type-name*	BIGINT
DECIMAL	*distinct-type-name*	DECIMAL (p,s)	*distinct-type-name*
	DECIMAL	*distinct-type-name*	DECIMAL (p,s)
NUMERIC	*distinct-type-name*	DECIMAL (p,s)	*distinct-type-name*
	DECIMAL	*distinct-type-name*	DECIMAL (p,s)
REAL	*distinct-type-name*	REAL	*distinct-type-name*
	distinct-type-name	DOUBLE	*distinct-type-name*
	REAL	*distinct-type-name*	REAL
DECFLOAT	*distinct-type-name*	DECFLOAT(n)	DECFLOAT(n)
	DECFLOAT	*distinct-type-name*	DECFLOAT(n)
FLOAT(*n*) where *n*<=21	*distinct-type-name*	REAL	*distinct-type-name*
	distinct-type-name	DOUBLE	*distinct-type-name*
	REAL	*distinct-type-name*	REAL
FLOAT(*n*) where *n*>21	*distinct-type-name*	DOUBLE	*distinct-type-name*
	DOUBLE	*distinct-type-name*	DOUBLE
FLOAT	*distinct-type-name*	DOUBLE	*distinct-type-name*
	DOUBLE	*distinct-type-name*	DOUBLE

Table 227. CAST functions on distinct types (continued)

Source type name	Function name	Parameter-type	Return-type
DOUBLE	*distinct-type-name*	DOUBLE	*distinct-type-name*
	DOUBLE	*distinct-type-name*	DOUBLE
DOUBLE PRECISION	*distinct-type-name*	DOUBLE	*distinct-type-name*
	distinct-type-name	CHAR (n)	*distinct-type-name*
	CHAR	*distinct-type-name*	CHAR (n)
	distinct-type-name	VARCHAR (n)	*distinct-type-name*
	DOUBLE	*distinct-type-name*	DOUBLE
CHAR CHARACTER	*distinct-type-name*	CHAR (n)	*distinct-type-name*
	CHAR	*distinct-type-name*	CHAR (n)
	distinct-type-name	VARCHAR (n)	*distinct-type-name*
VARCHAR CHARACTER VARYING CHAR VARYING	*distinct-type-name*	VARCHAR (n)	*distinct-type-name*
	VARCHAR	*distinct-type-name*	VARCHAR (n)
CLOB	*distinct-type-name*	CLOB (n)	*distinct-type-name*
	CLOB	*distinct-type-name*	CLOB (n)
GRAPHIC	*distinct-type-name*	GRAPHIC (n)	*distinct-type-name*
	GRAPHIC	*distinct-type-name*	GRAPHIC (n)
	distinct-type-name	VARGRAPHIC (n)	*distinct-type-name*
VARGRAPHIC	*distinct-type-name*	VARGRAPHIC (n)	*distinct-type-name*
	VARGRAPHIC	*distinct-type-name*	VARGRAPHIC (n)
DBCLOB	*distinct-type-name*	DBCLOB (n)	*distinct-type-name*
	DBCLOB	*distinct-type-name*	DBCLOB (n)
BINARY	*distinct-type-name*	BINARY(n)	*distinct-type-name*
	BINARY	*distinct-type-name*	BINARY(n)
	distinct-type-name	VARBINARY(n)	*distinct-type-name*
VARBINARY	*distinct-type-name*	VARBINARY(n)	*distinct-type-name*
	VARBINARY	*distinct-type-name*	VARBINARY(n)
BLOB	*distinct-type-name*	BLOB (n)	*distinct-type-name*
	BLOB	*distinct-type-name*	BLOB (n)
DATE	*distinct-type-name*	DATE	*distinct-type-name*
	DATE	*distinct-type-name*	DATE
TIME	*distinct-type-name*	TIME	*distinct-type-name*
	TIME	*distinct-type-name*	TIME

Table 227. CAST functions on distinct types (continued)

Source type name	Function name	Parameter-type	Return-type
TIMESTAMP	*distinct-type-name*	TIMESTAMP	*distinct-type-name*
	TIMESTAMP	*distinct-type-name*	TIMESTAMP(*p*) WITHOUT TIME ZONE
TIMESTAMP(*p*) WITH TIME ZONE	*distinct-type-name*	TIMESTAMP WITH TIME ZONE	*distinct-type-name*
	TIMESTAMP_TZ	*distinct-type-name*	TIMESTAMP(*p*) WITH TIME ZONE
ROWID	*distinct-type-name*	ROWID	*distinct-type-name*
	ROWID	*distinct-type-name*	ROWID

Notes: NUMERIC and FLOAT are not recommended when creating a distinct type for a portable application. Use DECIMAL and DOUBLE (or REAL) instead.

Built-in functions:
When a distinct type is defined, the built-in functions (such as AVG, MAX, and LENGTH) are not automatically supported for the distinct type. You can use a built-in function on a distinct type only after a sourced user-defined function, which is based on the built-in function, has been created for the distinct type. For information on defining sourced user-defined functions, see "CREATE FUNCTION (sourced)" on page 1493.

Arithmetic operators with distinct type operands:
A distinct type cannot be used with arithmetic operators even if its base data type is numeric.

For additional information see "Arithmetic with distinct type operands" on page 255.

Alternative syntax and synonyms:
The WITH COMPARISONS clause, which specifies that system-generated comparison operators are to be created for comparing two instances of the distinct type, can be specified as the last clause of the statement. Use WITH COMPARISONS only if it is required for compatibility with other products in the Db2 family. If the base data type is either BLOB, CLOB, or DBCLOB and WITH COMPARISONS is specified, a warning occurs as in previous releases.

To provide compatibility with previous releases of Db2 or other products in the Db2 family, Db2 supports the following clauses:

- DISTINCT TYPE as a synonym for TYPE
- TIMEZONE can be specified as an alternative to TIME ZONE

.

Examples for CREATE TYPE (distinct)

Example 1
Create a distinct type named SHOESIZE that is based on an INTEGER data type.

```
CREATE TYPE SHOESIZE AS INTEGER;
```

The successful execution of this statement also generates two cast functions. Function INTEGER(SHOESIZE) returns a value with data type INTEGER, and function SHOESIZE(INTEGER) returns a value with distinct type SHOESIZE.

Example 2

Create a distinct type named MILES that is based on a DOUBLE data type.

```
CREATE TYPE MILES AS DOUBLE;
```

The successful execution of this statement also generates two cast functions. Function DOUBLE(MILES) returns a value with data type DOUBLE, and function MILES(DOUBLE) returns a value with distinct type MILES.

Distinct types (Introduction to Db2 for z/OS)

Naming conventions
The rules for forming a name depend on the type of the object designated by the name.

Related tasks

Creating a distinct type (Db2 Application programming and SQL)

CREATE VARIABLE

The CREATE VARIABLE statement creates a global variable at the current server.

Invocation for CREATE VARIABLE

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES RUN behavior is in effect. For more information, see “Authorization IDs and dynamic SQL” on page 94.

Authorization for CREATE VARIABLE

The privilege set that is defined below must include at least one of the following:

- The CREATEIN privilege on the schema
- System DBADM authority
- SYSADM authority
- SYSCTRL authority
- Installation SYSOPR authority (when the current SQLID of the process is set to SYSINSTL)

Privilege set: The authorization ID that matches the schema name implicitly has the CREATEIN privilege on the schema. If the statement is embedded in an application program, the privilege set is the set of privileges that are held by the owner of the package. If the owner is a role, the implicit schema does not apply and this role needs to include one of the previously listed privileges or authorities.

If the statement is dynamically prepared, the privilege set is the privileges that are held by the SQL authorization ID of the process unless the process is within a trusted context and the ROLE AS OBJECT OWNER AND QUALIFIER clause is in effect. If the schema name is not the same as the SQL authorization ID of the process, one of the following conditions must be met:

- The privilege set includes SYSADM or SYSCTRL authority.
- The SQL authorization ID of the process has the CREATEIN privilege on the schema.

When the ROLE AS OBJECT OWNER AND QUALIFIER clause is in effect, the privilege set is the set privileges that are held by the role. If the schema name does not match this role, one of the following conditions must be met:

- The privilege set includes SYSADM or SYSCTRL authority.
- This role has the CREATEIN privilege on the schema.

Description for CREATE VARIABLE

variable-name

Names the global variable. The name, including the implicit or explicit qualifier, must not identify a global variable that exists at the current server. If the qualifier is not specified, the contents of the CURRENT SCHEMA special register is used.

The schema name must not begin with 'SYS' unless the schema name is 'SYSADM'.

data-type

Specifies the data type of the global variable.

built-in-type

The data type of the global variable is a built-in type. For information about the data types, see built-in-type. The data type cannot be ROWID or XML.

array-type-name

Specifies the name of a user-defined array type. The variable is an array that is defined with the "CREATE TYPE (array)" on page 1790 statement.

If you specify *array-type-name* without a schema name, Db2 resolves the array type by searching the schemas in the SQL path.

An array type with elements that are defined as character strings must be defined with CCSID UNICODE.

DEFAULT, DEFAULT NULL, DEFAULT *constant*, or DEFAULT *special-register*

The default value that is assigned to the global variable if a value is not explicitly specified. Specifies a value for the global variable when it is first referenced in the session. The default value is determined on this first reference. If the DEFAULT clause is not specified, the default for the global variable is the null value. Only DEFAULT NULL can be explicitly specified if *array-type-name* is specified.

DEFAULT NULL

Specifies null as the default value for the global variable. The value of a global variable is always nullable.

DEFAULT *constant*

Specifies that the value of the constant is the default value for the global variable. The value of the constant must conform to the rules for assigning that value to the global variable. *constant* cannot be any of the constants NAN, SNAN, or INFINITY.

DEFAULT *special-register*

Specifies that the value of the special register, when the global variable is instantiated, is used as the default value of the global variable. The value of the specified special register must conform to the rules for assigning that value to the global variable. The following special registers must not be specified:

- CURRENT GET_ACCEL_ARCHIVE
- CURRENT QUERY_ACCELERATION
- CURRENT TEMPORAL BUSINESS_TIME
- CURRENT TEMPORAL SYSTEM_TIME

Notes for CREATE VARIABLE

Session scope:

Global variables have a session scope. Although they are available for use to all sessions that are active at the current server, the value of the global variable is private for each session.

Modifications to the value of a global variable:

Global variables are not under transaction control. Modifications to the value of a global variable are not affected by either a COMMIT or ROLLBACK statement.

Privileges to use a global variable:
Reading from or writing to a global variable requires that the authorization ID or role that is in effect have the appropriate privileges on the global variable. The owner of the variable is implicitly granted all privileges on the variable.

Setting the default value:
After a global variable has been created, it is instantiated to its default value when it is first referenced within a given scope. If a global variable is referenced within a statement, it is instantiated independently from the execution of that statement.

Using a newly created global variable:
If a global variable is created within a session, it cannot be used by other sessions until the unit of work has committed. However, the newly created global variable can be used within the session in which it is created before the unit of work commits.

Examples for CREATE VARIABLE

Example 1: Create a global variable to indicate what printer to use for the session.

```
CREATE VARIABLE MYSCHEMA.MYJOB_PRINTER VARCHAR(30)
 DEFAULT 'Default printer';
```

Example 2: Create a global variable to indicate the department where an employee works.

```
CREATE VARIABLE SCHEMA1.GV_DEPTNO INTEGER
 DEFAULT 'Unassigned';
```

Example 3: Create user-defined array type myArrayIntType as an array of integers. Create global variable myGlobalVar with type myArrayIntType.

```
CREATE TYPE myArrayIntType AS INT ARRAY[];
CREATE VARIABLE myGlobalVar myArrayIntType;
```

CREATE VIEW

The CREATE VIEW statement creates a view on tables or views at the current server.

Invocation for CREATE VIEW

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES RUN behavior is in effect. For more information, see "Authorization IDs and dynamic SQL" on page 94.

Authorization for CREATE VIEW

For every table or view identified in the *fullselect*, the privilege set that is defined below must include at least one of the following:

- The SELECT privilege on the table or view
- Ownership of the table or view
- DBADM authority for the database (tables only)
- DATAACCESS authority
- SYSADM authority
- SQLADM authority (catalog tables only)
- System DBADM authority (catalog tables only)
- ACCESSCTRL authority (catalog tables only)
- SYSCTRL authority (catalog tables only)
- SECADM authority (catalog tables only)

If the database is implicitly created, the database privileges must be on the implicit database or on DSNDB04.

Authority requirements depend in part on the choice of the owner of the view. For information on how to choose the owner, see the description of *view-name* in "ALTER VIEW" on page 1373.

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the of the owner of the plan or package. If the application is bound in a trusted context with the ROLE AS OBJECT OWNER clause specified, a role is the owner. Otherwise, an authorization ID is the owner.

- If this privilege set includes SYSADM authority, the owner of the view can be any authorization ID. If that set includes SYSCTRL but not SYSADM authority, the following is true: the owner of the view can be any authorization ID, provided the view does not refer to user tables or views in the first FROM clause of its defining fullselect. (It could refer instead, for example, to catalog tables or views thereof.)

  If the view satisfies the rules in the preceding paragraph, and if no errors are present in the CREATE statement, the view is created, even if the owner has no privileges at all on the tables and views identified in the fullselect of the view definition.
- If the privilege set includes system DBADM authority, the owner of the view can be any authorization ID. However, to create a view on a user table, either the owner of the view or the creator must have the SELECT privilege on all the tables or views in the CREATE VIEW statement.
- If the privilege set lacks system DBADM, SYSADM and SYSCTRL but includes DBADM authority on at least one of the databases that contains a table from which the view is created, the owner of the view can be any authorization ID if all of the following conditions are true:
  - The value of subsystem parameter DBACRVW is set to YES.
  - The view is not based only on views.

  Note: The owner of the view must have the SELECT privilege on all tables and views in the CREATE VIEW statement, or, if the owner does not have the SELECT privilege on a table, the creator must have DBADM authority on the database that contains that table.
- If the privilege set lacks SYSADM, SYSCTRL, system DBADM, and DBADM authority, or if the authorization ID of the application plan or package fails to meet any of the previous conditions, the owner of the view must be the owner of the application plan or package.

If ROLE AS OBJECT OWNER is in effect, the schema qualifier must be the same as the role, unless the role has the CREATEIN privilege on the schema, SYSADM authority, system DBADM authority, or SYSCTRL authority.

If ROLE AS OBJECT OWNER is not in effect, one of the following rules applies:

- If the privilege set lacks the CREATIN privilege on the schema, SYSADM authority, system DBADM authority, or SYSCTRL authority, the schema qualifier (implicit or explicit) must be the same as one of the authorization ids of the process.
- If the privilege set includes system DBADM authority, SYSADM authority or SYSCTRL authority, the schema qualifier can be any valid schema name.

If the statement is dynamically prepared, the following rules apply:

- If the SQL authorization ID of the process has SYSADM authority, the owner of the view can be any authorization ID. If that authorization ID has SYSCTRL but not SYSADM authority, the following is true: the owner of the view can be any authorization ID, provided the view does not refer to user tables or views in the first FROM clause of its defining fullselect. (It could refer instead, for example, to catalog tables or views thereof.)

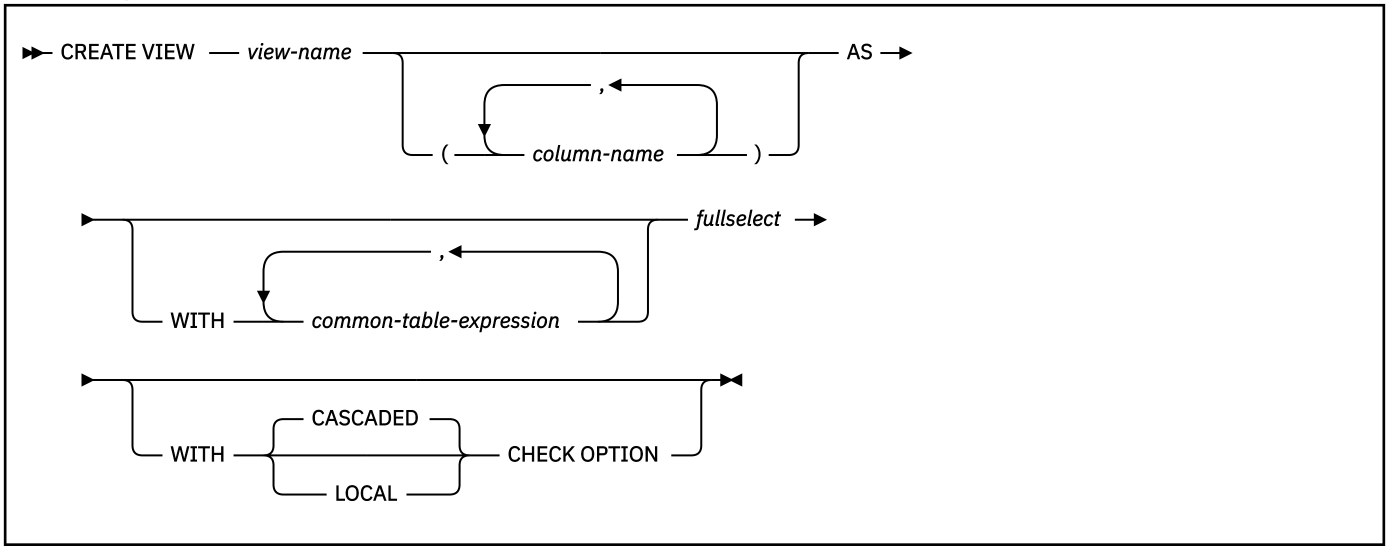
  If the view satisfies the rules in the preceding paragraph, and if no errors are present in the CREATE statement, the view is created, even if the owner has no privileges at all on the tables and views identified in the fullselect of the view definition.
- If the SQL authorization ID of the process has system DBADM authority, the owner of the view can be any authorization ID. However, to create a view on a user table, either the owner of the view or the

SQL authorization ID must have the SELECT privilege on all the tables or views in the CREATE VIEW statement.

- If SQL authorization ID of the process lacks system DBADM authority, SYSADM and SYSCTRL but includes DBADM authority on at least one of the databases that contains a table from which the view is created, the owner of the view can be different from the SQL authorization ID if all of the following conditions are true:
  - The value of field DBADM CREATE AUTH was set to YES on panel DSNTIPP during Db2 installation.
  - The view is not based only on views.

  Note: The owner of the view must have the SELECT privilege on all tables and views in the CREATE VIEW statement, or, if the owner does not have the SELECT privilege on a table, the creator must have DBADM authority on the database that contains that table.
- If the SQL authorization ID of the process lacks SYSADM, SYSCTRL, system DBADM authority, or DBADM authority, or if the SQL authorization ID of the process fails to meet any of the previous conditions, only the authorization IDs of the process can own the view. In this case, the privilege set is the privileges that are held by the authorization ID selected for ownership.

Syntax for CREATE VIEW



Description for CREATE VIEW

view-name

Names the view. The name, including the implicit or explicit qualifier, must not identify a table, view, alias, or synonym that exists at the current server or a table that exists in the SYSIBM.SYSPENDINGOBJECTS catalog table. The unqualified name must not be the same as an existing synonym.

If the name is qualified, the name can be a two-part or three-part name. If a three-part name is used, the first part must match the value of the field Db2 LOCATION NAME of installation panel DSNTIPR at the current server. (If the current server is not the local Db2, this name is not necessarily the name in the CURRENT SERVER special register.)

column-name,...

Names the columns in the view. If you specify a list of column names, it must consist of as many names as there are columns in the result table of the fullselect. Each name must be unique and unqualified. If you do not specify a list of column names, the columns of the view inherit the names of the columns of the result table of the fullselect.

You must specify a list of column names if the result table of the fullselect has duplicate column names or an unnamed column (a column derived from a constant, function, or expression that was not given a name by the AS clause). For more details about unnamed columns, see the information about names of result columns under "select-clause" on page 1007.

AS

Identifies the view definition.

WITH *common-table-expression*

Defines a common table expression for use with the fullselect that follows. The fullselect must not contain a period specification. For an explanation of common table expression, see "common-table-expression" on page 1065.

fullselect

Defines the view. At any time, the view consists of the rows that would result if the fullselect were executed.

The *fullselect* must conform to the following rules:

- The *fullselect* must not refer to any host variables or parameter markers (question marks), but can refer to global variables.
- The *fullselect* must not refer to any declared temporary tables.
- The *fullselect* must not include an invocation of the UNPACK function.
- The *fullselect* must not contain a period specification.
- The FROM clause of the *fullselect* must not include a *data-change-table-reference*.
- The FROM clause of the *fullselect* must not include a view for which an INSTEAD OF trigger is defined.
- The outer SELECT list of the outer *fullselect* must not result in a column that is an array.

For an explanation of *fullselect*, see "fullselect" on page 1058.

`WITH CASCADED CHECK OPTION` or `WITH LOCAL CHECK OPTIONS`

Specifies that every row that is inserted or updated through the view must conform to the definition of the view. A row that does not conform to the definition of the view is a row that cannot be retrieved using that view.

The CHECK OPTION clause must not be specified if the view is read-only, includes a subquery, references a function that is not deterministic or has an external action, or if the fullselect of the view refers to a created temporary table. If the CHECK OPTION clause is specified for an updatable view that does not allow inserts, it applies to updates only.

If the CHECK OPTION clause is omitted, the definition of the view is not used in the checking of any insert or update operations that use the view. Some checking might still occur during insert or update operations if the view is directly or indirectly dependent on another view that includes the CHECK OPTION clause. Because the definition of the view is not used, rows might be inserted or updated through the view that do not conform to the definition of the view.

The difference between the two forms of the check option, CASCADED and LOCAL, is meaningful only when a view is dependent on another view. The default is CASCADED. The view on which another view is directly or indirectly defined is an *underlying view*.

CASCADED

Update and insert operations on view V must satisfy the search conditions of view V and all underlying views, regardless of whether the underlying views were defined with a check option. Furthermore, every updatable view that is directly or indirectly defined on view V inherits those search conditions (the search conditions of view V and all underlying views of V) as a constraint on insert or update operations. WITH CASCADED CHECK OPTION must not be specified if a view on which the specified view definition is dependent has an INSTEAD OF trigger defined.

LOCAL

Update and insert operations on view V must satisfy the search conditions of view V and underlying views that are defined with a check option (either WITH CASCADED CHECK OPTION or WITH LOCAL CHECK OPTION). Furthermore, every updatable view that is directly or indirectly defined on view V inherits those search conditions (the search conditions of view V and all underlying views of V that are defined with a check option) as a constraint on insert or update operations.

The LOCAL form of the CHECK option lets you update or insert rows that do not conform to the search condition of view V. You can perform these operations if the view is directly or indirectly defined on a view that was defined without a check option.

Table 228 on page 1811 illustrates the effect of using the default check option, CASCADED. The information in Table 228 on page 1811 is based on the following views:

- CREATE VIEW V1 AS SELECT COL1 FROM T1 WHERE COL1 > 10
- CREATE VIEW V2 AS SELECT COL1 FROM V1 WITH CASCADED CHECK OPTION
- CREATE VIEW V3 AS SELECT COL1 FROM V2 WHERE COL1 < 100

Table 228. Examples using default check option, CASCADED

SQL statement	Description of result
INSERT INTO V1 VALUES(5)	Succeeds because V1 does not have a check option and it is not dependent on any other view that has a check option.
INSERT INTO V2 VALUES(5)	Results in an error because the inserted row does not conform to the search condition of V1 which is implicitly is part of the definition of V2.
INSERT INTO V3 VALUES(5)	Results in an error because the inserted row does not conform to the search condition of V1.
INSERT INTO V3 VALUES(200)	Succeeds even though it does not conform to the definition of V3 (V3 does not have the view check option specified); it does conform to the definition of V2 (which does have the view check option specified).

The difference between CASCADED and LOCAL is shown best by example. Consider the following updatable views, where x and y represent either LOCAL or CASCADED:

V1 is defined on Table T0.
V2 is defined on V1 WITH x CHECK OPTION.
V3 is defined on V2.
V4 is defined on V3 WITH y CHECK OPTION.
V5 is defined on V4.

This example shows V1 as an *underlying view* for V2 and V2 as *dependent* on V1.

Table 229 on page 1811 shows the views in which search conditions are checked during an insert or update operation:

Table 229. Views in which search conditions are checked during insert and update operations

View used in INSERT or UPDATE operation	x = LOCAL
	y = LOCAL
		x = CASCADED
		y = CASCADED
			x = LOCAL
			y = CASCADED
				x = CASCADED
				y = LOCAL

V1	None	None	None	None
V2	V2	V2, V1	V2	V2, V1
V3	V2	V2, V1	V2	V2, V1
V4	V4, V2	V4, V3, V2, V1	V4, V3, V2, V1	V4, V2, V1
V5	V4, V2	V4, V3, V2, V1	V4, V3, V2, V1	V4, V2, V1

Notes for CREATE VIEW

Owner privileges

The owner of a view always acquires the SELECT privilege on the view and the authority to drop the view. If all of the privileges that are required to create the view are held with the GRANT option before the view is created, the owner of the view receives the SELECT privilege with the GRANT option. Otherwise, the owner receives the SELECT privilege without the GRANT option. For example, assume that a view definition also refers to a user-defined function. If the owner's EXECUTE privilege on the user-defined function is held without the GRANT option, the owner acquires the SELECT privilege on the view without the GRANT option.

The owner can also acquire INSERT, UPDATE, and DELETE privileges on the view. Acquiring these privileges is possible if the view is not "read-only", which means a single table of view is identified in the first FROM clause of the fullselect. For each privilege that the owner has on the identified table or view (INSERT, UPDATE, and DELETE) before the new view is created, the owner acquires that privilege on the view. The owner receives the privilege with the GRANT option if the privilege is held on the table or view with the GRANT option. Otherwise, the owner receives the privileges without the GRANT option.

With appropriate Db2 authority, a process can create views for those who have no authority to create the views themselves. The owner of such a view has the SELECT privilege on the view, without the GRANT option, and can drop the view.

For more information on the ownership of an object, see "Authorization, privileges, permissions, masks, and object ownership" on page 90.

Authorization for views created for other users

When a process with appropriate authority creates a view for another user that does not have authorization for the underlying table or view, the SELECT privilege for the created view is implicitly granted to the user.

Considerations for row access control and column access control

The view definition might reference a table for which row access control or column access control is activated. If the view definition references a table for which row access control or column access control is activated, the WITH CHECK OPTION clause must not be specified if the search conditions from the view or from the underlying views will be checked during an insert or update operation. Note that the WITH CHECK OPTION clause is ignored if such search conditions do not exist.

Read-only views

A view is *read-only* if one or more of the following statements is true of its definition:

- The first FROM clause identifies more than one table or view, or identifies a table function, a nested table expression, a common table expression, or a collection-derived table.
- The first SELECT clause specifies the keyword DISTINCT.
- The outer fullselect contains a GROUP BY clause.
- The outer fullselect contains a HAVING clause.
- The first SELECT clause contains an aggregate function.
- It contains a subquery such that the base object of the outer fullselect, and of the subquery, is the same table.
- The first FROM clause identifies a read-only view.
- The first FROM clause identifies a system-maintained materialized query table.
- The outer fullselect is not a subselect (contains a set operator).

A read-only view cannot be the object of an SQL data change statement or a TRUNCATE statement. A view that includes GROUP BY or HAVING cannot be referred to in a subquery of a basic predicate.

Insertable views

A view is insertable if an INSTEAD OF trigger for the insert operation has been defined for the view, or if at least one column of the view is updatable (independent of an INSTEAD OF trigger for update).

Considerations for implicitly hidden columns

It is possible that the result table of the fullselect will include a column of a base table that is defined as implicitly hidden. This can occur when the implicitly hidden column is explicitly referenced in the fullselect of the view definition. However, the corresponding column of the view does not inherit the implicitly hidden attribute. Columns of a view cannot be defined as hidden.

Testing a view definition

You can test the semantics of your view definition by executing SELECT * FROM *view-name*.

The two forms of a view definition

Both the source and the operational form of a view definition are stored in the Db2 catalog. Those two forms are not necessarily equivalent because the operational form reflects the state that exists when the view is created. For example, consider the following statement:

```
CREATE VIEW V AS SELECT * FROM S;
```

In this example, S is a synonym or alias for A.T, which is a table with columns C1, C2, and C3®. The operational form of the view definition is equivalent to:

```
SELECT C1, C2, C3 FROM A.T;
```

Adding columns to A.T using ALTER TABLE and dropping S does not affect the operational form of the view definition. Thus, if columns are added to A.T or if S is redefined, the source form of the view definition can be misleading.

View restrictions

A view definition cannot contain references to remote objects. A view definition cannot map to more than 15 base table instances. A view definition cannot reference a declared global temporary table.

Restrictions involving pending definition changes

CREATE VIEW is not allowed if the view references a column on which there are pending definition changes.

Considerations for inline LOB columns

If the view references a table that contains an inline LOB column and Db2 determines that the inline attribute can be passed on to the view, the view will then inherit the inline attribute, otherwise the inline attribute is not inherited by the view.

Considerations for XML columns

If the view has an XML column and the column of the underlying base table for the view has an XML type modifier, the view column has the same type modifier. However, if there is an instead of trigger defined on the view, validation of the column, according to XML schemas in the type modifier, is not enforced during insert or update to this view.

Examples for CREATE VIEW

Example 1

Create the view DSN8C10.VPROJRE1. PROJNO, PROJNAME, PROJDEP, RESPEMP, FIRSTNME, MIDINIT, and LASTNAME are column names. The view is a join of tables and is therefore read-only.

```
CREATE VIEW DSN8C10.VPROJRE1
  (PROJNO,PROJNAME,PROJDEP,RESPEMP,
   FIRSTNME,MIDINIT,LASTNAME)
  AS SELECT ALL
  PROJNO,PROJNAME,DEPTNO,EMPNO,
  FIRSTNME,MIDINIT,LASTNAME
  FROM DSN8C10.PROJ, DSN8C10.EMP
  WHERE RESPEMP = EMPNO;
```

In the example, the WHERE clause refers to the column EMPNO, which is contained in one of the base tables but is not part of the view. In general, a column named in the WHERE, GROUP BY, or HAVING clause need not be part of the view.

Example 2

Create the view DSN8C10.FIRSTQTR that is the UNION ALL of three fullselects, one for each month of the first quarter of 2000. The common names are SNO, CHARGES, and DATE.

```
 CREATE VIEW DSN8C10.FIRSTQTR (SNO, CHARGES, DATE) AS
SELECT SNO, CHARGES, DATE
FROM MONTH1
WHERE DATE BETWEEN '01/01/2000' and '01/31/2000'
  UNION All
SELECT SNO, CHARGES, DATE
FROM MONTH2
WHERE DATE BETWEEN '02/01/2000' and '02/29/2000'
  UNION All
SELECT SNO, CHARGES, DATE
FROM MONTH3
WHERE DATE BETWEEN '03/01/2000' and '03/31/2000';
```

DECLARE CURSOR

The DECLARE CURSOR statement defines a cursor.

Invocation for DECLARE CURSOR

This statement can only be embedded in an application program. It is not an executable statement. It must not be specified in Java.

Authorization for DECLARE CURSOR

For each table or view identified in the SELECT statement of the cursor, the privilege set must include at least one of the following:

- The SELECT privilege
- Ownership of the object
- DBADM authority for the corresponding database (tables only)
- SYSADM authority
- SYSCTRL authority (catalog tables only)
- DATAACCESS authority

If the *select-statement* contains an SQL data change statement, the authorization requirements of that statement also apply to the DECLARE CURSOR statement.

The SELECT statement of the cursor is one of the following:

- The prepared select statement identified by *statement-name*
- The specified *select-statement*

If statement-name is specified:

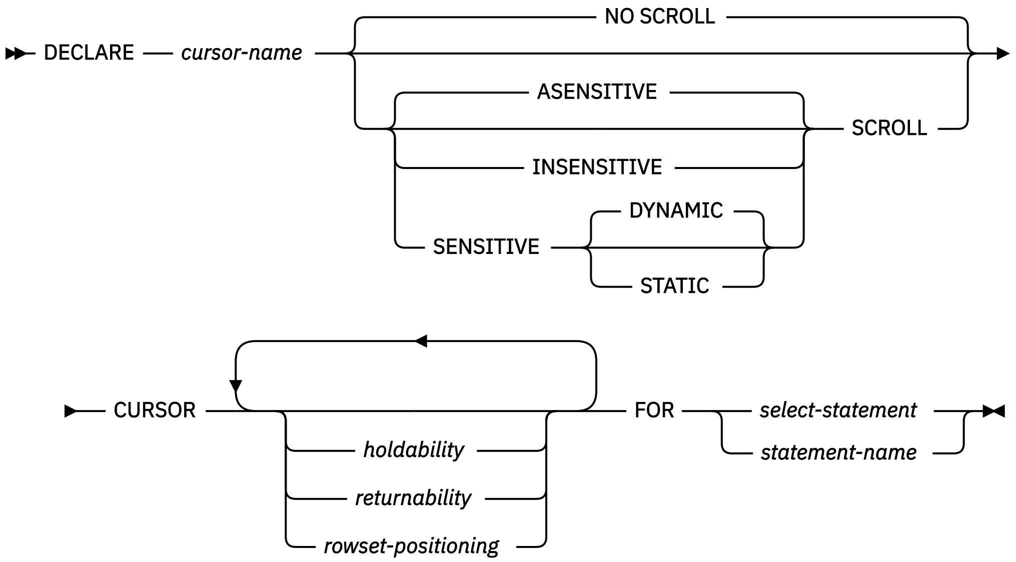
- The privilege set is determined by the DYNAMICRULES behavior in effect (run, bind, define, or invoke) and is summarized in Table 171 on page 1084. (For more information on these behaviors, including a list of the DYNAMICRULES bind option values that determine them, see “Authorization IDs and dynamic SQL” on page 94.)
- The authorization check is performed when the SELECT statement is prepared.

- The cursor cannot be opened unless the SELECT statement is successfully prepared.

If select-statement is specified:

- The privilege set consists of the privileges that are held by the authorization ID of the owner of the plan or package.
- If the plan or package is bound with VALIDATE(BIND), the authorization check is performed at bind time, and the bind is unsuccessful if any required privilege does not exist.
- If the plan or package is bound with VALIDATE(RUN), an authorization check is performed at bind time, but all required privileges need not exist at that time. If all privileges exist at bind time, no authorization checking is performed when the cursor is opened. If any privilege does not exist at bind time, an authorization check is performed the first time the cursor is opened within a unit of work. The OPEN is unsuccessful if any required privilege does not exist.

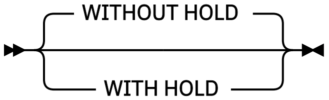
Syntax for DECLARE CURSOR



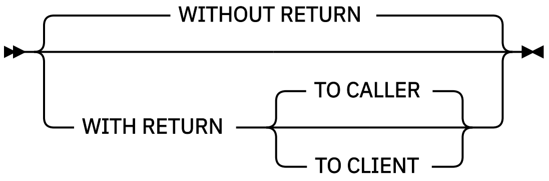
Notes:

[1] The same clause must not be specified more than once.

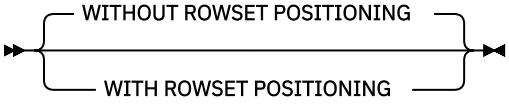
holdability:



returnability:



rowset-positioning:



Description for DECLARE CURSOR

cursor-name

Names the cursor. The name must not identify a cursor that has already been declared in the source program. The name is usually VARCHAR(128); however, if the cursor is defined WITH RETURN, the name is limited to VARCHAR(30).

NO SCROLL or SCROLL

Specifies whether the cursor is scrollable or not scrollable.

NO SCROLL

Specifies that the cursor is not scrollable. This is the default.

SCROLL

Specifies that the cursor is scrollable. For a scrollable cursor, whether the cursor has sensitivity to inserts, updates, or deletes depends on the cursor sensitivity option in effect for the cursor. If a sensitivity option is not specified, ASENSITIVE is the default.

ASENSITIVE

Specifies that the cursor should be as sensitive as possible. This is the default.

A cursor that defined as ASENSITIVE will be either insensitive or sensitive dynamic; it will not be sensitive static. For information about how the effective sensitivity of the cursor is returned to the application with the GET DIAGNOSTICS statement or in the SQLCA, see "OPEN" on page 2032.

The sensitivity of a cursor is a factor in the choice of access path. Explicitly specify the sensitivity level that you need, instead of specifying ASENSITIVE.

INSENSITIVE

Specifies that the cursor does not have sensitivity to inserts, updates, or deletes that are made to the rows underlying the result table. As a result, the size of the result table, the order of the rows, and the values for each row do not change after the cursor is opened. In addition, the cursor is read-only. The SELECT statement or *attribute-string* of the PREPARE statement cannot contain a FOR UPDATE clause, and the cursor cannot be used for positioned updates or deletes.

SENSITIVE

Specifies that the cursor has sensitivity to changes that are made to the database after the result table is materialized. The cursor is always sensitive to updates and deletes that are made using the cursor (that is, positioned updates and deletes using the same cursor). When the current value of a row no longer satisfies the *select-statement* or *statement-name*, that row is no longer visible through the cursor. When a row of the result table is deleted from the underlying base table, the row is no longer visible through the cursor.

If Db2 cannot make changes visible to the cursor, then an error is issued at bind time for OPEN CURSOR. Db2 cannot make changes visible to the cursor when the cursor implicitly becomes read-only. For example, when the result table must be materialized, as when the FROM clause of the SELECT statement contains more than one table or view. The current list of conditions that result in an implicit read-only cursor can be found in Read-only cursors.

The default is DYNAMIC.

DYNAMIC

Specifies that the result table of the cursor is dynamic, meaning that the size of the result table might change after the cursor is opened as rows are inserted into or deleted from the underlying table, and the order of the rows might change. Rows that are inserted, deleted, or updated by statements that are executed by the same application process as the cursor are visible to the cursor immediately. Rows that are inserted, deleted, or updated by statements that are executed by other application processes are visible only after the statements are committed. If a column for an ORDER BY clause is updated via a cursor or any means outside the process, the next FETCH statement behaves as if the updated row was deleted and re-inserted into the result table at its correct location. At the time of a positioned update, the cursor is positioned before the next row of the original location and there is no current row, making the row appear to have moved.

If a SENSITIVE DYNAMIC cursor is not possible, an error is returned. For example, if a temporary table is needed an error is returned. The SELECT statement of a cursor that is defined as SENSITIVE DYNAMIC cannot contain an SQL data change statement.

The *offset-clause* and the *fetch-clause* must not be specified for the outermost fullselect for a sensitive dynamic cursor.

STATIC

Specifies that the size of the result table and the order of the rows do not change after the cursor is opened. Rows inserted into the underlying table are not added to the result table regardless of how the rows are inserted. Rows in the result table do not move if columns in the ORDER BY clause are updated in rows that have already been materialized. Positioned updates and deletes are allowed if the result table is updatable. The SELECT statement of a cursor that is defined as SENSITIVE STATIC cannot contain an SQL data change statement.

A STATIC cursor has visibility to changes made by *this* cursor using positioned updates or deletes. Committed changes made outside this cursor are visible with the SENSITIVE option of the FETCH statement. A FETCH SENSITIVE can result in a *hole* in the result table (that is, a difference between the result table and its underlying base table). If an updated row in the base table of a cursor no longer satisfies the predicate of its SELECT statement, an update hole occurs in the result table. If a row of a cursor was deleted in the base table, a delete hole occurs in the result table. When a FETCH SENSITIVE detects an update hole, no data is returned (a warning is issued), and the cursor is left positioned on the update hole. When a FETCH SENSITIVE detects a delete hole, no data is returned (a warning is issued), and the cursor is left positioned on the delete hole.

Updates through a cursor result in an automatic re-fetch of the row. This re-fetch means that updates can create a hole themselves. The re-fetched row also reflects changes as a result of triggers updating the same row. It is important to reflect these changes to maintain the consistency of data in the row.

Using a function that is not deterministic (built-in or user-defined) in the WHERE clause of the *select-statement* or *statement-name* of a SENSITIVE STATIC cursor can cause misleading results. This situation occurs because Db2 constructs a temporary result table and retrieves rows from this table for FETCH INSENSITIVE statements. When Db2 processes a FETCH SENSITIVE statement, rows are fetched from the underlying table and predicates are re-evaluated. Using a function that is not deterministic can yield a different result on each FETCH SENSITIVE of the same row, which could also result in the row no longer being considered a match.

A FETCH INSENSITIVE on a SENSITIVE STATIC SCROLL cursor is not sensitive to changes made outside the cursor, unless a previous FETCH SENSITIVE has already refreshed that row; however, positioned updates and delete changes with the cursor are visible.

STATIC cursors are insensitive to insertions.

WITHOUT HOLD or WITH HOLD

Specifies whether the cursor should be prevented from being closed as a consequence of a commit operation.

WITHOUT HOLD

Does not prevent the cursor from being closed as a consequence of a commit operation. This is the default.

WITH HOLD

Prevents the cursor from being closed as a consequence of a commit operation. A cursor declared with WITH HOLD is closed at commit time if one of the following is true:

- The connection associated with the cursor is in the release pending status.
- The bind option DISCONNECT(AUTOMATIC) is in effect.
- The environment is one in which the option WITH HOLD is ignored.

When WITH HOLD is specified, a commit operation commits all of the changes in the current unit of work. For example, with a non-scrollable cursor, an initial FETCH statement is needed after a COMMIT statement to position the cursor on the row that follows the row that the cursor was positioned on before the commit operation.

WITH HOLD has no effect on an SQL data change statement within a SELECT statement. When a COMMIT is issued, the changes caused by the SQL data change statement are committed, regardless of whether or not the cursor is declared WITH HOLD.

All cursors are implicitly closed by a connect (Type 1) or rollback operation. A cursor is also implicitly closed by a commit operation if WITH HOLD is ignored or not specified.

Cursors that are declared with WITH HOLD in CICS or in IMS non-message-driven programs will not be closed by a rollback operation if the cursor was opened in a previous unit of work and no changes have been made to the database in the current unit of work. The cursor cannot be closed because CICS and IMS do not broadcast the rollback request to Db2 for a null unit of work.

If a cursor is closed before the commit operation, the effect is the same as if the cursor was declared without the option WITH HOLD.

WITH HOLD is ignored in IMS message driven programs (MPP, IFP, and message-driven BMP). WITH HOLD maintains the cursor position in a CICS pseudo-conversational program until the end-of-task (EOT).

For details on restrictions that apply to declaring cursors with WITH HOLD, see Held and non-held cursors (Db2 Application programming and SQL).

`WITHOUT RETURN` or `WITH RETURN`

Specifies whether the result table of the cursor is intended to be used as a result set that will be returned from a procedure. If *statement-name* is specified, the default is the corresponding prepare attribute of the statement. Otherwise, the default is `WITHOUT RETURN`.

`WITHOUT RETURN`

Specifies that the result table of the cursor is not intended to be used as a result set that will be returned from a procedure.

`WITH RETURN`

Specifies that the result table of the cursor is intended to be used as a result set that will be returned from a procedure. WITH RETURN is relevant only if the DECLARE CURSOR statement is contained within the source code for a procedure. In other cases, the precompiler might accept the clause, but it has not effect.

When a cursor that is declared using the WITH RETURN TO CALLER clause remains open at the end of a program or routine, that cursor defines a result set from the program or routine. Use the CLOSE statement to close a cursor that is not intended to be a result set from the program or routine. Although Db2 will automatically close any cursors that are not declared using with a WITH RETURN clause, the use of the CLOSE statement is recommended to increase the portability of applications.

For non-scrollable cursors, the result set consists of all rows from the current cursor position to the end of the result table. For scrollable cursors, the result set consists of all rows of the result table.

`TO CALLER`

Specifies that the cursor can return a result set to the caller of the procedure. The caller is the program or routine that executed the SQL CALL statement that invokes the procedure that contains the DECLARE CURSOR statement. For example, if the caller is a procedure, the result set, is returned to the procedure. If the caller is a client application, the result set is returned to the client application.

If the statement is contained within the source code for a procedure, WITH RETURN TO CALLER specifies that the cursor can be used as a result set cursor. A result set cursor is used when the result table of a cursor is to be returned from a procedure. Specifying TO CALLER is optional.

In other cases, the clause is ignored and the cursor cannot be used as a result set cursor.

TO CLIENT

Specifies that the cursor can return a result set to the client application. This cursor is invisible to any intermediate nested procedures. If a function or trigger calls the procedure (either directly or indirectly), the result set cannot be returned to the client and the cursor will be closed after the procedure finishes.

rowset-positioning

Specifies whether multiple rows of data can be accessed as a rowset on a single FETCH statement for the cursor. The default is WITHOUT ROWSET POSITIONING.

WITHOUT ROWSET POSITIONING

Specifies that the cursor can be used only with row-positioned FETCH statements. The cursor is to return a single row for each FETCH statement and the FOR *n* ROWS clause cannot be specified on a FETCH statement for this cursor. WITHOUT ROWSET POSITIONING or single row access refers to how data is fetched from the database engine. For remote access, data might be blocked and returned to the client in blocks.

WITH ROWSET POSITIONING

Specifies that the cursor can be used with either row-positioned or rowset-positioned FETCH statements. This cursor can be used to return either a single row or multiple rows, as a rowset, with a single FETCH statement. ROWSET POSITIONING refers to how data is fetched from the database engine. For remote access, if any row qualifies, at least 1 row is returned as a rowset. The size of the rowset depends on the number of rows specified on the FETCH statement and on the number of rows that qualify. Data might be blocked and returned to the client in blocks.

Db2 REXX applications do not support cursors that are declared WITH ROWSET POSITIONING. To allow a cursor for a SELECT statement in a Db2 REXX application to be used with row-positioned or rowset-positioned FETCH statements, specify WITH ROWSET POSITIONING in the attribute string of the PREPARE statement for the SELECT statement.

select-statement

Specifies the result table of the cursor. See “select-statement” on page 1064 for an explanation of *select-statement*.

The *select-statement* must not include parameter markers (except for REXX), but can include references to host variables. In host languages, other than REXX, the declarations of the host variables must precede the DECLARE CURSOR statement in the source program. In REXX, parameter markers must be used in place of host variables and the statement must be prepared.

The USING clause of the OPEN statement can be used to specify host variables that will override the values of the host variables or parameter markers that are specified as part of the statement in the DECLARE CURSOR statement.

The *select-statement* must not contain an SQL data change statement if the cursor is defined as SENSITIVE DYNAMIC or SENSITIVE STATIC.

The *select-statement* must not contain a fullselect that is a VALUES clause.

The outer select list of the *select-statement* of a scrollable cursor must not be an array value.

statement-name

Identifies the prepared *select-statement* that specifies the result table of the cursor whenever the cursor is opened. The *statement-name* must not be identical to a statement name specified in another DECLARE CURSOR statement of the source program. For an explanation of prepared SELECT statements, see "PREPARE" on page 2037.

The prepared *select-statement* must not contain an SQL data change statement if the cursor is defined as SENSITIVE DYNAMIC or SENSITIVE STATIC.

Notes for DECLARE CURSOR

A cursor in the open state designates a result table and a position relative to the rows of that table. The table is the result table specified by the SELECT statement of the cursor.

Read-only cursors:

If the result table is *read-only*, the cursor is *read-only*. The cursor that references a view with instead of triggers are read-only since positioned UPDATE and positioned DELETE statements are not allowed using those cursors. The result table is *read-only* if one or more of the following statements is true about the *select-statement* of the cursor:

- The first FROM clause identifies or contains any of the following:
  - More than one table or view
  - A catalog table with no updatable columns
  - A read-only view
  - A nested table expression
  - A table function
  - A system-maintained materialized query table
  - A single table that is a system-period temporal table, and a period specification for SYSTEM_TIME is used
  - A single view that directly or indirectly references a system-period temporal table in the FROM clause of the outer fullselect of the view definition, and a period specification for SYSTEM_TIME is used
- The first SELECT clause specifies the keyword DISTINCT, contains an aggregate function, or uses both
- It contains an SQL data change statement
- The outer subselect contains a GROUP BY clause, a HAVING clause, or both clauses
- It contains a subquery such that the base object of the outer subselect, and of the subquery, is the same table
- Any of the following operators or clauses are specified:
  - A set operator
  - An ORDER BY clause (except when the cursor is declared as SENSITIVE STATIC scrollable)
  - A FOR READ ONLY clause
- It is executed with isolation level UR and a FOR UPDATE clause is not specified.
- It is a VALUES clause.

If the result table is not read-only, the cursor can be used to update or delete the underlying rows of the result table.

Referencing columns that will be updated:

If a cursor uses FETCH statements to retrieve columns that will be updated later, specify FOR UPDATE OF when you select the columns. Then specify WHERE CURRENT OF in the subsequent UPDATE or DELETE statements. These clauses prevent Db2 from selecting access through an index on the columns that are being updated, which might otherwise cause Db2 to read the same row more than once.

For more information, see Updating previously retrieved data (Db2 Application programming and SQL).

Tables for which row or column access controls are enforced:

The *select-statement* of the cursor can reference a table for which row or column access controls are enforced. The row or column access controls do not effect the determination of whether the cursor is read-only and do not effect the cursor sensitivity.

Work file database requirement for static scrollable cursors:

To use a static scrollable cursor, you must first create a work file database and at least one table space with a 32KB page size in this database because a static scrollable cursor requires a temporary table for its result table while the cursor is open. Db2 chooses a table space to use for the temporary result table. Dynamic scrollable cursors do not require a declared temporary table.

For static scrollable cursor declarations that contain empty strings, Db2 assigns one byte in the temporary table space for each empty string. The following example shows a scrollable cursor declaration with an empty string:

```
EXEC SQL DECLARE CSROWSTAT SENSITIVE STATIC SCROLL CURSOR
  WITH ROWSET POSITIONING WITH HOLD FOR
  SELECT ID1,''
  FROM TB;
```

Cursors in COBOL and Fortran programs:

In COBOL and Fortran source programs, the DECLARE CURSOR statement must precede all statements that explicitly refer to the cursor by name. This rule does not necessarily apply to the other host languages because the precompiler provides a two-pass option for these languages. This rule applies to other host languages if the two-pass option is not used.

Cursors in REXX:

If host variables are used in a DECLARE CURSOR statement within a REXX procedure, the DECLARE CURSOR statement must be the object of a PREPARE and EXECUTE.

Scope of a cursor:

The scope of *cursor-name* is the source program in which it is defined; that is, the application program submitted to the precompiler. Thus, you can only refer to a cursor by statements that are precompiled with the cursor declaration. For example, a COBOL program called from another program cannot use a cursor that was opened by the calling program. Furthermore, a cursor defined in a Fortran subprogram can only be referred to in that subprogram. Cursors that specify WITH RETURN in a procedure and are left open are returned as result sets.

Although the scope of a cursor is the program in which it is declared, each package (or DBRM of a plan) created from the program includes a separate instance of the cursor, and more than one instance of the cursor can be used in the same execution of the program. For example, assume a program is precompiled with the CONNECT(2) option and its DBRM is used to create a package at location X and a package at location Y. The program contains the following SQL statements:

```
  DECLARE C CURSOR FOR ...
  CONNECT TO X
  OPEN C
  FETCH C INTO ...
  CONNECT TO Y
  OPEN C
  FETCH C INTO ...
```

The second OPEN C statement does not cause an error because it refers to a different instance of cursor C. The same notion applies to a single location if the packages are in different collections.

A SELECT statement is evaluated at the time the cursor is opened. If the same cursor is opened, closed, and then opened again, the results can be different. If the SELECT statement of the cursor contains CURRENT DATE, CURRENT TIME or CURRENT TIMESTAMP, all references to these special registers yields the same respective datetime value on each FETCH operation. The value is determined when the cursor is opened. Multiple cursors using the same SELECT statement can be opened concurrently. They are each considered independent activities.

Blocking of data:

To process data more efficiently, Db2 might block data for read-only cursors. If a cursor is not going to be used in a positioned UPDATE or positioned DELETE statement, define the cursor as FOR READ ONLY.

Positioned deletes and isolation level UR:

Specify FOR UPDATE if you want to use the cursor for a positioned DELETE and the isolation level is UR because of a BIND option. In this case, the isolation level is CS.

Returning a result set from a stored procedure:

A cursor that is declared in a stored procedure returns a result set when all of the following conditions are true:

- The cursor is declared with the WITH RETURN option. In a distributed environment, blocks of each result set of the cursor's data are returned with the CALL statement reply.
- The cursor is left open after exiting from the stored procedure. A cursor declared with the SCROLL option must be left positioned *before* the first row before exiting from the stored procedure.
- The cursor is declared with the WITH HOLD option if the stored procedure is defined to commit on return.

The result set is the set of all rows after the current position of the cursor after exiting the stored procedure. The result set is assumed to be read-only. If that same procedure is invoked again, open result set cursors for a stored procedure at a given site are automatically closed by the database management system.

Scrollable cursors specified with user-defined functions:

A row can be fetched more than once with a scrollable cursor. Therefore, if a scrollable cursor is defined with a function that is not deterministic in the select list of the cursor, a row can be fetched multiple times with different results for each fetch. (However, the value of a function that is not deterministic in the WHERE clause of a scrollable cursor is captured when the cursor is opened and remains unchanged until the cursor is closed.) Similarly, if a scrollable cursor is defined with a user-defined function with external action, the action is executed with every fetch.

Multiple instances of a cursor that is defined with RETURN TO CLIENT:

If the cursor is declared in a native SQL procedure, a cursor that is declared as WITH RETURN TO CLIENT can be opened even when a cursor with the same name is already in the open state. In this case, the already open cursor becomes a result set cursor and is no longer accessible by using its cursor name. A new cursor is opened and becomes accessible by using the cursor name. When a CLOSE statement is issued, the last instance of the cursor will be closed. Closing the new cursor does not make the cursor that was previously accessible by that name accessible by the cursor name again. Cursors that become result set cursors in this way cannot be accessed at the server and can be processed only at the client.

Examples for DECLARE CURSOR

The statements in the following examples are assumed to be in PL/I programs.

Example 1

Declare C1 as the cursor of a query to retrieve data from the table DSN8C10.DEPT. The query itself appears in the DECLARE CURSOR statement.

```
EXEC SQL DECLARE C1 CURSOR FOR
   SELECT DEPTNO, DEPTNAME, MGRNO
   FROM DSN8C10.DEPT
   WHERE ADMRDEPT = 'A00';
```

Example 2

Declare C1 as the cursor of a query to retrieve data from the table DSN8810.DEPT. Assume that the data will be updated later with a searched update and should be locked when the query executes. The query itself appears in the DECLARE CURSOR statement.

```
EXEC SQL DECLARE C1 CURSOR FOR
   SELECT DEPTNO, DEPTNAME, MGRNO
   FROM DSN8C10.DEPT
   WHERE ADMRDEPT = 'A00'
   FOR READ ONLY WITH RS USE AND KEEP EXCLUSIVE LOCKS;
```

Example 3

Declare C2 as the cursor for a statement named STMT2.

```
EXEC SQL DECLARE C2 CURSOR FOR STMT2;
```

Example 4

Declare C3 as the cursor for a query to be used in positioned updates of the table DSN8C10.EMP. Allow the completed updates to be committed from time to time without closing the cursor.

```
EXEC SQL DECLARE C3 CURSOR WITH HOLD FOR
  SELECT * FROM DSN8C10.EMP
    FOR UPDATE OF WORKDEPT, PHONENO, JOB, EDLEVEL, SALARY;
```

Instead of specifying which columns should be updated, you could use a FOR UPDATE clause without the names of the columns to indicate that all updatable columns are updated.

Example 5

In stored procedure SP1, declare C4 as the cursor for a query of the table DSN8C10.PROJ. Enable the cursor to return a result set to the caller of SP1, which performs a commit on return.

```
EXEC SQL DECLARE C4 CURSOR WITH HOLD WITH RETURN FOR
   SELECT PROJNO, PROJNAME
   FROM DSN8C10.PROJ
   WHERE DEPTNO = 'A01';
```

Example 6

In the following example, the DECLARE CURSOR statement associates the cursor name C5 with the results of the SELECT and specifies that the cursor is scrollable. C5 allows positioned updates and deletes because the result table can be updated.

```
EXEC SQL DECLARE C5 SENSITIVE STATIC SCROLL CURSOR FOR
   SELECT DEPTNO, DEPTNAME, MGRNO
   FROM DSN8C10.DEPT
   WHERE ADMRDEPT = 'A00';
```

Example 7

In the following example, the DECLARE CURSOR statement associates the cursor name C6 with the results of the SELECT and specifies that the cursor is scrollable.

```
EXEC SQL DECLARE C6 INSENSITIVE SCROLL CURSOR FOR
   SELECT DEPTNO, DEPTNAME, MGRNO
   FROM DSN8C10.DEPT
   WHERE DEPTNO;
```

Example 8

The following example illustrates how an application program might use dynamic scrollable cursors: First create and populate a table.

```
CREATE TABLE ORDER
      (ORDERNUM  INTEGER,
       CUSTNUM   INTEGER,
       CUSTNAME  VARCHAR(20),
       ORDERDATE CHAR(8),
       ORDERAMT  DECIMAL(8,3),
       COMMENTS  VARCHAR(20));
```

Populate the table by inserting or loading about 500 rows.

```
EXEC SQL DECLARE CURSOR ORDERSCROLL
   SENSITIVE DYNAMIC SCROLL FOR
   SELECT ORDERNUM, CUSTNAME, ORDERAMT, ORDERDATE FROM ORDER
   WHERE ORDERAMT > 1000
   FOR UPDATE OF COMMENTS;
```

Open the scrollable cursor.

```
OPEN CURSOR ORDERSCROLL;
```

Fetch forward from the scrollable cursor.

```
-- Loop-to-fill-screen
      -- do 10 times
       FETCH FROM ORDERSCROLL INTO :HV1, :HV2, :HV3, :HV4;
      -- end
```

Fetch RELATIVE from the scrollable cursor.

```
-- Skip-forward-100-rows
      FETCH RELATIVE +100
       FROM ORDERSCROLL INTO :HV1, :HV2, :HV3, :HV4;
```

```
-- Skip-backward-50-rows
      FETCH RELATIVE -50
       FROM ORDERSCROLL INTO :HV1, :HV2, :HV3, :HV4;
```

Fetch ABSOLUTE from the scrollable cursor.

```
-- Re-read-the-third-row
      FETCH ABSOLUTE +3
       FROM ORDERSCROLL INTO :HV1, :HV2, :HV3, :HV4;
```

Fetch RELATIVE from scrollable cursor.

```
-- Read-the-third-row-from current position
      FETCH SENSITIVE RELATIVE +3
       FROM ORDERSCROLL INTO :HV1, :HV2, :HV3, :HV4;
```

Do a positioned update through the scrollable cursor.

```
-- Update-the-current-row
      UPDATE ORDER SET COMMENTS = "Expedite"
       WHERE CURRENT OF ORDERSCROLL;
```

Close the scrollable cursor.

```
CLOSE CURSOR ORDERSCROLL;
```

Example 9

Declare C1 as the cursor of a query to retrieve a rowset from the table DEPT. The prepared statement is MYCURSOR.

```
EXEC SQL DECLARE C1 CURSOR
   WITH ROWSET POSITIONING FOR MYCURSOR;
```

DECLARE GLOBAL TEMPORARY TABLE

The DECLARE GLOBAL TEMPORARY TABLE statement defines a declared temporary table for the current application process. The declared temporary table resides in the work file database and its description does not appear in the system catalog. It is not persistent and cannot be shared with other application processes. Each application process that defines a declared temporary table of the same name has its own unique description and instance of the temporary table. When the application process terminates, the temporary table is dropped.

Invocation for DECLARE GLOBAL TEMPORARY TABLE

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization for DECLARE GLOBAL TEMPORARY TABLE

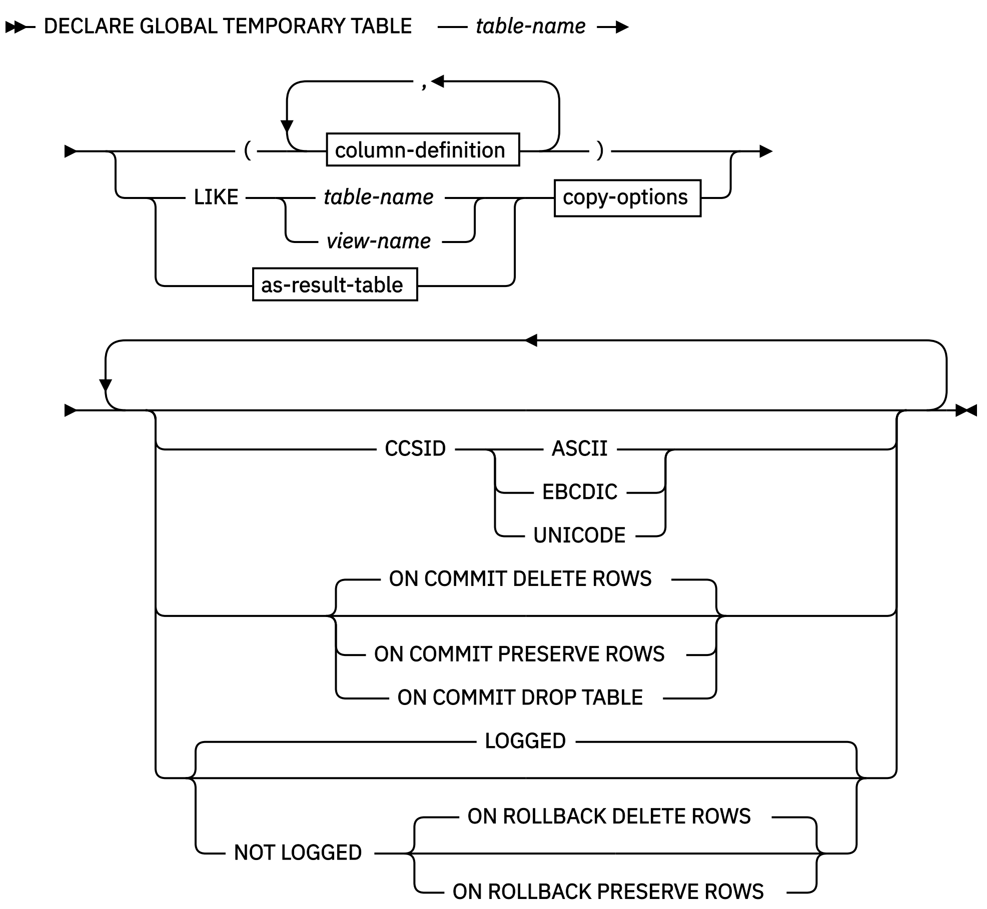
None are required, unless the LIKE clause or AS *fullselect* is specified. In those cases, additional privileges might be required.

PUBLIC implicitly has the following privileges without GRANT authority for declared temporary tables:

- The CREATETAB privilege to define a declared temporary table in the database that is defined AS WORKFILE, which is the database for declared temporary tables.
- The USE privilege to use the table spaces in the database that is defined as WORKFILE.
- All table privileges on the table and authority to drop the table. (Table privileges for a declared temporary table cannot be granted or revoked.)

These implicit privileges are not recorded in the Db2 catalog and cannot be revoked.

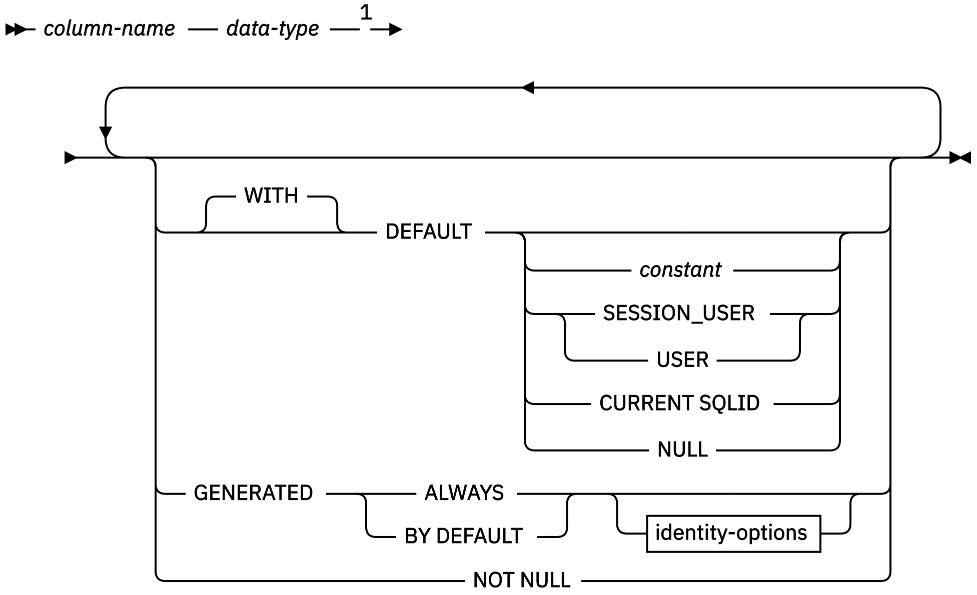
Syntax for DECLARE GLOBAL TEMPORARY TABLE



Notes:

[1] The same clause must not be specified more than one time.

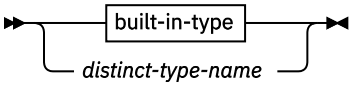
column-definition:



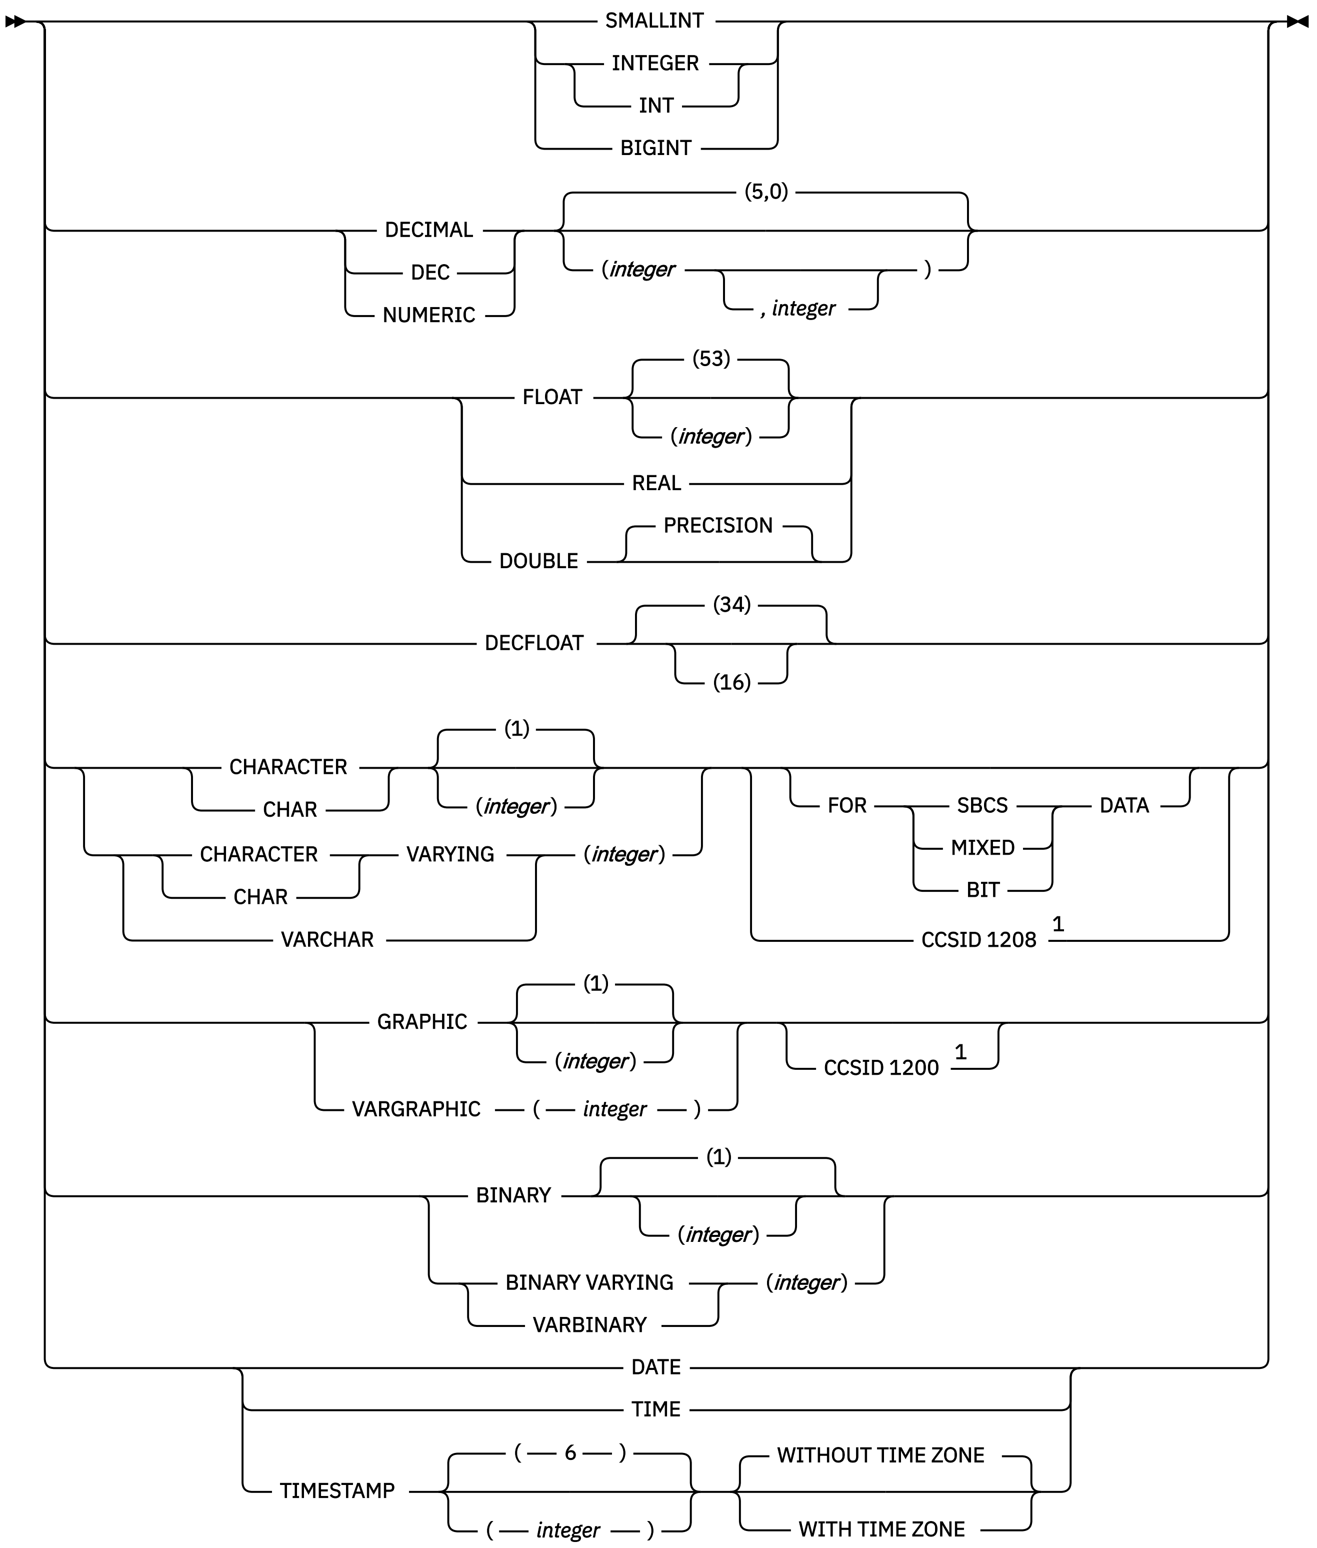
Notes:

[1] The same clause must not be specified more than once.

data-type:



built-in-type:

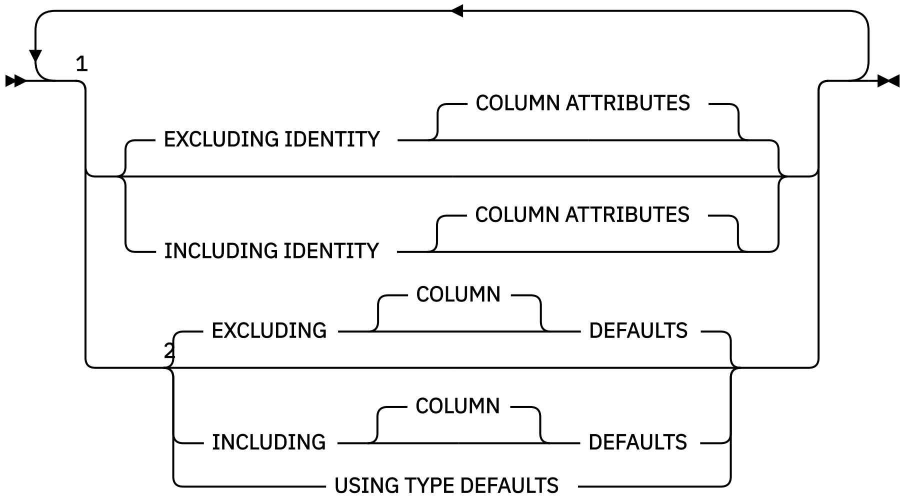


Notes:

[1] The CCSID clause must only be specified for a character string or a graphic string column in an EBCDIC created global temporary table.

as-result-table:

copy-options:

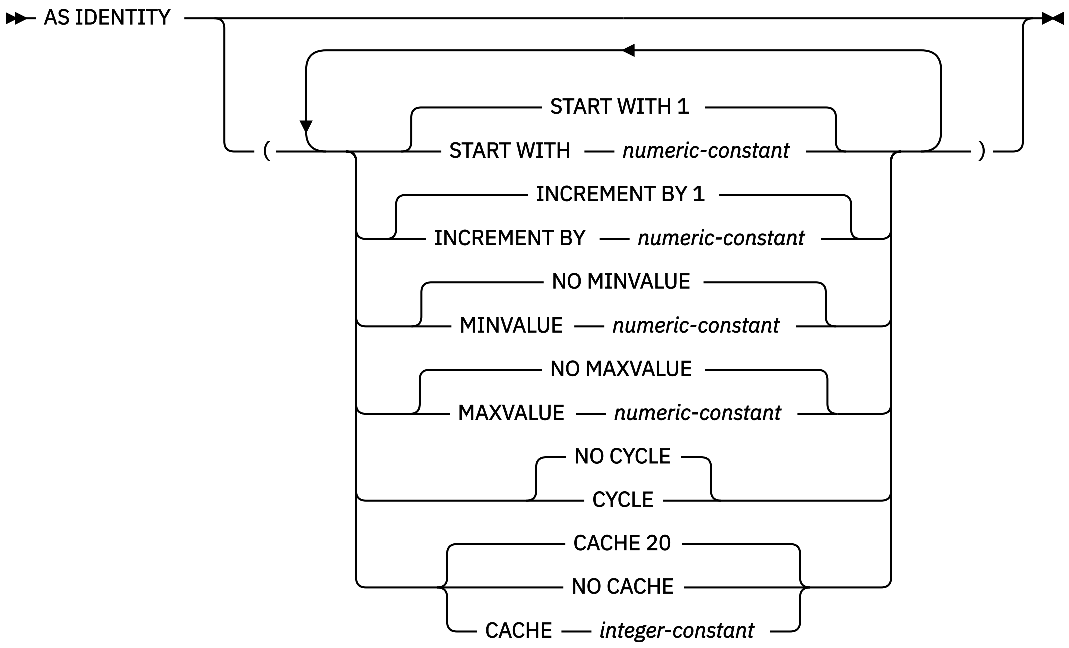


Notes:

[1] These clauses can be specified in any order and must not be specified more than one time.

[2] EXCLUDING COLUMN DEFAULTS, INCLUDING COLUMN DEFAULTS, and USING TYPE DEFAULTS must not be specified with the LIKE clause.

identity-options:



Notes:

[1] Separator commas can be specified between the attributes when an identity column is defined

Description for DECLARE GLOBAL TEMPORARY TABLE

table-name

Names the temporary table. The qualifier, if specified explicitly, must be SESSION. If the qualifier is not specified, it is implicitly defined to be SESSION.

If a table, view, synonym, or alias already exists with the same name and an implicit or explicit qualifier of SESSION:

- The declared temporary table is still defined with SESSION.*table-name*. An error is not issued because the resolution of a declared temporary table name does not include the persistent and shared names in the Db2 catalog tables.
- Any references to SESSION.*table-name* will resolve to the declared temporary table rather than to any existing SESSION.*table-name* whose definition is persistent and is in the Db2 catalog tables.

column-definition

Defines the attributes of a column for each instance of the table. The number of columns defined must not exceed 750. The maximum record size must not exceed 32683 bytes. The maximum row size must not exceed 32675 bytes (8 bytes less than the maximum record size).

column-name

Names the column. The name must not be qualified and must not be the same as the name of another column in the table.

data-type

Specifies the data type of the column. The data type can be any built-in data type that can be specified for the CREATE TABLE statement except for a LOB (BLOB, CLOB, and DBCLOB), ROWID, or XML type. The FOR *subtype* DATA clause can be specified as part of *data-type*. For more information on the data types and the rules that apply to them, see built-in-type.

DEFAULT

Specifies a default value for the column. This clause must not be specified more than once in the same *column-definition*.

Omission of NOT NULL and DEFAULT from a *column-definition* is an implicit specification of DEFAULT NULL.

If DEFAULT is specified without a value after it, the default value of the column depends on the data type of the column, as follows:

Data type
Default value

Numeric
0

Fixed-length character string
A string of blanks

Fixed-length graphic string
A string of blanks

Fixed-length binary string
Hexadecimal zeros

Varying-length string
A string of length 0

Date
CURRENT DATE

Time
CURRENT TIME

Timestamp
CURRENT TIMESTAMP(*p*) where *p* is the corresponding timestamp precision.

Timestamp with time zone
CURRENT TIMESTAMP(*p*) WITH TIME ZONE where *p* is the corresponding timestamp precision.

A default value other than the one that is listed above can be specified in one of the following forms:

constant

Specifies a constant as the default value for the column. The value of the constant must conform to the rules for assigning that value to the column. A hexadecimal graphic string constant (GX) cannot be specified.

SESSION_USER or USER

Specifies the value of the SESSION_USER (USER) special register at the time of an insert or update operation or LOAD as the default value for the column. The data type of the column must be a character string with a length attribute greater than or equal to the length attribute of the SESSION_USER special register.

CURRENT SQLID

Specifies the value of the SQL authorization ID of the process at the time of an SQL data change statement or LOAD as the default value for the column. The data type of the column must be a character string with a length attribute greater than or equal to the length attribute of the CURRENT SQLID special register.

NULL

Specifies null as the default value for the column. If NOT NULL was specified, DEFAULT NULL must not be specified within the same *column-definition*.

GENERATED

Specifies that Db2 generates values for the column. GENERATED must be specified if the column is to be considered an IDENTITY column. If DEFAULT is specified for the column for an update operation, Db2 generates a value for both GENERATED ALWAYS and GENERATED BY DEFAULT.

ALWAYS

Specifies that Db2 always generates a value for the column when a row is inserted into the table.

BY DEFAULT

Specifies that Db2 generates a value for the column when a row is inserted into the table unless a value is specified. BY DEFAULT is the recommended value only when you are using data propagation.

Defining a column as GENERATED BY DEFAULT does not necessarily guarantee the uniqueness of the values. To ensure uniqueness of the values, define a unique, single-column index on the column.

AS IDENTITY

Specifies that the column is an identity column for the table. A table can have only one identity column. AS IDENTITY can be specified only if the data type for the column is an exact numeric type with a scale of zero (SMALLINT, INTEGER, BIGINT, DECIMAL with a scale of zero).

An identity column is implicitly NOT NULL. An identity column cannot have a DEFAULT clause. For the descriptions of the identity attributes, see the description of the AS IDENTITY clause in "CREATE TABLE" on page 1645.

NOT NULL

Specifies that the column cannot contain nulls. Omission of NOT NULL indicates that the column can contain nulls.

LIKE *table-name* or *view-name*

Specifies that the columns of the table have the same name, data type, and nullability attributes as the columns of the identified table or view. If a table is identified, the column default attributes are also defined by that table. If row permissions or column access control is enforced for the table specified by *table-name*, row and column access controls are not inherited by the new table. The name specified must identify a table, view, synonym, or alias that exists at the current server. The identified table must not be an auxiliary table or an accelerator-only table.

The privilege set must include the SELECT privilege on the identified table or view.

This clause is similar to the LIKE clause on CREATE TABLE, but it has the following differences:

- If LIKE results in a column having a LOB data type, a ROWID data type, or distinct type, the DECLARE GLOBAL TEMPORARY TABLE statement fails.
- In addition to these data type restrictions, if any column has any other attribute value that is not allowed in a declared temporary table, that attribute value is ignored. The corresponding column in the new temporary table has the default value for that attribute unless otherwise indicated.

When the identified object is a table, the column name, data type, nullability, and default attributes are determined from the columns of the specified table; any identity column attributes are inherited only if the INCLUDING IDENTITY COLUMN ATTRIBUTES clause is specified.

as-result-table

Specifies that the table definition is based on the column definitions from the result of a query expression.

The behavior of these column attributes is controlled with the INCLUDING or USING TYPE DEFAULTS clauses, which are defined below.

AS *(fullselect)*

Specifies an implicit definition of *n* columns for the declared global temporary table, where *n* is the number of columns that would result from the *fullselect*. The columns of the new table are defined by the columns that result from the *fullselect*. Every select list element must have a unique name. The AS clause can be used in the *select-clause* to provide unique names. The implicit definition includes the column name, data type, and nullability characteristic of each of the result columns of *fullselect*. A column of the new table that corresponds to an implicitly hidden column of a base table referenced in the *fullselect* is not considered hidden in the new table.Row and column access controls that are enforced on the base table are not inherited by the new table.

The result table of the *fullselect* must not contain a column that has a LOB data type, a ROWID data type, an XML data type or a distinct type.

If *fullselect* results in other column attributes that are not applicable for a declared temporary table, those attributes are ignored in the implicit definition for the declared temporary table.

If *fullselect* results in a row change timestamp column, the corresponding column of the new table inherits only the data type of the row change timestamp column. The new column is not considered as a generated column.

The *fullselect* must not refer to variables or include parameter markers (question marks), but can refer to global variables. The outermost SELECT list of the outermost *fullselect* must not reference data that is encoded with different encoding schemes, unless that data is from EBCDIC and Unicode columns in an EBCDIC table. The outermost SELECT list of the outermost *fullselect* must not result in a column that is an array.

WITH NO DATA

Specifies that the *fullselect* is not executed. You can use the INSERT INTO statement with the same *fullselect* specified in the AS clause to populate the declared temporary table with the set of rows from the result table of the *fullselect*.

copy-options

Specifies whether identity column attributes and column defaults are inherited from the definition of the source of the result table.

`EXCLUDING IDENTITY COLUMN ATTRIBUTES` or `INCLUDING IDENTITY COLUMN ATTRIBUTES`

Specifies whether identity column attributes are inherited from the columns resulting from the *fullselect*, *table-name*, or *view-name*.

EXCLUDING IDENTITY COLUMN ATTRIBUTES

Specifies that the table does not inherit the identity attributes of the columns resulting from the *fullselect*, *table-name*, or *view-name*.

INCLUDING IDENTITY COLUMN ATTRIBUTES

Specifies that the table inherits the identity attributes, if any, of the columns resulting from the *fullselect* or *table-name*. In general, the identity attributes are copied if the element of the corresponding column in the table or *fullselect* is the name of a table column that directly or indirectly maps to the name of a base table column that is an identity column.

If the INCLUDING IDENTITY COLUMN ATTRIBUTES clause is specified with the AS fullselect clause, the columns of the new table do not inherit the identity attribute in the following cases:

- The select list of the *fullselect* includes multiple instances of an identity column name (that is, selecting the same column more than once).
- The select list of the *fullselect* includes multiple identity columns (that is, it involves a join).
- The identity column is included in an expression in the select list.
- The *fullselect* includes a set operation.

If INCLUDING IDENTITY COLUMN ATTRIBUTES is not specified, the new table will not have an identity column.

If the LIKE clause identifies a view, INCLUDING IDENTITY COLUMN ATTRIBUTES must not be specified.

EXCLUDING COLUMN DEFAULTS, INCLUDING COLUMN DEFAULTS, or USING TYPE DEFAULTS

Specifies whether the table inherits the default values of the columns of the fullselect. EXCLUDING COLUMN DEFAULTS, INCLUDING COLUMN DEFAULTS, and USING TYPE DEFAULTS must not be specified if the LIKE clause is specified.

EXCLUDING COLUMN DEFAULTS

Specifies that the table does not inherit the default values of the columns of the fullselect. The default values of the column of the new table are either null or there are no default values. If the column can be null, the default is the null value. If the column cannot be null, there is no default value, and an error occurs if a value is not provided for a column on an insert operation for the new table.

INCLUDING COLUMN DEFAULTS

Specifies that the table inherits the default values of the columns of the fullselect. A default value is the value that is assigned to the column when a value is not specified on an insert operation or LOAD. Columns resulting from the fullselect that are not updatable will not have a default defined in the corresponding column of the created table.

USING TYPE DEFAULTS

Specifies that the default values for the declared temporary table depend on the data type of the columns that result from *fullselect*, as follows:

Data type
Default value

Numeric
0

Fixed-length character string
Blanks

Fixed-length graphic string
Blanks

Fixed-length binary string
Hexadecimal zeros

Varying-length string
A string of length 0

Date
CURRENT DATE

Time
CURRENT TIME

Timestamp
CURRENT TIMESTAMP(*p*) where *p* is the corresponding timestamp precision.

Timestamp(*integer*) with time zone
CURRENT TIMESTAMP(*p*) WITH TIME ZONE where *p* is the corresponding timestamp precision.

CCSID *encoding-scheme*
Specifies the encoding scheme for string data that is stored in the table. For declared temporary tables, the encoding scheme for the data cannot be specified for the table space or database, and all data in one table space or the database need not use the same encoding scheme. Because there can be only one work file database for all declared temporary tables for each Db2 member, there can be a mixture of encoding schemes in both the database and each table space.

The CCSID clause can be specified for the declared temporary table, or for individual columns in the declared temporary table. If a CCSID clause is specified for the table, that CCSID specifies the encoding scheme for the table, regardless of whether the LIKE clause is also specified. If a CCSID clause is not specified for the table, the encoding scheme for the table is EBCDIC.

If a CCSID clause is specified for a column, the encoding scheme for the declared temporary table must be EBCDIC. If a CCSID clause is not specified for a column, and the LIKE clause is not specified for the table, the CCSID of the column is the same as the CCSID of the table. If the LIKE clause is specified, and the source table that is specified in the LIKE clause is an EBCDIC table with Unicode columns, the columns in the declared temporary table that correspond to the Unicode columns in the source table are also Unicode.

ASCII
Specifies that the data is encoded by using the ASCII CCSIDs of the server.

EBCDIC
Specifies that the data is encoded by using the EBCDIC CCSIDs of the server.

UNICODE
Specifies that the data is encoded by using the UNICODE CCSIDs of the server.

An error occurs if the CCSIDs for the encoding scheme have not been defined. Usually, each encoding scheme requires only a single CCSID. Additional CCSIDs are needed when mixed, graphic, or UNICODE data is used.

ON COMMIT
Specifies what happens to the table for a commit operation. The default is ON COMMIT DELETE ROWS.

DELETE ROWS
Specifies that all of the rows of the table are deleted if there is no open cursor that is defined as WITH HOLD that references the table.

PRESERVE ROWS
Specifies that all of the rows of the table are preserved. Thread reuse capability is not available to any application process or thread that contains, at its most recent commit, an active declared temporary table that was defined with the ON COMMIT PRESERVE ROWS clause.

DROP TABLE
Specifies that the table is implicitly dropped at commit if there is no open cursor that is defined as WITH HOLD that references the table. If there is an open cursor defined as WITH HOLD on the table at commit, the rows are preserved.

LOGGED or NOT LOGGED
Specifies whether operations for the table are to be logged. This option also applies to any indexes that are associated with the table. Indexes inherit the logging attribute from their associated tables.

LOGGED
Specifies that insert, update, or delete operations for the declared temporary table are logged. Create and drop actions for the table are also logged. This is the default option.

NOT LOGGED
Specifies that insert, update, or delete operations for the declared temporary table are not logged. However, create and drop actions for the table are logged.

ON ROLLBACK DELETE ROWS
Specifies that when a ROLLBACK or ROLLBACK TO SAVEPOINT statement is issued, all rows of the global temporary table are deleted. This is the default.

ON ROLLBACK PRESERVE ROWS
Specifies that when a ROLLBACK or ROLLBACK TO SAVEPOINT statement is issued, all rows of the global temporary table are preserved.

If a ROLLBACK or ROLLBACK TO SAVEPOINT statement is issued, the following actions occur for tables that were created or dropped:

- If the table was created within the unit of work or savepoint, the table is dropped.
- If the table was dropped within the unit of work or savepoint, the table is re-created without any data.

For statements that insert multiple rows, the ATOMIC and NOT ATOMIC CONTINUE ON SQLEXCEPTION options of the INSERT statement determine the result of an error. If ATOMIC is specified, an error during insertion causes all rows in the global temporary table to be deleted. If NOT ATOMIC CONTINUE ON SQLEXCEPTION is specified, an error during insertion causes all rows in the table to be deleted, but the next insert is processed. At the end of the insert, the table includes only the rows that were inserted after the last error.

Restriction: In CREATE TABLESPACE and ALTER TABLESPACE statements, LOG YES and LOG NO can be used as syntax alternatives for LOGGED and NOT LOGGED, respectively. These syntax alternatives cannot be used in a DECLARE GLOBAL TEMPORARY TABLE statement.

Notes for DECLARE GLOBAL TEMPORARY TABLE

Instantiation, scope, and termination

For the following explanations, P denotes an application process, and T is a declared temporary table executed in P:

- An empty instance of T is created when a DECLARE GLOBAL TEMPORARY TABLE statement is executed in P.
- Any SQL statement in P can reference T, and any of those references to T in P is a reference to that same instance of T. ()

  If a DECLARE GLOBAL TEMPORARY statement is specified within an SQL PL compound statement, the scope of the declared temporary table is the application process and not just the compound statement. A declared temporary table cannot be defined multiple times by the same name in other compound statements in that application process, unless the table has been dropped explicitly.
- If T was declared at a remote server, the reference to T must use the same Db2 connection that was used to declare T and that connection must not have been terminated after T was declared. When the connection to the database server at which T was declared terminates, T is dropped.
- If T was defined with the ON COMMIT DELETE ROWS clause specified implicitly or explicitly, when a commit operation terminates a unit of work in P and there is no open WITH HOLD cursor in P that is dependent on T, the commit deletes all rows from T.
- If T is defined with the ON COMMIT DROP TABLE clause, when a commit operation terminates a unit of work in P and no program in P has a WITH HOLD cursor open that is dependent on T, the commit includes the operation DROP TABLE T.
- When a rollback operation terminates a unit of work or savepoint in P, and that unit of work or savepoint includes the declaration of SESSION.T, the changes to table T are undone.

  When a rollback operation terminates a unit of work or savepoint in P, and that unit of work or savepoint includes the declaration of SESSION.T, the rollback drops table T.

  When a rollback operation terminates a unit of work or savepoint in P, and that unit of work or savepoint includes the drop of the declaration of declared temporary table SESSION.T, the rollback undoes the drop of table T.

- When the application process that declared T terminates, T is dropped.
- When a rollback operation terminates a unit of work or a savepoint in P, and that unit of work or savepoint includes a modification to SESSION.T the following actions occur:
  - If NOT LOGGED was specified, all rows from SESSION.T are deleted unless ON ROLLBACK PRESERVE ROWS was also specified.
  - If NOT LOGGED was not specified, the changes to table T are undone.
- If NOT LOGGED was specified and an INSERT, UPDATE or DELETE statement fails during execution (not a compilation error), all rows from SESSION.T are deleted.
- When a rollback operation terminates a unit of work or a savepoint in P, and that unit of work or savepoint includes the declaration of SESSION.T, the rollback includes the operation DROP SESSION.T.
- When a rollback operation terminates a unit of work or a savepoint in P, and that unit of work or savepoint includes the drop of a declared temporary table SESSION.T, the rollback undoes the drop of the table. If NOT LOGGED was specified, the table is also emptied.
- When the application process that declared T terminates or disconnects from the database, T is dropped and its instantiated rows are destroyed.

Privileges

When a declared temporary table is defined, PUBLIC is implicitly granted all table privileges on the table and authority to drop the table. These implicit privileges are not recorded in the Db2 catalog and cannot be revoked. This enables any SQL statement in the application process to reference a declared temporary table that has already been defined in that application process.

Referring to a declared temporary table in other SQL statements

Many SQL statements support declared temporary tables. To refer to a declared temporary table in an SQL statement other than DECLARE GLOBAL TEMPORARY TABLE, you must qualify the table name with SESSION. You can either specify SESSION explicitly in the table name or use the QUALIFIER bind option to specify SESSION as the qualifier for all SQL statements in the plan or package.

If you use SESSION as the qualifier for a table name but the application process does not include a DECLARE GLOBAL TEMPORARY TABLE statement for the table name, Db2 assumes that you are not referring to a declared temporary table. Db2 resolves such table references to a table whose definition is persistent and appears in the Db2 catalog tables.

With the exception of the DECLARE GLOBAL TEMPORARY TABLE statement, any static SQL statement that references a declared temporary table is incrementally bound at run time. This is because the definition of the declared temporary table does not exist until the DECLARE GLOBAL TEMPORARY statement is executed in the application process that contains those SQL statements and the definition does not persist when the application process finishes running.

When a plan or package is bound, any static SQL statement (other than the DECLARE GLOBAL TEMPORARY TABLE statement) that references a *table-name* that is qualified by SESSION, regardless of whether the reference is for a declared temporary table, is not completely bound. However, the bind of the plan or package succeeds if there are no other errors. No object dependencies, including non-DECLARE GLOBAL TEMPORARY TABLE objects, are recorded in the Db2 catalog for any such statements. These static SQL statements are then incrementally bound at run time when the static SQL statement is issued.

The incremental binds are necessary for the following reasons:

- The definition of the declared temporary table does not exist until the DECLARE GLOBAL TEMPORARY TABLE statement for the table is executed in the same application process that contains those SQL statements. Therefore, Db2 must wait until the plan or package is run to determine if SESSION.*table-name* refers to a base table or a declared temporary table.
- The definition of a declared temporary table does not persist after the table it is explicitly dropped (DROP statement), implicitly dropped (ON COMMIT DROP TABLE), or the application process that defined it finishes running. When the application process terminates or is re-used as a reusable

application thread, the instantiated rows of the table are deleted and the definition of the declared temporary table is dropped if it has not already been explicitly or implicitly dropped.

After the plan or package is bound, any static SQL statement that refers to a *table-name* that is qualified by SESSION has a new statement status of M in the Db2 catalog table (STATUS column of SYSIBM.SYSSTMT or SYSIBM.SYSPACKSTMT).

Thread reuse

If a declared temporary table is defined in an application process that is running as a local thread, the application process or local thread that declared the table qualifies for explicit thread reuse if:

- The table was defined with both the default ON COMMIT DELETE ROWS attribute and the NOT LOGGED ON ROLLBACK DELETE ROWS attribute.
- The table was defined with PRESERVE ROWS specified on either the ON COMMIT or NOT LOGGED ON ROLLBACK option and the table was explicitly dropped with the DROP TABLE statement before the thread's commit operation.
- The table was defined with the ON COMMIT DROP TABLE attribute. When a declared temporary table is defined with the ON COMMIT DROP TABLE and a commit occurs, the table is implicitly dropped if there are no open cursors defined with the WITH HOLD option.

When the thread is reused, the declared temporary table is dropped and its rows are destroyed. However, if you do not explicitly or implicitly drop all declared temporary tables before or when your thread performs a commit and the thread becomes idle waiting to be reused, as with all thread reuse situations, the idle thread holds resources and locks. This includes some declared temporary table resources and locks on the table spaces and the database descriptor (DBD) for the work file database. So, instead of using the implicit drop feature of thread reuse to drop your declared temporary tables, it is recommended that you:

- Use the DROP TABLE statement to explicitly drop your declared temporary tables before the thread performs a commit and becomes idle.
- Define the declared temporary tables with ON COMMIT DROP TABLE clause so that the tables are implicitly dropped when a commit occurs.

Explicitly dropping the tables before a commit occurs or having them implicitly dropped when the commit occurs enables you to maximize the use of declared temporary table resources and release locks when multiple threads are using declared temporary table.

Remote threads qualify for thread reuse differently than local threads. If a declared temporary table is defined (with or without ON COMMIT DELETE ROWS) in an application process that is running as a remote or DDF thread (also known as Database Access Thread or DBAT), the remote thread qualifies for thread reuse only when the declared temporary table is explicitly dropped before the thread performs a commit operation. Dropping the declared temporary table enables the remote thread to qualify for the implicit thread reuse that is supported for DDF threads via connection pooling and to become an inactive DBAT (type 1 inactive thread) or an inactive connection (type 2 inactive thread).

Parallelism support

Only I/O and CP parallelism are supported. Any query that involves a declared temporary table is limited to parallel tasks on a single CPC.

Restrictions on the use of declared temporary tables

Declared temporary tables cannot:

- Be specified in referential constraints.
- Be referenced in any SQL statements that are defined in an SQL function body (CREATE FUNCTION or ALTER FUNCTION statements), a trigger body (CREATE TRIGGER statement). If you refer a table name that is qualified with SESSION in a trigger body, Db2 assumes that you are referring to a base table.
- Be referenced in a CREATE INDEX statement unless the schema name of the index is SESSION.

In addition, do not refer to a declared temporary table in any of the following statements.

Statement

ALTER INDEX
ALTER TABLE
COMMENT
CREATE ALIAS
CREATE FUNCTION (TABLE LIKE clause)
CREATE MASK (ON *table-name* clause)
CREATE PERMISSION (ON *table-name* clause)
CREATE PROCEDURE (TABLE LIKE clause)

Statement

CREATE TRIGGER
CREATE VIEW
GRANT (table or view privileges)
LABEL
LOCK TABLE
REFRESH TABLE
RENAME
REVOKE (table or view privileges)

Declared global temporary tables and dynamic statement caching

The Db2 dynamic statement cache feature does not support dynamic SQL statements that reference declared temporary tables, even if the SQL statement also includes references to base or persistent tables. Db2 will not insert such statements into the dynamic statement cache. Instead, these dynamic statements are processed as if statement caching is not in effect. Declared temporary tables are unique and specific to an application process or Db2 thread, cannot be shared across threads, are not described in the Db2 catalog, and do not persist beyond termination of the Db2 thread or application process. These attributes prevent the use of the dynamic statement cache feature where tables and SQL statements are shared across threads or application processes.

Table space requirements in the work file database

Db2 stores all declared temporary tables in the work file database. You cannot define a declared temporary table unless a table space with at least an 32KB page size exists in the work file database.

Alternative syntax and synonyms

To provide compatibility with previous releases, Db2 allows you to specify:

- LONG VARCHAR as a synonym for VARCHAR(*integer*) and LONG VARGRAPHIC as a synonym for VARGRAPHIC(*integer*) when defining the data type of a column.

  However, the use of these synonyms is not encouraged because after the statement is processed, Db2 considers a LONG VARCHAR column to be VARCHAR and a LONG VARGRAPHIC column to be VARGRAPHIC.
- DEFINITION ONLY as a synonym for WITH NO DATA.
- TIMEZONE can be specified as an alternative to TIME ZONE.

Examples for DECLARE GLOBAL TEMPORARY TABLE

Example 1

Define a declared temporary table with column definitions for an employee number, salary, commission, and bonus.

```
DECLARE GLOBAL TEMPORARY TABLE SESSION.TEMP_EMP
   (EMPNO     CHAR(6)   NOT NULL,
    SALARY    DECIMAL(9, 2),
    BONUS     DECIMAL(9, 2),
    COMM      DECIMAL(9, 2))
    CCSID EBCDIC
    ON COMMIT PRESERVE ROWS;
```

Example 2

Assume that base table USER1.EMPTAB exists and that it contains three columns, one of which is an identity column. Declare a temporary table that has the same column names and attributes (including identity attributes) as the base table.

```
DECLARE GLOBAL TEMPORARY TABLE TEMPTAB1
   LIKE USER1.EMPTAB
```

```
       INCLUDING IDENTITY
       ON COMMIT PRESERVE ROWS;
```

In the above example, Db2 uses SESSION as the implicit qualifier for TEMPTAB1.

DECLARE STATEMENT

The DECLARE STATEMENT statement is used for application program documentation. It declares names that are used to identify prepared SQL statements.

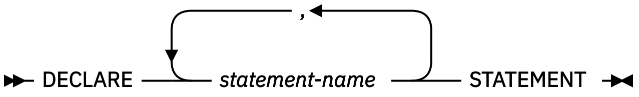
Invocation for DECLARE STATEMENT

This statement can only be embedded in an application program. It is not an executable statement.

Authorization for DECLARE STATEMENT

None required.

Syntax for DECLARE STATEMENT



Description for DECLARE STATEMENT

***statement-name* STATEMENT**
Lists one or more names that are used in your application program to identify prepared SQL statements.

Example for DECLARE STATEMENT

This example shows the use of the DECLARE STATEMENT statement in a PL/I program.

```
EXEC SQL DECLARE OBJECT_STATEMENT STATEMENT;

EXEC SQL INCLUDE SQLDA;
EXEC SQL DECLARE C1 CURSOR FOR OBJECT_STATEMENT;

( SOURCE_STATEMENT IS "SELECT DEPTNO, DEPTNAME,
  MGRNO FROM DSN8C10.DEPT WHERE ADMRDEPT = 'A00'"  )

EXEC SQL PREPARE OBJECT_STATEMENT FROM SOURCE_STATEMENT;
EXEC SQL DESCRIBE OBJECT_STATEMENT INTO SQLDA;

/* Examine SQLDA */

EXEC SQL OPEN C1;

DO WHILE (SQLCODE = 0);
  EXEC SQL FETCH C1 USING DESCRIPTOR SQLDA;

/* Print results */

END;

EXEC SQL CLOSE C1;
```

DECLARE TABLE

The DECLARE TABLE statement is used for application program documentation. It also provides the precompiler with information used to check your embedded SQL statements. (The DCLGEN subcommand can be used to generate declarations for tables and views described in any accessible Db2 catalog.

For more information about DCLGEN, see Declaring table and view definitions (Db2 Application programming and SQL) and DCLGEN (DECLARATIONS GENERATOR) (DSN) (Db2 Commands).)

Invocation for DECLARE TABLE

This statement can only be embedded in an application program. It is not an executable statement.

Authorization for DECLARE TABLE

None required.

Description for DECLARE TABLE

table-name **or** ***view-name***

Specifies the name of the table or view to document. If the table is defined in your application program, the description of the table in the SQL statement in which it is defined (for example, CREATE TABLE or DECLARE GLOBAL TEMPORARY TABLE statement) and the DECLARE TABLE statement must be identical.

column-name

Specifies the name of a column of the table or view.

The precompiler uses these names to check for consistency of names within your SQL statements. It also uses the data type to check for consistency of names and data types within your SQL statements.

built-in-type

Specifies the built-in data type of the column. Use one of the built-in data types.

SMALLINT

For a small integer.

INTEGER or INT

For a large integer.

BIGINT

For a big integer.

DECIMAL(*integer,integer*) or DEC(*integer,integer*)
DECIMAL(*integer*) or DEC(*integer*)
DECIMAL or DEC

For a decimal number. The first integer is the precision of the number. That is, the total number of digits, which can range from 1 to 31. The second integer is the scale of the number. That is, the number of digits to the right of the decimal point, which can range from 0 to the precision of the number.

You can use DECIMAL(*p*) for DECIMAL(*p*,0) and DECIMAL for DECIMAL(5,0).

You can also use the word NUMERIC instead of DECIMAL. For example, NUMERIC(8) is equivalent to DECIMAL(8). Unlike DECIMAL, NUMERIC has no allowable abbreviation.

FLOAT(*integer*)
FLOAT

For a floating-point number. If *integer* is between 1 and 21 inclusive, the format is single precision floating-point. If the integer is between 22 and 53 inclusive, the format is double precision floating-point.

You can use DOUBLE PRECISION or FLOAT for FLOAT(53).

REAL

For single precision floating-point.

DOUBLE or DOUBLE PRECISION

For double precision floating-point

DECFLOAT(*integer*)

For a decimal floating-point number. The value of *integer* must be either 16 or 34 and represents the number of significant digits that can be stored. If *integer* is omitted, the DECFLOAT column will be capable of representing 34 significant digits.

CHARACTER(*integer*) or CHAR(*integer*)
CHARACTER or CHAR

For a fixed-length character string of length *integer*, which can range 1–255. If the length specification is omitted, a length of 1 character is assumed.

CCSID 1208

Specifies that the column is a Unicode column encoded in UTF-8. This clause must not be specified for an ASCII or Unicode table.

VARCHAR(*integer*), CHAR VARYING(*integer*), or CHARACTER VARYING(*integer*)

For a varying-length character string of maximum length *integer*, which can range from 1 to the maximum record size minus 10 bytes. See Table 208 on page 1702 to determine the maximum record size.

CCSID 1208

Specifies that the column is a Unicode column encoded in UTF-8. This clause must not be specified for an ASCII or Unicode table.

CLOB(*integer* [K|M|G]), CHAR LARGE OBJECT(*integer* [K|M|G]), or CHARACTER LARGE OBJECT(*integer* [K|M|G])
CLOB, CHAR LARGE OBJECT, or CHARACTER LARGE OBJECT

For a character large object (CLOB) string of the specified maximum length in bytes. The maximum length must be in the range 1–2147483647. A CLOB column has a varying-length. It cannot be referenced in certain contexts regardless of its maximum length. For more information, see "Restrictions using LOBs" on page 117.

When *integer* is not specified, the default length is 1M. The maximum value that can be specified for *integer* depends on whether a units indicator is also specified as shown in the following list.

integer

The maximum value for *integer* is 2147483647. The maximum length of the string is *integer*.

***integer* K**

The maximum value for *integer* is 2097152. The maximum length is 1024 times *integer*.

***integer* M**

The maximum value for *integer* is 2048. The maximum length is 1,048,576 times *integer*.

***integer* G**

The maximum value for *integer* is 2. The maximum length is 1,073,741,824 times *integer*.

integer can be separated from K, M, or G by 0 or more spaces.

If you specify a value that evaluates to 2 gigabytes (2,147,483,648), Db2 uses a value that is one byte less, or 2147483647.

CCSID 1208

Specifies that the column is a Unicode column encoded in UTF-8. This clause must not be specified for an ASCII or Unicode table.

GRAPHIC(*integer*)
GRAPHIC

For a fixed-length graphic string of length *integer*, which can range 1–127. If the length specification is omitted, a length of 1 character is assumed.

CCSID 1200

Specifies that the column is a Unicode column encoded in UTF-16. This clause must not be specified for an ASCII or Unicode table.

VARGRAPHIC(*integer*)

For a varying-length graphic string of maximum length *integer*, which must range from 1 to *n*/2, where *n* is the maximum row size minus 2 bytes.

CCSID 1200

Specifies that the column is a Unicode column encoded in UTF-16. This clause must not be specified for an ASCII or Unicode table.

DBCLOB(*integer* [K|M|G])
DBCLOB

For a double-byte character large object (DBCLOB) string of the specified maximum length in double-byte characters. The maximum length must be in the range of 1–1,073,741,823. A DBCLOB column has a varying-length. It cannot be referenced in certain contexts regardless of its maximum length. For more information, see "Restrictions using LOBs" on page 117.

When *integer* is not specified, the default length is 1M. The meaning of *integer* K|M|G is similar to CLOB. The difference is that the number specified is the number of double-byte characters.

integer can be separated from K, M, or G by 0 or more spaces.

CCSID 1200
Specifies that the column is a Unicode column encoded in UTF-16. This clause must not be specified for an ASCII or Unicode table.

BINARY(*integer*)
A fixed-length binary string of length *integer*. The *integer* can range 1–255. If the length specification is omitted, a length of 1 byte is assumed.

BINARY VARYING(*integer*) or VARBINARY(*integer*)
A varying-length binary string of maximum length *integer*, which can range 1–32704. The length is limited by the page size of the table space.

BLOB (*integer* [K|M|G] or BINARY LARGE OBJECT(*integer* [K|M|G])
BLOB or BINARY LARGE OBJECT
For a binary large object (BLOB) string of the specified maximum length in bytes. The maximum length must be in the range of 1–2147483647. A BLOB column has a varying-length. It cannot be referenced in certain contexts regardless of its maximum length. For more information, see "Restrictions using LOBs" on page 117.

When *integer* is not specified, the default length is 1M. The meaning of *integer* K|M|G is the same as for CLOB.

integer can be separated from K, M, or G by 0 or more spaces.

DATE
For a date.

TIME
For a time.

TIMESTAMP(*integer*) WITHOUT TIME ZONE
For a timestamp. *integer* specifies the optional timestamp precision attribute and must be in the range 0–12. The timestamp precision denotes the number of fractional second digits that are included in the timestamp. The default is 6.

TIMESTAMP(*integer*) WITH TIME ZONE
For a timestamp with time zone. *integer* specifies the optional timestamp precision attribute and must be in the range 0–12. The timestamp precision denotes the number of fractional second digits that are included in the timestamp. The default is 6.

ROWID
For a row ID type.

A table can contain at most two ROWID columns. If it contains two, one column is implicitly generated by Db2 and the other column is explicitly defined as a ROWID without the IMPLICITLY HIDDEN attribute. The values in a ROWID column are unique for every row in the table and cannot be updated. You must specify NOT NULL with ROWID.

XML
For an XML document. Only well-formed XML documents can be inserted into an XML column.

If the XML column is the first XML column that you create for the table, a BIGINT DOCID column is implicitly created and is used to store a unique document identifier for the XML columns of a row.

distinct-type-name
Specifies the distinct type (user-defined data type) of the column. An implicit or explicit schema name qualifies the name.

NOT NULL
Specifies that the column does not allow null values and does not provide a default value.

NOT NULL WITH DEFAULT
Specifies that the column does not allow null values but provides a default value.

Notes for DECLARE TABLE

Error handling during processing: If an error occurs during the processing of the DECLARE TABLE statement, a warning message is issued, and the precompiler continues processing your source program.

Documenting a distinct type column: Although you can specify the name of a distinct type as the data type of a column in the DECLARE TABLE statement, use the built-in data type on which the distinct type is based instead. Using the base type enables the precompiler to check the embedded SQL statements for errors; otherwise, error checking is deferred until bind time.

To determine the source data type of the distinct type, check the value of column SOURCETYPE in catalog table SYSDATATYPES.

Examples for DECLARE TABLE

Example 1: Issue a DECLARE TABLE statement for the sample employee table, DSN8C10.EMP.

```
EXEC SQL DECLARE DSN8C10.EMP TABLE
     (EMPNO     CHAR(6)     NOT NULL,
      FIRSTNME  VARCHAR(12) NOT NULL,
      MIDINIT   CHAR(1)     NOT NULL,
      LASTNAME  VARCHAR(15) NOT NULL,
      WORKDEPT  CHAR(3)             ,
      PHONENO   CHAR(4)             ,
      HIREDATE  DATE                ,
      JOB       CHAR(8)             ,
      EDLEVEL   SMALLINT            ,
      SEX       CHAR(1)             ,
      BIRTHDATE DATE                ,
      SALARY    DECIMAL(9,2)        ,
      BONUS     DECIMAL(9,2)        ,
      COMM      DECIMAL(9,2)        );
```

Example 2: Issue a DECLARE TABLE statement for a table that includes a column with a distinct type.

Assume that table CANADIAN_SALES keeps information for your company's sales in Canada. The table includes one column, TOTAL, that is defined as a distinct type. The distinct type CANADIAN_DOLLAR was created with the following definition:

```
CREATE TYPE CANADIAN_DOLLAR AS DECIMAL(9,2);
```

The CANADIAN_SALES table was created with the following definition, which uses the distinct type CANADIAN_DOLLAR as the data type for the TOTAL column.

```
CREATE TABLE CANADIAN_SALES
     (PRODUCT_ITEM   INTEGER,
      MONTH          INTEGER,
      YEAR           INTEGER,
      TOTAL          CANADIAN_DOLLAR); -- TOTAL column data type is a distinct type
```

A DECLARE TABLE statement must include only built-in data types. Therefore, in the DECLARE TABLE statement for the CANADIAN_SALES table, you need to use the source data type for the CANADIAN_DOLLAR distinct type, which is DECIMAL(9,2).

```
DECLARE TABLE CANADIAN_SALES
     (PRODUCT_ITEM   INTEGER,
      MONTH          INTEGER,
      YEAR           INTEGER,
      TOTAL          DECIMAL(9,2)); -- Define the column using the source built-in data type
```

DECLARE VARIABLE

The DECLARE VARIABLE statement defines a CCSID for a host variable and the subtype of the variable. When it appears in an application program, the DECLARE VARIABLE statement causes the

Db2 precompiler to tag a host variable with a specific CCSID. When the host variable appears in an SQL statement, the Db2 precompiler places this CCSID into the structures that it generates for the SQL statement.

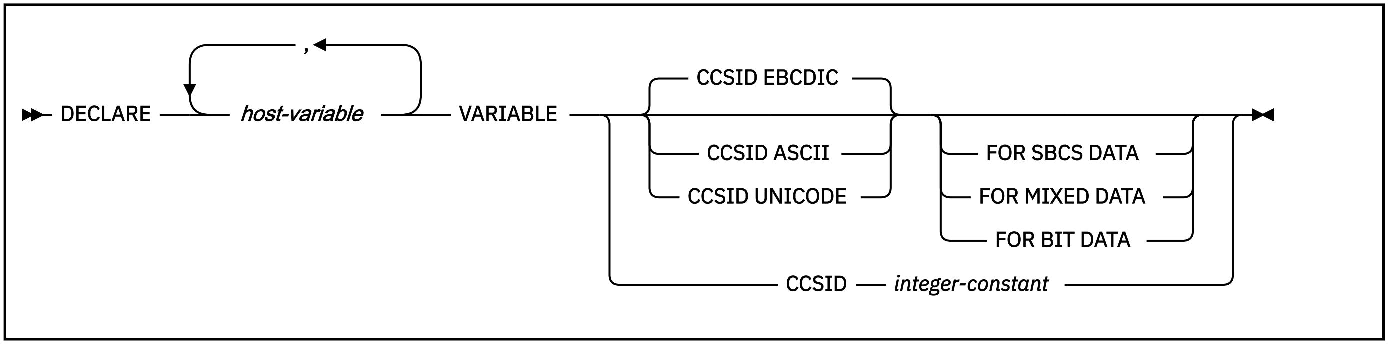
Invocation for DECLARE VARIABLE

This statement can only be embedded in an application program. It is not an executable statement.

Authorization for DECLARE VARIABLE

None required.

Syntax for DECLARE VARIABLE



Description for DECLARE VARIABLE

host-variable

Identifies a character or graphic string host variable defined in the program. An indicator variable cannot be specified for the host-variable.

CCSID ASCII, EBCDIC, or UNICODE

Specifies that the appropriate default CCSID for the specified encoding scheme of the server should be used.

CCSID ASCII

Specifies that the default ASCII CCSID for the type of the variable at the server should be used.

CCSID EBCDIC

Specifies that the default EBCDIC CCSID for the type of the variable at the server should be used. CCSID EBCDIC is the default if this option is not specified.

CCSID UNICODE

Specifies that the default UNICODE CCSID for the type of the variable at the server should be used.

FOR SBCS DATA, FOR MIXED DATA, or FOR BIT DATA

Specifies the type of data contained in the variable *host-variable*. The FOR clause cannot be specified when declaring a graphic host variable.

For ASCII or EBCDIC data, if this clause is not specified when declaring a character host variable, the default is FOR SBCS DATA if MIXED DATA = NO on the installation panel DSNTIPF. The default is FOR MIXED DATA if MIXED DATA = YES on the installation panel DSNTIPF.

For UNICODE data, the default is always FOR MIXED DATA, regardless of the setting of MIXED DATA on the installation panel DSNTIPF.

FOR SBCS DATA

Specifies that the values of the host variable can contain only SBCS (single-byte character set) data.

FOR MIXED DATA

Specifies that the values of the host variable can contain both SBCS data and DBCS data.

FOR BIT DATA

Specifies that the values of the host-variable are not associated with a coded character set and, therefore, are never converted. The CCSID of a FOR BIT DATA host variable is 65535.

CCSID *integer-constant*

Specifies that the values of the host variable contain data that is encoded using CCSID *integer-constant*. If the integer is an SBCS CCSID, the host variable is SBCS data. If the integer is a mixed data CCSID, the host variable is mixed data. For character host variables, the CCSID specified must be an SBCS, mixed CCSID, or UNICODE (UTF-8) CCSID. For graphic host variables, the CCSID specified must be a DBCS or UNICODE (UTF-16) CCSID. The valid range of values for the integer is 1 - 65533.

Notes for DECLARE VARIABLE

Placement of statement: The DECLARE VARIABLE statement can be specified anywhere in an application program that SQL statements are valid with the following exception. The DECLARE VARIABLE statement must occur before an SQL statement that refers to a host variable specified in the DECLARE VARIABLE statement.

CCSID exceptions for EXECUTE IMMEDIATE or PREPARE: When the host variable appears in an SQL statement, the Db2 precompiler places the appropriate numeric CCSID into the structures it generates for the SQL statement. This placement of the CCSID occurs for any SQL statement other than the EXECUTE IMMEDIATE or PREPARE statements. The placement of the CCSID also occurs for a *host-variable* in an EXECUTE IMMEDIATE or PREPARE statement, but it does not occur for a variable in a *string-expression* in an EXECUTE IMMEDIATE or PREPARE statement.

If a PL/1 application program contains at least one DECLARE VARIABLE statement, a *string-expression* in any EXECUTE IMMEDIATE or PREPARE statement cannot be preceded by a colon. An expression that consists of just a variable name preceded by a colon is interpreted as a *host-variable*.

Specific host languages: If a DECLARE VARIABLE statement is used in an assembler source program, the ONEPASS SQL processing option must not be used. If a DECLARE VARIABLE statement is used in a C, C++, or PL/I source program, the TWOPASS SQL processing option must be used. For those languages, or COBOL, the host-variable definition can either precede or follow a DECLARE VARIABLE statement that refers to that variable. If a DECLARE VARIABLE statement is used in a FORTRAN source program, then the host-variable definition must precede the DECLARE VARIABLE statement.

Example for DECLARE VARIABLE

Example: Define the following host variables using PL/I data types: FRED as fixed length bit data, JEAN as fixed length UTF-8 (mixed) data, DAVE as varying length UTF-8 (mixed) data, PETE as fixed length graphic UTF-16 data, and AMBER as varying length graphic UTF-16 data.

Use the DECLARE VARIABLE statement to specify a data subtype or CCSID for these host variables: FRED as CCSID EBCDIC, JEAN as CCSID 1208 or CCSID UNICODE, DAVE as CCSID 1208 or CCSID UNICODE, PETE as CCSID 1200 or CCSID UNICODE, and AMBER as CCSID 1200 or CCSID UNICODE.

```
EXEC SQL BEGIN DECLARE SECTION;
   DCL FRED CHAR(10);
       EXEC SQL DECLARE :FRED VARIABLE CCSID EBCDIC FOR BIT DATA;
   DCL JEAN CHAR(30);
       EXEC SQL DECLARE :JEAN VARIABLE CCSID 1208;
   DCL DAVE CHAR(9) VARYING;
       EXEC SQL DECLARE :DAVE VARIABLE CCSID UNICODE;
   DCL PETE GRAPHIC(10);
       EXEC SQL DECLARE :PETE VARIABLE CCSID 1200;
   DCL AMBER GRAPHIC(20) VARYING;
       EXEC SQL DECLARE :AMBER VARIABLE CCSID UNICODE;
EXEC SQL END DECLARE SECTION;
```

DELETE

The DELETE statement deletes rows from a table or view. Deleting a row from a view deletes the row from the table on which the view is based if no INSTEAD OF DELETE trigger is defined for this view. If such a trigger is defined, the trigger is activated instead.

The table or view can be at the current server or any Db2 subsystem with which the current server can establish a connection.

There are two forms of this statement:

- The *searched* DELETE form is used to delete one or more rows, optionally determined by a search condition.
- The *positioned* DELETE form specifies that one or more rows corresponding to the current cursor position are to be deleted.

Invocation for DELETE

This statement can be embedded in an application program or issued interactively. A positioned DELETE is embedded in an application program. Both the embedded and interactive forms are executable statements that can be dynamically prepared.

Authorization for DELETE

Authority requirements depend on whether the object identified in the statement is a user-defined table, a catalog table, or a view, and whether the statement is a searched DELETE and SQL standard rules are in effect:

When a table other than a catalog table is identified: The privilege set must include at least one of the following:

- The DELETE privilege on the table
- Ownership of the table
- DBADM authority on the database that contains the table
- SYSADM authority

If the database is implicitly created, the database privileges must be on the implicit database or on DSNDB04.

When a catalog table is identified: The privilege set must include at least one of the following:

- DBADM authority on the catalog database
- SYSCTRL authority
- SYSADM authority

When a view is identified: The privilege set must include at least one of the following:

- The DELETE privilege on the view
- SYSADM authority

If the *search-condition* in a searched DELETE contains a reference to a column of the table or view, or the *expression* in the *assignment-clause* contains a reference to a column of the table or view, the privilege set must include at least one of the following:

- The SELECT privilege on the table or view
- Ownership of the table or view
- DBADM authority on the database that contains the table, if the target is a table and that table that is not a catalog table
- DATAACCESS
- SYSADM authority

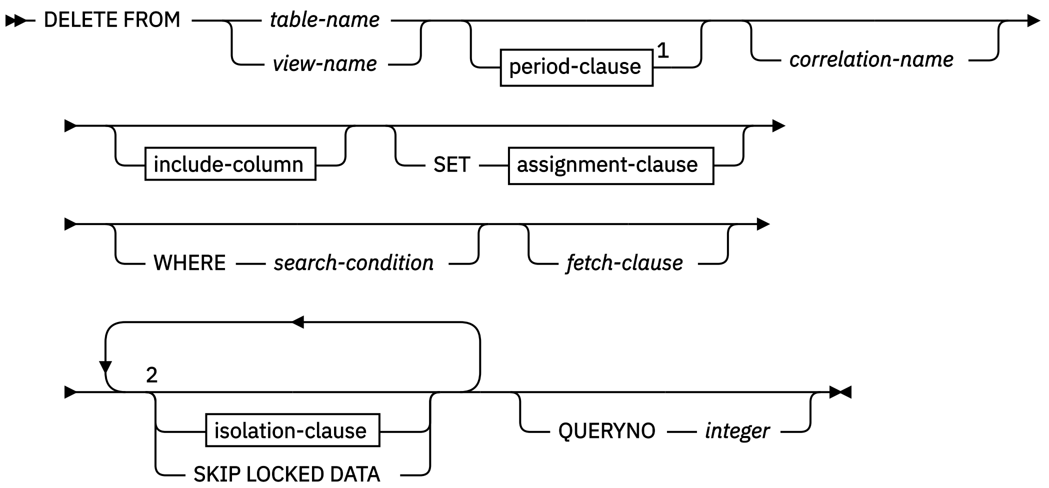
If the *search-condition* in a searched DELETE includes a subquery, or if the *assignment-clause* includes a *scalar-fullselect* or a *row-fullselect*, see "Authorization for queries" on page 1005 for an explanation of the authorization required.

The owner of a view, unlike the owner of a table, might not have DELETE authority on the view (or might have DELETE authority without being able to grant it to others). The nature of the view itself can preclude its use for DELETE. For more information, see the description of authority in "CREATE VIEW" on page 1807.

If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the statement is dynamically prepared, the privilege set is determined by the DYNAMICRULES behavior in effect (run, bind, define, or invoke) and is summarized in Table 171 on page 1084. (For more information on these behaviors, including a list of the DYNAMICRULES bind option values that determine them, see "Authorization IDs and dynamic SQL" on page 94.)

FL 509 If the statement attempts to delete a row in the SYSIBM.SYSAUDITPOLICIES catalog table that is subject to a tamper-proof audit policy, additional RACF authorization is required. During statement execution, the primary authorization ID or one of the groups associated with the primary authorization ID must be authorized to access the tamper-proof audit policy profile in RACF. For more information on the authorization rules, see Db2 audit policies (Managing Security).

searched delete:

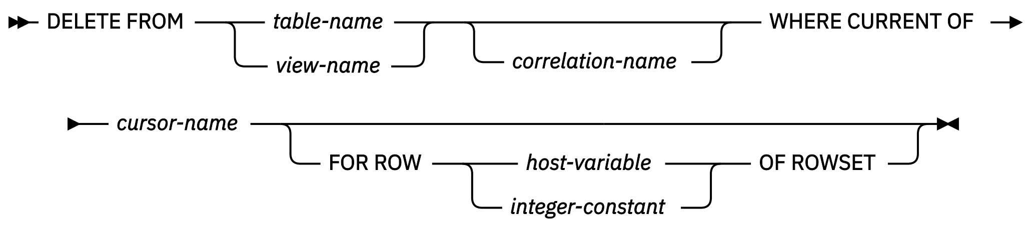


Notes:

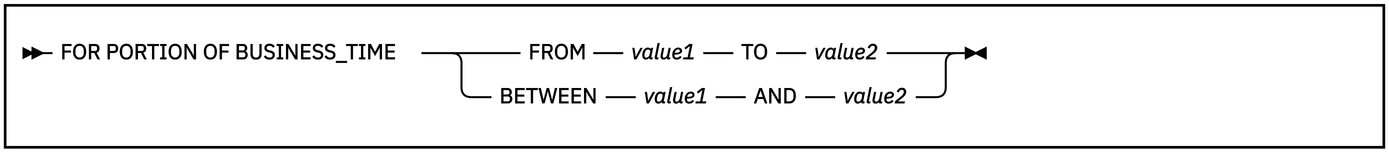
[1] If the *period-clause* is specified, the *fetch-clause* must not be specified.

[2] The same clause must not be specified more than one time.

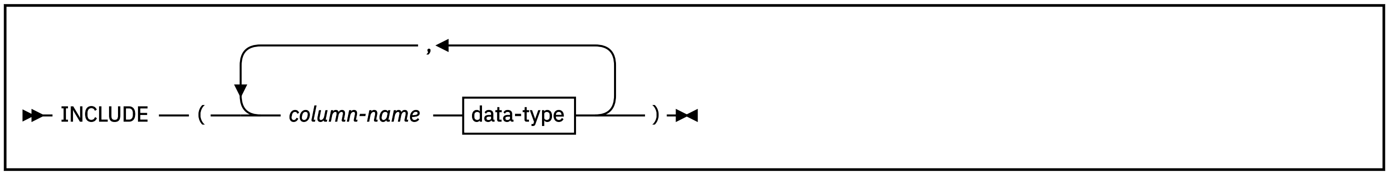
positioned delete:



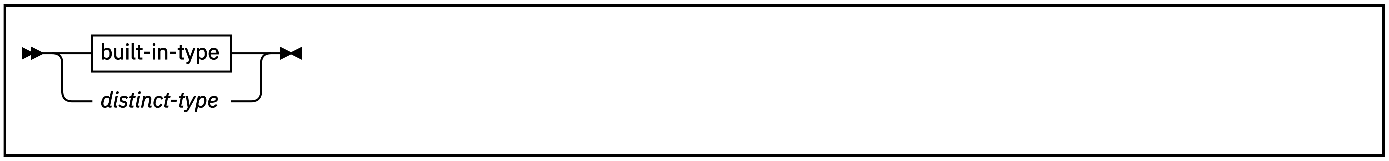
period-clause:



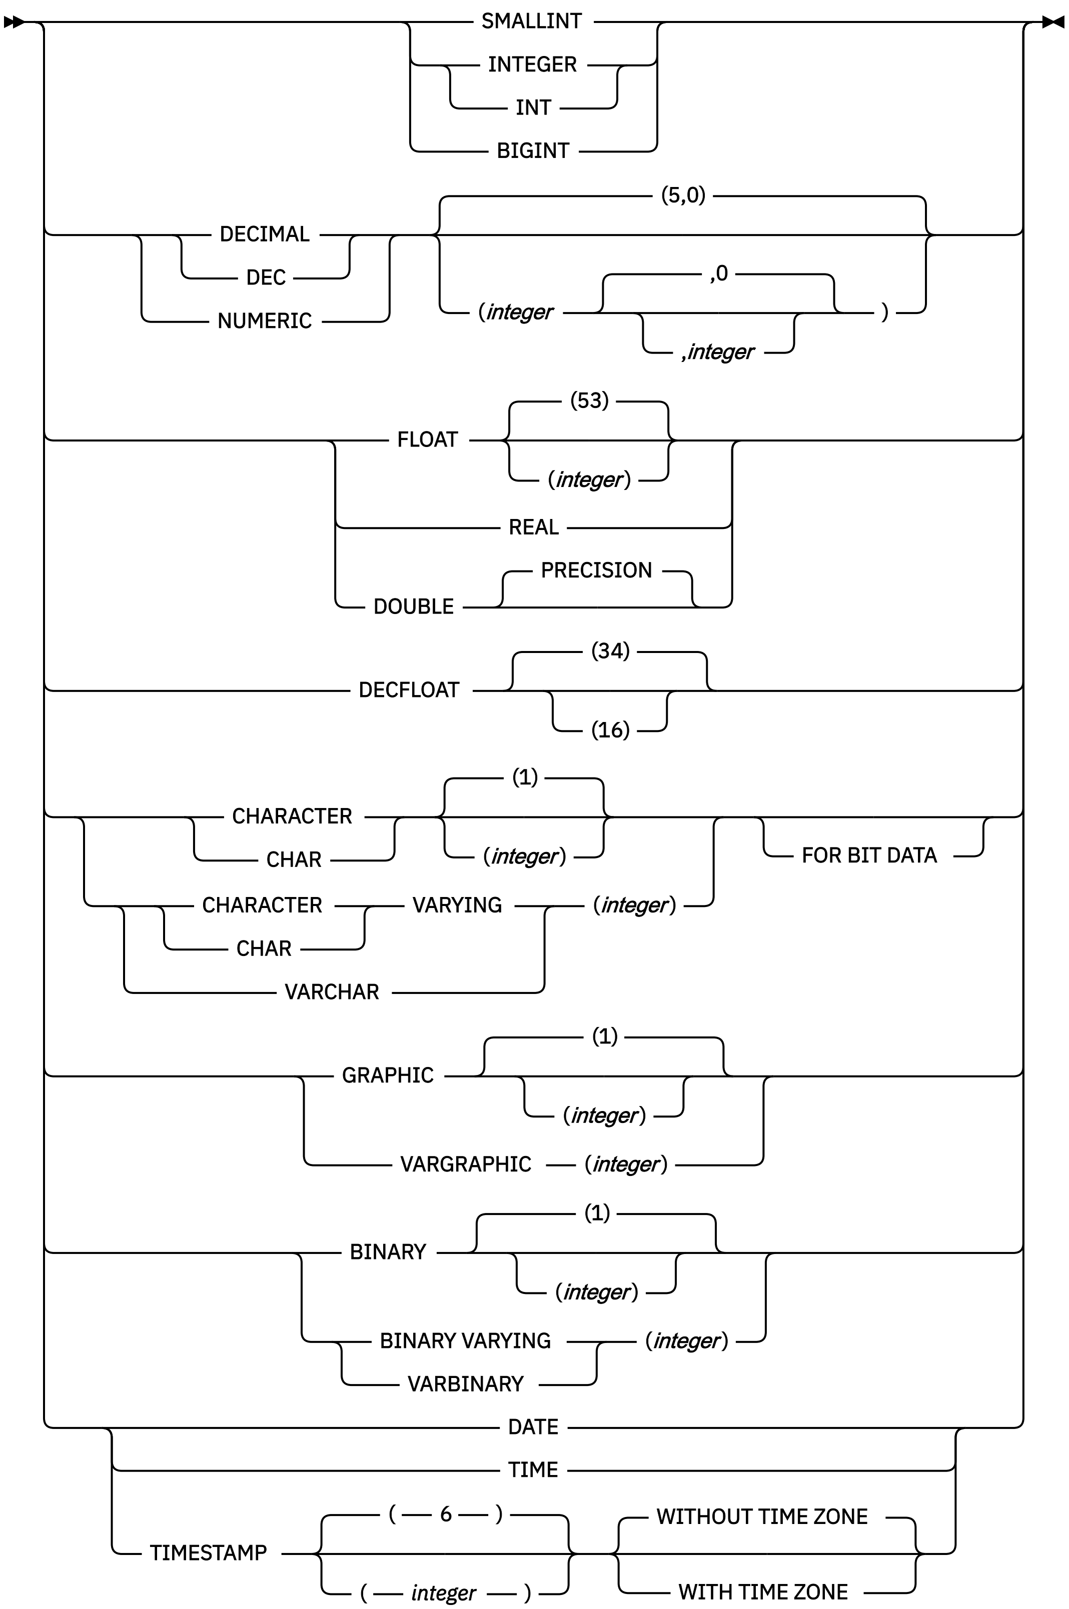
include-column:



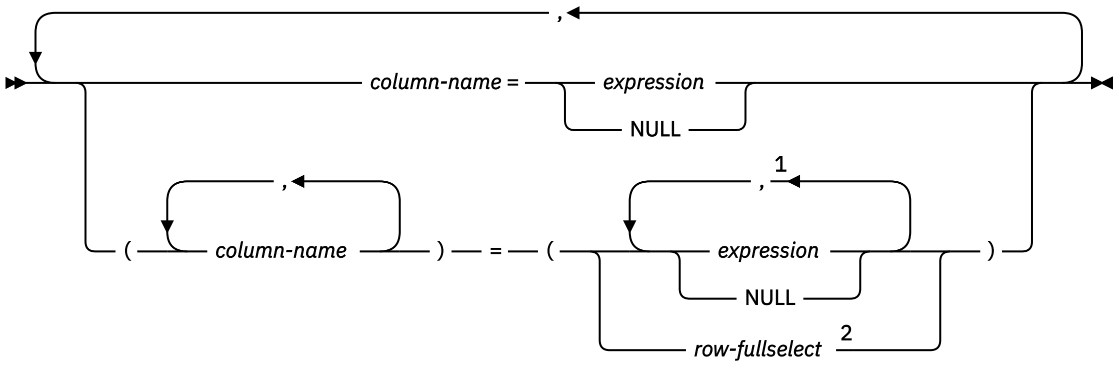
data-type:



built-in-type:



assignment clause:

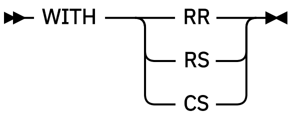


Notes:

[1] The number of *expressions* and NULL keywords must match the number of *column-names*.

[2] The number of columns in the select list must match the number of *column-names*.

isolation-clause:



Description for DELETE

`FROM` *table-name* or *view-name*

Identifies the table or view from which rows are to be deleted. The name must identify a table or view that exists at the Db2 subsystem that is identified by the implicitly or explicitly specified location name. The name must not identify:

- An auxiliary table
- A catalog table for which deletes are not allowed
- A view of such a catalog table
- A directory table
- A read-only view (see "CREATE VIEW" on page 1807)
- A view that is defined with an instead of trigger if the fetch-clause is specified.
- A created global temporary table if the fetch-clause is specified.
- An accelerator-only table if the fetch-clause is specified.
- A system-maintained materialized query table
- A table that is implicitly created for an XML column
- An archive-enabled table if the SYSIBMADM.GET_ARCHIVE global variable is set to Y, the ARCHIVESENSITIVE bind option is set to YES, and the operation is a positioned delete

In an IMS or CICS application, the Db2 subsystem that contains the identified table or view must be a remote server that supports two-phase commit.

period-clause

Specifies that a period clause applies to the target of the delete operation. The same period name must not be specified more than one time. If the target of the delete operation is a view:

- The FROM clause of the outer fullselect of the view definition must include a reference, directly or indirectly, to an application-period temporal table.
- An INSTEAD OF trigger must not be defined for that view.

FOR PORTION OF BUSINESS_TIME

Specifies that the delete only applies to row values for the portion of the BUSINESS_TIME period in the row that is specified by the period clause. BUSINESS_TIME must be a period that is defined on the table.

FOR PORTION OF BUSINESS_TIME must not be specified if the value of the CURRENT TEMPORAL BUSINESS_TIME special register is not NULL when the BUSTIMESENSITIVE bind option is set to YES.

FROM *value1* TO *value2*

Specifies that the delete operation applies to rows for the period that is specified from *value1* to *value2*. No rows are deleted if *value1* is greater than or equal to *value2*, or if *value1* or *value2* is the null value.

This clause must not be specified for an inclusive-inclusive period.

For the period condition that is specified with FROM *value1* TO *value2*, the period that is specified by *period-name* in a row of the target table of the delete:

- Overlaps the beginning of the specified period if the value of the begin column is less than *value1* and the value of the end column is greater than *value1*.
- Overlaps the end of the specified period if the value of the end column is greater than or equal to *value2* and the value of the begin column is less than *value2*.
- Is fully contained within the specified period if the value for the begin column for *period-name* in the row is greater than or equal to *value1* and the value for the corresponding end column in the row is less than or equal to *value2*.
- Is partially contained in the specified period if the row overlaps the beginning of the specified period or the end of the specified period.
- Fully overlaps the specified period if the period in the row overlaps the beginning of the specified period and overlaps the end of the specified period, .
- Is not contained in the period if both columns of *period-name* are less than or equal to *value1* or are greater than *value2*.

If the period *period-name* in a row is not contained in the specified period, the row is not deleted. Otherwise, the delete operation is applied based on the specification of the PORTION OF clause and how the values in the columns of *period-name* overlap the specified period as follows:

- If the period *period-name* in a row is fully contained within the specified period, the row is deleted.
- If the period *period-name* in a row is partially contained in the specified period and overlaps the beginning of the specified period:
  - The row is deleted.
  - A row is inserted using the original values from the row, except that the end column is set to *value1*, and new values are used for other generated columns.
- If the period *period-name* in a row is partially contained in the specified period and overlaps the end of the specified period:
  - The row is deleted.
  - A row is inserted using the original values from the row, except that the begin column is set to *value2*, and new values are used for other generated columns.
- If the period *period-name* in a row fully overlaps the specified period:
  - The row is deleted.
  - A row is inserted using the original values from the row, except that the end column is set to *value1*, a column defined as DATA CHANGE OPERATION is set to 'I', and new values are used for other generated columns.

  - An additional row is inserted using the original values from the row, except that the begin column is set to *value2*, a column defined as DATA CHANGE OPERATION is set to 'I', and new values are used for other generated columns.

Any existing delete triggers are activated for the rows that are deleted, and any existing insert triggers are activated for the rows that are implicitly inserted.

BETWEEN *value1* AND *value2*

Specifies that the delete operation applies to rows for the period that is specified from *value1* up to and including *value2*. No rows are deleted if *value1* is greater than *value2*, or if *value1* or *value2* is the null value. This clause must not be specified for an inclusive-exclusive period.

For the period clause that is specified with BETWEEN *value1* AND *value2*, period *period-name* in a row in the target of the delete covers one of the following ranges:

- Overlaps the beginning of the specified period if the value of the begin column is less than *value1* and the value of the end column is greater than or equal to *value1*.
- Overlaps the end of the specified period if the value of the end column is greater than *value2* and the value of the begin column is less than or equal to *value2*.
- Is fully contained within the specified period if the value for the begin column for *period-name* in the row is greater than or equal to *value1* and the value for the corresponding end column in the row is less than or equal to *value2*.
- Is partially contained in the specified period if the row overlaps the beginning of the specified period or the end of the specified period, but not both .
- fully overlaps the specified period if the period in the row overlaps the beginning of the specified period and overlaps the end of the specified period.
- Is not contained in the period if both columns of *period-name* are less than *value1* or greater than *value2*.

If the period *period-name* in a row is not contained in the specified period, the row is not deleted. Otherwise, the delete operation is based on the following items:

- The specification of the PORTION OF clause.
- How the values in the columns of *period-name* overlap the specified period.
- *spu* (smallest period unit), which depends on the data type of the columns of the period as follows:
  - For a period containing DATE columns, spu is 1 day.
  - For a period containing TIMESTAMP(6) columns, spu is 1 microsecond.

Based on those items, the delete operation is applied as follows:

- If the period *period-name* in a row is fully contained within the specified period, the row is deleted.
- If the period *period-name* in a row is partially contained in the specified period and overlaps the beginning of the specified period:
  - The row is deleted.
  - A row is inserted using the original values from the row, except that the end column is set to *value1* - spu, and new values are used for other generated columns.
- If the period *period-name* in a row is partially contained in the specified period and overlaps the end of the specified period:
  - The row is deleted.
  - A row is inserted using the original values from the row, except that the begin column is set to *value2* + spu, and new values are used for other generated columns.
- If the period *period-name* in a row fully overlaps the specified period:
  - The row is deleted.

- A row is inserted using the original values from the row, except that the end column is set to *value1* - spu, and new values are used for other generated columns.
- An additional row is inserted using the original values from the row, except that the begin column is set to *value2* + spu, and new values are used for other generated columns.

value1, value2

Specifies expressions that return a value of a built-in data type. The result of each expression must be comparable to the data type of the columns of the specified period. See the comparison rules described in "Assignment and comparison" on page 143. Each expression can contain any of the following supported operands:

- A constant
- A special register
- A variable
- An array element specification
- A built-in scalar function whose arguments are supported operands
- A CAST specification where the cast operand is a supported operand
- An expression that uses arithmetic operators and operands

Each expression must not have a timestamp precision that is greater than the precision of the columns for the period.

If the begin and end columns of the period are defined as TIMESTAMP WITHOUT TIME ZONE, each expression must not return a value of a timestamp with a time zone.

A period clause for a view must not contain an untyped parameter marker.

correlation-name

Specifies an alternate name that can be used within the *search-condition* to designate the table or view. (For an explanation of correlation names, see "Correlation names" on page 219.)

include-column

Specifies a set of columns that are included, along with the columns of *table-name* or *view-name*, in the result table of the DELETE statement when it is nested in the FROM clause of the outer fullselect that is used in a subselect, SELECT statement, or in a SELECT INTO statement. The included columns are appended to the end of the list of columns that is identified by *table-name* or *view-name*. If no value is assigned to a column that is specified by an *include-column*, a NULL value is returned for that column.

INCLUDE

Introduces a list of columns that are to be included in the result table of the DELETE statement. The included columns are only available if the DELETE statement is nested in the FROM clause of a SELECT statement or a SELECT INTO statement.

column-name

Specifies the name for a column of the result table of the DELETE statement that is not the same name as another included column nor a column in the table or view that is specified in *table-name* or *view-name*.

data-type

Specifies the data type of the included column. The included columns are nullable.

built-in-type

Specifies a built-in data type. See "CREATE TABLE" on page 1645 for a description of each built-in type.

The CCSID 1208 and CCSID 1200 clauses must not be specified for an INCLUDE column.

distinct-type

Specifies a distinct type. Any length, precision, or scale attributes for the column are those of the source type of the distinct type as specified by using the CREATE TYPE statement.

SET

Introduces the assignment of values to columns.

assignment-clause

The assignment-clause introduces a list of one or more *column-names* and the values that are to be assigned to the columns. The *column-names* are the only columns that can be set using the *assignment-clause*.

column-name

Identifies an INCLUDE column.

Assignments to included columns are only processed when the DELETE statement is nested in the FROM clause of a SELECT statement or a SELECT INTO statement. The columns that are named in the INCLUDE clause are the only columns that can be set using the SET clause. The null value is returned for an included column that is not set by using an explicit SET clause.

expression

Indicates the new value of the column. The *expression* is any expression of the type described in "Expressions" on page 244. It must not include an aggregate function.

A *column-name* in an expression must identify a column of the table or view. For each row that is deleted, the value of the column in the expression is the value of the column in the row before the row is deleted.

NULL

Specifies the null value as the new value of the column. Specify NULL only for nullable columns.

row-fullselect

Specifies a fullselect that returns a single row. The column values are assigned to each of the corresponding *column-names*. If the fullselect returns no rows, the null value is assigned to each column; an error occurs if any column that is to be deleted is not nullable. An error also occurs if there is more than one row in the result.

If the fullselect refers to columns that are to be deleted, the value of such a column in the fullselect is the value of the column in the row before the row is deleted.

WHERE

Specifies the rows to be deleted. You can omit the clause, give a search condition, or specify a cursor. For a created temporary table or a view of a created temporary table, you must omit the clause. When the clause is omitted, all the rows of the table or view are deleted.

search-condition

Is any search condition as described in Chapter 2, "Language elements in SQL," on page 75. Each *column-name* in the search condition, other than in a subquery, must identify a column of the table or view.

The search condition is applied to each row of the table or view and the deleted rows are those for which the result of the search condition is true.

If the search condition contains a subquery, the subquery can be thought of as being executed each time the search condition is applied to a row, and the results used in applying the search condition. In actuality, a subquery with no correlated references is executed just once, whereas it is possible that a subquery with a correlated reference must be executed once for each row.

Let T2 denote the object table of a DELETE statement and let T1 denote a table that is referred to in the FROM clause of a subquery of that statement. T1 must not be a table that can be affected by the DELETE on T2. Thus, the following rules apply:

- T1 must not be a dependent of T2 in a relationship with a delete rule of CASCADE or SET NULL, unless the result of the subquery is materialized before the DELETE action is executed.
- T1 must not be a dependent of T3 in a relationship with a delete rule of CASCADE or SET NULL if deletes of T2 cascade to T3.

fetch-clause

Limits the effects of the delete to a subset of the qualifying rows. See "fetch-clause" on page 1045 for details.

WHERE CURRENT OF *cursor-name*

Identifies the cursor to be used in the delete operation. *cursor-name* must identify a declared cursor as explained in the description of the DECLARE CURSOR statement in "DECLARE CURSOR" on page 1814. If the DELETE statement is embedded in a program, the DECLARE CURSOR statement must include *select-statement* rather than *statement-name*.

The table or view named must also be named in the FROM clause of the SELECT statement of the cursor, and the result table of the cursor must be capable of being deleted. For an explanation of read-only result tables, see Read-only cursors. Note that the object of the DELETE statement must not be identified as the object of the subquery in the WHERE clause of the SELECT statement of the cursor.

If the cursor is ambiguous and the plan or package was bound with CURRENTDATA(NO), Db2 might return an error to the application if DELETE WHERE CURRENT OF is attempted for any of the following:

- A cursor that is using block fetching
- A cursor that is using query parallelism
- A cursor that is positioned on a row that has been modified by this or another application process

When the DELETE statement is executed, the cursor must be open and positioned on a row or rowset of the result table.

- If the cursor is positioned on a single row, that row is the one deleted, and after the deletion the cursor is positioned before the next row of its result table. If there is no next row, the cursor positioned after the last row.
- If the cursor is positioned on a rowset, all rows corresponding to the rows of the current rowset are deleted, and after the deletion the cursor is positioned before the next rowset of its result table. If there is no next rowset, the cursor positioned after the last rowset.

A positioned DELETE must not be specified for a cursor that references a view on which an instead of delete trigger is defined, even if the view is an updatable view.

FOR ROW n OF ROWSET

Specifies which row of the current rowset is to be deleted. The corresponding row of the rowset is deleted, and the cursor remains positioned on the current rowset. If the rowset consists of a single row, or all other rows in the rowset have already been deleted, then the cursor is positioned before the next rowset of the result table. If there is no next rowset, the cursor is positioned after the last rowset.

host-variable or *integer-constant* is assigned to an integral value *k*. If *host-variable* is specified, it must be an exact numeric type with scale zero, must not include an indicator variable, and *k* must be in the range 1 - 32767. The cursor must be positioned on a rowset, and the specified value must be a valid value for the set of rows most recently retrieved for the cursor.

If the specified row cannot be deleted, an error is returned. It is possible that the specified row is within the bounds of the rowset most recently requested, but the current rowset contains less than the number of rows that were implicitly or explicitly requested when that rowset was established.

If, via a positioned delete against a sensitive static cursor that specifies a particular row of the current rowset, and that row has been identified as a delete hole (that is, a row in the result table whose corresponding row has deleted from the base table), an error is returned.

If, via a positioned delete against a sensitive static cursor that specifies a particular row of the current rowset, and that row has been identified as an update hole (that is, a row in the result table whose corresponding row has been updated so that it no longer satisfies a predicate of the SELECT statement), an error is returned.

It is possible for another application process to delete a row in the base table of the SELECT statement so that the specified row of the cursor no longer has a corresponding row in the base table. An attempt to delete such a row results in an error.

If the FOR ROW n OF ROWSET clause is not specified, the current position of cursor determines the rows that are affected by the statement:

- If the cursor is positioned on a single row, that row is the one deleted. After the row is deleted, the cursor is positioned before the next row of its result table. If there is no next row, the cursor positioned after the last row.
- If the cursor is positioned on a rowset, all rows corresponding to the rows of the current rowset are deleted. After the rows are deleted, the cursor is positioned before the next rowset of its result table. If there is no next rowset, the cursor positioned after the last rowset.

isolation-clause

Specifies the isolation level used when locating the rows to be deleted by the statement.

WITH

Introduces the isolation level, which may be one of the following:

RR

Repeatable read

RS

Read stability

CS

Cursor stability

The default isolation level of the statement is the isolation level of the package or plan in which the statement is bound, with the package isolation taking precedence over the plan isolation. When a package isolation is not specified, the plan isolation is the default.

SKIP LOCKED DATA

The SKIP LOCKED DATA clause specifies that rows are skipped when incompatible locks are held on the row by other transactions. These rows can belong to any accessed table that is specified in the statement. SKIP LOCKED DATA can be used only when isolation CS or RS is in effect and applies only to row level or page level locks.

For DELETE statements, SKIP LOCKED DATA can be specified only in the searched form of the DELETE statement. SKIP LOCKED DATA is ignored if it is specified when the isolation level that is in effect is repeatable read (WITH RR) or uncommitted read (WITH UR). The default isolation level of the statement depends on the isolation level of the package or plan with which the statement is bound, with the package isolation taking precedence over the plan isolation. When a package isolation is not specified, the plan isolation is the default.

QUERYNO *integer*

Specifies the number to be used for this SQL statement in EXPLAIN output and trace records. The number is used for the QUERYNO column of the plan table for the rows that contain information about this SQL statement. This number is also used in the QUERYNO column of the SYSIBM.SYSSTMT and SYSIBM.SYSPACKSTMT catalog tables.

If the clause is omitted, the number associated with the SQL statement is the statement number assigned during precompilation. Thus, if the application program is changed and then precompiled, that statement number might change.

Using the QUERYNO clause to assign unique numbers to the SQL statements in a program is helpful:

- For simplifying the use of optimization hints for access path selection
- For correlating SQL statement text with EXPLAIN output in the plan table

For more information about enabling and using optimization hints, see Influencing access path selection (Db2 Performance)

For information on accessing the plan table, see Investigating SQL performance by using EXPLAIN (Db2 Performance).

Notes for DELETE

Delete operation errors:
If an error occurs during the execution of any delete operation, no changes are made. If an error occurs during the execution of a positioned delete, the position of the cursor is unchanged. However, it is possible for an error to make the position of the cursor invalid, in which case the cursor is closed. It is also possible for a delete operation to cause a rollback, in which case the cursor is closed.

Position of cursor:
If an application process deletes a row on which any of its cursors are positioned, those cursors are positioned before the next row of the result table. Let C be a cursor that is positioned before row R (as a result of an OPEN, a DELETE through C, a DELETE through some other cursor, or a searched DELETE). In the presence of an SQL data change statements that affect the base table from which R is derived, the next FETCH operation referencing C does not necessarily position C on R. For example, the operation can position C on R', where R' is a new row that is now the next row of the result table.

Locking:
Unless appropriate locks already exist, one or more exclusive locks are acquired during the execution of a successful delete operation. Until the locks are released by a commit or rollback operation, the effect of the delete operation can only be perceived by the application process that performed the deletion and the locks can prevent other application processes from performing operations on the table. Locks are not acquired when rows are deleted from a declared temporary table unless all the rows are deleted (DELETE FROM T). When all the rows are deleted from a declared temporary table, a segmented table lock is acquired on the pages for the table and no other table in the table space is affected.

Triggers:
Delete operations can cause triggers to be activated. A trigger might cause other statements to be executed or might raise error conditions that are based on the deleted rows. If a DELETE statement on a view causes an INSTEAD OF trigger to be activated, referential integrity is checked against the updates that are performed in the trigger and not against the underlying tables of the view that cause the trigger to be activated.

Triggers defined on a table for which row or column access control is also enforced:
Row permissions and column masks are not applied to the initial values of transition variables and transition tables. Row and column access control that is enforced for the triggering table is also ignored for any transition variables or transition tables that are referenced in the trigger body or that are passed as arguments to user-defined functions that are invoked in the trigger body. To ensure that no security concern exists for SQL statements in the trigger action (access to sensitive data in transition variables and transition tables, for example), the trigger must be secure. For information about securing a trigger, see "CREATE TRIGGER (basic)" on page 1764 and "ALTER TRIGGER (basic)" on page 1360.

Referential integrity:
If the identified table or the base table of the identified view is a parent, the rows selected must not have any dependents in a relationship with a delete rule of RESTRICT or NO ACTION. In addition, the delete operation must not cascade to descendent rows that have dependents in a relationship with a delete rule of RESTRICT or NO ACTION.

If the delete operation is not prevented by a RESTRICT or NO ACTION delete rule, the selected rows are deleted and any rows that are dependents of the selected rows are also deleted.

- The nullable columns of foreign keys in any rows that are their dependents in a relationship governed by a delete rule of SET NULL are set to the null value.
- Any rows that are their dependents in a relationship governed by a delete rule of CASCADE are also deleted, and these rules apply, in turn, to those rows.

The only difference between NO ACTION and RESTRICT is when the referential constraint is enforced. RESTRICT (IBM SQL rules) enforces the rule immediately, and NO ACTION (SQL standard rules) enforces the rule at the end of the statement. This difference matters only in the case of a searched DELETE involving a self-referencing constraint that deletes more than one row. NO ACTION might allow the DELETE to be successful where RESTRICT (if it were allowed) would prevent it.

Check constraint:
A check constraint can prevent the deletion of a row in a parent table when there are dependents in a relationship with a delete rule of SET NULL. If deleting a row in the parent table would cause a column in a dependent table to be set to null and there is a check constraint that specifies that the column must not be null, the row is not deleted.

Referential constraints defined on a table for which row or column access control is enforced:
Row and column access controls do not effect referential constraints.

Nesting user-defined functions or stored procedures:
A DELETE statement can implicitly or explicitly refer to user-defined functions or stored procedures. This is known as *nesting* of SQL statements. A user-defined function or stored procedure that is nested within the DELETE must not access the table from which you are deleting rows.

Indexes with VARBINARY columns:
If the identified table has an index on a VARBINARY column or a column that is a distinct type that is based on VARBINARY data type, that index column cannot specify the DESC attribute. To use the SQL data change operation on the identified table, either drop the index or alter the data type of the column to BINARY and then rebuild the index.

Number of rows deleted:
Except as noted below, a delete operation sets SQLERRD(3) in the SQLCA to the number of deleted rows. This number does not include any rows that were deleted as a result of a CASCADE delete rule or a trigger.

DELETE FROM T without a WHERE clause deletes all rows of T. If a table T is contained in a segmented table space and is not a parent table, this deletion will be performed without accessing T. The SQLERRD(3) field is set to -1. (For a complete description of the SQLCA, including exceptions to the above, see Appendix E, “SQL communication area (SQLCA),” on page 2291.

Rules for positioned DELETE with SENSITIVE STATIC scrollable cursor:
When a SENSITIVE STATIC scrollable cursor has been declared, the following rules apply:

- *Delete attempt of delete holes or update holes.* If, with a positioned delete against a SENSITIVE STATIC scrollable cursor, an attempt is made to delete a row that has been identified as a delete hole (that is, a row in the result table whose corresponding row has been deleted from the base table), an error occurs.

  If an attempt is made to delete a row that has been identified as an update hole (that is, a row in the result table whose corresponding row has been updated so that it no longer satisfies the predicate of the SELECT statement), an error occurs.

- *Delete operations.* Positioned delete operations with SENSITIVE STATIC scrollable cursors perform as follows:

  1. The SELECT list items in the target row of the base table of the cursor are compared with the values in the corresponding row of the result table (that is, the result table must still agree with the base table). If the values are not identical, the delete operation is rejected and an error occurs. The operation can be attempted again after a successful FETCH SENSITIVE has occurred for the target row.
  2. The WHERE clause of the SELECT statement is re-evaluated to determine whether the current values in the base table still satisfy the search criteria. The values in the SELECT list are compared to determine that these values have not changed. If the WHERE clause evaluates as true, and the values in the SELECT list have not changed, the delete operation is allowed to proceed. Otherwise, an error occurs, the delete operation is rejected, and an update hole appears in the cursor.

3. After the base table row is successfully deleted, the temporary result table is updated and the row is marked as a delete hole.

- *Rollback of delete holes.* Delete holes are usually permanent. Once a delete hole is identified, it remains a delete hole until the cursor is closed. However, if a positioned delete using *this* cursor actually caused the creation of the hole (that is, this cursor was used to make the changes that resulted in the hole) and the delete was subsequently rolled back, then the row is no longer considered a delete hole.
- *Result table.* Any deletes, either positioned or searched, to rows of the base table on which a SENSITIVE STATIC scrollable cursor is defined are reflected in the result table if a positioned update or positioned delete is attempted with the scrollable cursor. A SENSITIVE STATIC scrollable cursor sees these deletes when a FETCH SENSITIVE is attempted.

If the FOR ROW *n* OF ROWSET clause is not specified, the entire rowset fetched by the most recent FETCH statement that returned data for the specified cursor is deleted.

Referencing columns that will be updated:

If a cursor uses FETCH statements to retrieve columns that will be updated later, specify FOR UPDATE OF when you select the columns. Then specify WHERE CURRENT OF in the subsequent UPDATE or DELETE statements. These clauses prevent Db2 from selecting access through an index on the columns that are being updated, which might otherwise cause Db2 to read the same row more than once.

For more information, see Updating previously retrieved data (Db2 Application programming and SQL).

Deleting rows from a table with multilevel security:

When you delete rows from a table with multilevel security, Db2 compares the security label of the user (the primary authorization ID) to the security label of the row. The delete proceeds according to the following rules:

- If the security label of the user and the security label of the row are equivalent, the row is deleted.
- If the security label of the user dominates the security label of the row, the user's write-down privilege determines the security the result of the DELETE statement:
  - If the user has write-down privilege or write-down control is not enabled, the row is deleted.
  - If the user does not have write-down privilege and write-down control is enabled, the row is not deleted.
- If the security label of the row dominates the security label of the user, the row is not deleted.

Deleting rows from a table for which row and column access control is enforced:

When a DELETE statement is issued for a table for which row access control is enforced, the rules specified in the row permissions affect whether a row can be deleted. Typically those rules are based on the authorization ID or role of the process.

A table for which row access control is enforced has at least one row permission, the default row permission that prevents all access to the table. When multiple row permissions are defined and enabled for a table, a row access control search condition is derived by using the logical OR operator to the search condition in each enabled permission. This row access control search condition is applied to the table to determine which rows are accessible to the authorization ID or role of the DELETE statement. If the WHERE clause is specified in the DELETE statement, the user-specified predicates are applied on the accessible rows to determine the rows to be deleted. If there is no WHERE clause, the accessible rows are the rows to be deleted.

If there are rows to be deleted, and there is a DELETE trigger for the table, the trigger is activated.

When a DELETE statement is issued for a table for which column access control is enforced, column masks do not affect the DELETE statement.

The preceding rules are not applicable to *include-columns*. *include-columns* are subject to the rules for the select list because they are not the columns of the object table of the DELETE statement.

Other SQL statements in the same unit of work:

The following statements cannot follow a DELETE statement in the same unit of work:

- An ALTER TABLE statement that changes the data type of a column (ALTER COLUMN SET DATA TYPE)
- An ALTER INDEX statement that changes the padding attribute of an index with varying-length columns (PADDED to NOT PADDED or vice versa)
- A CREATE TABLE statement that creates an accelerator-only table.
- An INSERT, UPDATE or DELETE statement that updates an accelerator-only table from a different accelerator

Considerations for a system-period temporal table:

If the DELETE statement has a search condition that contains a correlated subquery that references the history table (explicitly referencing the name of the history table or implicitly referenced through the use of a period specification in the FROM clause), the deleted rows that are stored as historical rows are potentially visible for delete operations for the rows that are subsequently processed for the statement.

The mass delete operation is not used for a DELETE statement that does not contain a search condition if the table is defined as a system-period temporal table.

If the CURRENT TEMPORAL SYSTEM_TIME special register is set to a non-null value, the underlying target of the DELETE statement cannot be a system-period temporal table. This restriction applies regardless of whether the system-period temporal table is directly or indirectly referenced.

Considerations for a history table:

When a row of a system-period temporal table is deleted, a historical copy of the row is inserted into the corresponding history table and the end timestamp of the historical row is captured in the form of a system determined value that corresponds to the time of the data change operation. If the value of the SYSIBM.TEMPORAL_LOGICAL_TRANSACTION_TIME built-in global variable at the time of the data change operation is null, the value is generated using a reading of the time-of-day clock during execution of the first data change statement in the unit of work that requires a value to be assigned to a row-begin column or transaction-start-ID column in a table, or a row in a systemperiod temporal table is deleted. Otherwise, the value is assigned from the SYSIBM.TEMPORAL_LOGICAL_TRANSACTION_TIME built-in global variable at the time of the data change operation. If a conflicting transaction is updating the same row in the system-period temporal table and the row that is to be inserted into the associated history table will have a value for the end column that is greater than the value of the corresponding begin column, an error is returned.

Considerations for an application-period temporal table:

A DELETE statement that contains a FOR PORTION OF BUSINESS_TIME clause for an application-period temporal table indicates the two points in time between which the specified delete operations are effective.

Suppose that FOR PORTION OF BUSINESS_TIME is specified and the period value for a row is only partially contained in the period that is specified from *value1* up to *value2* or between *value1* and *value2*. (The period value for a row is specified by the values of the begin column and end column.) In this case, the row is deleted and one or two rows are automatically inserted to represent the portion of the row that is not deleted. For each row that is automatically inserted as a result of a delete operation on the table, new values are generated for each generated column in the application-period temporal table. If a generated column is defined as part of a unique or primary key, parent key in a referential constraint, or unique index, an automatic insert might violate a constraint or index. In this case, an error is returned.

When an application-period table is the target of a DELETE statement and the value in effect for the CURRENT TEMPORAL BUSINESS_TIME special register is not the null value, Db2 adds the following additional predicates to the statement:

- inclusive-exclusive period:

```
    bt_begin <= CURRENT TEMPORAL BUSINESS_TIME AND
bt_end > CURRENT TEMPORAL BUSINESS_TIME
```

- inclusive-inclusive period:

```
    bt_begin <= CURRENT TEMPORAL BUSINESS_TIME AND
bt_end >= CURRENT TEMPORAL BUSINESS_TIME
```

In the preceding code, bt_begin and bt_end are the begin and end columns of the BUSINESS_TIME period of the target table of the DELETE statement.

Deleting rows from archive-enabled tables:

If the target of the DELETE statement is an archive-enabled table, existing rows in the associated archive table are not affected.

When a row of an archive-enabled table is deleted, the effect on the associated archive table is determined by the setting of the SYSIBMADM.MOVE_TO_ARCHIVE global variable. If the global variable is set to Y, a copy of a deleted row is inserted into the associated archive table. Otherwise, a copy of a deleted row is not inserted into the associated archive table.

A data change statement cannot reference an archive-enabled table when a system-period temporal table or application-period temporal table is also referenced.

Syntax alternatives:

For compatibility with other SQL implementations, the FROM keyword that immediately follows the DELETE keyword can be omitted.

Examples for DELETE

Assume that the statements in the examples are embedded in PL/I programs.

Example 1

From the table DSN8C10.EMP delete the row on which the cursor C1 is currently positioned.

```
   EXEC SQL DELETE FROM DSN8C10.EMP WHERE CURRENT OF C1;
```

Example 2

From the table DSN8C10.EMP, delete all rows for departments E11 and D21.

```
   EXEC SQL DELETE FROM DSN8C10.EMP
     WHERE WORKDEPT = 'E11' OR WORKDEPT = 'D21';
```

Example 3

From employee table X, delete the employee who has the most absences.

```
   EXEC SQL DELETE FROM EMP X
     WHERE ABSENT = (SELECT MAX(ABSENT) FROM EMP Y
     WHERE X.WORKDEPT = Y.WORKDEPT);
```

Example 4

Assuming that cursor CS1 is positioned on a rowset consisting of 10 rows of table T1, delete all 10 rows in the rowset.

```
EXEC SQL DELETE FROM T1 WHERE CURRENT OF CS1;
```

Example 5

Assuming cursor CS1 is positioned on a rowset consisting of 10 rows of table T1, delete the fourth row of the rowset.

```
EXEC SQL DELETE FROM T1 WHERE CURRENT OF CS1 FOR ROW 4 OF ROWSET;
```

Example 6

Delete rows in table T1 if the value for column COL2 matches the cardinality of array INTA. The array INTA is specified as an argument for the CARDINALITY function in the DELETE statement.

```
CREATE TYPE INTARRAY AS INTEGER ARRAY[6];
CREATE VARIABLE INTA AS INTARRAY;
SET INTA = ARRAY[1, 2, 3, 4, 5];
CREATE TABLE T1 (COL1 CHAR(7), COL2 INT);
INSERT INTO T1 VALUES('abc', 10);
DELETE FROM T1 WHERE COL2 = CARDINALITY(INTA);
```

Example 7

Delete only 3 rows from table T1 where the value of column C2 is greater than 10.

```
DELETE FROM T1
   WHERE C2 > 10
   FETCH FIRST 3 ROWS ONLY;
```

DESCRIBE

The DESCRIBE statement obtains information about an object. You can obtain the following types of information with this statement, each of which is described separately.

Cursors

Gets information about the result set that is associated with the cursor. This information, such as column information, is put into a descriptor. See "DESCRIBE CURSOR" on page 1864.

Input parameter markers of a prepared statement.

Gets information about the input parameter markers in a prepared statement. This information is put into a descriptor. See "DESCRIBE INPUT" on page 1866.

The output of a prepared statement

Gets information about a prepared statement or information about the select list columns in a prepared SELECT statement. This information is put into a descriptor. See "DESCRIBE OUTPUT" on page 1868.

Procedures

Gets information about the result sets returned by a stored procedure. The information, such as the number of result sets, is put into a descriptor. See "DESCRIBE PROCEDURE" on page 1874.

Tables

Gets information about a table or view. This information is put into a descriptor. See "DESCRIBE TABLE" on page 1876.

DESCRIBE CURSOR

The DESCRIBE CURSOR statement obtains information about the result set that is associated with the cursor. The information, such as column information, is put into a descriptor. Use DESCRIBE CURSOR for result set cursors from stored procedures. The cursor must be defined with the ALLOCATE CURSOR statement.

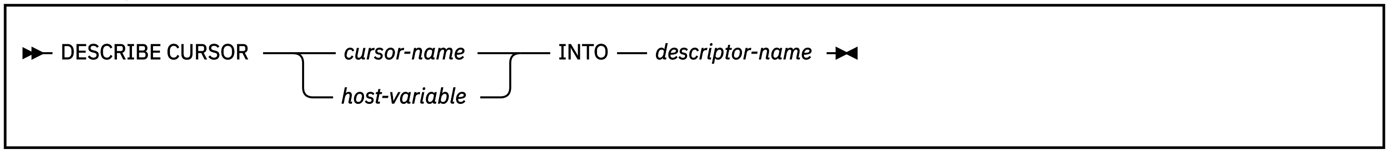
Invocation for DESCRIBE CURSOR

This statement can only be embedded in an application program. It is an executable statement that cannot be dynamically prepared.

Authorization for DESCRIBE CURSOR

None required.

Syntax for DESCRIBE CURSOR



Description for DESCRIBE CURSOR

cursor-name* or *host-variable

Identifies a cursor by the specified *cursor-name* or the cursor name contained in *host-variable*. The name must identify a cursor that has already been allocated in the source program.

A column of the result table of the cursor must not be an array.

If *host-variable* is used:

- It must be a character string variable that has a maximum length of 18 bytes.
- It must not be followed by an indicator variable.
- The cursor name must be left justified within the host variable and must not contain embedded blanks.
- If the length of the cursor name is less than the length of the host variable, it must be padded on the right with blanks.

Exception: The syntax described above applies to all languages except REXX. For REXX, the syntax is DESCRIBE CURSOR :*hostvar* INTO :*descriptor-name*.

INTO *descriptor-name*

Identifies an SQL descriptor area (SQLDA). The information returned in the SQLDA describes the columns in the result set associated with the named cursor.

The considerations for allocating and initializing the SQLDA are similar to those of a varying-list SELECT statement. For more information, see Including dynamic SQL for varying-list SELECT statements in your program (Db2 Application programming and SQL).

For REXX: The SQLDA is not allocated before it is used.

After the DESCRIBE CURSOR statement is executed, the contents of the SQLDA are the same as after a DESCRIBE for a SELECT statement, with the following exceptions:

- The first 5 bytes of the SQLDAID field are set to 'SQLRS'.
- Bytes 6 to 8 of the SQLDAID field are reserved. If the cursor is declared WITH HOLD in a stored procedure, the high-order bit of the 8th byte is set to 1.

These exceptions do not apply to a REXX SQLDA, which does not include the SQLDAID field.

Notes for DESCRIBE CURSOR

Using cursors for result sets

Column names are included in the information that DESCRIBE CURSOR obtains when the statement that generates the result set is either:

- Dynamic
- Static and the value of field DESCRIBE FOR STATIC on installation panel DSNTIP4 was YES when the package or stored procedure was bound. If the value of the field was NO, the returned information includes only the data type and length of the columns.

Using host variables

If the DESCRIBE CURSOR statement contains host variables, the contents of the host variables are assumed to be in the encoding scheme that was specified in the ENCODING parameter when the package or plan that contains the statement was bound.

Examples for DESCRIBE CURSOR

The statements in the following examples are assumed to be in PL/I programs.

Example 1
Place information about the result set associated with cursor C1 into the descriptor named by :sqlda1.

```
EXEC SQL DESCRIBE CURSOR C1 INTO :sqlda1
```

Example 2
Place information about the result set associated with the cursor named by :hv1 into the descriptor named by :sqlda2.

```
EXEC SQL DESCRIBE CURSOR :hv1 INTO :sqlda2
```

DESCRIBE INPUT

The DESCRIBE INPUT statement obtains information about the input parameter markers of a prepared statement.

For an explanation of prepared statements, see "PREPARE" on page 2037.

Invocation for DESCRIBE INPUT

This statement can only be embedded in an application program. It is an executable statement that cannot be dynamically prepared.

Authorization for DESCRIBE INPUT

The statement can be executed if the privilege set for PREPARE includes the EXPLAIN privilege.

Syntax for DESCRIBE INPUT

```
►►─ DESCRIBE INPUT ── statement-name ── INTO ── descriptor-name ─►◄
```

Description for DESCRIBE INPUT

statement-name
Identifies the prepared statement. When the DESCRIBE INPUT statement is executed, the name must identify a statement that has been prepared by the application process at the current server. An input parameter marker must not refer to an array value.

INTO *descriptor-name*
Identifies an SQL descriptor area (SQLDA), which is described in Appendix F, "SQL descriptor area (SQLDA)," on page 2301. See "Identifying an SQLDA in C or C++" on page 2317 for how to represent *descriptor-name* in C. The information returned in the SQLDA describes the parameter markers.

Before the DESCRIBE INPUT statement is executed, the user must set the SQLN field in the SQLDA and the SQLDA must be allocated. Considerations for initializing and allocating the SQLDA are similar to those for the DESCRIBE statement (see "DESCRIBE" on page 1864). An occurrence of an extended SQLVAR is needed for each parameter in addition to the required base SQLVAR only if the input data contains LOBs.

For REXX: The SQLDA is not allocated before it is used.

After the DESCRIBE INPUT statement is executed, all the fields in the SQLDA except SQLN are either set by Db2 or ignored. The SQLDA contents are similar to the contents returned for the DESCRIBE statement (see The SQLDA contents returned after DESCRIBE) with these exceptions:

- In the SQLDAID, Db2 sets the value of the seventh byte only to the space character or '2'. A value of '3' is never used. The value '2' indicates that two SQLVAR entries (an occurrence of both a base SQLVAR and an extended SQLVAR) are required for each parameter because the input data contains LOBs. The seventh byte is a space character when either of the following conditions is true:
  - The input data does not contain LOBs. Only a base SQLVAR occurrence is needed for each parameter.
  - Only a base SQLVAR occurrence is needed for each column of the result, and the SQLDA is not large enough to contain the returned information.
- The SQLD field is set to the number of parameter markers being described. The value is 0 if the statement being described does not have input parameter markers.
- The SQLNAME field is not used.
- The SQLDATATYPE is set to a nullable, regardless of the usage of the parameter markers in the prepared statement.
- The SQLDATATYPE-NAME is not used if an extended SQLVAR entry is present. DESCRIBE INPUT does not return information about distinct types.

For complete information on the contents of the fields, see Appendix F, “SQL descriptor area (SQLDA),” on page 2301.

Notes for DESCRIBE INPUT

Preparing the SQLDA for OPEN or EXECUTE: This note is relevant if you are applying DESCRIBE INPUT to a prepared statement and you intend to use the SQLDA in an OPEN or EXECUTE statement. To prepare the SQLDA for that purpose:

- Set SQLDATA to a valid address.
- If SQLTYPE is odd, set SQLIND to a valid address.

For the meaning of those fields in that context, see Appendix F, “SQL descriptor area (SQLDA),” on page 2301.

Support for extended dynamic SQL in a distributed environment: Unlike the DESCRIBE statement, which can be used in a distributed environment to describe static SQL statements generated by extended dynamic SQL, you cannot describe host variables in static SQL statements that are generated by extended dynamic SQL. A DESCRIBE INPUT statement issued against such static SQL statements always fails.

For information on how the DESCRIBE statement supports extended dynamic SQL, see Support for extended dynamic SQL in a distributed environment.

Using host variables: If the DESCRIBE INPUT statement contains host variables, the contents of the host variables are assumed to be in the encoding scheme that was specified in the ENCODING parameter when the package or plan that contains the statement was bound.

Example for DESCRIBE INPUT

Execute a DESCRIBE INPUT statement with an SQLDA that has enough SQLVAR occurrences to describe any number of input parameters a prepared statement might have. Assume that five parameter markers at most will need to be described and that the input data does not contain LOBs.

```
    /* STMT1_STR contains INSERT statement with VALUES clause  */
 EXEC SQL  PREPARE STMT1_NAME FROM :STMT1_STR;
… /* code to set SQLN to 5 and to allocate the SQLDA         */
 EXEC SQL  DESCRIBE INPUT STMT1_NAME INTO :SQLDA;
.
.
.
```

This example uses the first technique described in Allocating the SQLDA to allocate the SQLDA.

DESCRIBE OUTPUT

The DESCRIBE OUTPUT statement obtains information about a prepared statement.

For an explanation of prepared statements, see "PREPARE" on page 2037.

Invocation for DESCRIBE OUTPUT

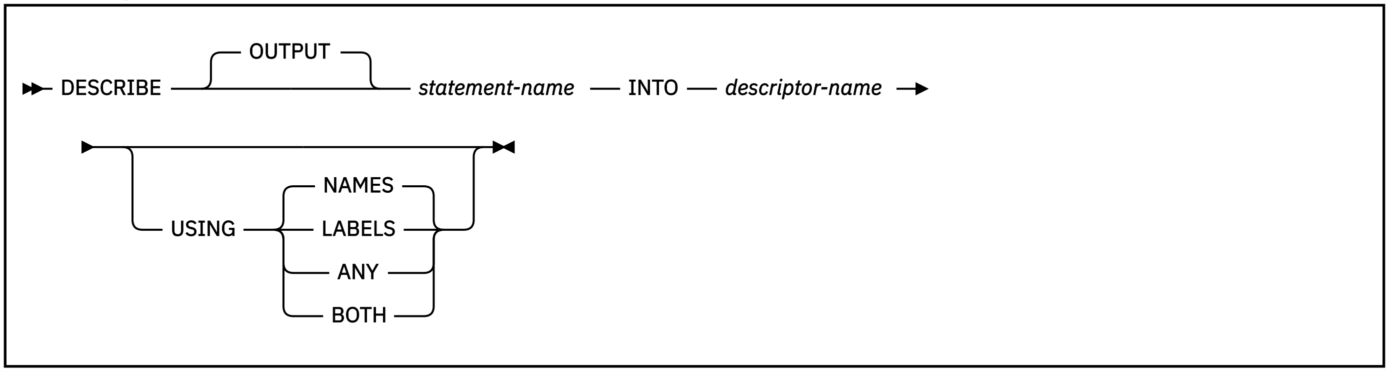
This statement can only be embedded in an application program. It is an executable statement that cannot be dynamically prepared. It must not be specified in Java.

Authorization for DESCRIBE OUTPUT

The statement can be executed if the privilege set for PREPARE includes the EXPLAIN privilege.

See "PREPARE" on page 2037 for the authorization required to create a prepared statement.

Syntax for DESCRIBE OUTPUT



Description for DESCRIBE OUTPUT

OUTPUT
When a *statement-name* is specified, optional keyword to indicate that the describe will return information about the select list columns in a the prepared SELECT statement.

statement-name
Identifies the prepared statement. When the DESCRIBE statement is executed, the name must identify a statement that has been prepared by the application process at the current server. A column of the result table of the prepared statement must not be an array.

INTO *descriptor-name*
Identifies an SQL descriptor area (SQLDA), which is described in Appendix F, "SQL descriptor area (SQLDA)," on page 2301. See "Identifying an SQLDA in C or C++" on page 2317 for how to represent *descriptor-name* in C.

For languages other than REXX: Before the DESCRIBE statement is executed, the user must set the following variable in the SQLDA and the SQLDA must be allocated.

SQLN
Indicates the number of SQLVAR occurrences provided in the SQLDA. Db2 does not change this value. For techniques to determine the number of required occurrences, see Allocating the SQLDA.

For REXX: The SQLDA is not allocated before it is used. An SQLDA consists of a set of stem variables. There is one occurrence of variable *stem*.SQLD, followed by zero or more occurrences of a set of variables that is equivalent to an SQLVAR structure. Those variables begin with *stem.n*.

After the DESCRIBE statement is executed, all the fields in the SQLDA except SQLN are either set by Db2 or ignored. For information on the contents of the fields, see The SQLDA contents returned after DESCRIBE.

USING

Indicates what value to assign to each SQLNAME variable in the SQLDA. If the requested value does not exist, SQLNAME is set to a length of 0.

NAMES

Assigns the name of the column. This is the default.

LABELS

Assigns the label of the column. (Column labels are defined by the LABEL statement.)

ANY

Assigns the label of the column. If the column has no label or the label is a string of length 0, the column name is used instead.

BOTH

Assigns both the label and name of the column. In this case, two or three occurrences of SQLVAR per column, depending on whether the result set contains distinct types, are needed to accommodate the additional information. To specify this expansion of the SQLVAR array, set SQLN to 2×*n* or 3×*n*, where *n* is the number of columns in the object being described. For each of the columns, the first *n* occurrences of SQLVAR, which are the base SQLVAR entries, contain the column names. Either the second or third *n* occurrences of SQLVAR, which are the extended SQLVAR entries, contain the column labels. If there are no distinct types, the labels are returned in the second set of SQLVAR entries. Otherwise, the labels are returned in the third set of SQLVAR entries.

Notes for DESCRIBE OUTPUT

Using PREPARE INTO clause:

Information about a prepared statement can also be obtained by using the INTO clause of the PREPARE statement.

Allocating the SQLDA:

Before the DESCRIBE or PREPARE INTO statement is executed, the value of SQLN must be set to a value greater than or equal to zero to indicate how many occurrences of SQLVAR are provided in the SQLDA. Also, enough storage must be allocated to contain the number of occurrences that SQLN specifies. To obtain the description of the columns of the result table of a prepared SELECT statement, the number of occurrences of SQLVAR must be at least equal to the number of columns. Furthermore, if USING BOTH is specified, or if the columns include LOBs or distinct types, the number of occurrences of SQLVAR should be two or three times the number of columns. See “Determining how many SQLVAR occurrences are needed” on page 2304 for more information.

First technique

Allocate an SQLDA with enough occurrences of SQLVAR to accommodate any select list that the application will have to process. At the extreme, the number of SQLVARs could equal three times the maximum number of columns allowed in a result table. After the SQLDA is allocated, the application can use the SQLDA repeatedly.

This technique uses a large amount of storage that is never deallocated, even when most of this storage is not used for a particular select list.

Second technique

Repeat the following two steps for every processed select list:

1. Execute a DESCRIBE statement with an SQLDA that has no occurrences of SQLVAR; that is, an SQLDA for which SQLN is zero.
2. Allocate a new SQLDA with enough occurrences of SQLVAR. Use the values that are returned in SQLD and SQLCODE to determine the number of SQLVAR entries that are needed. The value of SQLD is the number of columns in the result table, which is either the required number of occurrences of SQLVAR or a fraction of the required number (see “Determining how many SQLVAR occurrences are needed” on page 2304 for details). If the SQLCODE is +236, +237, +238, or +239, the number of SQLVAR entries that is needed is two or three times the value

in SQLD, depending on whether USING BOTH was specified. Set SQLN to reflect the number of SQLVAR entries that have been allocated.

3. Execute the DESCRIBE statement again, u

   This technique allows better storage management than the first technique, but it doubles the number of DESCRIBE statements.

   sing the new SQLDA.

Third technique

Allocate an SQLDA that is large enough to handle most (hopefully, all) select lists but is also reasonably small. If an execution of DESCRIBE fails because SQLDA is too small, allocate a larger SQLDA and execute the DESCRIBE statement again.

For the new larger SQLDA, use the values that are returned in SQLD and SQLCODE from the failing DESCRIBE statement to calculate the number of occurrences of SQLVAR that are needed, as described in technique two. Remember to check for SQLCODEs +236, +237, +238, and +239, which indicate whether *extended* SQLVAR entries are needed because the data includes LOBs or distinct types.

This third technique is a compromise between the first two techniques. Its effectiveness depends on a good choice of size for the original SQLDA.

SQLDA contents returned on DESCRIBE:

After a DESCRIBE statement is executed, the following list describes the contents of the SQLDA fields as they are set by Db2 or ignored. These descriptions do not necessarily apply to the uses of an SQLDA in other SQL statements (EXECUTE, OPEN, FETCH). For more on the other uses, see Appendix F, "SQL descriptor area (SQLDA)," on page 2301.

SQLDAID

Db2 sets the first 6 bytes to 'SQLDA ' (5 letters followed by the space character) and the eighth byte to a space character. The seventh byte is set to indicate the number of SQLVAR entries that are needed to describe each column of the result table as follows:

space

The value of space occurs when:

- USING BOTH was not specified and the columns being described do not include LOBs or distinct types. Each column only needs one SQLVAR entry. If the SQL standard option is yes, Db2 sets SQLCODE to warning code +236. Otherwise, SQLCODE is zero.
- USING BOTH was specified and the columns being described do not include LOBs or distinct types. Each column needs two SQLVAR entries. Db2 sets SQLD to two times the number of columns of the result table. The second set of SQLVARs is used for the labels.

2

Each column needs two SQLVAR entries. Two entries per column are required when:

- USING BOTH was not specified and the columns being described include LOBs or distinct types or both. Db2 sets the second set of SQLVAR entries with information for the LOBs or distinct types being described.
- USING BOTH was specified and the columns include LOBs but not distinct types. Db2 sets the second set of SQLVAR entries with information for the LOBs and labels for the columns being described.

3

Each column needs three SQLVAR entries. Three entries are required only when USING BOTH is specified and the columns being described include distinct types. The presence of LOB data does not matter. It is the distinct types and not the LOBs that cause the need for three SQLVAR entries per column when labels are also requested. Db2 sets the second set of SQLVAR entries with information for the distinct types (and LOBs, if any) and the third set of SQLVAR entries with the labels of the columns being described.

A REXX SQLDA does not contain this field.

SQLDABC

The length of the SQLDA in bytes. Db2 sets the value to SQLN×44+16.

A REXX SQLDA does not contain this field.

SQLD

If the prepared statement is a query, Db2 sets the value to the number of columns in the object being described. (For languages other than REXX, in the case where USING BOTH was specified and the result table does not include LOBs or distinct types, the value is actually twice the number of columns. For REXX, if USING BOTH is specified, the value is twice the number of columns, regardless of whether the result table include LOBs or distinct types.) Otherwise, if the statement is not a query, Db2 sets the value to 0.

SQLVAR

An array of field description information for the column being described. There are two types of SQLVAR entries—the base SQLVAR and the extended SQLVAR.

If the value of SQLD is 0, or is greater than the value of SQLN, no values are assigned to any occurrences of SQLVAR. If the value of SQLN was set so that there are enough SQLVAR occurrences to describe the specified columns (columns with LOBs or distinct types and a request for labels increase the number of SQLVAR entries that are needed), the values are assigned to the first *n* occurrences of SQLVAR so that the first occurrence of SQLVAR contains a description of the first column, the second occurrence of SQLVAR contains a description of the second column, and so on. This first set of SQLVAR entries are referred to as *base SQLVAR* entries. Each column always has a base SQLVAR entry.

If the DESCRIBE statement included the USING BOTH clause, or the columns being described include LOBs or distinct types, additional SQLVAR entries are needed. These additional SQLVAR entries are referred to as the *extended SQLVAR* entries. There can be up to two sets of extended SQLVAR entries for each column.

For REXX, the SQLVAR is a set of stem variables that begin with *stem*.*n*, instead of a structure. The REXX SQLDA uses only a base SQLVAR. However, REXX uses The way in which Db2 assigns values to the SQLVAR variables is the same as for other languages. That is, the *stem*.1 variables describe the first column in the result table, the *stem*.2 variables describe the second column in the result table, and so on. If USING BOTH is specified, the *stem*+1 variables also describe the first column in the result table, the *stem*.*n*+2 variables also describe the second column in the result table, and so on.

The base SQLVAR:

SQLTYPE

A code that indicates the data type of the column and whether the column can contain null values. For the possible values of SQLTYPE, see "SQLTYPE and SQLLEN" on page 2310.

SQLLEN

A length value depending on the data type of the result columns. SQLLEN is 0 for LOB and XML data types. For the other possible values of SQLLEN, see "SQLTYPE and SQLLEN" on page 2310.

In a REXX SQLDA, for DECIMAL or NUMERIC columns, Db2 sets the SQLPRECISION and SQLSCALE fields instead of the SQLLEN field.

SQLDATA

The CCSID of a string column. For possible values, see "SQLDATA" on page 2313.

In a REXX SQLDA, Db2 sets the SQLCCSID field instead of the SQLDATA field.

SQLIND

Reserved.

SQLNAME

The unqualified name or label of the column, depending on the value of USING (NAMES, LABELS, ANY, or BOTH). The field is a string of length 0 if the column does not have a name or label. For more details on unnamed columns, see the discussion of the names of result columns under “select-clause” on page 1007. This value is returned in the encoding scheme specified by the ENCODING bind option for the plan or package that contains the statement.

SQLLONGL
For REXX only, the length attribute of a LOB column. Other languages use SQLLONGLEN in the extended SQLVAR.

SQLCCSID
For REXX only, the length attribute of a LOB column.

SQLTNAME
For REXX only, the fully qualified distinct type name of the *n*th column in the result table. Other languages use SQLDATATYPE-NAME in the extended SQLVAR.

The extended SQLVAR:

SQLLONGLEN
The length attribute of a BLOB, CLOB, or DBCLOB column.

*****
Reserved.

SQLDATALEN
Not Used.

SQLDATATYPE-NAME
For a distinct type, the fully qualified distinct type name. Otherwise, the value is the fully qualified name of the built-in data type.

For a label, the label for the column.

This value is returned in the encoding scheme specified by the ENCODING bind option for the plan or package that contains this statement.

Performance considerations:
Although Db2 does not change the value of SQLN, you might want to reset this value after the DESCRIBE statement is executed. If the contents of SQLDA from the DESCRIBE statement is used in a later FETCH statement, set SQLN to *n* (where *n* is the number of columns of the result table) before executing the FETCH statement. For details, see Preparing the SQLDA for data retrieval

Preparing the SQLDA for data retrievals

This note is relevant if you are applying DESCRIBE to a prepared query and you intend to use the SQLDA in the FETCH statements you employ to retrieve the result table rows. To prepare the SQLDA for that task, you must set the SQLDATA field of SQLVAR. SQLIND must be set if SQLTYPE is odd, and SQLNAME must be set when overriding the CCSID. For the meaning of those fields in that context, see Appendix F, “SQL descriptor area (SQLDA),” on page 2301.

Also, SQLN and SQLDABC should be reset (if necessary) to *n* and *n*×44+16, where *n* is the number of columns in the result table. Doing so can improve performance when the rows of the result table are fetched.

Support for extended dynamic SQL in a distributed environment:

In a distributed environment where Db2 for z/OS is the server and the requester supports extended dynamic SQL, such as Db2 server for VSE and VM, a DESCRIBE statement that is executed against an SQL statement in the extended dynamic package appears to Db2 as a DESCRIBE statement against a static SQL statement in the Db2 package. A DESCRIBE statement cannot normally be issued against a static SQL statement. However, a DESCRIBE against a static SQL statement that is generated by extended dynamic SQL executes without error if the package has been rebound after field DESCRIBE FOR STATIC on installation panel DSNTIP4 has been set to YES.

YES indicates that Db2 generates an SQLDA for the DESCRIBE at bind time so that DESCRIBE requests for static SQL statements can be satisfied at execution time. For more information, see DESCRIBE FOR STATIC field (DESCSTAT subsystem parameter) (Db2 Installation and Migration).

Avoiding double preparation when using REOPT(ALWAYS) or REOPT(ONCE):

If bind option REOPT(ALWAYS) or REOPT(ONCE) is in effect, DESCRIBE causes the statement to be prepared if it is not already prepared. If issued before an OPEN or an EXECUTE, the DESCRIBE causes the statement to be prepared without input variables. If the statement has input variables, the statement must be prepared again when it is opened or executed. When REOPT(ONCE) is in effect, the statement is always prepared twice even if there are no input variables. Therefore, to avoid preparing statements twice, issue the DESCRIBE after the OPEN. For non-cursor statements, open and fetch processing are performed on the EXECUTE. So, if a DESCRIBE must be issued, the statement will be prepared twice.

The use of a prepared statement for an EXPLAIN statement can cause duplicate entries in the explain tables when the prepared statement specifies the REOPT(ALWAYS) bind option and is executed using the jcc driver.

Errors occurring on DESCRIBE:

In local and remote processing, the DEFER(PREPARE) and REOPT(ALWAYS)/REOPT(ONCE) bind options can cause some errors that are normally issued during PREPARE processing to be issued on DESCRIBE.

Considerations for implicitly hidden columns:

A DESCRIBED OUTPUT statement only returns information about implicitly hidden columns if the column (of a base table that is defined as implicitly hidden) is explicitly specified as part of the SELECT list of the final result table of the query described. If implicitly hidden columns are not part of the result table of a query, a DESCRIBE OUTPUT statement that returns information about that query will not contain information about any implicitly hidden columns.

Using host variables:

If the DESCRIBE statement contains host variables, the contents of the host variables are assumed to be in the encoding scheme that was specified in the ENCODING parameter when the package or plan that contains the statement was bound.

Considerations for array elements:

CCSID UNICODE is returned for a result column that corresponds to a reference to an array element with a datetime data type.

Example for DESCRIBE OUTPUT

In a PL/I program, execute a DESCRIBE statement with an SQLDA that has no occurrences of SQLVAR. If SQLD is greater than zero, use the value to allocate an SQLDA with the necessary number of occurrences of SQLVAR and then execute a DESCRIBE statement using that SQLDA.

```
EXEC SQL  BEGIN DECLARE SECTION;
  DCL  STMT1_STR   CHAR(200)  VARYING;
EXEC SQL  END DECLARE SECTION;
EXEC SQL  INCLUDE SQLDA;
EXEC SQL  DECLARE DYN_CURSOR CURSOR FOR STMT1_NAME;
… /* code to prompt user for a query, then to generate */
    /* a select-statement in the STMT1_STR            */
EXEC SQL  PREPARE STMT1_NAME FROM :STMT1_STR;
… /* code to set SQLN to zero and to allocate the SQLDA */
EXEC SQL  DESCRIBE STMT1_NAME INTO :SQLDA;
… /* code to check that SQLD is greater than zero, to set */
    /* SQLN to SQLD, then to re-allocate the SQLDA          */
EXEC SQL  DESCRIBE STMT1_NAME INTO :SQLDA;
… /* code to prepare for the use of the SQLDA             */
EXEC SQL  OPEN DYN_CURSOR;
… /* loop to fetch rows from result table                 */
EXEC SQL  FETCH DYN_CURSOR USING DESCRIPTOR :SQLDA;
.
.
.
```

DESCRIBE PROCEDURE

The DESCRIBE PROCEDURE statement gets information about the result sets returned by a stored procedure. The information, such as the number of result sets, is put into a descriptor.

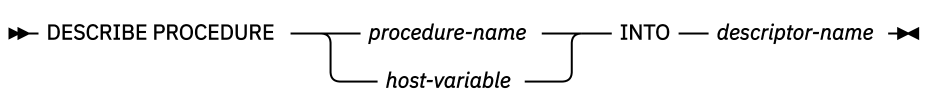
Invocation for DESCRIBE PROCEDURE

This statement can only be embedded in an application program. It is an executable statement that cannot be dynamically prepared.

Authorization for DESCRIBE PROCEDURE

None required.

Syntax for DESCRIBE PROCEDURE



Description for DESCRIBE PROCEDURE

procedure-name* or *host-variable

Identifies the stored procedure that returned one or more result sets. When the DESCRIBE PROCEDURE statement is executed, the procedure name must identify a stored procedure that the requester has already invoked using the SQL CALL statement. The procedure name can be specified as a one, two, or three-part name. The procedure name in the DESCRIBE PROCEDURE statement must be specified the same way that it was specified on the CALL statement. For example, if a two-part procedure name was specified on the CALL statement, you must specify a two-part procedure name in the DESCRIBE PROCEDURE statement.

If a host variable is used:

- It must be a character string variable with a length attribute that is not greater than 254.
- It must not be followed by an indicator variable.
- The value of the host variable is a specification that depends on the database server. Regardless of the server, the specification must:
  - Be left justified within the host variable
  - Not contain embedded blanks
  - Be padded on the right with blanks if its length is less than that of the host variable

Exception: The syntax described above applies to all languages except REXX. For REXX, the syntax is DESCRIBE PROCEDURE *:hostvar*.

INTO *descriptor-name*

Identifies an SQL descriptor area (SQLDA). The information returned in the SQLDA describes the result sets returned by the stored procedure.

Considerations for allocating and initializing the SQLDA are similar to those for DESCRIBE TABLE.

The contents of the SQLDA after executing a DESCRIBE PROCEDURE statement are:

- The first 5 bytes of the SQLDAID field are set to 'SQLPR'.

  A REXX SQLDA does not contain SQLDAID.
- Bytes 6 to 8 of the SQLDAID field are reserved.
- The SQLD field is set to the total number of result sets. A value of 0 in the field indicates there are no result sets.

- There is one SQLVAR entry for each result set.
- The SQLDATA field of each SQLVAR entry is set to the result set locator value associated with the result set.

  For a REXX SQLDA, SQLLOCATOR is set to the result set locator value.
- The SQLIND field of each SQLVAR entry is set to the estimated number of rows in the result set

  For a REXX SQLDA, the SQLIND field is not used for DESCRIBE.
- The SQLNAME field is set to the name of the cursor used by the stored procedure to return the result set. This value is returned in the encoding scheme specified by the ENCODING bind option for the plan or package that contains this statement.

Notes for DESCRIBE PROCEDURE

SQLDA information: A value of -1 in the SQLIND field indicates that an estimated number of rows in the result set is not provided. Db2 for z/OS always sets SQLIND to -1. For a REXX SQLDA, the SQLIND field is not used for DESCRIBE.

DESCRIBE PROCEDURE does not return information about the parameters expected by the stored procedure.

Assignment of locator values: Locator values are assigned to the SQLVAR entries in the SQLDA in the order that the associated cursors are opened at run time. Locator values are not provided for cursors that are closed when control is returned to the invoking application. If a cursor was closed and later re-opened before returning to the invoking application, the most recently executed OPEN CURSOR statement for the cursor is used to determine the order in which the locator values are returned for the procedure result sets. For example, assume procedure P1 opens three cursors A, B, C, closes cursor B and then issues another OPEN CURSOR statement for cursor B before returning to the invoking application. The locator values are assigned in the order A, C, B.

Alternatively, an ASSOCIATE LOCATORS statement can be used to copy the locator values to result set locator variables.

Using host variables: If the DESCRIBE PROCEDURE statement contains host variables, the contents of the host variables are assumed to be in the encoding scheme that was specified in the ENCODING parameter when the package or plan that contains the statement was bound.

Examples for DESCRIBE PROCEDURE

The statements in the following examples are assumed to be in PL/I programs.

Example 1: Place information about the result sets returned by stored procedure P1 into the descriptor named by SQLDA1. Assume that the stored procedure is called with a one-part name from current server SITE2.

```
   EXEC SQL CONNECT TO SITE2;
   EXEC SQL CALL P1;
   EXEC SQL DESCRIBE PROCEDURE P1 INTO :SQLDA1;
```

Example 2: Repeat the scenario in Example 1, but use a two-part name to specify an explicit schema name for the stored procedure to ensure that stored procedure P1 in schema MYSCHEMA is used.

```
   EXEC SQL CONNECT TO SITE2;
   EXEC SQL CALL MYSCHEMA.P1;
   EXEC SQL DESCRIBE PROCEDURE MYSCHEMA.P1 INTO :SQLDA1;
```

Example 3: Place information about the result sets returned by the stored procedure identified by host variable HV1 into the descriptor named by SQLDA2. Assume that host variable HV1 contains the value SITE2.MYSCHEMA.P1 and the stored procedure is called with a three-part name.

```
   EXEC SQL CALL SITE2.MYSCHEMA.P1;
   EXEC SQL DESCRIBE PROCEDURE :HV1 INTO :SQLDA2;
```

The preceding example would be invalid if host variable HV1 had contained the value MYSCHEMA.P1, a two-part name. For the example to be valid with that two-part name in host variable HV1, the current server must be the same as the location name that is specified on the CALL statement as the following statements demonstrate. This is the only condition under which the names do not have to be specified the same way and a three-part name on the CALL statement can be used with a two-part name on the DESCRIBE PROCEDURES statement.

```
   EXEC SQL CONNECT TO SITE2;
   EXEC SQL CALL SITE2.MYSCHEMA.P1;
   EXEC SQL ASSOCIATE LOCATORS (:LOC1, :LOC2)
            WITH PROCEDURE :HV1;
```

DESCRIBE TABLE

The DESCRIBE TABLE statement obtains information about a designated table or view.

Invocation for DESCRIBE TABLE

This statement can only be embedded in an application program. It is an executable statement that cannot be dynamically prepared. It must not be specified in Java.

Authorization for DESCRIBE TABLE

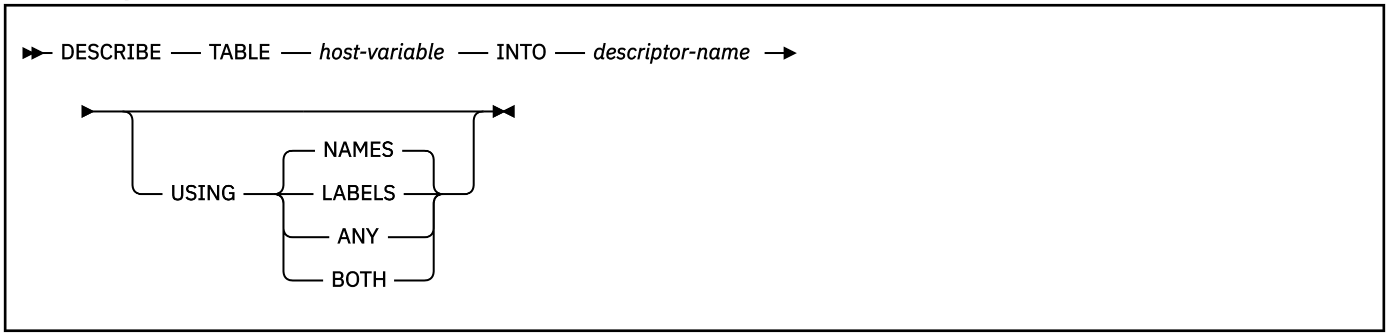
The privileges that are held by the authorization ID that owns the plan or package must include at least one of the following (if there is a plan, authorization checking is done only against the plan owner):

- Ownership of the table or view
- The SELECT, INSERT, UPDATE, DELETE, or REFERENCES privilege on the object
- The ALTER or INDEX privilege on the object (tables only)
- DBADM authority over the database that contains the object (tables only)
- SYSADM authority
- SYSCTRL authority (catalog tables only)
- ACCESSCTRL authority (catalog tables only)
- System DBADM
- DATAACCESS authority
- EXPLAIN authority
- SQLADM authority

If the database is implicitly created, the database privileges must be on the implicit database or on DSNDB04.

For an RRSAF application that does not have a plan and in which the requester and the server are Db2 for z/OS systems, authorization to execute the package is performed against the primary or secondary authorization ID of the process.

Syntax for DESCRIBE TABLE



Description for DESCRIBE TABLE

TABLE *host-variable*

Identifies the table or view. The name must not identify an auxiliary table. When the DESCRIBE statement is executed, the host variable must contain a name which identifies a table or view that exists at the current server. This variable must be a fixed-length or varying-length character string with a length attribute less than 256. The name must be followed by one or more blanks if the length of the name is less than the length of the variable. It cannot contain a period as the first character and it cannot contain embedded blanks. In addition, the quotation mark is the escape character regardless of the value of the string delimiter option. An indicator variable must not be specified for the host variable.

INTO *descriptor-name*

Identifies an SQL descriptor area (SQLDA), which is described in Appendix F, “SQL descriptor area (SQLDA),” on page 2301. See “Identifying an SQLDA in C or C++” on page 2317 for how to represent *descriptor-name* in C.

For languages other than REXX: Before the DESCRIBE statement is executed, the user must set the following variable in the SQLDA and the SQLDA must be allocated.

SQLN

Indicates the number of SQLVAR occurrences provided in the SQLDA. Db2 does not change this value. For techniques to determine the number of required occurrences, see *Allocating the SQLDA*.

For REXX: The SQLDA is not allocated before it is used. An SQLDA consists of a set of stem variables. There is one occurrence of variable *stem.*SQLD, followed by zero or more occurrences of a set of variables that is equivalent to an SQLVAR structure. Those variables begin with *stem.n*.

After the DESCRIBE statement is executed, all the fields in the SQLDA except SQLN are either set by Db2 or ignored. For information on the contents of the fields, see *The SQLDA contents returned after DESCRIBE*.

USING

Indicates what value to assign to each SQLNAME variable in the SQLDA. If the requested value does not exist, SQLNAME is set to a length of 0.

NAMES

Assigns the name of the column. This is the default.

LABELS

Assigns the label of the column. (Column labels are defined by the LABEL statement.)

ANY

Assigns the label of the column. If the column has no label or the label is a string of length 0, the column name is used instead.

BOTH

Assigns both the label and name of the column. In this case, two or three occurrences of SQLVAR per column, depending on whether the result set contains distinct types, are needed to accommodate the additional information. To specify this expansion of the SQLVAR array, set SQLN to 2x*n* or 3x*n*, where *n* is the number of columns in the object being described. For each of the columns, the first *n* occurrences of SQLVAR, which are the base SQLVAR entries, contain the column names. Either the second or third *n* occurrences of SQLVAR, which are the extended SQLVAR entries, contain the column labels. If there are no distinct types, the labels are returned in the second set of SQLVAR entries. Otherwise, the labels are returned in the third set of SQLVAR entries.

For a declared temporary table, the name of the column is assigned regardless of the value specified in the USING clause because declared temporary tables cannot have labels.

Notes for DESCRIBE TABLE

Allocating the SQLDA:

Before the DESCRIBE or PREPARE INTO statement is executed, the value of SQLN must be set to a value greater than or equal to zero to indicate how many occurrences of SQLVAR are provided in the SQLDA. Also, enough storage must be allocated to contain the number of occurrences that SQLN specifies. To obtain the description of the columns of the result table of a prepared SELECT statement, the number of occurrences of SQLVAR must be at least equal to the number of columns. Furthermore, if USING BOTH is specified, or if the columns include LOBs or distinct types, the number of occurrences of SQLVAR should be two or three times the number of columns. See “Determining how many SQLVAR occurrences are needed” on page 2304 for more information.

First technique

Allocate an SQLDA with enough occurrences of SQLVAR to accommodate any select list that the application will have to process. At the extreme, the number of SQLVARs could equal three times the maximum number of columns allowed in a result table. After the SQLDA is allocated, the application can use the SQLDA repeatedly.

This technique uses a large amount of storage that is never deallocated, even when most of this storage is not used for a particular select list.

Second technique

Repeat the following two steps for every processed select list:

1. Execute a DESCRIBE statement with an SQLDA that has no occurrences of SQLVAR; that is, an SQLDA for which SQLN is zero.
2. Allocate a new SQLDA with enough occurrences of SQLVAR. Use the values that are returned in SQLD and SQLCODE to determine the number of SQLVAR entries that are needed. The value of SQLD is the number of columns in the result table, which is either the required number of occurrences of SQLVAR or a fraction of the required number (see “Determining how many SQLVAR occurrences are needed” on page 2304 for details). If the SQLCODE is +236, +237, +238, or +239, the number of SQLVAR entries that is needed is two or three times the value in SQLD, depending on whether USING BOTH was specified. Set SQLN to reflect the number of SQLVAR entries that have been allocated.
3. Execute the DESCRIBE statement again, u

   This technique allows better storage management than the first technique, but it doubles the number of DESCRIBE statements.

   sing the new SQLDA.

Third technique

Allocate an SQLDA that is large enough to handle most (hopefully, all) select lists but is also reasonably small. If an execution of DESCRIBE fails because SQLDA is too small, allocate a larger SQLDA and execute the DESCRIBE statement again.

For the new larger SQLDA, use the values that are returned in SQLD and SQLCODE from the failing DESCRIBE statement to calculate the number of occurrences of SQLVAR that are needed, as described in technique two. Remember to check for SQLCODEs +236, +237, +238, and +239, which indicate whether *extended* SQLVAR entries are needed because the data includes LOBs or distinct types.

This third technique is a compromise between the first two techniques. Its effectiveness depends on a good choice of size for the original SQLDA.

SQLDA contents returned on DESCRIBE:

After a DESCRIBE statement is executed, the following list describes the contents of the SQLDA fields as they are set by Db2 or ignored. These descriptions do not necessarily apply to the uses of an SQLDA in other SQL statements (EXECUTE, OPEN, FETCH). For more on the other uses, see Appendix F, "SQL descriptor area (SQLDA)," on page 2301.

SQLDAID

Db2 sets the first 6 bytes to 'SQLDA ' (5 letters followed by the space character) and the eighth byte to a space character. The seventh byte is set to indicate the number of SQLVAR entries that are needed to describe each column of the result table as follows:

space

The value of space occurs when:

- USING BOTH was not specified and the columns being described do not include LOBs or distinct types. Each column only needs one SQLVAR entry. If the SQL standard option is yes, Db2 sets SQLCODE to warning code +236. Otherwise, SQLCODE is zero.
- USING BOTH was specified and the columns being described do not include LOBs or distinct types. Each column needs two SQLVAR entries. Db2 sets SQLD to two times the number of columns of the result table. The second set of SQLVARs is used for the labels.

2

Each column needs two SQLVAR entries. Two entries per column are required when:

- USING BOTH was not specified and the columns being described include LOBs or distinct types or both. Db2 sets the second set of SQLVAR entries with information for the LOBs or distinct types being described.
- USING BOTH was specified and the columns include LOBs but not distinct types. Db2 sets the second set of SQLVAR entries with information for the LOBs and labels for the columns being described.

3

Each column needs three SQLVAR entries. Three entries are required only when USING BOTH is specified and the columns being described include distinct types. The presence of LOB data does not matter. It is the distinct types and not the LOBs that cause the need for three SQLVAR entries per column when labels are also requested. Db2 sets the second set of SQLVAR entries with information for the distinct types (and LOBs, if any) and the third set of SQLVAR entries with the labels of the columns being described.

A REXX SQLDA does not contain this field.

SQLDABC

The length of the SQLDA in bytes. Db2 sets the value to SQLN×44+16.

A REXX SQLDA does not contain this field.

SQLD

If the prepared statement is a query, Db2 sets the value to the number of columns in the object being described. (For languages other than REXX, in the case where USING BOTH was specified and the result table does not include LOBs or distinct types, the value is actually twice the number of columns. For REXX, if USING BOTH is specified, the value is twice the number of columns, regardless of whether the result table include LOBs or distinct types.) Otherwise, if the statement is not a query, Db2 sets the value to 0.

SQLVAR

An array of field description information for the column being described. There are two types of SQLVAR entries—the base SQLVAR and the extended SQLVAR.

If the value of SQLD is 0, or is greater than the value of SQLN, no values are assigned to any occurrences of SQLVAR. If the value of SQLN was set so that there are enough SQLVAR occurrences to describe the specified columns (columns with LOBs or distinct types and a request for labels increase the number of SQLVAR entries that are needed), the values are assigned to the first *n* occurrences of SQLVAR so that the first occurrence of SQLVAR contains a description of the first column, the second occurrence of SQLVAR contains a description of the second column, and so on. This first set of SQLVAR entries are referred to as *base SQLVAR* entries. Each column always has a base SQLVAR entry.

If the DESCRIBE statement included the USING BOTH clause, or the columns being described include LOBs or distinct types, additional SQLVAR entries are needed. These additional SQLVAR entries are referred to as the *extended SQLVAR* entries. There can be up to two sets of extended SQLVAR entries for each column.

For REXX, the SQLVAR is a set of stem variables that begin with *stem*.*n*, instead of a structure. The REXX SQLDA uses only a base SQLVAR. However, REXX uses The way in which Db2 assigns values to the SQLVAR variables is the same as for other languages. That is, the *stem*.1 variables describe the first column in the result table, the *stem*.2 variables describe the second column in the result table, and so on. If USING BOTH is specified, the *stem*+1 variables also describe the first column in the result table, the *stem*.*n*+2 variables also describe the second column in the result table, and so on.

The base SQLVAR:

SQLTYPE
A code that indicates the data type of the column and whether the column can contain null values. For the possible values of SQLTYPE, see "SQLTYPE and SQLLEN" on page 2310.

SQLLEN
A length value depending on the data type of the result columns. SQLLEN is 0 for LOB and XML data types. For the other possible values of SQLLEN, see "SQLTYPE and SQLLEN" on page 2310.

In a REXX SQLDA, for DECIMAL or NUMERIC columns, Db2 sets the SQLPRECISION and SQLSCALE fields instead of the SQLLEN field.

SQLDATA
The CCSID of a string column. For possible values, see "SQLDATA" on page 2313.

In a REXX SQLDA, Db2 sets the SQLCCSID field instead of the SQLDATA field.

SQLIND
Reserved.

SQLNAME
The unqualified name or label of the column, depending on the value of USING (NAMES, LABELS, ANY, or BOTH). The field is a string of length 0 if the column does not have a name or label. For more details on unnamed columns, see the discussion of the names of result columns under "select-clause" on page 1007. This value is returned in the encoding scheme specified by the ENCODING bind option for the plan or package that contains the statement.

SQLLONGL
For REXX only, the length attribute of a LOB column. Other languages use SQLLONGLEN in the extended SQLVAR.

SQLCCSID
For REXX only, the length attribute of a LOB column.

SQLTNAME
For REXX only, the fully qualified distinct type name of the *n*th column in the result table. Other languages use SQLDATATYPE-NAME in the extended SQLVAR.

The extended SQLVAR:

SQLLONGLEN
The length attribute of a BLOB, CLOB, or DBCLOB column.

*****
Reserved.

SQLDATALEN
Not Used.

SQLDATATYPE-NAME
For a distinct type, the fully qualified distinct type name. Otherwise, the value is the fully qualified name of the built-in data type.

For a label, the label for the column.

This value is returned in the encoding scheme specified by the ENCODING bind option for the plan or package that contains this statement.

Performance considerations:
Although Db2 does not change the value of SQLN, you might want to reset this value after the DESCRIBE statement is executed. If the contents of SQLDA from the DESCRIBE statement is used in a later FETCH statement, set SQLN to *n* (where *n* is the number of columns of the result table) before executing the FETCH statement. For details, see Preparing the SQLDA for data retrieval

Using host variables:
If the DESCRIBE statement contains host variables, the contents of the host variables are assumed to be in the encoding scheme that was specified in the ENCODING parameter when the package or plan that contains the statement was bound.

Considerations for implicitly hidden columns:
A DESCRIBE TABLE statement does return information about implicitly hidden columns in tables.

DROP

The DROP statement removes an object at the current server. Except for storage groups, any objects that are directly or indirectly dependent on that object are also removed. Whenever an object is dropped, its description is deleted from the catalog at the current server, and any packages that refer to the object are invalidated.

Invocation for DROP

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES RUN behavior is in effect. For more information, see "Authorization IDs and dynamic SQL" on page 94.

Authorization for DROP

To drop the following objects, the privilege set must include at least one of the listed authorities or privileges:

Table, table space, or index:

- Ownership of the object (for an index, the owner is the owner of the table or index)
- DBADM authority
- SYSADM or SYSCTRL authority
- System DBADM
- Installation SYSOPR authority (when the current SQLID of the process is set to SYSINSTL)

If the table space is in a database that is implicitly created, the database privileges must be on the implicit database or on DSNDB04.

Database:

- The DROP privilege on the database
- DBADM or DBCTRL authority for the database
- SYSADM or SYSCTRL authority
- System DBADM

- Installation SYSOPR authority (when the current SQLID of the process is set to SYSINSTL)

If the database is implicitly created, the privileges must be on the implicit database or on DSNDB04.

Storage group:

- Ownership of the object
- SYSADM or SYSCTRL authority
- Installation SYSOPR authority (when the current SQLID of the process is set to SYSINSTL)

View:

- Ownership of the object
- SYSADM or SYSCTRL authority
- System DBADM authority

Alias for a table or view:

- Ownership of the object
- SYSADM or SYSCTRL authority
- System DBADM

Alias for a sequence:

- Ownership of the object
- The DROPIN privilege on the schema
- SYSADM or SYSCTRL authority
- System DBADM

Package:

- Ownership of the package
- The BINDAGENT privilege granted from the package owner
- PACKADM authority for the collection or for all collections
- SYSADM or SYSCTRL authority

Synonym:

Ownership of the synonym

Role or trusted context:

- Ownership of the object
- SYSADM or SYSCTRL authority
- SECADM

If the installation parameter SEPARATE SECURITY is NO, SYSADM authority has implicit SECADM and SYSCTRL authority and can drop a role or trusted context.

Row permission or column mask:

At least SECADM authority

User-defined type, global variable, sequence, stored procedure, trigger, or user-defined function:

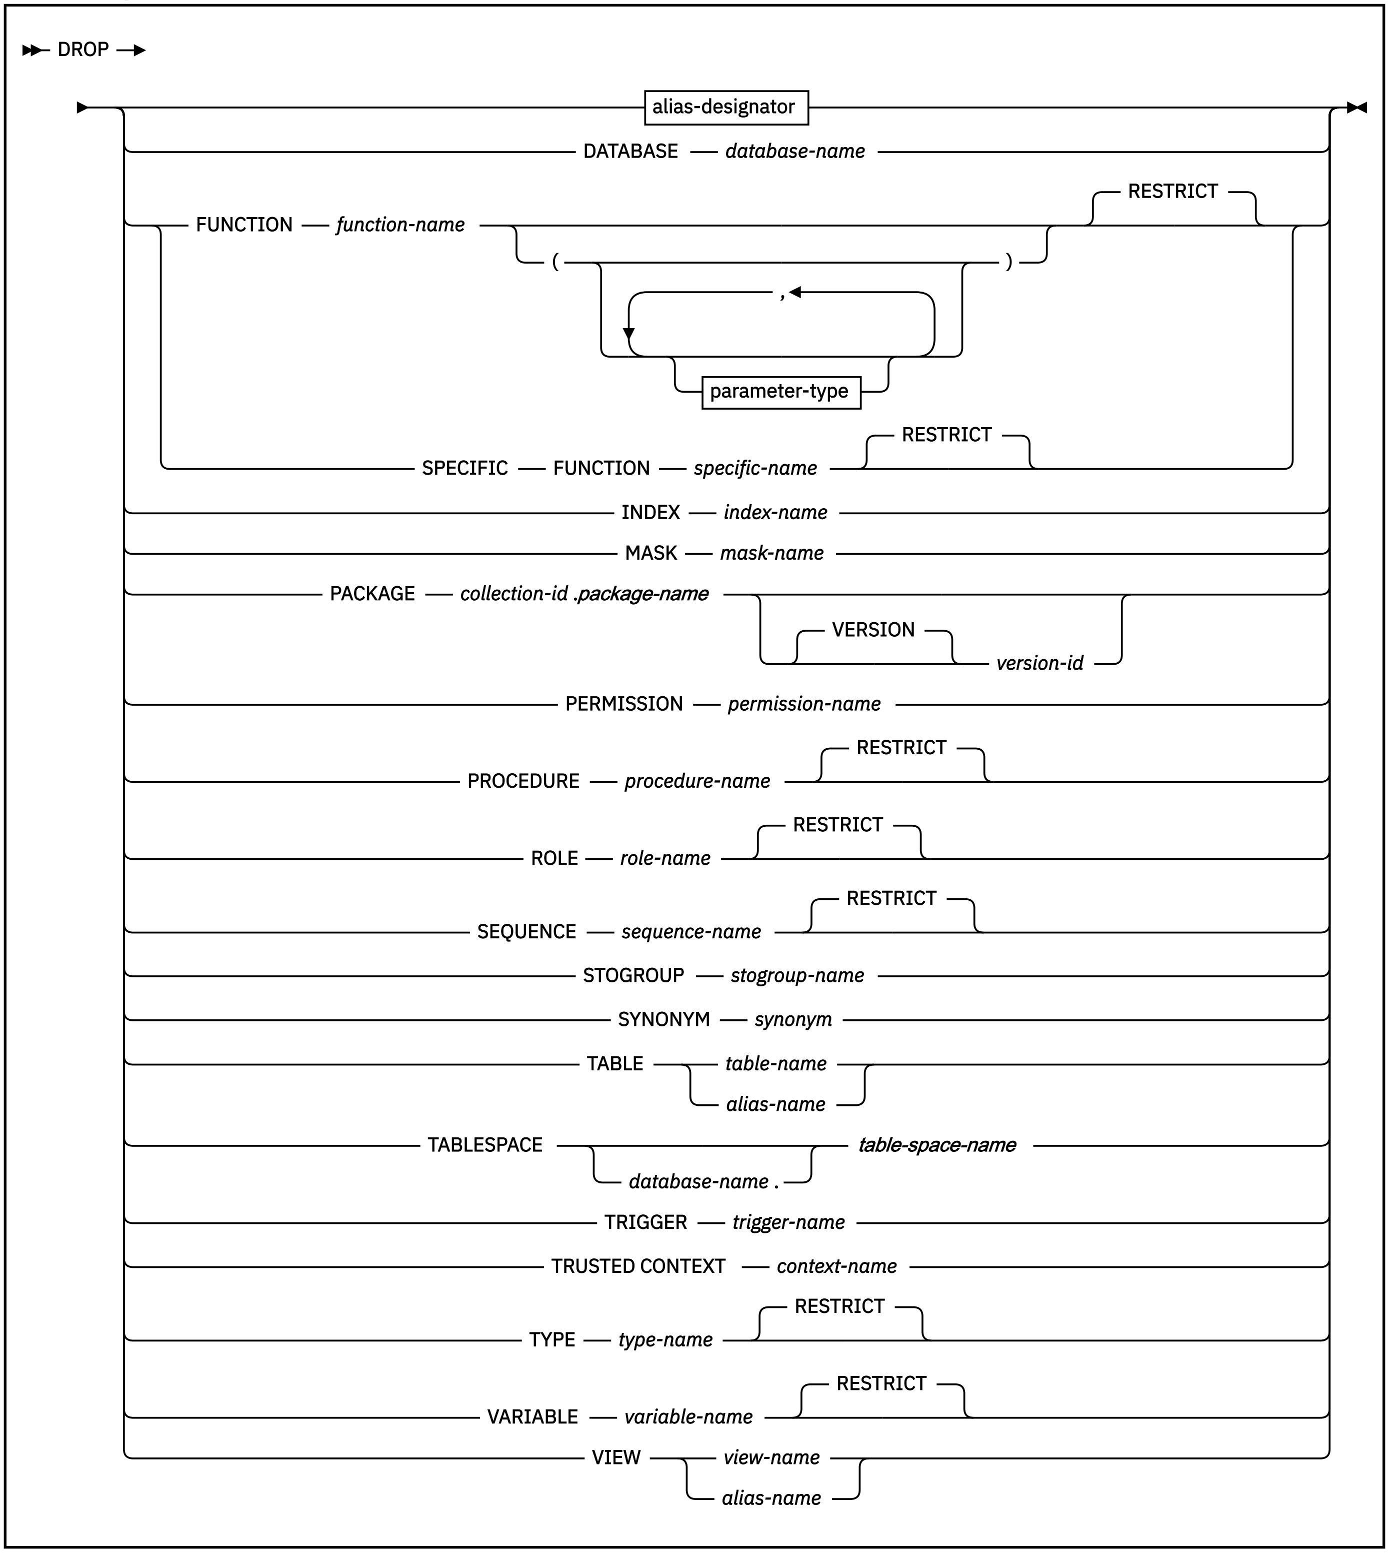
- Ownership of the object [34]
- The DROPIN privilege on the schema
- SYSADM or SYSCTRL authority
- System DBADM
- Installation SYSOPR authority (when the current SQLID of the process is set to SYSINSTL)

[34] Not applicable for stored procedures defined in releases of Db2 for z/OS prior to Version 6.

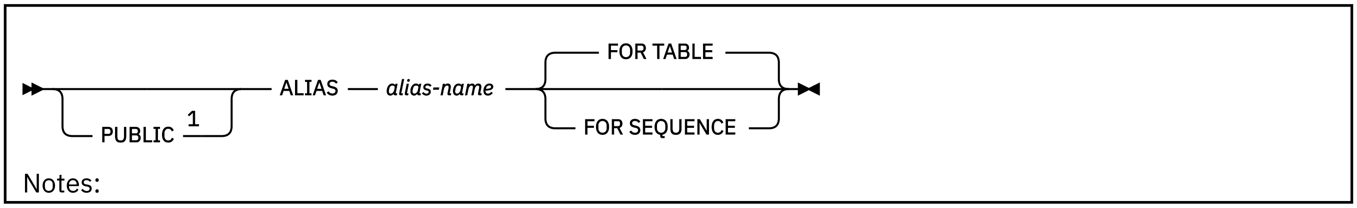
The authorization ID that matches the schema name implicitly has the DROPIN privilege on the schema.

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the statement is dynamically prepared, the privilege set is the union of the privilege sets that are held by each authorization ID of the process. If running in a trusted context with a role, the privilege set also includes those privileges that are held by the role that is associated with the primary authorization ID. However, the implicit schema match does not apply to the role when determining if DROPIN schema privilege is held.

Syntax for DROP



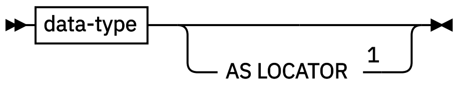
alias-designator:



Notes:

[1] If PUBLIC is specified, FOR SEQUENCE must also be specified.

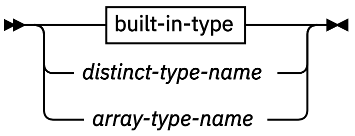
parameter type:



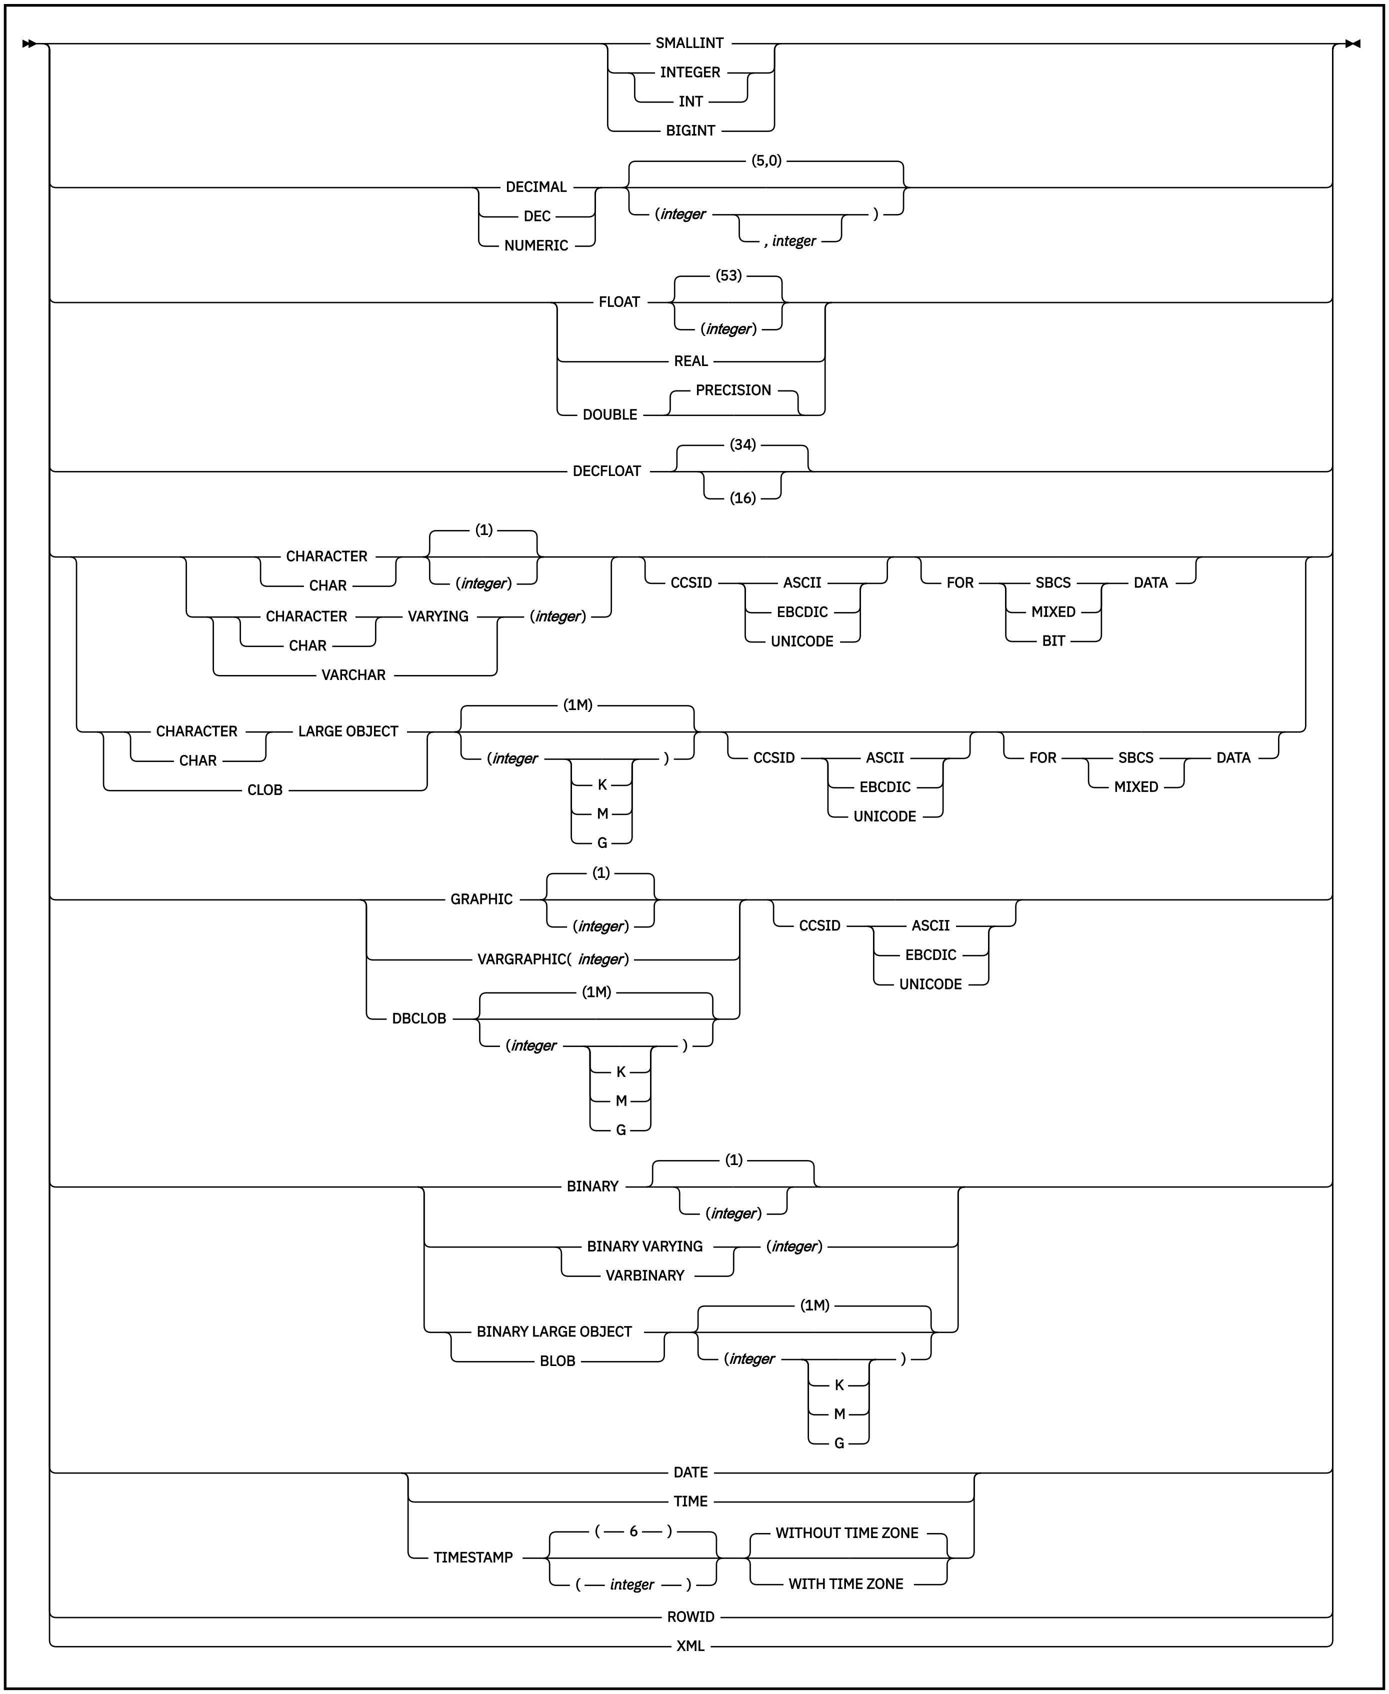
Notes:

[1] AS LOCATOR can be specified only for a LOB data type or a distinct type based on a LOB data type.

data type:



built-in-type:



Description for DROP

alias-designator

PUBLIC

Specifies that the alias to be dropped is a public alias. The *alias-name* must identify an alias that exists in the SYSPUBLIC schema.

If the PUBLIC keyword is specified, *alias-name* must identify a public alias that exists at the current server.

ALIAS alias-name

Identifies the alias to be dropped. The *alias-name* must identify an alias that exists at the current server.

Dropping an alias for a table or view has no effect on any view, materialized query table, or synonym that was defined using the alias. If the alias is referenced in the definition of a row permission or a column mask, it cannot be dropped.

Dropping an alias for a sequence has no effect on any view or materialized query table that was defined using the alias. If the alias is referenced in the definition of an inline SQL function, it cannot be dropped. When an alias for a sequence is dropped, all packages that refer to the sequence alias are invalidated.

If the alias is referenced in the definition of a row permission or a column mask, the alias cannot be dropped.

FOR TABLE

Specifies that the alias to be dropped is for a table or view. Dropping an alias for a table has no effect on any view, materialized query table, or synonym that was defined using the alias.

FOR SEQUENCE

Specifies that the alias to be dropped is for a sequence. Dropping an alias for a sequence has no effect on any view, or materialized query table that was defined using the alias.

DATABASE *database-name*

Identifies the database to drop. The name must identify a database that exists at the current server. DSNDB04 or DSNDB06 must not be specified. The privilege set must include SYSADM authority.

Whenever a database is dropped, all of its table spaces, tables, index spaces, and indexes are also dropped. Any pending changes to the definitions of the table spaces and indexes in the database are also dropped.

You can drop a database that contains a history table only if the database also contains the associated system-period temporal table. You can drop a database that contains a system-period temporal table when the associated history table is in another database. In this case, the action cascades to drop the history table in the other database.

You can drop a database that contains an archive table only if the database also contains the associated archive-enabled table. You can drop a database that contains an archive-enabled table when the associated archive table is contained in another database. In this case, the action cascades to drop the archive table in the other database.

The database cannot be dropped if it is associated with an accelerator-only table.

FUNCTION or SPECIFIC FUNCTION

Identifies the function to drop. The function must exist at the current server, and it must have been defined with the CREATE FUNCTION statement. The particular function can be identified by its name, function signature, or specific name. The specified function definition is dropped from the schema.

Functions that are implicitly generated by the CREATE TYPE statement cannot be dropped using the DROP statement. They are implicitly dropped when the distinct type is dropped.

As indicated by the default keyword RESTRICT, the function is not dropped if any of the following dependencies exist:

- Another function is sourced on the function.
- A view uses the function.
- A trigger package uses the function.

- The definition of a materialized query table uses the function.
- The definition of a row permission or a column mask uses the function.

When a function is dropped, all privileges on the function are also dropped. Any packages that are dependent on the function dropped are made inoperative. All package copies are also marked as VALID='NO'. If the function is a compiled SQL scalar function, the package associated with the function is also dropped.

All versions of a compiled SQL scalar function are dropped. To drop a specific version of a compiled SQL scalar function, use an "ALTER FUNCTION (compiled SQL scalar)" on page 1108 statement with the DROP VERSION clause.

FUNCTION *function-name*
Identifies the function by its name. The *function-name* must identify exactly one function. The function can have any number of parameters defined for it. If there is more than one function of the specified name in the specified or implicit schema, an error is returned.

FUNCTION *function-name (parameter-type,...)*
Identifies the function by its function signature, which uniquely identifies the function. The *function-name (parameter-type, ...)* must identify a function with the specified function signature. The specified parameters must match the data types in the corresponding position that were specified when the function was created. The number of data types, and the logical concatenation of the data types is used to identify the specific function instance which is to be dropped. Synonyms for data types are considered a match.

If the function was defined with a table parameter (the LIKE TABLE *name* AS LOCATOR clause was specified in the CREATE FUNCTION statement to indicate that one of the input parameters is a transition table), the function signature cannot be used to uniquely identify the function. Instead, use one of the other syntax variations to identify the function with its function name, if unique, or its specific name.

If *function-name ()* is specified, the function identified must have zero parameters.

function-name
Identifies the name of the function.

(parameter-type,...)
Identifies the parameters of the function.

If an unqualified distinct type name is specified, Db2 searches the SQL path to resolve the schema name for the distinct type.

For data types that have a length, precision, or scale attribute, use one of the following:

- Empty parentheses indicate that the database manager ignores the attribute when determining whether the data types match. For example, DEC() will be considered a match for a parameter of a function defined with a data type of DEC(7,2). Similarly DECFLOAT() will be considered a match for DECFLOAT(16) or DECFLOAT(34). However, FLOAT cannot be specified with empty parenthesis because its parameter value indicates a specific data type (REAL or DOUBLE).
- If a specific value for a length, precision, or scale attribute is specified, the value must exactly match the value that was specified (implicitly or explicitly) in the CREATE FUNCTION statement. If the data type is FLOAT, the precision does not have to exactly match the value that was specified because matching is based on the data type (REAL or DOUBLE).
- If length, precision, or scale is not explicitly specified, and empty parentheses are not specified, the default attributes of the data type are implied. The implicit length must exactly match the value that was specified (implicitly or explicitly) in the CREATE FUNCTION statement.

For data types with a subtype or encoding scheme attribute, specifying the FOR *subtype* DATA clause or the CCSID clause is optional. Omission of either clause indicates that Db2 ignores the attribute when determining whether the data types match. If you specify either clause, it must match the value that was implicitly or explicitly specified in the CREATE FUNCTION statement.

AS LOCATOR
Specifies that the function is defined to receive a locator for this parameter. If AS LOCATOR is specified, the data type must be a LOB or a distinct type based on a LOB.

SPECIFIC FUNCTION *specific-name*
Identifies the function by its specific name. The *specific-name* must identify a specific function that exists at the current server.

INDEX *index-name*
Identifies the index to drop. The name must identify a user-defined index that exists at the current server but must not identify a populated index on an auxiliary table or an index that was implicitly created for a table that contains an XML column. (For details on dropping user-defined indexes on catalog tables, see "SQL statements allowed on the catalog" on page 2727.) A populated index on an auxiliary table can only be dropped by dropping the base table. The name must not identify an auxiliary table for an object that is involved in a clone relationship.

If the index that is dropped was created by specifying the ENDING AT clause to define partition boundaries, the table is converted to use table-controlled partitioning. The high limit key for the last partition is set to the highest possible value for ascending key columns or the lowest possible value for descending key columns.

Whenever an index is directly or indirectly dropped, its index space is also dropped. The name of a dropped index space cannot be reused until a commit operation is performed. Any pending changes to the definitions of the index is also dropped.

If the index is a unique index used to enforce a unique constraint (primary or unique key), the unique constraint must be dropped before the index can be dropped. In addition, if a unique constraint supports a referential constraint, the index cannot be dropped unless the referential constraint is dropped.

However, a unique index (for a unique key only) can be dropped without first dropping the unique key constraint if the unique key was created in a release of Db2 before Version 7 and if the unique key constraint has no associated referential constraints. For information about dropping constraints, see "ALTER TABLE" on page 1227.

If the index is used for the foreign key of a temporal referential constraint, the referential constraint must be dropped before the index can be dropped.

If the table space is explicitly created and a unique index is dropped and that index was defined on a ROWID column that is defined as GENERATED BY DEFAULT, the table can still be used, but rows cannot be inserted into that table.

If the table space is implicitly created, the index cannot be dropped if it is defined on a ROWID column that is defined as GENERATED BY DEFAULT.

If an empty index on an auxiliary table is dropped, the base table is marked incomplete. If the base table space is implicitly created, the index on an auxiliary table cannot be dropped.

Drop index will result in the deletion of rows in the SYSCOLDIST and SYSCOLDISTATS catalog tables if no other indexes on the table have the same column group in their key sequence prefix.

MASK *mask-name*
Identifies the column mask to drop. The name must identify a column mask that exists at the current server.

PACKAGE *collection-id.package-name*
Identifies the package version to drop. The name plus the implicitly or explicitly specified *version-id* must identify a package version that exists at the current server. Omission of the *version-id* is an implicit specification of the null version.

The name must not identify a trigger package or a package that is associated with an SQL routine. A trigger package can only be dropped by dropping the associated trigger or subject table. A package that is associated with a native SQL procedure can only be dropped with an ALTER PROCEDURE statement with a DROP VERSION clause that specifies the particular version that is to be dropped, or with a DROP PROCEDURE statement if it is the only version that is defined for the procedure.

Specify this clause to drop a package that is created as the result of a BIND COPY command used to deploy a version of a native SQL procedure.

If a package has current, previous, and original copies, the DROP statement will drop all copies.

VERSION *version-id*

version-id is the version identifier that was assigned to the package's DBRM when the DBRM was created. If *version-id* is not specified, a null version is used as the version identifier.

Delimit the version identifier when it:

- Is generated by the VERSION(AUTO) precompiler option
- Begins with a digit
- Contains lowercase or mixed-case letters

For more on version identifiers, see the information on preparing an application program for execution in Creating a package version (Db2 Application programming and SQL).

PERMISSION *permission-name*

Identifies the row permission to drop. The name must identify a row permission that exists at the current server. The name must not identify the default row permission that was created implicitly by Db2.

PROCEDURE *procedure-name*

Identifies the stored procedure to drop. The name must identify a stored procedure that was defined with the CREATE PROCEDURE statement at the current server. The specified procedure definition is dropped from the schema. All privileges on the procedure are also dropped, and any packages that are dependent on the procedure are marked invalid. If the procedure is an SQL procedure, the package that is associated with the procedure is also dropped.

As indicated by the default keyword RESTRICT, the procedure is not dropped if any of the following dependencies exist:

- A trigger definition contains a CALL statement that identifies the procedure.
- An SQL routine definition contains a CALL statement that identifies the procedure.

All versions of a native SQL procedure are dropped. To drop a specific version of a native SQL procedure, use an "ALTER PROCEDURE (SQL - native)" on page 1189 statement with the DROP VERSION clause.

Use a DROP PACKAGE statement to drop a package for a version of a native SQL procedure that is created using the BIND COPY command.

ROLE *role-name*

Identifies the role to drop. *role-name* must identify a role that exists at the current server.

When a role is dropped, all privileges and authorities that have been previously granted to that role are revoked. If the role that is dropped is the owner of statements in the dynamic statement cache, the cached statements are invalidated.

The role is not dropped if any REVOKE restrictions are encountered. REVOKE restrictions include the following:

- Restrictions that are encountered when dependent privileges are included when the privileges of a role are revoked.
- The role is the grantor of any privilege or authority that used ACCESSCTRL or SECADM authority to perform the grant.

If RESTRICT is specified, the role is not dropped is any of the following dependencies exist:

- The role is associated with any trusted context or any user in a trusted context.

- The role is associated with a currently running thread.
- The role is the owner of any of the following objects:

Object	Object
Alias	Row permission
Array type	Sequence
Column mask	Storage group
Database	Stored procedure
Distinct type	Table
Global variable	Table space
Index	Trigger
JAR file	Trusted context
Materialized query table	User-defined function
Package	View
Role	

SEQUENCE *sequence-name*
Identifies the sequence to drop. The name must identify an existing sequence at the current server.

sequence-name must not be the name of an internal sequence object that is used by Db2 (including an implicitly generated sequence for a DB2_GENERATED_DOCID_FOR_XML column). Sequences that are generated by the system for identity columns or implicitly created databases cannot be dropped by using the DROP SEQUENCE statement. A sequence object for an identity column is implicitly dropped when the table that contains the identify column is dropped.

The default keyword RESTRICT indicates that the sequence is not dropped if any of the following dependencies exist:

- A trigger that uses the sequence in a NEXT VALUE or PREVIOUS VALUE expression exists.
- An inline SQL function that uses the sequences in a NEXT VALUE or PREVIOUS VALUE expression exists.

Whenever a sequence is dropped, all privileges on the sequence are also dropped, and the packages that refer to the sequence are invalidated. Dropping a sequence, even if the drop process is rolled back, results in the loss of the still-unassigned cache values for the sequence.

STOGROUP *stogroup-name*
Identifies the storage group to drop. The name must identify a storage group that exists at the current server but not a storage group that is used by any table space or index space.

For information on the effect of dropping the default storage group of a database, see Dropping a default storage group.

SYNONYM *synonym*
Identifies the synonym to drop. In a static DROP SYNONYM statement, the name must identify a synonym that is owned by the owner of the plan or package. In a dynamic DROP SYNONYM statement, the name must identify a synonym that is owned by the SQL authorization ID. Thus, using interactive SQL, a user with SYSADM authority can drop any synonym by first setting CURRENT SQLID to the owner of the synonym.

Dropping a synonym invalidates dependent packages and the dynamic statement cache. Dropping a synonym has no effect on any view, materialized query table, or alias that was defined using the synonym.

If the synonym is referenced in the definition of a row permission or a column mask, it cannot be dropped.

TABLE *table-name* or *alias-name*
Identifies the table to drop. The name must identify a table that exists at the current server. It must not identify any of the following types of tables:

- A catalog table
- A directory table
- FL 506 A table in a partitioned (non-UTS) table space
- A table that is implicitly created for an XML column
- A populated auxiliary table

A table in a partitioned (non-UTS) table space can be dropped only by dropping the table space. A populated auxiliary table or a table that is implicitly created for an XML column can be dropped only by dropping the associated base table.

If *alias-name* is specified, the actual table is dropped as if *table-name* were specified. However, the alias is not dropped. It can be dropped by using the DROP ALIAS statement.

When a table is directly or indirectly dropped, the following items are also dropped:

- All privileges on the table
- All referential constraints in which the table is a parent or dependent
- All synonyms, views, and indexes that are defined on the table
- All row permissions (including the default row permission)
- All column masks that are created for the table

FL 506 If the table space for the table is a universal table space, a LOB table space, or implicitly created, it is also dropped. However, if the containing database was implicitly created, it is not dropped. Any pending changes to the definitions of the dropped table space and indexes are also dropped.

For more information, see Dropping an implicitly created database.

When a table is directly or indirectly dropped, all materialized query tables that are defined on the table are also dropped. When a materialized query table is directly or indirectly dropped, the following items are also dropped:

- All privileges on the materialized query table
- All synonyms, views, and indexes that are defined on the materialized query table

Any alias that is defined on the materialized query table is not dropped. Any packages that are dependent on the dropped materialized query table are marked invalid.

You cannot use DROP TABLE to drop a clone table. You must use the ALTER TABLE statement with the DROP CLONE clause to drop a clone table. If a base table that is involved in a clone relationship is dropped, the associated clone table is also dropped. You cannot drop an auxiliary table for an object that is involved in a clone relationship.

The table cannot be dropped if it is defined as a history table for a system-period temporal table.

The table cannot be dropped if it is referenced in the definition of a row permission or a column mask.

To drop a system-period temporal table, the privilege set must also contain the authorization that is required to drop the history table. The history table is dropped when a system-period temporal table is dropped.

If a table with LOB columns is dropped, the auxiliary tables that are associated with the table and the indexes on the auxiliary tables are also dropped. FL 506 Db2 also drops the LOB table spaces that contain the auxiliary tables, regardless of whether the LOB table spaces were implicitly or explicitly created.

If a table with XML columns is dropped, all implicitly created objects for all XML columns are also dropped.

If an empty auxiliary table is dropped, the definition of the base table is marked incomplete. If the base table space is implicitly created, the auxiliary table cannot be dropped.

If the table has a security label column, the primary authorization ID of the DROP statement must have a valid security label, and the RACF SECLABEL class must be active.

If a table that uses hash organization is dropped, all catalog entries for the hash organization are cleaned up.

If an archive-enabled table is dropped, the archive table and any indexes that are defined on the archive table are also dropped. To drop an archive-enabled table, the privilege set must also contain the authorization that is required to drop the archive table. An archive table cannot be explicitly dropped by using the DROP statement.

TABLESPACE *database-name.table-space-name*

Identifies the table space to drop. The name must identify a table space that exists at the current server. The database name must not be DSNDB01 or DSNDB06. Omission of the database name is an implicit specification of DSNDB04. *table-space-name* must not identify a table space that is implicitly created for an XML column.

Whenever a table space is directly or indirectly dropped, all the tables in the table space are also dropped. The name of a dropped table space cannot be reused until a commit operation is performed. Any pending changes to the definitions of the table space and its indexes are also dropped.

A LOB table space can be dropped only if it does not contain an auxiliary table. If the LOB table space is implicitly created, it cannot be dropped.

Whenever a base table space that contains tables with LOB columns is dropped, all the auxiliary tables and indexes on those auxiliary tables that are associated with the base table space are also dropped.

Whenever a base table space that contains tables with XML columns is dropped, all implicitly created objects for all XML columns are also dropped.

The table space cannot be dropped if it contains a history table, an archive table, or is associated with an accelerator-only table.

TRIGGER *trigger-name*

Identifies the trigger to drop. The name must identify a trigger that exists at the current server.

Whenever a trigger is directly or indirectly dropped, all privileges on the trigger are also dropped and the associated trigger package is freed. The name of that trigger package is the same as the trigger name and the collection ID is the schema name.

When an INSTEAD OF trigger is dropped, the associated privilege is revoked from anyone that possesses the privilege as a result of an implicit grant that occurred when the trigger is created.

Dropping triggers causes certain packages to be marked invalid. For example, if *trigger-name* specifies an INSTEAD OF trigger on a view V, another trigger might depend on *trigger-name* through an update to the view V, and that trigger package is invalidated.

If a trigger has current, previous, and original copies, the DROP statement will drop all copies.

For an advanced trigger, all versions of the trigger are dropped. Use an ALTER TRIGGER statement with the DROP VERSION clause to drop a specific version of a trigger.

TRUSTED CONTEXT *context-name*

Identifies the trusted context to drop. The *context-name* must identify a trusted context that exists at the current server. When a trusted context is dropped, all associations to attributes (IP addresses, job names) and associations to users of the trusted context are dropped. If the trusted context is dropped while trusted connections for the context are active, the connections remain active until they terminate or the next attempt at reuse is made.

TYPE *type-name*

Identifies the user-defined type to drop. The name must identify a user-defined type that exists at the current server. The default keyword RESTRICT indicates that the user-defined type is not dropped if any of the following dependencies exist:

- The definition of a column of a table uses the user-defined type.

- The definition of an input or result parameter of a user-defined function uses the user-defined type.
- The definition of a parameter of a stored procedure uses the user-defined type.
- The definition of an extended index uses a cast function that is implicitly generated for the user-defined type.
- The definition of an SQL variable in a procedure or function uses the user-defined type.
- The definition of a row permission or a column mask uses the user-defined type.
- A sequence exists for which the data type of the sequence is the user-defined type.
- One of the following dependencies exists on one of the cast functions that are generated for the user-defined type:
  - Another function is sourced from one of the cast functions
  - A view uses one of the cast functions
  - A trigger package uses one of the cast functions
  - The definition of a materialized query table uses one of the cast functions

Whenever a user-defined type is dropped, all privileges on the distinct type are also dropped. In addition, the cast functions that were generated when the user-defined type was created and the privileges on those cast functions are also dropped.

`VARIABLE` *variable-name*

Identifies the global variable to drop. The name must identify a global variable that exists at the current server. The name must not identify a built-in global variable. The default keyword RESTRICT indicates that the global variable is not dropped if any of the following dependencies exist:

- The definition of a function, trigger, or view is dependent on the global variable

Packages that are dependent on the global variable are marked invalid when the global variable is dropped. If a statement that is in the dynamic statement cache depends on the global variable and the global variable is dropped, the statement in the dynamic statement cache will be invalidated if it is not in use.

`VIEW` *view-name* or *alias-name*

Identifies the view to drop. The name must identify a view that exists at the current server.

Whenever a view is directly or indirectly dropped, all privileges on the view and all synonyms and views that are defined on the view are also dropped. Whenever a view is directly or indirectly dropped, all materialized query tables defined on the view are also dropped.

If *alias-name* is specified, the actual view will be dropped as if *view-name* were specified. However, the alias is not dropped and can be dropped using the DROP ALIAS statement.

If the view is referenced in the definition of a row permission or a column mask, it cannot be dropped.

Notes for DROP

Restrictions on DROP:

DROP is subject to these restrictions:

- DROP DATABASE cannot be performed while a Db2 utility has control of any part of the database.
- DROP INDEX cannot be performed while a Db2 utility has control of the index or its associated table space.
- DROP INDEX cannot be performed if the index is a unique index that is defined on a ROWID column that is defined as GENERATED BY DEFAULT and there are pending changes to the definition of the table space or to any objects within the table space that are explicitly created.
- DROP INDEX cannot be performed if the index is an empty index on an auxiliary table that resides in an explicitly created LOB table space and there are pending changes to the definition of the base table space or to any objects within the base table space.

- DROP INDEX cannot be performed if the index is the hash overflow index for a table that uses hash organization.
- DROP TABLE cannot be performed while a Db2 utility has control of the table space that contains the table.
- DROP TABLE cannot be performed if the table is an empty auxiliary table and there are any pending changes to the definition of the base table space or to any objects within the base table space.
- DROP TABLESPACE cannot be performed while a Db2 utility has control of the table space.

In a data sharing environment, the following restrictions also apply:

- If any member has an active resource limit specification table (RLST) you cannot drop the database or table space that contains the table, the table itself, or any index on the table.
- If the member executing the drop cannot access the Db2-managed data sets, only the catalog and directory entries for those data sets are removed.

Objects that have certain dependencies cannot be dropped. For information on these restrictions, see Table 231 on page 1898.

Recreating objects:
After an index or table space is dropped, a commit must be performed before the object can be re-created with the same name. If a table that was created without an IN clause (thereby causing a table space to be implicitly created) is dropped, a table cannot be re-created with the same name until a commit is performed.

Dropping a parent table:
DROP is not DELETE and therefore does not involve delete rules.

Dropping a default storage group:
If you drop the default storage group of a database, the database no longer has a legitimate default. You must then specify USING in any statement that creates a table space or index in the database. You must do this until you either:

- Create another storage group with the same name using the CREATE STOGROUP statement, or
- Designate another default storage group for the database using the ALTER DATABASE statement.

Dropping an accelerator-only table:

- When an accelerator-only table is dropped and the accelerator is not active, use the SYSACCEL_DROP_TABLE procedure to drop the table in the accelerator.
- A DROP TABLE statement that identifies an accelerator-only table should be issued in a separate unit of work from other SQL statements.

Dropping an implicitly created database:
When a table that resides in an implicitly created table space is dropped, the implicitly created table space and related objects are dropped. However, the implicitly created database is not dropped. This can result in a large number of empty databases in a system. These databases might be eventually reused for newly created implicit table spaces. These implicitly created databases can be dropped using DROP DATABASE.

Dropping a table space or index:
To drop a table space or index, the size of the buffer pool associated with the table space or index must not be zero.

Dropping a LOB table space:

FL 506 When an auxiliary table that resides in a LOB table space is dropped, the LOB table space is automatically dropped. An explicitly created LOB table space can be dropped if it does not contain an auxiliary table.

Dropping a database when data sets for Db2 objects have already been deleted:
When some of the data sets for Db2 objects that associated with the database have already been deleted, DROP DATABASE will perform in the following manner:

For Db2-managed objects:
The DROP DATABASE statement will delete the underlying data sets if they exist. If the data sets do not exist, DROP DATABASE will delete only the catalog entries for those data sets.

For user-managed objects:
The DROP DATABASE statement will delete only the catalog entries for the data sets. The underlying data sets will need to be manually deleted after the DROP DATABASE statement is complete.

Dropping a table space in a work file database:
If one member of a data sharing group drops a table space in a work file database, or an entire work file database, that belongs to another member, Db2-managed data sets that the executing member cannot access are not dropped. However, the catalog and directory entries for those data sets are removed.

Dropping resource limit facility (governor) indexes, tables, and table spaces:
While the RLST is active, you cannot issue a DROP DATABASE, DROP INDEX, DROP TABLE, or DROP TABLESPACE statement for an object associated with an RLST that is active on any member of a data sharing group. See Resource limit facility implications for data sharing (Db2 Data Sharing Planning and Administration) for details.

Dropping a temporary table:
To drop a created temporary table or a declared temporary table, use the DROP TABLE statement.

Dropping a materialized query table:
To drop a materialized query table, use the DROP TABLE statement.

Dropping an alias:
Dropping a table or view does not drop its aliases. However, if you use the DROP TABLE statement and specify an alias for a table or view, the table or view will be dropped. To drop an alias, use the DROP ALIAS statement.

Dropping a table from an implicitly created table space:
If you drop a table from an implicitly created table space, the following related objects are also dropped:

- The enforcing primary and unique key indexes
- Any LOB table spaces, auxiliary tables, and auxiliary indexes
- The ROWID index (if the ROWID column is defined as GENERATED BY DEFAULT)

FL 506 If any LOB columns are defined on the table, the LOB table space is dropped.

Dropping an index on a base table and auxiliary table:
You can explicitly drop an empty index on an auxiliary table with the DROP INDEX statement, unless the base table space is implicitly created. An empty or populated index on an auxiliary table is implicitly dropped when:

- The auxiliary table is empty and it is explicitly dropped (empty indexes only).
- The associated base table for the auxiliary table is dropped.
- The base table space that contains the associated base table is dropped.

You can explicitly drop an empty auxiliary table with the DROP TABLE statement, unless the base table space is implicitly created. An empty or populated auxiliary table is implicitly dropped when:

- The associated base table for the auxiliary table is dropped.
- The base table space that contains the associated base table is dropped.

The following table shows which DROP statements implicitly or explicitly cause an auxiliary table and the index on that table to be dropped, as indicated by the 'D' in the column.

Table 230. Effect of various DROP statements on auxiliary tables and indexes that are in explicitly created table spaces

	Auxiliary table		Index on auxiliary table	
Statement	**Populated**	**Empty**	**Populated**	**Empty**
DROP TABLESPACE (base table space)	D	D	D	D
DROP TABLE (base table)	D	D	D	D
DROP TABLE (auxiliary table)		D		D
DROP INDEX (index on auxiliary table)				D

Note: D indicates that the table or index is dropped.

Dropping a migrated index or table space:
Here, "migration" means migrated by the Hierarchical Storage Manager (DFSMShsm). Db2 does not wait for any recall of the migrated data sets. Hence, recall is not a factor in the time it takes to execute the statement.

Dropping a trusted context:
The drop of a trusted context takes effect after the DROP TRUSTED CONTEXT statement is committed. If the DROP TRUSTED CONTEXT statement results in an error or is rolled back, the trusted context is not dropped.

Avoiding DROP failure due to excessive locking
Dropping a table space, database, or index with the COPY YES attribute deletes all corresponding records in the SYSCOPY and SYSLGRNX catalog statistics tables. The DROP fails if the lock structure size cannot accommodate the number of locks obtained during DROP processing. DROP failure is more likely if the SYSCOPY, SYSLGRNX, or other catalog statistics tables contain many entries, especially if the object you are dropping was created long ago or contains many partitions. DROP failure is also more likely if objects are copied frequently while the MODIFY RECOVERY and MODIFY STATISTICS utilities are run relatively infrequently.

To avoid DROP failure, run the MODIFY RECOVERY and MODIFY STATISTICS utilities on objects before dropping them. If you drop a clone table, you need to specify the CLONE keyword to delete recovery and statistics information for the clone objects from the catalog and directory. You can Specify AGE(*) or DATE(*) to remove all recovery and statistics information regardless of past update, copy, or cleanup frequency. Be aware that running the MODIFY utility with AGE(*) or DATE(*) will leave objects unrecoverable after they are dropped unless you make a copy or other form of back-up first.

Also, ensure that your applications commit drops frequently, especially for databases containing multiple table spaces, and table spaces containing multiple tables. You can also increase the size of your lock structures to accommodate the surge in lock requests during this type of activity.

Invalidation of packages:
This statement might invalidate all packages that depend on target objects, and sometimes other related objects through cascading effects, depending on the clauses and keywords specified and other factors. For more information, see Changes that invalidate packages (Db2 Application programming and SQL).

Dependencies when dropping objects:
If other objects depend on the object specified in a DROP statement, the dependent objects might also be dropped, invalidated, or become inoperative, or the DROP statement might fail. These effects also cascade to any objects that depend on the dropped dependent objects. To determine the full indirect effects of a DROP statement, check what happens for any dependent objects, check whether each dependent object has its own dependent objects, and the check the rules for those object types.

The following table indicates the result of DROP statements based on the type of object specified by the DROP statement and the type of dependent object. The letters have the following meanings:

D (cascaded drop)
If any dependent objects of the indicated types exist, they are also dropped. The effect cascades to any objects that depend on the dropped dependent objects.

R (restrict)
If any dependent objects of the indicated types exist, the DROP statement fails. Also, if any dependent object cannot be dropped because of a restrict dependency for its own dependent objects, the DROP statement fails.

V (invalidate)
If dependent packages exist, they become invalidated.

For example, assume that view B is defined on table A and view C is defined on view B. In the following table, the 'D' in the View column of the DROP TABLE row indicates that view B is dropped when table A is dropped. Next, because view C is dependent on view B, check the View column for DROP VIEW. The 'D' in the column indicates that view C will also be dropped.

Table 231. Effect of dropping objects that have dependencies

	Dependent object type														
DROP statement	**Alias**	**Column mask**	**Function**	**Global variable**	**Index**	**Procedure**	**Row permission**	**Sequence**	**Stogroup**	**Synonym**	**Table**	**Table space**	**Trigger**	**Type**	**View**
DROP ALIAS		R	V			V	R						V		
DROP FUNCTION			R “4” on page 1900			R “12” on page 1900							R		R
DROP INDEX “1” on page 1900			V			V							V		
DROP PROCEDURE			R “12” on page 1900			R “12” on page 1900							R		
DROP ROLE	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 231. Effect of dropping objects that have dependencies (continued)

	Dependent object type														
DROP statement	**Alias**	**Column mask**	**Function**	**Global variable**	**Index**	**Procedure**	**Row permission**	**Sequence**	**Stogroup**	**Synonym**	**Table**	**Table space**	**Trigger**	**Type**	**View**
DROP SEQUENCE			R"8" on page 1900			R "12" on page 1900							R		
DROP STOGROUP					R"5" on page 1900							R"5" on page 1900			
DROP SYNONYM		R													
DROP TABLE "6" on page 1900		R "16" on page 1900	D "14" on page 1900		D	V	R "16" on page 1900			D	D "15" on page 1900		D "7" on page 1900		D
DROP TABLESPACE			V		D	V					D		V		
DROP TRIGGER			V			V							V		
DROP TYPE		R	R "2" on page 1900		R "9" on page 1900	R "3" on page 1900	R	R			R		V"11" on page 1900		
DROP VARIABLE			R			V							R		R
DROP VIEW		R	D "14" on page 1900			V	R			D	D "15" on page 1900		D "10" on page 1900		D

Table notes:

1. The index space associated with the index is dropped.
2. If a function is dependent on the user-defined type being dropped, the user-defined type cannot be dropped unless the function is one of the cast functions that was created for the user-defined type.
3. If the definition of a parameter of a stored procedure uses the user-defined type, the user-defined type cannot be dropped.
4. If other user-defined functions are sourced on the user-defined function being dropped, the function cannot be dropped.
5. A storage group cannot be dropped if it is used by any table space or index space.
6. FL 506 If the table resides in an explicitly created universal table space or any implicitly created table space, the table space is also dropped.
7. When a subject table is dropped, any associated triggers and related trigger packages are also dropped.
8. This restriction is only for SQL functions.
9. The index in this case must be an expression-based index.
10. When a subject view is dropped, any associated triggers and related trigger packages are also dropped.
11. Any packages that have a dependency on an INSTEAD OF trigger will be marked invalid.
12. A routine or sequence that is referenced by a native SQL procedure cannot be dropped.
13. An alias or synonym cannot be dropped if there is a dependent inline SQL table function.
14. When a table or view is dropped, any dependent inline SQL table functions are also dropped.
15. When a table or view is dropped, any dependent materialized query tables are also dropped.
16. When a table is dropped, any row permission or column masks defined directly on the table are also dropped. If any row permissions or column masks reference the table in the body, the table cannot be dropped.

Alternative syntax and synonyms:

To provide compatibility with previous releases of Db2 or other products in the Db2 family, Db2 supports the following keywords:

- DATA TYPE or DISTINCT TYPE as a synonym for TYPE
- PROGRAM as a synonym for PACKAGE
- DROP ALIAS SYSPUBLIC.*name* can be specified as an alternative to DROP PUBLIC ALIAS SYSPUBLIC.*name*

Examples for DROP

Example 1

Drop table DSN8C10.DEPT.

```
DROP TABLE DSN8C10.DEPT;
```

Example 2

Drop table space DSN8S12D in database DSN8D12A.

```
DROP TABLESPACE DSN8D12A.DSN8S12D;
```

Example 3

Drop the view DSN8C10.VPROJRE1:

```
DROP VIEW DSN8C10.VPROJRE1;
```

Example 4

Drop the package DSN8CC0 with the version identifier VERSZZZZ. The package is in the collection DSN8CC61. Use the version identifier to distinguish the package to be dropped from another package with the same name in the same collection.

```
DROP PACKAGE DSN8CC61.DSN8CC0 VERSION VERSZZZZ;
```

Example 5

Drop the package DSN8CC0 with the version identifier "1994-07-14-09.56.30.196952". When a version identifier is generated by the VERSION(AUTO) precompiler option, delimit the version identifier.

```
DROP PACKAGE DSN8CC61.DSN8CC0 VERSION "1994-07-14-09.56.30.196952";
```

Example 6

Drop the distinct type DOCUMENT, if it is not currently in use:

```
DROP TYPE DOCUMENT;
```

Example 7

Assume that you are SMITH and that ATOMIC_WEIGHT is the only function with that name in schema CHEM. Drop ATOMIC_WEIGHT.

```
DROP FUNCTION CHEM.ATOMIC_WEIGHT;
```

Example 8

Assume that you are SMITH and that you created the function CENTER in schema SMITH. Drop CENTER, using the function signature to identify the function instance to be dropped.

```
DROP FUNCTION CENTER(INTEGER, FLOAT);
```

Example 9

Assume that you are SMITH and that you created another function named CENTER, which you gave the specific name FOCUS97, in schema JOHNSON. Drop CENTER, using the specific name to identify the function instance to be dropped.

```
DROP SPECIFIC FUNCTION JOHNSON.FOCUS97;
```

Example 10

Assume that you are SMITH and that stored procedure OSMOSIS is in schema BIOLOGY. Drop OSMOSIS.

```
DROP PROCEDURE BIOLOGY.OSMOSIS;
```

Example 11

Assume that you are SMITH and that trigger BONUS is in your schema. Drop BONUS.

```
DROP TRIGGER BONUS;
```

Example 12

Drop the role CTXROLE:

```
DROP ROLE CTXROLE;
```

Example 13

Drop the trusted context CTX1:

```
DROP TRUSTED CONTEXT CTX1;
```

Example 14

Drop public alias PUBALIAS1:

```
DROP PUBLIC ALIAS PUBALIAS1 FOR SEQUENCE;
```

END DECLARE SECTION

The END DECLARE SECTION statement marks the end of an SQL declare section.

Invocation for END DECLARE SECTION

This statement can only be embedded in an application program. It is not an executable statement. It must not be specified in Java or REXX.

Authorization for END DECLARE SECTION

None required.

Syntax for END DECLARE SECTION

```
▶▶─ END DECLARE SECTION ─▶◀
```

Description for END DECLARE SECTION

The END DECLARE SECTION statement can be coded in the application program wherever declarations can appear in accordance with the rules of the host language. It is used to indicate the end of an SQL declare section. An SQL declare section starts with a BEGIN DECLARE SECTION statement described in "BEGIN DECLARE SECTION" on page 1378.

The following rules are enforced by the precompiler only if the host language is C or the STDSQL(YES) precompiler option is specified:

- A variable referred to in an SQL statement must be declared within an SQL declare section of the source program.
- BEGIN DECLARE SECTION and END DECLARE SECTION statements must be paired and must not be nested.
- SQL declare sections can contain only host variable declarations, SQL INCLUDE statements that include host variable declarations, or DECLARE VARIABLE statements.

Notes for END DECLARE SECTION

SQL declare sections are only required if the STDSQL(YES) option is specified or the host language is C. However, SQL declare sections can be specified for any host language so that the source program can conform to IBM SQL. If SQL declare sections are used, but not required, variables declared outside an SQL declare section should not have the same name as variables declared within an SQL declare section.

Example for END DECLARE SECTION

```
EXEC SQL BEGIN DECLARE SECTION;
 -- host variable declarations
EXEC SQL END DECLARE SECTION;
```

EXCHANGE

The EXCHANGE statement switches the content of a base table and its associated clone table.

Invocation for EXCHANGE

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES RUN behavior is in effect. For more information, see "Authorization IDs and dynamic SQL" on page 94.

Authorization for EXCHANGE

The privilege set that is defined below must include at least one of the following privileges:

- The INSERT and DELETE privileges on both the base table and the clone table
- Ownership of the both the base table and the clone table
- DBADM authority for the database
- SYSADM authority
- DATAACCESS authority

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the statement is dynamically prepared, the privilege set is the union of the privilege sets that are held by each authorization ID of the process.

Syntax for EXCHANGE

```
►►─ EXCHANGE DATA BETWEEN TABLE ── table-name1 ── AND ── table-name2 ─►◄
```

Description for EXCHANGE

table-name1* and *table-name2
Identifies the base table and the associated clone table for which the exchange of data will take place. Either *table-name1* or *table-name2* can identify the base table. The other table name must identify a clone table that is associated with the specified base table. The name of the base table and the name of the clone table remain unchanged after a data exchange.

Notes for EXCHANGE

Committing after EXCHANGE
A commit is required before accessing a table after the EXCHANGE statement and between consecutive data exchanges using the EXCHANGE statement.

Table partitions
Data exchanges cannot be done for a subset of table partitions.

Package rebinds might be needed
You might need to rebind packages that reference the base or clone tables before the applications can pick up the exchanged data. For more information, see Changes that might require package rebinds (Db2 Application programming and SQL).

Example for EXCHANGE

Exchange the data of the EMPLOYEE table and its clone table, EMPCLONE.

```
EXCHANGE DATA BETWEEN TABLE EMPCLONE AND EMPLOYEE;
```

EXECUTE

The EXECUTE statement executes a prepared SQL statement.

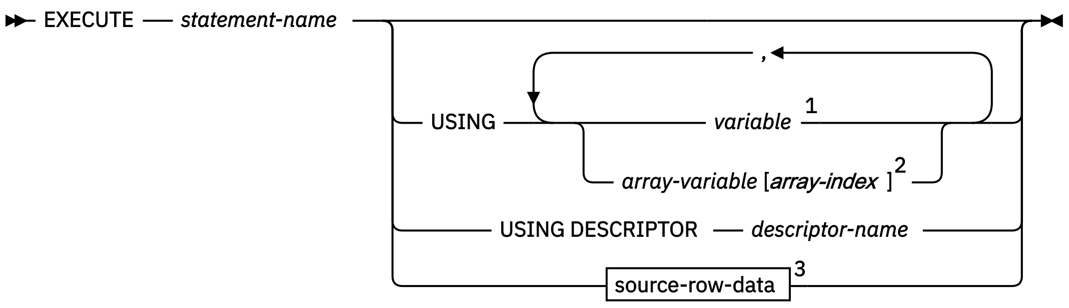
Invocation for EXECUTE

This statement can only be embedded in an application program. It is an executable statement that cannot be dynamically prepared. It must not be specified in Java.

Authorization for EXECUTE

See "PREPARE" on page 2037 for the authorization required to create a prepared statement.

Syntax for EXECUTE



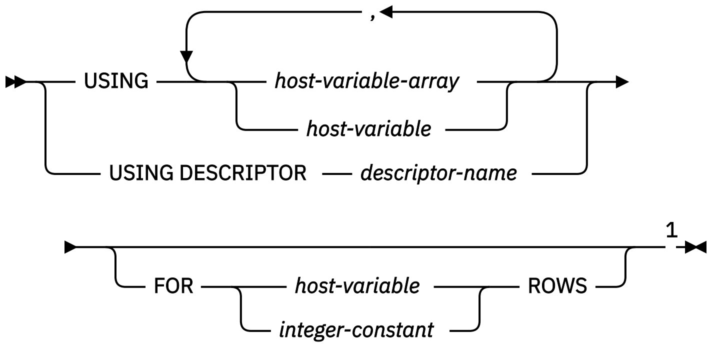
Notes:

[1] A global variable must only be specified in an SQL PL context.

[2] An array element must only be specified in an SQL PL context.

[3] This option can be specified only when *statement-name* refers to a dynamic INSERT or MERGE statement that is prepared with FOR MULTIPLE ROWS and is specified as part of the ATTRIBUTES clause on the PREPARE statement.

source-row-data:



Notes:

[1] The FOR n ROWS clause is required on the EXECUTE statement if it is not specified as part of the MERGE statement and a host-variable array is specified. The FOR n ROWS clause is also required if MERGE is used with multiple rows of source data. For an INSERT statement, the FOR n ROWS clause can only be specified for a dynamic statement that contains only a single multiple-row INSERT statement.

Description for EXECUTE

statement-name

Identifies the prepared statement to be executed. *statement-name* must identify a statement that was previously prepared within the unit of work and the prepared statement must not be a *select-statement*.

USING

Introduces a list of variables or an array element specification, whose values are substituted for the parameter markers (question marks) in the prepared statement. (For an explanation of parameter markers, see "PREPARE" on page 2037.) If the prepared statement includes parameter markers, you must include USING in the EXECUTE statement. USING is ignored if there are no parameter markers.

The *n*th value corresponds to the *n*th parameter marker in the prepared statement. Where appropriate, locator variables and file reference variables can be provided as the source of values for parameter markers.

For more on the substitution of values for parameter markers, see Parameter marker replacement.

variable,...

Identifies a variable or a host structure that is declared in the application program in accordance with the rules for declaring variables and host structures. When the statement is executed, a reference to a structure is replaced by a reference to each of its variables. The number of variables must be the same as the number of parameter markers in the prepared statement. The *n*th variable corresponds to the *n*th parameter marker in the prepared statement. Where appropriate, locator variables and file reference variables can be provided as the source of values for parameter markers. A global variable must not be specified.

An array global variable must only be specified if the EXECUTE statement is issued in SQL PL.

***array-variable*[*array-index*]**

Identifies an array element. An array element must only be specified if the EXECUTE statement is issued in SQL PL.

array-variable

Specifies an array variable.

[*array-index*]

An expression that specifies which element in the array to use.

For an ordinary array, the array index expression must be castable to INTEGER, and must not be the null value. The index value must be between 1 and the maximum cardinality that is defined for the array.

For an associative array, the array index expression must be castable to the index data type of the associative array, and must not be the null value.

array-index must not be:

- An expression that references the CURRENT DATE, CURRENT TIME, or CURRENT TIMESTAMP special register
- A nondeterministic function
- A function that is defined with EXTERNAL ACTION
- A function that is defined with MODIFIES SQL DATA
- A sequence expression

array-variable
Specifies an array variable.

USING DESCRIPTOR *descriptor-name*
Identifies an SQLDA that contains a valid description of the input host variables.

Before invoking the EXECUTE statement, you must set the following fields in the SQLDA:

- SQLN to indicate the number of SQLVAR occurrences that are provided in the SQLDA

  A REXX SQLDA does not contain this field.
- SQLABC to indicate the number of bytes of storage that are allocated for the SQLDA
- SQLD to indicate the number of variables that are used in the SQLDA when processing the statement
- SQLVAR entries to indicate the attributes of the variables

The SQLDA must have enough storage to contain all SQLVAR entries. If an SQLVAR entry includes a LOB value or a distinct type based on a LOB, there must be additional SQLVAR entries for each parameter. For more information on the SQLDA, which includes a description of the SQLVAR and an explanation on how to determine the number of SQLVAR entries, see Appendix F, “SQL descriptor area (SQLDA),” on page 2301.

SQLD must be set to a value that is greater than or equal to zero and less than or equal to SQLN. It must be the same as the number of parameter markers in the prepared statement. The *n*th variable described by the SQLDA corresponds to the *n*th parameter marker in the prepared statement.

See “Identifying an SQLDA in C or C++” on page 2317 for how to represent *descriptor-name* in C.

source-row-data
The prepared statement must be an INSERT or MERGE statement for which the FOR MULTIPLE ROWS clause is specified as part of the ATTRIBUTES clause on the PREPARE statement.

USING *host-variable-array* or *host-variable*
Introduces a list of host variables or host-variable arrays whose values are substituted for the parameter markers (question marks) in the prepared INSERT or MERGE statement. The number of columns specified in the INSERT or MERGE statement must be less than or equal to the total number of host variables or host-variable arrays that are specified.

host-variable-array
Identifies a host-variable array that must be defined in the application program in accordance with the rules for declaring a host-variable array. A reference to a structure is replaced by a reference to each of its variables. The number of variables must be the same as the number of parameter markers in the prepared statement. The *n*th variable supplies the value for the *n*th parameter marker in the prepared statement.

host-variable-array is supported in C/C++, COBOL, and PL/I. For more information, see “Host-variable arrays in PL/I, C, C++, and COBOL” on page 236.

host-variable
Identifies a variable that must be described in the application program in accordance with the rules for declaring host variables.

USING DESCRIPTOR *descriptor-name*
Identifies an SQLDA that must contain a valid description of the host-variable arrays or host variables that contain the values to insert.

Before invoking the EXECUTE statement for a dynamic INSERT or MERGE statement, you must set the following fields in the SQLDA:

- SQLN to indicate the number of SQLVAR entries that are provided in the SQLDA.
- SQLABC to indicate the number of bytes of storage that are allocated for the SQLDA.
- SQLD to indicate the number of variables, plus one, that are used in the SQLDA that provide values for columns that are the source of the INSERT or MERGE statement. SQLD must be set to a value that is greater than or equal to zero and less than or equal to SQLN.

- SQLVAR entries to indicate the attributes of an element of the host-variable array for the SQLVAR entries that correspond to values that are provided for the source columns of the INSERT or MERGE statement. Within each SQLVAR, the following fields are set:
  - SQLTYPE indicates the data type of the elements of the host-variable array.
  - SQLDATA points to the corresponding host-variable array.
  - SQLLEN and SQLLONGLEN indicate the length of a single element of the array.
- SQLNAME, the fifth and sixth bytes must contain a flag field and the seventh and eighth bytes must contain a binary small integer (halfword) that contains the dimension of the host-variable array and, if specified, the corresponding indicator array.

The SQLDA must have enough storage to contain a SQLVAR entry for each target column for which values are provided, plus an additional SQLVAR entry for the number of rows. The Db2 system generates code to enter the required information for this extra SQLVAR entry. Each SQLVAR entry describes a host variable, host-variable array, or buffer that contains the values for a column of the source table. The last SQLVAR entry contains the number of rows of data. For example, if the INSERT or MERGE statement is providing values for five columns of the target table, six SQLVAR entries must be provided. If any value is a LOB value, twice as many SQLVAR entries must be provided, and SQLN must be set to the number of SQLVAR entries. Thus, if the INSERT or MERGE statement is providing values for five columns of the source table, and some of the values to insert are LOB values, 12 SQLVAR entries must be provided.

The SQLVAR entry for the number of rows must also contain a flag value. See “Field descriptions of an occurrence of a base SQLVAR” on page 2305 for more information.

You set the SQLDATA and SQLIND pointers to the beginning of the corresponding arrays.

FOR *n* ROWS

Specifies the number of rows of source data, where *n* is *host-variable* or *integer-constant*. The values for the insert or merge operation are specified in the USING clause.

host-variable or *integer-constant* is assigned to an integral value *k*. If *host-variable* is specified, it must be an exact numeric type with a scale of zero and must not include an indicator variable. *k* must be in the range 0 to 32767.

FOR n ROWS cannot be specified on the EXECUTE statement if the statement being processed is a dynamic INSERT or MERGE statement that includes a FOR n ROWS clause.

Notes for EXECUTE

Excessive processor time:

Db2 can stop the execution of a prepared SQL statement if the statement is taking too much processor time to finish. When this happens, an error occurs. The application that issued the statement is not terminated; it is allowed to issue another SQL statement.

Parameter marker replacement:

Before the prepared statement is executed, each parameter marker in the statement is effectively replaced by its corresponding host variable. The replacement is an assignment operation in which the source is the value of the host variable and the target is a variable within Db2. The assignment rules are those described for assignment to a column in “Assignment and comparison” on page 143. For a typed parameter marker, the attributes of the target variable are those specified by the CAST specification. For an untyped parameter marker, the attributes of the target variable are determined according to the context of the parameter marker. For the rules that affect parameter markers, see Parameter markers.

Let V denote a host variable that corresponds to parameter marker P. The value of V is assigned to the target variable for P in accordance with the rules for assigning a value to a column:

- V must be compatible with the target.
- If V is a string, its length must not be greater than the length attribute of the target.

- If V is a number, the absolute value of its integral part must not be greater than the maximum absolute value of the integral part of the target.
- If the attributes of V are not identical to the attributes of the target, the value is converted to conform to the attributes of the target.
- If the target cannot contain nulls, V must not be null.

When the prepared statement is executed, the value used in place of P is the value of the target variable for P. For example, if V is CHAR(6) and the target is CHAR(8), the value used in place of P is the value of V padded on the right with two blanks.

Errors occurring on EXECUTE:
In local and remote processing, the DEFER(PREPARE) and REOPT(ALWAYS)/REOPT(ONCE) bind options can cause some errors that are normally issued during PREPARE processing to be issued on EXECUTE.

Considerations for executing data definition statements written in native SQL language:
A data definition statement written in native SQL language can only be executed one time. To execute the data definition statement multiple times, issue the PREPARE statement prior to each use of the EXECUTE statement for the data definition statement.

Examples for EXECUTE

Example 1

In this example, an INSERT statement with parameter markers is prepared and executed. S1 is a structure that corresponds to the format of DSN8C10.DEPT.

```
   EXEC SQL PREPARE DEPT_INSERT FROM
     'INSERT INTO DSN8C10.DEPT VALUES(?,?,?,?)';
   -- Check for successful execution and read values into S1
   EXEC SQL EXECUTE DEPT_INSERT USING :S1;
```

Example 2

Assume that the IWH.PROGPARM table has 9 columns. Prepare and execute a dynamic INSERT statement that inserts 5 rows of data into the IWH.PROGPARM table. The values to be inserted are provided in arrays, where all the values for a column are provided in an host-variable-array with the EXECUTE statement.

```
STMT = 'INSERT INTO IWH.PROGPARM  (IWHID, UPDATE_BY,UPDATE_TS,NAME,
                                   SHORT_DESCRIPTION, ORDERNO, PARMDATA,
                                   PARMDATALONG, VWPROGKEY)
VALUES ( ? , ? , ? , ? , ? , ? , ? , ? , ? )';
ATTRVAR = 'FOR MULTIPLE ROWS';
EXEC SQL PREPARE INS_STMT ATTRIBUTES :ATTRVAR FROM :STMT;
NROWS = 5;
EXEC SQL EXECUTE INS_STMT FOR :NROWS ROWS
           USING :V1, :V2, :V3, :V4, :V5, :V6, :V7, :V8, :V9;
```

In this example, each host variable in the USING clause represents an array of values for the corresponding column of the target of the INSERT statement.

Example 3

Using dynamically supplied values for an employee row, update the master EMPLOYEE table if the data is for an existing employee or insert a new row if the data is for a new employee.

```
hv_stmt =
  "MERGE INTO EMPLOYEE AS T
    USING (VALUES (CAST (? AS CHAR(6)), CAST (? AS VARCHAR(12)),
                  CAST (? AS CHAR(1)), CAST (? AS VARCHAR(15)),
                  CAST (? AS INTEGER)))
    AS S (EMPNO, FIRSTNAME, MI, LASTNAME, SALARY)
    ON T.EMPNO = S.EMPNO
    WHEN MATCHED THEN UPDATE
        SET SALARY = S.SALARY
    WHEN NOT MATCHED THEN INSERT (EMPNO, FIRSTNAME, MI, LASTNAME, SALARY)
        VALUES (S.EMPNO, S.FIRSTNAME, S.MI, S.LASTNAME, S.SALARY)
    NOT ATOMIC CONTINUE ON SQLEXCEPTION";
```

```
hv_attr = 'FOR MULTIPLE ROWS';
EXEC SQL
    PREPARE merge_stmt
     ATTRIBUTES :hv_attr FROM :hv_stmt;
hv_nrows = 5;
/* Initialize the hostvar array of hv_empno, hv_firstname... */
EXEC SQL
   EXECUTE merge_stmt
   USING :hv_empno, :hv_firstname, :hv_mi,
         :hv_lastname, :hv_salary
      FOR :hv_nrows ROWS;
```

Example 4

Suppose that the following array type, array variable, and table have been defined.

```
CREATE TYPE INTARRAY AS INTEGER ARRAY[100];
CREATE TYPE STRINGARRAY AS VARCHAR(10) ARRAY[100];
CREATE TABLE T1 (COL1 CHAR(10), COL2 INT);
```

Use as an array variable as an input value for an expression in an EXECUTE statement.

```
CREATE PROCEDURE PROCESSPERSONS (OUT WITHO STRINGARRAY, INOUT INT0 INT)
BEGIN
 DECLARE INTA INTARRAY;
 DECLARE STMT CHAR(100);
-- Initialize the array
 SET INTA = ARRAY[1,INTEGER(2),3+0,4,5,6] ;
-- Use dynamic sql with an array parameter marker to
--  provide a value for a dynamic INSERT statement
 SET STMT = 'INSERT INTO T1 VALUES('XYZ', CARDINALITY(CAST(? AS INTARRAY)))';
 PREPARE INS_STMT FROM STMT;
 EXECUTE INS_STMT USING INTA;
-- INTA is an array variable used as input for the
-- INSERT statement
…
END
```

EXECUTE IMMEDIATE

EXECUTE IMMEDIATE combines the basic functions of the PREPARE and EXECUTE statements. It can be used to prepare and execute an SQL statement that contains neither host variables nor parameter markers.

The EXECUTE IMMEDIATE statement:

- Prepares an executable form of an SQL statement from a string form of the statement
- Executes the SQL statement
- Destroys the executable form

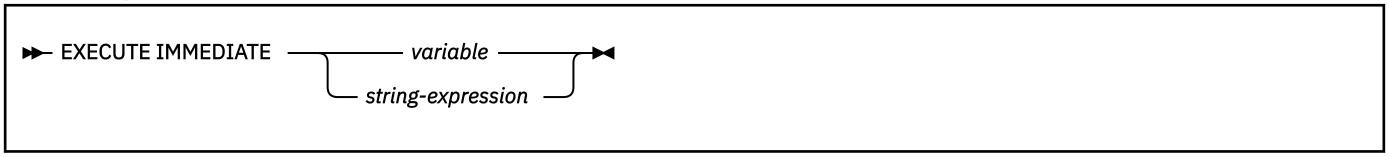
Invocation for EXECUTE IMMEDIATE

This statement can only be embedded in an application program. It is an executable statement that cannot be dynamically prepared. It must not be specified in Java.

Authorization for EXECUTE IMMEDIATE

The authorization rules are those defined for the dynamic preparation of the SQL statement specified by EXECUTE IMMEDIATE. For example, see “INSERT” on page 1991 for the authorization rules that apply when an INSERT statement is executed using EXECUTE IMMEDIATE.

Syntax for EXECUTE IMMEDIATE



Description for EXECUTE IMMEDIATE

variable

For languages other than PL/I, *variable* must be specified. It must identify a variable that is described in the application program in accordance with the rules for declaring character or graphic string variables. If the source string is over 32KB in length, the *variable* must be a CLOB or DBCLOB variable. The maximum source length is 2MB, although the variable can be declared larger than 2MB. An indicator variable must not be specified with a host variable. In Assembler, C, COBOL, and PL/I, a host variable must be a varying-length string variable. In C, it must not be a NUL-terminated string. In SQL PL, an SQL variable, SQL parameter, or transition variable can be used, and the value must not be null.

string-expression

string-expression is any PL/I expression that yields a string. *string-expression* cannot be preceded by a colon. Variables that are within *string-expression* that include operators or functions should not be preceded by a colon. When *string-expression* is specified, the precompiler-generated structures for *string-expression* use an EBCDIC CCSID and an informational message is returned.

Notes for EXECUTE IMMEDIATE

Rules for statement strings:

The value of the identified host variable or the specified *string-expression* is called the *statement string*.

The statement string must be one of the following SQL statements, and cannot be a *select-statement*:

Statements	Statements
• ALLOCATE CURSOR • ALTER • ASSOCIATE LOCATORS • COMMENT • COMMIT • CREATE • DECLARE GLOBAL TEMPORARY TABLE • DELETE • DROP • EXPLAIN • FREE LOCATOR • GRANT • HOLD LOCATOR • INSERT • LABEL • LOCK TABLE • MERGE	• SET CURRENT APPLICATION COMPATIBILITY • SET CURRENT DEGREE • SET CURRENT DECFLOAT ROUNDING MODE • SET CURRENT DEBUG MODE • SET CURRENT EXPLAIN MODE • SET CURRENT LOCALE LC_CTYPE • SET CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION • SET CURRENT OPTIMIZATION HINT • SET CURRENT PRECISION • SET CURRENT QUERY ACCELERATION • SET CURRENT REFRESH AGE • SET CURRENT ROUTINE VERSION • SET CURRENT RULES • SET CURRENT SQLID • SET ENCRYPTION PASSWORD • SET PATH • SET SCHEMA

Statements	Statements
- REFRESH TABLE - RELEASE SAVEPOINT - RENAME - REVOKE - ROLLBACK - SET *assignment-statement* - SAVEPOINT - SET CURRENT ACCELERATOR	- SET CURRENT TEMPORAL BUSINESS_TIME - SET CURRENT TEMPORAL SYSTEM_TIME - SET SESSION TIME ZONE - SIGNAL - TRANSFER OWNERSHIP - TRUNCATE - UPDATE

The statement string must not have any of the following attributes:

- Begin with EXEC SQL
- End with END-EXEC or a semicolon
- Include references to variables, other than global variables
- Include parameter markers
- Include references to transition tables

Errors and error handling:

When an EXECUTE IMMEDIATE statement is executed, the specified statement string is parsed and checked for errors. If the SQL statement is invalid, it is not executed and the error condition that prevents its execution is reported in the SQLCA. If the SQL statement is valid, but an error occurs during its execution, that error condition is reported in the SQLCA.

Db2 can stop the execution of a prepared SQL statement if the statement is taking too much CPU time to finish. When this happens an error occurs. The application that issued the statement is not terminated; it is allowed to issue another SQL statement.

Effect of the CURRENT EXPLAIN MODE special register:

If the CURRENT EXPLAIN MODE special register is set to EXPLAIN, the statement is prepared for explain only and is not executable, unless the statement is a SET statement. Attempting to execute the prepared statement will return an error. See the “CURRENT EXPLAIN MODE special register” on page 194 special register for more information.

Performance considerations:

If the same SQL statement is to be executed more than once, it is more efficient to use the PREPARE and EXECUTE statements rather than the EXECUTE IMMEDIATE statement.

Examples for EXECUTE IMMEDIATE

Example 1

In this PL/I example, the EXECUTE IMMEDIATE statement is used to execute a DELETE statement in which the rows to be deleted are determined by a search-condition specified by the value of PREDS.

```
EXEC SQL EXECUTE IMMEDIATE 'DELETE FROM DSN8C10.DEPT
  WHERE' || PREDS;
```

Example 2

Use C to execute the SQL statement in the host variable Qstring.

```
EXEC SQL INCLUDE SQLCA;
void main ()
  {
   EXEC SQL BEGIN DECLARE SECTION;
   char Qstring[100] =
     "INSERT INTO WORK_TABLE SELECT * FROM EMPPROJACT WHERE ACTNO >= 100";
```

```
 EXEC SQL END DECLARE SECTION;
.
.
.
 EXEC SQL EXECUTE IMMEDIATE :Qstring;
 return;
}
```

:

EXPLAIN

The EXPLAIN statement obtains information about access path selection for an *explainable statement*. A statement is explainable if it is a SELECT, MERGE, TRUNCATE, or INSERT statement, or the searched form of an UPDATE or DELETE statement. The information that is obtained is placed in a set of supplied user tables that are called *EXPLAIN tables*.

PSPI

The *plan table* contains information about the access path for the specified statement or statements. The *statement table* can be populated with information about the estimated cost of executing the explainable statement. The *function table* can be populated with information about how Db2 resolves the user-defined functions that are referred to in the explainable statement. Other EXPLAIN tables can be populated with additional information about the execution of the explainable statement. For a complete list of EXPLAIN tables, see EXPLAIN tables (Db2 Performance).

Using EXPLAIN for queries that reference system-period temporal tables that are enabled for system data versioning, the result will show the system-period temporal tables and the history tables in EXPLAIN output if the query needs to reference both tables to satisfy the query.

Invocation for EXPLAIN

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization for EXPLAIN

The authorization rules are those defined for the SQL statement specified in the EXPLAIN statement. For example, see the description of the DELETE statement for the authorization rules that apply when EXPLAIN records are captured for DELETE statements.

If the EXPLAIN statement is embedded in an application program, the authorization rules that apply are those defined for embedding the specified SQL statement in an application program. In addition, the owner of the plan or package must also have one of the following characteristics:

- Be the owner of a plan table named PLAN_TABLE
- Have an alias on a plan table named *owner*.PLAN_TABLE and have SELECT and INSERT privileges on the table

If the EXPLAIN statement is dynamically prepared, the authorization rules that apply are those defined for dynamically preparing the specified SQL statement. In addition, the SQL authorization ID of the process or the role this is associated with the process (if the EXPLAIN statement is running in a trusted context that specifies the ROLE AS OBJECT OWNER AND QUALIFIER clause) must also have one of the following characteristics:

- Be the creator of a plan table named PLAN_TABLE
- Have an alias on a plan table named *creator*.PLAN_TABLE and have SELECT and INSERT privileges on the table

For EXPLAIN statements with the PLAN and ALL keywords, the privilege set that is defined below must include at least one of the following:

- EXPLAIN

- SQLADM
- System DBADM
- The authorization rules that are defined for the SQL statement specified in the EXPLAIN statement. For example, the authorization rules that apply when EXPLAIN records are captured for a DELETE statement are the authorization rules for the DELETE statement.

The authorization rules are different if the STMTCACHE or STABILIZED DYNAMIC QUERY keywords are specified. The privilege set must include at least one of the following:

- SQLADM authority
- SYSADM authority
- The authority that is required to share the cached statement.
- System DBADM authority

For EXPLAIN statements that contain the STMTCACHE ALL clause, the privilege set must include at least one of the following:

- SQLADM authority
- System DBADM authority
- SYSADM authority

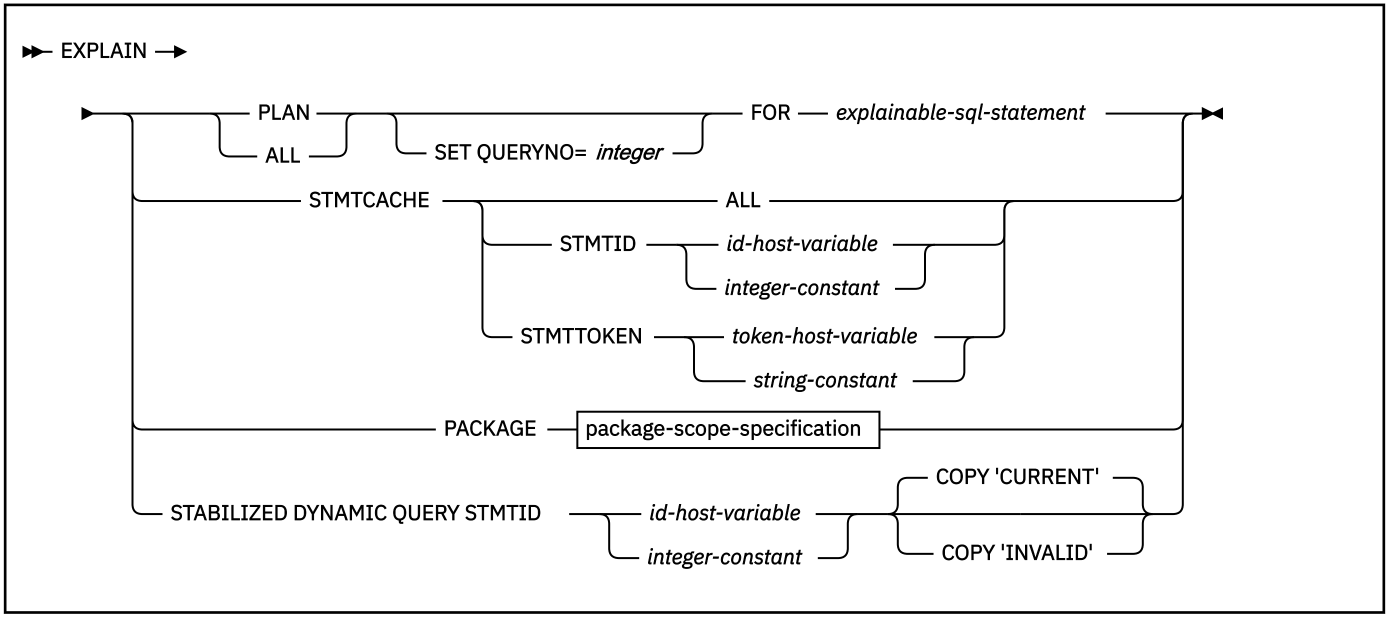
If the privilege set does not have the required authority, EXPLAIN records are captured only those statements that have the same authorization ID as the privilege set.

For the PACKAGE keyword, the privilege set must include at least one of the following:

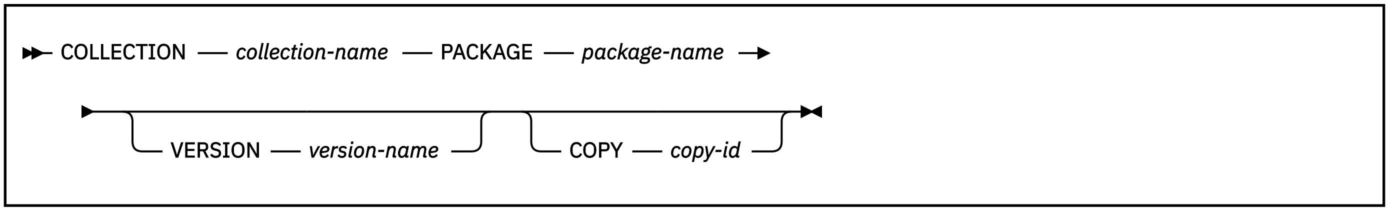
- SQLADM authority
- SYSADM authority
- SYSOPR authority
- SYSCTRL authority

Privilege set: The privilege set comprises the union of authorities that are held by the authorization IDs of the process. If the process is running in a trusted context with a role, this role would be included as an authorization ID of the process.

Syntax for EXPLAIN



package-scope-specification:



Description for EXPLAIN

PLAN

Specifies that access path information is captured for the SQL statement. Under this option, Db2 uses the access path selection process to generate the EXPLAIN records for the statement.

One row is inserted into the PLAN_TABLE for each step used in executing *explainable-sql-statement*. The steps for enforcing referential constraints are not included.

If a statement table exists, one row that provides a cost estimate of processing the explainable statement is inserted into the statement table. If the explainable statement is a SELECT FROM *data-change-statement*, two rows are inserted into the statement table.

If a function table exists, one row is inserted into the function table for each user-defined function that is referred to by the explainable statement.

If additional EXPLAIN tables exist, rows are also inserted into those tables.

For more information, see:

EXPLAIN tables (Db2 Performance)
PLAN_TABLE (Db2 Performance)
DSN_STATEMNT_TABLE (Db2 Performance)
DSN_FUNCTION_TABLE (Db2 Performance)

ALL

Has the same effect as PLAN.

SET QUERYNO = *integer*

Associates *integer* with *explainable-sql-statement*. The column QUERYNO is given the value *integer* in every row inserted into the plan table, statement table, or function table by the EXPLAIN statement. If QUERYNO is not specified, Db2 itself assigns a number. For an embedded EXPLAIN statement, the number is the statement number that was assigned by the precompiler and placed in the DBRM.

FOR *explainable-sql-statement*

Specifies the text of an SQL statement for which EXPLAIN records are captured. *explainable-sql-statement* can be any explainable SQL statement. A statement is explainable if it is a SELECT, MERGE, TRUNCATE, or INSERT statement, or the searched form of an UPDATE or DELETE statement. If the EXPLAIN statement is embedded in a program, the statement can contain references to host variables. If EXPLAIN is dynamically prepared, the statement can contain parameter markers. Host variables that appear in the statement must be defined in the statement's program.

The statement must refer to objects at the current server.

explainable-sql-statement must not contain a QUERYNO clause. To specify the value of the QUERYNO column, use the SET QUERYNO = *integer* clause of the EXPLAIN statement.

explainable-sql-statement cannot be a statement-name or a host-variable. To use capture EXPLAIN records for dynamic SQL statements, you must prepare the entire EXPLAIN statement dynamically.

To obtain information about an explainable SQL statement that references a declared temporary table, the EXPLAIN statement must be executed in the same application process in which the table was declared. For static EXPLAIN statements, the information is not obtained at bind-time but at run time when the EXPLAIN statement is incrementally bound.

STMTCACHE

Specifies that EXPLAIN records for the specified dynamic SQL statements in the dynamic statement cache are extracted and written to EXPLAIN tables. Under this option, no new access path selection processing occurs. The EXPLAIN records are extracted from the existing access paths that were selected when the dynamic SQL statements were prepared and entered the statement cache. In a data-sharing environment, the EXPLAIN records are extracted from the dynamic statement cache of the data sharing member where EXPLAIN STMTCACHE statement is executed.

ALL

Specifies that EXPLAIN records are extracted for all cached statements. STMTCACHE ALL returns one row for each cached statement to the DSN_STATEMENT_CACHE_TABLE. These rows contain identifying information about the statements in the cache, as well as statistics that reflect the execution of the statements by all processes that have executed the statement. Records are not returned to other EXPLAIN tables when STMTCACHE ALL is specified.

STMTID *id-host-variable* or *integer-constant*

Specifies that EXPLAIN records are extracted for the cached statement with the specified statement ID. The value contained in *id-host-variable* or specified by *integer-constant* identifies the statement ID. STMTCACHE STMTID returns rows to the following EXPLAIN tables:

- PLAN_TABLE
- DSN_STATEMNT_TABLE
- DSN_FUNCTION_TABLE
- DSN_STATEMENT_CACHE_TABLE

The statement ID is an integer that uniquely identifies a statement that has been cached in the dynamic statement cache. The statement ID of a cached statement can be retrieved through IFI monitor facilities from IFCID 316 or 124. Some diagnostic trace records, such as IFCIDs 0173, 0196, and 0337, also show the statement ID.

The QUERYNO column of each EXPLAIN table record that is returned contains the statement ID value.

STMTTOKEN *id-host-variable* or *string-constant*

Specifies that EXPLAIN records are extracted for the cached statements with the specified statement token and written to certain EXPLAIN tables. The value contained in *token-host-variable* or specified by *string-constant* identifies the statement token. STMTCACHE STMTTOKEN writes records to the following EXPLAIN tables:

- PLAN_TABLE
- DSN_STATEMNT_TABLE
- DSN_FUNCTION_TABLE
- DSN_STATEMENT_CACHE_TABLE

The statement token must be a character string that is no longer than 240 bytes. The application program that originally prepares and inserts a statement into the cache associates a statement token with the cached statement. The program can make this association with the RRSAF SET_ID function, or the sqleseti API if the program is connected remotely.

The STMTTOKEN column of each PLAN_TABLE record that is returned contains the statement token value. The QUERYNO column of each EXPLAIN table record that is returned contains the statement ID value.

For more information, see:

DSN_STATEMENT_CACHE_TABLE (Db2 Performance)
Capturing reoptimized access paths (Db2 Performance)

PACKAGE

Specifies that EXPLAIN records for all static SQL statements in the package that matches the specified scope are extracted and written to EXPLAIN tables. Under this option, no new access path selection processing occurs. The records are extracted from the existing access paths that were selected when the package was bound. The EXPLAIN information is added to the PLAN_TABLE that is owned by the current user. Other EXPLAIN tables are not populated.

COLLECTION *collection-name*

Specifies that EXPLAIN records are captured only for statements under the specified *collection-name*. *collection-name* is a string constant or a host variable that represents the collection name.

PACKAGE *package-name*

Specifies that EXPLAIN records are captured only for statements under the specified *package-name*. *package-name* is a string constant or a host variable that represents the package name.

VERSION *version-name*

Specifies that EXPLAIN records are captured only for statements under the specified *version-name*. *version-name* is a string constant or a host variable that represents the version name. If *version-name* is all blanks or an empty string, records are captured only for those versions of the package that contain all blanks for the version name.

If the VERSION clause is not specified, EXPLAIN records are captured for statements in all versions of the package *package-name*.

COPY *copy-id*

Specifies that EXPLAIN records are captured only for statements under the specified *copy-id*. *copy-id* must be one of the following values:

- CURRENT
- PREVIOUS
- ORIGINAL

If the COPY clause is not specified, statements, EXPLAIN records are captured for the current, previous, and original copies that exist for that package.

The HINT_USED column in the PLAN_TABLE is populated with `EXPLAIN PACKAGE:` *`copy-id`*. *copy-id* in the HINT_USED column will be one of the following values:

- "CURRENT" - the current copy
- "PREVIOUS" - the previous copy
- "ORIGINAL" - the original copy

STABILIZED DYNAMIC QUERY

Specifies that the explain records for the stabilized dynamic statement identified by the STMTID keyword are extracted and written to the following EXPLAIN tables:

- PLAN_TABLE
- DSN_STATEMNT_TABLE
- DSN_FUNCTION_TABLE

STMTID *id-host-variable* or *integer-constant*

Specifies that EXPLAIN information is captured for the statement with the specified statement identifier. This value is inserted into the PER_STMT_ID column of the EXPLAIN tables.

COPY *copy-id*

Specifies that EXPLAIN information is captured only for statements under the specified copy identifier value. *copy-id* is a string constant and must be one of the following values:

- CURRENT
- INVALID

The PLAN_TABLE.HINT_USED column is populated with the string 'EXPLAIN SDQ: copy-id-number' where *copy-id-number* is one of the following values:

CURRENT

The current copy.

INVALID
The invalid copy.

The QUERYNO column of each EXPLAIN table record that is returned is set to the default value 0, and the value of the COLLID column is set to 'DSNSTBLQRYEXPLAIN.'

Notes for EXPLAIN

Output from EXPLAIN:
Db2 inserts one or more rows of data into a plan table and other existing *EXPLAIN tables*.

For a list of all EXPLAIN tables, see EXPLAIN tables (Db2 Performance).

A plan table must exist before the operation that results in EXPLAIN output. You can find a sample CREATE TABLE statement for each EXPLAIN table in member DSNTESC of the *prefix*.SDSNSAMP library.

Unless you need the information that is provided by the additional EXPLAIN tables, it is not necessary to create those tables to use EXPLAIN. However, a statement cache table is required when the STMTCACHE ALL keyword is specified as part of an EXPLAIN statement.

Db2 uses the access path selection process to generate EXPLAIN records only for certain types of EXPLAIN statements, as shown in the following table.

Table 232. Origin of EXPLAIN records for various EXPLAIN statement options

Options Specified	**How Db2 Creates EXPLAIN records**
`EXPLAIN PLAN FOR` *`explainable-sql-statement`*	Uses the access path selection process to generate the EXPLAIN records
`EXPLAIN PACKAGE ...`	Extracts existing access path information from the package to create the EXPLAIN records.
`EXPLAIN STMTCACHE ...`	Extracts access path information from the dynamic statement cache to create the EXPLAIN records.
`EXPLAIN STABILIZED DYNAMIC QUERY ...`	Extracts access path information from catalog tables for the specified stabilized dynamic SQL statements.

Each row in an EXPLAIN table describes some aspect of a step in the execution of a query or subquery in an explainable statement. The column values for the row identify, among other things, the query or subquery, the tables and other objects involved, the methods used to carry out each step, and cost information about those methods.

Instances of these tables might also be created and used by certain optimization tools. For information about the meanings of different values in plan table and other EXPLAIN tables, see .

For information about how to correlate information across EXPLAIN tables, see Correlating information across EXPLAIN tables (Db2 Performance).

EXPLAIN tables might contain names that begin with "DSN" that have been generated by Db2.

Important: Do not manually manipulate the data in EXPLAIN tables that are created by optimization tools.

Column access control or row permissions enforced for EXPLAIN tables:
Column access control and row permissions can be enforced for EXPLAIN tables. However, row permissions and column masks are not applied when Db2 inserts rows into those tables.

If the specified statement references tables for which row or column access control is activated, the following information from row permission and column mask definitions created for the tables might appear in the EXPLAIN tables:

- DSN_FUNCTION_TABLE - user-defined functions
- DSN_PREDICAT_TABLE - predicates (except predicates in CASE WHEN clauses)
- DSN_STRUCT_TABLE - query blocks
- PLAN_TABLE - access path of subqueries

In addition, the complete or partial definition text might appear in EXPLAIN tables like DSN_FUNCTION_TABLE, DSN_PREDICAT_TABLE, DSN_QUERY_TABLE, DSN_SORTKEY_TABLE, DSN_STATEMENT_CACHE_TABLE, and DSN_STATEMENT_RUNTIME_INFO.

Impact to the existing access paths when the table has enforced column access control or row permissions:
The predicates from the row permissions are considered in the access path selection. Therefore, they are shown in the EXPLAIN tables for the performance tuning purpose.

Impact to EXPLAIN tables when referencing a non-existing object in a dynamic SQL statement
In some situations in which EXPLAIN is run on a dynamic SQL statement that references a non-existent object, a SQLCODE -204 is issued to indicate that the object is not defined in the Db2 subsystem. However, changes to the related EXPLAIN tables might not be rolled back.

Considerations when capturing EXPLAIN records for the acceleration of rowset queries:
A rowset query cannot be passed to an accelerator server for processing in the following cases:

- If the rowset query is run remotely
- If the rowset query is declared WITH RETURN
- If the rowset query is run under an SQL PL routine

You cannot use a static EXPLAIN statement to determine whether a rowset query is passed to an accelerator server, because you cannot specify the WITH ROWSET POSITIONING cursor attribute for a static EXPLAIN statement. Instead, you must use a dynamic EXPLAIN statement, where the WITH ROWSET POSITIONING clause is specified in the attribute string. You also can specify the WITH RETURN clause in the attribute string to see the ineligibility of result sets.

Also, the EXPLAIN statement cannot be used to determine that a rowset query cannot be passed to an accelerator server because the query is being run remotely or under an SQL PL routine. If the PREPARE of the EXPLAIN statement is run locally, Db2 determines if the rowset query can be accelerated as a local query offload. However, if the PREPARE of the EXPLAIN statement runs remotely, Db2 indicates that the rowset query cannot be accelerated. Instead, you can use the CURRENT EXPLAIN MODE special register to determine the behavior for eligible dynamic SQL statements during application execution. For more information, see "CURRENT EXPLAIN MODE special register" on page 194.

EXPLAIN tables
For a descriptions of the EXPLAIN tables, see EXPLAIN tables (Db2 Performance).

Examples for EXPLAIN

Example 1: Determine the steps required to execute the query 'SELECT X.ACTNO...'. Assume that no set of rows in the PLAN_TABLE has the value 13 for the QUERYNO column.

```
EXPLAIN PLAN SET QUERYNO = 13
FOR SELECT X.ACTNO, X.PROJNO, X.EMPNO, Y.JOB, Y.EDLEVEL
    FROM DSN8C10.EMPPROJACT X, DSN8C10.EMP Y
       WHERE X.EMPNO = Y.EMPNO
          AND X.EMPTIME > 0.5
          AND (Y.JOB = 'DESIGNER' OR Y.EDLEVEL >= 12)
       ORDER BY X.ACTNO, X.PROJNO;
```

Example 2: Retrieve the information returned in Example 1. Assume that a statement table exists, so also retrieve the estimated cost of processing the query. Use the following query, which joins the plan table and the statement table.

```
  SELECT * FROM PLAN_TABLE A, DSN_STATEMNT_TABLE B
    WHERE A.QUERYNO = 13 and B.QUERYNO = 13
    ORDER BY A.QBLOCKNO, A.PLANNO, A.MIXOPSEQ;
```

Example 3: Extract existing access path information to capture EXPLAIN records for the cached statement with statement ID 124. Assume that host variable SID contains 124.

```
EXPLAIN STMTCACHE STMTID :SID;
```

Example 4: Extract existing access path information to capture one row of EXPLAIN data for each statement in the dynamic statement cache. The records are written only to the DSN_STATEMENT_CACHE_TABLE.

```
EXPLAIN STMTCACHE ALL;
```

Example 5: Assume that you want to use the plan table that was created by ADMF001 and your authorization ID is SYSADM. If you have an alias on ADMF001.PLAN_TABLE (CREATE ALIAS SYSADM.PLAN_TABLE FOR ADMF001.PLAN_TABLE) and sufficient INSERT and SELECT privileges on the table, the following EXPLAIN statement will execute and ADMF001.PLAN_TABLE will be populated.

```
  EXPLAIN PLAN SET QUERYNO = 101
    FOR SELECT * FROM DSN8C10.EMP;
```

Example 6: Extract existing access path information to capture EXPLAIN records to the current user's PLAN_TABLE for all static SQL statements in the current copy of the package 'COLLA.PACK52604':

```
  EXPLAIN PACKAGE COLLECTION 'COLLA' PACKAGE 'PACK52604' COPY 'CURRENT';
```

EXPLAIN bind option (Db2 Commands)

FETCH

The FETCH statement positions a cursor on a row of its result table. It can return zero, one, or multiple rows and assigns the values of the rows to variables if there is a target specification.

Invocation for FETCH

This statement can only be embedded in an application program. It is an executable statement that cannot be dynamically prepared. Multiple row fetch is not supported in REXX, Fortran, or SQL Procedure applications[35]. The FETCH statement with the WITH CONTINUE clause is not supported in REXX.

[35] ASSEMBLER and other languages are supported, but this support is limited to statements that allow USING DESCRIPTOR. The precompiler does not recognize host-variable-arrays except in C/C++, COBOL, and PL/I.

Authorization for FETCH

See “DECLARE CURSOR” on page 1814 for an explanation of the authorization required to use a cursor.

For an assignment to a global variable or an element of an array global variable, the privilege set must include at least one of the following:

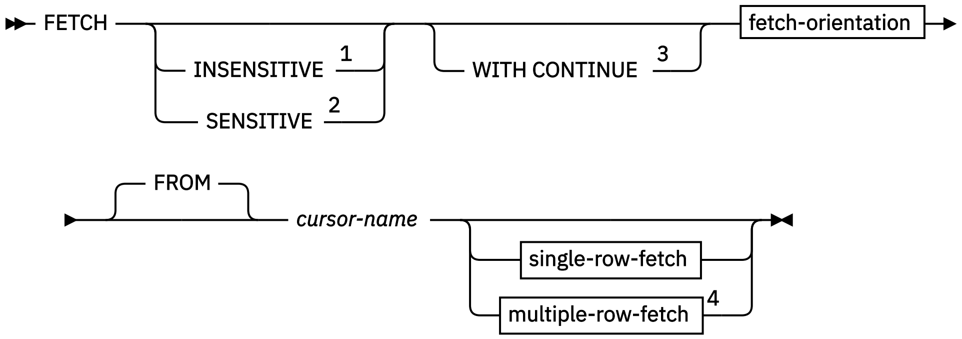
- The WRITE privilege on the variable
- Ownership of the variable
- DATAACCESS authority
- SYSADM authority

For an assignment to a transition variable, the privilege set must include at least one of the following:

- The UPDATE privilege on the table or view on which the trigger that contains the assignment statement is defined
- The UPDATE privilege on the column corresponding to the transition variable to be assigned a value
- Ownership of the table or view on which the trigger that contains the assignment statement is defined
- DBADM authority on the database that contains the table on which the trigger that contains the assignment statement is defined
- DATAACCESS authority
- SYSADM authority

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the package. If the statement is dynamically prepared, the privilege set is determined by the DYNAMICRULES behavior in effect (run, bind, define, or invoke) and is summarized in DYNAMICRULES behaviors and authorization checking. For more information on these behaviors, including a list of the DYNAMICRULES bind option values that determine them, see “Authorization IDs and dynamic SQL” on page 94.

Syntax for FETCH



Notes:

[1] The default depends on the sensitivity of the cursor. If INSENSITIVE is specified on the DECLARE CURSOR, then the default is INSENSITIVE and if SENSITIVE is specified on the DECLARE CURSOR, then the default is SENSITIVE.

[2] If INSENSITIVE or SENSITIVE is specified, *single-row-fetch* or *multiple-row-fetch* must be specified.

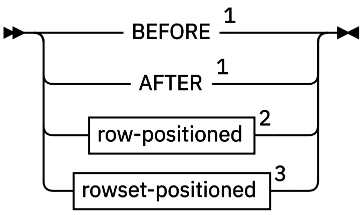
[3] If WITH CONTINUE is specified, *single-row-fetch* must be specified.

[4] If *multiple-row-fetch* is specified, a *rowset-positioned* fetch orientation must also be specified.

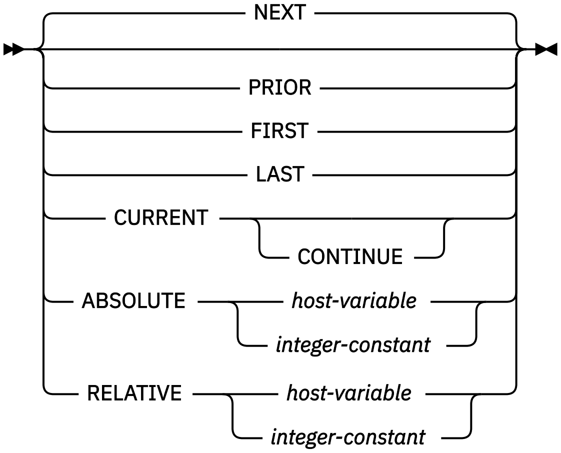
fetch-orientation

▸▸─▸◂

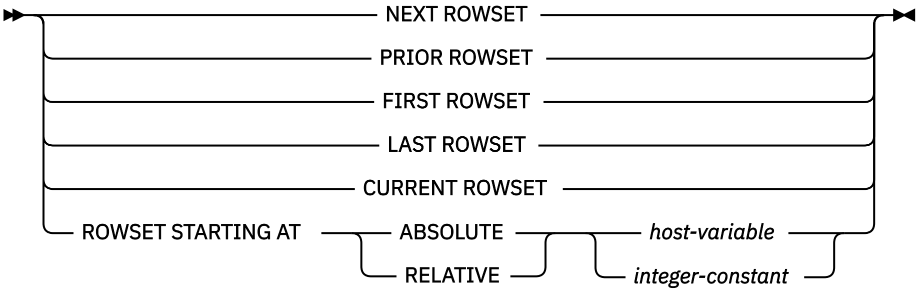
fetch-orientation



row-positioned



rowset-positioned



Notes:

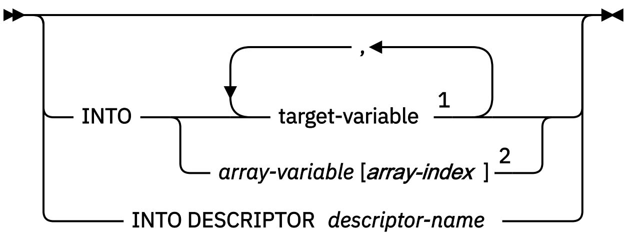
[1] If BEFORE or AFTER is specified, SENSITIVE, INSENSITIVE, *single-row-fetch*, or *multiple-row-fetch* must not be specified.

[2] A row-positioned fetch orientation can be specified only if *multiple-row-fetch* is not specified.

[3] If *multiple-row-fetch* is specified, a rowset-positioned fetch orientation must also be specified.

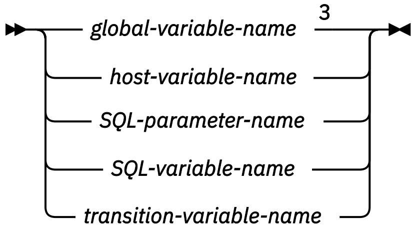
fetch-type

single-row-fetch

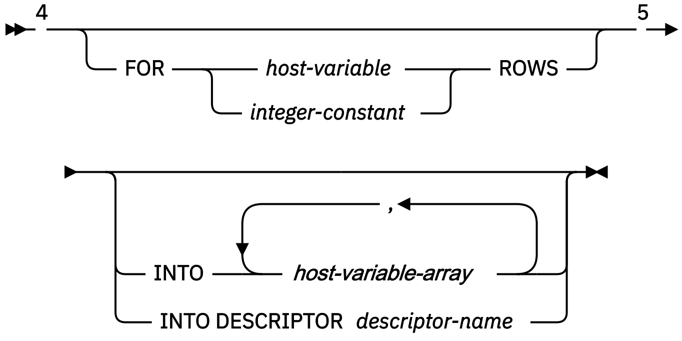


,
INTO
target-variable 1
array-variable [array-index] 2
INTO DESCRIPTOR descriptor-name

target-variable



multiple-row-fetch



Notes:

[1] For single-row-fetch, a host-variable-array can be specified instead of a host variable. The descriptor can describe host-variable-arrays. In either case, data is returned only for the first entry of the host-variable-array.

[2] An array element must only be specified in an SQL PL context.

[3] An array global variable must only be specified in an SQL PL context.

[4] This clause must not be specified if a *row-positioned* fetch orientation or if no fetch orientation was specified.

[5] This clause is optional. If this clause is not specified and either a rowset size has not been established yet or a row positioned FETCH statement was the last type of FETCH statement issued for this cursor, the rowset size is implicitly one. If the last FETCH statement issued for this cursor was a rowset positioned FETCH statement and this clause is not specified, the rowset size is the same size as the previous rowset positioned FETCH.

Description for FETCH

INSENSITIVE

Returns the row from the result table as it is. If the row has been previously fetched with a FETCH SENSITIVE, it reflects changes made outside this cursor before the FETCH SENSITIVE statement was issued. Positioned updates and deletes are reflected with FETCH INSENSITIVE if the same cursor was used for the positioned update or delete.

INSENSITIVE can only be specified for cursors declared as INSENSITIVE or SENSITIVE STATIC (or if the cursor is declared as ASENSITIVE and Db2 defaults to INSENSITIVE). Otherwise, if the cursor is declared as SENSITIVE DYNAMIC (or if the cursor is declared as ASENSITIVE and Db2 defaults to SENSITIVE DYNAMIC), an error occurs and the FETCH statement has no effect. For an INSENSITIVE cursor, specifying INSENSITIVE is optional because it is the default.

SENSITIVE

Updates the fetched row in the result table from the corresponding row in the base table of the cursor's SELECT statement and returns the current values. Thus, it reflects changes made outside this cursor. SENSITIVE can only be specified for a sensitive cursor. Otherwise, if the cursor is insensitive, an error occurs and the FETCH statement has no effect. For a SENSITIVE cursor, specifying SENSITIVE is optional because it is the default.

When the cursor is declared as SENSITIVE STATIC and a FETCH SENSITIVE is requested, the following steps are taken:

1. Db2 retrieves the row of the database that corresponds to the row of the result table that is about to be fetched.
2. If the corresponding row has been deleted, a "delete hole" occurs in the result table, a warning is issued, the cursor is repositioned on the "hole", and no data is fetched. (Db2 marks a row in the result table as a "delete hole" when the corresponding row in the database is deleted.)
3. If the corresponding row has not been deleted, the predicate of the underlying SELECT statement is re-evaluated. If the row no longer satisfies the predicate, an "update hole" occurs in the result table, a warning is issued, the cursor is repositioned on the "hole," and no data is fetched. (Db2 marks a row in the result table as an "update hole" when an update to the corresponding row in the database causes the row to no longer qualify for the result table.)
4. If the corresponding row does not result in a delete or an update hole in the result table, the cursor is repositioned on the row of the result table and the data is fetched.

WITH CONTINUE

Specifies that the Db2 subsystem should prepare to allow subsequent FETCH CURRENT CONTINUE operations to access any truncated LOB or XML result column following an initial FETCH operation that provides output variables that are not large enough to hold the entire LOB or XML columns. When the WITH CONTINUE clause is specified, the Db2 subsystem takes the following actions that can differ from the case where the FETCH statement does not include the WITH CONTINUE clause:

- If truncation occurs when returning an XML or LOB column, the Db2 subsystem will remember the truncation position and will not discard the remaining data.
- If truncation occurs when returning an XML or LOB column, the Db2 subsystem returns the total length that would have been required to hold all of the data of the LOB or XML column. This will either be in the first four bytes of the LOB host variable structure or in the 4 byte area that is pointed to by the SQLDATALEN pointer in the SQLVAR entry of the SQLDA for that host variable. What is returned depends on the programming method that is used. See Appendix F, “SQL descriptor area (SQLDA),” on page 2301 for details about the SQLDA contents.
- If returning XML data, the result column will be fully materialized in the database before the data is returned.

If the CURRENT CONTINUE clause is specified, the WITH CONTINUE behavior is assumed.

AFTER

Positions the cursor after the last row of the result table. Values are not assigned to host variables. The number of rows of the result table are returned in the SQLERRD1 and SQLERRD2 fields of the SQLCA for cursors with an effective sensitivity of INSENSITIVE or SENSITIVE STATIC.

BEFORE

Positions the cursor before the first row of the result table. Values are not assigned to host variables.

row-positioned

Positioning of the cursor with row-positioned fetch orientations NEXT, PRIOR, CURRENT and RELATIVE is done in relation to the current cursor position. Following a successful row-positioned FETCH statement, the cursor is positioned on a single row of data. If the cursor is enabled for rowsets, positioning is performed relative to the current row or the first row of the current rowset, and the cursor is positioned on a rowset consisting of a single row.

NEXT

Positions the cursor on the next row or rows of the result table relative to the current cursor position, and returns data if a target is specified. NEXT is the only row-positioned fetch operation that can be explicitly specified for cursors that are defined as NO SCROLL. NEXT is the default if no other cursor positioning is specified. If a specified row reflects a hole, a warning is issued and data values are not assigned to host variables for that row.

Table 233 on page 1924 lists situations for different cursor positions and the results when NEXT is used.

Table 233. Results when NEXT is used with different cursor positions

Current state of the cursor	**Result of FETCH NEXT**
Before the first row	Cursor is positioned on the first row"1" on page 1924 and data is returned if requested.
On the last row or after the last row	A warning occurs, values are not assigned to host variables, and the cursor position is unchanged.
Before a hole	For a SENSITIVE STATIC cursor, a warning occurs for a delete hole or an update hole, values are not assigned to host variables, and the cursor is positioned on the hole.
Unknown	An error occurs, values are not assigned to host variables, and the cursor position remains unknown.

Note:

1. This row is not applicable in the case of a forward-only cursor (that is when NO SCROLL was specified implicitly or explicitly).

PRIOR

Positions the cursor on the previous row or rows of the result table relative to the current cursor position, and returns data if a target is specified. If a specified row reflects a hole, a warning is issued, and data values are not assigned to host variables for that row.

Table 234 on page 1924 lists situations for different cursor positions and the results when PRIOR is used.

Table 234. Results when PRIOR is used with different cursor positions

Current state of the cursor	**Result of FETCH PRIOR**
Before the first row or on the first row	A warning occurs, values are not assigned to host variables, and the cursor position is unchanged.
After a hole	For a SENSITIVE STATIC cursor, a warning occurs for a delete hole or an update hole, values are not assigned to host variables, and the cursor is positioned on the hole.
After the last row	Cursor is positioned on the last row.
Unknown	An error occurs, values are not assigned to host variables, and the cursor position remains unknown.

FIRST

Positions the cursor on the first row of the result table, and returns data if a target is specified. For a SENSITIVE STATIC cursor, if the first row of the result table is a hole, a warning occurs for a delete hole or an update hole and values are not assigned to host variables.

LAST

Positions the cursor on the last row of the result table, and returns data if a target is specified. The number of rows of the result table is returned in the SQLERRD1 and SQLERRD2 fields of the SQLCA for an insensitive or sensitive static cursor. For a SENSITIVE STATIC cursor, if the last row of the result table is a hole, a warning occurs for a delete hole or an update hole and values are not assigned to host variables.

CURRENT

The cursor position is not changed, data is returned if a target is specified. If the cursor was positioned on a rowset of more than one row, the cursor position is on the first row of the rowset.

Table 235 on page 1925 lists situations in which errors occur with the CURRENT clause.

Table 235. Situations in which errors occur with CURRENT

Current state of the cursor	Result of FETCH CURRENT
Before the first row or after the last row	A warning occurs, values are not assigned to host variables, and the cursor position is unchanged.
On a hole	For a SENSITIVE STATIC, a warning occurs for a delete hole or an update hole, values are not assigned to host variables, and the cursor is positioned on the hole. If the cursor is defined as a rowset cursor, with isolation level UR or a sensitive dynamic scrollable cursor, it is possible that a different row will be returned than the FETCH that established the most recent cursor position. This can occur while fetching a row again when it is determined to not be there anymore. In this case, fetching continues moving forward to get the row of data.
Unknown	An error occurs, values are not assigned to host variables, and the cursor position remains unknown.

CONTINUE

The cursor positioning is not changed, and data is returned if a target is specified. The FETCH CURRENT CONTINUE statement retrieves remaining data for any LOB or XML column result values that were truncated on a previous FETCH or FETCH CURRENT CONTINUE statement. It assigns the remaining data for those truncated columns to the host variables that are referenced in the statement or pointed to by the descriptor. The data that is returned for previously-truncated result values begins at the point of truncation. This form of the CURRENT clause must only be used after a single-row FETCH WITH CONTINUE or FETCH CURRENT CONTINUE statement that has returned partial data for one or more LOB or XML columns. The cursor must be open and positioned on a row.

FETCH CURRENT CONTINUE must pass host variables entries for all columns in the SELECT list, even though the non-LOB columns or non-XML columns will not return any data.

ABSOLUTE

host-variable or *integer-constant* is assigned to an integral value *k*. If a *host-variable* is specified, it must be an exact numeric type with zero scale and must not include an indicator variable. The possible data types for the host variable are DECIMAL(*n*,0) or integer. The DECIMAL data type is limited to DECIMAL(18,0). An *integer-constant* can be up to 31 digits, depending on the application language.

If *k*=0, the cursor is positioned before the first row of the result table. Otherwise, ABSOLUTE positions the cursor to row *k* of the result table if *k*>0, or to *k* rows from the bottom of the table if *k*<0. For example, "ABSOLUTE -1" is the same as "LAST".

Data is returned if the specified position is within the rows of the result table, and a target is specified.

If an absolute position is specified that is before the first row or after the last row of the result table, a warning occurs, values are not assigned to host variables, and the cursor is positioned either before the first row or after the last row. If the resulting cursor position is after the last row for INSENSITIVE and SENSITIVE STATIC scrollable cursors, the number of rows of the result table are returned in the SQLERRD1 and SQLERRD2 fields of the SQLCA. If row *k* of the result table is a hole, a warning occurs and values are not assigned to host variables.

FETCH ABSOLUTE 0 results in positioning before the first row and a warning is issued. FETCH BEFORE results in positioning before the first row and no warning is issued.

Table 236 on page 1926 lists some synonymous specifications.

Table 236. Synonymous scroll specifications for ABSOLUTE

Specification	Alternative
ABSOLUTE 0 (but with a warning)	BEFORE (without a warning)
ABSOLUTE +1	FIRST
ABSOLUTE -1	LAST
ABSOLUTE -*m*, 0<m≤*n*	ABSOLUTE *n*+1-*m*
ABSOLUTE *n*	LAST
ABSOLUTE -*n*	FIRST
ABSOLUTE *x* (with a warning)	AFTER (without a warning)
ABSOLUTE -*x* (with a warning)	BEFORE (without a warning)

Note: Assume: 0<=*m*<=*n*<*x* Where, *n* is the number of rows in the result table.

RELATIVE

host-variable or *integer-constant* is assigned to an integral value *k*. If a *host-variable* is specified, it must be an exact numeric type with zero scale and must not include an indicator variable. The possible data types for the host variable are DECIMAL(*n*,0) or integer. The DECIMAL data type is limited to DECIMAL(18,0).

If the cursor is positioned before the first row, or after the last row of the result table, the cursor position is determined as follows:

- If *n* is 0, the cursor position is unchanged, values are not assigned to host variables, and a warning occurs
- If *n* is positive, and the cursor is positioned before the first row, the cursor is positioned on a rowset starting at row *n*
- If *n* is positive, and the cursor is positioned after the last row, a warning occurs
- If *n* is negative, and the cursor is positioned before the first row, a warning occurs
- If *n* is negative, and the cursor is positioned after the last row, the cursor is positioned on a rowset starting as row *n* from the end of the result table

An *integer-constant* can be up to 31 digits, depending on the application language.

Data is returned if the specified position is within the rows of the result table, and a target is specified.

RELATIVE positions the cursor to the row in the result table that is either *k* rows after the current row if *k*>0, or ABS*(k)* rows before the current row if *k*<0. For example, "RELATIVE -1" is the same as "PRIOR". If *k*=0, the position of the cursor does not change (that is, "RELATIVE 0" is the same as "CURRENT").

If a relative position is specified that results in positioning before the first row or after the last row, a warning is issued, values are not assigned to host variables, and the cursor is positioned either before the first row or after the last row. If the resulting cursor position is after the last row for INSENSITIVE and SENSITIVE STATIC scrollable cursors, the number of rows of the result table is returned in the SQLERRD1 and SQLERRD2 fields of the SQLCA. If the cursor is positioned on a hole and RELATIVE 0 is specified or if the target row is a hole, a warning occurs and values are not assigned to host variables.

If the cursor is defined as a rowset cursor, with isolation level UR or a sensitive dynamic scrollable cursor, it is possible that a different row will be returned than the FETCH that established the most recent cursor position. This can occur while fetching a row again when it is determined to not be there anymore. In this case, fetching continues moving forward to get the row data.

If the cursor position is unknown and RELATIVE 0 is specified, an error occurs.

Table 237 on page 1927 lists some synonymous specifications.

Table 237. Synonymous Scroll Specifications for RELATIVE

Specification	**Alternative**
RELATIVE +1	NEXT
RELATIVE -1	PRIOR
RELATIVE 0	CURRENT
RELATIVE +*r* (with a warning)	AFTER (without a warning)
RELATIVE -*r* (with a warning)	BEFORE (without a warning)

Note: *r* has to be large enough to position the cursor beyond either end of the result table.

rowset-positioned

Positioning of the cursor with rowset-positioned fetch orientations NEXT ROWSET, PRIOR ROWSET, CURRENT ROWSET, and ROWSET STARTING AT RELATIVE is done in relation to the current cursor position. Following a successful *rowset-positioned* FETCH statement, the cursor is positioned on a rowset of data. The number of rows in the rowset is determined either explicitly or implicitly. The FOR *n* ROWS clause in the multiple-row-fetch clause is used to explicitly specify the size of the rowset. Positioning is performed relative to the current row or first row of the current rowset, and the cursor is positioned on all rows of the rowset.

A rowset-positioned fetch orientation must not be specified if the current cursor position is not defined to access rowsets. NEXT ROWSET is the only rowset-positioned fetch orientation that can be specified for cursors that are defined as NO SCROLL.

If a row of the rowset reflects a hole, a warning is returned, data values are not assigned to host-variable arrays for that row (that is, the corresponding positions in the target host-variable arrays are untouched), and -3 is returned in all provided indicator variables for that row. If a hole is detected, and at least one indicator variable is not provided, an error occurs.

NEXT ROWSET

Positions the cursor on the next rowset of the result table relative to the current cursor position, and returns data if a target is specified. The next rowset is logically obtained by fetching the row that follows the current rowset and fetching additional rows until the number of rows that is specified implicitly or explicitly in the FOR n ROWS clause is obtained or the last row of the result table is reached.

If the cursor is positioned before the first row of the result table, the cursor is positioned on the first rowset.

If the cursor is positioned on the last row or after the last row of the result table, the cursor position is unchanged, values are not assigned to host-variable arrays, and a warning occurs.

If a row of the rowset reflects a hole, the following actions occur:

- A warning is returned.

- Data values are not assigned to the host-variable-arrays for that row (that is, the corresponding positions in the target host-variable-arrays are untouched).
- A value of -3 is returned in all of the indicator variables that are provided for the row.

If a hole is detected and at least one indicator variable is not provided, an error is returned.

If the cursor is not positioned because of a prior error, values are not assigned to the host-variable-array, and an error is returned. If a row of the rowset would be after the last row of the result table, values are not assigned to host-variable-arrays for that row and any subsequent requested rows of the rowset, and a warning is returned.

NEXT ROWSET is the only rowset positioned fetch orientation that can be explicitly be specified for cursors that are defined as NO SCROLL.

PRIOR ROWSET

Positions the cursor on the previous rowset of the result table relative to the current position, and returns data if a target is specified.

The prior rowset is logically obtained by fetching the row that precedes the current rowset and fetching additional rows until the number of rows that is specified implicitly or explicitly in the FOR n ROWS clause is obtained or the last row of the result table is reached.

If the cursor is positioned after the last row of the result table, the cursor is positioned on the last rowset.

If the cursor is positioned before the first row or on the first row of the result table, the cursor position is unchanged, values are not assigned to host-variable arrays, and a warning occurs.

If a row would be before the first row of the result table, the cursor is positioned on a partial rowset that consists of only those rows that are prior to the current position of the cursor starting with the first row of the result table, and a warning is returned. Values are not assigned to the host-variable-arrays for the rows in the rowset for which the warning is returned.

Although the rowset is logically obtained by fetching backwards from before the current rowset, the data is returned to the application starting with the first row of the rowset, to the end of the rowset.

If a row of the rowset reflects a hole, the following actions occur:

- A warning is returned.
- Data values are not assigned to the host-variable-arrays for that row (that is, the corresponding positions in the target host-variable-arrays are untouched).
- A value of -3 is returned in all of the indicator variables that are provided for the row.

If a hole is detected and at least one indicator variable is not provided, an error is returned.

If the cursor is not positioned because of a prior error, values are not assigned to the host-variable-array, and an error is returned.

FIRST ROWSET

Positions the cursor on the first rowset of the result table, and returns data if a target is specified.

If a row of the rowset reflects a hole, the following actions occur:

- A warning is returned.
- Data values are not assigned to the host-variable-arrays for that row (that is, the corresponding positions in the target host-variable-arrays are untouched).
- A value of -3 is returned in all of the indicator variables that are provided for the row.

If a hole is detected and at least one indicator variable is not provided, an error is returned.

If the result table contains fewer rows than specified implicitly or explicitly in the FOR *n* ROWS clause, values are not assigned to host-variable-arrays after the last row of the result table, and a warning is returned.

LAST ROWSET

Positions the cursor on the last rowset of the result table and returns data if a target is specified. The last rowset is logically obtained by fetching the last row of the result table and fetching prior rows until the number of rows in the rowset is obtained or the first row of the result table is reached. Although the rowset is logically obtained by fetching backwards from the bottom of the result table, the data is returned to the application starting with the first row of the rowset, to the end of the rowset, which is also the end of the result table.

If a row of the rowset reflects a hole, the following actions occur:

- A warning is returned.
- Data values are not assigned to the host-variable-arrays for that row (that is, the corresponding positions in the target host-variable-arrays are untouched).
- A value of -3 is returned in all of the indicator variables that are provided for the row.

If a hole is detected and at least one indicator variable is not provided, an error is returned.

If the result table contains fewer rows than specified implicitly or explicitly in the FOR *n* ROWS clause, the last rowset is the same as the first rowset, values are not assigned to host-variable-arrays after the last row of the result table, and a warning is returned.

CURRENT ROWSET

If the FOR *n* ROWS clause specifies a number different from the number of rows specified implicitly or explicitly in the FOR *n* ROWS clause on the most recent FETCH statement for this cursor, the cursor is repositioned on the specified number of rows, starting with the first row of the current rowset. If the cursor is positioned before the first row, or after the last row of the result table, the cursor position is unchanged, values are not assigned to host-variable arrays, and a warning occurs. If the FOR *n* ROWS clause is not specified, it is possible that the FETCH statement will position the cursor on a partial rowset when the FETCH CURRENT ROWSET statement is processed. In this case, Db2 attempts to position the cursor on a full rowset starting with the first row of the current rowset. Otherwise, the position of the cursor on the current rowset is unchanged. Data is returned if a target is specified.

With isolation level UR or a sensitive dynamic scrollable cursor, it is possible that different rows will be returned than the FETCH that established the most recent rowset cursor position. This can occur while refetching the first row of the rowset when it is determined to not be there anymore. In this case, fetching continues moving forward to get the first row of data for the rowset. This can also occur when changes have been made to other rows in the current rowset such that they no longer exist or have been logically moved within (or out of) the result table of the cursor.

If the cursor is not positioned because of a prior error, values are not assigned to the host-variable-array, and an error occurs.

If the current rowset contains fewer rows than specified implicitly or explicitly in the FOR *n* ROWS clause, values are not assigned to host-variable-arrays after the last row, and a warning is returned.

ROWSET STARTING AT ABSOLUTE or RELATIVE *host-variable* or *integer-constant*

Positions the cursor on the rowset beginning at the row of the result table that is indicated by the ABSOLUTE or RELATIVE specification, and returns data if a target is specified.

host-variable or *integer-constant* is assigned to an integral value *k*. If *host-variable* is specified, it must be an exact numeric type with scale zero, and must not include an indicator variable. The possible data types for the host variable are DECIMAL(n,0) or integer, where the DECIMAL data type is limited to DECIMAL(18,0). If a constant is specified, the value must be an integer.

If a row of the result table would be after the last row or before the first row of the result table, values are not assigned to host-variable-arrays for that row and a warning is returned.

ABSOLUTE

If k=0, an error occurs. If k>0, the first row of the rowset is row k. If k<0, the rowset is positioned on the ABS(k) rows from the bottom of the result table. Assume that ABS(k) is equal to the number of rows for the rowset and that there are enough row to return a complete rowset:

- FETCH ROWSET STARTING AT ABSOLUTE -k is the same as FETCH LAST ROWSET.
- FETCH ROWSET STARTING AT ABSOLUTE 1 is the same as FETCH FIRST ROWSET.

RELATIVE

If k=0 and the FOR *n* ROWS clause does not specify a number different from the number most recently specified implicitly or explicitly for this cursor, then the position of the cursor does not change (that is, "RELATIVE ROWSET 0" is the same as "CURRENT ROWSET"). If k=0 and the FOR *n* ROWS clause specifies a number different from the number most recently specified implicitly or explicitly for this cursor, then the cursor is repositioned on the specified number of rows, starting with the first row of the current rowset.

If the cursor is positioned before the first row, or after the last row of the result table, the cursor position is determined as follows:

- If n is 0, the cursor position is unchanged, values are not assigned to host variables, and a warning occurs. This is the same as FETCH CURRENT ROWSET.
- If *n* is positive, and the cursor is positioned before the first row, the cursor is positioned on a rowset starting a row *n*.
- If *n* is positive, and the cursor is positioned after the last row, a warning occurs.
- If *n* is negative, and the cursor is positioned before the first row, a warning occurs.
- If *n* is negative, and the cursor is positioned after the last row, the cursor is positioned on a rowset starting at row *n* from the bottom of the result table.

Otherwise, RELATIVE repositions the cursor so that the first row of the new rowset cursor position is on the row in the result table that is either k rows after the first row of the current rowset cursor position if k>0, or ABS(k) rows before the first row of the current rowset cursor position if k<0. Assume that ABS(k) is equal to the number of rows for the resulting rowset

- FETCH ROWSET STARTING AT RELATIVE -k is the same as FETCH PRIOR ROWSET.
- FETCH ROWSET STARTING AT RELATIVE k is the same as FETCH NEXT ROWSET.
- FETCH ROWSET STARTING AT RELATIVE 0 is the same as FETCH CURRENT ROWSET.

When ROWSET STARTING AT RELATIVE -n is specified and there are not enough rows between the current position of the cursor and the beginning of the result table to return a complete rowset:

- A warning is returned.
- Values are not assigned to the host-variable-arrays.
- The cursor is positioned before the first row.

If a row of the rowset reflects a hole, If a row of the rowset reflects a hole, the following actions occur:

- A warning is returned.
- Data values are not assigned to the host-variable-arrays for that row (that is, the corresponding positions in the target host-variable-arrays are untouched).
- A value of -3 is returned in all of the indicator variables that are provided for the row.

If a hole is detected and at least one indicator variable is not provided, an error is returned. If a row of the rowset is unknown, values are not assigned to host-variable arrays for that row, and an error is returned. If a row of the rowset would be after the last row or before the first row of the result table, values are not assigned to host-variable-arrays for that row, and a warning is returned.

cursor-name

Identifies the cursor to be used in the fetch operation. The cursor name must identify a declared cursor, as explained in the description of the DECLARE CURSOR statement in "DECLARE CURSOR" on page 1814, or an allocated cursor, as explained in "ALLOCATE CURSOR" on page 1088. When the FETCH statement is executed, the cursor must be in the open state.

If a single-row-fetch or multiple-row-fetch clause is not specified, the cursor position is adjusted as specified, but no data is returned to the user.

single-row-fetch

When *single-row-fetch* is specified, SENSITIVE or INSENSITIVE can be specified though there is a default. The default depends on the sensitivity of the cursor. If the sensitivity of the cursor is INSENSITIVE, then the default is INSENSITIVE. If the effective sensitivity of the cursor is SENSITIVE DYNAMIC or SENSITIVE STATIC, then the default is SENSITIVE. The single-row-fetch or multiple-row-fetch clause must not be specified when the FETCH BEFORE or FETCH AFTER option is specified. They are required when FETCH BEFORE or FETCH AFTER is not specified. If an individual fetch operation causes the cursor to be positioned or to remain positioned on a row if there is a target specification, the values of the result table are assigned to host variables as specified by the single-fetch-clause.

INTO *target-variable* or *array-variable*[*array-index*]

Identifies one or more targets for the assignment of output values. The number of targets in the INTO clause must equal the number of values that are to be assigned. The first value in the result row is assigned to the first target in the list, the second value to the second target, and so on. A target variable must not be specified more than once in the INTO clause. Each assignment to a target is made in sequence through the list according to the rules described in "Assignment and comparison" on page 143.

The value 'W' is assigned to the SQLWARN3 field of the SQLCA if the number of targets is less than the number of result column values.

If an error occurs on any assignment, the value is not assigned to the target, and no more values are assigned to the specified targets. Any values that have already been assigned remain assigned.

global-variable-name

Identifies the global variable that is the assignment target. A global variable must only be specified in an SQL PL context. When a global variable is specified as the assignment target, the cursor must be non-scrollable.

host-variable-name

Identifies the host variable that is the assignment target. For LOB output values, the target can be a regular host variable (if it is large enough), a LOB locator variable, or a LOB file reference variable.

SQL-parameter-name

Identifies the parameter that is the assignment target.

SQL-variable-name

Identifies the SQL variable that is the assignment target. SQL variables must be declared before they are used.

***array-variable* [*array-index*]**

Specifies an array element that is the target of the assignment.

array-variable

Specifies and array variable.

[*array-index*]

An expression that specifies which element in the array is the target of the assignment.

For an ordinary array, the array index expression must be castable to INTEGER, and must not be the null value. The index value must be between 1 and the maximum cardinality that is defined for the array.

For an associative array, the array index expression must be castable to the index data type of the associative array, and must not be the null value.

array-index must not be:

- An expression that references the CURRENT DATE, CURRENT TIME, or CURRENT TIMESTAMP special register
- A nondeterministic function
- A function that is defined with EXTERNAL ACTION
- A function that is defined with MODIFIES SQL DATA
- A sequence expression

transition-variable-name

Identifies the column that is to be updated in the transition table. A *transition-variable-name* must identify a column in the subject table of a trigger, optionally qualified by a correlation name that identifies the new value.

INTO DESCRIPTOR *descriptor-name*

Identifies an SQLDA that contains a valid description of the host output variables. Result values from the associated SELECT statement are returned to the application program in the output host variables.

Before the FETCH statement is processed, you must set the following fields in the SQLDA:

- SQLN to indicate the number of SQLVAR occurrences provided in the SQLDA

  A REXX SQLDA does not contain this field.
- SQLABC to indicate the number of bytes of storage allocated in the SQLDA
- SQLD to indicate the number of variables used in the SQLDA when processing the statement
- SQLVAR occurrences to indicate the attributes of the variables

The SQLDA must have enough storage to contain all SQLVAR occurrences. Each SQLVAR occurrence describes a host variable or buffer into which a value in the result table is to be assigned. If LOBs are present in the results, there must be additional SQLVAR entries for each column of the result table. If the result table contains only base types and distinct types, multiple SQLVAR entries are not needed for each column. However, extra SQLVAR entries are needed for distinct types as well as for LOBs in DESCRIBE and PREPARE INTO statements. For more information on the SQLDA, which includes a description of the SQLVAR and an explanation on how to determine the number of SQLVAR occurrences, see Appendix F, “SQL descriptor area (SQLDA),” on page 2301.

SQLD must be set to a value greater than or equal to zero and less than or equal to SQLN.

See “Identifying an SQLDA in C or C++” on page 2317 for how to represent *descriptor-name* in C.

multiple-row-fetch

Retrieves multiple rows of data from the result table of a query. The FOR *n* ROWS clause of the FETCH statement controls how many rows are returned on a single FETCH statement. The fetch orientation determines whether the resulting cursor position (for example, on a single row, rowset, before, or after the result table). Fetching stops when an error is returned, all requested rows are fetched, or the end of data condition is reached.

Fetching multiple rows of data can be done with scrollable or non-scrollable cursors. The operations used to define, open, and close a cursor used for fetching multiple rows of data are the same as for those used for single row FETCH statements.

If the BEFORE or AFTER option is specified, neither single-row-fetch or multiple-row-fetch can be specified.

FOR *host-variable* or *integer-constant* ROWS

host-variable or *integer-constant* is assigned to an integral value *k*. If a host variable is specified, it must be an exact numeric type with a scale of zero and must not include an indicator variable. Furthermore, *k* must be in the range, 0<k<=32767.

This clause must not be specified if a row-positioned fetch-orientation clause was specified. This clause must also not be specified for a cursor that is defined without rowset access.

If a rowset fetch orientation is specified and this clause is not specified, the number of rows in the resulting rowset is determined as follows:

- If the most recent FETCH statement for this cursor was a rowset-positioned FETCH, the number of rows of the rowset is implicitly determined by the number of rows that was most recently specified (implicitly or explicitly) for this cursor.
- When the most recent FETCH statement for this cursor was either FETCH BEFORE or FETCH AFTER and the most recent FETCH statement for this cursor prior to that was a rowset-positioned FETCH, the number of rows of the rowset is implicitly determined by the number of rows that were most recently specified (implicitly or explicitly) for this cursor.
- Otherwise, the rowset consists of a single row.

For result set cursors, the number of rows for a rowset cursor position, established in the procedure that defined the rowset, is not inherited by the caller when the rowset is returned. Use the FOR *n* ROWS clause on the first rowset FETCH statement for the result set in the calling program to establish the number of rows for the cursor. Otherwise, the rowset consists of a single row.

The cursor is positioned on the row or rowset that is specified by the orientation clause (for example, NEXT ROWSET), and those rows are fetched if a target is specified. After the cursor is positioned on the first row being fetched, the next k-1 rows are fetched. Fetching moves forward from the cursor position in the result table and continues until the end of data condition is returned, k-1 rows have been fetched, or an assignment error is returned.

The resulting cursor position depends on the fetch orientation that is specified:

- For a row-positioned fetch orientation, the cursor is positioned at the last row successfully retrieved.
- For a rowset-positioned fetch orientation, the cursor is positioned on all the rows retrieved.

The values from each individual fetch are placed in data areas that are described in the INTO or USING clause. If a target specification is provided for a rowset-positioned FETCH, the host-variable arrays must be specified as the target specification, and the arrays must be defined with a dimension of 1 or greater. The target specification must be defined as an array for a rowset-positioned FETCH even if the number of rows that is specified implicitly or explicitly is one. See Diagnostics information for rowset positioned FETCH statements.

INTO *host-variable-array*

Identifies for each column of the result table a host-variable-array to receive the data that is retrieved with this FETCH statement. If the number of host-variable-arrays is less than the number of columns of the result table, the SQLWARN3 field of the SQLCA is set to 'W'. No warning is given if there are more host-variable-arrays than the number of columns in the result table.

Each host-variable-array must be defined in the application program in accordance with the rules for declaring an array. A host-variable-array is used to return the values for a column of the result table. The number of rows to be fetched must be less than or equal to the dimension of each of the host-variable-arrays.

An optional indicator array can be specified for a host-variable-array. It should be specified if the SQLTYPE of any SQLVAR occurrence indicates that the column of the result table is nullable. Additionally, if an operation may result in null values, such as an UPDATE operation that results in a hole, is performed in the application, an indicator array should be specified. Otherwise an error occurs if null values are encountered. The indicators are returned as small integers.

host-variable-array is supported in C/C++, COBOL, and PL/I. For more information, see "Host-variable arrays in PL/I, C, C++, and COBOL" on page 236.

INTO DESCRIPTOR *descriptor-name*

Identifies an SQLDA that must contain a valid description of zero or more host-variable-arrays or buffers into which the values for a column of the result table are to be returned.

Before the FETCH statement is processed, you must set the following fields in the SQLDA:

- SQLN to indicate the number of SQLVAR occurrences provided in the SQLDA.
- SQLABC to indicate the number of bytes of storage allocated for the SQLDA.
- SQLD to indicate the number of variables used in the SQLDA when processing the statement.
- SQLVAR occurrences to indicate the attributes of an element of the host-variable-array. Within each SQLVAR representing an array:
  - SQLTYPE indicates the data type of the elements of the host-variable-array.
  - SQLDATA field points to the first element of the host-variable-array.
  - The length fields (SQLLEN and SQLLONGLEN) are set to indicate the maximum length of a single element of the array.
  - SQLNAME - The length of SQLNAME must be set to 8, and the first two bytes of the data portion of SQLNAME must be initialized to X'0000'. The fifth and sixth bytes must contain a flag field and the seventh and eighth bytes must be initialized to a binary small integer (half word) representation of the dimension of the host-variable-array, and the corresponding indicator array, if one is specified.

  The SQLVAR entry for the number of rows must also contain a flag value. The number of rows to be fetched must be less than or equal to the dimension of each of the host-variable arrays.

You set the SQLDATA and SQLIND pointers to the beginning of the corresponding arrays. The SQLDA must have enough storage to contain all SQLVAR occurrences. Each SQLVAR occurrence describes a host-variable-array or buffer into which the values for a column in the result table are to be returned. If any column of the result table is a LOB, two SQLVAR entries must be provided for each SQLVAR, and SQLN must be set to two times the number of SQLVARS. SQLD must be set to a value greater than or equal to zero and less than or equal to SQLN.

Notes for FETCH

Assignment to targets:

The *n*th target identified by the INTO clause or described in the SQLDA corresponds to the *n*th column of the result table of the cursor. The data type of target must be compatible with its corresponding value. If the value is numeric, the target must have the capacity to represent the whole part of the value. For a datetime value, the target must be a character string variable of a minimum length as defined in "String representations of datetime values" on page 120. When the target is a host variable, if the value is null, an indicator variable must be specified.

Assignments are made in sequence through the list. Each assignment to a target is made according to the rules described in Chapter 2, "Language elements in SQL," on page 75. If the number of targets is less than the number of values in the row, the SQLWARN3 field of the SQLCA is set to 'W'. There is no warning if there are more targets than the number of result columns. If the target is a host variable and the value is null, an indicator variable must be provided. If an assignment error occurs, the value is not assigned to the target and no more values are assigned to targets. Any values that have already been assigned to targets remain assigned.

If more than one assignment is included in the same assignment statement, all expressions are evaluated before the assignments are performed. For example, a reference to a variable in an expression always uses the value of the variable prior to any assignment in the assignment statement.

Normally, you use LOB locators to assign and retrieve data from LOB columns. However, because of compatibility rules, you can also use LOB locators to assign data to targets with other data types. For more information on using locators, see Saving storage when manipulating LOBs by using LOB locators (Db2 Application programming and SQL).

A timestamp without time zone value must not be assigned to a timestamp with time zone target.

The default encoding scheme for the data is the value in the bind option ENCODING, which is the option for application encoding. If this statement is used with functions such as LENGTH or SUBSTRING that are operating on LOB locators, and the LOB data that is specifies by the locator is in a different encoding scheme from the ENCODING bind option, LOB materialization and character conversion occur. To avoid LOB materialization and character conversion, select the LOB data from the SYSIBM.SYSDUMMYA, SYSIBM.SYSDUMMYE, or SYSIBM.SYSDUMMYU sample table.

Restrictions on using the WITH CONTINUE and CURRENT CONTINUE clauses:

When using the WITH CONTINUE clause, the Db2 system will only reserve truncated data for result set columns of the BLOB, CLOB, DBCLOB, or XML data type, and only when the output host variable data type is the appropriate LOB data type.

If an application uses FETCH WITH CONTINUE, and truncated data remains after the FETCH operation, the application cannot perform any intervening operation on that cursor before performing the FETCH CURRENT CONTINUE. If intervening operations on that cursor are performed, the truncated data is lost.

FETCH CURRENT CONTINUE is not supported with multi-row fetch. Also, FETCH CURRENT CONTINUE is not supported for non-LOB and non-XML columns that have been truncated. If truncation occurs for these non-LOB and non-XML columns, the truncated data will be discarded as usual.

Result column evaluation considerations:

If an error occurs as the result of an arithmetic expression in the SELECT list of an outer SELECT statement (division by zero, or overflow) or a numeric conversion error occurs, the result is the null value. As in any other case of a null value, an indicator variable must be provided and the main variable is unchanged. In this case, however, the indicator variable is set to -2. Processing of the statement continues as if the error had not occurred. (However, this error causes a positive SQLCODE.) If you do not provide an indicator variable, a negative value is returned in the SQLCODE field of the SQLCA. Processing of the statement terminates when the error is encountered. No value is assigned to the host variable or to later variables, though any values that have already been assigned to variables remain assigned.

If the specified host variable is not large enough to contain the result, a warning is returned and W is assigned to SQLWARN1 in the SQLCA. The actual length of the result is returned in the indicator variable associated with the host-variable, if an indicator is provided. It is possible that a warning may not be returned on a FETCH operation. This occurs as a result of optimizations, such as the use of system temporary tables or blocking. It is also possible that the returned warning applies to a previously fetched row. When a datetime value is returned, the length of the variable must be large enough to store the complete value. Otherwise, a warning or an error is returned.

Considerations when using the FETCH statement for a rowset cursor that was passed to an accelerator server for processing:

Db2 provides limited support for rowset queries that are passed to an accelerator server for processing. Db2 supports only high performance access to accelerated query data. The data is pre-fetched in rowsets and returned by using *multiple-row-fetch* statements, returning multiple rows of data in one FETCH statement. The following restrictions apply to FETCH statements that are executed against a rowset cursor that was accelerated:

- All FETCH requests must be rowset fetches.
- All FETCH requests must specify a FOR *n* ROWS clause.
- All FETCH requests must specify the same rowset size.
- All FETCH requests must specify target host variables. (The FETCH operation must have a target for positioning.)

Cursor positioning:

An open cursor has three possible positions:

- Before a row
- On a row or rowset
- After the last row

When a scrollable or non-scrollable cursor is opened, it is positioned before the first row in the result table. If a cursor is on a row, that row is called the current row of the cursor. If a cursor is on a rowset, the rows are called the current rowset of the cursor.

A cursor referred to in an UPDATE or DELETE statement must be positioned on a row or rowset. A cursor can only be on a row or rowset as a result of a FETCH statement.

If the cursor was declared SENSITIVE STATIC SCROLL, a row may be a *hole*, from which no values may be fetched, updated, or deleted. Holes do not exist with sensitive dynamic cursors because there is no temporary result table. For more information, see Holes in the result table of a scrollable cursor (Db2 Application programming and SQL).

For scrollable cursors, the cursor position after an error varies depending on the type of error:

- When an operation is attempted against an update or delete hole, or when an update or delete hole is detected, the cursor is positioned on the hole.
- When a FETCH operation is attempted past the end of file, the cursor is positioned after the last row.
- When a FETCH operation is attempted before the beginning of file, the cursor is positioned before the first row.
- When an error causes the cursor position to be invalid such as when a single row positioned update or positioned delete error occurs that causes a rollback, the cursor is closed.

Cursor position after exception condition:

If an error occurs during the execution of a fetch operation, the position of the cursor and the result of any later fetch is unpredictable. It is possible for an error to occur that makes the position of the cursor invalid, in which case the cursor is closed.

If an individual fetch operation specifies a destination that is outside the range of the cursor, a warning is issued (except for FETCH BEFORE or FETCH AFTER), the cursor is positioned before or after the result table, and values are not assigned to host variables.

Concurrency and scrollability:

The current row of a cursor cannot be updated or deleted by another application process if it is locked. Unless it is already locked because it was inserted or updated by the application process during the current unit of work, the current row of a cursor is not locked if:

- The isolation level is UR, or
- The isolation level is CS, and
  - The result table of the cursor is read-only
  - The bind option CURRENTDATA(NO) is in effect

A dynamic scrollable cursor is useful when it is more important to the application to see updated rows and newly inserted rows and there is no need to see deleted rows. The isolation level of CS should be used for maximum concurrency with dynamic scrollable cursors. Specifying an isolation level of RR or RS severely restricts the update of the table, thus defeating the purpose of a SENSITIVE DYNAMIC scrollable cursor. If the application needs a constant result table, a SENSITIVE STATIC scrollable cursor with an isolation level of CS should be used.

Sensitivity of SENSITIVE STATIC SCROLL cursors to database changes:

When SENSITIVE STATIC SCROLL has been declared, the following rules apply:

- For the result of an update operation to be visible within a cursor after "open," the update operation must be a positioned update executed against the cursor, or a FETCH SENSITIVE in a STATIC cursor must be executed against a row which has been updated by some other means (that is, a searched update, committed updates of others, or an update with another cursor in the same process).
- Another process can update the base table of the SELECT statement so that the current values no longer satisfy the WHERE clause. In this case, an "update hole" effectively exists during the time the values in the base table do not satisfy the WHERE clause, and the row is no longer accessible through the cursor. When an attempt is made to fetch a row that has been identified as an update hole, no values are returned, and a warning is issued.

  Under SENSITIVE STATIC SCROLL cursors, update holes are only identified during positioned update, positioned delete, and FETCH SENSITIVE operations. Each positioned update, positioned delete, and FETCH SENSITIVE operation does the necessary tests to determine if an update hole exists.

- For the result of a delete operation to be visible within a SENSITIVE STATIC SCROLL cursor, the delete operation must be a positioned delete executed against the cursor or a FETCH SENSITIVE in a STATIC cursor must be executed against a row that has been deleted by some other means (that is, a searched delete, committed deletes of others, or a delete with another cursor in the same process).
- Another process, or the even the same process, may delete a row in the base table of the SELECT statement so that a row of the cursor no longer has a corresponding row in the base table. In this case, a "delete hole" effectively exists, and that row is no longer accessible through the cursor. When an attempt is made to fetch a row that has been identified as a delete hole, no values are returned, and a warning is issued.

  Under SENSITIVE STATIC SCROLL cursors, delete holes are identified during positioned update, positioned delete, and FETCH SENSITIVE operations.
- Inserts into the base table or tables of SENSITIVE STATIC SCROLL cursors are not seen after the cursor is opened.

LOB locators:

When information is retrieved into LOB locators and it is not necessary to retain the locator across FETCH statements, it is a good practice to issue a FREE LOCATOR statement before issuing another FETCH statement because locator resources are limited.

Isolation level considerations:

The isolation level of the statement (specified implicitly or explicitly) can affect the result of a rowset-positioned FETCH statement. This is possible when changes are made to the tables underlying the cursor when isolation level UR is used with a dynamic scrollable cursor, or with other isolation levels when rows have been added by the application fetching from the cursor. These situations can occur with the following fetch orientations:

PRIOR ROWSET

With a dynamic scrollable cursor and isolation level UR, the content of a prior rowset can be affected by other activity within the table. It is possible that a row that previously qualified for the cursor, and was included as a member of the "prior" rowset, has since been deleted or modified before it is actually returned as part of the rowset for the current statement. To avoid this behavior, use an isolation level other than UR.

CURRENT ROWSET

With a dynamic scrollable cursor, additional rows can be added between rows that form the rowset that was returned to the user. With isolation level RR, these rows can only be added by the application fetching from the cursor. For isolation levels other than RR, other applications can insert rows that can affect the results of a subsequent FETCH CURRENT ROWSET. To avoid this behavior, use a static scrollable cursor instead of a dynamic scrollable cursor.

LAST ROWSET

With a dynamic scrollable cursor and isolation level UR, the content of the last rowset can be affected by other activity within the table. It is possible that a row that previously qualified for the cursor, and was included as a member of the "last" rowset, has since been deleted or modified before it is actually returned as part of the rowset for the current statement. To avoid this behavior, use an isolation level other than UR.

ROWSET STARTING AT RELATIVE *-n* (where *-n* is a negative number)

With a dynamic scrollable cursor and isolation level UR, the content of a prior rowset can be affected by other activity within the table. It is possible that a row that previously qualified for the cursor, and was included as a member of the "prior" rowset, has since been deleted or modified before it is actually returned as part of the rowset for the current statement. To avoid this behavior, use an isolation level other than UR.

Row positioned and rowset positioned FETCH statement interaction:

The following table demonstrates the interaction between row positioned and rowset positioned FETCH statements. The table is based on the following assumptions:

- TABLE T1 has 15 rows
- CURSOR CS1 is declared as follows:

```
DECLARE CS1 SCROLL CURSOR WITH ROWSET POSITIONING FOR
SELECT * FROM T1;
```

- An OPEN CURSOR statement has been successfully executed for CURSOR CS1 and the FETCH statements in the table are executed in the order that they appear in the table.

Table 238. Interaction between row positioned and rowset positioned FETCH statements

FETCH Statement	Cursor Position
FETCH FIRST	Cursor is positioned on row 1.
FETCH FIRST ROWSET	Cursor is positioned on a rowset of size 1, consisting of row 1.
FETCH FIRST ROWSET FOR 5 ROWS	Cursor is positioned on a rowset of size 5, consisting of rows 1, 2, 3, 4, and 5.
FETCH CURRENT ROWSET	Cursor is positioned on a rowset of size 5, consisting of rows 1, 2, 3, 4, and 5.
FETCH CURRENT	Cursor is positioned on row 1
FETCH FIRST ROWSET FOR 5 ROWS	Cursor is positioned on a rowset of size 5, consisting of rows 1, 2, 3, 4, and 5.
FETCH **or** FETCH NEXT	Cursor is positioned on row 2.
FETCH NEXT ROWSET	Cursor is positioned on a rowset of size 1, consisting of row 3.
FETCH NEXT ROWSET FOR 3 ROWS	Cursor is positioned on a rowset of size 3, consisting of rows 4,5, and 6.
FETCH NEXT ROWSET	Cursor is positioned on a rowset of size 3, consisting of rows 7,8, and 9.
FETCH LAST	Cursor is positioned on row 15.
FETCH LAST ROWSET FOR 2 ROWS	Cursor is positioned on a rowset of size 2, consisting of rows 14 and 15.
FETCH PRIOR ROWSET	Cursor is positioned on a rowset of size 2, consisting of rows 12 and 13.
FETCH ABSOLUTE 2	Cursor is positioned on row 2.
FETCH ROWSET STARTING AT ABSOLUTE 2 FOR 3 ROWS	Cursor is positioned on a rowset of size 3, consisting of rows 2, 3, and 4.
FETCH RELATIVE 2	Cursor is positioned on row 4.
FETCH ROWSET STARTING AT ABSOLUTE 2 FOR 4 ROWS	Cursor is positioned on a rowset of size 4, consisting of rows 2, 3, 4, and 5.
FETCH RELATIVE -1	Cursor is positioned on row 1.
FETCH ROWSET STARTING AT ABSOLUTE 3 FOR 2 ROWS	Cursor is positioned on a rowset of size 2, consisting of rows 3 and 4.
FETCH ROWSET STARTING AT RELATIVE 4	Cursor is positioned on a rowset of size 2, consisting of rows 7 and 8.
FETCH PRIOR	Cursor is positioned on row 6.
FETCH ROWSET STARTING AT ABSOLUTE 13 FOR 5 ROWS	Cursor is positioned on a rowset of size 3, consisting of rows 13, 14, and 15.

Table 238. Interaction between row positioned and rowset positioned FETCH statements (continued)

FETCH Statement	Cursor Position
FETCH FIRST ROWSET	Cursor is positioned on a rowset of size 5, consisting of rows 1, 2, 3, 4, and 5. **Note:** Even though the previous FETCH statement returned only 3 rows because EOF was encountered, Db2 will remember that 5 rows were requested by the previous FETCH statement.

Considerations for using the FOR n ROWS clause with the FETCH FIRST n ROWS ONLY clause:

A clause specifying the number of rows that you want can be specified in the SELECT statement of a cursor, the FETCH statement for a cursor, or both. However, these clauses have different effects:

- In the SELECT statement, a FETCH FIRST *n* ROWS ONLY clause controls the maximum number of rows that can be accessed with the cursor. When a FETCH statement attempts to retrieve a row beyond the number specified in the FETCH FIRST n ROWS ONLY clause of the SELECT statement, an end-of-data condition occurs.
- In a FETCH statement, a FOR *n* ROWS clause controls the number of rows that are returned for a single FETCH statement.

Both of these clauses can be specified.

Referencing columns that will be updated:

If a cursor uses FETCH statements to retrieve columns that will be updated later, specify FOR UPDATE OF when you select the columns. Then specify WHERE CURRENT OF in the subsequent UPDATE or DELETE statements. These clauses prevent Db2 from selecting access through an index on the columns that are being updated, which might otherwise cause Db2 to read the same row more than once.

For more information, see Updating previously retrieved data (Db2 Application programming and SQL).

Diagnostics information for rowset positioned FETCH statements:

A single FETCH statement from a rowset cursor might encounter zero, one, or more conditions. If the current cursor position is not valid for the fetch orientation, a warning occurs and the statement terminates. If a warning or non-terminating error (such as a bind out error) occurs during the fetch of a row, processing continues. In this case, a summary message is returned for the FETCH statement, and additional information about each fetched row is available with the GET DIAGNOSTICS statement. Use the GET DIAGNOSTICS statement to obtain information about all of the conditions that are encountered for one of these FETCH statements. See "GET DIAGNOSTICS" on page 1944 for more information.

The SQLCA returns some information about errors and warnings that are found while fetching from a rowset cursor. Processing stops when the end of data is encountered, or when a terminating condition occurs. After each FETCH statement from a rowset cursor, information is returned to the program through the SQLCA. The SQLCA is set as follows:

- SQLCODE contains the SQLCODE.
- SQLSTATE contains the SQLSTATE.
- SQLERRD1 and SQLERRD2 contain the number of rows of the result table if the cursor is positioned on the last row of the result table.
- SQLERRD3 contains the actual number of rows returned. If SQLERRD3 is less than the number of rows requested, an error or end-of-data condition occurred.
- SQLWARN flags are set to represent all the warnings that were accumulated while processing the FETCH statement.

Consider the following examples, where 10 rows are fetched with a single FETCH statement.

Example 1

Assume that an error is detected on the 5th row. SQLERRD3 is set to 4 for the 4 returned rows, SQLSTATE is set to 22537, and SQLCODE is set to -354. This information is also available from the GET DIAGNOSTICS statement (the information that is returned is generated from connected server, which may differ across different servers). For example:

```
GET DIAGNOSTICS :num_rows = ROW_COUNT, :num_cond = NUMBER;
-- Results of the statement:
-- num_rows = 4 and num_cond = 1 (1 condition)
```

```
GET DIAGNOSTICS CONDITION 1 :sqlstate = RETURNED_SQLSTATE,
:sqlcode = DB2_RETURNED_SQLCODE, :row_num = DB2_ROW_NUMBER;
-- Results of the statement:
-- sqlstate = 22537, sqlcode = -354, and row_num = 5
```

Example 2

Assume that an end-of-data condition is detected on the 6th row and that the cursor does not have immediate sensitivity to updates. SQLERRD3 is set to 5 for the 5 returned rows, SQLSTATE is set to 02000, and SQLCODE is set to +100. This information is also available from the GET DIAGNOSTICS statement. For example:

```
GET DIAGNOSTICS :num_rows = ROW_COUNT, :num_cond = NUMBER;
-- Results of the statement:
-- num_rows = 5 and num_cond = 1 (1 condition)
```

```
GET DIAGNOSTICS CONDITION 1 :sqlstate = RETURNED_SQLSTATE,
:sqlcode = DB2_RETURNED_SQLCODE, :row_num = DB2_ROW_NUMBER;
-- Results of the statement:
-- sqlstate = 02000, sqlcode = 100, and row_num = 6
```

Example 3

Assume that a bind error condition is detected on the 5th row, the condition is recorded, and processing continues. Also, assume that an end-of-data condition is detected on the 8th row. SQLERRD3 is set to 7 for the 7 returned rows, SQLSTATE is set to 02000, and SQLCODE is set to +100. Processing to complete the FETCH statement is performed, and the bind out error that occurred is noted. An additional SQLCODE is recorded for the bind out error. SQLCODE is set to –354, and SQLSTATE is set to 01668. Use the GET DIAGNOSTICS statement to determine what went on. For example:

```
GET DIAGNOSTICS :num_rows = ROW_COUNT, :num_cond = NUMBER;
-- Results of the statement:
-- num_rows = 7 and num_cond = 3 (3 conditions)
```

```
GET DIAGNOSTICS CONDITION 1 :sqlstate = RETURNED_SQLSTATE,
:sqlcode = RETURNED_SQLCODE, :row_num = DB2_ROW_NUMBER;
-- Results of the statement:
-- sqlstate = 01668, sqlcode = -354, and row_num = 0
```

```
GET DIAGNOSTICS CONDITION 2 :sqlstate = RETURNED_SQLSTATE,
:sqlcode = RETURNED_SQLCODE, :row_num = DB2_ROW_NUMBER;
-- Results of the statement:
-- sqlstate = 02000, sqlcode = 100, and row_num = 0
```

```
GET DIAGNOSTICS CONDITION 3 :sqlstate = RETURNED_SQLSTATE,
:sqlcode = RETURNED_SQLCODE, :row_num = DB2_ROW_NUMBER;
-- Results of the statement:
-- sqlstate = 22003, sqlcode = -302, and row_num = 5
```

In some cases, Db2 returns a warning if indicator variables are provided, or an error if indicator variables are not provided. These errors can be thought of as data mapping errors that result in a warning if indicator variables are provided.

- If indicator variables are provided, Db2 returns all rows to the user, marking the errors in the indicator variables. The SQLCODE and SQLSTATE contain the warning from the last data mapping error. The GET DIAGNOSTICS statement can be used to retrieve information about all the data mapping errors that have occurred.

- If some or no indicator variables are provided, all rows are returned as above until the first data mapping error that does not have indicator variables is detected. The rows successfully fetched are returned and the SQLSTATE, SQLCODE, and SQLWARN flags are set, if necessary. (The SQLCODE may be 0 or a positive value).

It is possible, if a data mapping error occurs, for the positioning of the cursor to be successful. In this case, the cursor is positioned on the rowset that encountered the data mapping error.

Consider the following examples, which try to fetch 10 rows with a single FETCH statement.

Example 1

Assume that indicators have been provided for values returned for column 1, but not for column 2. The 5th row has a data mapping error (+802) for column 1, and the 7th row has a data mapping error for column 2 (-802 is returned because an indicator was not provided for column 2). SQLERRD3 is set to 6 for the 6 returned rows, SQLSTATE and SQLCODE are set to the error from the 7th row fetched. The indicator variable for the 5th row column 1 indicates that a data mapping error was found. This information is also available from the GET DIAGNOSTICS statement, for example:

```
GET DIAGNOSTICS :num_rows = ROW_COUNT, :num_cond = NUMBER;
-- Results of the statement:
-- num_rows = 6 and num_cond = 2 (2 conditions)
```

```
GET DIAGNOSTICS CONDITION 1 :sqlstate = RETURNED_SQLSTATE,
:sqlcode = DB2_RETURNED_SQLCODE, :row_num = DB2_ROW_NUMBER;
-- Results of the statement:
-- sqlstate = 01519, sqlcode = +802, and row_num = 5
```

```
GET DIAGNOSTICS CONDITION 2 :sqlstate = RETURNED_SQLSTATE,
:sqlcode = DB2_RETURNED_SQLCODE, :row_num = DB2_ROW_NUMBER;
-- Results of the statement:
-- sqlstate = 22003, sqlcode = -802, and row_num = 7
```

The resulting cursor position is unknown.

Example 2

Assume that null indicators are provided, that rows 3 and 5 are holes, and that data exists for the other requested rows. SQLERRD3 is set to 10 to reflect that 10 fetches were completed and that information has been returned for the 10 requested rows. Eight rows actually contain data. For two rows, indicator variables are set to indicate no data was returned for those rows. SQLSTATE is set to 02502, SQLCODE is set to +222, and all null indicators for rows 3 and 5 are set to -3 to indicate that a hole was detected. This information is also available from the GET DIAGNOSTICS statement, for example:

```
GET DIAGNOSTICS :num_rows = ROW_COUNT, :num_cond = NUMBER;
-- Results of the statement:
-- num_rows = 10 and num_cond = 2 (2 conditions)
```

```
GET DIAGNOSTICS CONDITION 1 :sqlstate = RETURNED_SQLSTATE,
:sqlcode = DB2_RETURNED_SQLCODE, :row_num = DB2_ROW_NUMBER;
-- Results of the statement:
-- sqlstate = 02502, sqlcode = +222, and row_num = 3
```

```
GET DIAGNOSTICS CONDITION 2 :sqlstate = RETURNED_SQLSTATE,
:sqlcode = DB2_RETURNED_SQLCODE, :row_num = DB2_ROW_NUMBER;
-- Results of the statement:
-- sqlstate = 02502, sqlcode = +222, and row_num = 5
```

If a null indicator was not provided for any variable in a row that was a hole, an error occurs.

SQLCA usage summary:

For multiple-row-fetch, the fields of the SQLCA are set as follows:

Condition		Action: Resulting Values Stored in the SQLCA Fields		
Errors	**Data**	**SQLSTATE**	**SQLCODE**	**SQLERRD3**
No[1]	Return all requested rows	00000	0	Number of rows requested
No[1]	Return data for subset of requested rows, end of data	02000	+100	Number of rows
No[1]	Return all requested rows	sqlstate(2)	sqlcode(2)	Number of rows requested
Yes[1]	Return successfully fetched rows	sqlstate(3)	sqlcode(3)	Number of rows
Yes[1]	Return successfully fetched rows	sqlstate(4)	sqlcode(4)	Number of rows

Notes:

1. SQLWARN flags may be set in all cases, even if there are no other warnings or errors indicated. The warning flags are an accumulation of all warning flags set while processing the multiple-row-fetch.
2. sqlcode is the last positive SQLCODE, and sqlstate is the corresponding SQLSTATE value.
3. Database Server detected error. sqlcode is the first negative SQLCODE encountered, sqlstate is the corresponding SQLSTATE value.
4. Client detected error. sqlcode is the first negative SQLCODE encountered, sqlstate is one of the following SQLSTATEs: 22002, 22008, 22509, 22518, or 55021.

Providing indicator variables for error conditions:

If an error occurs as the result of an arithmetic expression in the SELECT list of an outer SELECT statement (division by zero or overflow) or a numeric conversion error occurs, the result is the null value. As in any other case of a null value, an indicator variable must be provided and the main variable is unchanged. In this case, however, the indicator variable is set to -2. Processing of the statement continues as if the error had not occurred. (However, this error causes a positive SQLCODE.)

If you do not provide an indicator variable, a negative value is returned in the SQLCODE field of the SQLCA. Processing of the statement terminates when the error is encountered. No value is assigned to the host variable or to later variables, though any values that have already been assigned to variables remain assigned. Additionally, a -3 is returned in all indicators provided by the application when a hole was detected for the row on a rowset positioned FETCH, and values were not returned for the row. Processing of the statement terminates if a hole is detected and at least one indicator variable was not provided by the application.

Alternative syntax and synonyms:

USING DESCRIPTOR can be specified as a synonym for INTO DESCRIPTOR.

Examples for FETCH

Example 1

The FETCH statement fetches the results of the SELECT statement into the application program variables DNUM, DNAME, and MNUM. When no more rows remain to be fetched, the not found condition is returned.

```
    EXEC SQL DECLARE C1 CURSOR FOR
      SELECT DEPTNO, DEPTNAME, MGRNO FROM DSN8C10.DEPT
      WHERE ADMRDEPT = 'A00';
     EXEC SQL OPEN C1;
     DO WHILE (SQLCODE = 0);
      EXEC SQL FETCH C1 INTO :DNUM, :DNAME, :MNUM;
     END;
     EXEC SQL CLOSE C1;
```

Example 2

For an example of FETCH statements with a dynamic scrollable cursor, see “Example 8” on page 1823.

Example 3

Fetch the last 5 rows of the result table C1 using cursor C1:

```
FETCH ROWSET STARTING AT ABSOLUTE -5
   FROM C1 FOR 5 ROWS INTO DESCRIPTOR :MYDESCR;
```

Example 4

Fetch 6 rows starting at row 10 for cursor CURS1, and fetch the data into three host-variable-arrays:

```
FETCH ROWSET STARTING AT ABSOLUTE 10
   FROM CURS1 FOR 6 ROWS
   INTO :hav1, :hva2, :hva3;
```

Alternatively, a descriptor could have been specified in an INTO DESCRIPTOR clause where the information in the SQLDA reflects the data types of the host-variable-arrays:

```
FETCH ROWSET STARTING AT ABSOLUTE 10
   FROM CURS1 FOR 6 ROWS
   INTO DESCRIPTOR :MYDESCR;
```

Example 5

Suppose that the following array type, array variable, and table have been defined.

```
CREATE TYPE INTARRAY AS INTEGER ARRAY[100];
CREATE TABLE T1 (COL1 CHAR(10), COL2 INT);
```

Use an array variable as an output target for a FETCH statement. The array variable is specified in the INTO clause of the FETCH statement.

```
CREATE PROCEDURE PROCESSINTARRAY (OUT INTOUTARRAY INTARRAY)
BEGIN
 DECLARE INTA INTARRAY;
 DECLARE INTB INTARRAY;
 DECLARE INTV INTEGER DEFAULT 1;
 DECLARE STMT CHAR(100);
 DECLARE C2 CURSOR FOR S1;
--
-- Initialize the array
--
 SET INTA = ARRAY[1,INTEGER(2),3+0,4,5,6] ;
--
-- Use dynamic SQL with an array parameter marker and a parameter marker
-- containing the index to retrieve the value from the array parameter.
-- The array is referenced in a predicate.
--
 SET STMT = 'SELECT COL1 FROM T1 WHERE COL2 = CAST(? AS INTARRAY)[?]';
 PREPARE S1 FROM STMT;
 OPEN C2 USING INTA, INTV;
 FETCH C2 INTO INTB ; -- INTB is an array variable that is used
                      -- as a target for the fetch statement.
 CLOSE C2;
SET INTOUTARRAY=INTB;
END
```

FREE LOCATOR

The FREE LOCATOR statement removes the association between a LOB locator variable and its value.

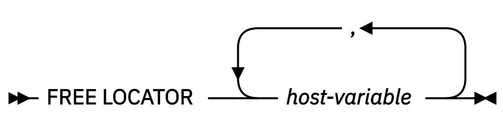
Invocation for FREE LOCATOR

This statement can only be embedded in an application program. It cannot be issued interactively. It is an executable statement that can be dynamically prepared. However, the EXECUTE statement with the USING clause must be used to execute the prepared statement. FREE LOCATOR cannot be used with the EXECUTE IMMEDIATE statement. It must not be specified in Java.

Authorization for FREE LOCATOR

None required.

Syntax for FREE LOCATOR



Description for FREE LOCATOR

host-variable, ...

Identifies one or more locator variables that must be declared in accordance with the rules for declaring locator variables. The locator variable type must be a binary large object locator, a character large object locator, or a double-byte character large object locator.

The *host-variable* must currently have a locator assigned to it. That is, a locator must have been assigned during this unit of work (by a FETCH, SELECT INTO, assignment statement, SET *host-variable* statement, or VALUES INTO statement) and must not subsequently have been freed (by a FREE LOCATOR statement); otherwise, an error is returned.

If more than one locator is specified and an error is returned on one of the locators, it is possible that some locators have been freed and others have not been freed.

Example for FREE LOCATOR

Assume that the employee table contains columns RESUME, HISTORY, and PICTURE and that locators have been established in a program to represent the column values. Free the CLOB locator variables LOCRES and LOCHIST, and the BLOB locator variable LOCPIC.

```
   EXEC SQL FREE LOCATOR :LOCRES, :LOCHIST, :LOCPIC
```

GET DIAGNOSTICS

The GET DIAGNOSTICS statement provides diagnostic information about the last SQL statement (other than a GET DIAGNOSTICS statement) that was executed. This diagnostic information is gathered as the previous SQL statement is executed. Some of the information available through the GET DIAGNOSTICS statement is also available in the SQLCA.

Invocation for GET DIAGNOSTICS

This statement can only be embedded in an application program. It is an executable statement that cannot be dynamically prepared.

Authorization for GET DIAGNOSTICS

None required.

Description for GET DIAGNOSTICS

Diagnostic information is provided in three main areas: statement information, condition information, and combined information. After the execution of an SQL statement, information about the execution of the statement is provided as statement information, and at least one instance of condition information is provided. The number of instances of the condition information is indicated by the NUMBER item that is available in the statement information. Combined information contains a text representation of all the information gathered about the execution of the SQL statement.

The diagnostic information that is provided is specific to the server. If you are connected to a server other than Db2 for z/OS, see that product's documentation for the diagnostic information that is returned.

CURRENT
Specifies that information is to be returned from the first diagnostics area. It corresponds to the previous SQL statement that was executed that was not a GET DIAGNOSTICS or compound statement. CURRENT is the default.

STACKED
Specifies that information is to be returned from the stacked diagnostics area. The stacked diagnostics area is only available within a handler in native SQL procedures, compiled SQL functions, and triggers. The stacked diagnostics area corresponds to the previous SQL statement (that was not a GET DIAGNOSTICS or compound statement) that was executed before the handler was entered. If the GET DIAGNOSTICS statement is the first statement within a handler, the current diagnostics area and the stacked diagnostics area contain the same diagnostics information.

statement-information
Provides information about the last SQL statement executed.

variable1
Identifies a variable described in the program in accordance with the rules for declaring variables. The data type of the variable must be the data type as specified in Data types for GET DIAGNOSTICS items.

The variable is assigned the value of the specified statement information item. If the value is truncated when assigning it to the variable, a warning is returned and the GET_DIAGNOSTICS_DIAGNOSTICS item of the diagnostics area is updated with the details of this condition. If a DIAGNOSTICS item is not set, the variable is set to a default value, based on its data type: 0 for an exact numeric field, an empty string for a VARCHAR field, and blanks for a CHAR field.

DB2_GET_DIAGNOSTICS_DIAGNOSTICS
Contains textual information about errors or warnings that might have occurred in the execution of the GET DIAGNOSTICS statement. The format of the information is similar to what would be returned by a GET DIAGNOSTICS :hv = ALL statement.

DB2_SQL_NESTING_LEVEL
Identifies the current level of nesting or recursion that is in effect when the GET DIAGNOSTICS statement was executed. Each level of nesting corresponds to a nested or recursive invocation of

a compiled SQL function, native SQL procedure, or trigger. If the GET DIAGNOSTICS statement is executed outside of a level of nesting, the value of zero is returned.

***statement-information-item-name*:**

DB2_LAST_ROW

For a multiple-row FETCH statement, contains a value of +100 if the last row currently in the table is in the set of rows that have been fetched. For cursors that are not sensitive to updates, there would be no need to do a subsequent FETCH, because the result would be an end-of-data indication. For cursors that are sensitive to updates, a subsequent FETCH may return more data if a row had been inserted before the FETCH was executed. For statements other than multiple-row FETCH statements, or for multiple-row FETCH statements that do not contain the last row, this variable contains the value 0.

An end of data warning might not occur and DB2_LAST_ROW might not contain +100 when the number of rows returned is equal to the number of rows requested and the last row of data returned is the last row of data.

DB2_NUMBER_PARAMETER_MARKERS

For a PREPARE statement, contains the number of parameter markers in the prepared statement. Otherwise, or if the server only returns an SQLCA, the value zero is returned.

DB2_NUMBER_RESULT_SETS

For a CALL statement, contains the actual number of result sets returned by the procedure. Otherwise, or if the server only returns an SQLCA, the value zero is returned.

DB2_NUMBER_ROWS

If the previous SQL statement was an OPEN or a FETCH that caused the size of the result table to be known, returns the number of rows in the result table. For SENSITIVE DYNAMIC cursors, this value can be thought of as an approximation because rows that are inserted and deleted will affect the next retrieval of this value. If the previous SQL statement was a PREPARE statement, returns the estimated number of rows in the result table for the prepared statement. Otherwise, or if the server only returns an SQLCA, the value zero is returned.

DB2_RETURN_STATUS

Identifies the status value returned from the stored procedure associated with the previously executed SQL statement, provided that the statement was a CALL statement that invoked a procedure that returns a status. Otherwise, or if the server only returns an SQLCA, the value zero is returned.

DB2_SQL_ATTR_CURSOR_HOLD

For an ALLOCATE or OPEN statement, indicates whether a cursor can be held open across multiple units of work.

- N indicates that this cursor does not remain open across multiple units of work.
- Y indicates that this cursor remains open across multiple units of work.

Otherwise, a blank is returned.

DB2_SQL_ATTR_CURSOR_ROWSET

For an ALLOCATE or OPEN statement, indicates whether or not a cursor can be accesses using rowset positioning.

- N indicates that this cursor supports only row positioned operations.
- Y indicates that this cursor supports rowset positioned operations.

Otherwise, a blank is returned.

DB2_SQL_ATTR_CURSOR_SCROLLABLE

For an ALLOCATE or OPEN statement, indicates whether or not a cursor can be scrolled forward and backward.

- N indicates that this cursor is not scrollable.
- Y indicates that this cursor is scrollable.

Otherwise, a blank is returned.

DB2_SQL_ATTR_CURSOR_SENSITIVITY

For an ALLOCATE or OPEN statement, indicates whether or not a cursor does or does not show updates to cursor rows made by other connections.

- I indicates insensitive.
- S indicates sensitive.

Otherwise, a blank is returned.

DB2_SQL_ATTR_CURSOR_TYPE

For an ALLOCATE or OPEN statement, indicates the type of cursor, whether a cursor type is forward-only, static, or dynamic.

- F indicates a forward cursor.
- D indicates a dynamic cursor.
- S indicates a static cursor.

Otherwise, a blank is returned.

MORE

Indicates whether some of the warning and errors from the previous SQL statement were stored or discarded.

- N indicates that all the warnings and errors from the previous SQL statement are stored in the diagnostic area.
- Y indicates that some of the warnings and errors from the previous SQL statement were discarded because the amount of storage needed to record warnings and errors exceeded 65535 bytes.

NUMBER

Returns the number of errors and warnings detected by the execution of the previous SQL statement, other than a GET DIAGNOSTICS statement, that have been stored in the diagnostics area. If the previous SQL statement returned an SQLSTATE of 00000 or no previous SQL statement has been executed, the number returned is one.

The GET DIAGNOSTICS statement itself may return information via the SQLSTATE parameter, but does not modify the previous contents of the diagnostics area, except for the DB2_GET_DIAGNOSTICS_DIAGNOSTICS item.

ROW_COUNT

Identifies the number of rows associated with the previous SQL statement that was executed.

If the previous SQL statement is a DELETE, INSERT, UPDATE, or MERGE statement, ROW_COUNT indicates the number of rows that are qualified to be deleted, inserted, or updated by that statement, excluding rows that are affected by triggers or referential integrity constraints. The count does not include rows that are inserted as a result of processing a FOR PORTION OF clause for in an SQL data change statement.

For the OPEN of a cursor for a SELECT with a data change statement, or a SELECT INTO statement, SQLERRD(3) contains the number of rows affected by the embedded data change statement. The value is 0 if the SQL statement fails, indicating that all changes made in executing the statement canceled.

A value of -1 indicates a mass delete from a table in a segmented table space and the DELETE statement did not include selection criteria, or a truncate operation. If the delete was against a view, then neither the DELETE statement nor the definition of the view included selection criteria.

For a REFRESH TABLE statement, SQLERRD(3) contains the number of rows inserted into the materialized query table.

If the previous SQL statement is a multiple-row FETCH, ROW_COUNT identifies the number of rows fetched.

Otherwise, or if the server only returns an SQLCA, the value zero is returned.

condition-information

Assigns the values of the specified condition information to the associated variables. The variable specified must be of the data type that is compatible with the data type of the specified diagnostic-ID or an error occurs. If the value of the condition is truncated when assigning it to the variable, an error occurs. If an indicator variable was provided, the length of the value is returned in the indicator variable.

If a DIAGNOSTICS item is not set, then the variable is set to a default value, based on the data type of the item. The specific value will be 0 for a numeric field, an empty string for a VARCHAR field, and blanks for a CHAR field.

variable2* or *integer

Identifies a variable described in the program in accordance with the rules for declaring variables. The value identifies the diagnostic for which information is requested. Each diagnostic that occurs while executing an SQL statement is assigned an integer. The value 1 indicates the first diagnostic, 2 indicates the second diagnostic, and so on. If the value is 1, the diagnostic information that is retrieved corresponds to the condition that is indicated by the SQLSTATE value actually returned by the execution of the previous SQL statement (other than a GET DIAGNOSTICS statement). The variable specified must be an integer data type, or an error occurs. An indicator variable is not allowed when this is a host variable; an error occurs. If a value is specified that is less than or equal to zero, or greater than the number of available diagnostics, an error occurs.

variable3

Identifies a variable described in the program in accordance with the rules for declaring variables. The data type of the variable must be the data type as specified in Data types for GET DIAGNOSTICS items for the indicated condition-information item.

condition-information-item-name

CATALOG_NAME

If the returned SQLSTATE is any one of the following values, the constraint that caused the error is a referential, check, or unique constraint. The location (RDB) name of the server that generated the condition is returned.

- Class 09 (Triggered Action Exception),
- Class 23 (Integrity Constraint Violation)
- Class 27 (Triggered Data Change Violation)
- 40002 (Transaction Rollback - Integrity Constraint Violation)
- 40004 (Transaction Rollback - Triggered Action Exception)

If the returned SQLSTATE is class 42 (Syntax Error or Access Rule Violation), the server name of the table that caused the error is returned.

If the returned SQLSTATE is class 44 (WITH CHECK OPTION Violation), the server name of the view that caused the error is returned.

Otherwise, the empty string is returned.

The actual server name may be different than the server name specified, either implicitly or explicitly, on the CONNECT statement because of the use of aliases or synonyms.

CONDITION_NUMBER

Returns the number of the diagnostic returned.

CURSOR_NAME

If the returned SQLSTATE is class 24 (Invalid Cursor State), the name of the cursor is returned. Otherwise, the empty string is returned.

DB2_ERROR_CODE1

Returns an internal error code. Otherwise, or if the server only returns an SQLCA, the value 0 is returned.

DB2_ERROR_CODE2
Returns an internal error code. Otherwise, or if the server only returns an SQLCA, the value 0 is returned.

DB2_ERROR_CODE3
Returns an internal error code. Otherwise, or if the server only returns an SQLCA, the value 0 is returned.

DB2_ERROR_CODE4
Returns an internal error code. Otherwise, or if the server only returns an SQLCA, the value 0 is returned.

DB2_INTERNAL_ERROR_POINTER
For some errors, this is a negative value that is an internal error pointer. Otherwise, the value 0 is returned.

DB2_LINE_NUMBER
Returns the line number where an error is encountered in parsing a dynamic statement. Also returns the line number where an error is encountered in parsing, binding, or executing a CREATE or ALTER statement for a native SQL procedure, compiled SQL function, or trigger. DB2_LINE_NUMBER also returns the line number when a CALL statement invokes a native SQL procedure and the procedure returns with an error. This information is not returned for an external SQL procedure.

This value will only be meaningful if the statement source contains new line control characters.

DB2_MESSAGE_ID
Corresponds to the message that is contained in the MESSAGE_TEXT diagnostic item (for example, DSNT102I or DSNU180I).

DB2_MODULE_DETECTING_ERROR
Returns an identifier indicating which module detected the error. For a SIGNAL statement that is issued from a routine, the value 'ROUTINE' is returned. Otherwise, the string 'DSN   ' is returned.

DB2_ORDINAL_TOKEN_n
Returns the *n*th token. *n* must be a value 1–100. For example, DB2_ORDINAL_TOKEN_1 would return the value of the first token, DB2_ORDINAL_TOKEN_2 the second token, and so on. A numeric value for a token is converted to characters before being returned. If there is no value for the token, or if the server only returns an SQLCA, an empty string is returned.

DB2_REASON_CODE
Contains the reason code for errors that have a reason code token in the message text. Otherwise, the value zero is returned.

DB2_RETURNED_SQLCODE
Returns the SQLCODE for the specified diagnostic.

DB2_ROW_NUMBER
For a statement that involves multiple rows, returns the number of the row where the condition was encountered, when such information is available and applicable. If SQLCODE +1 or +20237 is returned, DB2_ROW_NUMBER returns a value of 0.

DB2_SQLERRD_SET
A value of Y indicates that the DB2_SQLERRD1 through DB2_SQLERRD items might be set. These items are set only when communicating with a server that returns the SQLCA SQL communications area and not the new diagnostics area. Otherwise, a blank is returned.

DB2_SQLERRD1
Returns the value of sqlerrd(1) from the SQLCA that is returned by the server. Otherwise, the value zero is returned.

DB2_SQLERRD2
Returns the value of sqlerrd(2) from the SQLCA that is returned by the server. Otherwise, the value zero is returned.

DB2_SQLERRD3

Returns the value of sqlerrd(3) from the SQLCA that is returned by the server. Otherwise, the value zero is returned.

DB2_SQLERRD4

Returns the value of sqlerrd(4) from the SQLCA that is returned by the server. Otherwise, the value zero is returned.

DB2_SQLERRD5

Returns the value of sqlerrd(5) from the SQLCA that is returned by the server. Otherwise, the value zero is returned.

DB2_SQLERRD6

Returns the value of sqlerrd(6) from the SQLCA that is returned by the server. Otherwise, the value zero is returned.

DB2_TOKEN_COUNT

Returns the number of tokens available for the specified diagnostic ID.

MESSAGE_TEXT

Returns the message text that is associated with the SQLCODE. This is the short text, including substituted tokens. The message text does not contain the message number. When the SQLCODE is 0, the empty string is returned, even if the RETURNED_SQLSTATE value indicates a warning condition.

RETURNED_SQLSTATE

Returns the SQLSTATE for the specified diagnostic.

SERVER_NAME

If the previous SQL statement is a CONNECT, DISCONNECT, or SET CONNECTION statement, returns the name of the server specified in the previous statement is returned. Otherwise, the name of the server where the statement executes is returned.

connection-information-item-name

Provides information about the last SQL statement executed if it was a CONNECT statement.

DB2_AUTHENTICATION_TYPE

Contains an authentication type value of:

- ‘S' for a server authentication
- ‘C' for client authentication
- ‘T' for trusted server authentication
- Otherwise, or if the server only returns an SQLCA, a blank is returned

DB2_AUTHORIZATION_ID

Authorization ID used by connected server. Because of user ID translation and authorization exits, the local user ID may not be the authorized ID used by the server.

DB2_CONNECTION_STATE

Contains the connection state:

- -1 if the connection is unconnected
- 1 if the connection is connected

Otherwise, or if the server only returns an SQLCA, the value zero is returned.

DB2_CONNECTION_STATUS

Contains a value of:

- 1 if committable updates can be performed on the connection for this unit of work
- 2 if no committable updates can be performed on the connection for this unit of work

Otherwise, or if the server only returns an SQLCA, the value zero is returned.

DB2_SERVER_CLASS_NAME

For a CONNECT or SET CONNECTION statement, contains one of the following values:

- QAS for Db2 for i
- QDB2 forDb2 for z/OS
- QDB2/2 for Db2 for OS/2
- QDB2/6000 for Db2 for AIX®
- QDB2/6000 PE for Db2 for AIX Parallel Edition
- QDB2/AIX64 for Db2 for AIX 64-bit
- QDB2/HPUX for Db2 for HP-UX
- QDB2/HP64 for Db2 for HP-UX 64-bit
- QDB2/LINUX for Db2 for Linux, UNIX, and Windows
- QDB2/LINUX390 for Db2 for Linux, UNIX, and Windows
- QDB2/LINUXIA64 for Db2 for Linux, UNIX, and Windows
- QDB2/LINUXPPC forDb2 for Linux, UNIX, and Windows
- QDB2/LINUXPPC64 for Db2 for Linux, UNIX, and Windows
- QDB2/LINUXZ64 for Db2 for Linux, UNIX, and Windows
- QDB2/NT for Db2 for Linux, UNIX, and Windows
- QDB2/NT64 for Db2 for Linux, UNIX, and Windows
- QDB2/PTX for Db2 for NUMA-Q®
- QDB2/SCO for Db2 for SCO UnixWare
- QDB2/SGI for Db2 for Silicon Graphics
- QDB2/SNI for Db2 for Siemens Nixdorf
- QDB2/SUN for Db2 for SUN Solaris
- QDB2/SUN64 for Db2 for SUN Solaris 64-bit
- QDB2/Windows 95 for Db2 for Linux, UNIX, and Windows
- QSQLDS/VM for Db2 server for VSE and VM
- QSQLDS/VSE for Db2 server for VSE and VM

Otherwise, the empty string is returned.

DB2_ENCRYPTION_TYPE

The level of encryption for the connection:

- A indicates only the authentication tokens (authid and password) are encrypted.
- D indicates all data is encrypted for the connection.
- Otherwise, a blank is returned.

DB2_PRODUCT_ID

Returns a product signature. If the application server is an IBM relational database product, the form is *pppvvrrm*.

combined-information

Provides a text representation of all the information gathered about the execution of the SQL statement.

ALL

Indicates that all diagnostic items that are set for the last SQL statement executed are to be combined into one string. The format of the string is a semicolon separated list of all of the available diagnostic information in the form: *item-name*[(*condition-number*)]=*value-converted-to-character*...; as shown in the following example:

```
NUMBER=1;RETURNED_SQLSTATE=02000;DB2_RETURNED_SQLCODE=+100;
```

variable4

Identifies a variable described in the program in accordance with the rules for declaring variables. The data type of the variable must be VARCHAR. If the length of *variable4* is not sufficient to hold the full returned diagnostic string, the string is truncated, a warning is returned, and the GET_DIAGNOSTICS_DIAGNOSTICS item of the diagnostics area is updated with the details of this condition.

STATEMENT

Indicates that all statement-information-item-name diagnostic items that are set for the last SQL statement executed should be combined into one string. The format is the same as described for the ALL option.

CONDITION

Indicates that all condition-information-item-name diagnostic items that are set for the last SQL statement executed should be combined into one string. If *variable5* or integer is supplied after CONDITION, the format is the same as described above for the ALL option. If *variable5* or integer is not supplied, the format includes a condition number entry at the beginning of the information for that condition in the form:

CONDITION_NUMBER=*x*;*item-name*=*value-converted-to-character*;... where *x* is the number of the condition, as shown in the following example:

```
CONDITION_NUMBER=1;RETURNED_SQLSTATE=02000;RETURNED_SQLCODE=100;
   CONDITION_NUMBER=2;RETURNED_SQLSTATE=01004;
```

CONNECTION

Indicates that all connection-information-item-name diagnostic items that are set for the last SQL statement executed should be combined into one string. If *variable5* or integer is supplied after CONNECTION, the format is the same as described for the ALL option. If *variable5* or integer is not supplied, then the format includes a condition number entry at the beginning of the information for that condition in the form:

CONNECTION_NUMBER=*x*;*item-name*=*value-converted-to-character*;... where *x* is the number of the connection, as shown in the following example:

```
CONNECTION_NUMBER=1;CONNECTION_NAME=SVL1;DB2_PRODUCT_ID=DSN12015;
```

variable5* or *integer

Identifies a variable described in the program in accordance with the rules for declaring variables. The value identifies the diagnostic for which ALL CONDITION or ALL CONNECTION information is requested. The variable specified must be an integer data type or an error occurs. An indicator variable is not allowed when this is a host variable; an error occurs. If a value is specified that is less than or equal to zero or greater than the number of available diagnostics, an error occurs.

Notes for GET DIAGNOSTICS

Effect of the statement in a native SQL routine or trigger:

A successful GET DIAGNOSTICS statement does not change the contents of the diagnostics area, except for DB2_GET_DIAGNOSTICS_DIAGNOSTICS.

If you want information about an error, the GET DIAGNOSTICS statement must be the first executable statement specified in the handler that will handle the error condition.

If you want information about a warning and a handler will get control for the warning condition, the GET DIAGNOSTICS statement must be the first executable statement specified in that handler.

If you want information about a warning and a handler will not get control for the warning condition, the GET DIAGNOSTICS statement must be the next statement executed after that previous statement.

Considerations for the SQLSTATE and SQLCODE SQL variables

A successful GET DIAGNOSTICS statement does not change the value of the SQLSTATE and SQLCODE SQL variables (as used in SQL functions and SQL procedures).

Data types for items:

When a diagnostic item is assigned to a variable, SQL variable, or SQL parameter, the data type of the target must be compatible with the data type of the requested diagnostic item.

Data types for GET DIAGNOSTICS items

Table 239. Data types for GET DIAGNOSTICS items

Type of information	Item	Data type
Statement Information	DB2_GET_DIAGNOSTICS_DIAGNOSTICS	VARCHAR(32672)
	DB2_LAST_ROW	INTEGER
	DB2_NUMBER_PARAMETER_MARKERS	INTEGER
	DB2_NUMBER_RESULT_SETS	INTEGER
	DB2_NUMBER_ROWS	DECIMAL(31,0)
	DB2_RETURN_STATUS	INTEGER
	DB2_SQL_ATTR_CURSOR_HOLD	CHAR(1)
	DB2_SQL_ATTR_CURSOR_ROWSET	CHAR(1)
	DB2_SQL_ATTR_CURSOR_SCROLLABLE	CHAR(1)
	DB2_SQL_ATTR_CURSOR_SENSITIVITY	CHAR(1)
	DB2_SQL_ATTR_CURSOR_TYPE	CHAR(1)
	MORE	CHAR(1)
	NUMBER	INTEGER
	ROW_COUNT	DECIMAL(31,0)
Statement Information	DB2_SQL_NESTING_LEVEL	INTEGER

Table 239. Data types for GET DIAGNOSTICS items (continued)

Type of information	Item	Data type
Condition Information	CATALOG_NAME	VARCHAR(128)
	CONDITION_NUMBER	INTEGER
	CURSOR_NAME	VARCHAR(128)
	DB2_ERROR_CODE1	INTEGER
	DB2_ERROR_CODE2	INTEGER
	DB2_ERROR_CODE3	INTEGER
	DB2_ERROR_CODE4	INTEGER
	DB2_INTERNAL_ERROR_POINTER	INTEGER
	DB2_LINE_NUMBER	INTEGER
	DB2_MESSAGE_ID	CHAR(10)
	DB2_MODULE_DETECTING_ERROR	CHAR(8)
	DB2_ORDINAL_TOKEN_n	VARCHAR(515)
	DB2_REASON_CODE	INTEGER

	DB2_TOKEN_COUNT	INTEGER
	MESSAGE_TEXT	VARCHAR(32672)
	RETURNED_SQLSTATE	CHAR(5)
	SERVER_NAME	VARCHAR(128)
Connection Information	DB2_AUTHENTICATION_TYPE	CHAR(1)
	DB2_AUTHORIZATION_ID	VARCHAR(128)
	DB2_CONNECTION_STATE	INTEGER
	DB2_CONNECTION_STATUS	INTEGER
	DB2_ENCRYPTION_TYPE	CHAR(1)
	DB2_PRODUCT_ID	VARCHAR(8)
	DB2_SERVER_CLASS_NAME	CHAR(128)
Combined Information	ALL	VARCHAR(32672)

DRDA considerations

The GET DIAGNOSTICS statement is supported from a current Db2 for z/OS client, regardless of the level of the server (a Db2 for z/OS Version 7 or a Db2 for Windows Version 7, for example). When the application is connected to servers that do not support the Open Group Version 3 DRDA standard, the diagnostic information that is returned by the servers is available in the condition information.

Alternative syntax and synonyms:

To provide compatibility with previous releases of Db2 or other products in the Db2 family, Db2 supports the following keywords:

- RETURN_STATUS as a synonym for DB2_RETURN_STATUS
- EXCEPTION as a synonym for CONDITION

Examples for GET DIAGNOSTICS

Example 1

In an application, use the GET DIAGNOSTICS statement to determine how many rows were updated.

```
long rcount;
EXEC SQL UPDATE T1 SET C1 = C1 + 1;
EXEC SQL GET DIAGNOSTICS :rcount = ROW_COUNT;
```

After execution of this code segment, *rcount* will contain the number of rows that were updated.

Example 2

In an application, use the GET DIAGNOSTICS statement to handle multiple SQL Errors.

```
long numerrors, counter;
char retsqlstate[5];
long hva[5];
EXEC SQL INSERT INTO T1 FOR 5 ROWS VALUES (:hva) NOT ATOMIC
  CONTINUE ON SQLEXCEPTION;
EXEC SQL GET DIAGNOSTICS :numerrors = NUMBER;
for ( i=1;i < numerrors;i++)
    {
    EXEC SQL GET DIAGNOSTICS CONDITION :i :retsqlstate = RETURNED_SQLSTATE;
...
```

Execution of this code segment sets and prints *retsqlstate* with the SQLSTATE for each error that was encountered in the previous SQL statement.

Example 3

Retrieve information about a connection.

```
EXEC SQL GET DIAGNOSTICS CONDITION :HV_PRODUCT_ID = DB2_PRODUCT_ID;
```

Example 4

Use the GET DIAGNOSTICS statement to retrieve information that is similar to what is returned in the SQLCA

```
EXEC SQL GET DIAGNOSTICS CONDITION 1
     :dasqlcode   = DB2_RETURNED_SQLCODE,
     :datokencnt  = DB2_TOKEN_COUNT,
     :datoken1    = DB2_ORDINAL_TOKEN_1,
     :datoken2    = DB2_ORDINAL_TOKEN_2,
     :datoken3    = DB2_ORDINAL_TOKEN_3,
     :datoken4    = DB2_ORDINAL_TOKEN_4,
     :datoken5    = DB2_ORDINAL_TOKEN_5,
     :dasqlerrd1b = DB2_MESSAGE_ID,
     :damsgtext   = MESSAGE_TEXT,
     :dasqlerrp   = DB2_MODULE_DETECTING_ERROR,
     :dasqlstate  = RETURNED_SQLSTATE;
```

Example 5

:Specify the STACKED keyword on a GET DIAGNOSTICS statement that is used within a handler to access information in the diagnostics area that caused the handler to be activated:

```
CREATE PROCEDURE divide2 ( IN numerator INTEGER,
                           IN denominator INTEGER,
                             OUT divide_result INTEGER,
                           OUT divide_error VARCHAR(70))
             LANGUAGE SQL
  BEGIN
      DECLARE msg_text        CHAR(70) DEFAULT '';
      DECLARE divide_error    CHAR(70) DEFAULT '';

      DECLARE CONTINUE HANDLER FOR SQLEXCEPTION
         BEGIN
            INSERT .....;   -- insert row into a log table

              -- get diagnostic information for the INSERT statement
            GET CURRENT DIAGNOSTICS CONDITION 1 msg_text = MESSAGE_TEXT;

              -- get information about condition that activated the handler
            GET STACKED DIAGNOSTICS CONDITION 1 divide_error = MESSAGE_TEXT;
          END;

       SET divide_result = numerator/denominator;
  END;
```

The first GET DIAGNOSTICS statement obtains diagnostic information about the INSERT statement.

The second GET DIAGNOSTICS statement specifies the STACKED keyword. The use of the STACKED keyword allows access the stacked diagnostics area which contains the diagnostic information for the condition that caused the handler to be activated. The information about the original condition is still accessible within the handler even after another statement has been issued, such as the INSERT statement in the example.

Example 6: The following application logs information whenever a routine is invoked directly by an application rather than indirectly by another routine. The application uses the GET DIAGNOSTICS statement that specifies DB2_SQL_NESTING_LEVEL to obtain the current nesting level, and invokes the LOG_INVOCATION procedure if the nesting level is 1:

```
CREATE PROCEDURE TEST
    MODIFIES SQL DATA
    LANGUAGE SQL
    BEGIN
    DECLARE NESTING_LEVEL  INT     DEFAULT 0;

    GET DIAGNOSTICS NESTING_LEVEL = DB2_SQL_NESTING_LEVEL;

    --
    -- If routine is invoked at nesting level 1,
    -- invoke a routine to log the invocation.
    --
    IF (NESTING_LEVEL = 1) THEN
       CALL LOG_INVOCATION();
    END IF;

    --
    -- Remainder of procedure logic
    --
    ...
END
```

GRANT

The Db2 GRANT statement grants privileges to authorization IDs. There is a separate form of the statement for each of these classes of privilege:

- Collection
- Database
- Function or stored procedure

- Package
- Plan
- Schema
- Sequence
- System
- Table or view
- Type or JAR
- Variable
- Use

The applicable objects are always at the current server. The grants are recorded in the current server's catalog.

Invocation for GRANT

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES RUN behavior is in effect. For more information, see "Authorization IDs and dynamic SQL" on page 94.

If the authorization mechanism was not activated when the Db2 subsystem was installed, an error condition occurs.

Authorization for GRANT

To grant a privilege P, the privilege set must include one of the following:

- The privilege P WITH GRANT OPTION
- Ownership of the object on which P is a privilege
- SECADM authority

  Note: If installation parameter SEPARATE SECURITY is NO, SYSADM authority has implicit SECADM authority.
- ACCESSCTRL authority

  The presence of ACCESSCTRL authority in the privilege set allows the granting of all authorities except:

  – System DBADM
  – CREATE_SECURE_OBJECT privilege
  – DATAACCESS
  – ACCESSCTRL

    Note: If installation parameter SEPARATE SECURITY is NO, SYSCTRL authority has implicit ACCESSCTRL authority that allows the granting of all privileges except:

    - DBADM on databases
    - DELETE, INSERT, SELECT, and UPDATE on user tables or views
    - EXECUTE on plans, packages, functions, or stored procedures
    - PACKADM on collections
    - SYSADM authority
    - USAGE on distinct types, JARs, and sequences
    - READ, WRITE on global variables
- Installation SYSOPR authority (when the current SQLID of the process is set to SYSINSTL)

  The Installation SYSOPR authority with the current SQLID set to SYSINSTL allows the granting of the following privileges:

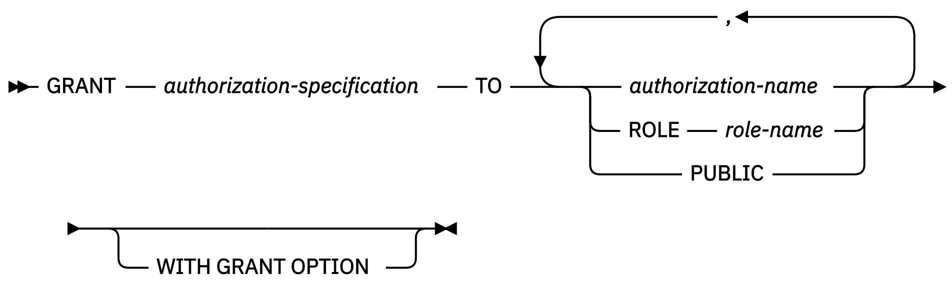
- All database, table, and table space privileges on objects in database DSNDB04 and system databases DSNRGFDB, DSNRLST, DSNOPTDB, DSNMDCDB, DSNADMDB, DSNATPDB, SN5JSDB, DSNMQDB, SYSIBMTA, SYSIBMTS, and DSNXSR
- The USE privilege on buffer pools and storage groups
- All privileges on plans that begin with 'DSN'
- All privileges on packages whose collection-ID and package-name begin with 'DSN'
- The EXECUTE privilege on system-defined routines.

To grant the CREATE_SECURE_OBJECT system privilege, the privileges that are held by the authorization ID of the statement must include SECADM authority.

Except for views, the GRANT option for privileges on a table is also inherent in DBADM authority for its database, provided DBADM authority was acquired with the GRANT option. See "CREATE VIEW" on page 1807 for a description of the rules that apply to views.

If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. The owner can be a role. If the statement is dynamically prepared, the privilege set is the privileges that are held by the SQL authorization ID of the process. However, if the process is running in a trusted context that is defined with the ROLE AS OBJECT OWNER CLAUSE, the privilege set is the privileges that are held by the role in effect.

Syntax for GRANT



Description for GRANT

authorization-specification
Specifies one or more privileges for the class of privilege. The same privilege must not be specified more than once.

TO
Specifies to what authorization IDs the privileges are granted.

authorization-name,...
Lists one or more authorization IDs.

ROLE *role-name*
Lists one or more role names. Each name must identify a role that exists at the current server.

The value of the CURRENT RULES special register determines whether you can use the ID or role of the GRANT statement itself (to grant privileges to yourself). When CURRENT RULES is:

DB2
You cannot use the ID or role of the GRANT statement.

STD
You can use the ID or role of the GRANT statement.

PUBLIC
Grants the privileges to all users at the current server, including database requesters using DRDA access.

CREATE_SECURE_OBJECT must not be granted to PUBLIC.

ACCESSCTRL, DATAACCESS and system DBADM authorities cannot be granted to PUBLIC.

WITH GRANT OPTION

Allows the named users to grant the privileges to others. Granting an administrative authority with this option allows the user to specifically grant any privilege belonging to that authority. If you omit WITH GRANT OPTION, the named users cannot grant the privileges to others unless they have that authority from some other source.

GRANT authority cannot be passed to PUBLIC. When WITH GRANT OPTION is used with PUBLIC, a warning is issued, and the named privileges are granted, but without GRANT authority.

If you grant the CREATE_SECURE_OBJECT system privilege, the WITH GRANT OPTION clause is ignored because the CREATE_SECURE_OBJECT system privilege cannot be granted to others.

GRANT ACCESSCTRL, DATAACCESS and system DBADM authorities cannot be passed to others. If WITH GRANT OPTION is used when granting these authorities, a warning is issued and the named authorities are granted, but without GRANT authority.

Notes for GRANT

A *grant* is the granting of a specific privilege by a specific grantor to a specific grantee. The grantor for a given GRANT statement is the authorization ID for the privilege set; that is, the SQL authorization ID of the process or a role, or the authorization ID of the owner of the plan or package. Grant statements that are made in a trusted context that is defined with the ROLE AS OBJECT OWNER clause result in the grantor being the role that is in effect. If the statement is prepared dynamically, the grantor is the role that is associated with the ID that is running the statement. If the statement is embedded in an application program that was bound in a trusted context that was defined with the ROLE AS OBJECT OWNER clause the owner of the plan or package is a role which is the grantor. If the ROLE AS OBJECT OWNER clause is not specified for the trusted context, the grantor is the authorization ID of the process.

The grantee, as recorded in the catalog, is an authorization ID or PUBLIC. Any instances of PUBLIC* in the catalog mean the same as PUBLIC.

Duplicate grants from the same grantor are not recorded in the catalog. Otherwise, the result of executing a GRANT statement is recorded as one or more grants in the current server's catalog.

If more than one privilege or *authorization-name* is specified after the TO keyword and one of the grants is in error, execution of the statement is stopped and no grants are made. The status of the privilege or privileges granted is recorded in the catalog for each *authorization-name*.

Different grantors can grant the same privilege to a single grantee. The grantee retains that privilege as long as one or more of those grants are recorded in the catalog. Privileges that imply other privileges are also termed *authorities*. Grants are removed from the catalog by executing SQL REVOKE statements.

Whenever a grant is made for a database, distinct type, package, plan, schema, stored procedure, table, trigger, user-defined function, view, or USE privilege for an object that does not exist, an SQL return code is issued and the grant is not made.

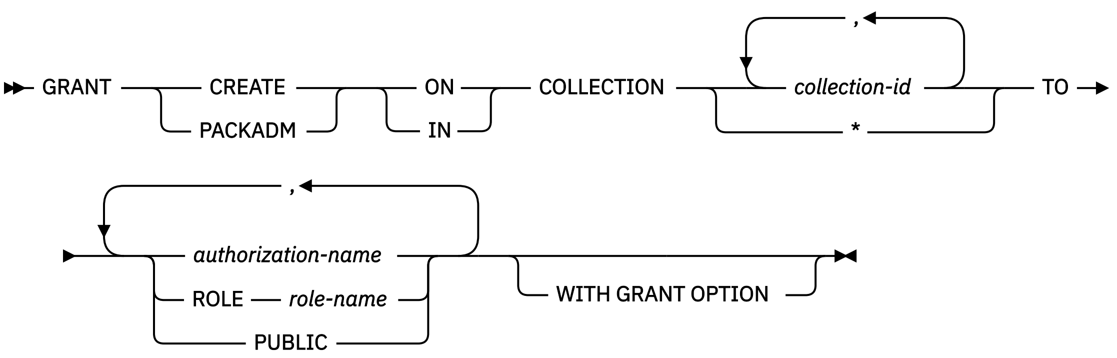
Related tasks

Granting privileges with the GRANT statement (Managing Security)

GRANT (collection privileges)

This form of the GRANT statement grants privileges on collections.

Syntax for GRANT (collection privileges)



Description for GRANT (collection privileges)

CREATE IN
Grants the privilege to use the BIND subcommand to create packages in the designated collections.

The word ON can be used instead of IN.

PACKADM ON
Grants package administrator authority for the designated collections.

The word IN can be used instead of ON.

COLLECTION *collection-id*,...
Identifies the collections on which the specified privilege is granted. The collections do not have to exist.

COLLECTION *
Indicates that the specified privilege is granted on all collections including those that do not currently exist.

TO
Refer to "GRANT" on page 1958 for a description of the TO clause.

WITH GRANT OPTION
Refer to "GRANT" on page 1958 for a description of the WITH GRANT OPTION clause.

Examples for GRANT (collection privileges)

Example 1: Grant the privilege to create new packages in collections QAACLONE and DSN8CC61 to CLARK.

```
GRANT CREATE IN COLLECTION QAACLONE, DSN8CC61 TO CLARK;
```

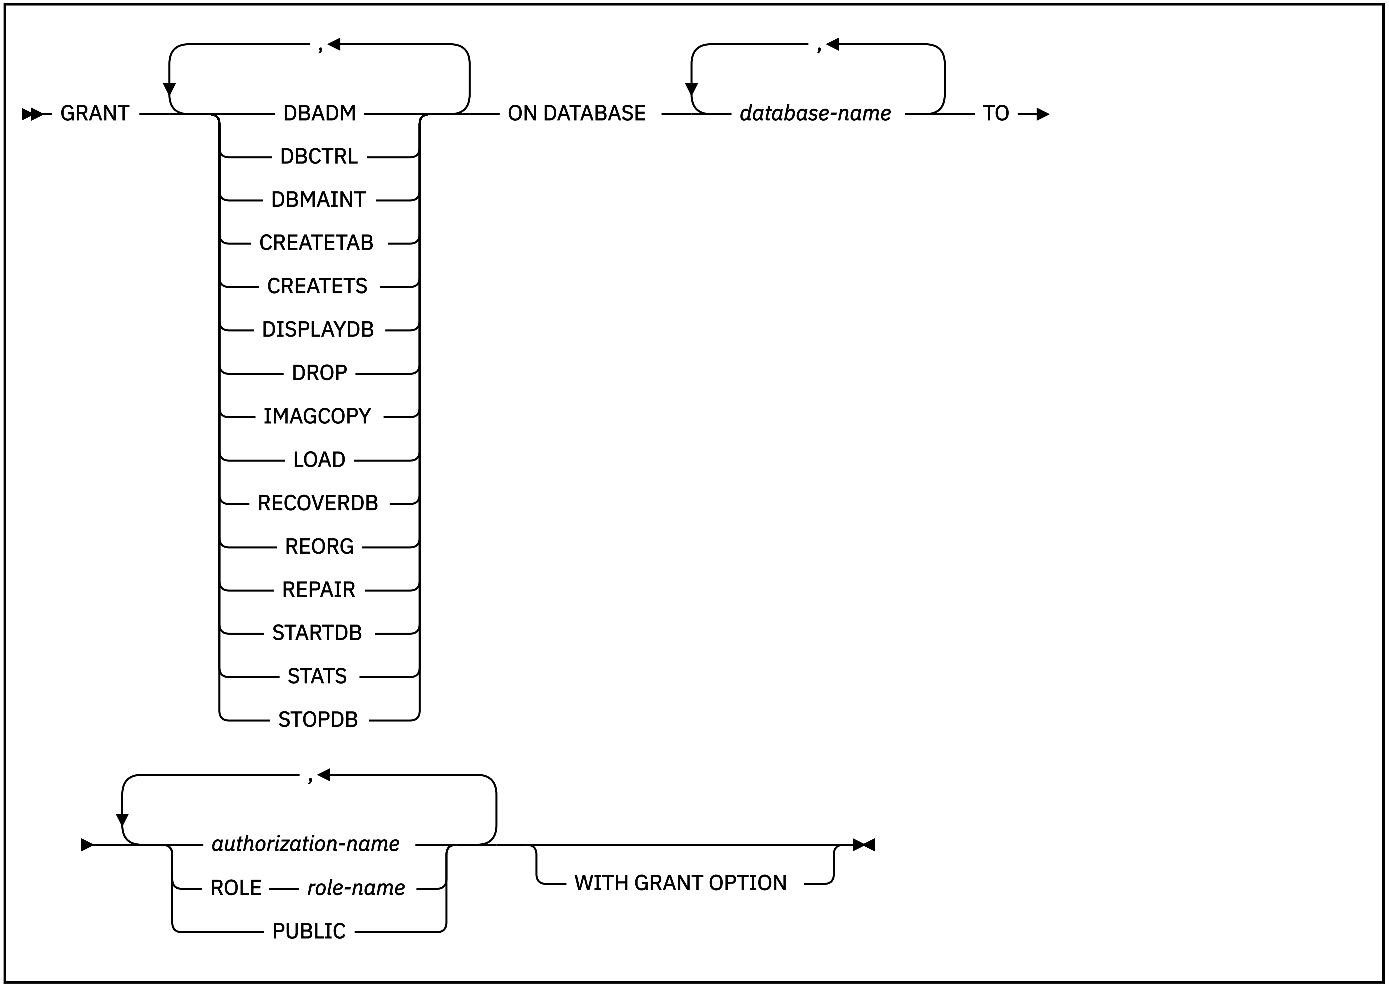
Example 2: Grant the privileges to create new packages in collection DSN8CC91 to role ROLE1:

```
GRANT CREATE IN COLLECTION DSN8CC91 TO ROLE ROLE1;
```

GRANT (database privileges)

This form of the GRANT statement grants privileges on databases.

Syntax for GRANT (database privileges)



Description for GRANT (database privileges)

Each keyword listed grants the privilege described, but only as it applies to or within the databases named in the statement.

DBADM
Grants the database administrator authority.

DBCTRL
Grants the database control authority.

DBMAINT
Grants the database maintenance authority.

CREATETAB
Grants the privilege to create new tables. To create tables in an implicitly created database, CREATETAB privileges are needed on the DSNDB04 database. For a work file database, PUBLIC implicitly has the CREATETAB privilege (without GRANT authority) to define declared temporary tables; this privilege is not recorded in the Db2 catalog, and it cannot be revoked.

CREATETS
Grants the privilege to create new table spaces.

DISPLAYDB

Grants the privilege to issue the DISPLAY DATABASE command.

DROP

Grants the privilege to issue the DROP or ALTER DATABASE statements for the designated databases.

IMAGCOPY

Grants the privilege to run the COPY, MERGECOPY, and QUIESCE utilities against table spaces of the specified databases, and to run the MODIFY RECOVERY utility.

LOAD

Grants the privilege to use the LOAD utility to load tables.

RECOVERDB

Grants the privilege to use the RECOVER and REPORT utilities to recover table spaces and indexes.

REORG

Grants the privilege to use the REORG utility to reorganize table spaces and indexes.

REPAIR

Grants the privilege to use the REPAIR and DIAGNOSE utilities.

STARTDB

Grants the privilege to issue the START DATABASE command.

STATS

Grants the privilege to use the RUNSTATS utility to update statistics, the CHECK utility to test whether indexes are consistent with the data they index, and the MODIFY STATISTICS utility to delete unwanted statistics history records from the corresponding catalog tables.

STOPDB

Grants the privilege to issue the STOP DATABASE command.

ON DATABASE *database-name,...*

Identifies databases on which privileges are to be granted. For each named database, the grantor must have all the specified privileges with the GRANT option. Each name must identify a database that exists at the current server. DSNDB01 must not be identified; however, a grant of a privilege on DSNDB06 implies the granting of the same privilege on DSNDB01 for utility operations only.

Database privileges granted on DSNDB04 are applicable to all implicitly created databases. This means that a user with the STOPDB privilege on DSNDB04 can also stop database objects in any implicitly created database. Similarly, having DBADM on DSNDB04 allows access to all tables in all implicitly created databases. However, having a database privilege on DSNDB04 does not allow granting of this privilege on an implicitly created database to others.

TO

Refer to "GRANT" on page 1958 for a description of the TO clause.

WITH GRANT OPTION

Refer to "GRANT" on page 1958 for a description of the WITH GRANT OPTION clause.

Examples for GRANT (database privileges)

Example 1: Grant drop privileges on database DSN8D12A to user PEREZ.

```
GRANT DROP
  ON DATABASE DSN8D12A
  TO PEREZ;
```

Example 2: Grant repair privileges on database DSN8D12A to all local users.

```
GRANT REPAIR
  ON DATABASE DSN8D12A
  TO PUBLIC;
```

Example 3: Grant authority to create new tables and load tables in database DSN8D12A to users WALKER, PIANKA, and FUJIMOTO, and give them grant privileges.

```
GRANT CREATETAB,LOAD
  ON DATABASE DSN8D12A
  TO WALKER,PIANKA,FUJIMOTO
  WITH GRANT OPTION;
```

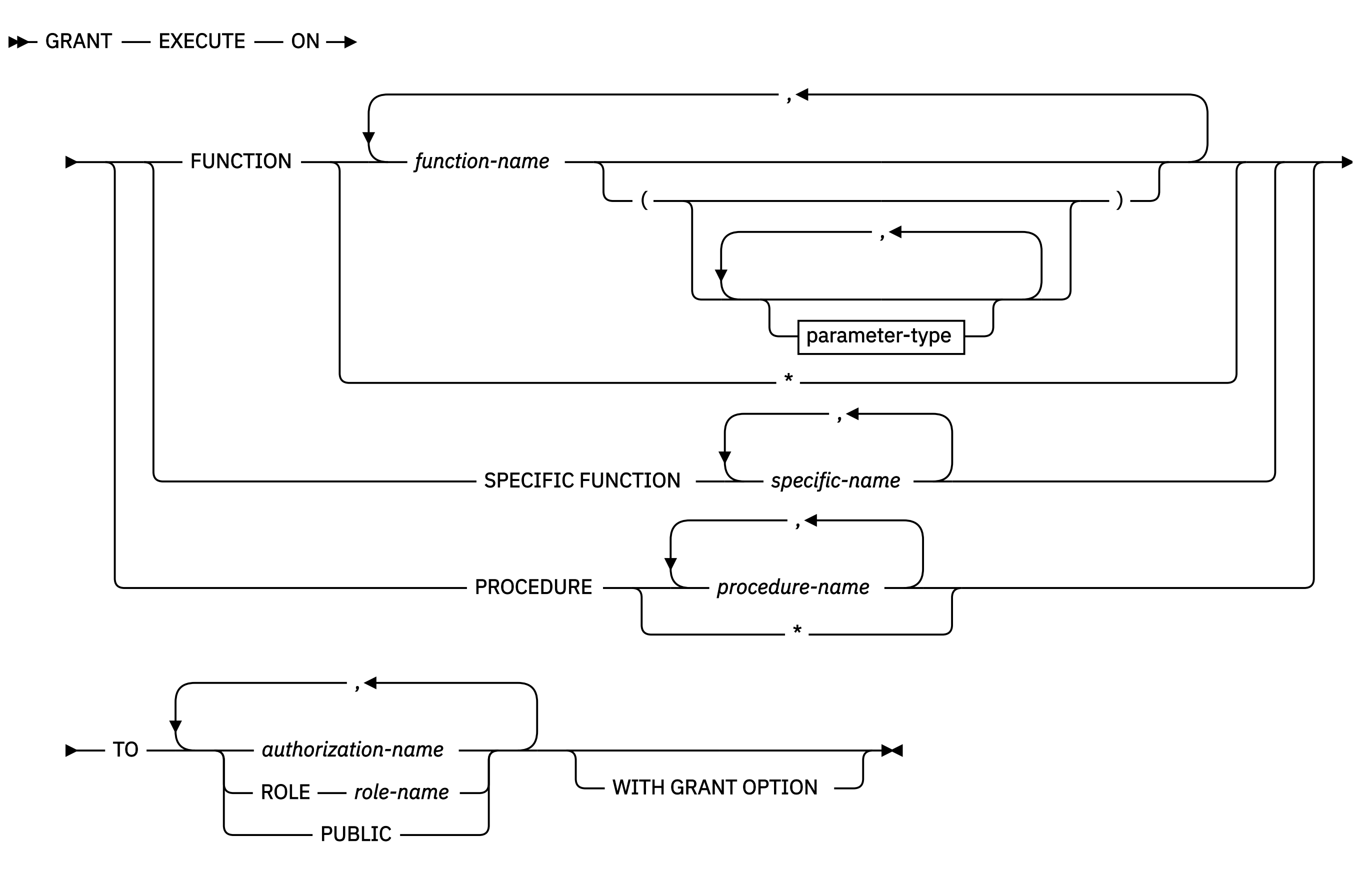
Example 4: Grant load privileges to database DSN9D91A to role ROLE1:

```
GRANT LOAD
  ON DATABASE DSN9D91A
  TO ROLE ROLE1;
```

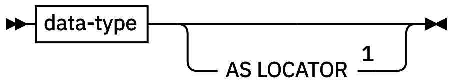
GRANT (function or procedure privileges)

This form of the GRANT statement grants privileges on user-defined functions, cast functions that are generated for distinct types, array types, and stored procedures.

Syntax for GRANT (function or procedure privileges)



parameter-type:



Notes:

[1] AS LOCATOR can be specified only for a LOB data type or a distinct type based on a LOB data type.

Description for GRANT (function or procedure privileges)

EXECUTE

Grants the privilege to run the identified user-defined function, cast function that was generated for a distinct type, or stored procedure.

FUNCTION or SPECIFIC FUNCTION

Identifies the function on which the privilege is granted. The function must exist at the current server, and it must be a function that was defined with the CREATE FUNCTION statement or a cast function that was generated by a CREATE TYPE statement. The function can be identified by name, function signature, or specific name.

If the function was defined with a table parameter (the LIKE TABLE was specified in the CREATE FUNCTION statement to indicate that one of the input parameters is a transition table), the function signature cannot be used to identify the function. Instead, identify the function with its function name, if unique, or with its specific name.

FUNCTION *function-name*

Identifies the function by its name. The *function-name* must identify exactly one function. The function can have any number of parameters defined for it. If there is more than one function of the specified name in the specified or implicit schema, an error is returned.

An asterisk (*) can be specified for an unqualified function name. The function can be identified as a qualified or unqualified *function-name*. For example, * indicates that the privilege is granted on all the functions in the default schema, including those that do not currently exist. *schema-name*.* indicates that the privilege is granted on all the functions in the specified schema, including those that do not currently exist. SYSADM authority is required if * or *schema-name*.* is specified. Specifying an asterisk does not affect any EXECUTE privileges that are already granted on a function.

FUNCTION *function-name (parameter-type,...)*

Identifies the function by its function signature, which uniquely identifies the function. The *function-name (parameter-type, ...)* must identify a function with the specified function signature. The specified parameters must match the data types in the corresponding position that were specified when the function was created. The number of data types, and the logical concatenation of the data types is used to identify the specific function instance on which the privilege is to be granted. Synonyms for data types are considered a match.

If the function was defined with a table parameter (the LIKE TABLE *name* AS LOCATOR clause was specified in the CREATE FUNCTION statement to indicate that one of the input parameters is a transition table), the function signature cannot be used to uniquely identify the function. Instead, use one of the other syntax variations to identify the function with its function name, if unique, or its specific name.

If *function-name ()* is specified, the function identified must have zero parameters.

function-name

Identifies the name of the function. If you do not explicitly qualify the function name with a schema name, the function name is implicitly qualified with a schema name as described in the preceding description for FUNCTION *function-name*.

(parameter-type,...)

Identifies the parameters of the function.

If an unqualified distinct type name is specified, Db2 searches the SQL path to resolve the schema name for the distinct type.

For data types that have a length, precision, or scale attribute, use one of the following:

- Empty parentheses indicate that the database manager ignores the attribute when determining whether the data types match. For example, DEC() will be considered a match for a parameter of a function defined with a data type of DEC(7,2). Similarly, DECFLOAT() will be considered a match for DECFLOAT(16) or DECFLOAT(34). However, FLOAT cannot be specified with empty parenthesis because its parameter value indicates a specific data type (REAL or DOUBLE).

- If a specific value for a length, precision, or scale attribute is specified, the value must exactly match the value that was specified (implicitly or explicitly) in the CREATE FUNCTION statement. If the data type is FLOAT, the precision does not have to exactly match the value that was specified because matching is based on the data type (REAL or DOUBLE).
- If length, precision, or scale is not explicitly specified, and empty parentheses are not specified, the default attributes of the data type are implied. The implicit length must exactly match the value that was specified (implicitly or explicitly) in the CREATE FUNCTION statement.

For data types with a subtype or encoding scheme attribute, specifying the FOR *subtype* DATA clause or the CCSID clause is optional. Omission of either clause indicates that Db2 ignores the attribute when determining whether the data types match. If you specify either clause, it must match the value that was implicitly or explicitly specified in the CREATE FUNCTION statement.

AS LOCATOR

Specifies that the function is defined to receive a locator for this parameter. If AS LOCATOR is specified, the data type must be a LOB or a distinct type based on a LOB.

SPECIFIC FUNCTION *specific-name*

Identifies the function by its specific name. The *specific-name* must identify a specific function that exists at the current server.

PROCEDURE *procedure-name*

Identifies a stored procedure that is defined at the current server. The name, including the implicit or explicit schema name, must identify a stored procedure that exists at the current server.

An asterisk (*) can be specified for an unqualified procedure name. The procedure can be identified as a qualified or unqualified *procedure-name*. For example, * indicates that the privilege is granted on all the procedures in the default schema, including those that do not currently exist. *schema-name*.* indicates that the privilege is granted on all the procedures in the specified schema, including those that do not currently exist. SYSADM authority is required if * or *schema-name*.* is specified. Specifying an asterisk does not affect any EXECUTE privileges that are already granted on a procedure.

TO

Refer to “GRANT” on page 1958 for a description of the TO clause.

WITH GRANT OPTION

Refer to “GRANT” on page 1958 for a description of the WITH GRANT OPTION clause.

Examples for GRANT (function or procedure privileges)

Example 1: Grant the EXECUTE privilege on function CALC_SALARY to user JONES. Assume that there is only one function in the schema with function name CALC_SALARY.

```
GRANT EXECUTE ON FUNCTION CALC_SALARY TO JONES;
```

Example 2: Grant the EXECUTE privilege on procedure VACATION_ACCR to all users at the current server.

```
GRANT EXECUTE ON PROCEDURE VACATION_ACCR TO PUBLIC;
```

Example 3: Grant the EXECUTE privilege on function DEPT_TOTALS to the administrative assistant and give the assistant the ability to grant the EXECUTE privilege on this function to others. The function has the specific name DEPT85_TOT. Assume that the schema has more than one function that is named DEPT_TOTALS.

```
GRANT EXECUTE ON SPECIFIC FUNCTION DEPT85_TOT TO ADMIN_A
      WITH GRANT OPTION;
```

Example 4: Grant the EXECUTE privilege on function NEW_DEPT_HIRES to HR (Human Resources). The function has two input parameters with data types of INTEGER and CHAR(10), respectively. Assume that the schema has more than one function that is named NEW_DEPT_HIRES.

```
   GRANT EXECUTE ON FUNCTION NEW_DEPT_HIRES (INTEGER, CHAR(10))
         TO HR;
```

You can also code the CHAR(10) data type as CHAR().

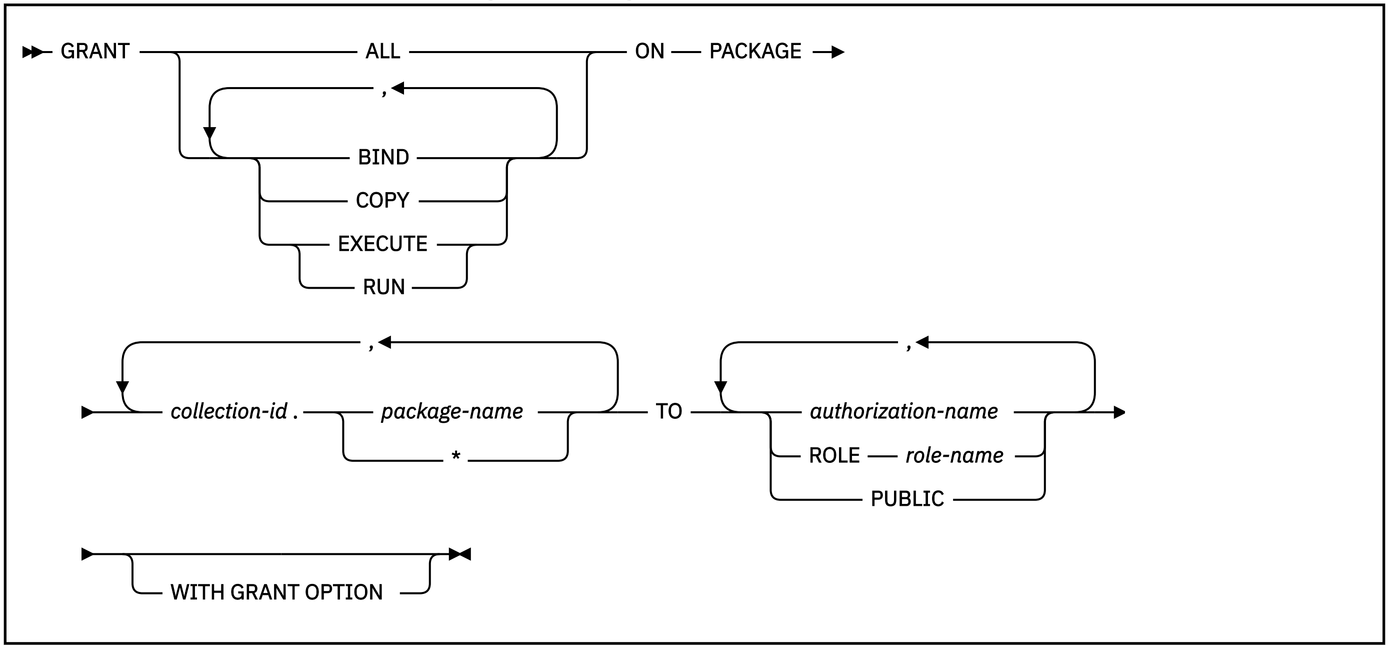
Example 5: Grant the EXECUTE privilege on function FIND_EMPDEPT to role ROLE1:

```
GRANT EXECUTE ON FUNCTION FIND_EMPDEPT TO ROLE ROLE1;
```

GRANT (package privileges)

This form of the GRANT statement grants privileges on packages.

Syntax for GRANT (package privileges)



Description for GRANT (package privileges)

BIND

Grants the privilege to use the BIND and REBIND subcommands for the designated packages.

The BIND package privilege can also be used to allow a user to add a new version of an existing package. For details on the authorization required to create new packages and new versions of existing packages, see "Notes for GRANT (package privileges)" on page 1971.

COPY

Grants the privilege to use the COPY option of the BIND subcommand for the designated packages.

EXECUTE

Grants the privilege to run application programs that use the designated packages and to specify the packages following PKLIST for the BIND PLAN and REBIND PLAN commands. RUN is an alternate name for the same privilege.

ALL

Grants all package privileges for which you have GRANT authority for the packages named in the ON clause.

ON PACKAGE *collection-id.package-name,...*

Identifies packages for which you are granting privileges. The granting of a package privilege applies to all versions of a package. The list can simultaneously contain items of the following two forms:

- *collection-id.package-name* explicitly identifies a single package. The name must identify a package that exists at the current server.
- *collection-id.** applies to every package in the indicated collection. This includes packages that currently exist and future packages. The grant applies to a collection at the current server, but the *collection-id* does not have to identify a collection that exists when the grant is made.

  To grant a privilege in this form requires PACKADM with the WITH GRANT OPTION over the collection or all collections, SYSADM, or SYSCTRL authority. Because of this fact, WITH GRANT OPTION, if included in the statement, is ignored for grants of this form, but not for grants for specific packages.

TO

Refer to "GRANT" on page 1958 for a description of the TO clause.

WITH GRANT OPTION

Refer to "GRANT" on page 1958 for a description of the WITH GRANT OPTION clause.

Notes for GRANT (package privileges)

The authorization required to add a new package or a new version of an existing package depends on the value of field BIND NEW PACKAGE on installation panel DSNTIPP. The default value is BINDADD.

If the value of BIND NEW PACKAGE is BINDADD, the owner must have one of the following to add a new package or a new version of an existing package to a collection:

- The BINDADD system privilege and either the CREATE IN privilege or PACKADM authority for the collection or for all collections
- SYSADM or SYSCTRL authority

If the value of BIND NEW PACKAGE is BIND, the owner must have one of the following to add a new package or a new version of an existing package to a collection:

- The BINDADD system privilege and either the CREATE IN privilege or PACKADM authority for the collection or for all collections
- SYSADM or SYSCTRL authority
- PACKADM authority for the collection or for all collections
- Users with the BIND package privilege can also add a new version of an existing package

Alternative syntax and synonyms: To provide compatibility with previous releases of Db2 or other products in the Db2 family, Db2 supports specifying PROGRAM as a synonym for PACKAGE.

Examples for GRANT (package privileges)

Example 1: Grant the privilege to copy all packages in collection DSN8CC61 to LEWIS.

```
   GRANT COPY ON PACKAGE DSN8CC61.* TO LEWIS;
```

Example 2: You have the BIND privilege with GRANT authority over the package CLCT1.PKG1. You have the EXECUTE privilege with GRANT authority over the package CLCT2.PKG2. You have no other privileges with GRANT authority over any package in the collections CLCT1 AND CLCT2. Hence, the following statement, when executed by you, grants LEWIS the BIND privilege on CLCT1.PKG1 and the EXECUTE privilege on CLCT2.PKG2, and makes no other grant. The privileges granted include no GRANT authority.

```
   GRANT ALL ON PACKAGE CLCT1.PKG1, CLCT2.PKG2 TO JONES;
```

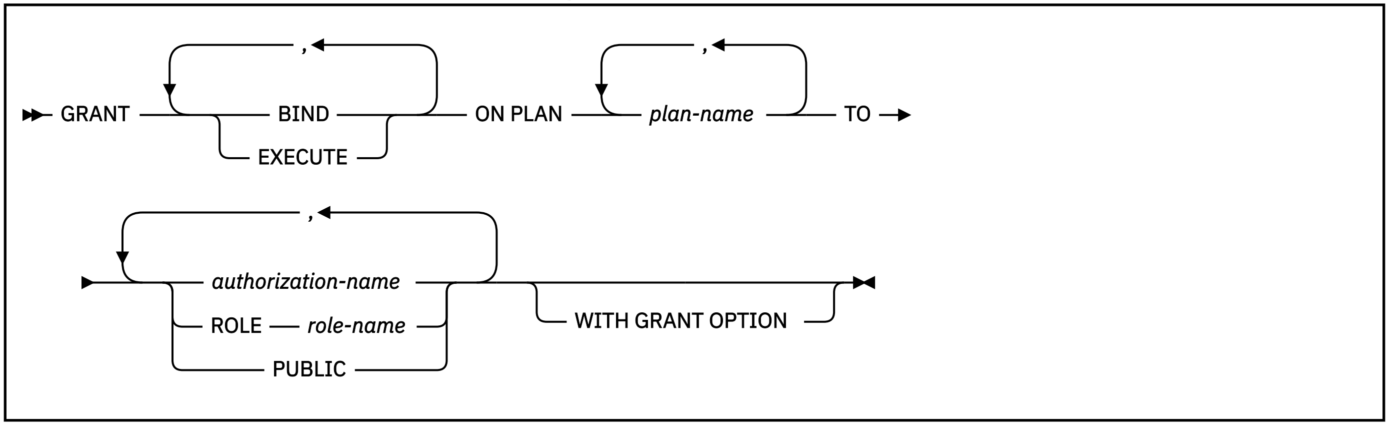
Example 3: Grant the privileges to run all packages in collection DSN9CC13 to role ROLE1:

```
GRANT EXECUTE ON PACKAGE DSN9CC13.* TO ROLE ROLE1;
```

GRANT (plan privileges)

This form of the GRANT statement grants privileges on plans.

Syntax for GRANT (plan privileges)



Description for GRANT (plan privileges)

BIND
Grants the privilege to use the BIND, REBIND, and FREE subcommands for the identified plans. (The authority to create new plans using BIND ADD is a system privilege.)

EXECUTE
Grants the privilege to run programs that use the identified plans.

ON PLAN *plan-name,...*
Identifies the application plans on which the privileges are granted. For each identified plan, you must have all specified privileges with the GRANT option.

TO
Refer to "GRANT" on page 1958 for a description of the TO clause.

WITH GRANT OPTION
Refer to "GRANT" on page 1958 for a description of the WITH GRANT OPTION clause.

Examples for GRANT (plan privileges)

Example 1: Grant the privilege to bind plan DSN8IP12 to user JONES.

```
   GRANT BIND ON PLAN DSN8IP12 TO JONES;
```

Example 2: Grant privileges to bind and execute plan DSN8CP12 to all users at the current server.

```
   GRANT BIND,EXECUTE ON PLAN DSN8CP12 TO PUBLIC;
```

Example 3: Grant the privilege to execute plan DSN8CP12 to users ADAMSON and BROWN with grant option.

```
   GRANT EXECUTE ON PLAN DSN8CP12 TO ADAMSON,BROWN WITH GRANT OPTION;
```

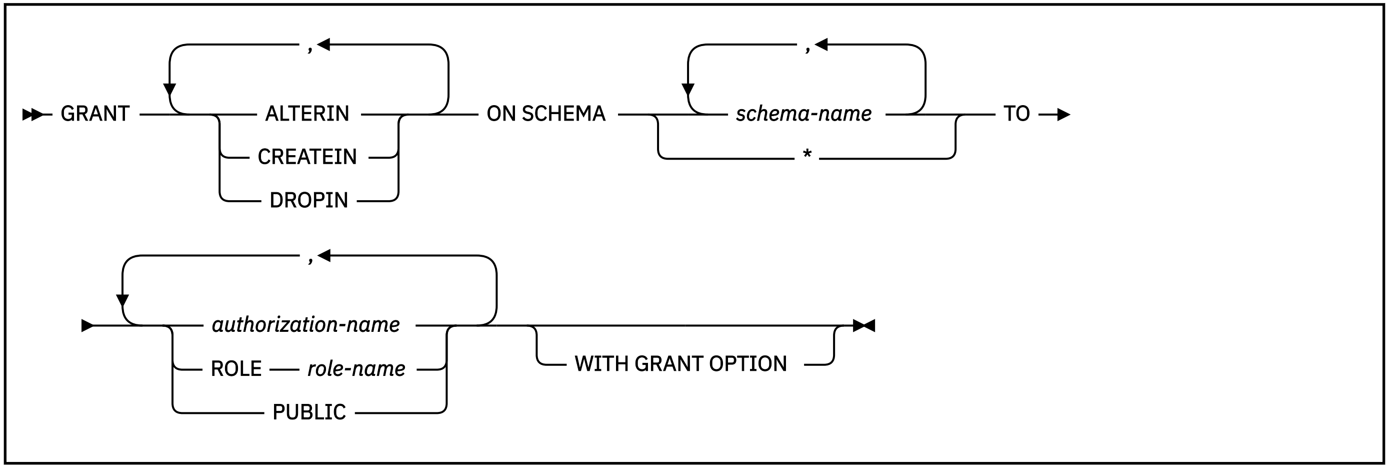
Example 4: Grant the privileges to bind the DSN91PLN plan to role ROLE1:

```
GRANT BIND ON PLAN DSN91PLN TO ROLE ROLE1;
```

GRANT (schema privileges)

This form of the GRANT statement grants privileges on schemas.

Syntax for GRANT (schema privileges)



Description for GRANT (schema privileges)

ALTERIN
Grants the privilege to alter stored procedures and user-defined functions, or specify a comment for distinct types, cast functions that are generated for distinct types, sequences, stored procedures, triggers, and user-defined functions in the designated schemas.

CREATEIN
Grants the privilege to create distinct types, sequences, stored procedures, triggers, and user-defined functions in the designated schemas.

DROPIN
Grants the privilege to drop distinct types, sequences, stored procedures, triggers, and user-defined functions in the designated schemas.

SCHEMA *schema-name*
Identifies the schemas on which the privilege is granted. The schemas do not need to exist when the privilege is granted.

SCHEMA *
Indicates that the specified privilege is granted on all schemas including those that do not currently exist.

TO
Refer to "GRANT" on page 1958 for a description of the TO clause.

WITH GRANT OPTION
Refer to "GRANT" on page 1958 for a description of the WITH GRANT OPTION clause.

Notes for GRANT (schema privileges)

Grant on SYSPUBLIC:
Privileges can be granted on the reserved schema SYSPUBLIC. Granting CREATEIN privilege allows the user to create a public alias and granting DROPIN privilege allows the user to drop any public alias.

Examples for GRANT (schema privileges)

Example 1: Grant the CREATEIN privilege on schema T_SCORES to user JONES.

```
GRANT CREATEIN ON SCHEMA T_SCORES TO JONES;
```

Example 2: Grant the CREATEIN privilege on schema VAC to all users at the current server.

```
    GRANT CREATEIN ON SCHEMA VAC TO PUBLIC;
```

Example 3: Grant the ALTERIN privilege on schema DEPT to the administrative assistant and give the grantee the ability to grant ALTERIN privileges on this schema to others.

```
    GRANT ALTERIN ON SCHEMA DEPT TO ADMIN_A
          WITH GRANT OPTION;
```

Example 4: Grant the CREATEIN, ALTERIN, and DROPIN privileges on schemas NEW_HIRE, PROMO, and RESIGN to HR (Human Resources).

```
    GRANT CREATEIN, ALTERIN, DROPIN ON SCHEMA NEW_HIRE, PROMO, RESIGN TO HR;
```

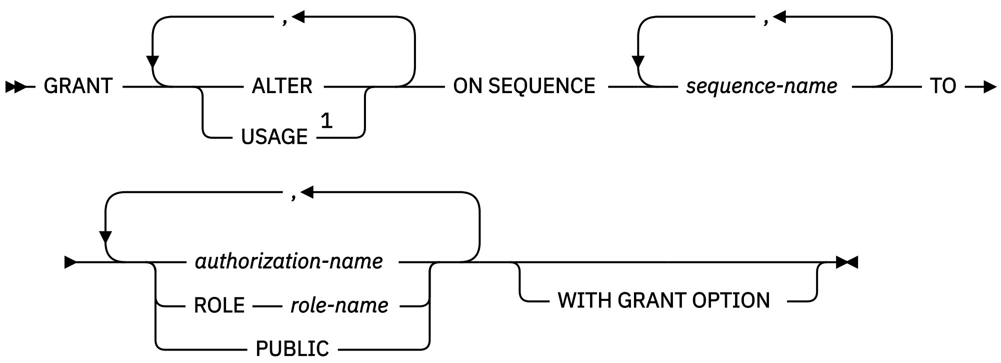
Example 5: Grant the ALTERIN privileges on the EMPLOYEE schema to role ROLE1:

```
GRANT ALTERIN ON SCHEMA EMPLOYEE TO ROLE ROLE1;
```

GRANT (sequence privileges)

This form of the GRANT statement grants privileges on a user-defined sequence.

Syntax for GRANT (sequence privileges)



Notes:

[1] The keyword SELECT is an alternative keyword for USAGE.

Description for GRANT (sequence privileges)

ALTER
Grants the privilege to alter a sequence or record a comment on a sequence.

USAGE
Grants the USAGE privilege to use a sequence. This privilege is needed when the NEXT VALUE or PREVIOUS VALUE expression is invoked for a sequence name.

SEQUENCE *sequence-name*
Identifies the sequence. The name, including the implicit or explicit schema qualifier, must uniquely identify an existing sequence at the current server. If no sequence by this name exists in the explicitly or implicitly specified schema, an error occurs. *sequence-name* must not be the name of an internal sequence object that is used by Db2.

TO
Refer to “GRANT” on page 1958 for a description of the TO clause.

WITH GRANT OPTION
Refer to “GRANT” on page 1958 for a description of the WITH GRANT OPTION clause.

Examples for GRANT (sequence privileges)

Example 1: Grant USAGE privilege on sequence MYNUM to user JONES.

```
GRANT USAGE
  ON SEQUENCE MYNUM
  TO JONES;
```

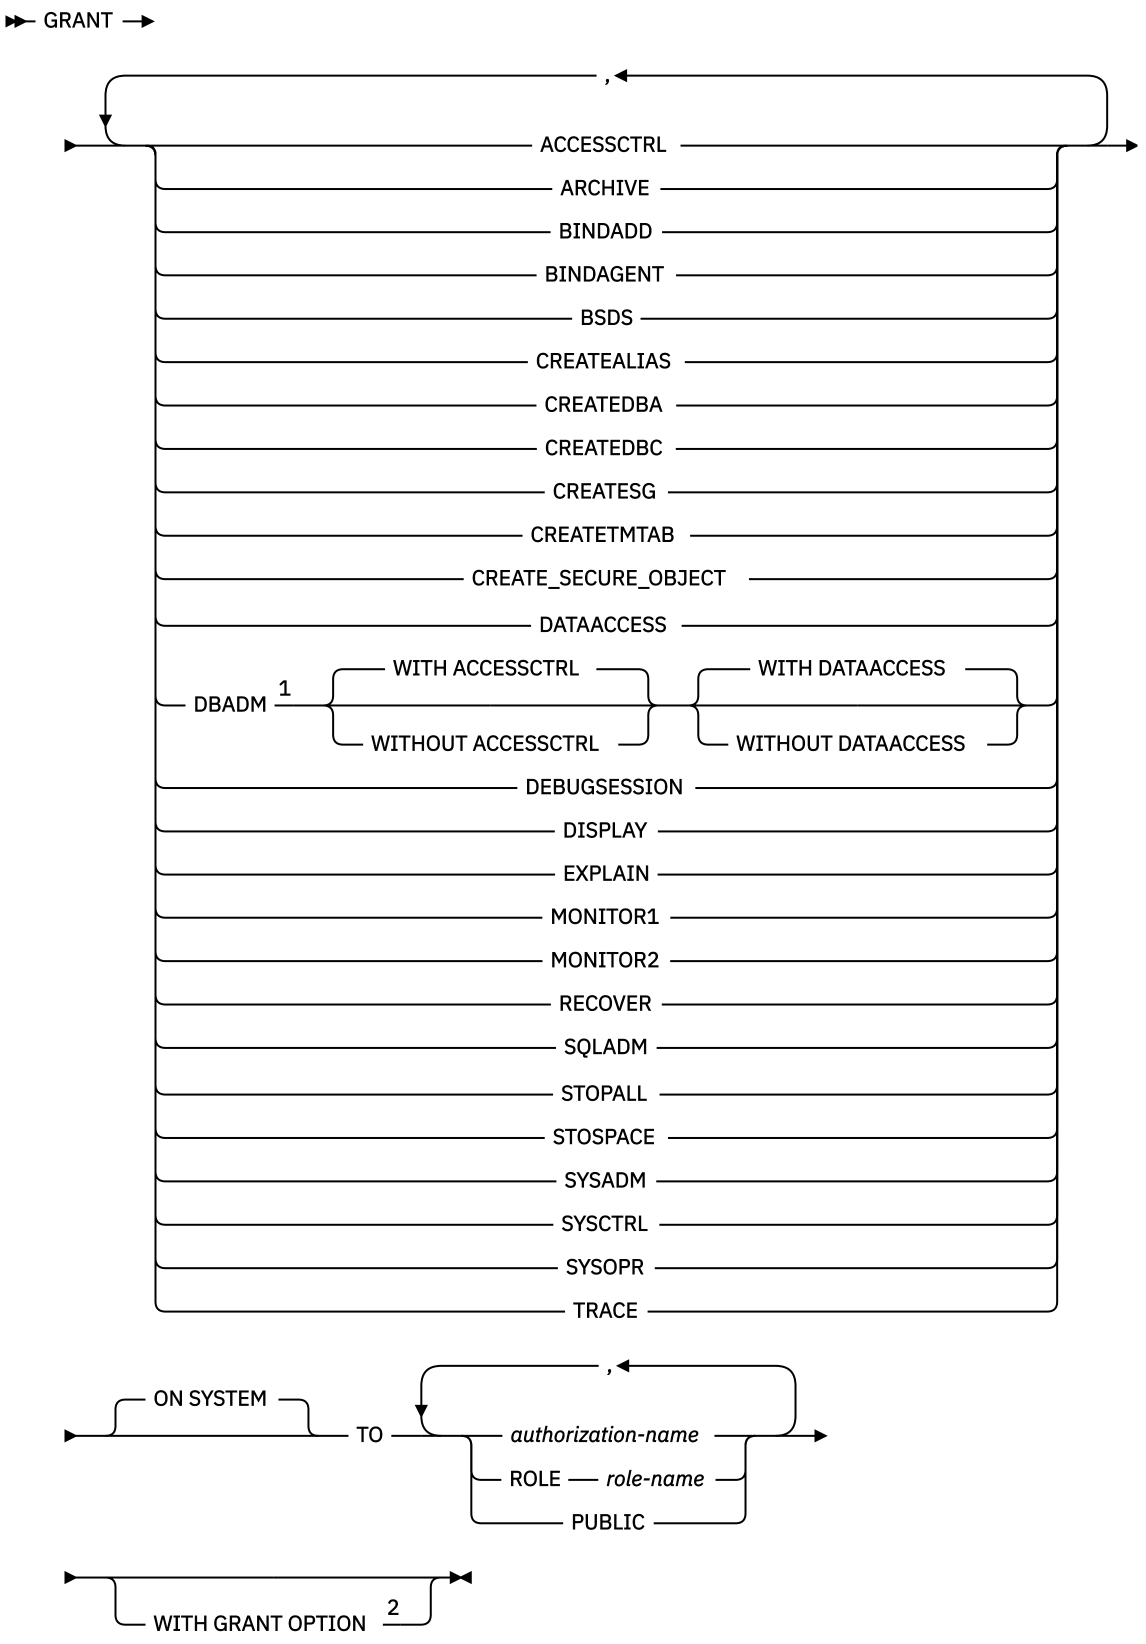
Example 2: Grant USAGE privileges on sequence ORDER_SEQ to role ROLE1:

```
GRANT USAGE ON SEQUENCE ORDER_SEQ TO ROLE ROLE1;
```

GRANT (system privileges)

This form of the GRANT statement grants system privileges.

Syntax for GRANT (system privileges)



Notes:

[1] The ACCESSCTRL and DATAACCESS clauses can be specified in any order.

[2] The WITH GRANT OPTION can be specified but is ignored for DBADM, DATAACCESS, and ACCESSCTRL. The WITH GRANT OPTION is also ignored if BINDAGENT grant is issued by SECADM authority.

Description for GRANT (system privileges)

ACCESSCTRL

Grants the ACCESSCTRL authority. ACCESSCTRL allows the user to grant all authorities and privileges, except system DBADM, DATAACCESS, ACCESSCTRL, and privileges on security related objects.

A warning is issued if the WITH GRANT OPTION is specified when granting this authority.

ACCESSCTRL cannot be granted to PUBLIC.

ARCHIVE

Grants the privilege to use the ARCHIVE LOG and SET LOG commands.

BINDADD

Grants the privilege to create plans and packages by using the BIND subcommand with the ADD option.

BINDAGENT

Grants the privilege to issue the BIND, FREE PACKAGE, or REBIND commands for plans and packages and the DROP PACKAGE statement on behalf of the grantor. The privilege also allows the holder to copy and replace plans and packages on behalf of the grantor.

A warning is issued if WITH GRANT OPTION is specified when granting this privilege.

When BINDAGENT is granted using SECADM authority, it grants the privilege to issue the BIND or REBIND commands for plans and packages by specifying any owner.

This SECADM granted BINDAGENT privilege will not allow the following:

- Rebind the package or plan without specifying OWNER keyword
- FREE PACKAGE or FREE PLAN
- COPY PACKAGE
- DROP PACKAGE

The BINDAGENT privilege cannot be granted to PUBLIC using SECADM authority.

If WITH GRANT OPTION is specified when granting this privilege using SECADM authority, the option is ignored.

BSDS

Grants the privilege to issue the RECOVER BSDS command.

CREATEALIAS

Grants the privilege to use the CREATE ALIAS statement.

CREATEDBA

Grants the privilege to issue the CREATE DATABASE statement and acquire DBADM authority over those databases.

CREATEDBC

Grants the privilege to issue the CREATE DATABASE statement and acquire DBCTRL authority over those databases.

CREATESG

Grants the privilege to create new storage groups.

CREATETMTAB

Grants the privilege to use the CREATE GLOBAL TEMPORARY TABLE statement.

CREATE_SECURE_OBJECT

Grants the privilege to create a secure object.

DATAACCESS

Grants the DATAACCESS authority. DATAACCESS allows the user to access data in all user tables, views, materialized query tables, and global variables in a Db2 subsystem, and allows the user to execute plans, packages, functions, and procedures, and use sequences.

DATAACCESS authority implicitly includes the SELECT privilege on all catalog tables and implicitly includes the INSERT, DELETE, and UPDATE privileges on updatable catalog tables, except for the SYSIBM.SYSAUDITPOLICIES catalog table.

A warning is issued if the WITH GRANT OPTION is specified when granting this authority.

DATAACCESS cannot be granted to PUBLIC.

DBADM

Grants the DBADM authority. DBADM allows the user to manage all objects in the Db2 subsystem, except security objects.

A warning is issued if the WITH GRANT OPTION is specified when granting this authority.

DBADM cannot be granted to PUBLIC.

WITH ACCESSCTRL

Specifies that the ACCESSCTRL authority is granted along with the system DBADM authority. ACCESSCTRL allows system DBADM to grant all authorities and privileges, except system DBADM, DATAACCESS, ACCESSCTRL authorities and privileges on security related objects. ACCESSCTRL can be used to REVOKE privileges using the BY clause.

WITH ACCESSCTRL is the default.

WITHOUT ACCESSCTRL

Specifies that system DBADM authority is not granted the ACCESSCTRL authority.

WITH DATAACCESS

Specifies that the DATAACCESS authority is granted along with the system DBADM authority. DATAACCESS allows the system DBADM to access data in all user tables, views, and materialized query tables in a Db2 subsystem and allows the user to execute plans, packages, functions, and procedures.

WITH DATAACCESS is the default.

WITHOUT DATAACCESS

Specifies that system DBADM authority is not granted the DATAACCESS authority.

DISPLAY

Grants the privilege to issue the DISPLAY commands, with the following exceptions:

- DISPLAY DYNQUERYCAPTURE
- DISPLAY ML
- DISPLAY PROFILE
- DISPLAY RLIMIT

No authorization is required for the DISPLAY UTILITY command.

DEBUGSESSION

Grants the privilege to attach a debug client to the current application process connection, which enables client application debugging of native SQL or Java procedures that are executed within the session.

EXPLAIN

Grants the privilege to issue the following without requiring the privileges needed to execute the statement:

- EXPLAIN statement with the options:
  - PLAN
  - ALL

- PREPARE statement
- DESCRIBE TABLE statement
- Explain dynamic SQL statements that execute under the special register CURRENT EXPLAIN MODE, when CURRENT EXPLAIN MODE = EXPLAIN
- BIND options: EXPLAIN(ONLY) and SQLERROR(CHECK)

  EXPLAIN(ONLY) allows to explain the statements.

  SQLERROR(CHECK) performs all syntax and semantic checks on the SQL statements that are being bound.

MONITOR1
Grants the privilege to obtain IFC data classified as serviceability data, statistics, accounting, and other performance data that does not contain potentially secure data.

MONITOR2
Grants the privilege to obtain IFC data classified as containing potentially sensitive data such as SQL statement text and audit data. Users with MONITOR2 privileges have MONITOR1 privileges.

RECOVER
Grants the privilege to issue the RECOVER INDOUBT command.

SQLADM
Grants the authority to perform the following actions without requiring any additional privileges:

- DESCRIBE TABLE statement
- EXPLAIN statement with the following options:
  - PLAN
  - ALL
  - STMTCACHE ALL
  - STMTID
  - STMTTOKEN
  - MONITORED STMTS
- PREPARE statement
- Explain dynamic SQL statements that execute under the special register CURRENT EXPLAIN MODE, when CURRENT EXPLAIN MODE = EXPLAIN
- BIND options: EXPLAIN(ONLY) and SQLERROR(CHECK)

  EXPLAIN(ONLY) allows to explain the statements.

  SQLERROR(CHECK) performs all syntax and semantic checks on the SQL statements that are being bound.
- START DYNQUERYCAPTURE command
- START ML command
- START PROFILE command
- START TRACE command
- STOP DYNQUERYCAPTURE command
- STOP ML command
- STOP PROFILE command
- STOP TRACE command
- DISPLAY DYNQUERYCAPTURE command
- DISPLAY ML command
- DISPLAY PROFILE command
- Execute the RUNSTATS utility and the MODIFY STATISTICS utility in any database.

- MONITOR2 privilege to obtain IFC data classified as containing potentially sensitive data, such as SQL statement text and audit data, as well as IFC data classified as serviceability data, statistics, accounting, and other performance data.

STOPALL
Grants the privilege to issue the STOP DB2 command.

STOSPACE
Grants the privilege to use the STOSPACE utility.

SYSADM
Grants all Db2 privileges except for a few reserved for installation SYSADM authority. The privileges the user possesses are all grantable, including the SYSADM authority itself. The privileges the user lacks restrict what the user can do with the directory and the catalog. Using WITH GRANT OPTION when granting SYSADM is redundant but valid. For more on SYSADM and installation SYSADM authority, see Managing administrative authorities (Managing Security).

SYSCTRL
Grants the system control authority, which allows the user to have most of the privileges of a system administrator but excludes the privileges to read or change user data. Using WITH GRANT OPTION when granting SYSCTRL is redundant but valid. For more information on SYSCTRL authority, see SYSCTRL (Managing Security).

SYSOPR
Grants the privilege to have system operator authority.

TRACE
Grants the privilege to issue the MODIFY TRACE, START TRACE, and STOP TRACE commands.

ON SYSTEM
Identifies that the system privilege is granted for the entire Db2 subsystem.

TO
Refer to "GRANT" on page 1958 for a description of the TO clause.

WITH GRANT OPTION
If you grant the SYSADM or SYSCTRL system privilege, WITH GRANT OPTION is valid but unnecessary. It is unnecessary because whoever is granted SYSADM or SYSCTRL has that authority and all the privileges it implies, with the GRANT option.

Examples for GRANT (system privileges)

Example 1
Grant DISPLAY privileges to user LUTZ.

```
GRANT DISPLAY
  TO LUTZ;
```

Example 2
Grant BSDS and RECOVER privileges to users PARKER and SETRIGHT, with the WITH GRANT OPTION.

```
GRANT BSDS,RECOVER
  TO PARKER,SETRIGHT
  WITH GRANT OPTION;
```

Example 3
Grant TRACE privileges to all local users.

```
GRANT TRACE
  TO PUBLIC;
```

Example 4
Grant ARCHIVE privileges to role ROLE1:

```
GRANT ARCHIVE TO ROLE ROLE1;
```

Example 5

SECADM Linda grants the privilege to Steve to create a secure object:

```
GRANT CREATE_SECURE_OBJECT
     TO STEVE;
```

Example 6

Grant system DBADM with ACCESSCTRL and with DATAACCESS to role, ADMINROLE and authid, SALLY. Since GRANT system DBADM also grants ACCESSCTRL and DATAACCESS by default, WITH ACCESSCTRL and WITH DATAACCESS clauses need not be specified explicitly.

```
GRANT DBADM ON SYSTEM
     TO ROLE ADMINROLE;
 GRANT DBADM, ACCESSCTRL, DATAACCESS
     ON SYSTEM
     TO SALLY;
```

Example 7

Grant system DBADM without ACCESSCTRL and without DATAACCESS to John. The WITHOUT ACCESSCTRL and WITHOUT DATAACCESS clauses need to be specified explicitly.

```
GRANT DBADM WITHOUT ACCESSCTRL
     WITHOUT DATAACCESS
     ON SYSTEM
     TO JOHN;
```

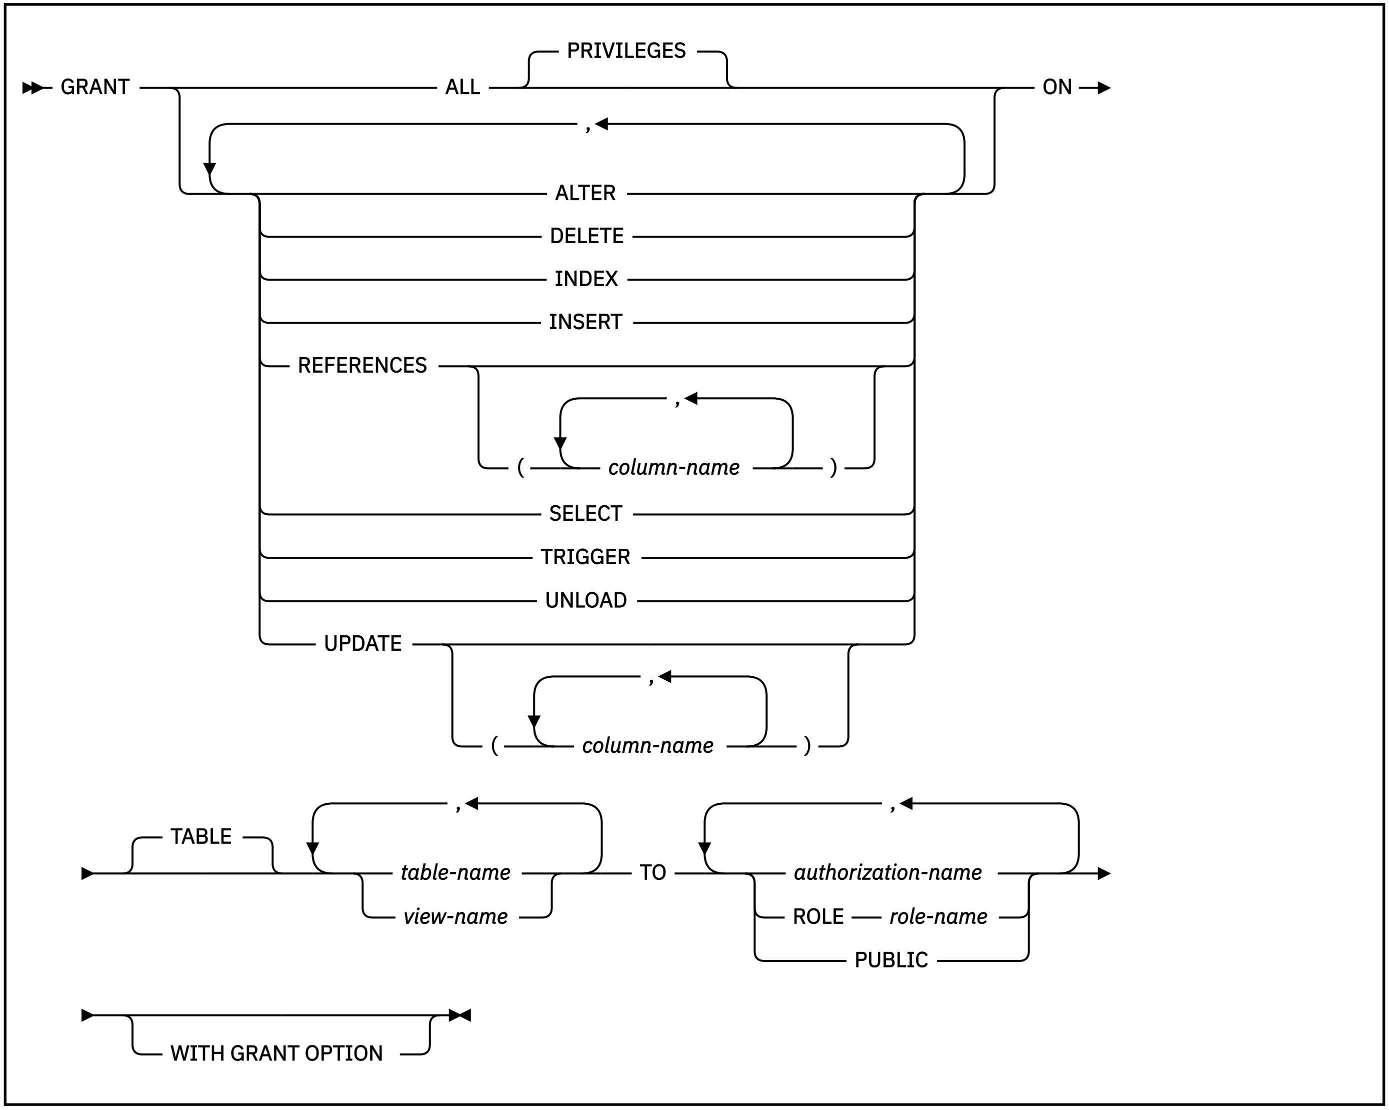
Explicit system privileges (Managing Security)

GRANT (table or view privileges)

This form of the GRANT statement grants privileges on tables and views.

Syntax for GRANT (table or view privileges)



Description for GRANT (table or view privileges)

ALL or ALL PRIVILEGES
Grants all table or view privileges for which you have GRANT authority, for the tables and views named in the ON clause.

If you do not use ALL, you must use one or more of the keywords in the following list. For each keyword that you use, you must have GRANT authority for that privilege on every table or view identified in the ON clause.

ALTER
Grants the privilege to alter the specified table or create a trigger on the specified table. ALTER cannot be used if the statement identifies an auxiliary table or a view.

DELETE
Grants the privilege to delete rows in the specified table or view. DELETE cannot be granted on an auxiliary table.

INDEX
Grants the privilege to create an index on the specified table. INDEX cannot be granted on a view.

INSERT
Grants the privilege to insert rows into the specified table or view. INSERT cannot be granted on an auxiliary table.

REFERENCES
Grants the privilege to add a referential constraint in which the specified table is a parent. If a list of column names is not specified or if REFERENCES is granted via the specification of ALL PRIVILEGES, the grantee can define referential constraints using all columns of the table as a parent key, even those added later via the ALTER TABLE statement. This privilege cannot be granted on a view or auxiliary table.

REFERENCES(*column-name,...*)
Grants the privilege to add or drop a referential constraint in which the specified table is a parent using only those columns that are specified in the column list as a parent key. Each *column-name* must be an unqualified name that identifies a column of the table identified in the ON clause. This privilege cannot be granted on a view or auxiliary table.

SELECT
Grants the privilege to create a view or read data from the specified table or view. SELECT cannot be granted on an auxiliary table.

TRIGGER
Grants the privilege to create a trigger on the specified table. TRIGGER cannot be granted on an auxiliary table or a view.

UNLOAD
Grants the privilege to use the UNLOAD utility. UNLOAD cannot be granted on an auxiliary table or a view.

UPDATE
Grants the privilege to update rows in the specified table or view. UPDATE cannot be granted on an auxiliary table.

UPDATE(*column-name,...*)
Grants the privilege to update only the columns named. Each *column-name* must be the unqualified name of a column of every table or view identified in the ON clause. Each *column-name* must not identify a column of an auxiliary table.

ON *table-name* or *view-name*
Specifies the tables or views on which you are granting the privileges. The list can be a list of table names or view names, or a combination of the two. A declared temporary table and a table that is implicitly created for an XML column must not be identified.

If you use GRANT ALL, then for each named table or view, the privilege set (described in "“Authorization for GRANT” on page 1959" in “GRANT” on page 1958) must include at least one privilege with the GRANT option.

TO
Refer to “GRANT” on page 1958 for a description of the TO clause.

WITH GRANT OPTION
Refer to “GRANT” on page 1958 for a description of the WITH GRANT OPTION clause.

Notes for GRANT (table or view privileges)

The REFERENCES privilege does not replace the ALTER privilege. It was added to conform to the SQL standard. To define a foreign key that references a parent table, you must have either the REFERENCES or the ALTER privilege, or both.

For a created temporary table, only ALL or ALL PRIVILEGES can be granted. Specific table privileges cannot be granted. In addition, only the ALTER, DELETE, INSERT, and SELECT privileges apply to a created temporary table.

For a view of a created temporary table, either ALL or the specific UPDATE, DELETE, INSERT and SELECT privileges can be granted. When ALL is specified only the UPDATE, DELETE, INSERT, and SELECT privileges apply to a view on created temporary table. However, the UPDATE operation of the view is not allowed.

To grant table privileges on a created temporary table, the privilege set must include one of the following:

- SYSADM
- DBADM on DSNDB06
- Ownership of the created temporary table

To grant table privileges on a view of a created temporary table, the privilege set must include one of the following:

- SYSADM
- ownership of the created temporary table

For a declared temporary table, no privileges can be granted. When a declared temporary table is defined, PUBLIC implicitly receives all table privileges (without GRANT authority) for the table. These privileges are not recorded in the Db2 catalog, and they cannot be revoked.

For an auxiliary table, only the INDEX privilege can be granted. DELETE, INSERT, SELECT, and UPDATE privileges on the base table that is associated with the auxiliary table extend to the auxiliary table.

- ALTER
- INDEX
- REFERENCES
- TRIGGER

Examples for GRANT (table or view privileges)

Example 1: Grant SELECT privileges on table DSN8C10.EMP to user PULASKI.

```
GRANT SELECT ON DSN8C10.EMP TO PULASKI;
```

Example 2: Grant UPDATE privileges on columns EMPNO and WORKDEPT in table DSN8C10.EMP to all users at the current server.

```
GRANT UPDATE (EMPNO,WORKDEPT) ON TABLE DSN8C10.EMP TO PUBLIC;
```

Example 3: Grant all privileges on table DSN8C10.EMP to users KWAN and THOMPSON, with the WITH GRANT OPTION.

```
GRANT ALL ON TABLE DSN8C10.EMP TO KWAN,THOMPSON WITH GRANT OPTION;
```

Example 4: Grant the SELECT and UPDATE privileges on the table DSN8C10.DEPT to every user in the network.

```
GRANT SELECT, UPDATE ON TABLE DSN8C10.DEPT
  TO PUBLIC;
```

Even with this grant, it is possible that some network users do not have access to the table at all, or to any other object at the subsystem where the table exists. Controlling access to the subsystem involves the communications databases at the subsystems in the network. The tables for the communication databases are described in Appendix G, “Db2 catalog tables,” on page 2321. Controlling access is described in Securing Db2 (Db2 for z/OS in IBM Documentation).

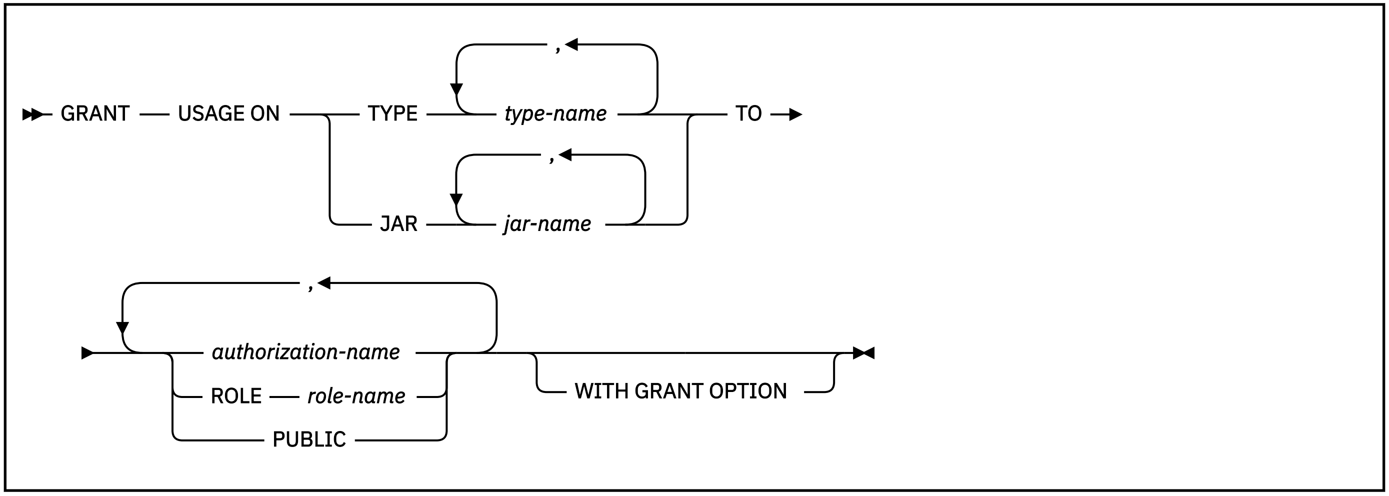
Example 5: Grant ALTER privileges on table DSN9910.EMP to role ROLE1:

```
GRANT ALTER ON TABLE DSN9910.EMP TO ROLE ROLE1;
```

GRANT (type or JAR file privileges)

This form of the GRANT statement grants the privilege to use distinct types, array types, or JAR files.

Syntax for GRANT (type or JAR file privileges)



Description for GRANT (type or JAR file privileges)

USAGE
Grants the privilege to use the distinct type in tables, functions procedures, or the privilege to use the JAR file.

TYPE *type-name*
Identifies the user-defined type. The name, including the implicit or explicit schema name, must identify a unique user-defined type that exists at the current server.

JAR *jar-name*
Identifies the JAR file. The name, including the implicit or explicit schema name, must identify a unique JAR file that exists at the current server.

TO
Refer to "GRANT" on page 1958 for a description of the TO clause.

WITH GRANT OPTION
Refer to "GRANT" on page 1958 for a description of the WITH GRANT OPTION clause.

Notes for GRANT (type or JAR file privileges)

Alternative syntax and synonyms: To provide compatibility with previous releases of Db2 or other products in the Db2 family, Db2 supports DATA TYPE or DISTINCT TYPE as a synonym for TYPE.

Examples for GRANT (type or JAR file privileges)

Example 1: Grant the USAGE privilege on distinct type SHOE_SIZE to user JONES. This GRANT statement does not give JONES the privilege to execute the cast functions that are associated with the distinct type SHOE_SIZE.

```
GRANT USAGE ON TYPE SHOE_SIZE TO JONES;
```

Example 2: Grant the USAGE privilege on distinct type US_DOLLAR to all users at the current server.

```
GRANT USAGE ON TYPE US_DOLLAR TO PUBLIC;
```

Example 3: Grant the USAGE privilege on distinct type CANADIAN_DOLLAR to the administrative assistant (ADMIN_A), and give this user the ability to grant the USAGE privilege on the distinct type to others. The administrative assistant cannot grant the privilege to execute the cast functions that are associated with the distinct type CANADIAN_DOLLAR because WITH GRANT OPTION does not give the administrative assistant the EXECUTE authority on these cast functions.

```
   GRANT USAGE ON TYPE CANADIAN_DOLLAR TO ADMIN_A
         WITH GRANT OPTION;
```

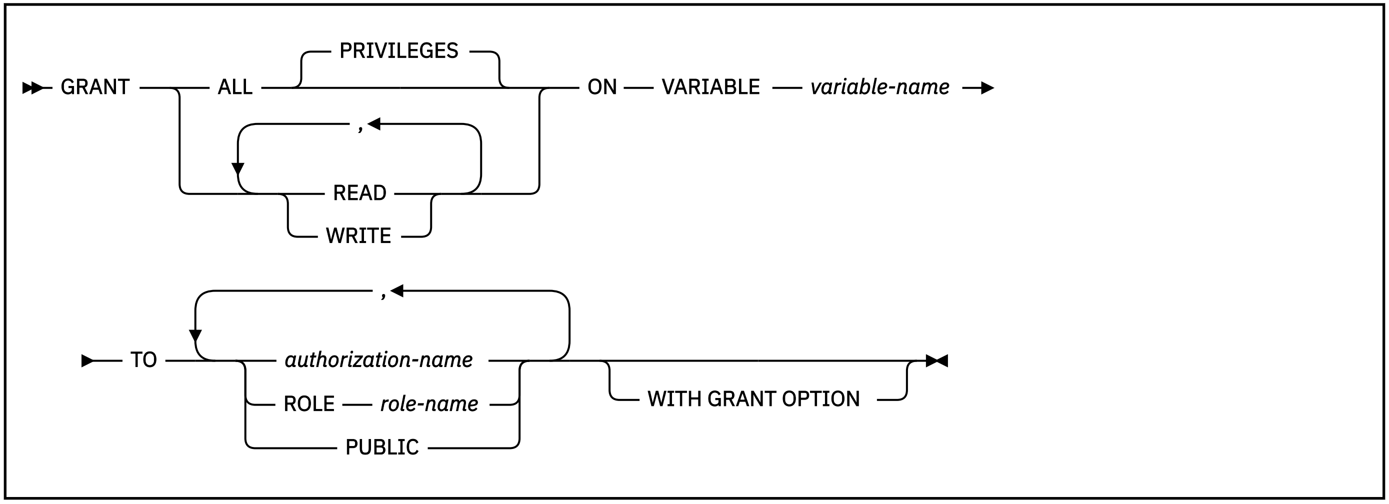
Example 4: Grant the USAGE privilege on the distinct type MILES to role ROLE1 at the current server:

```
GRANT USAGE ON TYPE MILES
    TO ROLE ROLE1;
```

GRANT (variable privileges)

This form of the GRANT statement grants privileges on global variables.

Syntax for GRANT (variable privileges)



Description for GRANT (variable privileges)

ALL PRIVILEGES
Grants both READ and WRITE privileges on the specified global variable.

READ
Grants the privilege to access the content of the specified global variable.

WRITE
Grants the privilege to modify the content of the specified global variable.

ON VARIABLE *variable-name*
Identifies the global variable for which you are granting privileges. *variable-name*, including an implicit or explicit qualifier, must identify a global variable that exists at the current server.

TO
Refer to "GRANT" on page 1958 for a description of the TO clause.

WITH GRANT OPTION
Refer to "GRANT" on page 1958 for a description of the WITH GRANT OPTION clause.

Examples for GRANT (variable privileges)

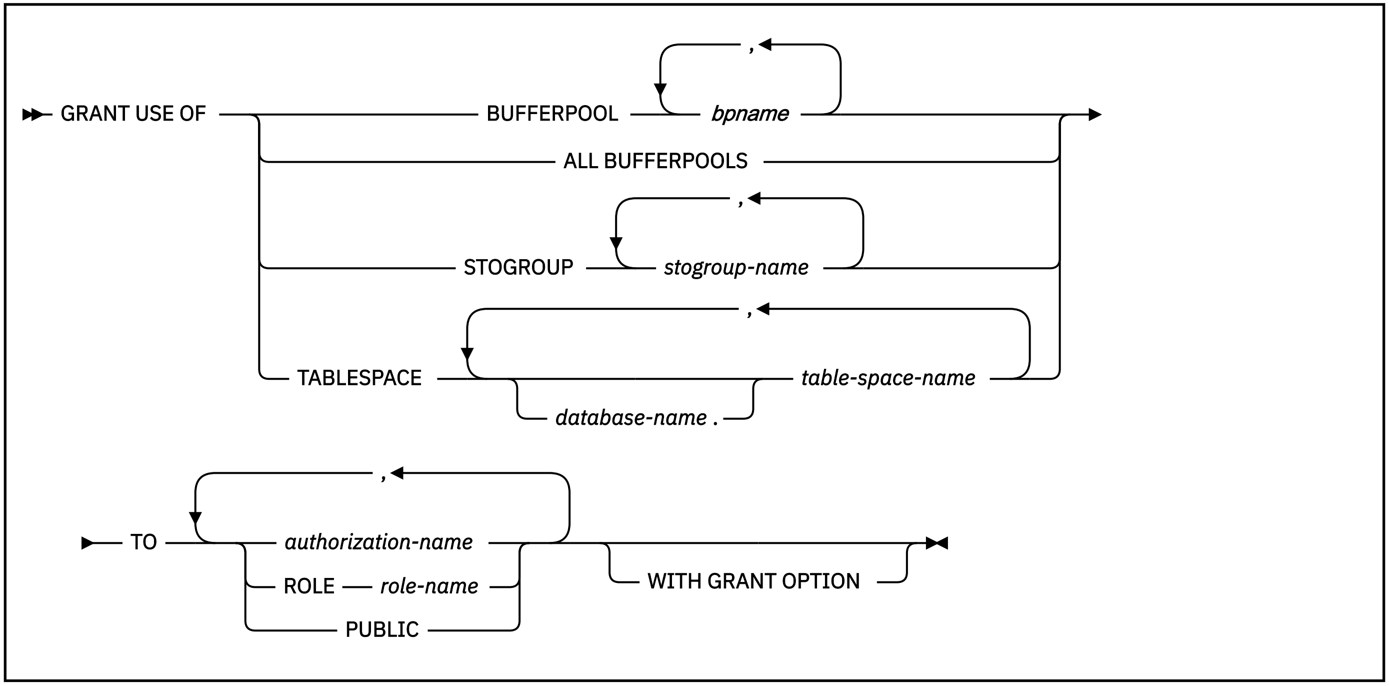
Example 1: Grant the read privilege on the ACCOUNTNO variable on the current server to user Jones:

```
GRANT READ ON VARIABLE ACCOUNTNO TO JONES;
```

GRANT (use privileges)

This form of the GRANT statement grants authority to use particular buffer pools, storage groups, or table spaces.

Syntax for GRANT (use privileges)



Description for GRANT (use privileges)

BUFFERPOOL *bpname,...*
Grants the privilege to refer to any of the identified buffer pools in a CREATE INDEX, CREATE TABLESPACE, ALTER INDEX, or ALTER TABLESPACE statement. See "Naming conventions" on page 79 for more details about *bpname*.

ALL BUFFERPOOLS
Grants the privilege to refer to any buffer pool in a CREATE INDEX, CREATE TABLESPACE, ALTER INDEX, or ALTER TABLESPACE statement.

STOGROUP *stogroup-name,...*
Grants the privilege to refer to any of the identified storage groups in a CREATE INDEX, CREATE TABLESPACE, ALTER INDEX, or ALTER TABLESPACE statement.

TABLESPACE *database-name.table-space-name,...*
Grants the privilege to refer to any of the identified table spaces in a CREATE TABLE statement. The default for *database-name* is DSNDB04.

You cannot grant the privilege for table spaces that are for declared temporary tables (table spaces in a work file database). For these table spaces, PUBLIC implicitly has the TABLESPACE privilege (without GRANT authority); this privilege is not recorded in the Db2 catalog, and it cannot be revoked.

TO
Refer to "GRANT" on page 1958 for a description of the TO clause.

WITH GRANT OPTION
Refer to "GRANT" on page 1958 for a description of the WITH GRANT OPTION clause.

Notes for GRANT (use privileges)

You can grant privileges for only one type of object with each statement. Thus, you can grant the use of several table spaces with one statement, but not the use of a table space and a storage group. For each object you identify, you must have the USE privilege with GRANT authority.

Examples for GRANT (use privileges)

Example 1: Grant authority to use buffer pools BP1 and BP2 to user MARINO.

```
GRANT USE OF BUFFERPOOL BP1,BP2
  TO MARINO;
```

Example 2: Grant to all local users the authority to use table space DSN8S12D in database DSN8D12A.

```
GRANT USE OF TABLESPACE
  DSN8D12A.DSN8S12D
  TO PUBLIC;
```

Example 3: Grant authority to use storage group SG1 to role ROLE1:

```
GRANT USE OF STOGROUP SG1
   TO ROLE ROLE1;
```

HOLD LOCATOR

The HOLD LOCATOR statement allows a LOB locator variable to retain its association with a value beyond a unit of work.

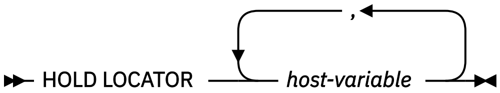
Invocation for HOLD LOCATOR

This statement can only be embedded in an application program. It cannot be issued interactively. It is an executable statement that can be dynamically prepared. However, the EXECUTE statement with the USING clause must be used to execute the prepared statement. HOLD LOCATOR cannot be used with the EXECUTE IMMEDIATE statement.

Authorization for HOLD LOCATOR

None required.

Syntax for HOLD LOCATOR



Description for HOLD LOCATOR

host-variable, ...

Identifies one or more locator variables that must be declared in accordance with the rules for declaring locator variables. The locator variable type must be a binary large object locator, a character large object locator, or a double-byte character large object locator.

The *host-variable* must currently have a locator assigned to it. That is, a locator must have been assigned during this unit of work (by a FETCH, SELECT INTO, assignment statement, SET *host-variable* statement, or VALUES INTO statement); otherwise, an error is returned.

If more than one locator is specified and an error is returned on one of the locators, it is possible that some locators have been held and others have not been held.

Notes for HOLD LOCATOR

A host-variable LOB locator variable that has the hold property is freed (has its association between it and its value removed) when:

- The SQL FREE LOCATOR statement is executed for the locator variable.
- The SQL ROLLBACK statement is executed.
- The SQL session is terminated.

Example for HOLD LOCATOR

Assume that the employee table contains columns RESUME, HISTORY, and PICTURE and that locators have been established in a program to represent the values represented by the columns. Give the CLOB locator variables LOCRES and LOCHIST, and the BLOB locator variable LOCPIC the hold property.

```
   EXEC SQL HOLD LOCATOR :LOCRES, :LOCHIST, :LOCPIC
```

INCLUDE

The INCLUDE statement inserts application code, including declarations and statements, into a source program.

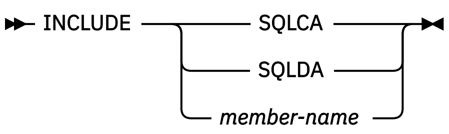
Invocation for INCLUDE

This statement can only be embedded in an application program. It is not an executable statement. It must not be specified in Java or REXX.

Authorization for INCLUDE

None required.

Syntax for INCLUDE



Description for INCLUDE

SQLCA

Indicates that the description of an SQL communication area (SQLCA) is to be included. INCLUDE SQLCA must not be specified more than once in the same application program. In COBOL, INCLUDE SQLCA must be specified in the Working-Storage Section or the Linkage Section. INCLUDE SQLCA must not be specified if the program is prepared (either with the Db2 precompiler or coprocessor) with the STDSQL(YES) SQL processing option.

For a description of the SQLCA, see Appendix E, “SQL communication area (SQLCA),” on page 2291.

SQLDA

Indicates that the description of an SQL descriptor area (SQLDA) is to be included. It must not be specified in a Fortran. For a description of the SQLDA, see Appendix F, “SQL descriptor area (SQLDA),” on page 2301.

member-name

Names a member of the partitioned data set to be the library input when your application program is prepared (either with the Db2 precompiler or coprocessor). It must be an SQL identifier.

The member can contain any host language source statements and any SQL statements other than an INCLUDE statement. In COBOL, INCLUDE *member-name* must not be specified in other than the Data Division or the Procedure Division.

Notes for INCLUDE

When your application program is prepared (either with the Db2 precompiler or coprocessor), the INCLUDE statement is replaced by source statements. Thus, the INCLUDE statement must be specified at a point in your application program where the resulting source statements are acceptable to the compiler.

The INCLUDE statement cannot refer to source statements that themselves contain INCLUDE statements.

The declarations that are generated by DCLGEN can be used in an application program by specifying the same member in the INCLUDE statement as in the DCLGEN LIBRARY parameter.

Example for INCLUDE

Include an SQL communications area in a PL/I program.

```
EXEC SQL INCLUDE SQLCA;
```

INSERT

The INSERT statement inserts rows into a table or view. Inserting a row into a view inserts the row into the table on which the view is based if no INSTEAD OF INSERT trigger is defined for this view. If such a trigger is defined, the trigger is activated instead.

The table or view can be at the current server or any Db2 subsystem with which the current server can establish a connection.

The INSERT statement has the following three forms:

VALUES form

The *VALUES form* of the INSERT statement inserts a single row into the table or view using the values provided or referenced.

***fullselect* form**

The *fullselect form* of the INSERT statement inserts one or more rows into the table or view using values from other tables, or views, or both.

FOR *n* ROWS form

The *FOR n ROWS form* of the INSERT statement inserts multiple rows into the table or view using values provided or referenced. Although not required, the values can come from host-variable arrays.

This form of INSERT is supported in SQL procedure applications. However, because host-variable arrays are not supported in SQL procedure applications, the support is limited to insertion of scalar values.

Invocation for INSERT

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization for INSERT

Authority requirements depend on whether the object identified in the statement is a user-defined table, a catalog table for which inserts are allowed, or a view:

When a user-defined table is identified: The privilege set must include at least one of the following:

- The INSERT privilege on the table
- Ownership of the table
- DBADM authority on the database that contains the table
- SYSADM authority
- DATAACCESS authority

If the database is implicitly created, the database privileges must be on the implicit database or on DSNDB04.

When a catalog table is identified: The privilege set must include at least one of the following:

- ACCESSCTRL authority
- DATAACCESS authority
- DBADM authority on the catalog database
- Installation SYSOPR authority
- SQLADM authority
- SYSCTRL authority
- SYSADM authority
- System DBADM authority

When a view is identified: The privilege set must include at least one of the following:

- DATAACCESS authority
- INSERT privilege on the view
- SYSADM authority

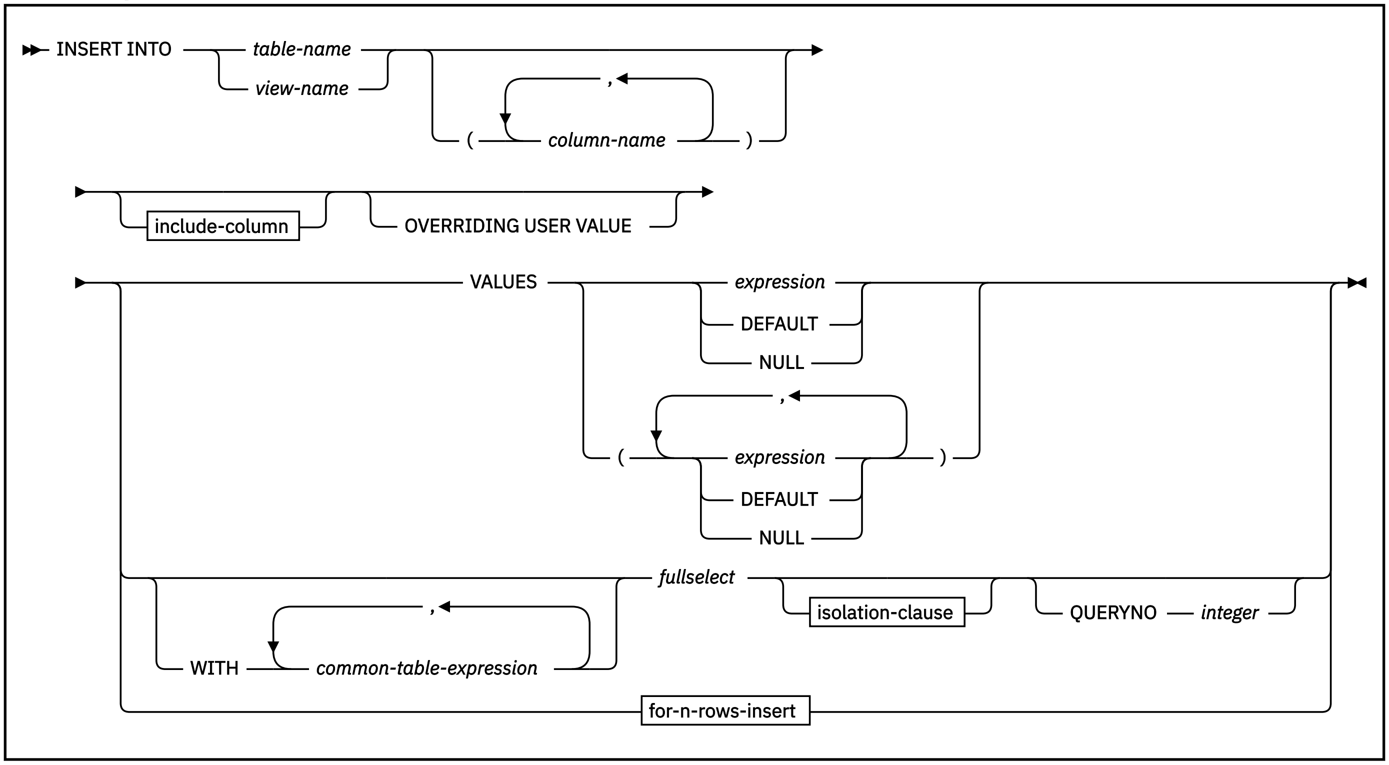
The owner of a view, unlike the owner of a table, might not have INSERT authority on the view (or can have INSERT authority without being able to grant it to others). The nature of the view itself can preclude its use for INSERT. For more information, see the discussion of authority in "CREATE VIEW" on page 1807.

If the INSERT statement is embedded in a SELECT statement, the privilege set must include the SELECT privilege on the table or view.

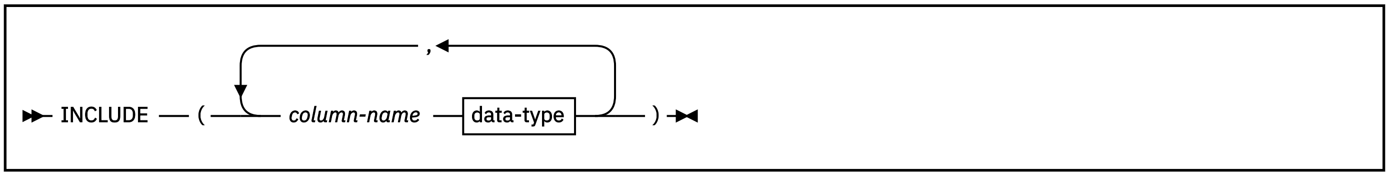
If a fullselect is specified, the privilege set must include authority to execute the fullselect. For more information about the authorization rules, see "Authorization for queries" on page 1005.

If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the statement is dynamically prepared, the privilege set is determined by the DYNAMICRULES behavior in effect (run, bind, define, or invoke) and is summarized in Table 171 on page 1084. (For more information on these behaviors, including a list of the DYNAMICRULES bind option values that determine them, see "Authorization IDs and dynamic SQL" on page 94.)

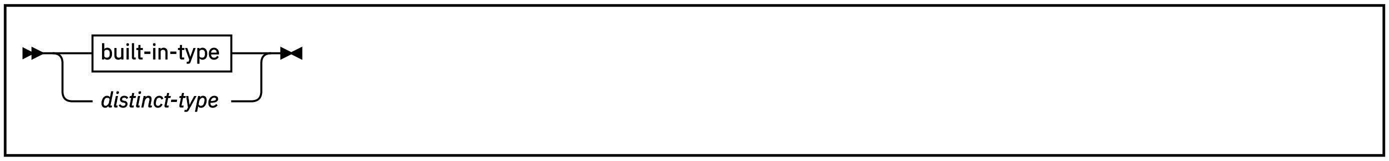
Syntax for INSERT



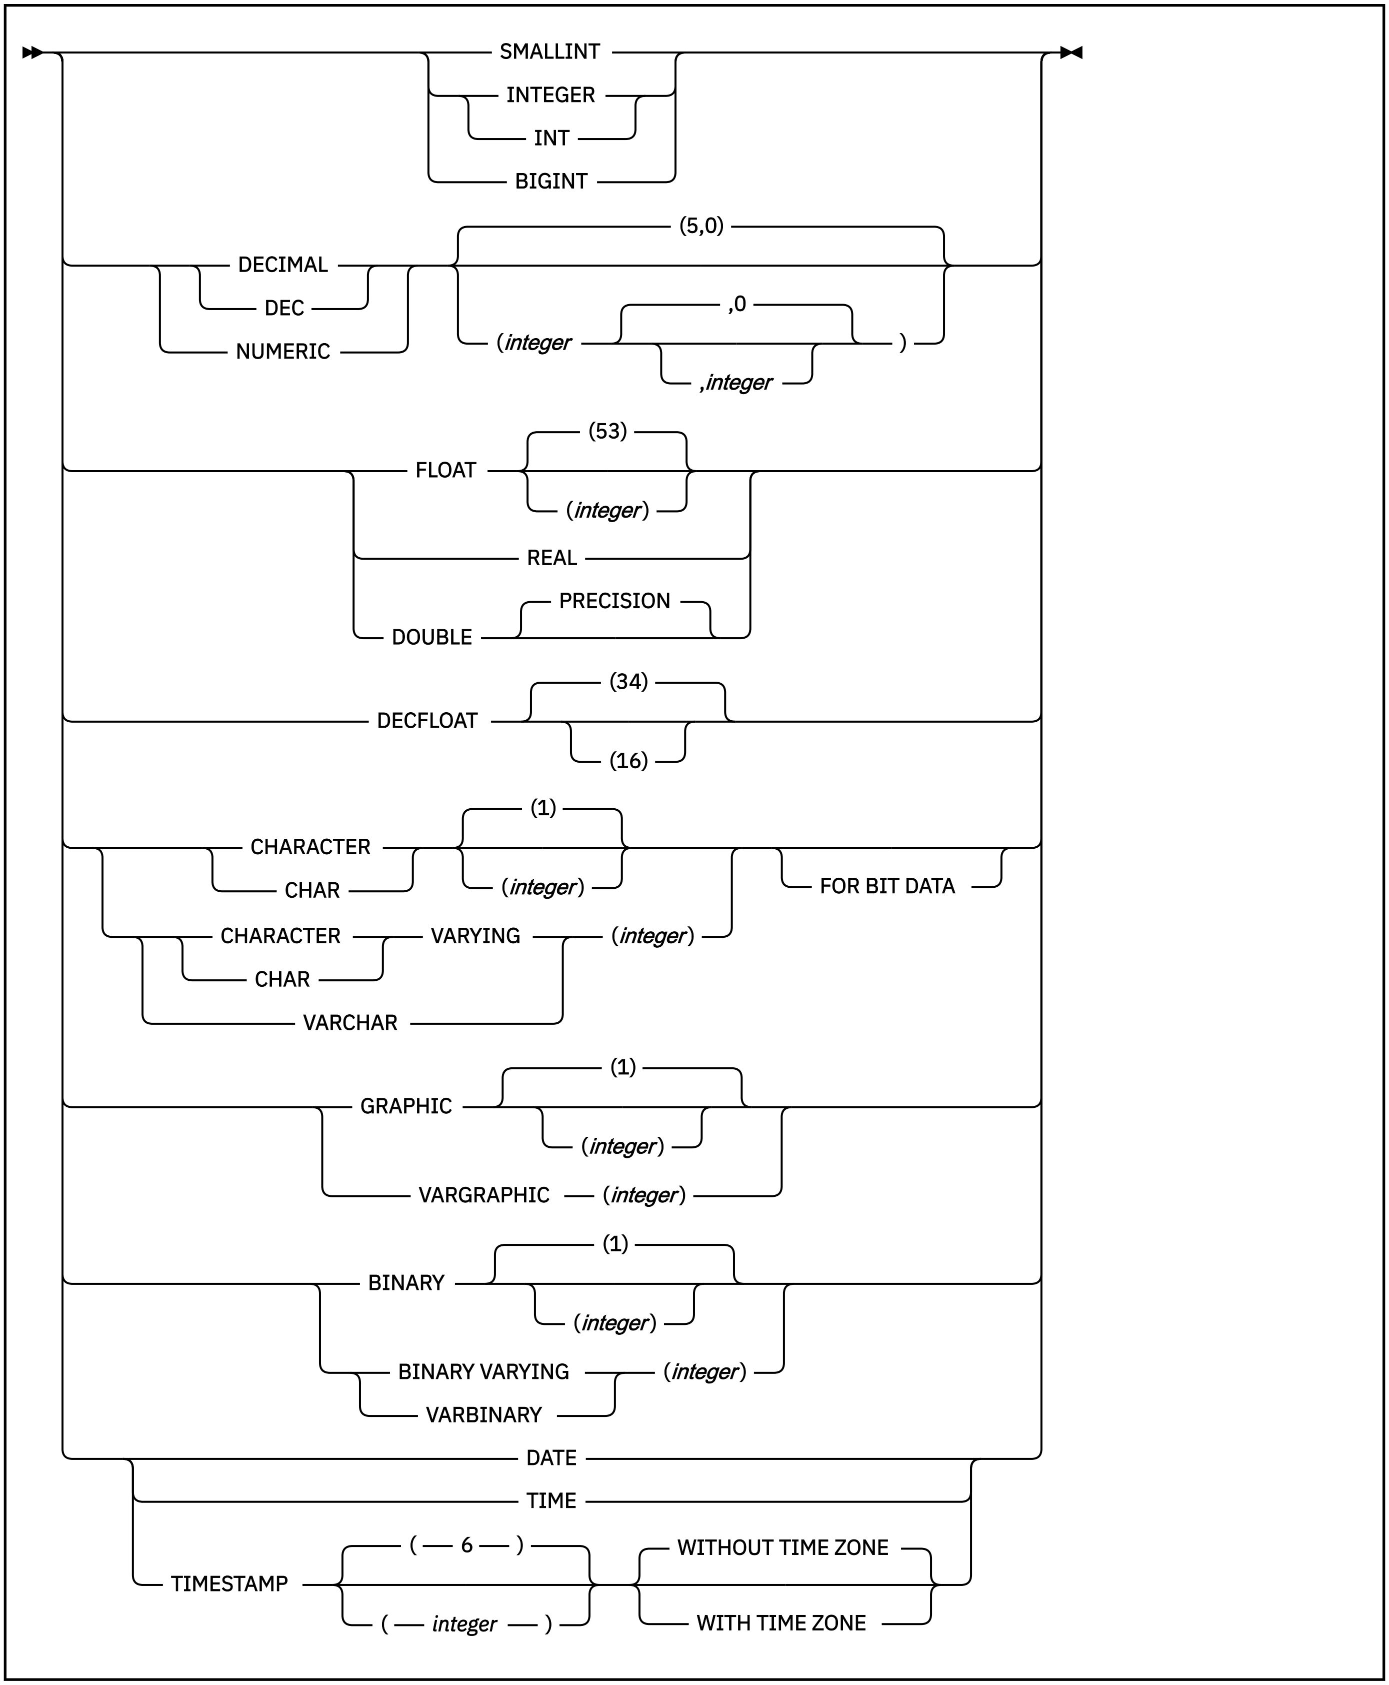
include-column:



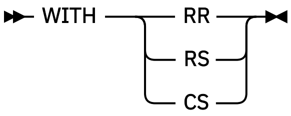
data-type:



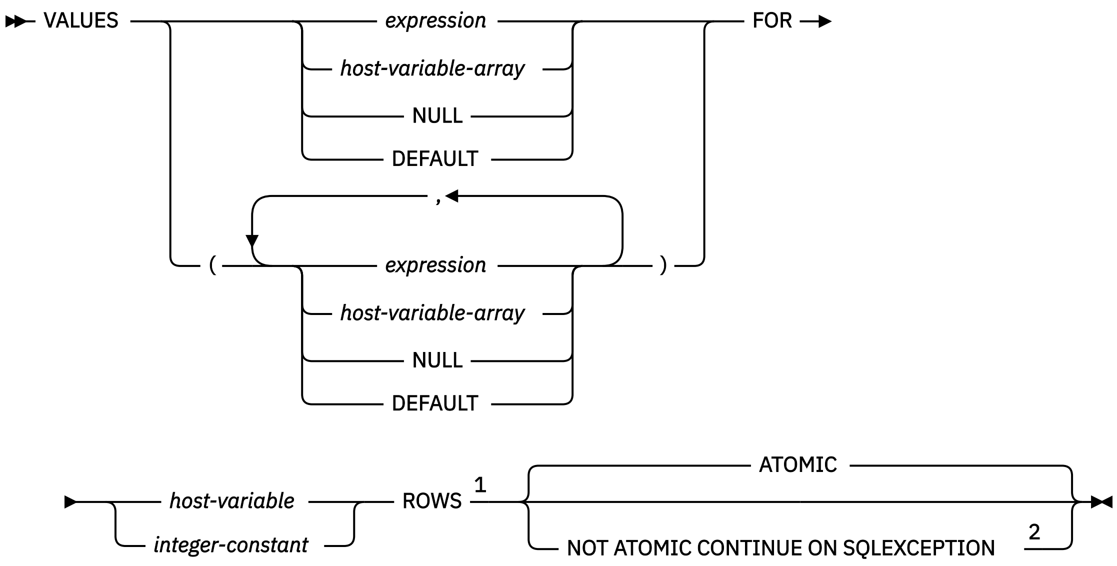
built-in-type:



isolation-clause:



for-n-rows-insert:



Notes:

[1] The FOR *n* ROWS clause must be specified for this form of a static INSERT statement. However, this clause is optional for a dynamic INSERT statement. For a dynamic statement, the FOR *n* ROWS clause can be specified on the EXECUTE statement.

[2] The ATOMIC or NOT ATOMIC CONTINUE ON SQLEXCEPTION clauses can be specified for a static multiple-row-insert. However, this clause must not be specified for a dynamic INSERT statement. For a dynamic statement, the ATOMIC or NOT ATOMIC CONTINUE ON SQLEXCEPTION clause is specified as an attribute on the PREPARE statement.

Description for INSERT

INTO *table-name* or *view-name*

Identifies the object of the INSERT statement. The name must identify a table or view that exists at the current server. The name must not identify:

- An auxiliary table
- A catalog table
- A directory table
- A read-only view unless an instead of trigger is defined for the insert operation on the view. (For a description of a read-only view, see "CREATE VIEW" on page 1807.)
- A view column that is derived from a constant, expression, or scalar function
- A view column that is derived from the base table column as some other column of the view
- A materialized query table
- A table that is implicitly created for an XML column

In an IMS or CICS application, the Db2 subsystem that contains the identified table or view must be a remote server that supports two-phase commit.

column-name,...

Specifies the columns for which insert values are provided. Each name must identify a column of the table or view. The columns can be identified in any order, but the same column must not be identified more than one time. If extended indicators are not enabled, a view column that cannot accept insert values must not be identified. If extended indicators are not enabled, and the object of the INSERT statement is a view with columns that cannot accept insert values, a list of column names must be specified, and the list must not identify those columns. If a qualifier is specified, it must be valid (that is, the table name must be the table or view name specified after the INTO keyword, and if a qualifier is specified for the table name, it must match the default qualifier).

Omission of the column list is an implicit specification of a list in which every column of the table (that is not defined as implicitly hidden) or view is identified in left-to-right order. This list is established when the statement is prepared and therefore does not include columns that were added to the table after the statement was prepared.

The effect of a rebind on INSERT statements that do not include a column list is that the implicit list of names is re-established. Therefore, the number of column values that an INSERT statement must specify can change, resulting in an error when the statement is rebound. For this reason, it is best to always specify the column names in INSERT statements.

include-column

Specifies a set of columns that are included, along with the columns of *table-name* or *view-name*, in the result table of the INSERT statement when it is nested in the FROM clause of the outer fullselect that is used in a subselect, a SELECT statement, or in a SELECT INTO statement. The included columns are appended to the end of the list of columns that is identified by *table-name* or *view-name*.

INCLUDE

Introduces a list of columns that is to be included in the result table of the INSERT statement. The included columns are only available if the INSERT statement is nested in the FROM clause of a SELECT statement or a SELECT INTO statement.

column-name

Specifies the name for a column of the result table of the INSERT statement that is not the same name as another included column nor a column in the table or view that is specified in *table-name* or *view-name*.

data-type

Specifies the data type of the included column. The included columns are nullable.

built-in-type

Specifies a built-in data type. See "CREATE TABLE" on page 1645 for a description of each built-in type.

The CCSID 1208 and CCSID 1200 clauses must not be specified for an INCLUDE column.

distinct-type

Specifies a distinct type. Any length, precision, or scale attributes for the column are those of the source type of the distinct type as specified by using the CREATE TYPE statement.

OVERRIDING USER VALUE

Specifies that the value specified in the VALUES clause or produced by a fullselect for a column that is defined as either GENERATED ALWAYS or GENERATED BY DEFAULT is ignored. Instead, a system-generated value is inserted, overriding the user-specified value.

If OVERRIDING USER VALUE is specified, the implicit or explicit list of column must include a column that is defined as either GENERATED ALWAYS or GENERATED BY DEFAULT. For example, a ROWID column, an identity column, or a row change timestamp column.

VALUES form descriptions

The following descriptions apply to the VALUES form of INSERT.

VALUES

Specifies one new row in the form of a list of values. The number of values in the VALUES clause must be equal to the number of names in the column list and the columns that are identified in the INCLUDE clause. The first value is inserted in the first column in the list, the second value in the second column, and so on. If more than one value is specified, the list of values must be enclosed in parentheses. Assignments to included columns are only processed when the INSERT statement is nested in the FROM clause in a SELECT statement or a SELECT INTO statement.

expression

Any expression of the type described in "Expressions" on page 244. The expression must not include a column name. If *expression* is a host variable, the host variable can identify a structure. Any host variable or structure that is specified must be described in the application program according to the rules for declaring host structures and variables.

If *expression* is a host variable, it can include an indicator variable or an indicator array (in the case of a host structure).

If extended indicators are enabled, and the expression is not a single variable, the extended indicator values of DEFAULT (-5) and UNASSIGNED (-7) must not be used for that expression.

In addition:

- A CAST specification can be used if either of the following is true:
  - The target column is defined as nullable.
  - The target column is defined as NOT NULL with a non-null default, the source of the CAST specification is a single host variable, and the data attributes (data type, length, precision, and scale) of the host variable are the same as the result of the cast specification.
- A scalar fullselect can be used if either of the following is true for each expression in the select list of the fullselect:
  - The target column that corresponds to the expression is defined as nullable.
  - The expression is not more complex than a reference to a single host variable for which the indicator is set to an extended indicator value of DEFAULT (-5) or UNASSIGNED (-7), or the expression is a CAST specification which would have been valid as a stand-alone expression.

DEFAULT

Specifies the default value for the column. If the column is a generated column, Db2 will generate a value for the column.

For information on default values of data types, see the description of the DEFAULT clause for "CREATE TABLE" on page 1645.

NULL

Specifies the null value as the value of the column. Specify NULL only for nullable columns.

If the implicit or explicit list of columns includes a ROWID, an identity column, or a row change timestamp column that was defined as GENERATED ALWAYS, you must specify DEFAULT unless you specify the OVERRIDING USER VALUE clause to indicate that any user-specified value will be ignored and a unique system-generated value will be inserted.

For a ROWID or identity column that is defined as GENERATED BY DEFAULT, you can specify a value. However, a value can be inserted into ROWID column defined BY DEFAULT only if a single-column unique index is defined on the ROWID column and the specified value is a valid row ID value that was previously generated by Db2. When a value is inserted into an identity column defined BY DEFAULT, Db2 does not verify that the specified value is a unique value for the column unless the identity column has a single-column unique index.

Although an implicitly hidden DOCID column for XML values is defined as `GENERATED ALWAYS`, you can include the DOCID column in the explicit list of columns and specify a value for it. However, Db2 will ignore the value.

fullselect form desriptions

The following descriptions apply to the *fullselect* form of INSERT.

WITH *common-table-expression*

Specifies a common table expression. For an explanation of common table expression, see "common-table-expression" on page 1065.

fullselect

Specifies a set of new rows in the form of the result table of a fullselect. If the result table is empty, SQLCODE is set to +100, and SQLSTATE is set to '02000'.

The base object of the INSERT statement and the base object of the fullselect or any subquery of the fullselect can be the same table. In this case, the fullselect is evaluated completely before any rows are inserted.

For an explanation of fullselect, see "fullselect" on page 1058.

The number of columns in the result table must be equal to the number of names in the column list and the columns that are identified in the INCLUDE clause. The value of the first column of the result is inserted in the first column in the list, the second value in the second column, and so on. Any values that are produced for a generated column must conform to the rules that are described for those columns under the VALUES clause. Assignments to included columns are only processed when the INSERT statement is nested in the FROM clause of a SELECT statement or a SELECT INTO statement.

If the expression that specifies the value of a result column is a variable, the host variable can include an indicator variable. When extended indicator variables are enabled, the target column that corresponds to an expression in the select list of the fullselect that involves a host variable with an extended indicator value of DEFAULT (-5) or UNASSIGNED (-7), must be defined as nullable and either of the following expressions:

- The expression must not be more complex than a reference to a single host variable.
- The expression must be a CAST specification with the following characteristics:
  - The source of the CAST specification must be a single host variable.
  - The data attributes (data type, length, precision, and scale) of the host variable are the same as the result of the cast specification.

If the object table is self-referencing, the fullselect must not return more than one row.

isolation-clause

Specifies the isolation level that is used when the fullselect is executed.

WITH

Introduces the isolation level, which can be one of the following values:

RR

Repeatable read

RS

Read stability

CS

Cursor stability

The default isolation level of the statement is the isolation level of the package or plan in which the statement is bound, with the package isolation taking precedence over the plan isolation. When a package isolation is not specified, the plan isolation is the default.

QUERYNO *integer*

Specifies the number to be used for this SQL statement in EXPLAIN output and trace records. The number is used for the QUERYNO column of the plan table for the rows that contain information about this SQL statement. This number is also used in the QUERYNO column of the SYSIBM.SYSSTMT and SYSIBM.SYSPACKSTMT catalog tables.

If the clause is omitted, the number that is associated with the SQL statement is the statement number that is assigned during precompilation. Thus, if the application program is changed and then precompiled, that statement number might change.

Using the QUERYNO clause to assign unique numbers to the SQL statements in a program is helpful:

- For simplifying the use of optimization hints for access path selection
- For correlating SQL statement text with EXPLAIN output in the plan table

For more information about enabling and using optimization hints, see Influencing access path selection (Db2 Performance)

For information on accessing the plan table, see Investigating SQL performance by using EXPLAIN (Db2 Performance).

FOR *n* ROWS form descriptions

The following descriptions apply to the FOR *n* ROWS form of the INSERT.

VALUES

Specifies the items for the rows to be inserted. The number of items in the VALUES clause must equal the number of names in the implicit or explicit column list. The first item in the list provides the value (or values) for the first column in the list. The second item in the list provides the value (or values) for the second column, and so on.

expression

Any expression of the type described in "Expressions" on page 244. The expression must not include a column name. For each row that is inserted, the corresponding column is assigned the value of the expression.

host-variable-array

Each host-variable array must be defined in the application program in accordance with the rules for declaring an array. A host-variable array contains the data for a column of table that is a target of the INSERT. The number of rows to be inserted must be less than or equal to the dimension of each of the host-variable arrays.

An optional indicator array can be specified for each host-variable array. It should be specified if the SQLTYPE of any SQLVAR occurrence indicates that the SQLVAR is nullable. The indicators must be small integers. The indicator array must be large enough to contain an indicator for each row of input data.

If extended indicator variables are enabled, the extended indicator variable values of DEFAULT or UNASSIGNED can be used inside the indicator array.

host-variable-array is supported in C/C++, COBOL, and PL/I. For more information, see "Host-variable arrays in PL/I, C, C++, and COBOL" on page 236.

DEFAULT

Specifies the default value for the column. If the column is a generated column, Db2 will generate a value for the column.

For information on default values of data types, see the description of the DEFAULT clause for "CREATE TABLE" on page 1645.

NULL

Specifies the null value as the value of the column in each row inserted. For each row inserted, the corresponding column is assigned the NULL value. Specify NULL only for nullable columns.

FOR *n* ROWS

Specifies the number of rows to be inserted, where *n* is *host-variable* or *integer-constant*. For a dynamic INSERT statement, this clause can be specified on the EXECUTE statement. For more information, see "EXECUTE" on page 1904. However, this clause is required when a dynamic SELECT statement contains more than one multiple-row INSERT statement.

host-variable or *integer-constant* is assigned to an integral value *k*. If *host-variable* is specified, it must be an exact numeric type with scale zero, and must not include an indicator variable.

Furthermore, *k* must be in the range, 0<k<=32767. *k* rows are inserted into the target table from the specified source data.

If the statement runs on accelerator, FOR *integer-constant* ROWS is supported only if the VALUES clause uses a host variable array.

If a parameter marker is specified in this clause, a value must be provided with the USING clause of the associated EXECUTE or OPEN statement.

ATOMIC or NOT ATOMIC CONTINUE ON SQLEXCEPTION
Specifies whether all of the rows should be inserted as an atomic operation or not.

ATOMIC
Specifies that if the insert for any row fails, all changes made to the database by any of the inserts, including changes made by successful inserts, are undone. This is the default.

NOT ATOMIC CONTINUE ON SQLEXCEPTION
Specifies that, regardless of the failure of any particular insert of a row, the INSERT statement will not undo any changes made to the database by the successful inserts of other rows, and inserting will be attempted for subsequent rows. However, the minimum level of atomicity is at least that of a single insert (that is, it is not possible for a partial insert to complete), including any triggers that might have been executed as a result of the INSERT statement.

This clause is only valid for a static INSERT statement. This clause must also not be specified if the INSERT statement is contained within a SELECT statement. For a dynamic INSERT statement, specify the clause on the PREPARE statement. For more information, see "PREPARE" on page 2037.

Notes for INSERT

Insert rules:
Insert values must satisfy the following rules. If they do not, or if any other errors occur during the execution of the INSERT statement, no rows are inserted and the position of the cursors are not changed.

- *Default values*. The value inserted in any column that is not in the column list is the default value of the column. Columns without a default value must be included in the column list. Similarly, if you insert into a view, the default value is inserted into any column of the base table that is not included in the view. Hence, all columns of the base table that are not in the view must have a default value.
- *Length*. If the insert value of a column is a number, the column must be a numeric column with the capacity to represent the integral part of the number. If the insert value of a column is a string, the column must be either a string column with a length attribute at least as great as the length of the string, or a datetime column if the string represents a date, time, or timestamp.
- *Assignment*. Insert values are assigned to columns in accordance with the assignment rules described in Chapter 2, "Language elements in SQL," on page 75.
- *Uniqueness constraints*. If the identified table or the base table of the identified view has one or more unique indexes, each row inserted into the table must conform to the constraints imposed by those indexes.
- *Referential constraints*. Each non-null insert value of a foreign key must be equal to some value of the parent key of the parent table in the relationship.
- *Check constraints*. The identified table or the base table of the identified view might have one or more check constraints. Each row inserted must conform to the conditions imposed by those constraints. Thus, each check condition must be true or unknown.
- *Field and validation procedures*. If the identified table or the base table of the identified view has a field or validation procedure, each row inserted must conform to the constraints imposed by that procedure.
- *Indexes with VARBINARY columns*. If the identified table has an index on a VARBINARY column or a column that is a distinct type that is based on VARBINARY data type, that index column cannot

specify the DESC attribute. To use the SQL data change operation on the identified table, either drop the index or alter the data type of the column to BINARY and then rebuild the index.

- *Views and the WITH CHECK OPTION*. For views defined with WITH CHECK OPTION, each row you insert into the view must conform to the definition of the view. If the view you name is dependent on other views whose definitions include WITH CHECK OPTION, the inserted rows must also conform to the definitions of those views. For an explanation of the rules governing this situation, see "CREATE VIEW" on page 1807.

  For views that are not defined with WITH CHECK OPTION, you can insert rows that do not conform to the definition of the view. Those rows cannot appear in the view but are inserted into the base table of the view.
- *Omitting the column list*. When you omit the column list, you must specify a value for every column that was present in the table when the INSERT statement was bound or (for dynamic execution) prepared.
- *Triggers*. An INSERT statement might cause triggers to be activated. A trigger might cause other statements to be executed or raise error conditions based on the insert values. If an INSERT statement for a view activates an INSTEAD OF trigger, the validity, referential integrity, and check constraints are checked against the data changes that are performed in the trigger, and not against the definition of the view that activates the trigger or the definition of the underlying tables or views.

  When triggers are processed for an INSERT statement that inserts multiple rows depends on the atomicity option that is in effect for the INSERT statement:

  - **ATOMIC**. The inserts are processed as a single statement. Any statement level triggers are activated one time for the statement, and the transition tables will include all of the rows that were inserted.
  - **NOT ATOMIC CONTINUE ON SQLEXCEPTION**. The inserts are processed separately. Any statement level triggers are processed for each row that is inserted, and the transition table includes the individual row that is inserted. When errors are encountered with this option in effect, processing continues, and some of the specified rows will not be inserted. In this case, if an insert trigger is defined on the underlying base table, the statement level triggers will only be activated for rows that were successfully inserted.

    Regardless of the failure of any particular source row, the INSERT statement will not undo any changes that are made to the database by the statement. Insert will be attempted for rows that follow the failed row. However, the minimum level of atomicity is at least that of a single source row (that is, it is not possible for a partial insert operation to complete), including any triggers that might have been activated as a result of the INSERT statement.

Inserting XML documents:

When XML documents are inserted into a table that contains an XML index, the XML values that are inserted into the index are cast to the data type that is specified on the CREATE INDEX statement. If the XML value cannot be cast to the specified data type, the XML value is ignored for the XML index but the document is still inserted into the table. If the data type that is specified for casting is DECFLOAT, values can be rounded when they are inserted into the index. If the index is unique, the rounding that happens during the cast can result in duplicate values.

Number of rows inserted:

Normally, after an INSERT statement completes execution, the value of SQLERRD(3) in the SQLCA is the number of rows inserted. The value in SQLERRD(3) does not include the number of rows that were inserted as the result of a trigger.

For a complete description of the SQLCA, including exceptions to the above statement, see Appendix E, "SQL communication area (SQLCA)," on page 2291.

Nesting user-defined functions or stored procedures:

An INSERT statement can implicitly or explicitly refer to user-defined functions or stored procedures. This is known as *nesting* of SQL statements. A user-defined function or stored procedure that is nested within the INSERT must not access the table into which you are inserting values.

Locking:

Unless appropriate locks already exist, one or more exclusive locks are acquired at the execution of a successful insert operation. Until a commit or rollback operation releases the locks, only the application process that performed the insert can access the inserted row. If LOBs are not inserted into the row, application processes that are running with uncommitted read can also access the inserted row. The locks can also prevent other application processes from performing operations on the table. However, application processes that are running with uncommitted read can access locked pages and rows.

Locks are not acquired on declared temporary tables.

Inserting rows into a table with multilevel security :

When you insert rows into a table with multilevel security, Db2 determines the value for the security label column of the row according to the following rules:

- If the user (the primary authorization ID) has write-down privilege or write-down control is not enabled, the user can set the security label for the row to any valid security label. The value that is specified must be assignable to a column that is defined as CHAR(8) FOR SBCS DATA NOT NULL. If the user does not specify a value for the security label or specifies DEFAULT, the security label of the row becomes the same as the security label of the user.
- If the user does not have write-down privilege and write-down control is enabled, the security label of the row becomes the same as the security label of the user.

Inserting rows into a table for which row or column access control is enforced:

When an INSERT statement is issued for a table for which row or column access control is enforced, the rules specified in the enabled row permissions or column masks determine whether the row can be inserted. Typically those rules are based on the authorization ID or role of the process. The following rules describe how the enabled row permissions and column masks are used during INSERT:

- A row to be inserted must not be effected by enabled column masks whose columns are referenced while deriving the source values for the row.

  When a column is referenced while deriving the values of a new row, if the column has an enabled column mask, the masked value is used to derive the new values. If the object table is also column access control activated, the column mask that is applied to derive the new values must ensure that the evaluation of the access control rules defined in the column mask resolves the column to itself, not to a constant or to an expression. If the column mask does not mask the column to itself, the new value cannot be used for insert and an error is returned at run time.

  If the OVERRIDING USER VALUE clause is specified, the corresponding values in the new row are ignored, and the above rule for column masks is not applicable to those values.
- If the row can be inserted, and there is a BEFORE INSERT trigger for the table, the trigger is activated.

  Within the trigger actions, the new values for insert can be modified in the transition variables. When the values return from the trigger, the final values for the new values are the ones for insert.
- A row to be inserted must conform to the enabled row permissions.

  When multiple enabled row permissions are defined for a table, a row access control search condition is derived by application of the logical OR operator to the search condition in each enabled row permission. A row that conforms to the enabled row permissions is a row that if the row is inserted it can be retrieved back using the row access control search condition.

  Column masks are not applicable in this process.
- If the rows can be inserted, and there is an AFTER INSERT trigger for the table, the trigger is activated.

The preceding rules are not applicable to the *include-columns*. The *include-columns* are subject to the rules for the select list because they are not the columns of the object table of the INSERT statement.

Extended indicators usage:

When extended indicators are enabled, indicator values other than positive values and 0 through -7 must not be specified. The DEFAULT and UNASSIGNED extended indicator values must not appear in contexts where they are not supported.

Extended indicators:

In an INSERT statement, the extended indicator value of UNASSIGNED has the effect of setting the column to its default value. If a target column is not updatable, it can only be assigned the extended indicator value of UNASSIGNED, unless it is an identity column defined as GENERATED ALWAYS. If the target column is an identity column defined as GENERATED ALWAYS, it must be assigned the DEFAULT keyword, or the extended indicator value of DEFAULT or UNASSIGNED.

Extended indicators and insert triggers:

The activation of insert triggers is not affected by the use of extended indicators. If all columns in the implicit or explicit column list have been assigned an extended indicator value of UNASSIGNED or DEFAULT, an insert in which all columns have their respective default values is attempted. If that insert is successful, the insert trigger is activated.

Extended indicators and deferred error checks:

When extended indicators are enabled, validation that would normally be done during statement preparation to recognize an insert into a non-updatable column is deferred until the statement is executed.

Table space data compression during an insert operation:

If the table space is defined with compression, and data is inserted into a table in the table space, the first rows are stored uncompressed. When a Db2-determined amount of data has been inserted into the table, a compression dictionary is created and stored in the table space. The rows that are inserted into the table after the dictionary is created are stored compressed using the compression dictionary.

Generated columns:

A generated column that is defined as GENERATED ALWAYS should not be specified in the *column-list* unless the corresponding entry in the VALUES list is DEFAULT or an extended indicator that specifies that a default value is to be assigned. Specify the `OVERRIDING USER VALUE` clause to indicate that any user-specified value should be ignored and Db2 should assign the default value when a row is inserted.

Inserting rows into system-period temporal tables:

When a row is inserted into a system-period temporal table, Db2 assigns values to the following columns as indicated:

- A row-begin column is assigned a value for the data type of the column. If the value of the SYSIBM.TEMPORAL_LOGICAL_TRANSACTION_TIME built-in global variable at the time of the insert is null, the value is generated using a reading of the time-of-day clock during execution of the first data change statement in the unit of work that requires a value to be assigned to a row-begin column or transaction-start-ID column in a table, or a row in a system-period temporal table is deleted. Otherwise, the row-begin column is assigned the value of the SYSIBM.TEMPORAL_LOGICAL_TRANSACTION_TIME built-in global variable at the time of the insert.
- A *row-end* column is assigned a value for the data type of the column.
- A *transaction-start-ID* column is assigned a unique value per unit of work or the null value. The null value is assigned to the *transaction-start-ID* column if the column is nullable. Otherwise, the value is generated by reading the time-of-day clock during execution of the first data change statement in the unit of work that requires a value to be assigned to a *row-begin* column or *transaction-start-ID* column in a table. This also occurs when a row in a system-period temporal table is deleted. If multiple rows are inserted within a single SQL transaction, the values for the *transaction-start-ID* column are the same for all the rows and are unique from the values that are generated for the column by another unit of work.

If the CURRENT TEMPORAL SYSTEM_TIME special register is set to a non-null value, the underlying target of the INSERT statement cannot be a system-period temporal table. This restriction applies regardless of whether the system-period temporal table is directly or indirectly referenced.

Inserting rows into application-period temporal tables:

When a row is inserted into an application-period temporal table, an error is returned if the period that is defined by the begin column and end column of the application period overlap with the period that is defined by the begin column and end column of the application period for another row in the table.

Inserting rows into archive-enabled tables:

You cannot insert rows into an archive-enabled table if the value of the SYSIBMADM.MOVE_TO_ARCHIVE global variable is Y. Otherwise, if this global variable is not set to Y, you can specify an archive-enabled table as the target of the INSERT statement. In this case, the content of the associated archive table is not affected.

A data change statement must not reference an archive-enabled table when a system-period temporal table or application-period temporal table is also referenced.

INSERT without a column list:

An INSERT statement without a column list does not include implicitly hidden columns, so columns that are defined as implicitly hidden must have a defined default value.

Inserting a row into catalog table SYSIBM.SYSSTRINGS:

If the object table is SYSIBM.SYSSTRINGS, only certain values can be specified, as described in Specifying conversion procedures (Db2 Administration Guide).

Datetime representation when using datetime registers:

As explained in Datetime special registers, when two or more datetime registers are implicitly or explicitly specified in a single SQL statement, they represent the same point in time. This is also true when multiple rows are inserted. When ATOMIC is in effect for the INSERT statement, the special registers are evaluated one time for the processing of the statement. If NOT ATOMIC is in effect, the special registers are evaluated as each row of source data is processed.

Non-atomic processing of an INSERT statement:

When NOT ATOMIC is specified the rows of source data are processed separately. Any references to special registers, sequence expressions, and functions in the INSERT statement are evaluated as each row of source data is processed, Statement level triggers are activated as each row of source data is processed.

If one or more errors occur during the execution of an insert of a row, processing continues. The row that was being inserted at the time of the error is not inserted. Execution continues with the next row to be inserted, and any other changes made during the execution of the multiple-row INSERT statement are not backed out. However, the insert of an individual row is an atomic action.

Diagnostics information for a multiple-row INSERT statement:

A single multiple-row INSERT statement might encounter multiple conditions. These conditions can be errors or warnings. Use the GET DIAGNOSTICS statement to obtain information about all of the conditions that are encountered for one of these INSERT statements. See "GET DIAGNOSTICS" on page 1944 for more information.

If a warning occurs during the execution of an insert of a row, processing continues.

When multiple errors or warnings occur with a non-atomic INSERT statement, diagnostic information for each row is available using the GET DIAGNOSTICS statement. The SQLSTATE and SQLCODE reflect a summary of what happened during the INSERT statement:

- **SQLSTATE 01659, SQLCODE +252.** All rows were inserted, but one or more warnings occurred.
- **SQLSTATE 22529, SQLCODE -253.** At least one row was successfully inserted, but one or more errors occurred. Some warnings might also have occurred.
- **SQLSTATE 22530, SQLCODE -254.** No row was inserted. One or more errors occurred while trying to insert multiple rows of data.
- **SQLSTATE 429BI, SQLCODE -20252.** More errors occurred that Db2 is capable of recording. Statement processing is terminated.

When ATOMIC is in effect, if an insert value violates any constraints or if any other error occurs during the execution of an insert of a row, all changes made during the execution of the multiple-row INSERT statement are backed out. The SQLCA reflects the last warning encountered.

After an INSERT statement that inserts multiple rows of data, both atomic and non-atomic, information is returned to the program through the SQLCA. The SQLCA is set as follows:

- SQLCODE contains the SQLCODE.
- SQLSTATE contains the SQLSTATE.
- SQLERRD3 contains the number of rows actually inserted. SQLERRD3 is the number of rows inserted, if this is less than the number of rows requested, then an error occurred.
- SQLWARN flags are set if they were set during any single insert operation.

The SQLCA is used to return information on errors and warnings found during a multiple-row insert. If indicator arrays are provided, the indicator variable values are used to determine if the value from the host-variable array, or NULL, will be used. The SQLSTATE contains the warning from the last data mapping error.

Specifying the number of rows for a dynamic multiple-row INSERT statement:

Be aware of these considerations when specifying the number of rows to be inserted with a dynamic multiple-row INSERT statement that uses host-variable arrays:

- The FOR n ROWS clause can be specified as part of an INSERT statement or as part of an EXECUTE statement, but not both
- In the INSERT statement, you can specify a numeric constant in the FOR n ROWS clause to indicate the number of rows to be inserted or specify a parameter marker to indicate that the number of rows will be specified with the associated EXECUTE or OPEN statement. A multiple-row INSERT statement that is contained within a SELECT statement must include a FOR n ROWS clause.
- In an EXECUTE statement, when a dynamic INSERT statement is not contained within a SELECT statement, the number of rows can be specified with either the FOR n ROWS clause or the USING clause of the EXECUTE statement:
  - If the INSERT statement did not contain a FOR n ROWS clause, a value for the number of rows to be inserted can be specified in the FOR n ROWS clause of the EXECUTE statement with a numeric constant or host variable.
  - If a parameter marker was specified as part of a FOR n ROWS clause in the INSERT statement, a value for the number of rows must be specified with the USING clause of the EXECUTE statement.
- In an OPEN statement, when a dynamic SELECT statement contains one or more INSERT statements that have FOR n ROWS clauses with parameter markers, the values for the number of rows to be inserted (that is, the values for the parameter markers) must be specified with the USING clause of the OPEN statement.

DRDA considerations for a multiple-row INSERT statement:

Db2 for z/OS limits the size of user data and control information to 10M (except for LOBs, which are processed in a different data stream) for a single multiple-row INSERT statement using host-variable arrays.

When a multiple-row INSERT statement is executed at a Db2 for z/OS requester, the number of rows being inserted at the requester might not be known in some cases. These cases include:

- The FOR *n* ROWS clause contains a constant value for *n* for either a static or dynamic INSERT statement.
- Host variables are specified on the USING clause of an EXECUTE statement for a dynamic INSERT statement.

In either case, if the number of rows that is being inserted is not known, the requester might flow more data than is required to the server. The number of rows that is actually inserted will be correct because the server knows the correct number of rows to insert. However, performance can be adversely affected. Consider the following scenario:

```
...
long serial_num [10];
struct {
short len;
char data [18];
}name [20]
...
EXEC SQL INSERT INTO T1 VALUES (:serial_num, :name) FOR 5 ROWS
```

At the requester, when this statement is executed, the number of rows being inserted, 5, is not known. As a result, the requester will flow 10 values for serial_num and 10 values for name to the server (because the maximum number of rows that can be inserted without error is 10, which is the size of the smallest host-variable array).

Use the following programming techniques to avoid or minimize problems:

- Avoid using constant values for *n* in the FOR *n* ROWS clause of INSERT statements. For static INSERT statements, this technique ensures that the value for *n* will be known at the requester.
- For dynamic INSERT statements, use the USING DESCRIPTOR clause instead of the USING *host-variables* clause on the EXECUTE statement. If a USING DESCRIPTOR clause is used on the EXECUTE statement, the value for 'n' must be indicated in the DESCRIPTOR.
- If neither of the above methods can be used:
  - Declare your host-variable arrays as small as possible, or indicate that the size of your host-variable arrays are the size of 'n' in your descriptor. This avoids sending large numbers of host-variable-array entries that will not be used to the server.
  - Ensure that varying length string arrays are initialized to a length of 0 (zero). This minimizes the amount of data that is sent to the server.
  - Ensure that decimal host-variable arrays are initialized to valid values. This avoids a negative SQLCODE from being returned if the requester encounters invalid decimal data.

Other SQL statements in the same unit of work:

The following statements cannot follow an INSERT statement in the same unit of work:

- An ALTER TABLE statement that changes the data type of a column (ALTER COLUMN SET DATA TYPE)
- An ALTER INDEX statement that changes the padding attribute of an index with varying-length columns (PADDED to NOT PADDED or vice versa)
- A CREATE TABLE statement that creates an accelerator-only table.
- An INSERT, UPDATE, or DELETE statement that updates accelerator-only tables from a different accelerator.

Examples for INSERT

Example 1

Insert values into sample table DSN8C10.EMP.

```
   INSERT INTO DSN8C10.EMP
     VALUES ('000205','MARY','T','SMITH','D11','2866',
              '1981-08-10','ANALYST',16,'F','1956-05-22',
             16345,500,2300);
```

Example 2

Assume that SMITH.TEMPEMPL is a created temporary table. Populate the table with data from sample table DSN8C10.EMP.

```
   INSERT INTO SMITH.TEMPEMPL
     SELECT *
     FROM DSN8C10.EMP;
```

Example 3

Assume that SESSION.TEMPEMPL is a declared temporary table. Populate the table with data from department D11 in sample table DSN8C10.EMP.

```
INSERT INTO SESSION.TEMPEMPL
  SELECT *
  FROM DSN8C10.EMP
  WHERE WORKDEPT='D11';
```

Example 4

Insert a row into sample table DSN8C10.EMP_PHOTO_RESUME. Set the value for column EMPNO to the value in host variable HV_ENUM. Let the value for column EMP_ROWID be generated because it was defined with a row ID data type and with clause GENERATED ALWAYS.

```
INSERT INTO DSN8C10.EMP_PHOTO_RESUME(EMPNO, EMP_ROWID)
  VALUES (:HV_ENUM, DEFAULT);
```

You can only insert user-specified values into ROWID columns that are defined as GENERATED BY DEFAULT and not as GENERATED ALWAYS. Therefore, in the above example, if you were to try to insert a value into EMP_ROWID instead of specifying DEFAULT, the statement would fail unless you also specify OVERRIDING USER VALUE. For columns that are defined as GENERATED ALWAYS, the OVERRIDING USER VALUE clause causes Db2 to ignore any user-specified value and generate a value instead.

For example, assume that you want to copy the rows in DSN8C10.EMP_PHOTO_RESUME to another table that has a similar definition (both tables have a ROWID columns defined as GENERATED ALWAYS). For the following INSERT statement, the OVERRIDING USER VALUE clause causes Db2 to ignore the EMP_ROWID column values from DSN8C10.EMP_PHOTO_RESUME and generate values for the corresponding ROWID column in B.EMP_PHOTO_RESUME.

```
INSERT INTO B.EMP_PHOTO_RESUME
  OVERRIDING USER VALUE
  SELECT * FROM DSN8C10.EMP_PHOTO_RESUME;
```

Example 5

Assume that the T1 table has one column. Insert a variable (:hv) number of rows of data into the T1 table. The values to be inserted are provided in a host-variable array (:hva).

```
EXEC SQL INSERT INTO T1 VALUES (:hva:hvind) FOR :hv ROWS ATOMIC;
```

In this example, :hva represents the host-variable array and :hvind represents the array of indicator variables.

Example 6

Assume that the T2 table has 2 columns, C1 is a SMALL INTEGER column, and C2 is an INTEGER column. Insert 10 rows of data into the T2 table. The values to be inserted are provided in host-variable arrays :hva1 (an array of INTEGERS) and :hva2 (an array of DECIMAL(15,0) values). The data values for :hva1 and :hva2 are represented in Table 240 on page 2007:

Table 240. Data values for :hva1 and :hva2

Array entry	:hva1	:hva2
1	1	32768
2	-12	90000
3	79	2
4	32768	19
5	8	36
6	5	24

Table 240. Data values for :hva1 and :hva2 (continued)

Array entry	:hva1	:hva2
7	400	36
8	73	4000000000
9	-200	2000000000
10	35	88

```
EXEC SQL INSERT INTO T2 (C1, C2)
  VALUES (:hva1:hvind1, :hva2:hvind2) FOR 10 ROWS
  NOT ATOMIC CONTINUE ON SQLEXCEPTION;
```

After execution of the INSERT statement, the following information will be in the SQLCA:

```
SQLCODE = -253
SQLSTATE = 22529
SQLERRD3 = 8
```

Although an attempt was made to insert 10 rows, only 8 rows of data were inserted. Processing continued after the first failed insert because NOT ATOMIC CONTINUE ON SQLEXCEPTION was specified. You can use the GET DIAGNOSTICS statement to find further information, for example:

```
GET DIAGNOSTICS :num_rows = ROW_COUNT, :num_cond = NUMBER;
```

The result of this statement is num_rows = 8 and num_cond = 2 (2 conditions).

```
GET DIAGNOSTICS CONDITION 2 :sqlstate = RETURNED_SQLSTATE,
                            :sqlcode = DB2_RETURNED_SQLCODE,
                            :row_num = DB2_ROW_NUMBER;
```

The result of this statement is sqlstate = 22003, sqlcode = -302, and row_num = 4.

```
GET DIAGNOSTICS CONDITION 1 :sqlstate = RETURNED_SQLSTATE,
                            :sqlcode = DB2_RETURNED_SQLCODE,
                            :row_num = DB2_ROW_NUMBER;
```

The result of this statement is sqlstate = 22003, sqlcode = -302, and row_num = 8.

Example 7

Assume the above table T2 with two columns. C1 is a SMALL INTEGER column, and C2 is an INTEGER column. Insert 8 rows of data into the T2 table. The values to be inserted are provided in host-variable arrays :hva1 (an array of INTEGERS) and :hva2 (an array of DECIMAL(15,0) values.) The data values for :hva1 and :hva2 are represented in Table 240 on page 2007.

```
EXEC SQL INSERT INTO T2 (C1, C2)
  VALUES (:hva1:hvind1, :hva2:hvind2) FOR 8 ROWS
  NOT ATOMIC CONTINUE ON SQLEXCEPTION;
```

After execution of the INSERT statement, the following information will be in the SQLCA:

```
SQLCODE = -253
SQLSTATE = 22529
SQLERRD3 = 6
```

Although an attempt was made to insert 8 rows, only 6 rows of data were inserted. Processing continued after the first failed insert because NOT ATOMIC CONTINUE ON SQLEXCEPTION was specified. You can use the GET DIAGNOSTICS statement to find further information, for example:

```
GET DIAGNOSTICS :num_rows = ROW_COUNT, :num_cond = NUMBER;
```

The result of this statement is num_rows = 68 and num_cond = 2 (2 conditions).

```
GET DIAGNOSTICS CONDITION 2 :sqlstate = RETURNED_SQLSTATE,
                            :sqlcode = DB2_RETURNED_SQLCODE,
                            :row_num = DB2_ROW_NUMBER;
```

The result of this statement is sqlstate = 22003, sqlcode = -302, and row_num = 4.

```
GET DIAGNOSTICS CONDITION 1 :sqlstate = RETURNED_SQLSTATE,
                            :sqlcode = DB2_RETURNED_SQLCODE,
                            :row_num = DB2_ROW_NUMBER;
```

The result of this statement is sqlstate = 22003, sqlcode = -302, and row_num = 8.

Example 8

Assume that table T1 has two columns. Insert a variable number (:hvn) or rows into T1. The values to be inserted are in host-variable arrays :hva and :hvb. In this example, the INSERT statement is contained within the SELECT statement of cursor CS1. The SELECT statement makes use of two other input host variables (:hv1 and :hv2) in the WHERE clause. Either a static or dynamic INSERT statement can be used.

```
-- Static INSERT statement:
DECLARE CS1 CURSOR WITH ROWSET POSITIONING FOR
   SELECT *
      FROM FINAL TABLE
         (INSERT INTO T1 VALUES (:hva, :hvb) FOR :hvn ROWS)
      WHERE C1 > :hv1 AND C2 < :hv2;
OPEN CS1;
-- Dynamic INSERT statement:
PREPARE INSSTMT FROM
   'SELECT *
       FROM FINAL TABLE
          (INSERT INTO T1 VALUES ( ? , ? ) FOR ? ROWS)
       WHERE C1 > ? AND C2 < ?';
DECLARE CS1 CURSOR WITH ROWSET POSITIONING FOR :INSSTMT;
OPEN CS1 USING :hva, :hvb, :hvn, :hv1, :hv2; (or OPEN CS1 USING DESCRIPTOR ...)
```

If the host-variable arrays for the multiple-row INSERT statement were to be specified using a descriptor, that descriptor (SQLDA) would have to describe all input host variables in the statement, and the order of the entries in the SQLDA should be the same as the order of the order of the host variables, host-variable arrays, and values for the FOR n ROWS clauses in the statement. For example, given the statement above, the SQLVAR entries in the descriptor must be assigned in the following order: :hvn, :hva, :hvb, :hv1, hv2. In addition, the SQLVAR entries for host-variable arrays must be tagged in the SQLDA as column arrays (by specifying a special value in part of the SQLNAME field for a host variable), and the SQLVAR entry for the number of rows value must be tagged in the SQLDA (by specifying another special value in part of the SQLNAME field for the host variable).

Example 9

Insert a row into table T1. The row contains the value 'xyz' for column COL1, and the cardinality of array INTA for column COL2.

```
CREATE TYPE INTARRAY AS INTEGER ARRAY [6];
CREATE VARIABLE INTA AS INTARRAY;
SET INTA = ARRAY [ 1, 2, 3, 4, 5 ];
CREATE TABLE T1 (COL1 CHAR(7), COL2 INT);
INSERT INTO T1 VALUES ('xyz', CARDINALITY(INTA));
```

Example 10

Insert the values from arrays CHARA and INTA into table T1. For a row of T1, a value of the CHARA array is used for column COL1, and the value of the INTA array with the same array index is used for column COL2.

```
CREATE TYPE INTARRAY AS INTEGER ARRAY[10];
CREATE TYPE CHARARRAY AS CHAR(7) ARRAY[10];
CREATE VARIABLE INTA AS INTARRAY;
CREATE VARIABLE CHARA AS CHARARRAY;
SET INTA = ARRAY[1, 2, 3, 4, 5];
SET CHARA = ARRAY['a', 'b', 'c', 'd'];
CREATE TABLE T1 (COL1 CHAR(7), COL2 INT);
INSERT INTO T1
```

```
SELECT *
FROM UNNEST(CHARA, INTA) AS (COL1, COL2);
```

Example 11

Insert three rows of data into table T1. For each inserted row, assign the value of the tenth element in the INTA array variable to the COL1 column.

```
CREATE TYPE INTARRAY AS INTEGER ARRAY[10];
CREATE VARIABLE INTA AS INTARRAY;
CREATE VARIABLE VAR1 AS INTEGER;
CREATE VARIABLE VAR2 AS INTEGER;
SET INTA = ARRAY[10, 20, 30, 40, 50, 60, 70, 80, 90, 100];
CREATE TABLE T1 (COL1 INT, COL2 CHAR(10));
SET VAR1 = 10;
SET VAR2 = 3;
-- Perform a multiple row insert (specifying a FOR n ROWS clause).
-- The value to be inserted is specified by a reference to an array element.
INSERT INTO T1 (COL1) VALUES(INTA[VAR1]) FOR VAR2 ROWS;
```

The result of the these operations is that a value of 100 is assigned to column COL1 for three rows.

LABEL

The LABEL statement adds or replaces labels in the descriptions of tables, views, aliases, or columns in the catalog at the current server.

Invocation for LABEL

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization for LABEL

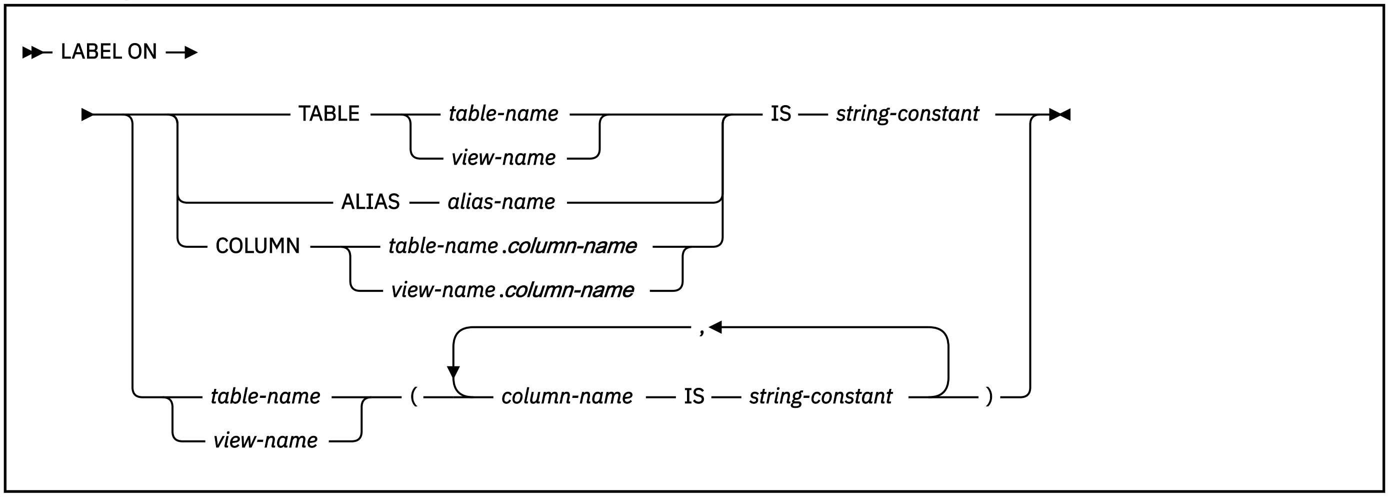
The privilege set that is defined below must include at least one of the following:

- Ownership of the table, view, or alias
- DBADM authority for its database (tables only)
- SYSADM or SYSCTRL authority
- System DBADM

If the database is implicitly created, the database privileges must be on the implicit database or on DSNDB04.

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the statement is dynamically prepared, the privilege set is determined by the DYNAMICRULES behavior in effect (run, bind, define, or invoke) and is summarized in Table 171 on page 1084. (For more details on these behaviors, including a list of the DYNAMICRULES bind option values that determine them, see "Authorization IDs and dynamic SQL" on page 94.)

Syntax for LABEL



Description for LABEL

TABLE *table-name* or *view-name*
Identifies the table or view to which the label applies. The name must identify a table or view that exists at the current server. *table-name* must not identify a declared temporary table. The label is placed into the LABEL column of the SYSIBM.SYSTABLES catalog table for the row that describes the table or view.

ALIAS *alias-name*
Identifies the alias to which the label applies. The name must identify an alias for a table or view that exists at the current server. The label is placed in the LABEL column of the SYSIBM.SYSTABLES catalog table for the row that describes the alias.

COLUMN *table-name.column-name* or *view-name.column-name*
Identifies the column to which the label applies. The name must identify a column of a table or view that exists at the current server. The name must not identify a column of a declared temporary table. The label is placed in the LABEL column of the SYSIBM.SYSCOLUMNS catalog table in the row that describes the column.

Do not use TABLE or COLUMN to define a label for more than one column in a table or view. Give the table or view name and then, in parentheses, a list in the form:

```
    column-name IS string-constant,
    column-name IS string-constant,...
```

See Example 2 below.

The column names must not be qualified, each name must identify a column of the specified table or view, and that table or view must exist at the current server.

IS
Introduces the label you want to provide.

string-constant
Can be any SQL character string constant of up to 30 bytes in length.

Examples for LABEL

Example 1: Enter a label on the DEPTNO column of table DSN8C10.DEPT.

```
   LABEL ON COLUMN DSN8C10.DEPT.DEPTNO
     IS 'DEPARTMENT NUMBER';
```

Example 2: Enter labels on two columns in table DSN8C10.DEPT.

```
    LABEL ON DSN8C10.DEPT
      (MGRNO IS 'EMPLOYEE NUMBER FOR THE MANAGER',
       ADMRDEPT IS 'ADMINISTERING DEPARTMENT');
```

LOCK TABLE

The LOCK TABLE statement requests a lock on a table or table space at the current server. The lock is not acquired if the process already holds an appropriate lock.

Invocation for LOCK TABLE

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization for LOCK TABLE

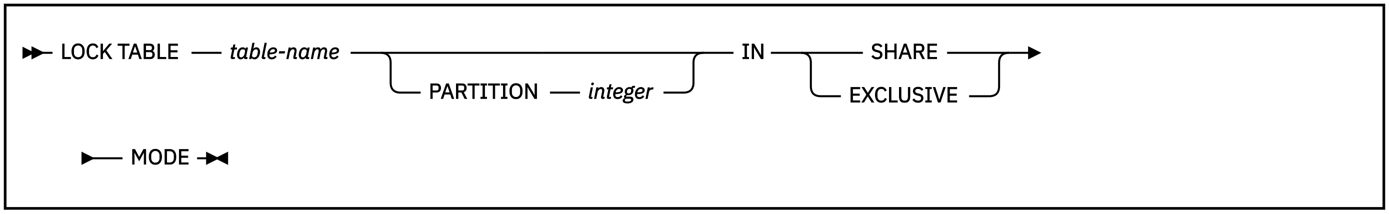
The privilege set that is defined below must include at least one of the following:

- The SELECT privilege on the identified table (the SELECT privilege does not apply to the auxiliary table)
- Ownership of the table
- DBADM authority for the database
- SYSADM or SYSCTRL authority
- DATAACCESS authority

If the database is implicitly created, the database privileges must be on the implicit database or on DSNDB04.

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the statement is dynamically prepared, the privilege set is determined by the DYNAMICRULES behavior in effect (run, bind, define, or invoke) and is summarized in Table 171 on page 1084. (For more details on these behaviors, including a list of the DYNAMICRULES bind option values that determine them, see “Authorization IDs and dynamic SQL” on page 94.)

Syntax for LOCK TABLE



Description for LOCK TABLE

table-name
: Identifies the table to be locked. The name must identify a table that exists at the current server. It must not identify a view, a temporary table (created or declared), an accelerator-only table, a catalog table, or a directory table. The lock might or might not apply exclusively to the table. The effect of locking an auxiliary table is to lock the LOB table space that contains the auxiliary table.

PARTITION *integer*
: Identifies the partition of a partitioned table space to lock. The table identified by *table-name* must belong to a partitioned table space. The value specified for *integer* must be an integer that is no greater than the number of partitions in the table space.

IN SHARE MODE

For a lock on a table that is not an auxiliary table, requests the acquisition of a lock that prevents other processes from executing anything but read-only operations on the table. For a lock on a LOB table space, IN SHARE mode requests a lock that prevents storage from being reallocated. When a LOB table space is locked, other processes can delete LOBs or update them to a null value, but they cannot insert LOBs with a nonnull value. The type of lock that the process holds after execution of the statement depends on what lock, if any, the process already holds.

IN EXCLUSIVE MODE

Requests the acquisition of an exclusive lock for the application process. Until the lock is released, it prevents concurrent processes from executing any operations on the table.

Exceptions: Unless the lock is on a LOB table space, a partitioned (non-UTS) table space, or a universal table space (UTS), concurrent processes that are running with an isolation level of uncommitted read (UR) can execute read-only operations on the table. Concurrent processes that are running with an isolation level of cursor stability (CS) with CURRENTDATA(NO) can execute read-only operations on the table when lock avoidance is used to read data that is already committed.

Be aware that an exclusive lock on a table space, table, or partition does not prevent other transactions from holding claims on the locked object.

Notes for LOCK TABLE

Releasing locks

If LOCK TABLE is a static SQL statement, the RELEASE option of bind determines when Db2 releases a lock. For RELEASE(COMMIT), Db2 releases the lock at the next commit point. For RELEASE(DEALLOCATE), Db2 releases the lock when the plan is deallocated (the application ends).

If LOCK TABLE is a dynamic SQL statement, Db2 uses RELEASE(COMMIT) and releases the lock at the next commit point, unless the table or table space is referenced by cached dynamic statements. Caching allows Db2 to keep prepared statements in memory past commit points. In this case, Db2 holds the lock until deallocation or until the commit after the prepared statements are freed from memory. Under some conditions, if a lock is held past a commit point, Db2 demotes the lock state of a segmented table or a nonsegmented table space to an intent lock at the commit point.

When you issue a MODIFY DDF command with the PKGREL(BNDOPT) or PKGREL(BNDPOOL) options, the use of processor resources for package allocation and deallocation are minimized for packages that use database access threads and are bound with the RELEASE(DEALLOCATE) option. When the MODIFY DDF PKGREL command is issued with these options, Db2 honors the RELEASE bind option even for dynamic SQL statements.

Syntax alternatives and synonyms

For compatibility with previous releases of Db2, PART can be specified as a synonym for PARTITION.

Example for LOCK TABLE

Obtain a lock on the sample table named DSN8C10.EMP, which resides in a partitioned table space. The lock obtained applies to every partition and prevents other application programs from either reading or updating the table. However, under one of the conditions that are noted above under **Exceptions**, Db2 might allow read-only operations on the table.

```
LOCK TABLE DSN8C10.EMP IN EXCLUSIVE MODE;
```

MERGE

The MERGE statement updates a target (a table or view) using data from a source (the result of a table reference or the specified input data). Rows in the target that match the input data can be deleted or updated as specified, and rows that do not exist in the target can be inserted. Updating, deleting, or inserting a row into a view updates, deletes, or inserts the row into the tables on which the view is based, if no INSTEAD OF trigger is defined on this view.

Invocation for MERGE

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization for MERGE

The privileges that are held by the privilege set that is defined below must include at least one of the following privileges:

- SYSADM authority
- Ownership of the table
- DATAACCESS authority
- If the search condition contains a reference to a column of the table or view, the SELECT privilege for the referenced table or view
- If the delete operation is specified, the DELETE privilege for the table or view
- If the insert operation is specified, the INSERT privilege for the table or view
- If the update operation is specified, at least one of the following privileges is required:
  - the UPDATE privilege for the table or view
  - the UPDATE privilege on each column that is updated
  - If the right side of the assignment clause contains a reference to a column of the table or view, the SELECT privilege for the referenced table or view

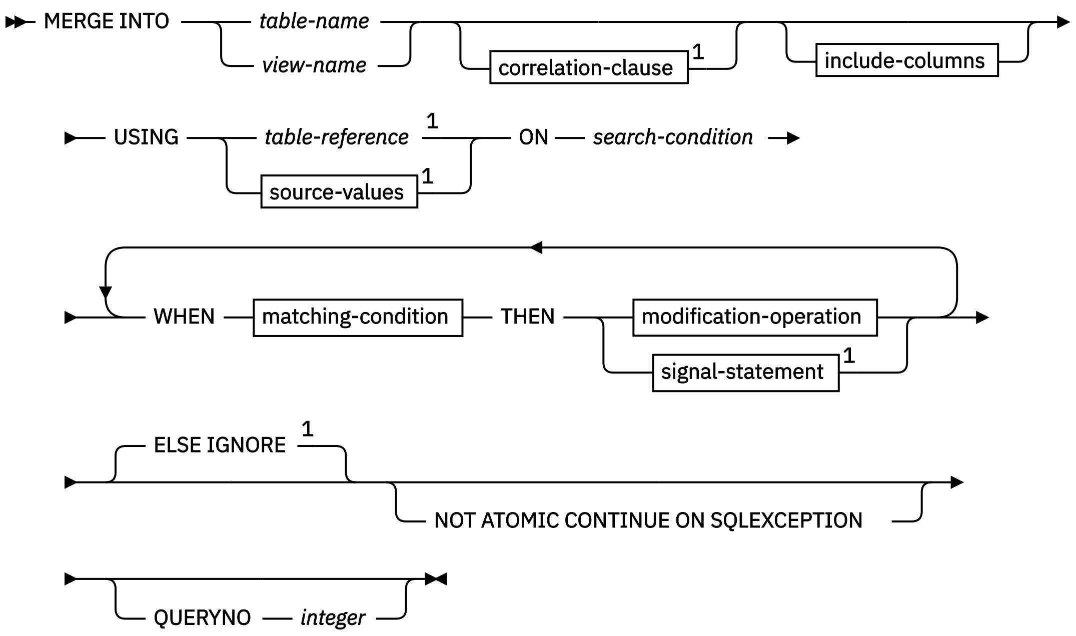
If the database is implicitly created, the database privileges must be on the implicit database or on DSNDB04.

If the insert operation or assignment clause includes a subquery, the privileges that are held by the privilege set must also include at least one of the following privileges:

- SYSADM authority
- The SELECT privilege on every table or view that is identified in the subquery
- Ownership of the tables or views that are identified in the subquery
- DATAACCESS authority

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the statement is dynamically prepared, the privilege set is determined by the DYNAMICRULES behavior in effect (run, bind, define, or invoke) and is summarized in Table 171 on page 1084. (For more information on these behaviors, including a list of the DYNAMICRULES bind option values that determine them, see “Authorization IDs and dynamic SQL” on page 94.)

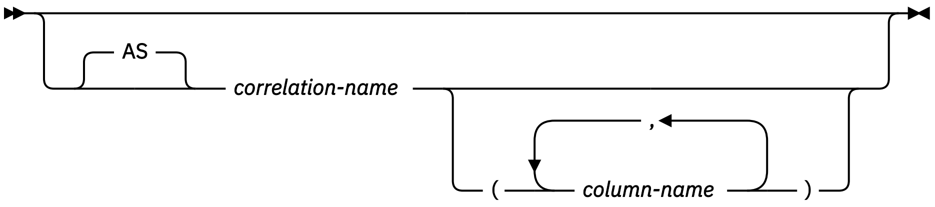
Syntax for MERGE



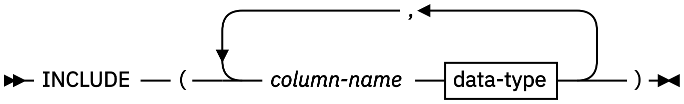
Notes:

[1] For information on the interaction between this option and the NOT ATOMIC CONTINUE ON SQLEXCEPTION clause, see "Considerations for the NOT ATOMIC CONTINUE ON SQLEXCEPTION clause" on page 2026.

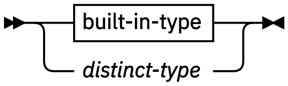
correlation-clause:



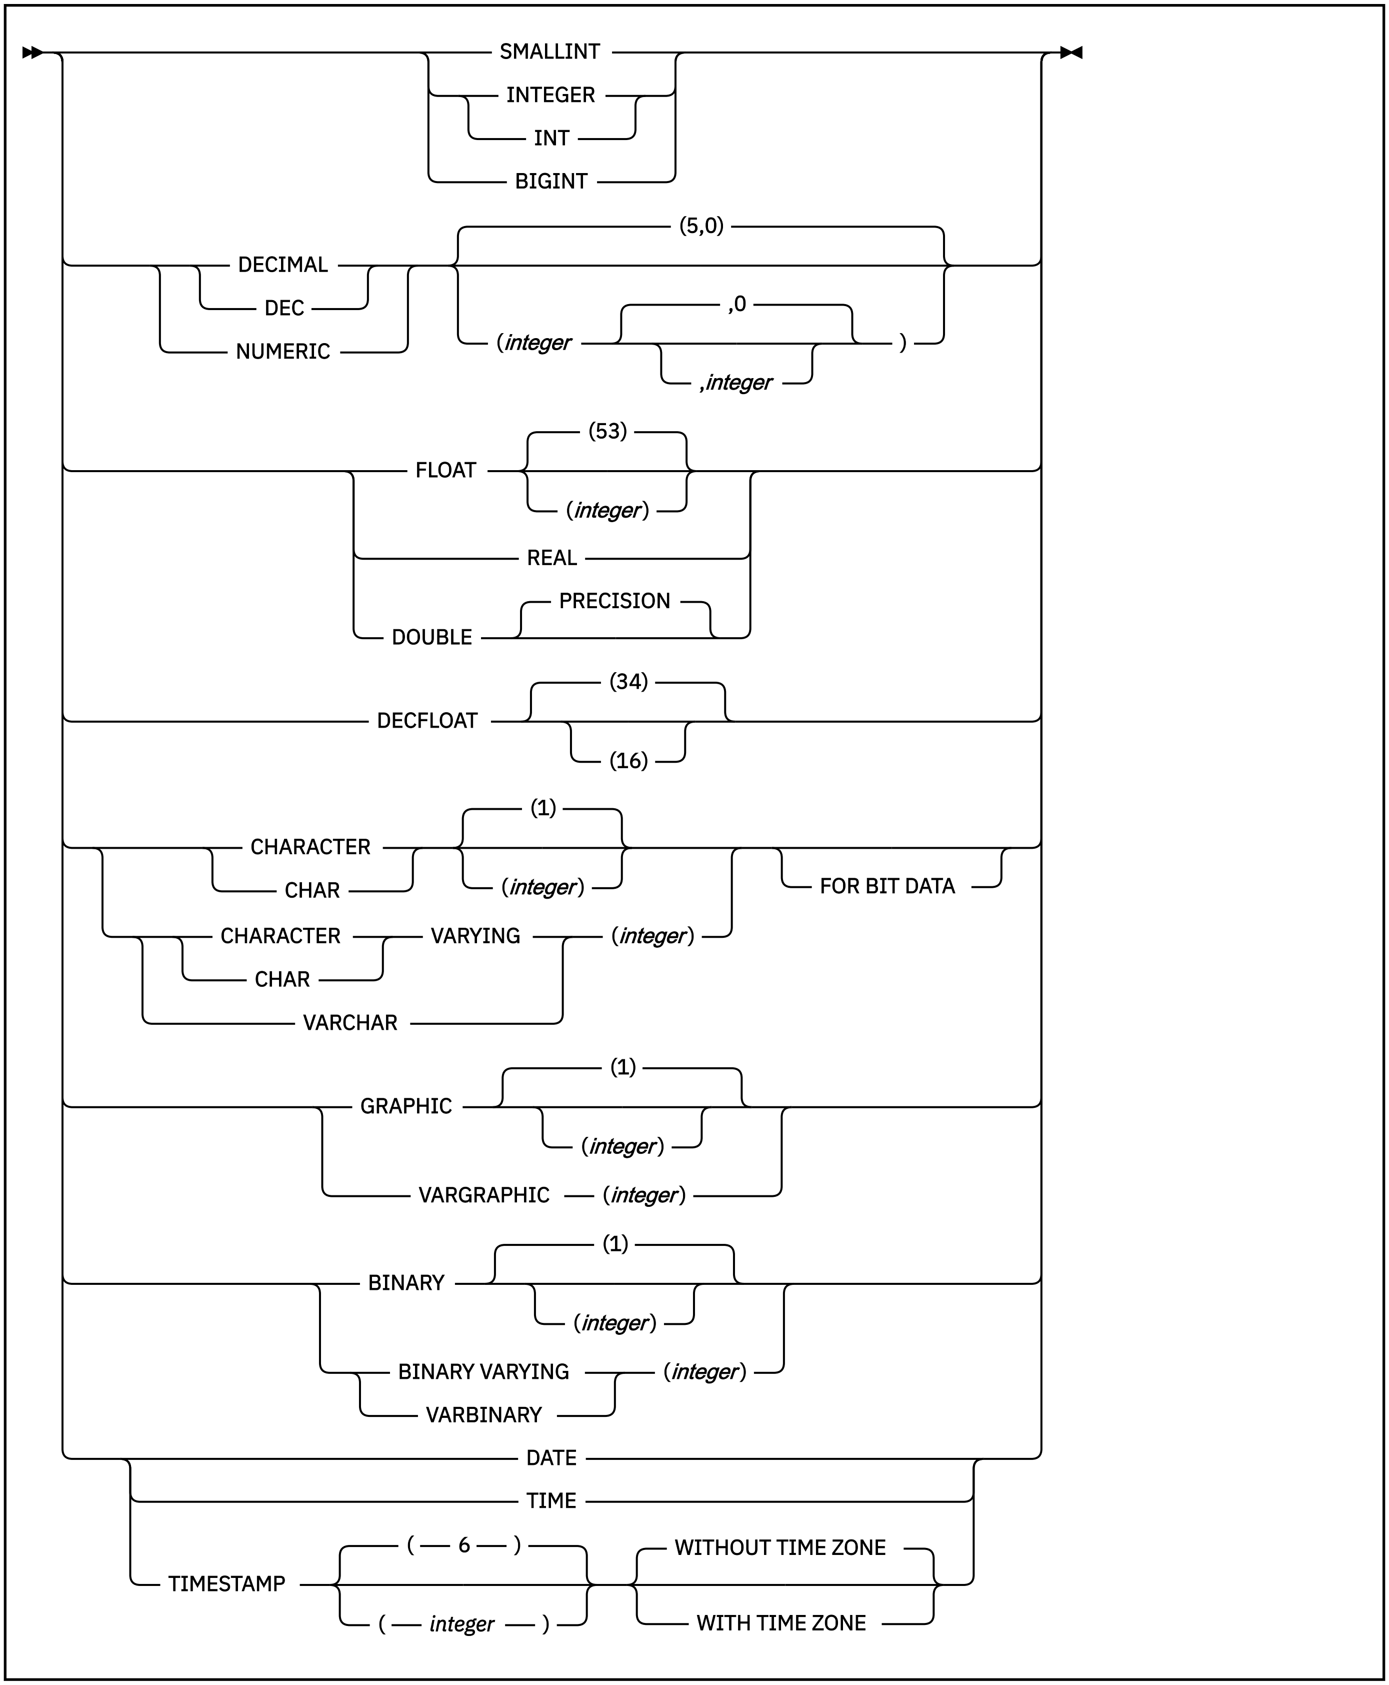
include-columns:



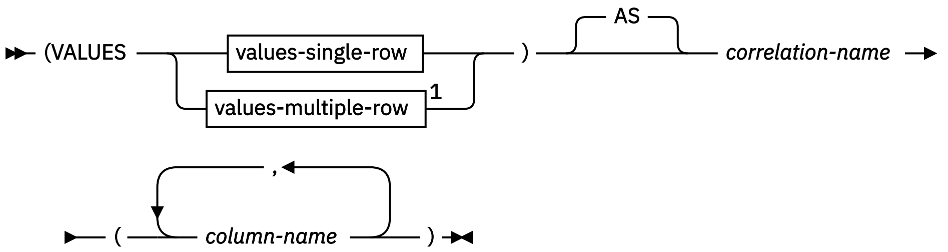
data-type:



built-in-type:



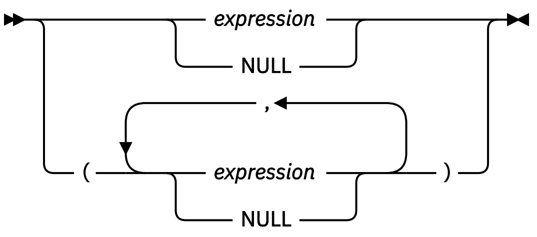
source-values:



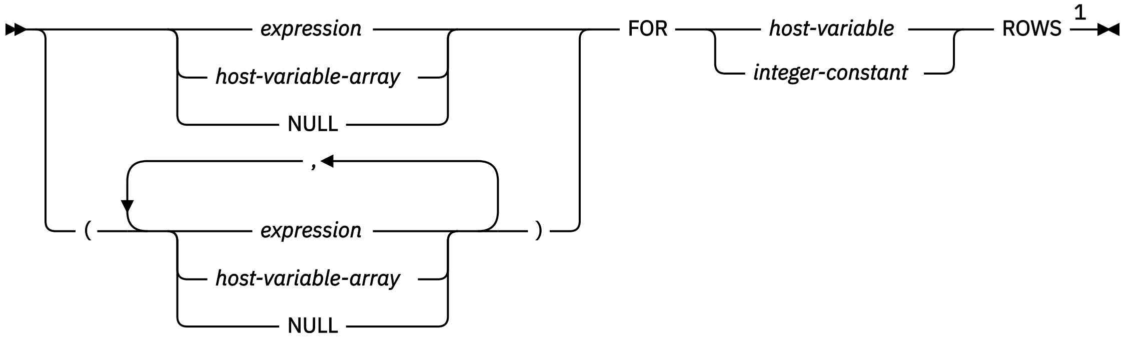
Notes:

[1] The NOT ATOMIC CONTINUE ON SQLEXCEPTION clause must be specified when *values-multiple-row* is specified.

values-single-row:



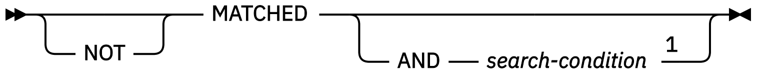
values-multiple-row:



Notes:

[1] For a static MERGE statement, if FOR n ROWS is not specified, *values-multiple-row* is treated as *values-single-row*. For a dynamic MERGE statement, FOR n ROWS does not need to be specified in the MERGE statement. It can be specified in the EXECUTE statement, but cannot be specified in both the MERGE and EXECUTE statements.

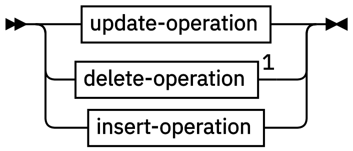
matching-condition:



Notes:

[1] For information on the interaction between this option and the NOT ATOMIC CONTINUE ON SQLEXCEPTION clause, see "Considerations for the NOT ATOMIC CONTINUE ON SQLEXCEPTION clause" on page 2026.

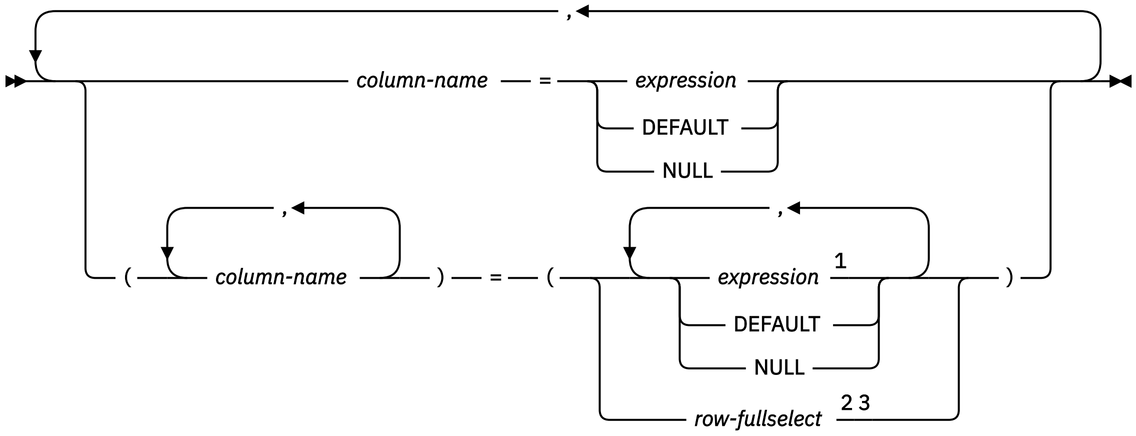
modification-operation:



Notes:

[1] For information on the interaction between this option and the NOT ATOMIC CONTINUE ON SQLEXCEPTION clause, see “Considerations for the NOT ATOMIC CONTINUE ON SQLEXCEPTION clause” on page 2026.

assignment-clause:



Notes:

[1] The number of expressions, DEFAULT, and NULL keywords must match the number of *column-names*.

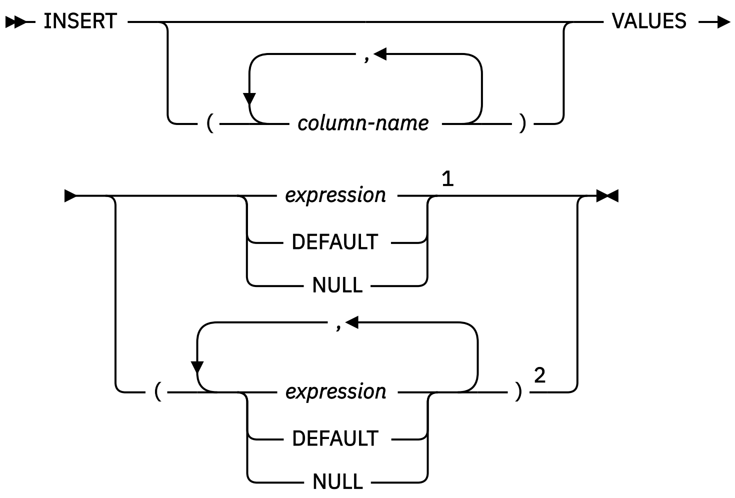
[2] The number of columns in the SELECT list must match the number of *column-names*.

[3] For information on the interaction between this option and the NOT ATOMIC CONTINUE ON SQLEXCEPTION clause, see “Considerations for the NOT ATOMIC CONTINUE ON SQLEXCEPTION clause” on page 2026.

update-operation:

delete-operation:

insert-operation:



Notes:

[1] The number of expressions, DEFAULT, and NULL keywords must match the number of *column-names*.

[2] The number of columns in the SELECT list must match the number of *column-names*.

Description for MERGE

INTO *table-name* or *view-name*

Identifies the target of the update, insert, or delete operations of the merge. The name must identify a table or view that exists at the current server. The name must not identify:

- A catalog table
- A directory table
- A created global temporary table
- A read-only view
- A system-maintained materialized query table
- A table that is implicitly created for an XML column
- An accelerator-only table

If a view is specified as the target of the MERGE statement, the view must not be defined with any INSTEAD OF triggers.

AS *correlation-name*

correlation-name provides an alternative name that can be used when referencing columns of target table.

The correlation name can be used within *search-condition*, *matching-condition*, or as part of a source value for an assignment, to designate the target table or view. The *correlation-name* is used to qualify references to the columns of the table or view. For a description of *correlation-clause*, see "table-reference" on page 1016.

column-name

Specifies a column name. When a *correlation-name* is specified, *column-names* can also be specified to give names to the columns of the target *table-name* or *view-name*. If a column list is specified, there must be a name in the column list for each column in the table or view.

include-columns

Specifies a set of columns that are included, along with the columns of the specified table or view, in the result table of the MERGE statement when it is nested in the FROM clause of the outer fullselect that is used in a SELECT statement, or in a SELECT INTO statement. The included columns are appended to the end of the list of columns that are identified by *table-name* or *view-name*. If a value is not specified for an included column, a null value is returned for that column.

INCLUDE

Introduces a list of columns that is to be included in the result table of the MERGE statement. The included columns are only available if the MERGE statement is nested in the FROM clause of a SELECT statement or a SELECT INTO statement. INCLUDE can only be specified when the MERGE statement is nested in the FROM clause of a SELECT statement.

column-name

Specifies the name for a column of the result table of the MERGE statement that is not the same name as another included column or a column in the table or view that is specified in *table-name* or *view-name*.

data-type

Specifies the data type of the included column. The included columns are nullable.

Columns with the following data types can not be used as INCLUDE columns:

- LONG VARCHAR,
- LONG VARGRAPHIC,
- XML
- LOBs
- distinct types that are based on any of the listed data types.

built-in-type

Specifies a built-in data type. See "CREATE TABLE" on page 1645 for a description of each built-in type.

The CCSID 1208 and CCSID 1200 clauses must not be specified for an INCLUDE column.

distinct-type

Specifies a distinct type. Any length, precision, or scale attributes for the column are those of the source type of the distinct type as specified by using the CREATE TYPE statement.

USING

Specifies a set of rows as a result table to be merged into the target.

table-reference

Specifies a set of rows as a result table to be merged into the target. If the result table is empty, a warning is returned.

source-values

VALUES *values-single-row* or *values-multiple-row*

Specifies the values for a set of rows as a result table to be merged into the target. *values-single-row* specifies a single row of source data. *values-multiple-row* specifies multiple rows of source data. The number of values must not exceed 750.

expression

Specifies an expression of the type that is described in "Expressions" on page 244. The expression must not include a column name. The expression must not reference a NEXT VALUE or PREVIOUS VALUE expression. If the expression is a single host variable, the host variable can identify a structure. Any host variable or structure that is specified must be described in the application program according to the rules for declaring host structures and variables.

host-variable-array

Specifies a host-variable array. Each host-variable array must be defined in the application program in accordance with the rules for declaring an array. A host-variable array contains the data to merge into a target column. The number of rows must be less than or equal to the dimension of each of the host-variable arrays. An optional indicator array can be specified for each host-variable array. An indicator array should be specified if the SQLTYPE of any SQLVAR occurrence indicates that a column is nullable. The indicator array can be enabled for extended indicator variables. The dimension of the indicator array must be large enough to contain an indicator for each row of input data.

A host structure is not supported in *host-variable-array*.

host-variable-array is supported in C/C++, COBOL, and PL/I. For more information, see "Host-variable arrays in PL/I, C, C++, and COBOL" on page 236.

NULL

Specifies a null value.

The *column-name* that is specified in *source-values* corresponding to the NULL keyword is used to determine the data type of the null value. The *column-name* that is specified in *source-values* must be referenced elsewhere in the MERGE statement such that its data type can be determined from the context in which it is used, and all such references must resolve to the same data type. References to date-time data types and CHAR or VARCHAR are considered the same type.

FOR *host-variable* or *integer-constant* ROWS

Specifies the number of rows to merge. For a dynamic MERGE statement, this clause can be specified on the EXECUTE statement. *host-variable* or *integer-constant* is assigned to a value *k*. If *host-variable* is specified, it must be an exact numeric type with a scale of zero and must not include an indicator variable. *k* must be in the range 1 - 32767. *k* rows are merged into the target from the specified source data.

If a parameter marker is specified in FOR *n* ROWS, a value must be provided with the USING clause of the associated EXECUTE statement.

AS *correlation-name*

Specifies a correlation name for the *source-values*. The *correlation-name* is used to qualify references to the columns of *source-values*.

column-name

Specifies a column name. When a *correlation-name* is specified, *column-names* can also be specified to give names to the columns of *source-values* for an assignment. If a column list is specified, there must be a name in the column list for each column in *source-values*.

ON *search-condition*

Specifies the predicates that are used to determine whether a row from *table-reference* or *source-values* matches rows in the target table.

Each *column-name* in the search condition must name a column of the target table or view, or *table-reference* or *source-values*. If a *column-name* exists in both the target and the *source-values*, the column name must be qualified.

Logically, a right join is performed between the target table and the *table-reference* (or *source-values*) using the ON *search-condition*. For those rows of the join result table where the search condition is true, the specified update or delete operation is performed. For those rows of the join result table where the result of the search condition is not true, the specified insert operation is performed.

A subquery is not allowed in the *search-condition* of the ON clause. The *search-condition* of the ON clause cannot contain expressions that use aggregate functions or non-deterministic scalar functions.

The *search-condition* of the ON clause must not include an IN predicate that includes a fullselect, or a quantified predicate that includes a fullselect.

WHEN *matching-condition*

Specifies the condition under which the *modification-operation* or the *signal-statement* is executed. Each *matching-condition* is evaluated in order of specification. When NOT ATOMIC CONTINUE ON SQLEXCEPTION is not specified, rows for which the *matching-condition* evaluates to true are not considered in subsequent matching conditions.

MATCHED

Indicates the operation to perform on the rows where the ON *search-condition* is true. Only UPDATE, DELETE, or *signal-statement* can be specified after the THEN clause.

AND *search-condition*

Specifies a further search condition to be applied against the rows that matched the ON search condition for the operation to be performed after THEN. The *search-condition* must not include an IN predicate that includes a fullselect, or a quantified predicate that includes a fullselect.

NOT MATCHED

Indicates the operation to perform on the rows where the ON *search-condition* is false or unknown, or the target table is empty. Only INSERT or *signal-statement* can be specified after the THEN clause, and must not reference a column of the target table.

AND *search-condition*

Specifies a further search condition to be applied against the rows that did not match the ON search condition for the operation to be performed after THEN. The *search-condition* must not include a column of the target table.

THEN *modification-operation*

Specifies the operation to be executed when the *matching-condition* evaluates to true.

update-operation

Specifies the update operation to be executed when the *matching-condition* evaluates to true.

UPDATE

Introduces the update operation.

When extended indicators are enabled, a column of the source table must not be referenced multiple times in a single *modification-operation*. Extended indicators are enabled when EXTENDEDINDICATOR(YES) is used, or when the WITH EXTENDED INDICATORS prepare attribute has been specified for the MERGE statement.

When NOT ATOMIC CONTINUE ON SQLEXCEPTION is specified, or the NOT ATOMIC CONTINUE ON SQLEXCEPTION clause is not specified, and *source-values* (VALUES) is specified, the rows that are updated from a source row are subject to more updates by subsequent source rows in the same statement. The update is cumulative.

An *update-operation* in a MERGE statement does not reset the AREO* status on a table.

SET

Introduces the assignment of values to column names.

assignment-clause

Specifies a list of column updates.

If *row-fullselect* is specified, the number of columns in the result of *row-fullselect* must match the number of *column-names* that are specified. If *row-fullselect* is not specified, the number of expressions, and NULL and DEFAULT keywords must match the number of *column-names* that are specified.

column-name

Identifies a column to update. *column-name* must identify a column of the specified table or view, and that column must be updatable. The column must not be a generated column, or a column of a view that is derived from a scalar function, a constant, or an expression. *column-name* can also identify an included column. The same *column-name* must not be specified more than one time. A view column that is derived from the same column as another column of the view can be updated, but both columns cannot be updated in the same MERGE statement.

Assignments to included columns are only processed when the MERGE statement is nested in the FROM clause of a SELECT statement or a SELECT INTO statement. There must be at least one assignment clause that specifies a *column-name* that is not an included column.

expression

Specifies the new value of the column. The expression is any expression of the type that is described in "Expressions" on page 244. The expression must not include an aggregate function.

The expression can contain references to columns of *table-name*, *view-name*, *table-reference*, or *source-values*. For each row that is updated, the value of a target column in an expression is the value of the column in the row before the row is updated. *expression* cannot contain references to an included column.

If *expression* is a reference to a single column of the source table, the source table column value might have been specified with an extended indicator value. The effects of extended indicator values apply to the corresponding target columns of the *assignment-clause*.

When extended indicators are enabled, the extended indicator values of DEFAULT (-5) or UNASSIGNED (-7) must not be used if *expression* is more complex than the following references:

- A single column of the source table
- A single host variable

DEFAULT

Specifies the default value for the column. DEFAULT can be specified only for columns that have a default value. DEFAULT must not be specified for a ROWID column. The value that is assigned depends on how the column is defined. For more information about default values, see the description of the DEFAULT clause in "CREATE TABLE" on page 1645.

DEFAULT must be specified for a column that was defined as GENERATED ALWAYS. A valid value can be specified for a column that was defined as GENERATED BY DEFAULT.

NULL

Specifies the null value as the new value of the column. Specify NULL only for nullable columns.

row-fullselect

Specifies a fullselect that returns a single row. The column values are assigned to each of the corresponding *column-names*. If the fullselect returns no rows, the null value is assigned to each column; an error occurs if any column that is to be updated is not nullable.

If the fullselect refers to columns that are to be updated, the value of such a column in the fullselect is the value of the column in the row before the row is updated.

delete-operation

Specifies the delete operation that is to be executed for the rows where the *matching-condition* evaluates to true.

DELETE

Introduces the delete operation.

insert-operation

Specifies the insert operation that is to be executed for the rows where the *matching-condition* evaluates to true.

INSERT

Specifies a list of column names and row value expressions to use for the insert operation.

The number of values for the row in the row-value expression must be equal to the number of names in the insert column list. The first value is inserted into the first column in the list, the second value into the second column, and so on.

(*column-name*,...)

Specifies the column for which the insert values are provided. Each name must identify a column of the table or view. The same column must not be identified more than once.

If extended indicators are not enabled, a view column that is not updatable must not be identified. If extended indicator variables are not enabled and the object of the insert operation is a view with non-updatable columns, a list of column names must be specified, and the list must not identify those columns. For an explanation of updatable columns in views, see "CREATE VIEW" on page 1807.

If an included column is not specified in the list of column names, the value of the included column is set to null. The column list cannot contain only included columns.

A view column that cannot accept insert values must not be specified. A value cannot be inserted into a view column that is derived from one of the following items:

- A constant, an expression, or a scalar function
- The same column of the base table as another column of the view

If the object of the operation is a view that contains columns that cannot accept insert values, a list of column names must be specified and the list must not specify these columns.

Omission of the column list is an implicit specification of a list in which every column of the table (that is not defined as implicitly hidden) or view is identified in left-to-right order. This list is established when the statement is prepared and therefore does not include columns that were added to the table after the statement was prepared.

VALUES

Introduces one or more rows of values to insert.

expression

Specifies an expression that does not include a column name of the target. If *expression* is a host variable, the host variable can include an indicator variable, or in the case of a host structure, an indicator array. When extended indicators are enabled, the extended indicator values of DEFAULT (-5) or UNASSIGNED (-7) must not be used if *expression* is more complex than the following references:

- A single column of the source table
- A single host variable
- A host variable that is being explicitly cast

In addition, a CAST specification can be used if either:

- The target column is defined as nullable.
- The target column is defined as NOT NULL with a non-null default, the source of the CAST specification is a single host variable, and the data attributes (data type, length, precision, and scale) of the host variable are the same as the result of the cast specification.

DEFAULT

Specifies the default value for the column. DEFAULT must only be specified for columns that have a default value. The value that is assigned depends on how the column is defined. For more information about default values, see the descriptions of the DEFAULT clause in "CREATE TABLE" on page 1645 and in "INSERT" on page 1991.

If the column is specified in the INCLUDE column list, the column value is set to null.

DEFAULT must be specified for a column that is defined as GENERATED ALWAYS. A valid value can be specified for a column that is defined as GENERATED BY DEFAULT.

NULL

Specifies the null value as the value of the column. Specify NULL only for nullable columns.

signal-statement

Specifies the SIGNAL statement that is to be executed to return an error when the *matching-condition* evaluates to true.

ELSE IGNORE

Specifies that no action is to be taken for the rows where no *matching-condition* evaluates to true. If all rows of *table-reference* are ignored, a warning is returned.

NOT ATOMIC CONTINUE ON SQLEXCEPTION

The rows of input data are processed separately. Any statement level triggers are processed for each row of source data that is processed, and the transition table includes the individual row that was processed. When errors are encountered and this option is in effect, processing continues, and some of the specified rows will not be processed. In this case, if an appropriate trigger is defined on the underlying base table, the statement level trigger will only be activated for rows that were successfully processed.

Regardless of the failure of any particular source row, the MERGE statement will not undo any changes that are made to the database by the statement. Merge will be attempted for rows that follow the failed row. However, the minimum level of atomicity is at least that of a single source row (that is, it is not possible for a partial merge to complete), including any triggers that might have been activated as a result of the MERGE statement.

QUERYNO *integer*

Specifies the number for this SQL statement that is used in EXPLAIN output and trace records. The number is used for the QUERYNO column of the plan table for the rows that contain information about this SQL statement. This number is also used in the QUERYNO column of the SYSIBM.SYSSTMT and SYSIBM.SYSPACKSTMT catalog tables.

If QUERYNO is not specified, the number that is associated with the SQL statement is the statement number that is assigned during precompilation. Thus, if the application program is changed and then precompiled, the statement number might change.

MERGE rules

If *table-reference* is specified:

- More than one *modification-operation* (*update-operation*, *delete-operation*, or *insert-operation*), or *signal-statement* can be specified in a single MERGE statement.
- Each row in the target can only be operated on once. A row in the target can only be identified as MATCHED with one row in the result table of the *table-reference*. A nested SQL operation (RI or trigger except INSTEAD OF trigger) cannot specify the target table (or a table within the same table hierarchy) as a target of an UPDATE, DELETE, INSERT, or MERGE statement.
- A row that is inserted by the MERGE statement cannot also be updated by that MERGE statement. There is no attempt to update a row in the target that did not already exist before the MERGE statement was executed.
- If an error occurs during execution of the MERGE statement, the whole statement is rolled back.

If NOT ATOMIC CONTINUE ON SQLEXCEPTION is specified, or the NOT ATOMIC CONTINUE ON SQLEXCEPTION clause is not specified and *source-values* (VALUES) is specified:

- A MERGE statement can contain one *update-operation* and one *insert-operation*.
- The rows that are updated from a source row are subject to more updates by subsequent source rows in the same statement. The update is cumulative.
- When NOT ATOMIC CONTINUE ON SQLEXCEPTION is specified, the rows of source data are processed separately. Any references to special registers, sequence expressions, and functions in the MERGE statement are evaluated as each row of source data is processed. Statement-level triggers are activated as each row of source data is processed.

- If one or more errors occur during the operation for a row of source data, processing continues. The row that was being processed at the time of the error is not inserted or updated. Execution continues with the next row to be processed, and any other changes that are made during the execution of the multiple-row MERGE statement are not backed out. However, the processing of an individual row is an atomic action.

For other rules that affect the update, insert, or delete portion of the MERGE statement, see the rules section of the corresponding statement description, in the following topics:

- "INSERT" on page 1991
- "DELETE" on page 1848
- "UPDATE" on page 2169

Notes for MERGE

Considerations for the NOT ATOMIC CONTINUE ON SQLEXCEPTION clause

When the NOT ATOMIC CONTINUE ON SQLEXCEPTION clause is specified, or the NOT ATOMIC CONTINUE ON SQLEXCEPTION clause is not specified and *source-values* (VALUES) is specified, the following clauses must not be specified:

- *table-reference*
- *correlation-clause* that contains a list of column names
- AND *search-condition*
- *delete-operation*
- SIGNAL
- ELSE IGNORE
- *row-fullselect*

In addition:

- The WHEN MATCHED clause must not be specified more than one time.
- The WHEN NOT MATCHED clause must not be specified more than one time.

Logical order of processing for a not-atomic MERGE statement

For a not-atomic MERGE statement (a MERGE statement that includes the NOT ATOMIC CONTINUE ON SQLEXCEPTION clause, or the NOT ATOMIC CONTINUE ON SQLEXCEPTION clause is not specified and source-values (VALUES) is specified), each source row is processed independently, as if a separate MERGE statement were executed for each source row. For example, a source row that causes an update of a target row activates any triggers (including statement-level triggers) when the update of the row is performed. Thus, if five rows are updated, any update triggers (including statement-level update triggers) are activated five times.

For a not-atomic MERGE statement, the logical order of processing for each row is:

1. Determine the row that is to be processed from the source and target.
2. Use the ON clause to classify these rows as either MATCHED or NOT MATCHED.
3. Evaluate any expression in any *assignment-clause* and *insert-operation*.
4. Apply the *modification-operation* to the applicable row. The triggers that are activated by the *modification-operation* are executed for the *modification-operation*. Statement-level triggers are activated even if no rows satisfy the *modification-operation*.

Logical order of processing for an atomic MERGE statement

For an atomic MERGE statement (the NOT ATOMIC CONTINUE ON SQLEXCEPTION clause is not specified), the source rows are processed as if a set of rows is processed by each WHEN clause. Thus, if five rows are updated, any row-level update triggers are activated five times. In addition, *n* statement-level update triggers are activated , where *n* is the number of WHEN clauses that contain an UPDATE, including any WHEN clauses that contain an UPDATE that did not process any of the source rows.

For an atomic MERGE, the logical order of processing is:

1. Determine the set of rows that are to be processed from the source and target. If any of the special registers CURRENT DATE, CURRENT TIME, or CURRENT TIMESTAMP are used in this statement, only one clock reading is done for the whole statement.
2. Use the ON clause to classify these rows as either MATCHED or NOT MATCHED.
3. Evaluate any *matching-condition* in the WHEN clauses.
4. Evaluate any expression in any *assignment-clause* and *insert-operation*.
5. Execute each *signal-statement*.
6. Apply each *modification-operation* to the applicable rows in the order of specification. The triggers that are activated by each *modification-operation* are executed for the *modification-operation*. Statement-level triggers are activated even if no rows satisfy the *modification-operation*. Each *modification-operation* can affect the triggers and referential constraints of each subsequent *modification-operation*.

Trigger considerations

A MERGE statement might cause triggers to be activated. A trigger might cause other statements to be executed or raise error conditions depending on the source data values. A before-update or before-insert trigger processes immediately before the update or insert operation.

If a source row results in an insert, any after-insert triggers are activated after the insert operation completes.

If a source row results in updates, any after-update triggers are activated after all of the update operations complete.

If a source row results in deletes, any after-delete triggers are activated after all of the delete operations complete.

Number of rows updated

After a MERGE statement is executed, the ROW_COUNT statement information item in the SQL Diagnostics Area (or SQLERRD(3) of the SQLCA) is the number of rows that are operated on by the MERGE statement, excluding rows that are identified by the ELSE IGNORE clause. The ROW_COUNT item and SQLERRD(3) do not include the number of rows that were operated on as a result of triggers.

For a description of ROW_COUNT, see "GET DIAGNOSTICS" on page 1944. For a description of the SQLCA, see Appendix E, "SQL communication area (SQLCA)," on page 2291.

SQLCA and GET DIAGNOSTICS considerations

The GET DIAGNOSTICS statement can be used immediately after the MERGE statement to check which input rows fail during the merge operation. The GET DIAGNOSTICS statement information item, NUMBER, indicates the number of conditions that are raised. The GET DIAGNOSTICS condition information item, DB2_ROW_NUMBER, indicates the input source rows that cause an error.

Considerations for a MERGE without a column list in *insert-operation*

A MERGE statement without a specified column list as part of *insert-operation* does not include implicitly hidden columns. Therefore, such columns must have a defined default value.

DRDA considerations when NOT ATOMIC CONTINUE ON SQLEXCEPTION is specified (or the NOT ATOMIC CONTINUE ON SQLEXCEPTION clause is not specified and *source-values* (VALUES) is specified)

Db2 Connect Version 9.1 and subsequent releases support the MERGE statement. The support is for CLI only, with no embedded static SQL support.

When you run a MERGE statement at a Db2 for z/OS requester, cases might exist where the requester does not know the number of rows in the source table. This situation includes the following cases:

- For static or dynamic MERGE statements, of the FOR *n* ROWS clause contains a constant value for *n*.

- For dynamic MERGE statements, of host variables are specified on the USING clause of an EXECUTE statement.

For both of these cases, if the number of rows in the source table is not known, the requester might send more data than is required to the server. The number of rows that are processed is correct because the server knows the correct numbers of rows to process. However, performance might be adversely affected. Consider the following example:

```
...long serial num [10];
struct { short len;
char data [18];
        }
name[20]...
EXEC SQL
MERGE INTO T1
  USING (VALUES (:serial_num, :name))
  FOR 5 ROWS...
```

When this statement is run at the requester, the number of rows to merge (five) is not known. As a result, the requester sends 10 values for `serial-name and name` to the server because 10 is the size of the smallest host-variable array and is, therefore, the maximum number of rows that can merge without causing an error.

Do the following to help minimize performance problems:

- Avoid using numeric constants in the FOR *n* ROWS clause of the MERGE statement. For static MERGE statements, avoiding numeric constants ensures that the values for *n* are known at the requester.
- For dynamic MERGE statements, use the USING DESCRIPTOR clause instead of the USING *host-variable* clause on the EXECUTE statement. If a USING DESCRIPTOR clause is used on the EXECUTE statement, the value for n must be indicated in the descriptor.
- If either of the previous methods cannot be used, perform the following actions:
  - Make your host-variable arrays as small as possible, or declare that the size of your host-variable arrays are the size of n in the descriptor. This action avoids sending many unused host-variable array entries to the server.
  - Ensure that varying length string arrays are initialized to a length of 0 (zero). Doing so minimizes the amount of data that is sent to the server.
  - Ensure that decimal host-variable arrays are initialized to valid values. Doing so causes the requester to avoid sending a negative SQLCODE if the requester encounters invalid decimal data.

Extended indicators usage

When extended indicators are enabled, indicator values other than positive values and 0 (zero) through -7 must not be specified. The DEFAULT and UNASSIGNED extended indicator values must not appear in contexts where they are not supported.

Extended indicators

In an update operation of the MERGE statement:

- An extended indicator value of UNASSIGNED has the same effect as if it had not been specified in the statement.
- An extended indicator value of DEFAULT must not be specified for a row-begin, row-end, transaction-start-ID, or generated expression column.
- An extended indicator value of UNASSIGNED must not be assigned to all of the target columns.

In an insert operation of the MERGE statement, an extended indicator value of UNASSIGNED has the effect of setting the column to its default value.

Extended indicators and update triggers

If a target column is assigned an extended indicator value of unassigned, that column is not considered to have been updated. That column is treated as if it had not been specified in the OF *column-name* list of any update trigger that is defined on the target table.

Extended indicators and insert triggers

The activation of insert triggers is not affected by the use of extended indicator variables. Suppose that all columns in the implicit or explicit column list are assigned an extended indicator value of unassigned or default. Then, assume that an insert operation where all columns are assigned to the respective default values is attempted. If that operation is successful, the insert trigger is activated.

Table space data compression during an insert operation

If the table space is defined with compression, and data is inserted into a table in the table space, the first rows are stored uncompressed. When a amount of data that is determined by Db2 is inserted into the table, a compression dictionary is created and stored in the table space. The rows that are inserted into the table after the dictionary is created are stored compressed by using the compression dictionary.

System-period temporal tables

When a MERGE statement is processed for a system-period temporal table, the rows are affected in the same way as if the specific data change operation was invoked.

Archive-enabled tables

Consider the case when the target of a MERGE statement is an archive-enabled table, and the merge operation includes an insert or update operation. In this case, the involved rows are affected in the same way as if the insert or update operation was directly invoked on the table.

Tables with enforced row and column access controls

For information about how enabled row permissions and column masks affect the update and insert operations in the MERGE statement, see the INSERT and UPDATE statement information.

Examples for MERGE

Example 1

For activities whose description has been changed, update the description in the RECORDS table. For new activities, insert into the RECORDS table. The RECORDS and ACTIVITIES tables both have ACTIVITY as a primary key.

```
MERGE INTO RECORDS AR
 USING (SELECT ACTIVITY, DESCRIPTION FROM ACTIVITIES) AC
 ON (AR.ACTIVITY = AC.ACTIVITY)
 WHEN MATCHED THEN
  UPDATE SET
  DESCRIPTION = AC.DESCRIPTION
 WHEN NOT MATCHED THEN
  INSERT
  (ACTIVITY, DESCRIPTION)
  VALUES (AC.ACTIVITY, AC.DESCRIPTION);
```

Example 2

Using the SHIPMENT table, merge rows into the INVENTORY table: Increase the quantity by the part count in the SHIPMENT table for rows that match; else insert a row for the new part number into the inventory table.

```
MERGE INTO INVENTORY AS IN
 USING (SELECT PARTNO, DESCRIPTION, COUNT FROM SHIPMENT
 WHERE SHIPMENT.PARTNO IS NOT NULL) AS SH
 ON (IN.PARTNO = SH.PARTNO)
 WHEN MATCHED THEN
  UPDATE SET
   DESCRIPTION = SH.DESCRIPTION,
   QUANTITY = IN.QUANTITY + SH.COUNT
 WHEN NOT MATCHED THEN
  INSERT
  (PARTNO, DESCRIPTION, QUANTITY)
  VALUES (SH.PARTNO, SH.DESCRIPTION, SH.COUNT);
```

Example 3

Using the TRANSACTION table, merge rows into the ACCOUNT table: Update the balance from the set of transactions against an account ID, and insert new accounts from the consolidated transactions where they do not already exist.

```
MERGE INTO ACCOUNT AS A
 USING (SELECT ID, SUM(AMOUNT) SUM_AMOUNT FROM TRANSACTION
  GROUP BY ID) AS T
  ON A.ID = T.ID
 WHEN MATCHED THEN
  UPDATE SET
   BALANCE = A.BALANCE + T.SUM_AMOUNT
 WHEN NOT MATCHED THEN
  INSERT
  (ID, BALANCE)
   VALUES (T.ID, T.SUM_AMOUNT);
```

Example 4

Using the TRANSACTION_LOG table, merge rows into the EMPLOYEE_FILE table: Update the phone and office with the latest TRANSACTION_LOG row based on the transaction time, and insert the latest new EMPLOYEE_FILE row where the row does not already exist.

```
MERGE INTO EMPLOYEE_FILE AS E
 USING (SELECT EMPID, PHONE, OFFICE
  FROM (SELECT EMPID, PHONE, OFFICE,
  ROW_NUMBER() OVER (PARTITION BY EMPID
  ORDER BY TRANSACTION_TIME DESC) RN
  FROM TRANSACTION_LOG) AS NT
  WHERE RN = 1) AS T
  ON E.EMPID = T.EMPID
 WHEN MATCHED THEN
  UPDATE SET
   (PHONE, OFFICE) =
   (T.PHONE, T.OFFICE)
 WHEN NOT MATCHED THEN
  INSERT
  (EMPID, PHONE, OFFICE)
  VALUES (T.EMPID, T.PHONE, T.OFFICE);
```

Example 5

Update the list of activities organized by Group A in the RECORDS table. Delete all outdated activities and update the activities information (DESCRIPTION and DATE) in the RECORDS table if they have been changed. For new upcoming activities, insert into the RECORDS table. Signal an error if the date of the activity is not known. The date of the activities in the RECORDS table must be specified. Each group has an activities table. For example, ACTIVITIES_GROUPA contains all activities that group A organizes, and the RECORDS table contains all upcoming activities organized by different groups in a company. The RECORDS table has (GROUP, ACTIVITY) as the primary key, and DATE is not nullable. All activities tables have ACTIVITY as the primary key. The LAST_MODIFIED column in the RECORDS table is defined with CURRENT TIMESTAMP as the default value.

```
MERGE INTO RECORDS AR
 USING (SELECT ACTIVITY, DESCRIPTION, DATE, LAST_MODIFIED
  FROM ACTIVITIES_GROUPA) AC
  ON (AR.ACTIVITY = AC.ACTIVITY) AND AR.GROUP = 'A'
 WHEN MATCHED AND AC.DATE IS NULL THEN
  SIGNAL SQLSTATE '70001'
   SET MESSAGE_TEXT =
    AC.ACTIVITY CONCAT ' CANNOT BE MODIFIED. REASON: DATE IS NOT KNOWN'
 WHEN MATCHED AND AC.DATE < CURRENT DATE THEN
  DELETE
 WHEN MATCHED AND AR.LAST_MODIFIED < AC.LAST_MODIFIED THEN
  UPDATE SET
  (DESCRIPTION, DATE, LAST_MODIFIED) = (AC.DESCRIPTION, AC.DATE, DEFAULT)
 WHEN NOT MATCHED AND AC.DATE IS NULL THEN
  SIGNAL SQLSTATE '70002'
   SET MESSAGE_TEXT =
    AC.ACTIVITY CONCAT ' CANNOT BE INSERTED. REASON: DATE IS NOT KNOWN'
 WHEN NOT MATCHED AND AC.DATE >= CURRENT DATE THEN
  INSERT
   (GROUP, ACTIVITY, DESCRIPTION, DATE)
   VALUES ('A', AC.ACTIVITY, AC.DESCRIPTION, AC.DATE)
 ELSE IGNORE;
```

Example 6

Update the descriptions for activities that exist in the RECORDS table. Otherwise, insert the activity and its description into the RECORDS table.

```
MERGE INTO RECORDS AR
  USING (VALUES (:hv_activity, :hv_description)
    FOR :hv_nrows ROWS)
    AS AC (ACTIVITY, DESCRIPTION)
  ON (AR.ACTIVITY = AC.ACTIVITY)
  WHEN MATCHED THEN UPDATE SET DESCRIPTION = AC.DESCRIPTION
  WHEN NOT MATCHED THEN INSERT (ACTIVITY, DESCRIPTION)
     VALUES (AC.ACTIVITY, AC.DESCRIPTION)
  NOT ATOMIC CONTINUE ON SQLEXCEPTION;
```

Example 7

Use the transaction data to merge rows into the account table. Update the balance from the transaction data against an account ID and insert new accounts from the transaction data where the accounts do not already exist.

```
MERGE INTO ACCOUNT AS A
  USING (VALUES (:hv_id, :hv_amount)
    FOR 3 ROWS)
    AS T (ID, AMOUNT)
  ON (A.ID = T.ID)
  WHEN MATCHED THEN UPDATE SET BALANCE = A.BALANCE + T.AMOUNT
  WHEN NOT MATCHED THEN INSERT (ID, BALANCE)
      VALUES (T.ID, T.AMOUNT)
  NOT ATOMIC CONTINUE ON SQLEXCEPTION;
```

Example 8

Update the list of activities that are organized by group A in the RECORDS table. Update the activities information (description and date when last modified) in the RECORDS table if the activities exist in the RECORDS table and are also organized by group A. Insert new activities into the RECORDS table.

```
-- hv_nrows = 3
-- hv_activity(1) = 'D'; hv_description(1) = 'Dance'; hv_date(1) = '03/01/07'
-- hv_activity(2) = 'S'; hv_description(2) = 'Singing'; hv_date(2) = '03/17/07'
-- hv_activity(3) = 'T'; hv_description(3) = 'Tai-chi'; hv_date(3) = '05/01/07'
-- hv_group = 'A';
-- note that hv_group is not an array. All 3 values contain the same values
MERGE INTO RECORDS AR
  USING (VALUES (:hv_activity, :hv_description, :hv_date, :hv_group)
     FOR :hv_nrows ROWS)
     AS AC (ACTIVITY, DESCRIPTION, DATE, GROUP)
  ON AR.ACTIVITY = AC.ACTIVITY AND AR.GROUP = AC.GROUP
  WHEN MATCHED
  THEN UPDATE SET (DESCRIPTION, DATE, LAST_MODIFIED)
                  = (AC.DESCRIPTION, AC.DATE, CURRENT TIMESTAMP)
  WHEN NOT MATCHED
  THEN INSERT (GROUP, ACTIVITY, DESCRIPTION, DATE, LAST_MODIFIED)
     VALUES (AC.GROUP, AC.ACTIVITY, AC.DESCRIPTION, AC.DATE, CURRENT TIMESTAMP)
  NOT ATOMIC CONTINUE ON SQLEXCEPTION;
```

Example 9

Use two arrays, CHARA and INTA, as input to a MERGE statement. Column COL2 is set to the cardinality of CHARA for matching rows, and COL2 is set to the cardinality of INTA for non-matching rows.

```
CREATE TYPE INTARRAY AS INTEGER ARRAY[6];
CREATE TYPE CHARARRAY AS CHAR(20) ARRAY[7];
CREATE VARIABLE INTA AS INTARRAY;
CREATE VARIABLE CHARA AS CHARARRAY;
CREATE VARIABLE SI INT;
SET CHARA = ARRAY['a', 'b', 'c'];
SET INTA = ARRAY [1, 2, 3, 4, 5];
CREATE TABLE T1 (COL1 CHAR(7), COL2 INT);
INSERT INTO T1 VALUES ('abc', 10);
MERGE INTO T1 AS A
 USING TABLE (VALUES ('rsk', 3 ) ) AS T (ID, AMOUNT)
 ON A.COL1 = T.ID
 WHEN MATCHED
  THEN UPDATE SET COL2 = CARDINALITY(CHARA)
 WHEN NOT MATCHED
  THEN INSERT (COL1, COL2 ) VALUES (T.ID, CARDINALITY(INTA));
```

OPEN

The OPEN statement opens a cursor so that it can be used to process rows from its result table.

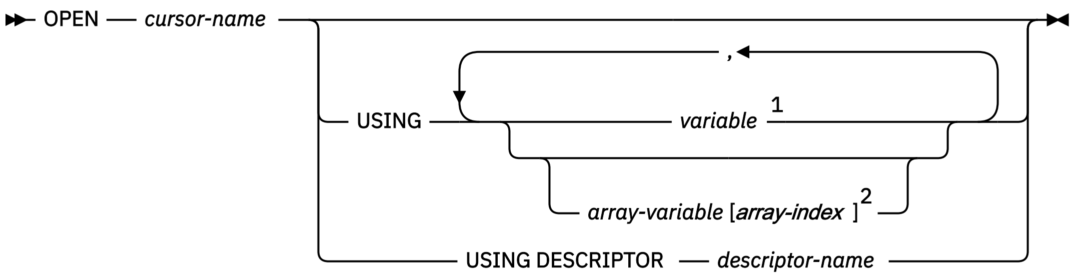
Invocation for OPEN

This statement can only be embedded in an application program. It is an executable statement that cannot be dynamically prepared. It must not be specified in Java.

Authorization for OPEN

See “DECLARE CURSOR” on page 1814 for the authorization required to use a cursor.

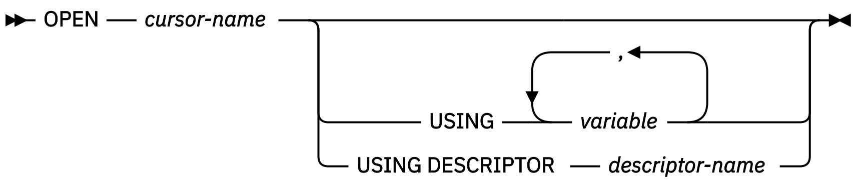
Syntax for OPEN



Notes:

[1] A global variable must only be specified in an SQL PL context.

[2] An array element must only be specified in an SQL PL context.



Description for OPEN

cursor-name

Identifies the cursor to be opened. The *cursor-name* must identify a declared cursor as explained in “DECLARE CURSOR” on page 1814. When the OPEN statement is executed, the cursor must be in the closed state.

The SELECT statement of the cursor is either one of the following types of SELECT statements:

- The *select-statement* that is specified in the DECLARE CURSOR statement
- The prepared *select-statement* that is identified by the *statement-name* that is specified in the DECLARE CURSOR statement.

If the statement has not been successfully prepared, or is not a *select-statement*, the cursor cannot be successfully opened.

The result table of the cursor is derived by evaluating the SELECT statement. The evaluation uses the current values of any special registers or PREVIOUS VALUE expressions that are specified in the SELECT statement, and the current values of any host variables that are specified in the SELECT statement or the USING clause of the OPEN statement. The rows of the result table can be derived during the execution of the OPEN statement, and a temporary copy of a result table can be created to hold those rows. They can be derived during the execution of later FETCH statements. In either case, the cursor is placed in the open state and positioned before the first row of its result table.

If the table is empty, the position of the cursor is effectively “after the last row.” The Db2 system does not indicate an empty table when the OPEN statement is executed. A subsequent fetch for the cursor might return the SQLSTATE warning of '02000'.

USING

Introduces a list of variables or array element expressions whose values are substituted for the parameter markers (question marks) in the statement of the cursor, depending on the declaration of the cursor:

- If the DECLARE CURSOR statement included *statement-name*, the statement was prepared with a PREPARE statement. The variables specified in the USING clause of the OPEN statement replace any parameter markers in the prepared statement. This reflects the typical use of the USING clause of the OPEN statement. For an explanation of parameter marker replacement, see “PREPARE” on page 2037.

  If the prepared statement includes parameter markers, you must use USING. If the prepared statement does not include parameter markers, USING is ignored.
- If the DECLARE CURSOR statement included *select-statement* and the SELECT statement included variables, the USING clause of the OPEN statement can be used to specify variables that are to override the values that were specified when the cursor was defined. In this case, the OPEN statement is executed as if each variable in the SELECT statement were a parameter marker except that the attributes of the target variable are the same as the variables in the SELECT statement. The effect is to override the values of the variables in the SELECT statement of the cursor with the values of the variables specified in the USING clause. The overriding value is always the value of the main variable because indicator variables are ignored in this context without warning.

The *n*th variable corresponds to the *n*th parameter marker in the prepared statement. Where appropriate, locator variables and file reference variables can be provided as the source of values for parameter markers.

variable

Identifies a variable or a host structure that is declared in the application program in accordance with the rules for declaring variables and host structures. When the statement is executed, a reference to a structure is replaced by a reference to each of its variables. The number of variables must be the same as the number of parameter markers in the prepared statement.

An array global variable must only be specified if the OPEN statement is issued in SQL PL.

***array-variable* [*array-index*]**

Identifies an array element. An array element must only be specified if the OPEN statement is issued in SQL PL.

array-variable

Specifies an array variable.

[*array-index*]

An expression that specifies which element in the array to use.

For an ordinary array, the array index expression must be castable to INTEGER, and must not be the null value. The index value must be between 1 and the maximum cardinality that is defined for the array.

For an associative array, the array index expression must be castable to the index data type of the associative array, and must not be the null value.

array-index must not be:

- An expression that references the CURRENT DATE, CURRENT TIME, or CURRENT TIMESTAMP special register

- A nondeterministic function
- A function that is defined with EXTERNAL ACTION
- A function that is defined with MODIFIES SQL DATA
- A sequence expression

DESCRIPTOR *descriptor-name*

Identifies an SQLDA that contains a valid description of the input host variables.

Before the OPEN statement is processed, the user must set the following fields in the SQLDA:

- SQLN to indicate the number of SQLVAR occurrences provided in the SQLDA

  A REXX SQLDA does not contain this field.
- SQLABC to indicate the number of bytes of storage allocated for the SQLDA
- SQLD to indicate the number of variables used in the SQLDA when processing the statement
- SQLVAR occurrences to indicate the attributes of the variables

The SQLDA must have enough storage to contain all SQLVAR occurrences. If LOBs or distinct types are present in the result table, there must be additional SQLVAR entries for each input host variable. For more information on the SQLDA, which includes a description of the SQLVAR and an explanation on how to determine the number of SQLVAR occurrences, see Appendix F, “SQL descriptor area (SQLDA),” on page 2301.

SQLD must be set to a value greater than or equal to zero and less than or equal to SQLN. It must be the same as the number of parameter markers in the prepared statement.

See “Identifying an SQLDA in C or C++” on page 2317 for how to represent *descriptor-name* in C.

Notes for OPEN

Errors occurring on OPEN: In local and remote processing, the DEFER(PREPARE) and REOPT(ALWAYS)/ REOPT(ONCE) bind options can cause some SQL statements to receive "delayed" errors. For example, an OPEN statement might receive an SQLCODE that normally occurs during PREPARE processing. Or a FETCH statement might receive an SQLCODE that normally occurs at OPEN time.

Closed state of cursors: All cursors in an application process are in the closed state when:

- The application process is started.
- A new unit of work is started for the application process unless the WITH HOLD option has been used in the DECLARE CURSOR statement.
- The application was precompiled with the CONNECT(1) option (which implicitly closes any open cursors).

A cursor can also be in the closed state because:

- A CLOSE statement was executed.
- An error was detected that made the position of the cursor unpredictable.

To retrieve rows from the result table of a cursor, you must execute a FETCH statement when the cursor is open. The only way to change the state of a cursor from closed to open is to execute an OPEN statement.

Effect of a temporary copy of a result table: Db2 can process a cursor in two different ways:

- It can create a temporary copy of the result table during the execution of the OPEN statement. You can specify INSENSITIVE SCROLL on the cursor to force the use of a temporary copy of the result table.
- It can derive the result table rows as they are needed during the execution of later FETCH statements.

If the result table is not read-only, Db2 uses the latter method. If the result table is read-only, either method could be used. The results produced by these two methods could differ in the following respects:

When a temporary copy of the result table is used: An error can occur that would otherwise not occur until some later FETCH statement. insert operations that are executed while the cursor is open cannot affect the result table once all the rows have been materialized in the temporary copy of the result table. For a scrollable insensitive cursor, update and delete operations that are executed while the cursor is open cannot affect the result table. For a scrollable sensitive static cursor, update and delete operations can affect the result table if the rows are subsequently fetched with sensitive FETCH statements.

When a temporary copy of the result table is not used: Insert, update, and delete operations that are executed while the cursor is open can affect the result table. The effect of such operations is not always predictable.

For example, if cursor C is positioned on a row of its result table defined as SELECT * FROM T, and you insert a row into T, the effect of that insert on the result table is not predictable because its rows are not ordered. A later FETCH C might or might not retrieve the new row of T. To avoid these changes, you can specify INSENSITIVE SCROLL for the cursor to force the use of a temporary copy of the result table.

Parameter marker replacement: Before the OPEN statement is executed, each parameter marker in the query is effectively replaced by its corresponding host variable. The replacement is an assignment operation in which the source is the value of the host variable and the target is a variable within Db2. The assignment rules are those described for assignment to a column in "Assignment and comparison" on page 143. For a typed parameter marker, the attributes of the target variable are those specified by the CAST specification. For an untyped parameter marker, the attributes of the target variable are determined according to the context of the parameter marker. For the rules that affect parameter markers, see Parameter markers.

Let V denote a host variable that corresponds to parameter marker P. The value of V is assigned to the target variable for P in accordance with the rules for assigning a value to a column:

- V must be compatible with the target.
- If V is a string, its length (excluding trailing blanks) must not be greater than the length attribute of the target.
- If V is a number, the absolute value of its integral part must not be greater than the maximum absolute value of the integral part of the target.
- If the attributes of V are not identical to the attributes of the target, the value is converted to conform to the attributes of the target.
- If the target cannot contain nulls, V must not be null.

When the SELECT statement of the cursor is evaluated, each parameter marker in the statement is effectively replaced by the value of its corresponding host variable. For example, if V is CHAR(6) and the target is CHAR(8), the value used in place of P is the value of V padded on the right with two blanks. For more on the process of replacement, see Parameter marker replacement.

Considerations for scrollable cursors: Following an OPEN *cursor* statement, a GET DIAGNOSTICS statement can be used to get the attributes of the cursor such as the following information (for more information, see "GET DIAGNOSTICS" on page 1944):

- DB2_SQL_ATTR_CURSOR _HOLD. Whether the cursor was defined with the WITH HOLD attribute.
- DB2_SQL_ATTR_CURSOR_SCROLLABLE. Scrollability of the cursor.
- DB2_SQL_ATTR_CURSOR_SENSITIVITY. Effective sensitivity of the cursor.

  The sensitivity information can be used by applications (such as an ODBC driver) to determine what type of FETCH (INSENSITIVE or SENSITIVE) to issue for a cursor defined as ASENSITIVE.
- DB2_SQL_ATTR_CURSOR_ROWSET. Whether the cursor can be used to access rowsets.
- DB2_SQL_ATTR_CURSOR_TYPE. Whether a cursor type is forward-only, static, or dynamic.

- The scrollability of the cursor is in SQLWARN1.
- The sensitivity of the cursor is in SQLWARN4.
- The effective capability of the cursor is in SQLWARN5.

Number of rows inserted: SQL data change statements and routines that modify SQL data embedded in the cursor definition are completely executed, and the result table is stored in a temporary table when the cursor opens. If statement execution is successful, the SQLERRD(3) field contains the sum of the number of rows that qualified for insert, update, and delete operations. If an error occurs during execution of an OPEN statement that involves a cursor that contains a data change statement within a fullselect, the results of that data change statement are rolled back.

Materialization of the rows of the result table and NEXT VALUE expressions: If the rows of the result table of a cursor are materialized when the cursor is opened and the SELECT statement of the cursor contains NEXT VALUE expressions, the expressions are processed when the cursor is opened. Otherwise, the NEXT VALUE expressions are evaluated as the rows of the result table are retrieved.

Opening the same cursor multiple times: A cursor in an SQL procedure that is declared as WITH RETURN TO CLIENT can be opened even when a cursor with the same name is already in the open state. In this case, the existing open cursor becomes a result set cursor and is no longer accessible by its cursor name. A new cursor is opened and becomes accessible by the cursor name. Closing the new cursor does not make the cursor that was previously accessible by that name accessible by the cursor name again. Cursors that become result set cursors in this way cannot be accessed at the server and can be processed only at the client.

Examples for OPEN

Example 1: Execute an OPEN statement, which places the cursor at the beginning of the rows to be fetched.

```
   EXEC SQL DECLARE C1 CURSOR FOR
     SELECT DEPTNO, DEPTNAME, MGRNO FROM DSN8C10.DEPT
     WHERE ADMRDEPT = 'A00';
   EXEC SQL OPEN C1;
    DO WHILE (SQLCODE = 0);
     EXEC SQL FETCH C1 INTO :DNUM, :DNAME, :MNUM;
   END;
    EXEC SQL CLOSE C1;
```

Example 2: Suppose that the following array type, array variable, and table have been defined.

```
CREATE TYPE INTARRAY AS INTEGER ARRAY[100];
CREATE TYPE STRINGARRAY AS VARCHAR(10) ARRAY[100];
CREATE TABLE T1 (COL1 CHAR(10), COL2 INT);
```

Use an array variable as input for a dynamic SQL statement. The dynamic statement references an array element in the array variable. The dynamic statement contains two parameter markers, one for the array variable and one for the index of the array element. The OPEN statement provides two input values in the USING clause: the array variable, and a variable that contains the index for the array element.

```
CREATE PROCEDURE PROCESSPERSONS (OUT WITHO STRINGARRAY, INOUT INT0 INT)
BEGIN
 DECLARE INTA INTARRAY;
 DECLARE INTB INTARRAY;
 DECLARE INTV INTEGER;
 DECLARE STMT CHAR(100);
 DECLARE C2 CURSOR FOR S1;
--
-- Initialize the array
--
 SET INTA = ARRAY[1,INTEGER(2),3+0,4,5,6] ;
--
-- Use dynamic SQL with an array parameter marker and a parameter marker
-- containing the index to retrieve the value from the array parameter.
-- The array is referenced in a predicate.
--
 SET STMT = 'SELECT COL1 FROM T1 WHERE COL2 = CAST(? AS INTARRAY)[?]';
 PREPARE S1 FROM STMT;
 OPEN C2 USING INTA, INTV; -- Input: INTA is an array, and INTV is the
                           -- index for the array element
 FETCH C2 INTO INTB ;      -- Output: INTB is an array variable
…
```

```
  CLOSE C2;
…
END
```

PREPARE

The PREPARE statement creates an executable SQL statement from a string form of the statement. The character-string form is called a *statement string*. The executable form is called a *prepared statement*.

Invocation for PREPARE

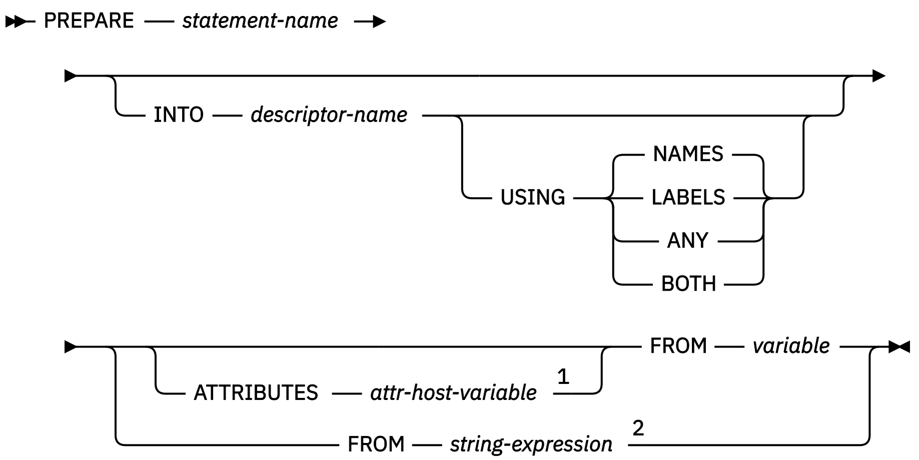
This statement can only be embedded in an application program. It is an executable statement that cannot be dynamically prepared. It must not be specified in Java.

Authorization for PREPARE

The authorization rules are those defined for the dynamic preparation of the SQL statement specified by the PREPARE statement. For example, see Chapter 6, “Queries,” on page 1005 for the authorization rules that apply when a SELECT statement is prepared.

The statement that is prepared using only the EXPLAIN privilege cannot be executed, and only the descriptive information can be obtained for that statement.

Syntax for PREPARE

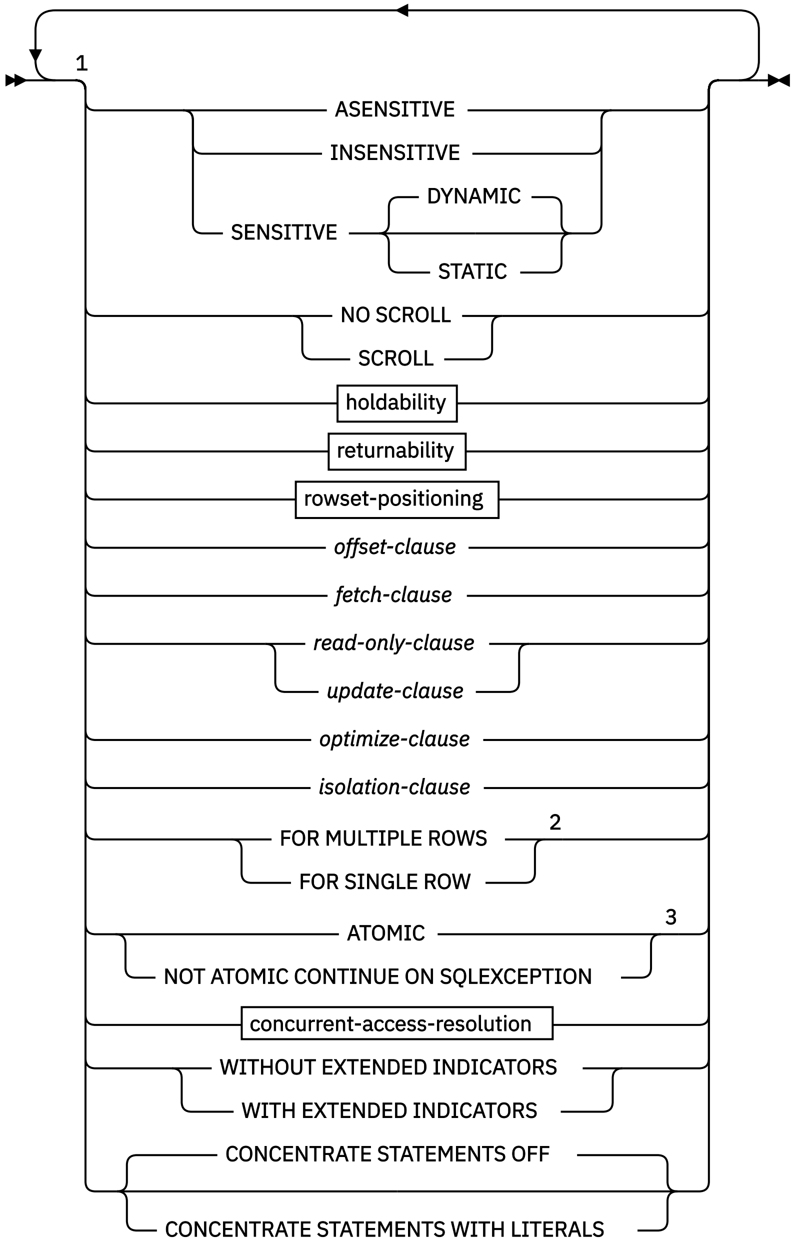


Notes:

[1] *attr-host-variable* must be a string host variable and the content must conform to the rules for attribute-string. The ATTRIBUTES clause can only be specified before *variable*.

[2] *string-expression* is only supported for PLI.

attribute-string



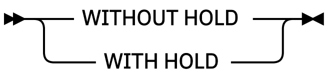
Notes:

[1] The same clause must not be specified more than one time. If the options are not specified, their defaults are whatever was specified for the corresponding option in an associated statement.

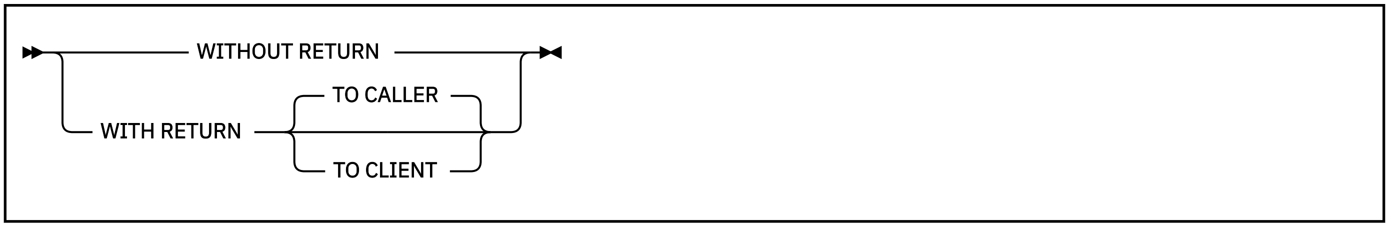
[2] The FOR SINGLE ROW or FOR MULTIPLE ROWS clause must only be specified for an INSERT or a MERGE statement.

[3] The ATOMIC or NOT ATOMIC CONTINUE ON SQLEXCEPTION clause must only be specified for an INSERT statement.

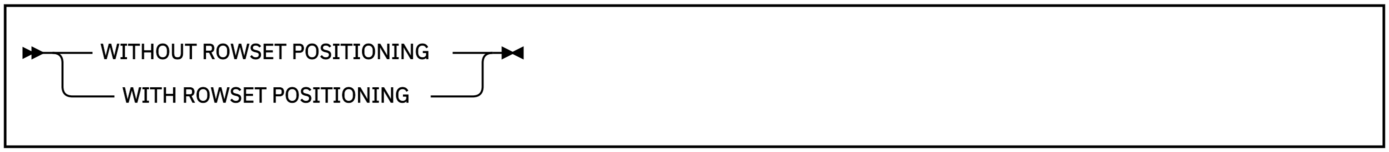
holdability:



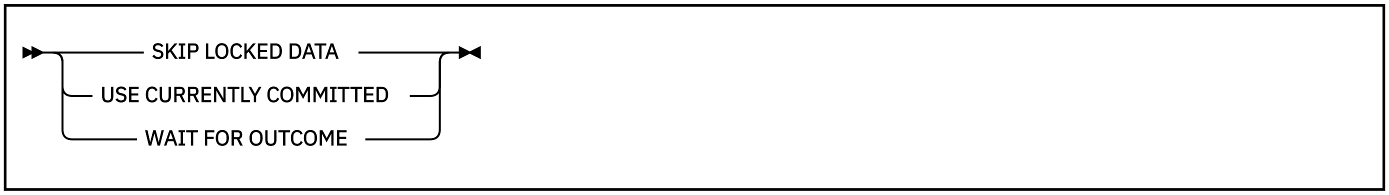
returnability:



rowset-positioning:



concurrent-access-resolution



Description for PREPARE

statement-name

Names the prepared statement. If the name identifies an existing prepared statement, that prepared statement is destroyed. The name must not identify a prepared statement that is the SELECT statement of an open cursor.

INTO

If you use INTO, and the PREPARE statement is successfully executed, information about the prepared statement is placed in the SQLDA specified by the descriptor name. Thus, the PREPARE statement:

```
EXEC SQL PREPARE S1 INTO :SQLDA FROM :V1;
```

is equivalent to:

```
EXEC SQL PREPARE S1 FROM :V1;
EXEC SQL DESCRIBE S1 INTO :SQLDA;
```

descriptor-name

Identifies the SQLDA. For languages other than REXX, SQLN must be set to indicate the number of SQLVAR occurrences. See "DESCRIBE" on page 1864 for information about how to determine the number of SQLVAR occurrences to use and for an explanation of the information that is placed in the SQLDA.

See "Identifying an SQLDA in C or C++" on page 2317 for how to represent *descriptor-name* in C.

USING

Indicates what value to assign to each SQLNAME variable in the SQLDA when INTO is used. If the requested value does not exist, SQLNAME is set to length 0.

NAMES

Assigns the name of the column. This is the default.

LABELS

Assigns the label of the column. (Column labels are defined by the LABEL statement.)

ANY

Assigns the label of the column. If the column has no label or the label is a string of length 0, the column name is used instead.

BOTH

Assigns both the label and name of the column. In this case, two or three occurrences of SQLVAR per column, depending on whether the result table contains distinct types, are needed to accommodate the additional information. To specify this expansion of the SQLVAR array, set SQLN to 2×*n* or 3×*n*, where *n* is the number of columns in the object being described. For each of the columns, the first *n* occurrences of SQLVAR, which are the base SQLVAR entries, contain the column names. Either the second or third *n* occurrences of SQLVAR, which are the extended SQLVAR entries, contain the column labels. If there are no distinct types, the labels are returned in the second set of SQLVAR entries. Otherwise, the labels are returned in the third set of SQLVAR entries.

A REXX SQLDA does not include the SQLN field, so you do not need to set SQLN for REXX programs.

ATTRIBUTES *attr-host-variable*

Specifies the attributes that are in effect if a corresponding attribute has not been specified as part of the associated statement. If attributes are specified as part of the associated statement, they are used instead of the corresponding attributes specified on the PREPARE statement. In turn, if attributes are specified in the PREPARE of a SELECT statement, they are used instead of the corresponding attributes specified on a DECLARE CURSOR statement.

attr-host-variable must identify a host variable that is described in the program in accordance with the rules for declaring string variables. *attr-host-variable* must be a string variable (either fixed-length or varying-length) that has a length attribute that does not exceed 32758 bytes. Leading and trailing blanks are removed from the value of the host variable. The host variable must contain a valid *attribute-string*.

An indicator variable can be used to indicate whether or not attributes are actually provided on the PREPARE statement. Thus, applications can use the same PREPARE statement regardless of whether attributes need to be specified or not.

The options that can be specified as part of the *attribute-string* are as follows:

ASENSITIVE, INSENSITIVE, SENSITIVE STATIC, or SENSITIVE DYNAMIC

Specifies the sensitivity of the cursor to inserts, updates, or deletes that made to the rows underlying the result table. The sensitivity of the cursor determines whether Db2 can materialize the rows of the result into a temporary table. The default is ASENSITIVE.

ASENSITIVE

Specifies that the cursor should be as sensitive as possible. A cursor that defined as ASENSITIVE will be either insensitive or sensitive dynamic; it will not be sensitive static. For information about how the effective sensitivity of the cursor is returned to the application with the GET DIAGNOSTICS statement or in the SQLCA, see "OPEN" on page 2032.

The sensitivity of a cursor is a factor in the choice of access path. Explicitly specify the sensitivity level that you need, instead of specifying ASENSITIVE.

INSENSITIVE

Specifies that the cursor does not have sensitivity to inserts, updates, or deletes that are made to the rows underlying the result table. As a result, the size of the result table, the order of the rows, and the values for each row do not change after the cursor is opened. In addition, the cursor is read-only. The SELECT statement or *attribute-string* of the PREPARE statement cannot contain a FOR UPDATE clause, and the cursor cannot be used for positioned updates or deletes.

SENSITIVE

Specifies that the cursor has sensitivity to changes made to the database after the result table is materialized. The cursor is always sensitive to positioned updates and deletes that are made using the same cursor. However, the *select-statement* of the cursor must not contain

[36] The scrollability and sensitivity of the cursor are independent and do not have to be specified together. Thus, the cursor might be defined as SCROLL INSENSITIVE, but the PREPARE statement might specify SENSITIVE STATIC as an override for the sensitivity.

an SQL data change statement if the cursor is defined as either SENSITIVE DYNAMIC or SENSITIVE STATIC. When the current value of a row no longer satisfies the *select-statement* or *statement-name*, that row is no longer visible through the cursor. When a row of the result table is deleted from the underlying base table, the row is no longer visible through the cursor.

In addition, the cursor has sensitivity to changes made to values outside the cursor (that is, by other cursors or committed changes by other application processes). If Db2 can not make changes made outside the cursor visible to the cursor, an error is issued at OPEN CURSOR. Whether the cursor is sensitive to changes made outside this cursor depends on whether DYNAMIC or STATIC is in effect for the cursor and whether SENSITIVE or INSENSITIVE FETCH statements are used.

Whether the cursor is sensitive to newly inserted rows depends on whether DYNAMIC or STATIC is in effect for the cursor. The default is DYNAMIC.

DYNAMIC

Specifies that the result table of the cursor is dynamic in that the size of the result table can change after the cursor is opened as rows are inserted into or deleted from the underlying table, and the order of the rows can change. Inserts, deletes, and updates that are made by the same application process are immediately visible. Inserts, deletes, and updates that are made by other application processes are visible after they are committed.

All FETCH statements for sensitive dynamic cursors are sensitive to changes made by this cursor, changes made by other cursors in the same application process, and committed changes made by other application processes.

If a SENSITIVE DYNAMIC cursor is not possible, an error is returned. The FETCH FIRST *n* ROWS ONLY clause and the OFFSET clause must not be specified (either in the outermost fullselect for the cursor or as prepare attributes) for a sensitive dynamic cursor.

STATIC

Specifies that the order of the rows and size of the result table is static. The size of the result table does not grow after the cursor is opened and the rows are materialized. The order of the rows is established as the result table is materialized. Rows that are inserted into the underlying table are not added to the result table of the cursor regardless of how the rows were inserted. Rows in the result table do not move if columns in the ORDER BY clause are updated in rows that have already been materialized.

Whether the changes that are made outside the cursor are visible to the cursor depends on the type of FETCH that is used with a SENSITIVE STATIC cursor. For more information, see Considerations for FETCH statements used with a sensitive static cursor.

Using a function that is not deterministic (built-in or user-defined) in the WHERE clause of *select-statement* or *statement-name* of a SENSITIVE STATIC cursor can cause misleading results. This occurs because Db2 constructs a temporary result table and retrieves rows from this table for INSENSITIVE FETCH statements. When Db2 processes a SENSITIVE FETCH statement, rows are fetched from the underlying table and predicates are re-evaluated if they contain non-correlated subqueries. Using a function that is not deterministic can yield a different result for the re-evaluated query causing the row to no longer be considered a match.

If SENSITIVE STATIC is specified and a sensitive static cursor is not possible, then an error is returned.

If ASENSITIVE, INSENSITIVE, SENSITIVE DYNAMIC, or SENSITIVE STATIC is specified as part of the ATTRIBUTES clause, SCROLL must be specified.

SCROLL or NO SCROLL

Specifies whether the cursor is scrollable.

SCROLL

Specifies that the cursor is scrollable.

NO SCROLL
Specifies that the cursor is not scrollable.

WITHOUT RETURN or WITH RETURN
Specifies whether the result table of the cursor is intended to be used as a result set that will be returned from a procedure. If *statement-name* is specified, the default is the corresponding prepare attribute of the statement. Otherwise, the default is WITHOUT RETURN.

WITHOUT RETURN
Specifies that the result table of the cursor is not intended to be used as a result set that will be returned from a procedure.

WITH RETURN
Specifies that the result table of the cursor is intended to be used as a result set that will be returned from a procedure. WITH RETURN is relevant only if the PREPARE statement is contained within the source code for a procedure. In other cases, the precompiler might accept the clause, but it has not effect.

When a cursor that is declared using the WITH RETURN TO CALLER clause remains open at the end of a program or routine, that cursor defines a result set from the program or routine. Use the CLOSE statement to close a cursor that is not intended to be a result set from the program or routine. Although Db2 will automatically close any cursors that are not declared using with a WITH RETURN clause, the use of the CLOSE statement is recommended to increase the portability of applications.

For non-scrollable cursors, the result set consists of all rows from the current cursor position to the end of the result table. For scrollable cursors, the result set consists of all rows of the result table.

TO CALLER
Specifies that the cursor can return a result set to the caller of the procedure. The caller is the program or routine that executed the SQL CALL statement that invokes the procedure that contains the PREPARE statement. For example, if the caller is a procedure, the result set, is returned to the procedure. If the caller is a client application, the result set is returned to the client application.

If the statement is contained within the source code for a procedure, WITH RETURN TO CALLER specifies that the cursor can be used as a result set cursor. A result set cursor is used when the result table of a cursor is to be returned from a procedure. Specifying TO CALLER is optional.

In other cases, the clause is ignored and the cursor cannot be used as a result set cursor.

TO CLIENT
Specifies that the cursor can return a result set to the client application. This cursor is invisible to any intermediate nested procedures. If a function or trigger calls the procedure (either directly or indirectly), the result set cannot be returned to the client and the cursor will be closed after the procedure finishes.

rowset-positioning
Specifies whether rows of data can be accessed as a rowset on a single FETCH statement for this cursor.

WITHOUT ROWSET POSITIONING
Specifies that the cursor can only be used with row positioned FETCH statements.

WITH ROWSET POSITIONING
Specifies that this cursor can be used with rowset positioned or row positioned FETCH statements

offset-clause
The *offset-clause* specifies the number of rows to skip from the beginning of the intermediate result table. *offset-row-count* is a constant that specifies a numeric value that is a positive number or zero. If the value is not BIGINT, the value is cast to a BIGINT value. The offset of the beginning row is zero (not 1). *offset-row-count* must not be the null value.

The *offset-clause* must not be specified for the outermost fullselect for a sensitive dynamic cursor.

For more information, see "offset-clause" on page 1043.

fetch-clause

The *fetch-clause* specifies the maximum number of rows that can be retrieved. *fetch-row-count* is a constant that specifies a numeric value that is a positive number or zero. If the value is not BIGINT, the value is cast to a BIGINT value. *fetch-row-count* must not be the null value.

The *fetch-clause* must not be specified for the outermost fullselect for a sensitive dynamic cursor.

The use of the *fetch-clause* can improve the performance of queries with potentially large result sets when only a limited number of rows are needed. If the clause is specified, the number of rows retrieved will not exceed *n*, where *n* is the value of the integer. An attempt to fetch *n*+1 rows is handled the same way as a normal end of data.

For more information, see "fetch-clause" on page 1045.

read-only-clause

Declares that the result table is read-only and therefore the cursor cannot be referred to in positioned UPDATE and DELETE statements.

update-clause

Identifies the columns that can updated in a later positioned UPDATE statement. Each column must be unqualified and must identify a column of the table or view identified in the first FROM clause of the fullselect. The clause must not be specified if the result table of the fullselect is read-only. The clause must also not be specified if a created temporary table is referenced in the first FROM clause of the select-statement.

If the clause is specified without a list of columns, the columns that can be updated include all the updatable columns of the table or view that is identified in the first FROM clause of the fullselect.

optimize-clause

Requests special optimization of the *select-statement*. If the clause is omitted, optimization is based on the assumption that all rows of the result table will be retrieved. If the clause is specified, optimization is based on the assumption that the number of rows retrieved will not exceed *n*, where *n* is the value of the integer. The clause does not limit the number of rows that can be fetched or affect the result in any way other than performance.

isolation-clause

Specifies the isolation level at which the select statement is executed. See "isolation-clause" on page 1070.

concurrent-access-resolution

Specifies the type concurrent access resolution to use for the select statement. Each clause in *concurrent-access-resolution* can only be specified one time. Only one of the clauses can be specified for each PREPARE statement. If none of the clauses is specified, the locking semantic depends on other attributes of the statement.

SKIP LOCKED DATA

Specifies to skip data on which incompatible locks are held by other transactions. See "SKIP LOCKED DATA" on page 1072.

USE CURRENTLY COMMITTED

Specifies that Db2 can use the currently committed version of the data when the data is in the process of being updated. USE CURRENTLY COMMITTED only applies in the following cases:

- The table that is being accessed is defined in a universal table space
- The access is for a select-statement with an isolation level of cursor stability (CS) or read stability (RS) specified in the isolation-clause:
  - When a read transaction accesses a record that is locked by an insert transaction, both ISOLATION(CS) and ISOLATION(RS) are applicable.
  - When a read transaction accesses a record that is locked by a delete transaction only ISOLATION(CS) is applicable and only when CURRENTDATA(NO) is in effect.

USE CURRENTLY COMMITTED is ignored if used in any other context.

When this clause is specified, the setting of the subsystem parameter EVALUNC applies. If the row qualifies, this clause determines if the row is accessed or skipped.

When this clause is specified and the subsystem parameter SKIPUNCI is in effect, PREPARE uses the specification of this clause. See the Notes section for more information.

When this clause is specified and XML data that does not support multiple XML versions is being selected, Db2 cannot determine whether the data has been committed. In this case, Db2 uses WAIT FOR OUTCOME behavior when accessing the data.

WAIT FOR OUTCOME
Specifies that Db2 waits for the commit or rollback when encountering data that is in the process of being updated or deleted. Rows that are in the process of being inserted are not skipped.

FOR MULTIPLE ROWS or FOR SINGLE ROW
Specifies if a variable number of rows will be provided with host-variable arrays for a dynamic INSERT or MERGE statement.

FOR MULTIPLE ROWS
Specifies that multiple rows can be provided with host-variable arrays on an EXECUTE statement for the statement that is being prepared. FOR MULTIPLE ROWS must only be specified for an INSERT or a MERGE statement.

FOR SINGLE ROW
Specifies that multiple rows must not be provided with host-variable arrays on an EXECUTE statement for the statement that is being prepared. FOR SINGLE ROW must only be specified for an INSERT or a MERGE statement.

ATOMIC or NOT ATOMIC CONTINUE ON SQLEXCEPTION
Specifies if all rows are inserted as an atomic operation. This clause can only be specified for dynamic INSERT statements.

ATOMIC
Specifies that if the insert for any row fails, all changes that are made to the database by any of the inserts, including changes that are made by successful inserts, are undone. This is the default.

NOT ATOMIC CONTINUE ON SQLEXCEPTION
Specifies that, regardless of the failure of any particular insert of a row, the INSERT statement will not undo any changes that are made to the database by the successful inserts of other rows, and inserting will be attempted for subsequent rows. However, the minimum level of atomicity is at least that of a single insert (that is, it is not possible for a partial insert operation to complete), including any triggers that might have been activated as a result of the INSERT statement.

This clause must not be specified if the INSERT statement is contained within a SELECT statement.

For preparing the MERGE statement, atomicity is specified only on the MERGE statement itself.

WITHOUT EXTENDED INDICATORS or WITH EXTENDED INDICATORS
Specifies whether the values that are provided for indicator variables during execution of an INSERT, MERGE, or UPDATE follow standard SQL semantics for indicating NULL values, or can use extended indicator values, including DEFAULT or UNASSIGNED.

WITH EXTENDED INDICATORS is ignored unless the statement is an INSERT statement with a VALUES clause, a MERGE statement, or an UPDATE statement.

CONCENTRATE STATEMENTS OFF or CONCENTRATE STATEMENTS WITH LITERALS
Specifies whether a dynamic SQL statement that specifies literal constants will be cached as a separate unique statement entry in the dynamic statement cache instead of sharing an existing statement in the cache. Dynamic SQL statements are eligible to share an existing statement in the

cache if the new statement meets all of the conditions for sharing a cached version of the same dynamic statement except that the new statement specifies one or more literal constants that are different than the cached statement.

CONCENTRATE STATEMENTS OFF
Specifies that the dynamic SQL statement that specifies literal constants will be cached as a unique statement entry if it specifies one or more constants that are different than the cached version of the same dynamic statement. `CONCENTRATE STATEMENTS OFF` is the default dynamic statement caching behavior.

CONCENTRATE STATEMENTS WITH LITERALS
Specifies that the dynamic SQL statement that specifies literal constants will share a cached version of the same dynamic statement that is also prepared using the `CONCENTRATE STATEMENTS WITH LITERALS` option if the new dynamic statement meets all of the conditions for sharing the cached statement and the constants that are specified can be reused in place of the constants in the cached statement.

FROM
Specifies the statement string. The statement string is the value of the specified *string-expression* or the identified *variable*.

variable
Must identify a variable that is described in the application program in accordance with the rules for declaring string variables. If the source string is over 32KB in length, the *variable* must be a CLOB or DBCLOB variable. The maximum source string length is 2MB although the variable can be declared larger than 2MB. An indicator variable must not be specified with a host variable. In PL/I, COBOL and Assembler language, a host variable must be a varying-length string variable. In C, a host variable must not be a NUL-terminated string. In SQL PL, an SQL variable is used in place of a host variable, and the value must not be null.

string-expression
string-expression is any PL/I expression that yields a string. *string-expression* cannot be preceded by a colon. Variables that are within *string-expression* that include operators or functions should not be preceded by a colon. When *string-expression* is specified, the precompiler-generated structures for *string-expression* use an EBCDIC CCSID and an informational message is returned.

Notes for PREPARE

Rules for statement strings:
The value of the specified *statement-name* is called the *statement string*. The statement string must be one of the following SQL statements:

Statements	Statements
• ALLOCATE CURSOR • ALTER • ASSOCIATE LOCATORS • COMMENT • COMMIT • CREATE • DECLARE GLOBAL TEMPORARY TABLE • DELETE • DROP • EXPLAIN • FREE LOCATOR • GRANT	• SET CURRENT APPLICATION COMPATIBILITY • SET CURRENT DEGREE • SET CURRENT DEBUG MODE • SET CURRENT DECFLOAT ROUNDING MODE • SET CURRENT EXPLAIN MODE • SET CURRENT LOCALE LC_CTYPE • SET CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION • SET CURRENT OPTIMIZATION HINT • SET CURRENT PRECISION • SET CURRENT QUERY ACCELERATION • SET CURRENT REFRESH AGE

Statements	Statements
• HOLD LOCATOR	• SET CURRENT ROUTINE VERSION
• INSERT	• SET CURRENT RULES
• LABEL	• SET CURRENT SQLID
• LOCK TABLE	• SET PATH
• MERGE	• SET SCHEMA
• REFRESH TABLE	• SET CURRENT TEMPORAL BUSINESS_TIME
• RELEASE SAVEPOINT RENAME	• SET CURRENT TEMPORAL SYSTEM_TIME
• REVOKE	• SET SESSION TIME ZONE
• ROLLBACK	• SIGNAL
• SAVEPOINT	• TRANSFER OWNERSHIP
• *select-statement*	• TRUNCATE
• SET *assignment-statement*	• UPDATE
• SET CURRENT ACCELERATOR	

The statement string must not have any of the following attributes:

- Begin with EXEC SQL
- End with END-EXEC or a semicolon
- Include references to variables, other than global variables
- Include references to transition variables

Parameter markers:

Although a statement string cannot include references to variables, other than global variables, it can include *parameter markers*. The parameter markers are replaced by the values of variables when the prepared statement is executed. A parameter marker is a question mark (?) that appears where a variable could appear if the statement string were a static SQL statement.

For an explanation of how parameter markers are replaced by values, see the EXECUTE statement, “OPEN” on page 2032, and Dynamically executing a data change statement (Db2 Application programming and SQL).

The two types of parameter markers are typed and untyped:

Typed parameter marker

A parameter marker that is specified with its target data type. A typed parameter marker has the general form:

```
    CAST(? AS data-type)
```

This invocation of a CAST specification is a "promise" that the data type of the parameter at run time will be of the data type that is specified or some data type that is assignable to the specified data type. For example, in the following UPDATE statement, the value of the argument of the TRANSLATE function will be provided at run time:

```
   UPDATE EMPLOYEE
     SET LASTNAME = TRANSLATE(CAST(? AS VARCHAR(12)))
    WHERE EMPNO = ?
```

The data type of the value that is provided for the TRANSLATE function will either be VARCHAR(12), or some data type that can be converted to VARCHAR(12). For more information, refer to “Assignment and comparison” on page 143.

Typed parameter markers can be used in dynamic SQL statements wherever a host variable is supported and the data type is based on the promise made in the CAST specification.

Untyped parameter marker

A parameter marker that is specified without its target data type. An untyped parameter marker has the form of a single question mark. The context in which the parameter marker appears determines its data type. For example, in the above UPDATE statement, the data type of the untyped parameter marker in the predicate is the same as the data type of the EMPNO column.

Untyped parameters markers can be used in dynamic SQL statements in selected locations where variables are supported. These locations and the resulting data type are found in the following tables. The tables group the locations into expressions, predicates, functions, and other statements to help show where untyped parameter markers are allowed. Untyped parameter markers are not supported in other locations.

Expressions

Location of untyped parameter marker	Data type (or error if not supported)
Alone in a select list. For example: `SELECT ?`	Error
Both operands of a single arithmetic operator, after considering operator precedence and the order of operation rules. Includes cases such as: `? + ? + 10`	DECFLOAT(34)
One operand of a single operator in an arithmetic expression (except datetime arithmetic expressions). Includes cases such as: `? + ? * 10`	The data type of the other operand
Any operand of a datetime expression. For example: `'timecol + ?' or '? - datecol'`	Error
A labeled duration in a datetime expression with a type unit other than SECONDS (the portion of a labeled duration that indicates the type of units cannot be a parameter marker).	DECIMAL(15,0)
A labeled duration in a datetime expression with a type unit of SECONDS (the portion of a labeled duration that indicates the type of units cannot be a parameter marker).	DECIMAL(27,12)
Both operands of a CONCAT operator	Error
One operand of a CONCAT operator when the other operand is any character data type except CLOB	If the other operand is CHAR(*n*) or VARCHAR(*n*), where n is less than 128, the data type is VARCHAR(254 - *n*). In all other cases, the data type is VARCHAR(254).
One operand of a CONCAT operator when the other operand is any graphic data type except DBCLOB	If the other operand is GRAPHIC(*n*) or VARGRAPHIC(*n*), where n is less than 64, the data type is VARGRAPHIC(127 -

Location of untyped parameter marker	Data type (or error if not supported)
	n). In all other cases, the data type is VARGRAPHIC(127).
One operand of a CONCAT operator when the other operand is any binary type except BLOB	If the other operand is BINARY(n) or VARBINARY(n) where n is less than 128, the data type is VARBINARY(255-n). In all other cases, the data type is VARBINARY(255)
One operand of a CONCAT operator when the other operand is a LOB string	The data type of the other operand (the LOB string)
The *expression* following the CASE keyword in a simple CASE expression	Error
Any or all *expressions* following the WHEN keyword in a simple CASE expression	The result of applying the "Rules for result data types" on page 166 to the expression following CASE and the expressions following WHEN that are not untyped parameter markers
A *result-expression* in any CASE expression when all the other *result-expression*s are either NULL or untyped parameter markers.	Error
A *result-expression* in any CASE expression when at least one other *result-expression* is neither NULL nor an untyped parameter marker.	The result of applying the "Rules for result data types" on page 166 to all the *result-expression*s that are not NULL or untyped parameter markers
Alone as a *column-expression* in a single-row VALUES clause that is not within an INSERT statement or the VALUES clause of in insert operation of a MERGE statement	Error
Alone as a *column-expression* in a single-row VALUES clause within an INSERT statement	The data type of the column or, if the column is defined as a distinct type, the source data type of the distinct type
Alone as a *column-expression* in a *values-single-row* or *values-multiple-row* clause of *source-table* for a MERGE statement	The data type of the column of the source-table, or if the data type is a distinct type, the source data type of the distinct type. The column of the source-table must be referenced elsewhere in the MERGE statement such that its data type can be determined from the context in which it is used, and all such references must resolve to the same data type.
Alone as a *column-expression* in the VALUES clause of an insert operation of a MERGE statement	The data type of the column or, if the column is defined as a distinct type, the source data type of the distinct type
Alone as a *column-expression* on the right side of *assignment-clause* for an update operation of a MERGE statement	The data type of the column or, if the column is defined as a distinct type, the source data type of the distinct type
Alone as a *column-expression* on the right side of a SET clause in an UPDATE statement	The data type of the column or, if the column is defined as a distinct type, the source data type of the distinct type

Location of untyped parameter marker	**Data type (or error if not supported)**
Alone as *offset-row-count* in an OFFSET clause	BIGINT
Alone as *fetch-row-count* in a FETCH clause	BIGINT

Predicates

Location of untyped parameter marker	**Data type (or error if not supported)**
Both operands of a comparison operator	Error
One operand of a comparison operator when the other operand is not an untyped parameter marker	The data type of the other operand. If the operand has a datetime data type, the result of DESCRIBE INPUT will show the data type as CHAR(255) although Db2 uses the datetime data type in any comparisons.
All the operands of a BETWEEN predicate	Error
Two operands of a BETWEEN predicate (either the first and second, or the first and third)	The data type of the operand that is not a parameter marker
Only one operand of a BETWEEN predicate	The result of applying the "Rules for result data types" on page 166 on the other operands that are not parameter markers
All the operands of an IN predicate, for example, `? IN (?,?,?)`	Error
The first and second operands of an IN predicate, for example, `? IN (?,A,B)`	The result of applying the "Rules for result data types" on page 166 on the operands in the IN list that are not parameter markers
The first operand of an IN predicate and zero or more operands of the IN list except for the first operand of the IN list, for example, `? IN (A,?,B,?)`	The result of applying the "Rules for result data types" on page 166 on the operands in the IN list that are not parameter markers
The first operand of an IN predicate when the right side is a fullselect of fullselect, for example, `? IN (fullselect)`	The data type of the selected column
Any or all operands of the IN list of the IN predicate and the first operand of the IN predicate is not an untyped parameter marker, for example, `A IN (?,A,?)`	The data type of the first operand (the operand on the left side of the IN list)
All the operands of a LIKE predicate	The first and second operands (*match-expression* and *pattern-expression*) are VARCHAR(4000). The third operand (*escape-expression*) is VARCHAR(1).
The first operand of a LIKE predicate (the *match-expression*) when at least one other operand (the *pattern-expression* or *escape-expression*) is not an untyped parameter marker.	VARCHAR(4000), VARGRAPHIC(2000), or VARBINARY(4000), depending on the data type of the first operand that is not an untyped parameter marker
The second operand of a LIKE predicate (the *pattern-expression*) when at least one other	VARCHAR(4000), VARGRAPHIC(2000), or VARBINARY(4000), depending on the data

Location of untyped parameter marker	Data type (or error if not supported)
operand (the *match-expression* or *escape-expression*) is not an untyped parameter marker. When the pattern specified in a LIKE predicate is a parameter marker and a fixed-length character host variable is used to replace the parameter marker, specify a value for the host variable that is the correct length. If you do not specify the correct length, the select does not return the intended results.	type of the first operand that in not an untyped parameter marker.
The third operand of a LIKE predicate (the *escape-expression*) when at least one other operand (the *match-expression* or *pattern-expression*) is not an untyped parameter marker	CHAR(1), GRAPHIC(1), or BINARY(1), depending on the data type of the first operand that in not an untyped parameter marker
Operand of a NULL predicate	Error

Functions

Location of untyped parameter marker	Data type (or error if not supported)
All arguments of COALESCE or NULLIF	Error
Any argument of COALESCE or NULLIF when at least one other argument is not an untyped parameter marker	The result of applying the "Rules for result data types" on page 166 on the arguments that are not untyped parameter markers, the data type of the other argument
First argument of COLLATION_KEY	VARGRAPHIC(2000)
Second argument of COLLATION_KEY	VARCHAR(255)
First argument of LOWER	VARCHAR(4000)
Second argument of LOWER	VARCHAR(255)
Any argument other than the first argument of MAX	The data type of the corresponding parameter in the function instance
Any argument other than the first argument of MIN	The data type of the corresponding parameter in the function instance
Both arguments of POSSTR or POSITION	VARCHAR(4000) for both arguments
One argument of POSSTR or POSITION when the other argument is a character data type	VARCHAR(4000)
One argument of POSSTR or POSITION when the other argument is a graphic data type	VARGRAPHIC(2000)
One argument of POSSTR or POSITION when the other argument is a BINARY or VARBINARY data type	VARBINARY(4000)
One argument of POSSTR or POSITION when the other argument is a BLOB	BLOB(4000)
First argument of SUBSTR or SUBSTRING	VARCHAR(4000)

Location of untyped parameter marker	Data type (or error if not supported)
Second or third argument of SUBSTR or SUBSTRING	INTEGER
One argument of TIMESTAMP	TIME
First argument of TIMESTAMP_FORMAT	VARCHAR(255)
First argument of TRANSLATE	Error
Second or third argument of TRANSLATE	VARCHAR(4000), VARGRAPHIC(2000), depending on whether the data type of the first argument is character or graphic
Fourth argument of TRANSLATE	VARCHAR(1) or VARGRAPHIC(1), depending on whether the data type of the first argument is character or graphic
Second argument of TRIM_ARRAY	BIGINT
array-index for *array-element-specification*	BIGINT
First argument of UPPER	VARCHAR(4000)
Second argument of UPPER	VARCHAR(255)
First argument of VARCHAR_FORMAT	TIMESTAMP WITHOUT TIME ZONE
Unary minus	DECFLOAT(34)
Unary plus	Error
The argument of any built-in scalar function (except those that are described in this table)	Error
The argument of a built-in aggregate function	Error
The argument of a user-defined scalar function, user-defined aggregate function, or user-defined table function	The data type of the corresponding parameter in the function instance

Statements

Location of untyped parameter marker	Data type (or error if not supported)
FOR *n* ROWS clause of an INSERT or MERGE statement	Integer
The value on the right side of a SET clause in an UPDATE statement or the UPDATE clause of the MERGE statement	The data type of the column of the source-table, or if the column is defined as a distinct type, the source data type of the distinct type. The column of the source-table must be referenced elsewhere in the MERGE statement such that its data type can be determined from the context in which it is used, and all such references must resolve to the same data type.
value, *value1*, or *value2* in a period specification or period clause	The data type of the columns of the period referenced in the period specification or period clause

Location of untyped parameter marker	Data type (or error if not supported)
value, *value1*, or *value2* in a period specification for a table, or period clause for a data change statement if the target of the statement is a table	The data type of the columns of the period referenced in the period specification or period clause
value, *value1*, or *value2* in a period specification for a view	Error
value1 or *value2* in a period clause in a data change statement if the target of the statement is a view	Error

Considerations for FETCH statements used with a sensitive static cursor:

Whether changes made outside the cursor are visible to the cursor depends on the type of FETCH that is used with a SENSITIVE STATIC cursor:

- A SENSITIVE FETCH is sensitive to all updates and deletes that are made by this cursor (including changes made by triggers) and committed updates and deletes by all other application processes because every fetched row is retrieved from the underlying base table and not a temporary table. This is the default type of FETCH statement for a SENSITIVE cursor.

  Changes that are made to the underlying data using this cursor result in an automatic refresh of the row. The changes that are made using this type of cursor can result in holes in the result table of the cursor. In addition, re-fetching rows (fetching rows that have already been retrieved) can result in holes in the result table. If a sensitive FETCH is issued to re-fetch a row and the row no longer qualifies for the search condition of the query, it results in a "delete hole" or an "update hole". In this case, no data is returned, and the cursor is left positioned on the hole.
- An INSENSITIVE FETCH is not sensitive to updates and deletes that are made outside this cursor; however, it is sensitive to all updates and deletes that are made by this cursor. Changes that made with triggers are not visible with an INSENSITIVE FETCH until the content of the rows are updated in the result table with a SENSITIVE FETCH statement. If an application does not want to be sensitive to changes that are made outside this cursor (that is, the application does not want to see changes made either with another cursor or by another application process), INSENSITIVE can be explicitly specified as part of the FETCH statement for a SENSITIVE STATIC cursor. This type of FETCH is useful for refreshing data in user data buffers. For more information, see INSENSITIVE.

Error checking:

When a PREPARE statement is executed, the statement string is parsed and checked for errors. If the statement string is invalid, a prepared statement is not created and the error condition that prevents its creation is reported in the SQLCA.

In local and remote processing, the DEFER(PREPARE) and REOPT(ALWAYS)/REOPT(ONCE) bind options can cause some SQL statements to receive "delayed" errors. For example, DESCRIBE, EXECUTE, and OPEN might receive an SQLCODE that normally occurs during PREPARE processing.

Reference and execution rules:

Prepared statements can be referred to in the following kinds of statements, with the following restrictions:

Type of statement	Restriction for prepared statement
DESCRIBE	no restriction
DECLARE CURSOR	Statement must be SELECT when the cursor is opened
EXECUTE	Statement must not be SELECT

A prepared statement can be executed many times. Indeed, if a prepared statement is not executed more than once and does not contain parameter markers, it is more efficient to use the EXECUTE IMMEDIATE statement rather than the PREPARE and EXECUTE statements.

Prepared statement persistence:

All prepared statements created by a unit of work are destroyed when the unit of work is terminated, with the following exceptions:

- A SELECT statement whose cursor is declared with the option WITH HOLD persists over the execution of a commit operation if the cursor is open when the commit operation is executed.
- SELECT, INSERT, UPDATE, MERGE, and DELETE statements that are bound with KEEPDYNAMIC(YES) are kept past the point of commit or rollback if your system is enabled for dynamic statement caching, and none of the following are true:
  - SQL RELEASE has been issued for the site
  - Bind option DISCONNECT(AUTOMATIC) was used
  - Bind option DISCONNECT(CONDITIONAL) was used and there are no hold cursors for the site
- INSERT, UPDATE, MERGE, and DELETE statements that are bound with or use the RELEASE(DEALLOCATE) option and that reference a declared global temporary table are kept past commit operations unless one of the following statements is true:
  - The declared global temporary table is defined with the ON COMMIT DROP TABLE option.
  - The statement also references a Db2 base object (for example, a table or view), and one of the following statements is true:
    - The base object reference is for a Db2 catalog table.
    - At the commit point, Db2 determines that another Db2 thread is waiting for an X-lock on the base object's database descriptor (DBD).
    - The statement references an XML function or operation, and at the commit point Db2 determines that the base object DBD S-lock for the XML operation must be released.
    - At the commit point, Db2 determines that a base object DBD S-lock that is used by the statement must be released and cannot be maintained across the commit point.
  - Db2 determines that another Db2 thread is waiting for an X-lock on the Db2 package that contains the statement.

Scope of a statement name:

The scope of a *statement-name* is the same as the scope of a *cursor-name*. See “DECLARE CURSOR” on page 1814 for more information about the scope of a *cursor-name*.

Preparation with PREPARE INTO and REOPT bind option:

If bind option REOPT(ALWAYS) or REOPT(ONCE) is in effect, PREPARE INTO is equivalent to a PREPARE and a DESCRIBE being performed. If a statement has input variables, the DESCRIBE causes the statement to be prepared with default values, and the statement must be prepared again when it is opened or executed. When REOPT(ONCE) is in effect, the statement is always prepared twice even if there are no input variables. Therefore, to avoid having a statement prepared twice, avoid using PREPARE INTO when REOPT(ALWAYS) or REOPT(ONCE) is in effect.

Relationship of cursor attributes on PREPARE statements and SELECT or DECLARE CURSOR statements:

Cursor attributes that are specified as part of the *select-statement* are used instead of any corresponding options that specified with the ATTRIBUTES clause on PREPARE. Attributes that are specified as part of the ATTRIBUTES clause of PREPARE take precedence over any corresponding option that is specified with the DECLARE CURSOR statement. The order for using cursor attributes is as follows:

- SELECT (highest priority)
- PREPARE statement ATTRIBUTES clause
- DECLARE CURSOR (lowest priority)

For example, assume that host variable MYQ has been set to the following SELECT statement:

```
       SELECT WORKDEPT, EMPNO, SALARY, BONUS, COMM
            FROM EMP
           WHERE WORKDEPT IN ('D11', 'D21')
           FOR UPDATE OF SALARY, BONUS, COMM
```

If the following PREPARE statement were issued, then the FOR UPDATE clause specified as part of the SELECT statement would be used instead of the FOR READ ONLY clause specified with the ATTRIBUTES clause as part of the PREPARE statement. Thus, the cursor would be updatable.

```
      attrstring = 'FOR READ ONLY';
      EXEC SQL PREPARE stmt1 ATTRIBUTES :attrstring FROM :MYQ;
```

Effect of the CURRENT EXPLAIN MODE special register:
If the CURRENT EXPLAIN MODE special register is set to EXPLAIN, the statement is prepared for explain only and is not executable, unless the statement is a SET statement. Attempting to execute the prepared statement will return an error. See the "CURRENT EXPLAIN MODE special register" on page 194 special register for more information.

Precedence of attributes for SELECT and UPDATE WHERE CURRENT OF for positioned updates:
If an UPDATE WHERE CURRENT OF statement and the associated SELECT statement are both prepared and both statements have the same PREPARE attributes, the values of the PREPARE attributes for the UPDATE WHERE CURRENT OF statement override the values of the PREPARE attributes for the SELECT statement.

Effect of extended indicator PREPARE attributes on dynamically executed positioned updates:
If an UPDATE statement with the WHERE CURRENT OF clause and the associated SELECT statement are both prepared, if extended indicator variables are used depends on the WITH EXTENDED INDICATORS or WITHOUT EXTENDED INDICATORS attributes in each of the PREPARE statements.

Interaction between EXTENDED INDICATOR attributes of PREPARE statements for SELECT and UPDATE statements

Extended indicator attribute of PREPARE for SELECT statement	Extended indicator attribute of PREPARE for UPDATE statement with WHERE CURRENT OF clause	Result
WITH EXTENDED INDICATORS	WITH EXTENDED INDICATORS	The PREPARE attributes of the UPDATE statement override the PREPARE attributes of the SELECT statement. Non-updatable columns can be in the select-list.
WITH EXTENDED INDICATORS	WITHOUT EXTENDED INDICATORS	The UPDATE statement is executed without extended indicator parameters.
WITH EXTENDED INDICATORS	Default (without attribute specified)	The PREPARE attributes of the SELECT statement override the default PREPARE attributes for the UPDATE statement. Non-updatable columns can be in the select-list.
WITHOUT EXTENDED INDICATORS	WITH EXTENDED INDICATORS	The PREPARE attributes of the UPDATE statement override the PREPARE attributes of the SELECT statement. Non-updatable columns are not in the implicit or explicit select-list.
WITHOUT EXTENDED INDICATORS	WITHOUT EXTENDED INDICATORS	The UPDATE statement is executed without extended indicator parameters.
WITHOUT EXTENDED INDICATORS	Default (without attribute specified)	The PREPARE attributes of the SELECT statement override the default PREPARE attributes for the

Extended indicator attribute of PREPARE for SELECT statement	Extended indicator attribute of PREPARE for UPDATE statement with WHERE CURRENT OF clause	Result
		UPDATE statement. The UPDATE statement is executed without extended indicator parameters.
Default (without attribute specified)	WITH EXTENDED INDICATORS	The PREPARE attributes of the UPDATE statement override the PREPARE attributes of the SELECT statement. Non-updatable columns are not in the implicit or explicit select-list.
Default (without attribute specified)	WITHOUT EXTENDED INDICATORS	The PREPARE attributes of the UPDATE statement override the PREPARE attributes of the SELECT statement. The UPDATE statement is executed without extended indicator parameters.
Default (without attribute specified)	Default (without attribute specified)	The UPDATE statement is executed without extended indicator parameters.

Interactions between the SKIPUNCI subsystem parameter and the PREPARE statement:

When the PREPARE statement is specified with either the CURRENTLY COMMITTED or WAIT FOR OUTCOME clauses and the subsystem parameter SKIPUNCI is in effect, the following table describes whether uncommitted inserts are skipped, or if the transaction will wait until a commit or rollback before completing:

Interaction between SKIPUNCI subsystem parameter and PREPARE statement

Value of SKIPUNCI subsystem parameter	PREPARE statement attributeworking	Skip uncommitted inserts, or wait for commit or rollback
YES	CURRENTLY COMMITTED	Skip
YES	WAIT FOR OUTCOME	Wait
YES	Not specified	Skip
NO	CURRENTLY COMMITTED	Skip
NO	WAIT FOR OUTCOME	Wait
NO	Not specified	Wait

Extended indicator variables and deferred error checks:

When extended indicator variables are enabled, the indicator value of unassigned causes the associated target column to be omitted from the statement. Because of that, validation that is normally done in statement preparation (to recognize an INSERT into, or UPDATE of, a non-updatable column) is deferred until statement execution. If statement validation fails, an error is returned when the statement is run, not when the statement is prepared.

Reuse of prepared statements in the dynamic statement cache with `CONCENTRATE STATEMENTS WITH LITERALS`

To be eligible for reuse of constants, the constants in both the new statement and the cached statement must have the same:

1. immediate usage context
2. data type
3. data type length and size

If Db2 determines that both instances of the constant meet the criteria for reuse, a cached statement that is prepared using the CONCENTRATE STATEMENTS WITH LITERALS option can be shared by the same SQL statement with different constants. Even though the new dynamic SQL statement will share the cached statement, the new statement will use its own literal constants when the statement is run, not the constants of the cached statement.

There are some exceptions. For example, the built-in function SUBSTR, for which, because of the immediate usage context, constant reuse in the cached statement that uses a different constant value can not be done without the risk of returning incorrect output or results. In such cases, only an SQL statement instance with the exact same constant value as the cached version of the statement is eligible for reuse. Db2 determines when and where this immediate usage context restriction applies.

When the CONCENTRATE STATEMENTS WITH LITERALS option is specified, Db2 considers the values of the literal constants for access path selection only for statements that are bound with the REOPT(ONCE) or REOPT(AUTO) bind options.

The DECFLOAT defined constants NAN, SNAN, and INFINITY can qualify for literal constant reuse.

The following examples show how PREPARE is used with CONCENTRATE STATEMENTS WITH LITERALS. X, Y, and Z are columns of defined as DECIMAL data type:

```
DECLARE C1 CURSOR
    FOR DYNSQL_WITH_LITERAL;

DYNSQL_SELECT = ‘SELECT X, Y, Z
                                FROM TABLE1
                                WHERE X < 9';

attrstring = ‘CONCENTRATE STATEMENTS WITH LITERALS';

EXEC SQL PREPARE DYNSQL_WITH_LITERAL
    ATTRIBUTES :attrstring
    FROM :DYNSQL_SELECT;

EXEC SQL OPEN C1;
```

```
DYNSQL_INSERT = ‘INSERT INTO
                                TABLE1 (X, Y, Z)
                                VALUES (8,109,29)';

attrstring = ‘CONCENTRATE STATEMENTS WITH LITERALS';

EXEC SQL PREPARE DYNSQL_INSERT_WITH_LITERAL
     ATTRIBUTES :attrstring
     FROM :DYNSQL_INSERT;

EXEC SQL EXECUTE DYNSQL_INSERT_WITH_LITERAL;
```

Examples for PREPARE

Example 1

In this PL/I example, an INSERT statement with parameter markers is prepared and executed. Before execution, values for the parameter markers are read into the host variables S1, S2, S3, S4, and S5.

```
   EXEC SQL PREPARE DEPT_INSERT FROM
     'INSERT INTO DSN8C10.DEPT VALUES(?,?,?,?,?)';
   -- Check for successful execution and read values into host variables
   EXEC SQL EXECUTE DEPT_INSERT USING :S1, :S2, :S3, :S4, :S5;
```

Example 2

Prepare a dynamic SELECT statement specifying the attributes of the cursor with a host variable on the PREPARE statement. Assume that the text of the SELECT statement is in a variable named stmttxt, and that the attributes of the cursor are in a variable named attrvar.

```
     EXEC SQL DECLARE mycursor CURSOR FOR mystmt;
     EXEC SQL PREPARE mystmt ATTRIBUTES :attrvar
                 FROM :stmttxt;
     EXEC SQL DESCRIBE mystmt INTO :mysqlda;
```

```
    EXEC SQL OPEN mycursor;
    EXEC SQL FETCH FROM mycursor USING DESCRIPTOR :mysqlda;
```

REFRESH TABLE

The REFRESH TABLE statement refreshes the data in a materialized query table. The statement deletes all rows in the materialized query table, executes the fullselect in the table definition to recalculate the data from the tables specified in the fullselect, inserts the calculated result into the materialized query table, and updates the catalog for the refresh timestamp and cardinality of the table. The table can exist at the current server or at any Db2 subsystem with which the current server can establish a connection.

Invocation for REFRESH TABLE

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES RUN behavior is in effect. For more information, see "Authorization IDs and dynamic SQL" on page 94.

Authorization for REFRESH TABLE

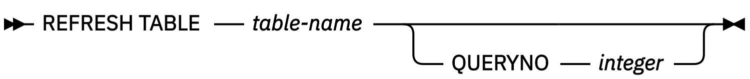
The privilege set for REFRESH TABLE must include at least one of the following authorities:

- Ownership of the materialized query table
- DBADM or DBCTRL authority on the database that contains the materialized query table
- SYSADM or SYSCTRL authority
- DATAACCESS authority

If the database is implicitly created, the database privileges must be on the implicit database or on DSNDB04.

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the statements dynamically prepared, the privilege set is determined by the DYNAMICRULES behavior in effect (run, bind, define, or invoke). For more information on these behaviors, including a list of the DYNAMICRULES bind option values, see "Authorization IDs and dynamic SQL" on page 94.

Syntax for REFRESH TABLE



Description for REFRESH TABLE

table-name
Identifies the table to be refreshed. The name must identify a materialized query table. REFRESH TABLE evaluates the fullselect in the *materialized-query-definition* clause to refresh the table. The isolation level for the fullselect is the isolation level of the materialized query table recorded when CREATE TABLE or ALTER TABLE was issued.

QUERYNO *integer*
Specifies the number to be used for this SQL statement in EXPLAIN output and trace records. The number is used for the QUERYNO column of the plan table for the rows that contain information about this SQL statement. This number is also used in the QUERYNO column of the SYSIBM.SYSSTMT and SYSIBM.SYSPACKSTMT catalog tables.

If the clause is omitted, the number associated with the SQL statement is the statement number assigned during precompilation. Thus, if the application program is changed and then precompiled, that statement number might change.

Notes for REFRESH TABLE

Automatic query rewrite using materialized query tables is not attempted for the fullselect in the materialized query table definition during the processing of REFRESH TABLE statement.

After successful execution of a REFRESH TABLE statement, the SQLCA field SQLERRD(3) will contain the number of rows inserted into the materialized query table.

The EXPLAIN output for REFRESH TABLE *table-name* is the same as the EXPLAIN output for INSERT INTO *table-name fullselect* where *fullselect* is from the materialized query table definition.

If the materialized query table has a security label column, the REFRESH TABLE statement does not do any checking for multilevel security with row-level granularity when it deletes and repopulates the data in the table by executing the fullselect. Instead, Db2 performs the checking for multilevel security with row-level granularity when the materialized query table is exploited in automatic query rewrite or is used directly.

The REFRESH TABLE statement can be used to remove a table space from the logical page list and reset recover-pending status. This can only be done by using REFRESH TABLE to repopulate a materialized query table where the materialized query table is the only table in the table space.

Example for REFRESH TABLE

Issue a statement to refresh the content of a materialized query table that is named SALESCOUNT. The statement recalculates the data from the fullselect that was used to define SALESCOUNT and refreshes the content of SALESCOUNT with the recalculated results.

```
REFRESH TABLE SALESCOUNT;
```

RELEASE (connection)

The RELEASE (connection) statement places one or more connections in the release pending state.

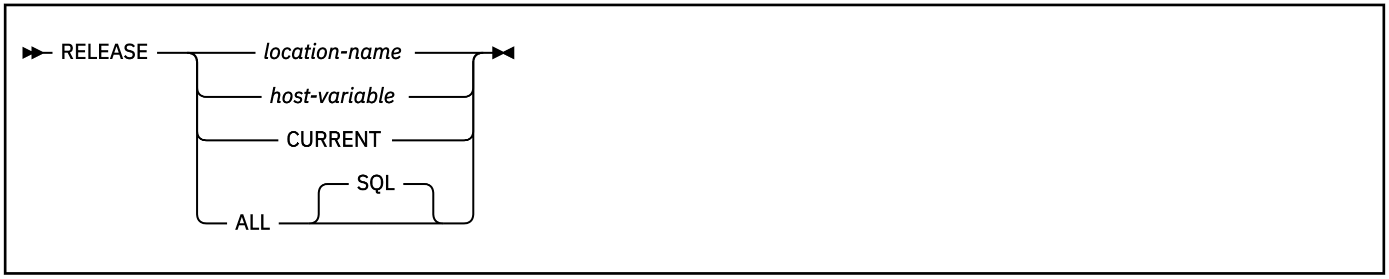
Invocation for RELEASE (connection)

This statement can only be embedded in an application program. It is an executable statement that cannot be dynamically prepared. It must not be specified in Java.

Authorization for RELEASE (connection)

None required.

Syntax for RELEASE (connection)



Description for RELEASE (connection)

location-name* or *host-variable

Identifies an SQL connection by the specified location name or the location name contained in the host variable. If a host variable is specified:

- It must be a character string variable with a length attribute that is not greater than 16. (A C NUL-terminated character string can be up to 17 bytes.)
- It must not be followed by an indicator variable.
- The location name must be left-justified within the host variable and must conform to the rules for forming an ordinary location identifier.
- If the length of the location name is less than the length of the host variable, it must be padded on the right with blanks.

The specified location name or the location name contained in the host variable must identify an existing SQL connection of the application process.

CURRENT
Identifies the current SQL connection of the application process. The application process must be in the connected state.

ALL or ALL SQL
Identifies all existing connections (including local, and SQL) of the application process. An error or warning does not occur if no connections exist when the statement is executed.

If the RELEASE (connection) statement is successful, each identified connection is placed in the release-pending state and, therefore, will be ended during the next commit operation. If the RELEASE (connection) statement is unsuccessful, the connection state of the application process and the states of its connections are unchanged.

Notes for RELEASE (connection)

RELEASE and CONNECT (Type 1): Using CONNECT (Type 1) semantics does not prevent using RELEASE (connection).

Scope of RELEASE: RELEASE (connection) does not close cursors, does not release any resources, and does not prevent further use of the connection.

Resource considerations for remote connections: Resources are required to create and maintain remote connections. Thus, a remote connection that is not going to be reused should be in the release pending status and one that is going to be reused should not be in the release pending status. Remote connections can also be ended during a commit operation as a result of the DISCONNECT(AUTOMATIC) or DISCONNECT(CONDITIONAL) bind option.

If the current SQL connection is in the release pending status when a commit operation is performed, the connection is ended and the application process is in the unconnected state. In this case, the next executed SQL statement should be CONNECT or SET CONNECTION.

Connection states: ROLLBACK does not reset the state of a connection from release pending to held.

If the current SQL connection is in the release pending state when a commit operation is performed, the connection is ended and the application process is in the unconnected state. In this case, the next executed SQL statement must be CONNECT or SET CONNECTION.

For further information, see "Application process connection states" on page 71.

Location names CURRENT and ALL: A database server named CURRENT or ALL can only be identified by a host variable or a delimited identifier. A connection in the release pending state is ended during a commit operation even though it has an open cursor defined with WITH HOLD.

Encoding scheme of a host variable: If the RELEASE statement contains host variables, the contents of the host variables are assumed to be in the encoding scheme that was specified in the ENCODING parameter when the package or plan that contains the statement was bound.

Examples for RELEASE (connection)

Example 1: The SQL connection to TOROLAB1 is not needed in the next unit of work. The following statement causes it to be ended during the next commit operation:

```
EXEC SQL RELEASE TOROLAB1;
```

Example 2: The current SQL connection is not needed in the next unit of work. The following statement causes it to be ended during the next commit operation:

```
EXEC SQL RELEASE CURRENT;
```

RELEASE SAVEPOINT

The RELEASE SAVEPOINT statement releases the identified savepoint and any subsequently established savepoints within a unit of recovery.

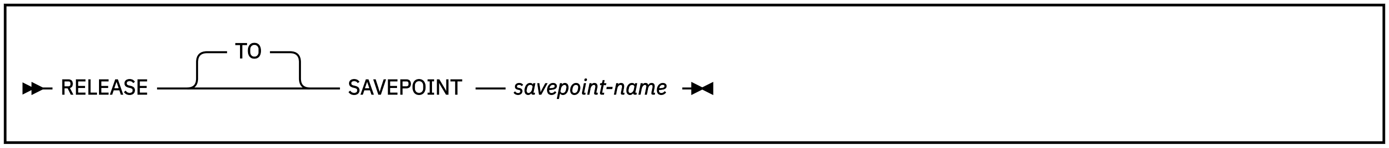
Invocation for RELEASE SAVEPOINT

This statement can be imbedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization for RELEASE SAVEPOINT

None required.

Syntax for RELEASE SAVEPOINT



Description for RELEASE SAVEPOINT

savepoint-name
Identifies the savepoint to release. If the named savepoint does not exist, an error occurs. The name must identify a savepoint that exists at the current server. After a savepoint is released, it is no longer maintained and rollback to the savepoint is no longer possible.

Notes for RELEASE SAVEPOINT

Savepoint names: The name of the savepoint that was released can be reused in another SAVEPOINT statement, regardless of whether the UNIQUE keyword was specified on an earlier SAVEPOINT statement that specified this same savepoint name.

Example for RELEASE SAVEPOINT

Assume that a main routine sets savepoint A and then invokes a subroutine that sets savepoints B and C. When control returns to the main routine, release savepoint A and any subsequently set savepoints. Savepoints B and C, which were set by the subroutine, are released in addition to A.

```
    ⋮
RELEASE SAVEPOINT A;
```

RENAME

The RENAME statement renames an existing table or index. An accelerator-only table cannot be renamed.

Invocation for RENAME

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES RUN behavior is in effect. For more information, see "Authorization IDs and dynamic SQL" on page 94.

Authorization for RENAME

To rename a table, the privilege set that is defined below must include at least one of the following privileges:

- Ownership of the table
- DBADM, DBCTRL, or DBMAINT authority for the database that contains the table
- SYSADM or SYSCTRL authority
- System DBADM

If the database is implicitly created, the database privileges must be on the implicit database or on DSNDB04.

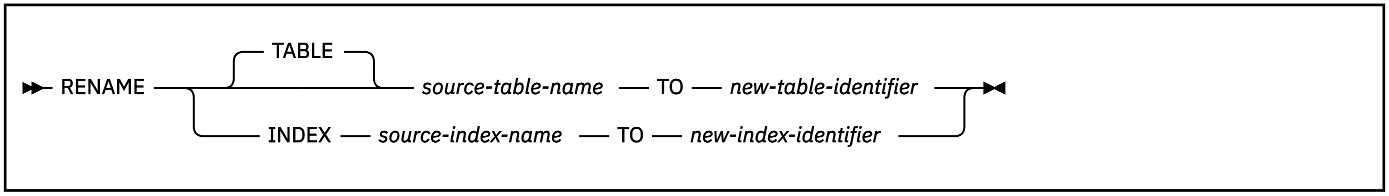
To rename an index, the privilege set that is defined below must include at least one of the following privileges:

- Ownership of the table for which the index is defined
- Ownership of the index that is being renamed
- DBADM, DBCTRL, or DBMAINT authority for the database that contains the index
- SYSADM or SYSCTRL authority
- System DBADM

If the database is implicitly created, the database privileges must be on the implicit database or on DSNDB04.

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the statement is dynamically prepared, the privilege set is the union of the privilege sets that are held by each authorization ID of the process.

Syntax for RENAME



Description for RENAME

source-table-name

Identifies the existing table that is to be renamed. The name, including the implicit or explicit qualifier, must identify a table that exists at the current server. The name must not identify any of the following types of tables:

- A declared temporary table
- A catalog table
- A directory table

- An active resource limit specification table
- A materialized query table
- A clone table
- A system-period temporal table
- A history table for a system-period temporal table
- A table with a trigger defined on it
- A table that is referenced in the definition of a row permission
- A table that is referenced in the definition of a column mask
- A view
- A synonym
- An archive-enabled table
- An archive table
- An SQL table function

If you specify a three-part name or alias for the source table, the source table must exist at the current server. If any view definitions or materialized query table definitions currently reference the source table, an error occurs.

new-table-identifier

Specifies the new name for the table without a qualifier. The qualifier of the *source-table-name* is used to qualify the new name for the table. The qualified name must not identify a table, view, alias, or synonym that exists at the current server, or a table that exists in the SYSIBM.SYSPENDINGOBJECTS catalog table.

For more information, see Guidelines for table names (Db2 Administration Guide).

source-index-name

Identifies the existing index that is to be renamed. The name, including an implicit or explicit qualifier, must identify an index that exists at the current server. The name must not identify a system defined catalog index, a directory index, an index on a declared temporary table, or an index on an active resource limit specification table.

new-index-identifier

Specifies that new name for the index without a qualifier. The qualifier of the *source-index-name* is used to qualify the new name for the index. The qualified name must not identify an index that exists at the current server or an index that exists in the SYSIBM.SYSPENDINGOBJECTS catalog table.

For more information, see Index names and guidelines (Db2 Administration Guide).

Notes for RENAME

Effects of the statement

The specified table or index is renamed to the new name. For a renamed table, all privileges and indexes on the table are preserved. For a renamed index, all privileges are preserved.

Invalidation of packages:

This statement might invalidate all packages that depend on target objects, and sometimes other related objects through cascading effects, depending on the clauses and keywords specified and other factors. For more information, see Changes that invalidate packages (Db2 Application programming and SQL).

Restriction when there are pending changes to the definition

A RENAME INDEX statement is not allowed if there are pending changes to the definition of the index.

A RENAME TABLE statement is not allowed if there are pending changes to the definition of the table .

Alias considerations

If an alias name is specified for *table-name*, the table must exist at the current server, and the table that is identified by the alias is renamed. The name of the alias is not changed and continues to refer to the old table name after the rename.

Changing the name of an alias with the RENAME statement is not supported. To change the name to which an alias refers, you must drop the alias and then re-create it.

PLAN_TABLE considerations

The RENAME INDEX statement does not update the contents of a plan table. Rows that exist in a plan table that are generated from a EXPLAIN statement can contain the name of an index in the access path selections. When an index is renamed, any entries in existing plan tables that refer to the old index name are not updated.

Transfer of authorization, referential integrity constraints, and indexes

All authorizations associated with the source table name are *transferred* to the new (target) table name. The authorization catalog tables are updated appropriately.

Referential integrity constraints involving the source table are updated to refer to the new table. The catalog tables are updated appropriately.

Indexes that are defined for the source table are *transferred* to the new table. The index catalog tables are updated appropriately.

Object identifier

Renamed tables and indexes keep the same object identifier as the original table or index.

Renaming registration tables

If an application registration table (ART) or object registration table (ORT) or an index of an ART or ORT is specified as the source table for RENAME, when RENAME completes, it is as if that table had been dropped. There is no ART or ORT once the ART or ORT table has been renamed.

Renaming a table with dependent views or SQL table functions

The RENAME TABLE statement returns an error if the target table is referenced in a view definition or an SQL table function, unless the RENAMETABLE subsystem parameter is set to ALLOW_DEP_VIEW_SQLTUDF.

Catalog table updates

Entries in the following catalog tables are updated to reflect the new table:

- SYSAUXRELS
- SYSCHECKS
- SYSCHECKS2
- SYSCHECKDEP
- SYSCOLAUTH
- SYSCOLDIST
- SYSCOLDIST_HIST
- SYSCOLDISTSTATS
- SYSCOLSTATS
- SYSCOLUMNS
- SYSCOLUMNS_HIST
- SYSCONSTDEP
- SYSFIELDS
- SYSFOREIGNKEYS
- SYSINDEXES
- SYSINDEXES_HIST
- SYSKEYCOLUSE
- SYSPLANDEP

- SYSPACKDEP
- SYSRELS
- SYSSEQUENCESDEP
- SYSSYNONYMS
- SYSTABAUTH
- SYSTABCONST
- SYSTABLES
- SYSTABLES_HIST
- SYSTABSTATS
- SYSTABSTATS_HIST

Entries in SYSSTMT and SYSPACKSTMT are not updated.

Entries in the following catalog tables are updated to reflect the new index:

- SYSDEPENDENCIES
- SYSINDEXES
- SYSINDEXES_HIST
- SYSINDEXESPART
- SYSINDEXESPART_HIST
- SYSINDEXSPACESTATS
- SYSINDEXSTATS
- SYSINDEXSTATS_HIST
- SYSKEYS
- SYSKEYTARGETS
- SYSKEYTARGETS_HIST
- SYSKEYTARGETSTATS
- SYSKEYTGTDIST
- SYSKEYTGTDIST_HIST
- SYSKEYTGTDISTSTATS
- SYSOBJROLEDEP
- SYSPACKDEP
- SYSPLANDEP
- SYSRELS
- SYSTABCONST
- SYSTABLEPART

Examples for RENAME

Example 1: Change the name of the EMP table to EMPLOYEE:

```
RENAME TABLE EMP TO EMPLOYEE;
```

Example 2: Change the name of the EMP_USA_HIS2002:

```
RENAME TABLE EMP_USA_HIS2002 TO EMPLOYEE_UNITEDSTATES_HISTORY2002;
```

Example 3: Change the name of the EMPINDX1 to EMPLOYEE_INDEX:

```
RENAME INDEX COMPANY.EMPINDX1 TO EMPLOYEE_INDEX;
```

REVOKE

The REVOKE statement revokes privileges from authorization IDs.

A separate form of the statement exists for each of the following privilege classes:

- Collection
- Database
- Function or stored procedure
- Package
- Plan
- Schema
- Sequence
- System
- Table or view
- Type or JAR file
- Variable
- Use

The applicable objects are always at the current server.

Invocation for REVOKE

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES RUN behavior is in effect. For more information, see "Authorization IDs and dynamic SQL" on page 94.

If the authorization mechanism was not activated when the Db2 subsystem was installed, an error condition occurs.

Authorization for REVOKE

If the BY clause is not specified, the authorization ID of the statement must have granted at least one of the specified privileges to every *authorization-name* specified in the FROM clause (including PUBLIC, if specified). If the BY clause is specified, the authorization ID of the statement must have SECADM or ACCESSCTRL authority.

Note: If installation parameter SEPARATE SECURITY is NO, SYSADM authority has implicit SECADM authority and SYSCTRL authority has implicit ACCESSCTRL authority.

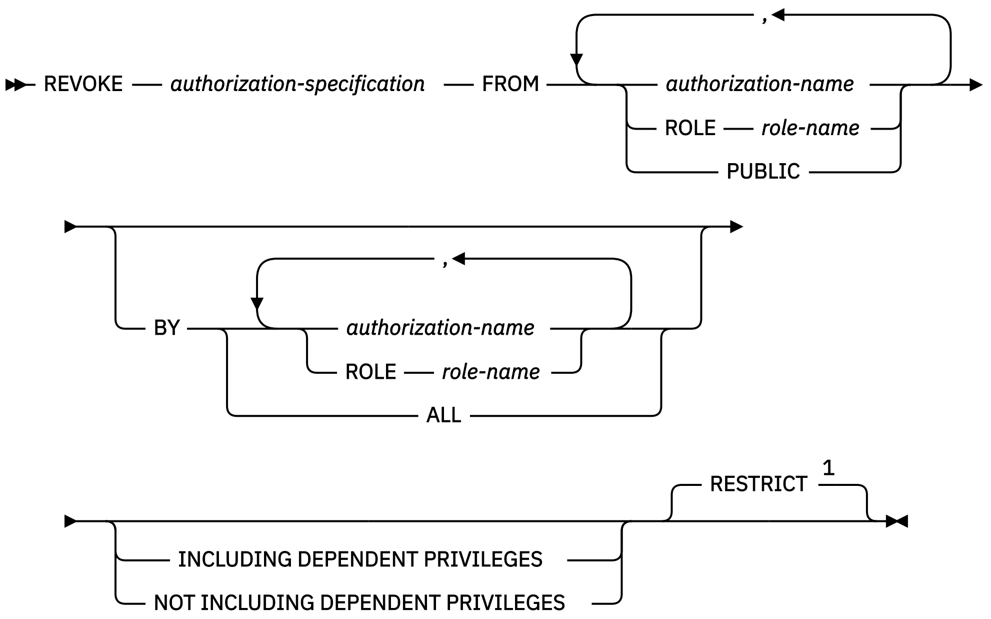
If the BY clause is specified and the privilege set includes ACCESSCTRL, all privileges and authorities can be revoked except for the following:

- System DBADM
- ACCESSCTRL
- DATAACCESS
- CREATE_SECURE_OBJECT privilege

To revoke the CREATE_SECURE_OBJECT privilege, with or without the BY clause, the privilege set must include SECADM authority.

If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. The owner can be a role. If the statement is dynamically prepared, the privilege set is the privileges that are held by the SQL authorization ID of the process. However, if the process is running in a trusted context that is defined with the ROLE AS OBJECT OWNER AND QUALIFIER CLAUSE, the privilege set is the privileges that are held by the role that is in effect.

Syntax for REVOKE



Notes:

[1] The RESTRICT clause is the default only for the forms of the REVOKE statement that allow it.

Description for REVOKE

authorization-specification
Specifies one or more privileges for the class of privilege. The same privilege must not be specified more than once.

FROM
Specifies from what authorization IDs the privileges are revoked.

authorization-name,...
Lists one or more authorization IDs. Do not use the same authorization ID more than one time. If the *authorization-name* is specified in lowercase, it must be delimited using double quotes.

The value of CURRENT RULES determines if you can use the ID of the REVOKE statement itself (to revoke privileges from yourself). When CURRENT RULES is:

Db2
You cannot use the ID of the REVOKE statement.

STD
You can use the ID of the REVOKE statement.

ROLE *role-name*
Lists one or more roles. Do not specify the same role more than one time.

PUBLIC
Revokes a grant of privileges to PUBLIC.

BY
Lists grantors who have granted privileges and revokes each named privilege that was explicitly granted to some named user by one of the named grantors. Only an authorization ID or role with

SYSADM or SYSCTRL authority can use BY, even if the authorization ID or role names only itself in the BY clause.

authorization-name,...

Lists one or more authorization IDs of users who were the grantors of the privileges named. Do not use the same authorization ID more than once. Each grantor that is listed must have explicitly granted some named privilege to all of the named users or roles.

ROLE *role-name*

Lists one or more roles that were the grantors of the privileges named. Do not specify the same role more than one time. Each grantor that is listed must have explicitly granted some named privilege to all of the named users or roles.

ALL

Revokes each named privilege from all named users who were explicitly granted the privilege, regardless of who granted it.

`INCLUDING DEPENDENT PRIVILEGES` or `NOT INCLUDING DEPENDENT PRIVILEGES`

Specifies whether revoking a privilege or an authority from an authorization ID or a role also results in revoking the grants that were made by that user. The default value is based on the authority that is being revoked and the REVOKE_DEP_PRIVILEGES system parameter:

- When ACCESSCTRL, DATAACCESS, or system DBADM authority is revoked, `NOT INCLUDING DEPENDENT PRIVILEGES` is assumed and the clause must be specified on the REVOKE statement.
- When the REVOKE_DEP_PRIVILEGES system parameter is set to NO, `NOT INCLUDING DEPENDENT PRIVILEGES` is assumed and an error is returned if the statement includes `INCLUDING DEPENDENT PRIVILEGES`.
- Otherwise, `INCLUDING DEPENDENT PRIVILEGES` is assumed and the clause must be specified on the REVOKE statement.

`INCLUDING DEPENDENT PRIVILEGES`

Specifies that revoking a privilege or an authority from an authorization ID or a role also results in revoking dependent privileges. This means that any grants that were made by the user will continue to be revoked, until all grants in the chain have been revoked.

`INCLUDING DEPENDENT PRIVILEGES` cannot be specified if the system parameter REVOKE_DEP_PRIVILEGES is set to NO, which enforces the behavior to not include the dependent privileges.

`NOT INCLUDING DEPENDENT PRIVILEGES`

Specifies that revoking a privilege or an authority from an authorization ID or a role does not cause the grants that were made by the user to be revoked. However, for the revoked privileges, all implications of the privilege being revoked are applied. For example, if the revoked privileges were required to bind a package successfully, that package would continue to be invalidated as a result of the package owner losing these privileges. An object might be dropped if a privilege is revoked that was used to create the object.

`NOT INCLUDING DEPENDENT PRIVILEGES` must be specified when ACCESSCTRL, DATAACCESS, or system DBADM authority is revoked.

`NOT INCLUDING DEPENDENT PRIVILEGES` cannot be specified if the system parameter REVOKE_DEP_PRIVILEGES is set toYES, which enforces the behavior to include dependent privileges in the revoke.

RESTRICT

Prevents the named privilege from being revoked when certain conditions apply. RESTRICT is the default only for the forms of the REVOKE statement that allow it. These forms are revoking the USAGE privilege on distinct types, the EXECUTE privilege on user-defined functions and stored procedures, the USAGE privilege on sequences, and READ or WRITE privileges for variables.

Notes for REVOKE

Revoked privileges

The privileges revoked from an authorization ID or a role are those that are identified in the statement and which were granted to the user by the grantor. Other privileges can be revoked as the result of revoking dependent privileges. For more on Db2 privileges, see Privileges and authorities (Managing Security).

Revoke dependent privileges

Revoking a privilege from a user can also cause that privilege to be revoked from other users. This was previously known as *cascade revoke*. When revoking a privilege from an authorization ID or a role, Db2 looks for and revokes any grants of the privilege where the grantor is the same as the authorization ID or role of the original revoke. The following rules must be true for privilege P' to be revoked from U3 when U1 revokes privilege P from U2:

- P and P' are the same privilege.
- U2 granted privilege P' to U3.
- No one granted privilege P to U2 prior to the grant by U1.
- U2 does not have installation SYSADM authority.

The rules also apply to the implicit grants that are made as a result of a CREATE VIEW statement.

Revoking dependent privileges does not occur under any of the following conditions:

- The privilege was granted by a current installation SYSADM user.
- The privilege is the USAGE privilege on a distinct type and the revokee owns any of these items:
  - A user-defined function or stored procedure that uses the distinct type
  - A table that has a column that uses the distinct type
  - A sequence whose data type is the distinct type
- The privilege is the USAGE privilege on a sequence and the revokee owns any of these items:
  - A trigger that has a NEXT VALUE or PREVIOUS VALUE expression that specifies the sequence
  - An inline SQL function that has a NEXT VALUE or PREVIOUS VALUE expression in the function body that specifies the sequence
- The privilege is the EXECUTE privilege on a user-defined function and the revokee owns any of these items:
  - A user-defined function that is sourced on the function
  - A view that uses the function
  - A trigger package that uses the function
  - A table that uses the function in a check constraint or a user-defined default type
- The privilege is the EXECUTE privilege on a stored procedure and the revoke owns any of these items:
  - A trigger package that refers to the stored procedure in a CALL statement.
- If the ACCESSCTRL administrative authority is revoked from a user, grants that are made by this ACCESSCTRL user are not revoked.

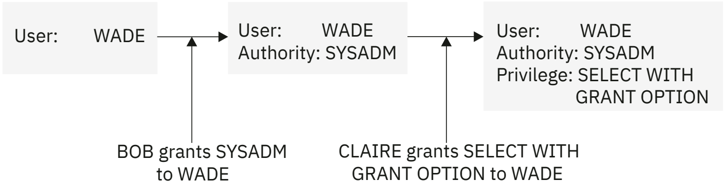
  If this user revoked grants made by it, those revokes will continue to revoke the dependent privileges, unless the behavior to not include the dependent privileges was specified either by using the system parameter REVOKE_DEP_PRIVILEGES or by using the REVOKE statement if REVOKE_DEP_PRIVILEGES is set to SQLSTMT.
- If SECADM is removed from a user, grants that are made by this SECADM user are not revoked.

  If this user revoked grants made by it, those revokes will continue to revoke the dependent privileges, unless the behavior to not include the dependent privileges was specified either by using the system parameter REVOKE_DEP_PRIVILEGES or by using the REVOKE statement if REVOKE_DEP_PRIVILEGES is set to SQLSTMT.

- If NOT INCLUDING DEPENDENT PRIVILEGES option is specified, the grants made by this user are not revoked.

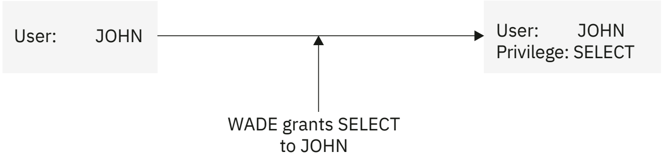
Refer to the diagrams for the following example:

1. Suppose BOB grants SYSADM authority to WADE. Later, CLAIRE grants the SELECT privilege on a table with the WITH GRANT OPTION to WADE.

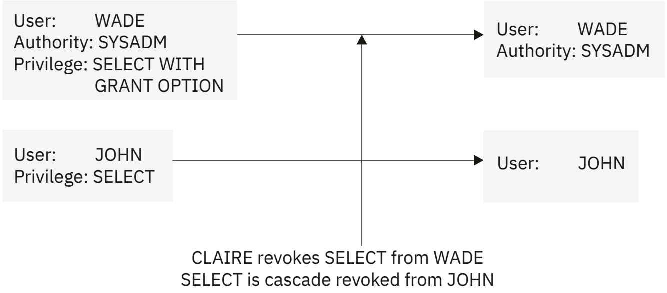


User: WADE
User: WADE
Authority: SYSADM
User: WADE
Authority: SYSADM
Privilege: SELECT WITH GRANT OPTION
BOB grants SYSADM to WADE
CLAIRE grants SELECT WITH GRANT OPTION to WADE

2. WADE grants the SELECT privilege to JOHN on the same table.



3. When CLAIRE revokes the SELECT privilege on the table from WADE, the SELECT privilege on that table is also revoked from JOHN.



User: WADE
Authority: SYSADM
Privilege: SELECT WITH GRANT OPTION
User: WADE
Authority: SYSADM
User: JOHN
Privilege: SELECT
User: JOHN
CLAIRE revokes SELECT from WADE
SELECT is cascade revoked from JOHN

The grant from WADE to JOHN is removed because WADE had not been granted the SELECT privilege from any other source before CLAIRE made the grant. The SYSADM authority granted to WADE from BOB does not affect the cascade revoke. For more on SYSADM and installation SYSADM authority, see Managing administrative authorities (Managing Security). For another example of cascading revokes, see Revoking privileges with the REVOKE statement (Managing Security).

Revoking a SELECT privilege that was exercised to create a view or materialized query table causes the view to be dropped, unless the owner of the view was directly granted the SELECT privilege from another source before the view was created. Revoking a SYSADM privilege that was required to create a view causes the view to be dropped. For details on when SYSADM authority is required to create a view, see *Authorization* in "CREATE VIEW" on page 1807.

Invalidation of packages

A revoke or cascaded revoke of any privilege or role that was exercised to create a package makes the package invalid when the revokee no longer holds the privilege from any other source. Corresponding authorization caches are cleared even if the revokee has the privilege from any other source. For more information, see Changes that invalidate packages (Db2 Application programming and SQL). [37]

Inoperative packages

A revoke or cascaded revoke of the EXECUTE privilege on a user-defined function that was exercised to create a package makes the package inoperative and causes the corresponding authorization caches to be cleared when the revokee no longer holds the privilege from any other source.[37]

Privileges belonging to an authority

You can revoke an administrative authority, but you cannot separately revoke the specific privileges inherent in that administrative authority.

Let P be a privilege inherent in authority X. A user with authority X can also have privilege P as a result of an explicit grant of P. In this case:

- If X is revoked, the user still has privilege P.
- If P is revoked, the user still has the privilege because it is inherent in X.

Revoking of privileges in a trusted context

Revokes that are made in a trusted context that is defined with the ROLE AS OBJECT OWNER clause result in the revoker being the role in effect. If the statement is prepared dynamically, the revoker is the role that is associated with the user that is running the statement. If the statement is embedded in a program, the revoker is the owner of the plan or package. If the ROLE AS OBJECT OWNER clause is not specified for the trusted context, the revoker is the authorization ID of the process.

Ownership privileges

The privileges inherent in the ownership of an object cannot be revoked.

Revoke not including dependent privileges

When a privilege is revoked from a user by specifying `NOT INCLUDING DEPENDENT PRIVILEGES`, the grants that were made by this user are not revoked and the grantor remains unchanged. If that user is later granted the same privilege and then this privilege is revoked by specifying `INCLUDING DEPENDENT PRIVILEGES`, that would also revoke all the grants that were previously made by this user. Refer to the following examples:

User U1 is granted SELECT on table T1 with GRANT OPTION:

1. U1 grants this privilege to U2.
2. SELECT privilege is revoked from U1 without including dependent privileges. As a result, the grant from U1 to U2 is not revoked.
3. U1 is again granted SELECT on T1.
4. SELECT is now revoked from U1 with including dependent privileges and the grant from U1 to U2 is now revoked.

1.

User U1 is granted SYSADM authority:

1. U1 grants privilege P1 to U2 and privilege P2 to U3.
2. SYSADM is revoked from U1 without including dependent privileges. The grants of privileges P1 and P2 to U2 and U3 are not revoked.
3. U1 is again granted SYSADM. U1 grants privilege P3 to U3.
4. SYSADM is now revoked from U1 including dependent privileges. Now, P1 granted to U2 and P2 and P3 granted to U3 are also revoked.

1.

Related tasks

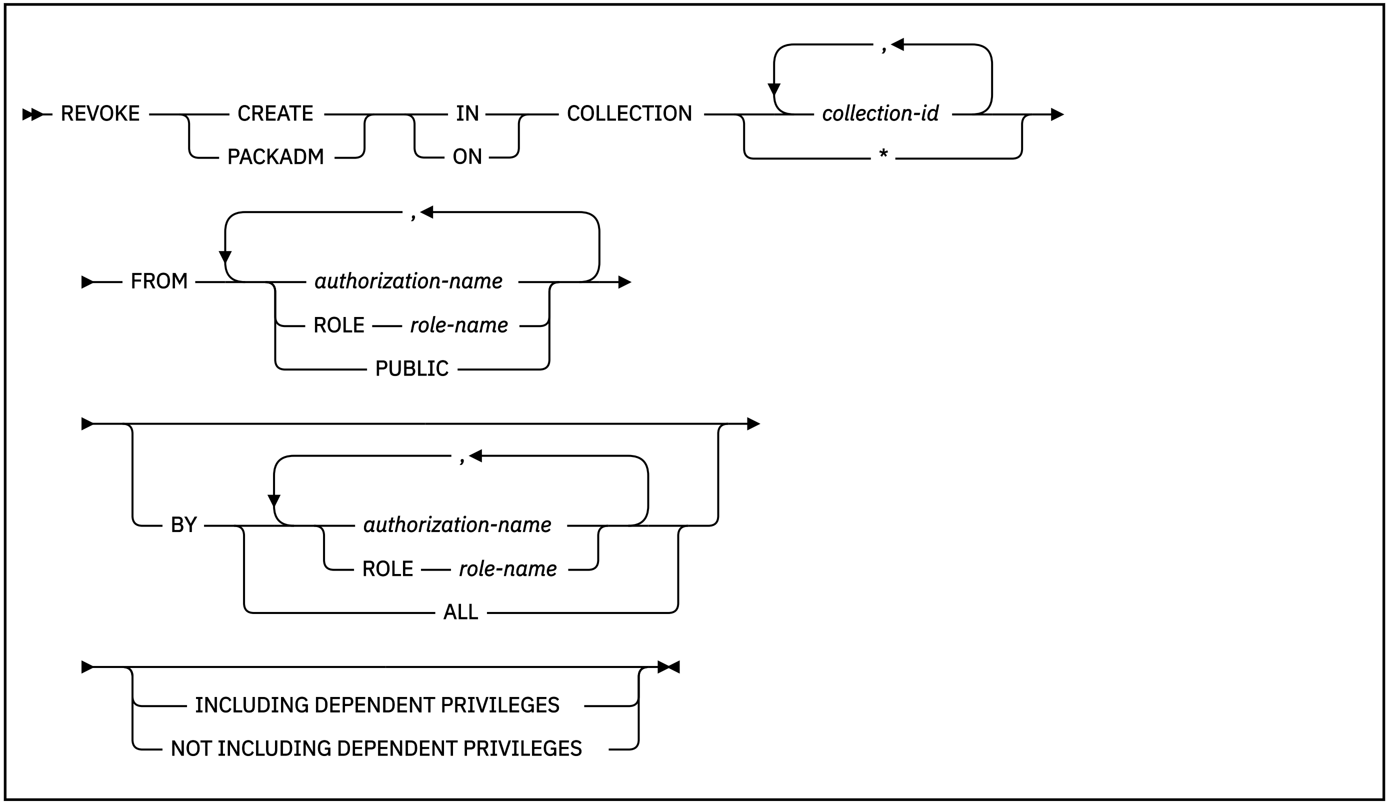
Revoking privileges with the REVOKE statement (Managing Security)

[37] Dependencies on stored procedures can be checked only if the procedure name is specified as a constant and not via a host variable in the CALL statement.

REVOKE (collection privileges)

This form of the REVOKE statement revokes privileges on collections.

Syntax for REVOKE (collection privileges)



Description for REVOKE (collection privileges)

CREATE IN
Revokes the privilege to use the BIND subcommand to create packages in the designated collections.

The word ON can be used instead of IN.

PACKADM ON
Revokes the package administrator authority for the designated collections.

The word IN can be used instead of ON.

COLLECTION *collection-id,...*
Identifies the collections on which the specified privilege is revoked. For each identified collection, you (or the indicated grantors) must have granted the specified privilege on that collection to all identified users (including PUBLIC if specified). The same collection must not be identified more than once.

COLLECTION *
Indicates that the specified privilege on COLLECTION * is revoked. You (or the indicated grantors) must have granted the specified privilege on COLLECTION * to all identified users (including PUBLIC if specified). Privileges granted on specific collections are not affected.

FROM
Refer to "REVOKE" on page 2065 for a description of the FROM clause.

BY
Refer to "REVOKE" on page 2065 for a description of the BY clause.

INCLUDING DEPENDENT PRIVILEGES or **NOT INCLUDING DEPENDENT PRIVILEGES**

Specifies whether revoking a privilege or an authority from an authorization ID or a role also results in revoking the grants that were made by that user. The default value is based on the authority that is being revoked and the REVOKE_DEP_PRIVILEGES system parameter:

- When ACCESSCTRL, DATAACCESS, or system DBADM authority is revoked, `NOT INCLUDING DEPENDENT PRIVILEGES` is assumed and the clause must be specified on the REVOKE statement.
- When the REVOKE_DEP_PRIVILEGES system parameter is set to NO, `NOT INCLUDING DEPENDENT PRIVILEGES` is assumed and an error is returned if the statement includes `INCLUDING DEPENDENT PRIVILEGES`.
- Otherwise, `INCLUDING DEPENDENT PRIVILEGES` is assumed and the clause must be specified on the REVOKE statement.

INCLUDING DEPENDENT PRIVILEGES

Specifies that revoking a privilege or an authority from an authorization ID or a role also results in revoking dependent privileges. This means that any grants that were made by the user will continue to be revoked, until all grants in the chain have been revoked.

`INCLUDING DEPENDENT PRIVILEGES` cannot be specified if the system parameter REVOKE_DEP_PRIVILEGES is set to NO, which enforces the behavior to not include the dependent privileges.

NOT INCLUDING DEPENDENT PRIVILEGES

Specifies that revoking a privilege or an authority from an authorization ID or a role does not cause the grants that were made by the user to be revoked. However, for the revoked privileges, all implications of the privilege being revoked are applied. For example, if the revoked privileges were required to bind a package successfully, that package would continue to be invalidated as a result of the package owner losing these privileges. An object might be dropped if a privilege is revoked that was used to create the object.

`NOT INCLUDING DEPENDENT PRIVILEGES` must be specified when ACCESSCTRL, DATAACCESS, or system DBADM authority is revoked.

`NOT INCLUDING DEPENDENT PRIVILEGES` cannot be specified if the system parameter REVOKE_DEP_PRIVILEGES is set toYES, which enforces the behavior to include dependent privileges in the revoke.

Examples for REVOKE (collection privileges)

Example 1: Revoke the privilege to create new packages in collections QAACLONE and DSN8CC61 from CLARK.

```
REVOKE CREATE IN COLLECTION QAACLONE, DSN8CC61 FROM CLARK;
```

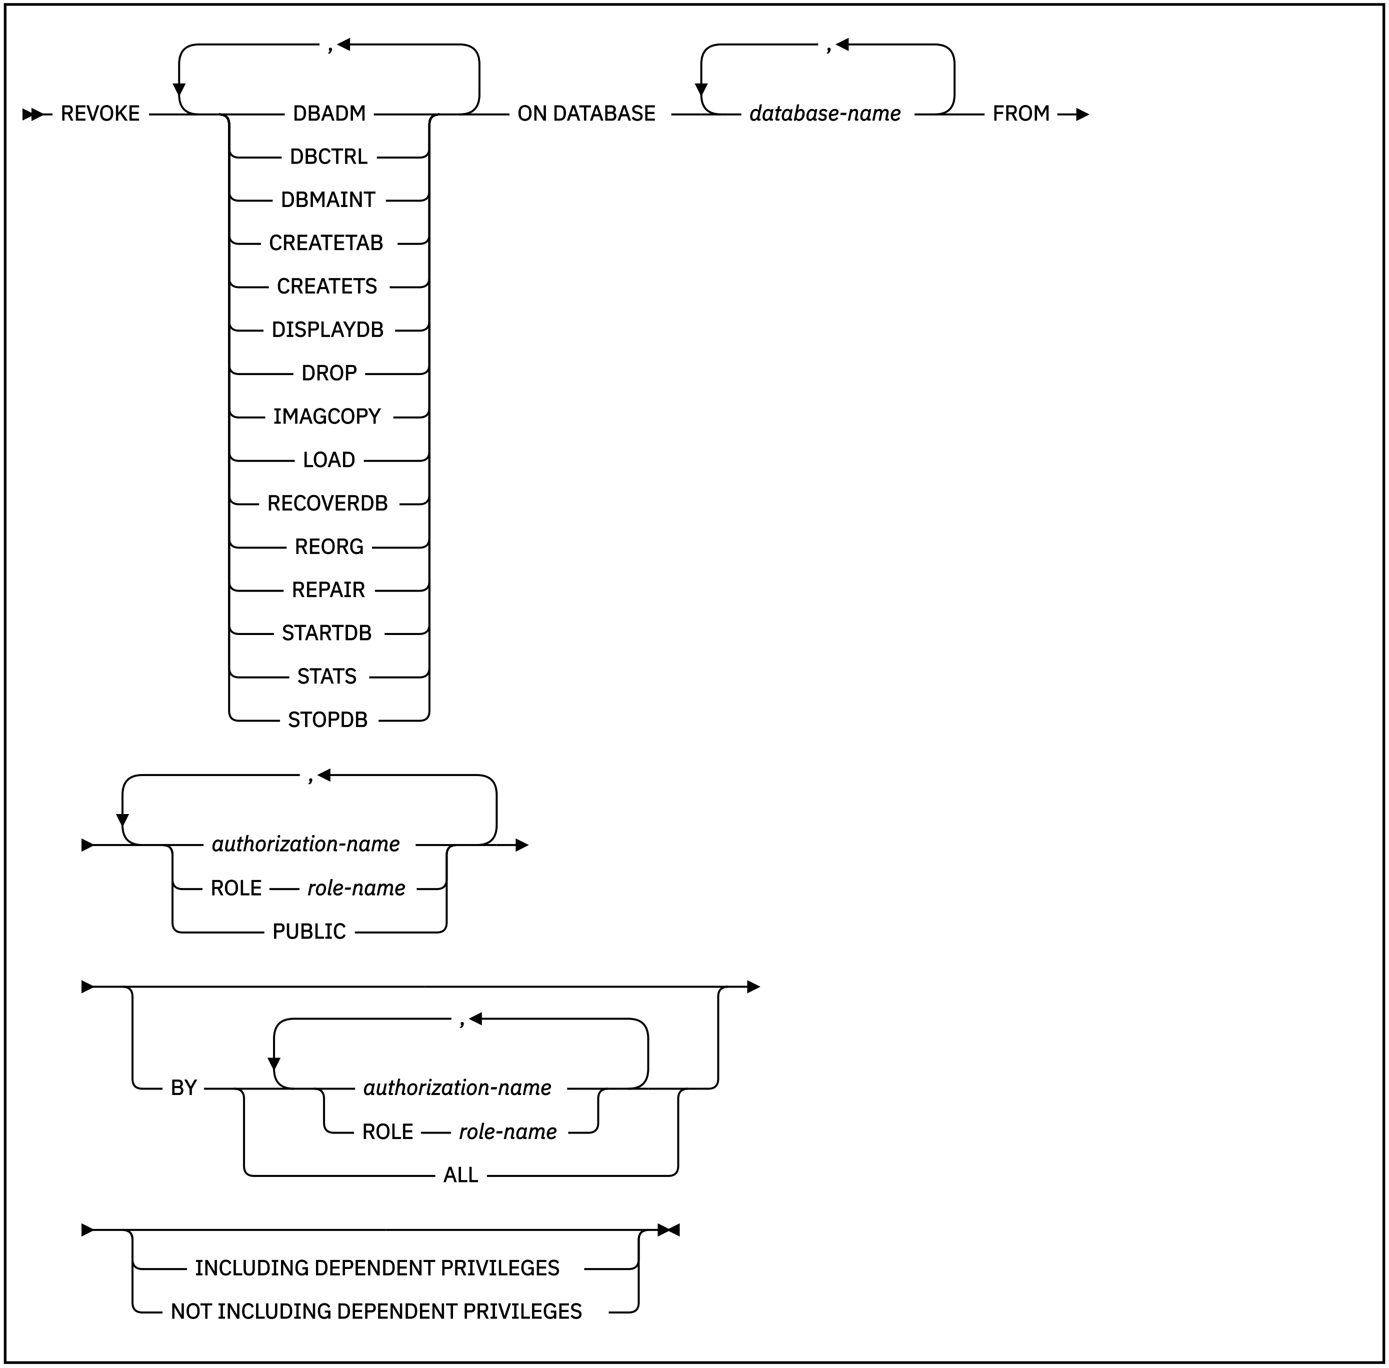
Example 2: Revoke the privilege to create new packages in collections DSN8CC91 from role ROLE1:

```
REVOKE CREATE IN COLLECTION DSN8CC91 FROM ROLE ROLE1;
```

REVOKE (database privileges)

This form of the REVOKE statement revokes database privileges.

Syntax for REVOKE (database privileges)



Description for REVOKE (database privileges)

Each keyword listed revokes the privilege described, but only as it applies to or within the databases named in the statement.

DBADM
: Revokes the database administrator authority.

DBCTRL
: Revokes the database control authority.

DBMAINT
Revokes the database maintenance authority.

CREATETAB
Revokes the privilege to create new tables. If CREATETAB privilege is revoked from DSNDB04, tables cannot be created in implicitly created databases. For a work file database, you cannot revoke the privilege from PUBLIC. When a work file database is created, PUBLIC implicitly receives the CREATETAB privilege (without GRANT authority); this privilege is not recorded in the Db2 catalog, and it cannot be revoked.

CREATETS
Revokes the privilege to create new table spaces.

DISPLAYDB
Revokes the privilege to issue the DISPLAY DATABASE command.

DROP
Revokes the privilege to issue the DROP or ALTER statements in the specified databases.

IMAGCOPY
Revokes the privilege to run the COPY, MERGECOPY, and QUIESCE utilities against table spaces of the specified databases, and to run the MODIFY RECOVERY utility.

LOAD
Revokes the privilege to use the LOAD utility to load tables.

RECOVERDB
Revokes the privilege to use the RECOVER and REPORT utilities to recover table spaces and indexes.

REORG
Revokes the privilege to use the REORG utility to reorganize table spaces and indexes.

REPAIR
Revokes the privilege to use the REPAIR and DIAGNOSE utilities.

STARTDB
Revokes the privilege to issue the START DATABASE command.

STATS
Revokes the privilege to use the RUNSTATS utility to update statistics, and the CHECK utility to test whether indexes are consistent with the data they index, and the MODIFY STATISTICS utility to delete unwanted statistics history records from the corresponding catalog tables.

STOPDB
Revokes the privilege to issue the STOP DATABASE command.

ON DATABASE *database-name,...*
Identifies databases on which you are revoking the privileges. For each database you identify, you (or the indicated grantors) must have granted at least one of the specified privileges on that database to all identified users (including PUBLIC, if specified). The same database must not be identified more than once.

FROM
Refer to "REVOKE" on page 2065 for a description of the FROM clause.

BY
Refer to "REVOKE" on page 2065 for a description of the BY clause.

`INCLUDING DEPENDENT PRIVILEGES` or `NOT INCLUDING DEPENDENT PRIVILEGES`
Specifies whether revoking a privilege or an authority from an authorization ID or a role also results in revoking the grants that were made by that user. The default value is based on the authority that is being revoked and the REVOKE_DEP_PRIVILEGES system parameter:

- When ACCESSCTRL, DATAACCESS, or system DBADM authority is revoked, `NOT INCLUDING DEPENDENT PRIVILEGES` is assumed and the clause must be specified on the REVOKE statement.
- When the REVOKE_DEP_PRIVILEGES system parameter is set to NO, `NOT INCLUDING DEPENDENT PRIVILEGES` is assumed and an error is returned if the statement includes `INCLUDING DEPENDENT PRIVILEGES`.

- Otherwise, INCLUDING DEPENDENT PRIVILEGES is assumed and the clause must be specified on the REVOKE statement.

INCLUDING DEPENDENT PRIVILEGES

Specifies that revoking a privilege or an authority from an authorization ID or a role also results in revoking dependent privileges. This means that any grants that were made by the user will continue to be revoked, until all grants in the chain have been revoked.

INCLUDING DEPENDENT PRIVILEGES cannot be specified if the system parameter REVOKE_DEP_PRIVILEGES is set to NO, which enforces the behavior to not include the dependent privileges.

NOT INCLUDING DEPENDENT PRIVILEGES

Specifies that revoking a privilege or an authority from an authorization ID or a role does not cause the grants that were made by the user to be revoked. However, for the revoked privileges, all implications of the privilege being revoked are applied. For example, if the revoked privileges were required to bind a package successfully, that package would continue to be invalidated as a result of the package owner losing these privileges. An object might be dropped if a privilege is revoked that was used to create the object.

NOT INCLUDING DEPENDENT PRIVILEGES must be specified when ACCESSCTRL, DATAACCESS, or system DBADM authority is revoked.

NOT INCLUDING DEPENDENT PRIVILEGES cannot be specified if the system parameter REVOKE_DEP_PRIVILEGES is set toYES, which enforces the behavior to include dependent privileges in the revoke.

Examples for REVOKE (database privileges)

Example 1: Revoke drop privileges on database DSN8D12A from user PEREZ.

```
REVOKE DROP
  ON DATABASE DSN8D12A
  FROM PEREZ;
```

Example 2: Revoke repair privileges on database DSN8D12A from all local users. (Grants to specific users will not be affected.)

```
REVOKE REPAIR
  ON DATABASE DSN8D12A
  FROM PUBLIC;
```

Example 3: Revoke authority to create new tables and load tables in database DSN8D12A from users WALKER, PIANKA, and FUJIMOTO.

```
REVOKE CREATETAB,LOAD
  ON DATABASE DSN8D12A
  FROM WALKER,PIANKA,FUJIMOTO;
```

Example 4: Revoke load privileges on database DSN8D12A from role ROLE1:

```
REVOKE LOAD
  ON DATABASE DSN8D12A
  FROM ROLE ROLE1;
```

REVOKE (function or procedure privileges)

This form of the REVOKE statement revokes privileges on user-defined functions, cast functions that were generated for distinct types, and stored procedures.

Syntax for REVOKE (function or procedure privileges)

Description for REVOKE (function or procedure privileges)

EXECUTE

Revokes the privilege to run the identified user-defined function, cast function that was generated for a distinct type, or stored procedure.

FUNCTION or SPECIFIC FUNCTION

Identifies the function from which the privilege is revoked. The function must exist at the current server, and it must be a function that was defined with the CREATE FUNCTION statement or a cast function that was generated by a CREATE TYPE statement. The function can be identified by name, function signature, or specific name.

If the function was defined with a table parameter (the LIKE TABLE was specified in the CREATE FUNCTION statement to indicate that one of the input parameters is a transition table), the function signature cannot be used to identify the function. Instead, identify the function with its function name, if unique, or with its specific name.

FUNCTION *function-name*

Identifies the function by its name. The *function-name* must identify exactly one function. The function can have any number of parameters defined for it. If there is more than one function of the specified name in the specified or implicit schema, an error is returned.

An * can be specified for a qualified or unqualified *function-name*. An * (or *schema-name*.*) indicates that the privilege is revoked for all the functions in the schema. You (or the indicated grantors) must have granted the privilege on FUNCTION * to all identified users (including PUBLIC if specified). Privileges granted on specific functions are not affected.

FUNCTION *function-name (parameter-type,...)*

Identifies the function by its function signature, which uniquely identifies the function. The *function-name (parameter-type, ...)* must identify a function with the specified function signature. The specified parameters must match the data types in the corresponding position that were specified when the function was created. The number of data types, and the logical concatenation of the data types is used to identify the specific function instance on which the privilege is to be granted. Synonyms for data types are considered a match.

If the function was defined with a table parameter (the LIKE TABLE *name* AS LOCATOR clause was specified in the CREATE FUNCTION statement to indicate that one of the input parameters is a transition table), the function signature cannot be used to uniquely identify the function. Instead, use one of the other syntax variations to identify the function with its function name, if unique, or its specific name.

If *function-name ()* is specified, the function identified must have zero parameters.

function-name

Identifies the name of the function. If you do not explicitly qualify the function name with a schema name, the function name is implicitly qualified with a schema name as described in the preceding description for FUNCTION *function-name*.

(parameter-type,...)

Identifies the parameters of the function.

If an unqualified distinct type name is specified, Db2 searches the SQL path to resolve the schema name for the distinct type.

For data types that have a length, precision, or scale attribute, use one of the following:

- Empty parentheses indicate that the database manager ignores the attribute when determining whether the data types match. For example, DEC() will be considered a match for a parameter of a function defined with a data type of DEC(7,2). Similarly DECFLOAT() will be considered a match for DECFLOAT(16) or DECFLOAT(34). However, FLOAT cannot be specified with empty parenthesis because its parameter value indicates a specific data type (REAL or DOUBLE).
- If a specific value for a length, precision, or scale attribute is specified, the value must exactly match the value that was specified (implicitly or explicitly) in the CREATE FUNCTION

statement. If the data type is FLOAT, the precision does not have to exactly match the value that was specified because matching is based on the data type (REAL or DOUBLE).

- If length, precision, or scale is not explicitly specified, and empty parentheses are not specified, the default attributes of the data type are implied. The implicit length must exactly match the value that was specified (implicitly or explicitly) in the CREATE FUNCTION statement.

For data types with a subtype or encoding scheme attribute, specifying the FOR *subtype* DATA clause or the CCSID clause is optional. Omission of either clause indicates that Db2 ignores the attribute when determining whether the data types match. If you specify either clause, it must match the value that was implicitly or explicitly specified in the CREATE FUNCTION statement.

AS LOCATOR

Specifies that the function is defined to receive a locator for this parameter. If AS LOCATOR is specified, the data type must be a LOB or a distinct type based on a LOB.

SPECIFIC FUNCTION *specific-name*

Identifies the function by its specific name. The *specific-name* must identify a specific function that exists at the current server.

PROCEDURE *procedure-name*

Identifies a stored procedure that is defined at the current server.

An * can be specified for a qualified or unqualified *procedure-name*. An * (or *schema-name*.*) indicates that the privilege is revoked for all the procedures in the schema. You (or the indicated grantors) must have granted the privilege on PROCEDURE * to all identified users (including PUBLIC if specified). Privileges granted on specific procedures are not affected.

FROM

Refer to "REVOKE" on page 2065 for a description of the FROM clause.

BY

Refer to "REVOKE" on page 2065 for a description of the BY clause.

`INCLUDING DEPENDENT PRIVILEGES` or `NOT INCLUDING DEPENDENT PRIVILEGES`

Specifies whether revoking a privilege or an authority from an authorization ID or a role also results in revoking the grants that were made by that user. The default value is based on the authority that is being revoked and the REVOKE_DEP_PRIVILEGES system parameter:

- When ACCESSCTRL, DATAACCESS, or system DBADM authority is revoked, `NOT INCLUDING DEPENDENT PRIVILEGES` is assumed and the clause must be specified on the REVOKE statement.
- When the REVOKE_DEP_PRIVILEGES system parameter is set to NO, `NOT INCLUDING DEPENDENT PRIVILEGES` is assumed and an error is returned if the statement includes `INCLUDING DEPENDENT PRIVILEGES`.
- Otherwise, `INCLUDING DEPENDENT PRIVILEGES` is assumed and the clause must be specified on the REVOKE statement.

`INCLUDING DEPENDENT PRIVILEGES`

Specifies that revoking a privilege or an authority from an authorization ID or a role also results in revoking dependent privileges. This means that any grants that were made by the user will continue to be revoked, until all grants in the chain have been revoked.

`INCLUDING DEPENDENT PRIVILEGES` cannot be specified if the system parameter REVOKE_DEP_PRIVILEGES is set to NO, which enforces the behavior to not include the dependent privileges.

`NOT INCLUDING DEPENDENT PRIVILEGES`

Specifies that revoking a privilege or an authority from an authorization ID or a role does not cause the grants that were made by the user to be revoked. However, for the revoked privileges, all implications of the privilege being revoked are applied. For example, if the revoked privileges were required to bind a package successfully, that package would continue to be invalidated as a result of the package owner losing these privileges. An object might be dropped if a privilege is revoked that was used to create the object.

`NOT INCLUDING DEPENDENT PRIVILEGES` must be specified when ACCESSCTRL, DATAACCESS, or system DBADM authority is revoked.

`NOT INCLUDING DEPENDENT PRIVILEGES` cannot be specified if the system parameter REVOKE_DEP_PRIVILEGES is set toYES, which enforces the behavior to include dependent privileges in the revoke.

RESTRICT

Prevents the EXECUTE privilege from being revoked on a user-defined function or stored procedure if the revokee owns any of the following objects and does not have the EXECUTE privilege from another source:

- A function that is sourced on the function
- A view that uses the function
- A trigger package that uses the function or stored procedure
- A table that uses the function in a check constraint or user-defined default clause
- A materialized query table whose fullselect uses the function
- An extended index that uses the function

Examples for REVOKE (function or procedure privileges)

Example 1: Revoke the EXECUTE privilege on function CALC_SALARY for user JONES. Assume that there is only one function in the schema with function CALC_SALARY.

```
REVOKE EXECUTE ON FUNCTION CALC_SALARY FROM JONES;
```

Example 2: Revoke the EXECUTE privilege on procedure VACATION_ACCR from all users at the current server.

```
REVOKE EXECUTE ON PROCEDURE VACATION_ACCR FROM PUBLIC;
```

Example 3: Revoke the privilege of the administrative assistant to grant EXECUTE privileges on function DEPT_TOTAL to other users. The administrative assistant will still have the EXECUTE privilege on function DEPT_TOTALS.

```
REVOKE EXECUTE ON FUNCTION DEPT_TOTALS
      FROM ADMIN_A;
```

Example 4: Revoke the EXECUTE privilege on function NEW_DEPT_HIRES for HR (Human Resources). The function has two input parameters with data types of INTEGER and CHAR(10), respectively. Assume that the schema has more than one function that is named NEW_DEPT_HIRES.

```
REVOKE EXECUTE ON FUNCTION NEW_DEPT_HIRES (INTEGER, CHAR(10))
      FROM HR;
```

You can also code the CHAR(10) data type as CHAR().

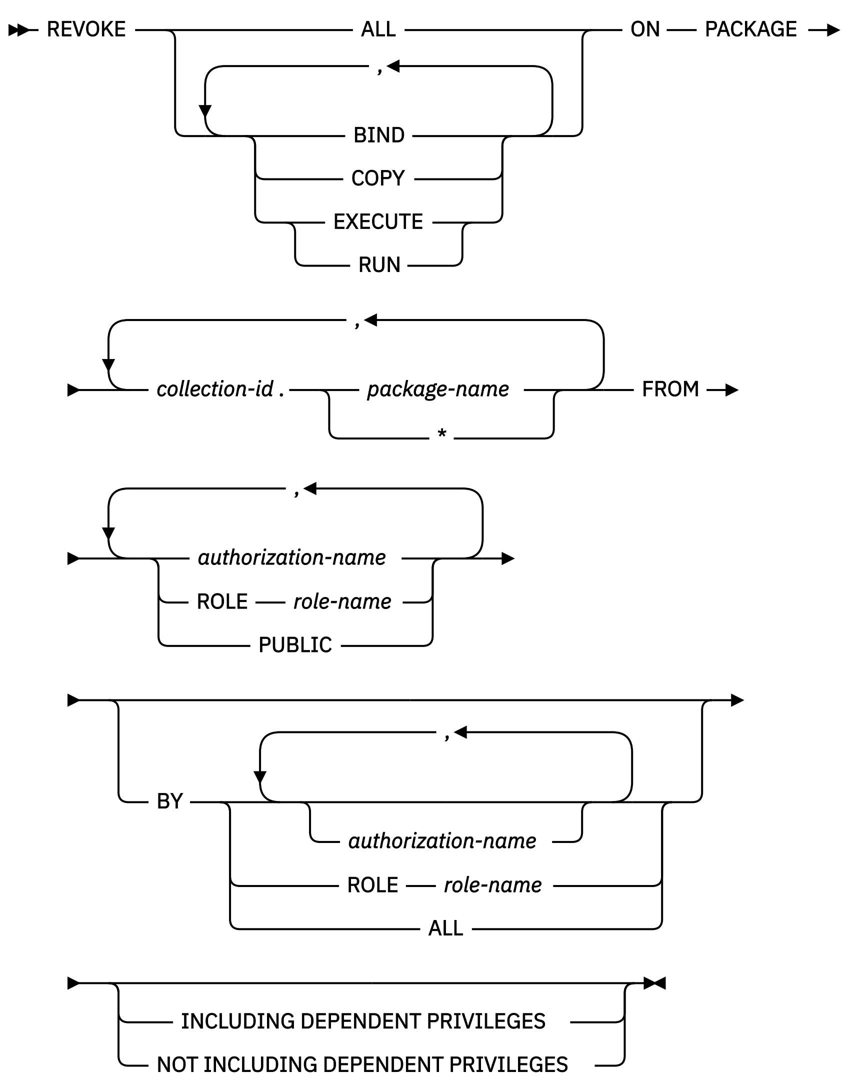
Example 5: Revoke the EXECUTE privilege on function FIND_EMPDEPT from role ROLE1:

```
REVOKE EXECUTE ON FUNCTION FIND_EMPDEPT
      FROM ROLE ROLE1;
```

REVOKE (package privileges)

This form of the REVOKE statement revokes privileges on packages.

Syntax for REVOKE (package privileges)



Description for REVOKE (package privileges)

BIND

Revokes the privilege to use the BIND and REBIND subcommands for the designated packages. In addition, if the value of field BIND NEW PACKAGE on installation panel DSNTIPP is BIND, the additional BIND privilege of adding new versions of packages is revoked. (For details, see "GRANT (package privileges)" on page 1970.)

COPY

Revokes the privilege to use the COPY option of the BIND subcommand for the designated packages.

EXECUTE

Revokes the privilege to run application programs that use the designated packages and to specify the packages following PKLIST for the BIND PLAN and REBIND PLAN commands. RUN is an alternate name for the same privilege.

ALL

Revokes all package privileges for which you have authority for the packages named in the ON clause.

ON PACKAGE *collection-id.package-name,...*

Identifies packages for which you are revoking privileges. The revoking of a package privilege applies to all versions of that package. For each package that you identify, you (or the indicated grantors) must have granted at least one of the specified privileges on that package to all identified users (including PUBLIC, if specified). An authorization ID with PACKADM authority over the collection or all collections, SYSADM, or SYSCTRL authority can specify all packages in the collection by using * for *package-name*. The same package must not be specified more than once.

FROM

Refer to "REVOKE" on page 2065 for a description of the FROM clause.

BY

Refer to "REVOKE" on page 2065 for a description of the BY clause.

`INCLUDING DEPENDENT PRIVILEGES` or `NOT INCLUDING DEPENDENT PRIVILEGES`

Specifies whether revoking a privilege or an authority from an authorization ID or a role also results in revoking the grants that were made by that user. The default value is based on the authority that is being revoked and the REVOKE_DEP_PRIVILEGES system parameter:

- When ACCESSCTRL, DATAACCESS, or system DBADM authority is revoked, `NOT INCLUDING DEPENDENT PRIVILEGES` is assumed and the clause must be specified on the REVOKE statement.
- When the REVOKE_DEP_PRIVILEGES system parameter is set to NO, `NOT INCLUDING DEPENDENT PRIVILEGES` is assumed and an error is returned if the statement includes `INCLUDING DEPENDENT PRIVILEGES`.
- Otherwise, `INCLUDING DEPENDENT PRIVILEGES` is assumed and the clause must be specified on the REVOKE statement.

`INCLUDING DEPENDENT PRIVILEGES`

Specifies that revoking a privilege or an authority from an authorization ID or a role also results in revoking dependent privileges. This means that any grants that were made by the user will continue to be revoked, until all grants in the chain have been revoked.

`INCLUDING DEPENDENT PRIVILEGES` cannot be specified if the system parameter REVOKE_DEP_PRIVILEGES is set to NO, which enforces the behavior to not include the dependent privileges.

`NOT INCLUDING DEPENDENT PRIVILEGES`

Specifies that revoking a privilege or an authority from an authorization ID or a role does not cause the grants that were made by the user to be revoked. However, for the revoked privileges, all implications of the privilege being revoked are applied. For example, if the revoked privileges were required to bind a package successfully, that package would continue to be invalidated as a result of the package owner losing these privileges. An object might be dropped if a privilege is revoked that was used to create the object.

`NOT INCLUDING DEPENDENT PRIVILEGES` must be specified when ACCESSCTRL, DATAACCESS, or system DBADM authority is revoked.

`NOT INCLUDING DEPENDENT PRIVILEGES` cannot be specified if the system parameter REVOKE_DEP_PRIVILEGES is set toYES, which enforces the behavior to include dependent privileges in the revoke.

Notes for REVOKE (package privileges)

Alternative syntax and synonyms: To provide compatibility with previous releases of Db2 or other products in the Db2 family, Db2 supports specifying PROGRAM as a synonym for PACKAGE.

Examples for REVOKE (package privileges)

Example 1: Revoke the privilege to copy all packages in collection DSN8CC61 from LEWIS.

```
REVOKE COPY ON PACKAGE DSN8CC61.* FROM LEWIS;
```

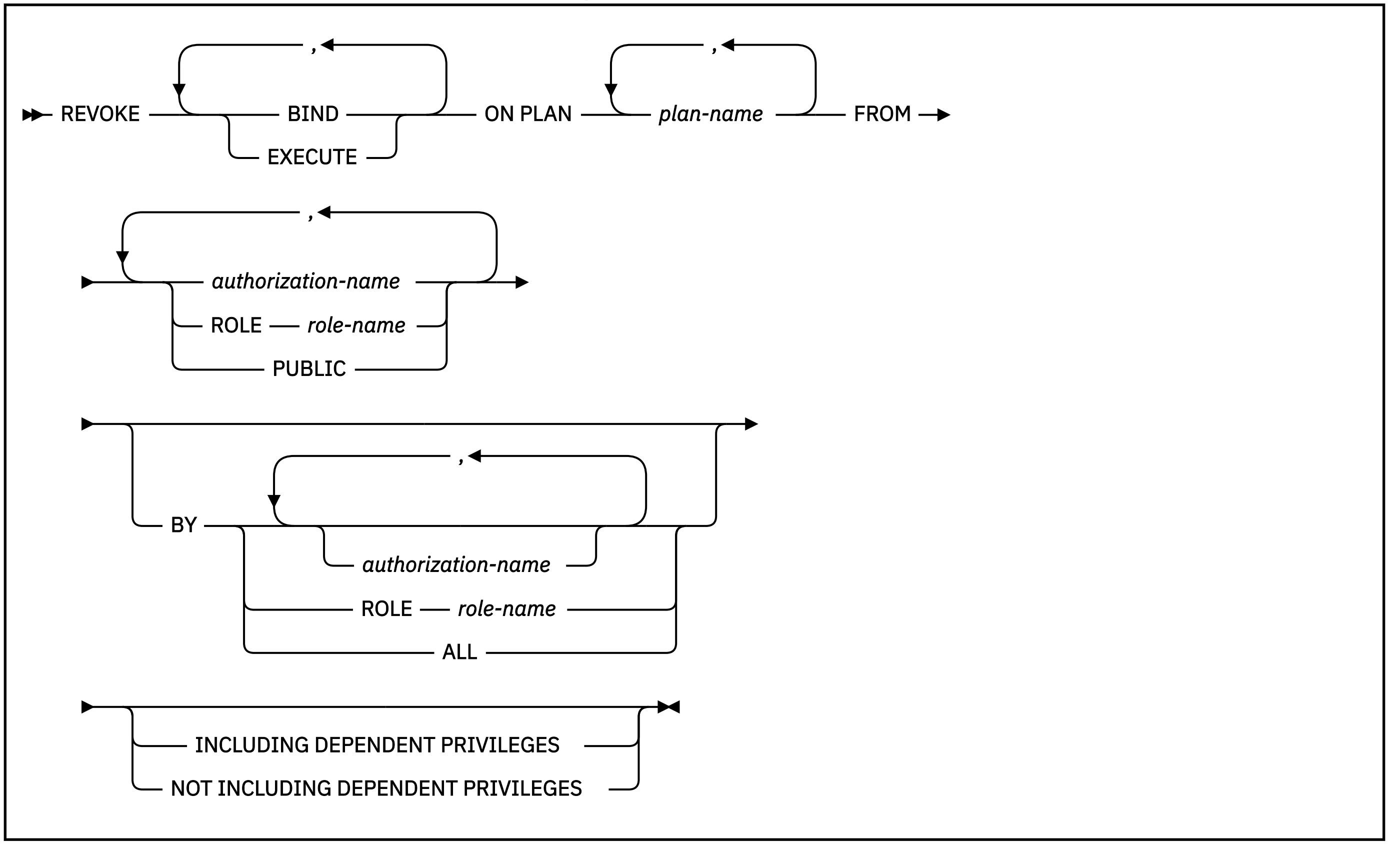
Example 2: Revoke the privilege to run all packages in collection DSN9CC13 from role ROLE1:

```
REVOKE EXECUTE ON PACKAGE DSN9CC13.* FROM ROLE ROLE1;
```

REVOKE (plan privileges)

This form of the REVOKE statement revokes privileges on application plans.

Syntax for REVOKE (plan privileges)



Description for REVOKE (plan privileges)

BIND
Revokes the privilege to use the BIND, REBIND, and FREE subcommands for the identified plans.

EXECUTE
Revokes the privilege to run application programs that use the identified plans.

ON PLAN *plan-name,...*
Identifies application plans for which you are revoking privileges. For each plan that you identify, you (or the indicated grantors) must have granted at least one of the specified privileges on that plan to all identified users (including PUBLIC, if specified). The same plan must not be specified more than once.

FROM
Refer to "REVOKE" on page 2065 for a description of the FROM clause.

BY
Refer to "REVOKE" on page 2065 for a description of the BY clause.

`INCLUDING DEPENDENT PRIVILEGES` or `NOT INCLUDING DEPENDENT PRIVILEGES`
Specifies whether revoking a privilege or an authority from an authorization ID or a role also results in revoking the grants that were made by that user. The default value is based on the authority that is being revoked and the REVOKE_DEP_PRIVILEGES system parameter:

- When ACCESSCTRL, DATAACCESS, or system DBADM authority is revoked, NOT INCLUDING DEPENDENT PRIVILEGES is assumed and the clause must be specified on the REVOKE statement.
- When the REVOKE_DEP_PRIVILEGES system parameter is set to NO, NOT INCLUDING DEPENDENT PRIVILEGES is assumed and an error is returned if the statement includes INCLUDING DEPENDENT PRIVILEGES.
- Otherwise, INCLUDING DEPENDENT PRIVILEGES is assumed and the clause must be specified on the REVOKE statement.

INCLUDING DEPENDENT PRIVILEGES

Specifies that revoking a privilege or an authority from an authorization ID or a role also results in revoking dependent privileges. This means that any grants that were made by the user will continue to be revoked, until all grants in the chain have been revoked.

INCLUDING DEPENDENT PRIVILEGES cannot be specified if the system parameter REVOKE_DEP_PRIVILEGES is set to NO, which enforces the behavior to not include the dependent privileges.

NOT INCLUDING DEPENDENT PRIVILEGES

Specifies that revoking a privilege or an authority from an authorization ID or a role does not cause the grants that were made by the user to be revoked. However, for the revoked privileges, all implications of the privilege being revoked are applied. For example, if the revoked privileges were required to bind a package successfully, that package would continue to be invalidated as a result of the package owner losing these privileges. An object might be dropped if a privilege is revoked that was used to create the object.

NOT INCLUDING DEPENDENT PRIVILEGES must be specified when ACCESSCTRL, DATAACCESS, or system DBADM authority is revoked.

NOT INCLUDING DEPENDENT PRIVILEGES cannot be specified if the system parameter REVOKE_DEP_PRIVILEGES is set toYES, which enforces the behavior to include dependent privileges in the revoke.

Examples for REVOKE (plan privileges)

Example 1: Revoke authority to bind plan DSN8IP12 from user JONES.

```
REVOKE BIND ON PLAN DSN8IP12 FROM JONES;
```

Example 2: Revoke authority previously granted to all users at the current server to bind and execute plan DSN8CP12. (Grants to specific users will not be affected.)

```
REVOKE BIND,EXECUTE ON PLAN DSN8CP12 FROM PUBLIC;
```

Example 3: Revoke authority to execute plan DSN8CP12 from users ADAMSON and BROWN.

```
REVOKE EXECUTE ON PLAN DSN8CP12 FROM ADAMSON,BROWN;
```

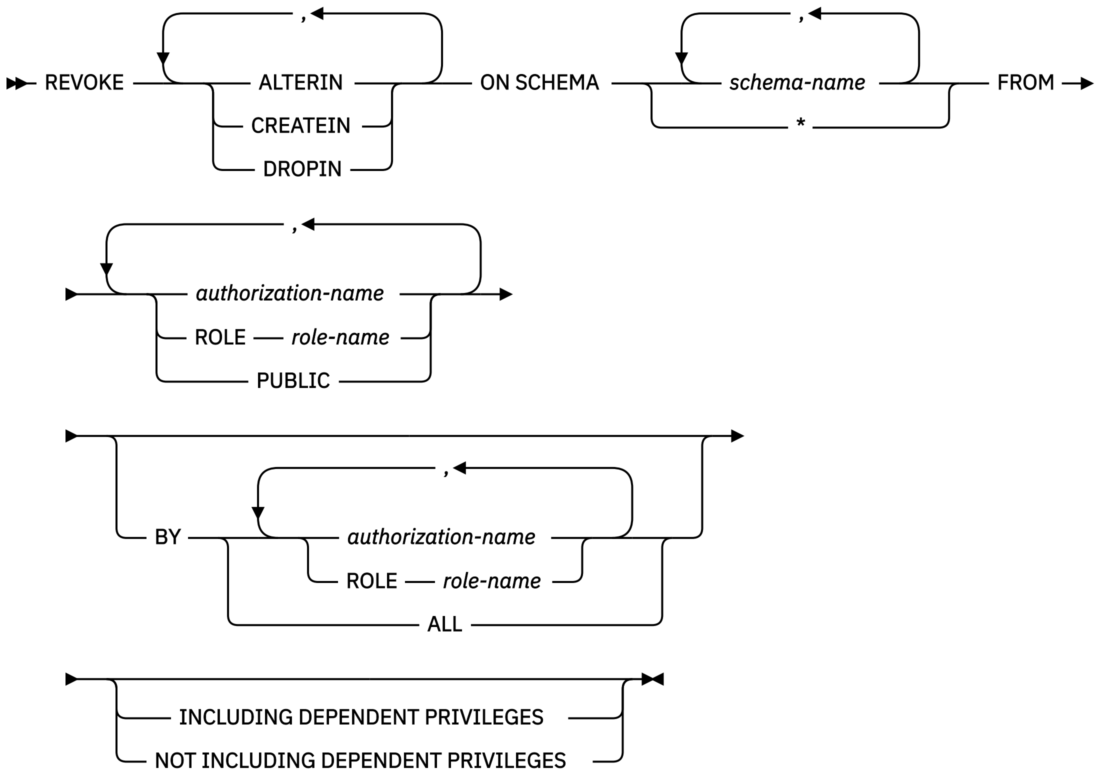
Example 4: Revoke authority to bind plan DSN91PLN from role ROLE1:

```
REVOKE BIND ON PLAN DSN91PLN FROM ROLE ROLE1;
```

REVOKE (schema privileges)

This form of the REVOKE statement revokes privileges on schemas.

Syntax for REVOKE (schema privileges)



Description for REVOKE (schema privileges)

ALTERIN
Revokes the privilege to alter sequences, stored procedures, and user-defined functions, or specify a comment for distinct types, cast functions that are generated for distinct types, sequences, stored procedures, triggers, and user-defined functions in the designated schemas.

CREATEIN
Revokes the privilege to create distinct types, sequences, stored procedures, triggers, and user-defined functions in the designated schemas.

DROPIN
Revokes the privilege to drop distinct types, sequences, stored procedures, triggers, and user-defined functions in the designated schemas.

SCHEMA *schema-name*
Identifies the schema on which the privilege is revoked.

SCHEMA *
Indicates that the specified privilege on all schemas is revoked. You (or the indicated grantors) must have previously granted the specified privilege on SCHEMA * to all identified users (including PUBLIC if specified). Privileges granted on specific schemas are not affected.

FROM
Refer to "REVOKE" on page 2065 for a description of the FROM clause.

BY
Refer to "REVOKE" on page 2065 for a description of the BY clause.

INCLUDING DEPENDENT PRIVILEGES or NOT INCLUDING DEPENDENT PRIVILEGES

Specifies whether revoking a privilege or an authority from an authorization ID or a role also results in revoking the grants that were made by that user. The default value is based on the authority that is being revoked and the REVOKE_DEP_PRIVILEGES system parameter:

- When ACCESSCTRL, DATAACCESS, or system DBADM authority is revoked, `NOT INCLUDING DEPENDENT PRIVILEGES` is assumed and the clause must be specified on the REVOKE statement.
- When the REVOKE_DEP_PRIVILEGES system parameter is set to NO, `NOT INCLUDING DEPENDENT PRIVILEGES` is assumed and an error is returned if the statement includes `INCLUDING DEPENDENT PRIVILEGES`.
- Otherwise, `INCLUDING DEPENDENT PRIVILEGES` is assumed and the clause must be specified on the REVOKE statement.

INCLUDING DEPENDENT PRIVILEGES

Specifies that revoking a privilege or an authority from an authorization ID or a role also results in revoking dependent privileges. This means that any grants that were made by the user will continue to be revoked, until all grants in the chain have been revoked.

`INCLUDING DEPENDENT PRIVILEGES` cannot be specified if the system parameter REVOKE_DEP_PRIVILEGES is set to NO, which enforces the behavior to not include the dependent privileges.

NOT INCLUDING DEPENDENT PRIVILEGES

Specifies that revoking a privilege or an authority from an authorization ID or a role does not cause the grants that were made by the user to be revoked. However, for the revoked privileges, all implications of the privilege being revoked are applied. For example, if the revoked privileges were required to bind a package successfully, that package would continue to be invalidated as a result of the package owner losing these privileges. An object might be dropped if a privilege is revoked that was used to create the object.

`NOT INCLUDING DEPENDENT PRIVILEGES` must be specified when ACCESSCTRL, DATAACCESS, or system DBADM authority is revoked.

`NOT INCLUDING DEPENDENT PRIVILEGES` cannot be specified if the system parameter REVOKE_DEP_PRIVILEGES is set toYES, which enforces the behavior to include dependent privileges in the revoke.

Examples for REVOKE (schema privileges)

Example 1: Revoke the CREATEIN privilege on schema T_SCORES from user JONES.

```
REVOKE CREATEIN ON SCHEMA T_SCORES FROM JONES;
```

Example 2: Revoke the CREATEIN privilege on schema VAC from all users at the current server.

```
REVOKE CREATEIN ON SCHEMA VAC FROM PUBLIC;
```

Example 3: Revoke the ALTERIN privilege on schema DEPT from the administrative assistant.

```
REVOKE ALTERIN ON SCHEMA DEPT FROM ADMIN_A;
```

Example 4: Revoke the ALTERIN and DROPIN privileges on schemas NEW_HIRE, PROMO, and RESIGN from HR (Human Resources).

```
REVOKE ALTERIN, DROPIN ON SCHEMA NEW_HIRE, PROMO, RESIGN FROM HR;
```

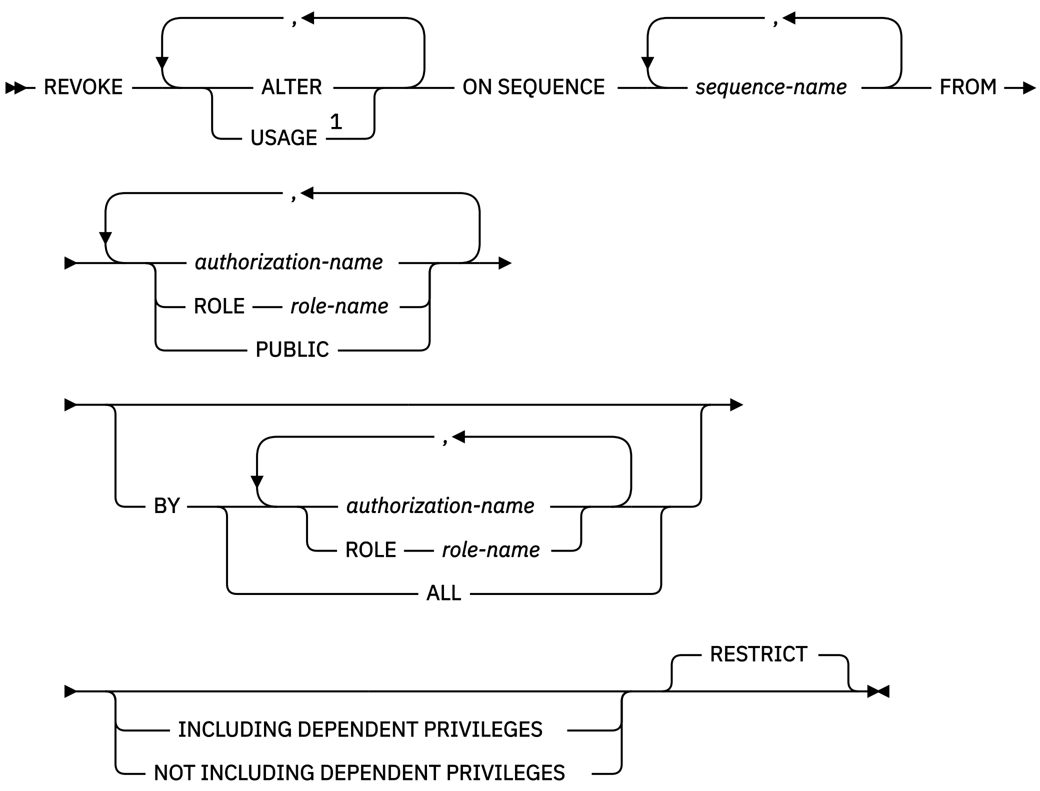
Example 5: Revoke the ALTERIN privilege on schemas EMPLOYEE from role ROLE1:

```
REVOKE ALTERIN ON SCHEMA EMPLOYEE FROM ROLE ROLE1;
```

REVOKE (sequence privileges)

This form of the REVOKE statement revokes the privileges on a user-defined sequence.

Syntax for REVOKE (sequence privileges)



Notes:

[1] The keyword SELECT is an alternative keyword for USAGE.

Description for REVOKE (sequence privileges)

ALTER
Revokes the privilege to alter a sequence or record a comment on a sequence.

USAGE
Revokes the USAGE privilege to use a sequence. This privilege is needed when the NEXT VALUE or PREVIOUS VALUE expression is invoked for a sequence name.

SEQUENCE *sequence-name*
Identifies the sequence. The name, including the implicit or explicit schema qualifier, must uniquely identify an existing sequence at the current server. If no sequence by this name exists in the explicitly or implicitly specified schema, an error occurs. *sequence-name* must not be the name of an internal sequence object that is generated by the system for an identity column.

FROM
Refer to "REVOKE" on page 2065 for a description of the FROM clause.

BY
Refer to "REVOKE" on page 2065 for a description of the BY clause.

`INCLUDING DEPENDENT PRIVILEGES` or `NOT INCLUDING DEPENDENT PRIVILEGES`
Specifies whether revoking a privilege or an authority from an authorization ID or a role also results in revoking the grants that were made by that user. The default value is based on the authority that is being revoked and the REVOKE_DEP_PRIVILEGES system parameter:

- When ACCESSCTRL, DATAACCESS, or system DBADM authority is revoked, `NOT INCLUDING DEPENDENT PRIVILEGES` is assumed and the clause must be specified on the REVOKE statement.
- When the REVOKE_DEP_PRIVILEGES system parameter is set to NO, `NOT INCLUDING DEPENDENT PRIVILEGES` is assumed and an error is returned if the statement includes `INCLUDING DEPENDENT PRIVILEGES`.
- Otherwise, `INCLUDING DEPENDENT PRIVILEGES` is assumed and the clause must be specified on the REVOKE statement.

INCLUDING DEPENDENT PRIVILEGES

Specifies that revoking a privilege or an authority from an authorization ID or a role also results in revoking dependent privileges. This means that any grants that were made by the user will continue to be revoked, until all grants in the chain have been revoked.

`INCLUDING DEPENDENT PRIVILEGES` cannot be specified if the system parameter REVOKE_DEP_PRIVILEGES is set to NO, which enforces the behavior to not include the dependent privileges.

NOT INCLUDING DEPENDENT PRIVILEGES

Specifies that revoking a privilege or an authority from an authorization ID or a role does not cause the grants that were made by the user to be revoked. However, for the revoked privileges, all implications of the privilege being revoked are applied. For example, if the revoked privileges were required to bind a package successfully, that package would continue to be invalidated as a result of the package owner losing these privileges. An object might be dropped if a privilege is revoked that was used to create the object.

`NOT INCLUDING DEPENDENT PRIVILEGES` must be specified when ACCESSCTRL, DATAACCESS, or system DBADM authority is revoked.

`NOT INCLUDING DEPENDENT PRIVILEGES` cannot be specified if the system parameter REVOKE_DEP_PRIVILEGES is set toYES, which enforces the behavior to include dependent privileges in the revoke.

RESTRICT

Prevents the USAGE privilege from being revoked on a sequence if the revokee owns one of the following objects and does not have the USAGE privilege from another source:

- A trigger that specifies the sequence in a NEXT VALUE or PREVIOUS VALUE expression
- An inline SQL function that specifies the sequence in a NEXT VALUE or PREVIOUS VALUE expression

Examples for REVOKE (sequence privileges)

Example 1: Revoke USAGE privilege on sequence MYNUM to user JONES.

```
REVOKE USAGE
  ON SEQUENCE MYNUM
  FROM JONES;
```

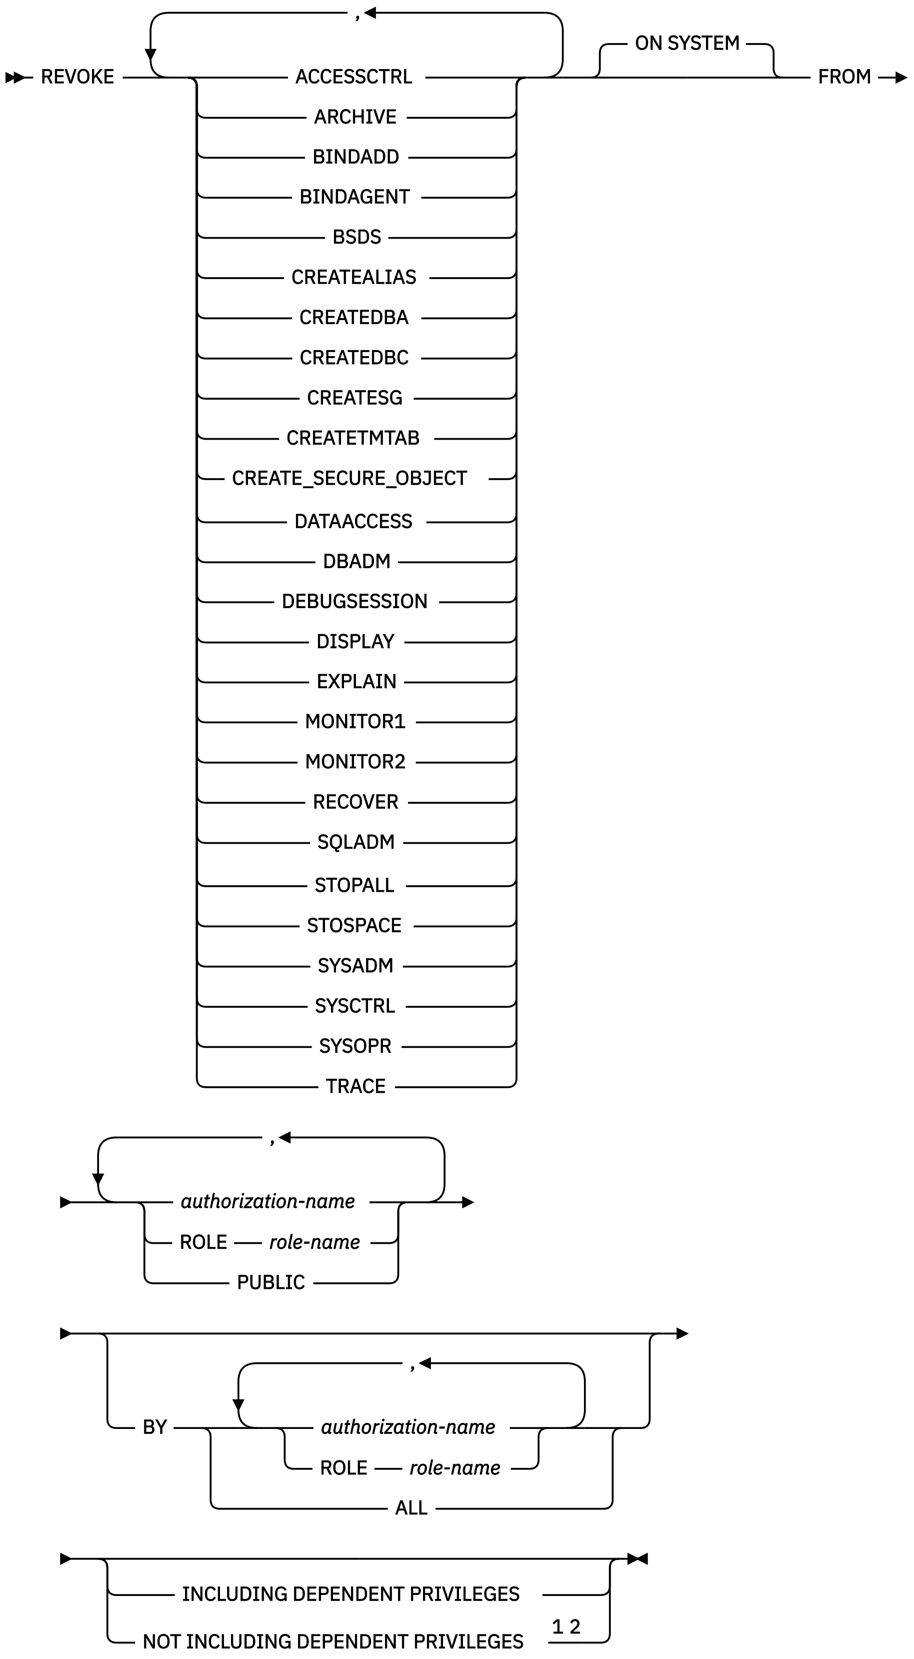
Example 2: Revoke the USAGE privilege on sequence ORDER_SEQ from role ROLE1:

```
REVOKE USAGE
  ON SEQUENCE ORDER_SEQ
  FROM ROLE ROLE1;
```

REVOKE (system privileges)

This form of the REVOKE statement revokes system privileges.

Syntax for REVOKE (system privileges)



Notes:

[1] INCLUDING DEPENDENT PRIVILEGES must not be specified when ACCESSCTRL, DATAACCESS, or DBADM is specified.
[2] NOT INCLUDING DEPENDENT PRIVILEGES must be specified when ACCESSCTRL, DATAACCESS, or DBADM is specified

Description for REVOKE (system privileges)

ACCESSCTRL
Revokes the ACCESSCTRL authority, but does not revoke any privileges that are dependent on it.

ARCHIVE
Revokes the privilege to use the ARCHIVE LOG command.

BINDADD
Revokes the privilege to create plans and packages using the BIND subcommand with the ADD option.

BINDAGENT
Revokes the privilege to issue the BIND, FREE PACKAGE, or REBIND subcommands for plans and packages and the DROP PACKAGE statement on behalf of the grantor. The privilege also allows the holder to copy and replace plans and packages on behalf of the grantor.

A revoke of this privilege does not cascade.

BSDS
Revokes the privilege to issue the RECOVER BSDS command.

CREATEALIAS
Revokes the privilege to use the CREATE ALIAS statement.

CREATEDBA
Revokes the privilege to issue the CREATE DATABASE statement and acquire DBADM authority over those databases.

CREATEDBC
Revokes the privilege to issue the CREATE DATABASE statement and acquire DBCTRL authority over those databases.

CREATESG
Revokes the privilege to create new storage groups.

CREATETMTAB
Revokes the privilege to use the CREATE GLOBAL TEMPORARY TABLE statement.

CREATE_SECURE_OBJECT
Revokes the privilege to create a secure object.

DATAACCESS
Revokes the DATAACCESS authority, but does not revoke any privileges that are dependent on it. Revoking DATAACCESS can result in authorization cache entries (plan, package, routine, and dynamic statement) being updated if they were dependent on it. The RESTRICT semantics on objects prevents the DATAACCESS authority from being revoked if the revokee owns an object that was created with dependencies on the authority to be revoked.

Revoking DATAACCESS is similar to revoking the individual privileges that DATAACCESS includes. For example, if a view was created based on the view owner having the SELECT privilege as acquired through the DATAACCESS authority, revoking DATAACCESS would be the equivalent of revoking the SELECT privilege and the view would be dropped.

DBADM
Revokes the DBADM authority from the user. If this user was also granted DATACCESS or ACCESSCTRL authority along with DBADM authority, DATACCESS or ACCESSCTRL would not be revoked.

DISPLAY
Revokes the privilege to use the following commands:

- The DISPLAY ARCHIVE command for archive log information

- The DISPLAY BUFFERPOOL command for the status of buffer pools
- The DISPLAY DATABASE command for the status of all databases
- The DISPLAY FUNCTION SPECIFIC command for statistics about accessed external user-defined functions
- The DISPLAY LOCATION command for statistics about threads with a distributed relationship
- The DISPLAY PROCEDURE command for statistics about accessed stored procedures
- The DISPLAY THREAD command for information on active threads with in Db2
- The DISPLAY TRACE command for a list of active traces

DEBUGSESSION

Revokes the privilege to create a debug session, which prevents client application debugging of native SQL or Java procedures that are executed within the session.

EXPLAIN

Revokes the privilege to issue the following:

- The EXPLAIN statement with the following options:
  - PLAN
  - ALL
- The PREPARE statement
- The DESCRIBE TABLE statement
- The ability to explain dynamic SQL statements that are executing with the special register CURRENT EXPLAIN MODE = EXPLAIN
- The BIND options EXPLAIN(ONLY) and SQLERROR(CHECK)

  EXPLAIN(ONLY) allows to explain the statements. SQLERROR(CHECK) performs all syntax and semantic checks on the SQL statements being bound.

MONITOR1

Revokes the privilege to obtain IFC data classified as serviceability data, statistics, accounting, and other performance data that does not contain potentially secure data.

MONITOR2

Revokes the privilege to obtain IFC data classified as containing potentially sensitive data such as SQL statement text and audit data. (Having the MONITOR2 privilege also implies having MONITOR1 privileges, however, revoking the MONITOR2 privilege does not cause the revoke of an explicitly granted MONITOR1 privilege.)

RECOVER

Revokes the privilege to issue the RECOVER INDOUBT command.

SQLADM

Revokes the privilege to issue the following:

- The DESCRIBE TABLE statement
- The EXPLAIN statement with the following options:
  - PLAN
  - ALL
  - STMTCACHE ALL
  - STMTID
  - STMTTOKEN
  - MONITORED STMTS
- The PREPARE statement
- The ability to explain dynamic SQL statements that are executing with the special register CURRENT EXPLAIN MODE = EXPLAIN

- The BIND options EXPLAIN(ONLY) and SQLERROR(CHECK)

  EXPLAIN(ONLY) allows to explain the statements. SQLERROR(CHECK) performs all syntax and semantic checks on the SQL statements being bound.
- The START command
- The STOP command
- The DISPLAY PROFILE command
- The ability to execute the RUNSTATS utility and the MODIFY STATISTICS utility in any database
- MONITOR2 privilege, which allows users to obtain IFC data that is classified as containing potentially sensitive data, such as SQL statement text and audit data, as well as IFC data that is classified as serviceability data, statistics, accounting, and other performance data.

STOPALL
Revokes the privilege to use the STOP DB2 command.

STOSPACE
Revokes the privilege to use the STOSPACE utility.

SYSADM
Revokes the system administrator authority.

SYSCTRL
Revokes the system control authority.

SYSOPR
Revokes the system operator authority.

TRACE
Revokes the privilege to use the MODIFY TRACE, START TRACE, and STOP TRACE commands.

ON SYSTEM
Identifies that the system privilege is revoked for the entire Db2 subsystem.

FROM
Refer to "REVOKE" on page 2065 for a description of the FROM clause.

BY
Refer to "REVOKE" on page 2065 for a description of the BY clause.

`INCLUDING DEPENDENT PRIVILEGES` or `NOT INCLUDING DEPENDENT PRIVILEGES`
Specifies whether revoking a privilege or an authority from an authorization ID or a role also results in revoking the grants that were made by that user. The default value is based on the authority that is being revoked and the REVOKE_DEP_PRIVILEGES system parameter:

- When ACCESSCTRL, DATAACCESS, or system DBADM authority is revoked, `NOT INCLUDING DEPENDENT PRIVILEGES` is assumed and the clause must be specified on the REVOKE statement.
- When the REVOKE_DEP_PRIVILEGES system parameter is set to NO, `NOT INCLUDING DEPENDENT PRIVILEGES` is assumed and an error is returned if the statement includes `INCLUDING DEPENDENT PRIVILEGES`.
- Otherwise, `INCLUDING DEPENDENT PRIVILEGES` is assumed and the clause must be specified on the REVOKE statement.

`INCLUDING DEPENDENT PRIVILEGES`
Specifies that revoking a privilege or an authority from an authorization ID or a role also results in revoking dependent privileges. This means that any grants that were made by the user will continue to be revoked, until all grants in the chain have been revoked.

`INCLUDING DEPENDENT PRIVILEGES` cannot be specified if the system parameter REVOKE_DEP_PRIVILEGES is set to NO, which enforces the behavior to not include the dependent privileges.

`NOT INCLUDING DEPENDENT PRIVILEGES`
Specifies that revoking a privilege or an authority from an authorization ID or a role does not cause the grants that were made by the user to be revoked. However, for the revoked privileges, all

implications of the privilege being revoked are applied. For example, if the revoked privileges were required to bind a package successfully, that package would continue to be invalidated as a result of the package owner losing these privileges. An object might be dropped if a privilege is revoked that was used to create the object.

`NOT INCLUDING DEPENDENT PRIVILEGES` must be specified when ACCESSCTRL, DATAACCESS, or system DBADM authority is revoked.

`NOT INCLUDING DEPENDENT PRIVILEGES` cannot be specified if the system parameter REVOKE_DEP_PRIVILEGES is set toYES, which enforces the behavior to include dependent privileges in the revoke.

Examples for REVOKE (system privileges)

Example 1: Revoke DISPLAY privileges from user LUTZ.

```
REVOKE DISPLAY
  FROM LUTZ;
```

Example 2: Revoke BSDS and RECOVER privileges from users PARKER and SETRIGHT.

```
REVOKE BSDS,RECOVER
  FROM PARKER,SETRIGHT;
```

Example 3: Revoke TRACE privileges previously granted to all local users. (Grants to specific users will not be affected.)

```
REVOKE TRACE
  FROM PUBLIC;
```

Example 4: Revoke ARCHIVE privileges from role ROLE1:

```
REVOKE ARCHIVE
  FROM ROLE ROLE1;
```

Example 5: SECADM Mary revokes the privilege to create a secure object from Steve that was granted by another SECADM.

```
REVOKE CREATE_SECURE_OBJECT
      FROM STEVE BY MARY;
```

Example 6: Revoke system DBADM from the role, ADMINROLE. This only revokes system DBADM authority from the role. If DATAACCESS and ACCESSCTRL authorities were granted during GRANT DBADM, those authorities are not revoked.

```
REVOKE DBADM ON SYSTEM
     FROM ROLE ADMINROLE
     NOT INCLUDING DEPENDENT PRIVILEGES;
```

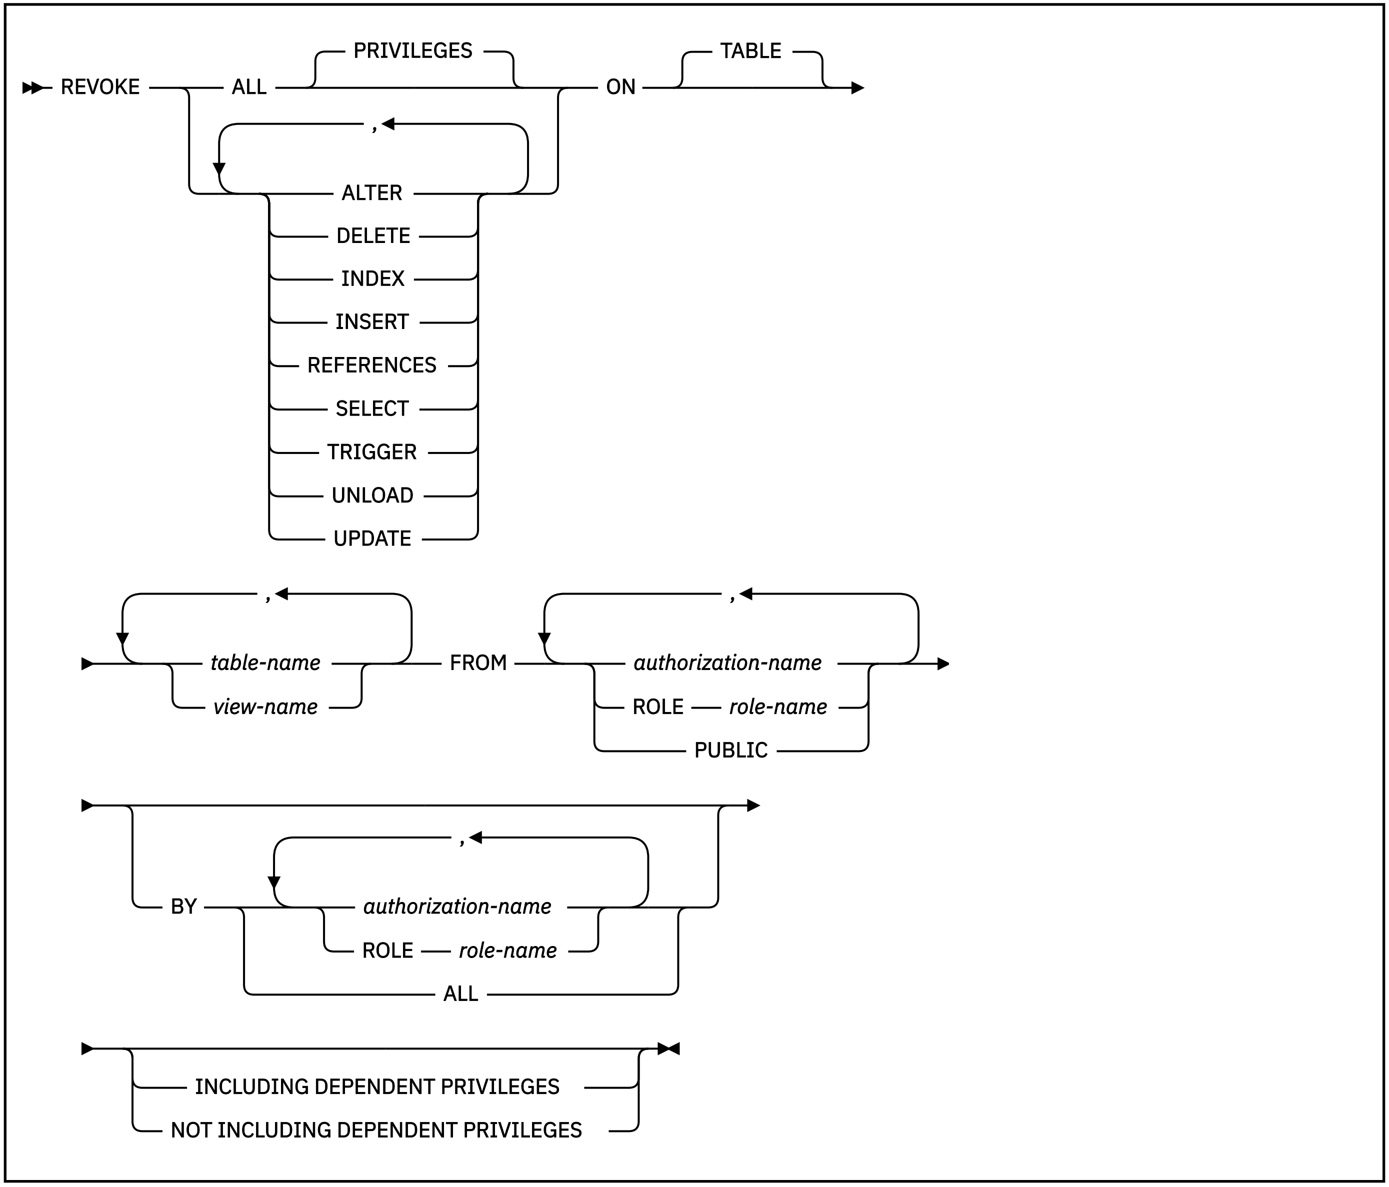
Example 7: Revoke system DBADM, DATAACCESS, and ACCESSCTRL authorities from the role, ADMINROLE.

```
REVOKE DBADM, DATAACCESS, ACCESSCTRL ON SYSTEM
     FROM ROLE ADMINROLE
     NOT INCLUDING DEPENDENT PRIVILEGES;
```

REVOKE (table or view privileges)

This form of the REVOKE statement revokes privileges on one or more tables or views.

Syntax for REVOKE (table or view privileges)



Description for REVOKE (table or view privileges)

ALL or ALL PRIVILEGES

If you specify ALL, the authorization ID of the statement must have granted a least one privilege on each identified table or view to each *authorization-name*. The privilege revoked from an authorization ID are those privileges on the table or view that the authorization ID of the statement granted to the authorization ID.

If you do not use ALL, you must use one or more of the keywords listed below. Each keyword revokes the privilege described, but only as it applies to the tables or views named in the ON clause.

ALTER

Revokes the privilege to alter the specified table or create a trigger on the specified table.

DELETE

Revokes the privilege to delete rows in the specified table or view.

INDEX
Revokes he privilege to create an index on the specified table.

INSERT
Revokes the privilege to insert rows into the specified table or view.

REFERENCES
Revokes the privilege to define and drop referential constraints. Although you can use a list of column names with the GRANT statement, you cannot use a list of column names with REVOKE; the privilege is revoked for all columns.

SELECT
Revokes the privilege to create a view or read data from the specified table or view. A view or a materialized query table is dropped when the SELECT privilege that was used to create it is revoked, unless the owner of the view or materialized query table was directly granted the SELECT privilege from another source before the view or materialized query table was created.

TRIGGER
Revokes the privilege to create a trigger on the specified table.

UNLOAD
Revokes the UNLOAD privilege to use the UNLOAD utility.

UPDATE
Revokes the privilege to update rows in the specified table or view. A list of column names can be used only with GRANT, not with REVOKE.

ON *table-name* or *view-name*
Names one or more tables or views on which you are revoking the privileges. The list can consist of table names, view names, or a combination of the two. A table or view must not be identified more than one time, and a declared temporary table and a table that is implicitly created for an XML column must not be identified.

FROM
Refer to "REVOKE" on page 2065 for a description of the FROM clause.

BY
If you omit BY, you must have granted each named privilege to each of the named users. More precisely, each privilege must have been granted to each user by a GRANT statement whose authorization ID is also the authorization ID of your REVOKE statement. Each of these grants is then revoked. (No single privilege need be granted on all tables and views.)

If BY is specified, each named grantor must satisfy the above requirement. In that case, the authorization ID of the statement need not satisfy the requirement unless it is one of the named grantors.

Refer to "REVOKE" on page 2065 for a description of the BY clause.

`INCLUDING DEPENDENT PRIVILEGES` or `NOT INCLUDING DEPENDENT PRIVILEGES`
Specifies whether revoking a privilege or an authority from an authorization ID or a role also results in revoking the grants that were made by that user. The default value is based on the authority that is being revoked and the REVOKE_DEP_PRIVILEGES system parameter:

- When ACCESSCTRL, DATAACCESS, or system DBADM authority is revoked, `NOT INCLUDING DEPENDENT PRIVILEGES` is assumed and the clause must be specified on the REVOKE statement.
- When the REVOKE_DEP_PRIVILEGES system parameter is set to NO, `NOT INCLUDING DEPENDENT PRIVILEGES` is assumed and an error is returned if the statement includes `INCLUDING DEPENDENT PRIVILEGES`.
- Otherwise, `INCLUDING DEPENDENT PRIVILEGES` is assumed and the clause must be specified on the REVOKE statement.

`INCLUDING DEPENDENT PRIVILEGES`
Specifies that revoking a privilege or an authority from an authorization ID or a role also results in revoking dependent privileges. This means that any grants that were made by the user will continue to be revoked, until all grants in the chain have been revoked.

`INCLUDING DEPENDENT PRIVILEGES` cannot be specified if the system parameter REVOKE_DEP_PRIVILEGES is set to NO, which enforces the behavior to not include the dependent privileges.

`NOT INCLUDING DEPENDENT PRIVILEGES`

Specifies that revoking a privilege or an authority from an authorization ID or a role does not cause the grants that were made by the user to be revoked. However, for the revoked privileges, all implications of the privilege being revoked are applied. For example, if the revoked privileges were required to bind a package successfully, that package would continue to be invalidated as a result of the package owner losing these privileges. An object might be dropped if a privilege is revoked that was used to create the object.

`NOT INCLUDING DEPENDENT PRIVILEGES` must be specified when ACCESSCTRL, DATAACCESS, or system DBADM authority is revoked.

`NOT INCLUDING DEPENDENT PRIVILEGES` cannot be specified if the system parameter REVOKE_DEP_PRIVILEGES is set toYES, which enforces the behavior to include dependent privileges in the revoke.

Notes for REVOKE (table or view privileges)

For a created temporary table, only ALL or ALL PRIVILEGES can be revoked. Specific table privileges cannot be revoked.

For a view of a created temporary table, either ALL or the specific UPDATE, DELETE, INSERT and SELECT privileges can be revoked.

For a declared temporary table, no privileges can be revoked because none can be granted. When a declared temporary table is defined, PUBLIC implicitly receives all table privileges (without GRANT authority) for the table. These privileges are not recorded in the Db2 catalog.

Examples for REVOKE (table or view privileges)

Example 1: Revoke SELECT privileges on table DSN8C10.EMP from user PULASKI.

```
REVOKE SELECT ON TABLE DSN8C10.EMP FROM PULASKI;
```

Example 2: Revoke update privileges on table DSN8C10.EMP previously granted to all local Db2 users. (Grants to specific users are not affected.)

```
REVOKE UPDATE ON TABLE DSN8C10.EMP FROM PUBLIC;
```

Example 3: Revoke all privileges on table DSN8C10.EMP from users KWAN and THOMPSON.

```
REVOKE ALL ON TABLE DSN8C10.EMP FROM KWAN,THOMPSON;
```

Example 4: Revoke the grant of SELECT and UPDATE privileges on the table DSN8C10.DEPT to every user in the network. Doing so does not affect users who obtained these privileges from some other grant.

```
REVOKE SELECT, UPDATE ON TABLE DSN8C10.DEPT
  FROM PUBLIC;
```

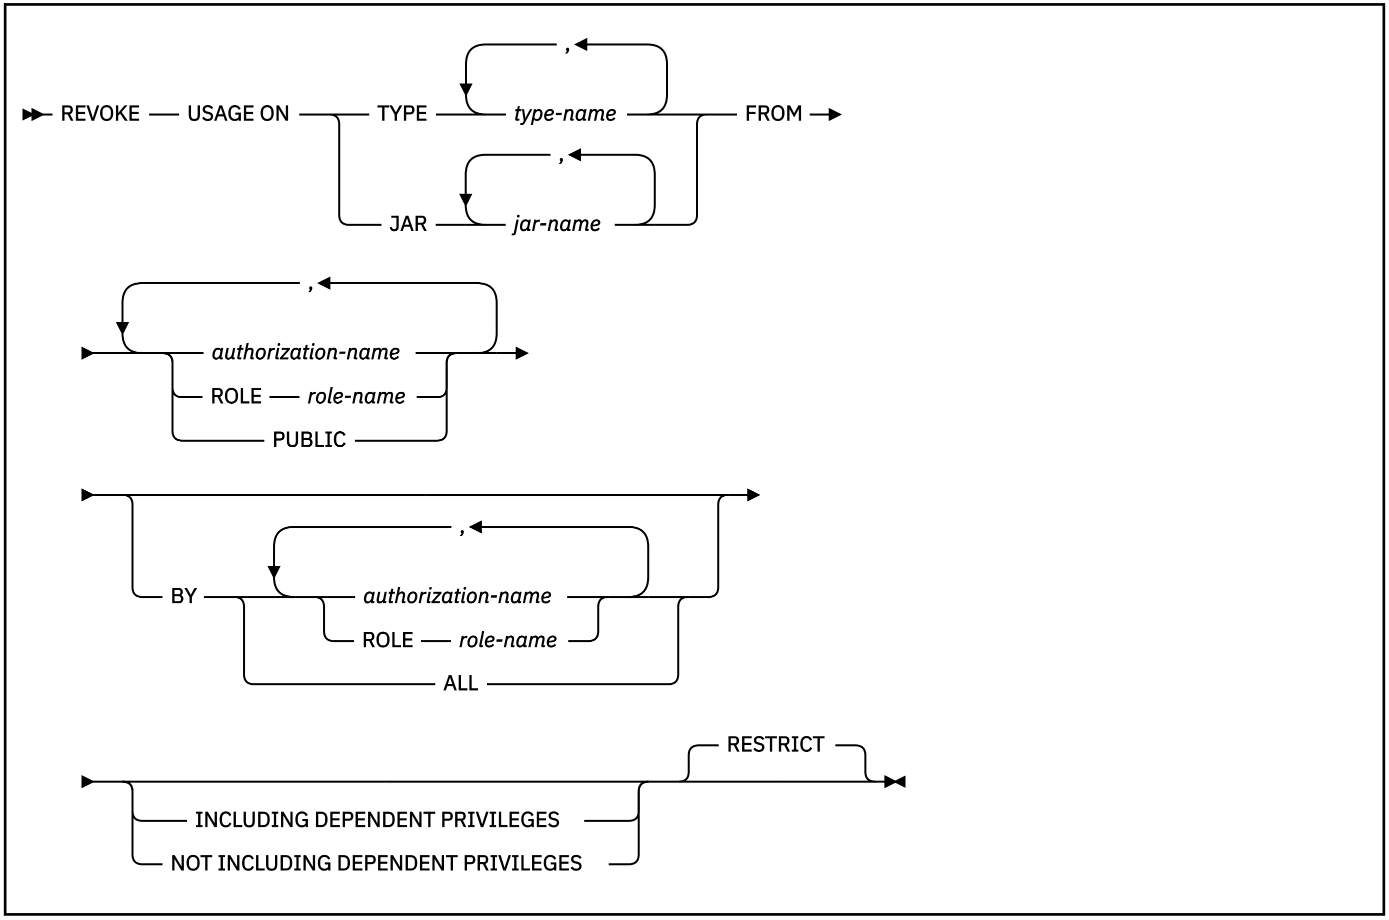
Example 5: Revoke the ALTER privileges on the table DSN8C10.EMP that were previously granted to role ROLE1:

```
REVOKE ALTER ON TABLE DSN8C10.EMP
  FROM ROLE ROLE1;
```

REVOKE (type or JAR file privileges)

This form of the REVOKE statement revokes the privilege to use distinct types, array types, or JAR files.

Syntax for REVOKE (type or JAR file privileges)



Description for REVOKE (type or JAR file privileges)

USAGE
Revokes the privilege to use the distinct type in tables, functions procedures, or the privilege to use the JAR file.

TYPE *type-name*
Identifies the user-defined type. The name, including the implicit or explicit schema name, must identify a unique user-defined type that exists at the current server.

JAR *jar-name*
Identifies the JAR file. The name, including the implicit or explicit schema name, must identify a unique JAR file that exists at the current server.

FROM
Refer to "REVOKE" on page 2065 for a description of the FROM clause.

BY
Refer to "REVOKE" on page 2065 for a description of the BY clause.

`INCLUDING DEPENDENT PRIVILEGES` or `NOT INCLUDING DEPENDENT PRIVILEGES`
Specifies whether revoking a privilege or an authority from an authorization ID or a role also results in revoking the grants that were made by that user. The default value is based on the authority that is being revoked and the REVOKE_DEP_PRIVILEGES system parameter:

- When ACCESSCTRL, DATAACCESS, or system DBADM authority is revoked, NOT INCLUDING DEPENDENT PRIVILEGES is assumed and the clause must be specified on the REVOKE statement.
- When the REVOKE_DEP_PRIVILEGES system parameter is set to NO, NOT INCLUDING DEPENDENT PRIVILEGES is assumed and an error is returned if the statement includes INCLUDING DEPENDENT PRIVILEGES.
- Otherwise, INCLUDING DEPENDENT PRIVILEGES is assumed and the clause must be specified on the REVOKE statement.

INCLUDING DEPENDENT PRIVILEGES

Specifies that revoking a privilege or an authority from an authorization ID or a role also results in revoking dependent privileges. This means that any grants that were made by the user will continue to be revoked, until all grants in the chain have been revoked.

INCLUDING DEPENDENT PRIVILEGES cannot be specified if the system parameter REVOKE_DEP_PRIVILEGES is set to NO, which enforces the behavior to not include the dependent privileges.

NOT INCLUDING DEPENDENT PRIVILEGES

Specifies that revoking a privilege or an authority from an authorization ID or a role does not cause the grants that were made by the user to be revoked. However, for the revoked privileges, all implications of the privilege being revoked are applied. For example, if the revoked privileges were required to bind a package successfully, that package would continue to be invalidated as a result of the package owner losing these privileges. An object might be dropped if a privilege is revoked that was used to create the object.

NOT INCLUDING DEPENDENT PRIVILEGES must be specified when ACCESSCTRL, DATAACCESS, or system DBADM authority is revoked.

NOT INCLUDING DEPENDENT PRIVILEGES cannot be specified if the system parameter REVOKE_DEP_PRIVILEGES is set toYES, which enforces the behavior to include dependent privileges in the revoke.

RESTRICT

Prevents the USAGE privilege from being revoked on a user-defined type or JAR file if any of the following conditions exist and the revokee does not have the USAGE privilege from another source:

- The revokee owns a function or stored procedure that uses the user-defined type or references the JAR file.
- The revokee owns a JAR file whose path references the JAR file for which USAGE is being revoked.
- The revokee owns a table that has a column that uses the user-defined type.
- A sequence exists for which the data type of the sequence is the user-defined type.

Notes for REVOKE (type or JAR file privileges)

Alternative syntax and synonyms: To provide compatibility with previous releases of Db2 or other products in the Db2 family, Db2 supports DATA TYPE or DISTINCT TYPE as a synonym for TYPE.

Examples for REVOKE (type or JAR file privileges)

Example 1: Revoke the USAGE privilege on distinct type SHOESIZE from user JONES.

```
REVOKE USAGE ON TYPE SHOESIZE FROM JONES;
```

Example 2: Revoke the USAGE privilege on distinct type US_DOLLAR from all users at the current server except for those who have been specifically granted USAGE and not through PUBLIC.

```
REVOKE USAGE ON TYPE US_DOLLAR FROM PUBLIC;
```

Example 3: Revoke the USAGE privilege on distinct type CANADIAN_DOLLARS from the administrative assistant (ADMIN_A).

```
   REVOKE USAGE ON TYPE CANADIAN_DOLLARS
         FROM ADMIN_A;
```

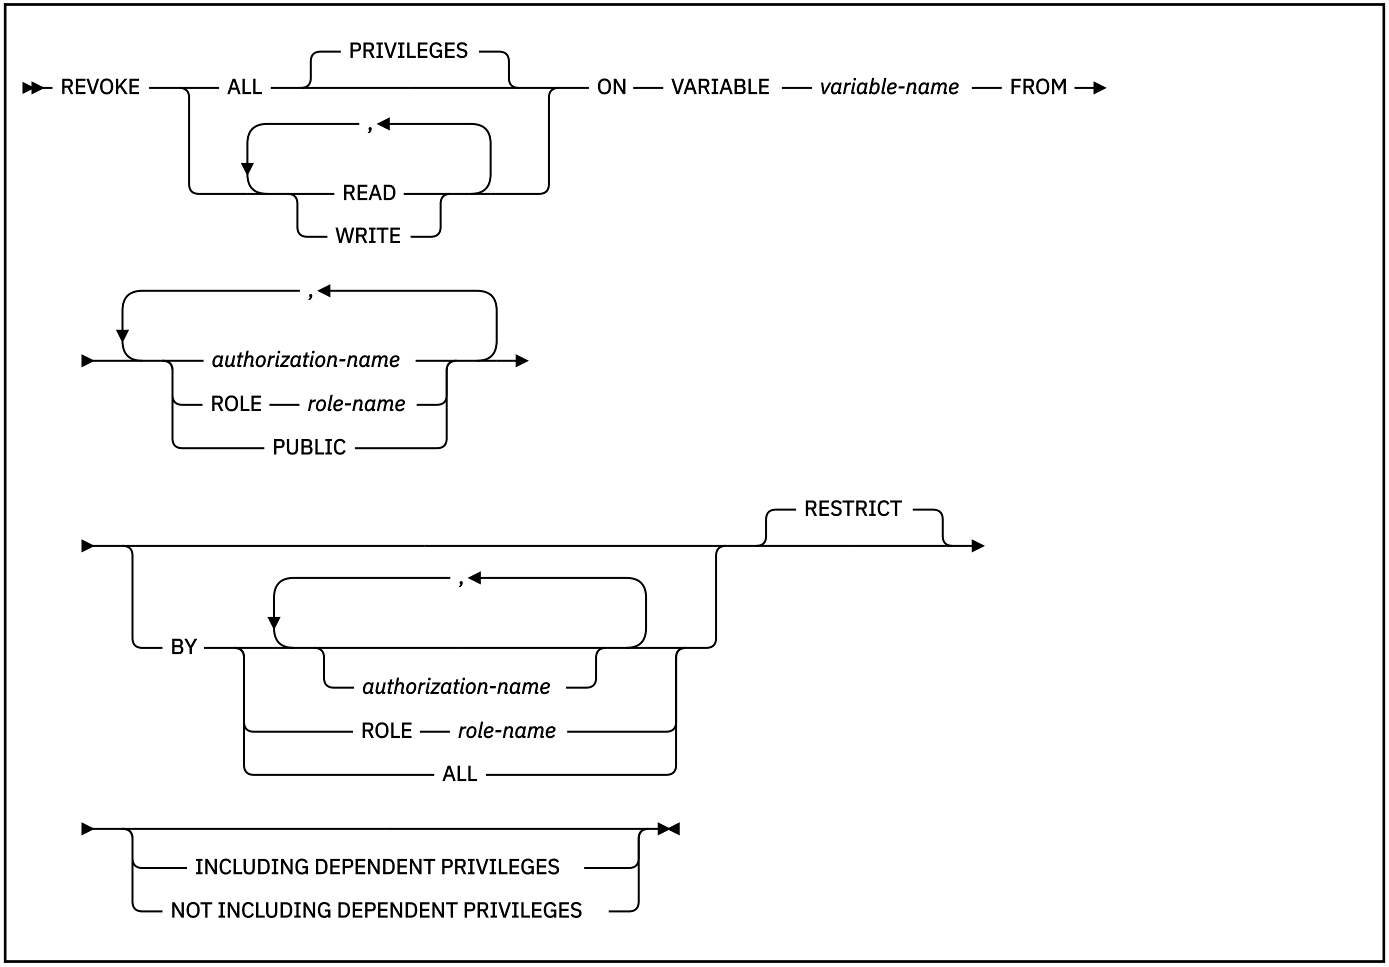
Example 4: Revoke the USAGE privilege on distinct type MILES from the role ROLE1:

```
   REVOKE USAGE ON TYPE MILES
         FROM ROLE ROLE1;
```

REVOKE (variable privileges)

This form of the REVOKE statement revokes privileges on global variables.

Syntax for REVOKE (variable privileges)



Description for REVOKE (variable privileges)

ALL PRIVILEGES
Revokes both READ and WRITE privileges on the specified global variable.

READ
Revokes the privilege to read the value of the specified global variable.

WRITE
Revokes the privilege to assign a value to the specified global variable.

ON VARIABLE *variable-name*

Identifies the global variable from which privileges are revoked. *variable-name* must identify a global variable that exists at the current server.

FROM

Refer to "REVOKE" on page 2065 for a description of the FROM clause.

BY

Refer to "REVOKE" on page 2065 for a description of the BY clause.

RESTRICT

Prevents the specified privileges from being revoked on a global variable if the following conditions exist:

- A function that is owned by the revokee references (READ or WRITE privilege) the specified global variable
- A view that is owned by the revokee references (READ or WRITE privilege) the specified global variable
- A trigger that is owned by the revokee references (READ or WRITE privilege) the specified global variable

INCLUDING DEPENDENT PRIVILEGES or NOT INCLUDING DEPENDENT PRIVILEGES

Specifies whether revoking a privilege or an authority from an authorization ID or a role also results in revoking the grants that were made by that user. The default value is based on the authority that is being revoked and the REVOKE_DEP_PRIVILEGES system parameter:

- When ACCESSCTRL, DATAACCESS, or system DBADM authority is revoked, `NOT INCLUDING DEPENDENT PRIVILEGES` is assumed and the clause must be specified on the REVOKE statement.
- When the REVOKE_DEP_PRIVILEGES system parameter is set to NO, `NOT INCLUDING DEPENDENT PRIVILEGES` is assumed and an error is returned if the statement includes `INCLUDING DEPENDENT PRIVILEGES`.
- Otherwise, `INCLUDING DEPENDENT PRIVILEGES` is assumed and the clause must be specified on the REVOKE statement.

INCLUDING DEPENDENT PRIVILEGES

Specifies that revoking a privilege or an authority from an authorization ID or a role also results in revoking dependent privileges. This means that any grants that were made by the user will continue to be revoked, until all grants in the chain have been revoked.

`INCLUDING DEPENDENT PRIVILEGES` cannot be specified if the system parameter REVOKE_DEP_PRIVILEGES is set to NO, which enforces the behavior to not include the dependent privileges.

NOT INCLUDING DEPENDENT PRIVILEGES

Specifies that revoking a privilege or an authority from an authorization ID or a role does not cause the grants that were made by the user to be revoked. However, for the revoked privileges, all implications of the privilege being revoked are applied. For example, if the revoked privileges were required to bind a package successfully, that package would continue to be invalidated as a result of the package owner losing these privileges. An object might be dropped if a privilege is revoked that was used to create the object.

`NOT INCLUDING DEPENDENT PRIVILEGES` must be specified when ACCESSCTRL, DATAACCESS, or system DBADM authority is revoked.

`NOT INCLUDING DEPENDENT PRIVILEGES` cannot be specified if the system parameter REVOKE_DEP_PRIVILEGES is set toYES, which enforces the behavior to include dependent privileges in the revoke.

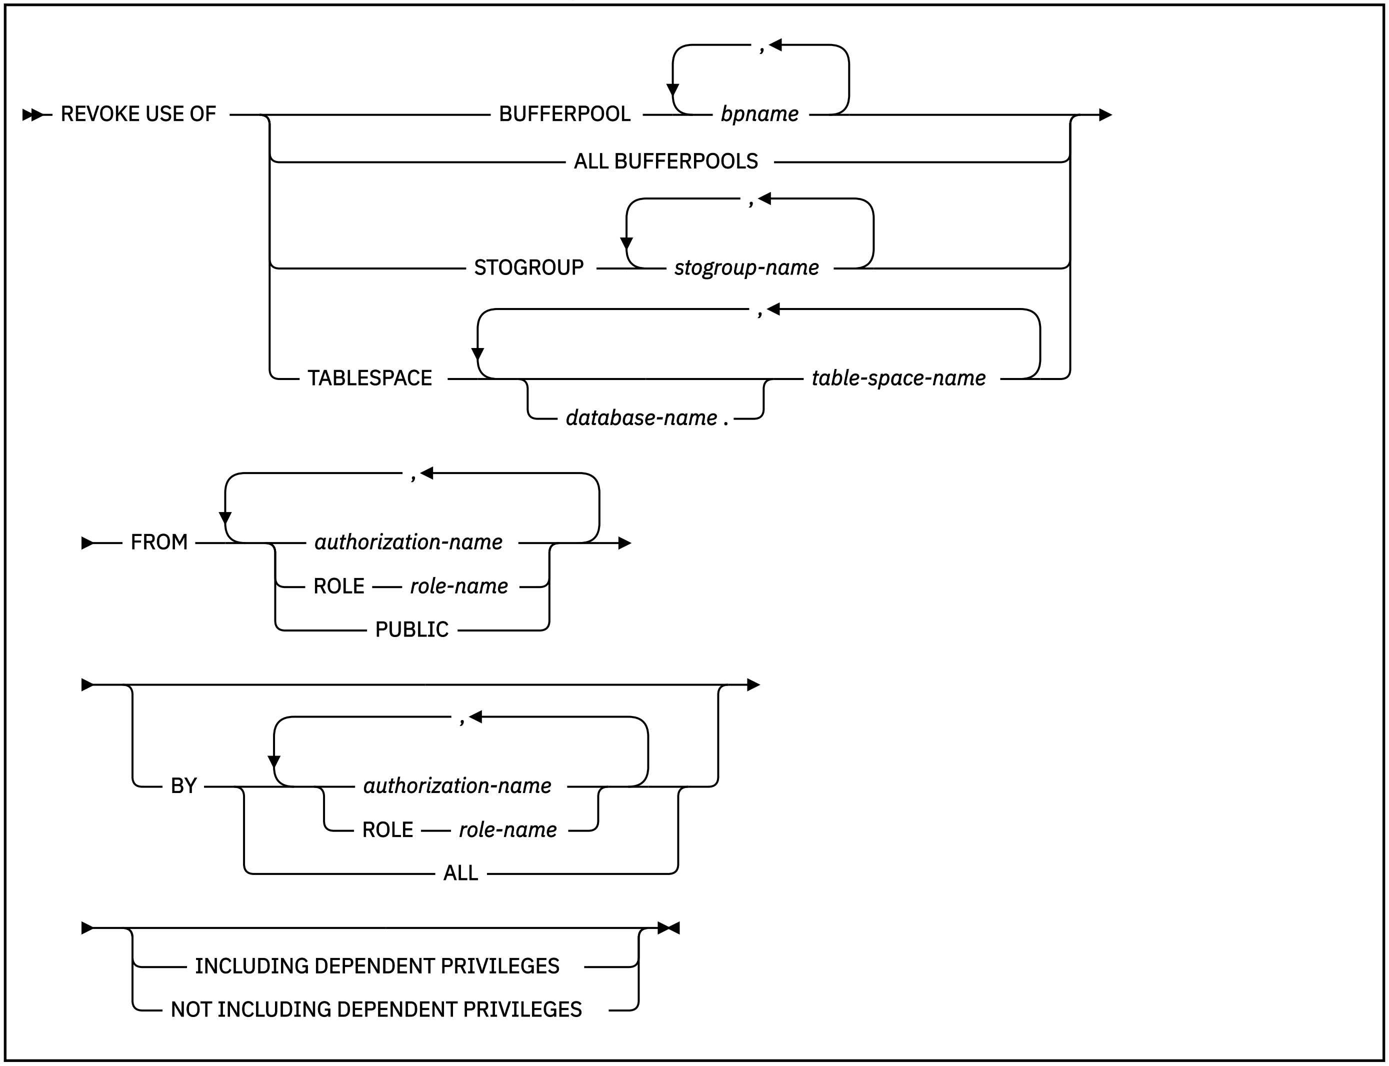
Notes for REVOKE (variable privileges)

Global variables and statements in the dynamic statement cache: If a cached dynamic statement depends on the revoked authorization for the specified global variable and the cache statement is not in use, the cached dynamic statement will be invalidated.

REVOKE (use privileges)

This form of the REVOKE statement revokes authority to use particular buffer pools, storage groups, or table spaces.

Syntax for REVOKE (use privileges)



Description for REVOKE (use privileges)

BUFFERPOOL *bpname,...*
Revokes the privilege to refer to any of the identified buffer pools in a CREATE INDEX, CREATE TABLESPACE, ALTER INDEX, or ALTER TABLESPACE statement. See "Naming conventions" on page 79 for more details about *bpname*.

ALL BUFFERPOOLS
Revokes the privilege to refer to any buffer pool in a CREATE INDEX, CREATE TABLESPACE, ALTER INDEX, or ALTER TABLESPACE statement.

STOGROUP *stogroup-name,...*
Revokes the privilege to refer to any of the identified storage groups in a CREATE INDEX, CREATE TABLESPACE, ALTER INDEX, or ALTER TABLESPACE statement.

TABLESPACE *database-name.table-space-name,...*
Revokes the privilege to refer to any of the specified table spaces in a CREATE TABLE statement. The default *database-name* is DSNDB04.

For table spaces in a work file database you cannot revoke the privilege from PUBLIC. When a table space is created in a work file database, PUBLIC implicitly receives the TABLESPACE privilege (without GRANT authority); this privilege is not recorded in the Db2 catalog, and it cannot be revoked.

FROM
Refer to "REVOKE" on page 2065 for a description of the FROM clause.

BY
Refer to "REVOKE" on page 2065 for a description of the BY clause.

`INCLUDING DEPENDENT PRIVILEGES` or `NOT INCLUDING DEPENDENT PRIVILEGES`
Specifies whether revoking a privilege or an authority from an authorization ID or a role also results in revoking the grants that were made by that user. The default value is based on the authority that is being revoked and the REVOKE_DEP_PRIVILEGES system parameter:

- When ACCESSCTRL, DATAACCESS, or system DBADM authority is revoked, `NOT INCLUDING DEPENDENT PRIVILEGES` is assumed and the clause must be specified on the REVOKE statement.
- When the REVOKE_DEP_PRIVILEGES system parameter is set to NO, `NOT INCLUDING DEPENDENT PRIVILEGES` is assumed and an error is returned if the statement includes `INCLUDING DEPENDENT PRIVILEGES`.
- Otherwise, `INCLUDING DEPENDENT PRIVILEGES` is assumed and the clause must be specified on the REVOKE statement.

`INCLUDING DEPENDENT PRIVILEGES`
Specifies that revoking a privilege or an authority from an authorization ID or a role also results in revoking dependent privileges. This means that any grants that were made by the user will continue to be revoked, until all grants in the chain have been revoked.

`INCLUDING DEPENDENT PRIVILEGES` cannot be specified if the system parameter REVOKE_DEP_PRIVILEGES is set to NO, which enforces the behavior to not include the dependent privileges.

`NOT INCLUDING DEPENDENT PRIVILEGES`
Specifies that revoking a privilege or an authority from an authorization ID or a role does not cause the grants that were made by the user to be revoked. However, for the revoked privileges, all implications of the privilege being revoked are applied. For example, if the revoked privileges were required to bind a package successfully, that package would continue to be invalidated as a result of the package owner losing these privileges. An object might be dropped if a privilege is revoked that was used to create the object.

`NOT INCLUDING DEPENDENT PRIVILEGES` must be specified when ACCESSCTRL, DATAACCESS, or system DBADM authority is revoked.

`NOT INCLUDING DEPENDENT PRIVILEGES` cannot be specified if the system parameter REVOKE_DEP_PRIVILEGES is set toYES, which enforces the behavior to include dependent privileges in the revoke.

Notes for REVOKE (use privileges)

You can revoke privileges for only one type of object with each statement. Thus you can revoke the use of several table spaces with one statement, but not the use of a table space and a storage group.

For each object you name, you (or the indicated grantors) must have granted the USE privilege on that object to all identified users (including PUBLIC, if specified). The same object must not be identified more than once.

Revoking the privilege USE OF ALL BUFFERPOOLS does not cascade to all other privileges that can be granted under that privilege. A user with the privilege USE OF ALL BUFFERPOOLS WITH GRANT OPTION can make two types of grants:

- GRANT USE OF ALL BUFFERPOOLS TO *userid*. This privilege is revoked when the original user's privilege is revoked.
- GRANT USE OF BUFFERPOOL BP*n* TO *userid*. This privilege is *not revoked* when the original user's privilege is revoked.

Examples for REVOKE (use privileges)

Example 1: Revoke authority to use buffer pool BP2 from user MARINO.

```
REVOKE USE OF BUFFERPOOL BP2
  FROM MARINO;
```

Example 2: Revoke a grant of the USE privilege on the table space DSN8S12D in the database DSN8D12A. The grant is to PUBLIC, that is, to everyone at the local Db2 subsystem. (Grants to specific users are not affected.)

```
REVOKE USE OF TABLESPACE DSN8D12A.DSN8S12D
  FROM PUBLIC;
```

Example 3: Revoke the authority to use storage group SG1 from role ROLE1:

```
REVOKE USE OF STOGROUP SG1
  FROM ROLE ROLE1;
```

ROLLBACK

The ROLLBACK statement can be used to end a unit of recovery and back out all the relational database changes that were made by that unit of recovery. If relational databases are the only recoverable resources used by the application process, ROLLBACK also ends the unit of work. ROLLBACK can also be used to back out only the changes made after a savepoint was set within the unit of recovery without ending the unit of recovery. Rolling back to a savepoint enables selected changes to be undone.

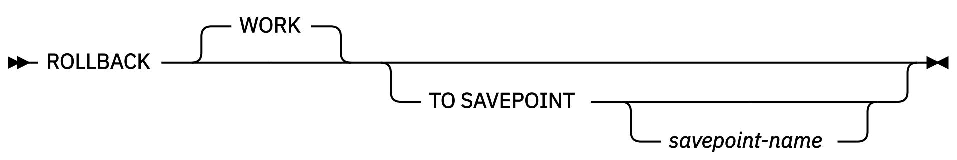
Invocation for ROLLBACK

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared. It can be used in the IMS or CICS environment only if the TO SAVEPOINT clause is specified.

Authorization for ROLLBACK

None required.

Syntax for ROLLBACK



Description for ROLLBACK

When ROLLBACK is used without the SAVEPOINT clause, the unit of recovery in which the ROLLBACK statement is executed is ended and a new unit of recovery is started.

All changes that are made by the following statements during the unit of recovery are backed out:

- ALTER
- COMMENT
- CREATE
- DELETE
- DROP
- EXPLAIN
- GRANT
- INSERT
- LABEL
- MERGE
- REFRESH TABLE
- RENAME
- REVOKE
- SELECT INTO with an SQL data change statement
- select-statement with an SQL data change statement
- TRUNCATE when the IMMEDIATE clause is not specified
- UPDATE

ROLLBACK without the TO SAVEPOINT clause also causes the following actions to occur:

- All locks that are implicitly acquired during the unit of recovery are released. See "LOCK TABLE" on page 2012 for an explanation of the duration of explicitly acquired locks.
- All cursors are closed, all prepared statements are destroyed, and any cursors that are associated with the prepared statements are invalidated.
- All rows and all logical work files of every created temporary table of the application process are deleted. (All the rows of a declared temporary table are not implicitly deleted. As with base tables, any changes that are made to a declared temporary table during the unit of recovery are undone to restore the table to its state at the last commit point.)
- All LOB locators, including those that are held, are freed.

TO SAVEPOINT

Specifies that the unit of recovery is not to be ended and that only a partial rollback (to a savepoint) is to be performed. If a savepoint name is not specified, rollback is to the last active savepoint. For example, if in a unit of recovery, savepoints A, B, and C are set in that order and then C is released, ROLLBACK TO SAVEPOINT causes a rollback to savepoint B.

savepoint-name

Identifies the savepoint to which to roll back. The name must identify a savepoint that exists at the current server.

All database changes (including changes made to a declared temporary tables but excluding changes made to created temporary tables) that were made after the savepoint was set are backed out. Changes that are made to created temporary tables are not logged and are not backed out; a warning is issued instead. (A warning is also issued when a created temporary table is changed and there is an active savepoint.)

In addition, none of the following items are backed out:

- The opening or closing of cursors
- Changes in cursor positioning
- The acquisition and release of locks
- The caching of the rolled back statements

Any savepoints that are set after the one to which rollback is performed are released. The savepoint to which rollback is performed is not released.

ROLLBACK with or without the TO SAVEPOINT clause has no effect on connections.

Notes for ROLLBACK

The following information applies only to rolling back all changes in the unit of recovery (the ROLLBACK statement without the TO SAVEPOINT clause):

- *Stored procedures.* The ROLLBACK statement cannot be used if the procedure is in the calling chain of a user-defined function or a trigger or if Db2 is not the commit coordinator.
- *IMS or CICS.* Using a ROLLBACK to SAVEPOINT statement in an IMS or CICS environment only rolls back Db2 resources. Any other recoverable resources updated in the environment are not rolled back. To do a rollback operation in these environments, SQL programs must use the call prescribed by their transaction manager. The effect of these rollback operations on Db2 data is the same as that of the SQL ROLLBACK statement.

  A rollback operation in an IMS or CICS environment might handle the closing of cursors that were declared with the WITH hold option differently than the SQL ROLLBACK statement does. If an application requests a rollback operation from CICS or IMS, but no work has been performed in Db2 since the last commit point, the rollback request will not be broadcast to Db2. If the application had opened cursors using the WITH HOLD option in a previous unit of work, the cursors will not be closed, and any prepared statements associated with those cursors will not be destroyed.
- *Implicit rollback operations:* In all Db2 environments, the abend of a process is an implicit rollback operation.

ROLLBACK and non-LOB table spaces that are not logged: If ROLLBACK is executed for a unit of work that includes changes to a non-LOB table space that is not logged (specifies the NOT LOGGED attribute), that table space is marked RECOVER-pending and the table space is placed in the logical page list. The table space is therefore not available after the rollback operation completes. For more information about the RECOVER utility, see RECOVER (Db2 Utilities).

ROLLBACK and declared global temporary tables that are not logged: When NOT LOGGED is specified on a declared global temporary table and Db2 must roll back because of an error such as a duplicate key error, rows are deleted or preserved depending on the option that was specified for ON ROLLBACK.

If the ON ROLLBACK DELETE ROWS option was specified for the table, insert, update, and delete activity is not logged. During a ROLLBACK or ROLLBACK TO SAVEPOINT operation, if the table was updated since the last COMMIT statement, all rows are deleted from the table. Any open cursors for the table do not have positions. If the declaration of the declared global temporary table was not committed, the declaration of the table is rolled back.

If the ON ROLLBACK PRESERVE ROWS option was specified for the table, insert, update, and delete activity is not logged. During a ROLLBACK or ROLLBACK TO SAVEPOINT operation, all rows in the table are preserved regardless of any updates to the table since the last COMMIT statement. Any open cursors for the table do not have positions. If the declaration of the declared global temporary table was not committed, the declaration of the table is rolled back.

Effect of ROLLBACK on global variables: Global variables are not controlled at the transaction level. Issuing a ROLLBACK statement does not affect the contents of a global variable.

Effect of ROLLBACK on insert operations: If execution of an INSERT statement results in creation of a data set in a table space, and the INSERT operation is rolled back, the inserted data is deleted, but the data set is not deleted.

Effect of ROLLBACK on prepared dynamic statements: All prepared dynamic statements in a package that is bound with KEEPDYNAMIC(YES) are kept past rollback points.

Examples for ROLLBACK

Example 1: Roll back all Db2 database changes made since the unit of recovery was started.

```
ROLLBACK WORK;
```

Example 2: After a unit of recovery started, assume that three savepoints A, B, and C were set and that C was released:

```
...
SAVEPOINT A ON ROLLBACK RETAIN CURSORS;
...
SAVEPOINT B ON ROLLBACK RETAIN CURSORS;
...
SAVEPOINT C ON ROLLBACK RETAIN CURSORS;
...
RELEASE SAVEPOINT C;
...
```

Roll back all Db2 database changes only to savepoint A:

```
ROLLBACK WORK TO SAVEPOINT A;
```

If a savepoint name was not specified (that is, `ROLLBACK WORK TO SAVEPOINT`), the rollback would be to the last active savepoint that was set, which is B.

SAVEPOINT

The SAVEPOINT statement sets a savepoint within a unit of recovery to identify a point in time within the unit of recovery to which relational database changes can be rolled back.

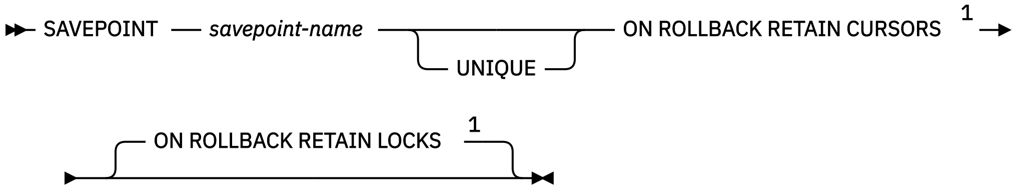
Invocation for SAVEPOINT

This statement can be imbedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization for SAVEPOINT

None required.

Syntax for SAVEPOINT



Notes:

[1] These clauses can be specified in either order.

Description for SAVEPOINT

savepoint-name
Names the savepoint. *savepoint-name* must not begin with 'SYS'.

UNIQUE
Specifies that the application program cannot reuse the savepoint name within the unit of recovery. An error occurs if a savepoint with the same name as *savepoint-name* already exists within the unit of recovery.

Omitting UNIQUE indicates that the application can reuse the savepoint name within the unit of recovery. If *svpt-name* identifies a savepoint that already exists within the unit of recovery and the savepoint was not created with the UNIQUE option, the existing savepoint is destroyed and a new savepoint is created. Destroying a savepoint to reuse its name for another savepoint is not the same as releasing the savepoint. Reusing a savepoint name destroys only one savepoint. Releasing a savepoint with the RELEASE SAVEPOINT statement releases the savepoint and all savepoints that have been subsequently set.

ON ROLLBACK RETAIN CURSORS

Specifies that any cursors that are opened after the savepoint is set are not tracked, and thus, are not closed upon rollback to the savepoint. Although these cursors remain open after rollback to the savepoint, they might not be usable. For example, if rolling back to the savepoint causes the insertion of a row on which the cursor is positioned to be rolled back, using the cursor to update or delete the row results in an error.

ON ROLLBACK RETAIN LOCKS

Specifies that any locks that are acquired after the savepoint is set are not tracked, and thus, are not released on rollback to the savepoint. ON ROLLBACK RETAIN LOCKS is the default behavior.

Example for SAVEPOINT

Assume that you want to set three savepoints at various points in a unit of recovery. Name the first savepoint A and allow the savepoint name to be reused. Name the second savepoint B and do not allow the name to be reused. Because you no longer need savepoint A when you are ready to set the third savepoint, reuse A as the name of the savepoint.

```
SAVEPOINT A ON ROLLBACK RETAIN CURSORS;
    ⋮
SAVEPOINT B UNIQUE ON ROLLBACK RETAIN CURSORS;
    ⋮
SAVEPOINT A ON ROLLBACK RETAIN CURSORS;
```

SELECT

The *select-statement* is the form of a query that can be directly specified in a DECLARE CURSOR statement, or prepared and then referenced in a DECLARE CURSOR statement. It can also be issued interactively using SPUFI or the command line processor which causes a result table to be displayed at your terminal. In any case, the table specified by *select-statement* is the result of the fullselect.

For a description of the SELECT statement, see "select-statement" on page 1064.

SELECT INTO

The SELECT INTO statement produces a result table that contains at most one row. The statement assigns the values in that row to variables. If the table is empty, the statement does not assign values to the host variables or global variables.

Invocation for SELECT INTO

This statement can only be embedded in an application program. It is an executable statement that cannot be dynamically prepared.

Authorization for SELECT INTO

The privilege set that is defined below must include at least one of the following:

- The SELECT privilege on every table and view identified in the statement
- Ownership of every table and view identified in the statement
- READ privileges on any global variables that are identified in the statement

- Ownership of any global variables that are identified in the statement
- DBADM authority for the database (tables only)
- DATAACCESS authority
- SYSADM authority
- SYSCTRL authority (catalog tables only)

If the SELECT INTO statement includes an SQL data change statement, the privilege set must also include at least the privileges (INSERT, UPDATE, or DELETE) that are associated with that SQL data change statement on the table or view.

For an assignment to a global variable or an element of an array global variable, the privilege set must include at least one of the following:

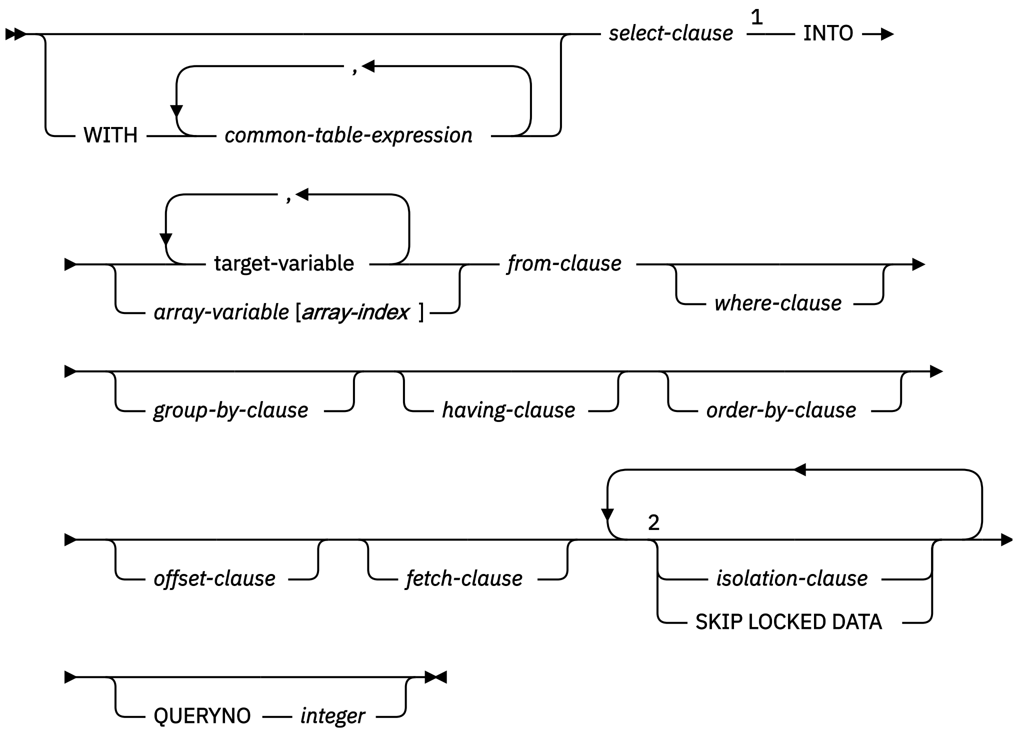
- The WRITE privilege on the variable
- Ownership of the variable
- DATAACCESS authority
- SYSADM authority

For an assignment to a transition variable, the privilege set must include at least one of the following:

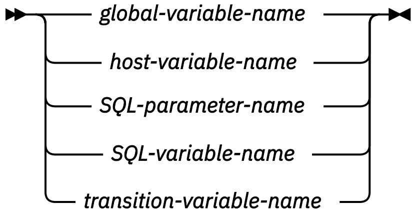
- The UPDATE privilege on the table or view on which the trigger that contains the assignment statement is defined
- The UPDATE privilege on the column corresponding to the transition variable to be assigned a value
- Ownership of the table or view on which the trigger that contains the assignment statement is defined
- DBADM authority on the database that contains the table on which the trigger that contains the assignment statement is defined
- DATAACCESS authority
- SYSADM authority

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the package. If the statement is dynamically prepared, the privilege set is determined by the DYNAMICRULES behavior in effect (run, bind, define, or invoke) and is summarized in DYNAMICRULES behaviors and authorization checking. For more information on these behaviors, including a list of the DYNAMICRULES bind option values that determine them, see "Authorization IDs and dynamic SQL" on page 94.

Syntax for SELECT INTO



target-variable



Notes:

[1] The *select-clause* cannot reference both a system-period temporal table and an archive-enabled table.

[2] The same clause must not be specified more than once.

Description for SELECT INTO

The result table is derived by logically evaluating the *isolation-clause*, *from-clause*, *where-clause*, *group-by-clause*, *having-clause*, *order-by-clause*, *offset-clause*, *fetch-clause*, and the *select-clause*, in this order. The actual order might be slightly different based on the plan that is chosen by the Db2 subsystem. See the topics under Chapter 6, “Queries,” on page 1005 for a description of these clauses.

The tables or views identified in the statement can exist at the current server or at any Db2 subsystem with which the current server can establish a connection.

WITH *common-table-expression*

Refer to “common-table-expression” on page 1065 for information about specifying a *common-table-expression*.

INTO *target-variable* or *array-variable*[*array-index*]

Identifies one or more targets for the assignment of output values. The number of targets in the INTO clause must equal the number of values that are to be assigned. The first value in the result row is assigned to the first target in the list, the second value to the second target, and so on. A target variable must not be specified more than once in the INTO clause. Each assignment to a target is made in sequence through the list, according to the rules described in “Assignment and comparison” on page 143.

The value 'W' is assigned to the SQLWARN3 field of the SQLCA if the number of targets is less than the number of result column values.

If an error occurs on any assignment, the value is not assigned to the target, and no more values are assigned to the specified targets. Any values that have already been assigned remain assigned.

global-variable-name
Identifies the global variable that is the assignment target.

host-variable-name
Identifies the host variable that is the assignment target. For LOB output values, the target can be a regular host variable (if it is large enough), a LOB locator variable, or a LOB file reference variable.

SQL-parameter-name
Identifies the parameter that is the assignment target.

SQL-variable-name
Identifies the SQL variable that is the assignment target. SQL variables must be declared before they are used.

transition-variable-name
Identifies the column that is to be updated in the transition table. A *transition-variable-name* must identify a column in the subject table of a trigger, optionally qualified by a correlation name that identifies the new value.

***array-variable* [*array-index*]**
Specifies an array element that is the target of the assignment.

An array element must not be specified as the target for an assignment if *common-table-expression* is also specified in the statement.

array-variable
Specifies an array variable.

[*array-index*]
An expression that specifies which element in the array is the target of the assignment.

For an ordinary array, the array index expression must be castable to INTEGER, and must not be the null value. The index value must be between 1 and the maximum cardinality that is defined for the array.

For an associative array, the array index expression must be castable to the index data type of the associative array, and must not be the null value.

array-index must not be:

- An expression that references the CURRENT DATE, CURRENT TIME, or CURRENT TIMESTAMP special register
- A nondeterministic function
- A function that is defined with EXTERNAL ACTION
- A function that is defined with MODIFIES SQL DATA
- A sequence expression
- A column that is not in a scalar fullselect.

The data type of a variable must be compatible with the value assigned to it. If the value is numeric, the variable must have the capacity to represent the integral part of the value. For a date or time value, the variable must be a character string variable of a minimum length as defined in “Assignment and comparison” on page 143.

Each assignment to a variable is made according to the rules described in “Assignment and comparison” on page 143. Assignments are made in sequence through the list.

If an error occurs as the result of an arithmetic expression in the SELECT list of a SELECT INTO statement (division by zero or overflow) or a numeric conversion error occurs, the result is the null value. As in any other case of a null value, an indicator variable must be provided and the main variable is unchanged. In this case, however, the indicator variable is set to -2. Processing of the statement continues as if the error had not occurred. (However, this error causes a positive SQLCODE.) If you do not provide an indicator variable, a negative value is returned in the SQLCODE field of the SQLCA. Processing of the statement terminates when the error is encountered.

If an error occurs, no value is assigned to the variable or to later variables, though any values that have already been assigned to variables remain assigned.

If an error occurs because the result table has more than one row, values might be assigned to the variables. If values are assigned to the variables, the row that is the source of the values is undefined and not predictable.

SKIP LOCKED DATA

Specifies that rows are skipped when incompatible locks are held on the row by other transactions. These rows can belong to any accessed table that is specified in the statement. SKIP LOCKED DATA can be used only when isolation CS or RS is in effect and applies only to row level or page level locks.

SKIP LOCKED DATA is ignored if it is specified when the isolation level that is in effect is repeatable read (WITH RR) or uncommitted read (WITH UR).

QUERYNO *integer*

Specifies the number to be used for this SQL statement in EXPLAIN output and trace records. The number is used for the QUERYNO columns of the plan tables for the rows that contain information about this SQL statement. This number is also used in the QUERYNO column of the SYSIBM.SYSSTMT and SYSIBM.SYSPACKSTMT catalog tables.

If the clause is omitted, the number associated with the SQL statement is the statement number assigned during precompilation. Thus, if the application program is changed and then precompiled, that statement number might change.

Using the QUERYNO clause to assign unique numbers to the SQL statements in a program is helpful:

- For simplifying the use of optimization hints for access path selection
- For correlating SQL statement text with EXPLAIN output in the plan table

For more information about enabling and using optimization hints,, see Influencing access path selection (Db2 Performance).

Notes for SELECT INTO

Assignment to targets

The *n*th target identified by the INTO clause or described in the SQLDA corresponds to the *n*th column of the result table of the cursor. The data type of target must be compatible with its corresponding value. If the value is numeric, the target must have the capacity to represent the whole part of the value. For a datetime value, the target must be a character string variable of a minimum length as defined in "String representations of datetime values" on page 120. When the target is a host variable, if the value is null, an indicator variable must be specified.

Assignments are made in sequence through the list. Each assignment to a target is made according to the rules described in Chapter 2, "Language elements in SQL," on page 75. If the number of targets is less than the number of values in the row, the SQLWARN3 field of the SQLCA is set to 'W'. There is no warning if there are more targets than the number of result columns. If the target is a host variable and the value is null, an indicator variable must be provided. If an assignment error occurs, the value is not assigned to the target and no more values are assigned to targets. Any values that have already been assigned to targets remain assigned.

If more than one assignment is included in the same assignment statement, all expressions are evaluated before the assignments are performed. For example, a reference to a variable in an expression always uses the value of the variable prior to any assignment in the assignment statement.

Normally, you use LOB locators to assign and retrieve data from LOB columns. However, because of compatibility rules, you can also use LOB locators to assign data to targets with other data types. For more information on using locators, see Saving storage when manipulating LOBs by using LOB locators (Db2 Application programming and SQL).

A timestamp without time zone value must not be assigned to a timestamp with time zone target.

Default encoding scheme

The default encoding scheme for the data is the value in the bind option ENCODING, which is the option for application encoding. If this statement is used with functions such as LENGTH or SUBSTRING that are operating on LOB locators, and the LOB data that is specifies by the locator is in a different encoding scheme from the ENCODING bind option, LOB materialization and character conversion occur. To avoid LOB materialization and character conversion, select the LOB data from the SYSIBM.SYSDUMMYA, SYSIBM.SYSDUMMYE, or SYSIBM.SYSDUMMYU sample table.

If the result table is empty

If the table is empty, the statement assigns +100 to SQLCODE, '02000' to SQLSTATE, and does not assign values to the host variables or global variables.

Number of rows inserted

If the SELECT INTO statement of the cursor contains an SQL data change statement, the SELECT INTO operation sets SQLERRD(3) to the number of rows inserted.

***offset-clause* considerations**

- The *offset-clause* can be used in the SELECT INTO statement when the query can result in more than a single row.
- To influence which row is returned, you can use the *order-by-clause*. When you specify the *order-by-clause*, the rows of the result are ordered, the specified number of rows are skipped, and the first row is returned. If the *fetch-clause* is not specified and the result table contains more than a single row, an error occurs.

***fetch-clause* considerations**

- The *fetch-clause* can be used in a SELECT INTO statement when the query can result in more than a single row. Specifying FETCH FIRST 1 ROW ONLY indicates that at most one row can be retrieved, regardless of how many rows are in the result table.
- Using the *fetch-clause* to explicitly limit the result table to a single row provides a way for a SELECT INTO statement to be used with a query that might return more than a single row. Using the clause helps you to avoid using a cursor when you know that you want to retrieve only one row. To influence which row is returned, you can use the *order-by-clause*. When you specify the *order-by-clause*, the rows of the result are ordered and then the first row is returned. If the *fetch-clause* is not specified and the result table contains more than a single row, an error occurs.

Examples for SELECT INTO

Example 1

Put the maximum salary in DSN8C10.EMP into the host variable MAXSALRY.

```
EXEC SQL SELECT MAX(SALARY)
  INTO :MAXSALRY
  FROM DSN8C10.EMP;
```

Example 2

Put the row for employee 528671, from DSN8C10.EMP, into the host structure EMPREC.

```
EXEC SQL SELECT * INTO :EMPREC
  FROM DSN8C10.EMP
  WHERE EMPNO = '528671'
END-EXEC.
```

Example 3

Put the row for employee 528671, from DSN8C10.EMP, into the host structure EMPREC. Assume that the row will be updated later and should be locked when the query executes.

```
EXEC SQL SELECT * INTO :EMPREC
  FROM DSN8C10.EMP
  WHERE EMPNO = '528671'
  WITH RS USE AND KEEP EXCLUSIVE LOCKS
END-EXEC.
```

Example 4

Using a SELECT INTO statement, retrieve the value of INTCOL1 from table T1 into an element in array MYINTARRAY1, which is indexed by the value of the expression INTCOL2+MYINTVAR+1.

```
SELECT INTCOL1 INTO MYINTARRAY1[INTCOL2+MYINTVAR+1]
 FROM T1
 WHERE INTCOL1 = MYINTARRAY1[INTCOL2] ;
```

Interaction between FETCH and OPTIMIZE FOR clauses (Db2 Performance)

Related reference

fetch-clause
The *fetch-clause* limits the number of rows that can be fetched.

SET CONNECTION

The SET CONNECTION statement establishes the database server of the process by identifying one of its existing connections.

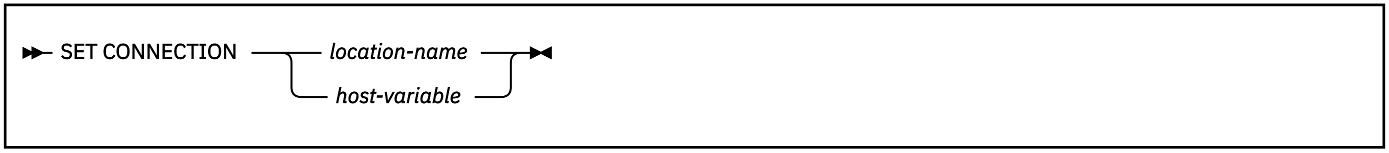
Invocation for SET CONNECTION

This statement can only be embedded in an application program. It is an executable statement that cannot be dynamically prepared. It must not be specified in Java.

Authorization for SET CONNECTION

None required.

Syntax for SET CONNECTION



Description for SET CONNECTION

location-name* or *host-variable

Identifies the SQL connection by the specified location name or the location name contained in the host variable. If a host variable is specified:

- It must be a character string variable with a length attribute that is not greater than 16. (A C NUL-terminated character string can be up to 17 bytes.)
- It must not be followed by an indicator variable.
- The location name must be left-justified within the host variable and must conform to the rules for forming an ordinary location identifier.
- If the length of the location name is less than the length of the host variable, it must be padded on the right with blanks.

Let S denote the specified location name or the location name contained in the host variable. S must identify an existing SQL connection of the application process. If S identifies the current SQL connection, the state of S and all other connections of the application process are unchanged. The following rules apply when S identifies a dormant SQL connection.

If the SET CONNECTION statement is successful:

- SQL connection S is placed in the current state.
- S is placed in the CURRENT SERVER special register.
- Information about server S is placed in the SQLERRP field of the SQLCA. If the server is an IBM product, the information has the form *pppvvrrm*.

  The product identifier (PRDID) value is an 8-byte character value in *pppvvrrm* format, where: *ppp* is a 3-letter product code; *vv* is the version;*rr* is the release; and *m* is the modification level. In Db2 12 for z/OS, the modification level indicates a range of function levels:

  `DSN12015` for `V12R1M500` or higher.
  `DSN12010` for `V12R1M100`.

  For more information, see Product identifier (PRDID) values in Db2 for z/OS (Db2 Administration Guide).
- Any previously current SQL connection is placed in the dormant state.

If the SET CONNECTION statement is unsuccessful, the connection state of the application process and the states of its SQL connections are unchanged.

Notes for SET CONNECTION

SET CONNECTION after CONNECT (Type 1): The use of CONNECT (Type 1) statements does not prevent the use of SET CONNECTION, but the statement either fails or does nothing because dormant SQL connections do not exist. The SQLRULES(DB2) bind option does not prevent the use of SET CONNECTION, but the statement is unnecessary because CONNECT (Type 2) statements can be used instead. Use the SET CONNECTION statement to conform to the SQL standard.

Status of locks, cursors, and prepared statements: When an SQL connection is used, made dormant, and then restored to the current state in the same unit of work, the status of locks, cursors, and prepared statements for that SQL connection reflects its last use by the application process.

Host variables: If the SET CONNECTION statement contains host variables, the contents of the host variables are assumed to be in the encoding scheme that was specified in the ENCODING parameter when the package or plan that contains the statement was bound.

Restrictions on array types and array variables: In any SQL statement other than a CALL statement, array types and array variables must not be referenced after a connection at a remote server has been established. This restriction includes an SQL statement that executes at a remote server as a result of a three-part name or alias that resolves to an object at a remote server. An exception is that an array element can be the target of a FETCH, SELECT INTO, SET *assignment-statement*, or VALUES INTO statement in an SQL routine even when the statement is executed at a remote server.

Example for SET CONNECTION

Execute SQL statements at TOROLAB1, execute SQL statements at TOROLAB2, and then execute more SQL statements at TOROLAB1.

```
EXEC SQL CONNECT TO TOROLAB1;

  -- execute statements referencing objects at TOROLAB1

EXEC SQL CONNECT TO TOROLAB2;

  -- execute statements referencing objects at TOROLAB2

EXEC SQL SET CONNECTION TOROLAB1;
```

```
    -- execute statements referencing objects at TOROLAB1
```

The first CONNECT statement creates the TOROLAB1 connection, the second CONNECT statement places it in the dormant state, and the SET CONNECTION statement returns it to the current state.

SET assignment-statement

The SET *assignment-statement* statement assigns values to variables and array elements.

Invocation for SET assignment-statement

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared if the targets of all assignments are global variables.

Authorization for SET assignment-statement

The privileges that are held by the privilege set must include those required to execute any of the expressions.

If a *row-subselect* is specified, see Chapter 6, "Queries," on page 1005 for an explanation of the authorization that is required for each subselect.

If a global variable or an element of an array global variable is referenced, the privilege set must include at least one of the following:

- The READ privilege on the variable
- Ownership of the variable
- DATAACCESS authority
- SYSADM authority

For an assignment to a global variable or an element of an array global variable, the privilege set must include at least one of the following:

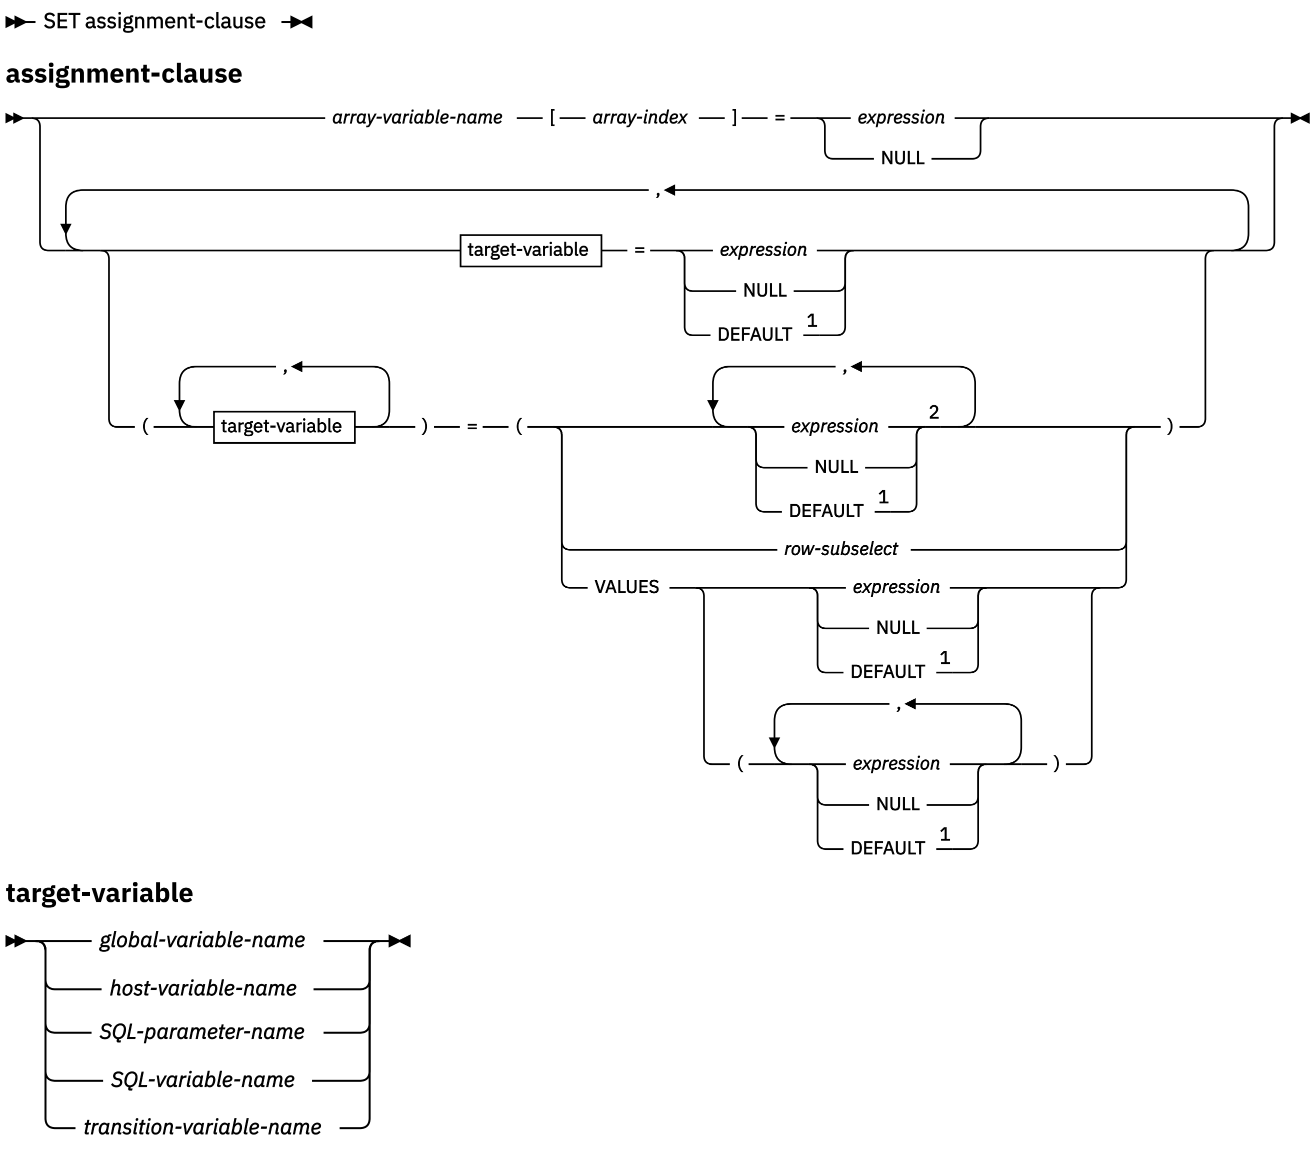
- The WRITE privilege on the variable
- Ownership of the variable
- DATAACCESS authority
- SYSADM authority

For an assignment to a transition variable, the privilege set must include at least one of the following:

- The UPDATE privilege on the table or view on which the trigger that contains the assignment statement is defined
- The UPDATE privilege on the column corresponding to the transition variable to be assigned a value
- Ownership of the table or view on which the trigger that contains the assignment statement is defined
- DBADM authority on the database that contains the table on which the trigger that contains the assignment statement is defined
- DATAACCESS authority
- SYSADM authority

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the package. If the statement is dynamically prepared, the privilege set is determined by the DYNAMICRULES behavior in effect (run, bind, define, or invoke) and is summarized in DYNAMICRULES behaviors and authorization checking. For more information on these behaviors, including a list of the DYNAMICRULES bind option values that determine them, see "Authorization IDs and dynamic SQL" on page 94.

Syntax for SET assignment-statement



Notes:

[1] DEFAULT must only be specified when the corresponding target is a global variable or a transition variable. If DEFAULT is specified for a transition variable in an advanced trigger, then all target variables must be transition variables, and all source values must be specified with the DEFAULT keyword.

[2] The number of source value specifications (expression, NULL, or DEFAULT) on the right side of the equal sign must match the number of target specifications on the left side of the statement.

Description for SET assignment-statement

***array-variable* [*array-index*]**

Specifies an array element that is the target of the assignment.

An array element must not be specified as the target for an assignment if *common-table-expression* is also specified in the statement.

array-variable

Specifies an array variable.

[*array-index*]

An expression that specifies which element in the array is the target of the assignment.

For an ordinary array, the array index expression must be castable to INTEGER, and must not be the null value. The index value must be between 1 and the maximum cardinality that is defined for the array.

For an associative array, the array index expression must be castable to the index data type of the associative array, and must not be the null value.

array-index must not be:

- An expression that references the CURRENT DATE, CURRENT TIME, or CURRENT TIMESTAMP special register
- A nondeterministic function
- A function that is defined with EXTERNAL ACTION
- A function that is defined with MODIFIES SQL DATA
- A sequence expression

The value that is to be assigned to an array element must be specified immediately following the array element. For example:

```
array-variable[array-index]=expression
```

expression

Specifies the value that is to be assigned to the corresponding assignment target. The expression is any expression of the type described in "Expressions" on page 244. All expressions are evaluated before any result is assigned to a target. If an expression refers to a variable or array element that is used in the list of assignment targets, the value of the variable or array element in the expression is the value of the variable or array element prior to any assignments.

Each assignment to a target is made according to the assignment rules described in "Assignment and comparison" on page 143. When the target variables and expressions are in the following form, the first value is assigned to the first target variable in the list, the second value is assigned to the second target variable in the list, and so on.

```
(target-variable,target-variable,…)=(expression,expression,…)
```

DEFAULT

Specifies that the new value for the variable is the initial default value for a global variable or the default value of a column that corresponds to a transition variable. DEFAULT can only be assigned to a global variable, or to a transition variable. If DEFAULT is specified for a transition variable in an advanced trigger, then all target variables must be transition variables, and all source values must be specified with the DEFAULT keyword.

A ROWID column must not be set to the DEFAULT keyword.

NULL

Specifies the null value and can only be specified for host variables that have an associated indicator variable.

VALUES

Specifies the values that are to be assigned to the corresponding assignment targets. When more than one value is specified, the values must be enclosed in parentheses. Each value can be an expression or NULL, as previously described. The following syntaxes are equivalent:

- (*target-variable*, *target-variable*) = (VALUES(*expression*, NULL))
- (*target-variable*, *target-variable*) = (*expression*, NULL)

A parameter marker must not be specified.

row-subselect

A subselect that returns a single row. The number of columns corresponds to the number of target variables that are specified for assignment. Each result column value is assigned to the corresponding variable. If the result of the row subselect is no rows, then null values are assigned. An error is returned if there is more than one row in the result. *row-subselect* can be specified only in the outermost subselect within SQL PL. *row-subselect* must not be specified in a basic trigger.

target-variable

Identifies one or more targets for the assignment of values. The number of targets must equal the number of values that are to be assigned.

If the statement is issued in a basic trigger, each target variable must be a transition variable.

The value that is to be assigned to each target variable can be specified immediately following the variable. For example:

```
variable=expression, variable=expression
```

Alternatively, sets of parentheses can be used to specify all of the target variables, and then all of the values. For example:

```
(variable,variable)=(expression,expression)
```

The data type of each variable in the variable list must be compatible with its corresponding result column. Each assignment to a *target-variable* is made in sequence through the list, according to the rules described in "Assignment and comparison" on page 143.

The value 'W' is assigned to the SQLWARN3 field of the SQLCA if the number of targets is less than the number of result column values.

If an error occurs on any assignment, the value is not assigned to the target, and no more values are assigned to the specified targets. Any values that have already been assigned remain assigned.

global-variable-name

Identifies the global variable that is the assignment target.

host-variable-name

Identifies the host variable that is the assignment target. For LOB output values, the target can be a regular host variable (if it is large enough), a LOB locator variable, or a LOB file reference variable.

SQL-parameter-name

Identifies the parameter that is the assignment target.

SQL-variable-name

Identifies the SQL variable that is the assignment target. SQL variables must be declared before they are used.

transition-variable-name

Identifies the column that is to be updated in the transition row. A transition variable name must identify a column in the subject table of a trigger, and is optionally qualified by a correlation name that identifies the new value.

transition-variable-name must not correspond to a begin column or end column of a BUSINESS_TIME period, and must not be specified if the statement contains a *period-clause*.

Notes for SET assignment-statement

Multiple assignments:

If more than one assignment is included in the same SET statement, all expressions and *row-subselects* are completely evaluated before the assignments are performed. Thus, references to a target variable in an expression or *row-subselect* are always the value of the target variable prior to any assignment in the SET statement.

LOBs assignments:

Normally, you use LOB locators to assign and retrieve data from LOB columns. However, because of compatibility rules, you can also use LOB locators to assign data to targets with other data types. For more information on using locators, see Saving storage when manipulating LOBs by using LOB locators (Db2 Application programming and SQL).

Default encoding scheme:

The default encoding scheme for the data is the value in the bind option ENCODING, which is the option for application encoding. If this statement is used with functions such as LENGTH or SUBSTRING that are operating on LOB locators, and the LOB data that is specifies by the locator is in a different encoding scheme from the ENCODING bind option, LOB materialization and character conversion occur. To avoid LOB materialization and character conversion, select the LOB data from the SYSIBM.SYSDUMMYA, SYSIBM.SYSDUMMYE, or SYSIBM.SYSDUMMYU sample table.

Examples for SET assignment-statement

Example 1: Set the host variable HVL to the value of the CURRENT PATH special register.

```
SET :HVL = CURRENT PATH;
```

Example 2: Set the host variable PATH to the contents of the SQL PATH special register, the host variable XTIME to the local time at the current server, and the host variable MEM to the current member of the data sharing environment.

```
SET :SERVER = CURRENT PATH,
    :XTIME = CURRENT TIME,
    :MEM = CURRENT MEMBER;
```

Example 3: Set the host variable DETAILS to a portion of a LOB value, using a LOB expression with a LOB locator to refer the extracted portion of the value.

```
SET :DETAILS = SUBSTR(:LOCATOR,1,35);
```

If the LOB data that is specified by the LOB locator LOCATOR is in a different encoding scheme from the value of the ENCODING bind option, and you want to avoid LOB materialization and character conversion, use the following statement instead of the SET statement:

```
SELECT SUBSTR(:LOCATOR,1,35)
   INTO :DETAILS
   FROM SYSIBM.SYSDUMMYU;
```

Example 4: Set host variable HV1 to the results of external function CALC_SALARY and host variable HV2 to the value of special register CURRENT PATH. Use an indicator value with HV1 in case CALC_SALARY returns a null value.

```
SET (:HV1:IND1, :HV2) =
    (CALC_SALARY(:HV3, :HF4), CURRENT PATH);
```

Example 5: Assume that you want to create a before trigger that sets the salary and commission columns to default values for newly inserted rows in the EMPLOYEE table and that you will define the trigger only with NEW in the REFERENCING clause. Assign the default values to the SALARY and COMMISSION columns.

```
SET (SALARY, COMMISSION) = (50000, 8000);
```

Example 6: Assume that you want to create a before trigger that detects any commission increases greater than 10% for updated rows in the EMPLOYEE table and limits the commission increase to 10%. You will define the trigger with both OLD and NEW in the REFERENCING clause. Limit an increase to the COMMISSION column to 10%.

```
SET NEWROW.COMMISSION = 1.1 * OLDROW.COMMISSION;
```

Example 7: Suppose that the associative array variable CANADACAPITALS has array type CAPITALSARRAY. Use SET *assignment-statement* statements to assign values to CANADACAPITALS.

```
SET CANADACAPITALS['British Columbia'] = 'Victoria';
SET CANADACAPITALS['Alberta'] = 'Edmonton';
SET CANADACAPITALS['Manitoba'] = 'Winnipeg';
SET CANADACAPITALS['Ontario'] = 'Toronto';
SET CANADACAPITALS['Nova Scotia'] = 'Halifax';
```

In the CANADACAPITALS array, the array index values are province names, and the associated array element values are the names of the corresponding capital cities. The order in which values are assigned to associative array elements does not matter. The elements of an associative array are stored in the array in ascending order of the associated array index values.

Example 8: Suppose that the associative array variables CANADACAPITALSA and CANADACAPITALSB have array type CAPITALSARRAY. The following SET *assignment-statement* statements have been used to assign values to CANADACAPITALSA.

```
SET CANADACAPITALSA['British Columbia'] = 'Victoria';
SET CANADACAPITALSA['Alberta'] = 'Edmonton';
SET CANADACAPITALSA['Manitoba'] = 'Winnipeg';
SET CANADACAPITALSA['Ontario'] = 'Toronto';
SET CANADACAPITALSA['Nova Scotia'] = 'Halifax';
```

Use a single SET *assignment-statement* statement to assign all of the values that are in CANADACAPITALSA to CANADACAPITALSB.

```
SET CANADACAPITALSB = CANADACAPITALSA;
```

Example 9: Suppose that P_PHONENUMBERS SQL array variable is defined as an ordinary array. Set P_PHONENUMBERS to an array of fixed numbers.

```
SET P_PHONENUMBERS = ARRAY[9055553907, 4165554213, 4085553678];
```

Example 10: Set the SQL array variable P_PHONENUMBERS to an array of numbers that are retrieved from the PHONENUMBER table.

```
SET P_PHONENUMBERS =
 ARRAY [SELECT NUMBER
 FROM PHONENUMBERS
 WHERE EMPID = 624];
```

Example 11: Suppose that no values have been assigned to SQL array variable P_PHONENUMBERS. Assign the value of SQL variable P_MYNUMBER to the first and tenth elements of P_PHONENUMBERS. After the first assignment, the cardinality of P_PHONENUMBERS is 1. After the second assignment, the cardinality is 10, and elements 2 to 9 have been implicitly assigned the null value.

```
SET P_PHONENUMBERS[1]  = P_MYNUMBER;
SET P_PHONENUMBERS[10] = P_MYNUMBER;
```

SET CURRENT ACCELERATOR

The SET CURRENT ACCELERATOR statement changes the value of the CURRENT ACCELERATOR special register.

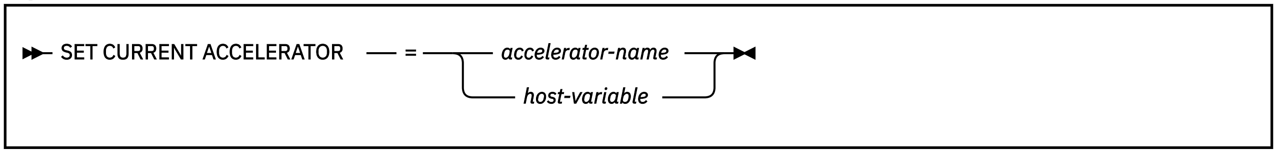
Invocation for SET CURRENT ACCELERATOR

This statement can be embedded in an application program, or it can be issued interactively. SET CURRENT ACCELERATOR is an executable statement that can be dynamically prepared.

Authorization for SET CURRENT ACCELERATOR

None required.

Syntax for SET CURRENT ACCELERATOR



Description for SET CURRENT ACCELERATOR

accelerator-name
A character string constant that represents an accelerator name or an accelerator logical name that is recorded in SYSIBM.LOCATIONS.

host variable
A variable that represents an accelerator name or an accelerator logical name that is recorded in SYSIBM.LOCATIONS.

The accelerator name or host variable that you specify must meet these criteria:

- It must be unique within the Db2 subsystem or data sharing group.
- It must be 8 characters or fewer.
- It must consist of the characters A-Z and 0-9.

Examples for SET CURRENT ACCELERATOR

The following statement sets the CURRENT ACCELERATOR special register so that ACCEL1 is the preferred accelerator.

```
SET CURRENT ACCELERATOR = ACCEL1;
```

The following statement sets the CURRENT ACCELERATOR special register to an alias that includes two accelerators, ACCLPRO1 and ACCLPRO2.

```
INSERT INTO SYSIBM.LOCATIONS (LOCATION, LINKNAME, DBALIAS)
VALUES ('IDAATEST', 'DSNACCELERATORALIAS', 'ACCLPRO1 ACCLPRO2');

SET CURRENT ACCELERATOR = IDAATEST;
```

Related tasks

Enabling acceleration of SQL queries (Db2 Performance)

Related reference

"CURRENT ACCELERATOR special register" on page 183The CURRENT ACCELERATOR special register specifies a particular accelerator to which Db2 sends dynamic SQL. The CURRENT ACCELERATOR special register does not apply to static SQL.

SET CURRENT APPLICATION COMPATIBILITY

The SET CURRENT APPLICATION COMPATIBILITY statement assigns a value to the CURRENT APPLICATION COMPATIBILITY special register. This special register allows users to control the package compatibility level behavior for dynamic SQL.

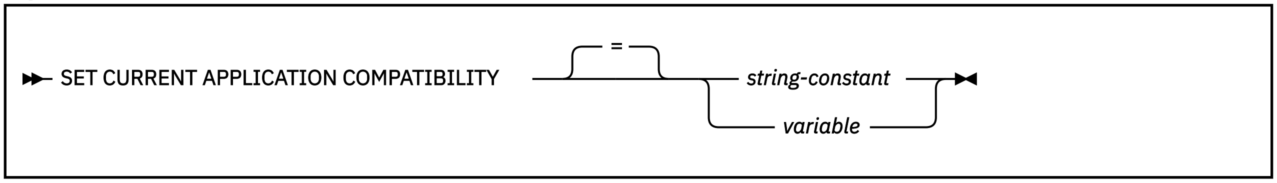
Invocation for SET CURRENT APPLICATION COMPATIBILITY

This statement can be embedded in an application program or dynamically prepared.

Authorization for SET CURRENT APPLICATION COMPATIBILITY

None required.

Syntax for SET CURRENT APPLICATION COMPATIBILITY



Description for SET CURRENT APPLICATION COMPATIBILITY

string-constant

Specifies a character string constant. The value must represent a valid release compatibility level, in uppercase.

variable

A variable with a data type of CHAR or VARCHAR. The value of *variable* must not be null and must represent a valid release compatibility level, in uppercase.

The value must:

- Be left-aligned within the *variable*
- Be padded on the right with blanks if its length is less than the *variable*

The following levels can be specified to set to specify the compatibility behavior of dynamic SQL statements in packages:

V*vv*R*r*M*mmm*

Compatibility with the behavior of the identified Db2 function level. For example, V12R1M510 specifies compatibility with the highest available Db2 12 function level. The equivalent function level or higher must be activated.

For the new capabilities that become available in each application compatibility level, see:

- SQL changes in Db2 13 application compatibility levels
- SQL changes in Db2 12 application compatibility levels

Tip: Extra program preparation steps might be required to increase the application compatibility level for applications that use data server clients or drivers to access Db2 for z/OS. For more information, see Setting application compatibility levels for data server clients and drivers (Db2 Application programming and SQL).

V12R1

Compatibility with the behavior of Db2 12 function level 500. This value has the same result as specifying V12R1M500.

V11R1

Compatibility with the behavior of Db2 11 new-function mode. After migration to Db2 12, this value has the same result as specifying V12R1M100. For more information, see V11R1 application compatibility level (Db2 Application programming and SQL)

V10R1

Compatibility with the behavior of DB2 10 new-function mode. For more information, see V10R1 application compatibility level (Db2 Application programming and SQL).

Notes:

- After the activation of function level 500 or higher, the source value for CURRENT APPLICATION COMPATIBILITY cannot be higher than the APPLCOMPAT bind option value.
- Function level V12R1M500 is the same as V12R1, and V12R1M100 is the same as V11R1.

Examples for SET CURRENT APPLICATION COMPATIBILITY

The following examples set the CURRENT APPLICATION COMPATIBILITY special register to 'V11R1' (in the second example, host variable HV1 = 'V11R1').

```
EXEC SQL SET CURRENT APPLICATION COMPATIBILITY = 'V11R1';
EXEC SQL SET CURRENT APPLICATION COMPATIBILITY = :HV1;
```

SET CURRENT APPLICATION ENCODING SCHEME

The SET CURRENT APPLICATION ENCODING SCHEME statement assigns a value to the CURRENT APPLICATION ENCODING SCHEME special register. This special register allows users to control which encoding scheme will be used for dynamic SQL statements after the SET statement has been executed.

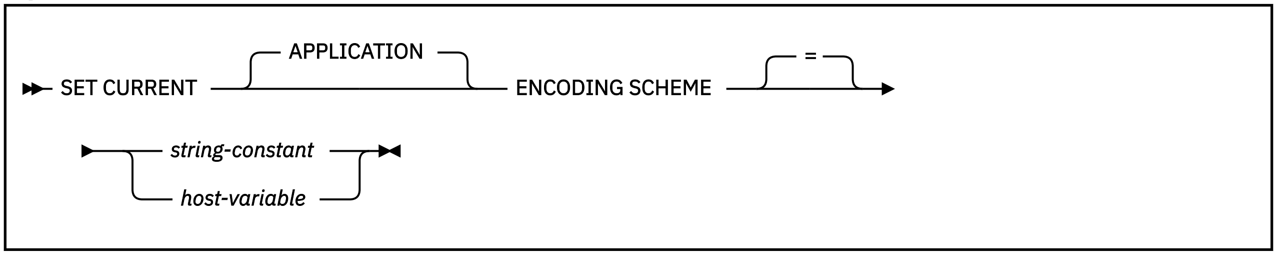
Invocation for SET CURRENT APPLICATION ENCODING SCHEME

This statement can be embedded only in an application program. It is an executable statement that cannot be dynamically prepared.

Authorization for SET CURRENT APPLICATION ENCODING SCHEME

None required.

Syntax for SET CURRENT APPLICATION ENCODING SCHEME



Description for SET CURRENT APPLICATION ENCODING SCHEME

string-constant
A character string constant that represents a valid encoding scheme (ASCII, EBCDIC, UNICODE, or a character representation of a number between 1 and 65533).

host variable
A variable with a data type of CHAR or VARCHAR. The value of *host-variable* must not be null and must represent a valid encoding scheme or a character representation of a number between 1 and 65533). An associated indicator variable must not be provided.

The value must:

- Be left justified within the host variable
- Be padded on the right with blanks if its length is less than that of the host variable

Examples for SET CURRENT APPLICATION ENCODING SCHEME

The following examples set the CURRENT APPLICATION ENCODING SCHEME special register to 'EBCDIC' (in the second example, Host variable HV1 = 'EBCDIC').

```
EXEC SQL SET CURRENT APPLICATION ENCODING SCHEME = 'EBCDIC';
EXEC SQL SET CURRENT ENCODING SCHEME  = :HV1;
```

Related reference

CURRENT APPLICATION ENCODING SCHEME special register
CURRENT APPLICATION ENCODING SCHEME specifies which encoding scheme is to be used for dynamic statements. It allows an application to indicate the encoding scheme that is used to process data. This register is not supported in REXX applications or in stored procedures written in REXX.

SET CURRENT DEBUG MODE

The SET CURRENT DEBUG MODE statement assigns a value to the CURRENT DEBUG MODE special register.

The special register sets the default value for the DEBUG MODE option for the following statements:

- CREATE FUNCTION statements that define an SQL scalar function
- ALTER FUNCTION statements that create or replace a version of an SQL scalar function
- CREATE PROCEDURE statements that define a native SQL or Java procedure
- ALTER PROCEDURE statements that create or replace a version of a native SQL procedure
- CREATE TRIGGER (advanced) statement that defines a trigger
- ALTER TRIGGER (advanced) statement that changes a trigger

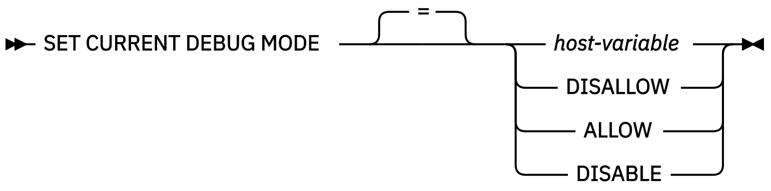
Invocation for SET CURRENT DEBUG MODE

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization for SET CURRENT DEBUG MODE

None required.

Syntax for SET CURRENT DEBUG MODE



Description for SET CURRENT DEBUG MODE

host-variable

Specifies a host variable that contains the debugging option. The host variable must conform to the following rules:

- Be a CHAR, VARCHAR, GRAPHIC, or VARGRAPHIC variable. The actual length of the contents of the host variable must not exceed the length of the special register.
- Include a keyword value of DISALLOW, ALLOW, or DISABLE that is left justified
- Be padded on the right with blanks if the host variable is a fixed length character

- Not contain lowercase letters or characters that cannot be specified in an ordinary identifier
- Not be empty or contain only blanks
- Not be the null value

DISALLOW
Specifies that DISALLOW DEBUG MODE is the default option for CREATE statements when defining an SQL scalar function, native SQL procedure, Java procedure, or trigger, ALTER statements that create or replace a version of an SQL scalar function or native SQL procedure, or ALTER statements that change a trigger.

ALLOW
Specifies that ALLOW DEBUG MODE is the default option for CREATE statements when defining an SQL scalar function, native SQL procedure, Java procedure, or trigger, ALTER statements that create or replace a version of an SQL scalar function or native SQL procedure, or ALTER statements that change a trigger.

DISABLE
Specifies that DISABLE DEBUG MODE is the default option for CREATE statements when defining an SQL scalar function, native SQL procedure, Java procedure, or trigger, ALTER statements that add a version of an SQL scalar function or native SQL procedure, or ALTER statements that change a trigger.

Examples for SET CURRENT DEBUG MODE

Example: The following statement sets the CURRENT DEBUG MODE special register so that the default option for CREATE PROCEDURE statements will be ALLOW DEBUG MODE:

```
   SET CURRENT DEBUG MODE = ALLOW;
```

Related reference

CURRENT DEBUG MODE special register
CURRENT DEBUG MODE specifies the default value for the DEBUG MODE option when advanced triggers and certain routines are created. The DEBUG MODE option specifies whether the trigger or routine should be built with the ability to run in debugging mode.

SET CURRENT DECFLOAT ROUNDING MODE

The SET CURRENT DECFLOAT ROUNDING MODE statement assigns a value to the CURRENT DECFLOAT ROUNDING MODE special register. The special register sets the default rounding mode that is used with decimal floating point values (DECFLOAT).

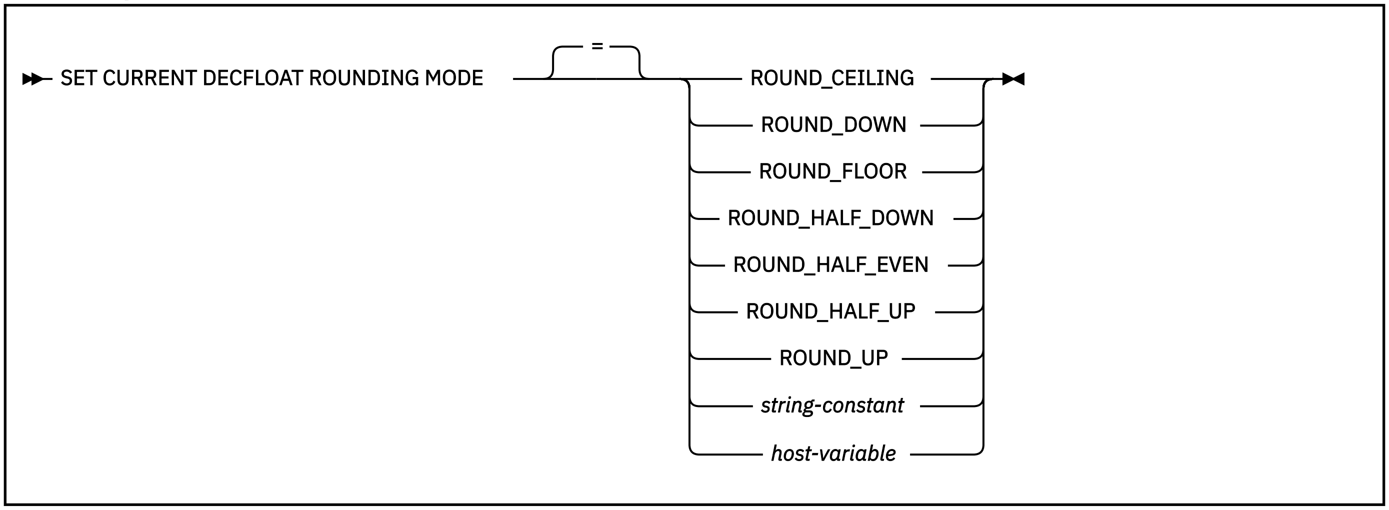
Invocation for SET CURRENT DECFLOAT ROUNDING MODE

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization for SET CURRENT DECFLOAT ROUNDING MODE

None required.

Syntax for SET CURRENT DECFLOAT ROUNDING MODE



Description for SET CURRENT DECFLOAT ROUNDING MODE

ROUND_CEILING
Round towards positive infinity. If all of the discarded digits are zero or if the sign is negative, the result is unchanged other than the removal of discarded digits. Otherwise, the result coefficient is incremented by 1 (round up).

ROUND_DOWN
Round towards 0 (truncation). The discarded digits are ignored.

ROUND_FLOOR
Round towards negative infinity. If all of the discarded digits are zero or if the sign is positive, the result is unchanged other than the removal of discarded digits. Otherwise, the sign is negative and the result coefficient is incremented by 1 (round down).

ROUND_HALF_DOWN
Round to nearest value; if values are equidistant, rounds down. If the discarded digits represent greater than half (0.5) of the value of a number in the next left position, the result coefficient is incremented by 1 (round up). Otherwise, the discarded digits are ignored. This rounding mode is not recommended when creating a portable application because it is not supported by the IEEE draft standard for floating-point arithmetic.

ROUND_HALF_EVEN
Round to nearest value; if values are equidistant, round so that the final digit is even. If the discarded digits represent greater than half (0.5) of the value of a number in the next left position, the result coefficient is incremented by 1 (round up). If the discarded digits represent less than half of the value, the result coefficient is not adjusted (that is, the discarded digits are ignored). Otherwise, the result coefficient is unaltered if its rightmost digit is even, or is incremented by 1 (round up) if its rightmost digit is odd (to make an even digit).

ROUND_HALF_UP
Round to nearest value; if values are equidistant, round up. If the discarded digits represent greater than or equal to half (0.5) of the value of a number in the next left position, the result coefficient is incremented by 1 (round up). Otherwise the discarded digits are ignored.

ROUND_UP
Round away from 0. If all of the discarded digits are zero, the result is unchanged other than the removal of discarded digits. Otherwise, the result coefficient is incremented by 1 (round up). This rounding mode is not recommended when creating a portable application because it is not supported by the IEEE draft standard for floating-point arithmetic.

string-constant
Specifies a string constant that contains a specification of the rounding mode. The string-constant must have the following characteristics:

- Must be a string constant. The actual length of the contents of the string constant, after trailing blanks have been removed, must not exceed 19 characters.
- Must not be the null value.
- Must not contain lower case letters or characters that cannot be specified in an ordinary identifier.
- Must specify one of the seven rounding mode keywords as a string constant.

host-variable

Specifies a variable that contains a specification of the rounding mode. The variable must have the following characteristics:

- Must have a length, after trailing blanks have been removed, that does not exceed 19 bytes.
- Must not be followed by an indicator variable.
- Must not be a CLOB or DBCLOB.
- Must include a rounding mode that is left justified and conforms to the rules for forming an ordinary identifier.
- Must not contain lower case letters or characters that cannot be specified in an ordinary identifier.
- Must be padded on the right with blanks if the variable is a fixed length string.
- Must contain one of the seven rounding mode keywords.

Examples for SET CURRENT DECFLOAT ROUNDING MODE

Example: The following statement sets the CURRENT DECFLOAT ROUNDING MODE to ROUND_CEILING, using a string constant and a keyword.

```
SET CURRENT DECFLOAT ROUNDING MODE = ROUND_CEILING;
```

Related reference

CURRENT DECFLOAT ROUNDING MODE special register
CURRENT DECFLOAT ROUNDING MODE specifies the default rounding mode that is used for DECFLOAT values.

SET CURRENT DEGREE

The SET CURRENT DEGREE statement assigns a value to the CURRENT DEGREE special register.

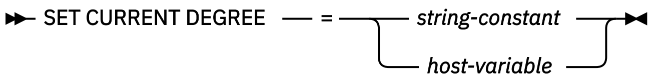
Invocation for SET CURRENT DEGREE

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization for SET CURRENT DEGREE

None required.

Syntax for SET CURRENT DEGREE



Description for SET CURRENT DEGREE

The value of CURRENT DEGREE is replaced by the value of the string constant or host variable. The value must be a character string that is not longer than 3 bytes and the value must be 'ANY', '1', or '1 '.

Notes for SET CURRENT DEGREE

If the value of CURRENT DEGREE is '1' when a query is dynamically prepared, the execution of that query will not use parallel operations. If the value of CURRENT DEGREE is 'ANY' when a query is dynamically prepared, the execution of that query can involve parallel operations.

For distributed applications, the default value at the server is used unless the requesting application issues the SQL statement SET CURRENT DEGREE. For requests using DRDA, the SET CURRENT DEGREE statement must be within the scope of the CONNECT statement.

The value specified in the SET CURRENT DEGREE statement remains in effect until it is changed by the execution of another SET CURRENT DEGREE statement or until deallocation of the application process. For applications that connect to Db2 using the call attachment facility, the value of register CURRENT DEGREE can be requested to remain in effect for a longer duration. For more information, see CAF connection functions (Db2 Application programming and SQL).

Examples for SET CURRENT DEGREE

Example 1: The following statement inhibits parallel operations:

```
   SET CURRENT DEGREE = '1';
```

Example 2: The following statement allows parallel operations:

```
   SET CURRENT DEGREE = 'ANY';
```

Related concepts

Related reference

CURRENT DEGREE special register
CURRENT DEGREE specifies the degree of parallelism for the execution of queries that are dynamically prepared by the application process.

CURRENT DEGREE field (CDSSRDEF subsystem parameter) (Db2 Installation and Migration)

CONNECT
The CONNECT statement connects an application process to a database server. This server becomes the *current server* for the process. The CONNECT statement of Db2 for z/OS is equivalent to *CONNECT (Type 2)* in *SQL Reference for Cross-Platform Development* - Version 6.

SET CURRENT EXPLAIN MODE

The SET CURRENT EXPLAIN MODE statement assigns a value to the CURRENT EXPLAIN MODE special register.

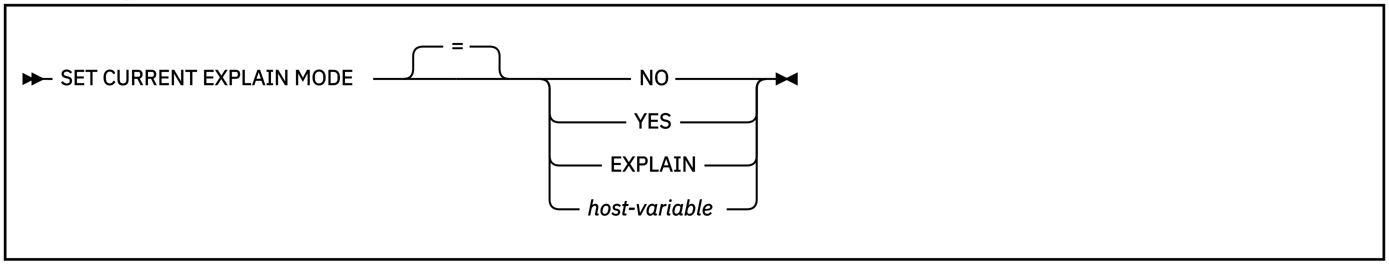
Invocation for SET CURRENT EXPLAIN MODE

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization for SET CURRENT EXPLAIN MODE

None required.

Syntax for SET CURRENT EXPLAIN MODE



Description for SET CURRENT EXPLAIN MODE

This statement replaces the value of the CURRENT EXPLAIN MODE special register with the value of the specified keyword or host variable.

NO
Specifies that no EXPLAIN information is captured. NO is the initial value of the EXPLAIN MODE special register.

YES
Enables the EXPLAIN facility and causes EXPLAIN information to be inserted into the EXPLAIN tables for eligible dynamic SQL statements after the statement is prepared and executed. All dynamic SQL statements are compiled and executed normally.

EXPLAIN
Enables the EXPLAIN facility and causes EXPLAIN information to be captured for any eligible dynamic SQL statement after the statement is prepared. This setting behaves similarly to YES, however, dynamic statements, except for SET statements, are not executed.

host-variable
host-variable must be a CHAR or VARCHAR value and must be NO, YES, or EXPLAIN. Leading blanks are not allowed. All input values must be uppercase, must be left justified within the host variable, and must be padded on the right with blanks if the length of the value is less than the length of the host variable.

For values YES and EXPLAIN, prepared statements are not saved into the dynamic statement cache.

Examples for SET CURRENT EXPLAIN MODE

Example 1: The following statement sets the CURRENT EXPLAIN MODE special register, so that EXPLAIN information will be captured for any subsequent eligible dynamic SQL statements during execution.

```
SET CURRENT EXPLAIN MODE = YES;
```

Related reference

CURRENT EXPLAIN MODE special register
The CURRENT EXPLAIN MODE special register contains the values that control the EXPLAIN behavior in regards to eligible dynamic SQL statements.

SET CURRENT GET_ACCEL_ARCHIVE

The SET CURRENT GET_ACCEL_ARCHIVE statement changes the value of the CURRENT GET_ACCEL_ARCHIVE special register.

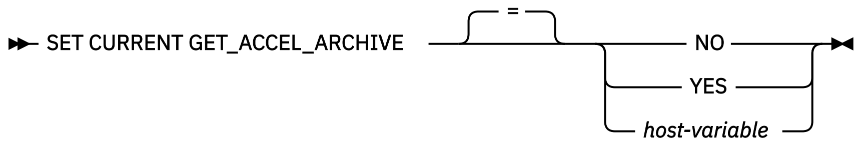
Invocation for SET CURRENT GET_ACCEL_ARCHIVE

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization for SET CURRENT GET_ACCEL_ARCHIVE

None required.

Syntax for SET CURRENT GET_ACCEL_ARCHIVE



Description for SET CURRENT GET_ACCEL_ARCHIVE

NO
Specifies that if a table is archived in an accelerator server, and a query references that table, the query does not use the data that is archived.

YES
Specifies that if a table is archived in an accelerator server, and a query references that table, the query uses the data that is archived.

host-variable
A variable with a data type of CHAR or VARCHAR. The length must not exceed 255 bytes. Valid values are YES or NO. If *host-variable* has an associated indicator variable, the value of that indicator variable must not indicate a null value. The value of *host-variable* must be left justified and must be padded on the right with blanks.

Examples for SET CURRENT GET_ACCEL_ARCHIVE

The following statement sets the CURRENT GET_ACCEL_ARCHIVE special register to NO to indicate that when a table is archived in an accelerator server, the table reference does not include the archived data.

```
SET CURRENT GET_ACCEL_ARCHIVE=NO;
```

Related tasks

Enabling acceleration of SQL queries (Db2 Performance)

Related reference

CURRENT GET_ACCEL_ARCHIVE special register
The CURRENT GET_ACCEL_ARCHIVE special register specifies whether a dynamic SQL query that references a table that is archived on an accelerator server uses the archived data. The special register does not apply to static SQL queries.

SET CURRENT LOCALE LC_CTYPE

The SET CURRENT LOCALE LC_CTYPE statement assigns a value to the CURRENT LOCALE LC_CTYPE special register. The special register allows control over the LC_CTYPE locale for statements that use a built-in function that refers to a locale, such as LCASE, UCASE, and TRANSLATE (with a single argument).

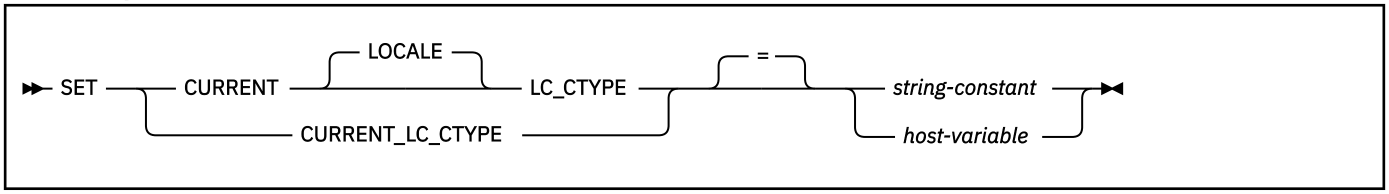
Invocation for SET CURRENT LOCALE LC_CTYPE

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization for SET CURRENT LOCALE LC_CTYPE

None required.

Syntax for SET CURRENT LOCALE LC_CTYPE



Description for SET CURRENT LOCALE LC_CTYPE

The value of CURRENT LOCALE LC_CTYPE is replaced by the value specified.

string-constant
A character string constant that must not be longer than 50 bytes and must represent a valid locale.

host-variable
A variable with a data type of CHAR or VARCHAR and a length that is not longer than 50 bytes. The value of *host-variable* must not be null and must represent a valid locale. If the host variable has an associated indicator variable, the value of the indicator variable must not indicate a null value.

The locale must:

- Be left justified within the host variable
- Be padded on the right with blanks if its length is less than that of the host variable

A locale can be specified in uppercase characters, lowercase characters, or a combination of the two. For more information, see CURRENT LOCALE LC_CTYPE.

Note: The existence of a locale is not validated when the CURRENT LOCALE LC_CTYPE special register is set. For example, a locale name that is misspelled is not detected, which could affect the way subsequent SQL operates. When the special register value is used at execution time, an error is returned if the locale does not exist. For example, if the LOWER function is invoked without specifying a locale name, the special register determines the locale that is used.

Examples for SET CURRENT LOCALE LC_CTYPE

Example 1: Set the CURRENT LOCALE LC_CTYPE special register to the locale 'En_US'.

```
EXEC SQL SET CURRENT LOCALE LC_CTYPE = 'En_US';
```

Example 2: Set the CURRENT LOCALE LC_CTYPE special register to the value of host variable HV1, which contains 'Fr_FR@EURO'.

```
EXEC SQL SET CURRENT LOCALE LC_CTYPE = :HV1;
```

Related concepts
z/OS Unicode Services User’s Guide and Reference
Related reference
CURRENT LOCALE LC_CTYPE special register

CURRENT LOCALE LC_CTYPE specifies the LC_CTYPE locale that will be used to execute SQL statements that use a built-in function that references a locale. Functions LCASE, UCASE, and TRANSLATE (with a single argument) refer to the locale when they are executed.

SET CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION

The SET CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION statement changes the value of the CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION special register.

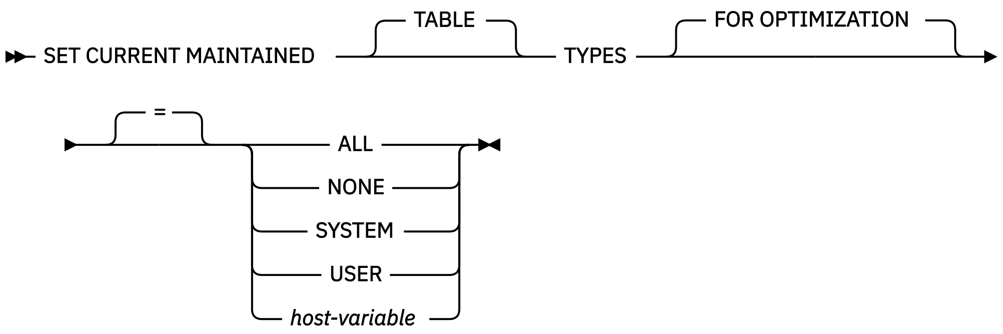
Invocation for SET CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization for SET CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION

None required.

Syntax for SET CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION



Description for SET CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION

The value indicates which materialized query tables that are enabled for optimization are considered when optimizing the processing of dynamic SQL queries.

ALL
Indicates that all materialized query tables will be considered.

NONE
Indicates that no materialized query tables will be considered.

SYSTEM
Indicates that only system-maintained materialized query tables that are refresh deferred will be considered.

USER
Indicates that only user-maintained materialized query tables that are refresh deferred will be considered.

host-variable
A variable of type CHAR or VARCHAR. The length of the contents of *host-variable* must not exceed 255 bytes. It cannot be set to null. If *host-variable* has an associated indicator variable, the value of that indicator variable must not indicate a null value.

The characters of *host-variable* must be left justified. The content of the host variable must be a string that would match what can be specified as keywords for the special register in the exact case intended as there is no conversion to uppercase characters.

Notes for SET CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION

The CURRENT REFRESH AGE special register needs to be set to a value other than zero in order for the specified types of objects to be considered for optimizing the processing of dynamic SQL queries.

The CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION special register affects dynamic statement cache matching.

Examples for SET CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION

Example 1: The following statement sets the CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION special register:

```
    SET CURRENT MAINTAINED TABLE TYPES ALL;
```

Example 2: The following example retrieves the current value of the CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION special register into the host variable called CURMAINTYPES.

```
    EXEC SQL VALUES (CURRENT MAINTAINED TABLE TYPES) INTO :CURMAINTYPES;
```

The value would be ALL if set by the previous example.

Example 3: The following example resets the CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION special register so that no materialized query tables can be considered to optimize the processing of dynamic SQL queries.

```
   SET CURRENT MAINTAINED TABLE TYPES NONE;
```

Related reference

CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION special register
CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION specifies a value that identifies the types of objects that can be considered to optimize the processing of dynamic SQL queries. This register contains a keyword representing table types.

SET CURRENT OPTIMIZATION HINT

The SET CURRENT OPTIMIZATION HINT statement assigns a value to the CURRENT OPTIMIZATION HINT special register.

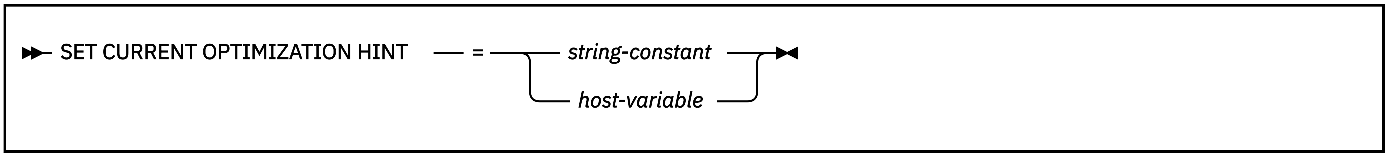
Invocation for SET CURRENT OPTIMIZATION HINT

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization for SET CURRENT OPTIMIZATION HINT

None required.

Syntax for SET CURRENT OPTIMIZATION HINT



Description for SET CURRENT OPTIMIZATION HINT

The value of special register CURRENT OPTIMIZATION HINT is replaced by the value of the string constant or host variable. The value must be a character string that is not longer than 128 bytes.

Notes for SET CURRENT OPTIMIZATION HINT

Using the OPTIMIZATION HINT special register: The CURRENT OPTIMIZATION HINT special register specifies whether optimization hints are used in determining the access path of dynamic statements. An empty string or all blanks indicates that Db2 uses normal optimization techniques and ignores optimization hints.

Example for SET CURRENT OPTIMIZATION HINT

Example 1: Assume that string constant 'NOHYB' identifies a user-defined optimization hint in owner.PLAN_TABLE. Set the CURRENT OPTIMIZATION HINT special register so that Db2 uses this optimization hint to generate the access path for dynamic statements.

```
   SET CURRENT OPTIMIZATION HINT = 'NOHYB';
```

If you set the register this way, Db2 validates and considers information in the rows in owner.PLAN_TABLE where the value in the OPTHINT column matches 'NOHYB' for dynamic SQL statements.

Example 2: Clear the CURRENT OPTIMIZATION HINT special register by specifying an empty string.

```
   SET CURRENT OPTIMIZATION HINT = '';
```

Related reference

CURRENT OPTIMIZATION HINT special register
CURRENT OPTIMIZATION HINT specifies the user-defined optimization hint that Db2 should use to generate the access path for dynamic statements.

SET CURRENT PACKAGE PATH

The SET CURRENT PACKAGE PATH statement assigns a value to the CURRENT PACKAGE PATH special register.

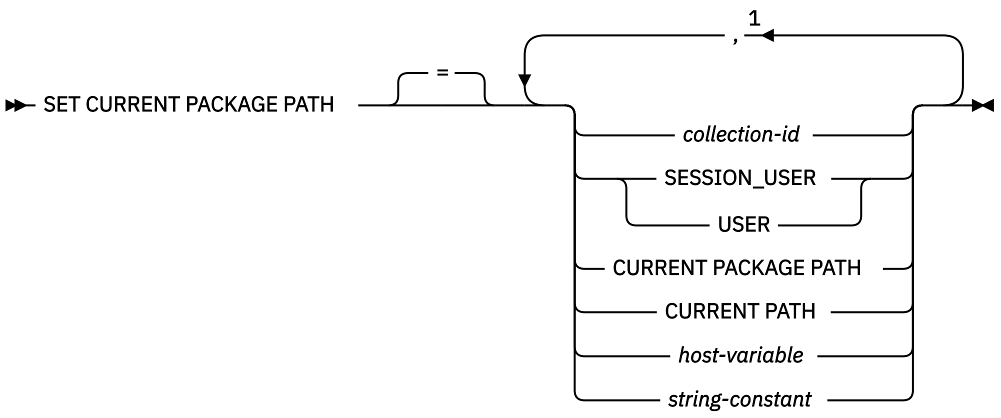
Invocation for SET CURRENT PACKAGE PATH

This statement can be embedded only in an application program. It is an executable statement that cannot be dynamically prepared.

Authorization for SET CURRENT PACKAGE PATH

None required.

Syntax for SET CURRENT PACKAGE PATH



Notes:

[1] SESSION_USER (or USER), CURRENT PACKAGE PATH, and CURRENT PATH can each be specified only once on the right side of the statement.

Description for SET CURRENT PACKAGE PATH

The value of CURRENT PACKAGE PATH is replaced by the values specified.

collection-id
Identifies a collection. *collection-id* must not be a delimited identifier that is empty or contains only blanks.

SESSION_USER or USER
Specifies the value of the SESSION_USER (USER) special register.

CURRENT PACKAGE PATH
Specifies the value of the CURRENT PACKAGE PATH special register before the execution of the SET CURRENT PACKAGE PATH statement.

CURRENT PATH
Specifies the value of the CURRENT PATH special register.

host-variable
Specifies a host variable that contains one or more collection IDs, separated by commas. The host variable must:

- Have a data type of CHAR or VARCHAR. The actual length of the contents of the host variable must not exceed the maximum length of the CURRENT PACKAGE PATH special register.
- Not be the null value if an indicator variable is provided.
- Contain an empty or blank string, or one or more collection IDs that are separated by commas.
- Be padded on the right with blanks if the host variable is fixed-length, or if the actual length of the host variable is longer than the content.
- Not contain a delimited identifier that is empty or contains only blanks.

string-constant
Specifies a string constant that contains one or more collection IDs, separated by commas. The string constant must:

- Have a length that does not exceed the maximum length of the CURRENT PACKAGE PATH special register.
- Contain an empty or blank string, or one or more collection IDs separated by commas.
- Not contain a delimited identifier that is empty or contains only blanks.

Notes for SET CURRENT PACKAGE PATH

Contents of host variable or string constant: The contents of a host variable or string constant are interpreted as a list of collection IDs if the value contains at least one comma. If multiple collection IDs are specified, they must be separated by commas. Each collection ID in the list must conform to the rules for forming an ordinary identifier or be specified as a delimited identifier.

Checking for the existence of collections: No validation that the collections exist is made at the time that the CURRENT PACKAGE PATH special register is set. For example, a collection ID that is misspelled is not detected, which could affect the way subsequent SQL operates. At package execution time, authorization to the specific package is checked, and if this authorization check fails, an error is issued.

Resulting contents of the special register: The special register string is built by taking each collection ID specified and removing trailing blanks, delimiting with double quotation marks, doubling any double quotation marks within the collection ID as necessary, and then separating each collection ID by a comma. If the same collection ID appears more than once in the list, the first occurrence of the collection is used, and a warning is issued. The length of the resulting list cannot exceed the length of the special register. For example, assume that the following statements are issued:

```
SET CURRENT PACKAGE PATH = MYPKGS, "ABC E", SYSIBM
SET :HVPKLIST = CURRENT PACKAGE PATH
```

These statements result in the value of the host variable being set to: "MYPKGS", "ABC E", "SYSIBM".

A collection ID that does not conform to the rules for an ordinary identifier must be specified as a delimited collection ID and must not be specified within a host variable or string constant.

Considerations for keywords: A difference exists between specifying a single keyword, such as SESSION_USER, as a single keyword or as a delimited identifier. To indicate that the current value of a special register that is specified as a single keyword should be used in the package path, specify the name of the special register as a keyword. If you specify the name of the special register as a delimited identifier, it is interpreted as a collection ID of that value. For example, assume that the current value of the SESSION_USER special register is SMITH and that the following statement is issued:

```
SET CURRENT PACKAGE PATH = SYSIBM, SESSION_USER, "USER"
```

The result is that the value of the CURRENT PACKAGE PATH special register is set to: "SYSIBM, "SMITH", "USER".

Specifying a collection ID in an SQL procedure: Because a host variable (SQL variable) in an SQL procedure does not begin with a colon, Db2 uses the following rules to determine whether a value that is specified in a SET PACKAGE PATH = *name* statement is a variable or a collection ID:

- If *name* is the same as a parameter or SQL variable in the SQL procedure, Db2 uses *name* as a parameter or SQL variable and assigns the value in *name* to the package path.
- If *name* is not the same as a parameter or SQL variable in the SQL procedure, Db2 uses *name* as a collection ID and assigns and the value in *name* is the package path.

DRDA classification: The SET CURRENT PACKAGE PATH statement is executed by the database server and, therefore, is classified as a non-local SET statement in DRDA. The SET CURRENT PACKAGE PATH statement requires a new level of DRDA support. If SET CURRENT PACKAGE PATH is issued when connected to the local server, the SET CURRENT PACKAGE PATH special register at the local server is set. Otherwise, when SET CURRENT PACKAGE PATH is issued when connected to a remote server, the SET CURRENT PACKAGE PATH special register at the remote server is set.

Examples for SET CURRENT PACKAGE PATH

Example 1: Set the CURRENT PACKAGE PATH special register to the list of collections COLL4 and COLL5, where :hvar1 contains the value COLL4,COLL5:

```
   SET CURRENT PACKAGE PATH :hvar1;
```

The value of CURRENT PACKAGE PATH is set to the following two collection IDs: "COLL4","COLL5".

Example 2: Set the CURRENT PACKAGE PATH special register to the list of collections: COLL1, COLL#2, COLL3, COLL4, and COLL5, where :hvar1 contains the value COLL4,COLL5:

```
  SET CURRENT PACKAGE PATH = "COLL1","COLL#2","COLL3", :hvar1;
```

The value of CURRENT PACKAGE PATH is set to the following five collection IDs: "COLL1,"COLL#2","COLL3","COLL4","COLL5".

Example 3: Clear the CURRENT PACKAGE PATH special register.

```
  SET CURRENT PACKAGE PATH = ' ';
```

Example 4: In preparation of calling a stored procedure that is named SUMARIZE, temporarily add two collections, COLL_PROD1" and "COLL_PROD2, to the end of the CURRENT PACKAGE PATH special register (the values of the collections are in host variables :prodcoll1 and prodcoll2, respectively). Because the stored procedure SUMARIZE is not defined with a COLLID value and is defined with INHERIT SPECIAL REGISTERS, the stored procedure will inherit the value of CURRENT PACKAGE PATH. When the stored procedure returns, set the value of the CURRENT PACKAGE PATH special register back to its original value.

```
SET :oldCPP = CURRENT PACKAGE PATH;
SET CURRENT PACKAGE PATH = CURRENT PACKAGE PATH, :prodcoll1, :prodcoll2;
CALL SUMARIZE(:V1,:V2);
SET CURRENT PACKAGE PATH = :oldCPP;
```

Related reference

CURRENT PACKAGE PATH special register
CURRENT PACKAGE PATH specifies a value that identifies the path used to resolve references to packages that are used to execute SQL statements. This special register applies to both static and dynamic statements.

SET CURRENT PACKAGESET

The SET CURRENT PACKAGESET statement assigns a value to the CURRENT PACKAGESET special register.

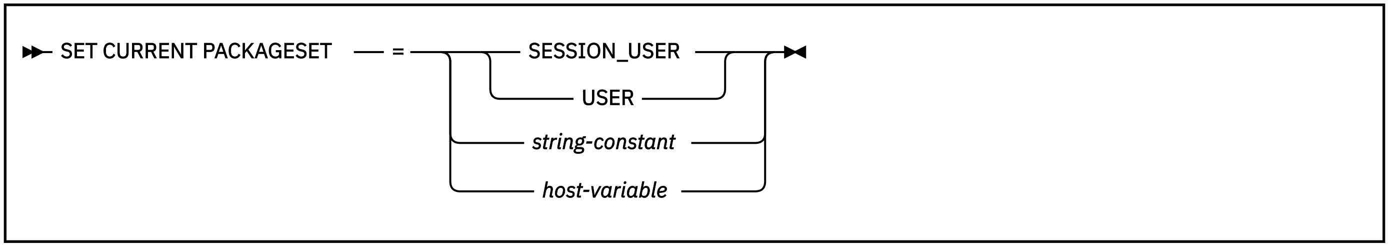
Invocation for SET CURRENT PACKAGESET

This statement can only be embedded in an application program. It is an executable statement that cannot be dynamically prepared.

Authorization for SET CURRENT PACKAGESET

None required.

Syntax for SET CURRENT PACKAGESET



Description for SET CURRENT PACKAGESET

The value of CURRENT PACKAGESET is replaced by the value of the SESSION_USER special register, *string-constant*, or *host-variable*. The value specified by *string-constant* or *host-variable* must be a character string that is not longer than 128 bytes.

Notes for SET CURRENT PACKAGESET

Selection of plan elements: A *plan element* is a DBRM that has been bound into the plan or a package that is implicitly or explicitly identified in the package list of the plan. Plan elements contain the control structures used to execute certain SQL statements.

Since a plan can have many elements, one of the first steps involved in the execution of an SQL statement that requires a control structure is the selection of the plan element that contains its control structure. The information used by Db2 to select plan elements includes the value of CURRENT PACKAGESET.

SET CURRENT PACKAGESET is used to specify the collection ID of a package that exists at the current server. SET CURRENT PACKAGESET is optional and should not be used without an understanding of the following rules for selecting a plan element.

If the CURRENT PACKAGESET special register is an empty string, Db2 searches for a DBRM or a package in one of these sequences:

At the local location (if CURRENT SERVER is blank or explicitly names that location), the order is:

1. All DBRMs bound directly to the plan
2. All packages that have already been allocated for the application process
3. All unallocated packages explicitly named in, and all collections completely included in, the package list of the plan. The order of search is the order those packages are named in the package list.

At a remote location, the order is:

1. All packages that have already been allocated for the application process at that location
2. All unallocated packages explicitly named in, and all collections completely included in, the package list of the plan, whose locations match the value of CURRENT SERVER. The order of search is the order those packages are named in the package list.

If the special register CURRENT PACKAGESET is set, Db2 skips the check for programs that are part of the plan and uses the value of CURRENT PACKAGESET as the collection. For example, if CURRENT PACKAGESET contains COL5, then Db2 uses COL5.PROG1.*timestamp* for the search. For more information, see Overriding the values that Db2 uses to resolve package lists (Db2 Application programming and SQL).

DRDA classification: SET CURRENT PACKAGESET is executed by the requester and is therefore classified as a local SET statement in DRDA.

CURRENT PACKAGESET special register with stored procedures and user-defined functions: The initial value of the CURRENT PACKAGESET special register in a stored procedure or user-defined function is the value of the COLLID parameter with which the stored procedure or user-defined function was defined. If the routine was defined without a value for the COLLID parameter, the value of the special register is inherited from the calling program. A stored procedure or user-defined function can use the SET CURRENT PACKAGESET statement to change the value of the special register. This allows the routine to select the version of the Db2 package that is used to process the SQL statements in a called routine that is not defined with a COLLID value.

When control returns from the stored procedure to the calling program, the special register CURRENT PACKAGESET is restored to the value it contained before the stored procedure was called.

Examples for SET CURRENT PACKAGESET

Example 1: Limit the plan element selection to packages in the PERSONNEL collection at the current server.

```
EXEC SQL SET CURRENT PACKAGESET = 'PERSONNEL';
```

Example 2: Eliminate collections as a factor in plan element selection.

```
EXEC SQL SET CURRENT PACKAGESET = '';
```

Related reference
CURRENT PACKAGESET special register

CURRENT PACKAGESET specifies an empty string, a string of blanks, or the collection ID of the package that will be used to execute SQL statements.

SET CURRENT PRECISION

The SET CURRENT PRECISION statement assigns a value to the CURRENT PRECISION special register.

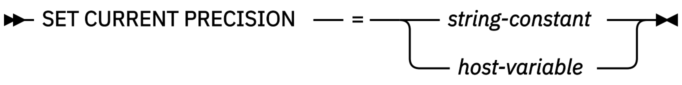
Invocation for SET CURRENT PRECISION

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization for SET CURRENT PRECISION

None required.

Syntax for SET CURRENT PRECISION



Description for SET CURRENT PRECISION

This statement replaces the value of the CURRENT PRECISION special register with the value of the string constant or host variable. The value must be a character string 5 bytes in length. The value must be 'DEC15,' 'DEC31,' or 'Dpp.s', where 'pp' is either 15 or 31 and 's' is a number between 1 and 9. If the form 'Dpp.s' is used, 'pp' represents the precision that will be used with the rules that are used for DEC15 or DEC31, and 's' represents the minimum divide scale to use for division operations. The separator used in the form 'Dpp.s' can be either the '.'or the ',' character, regardless of the setting of the default decimal point.

Example for SET CURRENT PRECISION

Set the CURRENT PRECISION special register so that subsequent statements that are prepared use DEC15 rules for decimal arithmetic.

```
   EXEC SQL SET CURRENT PRECISION = 'DEC15';
```

Related reference

CURRENT PRECISION special register
CURRENT PRECISION specifies the rules to be used when both operands in a decimal operation have precisions of 15 or less.

SET CURRENT QUERY ACCELERATION

The SET CURRENT QUERY ACCELERATION statement changes the value of the CURRENT QUERY ACCELERATION special register.

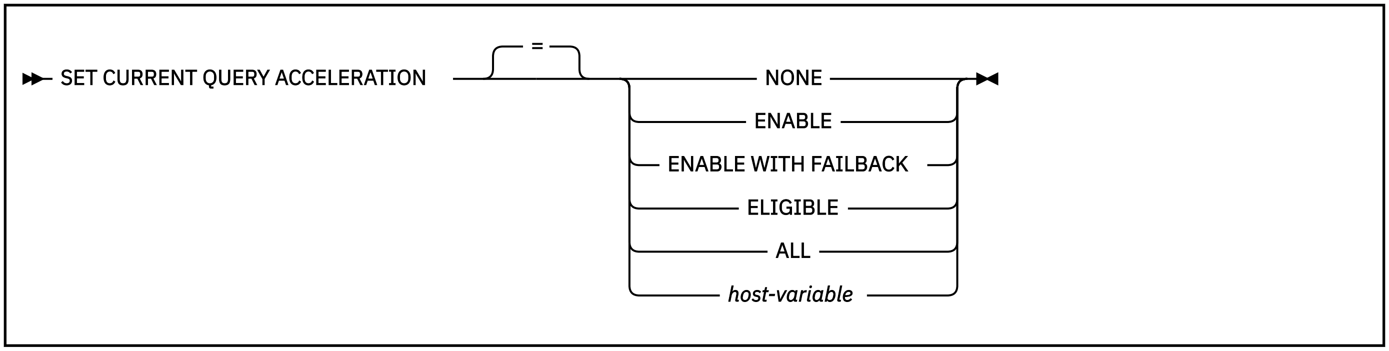
Invocation for SET CURRENT QUERY ACCELERATION

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization for SET CURRENT QUERY ACCELERATION

None required.

Syntax for SET CURRENT QUERY ACCELERATION



Description for SET CURRENT QUERY ACCELERATION

NONE

Specifies that no query acceleration is done.

ENABLE

Specifies that queries are accelerated only if Db2 determines that it is advantageous to do so. If an accelerator failure occurs while a query is running or if the accelerator returns an error, Db2 returns a negative SQLCODE to the application.

ENABLE WITH FAILBACK

Specifies that queries are accelerated only if Db2 determines that it is advantageous to do so. If the accelerator returns an error during the PREPARE or first OPEN for the query, Db2 executes the query without the accelerator. If the accelerator returns an error during a FETCH or a subsequent OPEN, Db2 returns the error to the user and does not execute the query.

Restriction: FL 504 If the query contains a passthrough-only expression, Db2 returns an error and does not accelerate the query, even if a matching user-defined function exists. For more information about passthrough-only expressions, see Accelerating queries with passthrough-only expressions.

ELIGIBLE

Specifies that queries are accelerated if they are eligible for acceleration. Db2 does not use cost information to determine whether to accelerate the queries. Queries that are not eligible for acceleration are executed by Db2. If an accelerator failure occurs while a query is running or if the accelerator returns an error, Db2 returns a negative SQLCODE to the application.

ALL

Specifies that queries are accelerated if they are eligible for acceleration. Db2 does not use cost information to determine whether to accelerate the queries. Queries that are not eligible for acceleration are not executed by Db2, and an SQL error is returned. If an accelerator failure occurs while a query is running or if the accelerator returns an error, Db2 returns a negative SQLCODE to the application.

Exceptions:

- If a dynamic query cannot be processed by IBM Db2 Analytics Accelerator because the tables do not exist on the accelerator, the query usually fails with an error message (-4742, reason code 12). However, such a query is processed by Db2 if it references tables with the following qualifiers only:
  - SYSIBM
  - SYSACCEL
  - DB2GSE
  - SYSXSR
  - DGTT

- Dynamic queries whose top query block is pruned, and which therefore return an empty result set, are processed by Db2. To check whether a query falls into this category, follow these steps:

  1. Explain the query using the Db2 EXPLAIN function. Use the following special register setting in the SQL statement:

     ```
     SET CURRENT QUERY ACCELERATION = NONE
     ```

  2. Check the PLAN_TABLE. If the top query block has been pruned, the entry for the query block shows PRUNED in the QBLOCK_TYPE column and no value in the ACCESSTYPE column.

host-variable

A variable with a data type of CHAR or VARCHAR. The length must not exceed 255 bytes. Valid values are NONE, ENABLE, ENABLE WITH FAILBACK, ELIGIBLE, or ALL. If *host-variable* has an associated indicator variable, the value of that indicator variable must not indicate a null value. The value of *host-variable* must be left justified and must be padded on the right with blanks.

Notes for SET CURRENT QUERY ACCELERATION

The precedence order (lowest to highest) for setting the value of the special register is as follows:

- The QUERY_ACCELERATION subsystem parameter
- The QUERYACCELERATION bind option, if specified
- An explicit SET CURRENT QUERY ACCELERATION statement

Examples for SET CURRENT QUERY ACCELERATION

The following statement sets the CURRENT QUERY ACCELERATION special register to NONE to indicate that no acceleration is done.

```
   SET CURRENT QUERY ACCELERATION NONE;
```

CURRENT QUERY ACCELERATION special register

The CURRENT QUERY ACCELERATION special register specifies a value that identifies when Db2 sends dynamic SQL queries to an accelerator server and what Db2 does if the accelerator server fails. The special register does not apply to static SQL queries.

SET CURRENT QUERY ACCELERATION WAITFORDATA

The SET CURRENT QUERY ACCELERATION WAITFORDATA statement assigns a value to the CURRENT QUERY ACCELERATION WAITFORDATA special register.

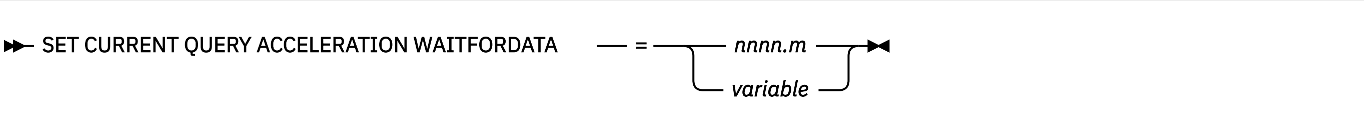
Invocation for SET CURRENT QUERY ACCELERATION WAITFORDATA

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization for SET CURRENT QUERY ACCELERATION WAITFORDATA

None required.

Syntax for SET CURRENT QUERY ACCELERATION WAITFORDATA



Description for SET CURRENT QUERY ACCELERATION WAITFORDATA

nnnn.m

Is a DECIMAL(5,1) numeric-constant value that specifies the maximum number of seconds that the accelerator will delay a query while the accelerator waits for the replication of committed Db2 data changes that occurred prior to Db2 running the query.

You can specify a value in the range of 0.0 - 3600.0 seconds. For example, a value of 20.0 represents 20.0 seconds (or 20000 milliseconds), and a value of 30.5 represents 30.5 seconds (or 30500 milliseconds). The maximum value of 3600.0 means that the query is delayed for 60 minutes.

The default value is 0.0, which means that the query is not delayed and is run immediately on the accelerator. Other WAITFORDATA behavior is not applied to the query.

The wait time value can also be specified as an INTEGER numeric constant value ranging from 0 - 3600 seconds, which Db2 will convert to a DECIMAL (5,1) value.

variable

Is a language host-variable or SQL variable that has a data type of DECIMAL(5,1) or other data type that is assignable to DECIMAL(5,1). Any value that is specified for *variable* must conform to the specifications for *nnnn.m*. Additionally, *variable* cannot be a global variable.

Notes for SET CURRENT QUERY ACCELERATION WAITFORDATA

The precedence order (lowest to highest) for setting the value of the special register is as follows:

- The QUERY_ACCEL_WAITFORDATA subsystem parameter
- The ACCELERATIONWAITFORDATA bind option, if specified
- An explicit SET CURRENT QUERY ACCELERATION WAITFORDATA statement

The WAITFORDATA special register is used only for dynamic queries and applies only when query acceleration behavior is also requested by using the CURRENT QUERY ACCELERATION special register. The WAITFORDATA special register is not applied to accelerated queries that reference only accelerator-only tables (AOTs).

The delay wait time begins when the query reaches the accelerator, not when the query starts running in Db2. For more information about how to determine appropriate WAITFORDATA delay time values for query acceleration with replication in your environment, see the IBM Db2 Analytics Accelerator for z/OS documentation for Hybrid Transactional and Analytical Processing (HTAP) and the WAITFORDATA feature.

Setting CURRENT QUERY ACCELERATION WAITFORDATA to a value greater than 0 specifies that Db2 and the accelerator will apply WAITFORDATA delay behavior and restrictions to *all* dynamic queries to be accelerated afterward. The following behaviors, requirements, and restrictions apply to using WAITFORDATA to delay queries:

- When Db2 sends a query to the accelerator, Db2 also sends the specified WAITFORDATA delay wait time and an internal value that represents the latest committed Db2 data change on the entire Db2 subsystem (for a data sharing environment, across all the Db2 subsystems of the data sharing group) at the time Db2 sends the query to the accelerator. The committed data change might or might not be related to an accelerated table that is referenced in the query, but the internal value that represents this committed change is still used for the query that is accelerated.
- If the specified WAITFORDATA delay wait time expires before the expected committed Db2 data change is replicated to the accelerator, the accelerator will fail the query and issue SQLCODE -904 accompanied by additional message information.

If the delay wait time expires on the first OPEN for the query in the current Db2 unit of work, the failing query qualifies for failback to Db2 if CURRENT QUERY ACCELERATION has been set to ENABLE WITH FAILBACK.

This default WAITFORDATA delay wait time expiration behavior can be changed by modifying the accelerator configuration settings for replication. For information about changing the default WAITFORDATA delay wait time expiration behavior, see the WAITFORDATA information in the IBM Db2 Analytics Accelerator for z/OS documentation.

- All accelerated Db2 tables referenced in the query must be subscribed to and enabled for replication to the target accelerator. If all accelerated tables in the query do not meet this requirement, the accelerator will fail the query and issue SQLCODE -904 accompanied by additional message information.

  If this failure occurs on the first OPEN for the query in the current Db2 unit of work, the failing query qualifies for failback to Db2 if CURRENT QUERY ACCELERATION has been set to ENABLE WITH FAILBACK.

  This default WAITFORDATA behavior can be changed by modifying the accelerator configuration settings for replication. For information about changing this default WAITFORDATA behavior requirement, see the WAITFORDATA information in the IBM Db2 Analytics Accelerator for z/OS documentation.
- WAITFORDATA behavior is dependent on the replication process. Therefore, accelerated queries can be directly affected by current replication status, function, and performance, possibly resulting in the accelerated query failing on the accelerator with SQLCODE -904 if replication is not functioning or performing properly.
- In the following situations, Db2 changes that are committed before the query is sent to the accelerator will not be available to the query when it is run on the accelerator, even if WAITFORDATA delay behavior is requested for the query:
  - The query specifies a Db2 accelerated table, but the same Db2 unit of work includes a previous uncommitted Db2 change that will not be available to the query when it is run on the accelerator. In this situation, accelerator WAITFORDATA behavior cannot be achieved for the query, and the query will not be accelerated. The Db2 change might or might not be related to the Db2 accelerated table that is referenced in the query.
  - The query specifies a Db2 accelerated table, but the same Db2 unit of work includes a previous uncommitted accelerator-only table (AOT) change. This uncommitted change resulted in the creation of an accelerator database *snapshot isolation* (SI) for this unit of work before the query was run; therefore, accelerator WAITFORDATA behavior cannot be achieved for the query, and the query will not be accelerated. This accelerator database SI can prevent committed and replicated Db2 changes, made by either this transaction or by a different transaction, from being available to the accelerated query, even if the Db2 changes are replicated to the accelerator before the query is run there.

  For these situations, Db2 will not accelerate the query but instead will run it only in Db2, if possible. If the QUERY ACCELERATION behavior requested does not allow the query to be run only in Db2 or if the query also references an AOT, then Db2 will fail the query and issue SQLCODE -4742. The default WAITFORDATA behavior for these situations can be changed only by modifying the transaction application with the changes that are described in the associated reason codes in SQLCODE -4742.

Examples for SET CURRENT QUERY ACCELERATION WAITFORDATA

The following statement sets the CURRENT QUERY ACCELERATION WAITFORDATA special register to 180 seconds, which specifies that the accelerator waits for the query to execute for as long as three minutes:

```
SET CURRENT QUERY ACCELERATION WAITFORDATA = 180.0;
```

The following statement sets the CURRENT QUERY ACCELERATION WAITFORDATA special register to 2.5 seconds:

```
SET CURRENT QUERY ACCELERATION WAITFORDATA = 2.5;
```

Related tasks

Enabling acceleration of SQL queries (Db2 Performance)

Related reference

CURRENT QUERY ACCELERATION WAITFORDATA special register
The CURRENT QUERY ACCELERATION WAITFORDATA special register specifies the maximum amount of time, if any, that the accelerator delays a dynamic SQL query while the accelerator waits for the replication of committed Db2 data changes that occurred prior to Db2 running the query. This special register does not apply to static SQL queries.

WAIT FOR DATA field (QUERY_ACCEL_WAITFORDATA subsystem parameter) (Db2 Installation and Migration)

CURRENT QUERY ACCELERATION special register
The CURRENT QUERY ACCELERATION special register specifies a value that identifies when Db2 sends dynamic SQL queries to an accelerator server and what Db2 does if the accelerator server fails. The special register does not apply to static SQL queries.

SET CURRENT REFRESH AGE

The SET CURRENT REFRESH AGE statement changes the value of the CURRENT REFRESH AGE special register.

The CURRENT REFRESH AGE value corresponding to ANY (99 999 999 999 999) cannot be used in timestamp arithmetic operations because the result would be outside the valid range of dates.

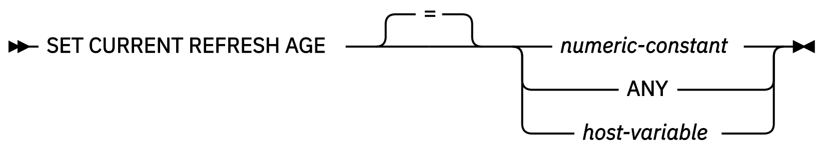
Invocation for SET CURRENT REFRESH AGE

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization for SET CURRENT REFRESH AGE

None required.

Syntax for SET CURRENT REFRESH AGE



Description for SET CURRENT REFRESH AGE

numeric-constant
A DECIMAL(20,6) value representing a timestamp duration. The value must be 0 or 99 999 999 999 999, the partial seconds of which is ignored and thus can be any value.

0
Indicates that query optimization using materialized query tables will not be attempted.

99999999999999
Indicates that any materialized query tables identified by the CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION special register may be used to optimize the processing of a query. This value represents 9999 years, 99 months, 99 days, 99 hours, 99 minutes, and 99 seconds.

ANY
Shorthand for 99999999999999.

host-variable

A variable of type DECIMAL(20,6) or other type that is assignable to DECIMAL(20,6). It cannot be set to null. If *host-variable* has an associated indicator variable, the value of that indicator variable must not indicate a null value. The value of *host-variable* must be 0 or 99 999 999 999 999, the partial seconds of which is ignored and thus can be any value.

Notes for SET CURRENT REFRESH AGE

Materialized query tables created or altered with DISABLE QUERY OPTIMIZATION specified are not eligible for automatic query rewrite. Thus, they are not affected by the setting of this special register.

Setting the CURRENT REFRESH AGE special register to a value other than zero should be done with caution. Allowing a materialized query table that may not represent the values of the underlying base table to be used to optimize the processing of a query may produce results that do not accurately represent the data in the underlying table. This situation may be acceptable when you know the underlying data has not changed or you are willing to accept the degree of error in the results based on your knowledge of the data.

Examples for SET CURRENT REFRESH AGE

Example: Set the CURRENT REFRESH AGE special register to 99 999 999 999 999 to indicate that any materialized query tables identified by the CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION special register can be used to optimize the processing of a query.

```
SET CURRENT REFRESH AGE ANY;
```

Related reference

CURRENT REFRESH AGE special register

CURRENT REFRESH AGE specifies a timestamp duration value. This duration is the maximum duration since a REFRESH TABLE statement has been processed on a system-maintained REFRESH DEFERRED materialized query table such that the materialized query table can be used to optimize the processing of a query. This special register affects dynamic statement cache matching.

SET CURRENT ROUTINE VERSION

The SET CURRENT ROUTINE VERSION statement assigns a value to the CURRENT ROUTINE VERSION special register. The special register sets the override value for the version identifier of native SQL procedures when they are invoked.

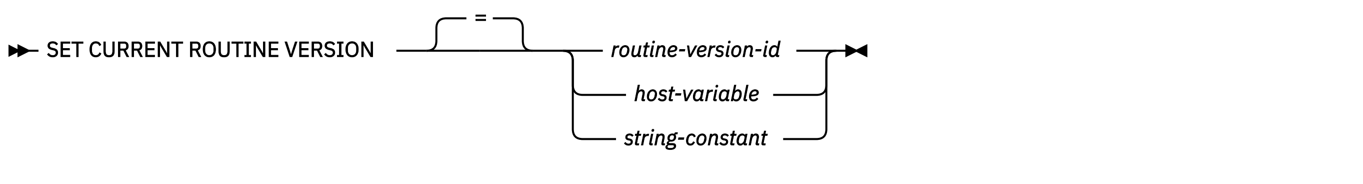
Invocation for SET CURRENT ROUTINE VERSION

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization for SET CURRENT ROUTINE VERSION

None required.

Syntax for SET CURRENT ROUTINE VERSION



Description for SET CURRENT ROUTINE VERSION

routine-version-id
Specifies a routine version identifier.

host-variable
Specifies a host variable that contains a version identifier. The host variable must conform to the following rules:

- Be a CHAR, VARCHAR, GRAPHIC, or VARGRAPHIC variable. The actual length of the contents of the host variable must not exceed the length of a version identifier.
- Include a routine version identifier that is left justified and conforms to the rules for forming an ordinary identifier or a delimited identifier, or must be blank or empty.
- Be padded on the right with blanks if the host variable is a fixed length character.
- Not be empty or contain only blanks if the identifier is delimited.
- Not be the null value.

string-constant
Specifies a string constant that contains a version identifier. The string constant must conform to the following rules:

- Have a length that does not exceed the length of a *routine-version-id*.
- Include a routine version identifier that is left justified and conforms to the rules for forming an ordinary identifier or a delimited identifier, or must be blank or an empty string
- Not be empty or contain only blanks if the identifier is delimited

Notes for SET CURRENT ROUTINE VERSION

Resetting the special register: To reset the special register, specify an empty string constant, a string of blanks, or a host variable that is empty or contains only blanks. A routine version override is not in effect when the special register is reset.

Implications of using the special register: Setting the CURRENT ROUTINE VERSION special register to a version identifier will affect all SQL procedures that are subsequently invoked using CALL statements that specify the name of the procedure using a host variable, until the value of CURRENT ROUTINE VERSION is changed. If a version of the procedure that is identified by the version identifier in the special register exists for an SQL procedure that is being invoked, that version of the procedure is used. Otherwise, the currently active version of the procedure (as noted in the catalog) is used.

When you use the CURRENT ROUTINE VERSION special register to test a version of one or more native SQL procedures, you should use a routine version identifier that is a value other than the default value (V1) on the CREATE PROCEDURE statement. This will avoid having the special register affect more procedures that you intend when testing a new version of a procedure. For example, assume that you want to run version VER2 of procedure P1, and procedure P1 invokes another procedure, P2. If a version exists for both procedures P1 and P2 with the routine version identifier VER2, that version will be used for both procedures.

Examples for SET CURRENT ROUTINE VERSION

Example: The following statement sets the CURRENT ROUTINE VERSION special register so that the override value for the version identifier of native SQL procedures will be the value that is specified in the host variable *rvid*:

```
   SET CURRENT ROUTINE VERSION = :rvid;
```

Related reference
CURRENT ROUTINE VERSION special register

CURRENT ROUTINE VERSION specifies the version identifier that is to be used when invoking a native SQL procedure. CURRENT ROUTINE VERSION is used for CALL statements that use a host variable to specify the procedure name.

SET CURRENT RULES

The SET CURRENT RULES statement assigns a value to the CURRENT RULES special register.

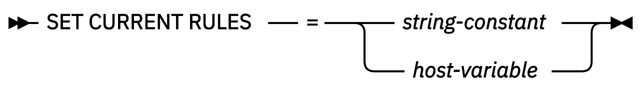
Invocation for SET CURRENT RULES

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization for SET CURRENT RULES

None required.

Syntax for SET CURRENT RULES



Description for SET CURRENT RULES

This statement replaces the value of the CURRENT RULES special register with the value of the string constant or host variable. The value must be a character string that is 3 bytes in length, and the value must be 'DB2' or 'STD'.

Notes for SET CURRENT RULES

For the effect of the values 'DB2' and 'STD' on the execution of certain SQL statements, see "CURRENT RULES special register" on page 205.

Example for SET CURRENT RULES

Set the SQL rules to be followed to Db2 rules.

```
EXEC SQL SET CURRENT RULES = 'DB2';
```

Related reference

CURRENT RULES special register
CURRENT RULES specifies whether certain SQL statements are executed in accordance with Db2 rules or the rules of the SQL standard.

SET CURRENT SQLID

The SET CURRENT SQLID statement assigns a value to the CURRENT SQLID special register.

Invocation for SET CURRENT SQLID

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared. The value to which special register CURRENT SQLID is set is used as the SQL authorization ID for dynamic SQL statements only if DYNAMICRULES run behavior is in effect. The CURRENT SQLID value is ignored for the other DYNAMICRULES behaviors.

Authorization for SET CURRENT SQLID

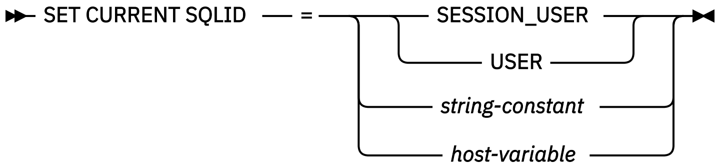
The specified value must be equal to one of the authorization IDs of the application process. This rule always applies, even when SET CURRENT SQLID is issued as a static SQL statement.

Exceptions:

- If any of the authorization IDs of the process has SYSADM authority, CURRENT SQLID can be set to any value when the SEPARATE SECURITY system parameter is set to NO. Note that the SEPARATE_SECURITY subsystem parameter does not apply to or affect users with installation SYSADM authority.
- If any of the authorization IDs has the installation SYSOPR authority, CURRENT SQLID can be set to SYSINSTL, regardless of the SEPARATE_SECURITY value.

CURRENT SQLID cannot be set to the name of a role.

Syntax for SET CURRENT SQLID



Description for SET CURRENT SQLID

The value of CURRENT SQLID is replaced based on the value that is specified. With certain exceptions, the specified value must be equal to one of the authorization IDs of the application process. For more information, see "Authorization for SET CURRENT SQLID" on page 2150.

SESSION_USER or USER
Specifies the value of the SESSION_USER (USER) special register.

string-constant
Specifies a character string constant of 8 characters or fewer that identifies an authorization ID. The content is not folded to uppercase.

host-variable
Specifies a character string constant of 8 characters or fewer that identifies a host variable that contains an authorization ID. The content is not folded to uppercase.

Notes for SET CURRENT SQLID

Effect on authorization IDs
SET CURRENT SQLID does not change the primary authorization ID of the process.

If the SET CURRENT SQLID statement is executed in a stored procedure or user-defined function package that has a dynamic SQL behavior other than run behavior, the SET CURRENT SQLID statement does not affect the authorization ID that is used for dynamic SQL statements in the package. The dynamic SQL behavior determines the authorization ID. For more information, see DYNAMICRULES bind option (Db2 Commands).

Effect on special register CURRENT PATH
When the value of the PATH special register depends on the value of the CURRENT SQLID special register, any changes to the CURRENT SQLID special register are not reflected in the value of the PATH special register until a commit operation is performed or a SET PATH statement is issued to change the SQL path to use the new value of the CURRENT SQLID.

DRDA classification
SET CURRENT SQLID is executed by the database server and is therefore classified as a non-local SET statement in DRDA.

Examples for SET CURRENT SQLID

Example 1

Set the CURRENT SQLID to the primary authorization ID.

```
SET CURRENT SQLID = SESSION_USER;
```

Example 2

Set the SQL authorization ID to 'GROUP34' (one of the authorization IDs of the process).

```
  SET CURRENT SQLID = 'GROUP34';
```

Related reference

CURRENT SQLID special register
CURRENT SQLID specifies the SQL authorization ID of the process.

SESSION_USER special register
SESSION_USER specifies the primary authorization ID of the process.

SET CURRENT TEMPORAL BUSINESS_TIME

The SET CURRENT TEMPORAL BUSINESS_TIME statement changes the value of the CURRENT TEMPORAL BUSINESS_TIME special register.

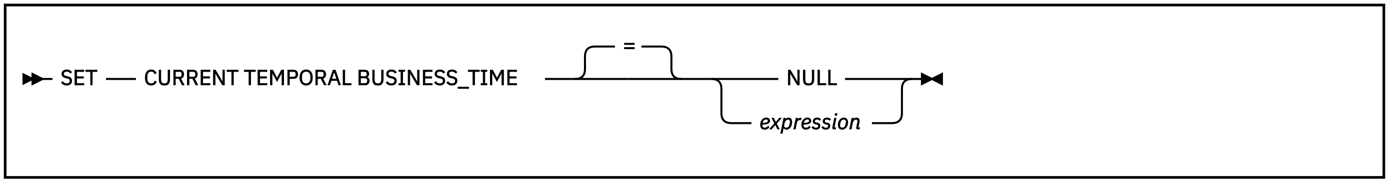
Invocation for SET CURRENT TEMPORAL BUSINESS_TIME

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization for SET CURRENT TEMPORAL BUSINESS_TIME

None required.

Syntax for SET CURRENT TEMPORAL BUSINESS_TIME



Description for SET CURRENT TEMPORAL BUSINESS_TIME

NULL

Specifies the null value.

expression

Specifies an expression that returns the null value or the value of one of the following built-in data types:

- Timestamp
- Character string
- Graphic string

If the expression is a character or graphic string, it must meet the following requirements:

- It must not be a CLOB or DBCLOB.
- The value of the expression must be a valid character-string or graphic-string representation of a timestamp.

- The result of the expression must be castable to TIMESTAMP(12).

expression can contain any of the following supported operands:

- Constant
- Special register
- Variable (host variable, SQL parameter, SQL variable, or global variable)
- Scalar function whose arguments are supported operands
- CAST specification where the cast operand is a supported operand
- Expression that uses arithmetic operators and operands

For more information, see:

“String representations of datetime values” on page 120
“Casting between data types” on page 130

Notes for SET CURRENT TEMPORAL BUSINESS_TIME

Transactions

The SET CURRENT TEMPORAL BUSINESS_TIME statement is not a committable operation. The ROLLBACK statement has no effect on CURRENT TEMPORAL BUSINESS_TIME.

Effects on other special registers

The setting of the CURRENT TEMPORAL BUSINESS_TIME special register does not affect other special registers, such as the CURRENT DATE and CURRENT TIMESTAMP special registers.

Examples for SET CURRENT TEMPORAL BUSINESS_TIME

Example of setting the special register to a valid value

Both of the following statements set the CURRENT TEMPORAL BUSINESS_TIME special register to '2008-01-06-00.00.00.000000000000'.

```
SET CURRENT TEMPORAL BUSINESS_TIME = TIMESTAMP('2008-01-01') + 5 DAYS ;
SET CURRENT TEMPORAL BUSINESS_TIME = '2008-01-06-00.00.00.000000000000';
```

Example of how setting the special register affects subsequent SQL statements

In the following example, the first statement sets the CURRENT TEMPORAL BUSINESS_TIME special register to last month. Assume that table att1 is an application-period temporal table. The setting of the CURRENT TEMPORAL BUSINESS_TIME special register affects the update of att1.

```
SET CURRENT TEMPORAL BUSINESS_TIME = CURRENT TIMESTAMP - 1 MONTH
UPDATE att1 SET c1 = 5 WHERE pk = 100
```

Assume that the att1 table has columns bt_begin and bt_end to indicate the beginning and end of the BUSINESS_TIME period. In this example, Db2 interprets the UPDATE statement as follows:

```
UPDATE att1 SET c1 = 5 WHERE pk = 100
AND bt_begin <= CURRENT TEMPORAL BUSINESS_TIME
AND bt_end > CURRENT TEMPORAL BUSINESS_TIME
```

Example of setting the special register so that it does not affect subsequent SQL statements

The following statement sets the CURRENT TEMPORAL BUSINESS_TIME special register to the null value. Subsequent SQL statements that reference application-period temporal tables are not affected by the CURRENT TEMPORAL BUSINESS_TIME special register.

```
SET CURRENT TEMPORAL BUSINESS_TIME = NULL
```

Related concepts

Data types

Db2 supports both IBM-supplied data types (built-in data types) and user-defined data types (distinct types).

Related reference

CURRENT TEMPORAL BUSINESS_TIME special register
The CURRENT TEMPORAL BUSINESS_TIME special register specifies a TIMESTAMP(12) value that is used in the default BUSINESS_TIME period specification for references to application-period temporal tables.

SET CURRENT TEMPORAL SYSTEM_TIME

The SET CURRENT TEMPORAL SYSTEM_TIME statement changes the value of the CURRENT TEMPORAL SYSTEM_TIME special register.

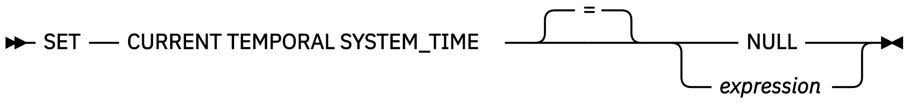
Invocation for SET CURRENT TEMPORAL SYSTEM_TIME

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization for SET CURRENT TEMPORAL SYSTEM_TIME

None required.

Syntax for SET CURRENT TEMPORAL SYSTEM_TIME



Description for SET CURRENT TEMPORAL SYSTEM_TIME

NULL
Specifies the null value.

expression
Specifies an expression that returns the null value or the value of one of the following built-in data types:

- Timestamp
- Character string
- Graphic string

If the expression is a character or graphic string, it must meet the following requirements:

- It must not be a CLOB or DBCLOB.
- The value of the expression must be a valid character-string or graphic-string representation of a timestamp.
- The result of the expression must be castable to TIMESTAMP(12).

expression can contain any of the following supported operands:

- Constant
- Special register
- Variable (host variable, SQL parameter, SQL variable, or global variable)
- Scalar function whose arguments are supported operands
- CAST specification where the cast operand is a supported operand
- Expression that uses arithmetic operators and operands

For more information, see:

“String representations of datetime values” on page 120
“Casting between data types” on page 130

Notes for SET CURRENT TEMPORAL SYSTEM_TIME

Transactions
The SET CURRENT TEMPORAL SYSTEM_TIME statement is not a committable operation. The ROLLBACK statement has no effect on CURRENT TEMPORAL SYSTEM_TIME.

Effects on other special registers
The setting of the CURRENT TEMPORAL SYSTEM_TIME special register does not affect other special registers, such as the CURRENT DATE and CURRENT TIMESTAMP special registers.

Examples for SET CURRENT TEMPORAL SYSTEM_TIME

Example of setting the special register to a valid value
Both of the following statements set the CURRENT TEMPORAL SYSTEM_TIME special register to '2008-01-06-00.00.00.000000000000'.

```
SET CURRENT TEMPORAL SYSTEM_TIME = TIMESTAMP('2008-01-01') + 5 DAYS;
SET CURRENT TEMPORAL SYSTEM_TIME = '2008-01-06-00.00.00.000000000000';
```

Example of setting the special register so that it does not affect subsequent SQL statements
The following statement sets the CURRENT TEMPORAL SYSTEM_TIME special register to the null value. Subsequent SQL statements that reference system-period temporal tables are not affected by the CURRENT TEMPORAL SYSTEM_TIME special register.

```
SET CURRENT TEMPORAL SYSTEM_TIME = NULL
```

Related concepts

Data types
Db2 supports both IBM-supplied data types (built-in data types) and user-defined data types (distinct types).

Related reference

CURRENT TEMPORAL SYSTEM_TIME special register
The CURRENT TEMPORAL SYSTEM_TIME special register specifies a TIMESTAMP(12) value that is used in the default SYSTEM_TIME period specification for references to system-period temporal tables.

SET ENCRYPTION PASSWORD

The SET ENCRYPTION PASSWORD statement sets the value of the encryption password and, optionally, the password hint. The ENCRYPT_TDES, DECRYPT_BIT, DECRYPT_CHAR, and DECRYPT_DB built-in functions use this password and password hint for data encryption unless the functions are invoked with an explicitly specified password and hint. The password is not tied to Db2 authentication and is used only for data encryption.

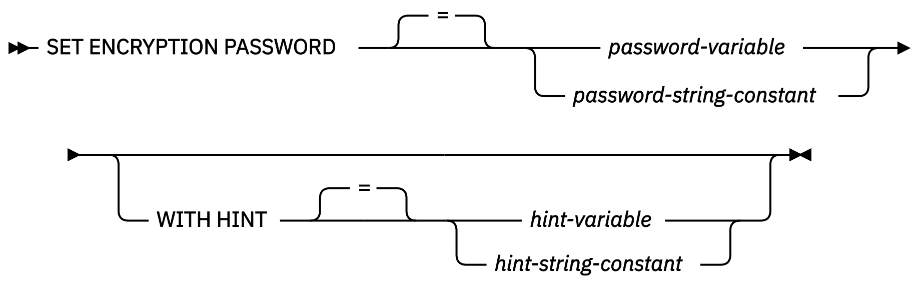
Invocation for SET ENCRYPTION PASSWORD

The statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization for SET ENCRYPTION PASSWORD

None required.

Syntax for SET ENCRYPTION PASSWORD



Description for SET ENCRYPTION PASSWORD

password-variable

Specifies a variable that contains an encryption password. The variable:

- Must be a CHAR or VARCHAR variable. The actual length of the contents of the variable must be between 6 and 127 inclusive or must be an empty string. If an empty string is specified, the default encryption password is set to no value.
- Must not be the null value.
- All characters are case-sensitive and are not converted to uppercase characters.

password-string-constant

A character constant that contains an encryption password. The length of the constant must be between 6 and 127 inclusive or must be an empty string. If an empty string is specified, the default encryption password is set to no value. All characters are case-sensitive and are not converted to uppercase characters.

WITH HINT

Indicates that a value is specified that will help you remember passwords (for example, 'Ocean' as a hint to remember 'Pacific'). If a hint value is specified, the hint is used as the default for encryption functions. The hint can subsequently be retrieved for an encrypted value using the GETHINT function. If this clause is not specified and a hint is not explicitly specified on the encryption function, no hint will be embedded in encrypted data result.

hint-variable

Specifies a variable that contains an encryption password hint. The variable:

- Must be a CHAR or VARCHAR variable. The actual length of the contents of the variable must not be greater than 32. If an empty string is specified, the default encryption password hint is set to an empty string.
- Must not be the null value.
- All characters are case-sensitive and are not converted to uppercase characters.

hint-string-constant

A character string constant that contains an encryption password hint. The length of the constant must not be greater than 32. If the value is an empty string, the default encryption password hint is set to an empty string.

Notes for SET ENCRYPTION PASSWORD

Normal Db2 mechanisms are used to transmit the host variable or constant to the database server.

Examples for SET ENCRYPTION PASSWORD

Example 1: Set the ENCRYPTION PASSWORD to the value in :hv1. Do not specify a hint for the password.

```
SET ENCRYPTION PASSWORD = :hv1
```

Example 2: Set the ENCRYPTION PASSWORD to the value in :hv1. Specify the value in :hv2 as the hint for the password.

```
SET ENCRYPTION PASSWORD = :hv1 WITH HINT :hv2
```

Related reference

ENCRYPTION PASSWORD special register
The ENCRYPTION PASSWORD special register specifies the encryption password and the password hint (if one exists) that are used by the ENCRYPT_TDES, DECRYPT_BIT, DECRYPT_CHAR, and DECRYPT_DB built-in functions.

ENCRYPT_TDES or ENCRYPT
The ENCRYPT_TDES function returns a value that is the result of encrypting the first argument by using the Triple DES encryption algorithm. The function can also set the password that is used for encryption.

DECRYPT_BINARY, DECRYPT_BIT, DECRYPT_CHAR, and DECRYPT_DB
The decryption functions return a value that is the result of decrypting encrypted data. The decryption functions can decrypt only values that are encrypted by using the ENCRYPT_TDES function.

SET PATH

The SET PATH statement assigns a value to the CURRENT PATH special register.

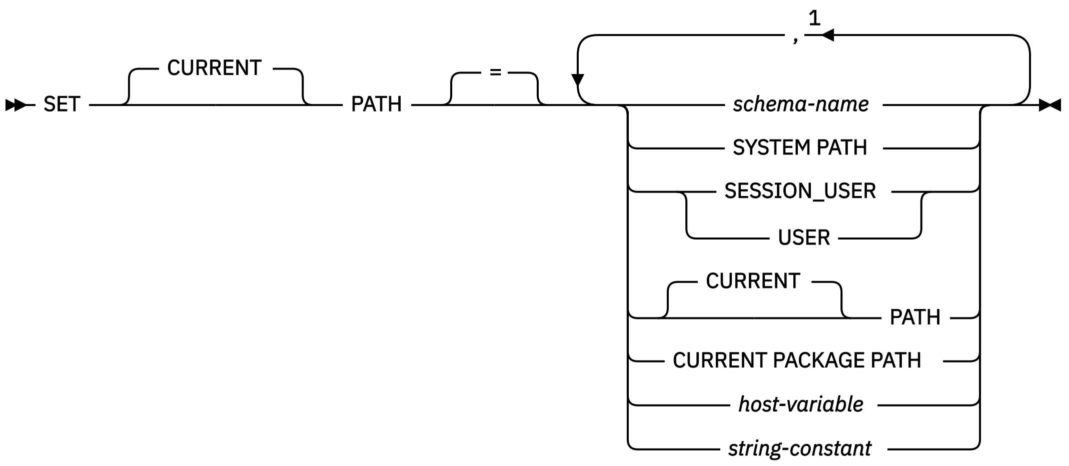
Invocation for SET PATH

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization for SET PATH

None required.

Syntax for SET PATH



Notes:

[1] SYSTEM PATH, SESSION_USER or USER, and CURRENT PATH can be specified only once each.

Description for SET PATH

The value of PATH is replaced by the values specified.

schema-name

Identifies a schema. Db2 does not verify that the schema exists. For example, a schema name that is misspelled is not detected, which could affect the way subsequent SQL operates.

SYSTEM PATH

Specifies the schema names "SYSIBM", "SYSFUN", "SYSPROC", "SYSIBMADM".

SESSION_USER or USER

Specifies the value of the SESSION_USER (USER) special register.

PATH

Specifies the value of the CURRENT PATH special register before the execution of this statement.

CURRENT PACKAGE PATH

Specifies the value of the CURRENT PACKAGE PATH special register.

host-variable

A variable with a data type of CHAR or VARCHAR. The value of *host-variable* must not be null and must represent a valid schema name.

The schema name must:

- Be left justified within the host variable
- Be padded on the right with blanks if its length is less than that of the host variable

string-constant

A character string constant that represents a valid schema name. The schema name must be left justified within the string constant.

If the schema name specified in *string-constant* will also be specified in other SQL statements and the schema name does not conform to the rules for ordinary identifiers, the schema name must be specified as a delimited identifier in the other SQL statements.

Notes for SET PATH

Restrictions on SET PATH:

These restrictions apply to the SET PATH statement:

- If the same schema name appears more than one time in the path, the first occurrence of the name is used and a warning is issued.
- The length of the CURRENT PATH special register limits the number of schema names that can be specified. The special register string is built by taking each schema name that is specified and removing trailing blanks, delimiting with double quotes, changing each double quote character to two double quote characters within the schema name as necessary, and then separating each schema name with a comma. The length of the resulting string cannot exceed 2048 bytes.
- The schema name SYSPUBLIC cannot be specified in the SQL path, even if you specify the value as a delimited identifier.

Specifying "SYSIBM", "SYSFUN", "SYSPROC", "SYSIBMADM":

Schemas "SYSIBM", "SYSFUN", "SYSPROC", "SYSIBMADM" do not need to be specified in the special register. If these schemas are not explicitly specified in the CURRENT PATH special register, each schema is implicitly assumed at the front of the SQL path; if any of these schemas are not specified, they are assumed in the order of "SYSIBM", "SYSFUN", "SYSPROC", "SYSIBMADM" (see "SQL path" on page 85 for an example). Only the schemas that are explicitly specified in the CURRENT PATH register are included in the 2048 byte limit.

To avoid having "SYSIBM", "SYSFUN", "SYSPROC", "SYSIBMADM" implicitly added to the front of the SQL path, explicitly specify them in the path when setting the value of the register. If you specify them at the end of the path, Db2 will check all the other schemas in the path first.

Specifying keywords versus delimited identifiers:

There is a difference between specifying a keyword and specifying a delimited identifier. For example, specifying SESSION_USER with and without escape characters. To indicate that the value of the SESSION_USER special register should be used in the SQL path, specify the keyword SESSION_USER.

If you specify SESSION_USER is as a delimited identifier instead (for example, "SESSION_USER"), it is interpreted as a schema name of 'SESSION_USER'. For example, assume that the current value of the SESSION_USER special register is SMITH and that the following statement is issued:

```
SET PATH = SYSIBM, SYSPROC, SESSION_USER, "SESSION_USER"
```

The result is that the value of the SQL path is set to: "SYSIBM","SYSPROC","SMITH","SESSION_USER".

Specifying a schema name in an SQL procedure:

Because a host variable (SQL variable) in an SQL procedure does not begin with a colon, Db2 uses the following rules to determine whether a value that is specified in a SET PATH=*name* statement is a variable or a *schema-name*:

- If *name* is the same as a parameter or SQL variable in the SQL procedure, Db2 uses *name* as a parameter or SQL variable and assigns the value in *name* to PATH.
- If *name* is not the same as a parameter or SQL variable in the SQL procedure, Db2 uses *name* as a *schema-name* and assigns the value *name* to PATH.

The use of the path to resolve object names:

For information on when the SQL path is used to resolve unqualified data type, function, and procedure names and when the CURRENT PATH special register provides the SQL path, see “SQL path” on page 85.

DRDA classification:

The SET PATH statement is executed by the database server and, therefore, is classified as a non-local SET statement in DRDA.

Alternative syntax and synonyms:

For compatibility with previous releases of Db2 or other products in the Db2 family, Db2 supports CURRENT FUNCTION PATH or CURRENT_PATH as a synonym for CURRENT PATH.

Examples for SET PATH

Example 1: Set the CURRENT PATH special register to the list of schemas: "SCHEMA1", "SCHEMA#2", "SYSIBM".

```
   SET PATH = SCHEMA1,"SCHEMA#2", SYSIBM;
```

When the SQL path specified in the special register is used for name resolution the system schemas which were not explicitly specified in the special register are implicitly assumed at the front of the SQL path, making the effective value of the path:

```
   SYSFUN, SYSPROC, SYSIBMADM, SCHEMA1, SCHEMA#2, SYSIBM
```

Example 2: Add schema SMITH and SYSPROC to the value of the CURRENT PATH special register that was set in Example 1.

```
   SET PATH = CURRENT PATH, SMITH, SYSPROC;
```

The effective value of the SQL path specified by the special register becomes:

```
   SYSFUN, SYSIBMADM, SCHEMA1, SCHEMA#2, SYSIBM, SMITH, SYSPROC
```

Related reference

CURRENT PATH special register

CURRENT PATH specifies the SQL path used to resolve unqualified data type names and function names in dynamically prepared SQL statements. It is also used to resolve unqualified procedure names that are specified as host variables in SQL CALL statements (CALL *host-variable*).

SET SCHEMA

The SET SCHEMA statement assigns a value to the CURRENT SCHEMA special register. If the package is bound with the DYNAMICRULES BIND option, this statement does not affect the qualifier that is used for unqualified database object references.

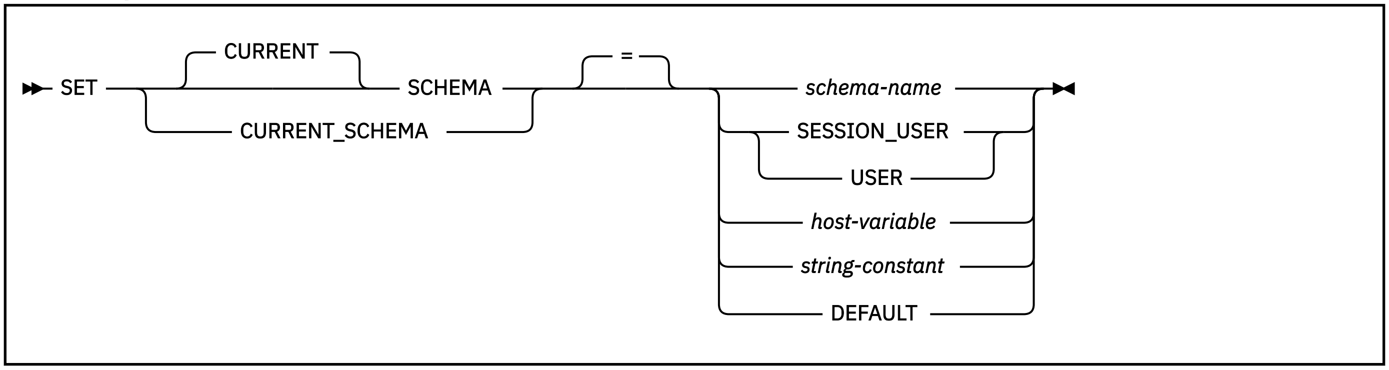
Invocation for SET SCHEMA

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization for SET SCHEMA

None required.

Syntax for SET SCHEMA



Description for SET SCHEMA

schema-name
Identifies a schema. No validation that the schema exists is made at the time the CURRENT SCHEMA is set. For example, if a schema name is misspelled, it could affect the way subsequent SQL operates.

SESSION_USER or USER
Specifies the value of the SESSION_USER (USER) special register.

host-variable
Specifies a host variable that contains a schema name. The content is not folded to uppercase.

The host variable must:

- Be a CHAR, VARCHAR, GRAPHIC, or VARGRAPHIC variable. The actual length of the contents of the *host-variable* must not exceed the length of a schema name.
- Not be set to null. If *host-variable* has an associated indicator variable, the value of that indicator variable must not indicate a null value.
- Include a schema name that is left justified and conforms to the rules for forming an ordinary identifier or delimited identifier. If the identifier is delimited, it must not be empty or contain only blanks.
- Be padded on the right with blanks if the host variable is fixed length.
- Not contain SESSION_USER, USER, or DEFAULT.

string-constant
Specifies a string constant that contains a schema name. The content is not folded to uppercase.

The string constant must:

- Have a length that does not exceed the maximum length of a schema name.
- Include a schema name that is left justified and conforms to the rules for forming an ordinary identifier or delimited identifier. If the identifier is delimited, it must not be empty or contain only blanks.
- Not contain SESSION_USER, USER, or DEFAULT.

DEFAULT

Specifies that CURRENT SCHEMA is to be set to its initial value, as if it had never been explicitly set during the application process. For information about the initial value of CURRENT SCHEMA, see "CURRENT SCHEMA special register" on page 206.

Notes for SET SCHEMA

Considerations for keywords:

There is a difference between specifying a single keyword (such as SESSION_USER or DEFAULT) as a single keyword or as a delimited identifier. To indicate that the current value of the SESSION_USER special register should be used for setting the current schema, specify SESSION_USER as a keyword. To indicate that the special register should be set to its default value, specify DEFAULT as a keyword. If SESSION_USER or DEFAULT is specified as a delimited identifier instead (for example, "SESSION_USER"), it is interpreted as a schema name of that value ("SESSION_USER").

Transaction considerations:

The SET SCHEMA statement is not a committable operation. ROLLBACK has no effect on CURRENT SCHEMA.

Usage of the assigned value:

The value of the CURRENT SCHEMA special register, as set by this statement, is used as the schema name in all dynamic SQL statements. The QUALIFIER bind option specifies the schema name for use as the qualifier for unqualified database object names in static SQL statements.

Impact on other special registers:

Setting the CURRENT SCHEMA special register does not affect any other special register. Therefore, the CURRENT SCHEMA is not be included in the SQL path that is used to resolve the schema name for unqualified references to function, procedures and user-defined types in dynamic SQL statements. To include the current schema value in the SQL path, whenever the SET SCHEMA statement is issued, also issue the SET PATH statement including the schema name from the SET SCHEMA statement.

Examples for SET SCHEMA

Example 1: The following statement sets the CURRENT SCHEMA special register.

```
   EXEC SQL SET SCHEMA RICK;
```

Example 2: The following example retrieves the current value of the CURRENT SCHEMA special register into the host variable called CURSCHEMA.

```
   EXEC SQL SELECT CURRENT SCHEMA INTO :CURSCHEMA
      FROM SYSIBM.SYSDUMMY1;
```

The value of the host variable is RICK.

Example 3: Assume that the following statements are issued:

```
SET CURRENT SQLID = 'USRT001';
SET CURRENT SCHEMA = 'USRT002';
```

At this point, the two special registers contain different values. Any subsequent CREATE statements will use USRT002 as the implicit qualifier, but the owner of the newly created objects is USRT001.

Example 4: Assume that the value of CURRENT SCHEMA is 'Jane' and that the default value of the PATH special register was established using that value (that is, the value of PATH is "SYSIBM", "SYSFUN", "SYSPROC", "SYSIBMADM", "JANE"). Change the value of the CURRENT SCHEMA special register to 'John'.

```
   SET CURRENT SCHEMA = 'JOHN';
```

To change the SQL path to use the updated CURRENT SCHEMA value of "JOHN", issue a SET PATH statement to change the value of the PATH special register to specify "JOHN" as the first schema to check:

```
SET PATH = 'JOHN', CURRENT PATH;
```

Alternatively, a commit would cause PATH to be re-initialized. Otherwise, the path remains "SYSIBM", "SYSFUN", "SYSPROC", "SYSIBMADM", "JANE"), which might cause unqualified object names to resolve to "JANE" when you want them to resolve to "JOHN".

SET SESSION TIME ZONE

The SET SESSION TIME ZONE statement assigns a value to the SESSION TIME ZONE special register.

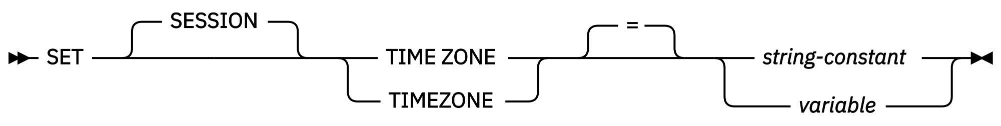
Invocation for SET SESSION TIME ZONE

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization for SET SESSION TIME ZONE

None required.

Syntax for SET SESSION TIME ZONE



Description for SET SESSION TIME ZONE

string-constant
: Identifies a time zone with a value of the form '±*th*:*tm*' , where *th* represents the time zone hour between -12 and +14, and *tm* represents the time zone minutes between 0 and 59, with values ranging from -12:59 to +14:00.

variable
: Specifies a variable that contains a time zone. The variable must be a CHAR or VARCHAR variable that is not followed by an indicator variable. The variable must not be the null value. The value must be left justified and be of the form '±*th*:*tm*' , where *th* represents the time zone hour between -12 and +14, and *tm* represents the time zone minutes between 0 and 59, with values ranging from -12:59 to +14:00.

Notes for SET SESSION TIME ZONE

Impact on other special registers:
: Setting the SESSION TIME ZONE special register does not affect the CURRENT TIMEZONE special register.

Syntax alternatives:
: SESSIONTIMEZONE can be specified as an alternative to SESSION TIME ZONE or TIME ZONE.

Example for SET SESSION TIME ZONE

Set the SESSION TIME ZONE as -8:00:

```
    SET SESSION TIME ZONE = '-8:00';
```

Related reference

SESSION TIME ZONE special register
The SESSION TIME ZONE special register specifies a value that identifies the time zone of the application process.

SIGNAL

The SIGNAL statement is used to signal an error. It causes an error to be returned with the specified SQLSTATE and error description.

For a description of the statement, see "SIGNAL statement" on page 2232.

TRANSFER OWNERSHIP

The TRANSFER OWNERSHIP statement transfers the ownership of a database or system object from one owner to another. The new owner can be an authorization ID or a role.

Invocation for TRANSFER OWNERSHIP

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES RUN behavior is in effect. For more information, see "Authorization IDs and dynamic SQL" on page 94.

Authorization for TRANSFER OWNERSHIP

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the package. If the owner of the package is a role, the role must hold the privileges for the privilege set.

If the statement is dynamically prepared, the privilege set is the privileges that are held by the SQL authorization ID of the process unless the process is within a trusted context and the ROLE AS OBJECT OWNER AND QUALIFIER clause is specified. If ROLE AS OBJECT OWNER is in effect, the role must hold the privileges for the privilege set.

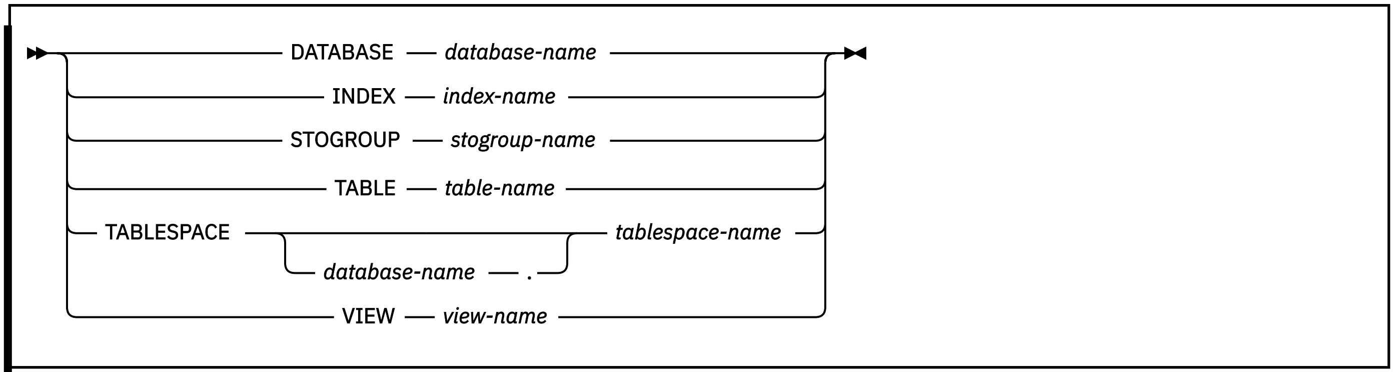
The privilege set must include at least one of the following privileges:

- Ownership of the object
- SECADM authority

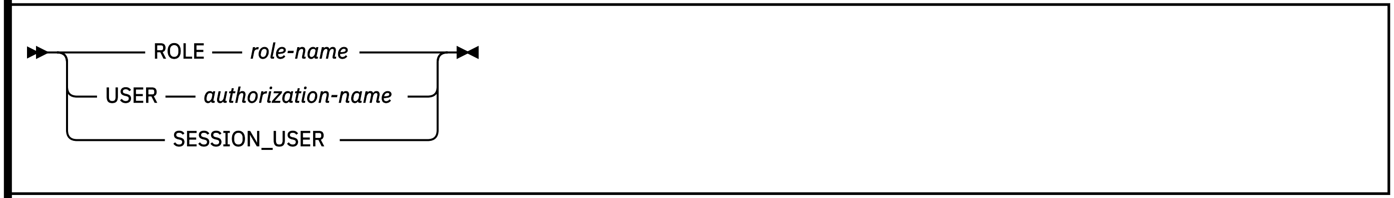
Explicit SECADM authority is always required regardless of the SEPARATE_SECURITY subsystem parameter setting. For more information, see Separating the SYSADM authority (Managing Security). If the Access Control Authorization exit is active, Db2 calls the exit to check for the SECADM authority. Only the SECADM authority is checked regardless of the SEPARATE_SECURITY system parameter value.

Syntax for TRANSFER OWNERSHIP

object:



new-owner:



Description for TRANSFER OWNERSHIP

DATABASE *database-name*

Identifies the database for ownership transfer. The database must exist on the current server. The name of the database must not identify DSNDB01, DSNDB04, DSNDB06, or any implicitly created database owned by SYSIBM. When the ownership of the database is transferred, the CREATOR and CREATORTYPE values for the database in SYSIBM.SYSDATABASE are updated with the authorization ID or role and the type of the new owner. Transferring the ownership of a database does not transfer the ownership of any other object in the database that was created by the current owner.

INDEX *index-name*

Identifies the index for ownership transfer. The index must exist on the current server. The index must not be defined on a catalog table, a directory table or a declared temporary table. When the ownership of the index is transferred, the OWNER and OWNERTYPE values for the index in SYSIBM.SYSINDEXES are updated with the authorization ID or role and the type of the new owner.

STOGROUP *stogroup-name*

Identifies the storage group for ownership transfer. The storage group must exist the current server. When the ownership of the storage group is transferred, the CREATOR and CREATORTYPE values for the group in SYSIBM.SYSSTOGROUP are updated with the authorization ID or role and the type of the new owner.

TABLE *table-name*

Identifies the table for ownership transfer. The table must exist on the current server, and it must not be a view, a catalog table, a directory table, a table with the SECURITY LABEL column, or a table that is implicitly created for an XML column. If the table is referenced by a qualified name, the name can be a two-part or three-part name. If a three-part name is used, the first part must match the value of the field Db2 LOCATION NAME on installation panel DSNTIPR at the current server. If the current server is not the local Db2, this name is not necessarily the name in the CURRENT SERVER special register.

If *table-name* is an alias for a table and *alias-name* is specified, ownership of the table is transferred to the new owner and the alias is unchanged.

When the ownership of a table is transferred, the ownership of any implicitly created object, such as a table space, auxiliary table, auxiliary table space, XML table, XML table space, or index, is also transferred if the table and the implicitly created object have the same owner. In addition, the ownership of an explicitly created auxiliary table or auxiliary table space is also transferred if the table and the explicitly created object have the same owner.

When the ownership of the table is transferred, the OWNER and OWNERTYPE values for the table in SYSIBM.SYSTABLES are updated with the authorization ID or role and the type of the new owner.

TABLESPACE *tablespace-name*

Identifies the table space for ownership transfer. The table space must exist on the current server, but it must not have been implicitly created for an XML column. The database must not be DSNDB01, DSNDB06, or DSNDB04. Omitting a database name implicitly specifies DSNDB04. When the ownership of the table space is transferred, the CREATOR and CREATORTYPE values for the table space in SYSIBM.SYSTABLESPACE are updated with the authorization ID or role and the type of the new owner.

VIEW *view-name*

Identifies the view for ownership transfer. The view must exist on the current server. If the view is referenced by a qualified name, the name can be a two-part or three-part name. If a three-part name is used, the first part must match the value of the field Db2 LOCATION NAME on installation panel DSNTIPR at the current server. If the current server is not the local Db2, this name is not necessarily the name in the CURRENT SERVER special register.

If *view-name* is an alias for a view and *alias-name* is specified, ownership of the view is transferred to the new owner and the alias is unchanged.

When the ownership of the view is transferred, the OWNER and OWNERTYPE values for the view in SYSIBM.SYSTABLES and SYSIBM.SYSVIEWS are updated with the authorization ID or role and the type of the new owner.

TO

Specifies the authorization ID or the role to which the ownership of an object is transferred.

ROLE *role-name*

Specifies the role to which the ownership of an object is transferred. The new role must exist on the current server.

USER *authorization-name*

Specifies the authorization ID to which the ownership of the object is transferred.

SESSION_USER

Specifies that the value of the SESSION_USER special register is used as the authorization ID to which the ownership of an object is transferred.

REVOKE PRIVILEGES

Specifies that the current owner no longer has any implicit privileges on the object after the transfer is complete. The corresponding authorization cache entries for the current owner are cleared.

If any packages or objects are dependent on an implicit privilege that the current owner has on the object of the statement, a TRANSFER OWNERSHIP statement fails because existing privileges are revoked. For the current owner to maintain access to those dependent packages, authorization must be explicitly granted to the current owner from another source before the TRANSFER OWNERSHIP statement is executed. For example, assume that a user created a package that references one of their tables. The user implicitly has the SELECT privilege on tables they created. To transfer that table to another owner and still be able to use the package, the user must be explicitly granted the SELECT privilege on the table before the TRANSFER OWNERSHIP statement is executed.

Notes for TRANSFER OWNERSHIP

- The TRANSFER OWNERSHIP statement does not change the schema of the transferred object.
- The ownership of any system object whose OWNER is SYSIBM or whose schema begins with SYS cannot be transferred.
- The new owner is automatically granted the same privileges that the current owner holds on the object at the time of the object's creation. For example, if the current owner has the DBADM authority on the database when the database was created, the new owner is automatically granted the DBADM authority on the database.
- An authorization ID with the SECADM authority cannot transfer the ownership of an object to itself.

- Db2 issues a warning when the current owner of an object attempts to transfer the ownership to itself.
- If the current owner of an object is a role, the dependency record for that role in SYSIBM.SYSOBJROLEDEP is deleted when the object ownership is transferred. If the new owner is a role, the dependency record for that role is added to SYSIBM.SYSOBJROLEDEP.
- A SECADM or ACCESSCTRL authority can use the REVOKE statement with the BY clause to revoke any privilege that is granted on the object by the current owner.
- When the ownership of an object is transferred, the new owner must have the same set of privileges on the object as specified in the dependency record of the object. The privileges are required for the object to continue to exist. The new owner does not need additional privileges that are required for creating the object. Consider the following examples.
  - If a view has SELECT and INSERT dependencies on an underlying table and when the ownership is transferred, the new owner of the view must be granted the same SELECT and INSERT privileges. If the dependencies are SELECT WITH GRANT OPTION and INSERT WITH GRANT OPTION, the new owner must be granted the same SELECT WITH GRANT OPTION and INSERT WITH GRANT OPTION privileges.
  - If a view has a dependency on a routine and when the ownership of the view is transferred, the new owner must be granted the EXECUTE privilege on the dependent routine.
  - If a table has a distinct type column and when the ownership of the table is transferred, the new owner must be granted the USAGE privilege on the distinct type.

Examples for TRANSFER OWNERSHIP

Example 1: Transfer the ownership of database DBCC001 to user USRT001 and remove the current owner's privileges on the database:

```
TRANSFER OWNERSHIP OF DATABASE DBCC001 TO USER USRT001
   REVOKE PRIVILEGES;
```

Example 2: Transfer the ownership of database DBCC002 to role OWNRROLE and remove the current owner's privileges on the database:

```
TRANSFER OWNERSHIP OF DATABASE DBCC002 TO ROLE OWNRROLE
   REVOKE PRIVILEGES;
```

Example 3: Transfer the ownership of database DBCC003 to session user SESSION_USER and remove the current owner's privileges on the database:

```
TRANSFER OWNERSHIP OF DATABASE DBCC003 TO SESSION_USER
   REVOKE PRIVILEGES;
```

Example 4: Transfer the ownership of table EMPLOYEE.DEPT to ROLE TBOWNR_ROLE and remove the current owner's privileges on the table:

```
TRANSFER OWNERSHIP OF TABLE EMPLOYEE.DEPT TO ROLE TBOWNR_ROLE
   REVOKE PRIVILEGES;
```

Example 5: Transfer the ownership of index EMPLOYEE.SALARYIX to USER IXOWNER and remove the current owner's privileges on the index:

```
TRANSFER OWNERSHIP OF INDEX EMPLOYEE.SALARYIX TO USER IXOWNER
   REVOKE PRIVILEGES;
```

TRUNCATE

The Db2 TRUNCATE statement deletes all rows for either base tables or declared global temporary tables. The base table can be in a simple table space, a segmented (non-UTS) table space, a partitioned (non-

UTS) table space, or a universal table space. If the table contains LOB or XML columns, the corresponding table spaces and indexes are also truncated.

Invocation for TRUNCATE

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization for TRUNCATE

The privilege set that is defined below must include at least one of the following privileges:

- The DELETE privilege for the table
- Ownership of the table
- DBADM authority for the database
- DATAACCESS authority
- SYSADM authority

If the database is implicitly created, the database privileges must be on the implicit database or on DSNDB04.

If the IGNORE DELETE TRIGGERS option is in effect, the privilege set must include at least one of the following privileges:

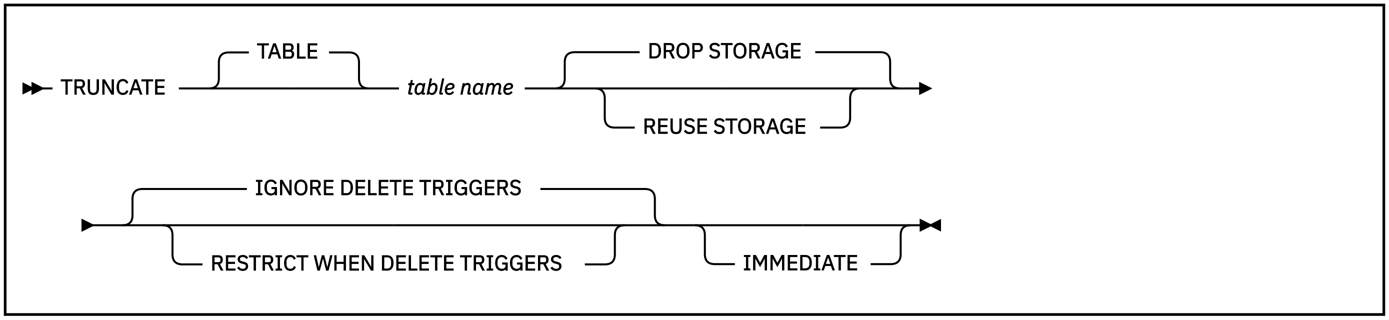
- The ALTER privilege for the table
- Ownership of the table
- DBADM authority for the database
- System DBADM authority
- SYSADM authority

If row access control is activated for the table, the privilege set must include at least one of the following privileges or authorities:

- Ownership of the table
- DBADM authority
- SYSADM authority
- SYSCTRL authority
- System DBADM authority

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the statement is dynamically prepared, the privilege set is determined by the DYNAMICRULES behavior in effect (run, bind, define, or invoke) and is summarized in "Dynamic preparation and execution" on page 1083. (For more details on these behaviors, including a list of the DYNAMICRULES bind option values that determine them, see "Authorization IDs and dynamic SQL" on page 94.)

Syntax for TRUNCATE



Description for TRUNCATE

table-name

Identifies the table that is to be truncated. The name must identify a table that exists at the current server. The name must not identify the following objects:

- a view
- an auxiliary table
- an XML table
- a catalog table
- a system-period temporal table
- an accelerator-only table

If *table-name* is a base table of a table space, all tables that are defined under the table will also be truncated (for example: auxiliary LOB table spaces and XML table spaces), and all of its associated indexes will also be truncated.

DROP STORAGE or REUSE STORAGE

Specifies whether to drop or reuse the existing storage that is allocated for the table.

DROP STORAGE

Specifies that all storage that is allocated for the table is released and made available for use for the same table or any other table that resides in the table space. The scope of DROP STORAGE is always at the table space level and the deallocated space is always available for reuse by all tables in the table space.

DROP STORAGE is the default.

REUSE STORAGE

Specifies that all storage that is allocated for the table will be emptied, but will continue to be allocated for the table. REUSE STORAGE is ignored for a table in a simple table space and the statement is processed as if DROP STORAGE is specified.

RESTRICT WHEN DELETE TRIGGERS or IGNORE DELETE TRIGGERS

Specifies what to do when delete triggers are defined on the table.

RESTRICT WHEN DELETE TRIGGERS

Specifies that an error is returned if delete triggers are defined on the table.

IGNORE DELETE TRIGGERS

Specifies that any delete triggers that are defined for the table are not activated by the truncate operation. Additional authorization is required for this option; see "Authorization for TRUNCATE" on page 2166.

IGNORE DELETE TRIGGERS is the default.

IMMEDIATE

Specifies that the truncate operation is processed immediately and cannot be undone. If the IMMEDIATE option is specified, the table must not contain any uncommitted updates. In the case of a table in a multi-table table space, if there are any uncommitted updates to any table in the table space, the truncate operation will fail. Also, if there are any uncommitted CREATE, ALTER or DROP statements for any table in the table space, the truncate operation will fail.

The truncated table is immediately available for use in the same unit of work. Although a ROLLBACK statement is allowed to execute after a TRUNCATE statement, the truncate operation is not undone, and the table remains in a truncated state. For example, if another data change operation is done on the table after the TRUNCATE IMMEDIATE statement and then the ROLLBACK statement is executed, the truncate operation will not be undone, but all other data change operations are undone.

If IMMEDIATE is not specified, a ROLLBACK statement can undo the truncate operation.

The IMMEDIATE option can be specified for a table in a segmented (non-UTS) table space or a universal table space which allows deallocated spaces to be reclaimed immediately for subsequent insert operations in the same unit of work without committing the truncate operation.

Notes for TRUNCATE

Rules and restrictions:

The truncate operation cannot be executed if the table is a parent table in an enforced referential constraint. The Db2 subsystem issues an error when it detects the existence of rule violations. Therefore, if the referential integrity constraint exists, the TRUNCATE statement will be restricted regardless of whether the child table contains rows.

The TRUNCATE statement cannot be used if the table is a system-maintained temporal table.

If the TRUNCATE statement is used on a tables where any of the following conditions is true, the truncate operation will perform in a similar way to a mass delete operation:

- Tables with Change Data Capture (CDC) attribute

  The Db2 subsystem allows a table with the CDC-enabled attribute to be truncated without imposing any new restrictions.
- Tables with multi-level security

  If the table contains a column that is defined as a security label, the truncate operation needs to examine each row to determine if the security label of the authorization ID or role has the authority to delete that row. However, if the primary authorization ID or role has write-down privilege, verification of each row in the table is not necessary.
- Tables with a VALIDPROC attribute

  If a VALIDPROC is defined for the table, the truncate operation needs to verify the validity of each row in the table.

TRUNCATE and table spaces that are not logged:

The TRUNCATE TABLE statement can be used to remove a table space from the logical page list and to reset recover-pending status. When the table space is a segmented (non-UTS) table space or universal table space, the table is the only table in the table space, and the table does not have a VALIDPROC, referential constraints, delete triggers, or a SECURITY LABEL column, use the TRUNCATE TABLE statement to empty the table and the table space will be removed from the LPL and recover-pending status will be reset.

Truncating rows from a table with activated row permissions or column access control:

Row permissions and column access control is not enforced for the TRUNCATE statement.

Examples for TRUNCATE

Example 1: Empty an unused inventory table regardless of any existing triggers and return its allocated space.

```
TRUNCATE TABLE INVENTORY
         DROP STORAGE
    IGNORE DELETE TRIGGERS;
```

Example 2: Empty an unused inventory table regardless of any existing delete triggers but preserve its allocated space for later reuse.

```
TRUNCATE TABLE INVENTORY
   REUSE STORAGE
   IGNORE DELETE TRIGGERS;
```

Example 3: Empty an unused inventory table permanently (a ROLLBACK statement cannot undo the truncate operation when the `IMMEDIATE` option is specified) regardless of any existing delete triggers and preserve its allocated space for immediate use.

```
TRUNCATE TABLE INVENTORY
    REUSE STORAGE
    IGNORE DELETE TRIGGERS
    IMMEDIATE;
```

UPDATE

The UPDATE statement updates the values of specified columns in rows of a table or view. Updating a row of a view updates a row of its base table if no INSTEAD OF UPDATE trigger is defined for this view. If such a trigger is defined, the trigger is activated instead.

The table or view can exist at the current server or at any Db2 subsystem with which the current server can establish a connection.

There are two forms of this statement:

- The *searched* UPDATE form is used to update one or more rows optionally determined by a search condition.
- The *positioned* UPDATE form specifies that one or more rows corresponding to the current cursor position are to be updated.

Invocation for UPDATE

This statement can be embedded in an application program or issued interactively. A positioned UPDATE can be embedded in an application program. Both forms are executable statements that can be dynamically prepared.

Authorization for UPDATE

Authority requirements depend on whether the object identified in the statement is a user-defined table, a catalog table for which updates are allowed, or a view, and whether SQL standard rules are in effect:

When a user-defined table is identified: The privilege set must include at least one of the following:

- DATAACCESS authority
- The UPDATE privilege on the table
- The UPDATE privilege on each column to be updated
- Ownership of the table
- DBADM authority on the database that contains the table
- SYSADM authority

If the database is implicitly created, the database privileges must be on the implicit database or on DSNDB04.

When a catalog table is identified: The privilege set must include at least one of the following:

- ACCESSCTRL authority
- DATAACCESS authority
- The UPDATE privilege on each column to be updated
- DBADM authority on the catalog database
- Installation SYSOPR authority
- SYSCTRL authority
- SYSADM authority
- SYSADM authority
- System DBADM authority

When a view is identified: The privilege set must include at least one of the following:

- DATAACCESS authority
- SYSADM authority
- UPDATE privilege on the view
- UPDATE privilege on each column to be updated

If the *expression* in the *assignment-clause* contains a reference to a column of the table or view, or if the *search-condition* in a searched UPDATE contains a reference to a column of the table or view, the privilege set must include at least one of the following:

- The SELECT privilege on the table or view
- Ownership of the table or view
- DBADM authority on the database that contains the table, if the target is a table and that table that is not a catalog table
- DATAACCESS
- SYSADM authority

When FOR PORTION OF BUSINESS_TIME is specified: The privilege set must include at least one of the following:

- The UPDATE privilege on the columns of the BUSINESS_TIME period
- The UPDATE privilege on the table
- Ownership of the table or view
- DBADM authority on the database that contains the table, if the target is a table and that table that is not a catalog table
- DATAACCESS
- SYSADM authority

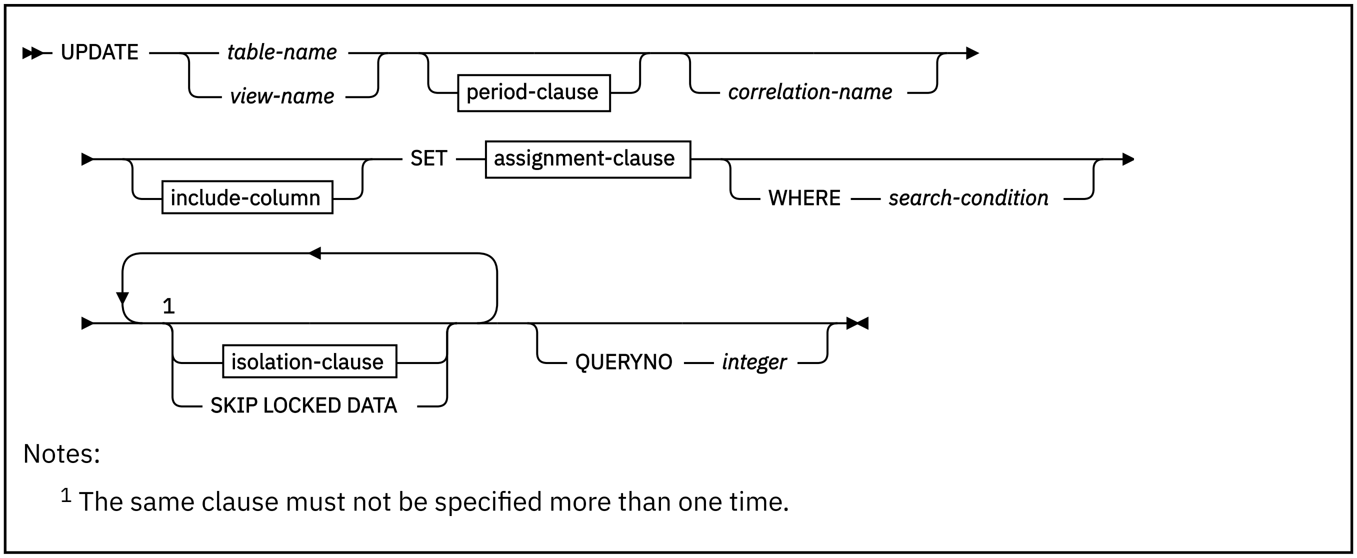
If the *search-condition* in a searched UPDATE includes a subquery, or if the *assignment-clause* includes a *scalar-fullselect* or a *row-fullselect*, see "Authorization for queries" on page 1005 for an explanation of the authorization required.

The owner of a view, unlike the owner of a table, might not have UPDATE authority on the view (or might have UPDATE authority without being able to grant it to others). The nature of the view itself can preclude its use for UPDATE. For more information, see the discussion of authority in "CREATE VIEW" on page 1807.

FL 509 If the statement attempts to update a row in the SYSIBM.SYSAUDITPOLICIES catalog table that is subject to a tamper-proof audit policy, additional RACF authorization is required. During statement execution, the primary authorization ID or one of the groups associated with the primary authorization ID must be authorized to access the tamper-proof audit policy profile in RACF. For more information on the authorization rules, see Db2 audit policies (Managing Security).

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the statement is dynamically prepared, the privilege set is determined by the DYNAMICRULES behavior in effect (run, bind, define, or invoke) and is summarized in "Dynamic preparation and execution" on page 1083. (For more information on these behaviors, including a list of the DYNAMICRULES bind option values that determine them, see "Authorization IDs and dynamic SQL" on page 94).

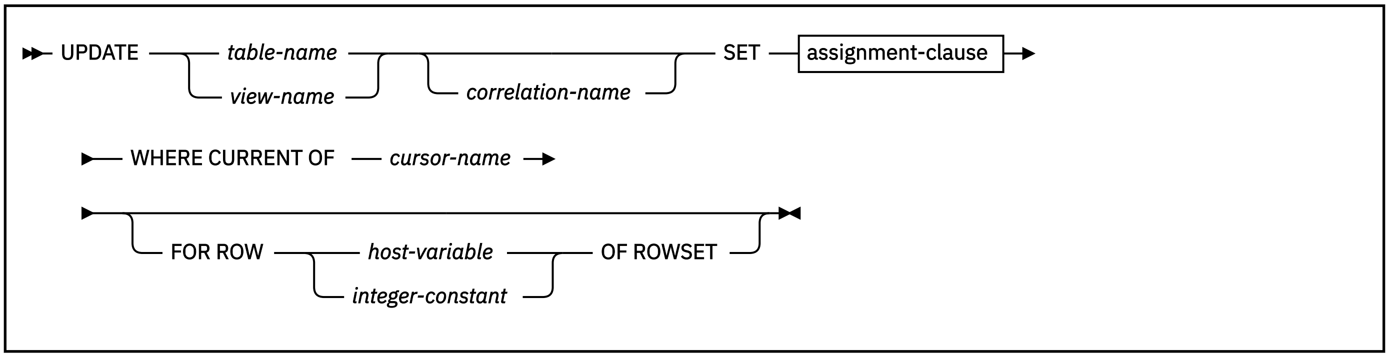
searched update:



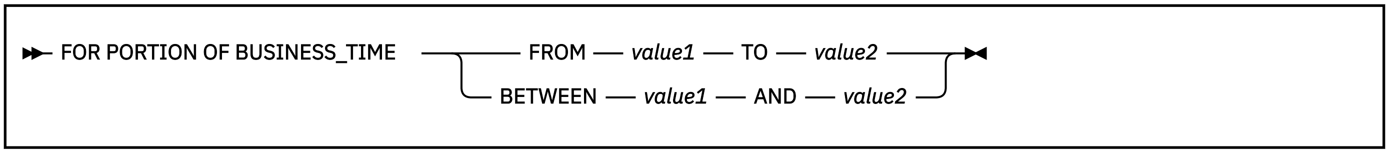
Notes:

[1] The same clause must not be specified more than one time.

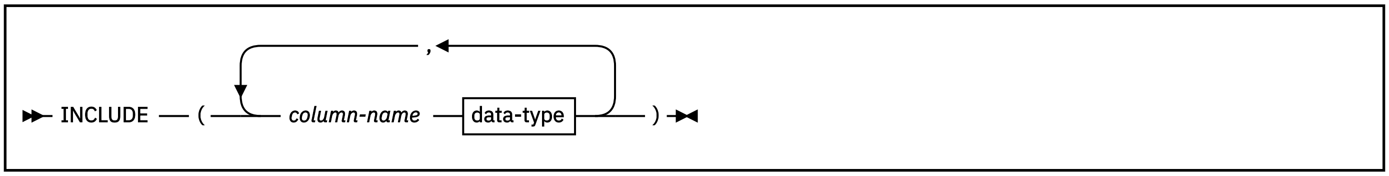
positioned update:



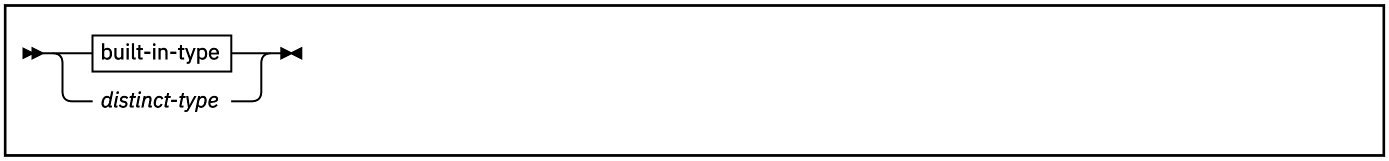
period-clause:



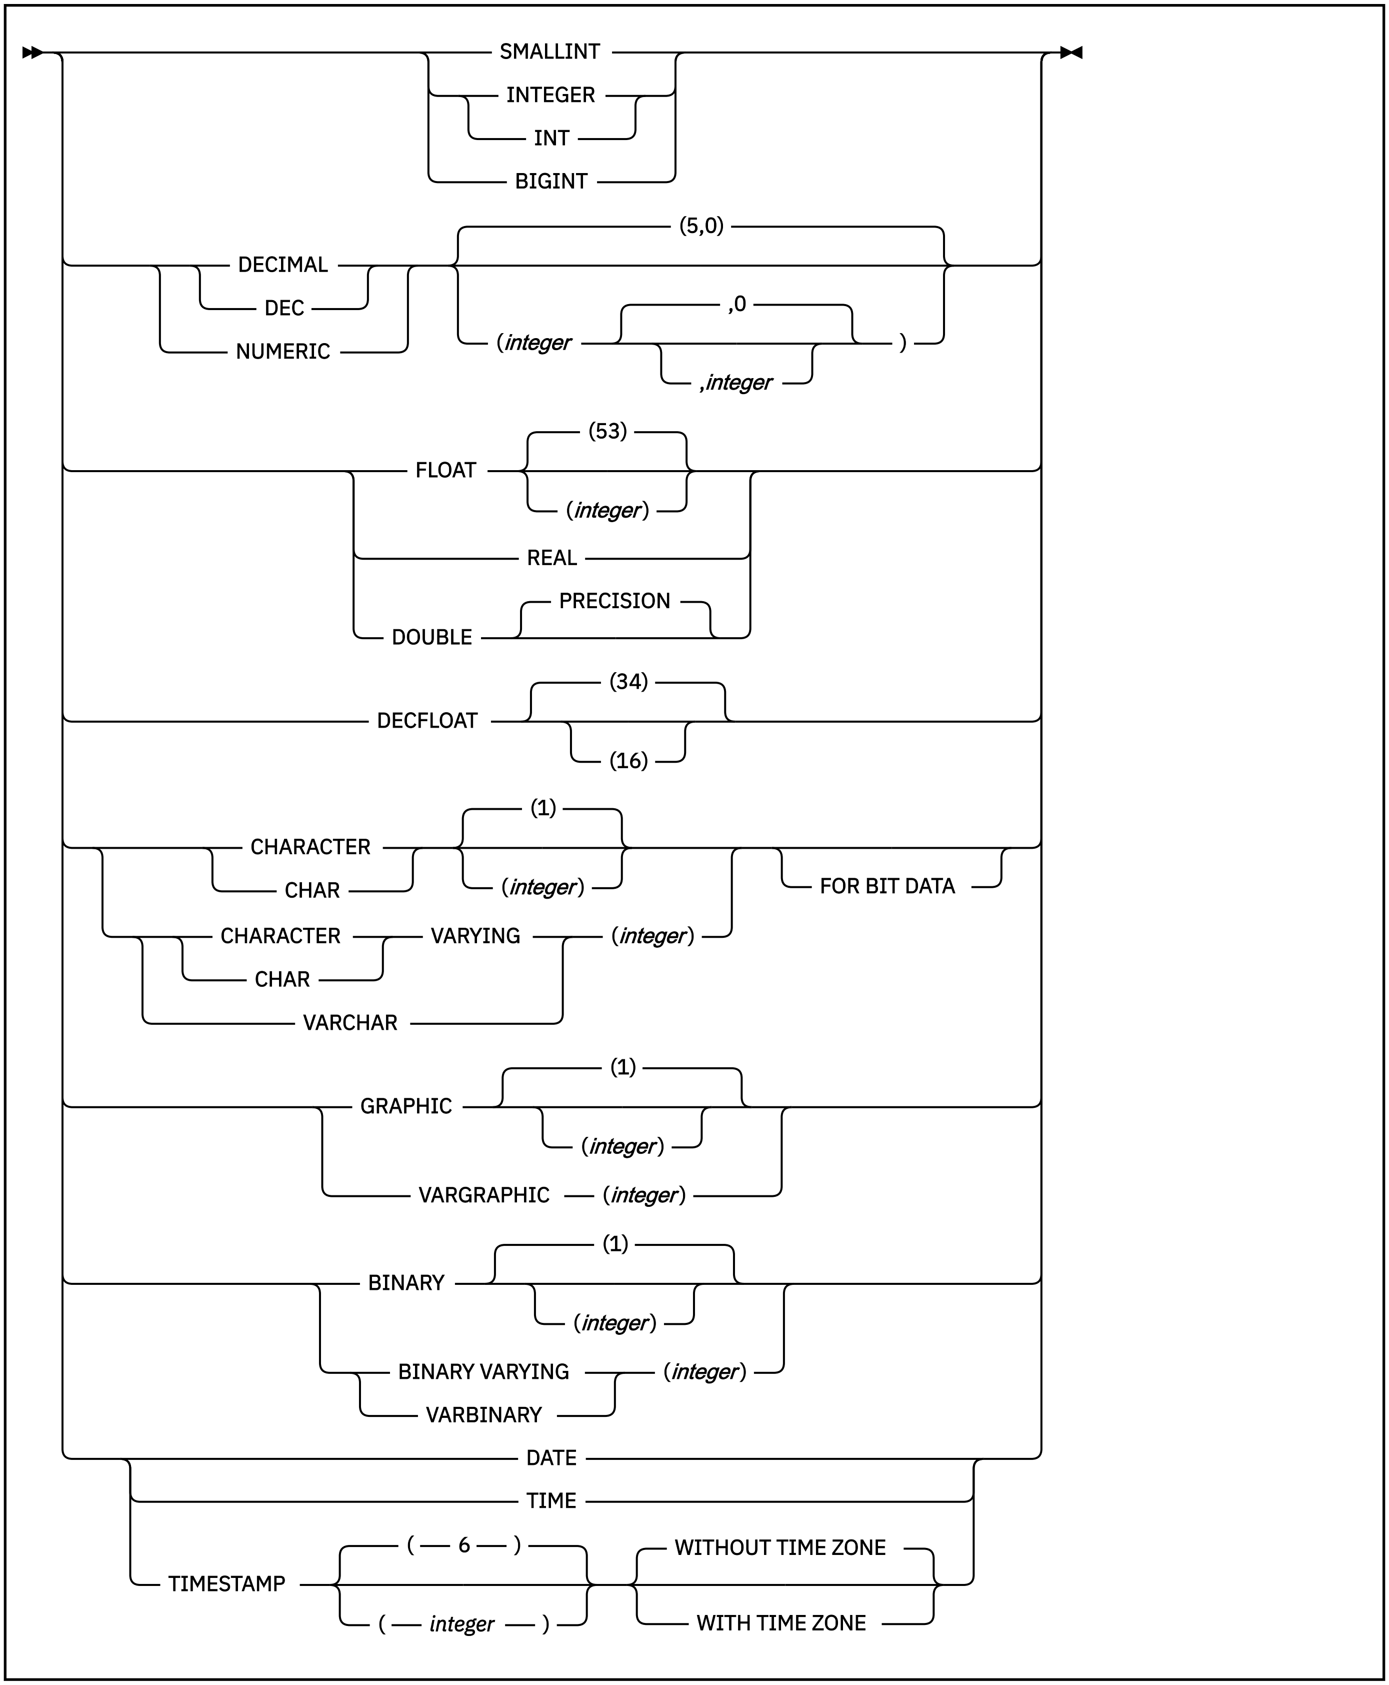
include-column:



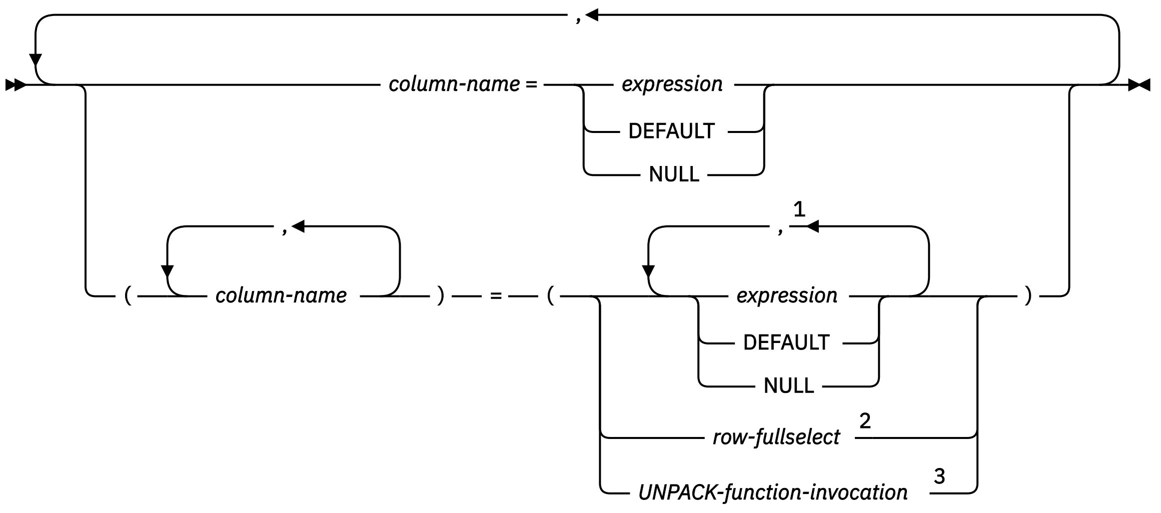
data-type:



built-in-type:



assignment clause:



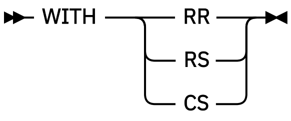
Notes:

[1] The number of *expressions*, DEFAULT, and NULL keywords must match the number of *column-names*. *Expressions* must not refer to UNPACK-function-invocation..

[2] The number of columns in the select list must match the number of *column-names*.

[3] The number of items returned from *UNPACK-function-invocation* must match the number of column names.

isolation-clause:



Description for UPDATE

table-name **or** ***view-name***

Identifies the object of the UPDATE statement. The name must identify a table or view that exists at the Db2 subsystem that is identified by the implicitly or explicitly specified location name. The name must not identify one of the following tables:

- An auxiliary table
- A created temporary table or a view of a created temporary table
- A catalog table with no updatable columns or a view of a catalog table with no updatable columns
- A directory table
- A read-only view that has no INSTEAD OF trigger defined for its update operations. (For a description of a read-only view, see "CREATE VIEW" on page 1807.)
- A system-maintained materialized query table
- A table that is implicitly created for an XML column
- An archive-enabled table if any of the following conditions are true:
  - The SYSIBMADM.MOVE_TO_ARCHIVE global variable is set to Y.
  - The SYSIBMADM.GET_ARCHIVE global variable is set to Y, the ARCHIVESENSITIVE bind option is set to YES, and the operation is a positioned update.

In an IMS or CICS application, the Db2 subsystem that contains the identified table or view must be a remote server that supports two-phase commit.

A catalog table or a view of a catalog table can be identified if every column identified in the SET clause is an updatable column. If a column of a catalog table is updatable, its description in Appendix G, "Db2 catalog tables," on page 2321 indicates that the column can be updated. If the object table is SYSIBM.SYSSTRINGS, any column other than IBMREQD can be updated, but the rows that are selected for update must be rows that are provided by the user (the value of the IBMREQD column is N) and only certain values can be specified as explained in How an entry in SYSIBM.SYSSTRINGS works with character conversion (Db2 Installation and Migration).

period-clause

Specifies that a period clause applies to the target of the update operation. The same period name must not be specified more than one time. If the target of the update operation is a view:

- The FROM clause of the outer fullselect of the view definition must include a reference, directly or indirectly, to an application-period temporal table.
- The result table of the outer fullselect of the view definition must include, explicitly or implicitly, the start and end columns of the BUSINESS_TIME period.
- An INSTEAD OF trigger must not be defined for the view.

FOR PORTION OF BUSINESS_TIME

Specifies that the update only applies to row values for the portion of the BUSINESS_TIME period in the row that is specified by the period clause. BUSINESS_TIME must be a period that is defined on the table.

FOR PORTION OF BUSINESS_TIME must not be specified if the value of the CURRENT TEMPORAL BUSINESS_TIME special register is not NULL when the BUSTIMESENSITIVE bind option is set to YES.

FROM *value1* TO *value2*

Specifies that the update applies to rows for the period that is specified from *value1* to *value2*. No rows are updated if *value1* is greater than or equal to *value2* or if *value1* or *value2* is the null value.

This clause must not be specified for an inclusive-inclusive period.

For the period condition that is specified with FROM *value1* TO *value2*, the period that is specified with *period-name* in a row of the target update:

- Overlaps the beginning of the specified period if the value of the begin column is less than *value1* and the value of the end column is greater than *value1*.
- Overlaps the end of the specified period if the value of the end column is greater than or equal to *value2* and the value of the begin column is less than *value2*.
- Is fully contained within the specified period if the value for the begin column is greater than or equal to *value1* and the value for the end column is less than or equal to *value2*.
- Is not contained in the period if both columns of *period-name* are less than *value1* or greater than or equal to *value2*.
- Is partially contained in the specified period if the period in the row overlaps the beginning of the specified period or the end of the specified period, but not both.
- Fully overlaps the specified period if the period in the row overlaps both the beginning and the end of the specified period.

If the period, *period-name* in a row is not contained in the specified period, the row is not updated. Otherwise, the update is applied based on the specification of PORTION OF and how the values in the columns of *period-name* overlap the specified period as follows:

- If the period, *period-name* in a row is fully contained within the specified period, the row is updated and the values of the begin column and end column of *period-name* are unchanged.
- If the period, *period-name* in a row is partially contained in the specified period and overlaps the beginning of the specified period:

  - The row is updated. In the updated row, the value of the begin column is set to *value1* and the value of the end column is the original value of the end column.
  - An additional row is inserted using the original values from the row, except that the end column is set to *value1*, and new values are used for other generated columns.
- If the period, *period-name* in a row is partially contained in the specified period and overlaps the end of the specified period:
  - The row is updated. In the updated row, the value of the begin column is the original value of the begin column and the end column is set to *value2*.
  - An additional row is inserted using the original values from the row, except that the begin column is set to *value2*, and new values are used for other generated columns.
- If the period, *period-name* in a row fully overlaps the specified period:
  - The row is updated. In the updated row, the value of the begin column is set to *value1* and the value of the end column is set to *value2*.
  - An additional row is inserted using the original values from the row, except that the end column is set to *value1*, a column defined as DATA CHANGE OPERATION is set to 'I', and new values are used for other generated columns.
  - An additional row is inserted using the original values from the row, except that the begin column is set to *value2*, a column defined as DATA CHANGE OPERATION is set to 'I', and new values are used for other generated columns.

Any existing update triggers are activated for the updated rows and any existing insert triggers are activated for rows that are implicitly inserted.

BETWEEN *value1* AND *value2*

Specifies that the update operation applies to rows for the period that is specified from *value1* up to and including *value2*. No rows are updated if *value1* is greater than *value2*, or if *value1* or *value2* is the null value. This clause must not be specified for an inclusive-exclusive period.

For the period clause that is specified with BETWEEN *value1* AND *value2*, period *period-name* in a row in the target of the update operation:

- Overlaps the beginning of the specified period if the value of the begin column is less than *value1* and the value of the end column is greater than *value1*.
- Overlaps the end of the specified period if the value of the end column is greater than or equal to *value2* and the value of the begin column is less than *value2*.
- Is fully contained within the specified period if the value for the begin column for *period-name* in the row is greater than or equal to *value1* and the value for the corresponding end column in the row is less than or equal to *value2*.
- Is partially contained in the specified period if the row overlaps the beginning of the specified period or the end of the specified period, but not both.
- Fully overlaps the specified period if the period in the row overlaps the beginning of the specified period and overlaps the end of the specified period.
- Is not contained in the period if both columns of *period-name* are less than *value1* or greater than *value2*.

If the period *period-name* in a row is not contained in the specified period, the row is not updated. Otherwise, the update operation is based on the following items:

- The specification of the PORTION OF clause.
- How the values in the columns of *period-name* overlap the specified period.
- *spu* (smallest period unit), which depends on the data type of the columns of the period as follows:
  - For a period containing DATE columns, spu is 1 day.
  - For a period containing TIMESTAMP(6) columns, spu is 1 microsecond.

Based on those items, the update operation is applied as follows:

- If the period *period-name* in a row is fully contained within the specified period, the row is updated and the values of the begin column and end column of *period-name* are unchanged.
- If the period *period-name* in a row is partially contained in the specified period and overlaps the beginning of the specified period:
  - The row is updated. In the updated row the value of the begin column is set to *value1* and the value of the end column is the original value of the end column.
  - A row is inserted using the original values from the row, except that the end column is set to *value1* - spu, and new values are used for other generated columns.
- If the period *period-name* in a row is partially contained in the specified period and overlaps the end of the specified period:
  - The row is updated. In the updated row the value of the begin column is the original value of the begin column and the end column is set to *value2*
  - A row is inserted using the original values from the row, except that the begin column is set to *value2* + spu, and new values are used for other generated columns.
- If the period *period-name* in a row fully overlaps the specified period:
  - The row is updated. In the updated row the value of the begin column is set to *value1* and the value of the end column is set to *value2*.
  - A row is inserted using the original values from the row, except that the end column is set to *value1* - spu, a column defined as DATA CHANGE OPERATION is set to 'I', and new values are used for other generated columns.
  - An additional row is inserted using the original values from the row, except that the begin column is set to *value2* + spu, a column defined as DATA CHANGE OPERATION is set to 'I', and new values are used for other generated columns.

value1*, *value2

Specifies expressions that return a value of a built-in data type. The result of each expression must be comparable to the data type of the columns of the specified period. See the comparison rules described in "Assignment and comparison" on page 143. Each expression can contain any of the following supported operands:

- A constant
- A special register
- A variable
- An array element specification
- A built-in scalar function whose arguments are supported operands
- A CAST specification where the cast operand is a supported operand
- An expression that uses arithmetic operators and operands

Each expression must not have a timestamp precision that is greater than the precision of the columns for the period.

If the begin and end columns of the period are defined as TIMESTAMP WITHOUT TIME ZONE, each expression must not return a value of a timestamp with a time zone.

A period clause for a view must not contain an untyped parameter marker.

correlation-name

Can be used within *search-condition* or *assignment-clause* to designate the table or view. (For an explanation of *correlation-name*, see "Correlation names" on page 219.)

include-column

Specifies a set of columns that are included, along with the columns of *table-name* or *view-name*, in the result table of the UPDATE statement when it is nested in the FROM clause of the outer fullselect that is used in a subselect, SELECT statement, or in a SELECT INTO statement. The included columns are appended to the end of the list of columns that is identified by *table-name* or *view-name*. If no value is assigned to a column that is specified by an *include-column*, a NULL value is returned for that column.

INCLUDE

Introduces a list of columns that are to be included in the result table of the UPDATE statement. The included columns are only available if the UPDATE statement is nested in the FROM clause of a SELECT statement or a SELECT INTO statement.

column-name

Specifies the name for a column of the result table of the UPDATE statement that is not the same name as another included column nor a column in the table or view that is specified in *table-name* or *view-name*.

data-type

Specifies the data type of the included column. The included columns are nullable.

built-in-type

Specifies a built-in data type. See "CREATE TABLE" on page 1645 for a description of each built-in type.

The CCSID 1208 and CCSID 1200 clauses must not be specified for an INCLUDE column.

distinct-type

Specifies a distinct type. Any length, precision, or scale attributes for the column are those of the source type of the distinct type as specified by using the CREATE TYPE statement.

SET

Introduces the assignment of values to column names.

assignment-clause

If *row-fullselect* is specified, the number of columns in the result of *row-fullselect* must match the number of *column-names* that are specified. If *row-fullselect* is not specified, the number of expressions, and NULL and DEFAULT keywords must match the number of *column-names* that are specified.

column-name

Identifies a column that is to be updated. *column-name* must identify a column of the specified table or view. If extended indicators are not enabled, that column must be an updatable column. The column must not identify a generated column or a view column where the column is derived from a scalar function, constant, or expression. *column-name* can also identify an INCLUDE column that must not be qualified. The same column name must not be specified more than once.

A column that is defined as part of a BUSINESS_TIME period must not be specified if the UPDATE statement contains a *period-clause*.

Assignments to included columns are only processed when the UPDATE statement is nested in the FROM clause of a SELECT statement or a SELECT INTO statement. There must be at least one assignment clause that specifies a *column-name* that is not an INCLUDE column. The null value is returned for an included column that is not set by using an explicit SET clause.

For a positioned update, allowable column names can be further restricted to those in a certain list. This list appears in the FOR UPDATE clause of the SELECT statement for the associated cursor. The clause can be omitted by using the conditions that are described in "Positioned updates of columns" on page 325.

A view column that is derived from the same column as another column of the view can be updated, but both columns cannot be updated in the same UPDATE statement.

expression

Indicates the new value of the column. The *expression* is any expression of the type described in "Expressions" on page 244. It must not include an aggregate function.

A *column-name* in an expression must identify a column of the table or view. For each row that is updated, the value of the column in the expression is the value of the column in the row before the row is updated.

If *expression* is a single host variable, the host variable can include an indicator with an extended indicator value. If extended indicators are enabled, and an expression in the assignment clause is not a single host variable, the extended indicator values of DEFAULT and UNASSIGNED must not be used.

A CAST specification can be used if either of the following is true:

- The target column is defined as nullable.
- The target column is defined as NOT NULL with a non-null default, the source of the CAST specification is a single host variable, and the data attributes (data type, length, precision, and scale) of the host variable are the same as the result of the cast specification.

DEFAULT

Specifies that the default value is used based on how the corresponding column is defined in the table. DEFAULT must not be specified for a ROWID column. The value that is assigned depends on how the column is defined.

- If the column is a generated expression, the column value will be generated by the Db2 subsystem based on the result of the expression.
- If the column is an identity column, row change timestamp column, row-begin column, row-end column, or transaction-start-ID column, the Db2 subsystem will generate a new value.
- If the column is defined using the `WITH DEFAULT` clause, the value is set to the default that is defined for the column.
- If the column is defined without specifying the `WITH DEFAULT` clause, the `GENERATED` clause, or the `NOT NULL` clause, the value is NULL.
- If the column is specified in the `INCLUDE` column list, the column value is set to null.

DEFAULT must be specified for a column that was defined as GENERATED ALWAYS. A valid value can be specified for a column that was defined as GENERATED BY DEFAULT.

If the column is defined using the `NOT NULL` clause and the `GENERATED` clause is not used, or the `WITH DEFAULT` clause is not used, the `DEFAULT` keyword cannot be specified for that column.

NULL

Specifies the null value as the new value of the column. Specify `NULL` only for nullable columns.

row-fullselect

Specifies a fullselect that returns a single row. The column values are assigned to each of the corresponding *column-names*. If the fullselect returns no rows, the null value is assigned to each column; an error occurs if any column to be updated is not nullable. An error also occurs if there is more than one row in the result.

For a positioned update, if the table or view that is the object of the UPDATE statement is used in the fullselect, a column from the instance of the table or view in the fullselect cannot be the same as *column-name*, a column being updated.

If the fullselect refers to columns to be updated, the value of such a column in the fullselect is the value of the column in the row before the row is updated.

UNPACK-function-invocation

Specifies an invocation of the UNPACK built-in function. The number of fields that are returned by the UNPACK function invocation must be the same as the number of *column-names*.

WHERE

Specifies the rows to be updated. You can omit the clause, give a search condition, or specify a cursor. If you omit the clause, all rows of the table or view are updated.

search-condition

Specifies any search condition described in Chapter 2, “Language elements in SQL,” on page 75. Each *column-name* in the search condition, other than in a subquery, must identify a column of the table or view.

The *search-condition* is applied to each row of the table or view and the updated rows are those for which the result of the *search-condition* is true. If the unique key or primary key is a parent key, the constraints are effectively checked at the end of the operation.

If the search condition contains a subquery, the subquery can be thought of as being executed each time the search condition is applied to a row, and the results used in applying the search condition. In actuality, a subquery with no correlated references is executed just once, whereas it is possible that a subquery with a correlated reference must be executed once for each row.

WHERE CURRENT OF *cursor-name*

Identifies the cursor to be used in the update operation. *cursor-name* must identify a declared cursor as explained in the description of the DECLARE CURSOR statement in “DECLARE CURSOR” on page 1814. If the UPDATE statement is embedded in a program, the DECLARE CURSOR statement must include *select-statement* rather than *statement-name*.

The object of the UPDATE statement must also be identified in the FROM clause of the SELECT statement of the cursor. The columns to be updated can be identified in the FOR UPDATE clause of that SELECT statement though they do not have to be identified. If the columns are not specified, the columns that can be updated include all the updatable columns of the table or view that is identified in the first FROM clause of the fullselect.

The result table of the cursor must not be read-only. For an explanation of read-only result tables, see Read-only cursors. Note that the object of the UPDATE statement must not be identified as the object of the subquery in the WHERE clause of the SELECT statement of the cursor.

When the UPDATE statement is executed, the cursor must be open and positioned on a row or rowset of the result table.

- If the cursor is positioned on a single row, that row is the one updated.
- If the cursor is positioned on a rowset, all rows corresponding to the rows of the current rowset are updated.

A positioned UPDATE must not be specified for a cursor that references a view on which an instead of update trigger is defined, even if the view is an updatable view.

FOR ROW *n* OF ROWSET

Specifies which row of the current rowset is to be updated. The corresponding row of the rowset is updated, and the cursor remains positioned on the current rowset.

host-variable or *integer-constant* is assigned to an integral value *k*. If *host-variable* is specified, it must be an exact numeric type with scale zero, must not include an indicator variable, and *k* must be in the range 1 - 32767.

The cursor must be positioned on a rowset, and the specified value must be a valid value for the set of rows most recently retrieved for the cursor. If the specified row cannot be updated, an error is returned. It is possible that the specified row is within the bounds of the rowset most recently requested, but the current rowset contains less than the number of rows that were implicitly or explicitly requested when that rowset was established.

If this clause is not specified, the cursor position determines the rows that will be affected. If the cursor is positioned on a single row, that row is the one updated. In the case where the most recent FETCH statement returned multiple rows of data (but not as a rowset), this position would be on the last row of data that was returned. If the cursor is positioned on a rowset, all rows corresponding to the current rowset are updated. The cursor position remains unchanged.

It is possible for another application process to update a row in the base table of the SELECT statement so that the specified row of the cursor no longer has a corresponding row in the base table. An attempt to update such a row results in an error.

isolation-clause

Specifies the isolation level used when locating the rows to be updated by the statement.

WITH

Introduces the isolation level, which may be one of the following:

RR

Repeatable read

RS

Read stability

CS

Cursor stability

The default isolation level of the statement is the isolation level of the package or plan in which the statement is bound, with the package isolation taking precedence over the plan isolation. When a package isolation is not specified, the plan isolation is the default.

SKIP LOCKED DATA

Specifies that rows are skipped when incompatible locks are held on the row by other transactions. These rows can belong to any accessed table that is specified in the statement. SKIP LOCKED DATA can be used only when isolation CS or RS is in effect and applies only to row level or page level locks.

SKIP LOCKED DATA can be specified only in the searched UPDATE statement (or the searched update operation of a MERGE statement). SKIP LOCKED DATA is ignored if it is specified when the isolation level that is in effect is repeatable read (WITH RR) or uncommitted read (WITH UR). The default isolation level of the statement depends on the isolation level of the package or plan with which the statement is bound, with the package isolation taking precedence over the plan isolation. When a package isolation is not specified, the plan isolation is the default.

QUERYNO *integer*

Specifies the number to be used for this SQL statement in EXPLAIN output and trace records. The number is used for the QUERYNO column of the plan table for the rows that contain information about this SQL statement. This number is also used in the QUERYNO column of the SYSIBM.SYSSTMT and SYSIBM.SYSPACKSTMT catalog tables.

If the clause is omitted, the number associated with the SQL statement is the statement number assigned during precompilation. Thus, if the application program is changed and then precompiled, that statement number might change.

Using the QUERYNO clause to assign unique numbers to the SQL statements in a program is helpful:

- For simplifying the use of optimization hints for access path selection
- For correlating SQL statement text with EXPLAIN output in the plan table

For more information about enabling and using optimization hints, see Influencing access path selection (Db2 Performance)

For information on accessing the plan table, see Investigating SQL performance by using EXPLAIN (Db2 Performance).

Notes for UPDATE

Update rules:

Update values must satisfy the following rules. If they do not, or if other errors occur during the execution of the UPDATE statement, no rows are updated and the position of the cursors are not changed.

- *Assignment*. Update values are assigned to columns using the assignment rules described in Chapter 2, “Language elements in SQL,” on page 75.
- *Validity*. Updates must obey the following rules. If they do not, or if any other errors occur during the execution of the UPDATE statement, no rows are updated.

  - *Fullselects:* The row-fullselect and expressions that contain a *scalar-fullselect* must return no more than one row.
  - *Unique constraints and unique indexes:* If the identified table (or base table of the identified view) has any unique indexes or unique constraints, each row that is updated in the table must conform to the limitations that are imposed by those indexes and constraints.

    All uniqueness checks are effectively made at the end of the statement. In the case of a multi-row update, this validation occurs after all the rows are updated.
  - *Check constraints:* If the identified table (or base table of the identified view) has any check constraints, each check constraint must be true or unknown for each row that is updated in the table.

    All checks constraints are effectively validated at the end of the statement. In the case of a multi-row update, this validation occurs after all the rows are updated.
  - *Views and the WITH CHECK OPTION*. For views defined with WITH CHECK OPTION, an updated row must conform to the definition of the view. If the view you name is dependent on other views whose definitions include WITH CHECK OPTION, the updated rows must also conform to the definitions of those views. For an explanation of the rules governing this situation, see "CREATE VIEW" on page 1807.

    For views that are not defined with WITH CHECK OPTION, you can change the rows so that they no longer conform to the definition of the view. Such rows are updated in the base table of the view and no longer appear in the view.
  - *Field and validation procedures*. The updated rows must conform to any constraints imposed by any field or validation procedures on the identified table (or on the base table of the identified view).
- *Referential constraints*. The value of the parent key in a parent row must not be changed. If the update value produces a foreign key that is nonnull, the foreign key must be equal to some value of the parent key of the parent table of the relationship.

  All referential constraints are effectively checked at the end of the statement. In the case of a multi-row update, this validation occurs after all the rows are updated.
- *Indexes with VARBINARY columns*. If the identified table has an index on a VARBINARY column or a column that is a distinct type that is based on VARBINARY data type, that index column cannot specify the DESC attribute. To use the SQL data change operation on the identified table, either drop the index or alter the data type of the column to BINARY and then rebuild the index.
- *Triggers*. An UPDATE statement might cause triggers to activate. A trigger might cause other statements to be executed or raise error conditions based on the update values. If an UPDATE statement for a view causes an instead of trigger to activate, validity, referential integrity, and check constraints are checked against the data changes that are performed in the trigger and not against the view that causes the trigger to activate or its underlying base tables.

Number of rows updated:

Normally, after an UPDATE statement completes execution, the value of SQLERRD(3) in the SQLCA is the number of rows updated. (For a complete description of the SQLCA, including exceptions to the preceding sentence, see Appendix E, "SQL communication area (SQLCA)," on page 2291.)

Nesting user-defined functions or stored procedures:

An UPDATE statement can implicitly or explicitly refer to user-defined functions or stored procedures. This is known as *nesting* of SQL statements. A user-defined function or stored procedure that is nested within the UPDATE must not access the table being updated.

Locking:

Unless appropriate locks already exist, one or more exclusive locks are acquired by the execution of a successful update operation. Until a commit or rollback operation releases the locks, only the application process that performed the insert can access the updated row. If LOBs are not updated, application processes that are running with uncommitted read can also access the updated row. The locks can also prevent other application processes from performing operations on the table. However, application processes that are running with uncommitted read can access locked pages and rows.

Locks are not acquired on declared temporary tables.

Datetime representation when using datetime registers:

As explained under Datetime special registers, when two or more datetime registers are implicitly or explicitly specified in a single SQL statement, they represent the same point in time. This is also true when multiple rows are updated.

Rules for positioned UPDATE with a SENSITIVE STATIC scrollable cursor:

When a SENSITIVE STATIC scrollable cursor has been declared, the following rules apply:

- *Update attempt of delete holes.* If, with a positioned update against a SENSITIVE STATIC scrollable cursor, an attempt is made to update a row that has been identified as a delete hole, an error occurs.
- *Update operations.* Positioned update operations with SENSITIVE STATIC scrollable cursors perform as follows:
  1. The SELECT list items in the target row of the base table of the cursor are compared with the values in the corresponding row of the result table (that is, the result table must still agree with the base table). If the values are not identical, then the update operation is rejected, and an error occurs. The operation may be attempted again after a successful FETCH SENSITIVE has occurred for the target row.
  2. The WHERE clause of the SELECT statement is re-evaluated to determine whether the current values in the base table still satisfy the search criteria. The values in the SELECT list are compared to determine that these values have not changed. If the WHERE clause evaluates as true, and the values in the SELECT have not changed, the update operation is allowed to proceed. Otherwise, the update operation is rejected, an error occurs, and an *update hole* appears in the cursor.
- *Update of update holes.* Update holes are not permanent. It is possible for another process, or a searched update in the same process, to update an update hole row so that it is no longer an update hole. Update holes become visible with a FETCH SENSITIVE for positioned updates and positioned deletes.
- *Result table.* After the base table is updated, the row is re-evaluated and updated in the temporary result table. At this time, it is possible that the positioned update changed the data such that the row does not qualify the search condition, in which case the row is marked as an update hole for subsequent FETCH operations.

Referencing columns that will be updated:

If a cursor uses FETCH statements to retrieve columns that will be updated later, specify FOR UPDATE OF when you select the columns. Then specify WHERE CURRENT OF in the subsequent UPDATE or DELETE statements. These clauses prevent Db2 from selecting access through an index on the columns that are being updated, which might otherwise cause Db2 to read the same row more than once.

For more information, see Updating previously retrieved data (Db2 Application programming and SQL).

Updating rows in a table with multilevel security:

When you update rows in a table with multilevel security, Db2 compares the security label of the user (the primary authorization ID) to the security label of the row. The update proceeds according to the following rules:

- If the security label of the user and the security label of the row are equivalent, the row is updated and the value of the security label is determined by whether the user has write-down privilege:
  - If the user has write-down privilege or write-down control is not enabled, the user can set the security label of the row to any valid security label. The value that is specified for the security label column must be assignable to a column that is defined as CHAR(8) FOR SBCS DATA NOT NULL.
  - If the user does not have write-down privilege and write-down control is enabled, the security label of the row is set to the value of the security label of the user.

- If the security label of the user dominates the security label of the row, the result of the UPDATE statement is determined by whether the user has write-down privilege:
  - If the user has write-down privilege or write-down control is not enabled, the row is updated and the user can set the security label of the row to any valid security label.
  - If the user does not have write-down privilege and write-down control is enabled, the row is not updated.
- If the security label of the row dominates the security label of the user, the row is not updated.

Updating rows in a table for which row or column access control is enforced:

When an UPDATE statement is issued for a table for which row or column access control is enforced, the rules specified in the enabled row permissions or column masks determine whether the row can be updated. Typically those rules are based on the authorization ID or role of the process. The following describes how enabled row permissions and column masks are used during UPDATE:

- Row permissions are used to identify the set of rows to be updated.

  When multiple enabled row permissions are defined for a table, a row access control search condition is derived by application of the logical OR operator to the search condition in each enabled permission. This row access control search condition is applied to the table to determine which rows are accessible to the authorization ID or role of the UPDATE statement. If the WHERE clause is specified in the UPDATE statement, the user-specified predicates are applied on the accessible rows to determine the rows to be updated. If there is no WHERE clause, the accessible rows are the rows to be updated.

  Column masks are not applicable in this step.

  If the table is not enforced by row access control, the WHERE clause determines the rows to be updated, otherwise all rows in the table are to be updated.
- If there are rows to be updated, the following rules determine whether those rows can be updated:
  - For every column to be updated, the new value of the column must not be affected by enabled column masks whose columns are referenced when deriving the new value.

    When a column is referenced while deriving the values of a new row, if the column has an enabled column mask, the masked value is used to derive the new values. If the object table is also column access control activated, the column mask applied to derive the new values must ensure the evaluation of the access control rules defined in the column mask resolves the column to itself, not to a constant or an expression. If the column mask does not mask the column to itself, the new value cannot be used for update and an error is returned at run time.
  - If the rows are updatable, and there is a BEFORE UPDATE trigger for the table, the trigger is activated.

    Within the trigger actions, the new values for update might be modified in transition variables. When the final values are returned from the trigger, the new values are used for the update.
  - The rows that are to be updated must conform to the enabled row permissions:

    For each row that is to be updated, the old values are replaced with the new values that were specified in the UPDATE statement. A row that conforms to the enabled row permissions is a row that, if updated, can be retrieved using the derived row access control search condition.
  - If the rows are updatable, and there is an AFTER UPDATE trigger for the table, the trigger is activated.

The above rules are not applicable to the included columns. The included columns are subject to the rules for the select list because they are not the columns of the object table of the UPDATE statement.

Extended indicators usage:

When extended indicators are enabled, indicator values other than positive values and 0 (zero) through -7 must not be specified. The DEFAULT and UNASSIGNED extended indicator values must not appear in contexts where they are not supported.

Extended indicators:

Specifying an indicator value with the extended indicator value of UNASSIGNED has the same effect as if the column had not been specified in the statement. Assigning an extended indicator value of DEFAULT assigns the default value to the column, and must only be specified for a column that is defined with a default value.

If a target column is not updatable, such as an identity column that is defined as GENERATED ALWAYS, it must be assigned the extended indicator value of UNASSIGNED.

An UPDATE statement must not specify the extended indicator value of UNASSIGNED for all target columns.

Extended indicators and update triggers:

If the indicator value for a target column is UNASSIGNED, that column is not considered to have been updated. That column is treated as if it had not been specified in the OF *column-name* list of any update trigger that is defined on the target table or view.

Extended indicators and deferred error checks:

When extended indicators are enabled, validation that would normally be done during statement preparation to recognize an insert into a non-updatable column is deferred until the statement is executed.

Considerations for a generated column:

A generated column that is defined as GENERATED ALWAYS should not be specified as the target of an assignment clause unless the value that is to be assigned is specified with the DEFAULT keyword or an extended indicator that specifies that a default value is to be assigned.

Considerations for a system-period temporal table:

When a row of a system-period temporal table is updated, Db2 updates the values of the row-begin and transaction-start-ID columns as follows:

- A row-begin column is assigned a value for the data type of the column. If the value of the SYSIBM. TEMPORAL_LOGICAL_TRANSACTION_TIME built-in global variable at the time of the update is null, the value is generated using a reading of the time-of-day clock during execution of the first data change statement in the unit of work that requires a value to be assigned to a row-begin column or transaction-start-ID column in a table, or a row in a system-period temporal table is deleted. Otherwise, the row-begin column is assigned the value of the SYSIBM.TEMPORAL_LOGICAL_TRANSACTION_TIME built-in global variable at the time of the insert.
- A transaction-start-ID column is assigned a unique timestamp value per unit of work or the null value. The null value is assigned to the transaction-start-ID column if the column is nullable. Otherwise, the value is generated by using the time-of-day clock during execution of the first data change statement in the unit of work that requires a value to be assigned to a row-begin column or transaction-start-ID column in a table. This also occurs when a row in a system-period temporal table is deleted. If multiple rows are updated within a single SQL unit of work, the values for the transaction-start-ID column are the same for all the rows and are unique from the values that are generated for the column for another unit of work.

If the UPDATE statement has a search condition that contains a correlated subquery that references historical rows (explicitly referencing the name of the history table or implicitly referenced through the use of a period specification in the FROM clause), the old version of the updated rows that are inserted as historical rows (into the history table) are potentially visible to update operations for the rows that are subsequently processed for the statement.

If the CURRENT TEMPORAL SYSTEM_TIME special register is set to a non-null value, the underlying target of the UPDATE statement cannot be a system-period temporal table. This restriction applies regardless of whether the system-period temporal table is directly or indirectly referenced.

Considerations for a history table:

When a row of a system-period temporal table is updated, a historical copy of the row is inserted into the corresponding history table and the end timestamp of the historical row is captured in the form of a system determined value that corresponds to the time of the data change operation. Db2 generates the value by using the time-of-day clock during the execution of the first data change statement in the transaction that requires a value to be assigned to a row-begin or transaction-start-

ID column in a table. This also occurs when a row in a system-period temporal table is deleted. If the value of the SYSIBM. TEMPORAL_LOGICAL_TRANSACTION_TIME built-in global variable at the time of the data change operation is null, the value is generated using a reading of the time-of-day clock during execution of the first data change statement in the unit of work that requires a value to be assigned to a row-begin column or transaction-start-ID column in a table, or a row in a system-period temporal table is deleted. Otherwise, the value is assigned from the SYSIBM.TEMPORAL_LOGICAL_TRANSACTION_TIME built-in global variable at the time of the data change operation.

Considerations for an application-period temporal table:

An UPDATE statement that contains a FOR PORTION OF BUSINESS_TIME clause for an application-period temporal table indicates the two points in time between which the specified updates are effective.

Suppose that FOR PORTION OF BUSINESS_TIME is specified, and the period value for a row is only partially contained in the period that is specified from *value1* up to *value2* or between *value1* and *value2*. (The period value for a row is specified by the values of the begin column and end column for the BUSINESS_TIME period.) In this case, the row is updated and one or two rows are automatically inserted to represent the portion of the row that is not changed. For each row that is automatically inserted as a result of an update operation on the table, new values are generated for each generated column in the application-period temporal table. If a generated column is defined as part of a unique or primary key, parent key in a referential constraint, or unique index, an automatic insert might violate a constraint or index. In this case, an error is returned.

When an application-period table is the target of an UPDATE statement and the value in effect for the CURRENT TEMPORAL BUSINESS_TIME special register is not the null value, Db2 adds the following additional predicates to the statement:

- inclusive-exclusive period:

```
    bt_begin <= CURRENT TEMPORAL BUSINESS_TIME AND
bt_end > CURRENT TEMPORAL BUSINESS_TIME
```

- inclusive-inclusive period:

```
    bt_begin <= CURRENT TEMPORAL BUSINESS_TIME AND
bt_end >= CURRENT TEMPORAL BUSINESS_TIME
```

In the preceding code, bt_begin and bt_end are the begin and end columns of the BUSINESS_TIME period of the target table of the UPDATE statement.

Archive-enabled tables:

A reference to an archive-enabled table as the target of the UPDATE statement does not affect rows in the associated archive table.

A data change statement must not reference an archive-enabled table when a system-period temporal table or application-period temporal table is also referenced.

Other SQL statements in the same unit of work:

The following statements cannot follow an UPDATE statement in the same unit of work:

- An ALTER TABLE statement that changes the data type of a column (ALTER COLUMN SET DATA TYPE)
- An ALTER INDEX statement that changes the padding attribute of an index with varying-length columns (PADDED to NOT PADDED or vice versa)
- A CREATE TABLE statement that creates an accelerator-only table.
- An INSERT, UPDATE, or DELETE statement that updates accelerator-only tables from a different accelerator.

Using UPDATE to reset AREO* status on a table:

An UPDATE statement will reset the AREO* state of a table if all conditions are true:

- The statement is a searched UPDATE statement. An UPDATE statement within a SELECT statement will not reset the AREO* state.
- The expression in the SET clause is not a *scalar-fullselect* or *row-fullselect*
- The update operation is against a table in a universal table space
- The table does not have row access control activated
- The SKIP LOCKED DATA clause is not specified
- The WHERE clause is not specified
- A resource unavailable condition is not encountered.

  No error or warning SQLCODE is returned if a resource unavailable condition is encountered. Only a resource unavailable console message will be displayed.

A DISPLAY DATABASE command can be used to determine if AREO* is reset.

Examples for UPDATE

Example 1

Change employee 000190's telephone number to 3565 in DSN8C10.EMP.

```
    UPDATE DSN8C10.EMP
      SET PHONENO='3565'
      WHERE EMPNO='000190';
```

Example 2

Give each member of department D11 a 100-dollar raise.

```
   UPDATE DSN8C10.EMP
     SET SALARY = SALARY + 100
     WHERE WORKDEPT = 'D11';
```

Example 3

Employee 000250 is going on a leave of absence. Set the employee's pay values (SALARY, BONUS, and COMMISSION) to null.

```
    UPDATE DSN8C10.EMP
      SET SALARY = NULL, BONUS = NULL, COMM = NULL
      WHERE EMPNO='000250';
```

Alternatively, the statement could also be written as follows:

```
    UPDATE DSN8C10.EMP
      SET (SALARY, BONUS, COMM) = (NULL, NULL, NULL)
      WHERE EMPNO='000250';
```

Example 4

Assume that a column named PROJSIZE has been added to DSN8C10.EMP. The column records the number of projects for which the employee's department has responsibility. For each employee in department E21, update PROJSIZE with the number of projects for which the department is responsible.

```
    UPDATE DSN8C10.EMP
      SET PROJSIZE = (SELECT COUNT(*)
                      FROM DSN8C10.PROJ
                      WHERE DEPTNO = 'E21')
      WHERE WORKDEPT = 'E21';
```

Example 5

Double the salary of the employee represented by the row on which the cursor C1 is positioned.

```
    EXEC SQL UPDATE DSN8C10.EMP
      SET SALARY = 2 * SALARY
      WHERE CURRENT OF C1;
```

Example 6

Assume that employee table EMP1 was created with the following statement:

```
   CREATE TABLE EMP1
     (EMP_ROWID    ROWID GENERATED ALWAYS,
      EMPNO        CHAR(6),
      NAME         CHAR(30),
      SALARY       DECIMAL(9,2),
      PICTURE      BLOB(250K),
      RESUME       CLOB(32K));
```

Assume that host variable *HV_EMP_ROWID* contains the value of the ROWID column for employee with employee number '350000'. Using that ROWID value to identify the employee and user-defined function UPDATE_RESUME, increase the employee's salary by $1000 and update that employee's resume.

```
   EXEC SQL UPDATE EMP1
     SET SALARY = SALARY + 1000,
         RESUME = UPDATE_RESUME(:HV_RESUME)
     WHERE EMP_ROWID = :HV_EMP_ROWID;
```

Example 7

In employee table X, give each employee whose salary is below average a salary increase of 10%.

```
  EXEC SQL UPDATE EMP X
    SET SALARY = 1.10 * SALARY
    WHERE SALARY < (SELECT AVG(SALARY) FROM EMP Y
    WHERE X.JOBCODE = Y.JOBCODE);
```

Example 8

Raise the salary of the employees in department 'E11' whose salary is below average to the average salary.

```
  EXEC SQL UPDATE EMP T1
    SET SALARY = (SELECT AVG(T2.SALARY) FROM EMP T2)
    WHERE WORKDEPT = 'E11' AND
          SALARY < (SELECT AVG(T3.SALARY) FROM EMP T3);
```

Example 9

Give the employees in department 'E11' a bonus equal to 10% of their salary.

```
  EXEC SQL
    DECLARE C1 CURSOR FOR
      SELECT BONUS
      FROM DSN8710.EMP
      WHERE WORKDEPT = 'E12'
      FOR UPDATE OF BONUS;
  EXEC SQL
    UPDATE DSN8710.EMP
      SET BONUS = ( SELECT .10 * SALARY FROM DSN8710.EMP Y
                    WHERE EMPNO = Y.EMPNO )
      WHERE CURRENT OF C1;
```

Example 10

Assuming that cursor CS1 is positioned on a rowset consisting of 10 rows in table T1, update all 10 rows in the rowset.

```
EXEC SQL UPDATE T1 SET C1 = 5 WHERE CURRENT OF CS1;
```

Example 11

Assuming that cursor CS1 is positioned on a rowset consisting of 10 rows in table T1, update the fourth row of the rowset.

```
short ind1, ind2;

int n, updt_value;

stmt = 'UPDATE T1 SET C1 = ? WHERE CURRENT OF CS1 FOR ROW ? OF ROWSET'
```

```
ind1 = 0;

ind2 = 0;

n = 4;

updt_value = 5;

...

strcpy(my_sqlda.sqldaid,"SQLDA");

my_sqlda.sqln = 2;

my_sqlda.sqld = 2;

my_sqlda.sqlvar[0].sqltype = 497;
my_sqlda.sqlvar[0].sqllen = 4;
my_sqlda.sqlvar[0].sqldata = (int *) &updt_value;
my_sqlda.sqlvar[0].sqlind = (short *) &ind1;

my_sqlda.sqlvar[1].sqltype = 497;
my_sqlda.sqlvar[1].sqllen = 4;
my_sqlda.sqlvar[1].sqldata = (int *) &n;
my_sqlda.sqlvar[1].sqlind = (short *) &ind2;

EXEC SQL PREPARE S1 FROM :stmt;

EXEC SQL EXECUTE S1 USING DESCRIPTOR :my_sqlda;
```

Example 12

Assume that table POLICY exists and that it is defined with a single inclusive-exclusive period, BUSINESS_TIME. The table contains a row where column BK has a value of 'P138', column CLIENT has a value of 'C882', column TYPE has a value of 'PPO', and the period has value ('2013-01-01', '2020-12-31'). Update the portion of the row beginning from '2014-01-01' to set the TYPE column to 'HMO':

```
UPDATE POLICY
    FOR PORTION OF BUSINESS_TIME
        FROM '2014-01-01' TO '9999-12-31'
        SET TYPE='HMO'
        WHERE BK='P138', CLIENT='C882';
```

After the UPDATE statement is processed, the table contains 2 rows in place of the original row. One row with period value ('2013-01-01', '2014-01-01') represents a value of 'PPO' for the TYPE column (the value before the update) and the other row with period value ('2014-01-01', '2020-12-31') represents a value of 'HMO' for the TYPE column (that began with the UPDATE statement).

Example 13

Suppose that the INTARRAY and CHARARRAY array types, the INTA, CHARA, and SI variables, and the T1 table are defined as follows:

```
CREATE TYPE INTARRAY AS INTEGER ARRAY [6];
CREATE TYPE CHARARRAY AS CHAR(20) ARRAY [7];
CREATE VARIABLE INTA AS INTARRAY;
CREATE VARIABLE CHARA AS CHARARRAY;
CREATE VARIABLE SI INT;
CREATE TABLE T1 (COL1 CHAR(7), COL2 INT);
```

Assign values to CHARA, INTA, and SI.

```
SET CHARA = ARRAY [ 'a', 'b', 'c' ];
SET INTA = ARRAY [ 1, 2, 3, 4, 5 ];
SET SI = 1;
```

Insert a row into table T1, and then update the row values using values from the CHARA and INTA arrays, which are indexed by the value of variable SI.

```
INSERT INTO T1 VALUES ('abc', 10);
UPDATE T1
 SET COL1 = CHARA[SI],
 COL2 = INTA[SI];
```

In the table row, COL1 now contains 'a', and COL2 contains 1.

Set the value of column COL2 for all rows to the cardinality of array INTA.

```
UPDATE T1
 SET COL2 = CARDINALITY(INTA);
```

In the table row, COL2 now contains 5.

Example 14

Assume that table POLICY exists and that it is defined with a single inclusive-inclusive period, BUSINESS_TIME. The table contains a row where column BK has a value of 'P138', column CLIENT has a value of 'C882', column TYPE has a value of 'PPO', and period has value ('2013-01-01', '2020-12-31'). Suppose that you issue the following UPDATE statement:

```
UPDATE POLICY
FOR PORTION OF BUSINESS_TIME
BETWEEN '2014-01-01' AND '9999-12-31'
SET TYPE='HMO'
WHERE BK='P138', CLIENT='C882';
```

After the UPDATE statement is processed, the table contains 2 rows in place of the original row. One row with period value ('2013-01-01', '2013-12-31') has a value of 'PPO' for the TYPE column (the value before the update) and the other row with period value ('2014-01-01', '2020-12-31') has a value of 'HMO' for the TYPE column.

VALUES

The VALUES statement provides a method for invoking a user-defined function from a trigger. Transition variables and transition tables can be passed to the user-defined function.

Invocation for VALUES

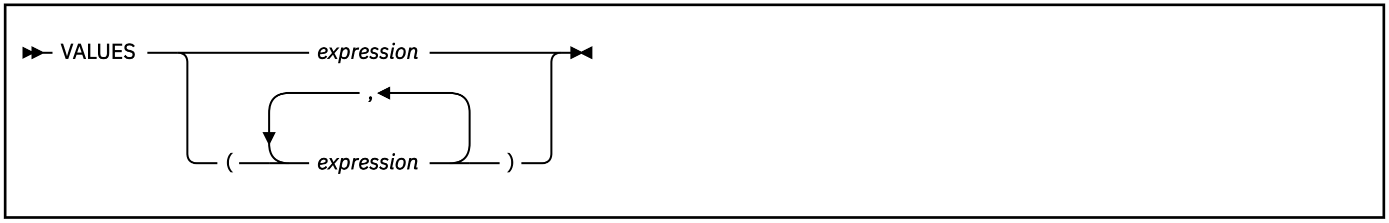
This statement can only be used in the triggered action of a basic trigger.

VALUES followed by a *sequence-reference* is a *values-clause*, which is a form of *fullselect*. For information about invocation of the *values-clause*, see “fullselect” on page 1058.

Authorization for VALUES

Authorization is required for any expressions that are used in the statement. For more information, see “Expressions” on page 244.

Syntax for VALUES



Description for VALUES

VALUES

Specifies one or more expressions. If more than one expression is specified, the expressions must be enclosed within parentheses.

expression

Any expression of the type described in “Expressions” on page 244. The expression must not contain a host variable.

The expressions are evaluated, but the resulting values are discarded and are not assigned to any output variables.

If a user-defined function is specified as part of an expression, the user-defined function is invoked. If a negative SQLCODE is returned when the function is invoked, Db2 stops executing the trigger and rolls back any triggered actions that were performed.

Example for VALUES

Example: Create an after trigger EMPISRT1 that invokes user-defined function NEWEMP when the trigger is activated. An insert operation on table EMP activates the trigger. Pass transition variables for the new employee number, last name, and first name to the user-defined function.

```
CREATE TRIGGER EMPISRT1
   AFTER INSERT ON EMP
   REFERENCING NEW AS N
   FOR EACH ROW
   MODE DB2SQL
   BEGIN ATOMIC
      VALUES(NEWEMP(N.EMPNO, N.LASTNAME, N.FIRSTNAME));
   END
```

VALUES INTO

The VALUES INTO statement assigns one or more values to variables.

Invocation for VALUES INTO

This statement can only be embedded in an application program. It is an executable statement that cannot be dynamically prepared.

Authorization for VALUES INTO

The privileges that are held by the authorization ID of the statement must include at least one of the following privileges or authorities:

- The SELECT privilege on every table and view identified in the statement
- Ownership of every table and view identified in the statement
- READ and WRITE privileges on any global variables that are identified in the statement
- Ownership of any global variables that are identified in the statement
- DBADM authority for the database (tables only)
- DATAACCESS authority
- SYSADM authority
- SYSCTRL authority (catalog tables only)

For an assignment to a global variable or an element of an array global variable, the privilege set must include at least one of the following:

- The WRITE privilege on the variable
- Ownership of the variable
- DATAACCESS authority
- SYSADM authority

For an assignment to a transition variable, the privilege set must include at least one of the following:

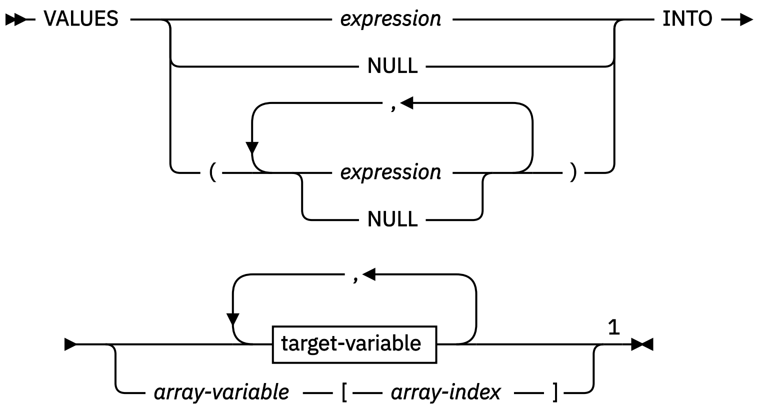
- The UPDATE privilege on the table or view on which the trigger that contains the assignment statement is defined
- The UPDATE privilege on the column corresponding to the transition variable to be assigned a value

- Ownership of the table or view on which the trigger that contains the assignment statement is defined
- DBADM authority on the database that contains the table on which the trigger that contains the assignment statement is defined
- DATAACCESS authority
- SYSADM authority

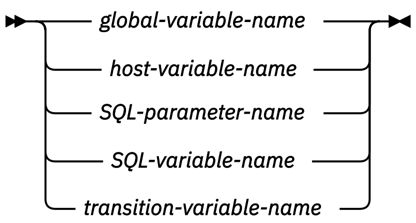
Privilege set: The privilege set is the privileges that are held by the owner of the package.

Authorization is required for any expressions that are used in the statement. For more information, see "Expressions" on page 244.

Syntax for VALUES INTO



target-variable



Notes:

[1] The number of source value specifications (*expression*, NULL, or DEFAULT) on the right side of the equal sign must match the number of target specifications on the left side of the statement.

Description for VALUES INTO

VALUES

Introduces a single row that consists of one or more columns. If more than one value is specified, the list of values must be enclosed within parentheses.

expression

The expression is any expression of the type described in "Expressions" on page 244. The expression must not include a column name.

NULL

The null value. NULL can only be specified for host variables that have an associated indicator variable.

INTO *target-variable* or *array-variable*[*array-index*]

Identifies one or more targets for the assignment of output values. The number of targets in the INTO clause must equal the number of values that are to be assigned. The first value in the result row is assigned to the first target in the list, the second value to the second target, and so on. A target variable must not be specified more than once in the INTO clause. Each assignment to a target is made in sequence through the list, according to the rules described in "Assignment and comparison" on page 143.

The value 'W' is assigned to the SQLWARN3 field of the SQLCA if the number of targets is less than the number of result column values.

If an error occurs on any assignment, the value is not assigned to the target, and no more values are assigned to the specified targets. Any values that have already been assigned remain assigned.

global-variable-name
Identifies the global variable that is the assignment target.

host-variable-name
Identifies the host variable that is the assignment target. For LOB output values, the target can be a regular host variable (if it is large enough), a LOB locator variable, or a LOB file reference variable.

SQL-parameter-name
Identifies the parameter that is the assignment target.

SQL-variable-name
Identifies the SQL variable that is the assignment target. SQL variables must be declared before they are used.

transition-variable-name
Identifies the column that is to be updated in the transition table. A *transition-variable-name* must identify a column in the subject table of a trigger, optionally qualified by a correlation name, that identifies the new value.

***array-variable* [*array-index*]**
Specifies an array element that is the target of the assignment.

An array element must not be specified as the target for an assignment if *common-table-expression* is also specified in the statement.

array-variable
Specifies an array variable.

[*array-index*]
An expression that specifies which element in the array is the target of the assignment.

For an ordinary array, the array index expression must be castable to INTEGER, and must not be the null value. The index value must be between 1 and the maximum cardinality that is defined for the array.

For an associative array, the array index expression must be castable to the index data type of the associative array, and must not be the null value.

array-index must not be:

- An expression that references the CURRENT DATE, CURRENT TIME, or CURRENT TIMESTAMP special register
- A nondeterministic function
- A function that is defined with EXTERNAL ACTION
- A function that is defined with MODIFIES SQL DATA
- A sequence expression

Notes for VALUES INTO

Assignment to targets:
The *n*th target identified by the INTO clause corresponds to the *n*th column of the result table of the cursor. The data type of the target must be compatible with its corresponding value. If the value is numeric, the target must have the capacity to represent the whole part of the value. For a datetime value, the target must be a character string variable of a minimum length as defined in "String

representations of datetime values" on page 120. When the value that is to be assigned is null, an indicator variable must be specified for the target variable.

Assignments are made in sequence through the list. Each assignment to a target is made according to the rules described in Chapter 2, "Language elements in SQL," on page 75. If the number of targets is less than the number of values in the row, the SQLWARN3 field of the SQLCA is set to 'W'. There is no warning if there are more targets than the number of result columns. If a null value is assigned to a target variable, an indicator variable must be provided. If an assignment error occurs, the value is not assigned to the target and no more values are assigned to targets. Any values that have already been assigned to targets remain assigned. However, if LOB values are involved, there is a possibility that the corresponding target was modified, but the variable's contents are unpredictable.

If more than one assignment is included in the same assignment statement, all expressions are evaluated before the assignments are performed. For example, a reference to a variable in an expression always uses the value of the variable prior to any assignment in the assignment statement.

Normally, you use LOB locators to assign and retrieve data from LOB columns. However, because of compatibility rules, you can also use LOB locators to assign data to targets with other data types. For more information on using locators, see Saving storage when manipulating LOBs by using LOB locators (Db2 Application programming and SQL).

Default encoding scheme:
The default encoding scheme for the data is the value in the bind option ENCODING, which is the option for application encoding. If this statement is used with functions such as LENGTH or SUBSTRING that are operating on LOB locators, and the LOB data that is specifies by the locator is in a different encoding scheme from the ENCODING bind option, LOB materialization and character conversion occur. To avoid LOB materialization and character conversion, select the LOB data from the SYSIBM.SYSDUMMYA, SYSIBM.SYSDUMMYE, or SYSIBM.SYSDUMMYU sample table.

Examples for VALUES INTO

Example 1: Assign the value of the CURRENT PATH special register to host variable *HV1*.

```
   EXEC SQL VALUES(CURRENT PATH)
            INTO :HV1;
```

Example 2: Assign the value of the CURRENT MEMBER special register to host variable *MEM*.

```
   EXEC SQL VALUES(CURRENT MEMBER)
            INTO :MEM;
```

Example 3: Assume that LOB locator *LOB1* is associated with a CLOB value. Assign a portion of the CLOB value to host variable *DETAILS* using the LOB locator.

```
   EXEC SQL VALUES (SUBSTR(:LOB1,1,35))
            INTO :DETAILS;
```

If the LOB data that is specified by the LOB locator *LOB1* is in a different encoding scheme from the value of the ENCODING bind option, and you want to avoid LOB materialization and character conversion, use the following statement instead of the VALUES INTO statement:

```
   EXEC SQL SELECT SUBSTR(:LOB1,1,35)
            INTO :DETAILS
            FROM SYSIBM.SYSDUMMYU;
```

Example 4: Using a VALUES INTO statement, retrieve the value of INTVAR1 into an element in array MYINTARRAY1, which is indexed by the value of the expression INTCOL2+MYINTVAR+1.

```
VALUES INTVAR1 INTO MYINTARRAY1[INTCOL2+MYINTVAR+1];
```

WHENEVER

The WHENEVER statement specifies the host language statement to be executed when a specified exception condition occurs.

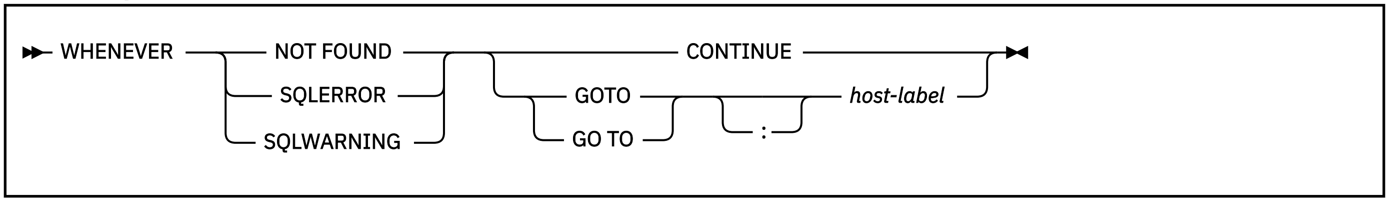
Invocation for WHENEVER

This statement can only be embedded in an application program. It is not an executable statement. It must not be specified in Java or REXX.

Authorization for WHENEVER

None required.

Syntax for WHENEVER



Description for WHENEVER

The `NOT FOUND`, `SQLERROR`, or `SQLWARNING` clause is used to identify the type of exception condition.

NOT FOUND
Identifies any condition that results in an SQLCODE of +100 (equivalently, an SQLSTATE code of '02000').

SQLERROR
Identifies any condition that results in a negative SQLCODE.

SQLWARNING
Identifies any condition that results in a warning condition (SQLWARN0 is W), or that results in a positive SQLCODE other than +100.

The `CONTINUE` or `GO TO` clause specifies the next statement to be executed when the identified type of exception condition exists.

CONTINUE
Specifies the next sequential statement of the source program.

GOTO or GOTO *host-label*
Specifies the statement identified by *host-label*. For *host-label*, substitute a single token, optionally preceded by a colon. The form of the token depends on the host language. In COBOL, for example, it can be *section-name* or an unqualified *paragraph-name*.

Notes for WHENEVER

There are three types of WHENEVER statements:

- WHENEVER NOT FOUND
- WHENEVER SQLERROR
- WHENEVER SQLWARNING

Every executable SQL statement in an application program is within the scope of one implicit or explicit WHENEVER statement of each type. The scope of a WHENEVER statement is related to the listing sequence of the statements in the application program, not their execution sequence.

An SQL statement is within the scope of the last WHENEVER statement of each type that is specified before that SQL statement in the source program. If a WHENEVER statement of some type is not specified before an SQL statement, that SQL statement is within the scope of an implicit WHENEVER statement of that type in which `CONTINUE` is specified. If a WHENEVER statement is specified in a Fortran subprogram, its scope is that subprogram, not the source program.

The GET DIAGNOSTICS statement can be used to provide additional information.

Examples for WHENEVER

The following statements can be embedded in a COBOL program.

Example 1: Go to the label HANDLER for any statement that produces an error.

```
   EXEC SQL WHENEVER SQLERROR GOTO HANDLER END-EXEC.
```

Example 2: Continue processing for any statement that produces a warning.

```
   EXEC SQL WHENEVER SQLWARNING CONTINUE END-EXEC.
```

Example 3: Go to the label ENDDATA for any statement that does not return.

```
   EXEC SQL WHENEVER NOT FOUND GO TO ENDDATA END-EXEC.
```

Chapter 8. SQL procedural language (SQL PL)

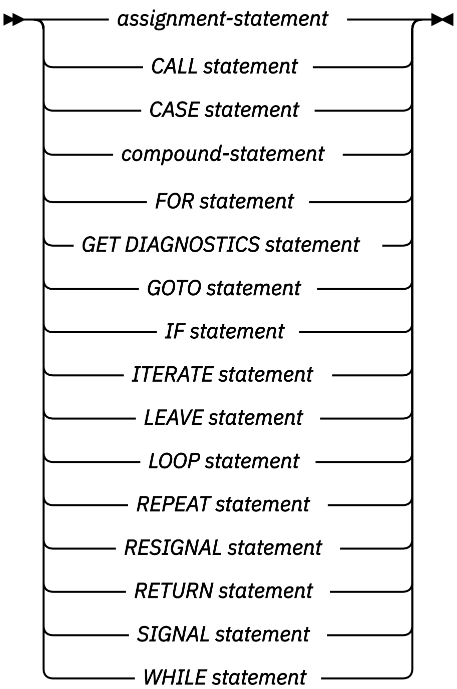
SQL can be used as a structured programming language to write the body for SQL functions, native SQL procedures, and advanced triggers. This is known as the SQL procedural language (SQL PL). SQL PL includes a set of SQL control statements.

SQL procedures and SQL functions are collectively referred to as SQL routines. SQL procedures are created by specifying an SQL routine body on the CREATE PROCEDURE statement. SQL functions are created by specifying an SQL routine body on the CREATE FUNCTION statement. Triggers are created by specifying an SQL trigger body on the CREATE TRIGGER statement.

SQL control statements

SQL control statements are SQL statements that allow SQL to be used as a structured programming language. SQL control statements provide the capability to control the logic flow, declare and set variables, and handle warnings and exceptions. Some SQL control statements include other nested SQL statements.

SQL-control-statement:



Control statements are supported in native SQL procedures, compiled SQL functions, and advanced triggers.

- SQL functions are created by specifying LANGUAGE SQL and an SQL routine body in a CREATE FUNCTION (compiled SQL) statement. An SQL function can be changed. A new SQL routine body can be specified in an ALTER FUNCTION (compiled SQL) statement.
- SQL procedures are created by specifying LANGUAGE SQL and an SQL routine body in a CREATE PROCEDURE (SQL - native) statement. An SQL procedure can be changed. A new SQL routine body can be specified in an ALTER PROCEDURE (SQL - native) statement.
- Triggers are created by specifying a trigger body on the CREATE TRIGGER (advanced) statement. See "CREATE TRIGGER (advanced)" on page 1735. Advanced triggers can be changed. The body of a trigger can be changed by specifying the OR REPLACE clause on a CREATE TRIGGER (advanced) statement, or with an ALTER TRIGGER (advanced) statement.

The SQL routine body or trigger body is the executable part of the routine or trigger and is transformed by Db2 into a program. The body must be a single SQL statement, which might be an SQL control statement.

The remainder of this section contains a description of the control statements that are supported by SQL routines and advanced triggers, and includes syntax diagrams, semantic descriptions, usage notes, and examples of the use of the statements that constitute the SQL routine body or trigger body. In addition, you can find information about referencing SQL parameters and variables in "References to SQL parameters and variables in SQL PL" on page 2198.

The two common elements that are used in describing specific SQL control statements are:

- SQL control statements as described above
- "SQL-procedure-statement (SQL PL)" on page 2202

Related reference

CREATE PROCEDURE (SQL - native)
The CREATE PROCEDURE statement defines an SQL procedure, or a version of a procedure, at the current server and specifies the source statements for the procedure.

CREATE FUNCTION (compiled SQL scalar)
The CREATE FUNCTION (compiled SQL scalar) statement defines a compiled SQL scalar function at the current server and specifies the source statements for the function. The body of the function is written in the SQL procedural language. The function returns a single value each time it is invoked.

CREATE TRIGGER (advanced)

References to SQL parameters and variables in SQL PL

Variables can be referenced in SQL statements in SQL functions, SQL procedures, and triggers. However, host variables cannot be specified in these objects. Instead, depending on the context, SQL variables, SQL parameters, transition variables, and global variables can be referenced anywhere in an SQL statement where an expression or variable can be specified in SQL functions, SQL procedures, and triggers. SQL variables can be referenced anywhere in the compound statement in which they are declared, including any SQL statement that is directly or indirectly nested within that compound statement. SQL parameters can be referenced in an SQL function or SQL procedure body. Transition variables can be referenced in a trigger body.

Ambiguity can arise in an SQL statement with variables, particularly when two or more variables have the same name or when a variable and another object have the same name. In such situations, it might be confusing to determine which variable is referenced and whether the identifier is the name of a variable or another object, such as a column. If the identifier is the name of a variable, it might be difficult to determine whether the reference is intended for an SQL variable, SQL parameter, transition variable, or global variable.

The name of an SQL variable, SQL parameter, or global variable in an SQL function or SQL procedure can be the same as the name of a column in a table or view referenced in the function or procedure. The name of an SQL variable, transition variable, or global variable in a trigger can be the same as the name of a column in a table or view that is referenced in the trigger. The name of an SQL variable can also be the same as the name of another SQL variable declared in the same function, procedure, or trigger. This can occur when the two SQL variables are declared in different compound statements. The *compound-statement* that contains the declaration of an SQL variable determines the scope of that variable. See "compound-statement" on page 2211 for additional information.

Names that are the same should be explicitly qualified. Qualifying a name can clarify whether the name refers to a column, global variable, SQL variable, SQL parameter, or transition variable:

- An SQL parameter can be qualified with the name of the SQL function or SQL procedure.
- An SQL variable can be qualified with the label of the compound statement where an SQL variable is declared.
- A transition variable can be qualified with the correlation name specified in the CREATE TRIGGER or ALTER TRIGGER statement.

- A global variable can be qualified with the schema implicitly or explicitly specified when the global variable is created.

If the name is not qualified, or qualified but still ambiguous, the following rules describe how the name is resolved. The name is resolved by checking for a match in the following order:

- If the tables and views specified in an SQL function or SQL procedure at the time the function or procedure is created, the name is first checked as a column.
- If not found as a column, the name is checked as an SQL variable, SQL parameter, or transition variable. An SQL variable can be declared within the *compound-statement* that contains the reference, or within a compound statement in which that compound statement is nested. If two SQL variables, an SQL variable and an SQL parameter, or an SQL variable and a transition variable, have the same name, the SQL variable that is declared in the innermost compound statement is used.
- If not found as an SQL variable name, the name is checked as an SQL parameter name or transition variable.
- If not found as an SQL parameter or transition variable, the name is checked as a global variable.

If the name is still not resolved as a column, SQL variable, SQL parameter, global variable, or transition variable and the scope of the name included a table or view that does not exist at the current server, it is assumed to be a column. If all the tables and views exist at the current server, it is assumed to be a global variable. Otherwise, an error is returned.

The name of an SQL variable, SQL parameter, transition variable, or global variable in an SQL function, SQL procedure, or trigger can be the same as an identifier used as a name in certain SQL statements. Qualified names for SQL variables, SQL parameters, or transition variables are not supported in these statements. The following rules describe how the name is resolved in these statements.

- In the SET PATH or SET SCHEMA statements, the name is checked as an SQL variable, SQL parameter, transition variable, or global variable. If an SQL variable, SQL parameter, transition variable, or global variable by that name is not found, the name is assumed to be a schema name.
- In the CONNECT, RELEASE, and SET CONNECTION statements, the name is used as a server name.
- In the CALL statement, the name is used as the procedure name.
- In the ASSOCIATE LOCATORS, or DESCRIBE PROCEDURE statement, the name is used as the procedure name.

Related concepts

Variables
A *variable* in an SQL statement specifies a value that can be changed when the SQL statement is executed. There are several types of variables used in SQL statements.

References to SQL condition names

A condition name can only be referenced within the compound statement in which it is declared, including any compound statements that are nested within that compound statement. When there is a reference to a condition name, the condition that is declared in the innermost compound statement is the condition that is used.

The name of an SQL condition can be the same as the name of another SQL condition that is declared in the same routine or advanced trigger. This can occur when the two SQL conditions are declared in different *compound-statements*. The *compound-statement* that contains the declaration of an SQL condition name determines the scope of that condition name. A condition name must be unique within the compound statement in which it is declared, excluding any declarations in compound statements that are nested within that compound statement. A condition name can only be referenced within the compound statement in which it is declared, including any compound statements that are nested within that compound statement. When there is a reference to a condition name, the condition that is declared in the innermost compound statement is the condition that is used. See "compound-statement" on page 2211 for additional information.

References to SQL cursor names

A cursor name can only be referenced within the compound statement in which it is declared, including any compound statements that are nested within that compound statement.

The name of an SQL cursor can be the same as the name of another SQL cursor that is declared in the same routine or advanced trigger. This can occur when the two SQL cursors are declared in different compound statements. The compound statement that contains the declaration of an SQL cursor determines the scope of that cursor name. A cursor name must be unique within the compound statement in which it is declared, excluding any declarations in compound statements that are nested within that compound statement. A cursor name can only be referenced within the compound statement in which it is declared, including any compound statements that are nested within that compound statement. When there is a reference to a cursor name, the cursor that is declared in the innermost compound statement is the cursor that is used. See "compound-statement" on page 2211 for additional information.

References to SQL labels

Labels can be specified on most SQL procedure statements in an SQL function, SQL procedure, or advanced trigger. If a label is specified on an SQL procedure statement, it must be unique from other labels within the same scope. A label must not be the same as any other label within the same compound statement, must not be the same as a label specified on the compound statement itself, and if the compound statement is nested within another compound statement, the label must not be the same as the label specified on any higher level compound statement. The label must not be the same as the name of the SQL function or SQL procedure.

Specifying a label for an SQL procedure statement defines that label and determines the scope of that label. A label name can only be referenced within the compound statement in which it is defined, including a reference from any statement that is directly or indirectly nested within that compound statement. The FOR statement is considered the same as a compound statement with respect to defining and referencing labels. A label can be specified as the target of a GOTO, LEAVE, or ITERATE statement, subject to the rules for the statement that references the label as a target.

References to SQL statement names

The name of an SQL statement can be the same as the name of another SQL statement declared in the same routine or advanced trigger.

This can occur when the two SQL statements are declared in different compound statements. The compound statement that contains the declaration of an SQL statement name determines the scope of that statement name. A statement name must be unique within the compound statement in which it is declared, excluding any declarations in compound statements that are nested within that compound statement. A statement name can only be referenced within the compound statement in which it is declared, including any compound statements that are nested within that compound statement. When there is a reference to a statement name, the statement that is declared in the innermost compound statement is the statement that is used.

Summary of name scoping in nested compound statements

Nested compound statements can be used within an SQL routine or advanced trigger to define the scope of SQL variable declarations, cursors, condition names, and condition handlers.

In addition, labels have a defined scope in the context of nested compound statements. However, the rules for name spaces and how non-unique names can be referenced, differs depending on the type of name. The following table summarizes these differences:

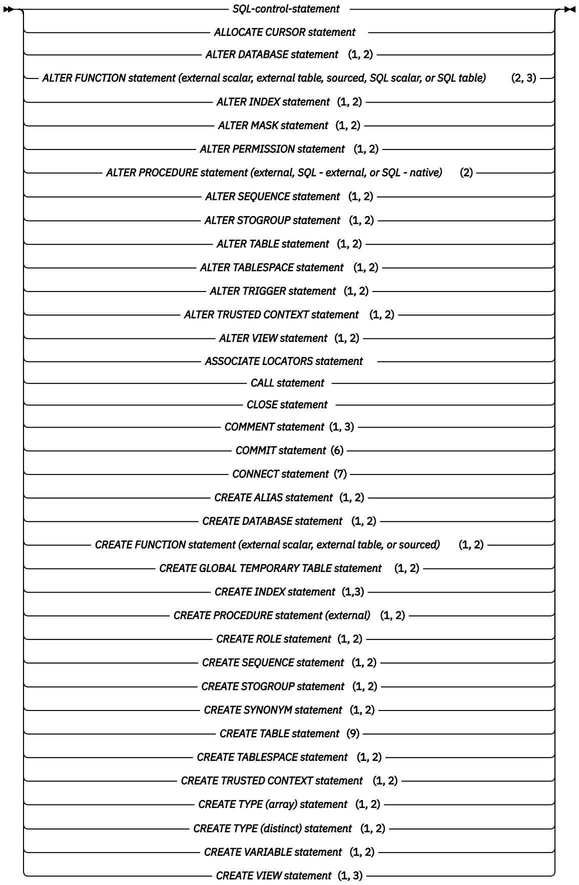
Table 241. Scope and qualification of names within nested compound statements

Type of name	Name can be qualified	Name must be unique within	Name can be referenced within
SQL variable	Yes. The name can be qualified with the label of the compound statement in which the variable is declared	the compound statement in which it is declared, excluding any declarations in compound statements that are nested within that compound statement	The compound statement in which it is declared, including any compound statements that are nested within that compound statement. When multiple SQL variables are defined with the same name, a label can be used to explicitly refer to a specific variable that is not the most local in scope
condition name	No	the compound statement in which it is declared, excluding any declarations in compound statements that are nested within that compound statement	The compound statement in which it is declared, including any compound statements that are nested within that compound statement. Condition names can be used in the declaration of a condition handler, or in a SIGNAL or RESIGNAL statement. If multiple conditions are defined with the same name, there is no way to explicitly refer to the condition that is not the most local in scope.
cursor name	No	the routine	The compound statement in which it is declared, including any compound statements that are nested within that compound statement. If the cursor is defined as a result set cursor, the invoking application can access the result set.
label	No	the compound statement that defined the label, including any definitions in compound statements that are nested within that compound statement	The compound statement in which it is defined, including any compound statements that are nested within that compound statement. Use a label to qualify the name of an SQL variable or as the target of a GOTO, LEAVE, or ITERATE statement, subject to the rules for these statements.

SQL-procedure-statement (SQL PL)

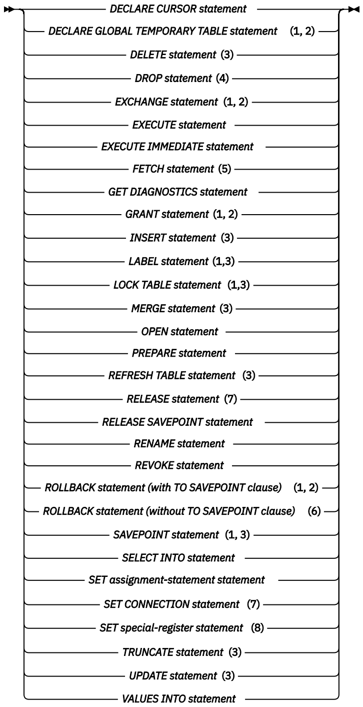
An SQL control statement can allow multiple SQL statements to be specified within the SQL control statement. These statements are defined as SQL procedure statements.

Syntax



SQL-control-statement
ALLOCATE CURSOR statement
ALTER DATABASE statement (1, 2)
ALTER FUNCTION statement (external scalar, external table, sourced, SQL scalar, or SQL table) (2, 3)
ALTER INDEX statement (1, 2)
ALTER MASK statement (1, 2)
ALTER PERMISSION statement (1, 2)
ALTER PROCEDURE statement (external, SQL - external, or SQL - native) (2)
ALTER SEQUENCE statement (1, 2)
ALTER STOGROUP statement (1, 2)
ALTER TABLE statement (1, 2)
ALTER TABLESPACE statement (1, 2)
ALTER TRIGGER statement (1, 2)
ALTER TRUSTED CONTEXT statement (1, 2)
ALTER VIEW statement (1, 2)
ASSOCIATE LOCATORS statement
CALL statement
CLOSE statement
COMMENT statement (1, 3)
COMMIT statement (6)
CONNECT statement (7)
CREATE ALIAS statement (1, 2)
CREATE DATABASE statement (1, 2)
CREATE FUNCTION statement (external scalar, external table, or sourced) (1, 2)
CREATE GLOBAL TEMPORARY TABLE statement (1, 2)
CREATE INDEX statement (1,3)
CREATE PROCEDURE statement (external) (1, 2)
CREATE ROLE statement (1, 2)
CREATE SEQUENCE statement (1, 2)
CREATE STOGROUP statement (1, 2)
CREATE SYNONYM statement (1, 2)
CREATE TABLE statement (9)
CREATE TABLESPACE statement (1, 2)
CREATE TRUSTED CONTEXT statement (1, 2)
CREATE TYPE (array) statement (1, 2)
CREATE TYPE (distinct) statement (1, 2)
CREATE VARIABLE statement (1, 2)
CREATE VIEW statement (1, 3)

Syntax (continued)



DECLARE CURSOR statement
DECLARE GLOBAL TEMPORARY TABLE statement (1, 2)
DELETE statement (3)
DROP statement (4)
EXCHANGE statement (1, 2)
EXECUTE statement
EXECUTE IMMEDIATE statement
FETCH statement (5)
GET DIAGNOSTICS statement
GRANT statement (1, 2)
INSERT statement (3)
LABEL statement (1,3)
LOCK TABLE statement (1,3)
MERGE statement (3)
OPEN statement
PREPARE statement
REFRESH TABLE statement (3)
RELEASE statement (7)
RELEASE SAVEPOINT statement
RENAME statement
REVOKE statement
ROLLBACK statement (with TO SAVEPOINT clause) (1, 2)
ROLLBACK statement (without TO SAVEPOINT clause) (6)
SAVEPOINT statement (1, 3)
SELECT INTO statement
SET assignment-statement statement
SET CONNECTION statement (7)
SET special-register statement (8)
TRUNCATE statement (3)
UPDATE statement (3)
VALUES INTO statement

Notes:

The following notes are used both in the preceding syntax diagram and sometimes also in the following table.

1. The statement is not allowed in an *SQL-routine-body* for an SQL function.
2. The statement is not allowed in an *SQL-trigger-body* for a trigger, and a procedure containing the statement must not be invoked directly, or indirectly, from the body of a BEFORE trigger.
3. The statement is not allowed in an *SQL-trigger-body* for a BEFORE trigger, and a procedure containing the statement must not be invoked directly, or indirectly, from the body of a BEFORE trigger.
4. The only DROP statements that are allowed are DROP TABLE, DROP VIEW, and DROP INDEX.
5. A FETCH statement must not specify a *fetch-orientation* clause, *multiple-row-fetch* clause, the WITH CONTINUE or the CURRENT CONTINUE clauses.
6. The COMMIT and ROLLBACK (without the TO SAVEPOINT clause) statements must only be specified within the body of an SQL procedure.
7. The CONNECT, RELEASE *connection*, and SET CONNECTION statements must only be specified within the body of an SQL procedure.
8. SET *special-register* statements are allowed in an *SQL-trigger-body* for a trigger, except for SET CURRENT PACKAGE PATH and SET CURRENT PACKAGESET.
9. A CREATE TABLE statement must not include a column defined as a LOB or XML column.

The following table summarizes which SQL statements can be used in *SQL-procedure-body*, *SQL-function-body*, or in a *SQL-trigger-body* or procedure referenced in a BEFORE trigger. (That is, it corresponds to notes “1” on page 2203, “2” on page 2203, and “3” on page 2203 in the syntax diagram.)

Statement	Allowed in SQL procedure body?	Allowed in SQL function body?	Allowed in SQL trigger body or procedure invoked by a BEFORE trigger?
SQL-control-statement	Yes	Yes	Yes

Statement	Allowed in SQL procedure body?	Allowed in SQL function body?	Allowed in SQL trigger body or procedure invoked by a BEFORE trigger?
ALLOCATE CURSOR	Yes	Yes	Yes
ALTER DATABASE	Yes	No	No
ALTER FUNCTION (external scalar, external table, sourced, SQL scalar, or SQL table)	Yes“3” on page 2203	Yes“3” on page 2203,	No
ALTER MASK	Yes	No	No
ALTER PERMISSION	Yes	No	No
ALTER PROCEDURE (external, SQL - external, or SQL - native)	Yes	Yes	No
ALTER SEQUENCE	Yes	No	No
ALTER STOGROUP	Yes	No	No
ALTER TABLE	Yes	No	No
ALTER TABLESPACE	Yes	No	No
ALTER TRIGGER	Yes	No	No
ALTER TRUSTED CONTEXT	Yes	No	No
ALTER VIEW	Yes	No	No
ASSOCIATE LOCATORS	Yes	Yes	Yes
CALL	Yes	Yes	Yes
CLOSE	Yes	Yes	Yes
COMMENT	Yes	No	Yes “3” on page 2203
COMMIT	No	No	Yes
CONNECT	Yes	Yes	No
CREATE ALIAS	Yes	No	No
CREATE DATABASE	Yes	No	No
CREATE FUNCTION	Yes	No	No
CREATE GLOBAL TEMPORARY TABLE	Yes	No	No
CREATE INDEX	Yes	No	No
CREATE PROCEDURE (external)	Yes	No	No
CREATE ROLE	Yes	No	No
CREATE SEQUENCE	Yes	No	No
CREATE STOGROUP	Yes	No	No
CREATE SYNONYM	Yes	No	No
CREATE TABLE	Yes “9” on page 2203	Yes “9” on page 2203	Yes “3” on page 2203, “9” on page 2203

Statement	Allowed in SQL procedure body?	Allowed in SQL function body?	Allowed in SQL trigger body or procedure invoked by a BEFORE trigger?
CREATE TABLESPACE	Yes	No	No
CREATE TRUSTED CONTEXT	Yes	No	No
CREATE TYPE (array)	Yes	No	No
CREATE TYPE (distinct)	Yes	No	No
CREATE VARIABLE	Yes	No	No
CREATE VIEW	Yes	No	Yes "3" on page 2203
DECLARE CURSOR	Yes	Yes	Yes
DELETE	Yes	No	Yes "3" on page 2203
DROP	Yes	No	Yes
EXCHANGE	Yes	No	No
EXECUTE	Yes	Yes	Yes
EXECUTE IMMEDIATE	Yes	Yes	Yes
FETCH	Yes "4" on page 2203	Yes "4" on page 2203	Yes "4" on page 2203
GET DIAGNOSTICS	Yes	Yes	Yes
GRANT	Yes	No	No
INSERT	Yes	Yes	Yes "3" on page 2203
LABEL	Yes	No	Yes "3" on page 2203
LOCK TABLE	Yes	No	Yes "3" on page 2203
MERGE	Yes	Yes	Yes "3" on page 2203
OPEN	Yes	Yes	Yes
PREPARE	Yes	Yes	Yes
REFRESH TABLE	Yes	Yes	Yes "3" on page 2203
RELEASE *connection*	Yes	No	No
RELEASE SAVEPOINT	Yes	No	No
RENAME	Yes	No	No
REVOKE	Yes	No	No
ROLLBACK (with TO SAVEPOINT clause)	Yes	No	No
ROLLBACK (without TO SAVEPOINT clause)	Yes	Yes	No
SAVEPOINT	Yes	No	No
SELECT INTO	Yes	Yes	Yes
SET *assignment-statement*	Yes	Yes	Yes "8" on page 2203
SET CONNECTION	Yes	No	No

Statement	Allowed in SQL procedure body?	Allowed in SQL function body?	Allowed in SQL trigger body or procedure invoked by a BEFORE trigger?
SET *special-register*	Yes	Yes "8" on page 2203	Yes
TRUNCATE	Yes	Yes	Yes "3" on page 2203
UPDATE	Yes	Yes	Yes "3" on page 2203
VALUES INTO	Yes	Yes	Yes

Description

SQL-control-statement
Specifies an SQL statement that provides the capability to control logic flow, declare and set variables, and handle warnings and exceptions, as defined in this section. Control statements are supported in SQL routines.

SQL-statement
Specifies an SQL statement. These statements are described in Chapter 7, "Statements," on page 1075.

Notes

Comments

Comments can be included within the body of an SQL routine. In addition to the double-dash form of comments (--), a comment can begin with /* and end with */. The following rules apply to this form of comment:

- The beginning characters /* must be adjacent and on the same line.
- The ending characters */ must be adjacent and on the same line.
- Comments can be started wherever a space is valid.
- Comments can be continued to the next line.

Detecting and processing error and warning conditions

As an SQL statement is executed, Db2 stores information about the processing of the statement in a diagnostics area (including the SQLSTATE and SQLCODE), unless otherwise noted in the description of the SQL statement. A completion condition can indicate that the SQL statement completed successfully, completed with a warning condition, or completed with a not found condition. An exception condition indicates that the SQL statement was not successful.

A condition handler can be defined to execute when an exception condition, a warning condition, or a not found condition occurs in a compound statement. The declaration of a condition handler includes the code that is executed when the condition handler is activated. When a condition other than a successful completion occurs in the processing of *SQL-procedure-statement* and a condition handler that can handle the condition is within scope, one such condition handler will be activated to process the condition. See "compound-statement" on page 2211 for information about defining condition handlers. The code in the condition handler can check for a warning condition, a not found condition, or an exception condition and can take the appropriate action. Use one of the following methods at the beginning of the body of a condition handler to check the condition in the diagnostics area that caused the handler to be activated.

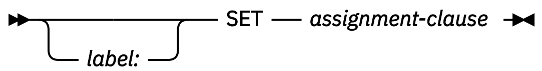
- Issue a GET DIAGNOSTICS statement to request the information from the diagnostics area. See "GET DIAGNOSTICS" on page 1944.
- Test the SQLSTATE and SQLCODE SQL variables.

If the condition is a warning and no handler exists for the condition, the previous two methods can be used outside of the body of a condition handler, if they are used immediately following the statement for which the condition is wanted. If the condition is an error and no handler exists for the condition, the routine terminates with the error condition.

assignment-statement

The assignment statement assigns a value to variables or array elements. For example, the target value can be an SQL parameter or an SQL variable.

Syntax



Description

label

Specifies the label for *assignment-statement*. The label name cannot be the same as the routine name, advanced trigger name, or another label within the same scope. For additional information, see "References to SQL labels" on page 2200.

See "SET assignment-statement" on page 2117 for details.

Notes

Assignment rules: Assignment statements in SQL routines and triggers must conform to the SQL assignment rules. For example, the data type of the target and source must be compatible. See "Assignment and comparison" on page 143 for assignment rules.

When a string is assigned to a fixed-length variable and the length of the string is less than the length attribute of the target, the string is padded on the right with the necessary number of single-byte or double-byte blanks. When a string is assigned to a variable and the string is longer than the length attribute of the variable, the value is truncated and a warning is returned.

If truncation of the whole part of a number occurs on assignment to a numeric variable, the value is truncated and a warning is returned.

Assignments involving SQL parameters for SQL procedures: An IN parameter can appear on the left or right side in an assignment statement. When control returns to the caller, the original value of the IN parameter is retained. An OUT parameter can also appear on the left or right side in an assignment statement. If used without first being assigned a value, the value is undefined. When control returns to the caller, the last value that is assigned to an OUT parameter is returned to the caller. For an INOUT parameter, the first value of the parameter is determined by the caller, and the last value that is assigned to the parameter is returned to the caller.

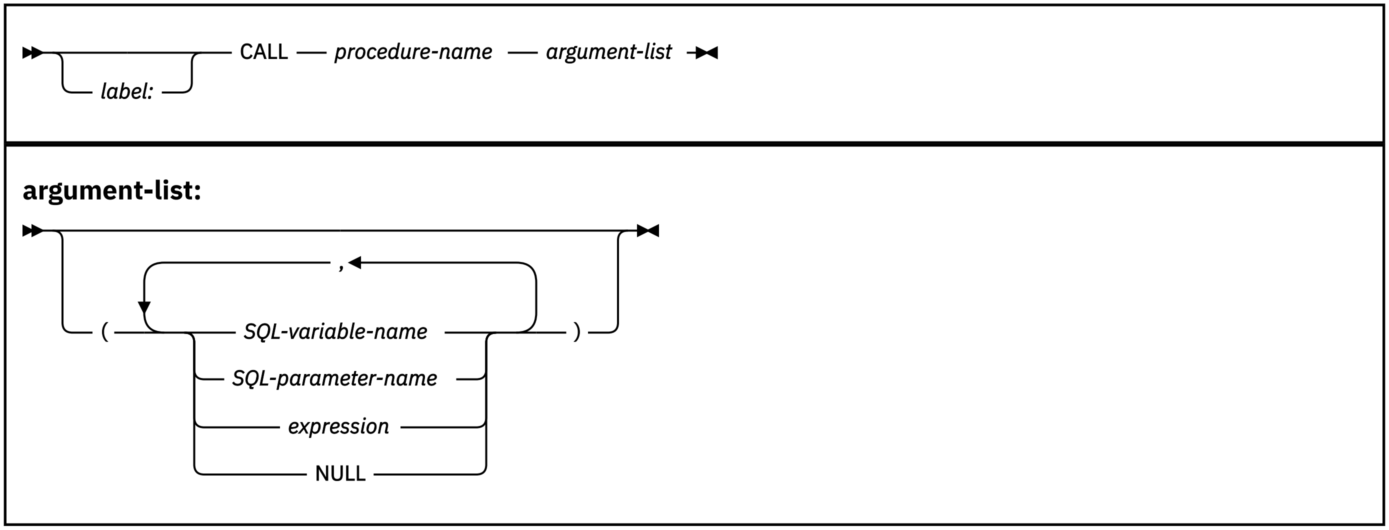
Multiple assignments: If more than one assignment is included in the same assignment statement, all *expressions* are evaluated before the assignments are performed. Thus, references to an SQL variable or SQL parameter in an expression always use the value of the SQL variable or SQL parameter prior to any assignment in the assignment statement.

Considerations for SQLSTATE and SQLCODE SQL variables: Assignment to these variables is not prohibited. However, it is not recommended as assignment does not affect the diagnostic area or result in the activation of condition handlers. Furthermore, processing an assignment to these SQL variables causes the specified values for the assignment to be overlayed with the SQL return codes returned from executing the statement that does the assignment.

CALL statement

The CALL statement invokes a stored procedure.

Syntax



Description

label

Specifies the label for the CALL statement. The label name cannot be the same as the routine name, advanced trigger name, or another label within the same scope. For additional information, see "References to SQL labels" on page 2200.

procedure-name

Identifies the stored procedure to call. The procedure name must identify a stored procedure that exists at the current server.

argument-list

Identifies a list of values to be passed as parameters to the stored procedure. The *n*th value corresponds to the *n*th parameter in the procedure. The number of parameters must be the same as the number of parameters defined for the stored procedure. See "CALL" on page 1379 for more information.

Control is passed to the stored procedure according to the calling conventions for SQL routines. When execution of the stored procedure is complete, the value of each parameter of the stored procedure is assigned to the corresponding parameter of the CALL statement defined as OUT or INOUT.

SQL-variable-name

Specifies an SQL variable as an argument to the stored procedure. For an explanation of references to SQL variables, see "References to SQL parameters and variables in SQL PL" on page 2198.

SQL-parameter-name

Specifies an SQL parameter as an argument to the stored procedure. For an explanation of references to SQL parameters, see "References to SQL parameters and variables in SQL PL" on page 2198.

expression

The parameter is the result of the specified *expression*, which is evaluated before the stored procedure is invoked. If *expression* is a single *SQL-parameter-name* or *SQL-variable-name*, the corresponding parameter of the procedure can be defined as IN, INOUT, or OUT. Otherwise, the corresponding parameter of the procedure must be defined as IN. If the result of the *expression* can be the null value, either the description of the procedure must allow for null parameters or the corresponding parameter of the stored procedure must be defined as OUT.

The following additional rules apply depending on how the corresponding parameter was defined in the CREATE PROCEDURE statement for the procedure:

- IN *expression* can contain references to multiple SQL parameters or variables. In addition to the rules stated in "Expressions" on page 244 for *expression*, *expression* cannot include a column name, an aggregate function, or a user-defined function that is sourced on an aggregate function.
- INOUT or OUT *expression* can only be a single SQL parameter or variable.

NULL

The parameter is a null value. The corresponding parameter of the procedure must be defined as IN and the description of the procedure must allow for null parameters.

Notes

See "CALL" on page 1379 for more information on the SQL CALL statement.

Examples

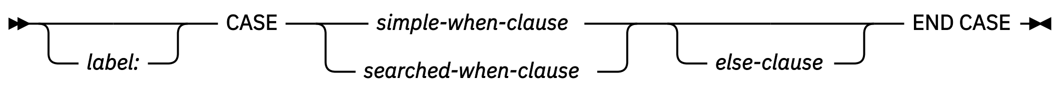
Call stored procedure proc1 and pass SQL variables as parameters.

```
CALL proc1(v_empno, v_salary)
```

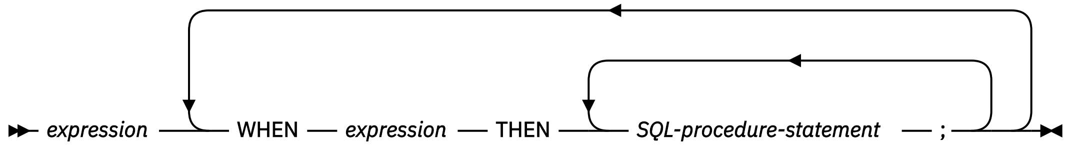
CASE statement

The CASE statement selects an execution path based on multiple conditions. A CASE statement operates in the same way as a CASE expression.

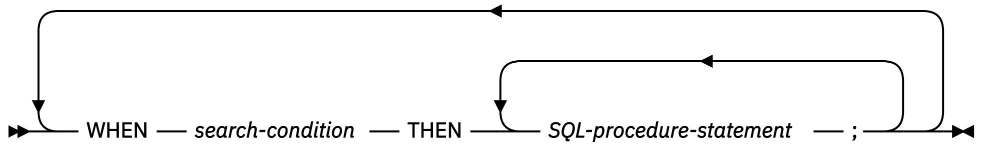
Syntax



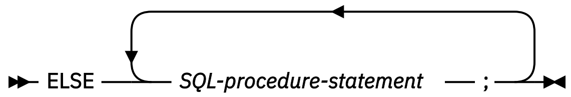
simple-when-clause:



searched-when-clause:



else-clause:



Description

label

Specifies the label for the CASE statement. The label name cannot be the same as the routine name, advanced trigger name, or another label within the same scope. For additional information, see "References to SQL labels" on page 2200.

CASE

Begins a *case-expression*.

simple-when-clause

The value of the *expression* prior to the first WHEN keyword is tested for equality with the value of the *expression* that follows each WHEN keyword. If the comparison is true, the statements in the associated THEN clause are executed and processing of the CASE statement ends. If the result is unknown or false, processing continues to the next comparison. If the result does not match any of the comparisons, and an ELSE clause is present, the statements in the ELSE clause are executed.

searched-when-clause

The *search-condition* following the WHEN keyword is evaluated. If it evaluates to true, the statements in the associated THEN clause are executed and processing of the CASE statement ends. If it evaluates to false, or unknown, the next *search-condition* is evaluated. If no *search-condition* evaluates to true and an ELSE clause is present, the statements in the ELSE clause are executed.

When *searched-when-clause* is used, *search-condition* cannot contain a *fullselect*.

SQL-procedure-statement

Specifies a statement to execute. See"SQL-procedure-statement (SQL PL)" on page 2202.

search-condition

Specifies a condition that is true, false, or unknown about a row or group of table data.

ELSE *SQL-procedure-statement*

If none of the conditions specified in the *simple-when-clause* or *searched-when-clause* are true, the statements specified in *SQL-procedure-statement* are executed.

If none of the conditions specified in the WHEN clauses are true and an ELSE is not specified, an error is issued when the statement executes, and the execution of the CASE statement is terminated.

END CASE

Ends a *case-statement*.

Examples

Example 1: Use a simple case statement WHEN clause to update column DEPTNAME in table DEPT, depending on the value of SQL variable *v_workdept*.

```
CASE v_workdept
 WHEN 'A00'
  THEN UPDATE DEPT SET
   DEPTNAME = 'DATA ACCESS 1';
 WHEN 'B01'
  THEN UPDATE DEPT SET
   DEPTNAME = 'DATA ACCESS 2';
 ELSE UPDATE DEPT SET
   DEPTNAME = 'DATA ACCESS 3';
END CASE
```

Example 2: Use a searched case statement WHEN clause to update column DEPTNAME in table DEPT, depending on the value of SQL variable *v_workdept*.

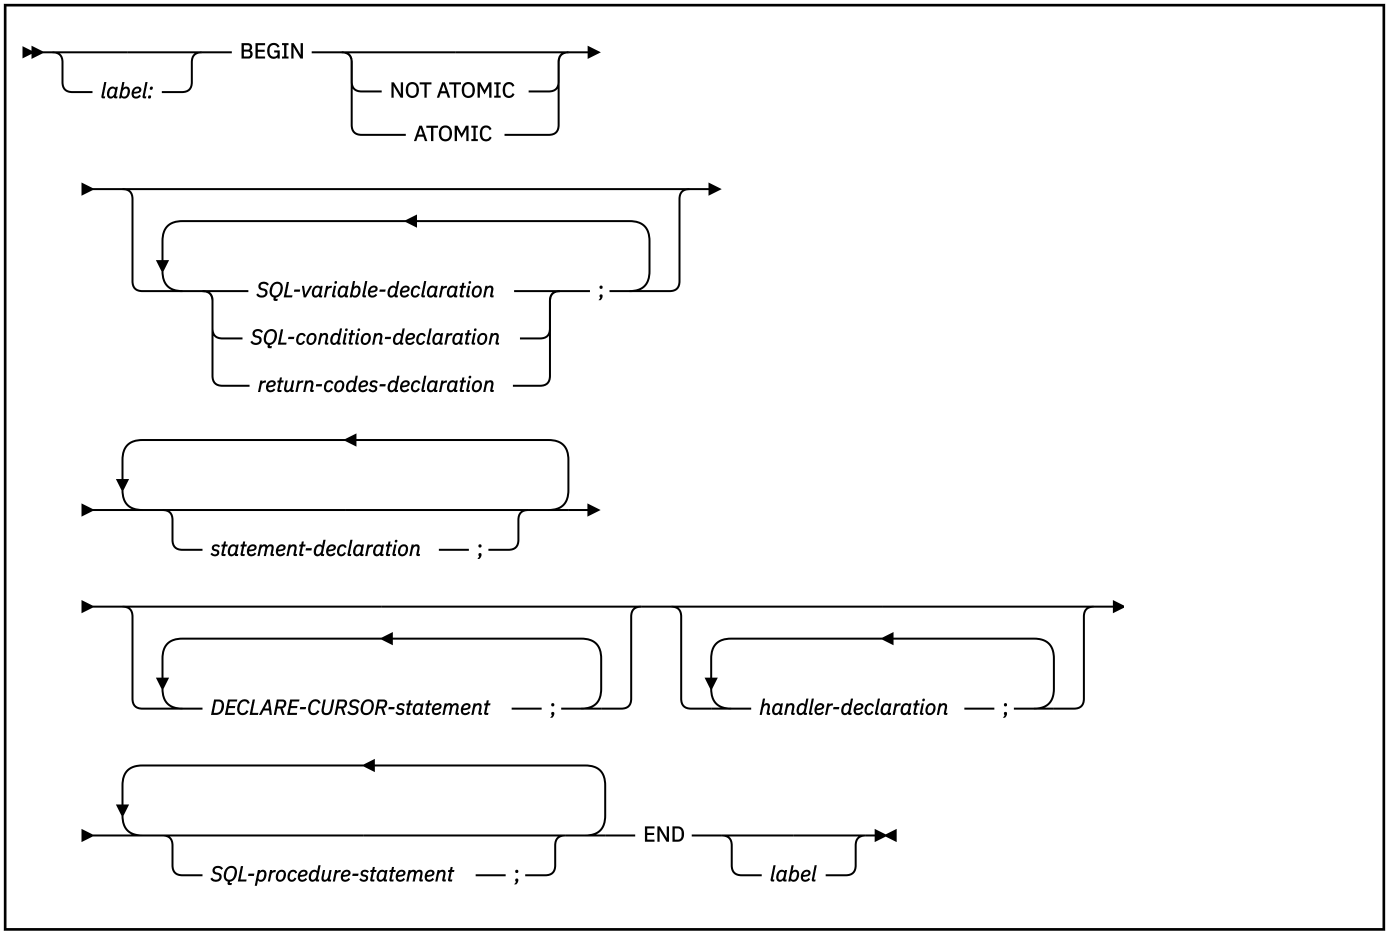
```
CASE
 WHEN v_workdept < 'B01'
  THEN UPDATE DEPT SET
   DEPTNAME = 'DATA ACCESS 1';
 WHEN v_workdept < 'C01'
  THEN UPDATE DEPT SET
   DEPTNAME = 'DATA ACCESS 2';
 ELSE UPDATE DEPT SET
```

```
    DEPTNAME = 'DATA ACCESS 3';
END CASE
```

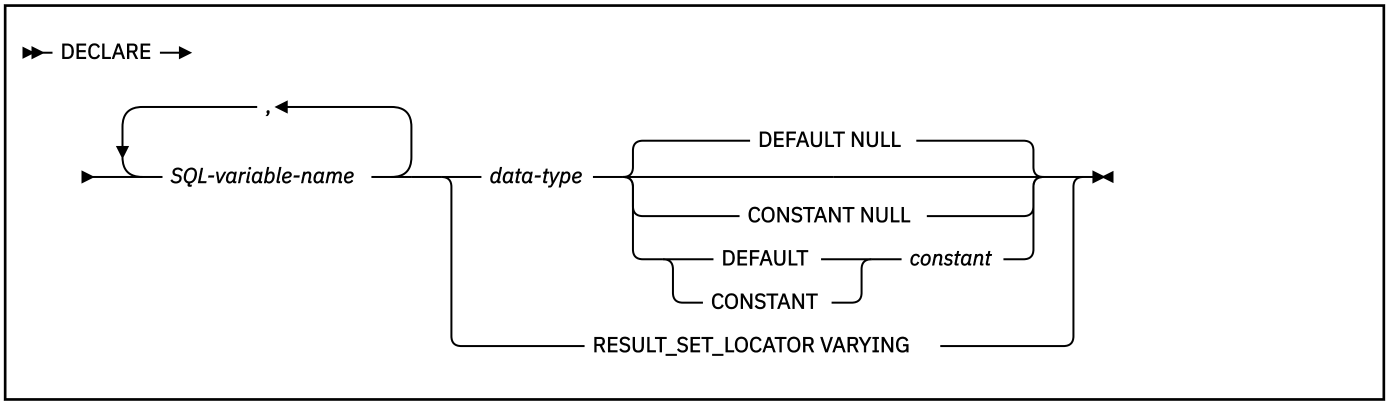
compound-statement

A compound statement groups other statements together in an SQL routine or advanced trigger. A compound statement allows the declaration of SQL variables, cursors, and condition handlers.

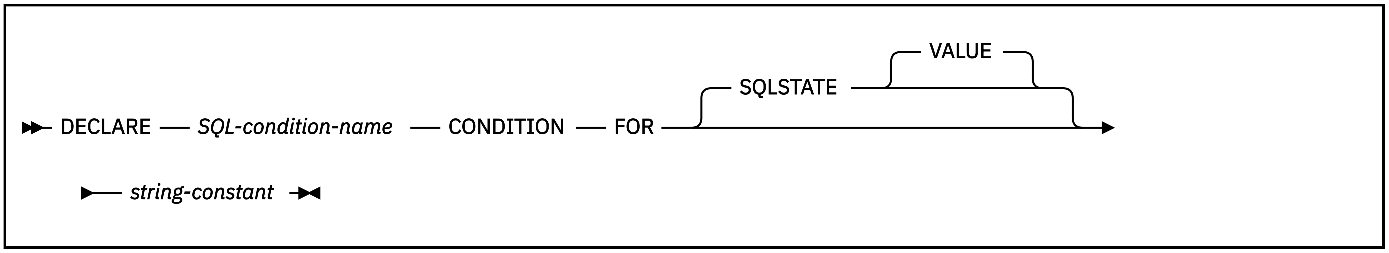
Syntax



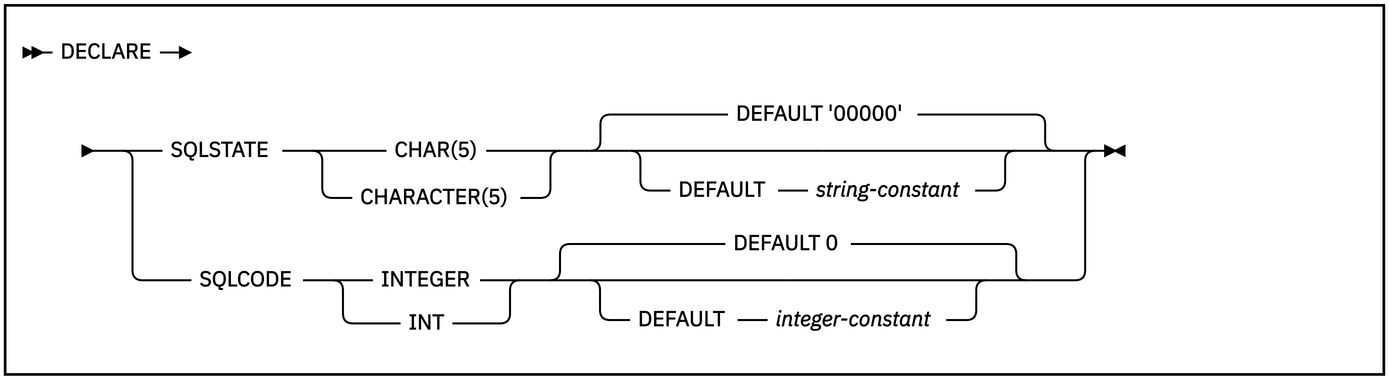
SQL-variable-declaration:



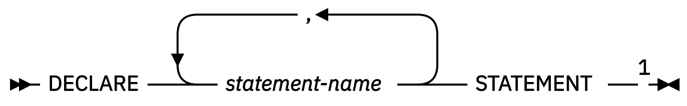
SQL-condition-declaration:



return-codes-declaration:



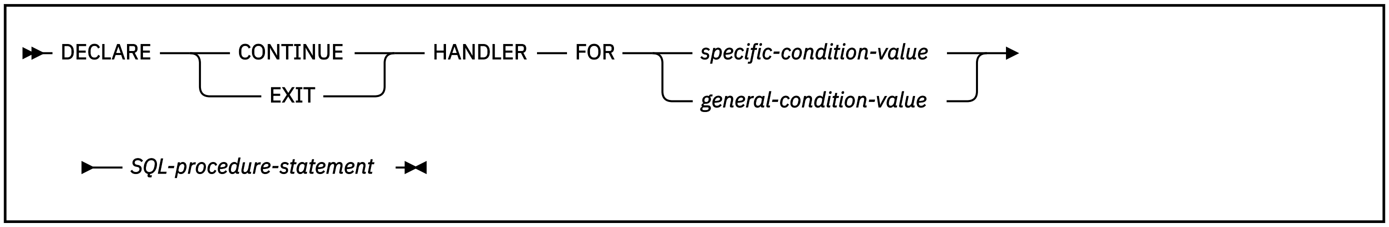
statement-declaration:



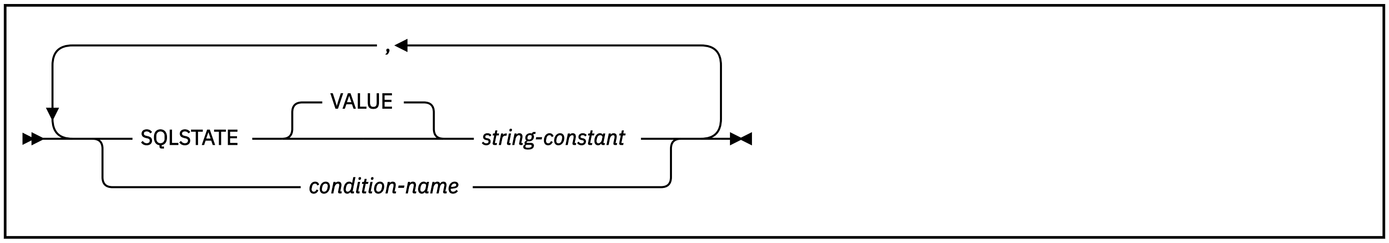
Notes:

[1] The statement is not allowed in an *SQL-routine-body* for an SQL function.

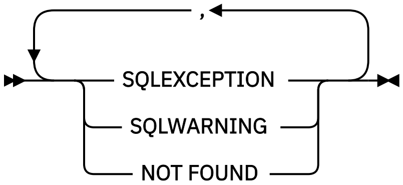
handler-declaration:



specific-condition-value:



general-condition-value:



Description

label

Specifies the label for the compound-statement. If the beginning label is specified, it can be used to qualify SQL variables declared in the compound statement and can also be specified as the target on a LEAVE statement. If the ending label is specified, it must be the same as beginning label. The label name cannot be the same as the routine name, trigger name, or another label within the same scope.

ATOMIC or NOT ATOMIC

Specifies whether an unhandled exception condition within a compound-statement causes that compound statement to be rolled back. The default for the outermost compound statement in an advanced trigger is ATOMIC; otherwise the default is NOT ATOMIC.

ATOMIC

ATOMIC indicates that an unhandled exception condition within the compound-statement causes the compound-statement to be rolled back. ATOMIC must not be specified in a compound statement in an SQL scalar function, in an SQL procedure, or in a compound statement that is nested within another compound statement that is defined as ATOMIC.

NOT ATOMIC

NOT ATOMIC indicates that an unhandled exception condition within the compound-statement does not cause the compound-statement to be rolled back. NOT ATOMIC must not be specified in the outermost compound statement of an advanced trigger.

SQL-variable-declaration

Declares a variable that is local to the compound statement.

SQL-variable-name

Defines the name of a variable. Db2 converts all SBCS SQL variable names that are not delimited to uppercase. *SQL-variable-name* must be unique within the compound statement in which is it declared, excluding any declarations in compound statements that are nested within that compound statement. *SQL-variable-name* must not be the same as a parameter name. See "References to SQL parameters and variables in SQL PL" on page 2198 for information about how SQL variable names are resolved when there are columns with the same name as an SQL variable involved in a statement, or when multiple SQL variables exist with the same name in the routine body.

SQL-variable-name can only be referenced within the compound statement in which it is declared, including any compound statement that is nested within that compound statement. If the compound statement where the variable is declared has a label, references to the variable name can be qualified with that label. For example, an SQL variable V that is declared in a compound statement that is labeled C can be referenced as C.V.

data-type

Specifies the data type and length of the variable. SQL variables follow the same rules for default lengths and maximum lengths as SQL routine parameters. See "CREATE FUNCTION (compiled SQL scalar)" on page 1423 for descriptions of SQL data types and lengths.

DEFAULT or CONSTANT

Specifies a value for the SQL variable when the compound statement in which it is declared is entered. If neither DEFAULT nor CONSTANT is specified, the default for the SQL variable is the null value. Only DEFAULT NULL can be explicitly specified if *array-type-name* is specified. Only DEFAULT NULL or CONSTANT NULL can be specified for an SQL variable with the XML data type.

DEFAULT
Defines the default for the SQL variable. The specified constant must represent a value that could be assigned to the variable in accordance with the rules of assignment as described in "Assignment and comparison" on page 143.

CONSTANT
Specifies that the SQL variable has a fixed value that cannot be changed. An SQL variable that is defined using CONSTANT cannot be used as the target of any assignment operation. The specified constant must represent a value that could be assigned to the variable in accordance with the rules of assignment as described in "Assignment and comparison" on page 143.

Variables that are named SQLCODE and SQLSTATE cannot be defined using CONSTANT.

NULL
Specifies NULL as the default for the SQL variable.

constant
Specifies a constant as the default for the SQL variable.

RESULT_SET_LOCATOR VARYING
Specifies the data type for a result set locator variable.

SQL-condition-declaration
Declares a condition name and corresponding SQLSTATE value.

SQL-condition-name
Specifies the name of the condition. The condition name must be unique within the compound statement in which it is declared, excluding any declarations that are in compound statements that are nested within that compound statement. A condition name can only be referenced within the compound statement in which it is declared, including any compound statements that are nested within that compound statement.

FOR SQLSTATE ***string-constant***
Specifies the SQLSTATE that is associated with the condition. The string must be specified as five characters enclosed in single quotes, and the SQLSTATE class (the first two characters) must not be '00'.

return-codes-declaration
Declares special variables named SQLSTATE and SQLCODE. These variables are automatically set to the SQLSTATE and SQLCODE values for the first condition in the diagnostics area after executing an SQL statement other than GET DIAGNOSTICS or an empty compound statement.

The SQLSTATE and SQLCODE SQL variables are only intended to be used as a means of obtaining the SQL return codes that resulted from processing the previous SQL statement other than GET DIAGNOSTICS. If there is any intention to use the SQLSTATE and SQLCODE values, save the values immediately to other SQL variables to avoid having the values replaced by the SQL return codes returned after executing the next SQL statement. If a handler is defined that handles an SQLSTATE, you can use an assignment statement to save that SQLSTATE (or the associated SQLCODE) value in another SQL variable, if the assignment is the first statement in the handler.

Assignment to these variables is not prohibited; however, it is not recommended. Assignment to these variables is ignored by condition handlers, and processing an assignment to these special variables causes the specified values for the assignment to be overlayed with the SQL return codes returned from executing the statement that does the assignment. The SQLSTATE and SQLCODE SQL variables cannot be set to NULL.

statement-declaration
Declares a list of one or more names that are local to the compound statement. A statement name cannot be the same as another statement name within the same compound statement.

DECLARE-CURSOR-statement
Declares a cursor in the procedure body. Each cursor must have a unique name within the routine. The cursor can only be referenced from within the compound statement in which it is declared, including any compound statements that are nested within that compound statement. Use an OPEN statement

to open the cursor, a FETCH statement to read a row using the cursor, and a CLOSE statement to close the cursor. If the cursor is intended for use as a result set cursor:

- Specify WITH RETURN when the cursor is declared
- Create the procedure using the DYNAMIC RESULT SETS clause with a non-zero value
- Do not specify a CLOSE statement for the cursor in the compound statement

For additional information about declaring a cursor, see "DECLARE CURSOR" on page 1814.

handler-declaration

Specifies a condition handler, an *SQL-procedure-statement* to execute when an exception or completion condition occurs in the compound-statement. The *SQL-procedure-statement* executes when a condition handler receives control.

A condition handler declaration cannot reference the same condition value or SQLSTATE value more than one time. It cannot reference an SQLSTATE value and a condition name that represent the same SQLSTATE value.

When two or more condition handlers are declared in a compound statement, no two condition handler declarations can specify the same:

- general condition category
- specific condition, either as an SQLSTATE value or as a condition name that represents the same value

A condition handler is active for the set of *SQL-procedure-statements* that follow the condition handler declarations within the compound statement in which the condition handler is declared, including any nested compound statements.

CONTINUE

Specifies that after the condition handler is activated and completes successfully, control is returned to the SQL statement that follows the statement that raised the condition. However, if the condition is an error condition and it was encountered while evaluating a search condition, as in a CASE, FOR, IF, REPEAT or WHILE statement, control returns to the statement that follows the corresponding END CASE, END FOR, END IF, END REPEAT, or END WHILE.

EXIT

Specifies that after the condition handler is activated and completes successfully, control is returned to the end of the compound statement that declared the condition handler.

The conditions that can cause the handler to gain control are:

SQLSTATE *string-constant*

Specifies that the handler is invoked when the specific SQLSTATE occurs. The first two characters of the SQLSTATE value must not be '00'.

SQL-condition-name

Specifies that the handler is invoked when the specific SQLSTATE that is associated with the condition name occurs. The *SQL-condition-name* must be declared within the compound statement that contains the handler declarations, or within a compound statement in which that compound statement is nested.

SQLEXCEPTION

Specifies that the handler is invoked when an SQLEXCEPTION occurs. An SQLEXCEPTION is an SQLSTATE in which the class code is a value other than '00', '01', or '02'. For more information on SQLSTATE values, see SQLSTATE values and common error codes (Db2 Codes).

SQLWARNING

Specifies that the handler is invoked when an SQLWARNING occurs. An SQLWARNING is an SQLSTATE value with a class code of '01'.

NOT FOUND

Specifies that the handler is invoked when a NOT FOUND condition occurs. NOT FOUND corresponds to an SQLSTATE value with a class code of '02'.

Notes

Unlike host variables, SQL variables are not preceded by colons when they are used in SQL statements.

Nesting compound statements: Compound statements can be nested. Nested compound statements can be used to scope variable definitions, condition names, condition handlers, and cursors to a subset of the statements in a routine. This can simplify the processing that is done for each SQL routine statement. Nested compound statements enable the use of a compound statement within the declaration of a condition handler.

The scope of a cursor: The scope of a cursor name is the compound statement in which it is declared, including any compound statements that are nested within that compound statement. A cursor name can only be referenced within the compound statement in which it is declared, including any compound statements that are nested within that compound statement.

Considerations for statement-name: The scope of a *statement-name* that is declared in a compound statement is the compound statement and any nested compound statements (unless the same *statement-name* is declared in a nested compound statement). If a *statement-name* is used in a DECLARE CURSOR statement or a PREPARE statement and has not been declared in the compound statement where it is used or any outer compound statements in which it is nested, the statement-name is assumed to be declared globally for the routine.

Condition handlers: Condition handlers in SQL routines and advanced triggers are similar to WHENEVER statements that are used in external SQL application programs. A condition handler can be defined to automatically get control when an exception, warning, or not found condition occurs. The body of a condition handler contains code that is executed when the condition handler is activated. A condition handler can be activated as the result of an exception, a warning, or a not found condition that is returned by Db2 for the processing of an SQL statement. Or the condition that activates the handler can be the result of a SIGNAL or RESIGNAL statement that is issued within the SQL routine or trigger body.

A condition handler is declared within a compound statement, and it is active for the set of *SQL-procedure-statements* that follow all of the condition handler declarations within the compound statement in which the condition handler is declared. For example, the scope of a condition handler declaration H is the list of *SQL-procedure-statements* that follow the condition handler declarations that are contained within the compound statement in which H appears. This means that the scope of H does not include the statements that are contained in the body of the condition handler H, implying that a condition handler cannot handle conditions that arise inside its own body. Similarly, for any two condition handlers H1 and H2 that are declared in the same compound statement, H1 will not handle conditions that arise in the body of H2, and H2 will not handle conditions that arise in the body of H1.

The declaration of a condition handler specifies the condition that activates it, the type of condition handler (CONTINUE or EXIT), and the handler action. The type of condition handler determines to where control is returned after the handler action successfully completes.

Condition handler activation: When a condition other than a successful completion occurs in the processing of *SQL-procedure-statement*, if a condition handler that could handle the condition is within scope, one such condition handler will be activated to process the condition.

In a routine with nested compound statements, condition handlers that could handle a specific condition might exist at several levels of the nested compound statements. The condition handler that is activated is a condition handler that is declared innermost to the scope in which the condition was encountered. If more than one condition handler at the nesting level could handle the condition, the condition handler that is activated is the most appropriate handler that is declared in that compound statement.

The most appropriate handler is the condition handler that most closely matches the SQLSTATE or the exception or completion condition. For a given compound statement, when both a specific handler for a condition and a general handler are declared that address the same condition, the specific handler takes precedence over the general handler.

For example, if the innermost compound statement declares a specific handler for SQLSTATE '22001', as well as a general handler for SQLEXCEPTION, the specific handler for SQLSTATE '22001' is the most appropriate handler when SQLSTATE '22001' is encountered. In this case, the specific handler is activated.

When a condition handler is activated, the condition handler action is executed. If the handler action completes successfully or with an unhandled warning, the diagnostics area is cleared, and the type of the condition handler (CONTINUE or EXIT handler) determines to where control is returned. Additionally, the SQLSTATE and SQLCODE SQL variables are cleared when a handler completes successfully or with an unhandled warning.

If the handler action does not complete successfully and an appropriate handler exists for the condition that is encountered in the handler action, that condition handler is activated. Otherwise, the condition that is encountered within the condition handler is unhandled.

Unhandled conditions: If a condition is encountered and an appropriate handler does not exist for that condition, the condition is unhandled.

- If the unhandled condition is an exception, the SQL routine or advanced trigger that contains the failing statement is terminated with an unhandled exception condition.
- If the unhandled condition is a warning or is a not found condition, processing continues with the next statement. Note that the processing of the next SQL statement will cause information about the unhandled condition in the diagnostics area to be overwritten, and evidence of the unhandled condition will no longer exist.

  If an SQL routine or advanced trigger completes with an unhandled warning or not found condition, the condition is returned to the invoking statement. If a basic trigger completes with an unhandled warning or not found condition, the condition is not returned to the invoking statement.

Considerations for using SIGNAL and RESIGNAL statements with nested compound statements: If an *SQL-procedure-statement* that is specified in the condition handler is either a SIGNAL or RESIGNAL statement with an exception SQLSTATE, the compound statement terminates with the specified exception. This happens even when this condition handler or another condition handler in the same compound statement specifies CONTINUE, since these condition handlers are not in the scope of this exception. If a compound statement is nested in another compound statement, condition handlers in the higher level compound statement can handle the exception because those condition handlers are within the scope of the exception.

SQLSTATE and SQLCODE variables in SQL routines and advanced triggers: To help debug your SQL routines and advanced triggers, you might find it useful to check the SQLSTATE and SQLCODE value after executing a statement. An SQLCODE or SQLSTATE variable can be declared and subsequently referenced in an SQL routine or advanced trigger. You could insert the value of the SQLCODE and SQLSTATE into a table at various points in the SQL routine or advanced trigger, or return the SQLCODE and SQLSTATE values in a diagnostics string as an OUT parameter for an SQL procedure. To use the SQLCODE and SQLSTATE values, you must declare the following SQL variables in the SQL routine or advanced trigger body:

When you reference the SQLCODE or SQLSTATE variables in an SQL routine or advanced trigger, Db2 sets the value of SQLCODE to 0 and SQLSTATE to '00000' for the subsequent statement. You can also use CONTINUE condition handlers to assign the value of the SQLSTATE and SQLCODE variables to variables in your SQL routine or advanced trigger body. You can then use these SQL variables to control your routine or trigger logic, or pass the value back as an output parameter. In the following example, the SQL routine returns control to the statement following each SQL statement with the SQLCODE set in a SQL variable called RETCODE:

```
DECLARE SQLCODE INTEGER DEFAULT 0;
DECLARE retcode INTEGER DEFAULT 0;
DECLARE CONTINUE HANDLER FOR SQLEXCEPTION SET retcode = SQLCODE;
DECLARE CONTINUE HANDLER FOR SQLWARNING SET retcode = SQLCODE;
DECLARE CONTINUE HANDLER FOR NOT FOUND SET retcode = SQLCODE;
```

The compound statement itself does not affect the SQLSTATE and SQLCODE SQL variables. However, SQL statements contained within the compound statement can affect the SQLSTATE and SQLCODE SQL variables. At the end of the compound statement, the SQLSTATE and SQLCODE SQL variables reflect the result of the last SQL statement executed within the compound statement that caused a change to the SQLSTATE and SQLCODE SQL variables. If the SQLSTATE and SQLCODE SQL variables were not changed within the compound statement, they contain the same values as when the compound statement was entered.

Null values in SQL parameters and SQL variables: If the value of an SQL parameter or SQL variable is null and it is used in an SQL statement that does not allow an indicator variable, an error is returned.

Effect on open cursors: At the end of the compound statement, all open cursors that are declared in that compound statement, except cursors that are used to return result sets, are closed.

Atomic processing of a compound statement: Atomic processing is not supported for a compound statement. If atomic behavior is needed for a block of code in a compound statement, set a savepoint before the nested compound statement is entered. This will allow changes to be undone with a ROLLBACK TO SAVEPOINT statement.

Examples

Example 1: Create a procedure body with a compound statement that performs the following actions:

1. Declares SQL variables.
2. Declares a cursor to return the salary of employees in a department determined by an IN parameter.
3. Declares an EXIT handler for the condition NOT FOUND (end of file). The SQL procedure statement of the handler assigns the value 6666 to the OUT parameter *medianSalary*.
4. Selects the number of employees in the given department into the SQL variable *v_numRecords*.
5. Fetches rows from the cursor in a WHILE loop until the salary records for 50% + 1 of the employees in the department have been retrieved.
6. Returns the median salary.

```
CREATE PROCEDURE DEPT_MEDIAN
   (IN deptNumber SMALLINT,
    OUT medianSalary DOUBLE)
   LANGUAGE SQL
   BEGIN
     DECLARE v_numRecords INTEGER DEFAULT 1;
     DECLARE v_counter INTEGER DEFAULT 0;
     DECLARE c1 CURSOR FOR
       SELECT salary FROM staff
         WHERE DEPT = deptNumber
         ORDER BY salary;
     DECLARE EXIT HANDLER FOR NOT FOUND
       SET medianSalary = 6666;

     /* initialize OUT parameter */
     SET medianSalary = 0;
     SELECT COUNT(*) INTO v_numRecords FROM staff
       WHERE DEPT = deptNumber;
     OPEN c1;
     WHILE v_counter < (v_numRecords / 2 + 1) DO
       FETCH c1 INTO medianSalary;
       SET v_counter = v_counter + 1;
     END WHILE;
     CLOSE c1;
   END
```

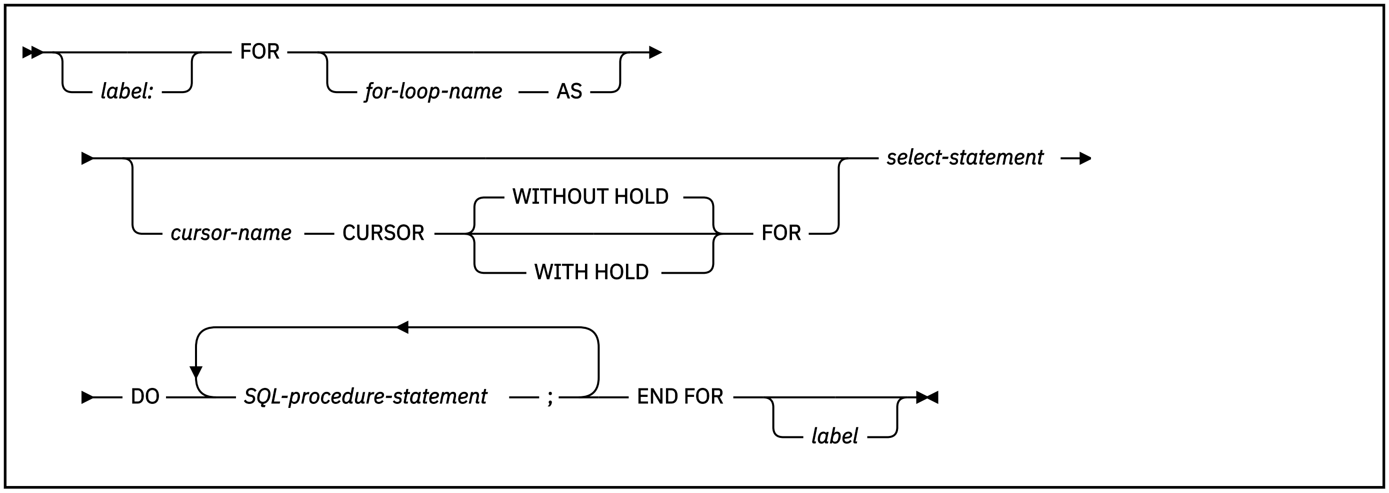
Example 2: Define an exit handler for any error, warning, or case of end of data. When this procedure is invoked successfully, the value 45000 is returned for the output parameter:

```
CREATE PROCEDURE JMBLIB.PROCL(OUT MEDIANSALARY INT)
  LANGUAGE SQL
  BEGIN
   DECLARE CHAR1 CHAR;
   DECLARE C1 CURSOR FOR SELECT *
     FROM SYSIBM.SYSDUMMY1;
   DECLARE EXIT HANDLER FOR NOT FOUND,
        SQLEXCEPTION,
        SQLWARNING
    RETURN;
   OPEN C1;
   FETCH C1 INTO CHAR1;
   SET MEDIANSALARY = 45000;
   FETCH C1 INTO CHAR1;
   SET MEDIANSALARY = 50000;
  END
```

FOR statement

The FOR statement executes a statement for each row of a table. An implicit compound statement is generated to implement the FOR statement.

Syntax



Description

label

Specifies the label for the FOR statement. If the ending label is specified, it must be the same as the beginning label. The label name cannot be the same as the routine name, advanced trigger name, or another label within the same scope. For more information, see "References to SQL labels" on page 2200.

for-loop-name

Specifies the label for the implicit compound statement that is generated to implement the FOR statement. *for-loop-name* follows the rules for the label of a compound statement except that it cannot be used with an ITERATE, GOTO, or LEAVE statement within the FOR statement. *for-loop-name* must not be the same as any label within the same scope.

for-loop-name can be used to qualify generated SQL variables that correspond to the columns that are returned by *select-statement*.

cursor-name

Names a cursor that is generated to select rows from the result table of *select-statement*. If *cursor-name* is not specified, a unique cursor name is generated.

cursor-name cannot be referenced outside of the FOR statement and cannot be specified on an OPEN, FETCH, or CLOSE statement.

WITH HOLD or WITHOUT HOLD

Specifies whether the cursor should be prevented from being closed as a consequence of a commit operation.

WITHOUT HOLD

Specifies that the cursor is not prevented from being closed as a consequence of a commit operation. WITHOUT HOLD is the default.

WITH HOLD

Specifies that the cursor should not be closed as a consequence of a commit operation. A cursor that is declared using the WITH HOLD clause is implicitly closed at commit time only if the connection that is associated with the cursor is ended during the commit operation. For more information, see "DECLARE CURSOR" on page 1814.

select-statement
Specifies the select statement of the cursor. Each expression in the SELECT list must have a name. If an expression is not a simple column name, the AS clause must be used to name the expression. If the AS clause is specified, that name is used for the variable and must be unique.

select-statement must not include a *values-clause*.

The SELECT list must not include an untyped array value.

SQL-procedure-statement
Specifies the SQL statements to be executed for each row of the table. The SQL statements must not include an OPEN, FETCH, or CLOSE statement that specifies the cursor name of the FOR statement.

Notes

FOR statement rules: The FOR statement executes one or multiple statements for each row in the result table of the cursor. The cursor is defined by specifying a SELECT list that describes the columns and rows selected. The statements within the FOR statement are executed for each row selected.

The SELECT list must consist of unique column names, and the objects referenced in the *select-statement* must exist at the current server when the routine or trigger is created. If the FOR statement is contained in a routine or trigger that is defined with the WITH EXPLAIN attribute, the PLAN_TABLE must exist when the routine or trigger is created.

The cursor specified in a FOR statement cannot be referenced outside the FOR statement and cannot be specified on an OPEN, FETCH, or CLOSE statement.

Handler warning: Handlers can be used to handle errors that might occur on the open of the cursor or fetch of a row using the cursor in the FOR statement. Handlers defined to handle these open or fetch conditions should not be CONTINUE handlers as they might cause the FOR statement to loop indefinitely.

Examples

In the following example, the FOR statement is used to specify a cursor that selects three columns from the employee table. For every row selected, SQL variable *fullname* is set to the last name followed by a comma, the first name, a blank, and the middle initial. Each value for *fullname* is inserted into table TNAMES.

```
BEGIN
  DECLARE fullname CHAR(40);
  FOR v1 AS
      c1 CURSOR FOR
   SELECT firstname, midinit, lastname FROM employee
    DO
      SET fullname =
          lastname CONCAT ', '
                   CONCAT firstname
                   CONCAT ' '
                   CONCAT midinit;
      INSERT INTO TNAMES VALUES ( fullname );
  END FOR;
END;
```

GET DIAGNOSTICS statement

The GET DIAGNOSTICS statement obtains information about the previous SQL statement that was executed.

See "GET DIAGNOSTICS" on page 1944.

When you need to specify a variable in a GET DIAGNOSTICS statement that is used within an SQL routine, you would use either *SQL-variable-name* or *SQL-parameter-name*. In an embedded GET DIAGNOSTICS statement, you would use a *host-variable*. You can replace the instances of *host-variable* in the description of "GET DIAGNOSTICS" on page 1944 with *SQL-variable-name* or *SQL-parameter-name*.

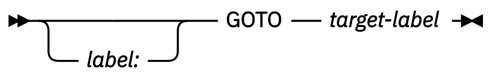
Effects of the statement: The GET DIAGNOSTICS statement does not change the contents of the diagnostics area except for DB2_GET_DIAGNOSTICS_DIAGNOSTICS.

Considerations for the SQLSTATE and SQLCODE SQL variables: The GET DIAGNOSTICS statement does not change the value of the SQLSTATE and SQLCODE SQL variables.

The stacked diagnostics area: The stacked diagnostics area is only available within a handler in a native SQL procedure and non-inline SQL functions.

GOTO statement

Syntax



Description

label

Specifies the label for the GOTO statement. The label name cannot be the same as the routine name or advanced trigger name in which the label is used or another label in the same scope.

target-label

Specifies a label of the statement where processing is to continue. *target-label* must be defined as a label for an SQL procedure statement. The target label must be accessible to the GOTO statement as defined in "References to SQL labels" on page 2200, subject to the following restrictions:

- If the GOTO statement is in a condition handler, *target-label* must be defined in that condition handler.
- If the GOTO statement is not defined in a condition handler, *target-label* must not be defined in a condition handler.

Notes

Using a GOTO statement: It is recommended that the GOTO statement be used sparingly. This statement interferes with the normal sequence of processing SQL statements, thus making a routine more difficult to read and maintain. Before using a GOTO statement, determine whether another statement, such as IF or LEAVE, can be used in place, to eliminate the need for a GOTO statement.

Effect on open cursors: When a GOTO statement transfers control out of a compound statement, all open cursors that are declared in the compound statement that contains the GOTO statement are closed, except cursors that are used to return result sets.

Examples

Example 1: In the following procedure, the GOTO statement branches outside of the current compound statement to a higher level:

```
CREATE PROCEDURE TESTGOTO5 ( )
P1: BEGIN
   DECLARE I ,A INTEGER;
     SET I = 1;
  LAB1: SET A = 1;
    BEGIN
      LAB2: SET A = 2;
         BEGIN
           SET I = I+1;
           IF I<3 THEN GOTO LAB1;
           END IF;
         END;
    END;
END P1
```

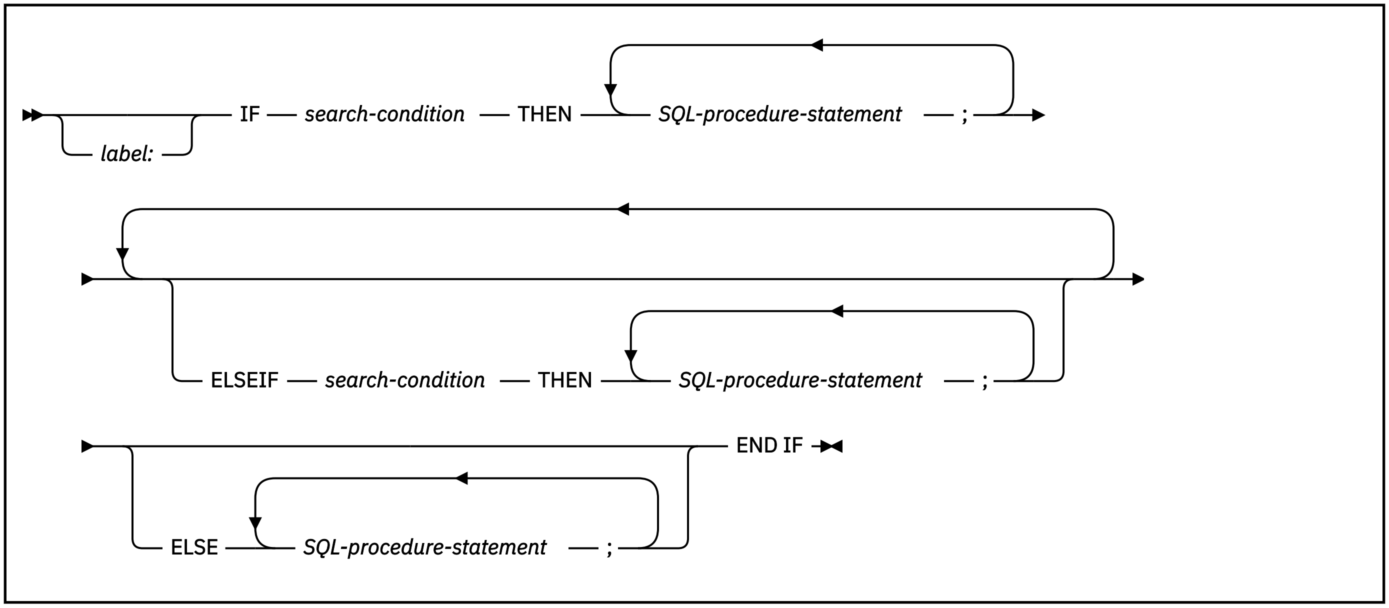
Example 2: In the following example, cursors are declared at multiple levels. The GOTO statement that specified TargLabel as the target label, results in the closing of cursors C1, C2, and C3. This is because cursors C1, C2, and C3 are all declared directly or indirectly in the compound statement with the label L1. The GOTO statement causes control to transfer out of the compound statement with label L1, so the cursors that are defined within that compound statement (at any level) are closed.

```
L0: BEGIN
      DECLARE CURSOR C0 ...
  ...
  TARGLABEL: ...
  ...
  L1: BEGIN
        DECLARE CURSOR C1 ...
        ...
      L2: BEGIN
            DECLARE CURSOR C2 ...
            ...
            GOTO TARGLABEL;
            ...
          L3: BEGIN
               DECALUE CURSOR C3 ...
            ...
          END L3;
      END L2;
   END L1;
END L0
```

IF statement

The IF statement executes different sets of SQL statements based on the result of search conditions.

Syntax



Description

label

Specifies the label for the IF statement. The label name cannot be the same as the routine name, advanced trigger name, or another label name within the same scope. For additional information, see "References to SQL labels" on page 2200.

search-condition

Specifies the *search-condition* for which an SQL statement should be executed. If the condition is unknown or false, processing continues to the next search condition, until either a condition is true or processing reaches the ELSE clause.

SQL-procedure-statement

Specifies an SQL statement to be executed if the preceding *search-condition* is true. See "SQL-procedure-statement (SQL PL)" on page 2202.

Examples

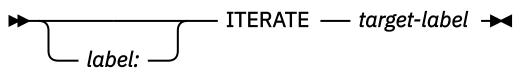
Assign a value to the SQL variable *new_salary* based on the value of SQL variable rating.

```
IF rating = 1
 THEN SET new_salary =
  new_salary + (new_salary * .10);
 ELSEIF rating = 2
  THEN SET new_salary =
   new_salary + (new_salary * .05);
 ELSE SET new_salary =
  new_salary + (new_salary * .02);
END IF;
```

ITERATE statement

The ITERATE statement causes the flow of control to return to the beginning of a labeled loop.

Syntax



Description

label

Specifies the label for the ITERATE statement. The label name cannot be the same as the routine name, advanced trigger name, or another label within the same scope. For additional information, see "References to SQL labels" on page 2200.

target-label

Specifies the label of the FOR, LOOP, REPEAT, or WHILE statement to which the flow of control is passed. *target-label* must be defined as a label for a FOR, LOOP, REPEAT, or WHILE statement. The ITERATE statement must be in that FOR, LOOP, REPEAT, or WHILE statement, or in the block of code that is directly or indirectly nested within that statement, subject to the following restrictions:

- If the ITERATE statement is in a condition handler, *target-label* must be defined in that condition handler.
- If the ITERATE statement is not in a condition handler, *target-label* must not be defined in a condition handler.

Examples

Example 1: This example uses a cursor to return information for a new department. If the not_found condition handler is invoked, the flow of control passes out of the loop. If the value of *v_dept* is 'D11', an ITERATE statement causes the flow of control to be passed back to the top of the LOOP statement. Otherwise, a new row is inserted into the table.

```
CREATE PROCEDURE ITERATOR ()
  LANGUAGE SQL
  MODIFIES SQL DATA
  BEGIN
```

```
    DECLARE v_dept CHAR(3);
    DECLARE v_deptname VARCHAR(29);
    DECLARE v_admdept CHAR(3);
    DECLARE at_end INTEGER DEFAULT 0;
    DECLARE not_found CONDITION FOR SQLSTATE '02000';
    DECLARE c1 CURSOR FOR
      SELECT deptno,deptname,admrdept
        FROM department
        ORDER BY deptno;
    DECLARE CONTINUE HANDLER FOR not_found
      SET at_end = 1;
    OPEN c1;
    ins_loop:
    LOOP
      FETCH c1 INTO v_dept, v_deptname, v_admdept;
      IF at_end = 1 THEN
        LEAVE ins_loop;
      ELSEIF v_dept = 'D11' THEN
        ITERATE ins_loop;
      END IF;
      INSERT INTO department (deptno,deptname,admrdept)
                       VALUES('NEW', v_deptname, v_admdept);
    END LOOP;
    CLOSE c1;
  END
```

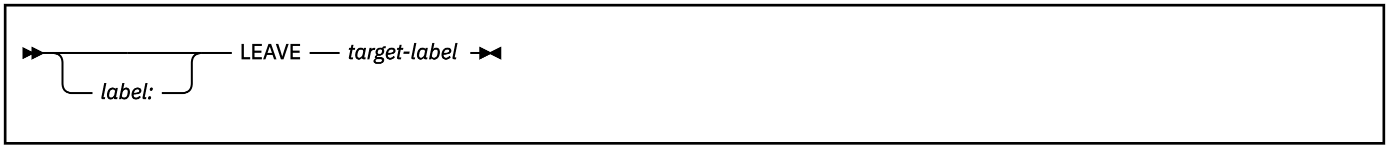
Example 2: An ITERATE statement can be issued from a nested block to cause that flow of control to return to the beginning of a loop at a higher level. In the following example, the ITERATE statement within the LAB2 compound statement causes the flow of control to return to the beginning of the LAB1 LOOP statement:

```
LAB1: LOOP
   SET A = 0;
   LAB2: BEGIN
     ...
     LAB3: BEGIN
        ...
        ITERATE LAB1;  --    Multilevel ITERATE
        ...
     END LAB3;
     ...
     ITERATE LAB1;   --  Multilevel ITERATE
     ...
   END LAB2;
END LOOP;S
```

LEAVE statement

The LEAVE statement transfers program control out of a FOR, LOOP, REPEAT, WHILE, or compound statement.

Syntax



Description

label

Specifies the label for the LEAVE statement. The label name cannot be the same as the routine name, advanced trigger name, or the same as another label that is within the same scope. For additional information, see "References to SQL labels" on page 2200.

target-label

Specifies the label of the compound, FOR, LOOP, REPEAT, or WHILE statement to exit. *target-label* must be defined as a label for a compound, FOR, LOOP, REPEAT, or WHILE statement, or in a block of code that is directly or indirectly nested within that statement, subject to the following rules:

- If the LEAVE statement is in a condition handler, *target-label* must be defined in that condition handler.
- If the LEAVE statement is not in a condition handler, *target-label* must not be defined in a condition handler.

Notes

Effect on open cursors: When a LEAVE statement transfers control out of a compound statement, all open cursors in the compound statement, except cursors that are used to return result sets, are closed.

Examples

Example 1: The example contains a loop that fetches data for cursor c1. If the value of SQL variable *at_end* is not zero, the LEAVE statement transfers control out of the loop.

```
CREATE PROCEDURE LEAVE_LOOP (OUT COUNTER INTEGER)
  LANGUAGE SQL
  BEGIN
    DECLARE v_counter INTEGER;
    DECLARE v_firstnme VARCHAR(12);
    DECLARE v_midinit CHAR(1);
    DECLARE v_lastname VARCHAR(15);
    DECLARE at_end SMALLINT DEFAULT 0;
    DECLARE not_found CONDITION FOR SQLSTATE '02000';
    DECLARE c1 CURSOR FOR
      SELECT firstnme, midinit, lastname
      FROM employee;
    DECLARE CONTINUE HANDLER FOR not_found
      SET at_end = 1;
    SET v_counter = 0;
    OPEN c1;
   fetch_loop:
    LOOP
      FETCH c1 INTO v_firstnme, v_midinit, v_lastname;
      IF at_end <> 0 THEN
       LEAVE fetch_loop;
      END IF;
      SET v_counter = v_counter + 1;
    END LOOP fetch_loop;
    SET counter = v_counter;
    CLOSE c1;
  END
```

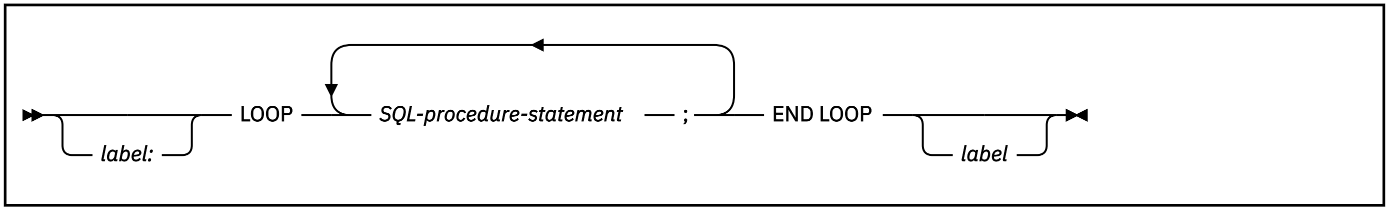
Example 2: A LEAVE statement can be issued from a nested block to leave a statement at a higher level. In the following example, the LEAVE statement within the LAB2 compound statement causes the LAB1 LOOP statement to terminate:

```
LAB1: LOOP
    ...
    LAB2: BEGIN
     SET A = 0;
     ...
     LAB3: BEGIN
        ...
        LEAVE LAB1;  --    Multilevel LEAVE
        ...
     END LAB3;
     ...
     LEAVE LAB1;   --  Multilevel LEAVE
     ...
   END LAB2;
END LOOP;S
```

LOOP statement

The LOOP statement executes a statement or group of statements multiple times.

Syntax



Description

label

Specifies the label for the LOOP statement. If the ending label is specified, a matching beginning label must be specified. A label name cannot be the same as the routine name, advanced trigger name, or another label within the same scope. For additional information, see "References to SQL labels" on page 2200.

SQL-procedure-statement

Specifies an SQL statement to be executed in the loop. The statement must be one of the statements listed under "SQL-procedure-statement (SQL PL)" on page 2202.

Notes

Considerations for the diagnostics area: At the beginning of the first iteration of the LOOP statement, and with every subsequent iteration, the diagnostics area is cleared.

Considerations for the SQLSTATE and SQLCODE SQL variables: Prior to executing the first SQL-procedure-statement within that LOOP statement, the SQLSTATE and SQLCODE values reflect the last values that were set prior to the LOOP statement. If the loop is terminated with a GOTO or a LEAVE statement, the SQLSTATE and SQLCODE values reflect successful completion of that statement. When the LOOP statement iterates, the SQLSTATE and SQLCODE values reflect the result of the last SQL statement that is executed within the LOOP statement.

Examples

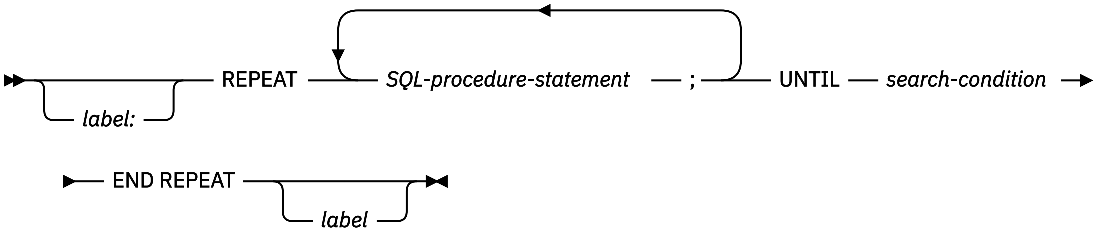
This procedure uses a LOOP statement to fetch values from the employee table. Each time the loop iterates, the OUT parameter counter is incremented and the value of *v_midinit* is checked to ensure that the value is not a single space (' '). If *v_midinit* is a single space, the LEAVE statement passes the flow of control outside of the loop.

```
CREATE PROCEDURE LOOP_UNTIL_SPACE(OUT counter INTEGER)
   LANGUAGE SQL
   BEGIN
      DECLARE v_counter INTEGER DEFAULT 0;
      DECLARE v_firstnme VARCHAR(12);
      DECLARE v_midinit CHAR(1);
      DECLARE v_lastname VARCHAR(15);
      DECLARE c1 CURSOR FOR
         SELECT firstnme, midinit, lastname
           FROM employee;
      DECLARE EXIT HANDLER FOR NOT FOUND
         SET counter = -1;
      OPEN c1;
      fetch_loop:
      LOOP
        FETCH c1 INTO v_firstnme, v_midinit, v_lastname;
        IF v_midinit = ' ' THEN
           LEAVE fetch_loop;
        END IF;
        SET v_counter = v_counter + 1;
      END LOOP fetch_loop;
      SET counter = v_counter;
      CLOSE c1;
   END
```

REPEAT statement

The REPEAT statement executes a statement or group of statements until a search condition is true.

Syntax



Description

label

Specifies the label for the REPEAT statement. If an ending label is specified, a matching beginning label must be specified. A label name cannot be the same as the routine name, advanced trigger name, or another label within the same scope. For additional information, see "References to SQL labels" on page 2200.

SQL-procedure-statement

Specifies an SQL statement to be executed within the REPEAT loop. The statement must be one of the statements listed under "SQL-procedure-statement (SQL PL)" on page 2202.

search-condition

Specifies a condition that is evaluated after each execution of the REPEAT loop. If the condition is true, the REPEAT loop will exit. If the condition is unknown or false, the looping continues.

Notes

Considerations for the diagnostics area: At the beginning of the first iteration of the REPEAT statement, and with every subsequent iteration, the diagnostics area is cleared.

Considerations for the SQLSTATE and SQLCODE SQL variables: At the beginning of the first iteration of the REPEAT statement, the SQLSTATE and SQLCODE values reflect the values that were set prior to the REPEAT statement. At the beginning of iterations 2 through *n* of the REPEAT statement, the SQLSTATE and SQLCODE SQL values reflect the result of evaluating the search condition in the UNTIL clause of that REPEAT. If the loop is terminated with a GOTO, ITERATE, or LEAVE statement, the SQLSTATE and SQLCODE values reflect the successful completion of that statement. Otherwise, after the END REPEAT of the REPEAT statement completes, the SQLSTATE and SQLCODE reflect the result of evaluating the search condition in the UNTIL clause of that REPEAT statement.

Examples

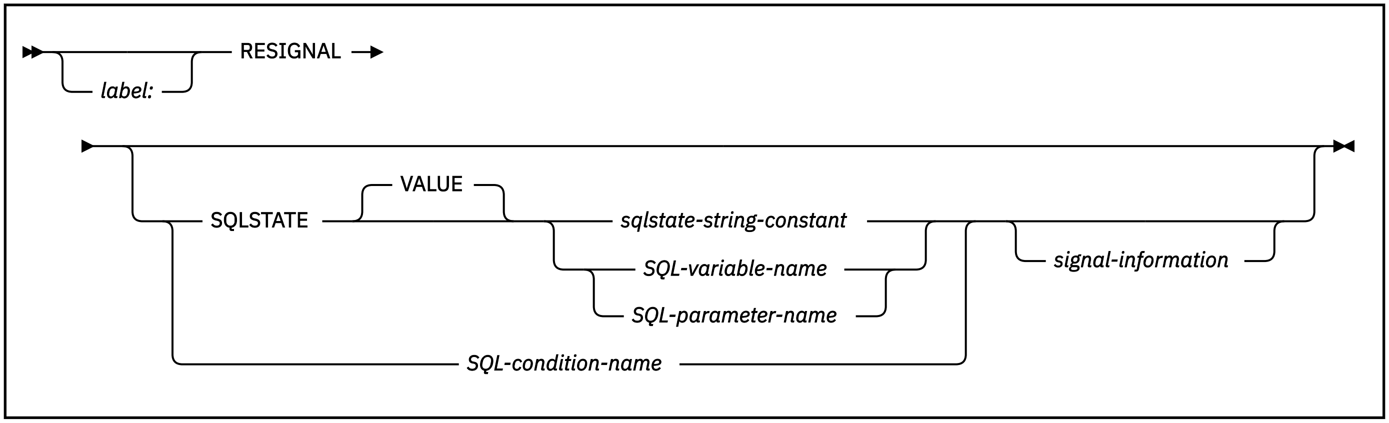
Use a REPEAT statement to fetch rows from a table.

```
fetch_loop:
REPEAT
 FETCH c1 INTO
  v_firstnme, v_midinit, v_lastname;
UNTIL
    SQLCODE <> 0
END REPEAT fetch_loop
```

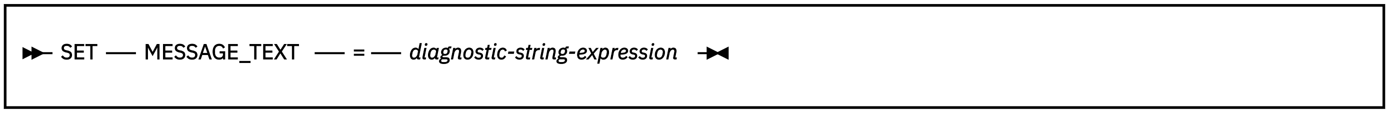
RESIGNAL statement

The RESIGNAL statement is used within a condition handler to resignal the condition that activated the handler, or to raise an alternate condition so that it can be processed at a higher level. It causes an exception, warning, or not found condition to be returned along with optional message text.

Syntax



signal-information:



Description

label
Specifies the label for the RESIGNAL statement. A label name cannot be the same as the routine name, advanced trigger name, or another label within the same scope. For additional information, see "References to SQL labels" on page 2200.

SQLSTATE VALUE
Specifies the SQLSTATE that will be returned. Any valid SQLSTATE value can be used. It must be a character string constant with exactly five characters that follow the rules for SQLSTATE values:

- Each character must be from the set of digits ('0' through '9') or non-accented upper case letter ('A' through 'Z').
- The SQLSTATE class (the first two characters) cannot be '00' because it represents successful completion.

If the SQLSTATE does not conform to these rules, an error occurs.

sqlstate-string-constant
A character string constant with an actual length of five bytes that is a valid SQLSTATE value.

SQL-variable-name* or *SQL-parameter-name
Specifies an SQL variable or SQL parameter that is defined for the routine.

SQL-variable-name
Specifies an SQL variable that is declared within the *compound-statement* that contains the RESIGNAL statement or within a compound statement in which that compound statement is nested. *SQL-variable-name* must be defined as CHAR or VARCHAR data type with an actual length of five bytes, must not be null, and must contain a valid SQLSTATE value.

SQL_parameter-name
Specifies an SQL parameter that is defined for the routine that contains the SQLSTATE value. The SQL parameter must be defined as CHAR or VARCHAR data type with an actual length of five bytes, must not be null, and must contain a valid SQLSTATE value.

SQL-condition-name

Specifies the name of the condition that will be returned. *SQL-condition-name* must be declared within the *compound-statement* that contains the RESIGNAL statement, or within a compound statement in which that compound statement is nested.

SET MESSAGE_TEXT

Specifies a string that describes the error or warning. The string is returned in the SQLERRMC field of the SQLCA or with the GET DIAGNOSTICS statement.

diagnostic-string-expression

An expression with a data type of CHAR or VARCHAR that returns a character string of up to 1000 bytes that describes the error or warning condition. For information on how to obtain the complete message text, see "GET DIAGNOSTICS" on page 1944.

Notes

While any valid SQLSTATE value can be used in the RESIGNAL statement, programmers should define new SQLSTATEs based on ranges reserved for applications. This practice prevents the unintentional use of an SQLSTATE value that might be defined by the database manager in a future release.

If the SQLSTATE or condition indicates that an exception is signaled (SQLSTATE class other than '01' or '02'):

- If a condition handler exists in the same compound statement as the RESIGNAL statement, and the compound statement contains a condition handler for SQLEXCEPTION or the specified SQLSTATE or condition, the exception is handled and control is transferred to that condition handler.
- If the compound statement is nested and an outer level compound statement has a condition handler for SQLEXCEPTION or the specified SQLSTATE or condition, the exception is handled and control is transferred to that condition handler.
- Otherwise, the exception is not handled and control is immediately returned to the end of the compound statement.

If an SQLSTATE or a condition indicates that a warning or a not found condition is signaled:

- If a condition handler exists in the same compound statement as the RESIGNAL statement, and the compound statement contains a condition handler for SQLWARNING, NOT FOUND, or the specified SQLSTATE or condition, the warning or not found condition is handled and control is transferred to that condition handler.
- If the compound statement is nested and an outer level compound statement contains a condition handler for SQLWARNING, NOT FOUND, or the specified SQLSTATE or condition, the warning or not found condition is handled and control is returned to that condition handler.
- Otherwise, the warning is not handled and processing continues with the next statement.

Considerations for the diagnostics area: The RESIGNAL statement might modify the contents of the current diagnostics area. If an SQLSTATE or *condition-name* is specified as part of the RESIGNAL statement, the RESIGNAL statement starts with a clear diagnostics area and sets the RETURNED_SQLSTATE to reflect the specified SQLSTATE or *condition-name*. If message text is specified, the MESSAGE_TEXT item of the condition area is assigned the specified value. DB2_RETURNED_SQLCODE is set to +438 or -438 corresponding to the specified SQLSTATE or *condition-name*.

Processing a RESIGNAL statement: If the RESIGNAL statement is specified without an SQLSTATE clause or a *condition-name*, the SQL routine resignals the identical condition that invoked the handler and the SQLCODE is not changed.

When a RESIGNAL statement is issued and an SQLSTATE or *condition-name* is specified, the SQLCODE is based on he SQLSTATE value as follows:

- If the specified SQLSTATE class is either '01' or '02', a warning or not found is signaled and the SQLCODE is set to +438.
- Otherwise, an exception is returned and the SQLCODE is set to -438.

Examples

The following example detects a division by zero error. The IF statement uses a SIGNAL statement to invoke the overflow condition handler. The condition handler uses a RESIGNAL statement to return a different SQLSTATE to the client application.

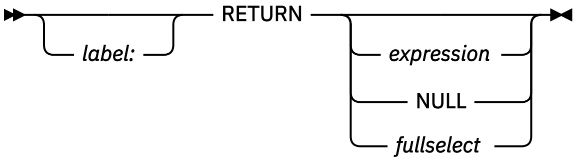
```
CREATE PROCEDURE divide (IN numerator INTEGER,
        IN denominator INTEGER,
        OUT divide_result INTEGER)
  LANGUAGE SQL
  CONTAINS SQL
  BEGIN
   DECLARE overflow CONDITION for SQLSTATE '22003';
   DECLARE CONTINUE HANDLER FOR overflow
     RESIGNAL SQLSTATE '22375';
   IF denominator = 0 THEN
     SIGNAL overflow;
   ELSE
     SET divide_result = numerator / denominator;
   END IF;
  END
```

RETURN statement

The RETURN statement is used to return from the routine.

- For an SQL scalar function, the scalar result of the function is returned. The body of an SQL scalar function must contain at least one RETURN statement and a RETURN statement must be executed when the function is invoked.
- For an SQL table function, the result table of the function is returned. A RETURN statement must be specified in the body of an SQL table function.
- For an SQL procedure, the RETURNS statement optionally returns an integer status value.

Syntax



Description

label

Specifies the label for the RETURN statement. A label name cannot be the same as the routine name or another label within the same scope. For additional information, see "References to SQL labels" on page 2200.

expression

Specifies a value that is returned from the routine.

- If the routine is a scalar function, the data type of the result must be assignable to the data type that is defined for the function result, using the storage assignment rules as described in "Assignment and comparison" on page 143. The RETURN statement must not contain a period specification.

  The body of any SQL function must not contain a reference to an aggregate function, or a reference to a user-defined function that is sourced on an aggregate function, or an OLAP specification.

  In the body of an inlined SQL function, the RETURN statement must not contain a scalar fullselect. If the expression does not conform to this rule, Db2 attempts to define a compiled function. To determine what type of SQL scalar function is created, refer to the INLINE column of the SYSIBM.SYSROUTINES catalog table. For more information about creating the two types of SQL scalar functions, see “CREATE FUNCTION (inlined SQL scalar)” on page 1484 and “CREATE FUNCTION (compiled SQL scalar)” on page 1423.

- If the routine is a table function, a scalar expression (other than a scalar fullselect) cannot be specified. The data type of the result column of the fullselect must be assignable to the data type that is defined for the function result, using the storage assignment rules as described in “Assignment and comparison” on page 143. The outer fullselect in the RETURN statement of an SQL table function must not contain an *offset-clause* or *fetch-clause*, and the RETURN statement must not contain a period specification.
- If the routine is a procedure, the data type of *expression* must be INTEGER.

NULL

The null value is returned from the SQL routine.

- If the routine is a scalar function, the null value is returned.
- If the routine is a table function, NULL must not be specified.
- If the routine is a procedure, NULL must not be specified.

fullselect

Specifies the row or rows that are returned from the routine.

- If the routine is a scalar function, the function is a compiled function and the fullselect must return one column and, at most, one row. The data type of the result column must be assignable to the data type that is defined for the function result, using the storage assignment rules as described in “Assignment and comparison” on page 143.
- If the routine is a table function, the fullselect can return zero or more rows with one or more columns. The number of columns in the fullselect must match the number of columns in the function result. In addition, the data types of the result table columns of the fullselect must be assignable to the data types of the columns that are defined for the function result, using the storage assignment rules as described in “Assignment and comparison” on page 143.
- If the routine is a procedure, fullselect must not be specified.

Notes

Considerations for SQL functions: A RETURN statement in an SQL function must specify *expression*, NULL, or *fullselect*. For an inlined SQL scalar function, only a single *expression* can be specified in the RETURN statement, and the *expression* must not include a scalar fullselect. Only a single RETURN statement can be specified in the routine body of an SQL table function. The execution of an SQL function must end with a RETURN statement.

A data change table reference is not allowed in a RETURN statement in an SQL function.

Considerations for SQL procedures:

- **When a RETURN statement is used within an SQL procedure:** If a RETURN statement with a specified return value was used to return from a procedure, the SQLCODE, SQLSTATE, and message length in the SQLCA are initialized to zeros and the message text is set to blanks. An error is not returned to the caller.
- **When a RETURN statement is not used within an SQL procedure or when no value is specified:** If a RETURN statement was not used to return from a procedure or if a value is not specified on the RETURN statement, one of the following values is set:
  - If the procedure returns with an SQLCODE that is greater or equal to zero, the specified target for DB2_RETURN_STATUS in a GET DIAGNOSTICS statement will be set to a value of zero.
  - If the procedure returns with an SQLCODE that is less than zero, the specified target for DB2_RETURN_STATUS in a GET DIAGNOSTICS statement will be set to a value of '-1'.
- **When the value is returned from an SQL procedure:** When a value is returned from a procedure, the caller may access the value using one of the following methods:
  - The GET DIAGNOSTICS statement to retrieve the RETURN_STATUS when the SQL procedure was called from another SQL procedure.

- The parameter bound for the return value parameter marker in the escape clause CALL syntax (?=CALL...) in a CLI application.
- Directly from the SQLCA returned from processing the CALL of an SQL procedure by retrieving the value of sqlerrd[0]. When the SQLCODE is less than zero, the sqlerrd[0] value is not set. The application should assume a return status value of '-1'.

Restrictions:

- The RETURN statement must not be specified in a trigger.
- An SQL table function must contain a single RETURN statement.

Examples

Example 1: Use a RETURN statement to return from an SQL procedure with a status value of zero if successful or '-200' if not successful.

```
BEGIN
       . . .
           GOTO FAIL;
       . . .
SUCCESS: RETURN 0;
   FAIL: RETURN -200;
END
```

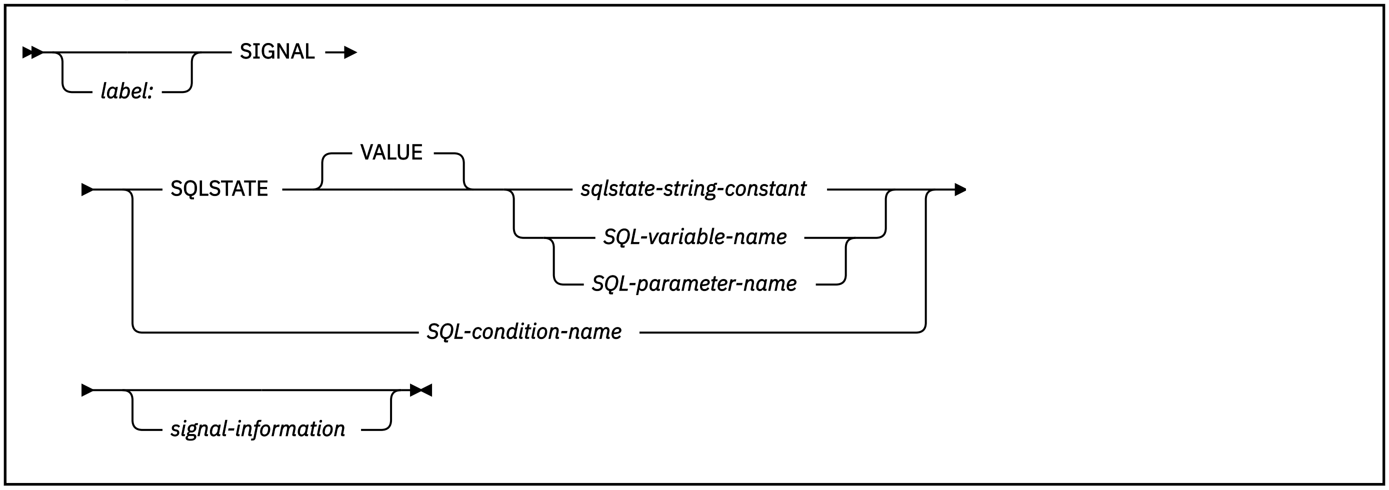
Example 2: Define a scalar function that returns the tangent of a value using the existing sine and cosine functions:

```
 CREATE FUNCTION TAN (X DOUBLE)
       RETURNS DOUBLE
       LANGUAGE SQL CONTAINS SQL NO EXTERNAL ACTION
       DETERMINISTIC
       RETURN SIN(x)/COS(x)
```

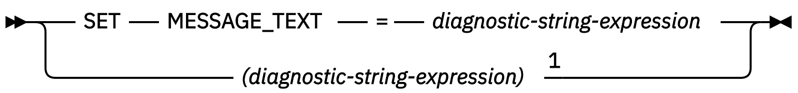
SIGNAL statement

The SIGNAL statement is used to return an exception or warning condition. It causes an error or warning to be returned with the specified SQLSTATE, along with optional message text. The SIGNAL statement places the specified condition information in the cleared diagnostics area.

Syntax



signal-information:



Notes:

[1] *(diagnostic-string-expression)* must only be specified within a trigger body.

Description

label

Specifies the label for the SIGNAL statement. A label name cannot be the same as the routine name, advanced trigger name, or another label within the same scope. For additional information, see "References to SQL labels" on page 2200.

SQLSTATE VALUE

Specifies the SQLSTATE that will be returned. Any valid SQLSTATE value can be used. It must be a character string constant with exactly five characters that follow the rules for SQLSTATEs:

- Each character must be from the set of digits ('0' through '9') or non-accented upper case letter ('A' through 'Z').
- The SQLSTATE class (the first two characters) cannot be '00' because it represents successful completion.

In the context of a MERGE statement, the following rules also apply:

- The SQLSTATE class (first two characters) cannot be '01' or '02', because these are not error classes.
- If the SQLSTATE class starts with the numbers '0' through '6' or the letters 'A' through 'H', the subclass (the last three characters) must start with a letter in the range of 'I' through 'Z'.
- If the SQLSTATE class starts with the numbers '7', '8', '9', or the letters 'I' through 'Z', the subclass can be any of '0' through '9' or 'A' through 'Z'.

If the SQLSTATE does not conform to these rules, an error occurs.

sqlstate-string-constant

A character string constant with an actual length of five bytes that is a valid SQLSTATE value.

SQL-variable-name* or *SQL-parameter-name

Specifies an SQL variable or SQL parameter that contains a valid SQLSTATE value.

SQL-variable-name

Specifies an SQL variable that is declared within the *compound-statement* that contains the SIGNAL statement, or within a compound statement in which that compound statement is nested. *SQL-variable-name* must be defined as a CHAR or VARCHAR data type with an actual length of five bytes, must not be null, and must contain a valid SQLSTATE value.

SQL-parameter-name

Specifies an SQL parameter that is defined for the routine and contains the SQLSTATE value. The SQL parameter must be defined as a CHAR or VARCHAR data type with an actual length of five bytes, must not be null, and must contain a valid SQLSTATE value.

SQL-condition-name

Specifies the name of the condition that will be returned. The *SQL-condition-name* must be declared within the compound statement that contains the SIGNAL statement, or within a compound statement in which that compound statement is nested.

SET MESSAGE_TEXT

Specifies a string that describes the error or warning. The string is returned in the SQLERRMC field of the SQLCA or with the GET DIAGNOSTICS statement.

diagnostic-string-expression

An expression with a data type of CHAR or VARCHAR that returns a character string of up to 1000 bytes that describes the error or warning condition. For information on how to obtain the complete message text, see "GET DIAGNOSTICS" on page 1944.

(diagnostic-string-expression)

An expression with a data type of CHAR or VARCHAR that returns a character string of up to 1000 bytes that describes the error or warning condition. For information on how to obtain the complete message text, see "GET DIAGNOSTICS" on page 1944.

This syntax variation is only provided within the scope of a CREATE TRIGGER statement for compatibility with previous versions of Db2. To conform with the ANS and ISO standards, this form should not be used.

Notes

While any valid SQLSTATE value can be used in the SIGNAL statement, programmers should define new SQLSTATEs based on ranges reserved for applications. This practice prevents the unintentional use of an SQLSTATE value that might be defined by the database manager in a future release.

If the SQLSTATE or condition indicates that an exception is signaled:

- If a condition handler exists in the same compound statement as the SIGNAL statement, and the compound statement contains a condition handler for SQLEXCEPTION or the specified SQLSTATE or condition, the exception is handled and control is transferred to that condition handler.
- If the compound statement is nested and the outer level compound statement has a condition handler for SQLEXCEPTION or the specified SQLSTATE or condition, the exception is handled and control is transferred to that condition handler.
- Otherwise, the exception is not handled and control is immediately returned to the end of the compound statement.

If the SQLSTATE or condition indicates that a warning or not found condition is signaled:

- If a condition handler exists in the same compound statement as the SIGNAL statement, and the compound statement contains a condition handler for SQLWARNING, NOT FOUND, or the specified SQLSTATE or condition, the warning or not found condition is handled and control is transferred to that condition handler.
- If the compound statement is nested and an outer level compound statement contains a condition handler for SQLWARNING, NOT FOUND, or the specified SQLSTATE or condition, the warning or not found condition is handled and control is transferred to that condition handler.
- Otherwise, the warning or not found condition is not handled and processing continues with the next statement.

Considerations for the diagnostics area: The SIGNAL statement starts with a clear diagnostics area and sets the RETURNED_SQLSTATE to reflect the specified SQLSTATE or *condition-name*. If message text is specified, the MESSAGE_TEXT item of the condition area is assigned the specified value. DB2_RETURNED_SQLCODE is set to +438 or -438 corresponding to the specified SQLSTATE or *condition-name*.

Examples

Example 1: The following example shows an SQL procedure for an order system that signals an application error when a customer number is not known to the application. The ORDERS table includes a foreign key to the CUSTOMER table, requiring that the CUSTNO exist before an order can be inserted.

```
CREATE PROCEDURE SUBMIT_ORDER
            (IN ONUM INTEGER, IN CNUM INTEGER,
             IN PNUM INTEGER, IN QNUM INTEGER)
 LANGUAGE SQL
 SPECIFIC SUBMIT_ORDER
 MODIFIES SQL DATA
BEGIN
```

```
    DECLARE EXIT HANDLER FOR SQLSTATE VALUE '23503'
      SIGNAL SQLSTATE '75002'
          SET MESSAGE_TEXT = 'Customer number is not known';
    INSERT INTO ORDERS (ORDERNO, CUSTNO, PARTNO, QUANTITY)
       VALUES (ONUM, CNUM, PNUM, QNUM);
END
```

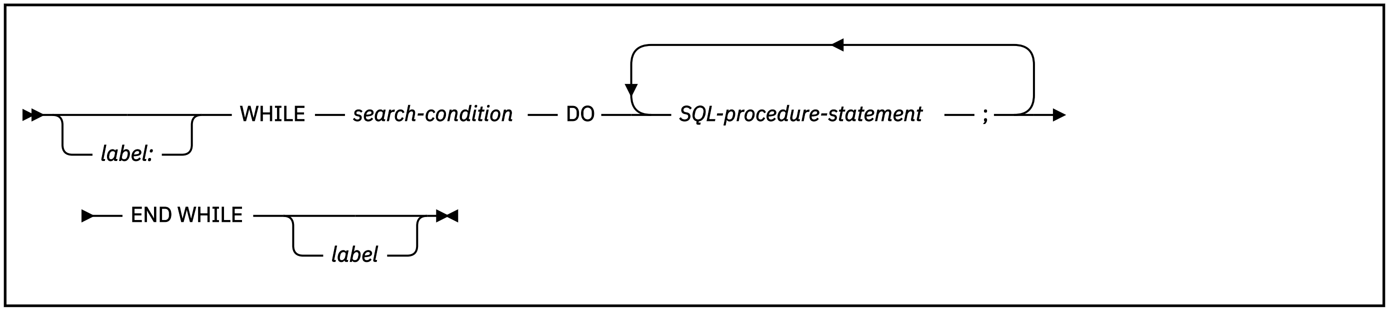
Example 2: The following example shows a trigger for an order system that allows orders to be recorded in an ORDERS table (ORDERNO, CUSTNO, PARTNO, QUANTITY) only if there is sufficient stock in the PARTS tables. When there is insufficient stock for an order, SQLSTATE '75001' is returned along with an appropriate error description.

```
  CREATE TRIGGER CK_AVAIL
        NO CASCADE BEFORE INSERT ON ORDERS
        REFERENCING NEW AS NEW_ORDER
        FOR EACH ROW MODE DB2SQL
        WHEN (NEW_ORDER.QUANTITY > (SELECT ON_HAND FROM PARTS
                                    WHERE NEW_ORDER.PARTNO = PARTS.PARTNO))
          BEGIN ATOMIC
            SIGNAL SQLSTATE '75001' ('Insufficient stock for order');
          END
```

WHILE statement

The WHILE statement repeats the execution of a statement or group of statements while a specified condition is true.

Syntax



Description

label
Specifies the label for the WHILE statement. If the ending label is specified, it must be the same as the beginning label. A label name cannot be the same as the routine name, advanced trigger name, or another label within the same scope. For additional information, see "References to SQL labels" on page 2200.

search-condition
Specifies a condition that is evaluated before each execution of the loop. If the condition is true, the SQL procedure statements in the loop are executed.

SQL-procedure-statement
Specifies a statement to be run within the WHILE loop. The statement must be one of the statements listed under "SQL-procedure-statement (SQL PL)" on page 2202.

Notes

Considerations for the diagnostics area: At the beginning of the first iteration of the WHILE statement, and with every subsequent iteration, the diagnostics area is cleared.

Considerations for the SQLSTATE and SQLCODE SQL variables: With each iteration of the WHILE statement, when the first SQL-procedure-statement is executed, the SQLSTATE and SQLCODE SQL variables reflect the result of evaluating the search condition of that WHILE statement. If the loop is terminated with a GOTO, ITERATE, or LEAVE statement, the SQLSTATE and SQLCODE values reflect the successful completion of that statement. Otherwise, after the END WHILE of the WHILE statement completes, the SQLSTATE and SQLCODE reflect the result of evaluating that search condition of that WHILE statement.

Examples

Use a WHILE statement to fetch rows from a table while SQL variable *at_end*, which indicates whether the end of the table has been reached, is 0.

```
WHILE at_end = 0 DO
 FETCH c1 INTO
  v_firstnme, v_midinit,
  v_lastname, v_edlevel, v_salary;
 IF SQLCODE=100 THEN SET at_end=1;
 END IF;
END WHILE;
```

Appendix A. Limits in Db2 for z/OS

Db2 for z/OS has system limits, object and SQL limits, length limits for identifiers and strings, and limits for certain data type values.

System storage limits might preclude the limits specified in this section. The limit for items not that are not specified below is limited by system storage.

The following table shows the length limits for identifiers.

Table 242. Identifier length limits. The term *byte(s)* in this table means the number of bytes for the UTF-8 representation unless noted otherwise.

Item	Limit
External-java-routine-name	1305 bytes
Name of an alias "1" on page 2238, auxiliary table, collection, clone table, constraint, correlation, cursor (except for DECLARE CURSOR WITH RETURN or the EXEC SQL utility), distinct type (both parts of two-part name), function (both parts of two-part name), host identifier, index, JARs, parameter, procedure, role, schema, sequence, specific, statement, storage group, savepoint, SQL condition, SQL label, SQL parameter, SQL variable, synonym, table, trigger, view, XML attribute name, XML element name	128 bytes
Name of an authorization ID or name of a security label.	8 bytes
Routine version identifier	64 EBCDIC bytes, and the UTF-8 representation of the name must not exceed 122 bytes.
Name of a column	30 bytes "1" on page 2238
Name of cursor that is created with DECLARE CURSOR WITH RETURN	30 bytes
Name of cursor that is created with the EXEC SQL utility	8 bytes
Name of a location	16 bytes
Name of a database, table space, or buffer pool	8 bytes
Name of a plan or program	8 bytes
Name of a package	8 bytes (Only 8 EBCDIC characters are used for packages that are created with the BIND PACKAGE command. 128 bytes can be used for packages that are created as a result of the CREATE FUNCTION (SQL scalar) statement, the CREATE PROCEDURE (SQL - native) statement, the CREATE TRIGGER statement, or a BIND command that specifies a zFS file as DBRM library.)
Name of a profile that is created with CREATE TRUSTED CONTEXT or ALTER TRUSTED CONTEXT	127 bytes
Name of an ICF catalog.	8 bytes

Table 242. Identifier length limits. The term *byte(s)* in this table means the number of bytes for the UTF-8 representation unless noted otherwise. *(continued)*

Item	Limit

Notes:

1. If the column name length or the distinct type schema or name length is greater than 30 Unicode bytes, truncation occurs in the SQLNAME field of the SQLDA when those objects are described in an application.

Table 243 on page 2238 shows the minimum and maximum limits for numeric values.

Table 243. Numeric limits

Item	Limit
Smallest SMALLINT value	-32768
Largest SMALLINT value	32767
Smallest INTEGER value	-2147483648
Largest INTEGER value	2147483647
Smallest BIGINT value	-9223372036854775808
Largest BIGINT value	9223372036854775807
Smallest REAL value	About $-7.2\text{x}10^{75}$
Largest REAL value	About $7.2\text{x}10^{75}$
Smallest positive REAL value	About $5.4\text{x}10^{-79}$
Largest negative REAL value	About $-5.4\text{x}10^{-79}$
Smallest FLOAT value	About $-7.2\text{x}10^{75}$
Largest FLOAT value	About $7.2\text{x}10^{75}$
Smallest positive FLOAT value	About $5.4\text{x}10^{-79}$
Largest negative FLOAT value	About $-5.4\text{x}10^{-79}$
Smallest DECIMAL value	$1 - 10^{31}$
Largest DECIMAL value	$10^{31} - 1$
Largest decimal precision	31
Smallest DECFLOAT(16) value[1]	$-9.999999999999999\text{x}10^{384}$
Largest DECFLOAT(16) value[1]	$9.999999999999999\text{x}10^{384}$
Smallest positive DECFLOAT(16) value[1]	$1.000000000000000\text{x}10^{-383}$
Largest negative DECFLOAT(16) value[1]	$-1.000000000000000\text{x}10^{-383}$
Smallest DECFLOAT(34) value[1]	$-9.999999999999999999999999999999999\text{x}10^{6144}$.
Largest DECFLOAT(34) value[1]	$9.999999999999999999999999999999999\text{x}10^{6144}$.
Smallest positive DECFLOAT(34) value[1]	$1.000000000000000000000000000000000\text{x}10^{-6143}$
Largest negative DECFLOAT(34) value[1]	$-1.000000000000000000000000000000000\text{x}10^{-6143}$
Coefficient length for DECFLOAT values	DECFLOAT(16) is 16 digits; DECFLOAT(34) is 34 digits

Table 243. Numeric limits (continued)

Item	Limit
Maximum Exponent (E_{max}) for DECFLOAT values	DECFLOAT(16) is 384; DECFLOAT(34) is 6144
Minimum Exponent (E_{min}) for DECFLOAT values	DECFLOAT(16) is -383; DECFLOAT(34) is -6143
Bias for DECFLOAT values	DECFLOAT(16) is 398; DECFLOAT(34) is 6176

Note:

1. These are the limits for normal numbers in DECFLOAT. DECFLOAT also contains special values such as NaN and Infinity that are also valid. DECFLOAT also supports subnormal numbers that are outside of the documented range.

The following table shows the length limits for strings.

Table 244. String length limits

Item	Limit
Maximum length of CHAR	255 bytes
Maximum length of GRAPHIC	127 double-byte characters
Maximum length of BINARY	255 bytes
Maximum length"1" on page 2240 of VARCHAR	• 4046 bytes for a column in a table in a table space with 4 KB pages • 8128 bytes for a column in a table in a table space with 8 KB pages • 16320 bytes for a column in a table in a table space with 16 KB pages • 32704 bytes for a column in a table in a table space with 32 KB pages Otherwise, 32704 bytes
Maximum length of VARCHAR that can be indexed by an XML index	1000 bytes after conversion to UTF-8
Maximum length"1" on page 2240 of VARGRAPHIC	• 2023 double-byte characters for a column in a table in a table space with 4 KB pages • 4064 double-byte characters for a column in a table in a table space with 8 KB pages • 8160 double-byte characters for a column in a table in a table space with 16 KB pages • 16352 double-byte characters for a column in a table in a table space with 32 KB pages Otherwise, 16352 double-byte characters

Table 244. String length limits (continued)

Item	Limit
Maximum length"1" on page 2240 of VARBINARY	• 4046 bytes for a column in a table in a table space with 4 KB pages • 8128 bytes for a column in a table in a table space with 8 KB pages • 16320 bytes for a column in a table in a table space with 16 KB pages • 32704 bytes for a column in a table in a table space with 32 KB pages Otherwise, 32704 bytes
Maximum length of CLOB	2147483647 bytes (2 GB - 1 byte)
Maximum length of DBCLOB	1073741823 double-byte characters
Maximum length of BLOB	2147483647 bytes (2 GB - 1 byte)
Maximum length of a character constant	32704 UTF-8 bytes
Maximum length of a hexadecimal character constant	32704 hexadecimal digits
Maximum length of a graphic string constant	16352 double-byte characters (32704 bytes when expressed in UTF-8)
Maximum length of a hexadecimal graphic string constant	32704 hexadecimal digits
Maximum length of a text string used for a scalar expression	4000 UTF-8 bytes
Maximum length of a concatenated character string	2147483647 bytes (2 GB - 1 byte)
Maximum length of a concatenated graphic string	1073741824 double-byte characters
Maximum length of a concatenated binary string	2147483647 bytes (2 GB - 1 byte)
Maximum length of XML pattern text	4000 bytes after conversion to UTF-8
Maximum length of an XML element or attribute name in an XML document	1000 bytes
Maximum length of a namespace uri	1000 bytes
Maximum length of a namespace prefix	998 bytes
Largest depth of an internal XML tree	128 levels

Note:

1. The maximum length can be achieved only if the column is the only column in the table. Otherwise, the maximum length depends on the amount of space remaining on a page.

The following table shows the minimum and maximum limits for datetime values.

Table 245. Datetime limits

Item	Limit
Smallest DATE value (shown in ISO format)	0001-01-01
Largest DATE value (shown in ISO format)	9999-12-31

Table 245. Datetime limits (continued)

Item	Limit
Smallest TIME value (shown in ISO format)	00.00.00
Largest TIME value (shown in ISO format)	24.00.00
Smallest TIMESTAMP WITHOUT TIME ZONE value	0001-01-01-00.00.00.000000000000
Largest TIMESTAMP WITHOUT TIME ZONE value	9999-12-31-24.00.00.000000000000 "1" on page 2241
Smallest TIMESTAMP WITH TIME ZONE value	0001-01-01-00.00.00.000000000000 +00:00
Largest TIMESTAMP WITH TIME ZONE value	9999-12-31-24.00.00.000000000000 +00:00 "1" on page 2241
TIMESTAMP precision range	0 to 12
TIME ZONE hour range	-24 to 24
TIME ZONE minute range	0 to 59

Note:

1. The maximum value is stated as a UTC value. When a timestamp without a time zone is compared to a timestamp with time zone, a necessary adjustment is made using the implicit time zone. During that adjustment, the timestamp without time zone could be converted to a value that is greater than the maximum value for a timestamp with time zone value (this could occur on operations such as comparison and assignment). This situation can be avoided by using '9999-12-30-00.00.00.000000000000' as the maximum value for timestamp without time zone and '9999-12-30-00.00.00.000000000000 +00:00' as the maximum value for timestamp with time zone columns.

The following table shows the Db2 limits on SQL statements.

Table 246. Db2 limits on SQL statements

Item	Limit
Maximum number of columns that are in a table or view (the value depends on the complexity of the CREATE VIEW statement) or columns returned by a table function.	750 or fewer (including hidden columns) 749 if the table is a dependent
Maximum number of columns that can be referenced in the target of MERGE statement.	749
Maximum number of expressions that can be referenced in the source of a MERGE statement.	750
Approximate maximum number of base tables in a SELECT, UPDATE, INSERT, MERGE, or DELETE statement or view	1024
Maximum number of tables in a FROM clause	225 or fewer, depending on the complexity of the statement
Maximum number of rows inserted with a single MERGE statement or FOR *n* ROWS form of INSERT statement	32767
Maximum row and record sizes for a table	See the maximum record size table under CREATE TABLE.
Maximum number of volume IDs in a storage group	133

Table 246. Db2 limits on SQL statements (continued)

Item	Limit
Maximum number of partitions in a partitioned table space or partitioned index	4096 for most table space types, depending on the DSSIZE value and buffer pool page size. 64 for table spaces not defined with a DSSIZE greater than 2GB (or the LARGE clause“1” on page 2244).
Maximum sum of the lengths of limit key values of a partition boundary	765 UTF-8 bytes
Maximum size of a partition (table space or index)	For partition-by-range table spaces with relative numbering: 1 TB For table spaces that are defined with a DSSIZE greater than 4 GB: 256 GB, depending on the page size (for 1 to 64 partitions for 4 KB pages, for 1 to 128 partitions for 8 KB pages, for 1 - 256 partitions for 16 KB pages, and 1 - 512 partitions for 32 KB pages) For table spaces that are defined with a DSSIZE of 4 GB (or the LARGE clause“1” on page 2244): 4 GB, for 1 - 4096 partitions For table spaces with a DSSIZE not greater than 2 GB (and not defined with the LARGE clause“1” on page 2244): 4 GB, for 1 - 16 partitions 2 GB, for 17 - 32 partitions 1 GB, for 33 - 64 partitions
Maximum size of a non-partitioned index for a partitioned table space	For 5-byte EA table spaces: 16 TB for 4 KB pages 32 TB for 8 KB pages 64 TB for 16 KB pages 128 TB for 32 KB pages For table spaces that are defined with the LARGE clause“1” on page 2244: 16 TB
Maximum length of an index key	• Partitioning index: 255-*n* • Nonpartitioning index that is padded: 2000-*n* • Nonpartitioning index that is not padded: 2000 - *n* - 2*m* - 3*d* **n** Number of columns in the key that allow nulls **m** Number of varying-length columns in the key **d** Number of DECFLOAT columns in the key

Table 246. Db2 limits on SQL statements (continued)

Item	Limit
Maximum number of bytes used in the partitioning of a partitioned index	255 (This maximum limit is subject to additional limitations, depending on the number of partitions in the table space. The number of partitions * (106 + limit key size) must be less than 65394.)
Maximum number of columns in an index key	64
Maximum number of expressions in an index key	64
Maximum number of subqueries in a statement	224
Maximum total length of host and indicator variables pointed to in an SQLDA	32767 bytes 2147483647 bytes (2 GB - 1 byte) for a LOB, subject to the limitations that are imposed by the application environment and host language
Maximum size of application SQLDA for any statement that references host variables or parameter markers	99016 bytes
Maximum length of host variable used for insert or update operation	32704 bytes for a non-LOB 2147483647 bytes (2 GB - 1 byte) for a LOB, subject to the limitations that are imposed by the application environment and host language
Maximum number of host variables or parameter markers in a statement	16000 for a distributed application that originated from a client other than z/OS. Otherwise: • 2205 for an application without any LOB or distinct type host variables or parameter markers • 750 for an application with one or more LOB or distinct type host variables or parameter markers
Maximum length of an SQL statement	2097152 bytes
Maximum number of elements in a select list	750 or fewer, depending on whether the select list is for the result table of static scrollable cursor“2” on page 2244
Maximum number of elements in an IN list	32767
Maximum number of predicates in a WHERE or HAVING clause	Limited by storage
Maximum number of elements in a CUBE grouping	16
Maximum total length of columns of a query operation requiring sort and evaluating aggregate functions (MULTIPLE DISTINCT and GROUP BY)	65529 bytes
Maximum length of a sort key	32707 bytes
Maximum length of a check constraint	3800 bytes
Maximum number of bytes that can be passed in a single parameter of an SQL CALL statement	32765 bytes for a non-LOB 2147483647 bytes (2 GB - 1 byte) for a LOB, subject to the limitations imposed by the application environment and host language

Table 246. Db2 limits on SQL statements (continued)

Item	Limit
Maximum number of stored procedures, triggers, and user-defined functions that an SQL statement can implicitly or explicitly reference	64 nesting levels
Maximum number of parameters in a procedure or function	The SQL statement that contains the parameter list cannot exceed the maximum length of an SQL statement.
Maximum length of the SQL path	2048 bytes
Maximum length of a WLM environment name in a CREATE PROCEDURE, CREATE FUNCTION, ALTER PROCEDURE, or ALTER FUNCTION statement.	32 bytes
Maximum number of XPath level in the XMLPATTERN clause of the CREATE INDEX statement.	50 nesting levels

Note:

1. CREATE TABLESPACE statements support the LARGE clause for compatibility with earlier releases of Db2 for z/OS. However, the DSSIZE clause is the preferred method for specifying maximum partition size of 4 GB or larger. Do not specify LARGE if a DSSIZE clause is specified. For more information, see "Non-large table spaces (deprecated)" in Table space types and characteristics in Db2 for z/OS (Db2 Administration Guide).
2. If the scrollable cursor is read-only, the maximum number is 749 less the number of columns in the ORDER BY that are not in the select list. If the scrollable cursor is not read-only, the maximum number is 747.

The following table shows the Db2 system limits.

Table 247. Db2 system limits

Item	Limit
Maximum number of concurrent Db2 or application agents	Limited by the EDM pool size, buffer pool size, and the amount of storage that is used by each Db2 or application agent
Maximum number of concurrently active audit policies	32
Maximum size of a non-LOB table or table space	128 terabytes (TB)
Maximum size of a simple or segmented table space	64 GB
Maximum size of a physical log record	36,000 bytes
Maximum size of a log space	6-byte format: 2^{48} bytes 10-byte format: 2^{80} bytes
Maximum size of an active log data set	768 GB minus 1 byte
Maximum size of an archive log data set	768 GB minus 1 byte
Maximum number of active log copies	2
Maximum number of archive log copies	2
Maximum number of active log data sets (each copy)	93
Maximum number of archive log volumes (each copy)	10000
Maximum number of databases accessible to an application or user	Limited by system storage and EDM pool size

Table 247. Db2 system limits (continued)

Item	**Limit**
Maximum number of databases	65217
Maximum number of implicitly created databases	Maximum value of the sequence SYSIBM.DSNSEQ_IMPLICITDB, with a default of 10000
Maximum number of internal objects for each database [1]	32767
Maximum number of indexes on declared global temporary tables	10000
Maximum size of an EDM pool	The installation parameter maximum depends on available space
Maximum number of rows per page	255 for all table spaces except catalog and directory tables spaces, which have a maximum of 127
Maximum simple or segmented data set size	2 GB
Maximum partitioned data set size	See item "maximum size of a partition" in Table 246 on page 2241
Maximum LOB data set size	256 GB
Maximum number of data sets for a LOB table space	254
Maximum storage per thread for LOB data	2 GB
Maximum number of table spaces that can be defined in a work file database	500
Maximum number of tables and triggers that can be defined in a work file database	11767
Maximum number of active profiles in DSN_PROFILE_TABLE profile table	4096

Note:

1. The number of internal object descriptors (OBDs) for external objects are as follows:
    - Table space: 2
    - Table: 1
    - Index: 2
    - Check constraint: 1
    - Referential integrity relationship: 2
    - Auxiliary relationship for each LOB column: 1
    - XML relationship for each XML column: 1
    - Trigger: 1
    - View that has an INSTEAD OF trigger: 1

Appendix B. Reserved schema names and reserved words in Db2 for z/OS

Restrictions exist on the use of certain words that are used by Db2 for z/OS. In some cases, these names are reserved and cannot be used by application programs. In other cases, certain names are not recommended for use by application programs though not prevented from being used by the database manager.

Reserved schema names in Db2 for z/OS

In general, for certain objects, schema names that begin with the prefix SYS are reserved. The schema name for these objects cannot begin with SYS except for certain exceptions.

The schema name for the objects listed in the following table must follow the restrictions listed in the table.

Recommendations:

- Do not to use SESSION as a schema name.
- Do not use SYSPUBLIC as a schema name for a table or view.

Table 248. Objects with schema name restrictions and exceptions.

Object	**Schema name restriction**	**Schema name exceptions**
Distinct types	Cannot begin with SYS	The schema name can be: • SYSADM • SYSTOOLS[1]
User-defined functions	Cannot begin with SYS	The schema name can be: • SYSADM • SYSTOOLS[1] • SYSFUN[2]
Stored procedures	Cannot begin with SYS	The schema name can be: • SYSADM • SYSFUN[2] • SYSIBM • SYSIBMADM • SYSPROC • SYSTOOLS[1]
Sequences	Cannot begin with SYS	The schema name can be: • SYSADM
Triggers	Cannot begin with SYS	The schema name can be: • SYSADM • SYSTOOLS[1]

Table 248. Objects with schema name restrictions and exceptions. (continued)

Object	Schema name restriction	Schema name exceptions
Column masks	Cannot begin with SYS	The schema name can be: • SYSADM
Row permissions	Cannot begin with SYS	The schema name can be: • SYSADM

Notes:

1. If the user who executes the CREATE statement has the SYSADM or SYSCTRL privilege.
2. For external user-defined scalar functions or external user-defined table functions if the user who executes the CREATE statement has the SYSADM or SYSCTRL privilege.

Reserved words in Db2 for z/OS

Reserved words in Db2 for z/OS

Keywords can be used as ordinary identifiers, except in a context where they could also be interpreted as SQL syntax. When a keyword can be interpreted as SQL syntax the keyword is considered a *reserved word* in that context, which means that it cannot be used as an ordinary identifier. However, a keyword can be used as an identifier in a context where it is a reserved word, by specifying it as a delimited identifier. For example:

- ALL cannot be a column name in a SELECT statement, unless it is delimited. However, if the quotation mark (") is the escape character that begins and ends delimited identifiers, “ALL” can be used as a column name in a SELECT statement.
- COUNT cannot be used as a column name in a SELECT statement, unless it is also specified as delimited.

New reserved words for Db2 12 are identified by note “1” on page 2257 in the following table. Some topics in this information might also indicate words that cannot be used in the specific context that is being described.

IBM SQL has additional reserved words that Db2 for z/OS does not enforce. Therefore, you should not use these additional reserved words as ordinary identifiers in names that have a continuing use. For a list of the reserved words, see PDF *SQL Reference for Cross-Platform Development* - Version 6 for a list of the words.

Reserved schema names in Db2 for z/OS
In general, for certain objects, schema names that begin with the prefix SYS are reserved. The schema name for these objects cannot begin with SYS except for certain exceptions.

Appendix C. Characteristics of SQL statements in Db2 for z/OS

Db2 allows specific actions on each SQL statement, and only certain SQL statements are allowed in external routines and SQL procedures.

Actions allowed on SQL statements

Specific Db2 statements can be executed, prepared interactively or dynamically, or processed by the requester, the server, or the precompiler or coprocessor.

The following table shows whether a specific Db2 statement can be executed, prepared interactively or dynamically, or processed by the requester, the server, or the precompiler or coprocessor. The letter **Y** means *yes*.

Table 250. Actions allowed on SQL statements in Db2 for z/OS

Table 250. Actions allowed on SQL statements in Db2 for z/OS (continued)

		Interactively or dynamically prepared	Processed by		
SQL statement	**Executable**		**Requesting system**	**Server**	**Precompiler or coprocessor**

Note:

1. The statement can be dynamically prepared. It cannot be issued dynamically.
2. The statement can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.
3. The statement can be dynamically prepared, but only from an ODBC or CLI driver that supports dynamic CALL statements.
4. The requesting system processes the PREPARE statement when the statement being prepared is ALLOCATE CURSOR or ASSOCIATE LOCATORS.
5. The value to which special register CURRENT SQLID is set is used as the SQL authorization ID for dynamic SQL statements only when DYNAMICRULES run behavior is in effect. The CURRENT SQLID value is ignored for the other DYNAMICRULES behaviors.
6. This statement can be used only in the triggered action of a trigger.
7. Local special registers can be referenced in a VALUES INTO statement if it results in the assignment of a single host-variable, not if it results in setting more than one value.
8. Some processing also occurs at the requester.

SQL statement data access classification for routines

Certain SQL statements can be executed in a stored procedure or in a user-defined function. Whether the statements can be executed depends on the level of SQL data access with which the routine is defined.

The following table indicates whether an SQL statement (specified in the first column) is allowed to execute in a routine with the specified SQL data access classification. The letter **Y** means *yes*.

In general, if an executable SQL statement is encountered in a routine defined as NO SQL, SQLSTATE 38001 is returned. If the routine is defined to allow some level of SQL access, SQL statements that are not supported in any context return SQLSTATE 38003. SQL statements not allowed for routines defined as CONTAINS SQL return SQLSTATE 38004, and SQL statements not allowed for READS SQL DATA return SQLSTATE 38002.

WHENEVER	Y"1" on page 2265	Y	Y	Y

Notes:

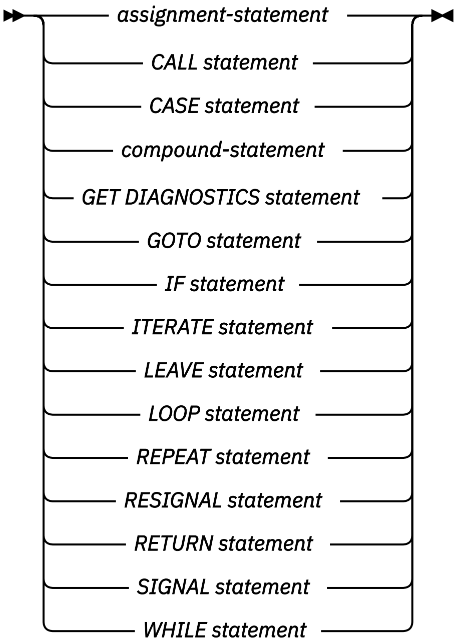
1. Although the SQL option implies that no SQL statements can be specified, non-executable statements are not restricted.
2. The stored procedure that is called must have the same or more restrictive level of SQL data access than the current level in effect. For example, a routine defined as MODIFIES SQL DATA can call a stored procedure defined as MODIFIES SQL DATA, READS SQL DATA, CONTAINS SQL, or NO SQL. A routine defined as CONTAINS SQL can call a procedure defined as CONTAINS SQL or NO SQL.
3. The statement specified for the EXECUTE statement must be a statement that is allowed for the particular level of SQL data access in effect. For example, if the level in effect is READS SQL DATA, the statement must not be an INSERT, UPDATE, MERGE, or DELETE statement.
4. The statement is supported only if it does not contain a subquery or query-expression.

Appendix D. SQL control statements for external SQL procedures

SQL control statements for external SQL procedures can be used only with SQL procedures that are created with the FENCED or EXTERNAL clause. *SQL control statements* provide the capability to control the logic flow, declare and set variables, and handle warnings and exceptions. Some SQL control statements include other nested SQL statements.

Deprecated function: External SQL procedures are deprecated and not as fully supported as native SQL procedures. For best results, create native SQL procedures instead. For more information, see Creating native SQL procedures (Db2 Application programming and SQL) and Migrating an external SQL procedure to a native SQL procedure (Db2 Application programming and SQL).

SQL-control-statement:



Control statements are supported in SQL procedures. External SQL procedures are created by specifying either FENCED or EXTERNAL, LANGUAGE SQL, and an SQL routine body on the "CREATE PROCEDURE (SQL - external) (deprecated)" on page 1592 statement. The SQL routine body must be a single SQL statement which may be an SQL control statement.

The remainder of this section contains a description of the control statements that are supported for external SQL procedures, and includes syntax diagrams, semantic descriptions, usage notes, and examples of the use of the statements that constitute the SQL routine body. In addition, you can find information about referencing SQL parameters and variables in "References to SQL parameters and SQL variables in external SQL procedures" on page 2268.

The two common elements that are used in describing specific SQL control statements are:

- SQL control statements as described above
- "SQL-procedure-statement (external)" on page 2268

References to SQL parameters and SQL variables in external SQL procedures

SQL parameters, SQL variables, and transition variables can be referenced anywhere in the statement where an expression or a host variable can be specified. SQL parameters and SQL variables can be referenced anywhere in the compound statement in which they are declared and can be qualified with the label name that is specified at the beginning of the compound statement. Host variables cannot be specified in SQL routines. Use SQL variables, SQL parameters, and global variables instead of host variables in SQL routines. Use SQL variables, transition variables, and global variables in triggers.

All SQL parameters and SQL variables are considered nullable. The name of an SQL parameter or SQL variable in an SQL routine can be the same as the name of a column in a table or view that the SQL routine references. Names that are the same should be explicitly qualified. Qualifying a name clearly indicates whether the name refers to a column, SQL variable, or SQL parameter.

If the name is not qualified, the following rules describe whether the name refers to the column, the SQL variable, or the SQL parameter:

- The name is checked first as an SQL variable name and then as an SQL parameter name.
- If an SQL variable or SQL parameter by that name is not found, the name is assumed to be a column name.

The name of an SQL variable or SQL parameter in an SQL routine can be the name of an identifier that is used in certain SQL statements. If the name is not qualified, the following rules describe whether the name refers to the identifier, the SQL variable, or the SQL parameter:

- In the SET PATH and SET SCHEMA statements, the name is checked as an SQL variable name or an SQL parameter name. If an SQL variable or SQL parameter by that name is not found, the name is assumed to be an identifier.
- In the ASSOCIATE LOCATORS, CONNECT statement, the SET CONNECTION statement, and the RELEASE (connection) statement the name is used as an identifier.

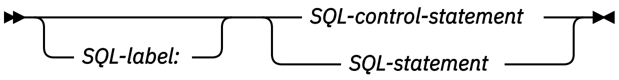
Related concepts

Variables
A *variable* in an SQL statement specifies a value that can be changed when the SQL statement is executed. There are several types of variables used in SQL statements.

SQL-procedure-statement (external)

An SQL control statement may allow multiple SQL statements to be specified within the SQL control statement. These statements are defined as SQL procedure statements.

Syntax



Description

SQL-label
Specifies a label for the statement. *SQL-label* must not be a delimited identifier that includes lowercase letters or special characters. The label must be unique within the procedure.

SQL-control-statement
Specifies an SQL statement that provides the capability to control logic flow, declare and set variables, and handle warnings and exceptions, as defined in this section. Control statements are supported in SQL procedures.

SQL-statement
Specifies an SQL statement. These statements are described in Chapter 7, “Statements,” on page 1075.

Notes

Comments: Comments can be included within the body of an SQL procedure. In addition to the double-dash form of comments (--), a comment can begin with /* and end with */. The following rules apply to this form of comment:

- The beginning characters /* must be adjacent and on the same line.
- The ending characters */ must be adjacent and on the same line.
- Comments can be started wherever a space is valid.
- Comments can be continued to the next line.

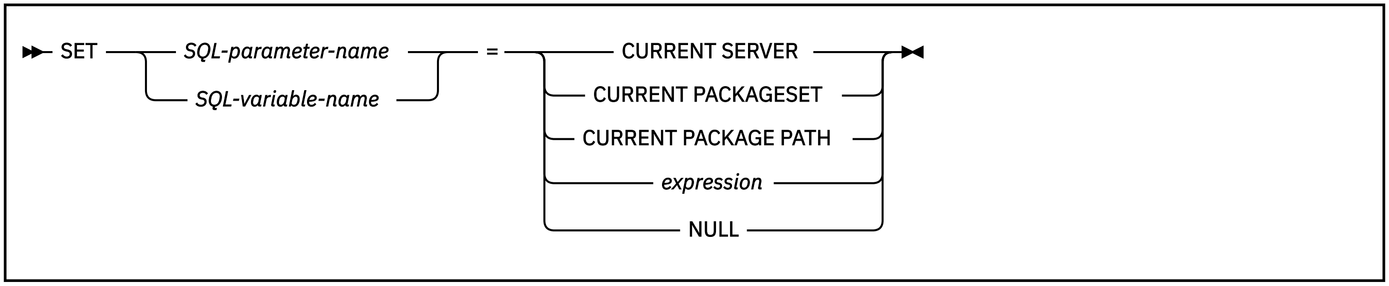
Handling errors and warnings: Conditions can be detected within an SQL procedure by using the following methods:

- Test the special SQL variables SQLSTATE and SQLCODE.
- Issue a GET DIAGNOSTICS statement to request the condition information. See “GET DIAGNOSTICS” on page 1944.
- Define condition handlers to detect and process conditions. See “compound-statement” on page 2274 for information about defining condition handlers.

assignment-statement (SQL control statements for external routines)

The assignment statement assigns a value to an SQL parameter or to an SQL variable.

Syntax



Description

SQL-parameter-name
Identifies the parameter that is the assignment target. The parameter must be specified in *parameter-declaration* in the CREATE PROCEDURE statement and must be defined as OUT or INOUT.

SQL-variable-name
Identifies the SQL variable that is the assignment target. SQL variables can be declared in a compound-statement and must be declared before it is used. For information on declaring SQL variables, see “compound-statement” on page 2274.

***expression* or NULL**
Specifies the expression or value that is the assignment source. The expression can be any expression of the type described in “Expressions” on page 244 except it cannot contain a reference to local special registers (CURRENT SERVER, CURRENT PACKAGESET, or CURRENT PACKAGE PATH).

Notes

Assignment rules: Assignment statements in SQL procedures must conform to the SQL assignment rules. For example, the data type of the target and source must be compatible. See "Assignment and comparison" on page 143 for assignment rules.

When a string is assigned to a fixed-length variable and the length of the string is less than the length attribute of the target, the string is padded on the right with the necessary number of single-byte or double-byte blanks. When a string is assigned to a variable and the string is longer than the length attribute of the variable, the value is truncated and a warning is returned.

The ENCODING bind option is not used during processing of assignments to string variables. For example, assume that the system does not use mixed or DBCS, and the system EBCDIC SBCS CCSID is 37. Character conversion will not occur on assignment even if CCSID 500 is specified for the ENCODING bind parameter for the package for the procedure.

If truncation of the whole part of a number occurs on assignment to a numeric variable, the value is truncated and a warning is returned.

Assignments involving SQL parameters:

- An IN parameter can appear on the left side of an assignment statement. When control returns to the caller, the original value of an IN parameter is passed to the caller.
- An OUT parameter can appear on the left or right side of an assignment statement. When control returns to the caller, the last value that is assigned to an OUT parameter is returned to the caller.
- An INOUT parameter can appear on the left or right side of an assignment statement. The first value of the parameter is determined by the caller, and the last value that is assigned to the parameter is returned to the caller.
- A LOB parameter can not be used as an output value in an SQL statement in an SQL procedure when connected to a remote site. To circumvent the restriction, use a LOB SQL variable instead of a LOB parameter.

Considerations for SQLSTATE and SQLCODE SQL variables: Assignment to these variables is not prohibited. However, it is not recommended as assignment does not affect the diagnostic area or result in the activation of condition handlers. Furthermore, processing an assignment to these SQL variables causes the specified values for the assignment to be overlayed with the SQL return codes returned from executing the statement that does the assignment.

Examples

Increase the SQL variable *p_salary* by 10 percent.

```
SET p_salary = p_salary + (p_salary * .10)
```

Set SQL variable *p_salary* to the null value.

```
SET p_salary = NULL
```

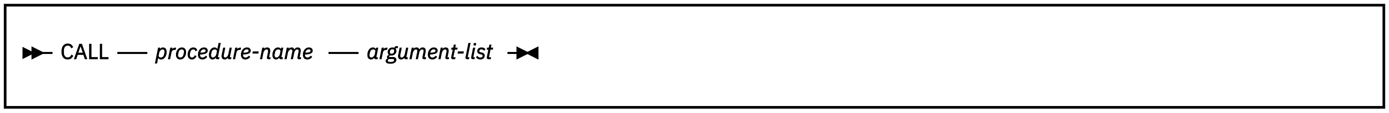
Set SQL variable *midinit* to the first character of SQL variable *midname*.

```
SET midinit = SUBSTR(midname,1,1)
```

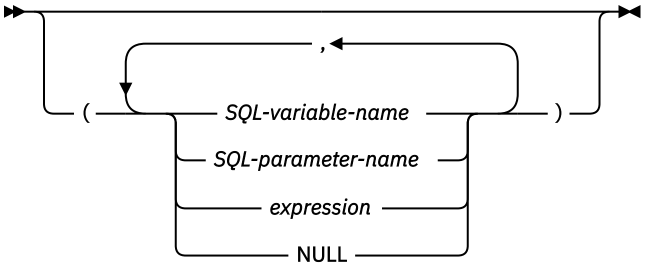
CALL statement

The CALL statement invokes a stored procedure.

Syntax



argument-list:



Description

procedure-name

Identifies the stored procedure to call. The procedure name must identify a stored procedure that exists at the current server.

argument-list

Identifies a list of values to be passed as parameters to the stored procedure. The number of parameters must be the same as the number of parameters defined for the stored procedure. See "CALL" on page 1379 for more information.

Control is passed to the stored procedure according to the calling conventions for SQL procedures. When execution of the stored procedure is complete, the value of each parameter of the stored procedure is assigned to the corresponding parameter of the CALL statement defined as OUT or INOUT.

SQL-variable-name

Specifies an SQL variable as an argument to the stored procedure. For an explanation of references to SQL variables, see "References to SQL parameters and SQL variables in external SQL procedures" on page 2268.

SQL-parameter-name

Specifies an SQL parameter as an argument to the stored procedure. For an explanation of references to SQL parameters, see "References to SQL parameters and SQL variables in external SQL procedures" on page 2268.

expression

The parameter is the result of the specified *expression*, which is evaluated before the stored procedure is invoked. If *expression* is a single *SQL-parameter-name* or *SQL-variable-name*, the corresponding parameter of the procedure can be defined as IN, INOUT, or OUT. Otherwise, the corresponding parameter of the procedure must be defined as IN. If the result of the *expression* can be the null value, either the description of the procedure must allow for null parameters or the corresponding parameter of the stored procedure must be defined as OUT.

The following additional rules apply depending on how the corresponding parameter was defined in the CREATE PROCEDURE statement for the procedure:

- IN *expression* can contain references to multiple SQL parameters or variables. In addition to the rules stated in "Expressions" on page 244 for *expression*, *expression* cannot include a column name, an aggregate function, or a user-defined function that is sourced on an aggregate function.
- INOUT or OUT *expression* can only be a single SQL parameter or variable.

NULL

The parameter is a null value. The corresponding parameter of the procedure must be defined as IN and the description of the procedure must allow for null parameters.

Notes

See “CALL” on page 1379 for more information on the SQL CALL statement.

Examples

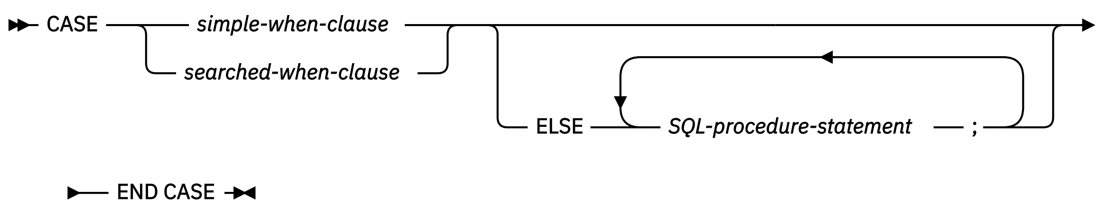
Call stored procedure proc1 and pass SQL variables as parameters.

```
CALL proc1(v_empno, v_salary)
```

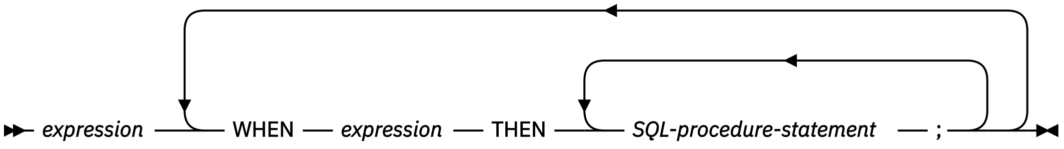
CASE statement

The CASE statement selects an execution path based on the evaluation of one or more conditions. A CASE statement operates in the same way as a CASE expression.

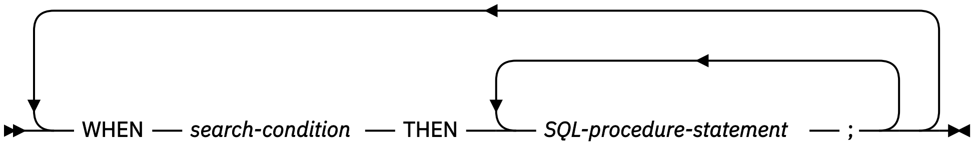
Syntax



simple-when-clause:



searched-when-clause:



Description

CASE
Begins a *case-expression*.

simple-when-clause
Specifies the *expression* prior to the first WHEN keyword that is tested for equality with the value of each *expression* that follows the WHEN keyword, and the result to be executed when those expressions are equal. If the comparison is true, the THEN statement is executed. If the result is unknown or false, processing continues to the next expression or the ELSE statement.

The data type of the *expression* prior to the first WHEN keyword must be comparable to the data types of each *expression* that follows the WHEN keywords.

searched-when-clause
Specifies the *search-condition* that is applied to each row or group of table data presented for evaluation, and the result when that condition is true. *search-condition* cannot contain a *fullselect*. If

the search condition is true, the THEN statement is executed. If the condition is unknown or false, processing continues to the next search condition or the ELSE statement.

SQL-procedure-statement
Specifies a statement that follows the THEN and ELSE keyword. The statement specifies the result of a *searched-when-clause* or a *simple-when-clause* that is true, or the result if no case is true. The statement must be one of the statements listed under "SQL-procedure-statement (external)" on page 2268.

search-condition
Specifies a condition that is true, false, or unknown about a row or group of table data.

ELSE *SQL-procedure-statement*
If none of the conditions specified in the *simple-when-clause* or *searched-when-clause* are true, the statements in the *else-clause* are executed.

If none of the conditions specified in the WHEN clause are true and an ELSE clause is not specified, an error is returned at run time, and the execution of the CASE statement is terminated.

END CASE
Ends a *case-statement*.

Notes

If none of the conditions specified in the WHEN clause are true and an ELSE clause is not specified, an error is returned at run time, and the execution of the CASE statement is terminated.

CASE statements that use a simple case statement WHEN clause can be nested up to three levels. CASE statements that use a searched statement WHEN clause have no limit to the number of nesting levels.

Considerations for the SQLSTATE and SQLCODE SQL variables: When the first SQL-procedure-statement in the CASE statement is executed, the SQLSTATE and SQLCODE SQL variables reflect the result of evaluating the expression or search conditions of that CASE statement. If a CASE statement does not include an ELSE clause and none of the search conditions evaluate to true, an error is returned.

Examples

Example 1: Use a simple case statement WHEN clause to update column DEPTNAME in table DEPT, depending on the value of SQL variable *v_workdept*.

```
CASE v_workdept
 WHEN 'A00'
  THEN UPDATE DEPT SET
   DEPTNAME = 'DATA ACCESS 1';
 WHEN 'B01'
  THEN UPDATE DEPT SET
   DEPTNAME = 'DATA ACCESS 2';
 ELSE UPDATE DEPT SET
   DEPTNAME = 'DATA ACCESS 3';
END CASE
```

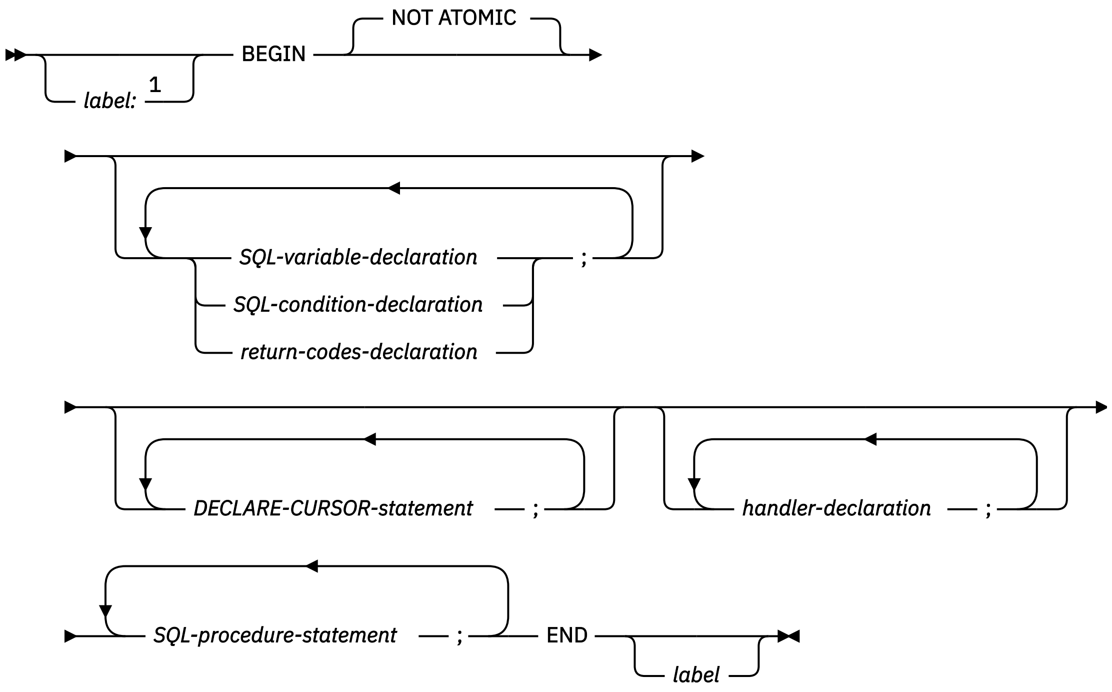
Example 2: Use a searched case statement WHEN clause to update column DEPTNAME in table DEPT, depending on the value of SQL variable *v_workdept*.

```
CASE
 WHEN v_workdept < 'B01'
  THEN UPDATE DEPT SET
   DEPTNAME = 'DATA ACCESS 1';
 WHEN v_workdept < 'C01'
  THEN UPDATE DEPT SET
   DEPTNAME = 'DATA ACCESS 2';
 ELSE UPDATE DEPT SET
   DEPTNAME = 'DATA ACCESS 3';
END CASE
```

compound-statement

A compound statement contains a group of statements and declarations for SQL variables, cursors, and condition handlers.

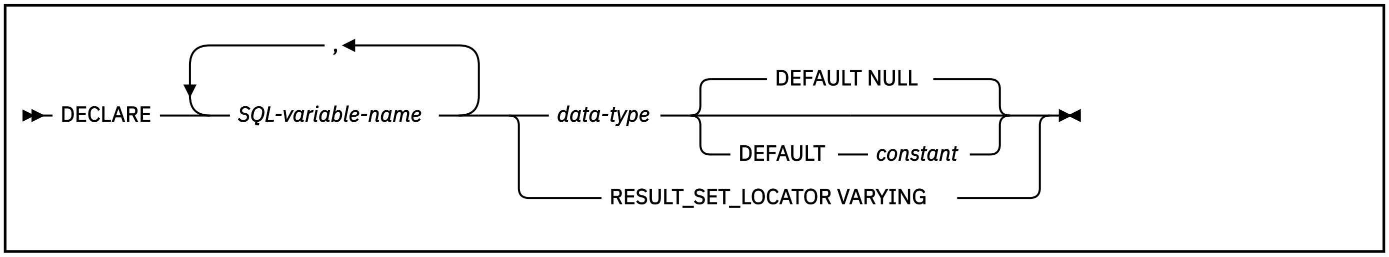
Syntax



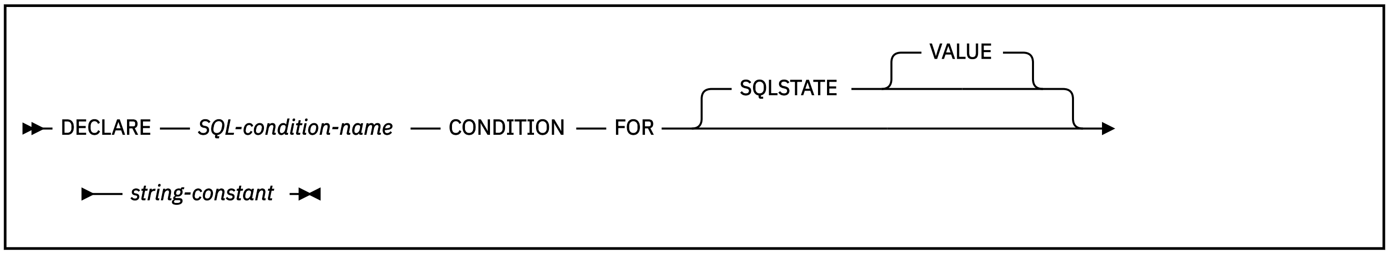
Notes:

[1] Only one *label:* can be specified for each *SQL-procedure-statement*. If an ending label is specified for this beginning label, the labels must be the same.

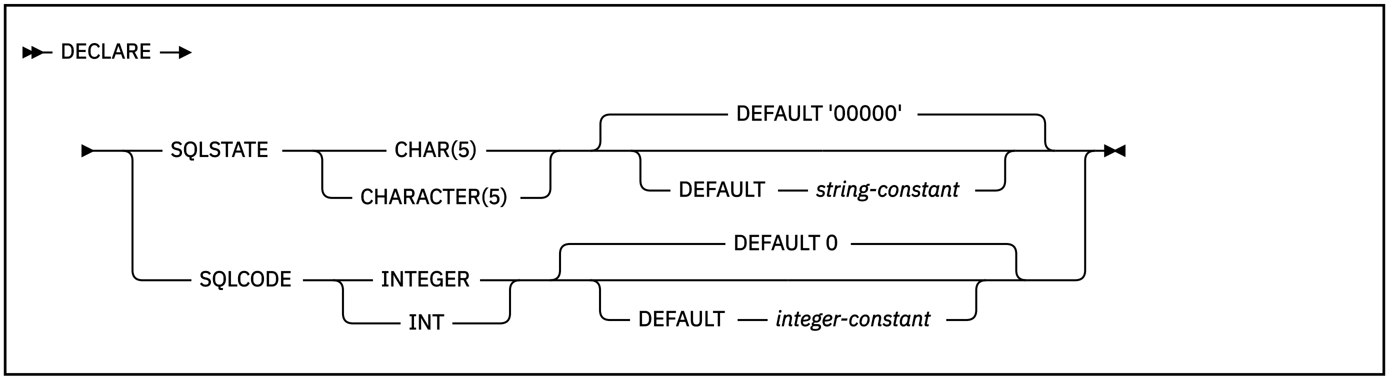
SQL-variable-declaration:



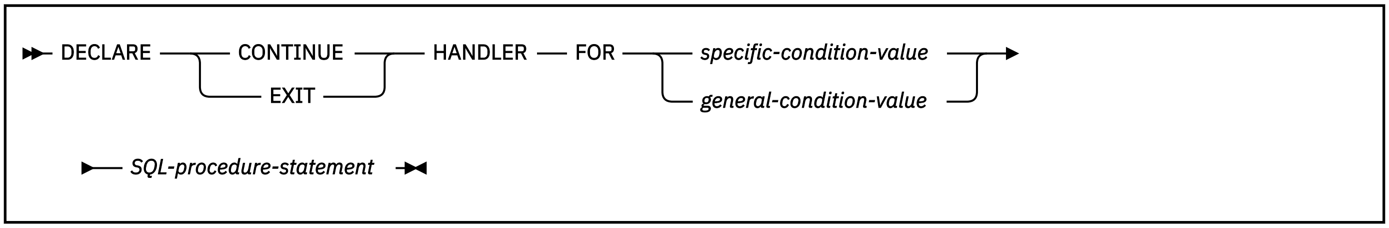
SQL-condition-declaration:



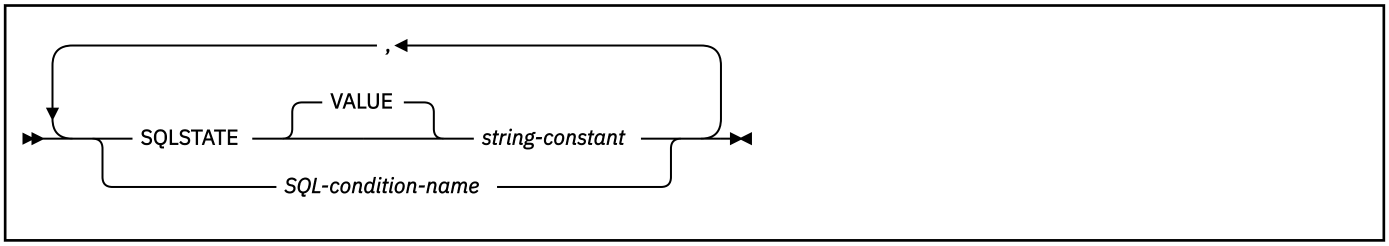
return-codes-declaration:



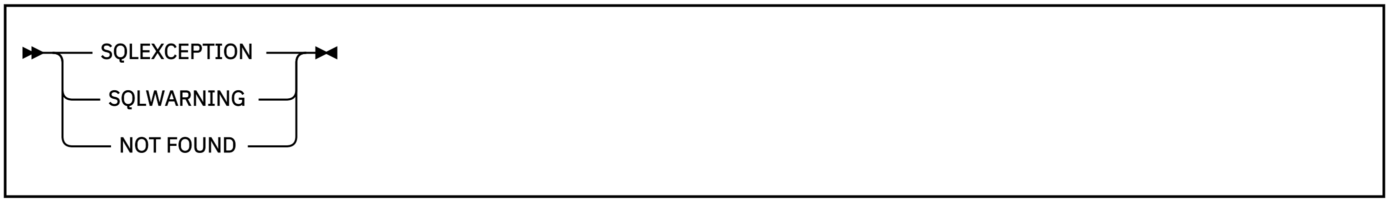
handler-declaration:



specific-condition-value:



general-condition-value:



Description

label

Defines the label for the code block. If the beginning label is specified, it can be used to qualify SQL variables declared in the compound statement and can also be specified on a LEAVE statement. If the ending label is specified, it must be the same as the beginning label.

NOT ATOMIC

NOT ATOMIC indicates that an error within the compound statement does not cause the compound statement to be rolled back.

SQL-variable-declaration

Declares a variable that is local to the compound statement.

SQL-variable-name

A qualified or unqualified name that designates a variable in an SQL procedure body. The unqualified form of *SQL-variable-name* is an SQL identifier and must not be a delimited identifier that contains lowercase letters or special characters. The qualified form is an SQL procedure statement label followed by a period (.) and an SQL identifier.

Db2 folds all SBCS SQL variable names to uppercase. SQL variable names should not be the same as column names. If an SQL statement contains an SQL variable or parameter and a column reference with the same name, Db2 interprets the name as an SQL variable or parameter name. To refer to the column, qualify the column name with the table name. Further, to avoid ambiguous variable references and to ensure compatibility with other Db2 platforms, qualify the SQL variable or parameter name with the label of the SQL procedure statement.

data-type

Specifies the data type and length of the variable. SQL variables follow the same rules for default lengths and maximum lengths as SQL procedure parameters. See "CREATE PROCEDURE (SQL - external) (deprecated)" on page 1592 for a description of SQL data types and lengths.

DEFAULT *constant* or NULL

Defines the default for the SQL variable. The variable is initialized when the SQL procedure is called. If a default value is not specified, the variable is initialized to NULL.

RESULT_SET_LOCATOR VARYING

Specifies the data type for a result set locator variable.

SQL-condition-declaration

Declares a condition name and corresponding SQLSTATE value.

SQL-condition-name

Specifies the name of the condition. The condition name is an SQL identifier and must not be a delimited identifier that includes lowercase letters or special characters. *SQL-condition-name* must be unique within the procedure body and can be referenced only within the compound statement in which it is declared.

FOR SQLSTATE *string-constant*

Specifies the SQLSTATE that is associated with the condition. The string must be specified as five characters enclosed in single quotes, and cannot be '00000'.

return-codes-declaration

Declares special variables called SQLSTATE and SQLCODE that are set automatically to the value returned after processing an SQL statement. Both the SQLSTATE and SQLCODE variables can be declared only in the outermost compound statement of the SQL procedure. Assignment to these variables is not prohibited; however, assignment is ignored by exception handlers, and processing the next SQL statement replaces the assigned value.

DECLARE-CURSOR-statement

Declares a cursor. Each cursor in the procedure body must have a unique name. An OPEN statement must be specified to open the cursor, and a FETCH statement can be specified to read rows. The cursor can be referenced only from within the compound statement. For more information on declaring a cursor, see "DECLARE CURSOR" on page 1814.

handler-declaration

Specifies a set of statements to execute when an exception or completion condition occurs in the compound statement. *SQL-procedure-statement* is the set of statements that execute when the handler receives control. See "SQL-procedure-statement (external)" on page 2268 for information on *SQL-procedure-statement*.

A handler is active only within the compound statement in which it is declared.

The actions that a handler can perform are:

CONTINUE

Specifies that after the condition handler is activated and completes successfully, control is returned to the SQL statement that follows the statement that raised the condition. However, if the condition is an error condition and it was encountered while evaluating a search condition, as in a CASE, IF, REPEAT or WHILE statement, control returns to the statement that follows the corresponding END CASE, END IF, END REPEAT, or END WHILE.

EXIT

After the handler is invoked successfully, control is returned to the end of the compound statement.

The conditions that can cause the handler to gain control are:

SQLSTATE *string-constant*
Specifies an SQLSTATE for which the handler is invoked. The SQLSTATE cannot be '00000'.

SQL-condition-name
Specifies a condition name for which the handler is invoked. The condition name must be previously defined in a condition declaration.

SQLEXCEPTION
Specifies that the handler is invoked when an SQLEXCEPTION occurs. An SQLEXCEPTION is an SQLSTATE in which the class code is a value other than '00', '01', or '02'. For more information on SQLSTATE values, see SQLSTATE values and common error codes (Db2 Codes).

SQLWARNING
Specifies that the handler is invoked when an SQLWARNING occurs. An SQLWARNING is an SQLSTATE value with a class code of '01'.

NOT FOUND
Specifies that the handler is invoked when a NOT FOUND condition occurs. NOT FOUND corresponds to an SQLSTATE value with a class code of '02'.

Notes

The order of statements in a compound statement must be:

1. SQL variable, condition declarations, and return codes declarations
2. Cursor declarations
3. Handler declarations
4. SQL procedure statements

Compound statements cannot be nested.

Unlike host variables, SQL variables are not preceded by colons when they are used in SQL statements.

The following rules apply to handlers:

- A handler declaration that contains SQLEXCEPTION, SQLWARNING, or NOT FOUND cannot contain additional SQLSTATE or condition names.
- Handler declarations within the same compound statement cannot contain duplicate conditions.
- A handler declaration cannot contain the same condition code or SQLSTATE value more than once, and cannot contain an SQLSTATE value and a condition name that represent the same SQLSTATE value.
- A handler is activated when it is the most appropriate handler for an exception or completion condition.
- If there is no handler for an SQL error, the error is passed to the caller in the SQLCA.
- A handler cannot be activated by an assignment statement that assigns a value to SQLSTATE.

The following rules and recommendations apply to the SQLCODE and SQLSTATE SQL variables:

- A null value cannot be assigned to SQLSTATE or SQLCODE.
- The SQLSTATE and SQLCODE variable values should be saved immediately to temporary variables if there is any intention to use the values. If a handler exists for SQLSTATE, this assignment must be done as the first statement to be processed in the handler to avoid having the value replaced by the next SQL procedure statement. If the condition raised by the SQL statement is handled, the value is changed by the first SQL statement contained in the handler.
