Notes

Before using this information and the product it supports, be sure to read the general information under "Notices" at the end of this information.

Subsequent editions of this PDF will not be delivered in IBM Publications Center. Always download the latest edition from IBM Documentation.

2024-04-30 edition

This edition applies to Db2® 12 for z/OS® (product number 5650-DB2), Db2 12 for z/OS Value Unit Edition (product number 5770-AF3), and to any subsequent releases until otherwise indicated in new editions. Make sure you are using the correct edition for the level of the product.

Specific changes are indicated by a vertical bar to the left of a change. A vertical bar to the left of a figure caption indicates that the figure has changed. Editorial changes that have no technical significance are not noted.

Contents

About this information

This book is a reference for Structured Query Language (SQL) for Db2 for z/OS, including the SQL procedural language (SQL PL). Unless otherwise stated, references to SQL in this book imply SQL for Db2 for z/OS, and all objects described in this book are objects of Db2 for z/OS.

The syntax and semantics of most SQL statements are essentially the same in all IBM® relational database products, and the language elements common to the products provide a base for the definition of IBM SQL. Consult *IBM DB2 SQL Reference for Cross-Platform Development* if you intend to develop applications that adhere to IBM SQL.

Throughout this information, "Db2" means "Db2 12 for z/OS". References to other Db2 products use complete names or specific abbreviations.

Important: To find the most up to date content for Db2 12 for z/OS, always use IBM Documentation or download the latest PDF file from PDF format manuals for Db2 12 for z/OS (Db2 for z/OS in IBM Documentation).

Most documentation topics for Db2 12 for z/OS assume that the highest available function level is activated and that your applications are running with the highest available application compatibility level, with the following exceptions:

- The following documentation sections describe the Db2 12 migration process and how to activate new capabilities in function levels:
  - Migrating to Db2 12 (Db2 Installation and Migration)
  - What's new in Db2 12 (Db2 for z/OS What's New?)
  - Adopting new capabilities in Db2 12 continuous delivery (Db2 for z/OS What's New?)
- FL 501 A label like this one usually marks documentation changed for function level 500 or higher, with a link to the description of the function level that introduces the change in Db2 12. For more information, see How Db2 function levels are documented (Db2 for z/OS What's New?).

The availability of new function depends on the type of enhancement, the activated function level, and the application compatibility levels of applications. In the initial Db2 12 release, most new capabilities are enabled only after the activation of function level 500 or higher.

Virtual storage enhancements
Virtual storage enhancements become available at the activation of the function level that introduces them or higher. Activation of function level 100 introduces all virtual storage enhancements in the initial Db2 12 release. That is, activation of function level 500 introduces no virtual storage enhancements.

Subsystem parameters
New subsystem parameter settings are in effect only when the function level that introduced them or a higher function level is activated. Many subsystem parameter changes in the initial Db2 12 release take effect in function level 500. For more information about subsystem parameter changes in Db2 12, see Subsystem parameter changes in Db2 12 (Db2 for z/OS What's New?).

Optimization enhancements
Optimization enhancements become available after the activation of the function level that introduces them or higher, and full prepare of the SQL statements. When a full prepare occurs depends on the statement type:

- For static SQL statements, after bind or rebind of the package
- For non-stabilized dynamic SQL statements, immediately, unless the statement is in the dynamic statement cache
- For stabilized dynamic SQL statements, after invalidation, free, or changed application compatibility level

Activation of function level 100 introduces all optimization enhancements in the initial Db2 12 release. That is, function level 500 introduces no optimization enhancements.

SQL capabilities

New SQL capabilities become available after the activation of the function level that introduces them or higher, for applications that run at the equivalent application compatibility level or higher. New SQL capabilities in the initial Db2 12 release become available in function level 500 for applications that run at the equivalent application compatibility level or higher. You can continue to run SQL statements compatibly with lower function levels, or previous Db2 releases, including Db2 11 and DB2® 10. For details, see Application compatibility levels in Db2 12 (Db2 Application programming and SQL)

Who should read this information

This information is intended for end users, application programmers, system and database administrators, and for persons involved in error detection and diagnosis.

This information is a reference rather than a tutorial. It assumes that you are already familiar with SQL programming concepts.

When you first use this information, consider reading Chapters 1 and 2 sequentially. These chapters describe the basic concepts of relational databases and SQL, the basic syntax of SQL, and the language elements that are common to many SQL statements. The rest of the chapters and appendixes are designed for the quick location of answers to specific SQL questions. They provide you with query forms, SQL statements, SQL procedure statements, Db2 limits, SQLCA, SQLDA, catalog tables, and SQL reserved words.

Db2 Utilities Suite for z/OS

Important: Db2 Utilities Suite for z/OS is available as an optional product. You must separately order and purchase a license to such utilities, and discussion of those utility functions in this publication is not intended to otherwise imply that you have a license to them.

Db2 12 utilities can use the DFSORT program regardless of whether you purchased a license for DFSORT on your system. For more information about DFSORT, see https://www.ibm.com/support/pages/dfsort.

Db2 utilities can use IBM Db2 Sort for z/OS as an alternative to DFSORT for utility SORT and MERGE functions. Use of Db2 Sort for z/OS requires the purchase of a Db2 Sort for z/OS license. For more information about Db2 Sort for z/OS, see Db2 Sort for z/OS documentation.

Terminology and citations

When referring to a Db2 product other than Db2 for z/OS, this information uses the product's full name to avoid ambiguity.

The following terms are used as indicated:

Db2

Represents either the Db2 licensed program or a particular Db2 subsystem.

IBM rebranded DB2 to Db2, and Db2 for z/OS is the new name of the offering that was previously known as "DB2 for z/OS". For more information, see Revised naming for IBM Db2 family products on IBM z/OS platform. As a result, you might sometimes still see references to the original names, such as "DB2 for z/OS" and "DB2", in different IBM web pages and documents. If the PID, Entitlement Entity, version, modification, and release information match, assume that they refer to the same product.

IBM OMEGAMON® for Db2 Performance Expert on z/OS

Refers to any of the following products:

- IBM IBM OMEGAMON for Db2 Performance Expert on z/OS

- IBM Db2 Performance Monitor on z/OS
- IBM Db2 Performance Expert for Multiplatforms and Workgroups
- IBM Db2 Buffer Pool Analyzer for z/OS

C, C++, and C language
Represent the C or C++ programming language.

CICS®
Represents CICS Transaction Server for z/OS.

IMS
Represents the IMS Database Manager or IMS Transaction Manager.

MVS™
Represents the MVS element of the z/OS operating system, which is equivalent to the Base Control Program (BCP) component of the z/OS operating system.

RACF®
Represents the functions that are provided by the RACF component of the z/OS Security Server.

Accessibility features for Db2 for z/OS

Accessibility features help a user who has a physical disability, such as restricted mobility or limited vision, to use information technology products successfully.

Accessibility features

The following list includes the major accessibility features in z/OS products, including Db2 for z/OS. These features support:

- Keyboard-only operation.
- Interfaces that are commonly used by screen readers and screen magnifiers.
- Customization of display attributes such as color, contrast, and font size

Tip: IBM Documentation (which includes information for Db2 for z/OS) and its related publications are accessibility-enabled for the IBM Home Page Reader. You can operate all features using the keyboard instead of the mouse.

Keyboard navigation

For information about navigating the Db2 for z/OS ISPF panels using TSO/E or ISPF, refer to the *z/OS TSO/E Primer*, the *z/OS TSO/E User's Guide*, and the *z/OS ISPF User's Guide*. These guides describe how to navigate each interface, including the use of keyboard shortcuts or function keys (PF keys). Each guide includes the default settings for the PF keys and explains how to modify their functions.

Related accessibility information

IBM and accessibility

See the *IBM Accessibility Center* at http://www.ibm.com/able for more information about the commitment that IBM has to accessibility.

How to send your comments about Db2 for z/OS documentation

Your feedback helps IBM to provide quality documentation.

Send any comments about Db2 for z/OS and related product documentation by email to db2zinfo@us.ibm.com.

To help us respond to your comment, include the following information in your email:

- The product name and version
- The address (URL) of the page, for comments about online documentation
- The book name and publication date, for comments about PDF manuals
- The topic or section title
- The specific text that you are commenting about and your comment

PDF format manuals for Db2 12 for z/OS (Db2 for z/OS in IBM Documentation)

How to read syntax diagrams

Certain conventions apply to the syntax diagrams that are used in IBM documentation.

Apply the following rules when reading the syntax diagrams that are used in Db2 for z/OS documentation:

- Read the syntax diagrams from left to right, from top to bottom, following the path of the line.

  The ►►── symbol indicates the beginning of a statement.

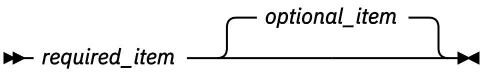
  The ──► symbol indicates that the statement syntax is continued on the next line.

  The ►── symbol indicates that a statement is continued from the previous line.

  The ──►◄ symbol indicates the end of a statement.
- Required items appear on the horizontal line (the main path).

  
- Optional items appear below the main path.

  
  If an optional item appears above the main path, that item has no effect on the execution of the statement and is used only for readability.

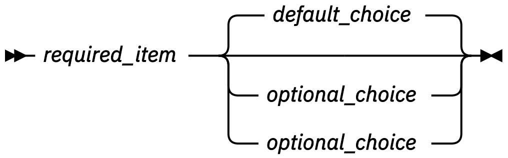
  


- If you can choose from two or more items, they appear vertically, in a stack.

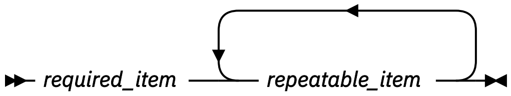
  If you *must* choose one of the items, one item of the stack appears on the main path.

  
  If choosing one of the items is optional, the entire stack appears below the main path.

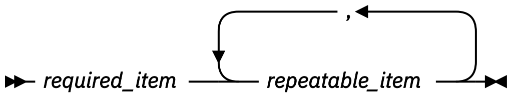
  
  If one of the items is the default, it appears above the main path and the remaining choices are shown below.



- An arrow returning to the left, above the main line, indicates an item that can be repeated.



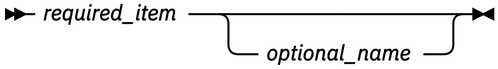
If the repeat arrow contains a comma, you must separate repeated items with a comma.



A repeat arrow above a stack indicates that you can repeat the items in the stack.

- Sometimes a diagram must be split into fragments. The syntax fragment is shown separately from the main syntax diagram, but the contents of the fragment should be read as if they are on the main path of the diagram.

fragment-name



- For some references in syntax diagrams, you must follow any rules described in the description for that diagram, and also rules that are described in other syntax diagrams. For example:
  - For *expression*, you must also follow the rules described in "Expressions" on page 244.
  - For references to *fullselect*, you must also follow the rules described in "fullselect" on page 1058.
  - For references to *search-condition*, you must also follow the rules described in "Search conditions" on page 318.
- With the exception of XPath keywords, keywords appear in uppercase (for example, FROM). Keywords must be spelled exactly as shown.
- XPath keywords are defined as lowercase names, and must be spelled exactly as shown.
- Variables appear in all lowercase letters (for example, *column-name*). They represent user-supplied names or values.
- If punctuation marks, parentheses, arithmetic operators, or other such symbols are shown, you must enter them as part of the syntax.

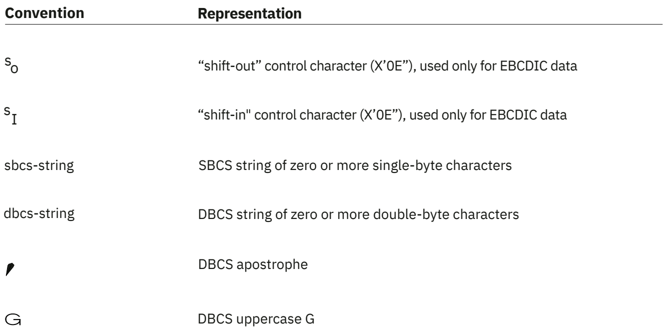
Conventions for describing mixed data values

When mixed data values are shown in examples, certain conventions are used to represent these values.

At sites using a double-byte character set (DBCS), character strings can include a mixture of single-byte and double-byte characters. When mixed data values are shown in the examples, the conventions shown in the following example apply:



Convention	Representation
s_O	“shift-out” control character (X’0E”), used only for EBCDIC data
s_I	“shift-in" control character (X’0E”), used only for EBCDIC data
sbcs-string	SBCS string of zero or more single-byte characters
dbcs-string	DBCS string of zero or more double-byte characters
’	DBCS apostrophe
Ｇ	DBCS uppercase G

Figure 1. Conventions used when mixed data values are shown in examples

Industry standards for SQL

Db2 for z/OS conforms to the following industry standards for SQL:

- *ISO/IEC FCD 9075-1:2016, Information technology - Database languages - SQL - Part 1: Framework (SQL/Framework)*
- *ISO/IEC FCD 9075-2:2016, Information technology - Database languages - SQL - Part 2: Foundation (SQL/Foundation)*
- *ISO/IEC FCD 9075-3:2016, Information technology - Database languages - SQL - Part 3: Call-Level Interface (SQL/CLI)*
- *ISO/IEC FCD 9075-4:2016, Information technology - Database languages - SQL - Part 4: Persistent Stored Modules (SQL/PSM)*
- *ISO/IEC FCD 9075-10:2016, Information technology - Database languages - SQL - Part 10: Object Language Bindings (SQL/OLB)*
- *ISO/IEC FCD 9075-11:2016, Information technology - Database languages - SQL - Part 11: Information and Definition Schemas (SQL/Schemata)*
- *ISO/IEC FCD 9075-13:2016, Information technology - Database languages - SQL - Part 13: Java Routines and Types (SQL/JRT)*
- *ISO/IEC FCD 9075-14:2016, Information technology - Database languages - SQL - Part 14: XML-Related Specifications (SQL/XML)*

Chapter 1. Db2 for z/OS and SQL concepts

Many structures and processes are associated with a relational database. The structures are the key components of a Db2 database system, and the processes are the interactions that occur when applications access the database system.

In a relational database, data is perceived to exist in one or more *tables*. Each table contains a specific number of *columns* and a number of unordered *rows*. Each column in a table is related in some way to the other columns. Thinking of the data as a collection of tables gives you an easy way to visualize the data that is stored in a Db2 database.

Tables are at the core of a Db2 database. However, a Db2 database involves more than just a collection of tables; a Db2 database also involves other objects, such as views and indexes, and larger data containers, such as table spaces.

With Db2 for z/OS and the other Db2 products, you can define and manipulate your data by using structured query language (SQL). SQL is the standard language for accessing data in relational databases.

Submitting SQL statements to Db2

You can use several different methods to send SQL statements to Db2 in several ways.

You can issue SQL statements from interactively from a keyboard at a terminal or through a terminal emulator.

Another way to issue SQL statements is through application programs. The programs can contain SQL statements that are statically embedded in the application. Alternatively, application programs can create their SQL statements dynamically, for example, in response to information that a user provides by filling in a form.

The method of preparing an SQL statement for execution and the persistence of its operational form distinguish static SQL from dynamic SQL.

Related concepts

How SQL statements are invoked
SQL statements are invoked in different ways depending on whether the statement is an executable or nonexecutable statement or the *select-statement*.

Related tasks

Overview of programming applications that access Db2 for z/OS data (Db2 Application programming and SQL)

Static SQL

The source form of a *static SQL statement* is embedded within an application program written in a host language such as COBOL. The statement is prepared before the program is executed and the operational form of the statement persists beyond the execution of the program.

Static SQL statements in a source program must be processed before the program is compiled. This processing can be accomplished through the Db2 coprocessor or Db2 precompiler. The Db2 coprocessor or Db2 precompiler checks the syntax of the SQL statements, turns them into host language comments, and generates host language statements to invoke Db2.

The preparation of an SQL application program includes processing of the SQL statements, the preparation of its static SQL statements, and compilation of the modified source program.

Related concepts

How SQL statements are invoked

SQL statements are invoked in different ways depending on whether the statement is an executable or nonexecutable statement or the *select-statement*.

Related tasks

Overview of programming applications that access Db2 for z/OS data (Db2 Application programming and SQL)

Processing SQL statements for program preparation (Db2 Application programming and SQL)

Embedded dynamic SQL

Programs that contain *embedded dynamic SQL* statements must be precompiled like those that contain static SQL, but unlike static SQL, the dynamic statements are constructed and prepared at run time.

The source form of a dynamic statement is a character string that is passed to Db2 by the program using the static SQL PREPARE or EXECUTE IMMEDIATE statement. A statement that is prepared using the PREPARE statement can be referenced in a DECLARE CURSOR, DESCRIBE, or EXECUTE statement. Whether the operational form of the statement is persistent depends on whether dynamic statement caching is enabled.

SQL statements embedded in a REXX application are dynamic SQL statements. SQL statements submitted to an interactive SQL facility and to the CALL Level Interface (CLI) are also dynamic SQL.

Related concepts

Embedding a statement in an application program
You can include SQL statements in a source program that will be submitted to the Db2 precompiler or coprocessor. Such statements are said to be *embedded* in the application program. An embedded statement can be placed anywhere in the application program where a host language statement is allowed. Each embedded statement must be preceded by a keyword (or keywords) to indicate that the statement is an SQL statement.

Dynamic preparation and execution
Your application program can dynamically build an SQL statement in the form of a character string placed in a host variable. In general, the statement is built from some data available to the application program (for example, input from a workstation).

Dynamic SQL applications (Introduction to Db2 for z/OS)

Embedded dynamic SQL (Introduction to Db2 for z/OS)

Related tasks

Including dynamic SQL in your program (Db2 Application programming and SQL)

Deferred embedded SQL

A *deferred embedded* SQL statement is neither fully static nor fully dynamic.

Like a static statement, it is embedded within an application, but like a dynamic statement, it is prepared during the execution of the application. Although prepared at run time, a deferred embedded SQL statement is processed with bind-time rules such that the authorization ID and qualifier determined at bind time for the plan or package owner are used.

Interactive SQL

Interactive SQL refers to SQL statements that you submit to Db2 by using SPUFI (SQL processor using file input), the command line processor, or by using a query tool, such as QMF for Workstation.

The easiest and most efficient way to run SQL is to use a query tool. QMF for Workstation is a popular query tool that lets you enter and run your SQL statements easily. This topic acquaints you with using QMF for Workstation to create and run SQL statements. QMF for Workstation simplifies access to Db2 from a workstation. In fact, was QMF for Workstation built for Db2.

Although this topic focuses on QMF for Workstation, other options are available. You can use QMF for WebSphere® to enter and run SQL statements from your web browser or useQMF for TSO/CICS to enter and run SQL statements from TSO or CICS. In addition, you can enter and run SQL statements at a TSO terminal by using the SPUFI (SQL processor using file input) facility. SPUFI prepares and executes these statements dynamically. All of these tools prepare and dynamically execute the SQL statements.

The Db2 Query Management Facility (QMF) family of technologies establish pervasive production and sharing of business intelligence for information-oriented tasks in the organization. QMF offers many strengths, including the following:

- Support for functionality in the Db2 database, including long names, Unicode, and SQL enhancements
- Drag-and-drop capability for building OLAP analytics, SQL queries, pivot tables, and other business analysis and reports
- Executive dashboards and data visual solutions that offer visually rich, interactive functionality and interfaces for data analysis
- Support for QMF for WebSphere, a tool that turns any web browser into a zero-maintenance, thin client for visual on demand access to enterprise Db2 data
- Re-engineered cross-platform development environment
- New security model for access control and personalization

The visual solutions previously provided by QMF Vision are now included in the core QMF technology.

In addition to QMF for Workstation, which this topic describes, the QMF family includes the following editions:

- QMF Enterprise Edition provides the entire QMF family of technologies, enabling enterprise-wide business information across user and database operating systems. This edition consists of:
  - QMF for TSO/CICS
  - QMF High Performance Option
  - QMF for Workstation
  - QMF for WebSphere
  - DataQuant for Workstation
  - DataQuant for WebSphere
- QMF Classic Edition supports users who work with traditional mainframe terminals and emulators (including WebSphere Host On Demand) to access Db2 databases. This edition consists of QMF for TSO/CICS.

Executing SQL by using SPUFI (Db2 Application programming and SQL)

SQL Call Level Interface and Open Database Connectivity

The Db2 Call Level Interface (CLI) is an application programming interface in which functions are provided to application programs to process dynamic SQL statements.

Db2 CLI allows users to access SQL functions directly through a call interface. CLI programs can also be compiled using an Open Database Connectivity (ODBC) Software Developer's Kit, available from Microsoft or other vendors, enabling access to ODBC data sources. Unlike using embedded SQL, no precompilation is required. Applications developed using this interface can be executed on a variety of databases without being compiled against each of databases. Through the interface, applications use procedure calls at execution time to connect to databases, to issue SQL statements, and to get returned data and status information.

Introduction to Db2 ODBC (Db2 Programming for ODBC)

Conceptual view of a Db2 ODBC application (Db2 Programming for ODBC)

Related information

ODBC functions (Db2 Programming for ODBC)

Java database connectivity and embedded SQL for Java

Db2 provides two standards-based Java™ programming APIs: Java Database Connectivity (JDBC) and embedded SQL for Java (SQL/OLB or SQLJ). Both can be used to create Java applications and applets that access Db2.

Static SQL cannot be used by JDBC. SQLJ applications use JDBC as a foundation for such tasks as connecting to databases and handling SQL errors, but can contain embedded static SQL statements in the SQLJ source files. An SQLJ file has to be translated with the SQLJ translator before the resulting Java source code can be compiled.

Use of QMF for Workstation

QMF for Workstation is a tool that helps you build and manage powerful queries without requiring previous experience with SQL.

With the query-related features of Db2 Query Management Facility (QMF) and QMF for Workstation in particular, you can perform the following tasks:

- Build powerful queries without knowing SQL
- Analyze query results online, including OLAP analysis
- Edit query results to update Db2 data
- Format traditional text-based reports and reports with rich formatting
- Display charts and other complex visuals
- Send query results to an application of your choice
- Develop applications using robust API commands

How SQL statements are entered and processed

You can create your SQL statements using QMF for Workstation in several ways:

- Use the Database Explorer window to easily find and run saved queries that everyone at the same database server can share.
- If you know SQL, type the SQL statement directly in the window.
- If you don't know SQL, use the prompted or diagram interface to build the SQL statement.

The Database Explorer presents the objects that are saved on a server in a tree structure. By expanding and collapsing branches, you can easily locate and use saved queries. You can open the selected query and see the SQL statements or run the query.

If you need to build a new query, you can enter the SQL statements directly in the query window, or you can create the SQL statements using diagrams or prompts. As you build a query by using diagrams or prompts, you can open a view to see the SQL that is being created.

How you can work with query results

When you finish building the query, you can click the **Run Query** button to execute the SQL statements. After you run the query, QMF for Workstation returns the query results in an interactive window.

The query results are formatted by the comprehensive formatting options of QMF for Workstation. A robust expression language lets you conditionally format query results by retrieved column values. You can add calculated columns to the query results and group data columns on both axes with or without summaries. You can also use extensive drag-and-drop capabilities to easily restructure the appearance of the query results.

In addition to formatting the query results, you can perform the following actions:

- Create traditional text-based reports or state-of-the-art reports with rich formatting.
- Display query results by using charts and other complex visuals.
- Share reports by storing them on the database server.
- Send query results to various applications such as Microsoft Excel or Lotus® 1-2-3.

Db2 database objects overview

In Db2 for z/OS, you use database objects, such as tables, table spaces, indexes, index spaces, keys, views, and databases to organize and access your data.

The brief descriptions here show how the structures fit into an overall view of Db2. The following figure shows how some Db2 structures contain others. To some extent, the notion of "containment" provides a hierarchy of structures.

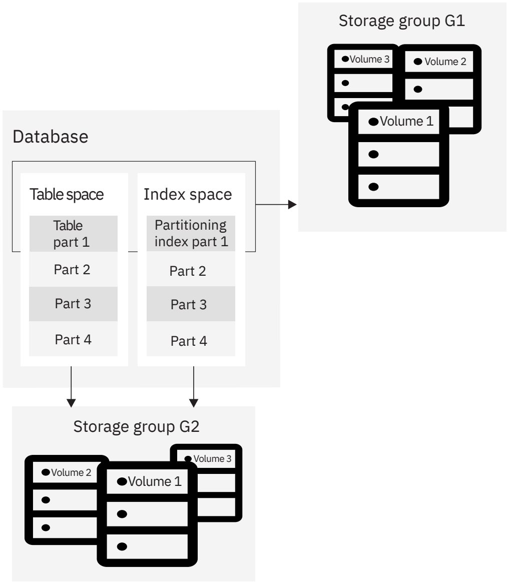

Figure 2. A hierarchy of Db2 structures

The Db2 structures from the most to the least inclusive are:

Databases
A set of Db2 structures that include a collection of tables, their associated indexes, and the table spaces in which they reside.

Storage groups
A set of volumes on disks that hold the data sets in which tables and indexes are stored.

Table spaces
A logical unit of storage in a database. A table space is a page set. The recommended partition-by-growth and partition-by-range table space types always contain data for only a single table. However, the segmented (non-UTS) and simple table space types, which are deprecated, can each contain one or more tables. For more information, see Table space types and characteristics in Db2 for z/OS (Db2 Administration Guide).

Deprecated function: FL 504 Non-UTS table spaces for base tables are deprecated. CREATE TABLESPACE statements that run at application compatibility level V12R1M504 or higher always create a partition-by-growth or partition-by-range table space, and CREATE TABLE statements that specify a non-UTS table space (including existing multi-table segmented table spaces) return an error. However, you can use a lower application compatibility level to create table spaces of the deprecated types if needed, such as for recovery situations. For instructions, see Creating non-UTS table spaces (deprecated) (Db2 Administration Guide).

Tables

All data in a Db2 database is presented in *tables*, which are collections of rows all having the same columns. A table that holds persistent user data is a *base table*. A table that stores data temporarily is a *temporary table*.

Views

A *view* is an alternative way of representing data that exists in one or more tables. A view can include all or some of the columns from one or more base tables.

Indexes

An *index* is an ordered set of pointers to the data in a Db2 table. The index is stored separately from the table. An index is either a simple index or an extended index. An extended index is one of the following objects:

- An expression-based index
- A spatial index
- An XML index

Related concepts

Implementing your database design (Db2 Administration Guide)
Storage structures (Introduction to Db2 for z/OS)

Db2 schemas and schema qualifiers

The objects in a relational database are organized into sets called schemas. A *schema* is a collection of named objects that provides a logical classification of objects in the database. The first part of a schema name is the qualifier.

A schema provides a logical classification of objects in the database. The objects that a schema can contain include tables, indexes, table spaces, distinct types, functions, stored procedures, and triggers. An object is assigned to a schema when it is created.

The *schema name* of the object determines the schema to which the object belongs. A user object, such as a distinct type, function, procedure, sequence, or trigger should not be created in a *system schema*, which is any one of a set of schemas that are reserved for use by the Db2 subsystem.

When a table, index, table space, distinct type, function, stored procedure, or trigger is created, it is given a qualified two-part name. The first part is the schema name (or the qualifier), which is either implicitly or explicitly specified. The default schema is the authorization ID of the owner of the plan or package. The second part is the name of the object.

In previous versions, CREATE statements had certain restrictions when the value of CURRENT SCHEMA was different from CURRENT SQLID value. Although those restrictions no longer exist, you now must consider how to determine the qualifier and owner when CURRENT SCHEMA and CURRENT SQLID contain different values. The rules for how the owner is determined depend on the type of object being created.

CURRENT SCHEMA and CURRENT SQLID affect only dynamic SQL statements. Static CREATE statements are not affected by either CURRENT SCHEMA or CURRENT SQLID.

The following table summarizes the effect of CURRENT SCHEMA in determining the schema qualifier and owner for these objects:

- Alias

- Auxiliary table
- Created global temporary table
- Table
- View

Table 1. Schema qualifier and owner for objects

Specification of name for new object being created	Schema qualifier of new object	Owner of new object
name (no qualifier)	value of CURRENT SCHEMA	value of CURRENT SQLID
abc.name (single qualifier)	abc	abc
......abc.name (multiple qualifiers)	abc	abc

The following table summarizes the effect of CURRENT SCHEMA in determining the schema qualifier and owner for these objects:

- User-defined type
- User-defined function
- Procedure
- Sequence
- Trigger

Table 2. Schema qualifier and owner for additional objects

Specification of name for new object being created	Schema qualifier of new object	Owner of new object
name (no qualifier)	value of CURRENT SCHEMA	value of CURRENT SQLID
abc.name (single qualifier)	abc	value of CURRENT SQLID
......abc.name (multiple qualifiers)	abc	value of CURRENT SQLID

Related reference

Reserved schema names in Db2 for z/OS
In general, for certain objects, schema names that begin with the prefix SYS are reserved. The schema name for these objects cannot begin with SYS except for certain exceptions.

Db2 tables

Tables are logical structures that Db2 maintains. Db2 supports several different types of tables.

Tables are made up of columns and rows. The rows of a relational table have no fixed order. The order of the columns, however, is always the order in which you specified them when you defined the table.

At the intersection of every column and row is a specific data item, which is called a *value*. A *column* is a set of values of the same type. A *row* is a sequence of values such that the *n*th value is a value of the *n*th column of the table. Every table must have one or more columns, but the number of rows can be zero.

Db2 accesses data by referring to its content instead of to its location or organization in storage.

Db2 supports the following types of tables:

accelerator-only table
A table that stores rows only in the accelerator, not in Db2. The table and column definition of the accelerator-only table is contained in Db2 catalog tables. Any queries that reference the accelerator-only table, must be executed in the accelerator. If a query that references an accelerator-only table

is not eligible for query acceleration, an error is issued. To change the contents of an accelerator-only table, the data change statement must be executed in the accelerator.

archive table

A table that stores rows that are deleted from another table.

archive-enabled table

A table that has an associated archive table. When rows are deleted from an archive-enabled table, Db2 can automatically insert those rows into an archive table.

auxiliary table

A table created with the SQL statement CREATE AUXILIARY TABLE and used to hold the data for a column that is defined in a base table.

base table

The most common type of table in Db2. You create a base table with the SQL CREATE TABLE statement. The Db2 catalog table, SYSIBM.SYSTABLES, stores the description of the base table. The table description and table data are persistent. All programs and users that refer to this type of table refer to the same description of the table and to the same instance of the table.

clone table

A table that is structurally identical to a base table. You create a clone table by using an ALTER TABLE statement for the base table that includes an ADD CLONE clause. The clone table is created in a different instance of the same table space as the base table, is structurally identical to the base table in every way, and has the same indexes, before triggers, and LOB objects. In the Db2 catalog, the SYSTABLESPACE table indicates that the table space has only one table in it, but SYSTABLESPACE.CLONE indicates that a clone table exists. Clone tables can be created only in a partition-by range or partition-by-growth table space that is managed by Db2. The base and clone table each have separate underlying VSAM data sets (identified by their data set instance numbers) that contain independent rows of data.

empty table

A table with zero rows.

history table

A table that is used to store historical versions of rows from the associated system-period temporal table.

materialized query table

A table, which you define with the SQL CREATE TABLE statement, that contains materialized data that is derived from one or more source tables. Materialized query tables are useful for complex queries that run on large amounts of data. Db2 can precompute all or part of such queries and use the precomputed, or materialized, results to answer the queries more efficiently. Materialized query tables are commonly used in data warehousing and business intelligence applications.

Several Db2 catalog tables, including SYSIBM.SYSTABLES and SYSIBM.SYSVIEWS, store the description of the materialized query table and information about its dependency on a table, view, or function. The attributes that define a materialized query table tell Db2 whether the table is:

- System-maintained or user-maintained.
- Refreshable: All materialized tables can be updated with the REFRESH TABLE statement. Only user-maintained materialized query tables can also be updated with the LOAD utility and the UPDATE, INSERT, and DELETE SQL statements.
- Enabled for query optimization: You can enable or disable the use of a materialized query table in automatic query rewrite.

Materialized query tables can be used to improve the performance of dynamic SQL queries. If Db2 determines that a portion of a query could be resolved using a materialized query table, the query might be rewritten by Db2 to use the materialized query table. This decision is based in part on the settings of the CURRENT REFRESH AGE and the CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION special registers.

result table

A table that contains a set of rows that Db2 selects or generates, directly or indirectly, from one or more base tables in response to an SQL statement. Unlike a base table or a temporary table, a result table is not an object that you define using a CREATE statement.

sample table

One of several tables shipped with the Db2 licensed program that contains sample data. Many examples in this information are based on sample tables.

temporal table

A table that records the period of time when a row is valid.

Db2 supports two types of periods, which are the system period (SYSTEM_TIME) and the application period (BUSINESS_TIME). The system period consists of a pair of columns with system-maintained values that indicates the period of time when a row is valid. The application period consists of a pair of columns with application-maintained values that indicates the period of time when a row is valid.

system-period temporal table

A system-period temporal table is a base table that is defined with system-period data versioning. You can modify an existing table to become a system-period temporal table by specifying the ADD PERIOD SYSTEM_TIME clause on the ALTER TABLE statement. After creating a history table that corresponds to the system-period temporal table, you can define system-period data versioning on the table by issuing the ALTER TABLE ADD VERSIONING statement with the USE HISTORY table clause.

application-period temporal table

An application-period temporal table is a base table that includes an application period (BUSINESS_TIME). You can modify an existing table to become an application-period temporal table by specifying the ADD PERIOD BUSINESS_TIME clause on the ALTER TABLE statement.

bitemporal table

A bitemporal table is a table that is both a system-period temporal table and an application-period temporal table. You can use a bitemporal table to keep application period information and system-based historical information. Therefore, you have a lot of flexibility in how you query data, based on periods of time.

temporary table

A table that is defined by the SQL statement CREATE GLOBAL TEMPORARY TABLE or DECLARE GLOBAL TEMPORARY TABLE to hold data temporarily. Temporary tables are especially useful when you need to sort or query intermediate result tables that contain many rows, but you want to store only a small subset of those rows permanently.

created global temporary table

A table that you define with the SQL CREATE GLOBAL TEMPORARY TABLE statement. The Db2 catalog table, SYSIBM.SYSTABLES, stores the description of the created temporary table. The description of the table is persistent and shareable. However, each individual application process that refers to a created temporary table has its own distinct instance of the table. That is, if application process A and application process B both use a created temporary table named TEMPTAB:

- Each application process uses the same table description.
- Neither application process has access to or knowledge of the rows in the other application instance of TEMPTAB.

declared global temporary table

A table that you define with the SQL DECLARE GLOBAL TEMPORARY TABLE statement. The Db2 catalog does not store a description of the declared temporary table. Therefore, the description and the instance of the table are not persistent. Multiple application processes can refer to the same declared temporary table by name, but they do not actually share the same description or instance of the table. For example, assume that application process A defines a declared temporary table named TEMP1 with 15 columns. Application process B defines a declared temporary table named TEMP1 with five columns. Each application process uses its own description of TEMP1; neither application process has access to or knowledge of rows in the other application instance of TEMP1.

XML table

A special table that holds only XML data. When you create a table with an XML column, Db2 implicitly creates an XML table space and an XML table to store the XML data.

Types of tables (Db2 Administration Guide)

Related reference

CREATE TABLE

The CREATE TABLE statement defines a table. The definition must include its name and the names and attributes of its columns. The definition can include other attributes of the table, such as its primary key and its table space.

ALTER TABLE

The ALTER TABLE statement changes the description of a table at the current server.

Db2 keys

A *key* is a column or an ordered collection of columns that is identified in the description of a table, an index, or a referential constraint. Keys are crucial to the table structure in a relational database.

Keys are important in a relational database because they ensure that each record in a table is uniquely identified, they help establish and enforce referential integrity, and they establish relationships between tables. The same column can be part of more than one key.

A *composite key* is an ordered set of two or more columns of the same table. The ordering of the columns is not constrained by their actual order within the table. The term *value*, when used with respect to a composite key, denotes a composite value. For example, consider this rule: "The value of the foreign key must be equal to the value of the primary key." This rule means that each component of the value of the foreign key must be equal to the corresponding component of the value of the primary key.

Db2 supports several types of keys.

Unique keys

A *unique constraint* is a rule that the values of a key are valid only if they are unique. A key that is constrained to have unique values is a *unique key*. Db2 uses a *unique index* to enforce the constraint during the execution of the LOAD utility and whenever you use an INSERT, UPDATE, or MERGE statement to add or modify data. Every unique key is a key of a unique index. You can define a unique key by using the UNIQUE clause of either the CREATE TABLE or the ALTER TABLE statement. A table can have any number of unique keys.

The columns of a unique key cannot contain null values.

Primary keys

A *primary key* is a special type of unique key and cannot contain null values. For example, the DEPTNO column in the DEPT table is a primary key.

A table can have no more than one primary key. Primary keys are optional and can be defined in CREATE TABLE or ALTER TABLE statements.

The unique index on a primary key is called a *primary index*. When a primary key is defined in a CREATE TABLE statement or ALTER TABLE statement, Db2 automatically creates the primary index.

If a unique index already exists on the columns of the primary key when it is defined in the ALTER TABLE statement, this unique index is designated as the primary index when Db2 is operating in new-function mode and implicitly created the table space.

Parent keys

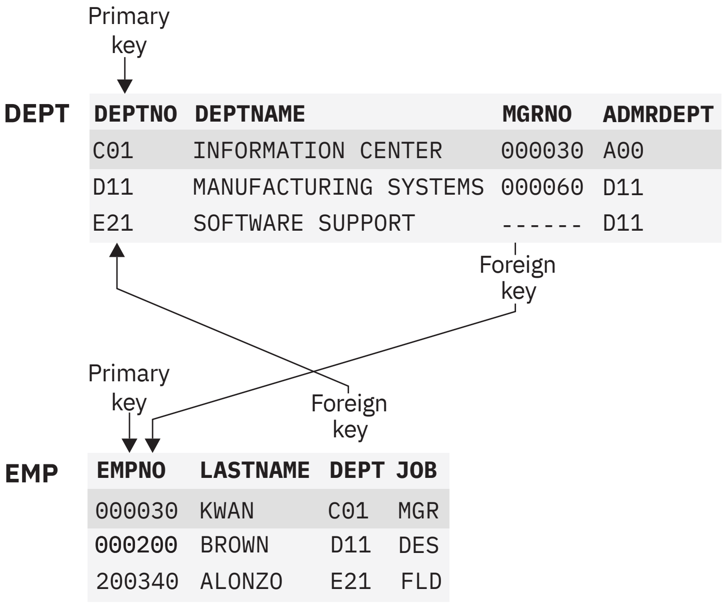
A *parent key* is either a primary key or a unique key in the parent table of a referential constraint. The values of a parent key determine the valid values of the foreign key in the constraint.

Foreign keys

A *foreign key* is a key that is specified in the definition of a referential constraint in a CREATE or ALTER TABLE statement. A foreign key refers to or is related to a specific parent key.

Unlike other types of keys, a foreign key does not require an index on its underlying column or columns. A table can have zero or more foreign keys. The value of a composite foreign key is null if any component of the value is null.

The following figure shows the relationship between some columns in the DEPT table and the EMP table.



DEPTNO	DEPTNAME	MGRNO	ADMRDEPT
C01	INFORMATION CENTER	000030	A00
D11	MANUFACTURING SYSTEMS	000060	D11
E21	SOFTWARE SUPPORT	------	D11

EMPNO	LASTNAME	DEPT	JOB
000030	KWAN	C01	MGR
000200	BROWN	D11	DES
200340	ALONZO	E21	FLD

Figure 3. Relationship between DEPT and EMP tables

Figure notes: Each table has a primary key:

- DEPTNO in the DEPT table
- EMPNO in the EMP table

Each table has a foreign key that establishes a relationship between the tables:

- The values of the foreign key on the DEPT column of the EMP table match values in the DEPTNO column of the DEPT table.
- The values of the foreign key on the MGRNO column of the DEPT table match values in the EMPNO column of the EMP table when an employee is a manager.

To see a specific relationship between rows, notice how the shaded rows for department C01 and employee number 000030 share common values.

Related concepts
Referential constraints (Introduction to Db2 for z/OS)

Constraints

A *constraint* is rules that Db2 enforces for column values to prevent duplicate values or set restrictions on data added to a table.

Db2 uses the following types of constraints.

Related concepts

Ways to maintain data integrity (Db2 Application programming and SQL)

Unique constraints

A *unique constraint* is a rule that the values of a key are valid only if they are unique in a table.

Unique constraints are optional and can be defined in the CREATE TABLE or ALTER TABLE statements with the PRIMARY KEY clause or the UNIQUE clause. The columns specified in a unique constraint must be defined as NOT NULL. A unique index enforces the uniqueness of the key during changes to the columns of the unique constraint.

A table can have an arbitrary number of unique constraints, with at most one unique constraint defined as a primary key. A table cannot have more than one unique constraint on the same set of columns.

A unique constraint that is referenced by the foreign key of a referential constraint is called the *parent key*.

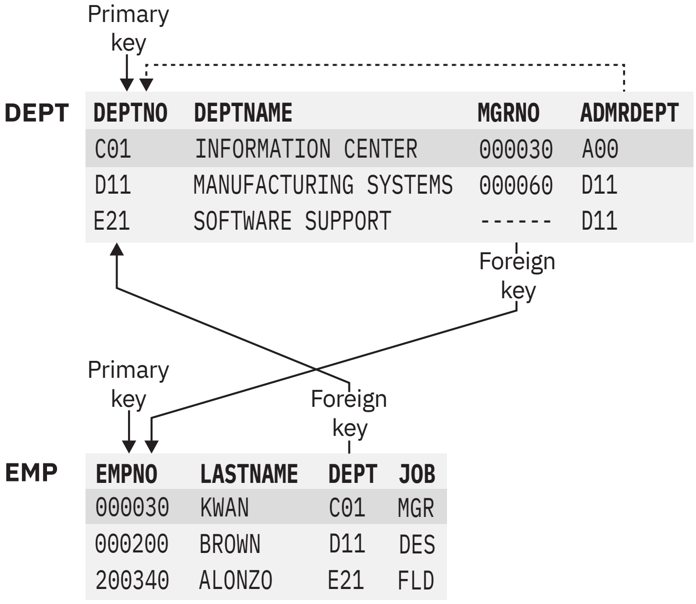
Referential constraints

Db2 ensures referential integrity between your tables when you define referential constraints.

Referential integrity is the state in which all values of all foreign keys are valid. Referential integrity is based on *entity integrity*. Entity integrity requires that each entity have a unique key. For example, if every row in a table represents relationships for a unique entity, the table should have one column or a set of columns that provides a unique identifier for the rows of the table. This column (or set of columns) is called the parent key of the table. To ensure that the parent key does not contain duplicate values, a unique index must be defined on the column or columns that constitute the parent key. Defining the parent key is called entity integrity.

A *referential constraint* is the rule that the nonnull values of a foreign key are valid only if they also appear as values of a parent key. The table that contains the parent key is called the *parent table* of the referential constraint, and the table that contains the foreign key is a *dependent* of that table.

The relationship between some rows of the DEPT and EMP tables, shown in the following figure, illustrates referential integrity concepts and terminology. For example, referential integrity ensures that every foreign key value in the DEPT column of the EMP table matches a primary key value in the DEPTNO column of the DEPT table.



DEPT

DEPTNO	DEPTNAME	MGRNO	ADMRDEPT
C01	INFORMATION CENTER	000030	A00
D11	MANUFACTURING SYSTEMS	000060	D11
E21	SOFTWARE SUPPORT	------	D11

EMP

EMPNO	LASTNAME	DEPT	JOB
000030	KWAN	C01	MGR
000200	BROWN	D11	DES
200340	ALONZO	E21	FLD

Figure 4. Referential integrity of DEPT and EMP tables

Two parent and dependent relationships exist between the DEPT and EMP tables.

- The foreign key on the DEPT column establishes a parent and dependent relationship. The DEPT column in the EMP table depends on the DEPTNO in the DEPT table. Through this foreign key relationship, the DEPT table is the parent of the EMP table. You can assign an employee to no department (by specifying a null value), but you cannot assign an employee to a department that does not exist.
- The foreign key on the MGRNO column also establishes a parent and dependent relationship. Because MGRNO depends on EMPNO, EMP is the parent table of the relationship, and DEPT is the dependent table.

You can define a primary key on one or more columns. A primary key that includes two or more columns is called a *composite key*. A foreign key can also include one or more columns. When a foreign key contains multiple columns, the corresponding primary key must be a composite key. The number of foreign key columns must be the same as the number of columns in the parent key, and the data types of the corresponding columns must be compatible. (The sample project activity table, DSN8C10.PROJACT, is an example of a table with a primary key on multiple columns, PROJNO, ACTNO, and ACSTDATE.)

A table can be a dependent of itself; this is called a *self-referencing table*. For example, the DEPT table is self-referencing because the value of the administrative department (ADMRDEPT) must be a department ID (DEPTNO). To enforce the self-referencing constraint, Db2 requires that a foreign key be defined.

Similar terminology applies to the rows of a parent-and-child relationship. A row in a dependent table, called a *dependent row*, refers to a row in a parent table, called a *parent row*. But a row of a parent table is not always a parent row—perhaps nothing refers to it. Likewise, a row of a dependent table is not always a dependent row—the foreign key can allow null values, which refer to no other rows.

Referential constraints are optional. You define referential constraints by using CREATE TABLE and ALTER TABLE statements.

Db2 enforces referential constraints when the following actions occur:

- An INSERT statement is applied to a dependent table.
- An UPDATE statement is applied to a foreign key of a dependent table or to the parent key of a parent table.
- A MERGE statement that includes an insert operation is applied to a dependent table.
- A MERGE statement that includes an update operation is applied to a foreign key of a dependent table or to the parent key of a parent table.
- A DELETE statement is applied to a parent table. All affected referential constraints and all delete rules of all affected relationships must be satisfied in order for the delete operation to succeed.
- The LOAD utility with the ENFORCE CONSTRAINTS option is run on a dependent table.
- The CHECK DATA utility is run.

Another type of referential constraint is an *informational referential constraint*. This type of constraint is not enforced by Db2 during normal operations. An application process should verify the data in the referential integrity relationship. An informational referential constraint allows queries to take advantage of materialized query tables.

The order in which referential constraints are enforced is undefined. To ensure that the order does not affect the result of the operation, there are restrictions on the definition of delete rules and on the use of certain statements. The restrictions are specified in the descriptions of the SQL statements CREATE TABLE, ALTER TABLE, INSERT, UPDATE, MERGE, and DELETE.

The rules of referential integrity involve the following concepts and terminology:

parent key
  A primary key or a unique key of a referential constraint.

parent table
  A table that is a parent in at least one referential constraint. A table can be defined as a parent in an arbitrary number of referential constraints.

dependent table
A table that is a dependent in at least one referential constraint. A table can be defined as a dependent in an arbitrary number of referential constraints. A dependent table can also be a parent table.

descendent table
A table that is a dependent of another table or a table that is a dependent of a descendent table.

referential cycle
A set of referential constraints in which each associated table is a descendent of itself.

parent row
A row that has at least one dependent row.

dependent row
A row that has at least one parent row.

descendent row
A row that is dependent on another row or a row that is a dependent of a descendent row.

self-referencing row
A row that is a parent of itself.

self-referencing table
A table that is both parent and dependent in the same referential constraint. The constraint is called a *self-referencing constraint*.

A temporal referential constraint can be defined for a table that contains a BUSINESS_TIME period. The PERIOD BUSINESS_TIME clause is used in both the FOREIGN KEY clause and the REFERENCES clause to indicate that there must not be a row in the child table for which the period of time represented by the BUSINESS_TIME period value for that row is not contained in the BUSINESS_TIME period of one or more corresponding rows in the parent table. Unlike normal referential constraints, it is not necessary that there be exactly one corresponding row in the parent table where the BUSINESS_TIME period contains the BUSINESS_TIME period of the child row. As long as the BUSINESS_TIME period of a row in the child table is contained in the union of the BUSINESS_TIME periods of two or more contiguous matching rows in the parent table, the temporal referential constraint is satisfied.

Additionally, the following indexes must be defined:

- A unique index on the parent table with the BUSINESS_TIME WITHOUT OVERLAPS clause.
- A non-unique index on the child table with the BUSINESS_TIME WITH OVERLAPS clause. Alternatively, the index on the child table, can be defined without the BUSINESS_TIME WITH OVERLAPS clause if the end of the index key includes the end column followed by the begin column of the BUSINESS_TIME period (both in ascending order).

The following rules provide referential integrity:

insert rule
A nonnull insert value of the foreign key must match some value of the parent key of the parent table. The value of a composite foreign key is null if any component of the value is null.

update rule
A nonnull update value of the foreign key must match some value of the parent key of the parent table. The value of a composite foreign key is treated as null if any component of the value is null.

delete rule
Controls what happens when a row of the parent table is deleted. The choices of action, made when the referential constraint is defined, are RESTRICT, NO ACTION, CASCADE, or SET NULL. SET NULL can be specified only if some column of the foreign key allows null values.

More precisely, the delete rule applies when a row of the parent table is the object of a delete or propagated delete operation and that row has dependents in the dependent table of the referential constraint. A *propagated delete* refers to the situation where dependent rows are deleted when parent rows are deleted. Let *P* denote the parent table, let *D* denote the dependent table, and let *p* denote a parent row that is the object of a delete or propagated delete operation. If the delete rule is:

- RESTRICT or NO ACTION, an error occurs and no rows are deleted.

- CASCADE, the delete operation is propagated to the dependent rows of *p* in *D*.
- SET NULL, each nullable column of the foreign key of each dependent row of *p* in *D* is set to null.

Each referential constraint in which a table is a parent has its own delete rule, and all applicable delete rules are used to determine the result of a delete operation. Thus, a row cannot be deleted if it has dependents in a referential constraint with a delete rule of RESTRICT or NO ACTION or the deletion cascades to any of its descendents that are dependents in a referential constraint with the delete rule of RESTRICT or NO ACTION.

The deletion of a row from parent table *P* involves other tables and can affect rows of these tables:

- If *D* is a dependent of *P* and the delete rule is RESTRICT or NO ACTION, *D* is involved in the operation but is not affected by the operation and the deletion from the parent table *P* does not take place.
- If *D* is a dependent of *P* and the delete rule is SET NULL, *D* is involved in the operation and rows of *D* might be updated during the operation.
- If *D* is a dependent of *P* and the delete rule is CASCADE, *D* is involved in the operation and rows of *D* might be deleted during the operation. If rows of *D* are deleted, the delete operation on *P* is said to be propagated to *D*. If *D* is also a parent table, the actions described in this list apply, in turn, to the dependents of *D*.

Any table that can be involved in a delete operation on *P* is said to be *delete-connected* to *P*. Thus, a table is delete-connected to table *P* if it is a dependent of *P* or a dependent of a table to which delete operations from *P* cascade.

Check constraints

A *check constraint* is a rule that specifies the values that are allowed in one or more columns of every row of a base table.

Like referential constraints, check constraints are optional and you define them by using the CREATE TABLE and ALTER TABLE statements. The definition of a check constraint restricts the values that a specific column of a base table can contain.

A table can have any number of check constraints. Db2 enforces a check constraint by applying the restriction to each row that is inserted, loaded, or updated. One restriction is that a column name in a check constraint on a table must identify a column of that table.

For example, you can create a check constraint to ensure that all employees earn a salary of $30,000 or more:

```
CHECK (SALARY>= 30000)
```

Related concepts
Check constraints (Db2 Application programming and SQL)

Db2 table columns

A column definition has two basic components, the column name and the data type.

A *column* contains values that have the same data type. If you are familiar with the concepts of records and fields, you can think of a *value* as a field in a record. A value is the smallest unit of data that you can manipulate with SQL. For example, in the EMP table, the EMPNO column identifies all employees by a unique employee number. The HIREDATE column contains the hire dates for all employees. You cannot overlap columns.

Online schema enhancements provide flexibility that lets you change a column definition. Carefully consider the decisions that you make about column definitions. After you implement the design of your tables, you can change a column definition with minimal disruption of applications.

Throughout the implementation phase of database design, refer to the complete descriptions of SQL statement syntax and usage for each SQL statement that you work with.

Column names

Following column naming guidelines that are developed for your organization ensures that you make good choices that are consistent.

Generally, the database administrator (DBA) is involved in determining the names of attributes (or columns) during the physical database design phase. To make the right choices for column names, DBAs follow the guidelines that the data administrators developed.

Sometimes columns need to be added to the database after the design is complete. In this case, Db2 rules for unique column names must be followed. Column names must be unique within a table, but you can use the same column name in different tables. Try to choose a meaningful name to describe the data in a column to make your naming scheme intuitive.

For more information, see "Column names" on page 218 and "Naming conventions" on page 79.

Related reference

Employee table (DSN8C10.EMP) (Introduction to Db2 for z/OS)

Data types of columns

Every column in every Db2 table has a data type. The data type influences the range of values that the column can have and the set of operators and functions that apply to it.

You specify the data type of each column at the time that you create the table. You can also change the data type of a table column. The new data type definition is applied to all data in the associated table when the table is reorganized.

Some data types have parameters that further define the operators and functions that apply to the column. Db2 supports both IBM-supplied data types and user-defined data types. The data types that IBM supplies are sometimes called *built-in data types*.

In Db2 for z/OS, user-defined data types are called *distinct types*.

How Db2 compares values of different data types

Db2 compares values of different types and lengths. A comparison occurs when both values are numeric, both values are character strings, or both values are graphic strings. Comparisons can also occur between character and graphic data or between character and datetime data if the character data is a valid character representation of a datetime value. Different types of string or numeric comparisons might have an impact on performance.

Related concepts

Entity attributes in database design (Introduction to Db2 for z/OS)

Data types of columns (Db2 Application programming and SQL)

Assignment and comparison

The basic operations of SQL are assignment and comparison.

Casting between data types
There are many occasions when a value with a given data type needs to be *cast* (changed) to a different data type or to the same data type with a different length, precision, or scale.

Rules for result data types
Rules that are applied to the operands of an operation determine the data type of the result. Certain rules apply in certain situations and apply depending on the data type of operands.

Distinct types (Introduction to Db2 for z/OS)

String data types

Db2 supports several types of string data: character strings, graphic strings, and binary strings.

Character strings contain text and can be either a fixed-length or a varying-length. *Graphic strings* contain graphic data, which can also be either a fixed-length or a varying-length. *Binary strings* contain strings of binary bytes and can be either a fixed-length or a varying-length. All of these types of string data can be represented as large objects.

The following table describes the different string data types and indicates the range for the length of each string data type.

Table 3. String data types

Data type	Denotes a column of...
CHARACTER(*n*)	Fixed-length character strings with a length of *n* bytes. *n* must be greater than 0 and not greater than 255. The default length is 1.
VARCHAR(*n*)	Varying-length character strings with a maximum length of *n* bytes. *n* must be greater than 0 and less than a number that depends on the page size of the table space. The maximum length is 32704.
CLOB(*n*)	Varying-length character strings with a maximum of *n* characters. *n* cannot exceed 2,147,483,647. The default length is 1M.
GRAPHIC(*n*)	Fixed-length graphic strings that contain *n* double-byte characters. *n* must be greater than 0 and less than 128. The default length is 1.
VARGRAPHIC(*n*)	Varying-length graphic strings. The maximum length, *n*, must be greater than 0 and less than a number that depends on the page size of the table space. The maximum length is 16352.
DBCLOB(*n*)	Varying-length strings of double-byte characters with a maximum of *n* double-byte characters. *n* cannot exceed 1,073,741,824. The default length is 1M.
BINARY(*n*)	Fixed-length or varying-length binary strings with a length of *n* bytes. *n* must be greater than 0 and not greater than 255. The default length is 1.
VARBINARY(*n*)	Varying-length binary strings with a length of *n* bytes. The length of *n* must be greater than 0 and less than a number that depends on the page size of the table space. The maximum length is 32704.
BLOB(*n*)	Varying-length binary strings with a length of *n* bytes. *n* cannot exceed 2,147,483,647. The default length is 1M.

In most cases, the content of the data that a column is to store dictates the data type that you choose.

Example

For example, assume that the DEPT table has a column, DEPTNAME. The data type of the DEPTNAME column is VARCHAR(36). Because department names normally vary considerably in length, the choice of a varying-length data type seems appropriate. If you choose a data type of CHAR(36), for example, the result is a lot of wasted, unused space. In this case, Db2 assigns all department names, regardless of length, the same amount of space (36 bytes). A data type of CHAR(6) for the employee number (EMPNO) is a reasonable choice because all values are fixed-length values (6 bytes).

Fixed-length and variable-length character strings

Using VARCHAR saves disk space, but it incurs a 2-byte overhead cost for each value. Using VARCHAR also requires additional processing for varying-length rows. Therefore, using CHAR is preferable to VARCHAR, unless the space that you save by using VARCHAR is significant. The savings are not significant if the maximum column length is small or if the lengths of the values do not have a significant variation.

Recommendation: Generally, do not define a column as VARCHAR(*n*) or CLOB(*n*) unless *n* is at least 18 characters.

String subtypes

If an application that accesses your table uses a different encoding scheme than your DBMS uses, the following string subtypes can be important:

BIT
Does not represent characters.

SBCS
Represents single-byte characters.

MIXED
Represents single-byte characters and multibyte characters.

String subtypes apply only to CHAR, VARCHAR, and CLOB data types. However, the BIT string subtype is not allowed for the CLOB data type.

Graphic and mixed data

When columns contain *double-byte character set* (DBCS) characters, you can define them as either graphic data or mixed data.

Graphic data can be either GRAPHIC, VARGRAPHIC, or DBCLOB. Using VARGRAPHIC saves disk space, but it incurs a 2-byte overhead cost for each value. Using VARGRAPHIC also requires additional processing for varying-length rows. Therefore, using GRAPHIC data is preferable to using VARGRAPHIC unless the space that you save by using VARGRAPHIC is significant. The savings are not significant if the maximum column length is small or if the lengths of the values do not vary significantly.

Recommendation: Generally, do not define a column as VARGRAPHIC(*n*) unless *n* is at least 18 double-byte characters (which is a length of 36 bytes).

Mixed-data character string columns can contain both *single-byte character set* (SBCS) and DBCS characters. You can specify the mixed-data character string columns as CHAR, VARCHAR, or CLOB with MIXED DATA.

Recommendation: If all of the characters are DBCS characters, use the graphic data types. (Kanji is an example of a language that requires DBCS characters.) For SBCS characters, use mixed data to save 1 byte for every single-byte character in the column.

Encoding schemes for string data

For string data, all characters are represented by a common encoding representation (Unicode, ASCII, or EBCDIC). Encoding schemes apply to string data types and to distinct types that are based on string types.

Multinational companies that engage in international trade often store data from more than one country in the same table. Some countries use different coded character set identifiers. Db2 for z/OS supports the Unicode encoding scheme, which represents many different geographies and languages. If you need to perform character conversion on Unicode data, the conversion is more likely to preserve all of your information.

In some cases, you might need to convert characters to a different encoding representation. The process of conversion is known as *character conversion*. Most users do not need a knowledge of character conversion. When character conversion does occur, it does so automatically and a successful conversion is invisible to the application and users.

Distinct types (Introduction to Db2 for z/OS)

Character strings
A *character string* is a sequence of bytes. The length of the string is the number of bytes in the sequence. If the length is zero, the value is called the *empty string*. The empty string should not be confused with the null value.

Graphic strings
A *graphic string* is a sequence of double-byte characters.

Binary strings
A *binary string* is a sequence of bytes.

Introduction to character conversion (Db2 Internationalization Guide)

Department table (DSN8C10.DEPT) (Introduction to Db2 for z/OS)

Numeric data types

Db2 supports several types of numeric data types, each of which has its own characteristics.

For numeric data, use numeric columns rather than string columns. Numeric columns require less space than string columns, and Db2 verifies that the data has the assigned type.

For example, assume that Db2 calculates a range between two numbers. If the values have a string data type, Db2 assumes that the values can include all combinations of alphanumeric characters. In contrast, if the values have a numeric data type, Db2 can calculate a range between the two values more efficiently.

The following table describes the numeric data types.

Table 4. Numeric data types

Data type	Denotes a column of...
SMALLINT	Small integers. A *small integer* is binary integer with a precision of 15 bits. The range is -32768 to +32767.
INTEGER or INT	Large integers. A *large integer* is binary integer with a precision of 31 bits. The range is -2147483648 to +2147483647.
BIGINT	Big integers. A *big integer* is a binary integer with a precision of 63 bits. The range of big integers is -9223372036854775808 to +9223372036854775807.
DECIMAL or NUMERIC	A *decimal* number is a packed decimal number with an implicit decimal point. The position of the decimal point is determined by the precision and the scale of the number. The scale, which is the number of digits in the fractional part of the number, cannot be negative or greater than the precision. The maximum precision is 31 digits. All values of a decimal column have the same precision and scale. The range of a decimal variable or the numbers in a decimal column is -*n* to +*n*, where *n* is the largest positive number that can be represented with the applicable precision and scale. The maximum range is 1 - 10^{31} to 10^{31} - 1.

Table 4. Numeric data types (continued)

Data type	Denotes a column of...
DECFLOAT	A *decimal floating-point* value is an IEEE 754r number with a decimal point. The position of the decimal point is stored in each decimal floating-point value. The maximum precision is 34 digits. The range of a decimal floating-point number is either 16 or 34 digits of precision; the exponent range is respectively 10-383 to 10+384 or 10-6143 to 10+6144.
REAL	A *single-precision floating-point* number is a short floating-point number of 32 bits. The range of single-precision floating-point numbers is approximately -7.2E+75 to 7.2E+75. In this range, the largest negative value is about -5.4E-79, and the smallest positive value is about 5.4E-079.
DOUBLE	A *double-precision floating-point* number is a long floating-point number of 64-bits. The range of double-precision floating-point numbers is approximately -7.2E+75 to 7.2E+75. In this range, the largest negative value is about -5.4E-79, and the smallest positive value is about 5.4E-79.

Note: IBM zSystems and z/Architecture® use the System/390® format and support IEEE floating-point format.

For integer values, use SMALLINT, INTEGER, or BIGINT (depending on the range of the values). Do not use DECIMAL for integer values.

You can define an exact numeric column as an identity column. An *identity column* has an attribute that enables Db2 to automatically generate a unique numeric value for each row that is inserted into the table. Identity columns are ideally suited to the task of generating unique primary-key values. Applications that use identity columns might be able to avoid concurrency and performance problems that sometimes occur when applications implement their own unique counters.

Date, time, and timestamp data types

Although storing dates and times as numeric values is possible, using datetime data types is recommended. The datetime data types are DATE, TIME, and TIMESTAMP.

The following table describes the data types for dates, times, and timestamps.

Table 5. Date, time, and timestamp data types

Data type	Denotes a column of...
DATE	A *date* is a three-part value representing a year, month, and day in the range of 0001-01-01 to 9999-12-31.
TIME	A *time* is a three-part value representing a time of day in hours, minutes, and seconds, in the range of 00.00.00 to 24.00.00.
TIMESTAMP	A *timestamp* is a seven-part value representing a date and time by year, month, day, hour, minute, second, and microsecond, in the range of 0001-01-01-00.00.00.000000000 to 9999-12-31-24.00.00.000000000 with nanosecond precision. Timestamps can also hold timezone information.

Db2 stores values of datetime data types in a special internal format. When you load or retrieve data, Db2 can convert it to or from any of the formats in the following table.

Table 6. Date and time format options

Format name	Abbreviation	Typical date	Typical time
International Standards Organization	ISO	2003-12-25	13.30.05

Table 6. Date and time format options (continued)

Format name	Abbreviation	Typical date	Typical time
IBM USA standard	USA	12/25/2003	1:30 PM
IBM European standard	EUR	25.12.2003	13.30.05
Japanese Industrial Standard Christian Era	JIS	2003-12-25	13:30:05

GUPI

Example 1

The following query displays the dates on which all employees were hired, in IBM USA standard form, regardless of the local default:

```
SELECT EMPNO, CHAR(HIREDATE, USA) FROM EMP;
```

Example 2

When you use datetime data types, you can take advantage of Db2 built-in functions that operate specifically on datetime values, and you can specify calculations for datetime values. Assume that a manufacturing company has an objective to ship all customer orders within five days. You define the SHIPDATE and ORDERDATE columns as DATE data types. The company can use datetime data types and the DAYS built-in function to compare the shipment date to the order date. Here is how the company might code the function to generate a list of orders that have exceeded the five-day shipment objective:

```
DAYS(SHIPDATE) — DAYS(ORDERDATE)> 5
```

As a result, programmers do not need to develop, test, and maintain application code to perform complex datetime arithmetic that needs to allow for the number of days in each month.

GUPI

You can use the following sample user-defined functions (which come with Db2) to modify the way dates and times are displayed.

- ALTDATE returns the current date in a user-specified format or converts a user-specified date from one format to another.
- ALTTIME returns the current time in a user-specified format or converts a user-specified time from one format to another.

At installation time, you can also supply an exit routine to make conversions to and from any local standard.

When loading date or time values from an outside source, Db2 accepts any of the date and time format options that are listed in this information. Db2 converts valid input values to the internal format. For retrieval, a default format is specified at Db2 installation time. You can subsequently override that default by using a precompiler option for all statements in a program or by using the scalar function CHAR for a particular SQL statement and by specifying the format that you want.

Related concepts

Datetime constants
A *datetime constant* is a character string constant of a particular format.

XML data type

The XML data type is used to define columns of a table that store XML values. This pureXML® data type provides the ability to store well-formed XML documents in a database.

All XML data is stored in the database in an internal representation. Character data in this internal representation is in the UTF-8 encoding scheme.

XML values that are stored in an XML column have an internal representation that is not a string and not directly comparable to string values. An XML value can be transformed into a serialized string value that represents the XML document by using the XMLSERIALIZE function or by retrieving the value into an application variable of an XML, string, or binary type. Similarly, a string value that represents an XML document can be transformed to an XML value by using the XMLPARSE function or by storing a value from a string, binary, or XML application data type in an XML column.

The size of an XML value in a Db2 table has no architectural limit. However, serialized XML data that is stored in or retrieved from an XML column is limited to 2 GB.

Validation of an XML document against an XML schema, typically performed during INSERT or UPDATE into an XML column, is supported by the XML schema repository (XSR). If an XML column has an XML type modifier, documents that are inserted into the column or updated in the column are automatically validated against an XML schema.

Large object data types

You can use large object data types to store audio, video, images, and other files that are larger than 32 KB.

The VARCHAR, VARGRAPHIC, and VARBINARY data types have a storage limit of 32 KB. However, applications often need to store large text documents or additional data types such as audio, video, drawings, images, and a combination of text and graphics. For data objects that are larger than 32 KB, you can use the corresponding large object (LOB) data types to store these objects.

Db2 provides three data types to store these data objects as strings of up to 2 GB in size:

Character large objects (CLOBs)
Use the CLOB data type to store SBCS or mixed data, such as documents that contain single character set. Use this data type if your data is larger (or might grow larger) than the VARCHAR data type permits.

Double-byte character large objects (DBCLOBs)
Use the DBCLOB data type to store large amounts of DBCS data, such as documents that use a DBCS character set.

Binary large objects (BLOBs)
Use the BLOB data type to store large amounts of noncharacter data, such as pictures, voice, and mixed media.

If your data does not fit entirely within a data page, you can define one or more columns as LOB columns. An advantage to using LOBs is that you can create user-defined functions that are allowed only on LOB data types.

Related concepts

Large objects (LOBs)
The term *large object (LOB)* refers to any of the following data types: CLOB, DBCLOB, or BLOB.

Related tasks

Creating large objects (Introduction to Db2 for z/OS)

ROWID data type

You use the ROWID data type to uniquely identify rows in a Db2 subsystem.

Db2 can generate a value for the column when a row is added, depending on the option that you choose (GENERATED ALWAYS or GENERATED BY DEFAULT) when you define the column. You can use a ROWID column in a table for several reasons.

- You can define a ROWID column to include LOB data in a table.
- You can use direct-row access so that Db2 accesses a row directly through the ROWID column. If an application selects a row from a table that contains a ROWID column, the row ID value implicitly contains the location of the row. If you use that row ID value in the search condition of subsequent SELECT statements, Db2 might be able to navigate directly to the row.

Requirement: To use direct row access, you must use a retrieved ROWID value before you commit. When your application commits, it releases its claim on the table space. After the commit, if a REORG is run on your table space, the physical location of the rows might change.

- You can define a ROWID column with the IMPLICITLY HIDDEN attribute. Such columns are returned only for SQL statements that explicitly name the column. SQL statements that only imply selection of the column, such as statements that specify SELECT *, do not return the column.

Related concepts

Row ID values
A *row ID* is a value that uniquely identifies a row in a table. A column or a host variable can have a row ID data type.

Related reference

ROWID
The ROWID function returns a row ID representation of its argument.

Distinct types

A *distinct type* is a user-defined data type that is based on existing built-in Db2 data types.

A distinct type is internally the same as a built-in data type, but Db2 treats them as a separate and incompatible type for semantic purposes.

Defining your own distinct type ensures that only functions that are explicitly defined on a distinct type can be applied to its instances.

Examples

GUPI

Example 1

You might define a US_DOLLAR distinct type that is based on the Db2 DECIMAL data type to identify decimal values that represent United States dollars. The US_DOLLAR distinct type does not automatically acquire the functions and operators of its source type, DECIMAL.

Although you can have different distinct types that are based on the same built-in data types, distinct types have the property of *strong typing*. With this property, you cannot directly compare instances of a distinct type with anything other than another instance of that same type. Strong typing prevents semantically incorrect operations (such as explicit addition of two different currencies) without first undergoing a conversion process. You define which types of operations can occur for instances of a distinct type.

If your company wants to track sales in many countries, you must convert the currency for each country in which you have sales.

Example 2

You can define a distinct type for each country. For example, to create US_DOLLAR types and CANADIAN_DOLLAR types, you can use the following CREATE DISTINCT TYPE statements:

```
CREATE DISTINCT TYPE US_DOLLAR AS DECIMAL (9,2);
CREATE DISTINCT TYPE CANADIAN_DOLLAR AS DECIMAL (9,2);
```

Example 3

After you define distinct types, you can use them in your CREATE TABLE statements:

```
CREATE TABLE US_SALES
  (PRODUCT_ITEM_NO INTEGER,
   MONTH           INTEGER,
   YEAR            INTEGER,
   TOTAL_AMOUNT    US_DOLLAR);
CREATE TABLE CANADIAN_SALES
  (PRODUCT_ITEM_NO INTEGER,
   MONTH           INTEGER,
   YEAR            INTEGER,
   TOTAL_AMOUNT    CANADIAN_DOLLAR);
```

GUPI

User-defined functions support the manipulation of distinct types.

Related concepts

String data types (Introduction to Db2 for z/OS)

Distinct types
A *distinct type* is a user-defined data type that shares its internal representation with a built-in data type (its *source type*), but is considered to be a separate and incompatible data type for most operations.

User-defined type assignments
User-defined type assignments include distinct type assignments and array assignments.

User-defined type comparisons
User-defined type comparisons include distinct type comparisons and array comparisons.

Null values in table columns

Some columns cannot have a meaningful value in every row. Db2 uses a special value indicator, the *null value*, to stand for an unknown or missing value. A null value is a special value that Db2 interprets to mean that no data is present.

If you do not specify otherwise,Db2 allows any column to contain null values. Users can create rows in the table without providing a value for the column.

Using the NOT NULL clause enables you to disallow null values in the column. Primary keys must be defined as NOT NULL.

Example

GUPI

For example, The table definition for the DEPT table specifies when you can use a null value. Notice that you can use nulls for the MGRNO column only:

```
CREATE TABLE DEPT
      (DEPTNO    CHAR(3)           NOT NULL,
       DEPTNAME  VARCHAR(36)       NOT NULL,
       MGRNO     CHAR(6)                   ,
       ADMRDEPT  CHAR(3)           NOT NULL,
       PRIMARY KEY (DEPTNO)                )
  IN MYDB.MYTS;
```

GUPI

Before you decide whether to allow nulls for unknown values in a particular column, you must be aware of how nulls affect results of a query:

Nulls in application programs

Nulls do not satisfy any condition in an SQL statement other than the special IS NULL predicate. Db2 sorts null values differently than non-null values. Null values do not behave like other values. For example, if you ask Db2 whether a null value is larger than a given known value, the answer is UNKNOWN. If you then ask Db2 whether a null value is smaller than the same known value, the answer is still UNKNOWN.

If getting a value of UNKNOWN is unacceptable for a particular column, you could define a default value instead. Programmers are familiar with the way default values behave.

Nulls in join operations

Nulls need special handling in join operations. If you perform a join operation on a column that can contain null values, consider using an outer join.

Related concepts

When to use null or default values (Introduction to Db2 for z/OS)

Data types
Db2 supports both IBM-supplied data types (built-in data types) and user-defined data types (distinct types).

CREATE TABLE
The CREATE TABLE statement defines a table. The definition must include its name and the names and attributes of its columns. The definition can include other attributes of the table, such as its primary key and its table space.

ALTER TABLE
The ALTER TABLE statement changes the description of a table at the current server.

Default values for table columns

Db2 defines some default values, and you define others (by using the DEFAULT clause in the CREATE TABLE or ALTER TABLE statement).

If a column is defined as NOT NULL WITH DEFAULT or if you do not specify NOT NULL, Db2 stores a default value for a column whenever an insert or load does not provide a value for that column. If a column is defined as NOT NULL, Db2 does not supply a default value.

Default values defined by Db2

Db2 generates a default value for ROWID columns. Db2 also determines default values for columns that users define with NOT NULL WITH DEFAULT, but for which no specific value is specified, as shown in the following table.

Table 7. Db2-defined default values for data types

For columns of...	Data types	Default
Numbers	SMALLINT, INTEGER, BIGINT, DECIMAL, NUMERIC, REAL, DOUBLE, DECFLOAT, or FLOAT	0
Fixed-length strings	CHAR or GRAPHIC BINARY	Blanks Hexadecimal zeros
Varying-length strings	VARCHAR, CLOB, VARGRAPHIC, DBCLOB, VARBINARY, or BLOB	Empty string
Dates	DATE	CURRENT DATE
Times	TIME	CURRENT TIME
Timestamps	TIMESTAMP	CURRENT TIMESTAMP
ROWIDs	ROWID	Db2-generated

User-defined default values

You can specify a particular default value, such as:

```
DEFAULT 'N/A'
```

When you choose a default value, you must be able to assign it to the data type of the column. For example, all string constants are VARCHAR. You can use a VARCHAR string constant as the default for a CHAR column even though the type isn't an exact match. However, you could not specify a default value of 'N/A' for a column with a numeric data type.

In the next example, the columns are defined as CHAR (fixed length). The special registers (USER and CURRENT SQLID) that are referenced contain varying length values.

For example, if you want a record of each user who inserts any row of a table, define the table with two additional columns:

```
PRIMARY_ID      CHAR(8)     WITH DEFAULT USER,
SQL_ID          CHAR(8)     WITH DEFAULT CURRENT SQLID,
```

You can then create a view that omits those columns and allows users to update the view instead of the base table. Db2 then adds, by default, the primary authorization ID and the SQLID of the process.

When you add columns to an existing table, you must define them as nullable or as not null with default. Assume that you add a column to an existing table and specify not null with default. If Db2 reads from the table before you add data to the column, the column values that you retrieve are the default values. With few exceptions, the default values for retrieval are the same as the default values for insert.

Default values for ROWID

Db2 always generates the default values for ROWID columns.

Implementing Db2 tables (Db2 Administration Guide)

When to use null or default values

Using a null value is easier and better than using a default value in some situations.

Suppose that you want to find out the average salary for all employees in a department. The salary column does not always need to contain a meaningful value, so you can choose between the following options:

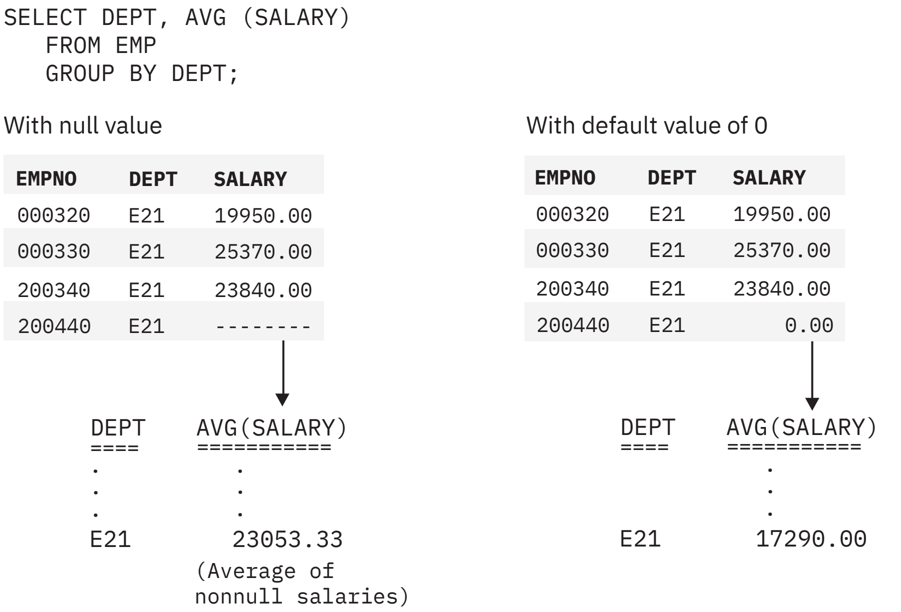
- Allowing null values for the SALARY column
- Using a non-null default value (such as, 0)

By allowing null values, you can formulate the query easily, and Db2 provides the average of all known or recorded salaries. The calculation does not include the rows that contain null values. In the second case, you probably get a misleading answer unless you know the nonnull default value for unknown salaries and formulate your query accordingly.

The following figure shows two scenarios. The table in the figure excludes salary data for employee number 200440, because the company just hired this employee and has not yet determined the salary. The calculation of the average salary for department E21 varies, depending on whether you use null values or nonnull default values.

- The left side of the figure assumes that you use null values. In this case, the calculation of average salary for department E21 includes only the three employees (000320, 000330, and 200340) for whom salary data is available.
- The right side of the figure assumes that you use a nonnull default value of zero (0). In this case, the calculation of average salary for department E21 includes all four employees, although valid salary information is available for only three employees.

As you can see, only the use of a null value results in an accurate average salary for department E21.



```
SELECT DEPT, AVG (SALARY)
   FROM EMP
   GROUP BY DEPT;
```

With null value

EMPNO	DEPT	SALARY
000320	E21	19950.00
000330	E21	25370.00
200340	E21	23840.00
200440	E21	--------

```
DEPT    AVG(SALARY)
====    ===========
.           .
.           .
.           .
E21         23053.33
        (Average of
        nonnull salaries)
```

With default value of 0

EMPNO	DEPT	SALARY
000320	E21	19950.00
000330	E21	25370.00
200340	E21	23840.00
200440	E21	0.00

```
DEPT    AVG(SALARY)
====    ===========
              .
              .
              .
E21         17290.00
```

Figure 5. When nulls are preferable to default values

Null values are distinct in most situations so that two null values are not equal to each other.

Example

GUPI

The following example shows how to compare two columns to see if they are equal or if both columns are null:

```
WHERE E1.DEPT IS NOT DISTINCT FROM E2.DEPT
```

GUPI

Null values in table columns (Introduction to Db2 for z/OS)

Default values for table columns (Introduction to Db2 for z/OS)

Assignment and comparison

The basic operations of SQL are assignment and comparison.

Check constraints for column values

You can use check constraints to ensure that only values from the domain for the column or attribute are allowed.

By using check constraints, programmers can avoid developing, testing, and maintaining application code that performs these checks.

You can choose to define check constraints by using the SQL CREATE TABLE statement or ALTER TABLE statement. For example, you might want to ensure that each value in the SALARY column of the EMP table contains more than a certain minimum amount.

Db2 enforces a check constraint by applying the relevant search condition to each row that is inserted, updated, or loaded. An error occurs if the result of the search condition is false for any row.

Check constraints that insert table rows

When you use the INSERT statement or the MERGE statement to add a row to a table, Db2 automatically enforces all check constraints for that table. If the data violates any check constraint that is defined on that table, Db2 does not insert the row.

GUPI

Example 1

Assume that the NEWEMP table has the following two check constraints:

- Employees cannot receive a commission that is greater than their salary.
- Department numbers must be between '001' to '100,' inclusive.

Consider this INSERT statement, which adds an employee who has a salary of $65,000 and a commission of $6000:

```
INSERT INTO NEWEMP
  (EMPNO, FIRSTNME, LASTNAME, DEPT, JOB, SALARY, COMM)
  VALUES ('100125', 'MARY', 'SMITH','055', 'SLS', 65000.00, 6000.00);
```

The INSERT statement in this example succeeds because it satisfies both constraints.

Example 2

Consider this INSERT statement:

```
INSERT INTO NEWEMP
  (EMPNO, FIRSTNME, LASTNAME, DEPT, JOB, SALARY, COMM)
  VALUES ('120026', 'JOHN', 'SMITH','055', 'DES', 5000.00, 55000.00 );
```

The INSERT statement in this example fails because the $55,000 commission is higher than the $5,000 salary. This INSERT statement violates a check constraint on NEWEMP.

GUPI

Check constraints that update tables

Db2 automatically enforces all check constraints for a table when you use the UPDATE statement or the MERGE statement to change a row in the table. If the intended update violates any check constraint that is defined on that table, Db2 does not update the row.

GUPI

Example 1

Assume that the NEWEMP table has the following two check constraints:

- Employees cannot receive a commission that is greater than their salary.
- Department numbers must be between '001' to '100,' inclusive.

Consider this UPDATE statement:

```
UPDATE NEWEMP
  SET DEPT = '011'
  WHERE FIRSTNME = 'MARY' AND LASTNAME= 'SMITH';
```

This update succeeds because it satisfies the constraints that are defined on the NEWEMP table.

Example 2

Consider this UPDATE statement:

```
UPDATE NEWEMP
  SET DEPT = '166'
  WHERE FIRSTNME = 'MARY' AND LASTNAME= 'SMITH';
```

This update fails because the value of DEPT is '166,' which violates the check constraint on NEWEMP that DEPT values must be between '001' and '100.'

CREATE TABLE

The CREATE TABLE statement defines a table. The definition must include its name and the names and attributes of its columns. The definition can include other attributes of the table, such as its primary key and its table space.

Db2 indexes

An *index* is an ordered set of pointers to rows of a table. Db2 can use indexes to improve performance and ensure uniqueness. Understanding the structure of Db2 indexes can help you achieve the best performance for your system.

Conceptually, you can think of an index to the rows of a Db2 table like you think of an index to the pages of a book. Each index is based on the values of data in one or more columns of a table.

The main purpose of an index is to improve performance for access to the data. In most cases, access to data is faster with an index than with a scan of the data. For example, you can create an index on the DEPTNO column of the sample DEPT table so that Db2 can easily locate a specific department and avoid reading through each row of, or *scanning*, the table.

An index is stored separately from the data in the table. Each index is physically stored in its own index space. When you define an index by using the CREATE INDEX statement, Db2 builds this structure and maintains it automatically. However, you can perform necessary maintenance such as reorganizing it or recovering the index.

Another purpose of an index is to ensure uniqueness. For example, a unique index on the employee table ensures that no two employees have the same employee number.

In most cases, the users of an index are unaware that it is being used because Db2 decides whether to use the index to access the table.

Db2 supports simple indexes and extended indexes. An extended index is one of the following objects:

- An expression-based index
- A spatial index
- An XML index

Be aware that indexes have both benefits and disadvantages. A greater number of indexes can simultaneously improve the access performance of a particular transaction and require additional processing for inserting, updating, and deleting index keys.

Related concepts

Creation of indexes (Introduction to Db2 for z/OS)

Related reference

CREATE INDEX

The CREATE INDEX statement creates a partitioning index or a secondary index and an index space at the current server. The columns included in the key of the index are columns of a table at the current server.

Db2 views

A *view* is an alternative way of representing data that exists in one or more tables. A view can include all or some of the columns from one or more base tables.

A view is a named specification of a result table. Conceptually, creating a view is somewhat like using binoculars. You might look through binoculars to see an entire landscape or to look at a specific image within the landscape, such as a tree.

You can create Db2 views that achieve the following goals:

- Combines data from different base tables
- Based on other views or on a combination of views and tables
- Omit certain data, thereby shielding some table data from users

In fact, these are common underlying reasons to use a view. Combining information from base tables and views simplifies retrieving data for a user, and limiting the data that a user can see is useful for security. You can use views for a number of different purposes. A view can:

- Control access to a table
- Make data easier to use
- Simplify authorization by granting access to a view without granting access to the table
- Show only portions of data in the table
- Show summary data for a given table
- Combine two or more tables in meaningful ways
- Show only the selected rows that are pertinent to the process that uses the view

How to access data in Db2 views

To retrieve or access information from a view, you use views like you use base tables. You can use a SELECT statement to show the information from the view. The SELECT statement can name other views and tables, and it can use the WHERE, GROUP BY, and HAVING clauses. It cannot use the ORDER BY clause or name a host variable.

Whether a view can be used in an insert, update, or delete operation depends on its definition. For example, if a view includes a foreign key of its base table, INSERT and UPDATE operations that use the view are subject to the same referential constraint as the base table. Likewise, if the base table of a view is a parent table, DELETE operations that use the view are subject to the same rules as DELETE operations on the base table. *Read-only* views cannot be used for insert, update, and delete operations.

How to create Db2 views

To define a view, you use the CREATE VIEW statement and assign a name (up to 128 characters in length) to the view. Specifying the view in other SQL statements is effectively like running an SQL SELECT statement. At any time, the view consists of the rows that would result from the SELECT statement that it contains. You can think of a view as having columns and rows just like the base table on which the view is defined.

You also can specify a period specification for a view, subject to certain restrictions.

Examples of creating Db2 views

GUPI

Example 1

The following figure shows a view of the EMP table that omits sensitive employee information and renames some of the columns.

Base table, **EMP:**

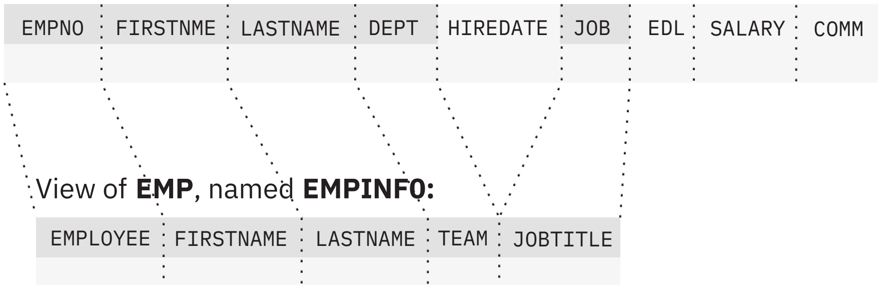

Figure 6. A view of the EMP table

Figure note: The EMPINFO view represents a table that includes columns named EMPLOYEE, FIRSTNAME, LASTNAME, TEAM, and JOBTITLE. The data in the view comes from the columns EMPNO, FIRSTNME, LASTNAME, DEPT, and JOB of the EMP table.

Example 2

The following CREATE VIEW statement defines the EMPINFO view that is shown in the preceding figure:

```
CREATE VIEW EMPINFO (EMPLOYEE, FIRSTNAME, LASTNAME, TEAM, JOBTITLE)
  AS SELECT EMPNO, FIRSTNME, LASTNAME, DEPT, JOB
  FROM EMP;
```

When you define a view, Db2 stores the definition of the view in the Db2 catalog. However, Db2 does not store any data for the view itself, because the data exists in the base table or tables.

Example 3

You can narrow the scope of the EMPINFO view by limiting the content to a subset of rows and columns that includes departments A00 and C01 only:

```
CREATE VIEW EMPINFO (EMPLOYEE, FIRSTNAME, LASTNAME, TEAM, JOBTITLE)
  AS SELECT EMPNO, FIRSTNME, LASTNAME, WORKDEPT, JOB
  FROM EMP
  WHERE WORKDEPT = 'A00' OR WORKDEPT = 'C01';
```

GUPI

In general, a view inherits the attributes of the object from which it is derived. Columns that are added to the tables after the view is defined on those tables do not appear in the view.

Restriction: You cannot create an index for a view. In addition, you cannot create any form of a key or a constraint (referential or otherwise) on a view. Such indexes, keys, or constraints must be built on the tables that the view references.

Implementing Db2 views (Db2 Administration Guide)

Aliases

An *alias* is a substitute for the three-part name of a table or view.

An alias can be defined at a local server and can refer to a table or view that is at the current server or a remote server. The alias name can be used wherever the table name or view name can be used to refer to the table or view in an SQL statement.

Suppose that data is occasionally moved from one Db2 subsystem to another. Ideally, users who query that data are not affected when this activity occurs. They always want to log on to the same system and access the same table or view, regardless of where the data resides. You can achieve this result by using an alias for an object name.

An alias can be a maximum of 128 characters, qualified by an owner ID. You use the CREATE ALIAS and DROP ALIAS statements to manage aliases.

GUPI For example, assume that you create an alias with the following statement:

```
CREATE ALIAS TESTTAB FOR USIBMSTODB22.IDEMP01.EMP;
```

If a user with the ID JONES dynamically creates the alias, JONES owns the alias, and you query the table like this:

```
SELECT SUM(SALARY), SUM(BONUS), SUM(COMM)
  FROM JONES.TESTTAB;
```

GUPI

The object for which you are defining an alias does not need to exist when you execute the CREATE ALIAS statement. However, the object must exist when a statement that refers to the alias executes.

When you want an application to access a server other than the server that is specified by a location name, you do not need to change the location name. Instead, you can use a location alias to override the location name that an application uses to access a server. As a result, a Db2 for z/OS requester can access multiple Db2 databases that have the same name but different network addresses. Location aliases allow easier migration to a Db2 server and minimize application changes.

After you create an alias, anyone who has authority over the object that the alias is referencing can use that alias. A user does not need a separate privilege to use the alias.

Related reference

CREATE ALIAS
The CREATE ALIAS statement defines an alias for a table, a view, or a sequence. The definition is recorded in the Db2 catalog at the current server.

Triggers

A *trigger* defines a set of actions that are executed when a delete, insert, or update operation occurs on a specified table or view. When such an operation is executed, the trigger is said to be *activated*.

Db2 supports two types of triggers, basic and advanced:

- *Basic triggers* support a limited set of SQL statements, and require the MODE DB2SQL clause on the CREATE TRIGGER statement. You can identify basic triggers by querying the SYSIBM.SYSTRIGGERS catalog table. Blank values in the SQLPL column identify basic triggers. For more information, see "CREATE TRIGGER (basic)" on page 1764.
- *Advanced triggers* support a larger set of SQL statements, including SQL procedure language (SQL PL). A CREATE TRIGGER statement for an advanced trigger must not specify the MODE DB2SQL clause. Advanced triggers are supported at application compatibility level V12R1M500 or higher. You can identify advanced triggers by querying the SYSIBM.SYSTRIGGERS catalog table. 'Y' values in the SQLPL column identify advanced triggers. For more information about advanced triggers, see "CREATE TRIGGER (advanced)" on page 1735.

For a detailed comparison of the types, see "Basic and advanced triggers" on page 34.

You can use triggers along with referential constraints and check constraints to enforce data integrity rules. Triggers are more powerful than constraints because you can use them to do the following things:

- Update other tables
- Automatically generate or transform values for inserted or updated rows
- Invoke functions that perform operations both inside and outside of Db2

For example, assume that you need to prevent an update to a column when a new value exceeds a certain amount. Instead of preventing the update, you can use a trigger. The trigger can substitute a valid value and invoke a procedure that sends a notice to an administrator about the attempted invalid update.

You define triggers with the CREATE TRIGGER statement.

Triggers move the business rule application logic into the database, which results in faster application development and easier maintenance. The business rule is no longer repeated in several applications, and the rule is centralized to the trigger. For example, Db2 can check the validity of the changes that any application makes to a salary column, and you are not required to change application programs when the logic changes.

There are a number of criteria that are defined when creating a trigger, which are used to determine when a trigger should be activated.

- The *subject table* (also known as the triggering table) defines the table or view for which the trigger is defined.
- The *trigger event* defines a specific SQL operation that modifies the subject table. The operation could be a delete, insert, or update.
- The *trigger activation time* defines whether the trigger should be activated before or after the trigger event is performed on the subject table.

The statement that causes a trigger to be activated includes a set of *affected rows*. These are the rows of the subject table that are being deleted, inserted or updated. The *trigger granularity* defines whether the actions of the trigger are to be performed once for the statement, or once for each of the rows in the set of affected rows.

The *trigger action* consists of an optional search condition and a set of SQL statements that are executed whenever the trigger is activated. The SQL statements are only executed if no search condition is specified, or the specified search condition evaluates to true.

The triggered action can refer to the values in the set of affected rows. This is supported through the use of *transition variables*. Transition variables use the names of the columns in the subject table, qualified by a specified name that identifies whether the reference is to the old value (prior to the update) or the new value (after the update). The new value can also be changed using an assignment in a before update or insert trigger.

Another means of referring to the values in the set of affected rows is by using *transition tables*. Transition tables also use the names of the columns of the subject table, but have a name specified that allows the complete set of affected rows to be treated as a table. Transition tables can only be used in after triggers, and cannot be modified. Separate transition tables can be defined for old and new values.

Multiple triggers can be specified for a combination of table, event, or activation time. The order in which the triggers are activated is the same as the order in which they were created. Thus, the most recently created trigger is the last trigger that is activated.

The activation of a trigger might cause *trigger cascading*. This is the result of the activation of one trigger that executes SQL statements that cause the activation of other triggers, or even the same trigger again. The triggered actions might also cause updates as a result of the original modification, which might result in the activation of additional triggers. With trigger cascading, a significant chain of triggers might be activated, causing significant change to the database as a result of a single delete, insert or update statement.

The actions that are performed in the trigger are considered to be part of the operation that caused the trigger to be executed.

- The database manager ensures that the operation and the triggers that are executed as a result of that operation either all complete or are all backed out. Operations that occurred prior to the triggering operation are not affected.
- The database manager effectively checks all constraints (except for a constraint with a RESTRICT delete rule) after the operation and the associated triggers have been executed.

Basic and advanced triggers

Basic and advanced triggers offer different functionality. See the corresponding syntax diagrams for the CREATE TRIGGER (basic) and CREATE TRIGGER (advanced) SQL statements for more information. The following table identifies some behavioral differences between the two types of triggers.

Table 8. Behavioral differences of basic and advanced triggers

Behavior	Basic Trigger	Advanced Trigger
CREATE or ALTER TRIGGER statement invocation	CREATE or ALTER TRIGGER (basic) statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.	CREATE or ALTER TRIGGER (advanced) statement can be issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.
Authorization requirement	The privilege set must include SYSADM or the SELECT privilege on the table or view on which the trigger is defined, if the REFERENCING clause is included in the trigger definition.	The privilege set must include SYSADM or the SELECT privilege for the triggering table or view on which the trigger is defined.
Default encoding scheme	The default encoding scheme is Unicode.	The default encoding scheme is determined from the value of the DEFAULT APPLICATION ENCODING SCHEME field on the installation panel DSNTIPF.
Null attribute for transition variables	A transition variable is defined with the same null attribute as the column it is associated with.	All transition variables are nullable.
Unhandled warnings at completion of a trigger	Unhandled warnings are not returned to the statement that activated a trigger. When processing in a trigger completes with a warning, the warning is not returned to the statement that activated the trigger.	Unhandled warnings are returned to the statement that activated a trigger. When processing in a trigger completes with a warning, the warning is returned to the statement that activated the trigger.
Transition variables passed as OUT or INOUT arguments to a procedure	Changes to transition variables in a procedure are not visible on return to the invoking environment, and changes to transition variables (for an AFTER trigger) are not disallowed.	Changes to transition variables in a procedure are visible on return to the invoking environment, and changes to transition variables (for an AFTER trigger) are disallowed.
Stand-alone *fullselect* and VALUES statements	Supported.	Not supported. Use a SELECT INTO statement or VALUES INTO statement instead.

Related concepts

Creation of triggers (Introduction to Db2 for z/OS)

User-defined types

A *user-defined data type* is a data type that is defined to the database using a CREATE statement.

A user-defined data type is a distinct type or an array type.

A *distinct type* is a user-defined type that shares its internal representation with a built-in data type (its source type), but is considered to be a separate and incompatible data type for most operations. A distinct type is created with an SQL CREATE TYPE (distinct) statement. A distinct type can be used to define a column of a table, or a parameter of a routine.

An *array type* is a user-defined data type that consists of an ordered set of elements of a single built-in data type. Elements can be accessed and modified by their index position. An array type is created with an SQL CREATE TYPE (array) statement. An array type can be used as a parameter of an SQL routine, as a variable in an SQL routine, and as a global variable.

Related concepts

Array types
A user-defined *array type* is a data type that is defined as an array of elements. A user-defined array type can be either an *ordinary array* or *associative array*.

Distinct types
A *distinct type* is a user-defined data type that shares its internal representation with a built-in data type (its *source type*), but is considered to be a separate and incompatible data type for most operations.

Related reference

CREATE TYPE
The CREATE TYPE statement defines a user-defined data type at the current server.

Routines

A *routine* is an executable SQL object. The two types of routines are functions and stored procedures.

Functions

A *function* is a routine that can be invoked from within other SQL statements and that returns a value or a table.

Functions are classified as either SQL functions or external functions. SQL functions are written using SQL statements, including SQL procedural language (SQL PL). External functions reference a host language program. The host language program can contain SQL, but does not require SQL.

You define functions by using the CREATE FUNCTION statement. You can classify functions as built-in functions, user-defined functions, or cast functions that are generated for distinct types. Functions can also be classified as aggregate, scalar, or table functions, depending on the input data values, result values, and the context in which they can be invoked.

Related concepts

Functions
A *function* is an operation denoted by a function name followed by zero or more operands that are enclosed in parentheses. It represents a relationship between a set of input values and a set of result values.

Related tasks

Creating a user-defined function (Db2 Application programming and SQL)

Procedures

A *procedure*, also known as a stored procedure, is a routine that you can call to perform operations that can include SQL statements.

Procedures are classified as either SQL procedures or external procedures. SQL procedures contain only SQL statements, including SQL procedural language (SQL PL). External procedures reference a host language program that might or might not contain SQL statements.

Db2 for z/OS supports the following types of procedures:

Native SQL procedures

The procedure body is written exclusively in SQL statements, including SQL procedural language (SQL PL) statements. The procedure body is contained and specified in the procedure definition along with various attributes of the procedure. A package is generated for a native SQL procedure. It contains the procedure body, including control statements. It might sometimes also include statements generated by Db2. Each time that the procedure is invoked, the package executes one or more times.

All SQL procedures that are created with a CREATE PROCEDURE statement that does not specify the FENCED or EXTERNAL options are native SQL procedures. More capabilities are supported for native SQL procedures, they usually perform better than external SQL procedures, and no associated C program is generated for them.

See "CREATE PROCEDURE (SQL - native)" on page 1602.

External stored procedures

The procedure body is an external program that is written in a programming language such as C, C++, COBOL, or Java and it can contain SQL statements. The source code for an external stored procedure is separate from the procedure definition and is bound into a package. The name of the external executable is specified as part of the procedure definition along with various attributes of the procedure. All programs must be designed to run using Language Environment. Your COBOL and C++ stored procedures can contain object-oriented extensions. Each time that the stored procedure is invoked, the logic in the procedure controls whether the package executes and how many times.

For more information, see Creating external stored procedures (Db2 Application programming and SQL).

See "CREATE PROCEDURE (external)" on page 1575.

External SQL procedures (deprecated)

The procedure body is written exclusively in SQL statements, including SQL procedural language (SQL PL) statements. The procedure body is specified in the procedure definition along with various attributes of the procedure. A C program and an associated package are generated for an external SQL procedure. It contains the procedure body, including control statements. It might sometimes also include statements generated by Db2.Each time that the procedure is invoked, the package executes one or more times.

Native SQL procedures are more fully supported, easier to maintain, and typically perform better than external SQL procedures, which are deprecated.

See "CREATE PROCEDURE (SQL - external) (deprecated)" on page 1592.

SQL control statements are supported in SQL procedures. Control statements are SQL statements that allow SQL to be used in a manner similar to writing a program in a structured programming language. SQL control statements provide the capability to control the logic flow, declare and set variables, and handle warnings and exceptions. Some SQL control statements include other nested SQL statements.

SQL procedures provide the same benefits as procedures in a host language. That is, a common piece of code needs to be written and maintained only once and can be called from several programs.

SQL procedures provide additional benefits when they contain SQL statements. In this case, SQL procedures can reduce or eliminate network delays that are associated with communication between the client and server and between each SQL statement. SQL procedures can improve security by providing a user the ability to invoke only a procedure instead of providing them with the ability to execute the SQL that the procedure contains.

You define procedures by using the CREATE PROCEDURE statement.

Related concepts

Use of an application program as a stored procedure (Introduction to Db2 for z/OS)

External stored procedures (Db2 Application programming and SQL)

SQL control statements for external SQL procedures

SQL control statements for external SQL procedures can be used only with SQL procedures that are created with the FENCED or EXTERNAL clause. *SQL control statements* provide the capability to control the logic flow, declare and set variables, and handle warnings and exceptions. Some SQL control statements include other nested SQL statements.

SQL procedural language (SQL PL)

Related tasks

Implementing Db2 stored procedures (Stored procedures provided by Db2)

Related reference

Procedures that are supplied with Db2

A *procedure* is an application program that can be started through the SQL CALL statement. The procedure is specified by a procedure name, which may be followed by arguments that are enclosed within parentheses. This information contains syntax diagrams, semantic descriptions, rules, and examples of the use of the system supplied procedures.

Sequences

A *sequence* is a stored object that simply generates a sequence of numbers in a monotonically ascending (or descending) order. A sequence provides a way to have Db2 automatically generate unique integer primary keys and to coordinate keys across multiple rows and tables.

A sequence can be used to exploit parallelization, instead of programmatically generating unique numbers by locking the most recently used value and then incrementing it.

Sequences are ideally suited to the task of generating unique key values. One sequence can be used for many tables, or a separate sequence can be created for each table requiring generated keys. A sequence has the following properties:

- Guaranteed, unique values, assuming that the sequence is not reset and does not allow the values to cycle
- Monotonically increasing or decreasing values within a defined range
- Can increment with a value other than 1 between consecutive values (the default is 1).
- Recoverable. If Db2 should fail, the sequence is reconstructed from the logs so that Db2 guarantees that unique sequence values continue to be generated across a Db2 failure.

Values for a given sequence are automatically generated by Db2. Use of Db2 sequences avoids the performance bottleneck that results when an application implements sequences outside the database. The counter for the sequence is incremented (or decremented) independently of the transaction. In some cases, gaps can be introduced in a sequence. A gap can occur when a given transaction increments a sequence two times. The transaction might see a gap in the two numbers that are generated because there can be other transactions concurrently incrementing the same sequence. A user might not realize that other users are drawing from the same sequence. Furthermore, it is possible that a given sequence can appear to have generated gaps in the numbers, because a transaction that might have generated a sequence number might have rolled back or the Db2 subsystem might have failed. Updating a sequence is not part of a transaction's unit of recovery.

A sequence is created with a CREATE SEQUENCE statement. A sequence can be referenced using a *sequence-reference*. A sequence reference can appear most places that an expression can appear. A sequence reference can specify whether the value to be returned is a newly generated value, or the previously generated value.

Although there are similarities, a sequence is different than an identity column. A sequence is an object, whereas an identity column is a part of a table. A sequence can be used with multiple tables, but an identity column is tied to a single table.

Related reference

CREATE SEQUENCE
The CREATE SEQUENCE statement creates a sequence at the current server.

Db2 system objects

Unlike the Db2 data structures that users create and access, Db2 controls and accesses system objects.

Db2 has a comprehensive infrastructure that enables it to provide data integrity, performance, and the ability to recover user data. In addition, Parallel Sysplex® data sharing uses shared system objects.

Related concepts

Db2 database objects overview (Introduction to Db2 for z/OS)

Db2 catalog

Db2 maintains a set of tables that contain information about the data that Db2 controls. These tables are collectively known as the *catalog*.

The catalog tables contain information about Db2 objects such as tables, views, and indexes. When you create, alter, or drop an object, Db2 inserts, updates, or deletes rows of the catalog that describe the object.

The Db2 catalog consists of tables of data about everything defined to the Db2 system, including table spaces, indexes, tables, copies of table spaces and indexes, and storage groups. The system database DSNDB06 contains the Db2 catalog.

When you create, alter, or drop any structure, Db2 inserts, updates, or deletes rows of the catalog that describe the structure and tell how the structure relates to other structures. For example, SYSIBM.SYSTABLES is one catalog table that records information when a table is created. Db2 inserts a row into SYSIBM.SYSTABLES that includes the table name, its owner, its creator, and the name of its table space and its database.

To understand the role of the catalog, consider what happens when the EMP table is created. Db2 records the following data:

Table information
To record the table name and the name of its owner, its creator, its type, the name of its table space, and the name of its database, Db2 inserts a row into the catalog.

Column information
To record information about each column of the table, Db2 inserts the name of the table to which the column belongs, its length, its data type, and its sequence number by inserting a row into the catalog for each column of the table.

Authorization information
To record that the owner of the table has authorization to create the table, Db2 inserts a row into the catalog.

Tables in the catalog are like any other database tables with respect to retrieval. If you have authorization, you can use SQL statements to look at data in the catalog tables in the same way that you retrieve data from any other table in the Db2 database. Db2 ensures that the catalog contains accurate object descriptions. If you are authorized to access the specific tables or views on the catalog, you can use SELECT on the catalog. You can use INSERT, UPDATE, and DELETE statements on updatable catalog tables, but you cannot use TRUNCATE or MERGE on the catalog.

The *communications database* (CDB) is part of the Db2 catalog. The CDB consists of a set of tables that establish conversations with remote database management systems (DBMSs). The distributed data facility (DDF) uses the CDB to send and receive distributed data requests.

Tip: For best results, check the consistency of the Db2 catalog and directory regularly, even outside of the migration process. For detailed instructions, see Verify the integrity of Db2 table spaces and Check for consistency between catalog tables.

Related reference

Db2 catalog tables
Db2 for z/OS maintains a set of tables (in database DSNDB06) called the Db2 catalog.

Db2 directory

The Db2 directory contains information that Db2 uses during normal operation.

You can use SQL to retrieve data only from the directory tables that are listed in Appendix H, "Db2 directory tables," on page 2757. You can submit queries against the Db2 catalog for Db2 directory objects.

The directory consists of a set of Db2 tables that are stored in table spaces in system database DSNDB01. Each of the table spaces that are listed in the following table is contained in a VSAM linear data set.

Table 9. Directory table spaces

Table space name	Description
SCT02	Contains the internal form of SQL statements that are contained in an application. If you bound a plan with SQL statements in a prior release, Db2 created a structure in SCT02.
SPT01 Skeleton package	Contains the internal form of SQL statements that are contained in a package.
SYSSPUXA	Contains the contents of a package selection.
SYSSPUXB	Contains the contents of a package explain block.
SYSLGRNX Log range	Tracks the opening and closing of table spaces, indexes, or partitions. By tracking this information and associating it with relative byte addresses (RBAs) as contained in the Db2 log, Db2 can reduce recovery time by reducing the amount of log that must be scanned for a particular table space, index, or partition.
SYSUTILX System utilities	Contains a row for every utility job that is running. The row persists until the utility is finished. If the utility terminates without completing, Db2 uses the information in the row when you restart the utility.
DBD01 Database descriptor (DBD)	Contains internal information, called *database descriptors* (DBDs), about the databases that exist within the Db2 subsystem. Each database has exactly one corresponding DBD that describes the database, table spaces, tables, table check constraints, indexes, and referential relationships. A DBD also contains other information about accessing tables in the database. Db2 creates and updates DBDs whenever their corresponding databases are created or updated.
SYSDBDXA	Contains the contents of a DBD section.

Tip: For best results, check the consistency of the Db2 catalog and directory regularly, even outside of the migration process. For detailed instructions, see Verify the integrity of Db2 table spaces and Check for consistency between catalog tables.

Active and archive logs

Db2 records all data changes and other significant events in a log.

If you keep these logs, Db2 can re-create those changes for you in the event of a failure or roll the changes back to a previous point in time.

Db2 writes each log record to a disk data set called the *active log*. When the active log is full, Db2 copies the contents of the active log to a disk or magnetic tape data set called the *archive log*.

You can choose either single logging or dual logging.

- A single active log contains up to 93 active log data sets.
- With dual logging, the active log has twice the capacity for active log data sets, because two identical copies of the log records are kept.

Each Db2 subsystem manages multiple active logs and archive logs. The following facts are true about each Db2 active log:

- Each log can be duplexed to ensure high availability.
- Each active log data set is a VSAM linear data set (LDS).
- Db2 supports striped active log data sets, however striping is generally unnecessary with the latest devices, and is not recommended in most cases.

  Important: Do not use striped active logs for disaster recovery.

Related tasks

Improving Db2 log performance (Db2 Performance)

Related information

Reading log records (Db2 Administration Guide)

Bootstrap data set

The *bootstrap data set* (*BSDS*) is a VSAM key-sequenced data set (KSDS). This KSDS contains information that is critical to Db2, such as the names of the logs. Db2 uses information in the BSDS for system restarts and for any activity that requires reading the log.

Specifically, the BSDS contains:

- An inventory of all active and archive log data sets that are known to Db2. Db2 uses this information to track the active and archive log data sets. Db2 also uses this information to locate log records to satisfy log read requests during normal Db2 system activity and during restart and recovery processing.
- A wrap-around inventory of all recent Db2 checkpoint activity. Db2 uses this information during restart processing.
- The distributed data facility (DDF) communication record, which contains information that is necessary to use Db2 as a distributed server or requester.
- Information about buffer pools.

Because the BSDS is essential to recovery in the event of subsystem failure, during installation Db2 automatically creates two copies of the BSDS and, if space permits, places them on separate volumes.

The BSDS can be duplexed to ensure availability.

For instructions, see Convert BSDS records to the extended 10-byte format: DSNTIJCB (Db2 Installation and Migration).

Related tasks

Managing the log and the bootstrap data set (Db2 Administration Guide)

Convert BSDS records to the extended 10-byte format: DSNTIJCB (Db2 Installation and Migration)

Buffer pools

Buffer pools are areas of virtual storage that temporarily store pages of table spaces or indexes.

When an application program accesses a row of a table, Db2 places the page that contains that row in a buffer. Access to data in this temporary storage is faster than accessing data on a disk. If the required data is already in a buffer, the application program does not need to wait for it to be retrieved from disk, so the time and cost of retrieving the page is reduced.

Buffer pools require monitoring and tuning. Buffer pool sizes are critical to the performance characteristics of an application or group of applications that access data in those buffer pools.

You can specify default buffer pools for user data and for indexes. A special type of buffer pool that is used only in Parallel Sysplex data sharing is the *group buffer pool*, which resides in the coupling facility. Group buffer pools reside in a special PR/SM LPAR logical partition called a *coupling facility*, which enables several Db2 subsystems to share information and control the coherency of data.

Buffer pools reside in the database services address space (*ssnm*DBM1). The maximum size of a buffer pool is 16 TB.

Data definition control support database

The *data definition control support* (DDCS) database refers to a user-maintained collection of tables that are used by data definition control support to restrict the submission of specific Db2 DDL (data definition language) statements to selected application identifiers (plans or collections of packages).

This database is automatically created during installation. After this database is created, you must populate the tables to use this facility. The system name for this database is DSNRGFDB.

The resource limit facility

The *resource limit facility* (sometimes abbreviated RLF) enables you to control the amount of processor resources that are used by SQL statements.

GUPI

Resource limits apply to the following types of SQL statements:

- SELECT
- INSERT
- UPDATE
- MERGE
- TRUNCATE
- DELETE

You can specify resource limits for dynamic SQL statements and static SQL statements. Resource limits apply to SQL statement regardless of whether they are issued locally or remotely. The resource limit facility does not apply to primary or secondary authorization IDs that have installation SYSADM or installation SYSOPR authority.

You can establish a single limit for all users, different limits for individual users, or both. You can choose to have these limits applied before the statement is executed through *predictive governing*, or while a statement is running, through *reactive governing*. You can also use reactive and predictive governing in combination. You define these limits in one or more *resource limit tables*, named DSNRLST*xx* or DSNRLMT*xx*, depending on the monitoring purpose. GUPI

Work file database

Use the *work file database* as storage for processing SQL statements that require working space, such as that required for a sort.

The work file database is used as storage for Db2 work files for processing SQL statements that require working space (such as the space that is required for a sort), and as storage for created global temporary tables and declared global temporary tables.

Db2 creates a work file database and some table spaces in it for you at installation time. You can create additional work file table spaces at any time. You can drop, re-create, and alter the work file database or the table spaces in it, or both, at any time.

In a non-data-sharing environment, the work file database is named DSNDB07. In a data sharing environment, each Db2 member in the data sharing group has its own work file database.

You can also use the work file database for all temporary tables.

SEPARATE WORK FILES field (WFDBSEP subsystem parameter) (Db2 Installation and Migration)

Application processes and transactions

An application process involves running one or more programs. Different application processes might involve running different programs or running the same program at different times. When an application interacts with a Db2 database, a transaction begins.

Many different types of programs access Db2 data: user-written applications, SQL statements that users enter dynamically, and even utilities. The single term that describes any type of access to Db2 data is called an *application process*. All SQL programs run as part of an application process.

A *transaction* is a sequence of actions between the application and the database; the sequence begins when data in the database is read or written. A transaction is also known as a *unit of work*.

For example, Consider what happens when you access funds in a bank account. A banking transaction might involve the transfer of funds from one account to another. During the transaction, an application program first subtracts the funds from the first account, and then it adds the funds to the second account. Following the subtraction step, the data is inconsistent. Consistency is reestablished after the funds are added to the second account.

To ensure data consistency, Db2 uses a variety of techniques that include a commit operation, a rollback operation, and locking.

When the subtraction and addition steps of the banking transaction are complete, the application can use the commit operation to end the transaction, thereby making the changes available to other application processes. The *commit* operation makes the database changes permanent.

Consider what happens if more than one application process requests access to the same data at the same time. Or, under certain circumstances, an SQL statement might run concurrently with a utility on the same table space. Db2 uses locks to maintain data integrity under these conditions to prevent, for example, two application processes from updating the same row of data simultaneously.

Db2 acquires locks to prevent uncommitted changes that are made by one application process from being perceived by any other. Db2 automatically releases all locks that it has acquired on behalf of an application process when that process ends, but an application process can also explicitly request that locks be released sooner. A commit operation releases locks that an application process has acquired and commits database changes that were made by the same process.

Db2 also provides a way to *back out* uncommitted changes that an application process makes. A back out might be necessary in the event of a failure on the part of an application process or in a *deadlock* situation. Deadlock occurs when contention for the use of a resource, such as a table, cannot be resolved. An application process, however, can explicitly request that its database changes be backed out. This operation is called *rollback*. The interface that an SQL program uses to explicitly specify these commit and rollback operations depends on the environment. For example, in the JDBC environment, applications use commit and rollback methods to commit or roll back transactions.

Related concepts

Application processes, concurrency, and recovery

All SQL programs execute as part of an *application process*. An application process involves the execution of one or more programs, and it is the unit to which Db2 allocates resources and locks.

Different application processes might involve the execution of different programs, or different executions of the same program. The means of initiating and terminating an application process are dependent on the environment.

Locking, commit, and rollback

More than one application process might request access to the same data at the same time. Furthermore, under certain circumstances, an SQL statement can execute concurrently with a utility on the same table space. *Locking* is used to maintain data integrity under such conditions, preventing, for example, two application processes from updating the same row of data simultaneously.

Db2 implicitly acquires locks to prevent uncommitted changes made by one application process from being perceived by any other. Db2 will implicitly release all locks it has acquired on behalf of an application process when that process ends, but an application process can also explicitly request that locks be released sooner. A *commit* operation releases locks acquired by the application process and commits database changes made by the same process.

Db2 provides a way to *back out* uncommitted changes made by an application process. This might be necessary in the event of a failure on the part of an application process, or in a *deadlock* situation. An application process, however, can explicitly request that its database changes be backed out. This operation is called *rollback*.

The interface used by an SQL program to explicitly specify these commit and rollback operations depends on the environment. If the environment can include recoverable resources other than Db2 databases, the SQL COMMIT and ROLLBACK statements cannot be used. Thus, these statements cannot be used in an IMS, CICS, or WebSphere environment.

Unit of work

A *unit of work* is a recoverable sequence of operations within an application process. A unit of work is sometimes called a *logical unit of work*.

At any time, an application process has a single unit of work, but the life of an application process can involve many units of work as a result of commit or full rollback operations.

A unit of work is initiated when an application process is initiated. A unit of work is also initiated when the previous unit of work is ended by something other than the end of the application process. A unit of work is ended by a commit operation, a full rollback operation, or the end of an application process. A commit or rollback operation affects only the database changes made within the unit of work it ends. While these changes remain uncommitted, other application processes are unable to perceive them unless they are running with an isolation level of uncommitted read. The changes can still be backed out. Once committed, these database changes are accessible by other application processes and can no longer be backed out by a rollback. Locks acquired by Db2 on behalf of an application process that protects uncommitted data are held at least until the end of a unit of work.

The initiation and termination of a unit of work define *points of consistency* within an application process. A point of consistency is a claim by the application that the data is consistent. For example, a banking transaction might involve the transfer of funds from one account to another. Such a transaction would require that these funds be subtracted from the first account, and added to the second. Following the subtraction step, the data is inconsistent. Only after the funds have been added to the second account is consistency reestablished. When both steps are complete, the commit operation can be used to end the unit of work, thereby making the changes available to other application processes. The following figure illustrates this concept.

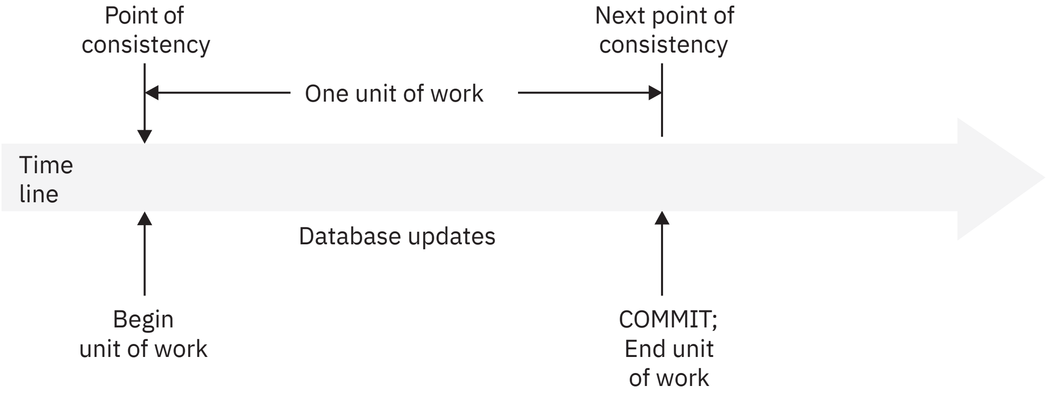

Figure 7. Unit of work with a commit operation

Unit of recovery

A *Db2 unit of recovery* is a recoverable sequence of operations executed by Db2 for an application process.

If a unit of work involves changes to other recoverable resources, the unit of work will be supported by other units of recovery. If relational databases are the only recoverable resources used by the application process, then the scope of the unit of work and the unit of recovery are the same and either term can be used.

Rolling back work

Db2 can back out all changes made in a unit of recovery or only selected changes. Only backing out all changes results in a point of consistency.

Rolling back all changes

The SQL ROLLBACK statement without the TO SAVEPOINT clause specified causes a full rollback operation. If such a rollback operation is successfully executed, Db2 backs out uncommitted changes to restore the data consistency that existed when the unit of work was initiated.

That is, Db2 undoes the work, as shown in the following figure:

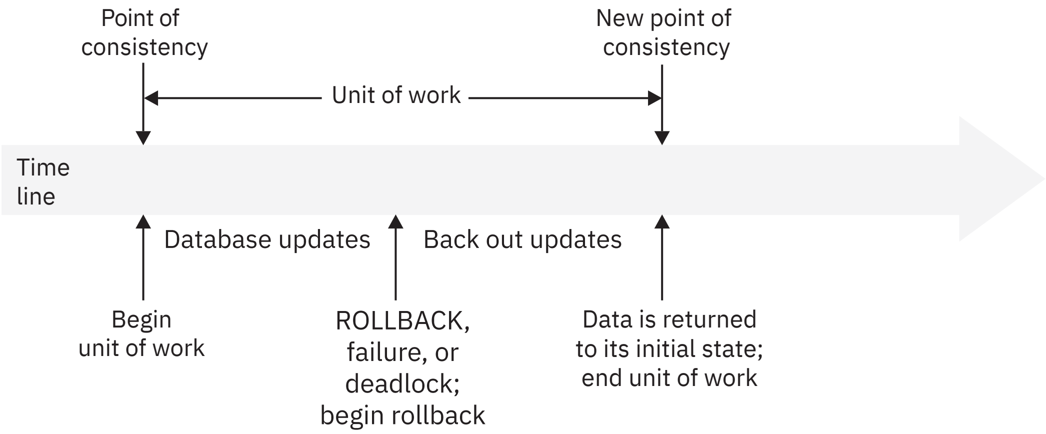

Figure 8. Rolling back all changes from a unit of work

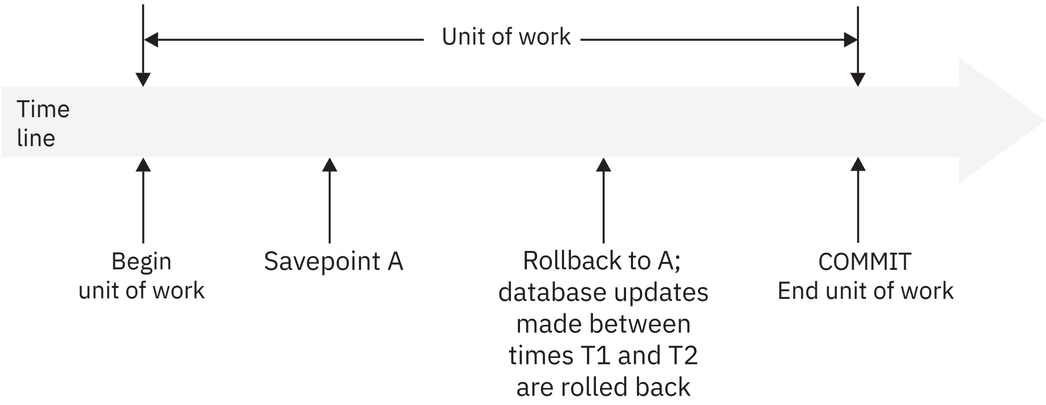
Rolling back selected changes using savepoints

A *savepoint* represents the state of data at some particular time during a unit of work. An application process can set savepoints within a unit of work, and then as logic dictates, roll back only the changes that were made after a savepoint was set.

For example, part of a reservation transaction might involve booking an airline flight and then a hotel room. If a flight gets reserved but a hotel room cannot be reserved, the application process might want to undo the flight reservation without undoing any database changes made in the transaction prior to making the flight reservation. SQL programs can use the SQL SAVEPOINT statement to set savepoints, the SQL ROLLBACK statement with the TO SAVEPOINT clause to undo changes to a specific savepoint or the last savepoint that was set, and the SQL RELEASE SAVEPOINT statement to delete a savepoint. The following figure illustrates this concept.



Unit of work
Time line
Begin unit of work
Savepoint A
Rollback to A; database updates made between times T1 and T2 are rolled back
COMMIT End unit of work

Figure 9. Rolling back changes to a savepoint within a unit of work

Packages and application plans

A *package* contains control structures that Db2 uses when it runs SQL statements. An *application plan* relates an application process to a local instance of Db2 and specifies processing options.

Packages are produced during program preparation. You can think of the control structures as the bound or operational form of SQL statements. All control structures in a package are derived from the SQL statements that are embedded in a single source program.

An application plan contains a list of package names.

Db2 applications require an application plan. Packages make application programs more flexible and easier to maintain.

In general, you create plans and packages by using the Db2 commands BIND PLAN and BIND PACKAGE.

Example

The following figure shows an application plan that contains two packages. Suppose that you decide to change the SELECT statement in package AA to select data from a different table. In this case, you need to bind only package AA again and not package AB.

GUPI

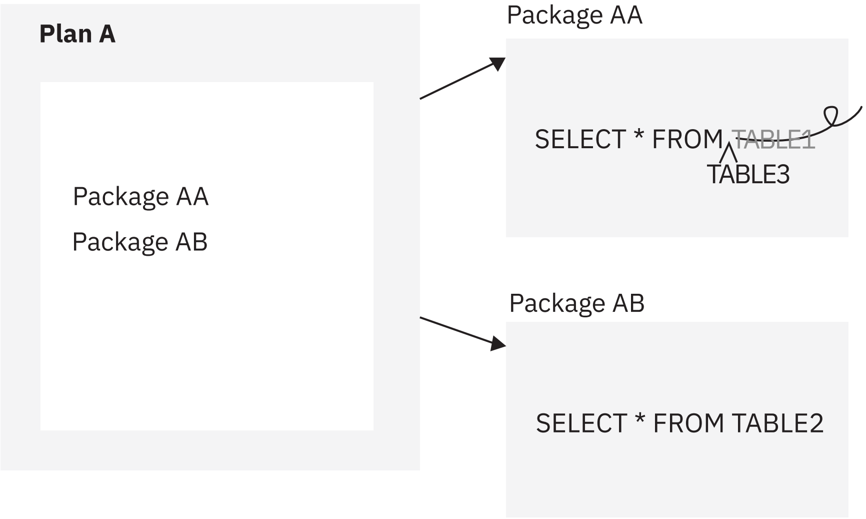


Figure 10. Application plan and packages

GUPI

Packages for triggers and routines

A *trigger package* is a special type of package that is created when you issue a CREATE TRIGGER statement. It contains the trigger body and the WHEN clause for the trigger. When the trigger activates, the package executes one or more times.

Packages are also generated, or explicitly created for certain SQL routines, including stored procedures and certain types of user defined functions. The package for a routine contains the routine body, including control statements. The package might also contain statements that are generated by Db2. Each time that the routine is invoked, the package executes one or more times.

Specifically, Db2 generates a package automatically for the following types of SQL routines:

- External scalar functions
- External table functions
- Compiled SQL scalar functions
- Native SQL procedures
- External SQL procedures

For external stored procedures, you explicitly bind the source code for the stored procedure into a package before or you issue the CREATE PROCEDURE statement. Each time that the external procedure is invoked, the package executes one or more times.

Packages for JDBC, SQLJ, and ODBC applications

Packages for JDBC, SQLJ, and ODBC applications serve different purposes. For more information, see Preparing and running JDBC and SQLJ programs (Db2 Application Programming for Java) and Db2 ODBC run time environment setup (Db2 Programming for ODBC).

Subsystem parameters

Subsystem parameters are settings that apply to a Db2 for z/OS subsystem. For example, the AUTH subsystem parameter controls whether Db2 checks authorizations. Many users colloquially refer to subsystem parameters as *zparms*.

Generally, system administrators set the value of subsystem parameters when they install or migrate Db2. After installation or migration, a system administrator can change the values of subsystem parameters if needed. However, because these parameters can affect the entire subsystem, system administrators should first carefully evaluate and plan for the impact of any changed values. In some cases, changing the value of a subsystem parameter requires Db2 to be stopped and restarted.

Most subsystem parameters are listed on installation panels. However, some parameters are not. For a list of subsystem parameters, including those parameters that are not on panels, see Directory of subsystem parameters, panel fields, and application default values (Db2 Installation and Migration). This list includes important characteristics of each parameter, including whether changing a the parameter requires you to stop and restart Db2.

Subsystem parameter values are contained in a load module that is generated by installation job DSNTIJUZ. The name of this subsystem parameters load module is specified in the PARAMETER MODULE field of installation panel DSNTIPO3. The default name is DSNZPARM. However, to avoid naming conflicts with other members, you should use a different name. Sometimes the naming convention DSNZP*xxx* is used. In a data sharing environment, each member must have its own subsystem parameter load module.

One way to check the subsystem parameter values is to call stored procedure SYSPROC.ADMIN_INFO_SYSPARM by running sample job DSNTEJ6Z.

Some Db2subsystem parameters are considered *security parameters*. These parameters can be updated only by processes with a privilege set that includes installation SYSADM authority or SECADM authority. for more information, see Security parameters in Db2 for z/OS (Db2 Installation and Migration).

Storage structures

In Db2, a *storage structure* is a set of one or more VSAM data sets that hold Db2 tables or indexes. A storage structure is also called a *page set*.

The two primary types of storage structures in Db2 for z/OS are table spaces and index spaces.

Implementing Db2 table spaces (Db2 Administration Guide)

Db2 databases

Db2 *databases* are a set of Db2 structures that include a collection of tables, their associated indexes, and the table spaces in which they reside. You define a database by using the CREATE DATABASE statement.

Whenever a table space is created, it is explicitly or implicitly assigned to an existing database. If you create a table space and do not specify a database name, the table space is created in the default database, DSNDB04. In this case, Db2 implicitly creates a database or uses an existing implicitly created database for the table. All users who have the authority to create table spaces or tables in database DSNDB04 have authority to create tables and table spaces in an implicitly created database. If the table space is implicitly created, and you do not specify the IN clause in the CREATE TABLE statement, Db2 implicitly creates the database to which the table space is assigned.

A single database, for example, can contain all the data that is associated with one application or with a group of related applications. Collecting that data into one database allows you to start or stop access to all the data in one operation. You can also grant authorization for access to all the data as a single unit. Assuming that you are authorized to access data, you can access data that is stored in different databases.

Generally, it is best to minimize the number of table spaces in each database. For the recommended partition-by-range and partition-by-growth table space types, each table space contains only a single table. However, if you do use multi-table segmented (non-UTS) table spaces, which are deprecated, minimize the number of tables in each table space. Too many table spaces and tables in a database can cause decreases in performance and manageability issues. If you reduce the number of table spaces and tables in a database, you improve performance, minimize maintenance, increase concurrency, and decrease log volume.

Deprecated function: FL 504 Non-UTS table spaces for base tables are deprecated. CREATE TABLESPACE statements that run at application compatibility level V12R1M504 or higher always create a partition-by-growth or partition-by-range table space, and CREATE TABLE statements that specify a non-UTS table space (including existing multi-table segmented table spaces) return an error. However, you can use a lower application compatibility level to create table spaces of the deprecated types if needed, such as for recovery situations. For instructions, see Creating non-UTS table spaces (deprecated) (Db2 Administration Guide).

The following figure shows how the main Db2 data structures fit together. Two databases, A and B, are represented as squares. Each database contains a table space and index space. Each index space contains one index. In database B, the table space is partitioned and contains table B1, partitions 1 - 4. The index space contains one partitioning index, parts 1 - 4.

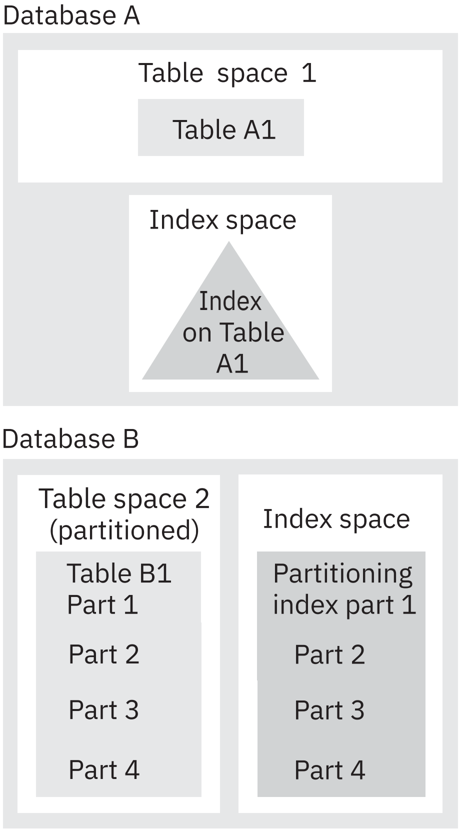

Figure 11. Data structures in a Db2 database

When you migrate Db2 12, Db2 adopts the default database and default storage group that you used in the previous version. You have the same authority for the Db2 12 as you did in the previous version.

Reasons to define a database

In Db2 for z/OS, a database is a logical collection of table spaces and index spaces. Consider the following factors when deciding whether to define a new database for a new set of objects:

- You can start and stop an entire database as a unit; you can display the statuses of all its objects by using a single command that names only the database. Therefore, place a set of tables that are used together into the same database. (The same database holds all indexes on those tables.)
- Some operations lock an entire database. For example, some phases of the LOAD utility prevent some SQL statements (CREATE, ALTER, and DROP) from using the same database concurrently. Therefore, placing many unrelated tables in a single database is often inconvenient.

  When one user is executing a CREATE, ALTER, or DROP statement for a table, no other user can access the database that contains that table. QMF users, especially, might do a great deal of data definition; the QMF operations SAVE DATA and ERASE *data-object* are accomplished by creating and dropping Db2 tables. For maximum concurrency, create a separate database for each QMF user.
- The internal database descriptors (DBDs) might become inconveniently large. DBDs grow as new objects are defined, but they do not immediately shrink when objects are dropped; the DBD space for a dropped object is not reclaimed until the MODIFY RECOVERY utility is used to delete records of obsolete copies from SYSIBM.SYSCOPY. DBDs occupy storage and are the objects of occasional input and output operations. Therefore, limiting the size of DBDs is another reason to define new databases.

Related concepts

Creation of databases (Introduction to Db2 for z/OS)

Db2 table spaces

A Db2 *table space* is a set of volumes on disks that hold the data sets in which tables are actually stored. Every table is stored in table space.

A table space consists of a number of VSAM linear data sets. Table spaces are divided into equal-sized units, called *pages*. Each page is read from disk to the assigned buffer pool, or written from the buffer pool to disk, in a single operation. The page size is controlled by the buffer pool that you assign to the table space (4 KB, 8 KB, 16 KB, or 32 KB in size) for the data. The default page size is 4 KB.

Data in most table spaces can be compressed, which can allow you to store more data on each data page.

You can let Db2 create and manage the table space for you by issuing a CREATE TABLE statement that does not specify an existing table space. Db2 creates a partition-by-growth or partition-by-range table space. For more information, see Creation of table spaces (Introduction to Db2 for z/OS).

You can also explicitly define table spaces by issuing CREATE TABLESPACE statements. You specify the database that the table space belongs to, and the storage group that it uses. When you create a table space, certain options that you specify control the type of table space that is created.

Deprecated function: FL 504 Non-UTS table spaces for base tables are deprecated. CREATE TABLESPACE statements that run at application compatibility level V12R1M504 or higher always create a partition-by-growth or partition-by-range table space, and CREATE TABLE statements that specify a non-UTS table space (including existing multi-table segmented table spaces) return an error. However, you can use a lower application compatibility level to create table spaces of the deprecated types if needed, such as for recovery situations. For instructions, see Creating non-UTS table spaces (deprecated) (Db2 Administration Guide).

For descriptions of the various table space types, see Table space types and characteristics in Db2 for z/OS (Db2 Administration Guide).

Segmented non-UTS table spaces, which are deprecated, can contain more than one table. However, with the recommended partition-by-growth and partition-by-range table spaces, each table space contains only a single table.

Conversion from index-controlled partitioning to Universal Table Space (UTS)

Partitions

A *partition* is a page set that corresponds to a single data set that can be processed or extended independently.

Db2 usually distributes the data evenly across the partitions of a table space when it is created. However, the distribution of the data might become uneven over time, as inserts and deletes occur. You can rebalance data among the partitions by redefining partition boundaries with no impact to availability. You can also add a partition to the table and to each partitioned index on the table; the new partition becomes available immediately.

You can spread the partitions of a large table over several Db2 storage groups or data sets. The partitions of the table do not all need to use the same storage group.

You can also put different partitions on different device types, which means that you can put frequently accessed data in separate partitions and place these partitions on faster devices.

You can use separate jobs for mass update, delete, or insert operations instead of using one large job; each smaller job can work on a different partition. Separating the large job into several smaller jobs that run concurrently can reduce the elapsed time for the whole task.

For certain read-only queries, Db2 can use parallel processing on more than one partition. Parallel processing (for read-only queries) is most efficient when you spread the partitions over different disk volumes and allow each I/O stream to operate on a separate channel. Use the Parallel Sysplex data sharing technology to process a single read-only query across many Db2 subsystems in a data sharing group. You can optimize Parallel Sysplex query processing by placing each Db2 subsystem on a separate central processor complex.

Certain table space types do not have partitions, including segmented (non-UTS) table spaces and simple table spaces. However, all such table spaces are deprecated.

Growth-based partitions

Partitioned (non-UTS) table spaces (deprecated) (Db2 Administration Guide)

Segments

A *segment* is a group of pages that holds the rows of a single table. All segments in a table space are the same size.

Related reference

DEFAULT PARTITION SEGSIZE field (DPSEGSZ subsystem parameter) (Db2 Installation and Migration)

Db2 index spaces

An *index space* is a Db2 storage structure that contains a single index.

When you create an index by using the CREATE INDEX statement, an index space is automatically defined in the same database as the table. You can define a unique name for the index space, or Db2 can derive a unique name for you. Under certain circumstances, Db2 implicitly creates index spaces.

Rules for primary and secondary space allocation

You can specify the primary and secondary space allocation or let Db2 choose them. Having Db2 choose the values, especially the secondary space quantity, increases the possibility of reaching the maximum data set size before running out of extents.

In the following rules that describe how allocation works, these terms are used:

PRIQTY, SECQTY
The keywords for CREATE TABLESPACE, ALTER TABLESPACE, CREATE INDEX, and ALTER INDEX.

specified-priqty
The user-specified value for PRIQTY.

specified-secqty
The user-specified value for SECQTY.

actual-priqty
The actual primary space allocation, in kilobytes.

actual-priqty-cylinders
The actual primary space allocation, in cylinders.

actual-secqty
The actual secondary space allocation, in kilobytes.

actual-secqty-cylinders
The actual secondary space allocation, in cylinders.

calculated-extent-cylinders
A value that is calculated by Db2 using a *sliding scale*. A sliding scale means that the first secondary extent allocations are smaller than later secondary allocations. For example, Figure 12 on page 52 shows the sliding scale of secondary extent allocations that Db2 uses for a 64-GB data set. The size of each secondary extent is larger for each secondary extent that is allocated up to the 127th extent. For the 127th secondary extent and any subsequent extents, the secondary size allocation is 559 cylinders.

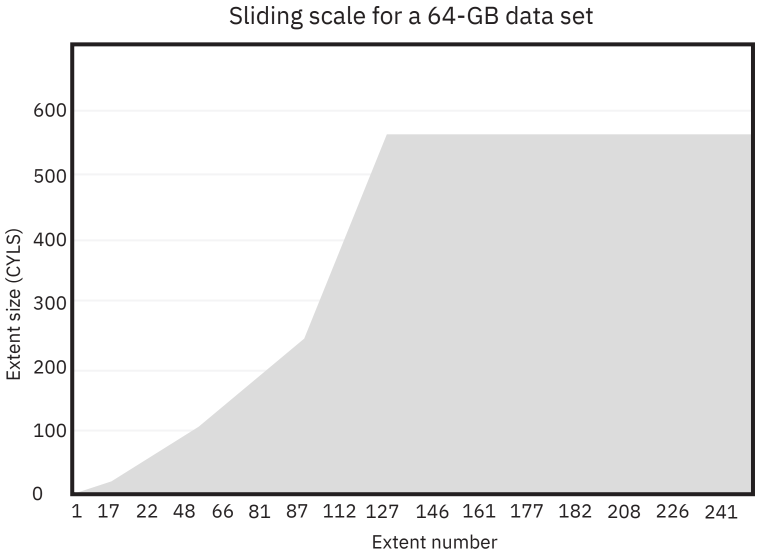

Figure 12. Sliding scale allocation of secondary extents for a 64 GB data set

Rules

Rule 1: (for primary space allocation)
If PRIQTY is specified and *specified-priqty* is not equal to -1, *actual-priqty* is at least *specified-priqty* KB.

If PRIQTY is not specified or *specified-priqty* is equal to -1, *actual-priqty* is determined as follows:

- For a table space, if the TSQTY subsystem parameter value is specified and is greater than 0, *actual-priqty* is at least the value of TSQTY.

  If the TSQTY subsystem parameter is not specified or is 0, *actual-priqty* is one cylinder for a non-LOB table space. *actual-priqty* is 10 cylinders for a LOB table space.
- For an index, if the IXQTY subsystem parameter value is specified and is greater than 0, *actual-priqty* is at least the value of IXQTY.

  If the IXQTY subsystem parameter is not specified or is 0, *actual-priqty* is one cylinder.

Rule 2: (for secondary space allocation)
If SECQTY is not specified, the following formulas determine *actual-secqty*:

- If the maximum size of a data set in the table space or index is less than 32 GB, the formula is:

  ```
  actual-secqty-cylinders=
  MAX(0.1*actual-priqty-cylinders, MIN(calculated-extent-cylinders, 127))
  ```
- If the maximum size of a data set in the table space or index is 32 GB or greater, the formula is:

  ```
  actual-secqty-cylinders=
  MAX(0.1*actual-priqty-cylinders, MIN(calculated-extent-cylinders, 559))
  ```

Rule 3 (for secondary space allocation)

If SECQTY is 0, *actual-secqty* is 0.

Rule 4 (for secondary space allocation)

If SECQTY is specified and *specified-secqty* is not equal to -1 or 0, the following formulas determine *actual-secqty*. If the maximum size of a data set in the table space or index is less 32 GB, the formula is:

```
actual-secqty-cylinders=
MAX(MIN(calculated-extent-cylinders, 127),specified-secqty-cylinders)
```

If the maximum size of a data set in the table space or index is 32 GB or greater, the formula is:

```
actual-secqty-cylinders=
MAX(MIN(calculated-extent-cylinders, 559),specified-secqty-cylinders)
```

Rule 5 (for secondary space allocation):

When a table space requires a new piece, the primary allocation quantity of the new piece is determined by using the maximum of the following values:

- The quantity that is calculated through sliding scale methodology
- The primary quantity from rule 1
- The specified SECQTY value

ALTER INDEX
The ALTER INDEX statement changes the description of an index at the current server.

Db2 hash spaces (deprecated)

A *hash space* is a defined disk space that organizes table data for hash access. Hash-organized table spaces are deprecated and likely to be unsupported in the future.

Deprecated function:

FL 504 Hash-organized tables are deprecated. Beginning in Db2 12, packages that are bound with APPLCOMPAT(V12R1M504) or higher cannot create hash-organized tables or alter existing tables to use hash-organization. Existing hash-organized tables remain supported, but they are likely to be unsupported in the future.

When you organize a table for hash access, Db2 requires a defined amount of disk space to contain table data. You can specify the amount of disk space to allocate to the hash space when you create a table or alter an existing table. The hash space on a table must be large enough to contain new rows that are added to the table. If a hash space is full, new rows are relocated to the overflow index, which reduces the performance of hash access on that table. Hash spaces can contain only a single table in a partition-by-range or partition-by-growth table space.

Monitoring hash access (deprecated) (Db2 Performance)

Db2 storage groups

Db2 *storage groups* are a set of volumes on disks that hold the data sets in which tables and indexes are stored.

The description of a storage group names the group and identifies its volumes and the VSAM (Virtual Storage Access Method) catalog that records the data sets. The default storage group, SYSDEFLT, is created when you install Db2.

Within the storage group, Db2 does the following actions:

- Allocates storage for table spaces and indexes
- Defines the necessary VSAM data sets
- Extends and deletes VSAM data sets
- Alters VSAM data sets

All volumes of a given storage group must have the same device type. However, parts of a single database can be stored in different storage groups.

Db2 can manage the auxiliary storage requirements of a database by using Db2 storage groups. Data sets in these Db2 storage groups are called "Db2-managed data sets."

These Db2 storage groups are not the same as storage groups that are defined by the DFSMS storage management subsystem (DFSMSsms).

You have several options for managing Db2 data sets:

- Let Db2 manage the data sets. This option means less work for Db2 database administrators.

  After you define a Db2 storage group, Db2 stores information about it in the Db2 catalog. (This catalog is not the same as the integrated catalog facility catalog that describes Db2 VSAM data sets). The catalog table SYSIBM.SYSSTOGROUP has a row for each storage group, and SYSIBM.SYSVOLUMES has a row for each volume. With the proper authorization, you can retrieve the catalog information about Db2 storage groups by using SQL statements.

  When you create table spaces and indexes, you name the storage group from which space is to be allocated. You can also assign an entire database to a storage group. Try to assign frequently accessed objects (indexes, for example) to fast devices, and assign seldom-used tables to slower devices. This approach to choosing storage groups improves performance.

  If you are authorized and do not take specific steps to manage your own storage, you can still define tables, indexes, table spaces, and databases. A default storage group, SYSDEFLT, is defined when Db2 is installed. Db2 uses SYSDEFLT to allocate the necessary auxiliary storage. Information about SYSDEFLT, as with any other storage group, is kept in the catalog tables SYSIBM.SYSSTOGROUP and SYSIBM.SYSVOLUMES.

  For both user-managed and Db2-managed data sets, you need at least one integrated catalog facility (ICF) catalog; this catalog can be either a user catalog or a master catalog. These catalogs are created with the ICF. You must identify the catalog of the ICF when you create a storage group or when you create a table space that does not use storage groups.
- Let SMS manage some or all the data sets, either when you use Db2 storage groups or when you use data sets that you have defined yourself. This option offers a reduced workload for Db2 database administrators and storage administrators. You can specify SMS classes when you create or alter a storage group.
- Define and manage your own data sets using VSAM Access Method Services. This option gives you the most control over the physical storage of tables and indexes.

Recommendation: Use Db2 storage groups and whenever you can, either specifically or by default. Also use SMS managed Db2 storage groups whenever you can.

Related tasks

Choosing data page sizes for LOB data (Db2 Performance)

Application processes, concurrency, and recovery

All SQL programs execute as part of an *application process*. An application process involves the execution of one or more programs, and it is the unit to which Db2 allocates resources and locks.

Different application processes might involve the execution of different programs, or different executions of the same program. The means of initiating and terminating an application process are dependent on the environment.

Locking, commit, and rollback

More than one application process might request access to the same data at the same time. Furthermore, under certain circumstances, an SQL statement can execute concurrently with a utility on the same table space. *Locking* is used to maintain data integrity under such conditions, preventing, for example, two application processes from updating the same row of data simultaneously.

Db2 implicitly acquires locks to prevent uncommitted changes made by one application process from being perceived by any other. Db2 will implicitly release all locks it has acquired on behalf of an application process when that process ends, but an application process can also explicitly request that locks be released sooner. A *commit* operation releases locks acquired by the application process and commits database changes made by the same process.

Db2 provides a way to *back out* uncommitted changes made by an application process. This might be necessary in the event of a failure on the part of an application process, or in a *deadlock* situation. An application process, however, can explicitly request that its database changes be backed out. This operation is called *rollback*.

The interface used by an SQL program to explicitly specify these commit and rollback operations depends on the environment. If the environment can include recoverable resources other than Db2 databases, the SQL COMMIT and ROLLBACK statements cannot be used. Thus, these statements cannot be used in an IMS, CICS, or WebSphere environment.

Unit of work

A *unit of work* is a recoverable sequence of operations within an application process. A unit of work is sometimes called a *logical unit of work*.

At any time, an application process has a single unit of work, but the life of an application process can involve many units of work as a result of commit or full rollback operations.

A unit of work is initiated when an application process is initiated. A unit of work is also initiated when the previous unit of work is ended by something other than the end of the application process. A unit of work is ended by a commit operation, a full rollback operation, or the end of an application process. A commit or rollback operation affects only the database changes made within the unit of work it ends. While these changes remain uncommitted, other application processes are unable to perceive them unless they are running with an isolation level of uncommitted read. The changes can still be backed out. Once committed, these database changes are accessible by other application processes and can no longer be backed out by a rollback. Locks acquired by Db2 on behalf of an application process that protects uncommitted data are held at least until the end of a unit of work.

The initiation and termination of a unit of work define *points of consistency* within an application process. A point of consistency is a claim by the application that the data is consistent. For example, a banking transaction might involve the transfer of funds from one account to another. Such a transaction would require that these funds be subtracted from the first account, and added to the second. Following the subtraction step, the data is inconsistent. Only after the funds have been added to the second account is consistency reestablished. When both steps are complete, the commit operation can be used to end the unit of work, thereby making the changes available to other application processes. The following figure illustrates this concept.

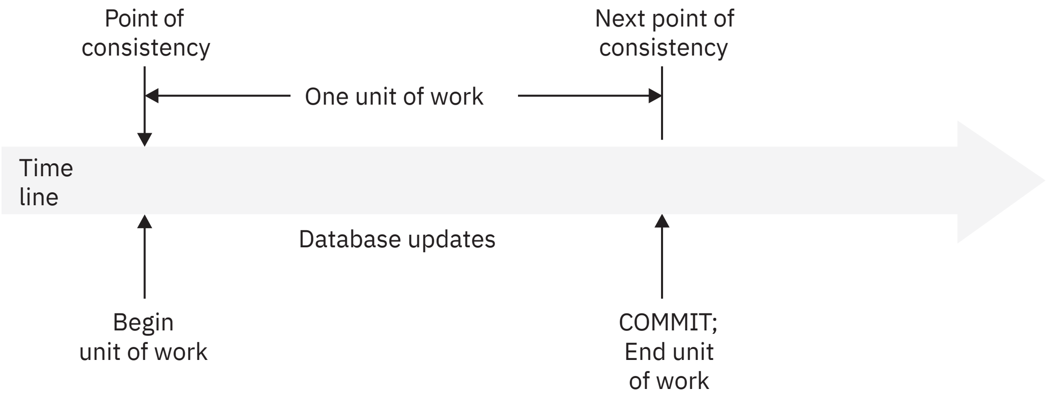

Figure 13. Unit of work with a commit operation

Unit of recovery

A *Db2 unit of recovery* is a recoverable sequence of operations executed by Db2 for an application process.

If a unit of work involves changes to other recoverable resources, the unit of work will be supported by other units of recovery. If relational databases are the only recoverable resources used by the application process, then the scope of the unit of work and the unit of recovery are the same and either term can be used.

Rolling back work

Db2 can back out all changes made in a unit of recovery or only selected changes. Only backing out all changes results in a point of consistency.

Rolling back all changes

The SQL ROLLBACK statement without the TO SAVEPOINT clause specified causes a full rollback operation. If such a rollback operation is successfully executed, Db2 backs out uncommitted changes to restore the data consistency that existed when the unit of work was initiated.

That is, Db2 undoes the work, as shown in the following figure:

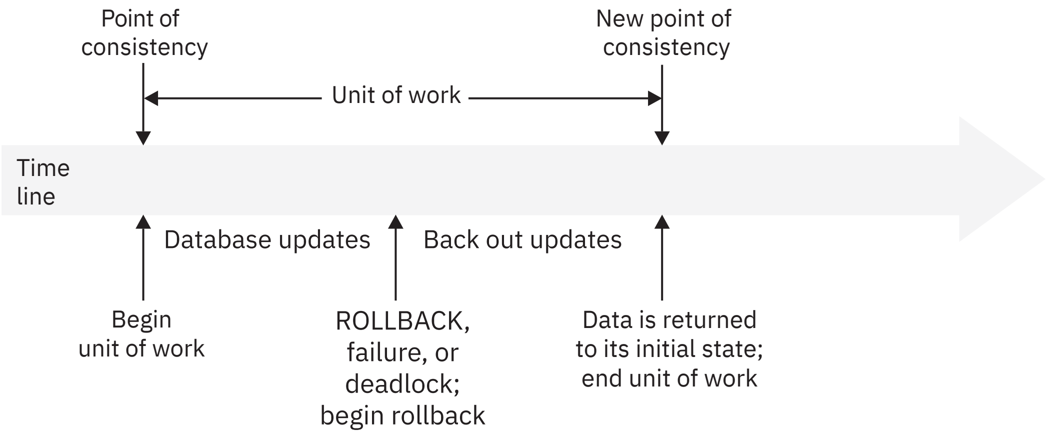

Figure 14. Rolling back all changes from a unit of work

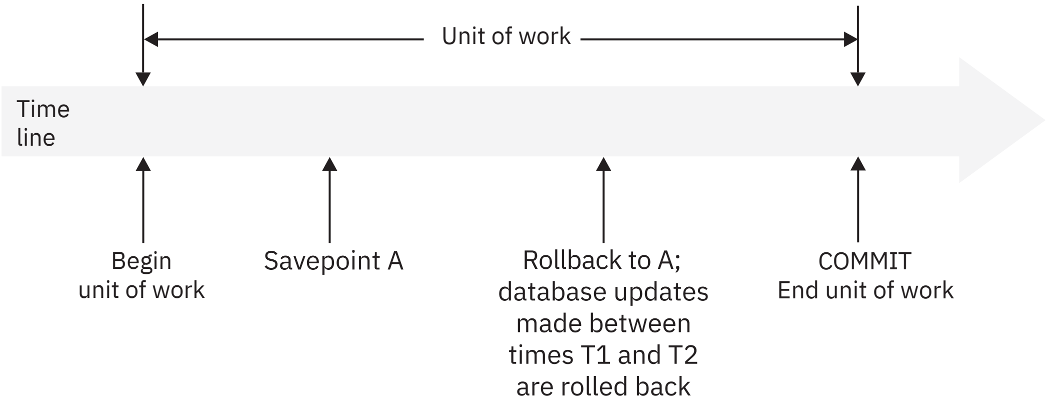
Rolling back selected changes using savepoints

A *savepoint* represents the state of data at some particular time during a unit of work. An application process can set savepoints within a unit of work, and then as logic dictates, roll back only the changes that were made after a savepoint was set.

For example, part of a reservation transaction might involve booking an airline flight and then a hotel room. If a flight gets reserved but a hotel room cannot be reserved, the application process might want to undo the flight reservation without undoing any database changes made in the transaction prior to making the flight reservation. SQL programs can use the SQL SAVEPOINT statement to set savepoints, the SQL ROLLBACK statement with the TO SAVEPOINT clause to undo changes to a specific savepoint or the last savepoint that was set, and the SQL RELEASE SAVEPOINT statement to delete a savepoint. The following figure illustrates this concept.



Unit of work
Time line
Begin unit of work
Savepoint A
Rollback to A; database updates made between times T1 and T2 are rolled back
COMMIT End unit of work

Figure 15. Rolling back changes to a savepoint within a unit of work

Packages and application plans

A *package* contains control structures that Db2 uses when it runs SQL statements. An *application plan* relates an application process to a local instance of Db2 and specifies processing options.

Packages are produced during program preparation. You can think of the control structures as the bound or operational form of SQL statements. All control structures in a package are derived from the SQL statements that are embedded in a single source program.

An application plan contains a list of package names.

Db2 applications require an application plan. Packages make application programs more flexible and easier to maintain.

In general, you create plans and packages by using the Db2 commands BIND PLAN and BIND PACKAGE.

Example

The following figure shows an application plan that contains two packages. Suppose that you decide to change the SELECT statement in package AA to select data from a different table. In this case, you need to bind only package AA again and not package AB.

GUPI

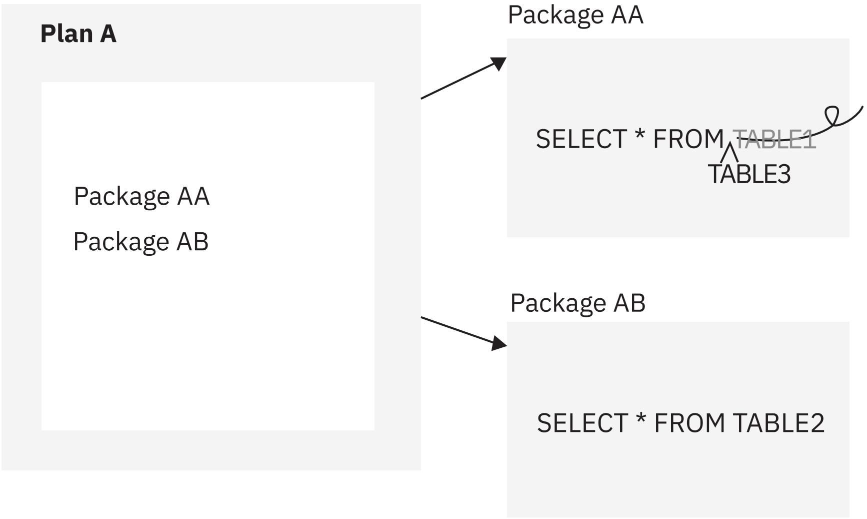


Figure 16. Application plan and packages

GUPI

Packages for triggers and routines

A *trigger package* is a special type of package that is created when you issue a CREATE TRIGGER statement. It contains the trigger body and the WHEN clause for the trigger. When the trigger activates, the package executes one or more times.

Packages are also generated, or explicitly created for certain SQL routines, including stored procedures and certain types of user defined functions. The package for a routine contains the routine body, including control statements. The package might also contain statements that are generated by Db2. Each time that the routine is invoked, the package executes one or more times.

Specifically, Db2 generates a package automatically for the following types of SQL routines:

- External scalar functions
- External table functions
- Compiled SQL scalar functions
- Native SQL procedures
- External SQL procedures

For external stored procedures, you explicitly bind the source code for the stored procedure into a package before or you issue the CREATE PROCEDURE statement. Each time that the external procedure is invoked, the package executes one or more times.

Packages for JDBC, SQLJ, and ODBC applications

Packages for JDBC, SQLJ, and ODBC applications serve different purposes. For more information, see Preparing and running JDBC and SQLJ programs (Db2 Application Programming for Java) and Db2 ODBC run time environment setup (Db2 Programming for ODBC).

SET CURRENT PACKAGE PATH
The SET CURRENT PACKAGE PATH statement assigns a value to the CURRENT PACKAGE PATH special register.

SET CURRENT PACKAGESET

The SET CURRENT PACKAGESET statement assigns a value to the CURRENT PACKAGESET special register.

CREATE FUNCTION
The CREATE FUNCTION statement registers a user-defined function with a database server. Each type of function that you can register with this statement is described separately.

CREATE PROCEDURE
The CREATE PROCEDURE statement registers a stored procedure with a database server. You can register the following types of procedures with this statement, each of which is described separately.

CREATE TRIGGER (basic)

Character conversion

A *string* is a sequence of bytes that can represent characters. Within a string, all the characters are represented by a common encoding representation. In some cases, it might be necessary to convert these characters to a different encoding representation. The process of conversion is known as *character conversion*.

Character conversion, when required, is automatic, and when successful, it is transparent to the application.

In client/server environments, character conversion can occur when an SQL statement is executed remotely. Consider, for example, the following two cases. In either case, the data could have a different representation at the sending and receiving systems.

- The values of data sent from the requester to the current server
- The values of data sent from the current server to the requester

Conversion can also occur during string operations on the same system, as in the following examples:

- An overriding CCSID is specified.

  For example, an SQL statement with a descriptor, which requires an SQLDA. In the SQLDA, the CCSID is in the SQLNAME field for languages other than REXX, and in the SQLCCSID field for REXX. (For more information, see Appendix F, “SQL descriptor area (SQLDA),” on page 2301). A DECLARE VARIABLE statement can also be issued to associate a CCSID with the host variables into which data is retrieved from a table.
- The value of the ENCODING bind option or the APPLICATION ENCODING SCHEMA option of the CREATE PROCEDURE or ALTER PROCEDURE statement for a native SQL procedure (static SQL statements) or the CURRENT APPLICATION ENCODING SCHEME special register (for dynamic SQL) is different than encoding scheme of the data being retrieved.
- A mixed character string is assigned to an SBCS column or host variable.
- An SQL statement refers to data that is defined with different CCSIDs.

The text of an SQL statement is also subject to character conversion because it is a character string.

The following list defines some of the terms used for character conversion.

ASCII
Acronym for American Standard Code for Information Interchange, an encoding scheme used to represent characters. The term ASCII is used throughout this information to refer to IBM-PC Data or ISO 8-bit data.

character set
A defined set of characters, a character being the smallest component of written language that has semantic value. For example, the following character set appears in several code pages:

- 26 nonaccented letters A through Z
- 26 nonaccented letters a through z
- digits 0 through 9
- . , : ; ? ( ) ' "/- _ & + % * = < >

code page

A set of assignments of characters to code points. For example, in EBCDIC, "A" is assigned code point X'C1', and "B" is assigned code point X'C2'. In Unicode UTF-8, "A" is assigned code point X'41', and "B" is assigned code point X'42'. Within a code page, each code point has only one specific meaning.

code point

A unique bit pattern that represents a character. It is a numerical index or position in an encoding table used for encoding characters.

coded character set

A set of unambiguous rules that establishes a character set and the one-to-one relationships between the characters of the set and their coded representations. It is the assignment of each character in a character set to a unique numeric code value.

coded character set identifier (CCSID)

A two-byte, unsigned binary integer that uniquely identifies an encoding scheme and one or more pairs of character sets and code pages.

EBCDIC

Acronym for Extended Binary-Coded Decimal Interchange Code, an encoding scheme used to represent character data, a group of coded character sets that consist of 8 bit coded characters. EBCDIC coded character sets use the first 64 code positions (X'00' to X'3F') for control codes. The range X'41' to X'FE' is used for single-byte characters. For double-byte characters, the first byte is in the range X'41' to X'FE' and the second byte is also in the range X'41' to X'FE', while X'4040' represents a double-byte space.

encoding scheme

A set of rules used to represent character data. All string data stored in a table must use the same encoding scheme and all tables within a table space must use the same encoding scheme, except for global temporary tables, declared temporary tables, and work file table spaces. Db2 supports these encoding schemes:

- ASCII
- EBCDIC
- Unicode

substitution character

A unique character that is substituted during character conversion for any characters in the source encoding representation that do not have a match in the target encoding representation.

Unicode

A universal encoding scheme for written characters and text that enables the exchange of data internationally. It provides a character set standard that can be used all over the world. It provides the ability to encode all characters used for the written languages of the world and treats alphabetic characters, ideographic characters, and symbols equivalently because it specifies a numeric value and a name for each of its characters. It includes punctuation marks, mathematical symbols, technical symbols, geometric shapes, and dingbats. Db2 supports these two encoding forms:

- UTF-8: Unicode Transformation Format, a 8 bit encoding form designed for ease of use with existing ASCII-based systems. UTF-8 can encode any of the Unicode characters. A UTF-8 character is 1,2,3, or 4 bytes in length. A UTF-8 data string can contain any combination of SBCS and MBCS data, including supplementary characters. The CCSID value for data in UTF-8 format is 1208. UTF-8 has multiple code points for spaces, including the '20'X single-byte space that Db2 uses for padding UTF-8 data.
- UTF-16: Unicode Transformation Format, a 16 bit encoding form designed to provide code values for over a million characters and a superset of UCS-2. UTF-16 can encode any of the Unicode characters. In UTF-16 encoding, characters are 2 bytes in length, except for supplementary characters, which take two 2 byte string units per character. The CCSID value for data in UTF-16 format is 1200. UTF-16 has multiple code points for spaces, including the '0020'X single-byte space that Db2 uses for padding UTF-16 data.

Character data (CHAR, VARCHAR, and CLOB) is encoded in Unicode UTF-8. Character strings are also used for mixed data (that is a mixture of single-byte characters and multi-byte characters) and for data that is not associated with any character set (called bit data). Graphic data (GRAPHIC, VARGRAPHIC, and DBCLOB) is encoded in Unicode UTF-16. For a comparison of some UTF-8 and UTF-16 code points for some sample characters, see Character sets and code pages (Introduction to Db2 for z/OS). This table shows how a UTF-8 character can be 1 to 4 bytes in length, a non-supplementary UTF-16 character is 2 bytes in length, and how a supplementary character in either UTF-8 or UTF-16 takes two 2 byte code points.

Character conversion can affect the results of several SQL operations. In this information, the effects are described in:

“String assignments” on page 149
“Conversion rules for comparisons” on page 159
“Character conversion in set operations and concatenations” on page 1063

Character sets and code pages

Even with the same encoding scheme, different CCSIDs exist, and the same code point can represent a different character in different CCSIDs. Furthermore, a byte in a character string does not necessarily represent a character from a single-byte character set (SBCS).

The following figure shows how a typical character set might map to different code points in two different code pages.

	0	1	2	3	4	5		E	F
0				0	@	P		Â	
1				1	A	Q		À	α

Unicode Consortium

Coded character sets and CCSIDS

The IBM *character data representation architecture (CDRA)* deals with the differences in string representation and encoding. The *Coded Character Set Identifier (CCSID)* is a key element of this architecture. A CCSID is a 2 byte (unsigned) binary number that uniquely identifies an encoding scheme and one or more pairs of character sets and code pages.

A CCSID is an attribute of strings, just as length is an attribute of strings. All values of the same string column have the same CCSID.

Character conversion is described in terms of CCSIDs of the source and target. With Db2 for z/OS, two methods are used to identify valid source and target combinations and to perform the conversion from one coded character set to another:

- Db2 catalog table SYSIBM.SYSSTRINGS

Each row in the catalog table describes a conversion from one coded character set to another.

- z/OS support for Unicode.

In some cases, no conversion is necessary even though the strings involved have different CCSIDs.

Different types of conversions might be supported by each database manager. Round-trip conversions attempt to preserve characters in one CCSID that are not defined in the target CCSID so that if the data is subsequently converted back to the original CCSID, the same original characters result. Enforced subset match conversions do not attempt to preserve such characters. Which type of conversion is used for a specific source and target CCSID is product-specific.

SYSSTRINGS catalog table

The SYSSTRINGS table contains information about character conversion. Each row describes a conversion from one coded character set to another. The schema is SYSIBM.

Determining the encoding scheme and CCSID of a string

An encoding scheme and a CCSID are attributes of strings, just as length is an attribute of strings. All values of the same string column have the same encoding scheme and CCSID.

Every string has an encoding scheme and a CCSID that identifies the manner in which the characters in the string are encoded. Strings can be encoded in ASCII, EBCDIC, or Unicode.

The CCSID that is associated with a string value depends on the SQL statement in which the data is referenced and the type of expression. Use the Type 1 rules when the SQL statement meets the following conditions:

- The SQL statement operates with a single set of CCSIDs (SBCS, mixed, and graphic). An SQL statement that does not contain any of the following items operates with a single set of CCSIDs:
  - References to columns from multiple tables or views that are defined with CCSIDs from more than one set of CCSIDs (SBCS, mixed, and graphic)
  - References to an EBCDIC table that contains a Unicode column
  - Graphic hexadecimal (GX) or hexadecimal Unicode (UX) string constants
  - References to the XMLCLOB built-in function
  - Cast specifications with a CCSID clause
  - User-defined table functions
- The SQL statement is not one of the following statements:
  - CALL statement
  - SET assignment statement
  - SET special register
  - VALUES statement
  - VALUES INTO statement
- One of the following built-in functions is not referenced:
  - ASCII_CHR
  - ASCII_STR (or ASCIISTR)
  - CHR
  - DECRYPT_BIT

  - DECRYPT_CHAR
  - DECRYPT_DATAKEY_BIT
  - DECRYPT_DATAKEY_CLOB
  - DECRYPT_DATAKEY_DBCLOB
  - DECRYPT_DATAKEY_VARCHAR
  - DECRYPT_DATAKEY_VARGRAPHIC
  - DECRYPT_DB
  - EBCDIC_CHR
  - EBCDIC_STR
  - GETVARIABLE
  - JSON_VAL
  - NORMALIZE_STRING
  - UNICODE_STR (or UNISTR)
  - XMLSERIALIZE
- The SQL statement does not include a collection-derived table (UNNEST).

Use the Type 2 rules when the statement does not meet the conditions for Type 1 rules.

For those SQL statements and tools that use a SYSDUMMY*x* table, use the SYSDUMMY*x* table that has the same encoding scheme as the other objects in your SQL statement, to avoid conversions. A SYSDUMMY*x* table is available in each encoding scheme. For example, suppose that your SQL statement references a SYSDUMMY*x* table that is in a different encoding scheme from other objects in the statement. Db2 treats this statement as one that references objects with different CCSIDs (Type 2 rules), and conversion is likely to occur. To avoid this situation, reference the SYSDUMMY*x* table that has the same encoding scheme as the other objects in your SQL statement. See SYSDUMMYx tables (Introduction to Db2 for z/OS) for more information.

Table 10 on page 64 describes the rules for determining the CCSID of derived string data when the source data has a string type.

Table 10. Rules for determining the CCSID that is associated with string data derived from string data

Source of the string data	Type 1 rules	Type 2 rules
String constant	If the statement references a table or view, the encoding scheme of that table or view determines the encoding scheme for the string constant. The CCSID is the appropriate character string CCSID of the encoding scheme.	The CCSID is the appropriate character string CCSID of the application encoding scheme.“1” on page 66
Datetime constant	If the statement references a table or view, the encoding scheme of that table or view determines the encoding scheme for the string constant. Otherwise, the default EBCDIC encoding scheme is used for the string constant. The CCSID is the appropriate character string CCSID of the encoding scheme.	The CCSID is the appropriate character string CCSID of the application encoding scheme.“1” on page 66

Table 10. Rules for determining the CCSID that is associated with string data derived from string data (continued)

Source of the string data	Type 1 rules	Type 2 rules
Hexadecimal string constant (X'...')	If the statement references a table or view, the encoding scheme of that table or view determines the encoding scheme for the string constant. Otherwise, the default EBCDIC encoding scheme is used for the string constant. The CCSID is the appropriate graphic string CCSID of the encoding scheme.	The CCSID is the appropriate character string CCSID of the application encoding scheme."1" on page 66
Graphic string constant (G'...')	If the statement references a table or view, the encoding scheme of that table or view determines the encoding scheme for the graphic string constant. Otherwise, the default EBCDIC encoding scheme is used for the graphic string constant. The CCSID is the graphic string CCSID of the encoding scheme.	The CCSID is the graphic string CCSID of the application encoding scheme."1" on page 66
Graphic hexadecimal constant (GX'...')	Not applicable.	The CCSID is the graphic string CCSID of the application encoding scheme, which must be ASCII or EBCDIC.
Hexadecimal Unicode string constant (UX'....')	Not applicable.	The CCSID is 1200 (UTF-16).
Special register	If the statement references a table or view, the encoding scheme of that table or view determines the encoding scheme for the special register. Otherwise, the default EBCDIC encoding scheme is used for the special register. The CCSID is the appropriate character string CCSID of the encoding scheme.	The CCSID is the appropriate CCSID of the application encoding scheme."1" on page 66
Column of a table	The CCSID is the CCSID that is associated with the column of the table.	The CCSID is the CCSID that is associated with the column of the table.
Column of a view	The CCSID is the CCSID of the column of the result table of the fullselect of the view definition.	The CCSID is the CCSID of the column of the result table of the fullselect of the view definition.
Expression	The CCSID is the CCSID of the result of the expression.	The CCSID is the CCSID of the result of the expression.

Table 10. Rules for determining the CCSID that is associated with string data derived from string data (continued)

Source of the string data	Type 1 rules	Type 2 rules
Result of a built-in function	If the description of the function, in Chapter 4, "Built-in functions," on page 341, indicates what the CCSID of the result is, the CCSID is that CCSID. Otherwise, if the description of the function refers to this table for the CCSID, the CCSID is the appropriate CCSID of the CCSID set that is used by the statement for the data type of the result.	If the description of the function, in Chapter 4, "Built-in functions," on page 341, indicates what the CCSID of the result is, the CCSID is that CCSID. Otherwise, if the description of the function refers to this table for the CCSID, the CCSID is the appropriate CCSID of the application encoding scheme for the data type of the result. "1" on page 66
Parameter of a user-defined routine	The CCSID is the CCSID that was determined when the function or procedure was created.	The CCSID is the CCSID that was determined when the function or procedure was created.
The expression in the RETURN statement of a CREATE statement for a user-defined SQL scalar function	If the expression in the RETURN statement is string data, the encoding scheme is the same as for the parameters of the function. The CCSID is determined from the encoding scheme and the attributes of the data.	The CCSID is determined from the CCSID of the result of the expression specified in the RETURN statement.
String host variable	If the statement references a table or view, the encoding scheme of that table or view determines the encoding scheme for the host variable. Graphic variables are an exception if the table or view is EBCDIC or ASCII and the value of the MIXED DATA field on the DSNTIPF panel is NO. In this case, the Unicode encoding scheme is used for the graphic host variable. Otherwise, the default EBCDIC encoding scheme is used for the host variable. The CCSID is the appropriate CCSID of the data type of the host variable.	At package prepare time, the CCSID is the appropriate CCSID of the data type of the host variable for the application encoding scheme. Graphic variables are an exception if the application or encoding scheme is EBCDIC or ASCII and the value of the MIXED DATA field on the DSNTIPF panel is NO. In this case, the Unicode encoding scheme is used for the graphic host variable. At run time, the CCSID specified in the declare variable statement, or as an override in the SQLDA. Otherwise, the CCSID is the appropriate CCSID of the application encoding scheme for the data type of the host variable.

Notes:

1. If the context is within a check constraint or a package for a basic trigger, the CCSID is the appropriate CCSID for Unicode, instead of the application encoding scheme. If the context is within a package for an advanced trigger, the CCSID is determined from the implicitly or explicitly specified APPLICATION ENCODING SCHEME option; otherwise the CCSID is the appropriate CCSID for Unicode instead of the application encoding scheme.

"Determining the encoding scheme and CCSID of a string" on page 63 shows the rules for determining the CCSID of derived string data when the source data has a numeric type.

Table 11. Rules for determining the CCSID that is associated with string data derived from numeric data

Source of the numeric data	Type 1 rules	Type 2 rules
Numeric data	If the statement references a table or view, the encoding scheme of that table or view determines the encoding scheme for the string data that is derived from a numeric value. Otherwise, the default EBCDIC encoding scheme is used for the string data derived from a numeric value. The CCSID is the appropriate character or graphic string CCSID of the application encoding scheme.	The CCSID is the appropriate character or graphic string CCSID of the application encoding scheme. "1" on page 67

Notes:

1. If the context is within a check constraint or a package for a basic trigger, the CCSID is the appropriate CCSID for Unicode, instead of the application encoding scheme. If the context is within a package for an advanced trigger, the CCSID is determined from the implicitly or explicitly specified APPLICATION ENCODING SCHEME option; otherwise the CCSID is the appropriate CCSID for Unicode instead of the application encoding scheme.

The following examples show how these rules are applied.

Example 1: Assume that the default encoding scheme for the installation is EBCDIC and that the installation does not support mixed and graphic data. The following statement conforms to the rules for Type 1 in Table 10 on page 64. Therefore, the X'40' is interpreted as EBCDIC SBCS data because the statement references a table that is in EBCDIC. The CCSID for X'40' is the default EBCDIC SBCS CCSID for the installation.

```
SELECT * FROM EBCDIC_TABLE WHERE COL1 = X'40';
```

the result of the query includes each row that has a value in column COL1 that is equal to a single EBCDIC blank.

Example 2: The following statement references data from two different tables that use different encoding schemes. This statement does not conform to the rules for Type 1 statements in Table 10 on page 64. Therefore, the rules for Type 2 statements are used. The CCSID for X'40' is dependent on the current application encoding scheme. Assuming that the current application encoding scheme is EBCDIC, X'40' represents a single EBCDIC blank.

```
SELECT * FROM EBCDIC_TABLE, UNICODE_TABLE WHERE COL1 = X'40';
```

as with Example 1, the result of the query includes each row that has a value in column COL1 that is equal to a single EBCDIC blank. If the current application encoding scheme were ASCII or Unicode, X'40' would represent something different and the results of the query would be different.

Expanding conversions

An *expanding conversion* occurs when the length of the converted string is greater than that of the source string.

For example, an expanding conversion occurs when an ASCII mixed data string that contains DBCS characters is converted to EBCDIC mixed data. To prevent the loss of data on expanding conversions, use a varying-length string variable with a maximum length that is sufficient to contain the expansion.

Expanding conversions also can occur when string data is converted to or from Unicode. It can also occur between UTF-8 and UTF-16, depending on the data being converted. UTF-8 uses 1, 2, 3, or 4 bytes per character. UTF-16 uses 2 bytes per character, except for supplementary characters, which use two 2 byte code points for each character. If UTF-8 were being converted to UTF-16, a 1 byte character would be expanded to 2 bytes.

Contracting conversions

A *contracting conversion* occurs when the length of the converted string is smaller than that of the source string.

For example, a contracting conversion occurs when an EBCDIC mixed data string that contains DBCS characters is converted to ASCII mixed data due to the removal of shift codes.

Contracting conversions also can occur when string data is converted to or from Unicode data. It can also occur between UTF-8 and UTF-16, depending on the data being converted.

Distributed relational databases

The database managers in a distributed relational database communicate and cooperate with each other in a way that allows a Db2 application program to use SQL to access data at any of the interconnected computer systems.

A *distributed relational database* consists of a set of tables and other objects that are spread across different, but interconnected, computer systems. Each computer system has a relational database manager, such as Db2, that manages the tables in its environment. The database managers communicate and cooperate with each other in a way that allows a Db2 application program to use SQL to access data at any of the computer systems. The Db2 subsystem where the application plan is bound is known as the *local Db2 subsystem*. Any database server other than the local Db2 subsystem is considered a *remote database server*, and access to its data is a distributed operation.

Distributed relational databases are built on formal requester-server protocols and functions. An *application requester* component supports the application end of a connection. It transforms an application's database request into communication protocols that are suitable for use in the distributed database network. These requests are received and processed by an *application server* component at the database server end of the connection. Working together, the application requester and application server handle the communication and location considerations so that the application is isolated from these considerations and can operate as if it were accessing a local database.

For more information on Distributed Relational Database Architecture™ (DRDA) communication protocols, see DRDA Volume 1: Distributed Relational Database Architecture (Open Group Library - Data Management Standards).

Related tasks

Improving performance for applications that access distributed data (Db2 Performance)

Connections

A *connection* is an association between an application process and a local or remote database server. Connections are managed by applications.

An application process must be connected to the application server facility of a database manager before SQL statements that reference tables or views can be executed. An application can use the CONNECT statement to establish a connection to a database server and make that database server the current server of the application process.

Commit processing

When Db2 for z/OS acts as a requester, it negotiates with the database server during the connection process to determine how to perform commits. If the remote server does not support two-phase commit protocol, Db2 downgrades to perform one-phase commits. Otherwise, Db2 always performs two-phase commits, which allow applications to update one or more databases in a single unit of work and are more reliable than one-phase commits. Two-phase commit is a two-step process:

1. First, all database managers involved in the same unit of work are pooled to determine whether they are ready to commit.
2. Then, if all database managers respond positively, they are directed to execute commit processing. If all database managers do not respond positively, they are directed to execute backout processing.

Db2 can also provide coordination for transactions that include both two-phase commit resources and one-phase commit resources. If an application has multiple connections to several different database servers, and if any of the connections are one-phase commit connections, then only one database that is involved in the transaction can be updated. The connections to all the other databases that are involved in the transaction are read-only.

To execute a static SQL statement that references tables or views, the bound form of the statement is taken from a package that the database manager previously created through a bind operation or when a version of a native SQL procedure was defined.

Supported SQL statements and clauses

For the most part, an application can use the statements and clauses that are supported by the database manager of the current server, even though that application might be running via the application requester of a database manager that does not support some of those statements and clauses. Restrictions to this general rule for Db2 for z/OS are documented in PDF *SQL Reference for Cross-Platform Development* - Version 6.

Distributed unit of work

The *distributed unit of work facility* provides for the remote preparation and execution of SQL statements.

An application process at computer system A can connect to a database server at computer system B and, within one or more units of work, execute any number of static or dynamic SQL statements that reference objects at B. All objects referenced in a single SQL statement must be managed by the same database server. Any number of database servers can participate in the same unit of work, and any number of connections can exist between an application process and a database server. A commit or rollback operation that does not specify a savepoint ends the unit of work.

Connection management

How connections are managed depends on what states the SQL connection and the application process are in.

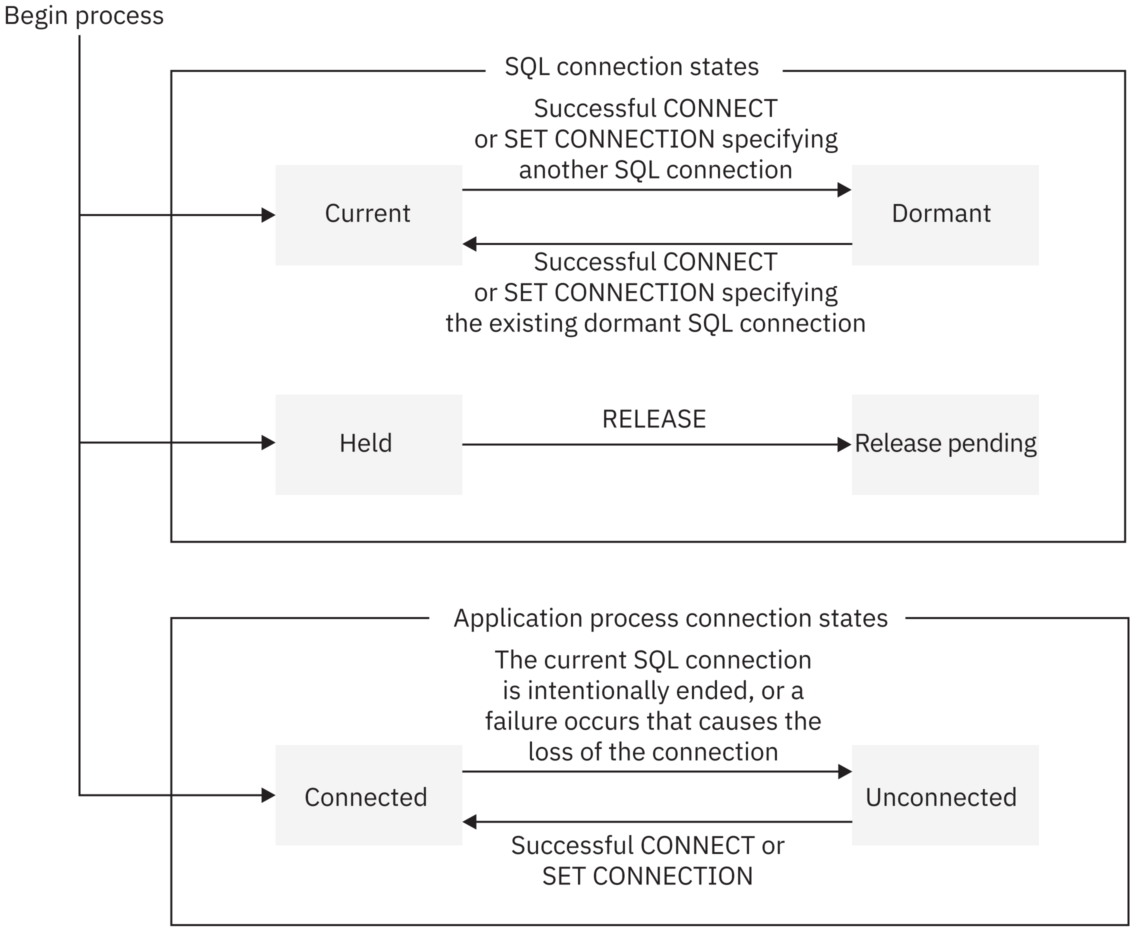
At any time:

- An SQL connection is in one of the following states:
  - Current and held
  - Current and release-pending
  - Dormant and held
  - Dormant and release-pending
- An application process is in the connected or unconnected state, and has a set of zero or more SQL connections. Each SQL connection is uniquely identified by the name of the database server at the other end of the connection. Only one SQL connection is active (current) at a time.

Initial state of an application process: An application process is initially in the connected state, and it has exactly one SQL connection. The server of that connection is the local Db2 subsystem.

Initial state of an SQL connection: An SQL connection is initially in the current and held state.

The following figure shows the state transitions:



Begin process
SQL connection states
Successful CONNECT or SET CONNECTION specifying another SQL connection
Current
Dormant
Successful CONNECT or SET CONNECTION specifying the existing dormant SQL connection
Held
RELEASE
Release pending
Application process connection states
The current SQL connection is intentionally ended, or a failure occurs that causes the loss of the connection
Connected
Unconnected
Successful CONNECT or SET CONNECTION

Figure 20. State transitions for an SQL connection and an application process connection in a distributed unit of work

SQL connection states

If an application process successfully executes a CONNECT statement, the SQL connection states of the connections change.

If an application process successfully executes a CONNECT statement:

- The current connection is placed in the dormant and held state.
- The new connection is placed in the current and held state.
- The location name is added to the set of existing connections.

If the location name is already in the set of existing connections, an error is returned.

An SQL connection in the dormant state is placed in the current state using:

- The SET CONNECTION statement, or
- The CONNECT statement, if the SQLRULES(DB2) bind option is in effect.

When an SQL connection is placed in the current state, the previously-current SQL connection, if any, is placed in the dormant state. No more than one SQL connection in the set of existing connections of an application process can be current at any time. Changing the state of an SQL connection from current to dormant or from dormant to current has no effect on its held or release-pending state.

An SQL connection is placed in the release-pending state by the RELEASE statement. When an application process executes a commit operation, every release-pending connection of the process is ended. Changing the state of an SQL connection from held to release-pending has no effect on its current or dormant state. Thus, an SQL connection in the release-pending state can still be used until the next commit operation. No way exists to change the state of a connection from release-pending to held.

Application process connection states

In a distributed unit of work, an application process can be in a connected or unconnected state. Depending on the state, the application process can execute only certain SQL statements successfully.

A connection to a different database server can be established by the explicit or implicit execution of a CONNECT statement. The following rules apply:

- An application process cannot have more than one SQL connection to the same database server at the same time.
- When an application process executes a SET CONNECTION statement, the specified location name must be in the set of existing connections of the application process.
- When an application process executes a CONNECT statement and the SQLRULES(STD) bind option is in effect, the specified location must not be in the set of existing connections of the application process.

If an application process has a current SQL connection, the application process is in a *connected* state. The CURRENT SERVER special register contains the name of the database server of the current SQL connection. The application process can execute SQL statements that refer to objects managed by that server. If the server is a Db2 subsystem, the application process can also execute certain SQL statements that refer to objects managed by a Db2 subsystem with which that server can establish a connection.

An application process in an unconnected state enters a connected state when it successfully executes a CONNECT or SET CONNECTION statement.

If an application process does not have a current SQL connection, the application process is in an *unconnected* state. The CURRENT SERVER special register contains blanks. The only SQL statements that can be executed successfully are CONNECT, RELEASE, COMMIT, ROLLBACK, and any of the following local SET statements.

- SET CONNECTION
- SET CURRENT APPLICATION ENCODING SCHEME
- SET CURRENT PACKAGE PATH
- SET CURRENT PACKAGESET
- SET *host-variable* = CURRENT APPLICATION ENCODING SCHEME
- SET *host-variable* = CURRENT PACKAGESET
- SET *host-variable* = CURRENT SERVER

Because the application process is in an unconnected state, a COMMIT or ROLLBACK statement is processed by the local Db2 subsystem.

An application process in a connected state enters an unconnected state when its current SQL connection is intentionally ended, or the execution of an SQL statement is unsuccessful because of a failure that causes a rollback operation at the current server and loss of the SQL connection. SQL connections are intentionally ended when an application process successfully executes a commit operation and either of the following are true:

- The SQL connection is in the release-pending state.
- The SQL connection is not in the release-pending state, but it is a remote connection and either of the following are true:
  - The DISCONNECT(AUTOMATIC) bind option is in effect
  - The DISCONNECT(CONDITIONAL) bind option is in effect and an open WITH HOLD cursor is not associated with the connection

An implicit CONNECT to a default Db2 subsystem is executed when an application process executes an SQL statement other than COMMIT, CONNECT TO, CONNECT RESET, SET CONNECTION, RELEASE, or ROLLBACK, and if all of the following conditions apply:

- The CURRENTSERVER bind option was specified when creating the application plan of the application process and the identified server is not the local Db2.
- An explicit CONNECT statement has not already been successfully or unsuccessfully executed by the application process.
- An implicit connection has not already been successfully or unsuccessfully executed by the application process. An implicit connection occurs as the result of execution of an SQL statement that contains a three-part name in a package that is bound with the DBPROTOCOL(DRDA) option.

If the implicit CONNECT fails, the application process is placed in an *unconnected* state.

When a connection is ended, all resources that were acquired by the application process through the connection and all resources that were used to create and maintain the connection are returned to the connection pool. For example, if application process *P* placed the connection to application server *X* in the release-pending state, all cursors of *P* at *X* are closed and returned to the connection pool when the connection is ended during the next commit operation.

When a connection is ended as a result of a communications failure, the application process is placed in an unconnected state.

All connections of an application process are ended when the process ends.

Remote unit of work

The *remote unit of work facility* also provides for the remote preparation and execution of SQL statements, but in a much more restricted fashion than the distributed unit of work facility.

An application process at computer system A can connect to a database server at computer system B and, within one or more units of work, execute any number of static or dynamic SQL statements that reference objects at B. All objects referenced in a single SQL statement must be managed by the same database server, and all SQL statements in the same unit of work must be executed by the same database server. However, unlike a distributed unit of work, an application process can have only one connection at a time. The process cannot connect to a new server until it executes a commit or rollback operation on the current server to end that unit of work. This restricts the situations in which a CONNECT statement can be executed.

Connection management

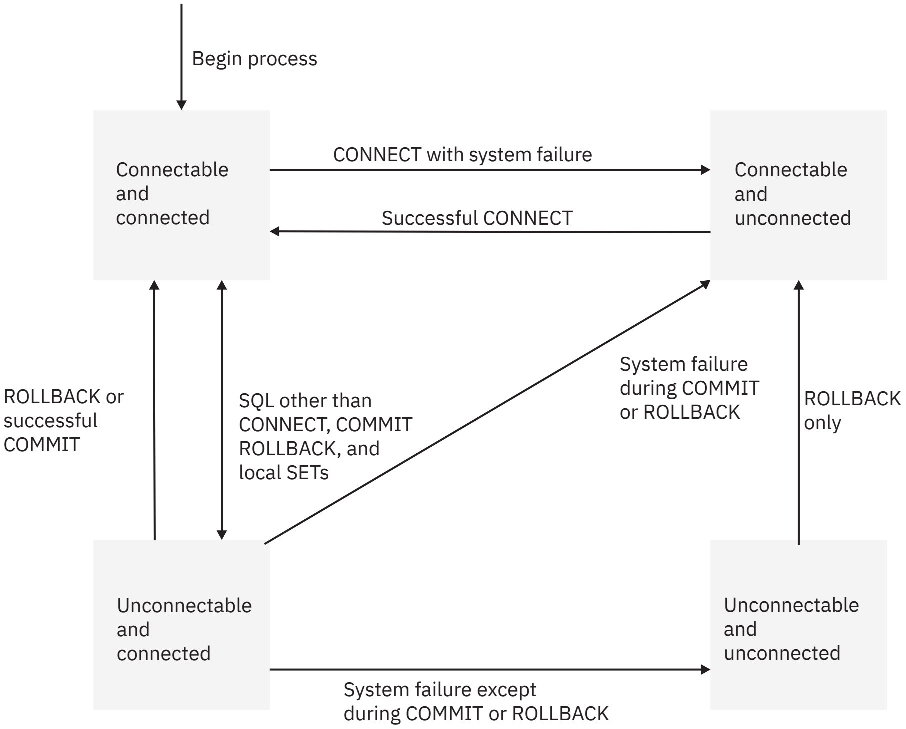
How connections are managed depends on what states the SQL connection and the application process are in.

An application process is in one of four states at any time:

- Connectable and connected
- Unconnectable and connected
- Connectable and unconnected
- Unconnectable and unconnected

Initial state of an application process: An application process is initially in the connectable and connected state. The database server to which the application process is connected is determined by a product-specific option that might involve an implicit CONNECT operation. An implicit connect operation cannot occur if an implicit or explicit connect operation has already successfully or unsuccessfully occurred. Thus, an application process cannot be implicitly connected to a database server more than once. Other rules for implicit connect operations are product-specific.

Figure 21 on page 73 shows the state transitions:



Begin process
Connectable and connected
CONNECT with system failure
Connectable and unconnected
Successful CONNECT
ROLLBACK or successful COMMIT
SQL other than CONNECT, COMMIT ROLLBACK, and local SETs
System failure during COMMIT or ROLLBACK
ROLLBACK only
Unconnectable and connected
Unconnectable and unconnected
System failure except during COMMIT or ROLLBACK

Figure 21. State transitions for an application process connection in a remote unit of work

In the following descriptions of application process connections, CONNECT can mean:

- CONNECT TO
- CONNECT RESET
- CONNECT *authorization*

It cannot mean CONNECT with no operand, which is used to return information about the current server.

Consecutive CONNECT statements can be executed successfully because CONNECT does not remove an application process from the connectable state. A CONNECT statement does not initiate a new unit of work; a unit of work is initiated by the first SQL statement that accesses data. CONNECT cannot execute successfully when it is preceded by any SQL statement other than CONNECT, COMMIT, RELEASE, ROLLBACK, or SET CONNECTION. To avoid an error, execute a commit or rollback operation before a CONNECT statement is executed.

Connectable and connected state: In the connectable and connected state, an application process is connected to a database server, and CONNECT statements that target the current server can be executed. An application process re-enters this state when either of the following is true:

- The process completes a rollback or a successful commit from an unconnectable and connected state.
- The process successfully executes a CONNECT statement from a connectable and unconnected state.

Unconnectable and connected state: In the unconnectable and connected state, an application process is connected to a database server, and only a CONNECT statement with no operands can be executed. An application process enters this state from a connectable and connected state when it executes any SQL statement other than CONNECT, COMMIT, or ROLLBACK.

Connectable and unconnected state: In the connectable and unconnected state, an application process is not connected to a database server. The only SQL statement that can be executed is CONNECT. An application process enters this state if any of the following is true:

- The process does not successfully execute a CONNECT statement from a connectable and connected state.
- The process executes a COMMIT statement when the SQL connection is in a release-pending state.
- A system failure occurs during a COMMIT or ROLLBACK from an unconnectable and connected state.

- The process executes a ROLLBACK statement from an unconnectable and unconnected state.

Other product-specific reasons can also cause an application process to enter the connectable and unconnected state.

Unconnectable and unconnected state: In the unconnectable and unconnected state, an application process is not connected to a database server and CONNECT statements cannot be executed. The only SQL statement that can be executed is ROLLBACK. An application process enters this state from an unconnectable and connected state as a result of a system failure, except during a COMMIT or ROLLBACK, at the server.

Chapter 2. Language elements in SQL

An understanding of the basic syntax of SQL and language elements that are common to many SQL statements can be helpful in using SQL with Db2 for z/OS. The most basic elements of SQL syntax are characters and tokens.

The following topics provide information about more language elements:

Characters and tokens in SQL

The most basic elements of SQL syntax are characters and tokens. Tokens are the basic syntactical units of the SQL language.

Characters

The basic symbols of keywords and operators in the SQL language are *characters*. Characters are classified as letters, digits, or special characters.

- A *letter* is any of the 26 uppercase (A–Z) and 26 lowercase (a–z) letters of the English alphabet.[1]
- A *digit* is any one of the characters 0–9.
- A *special character* is any character other than a letter or a digit.

[1] Letters also include three code points reserved as alphabetic extenders for national languages ($, #, and @ in the United States). These three code points (X'5B', X'7B', and X'7C') should be avoided because they represent different characters depending on the CCSID.

Tokens

The basic syntactical units of the SQL language are called *tokens*. A token consists of one or more characters of which none are blanks, control characters, or characters within a string constant or delimited identifier.

Tokens are classified as *ordinary* or *delimiter* tokens:

- An *ordinary token* is a numeric constant, an ordinary identifier, a host identifier, or a keyword. The following examples are ordinary tokens:

```
   1        .1        +2        SELECT        E        3
```

- A *delimiter token* is a string constant, a delimited identifier, an operator symbol, or any of the special characters shown in the syntax diagrams. A question mark (?) is also a delimiter token when it serves as a parameter marker, as explained in "PREPARE" on page 2037. The following examples include delimiter tokens:

```
   ,        'string'        "fld1"        =        .
```

Spaces

A *space* is a sequence of one or more blank characters.

Control characters

A *control character* is a special character that is used for string alignment. Treated similar to a space, a control character does not cause a particular action to occur. The following table shows the control characters that Db2 recognizes and their hexadecimal values.

Table 12. Hexadecimal values for the control characters that Db2 recognizes

Control character	EBCDIC hex value	UTF-8 hex value	UTF-16 hex value
Tab	05	09	U+0009
Form feed	0C	0C	U+000C
Carriage return	0D	0D	U+000D
New line	15	C285	U+0085
Line feed	25	0A	U+000A
DBCS space	-	-	U+3000

Tokens, other than string constants and certain delimited identifiers, must not include a control character or space. A control character or space can follow a token. A delimiter token, control character, or a space must follow every ordinary token. If the syntax does not allow a delimiter token to follow an ordinary token, a control character or a space must follow that ordinary token.

Trigraph characters

The left bracket ([) and right bracket (]) characters are used in syntax to refer to an array element. Those characters cannot be specified with some CCSIDs. The following trigraphs can be used as an alternative way to specify left and right brackets:

- The string ??(can be specified in place of a left bracket ([).
- The string ??) can be specified in place of a right bracket (]).

Comments

Dynamic SQL statements can include SQL comments. Static SQL statements can include host language comments or SQL comments. Comments can be specified wherever a space can be specified, except within a delimiter token or between the keywords EXEC and SQL. In Java, SQL comments are not allowed within embedded Java expressions. There are two types of SQL comments:

Simple comments
Simple comments are introduced with two consecutive hyphens (--). Simple comments cannot continue past the end of the line.

Bracketed comments
Bracketed comments are introduced with /* and end with */. A bracketed comment can continue past the end of the line.

The following example shows how to include comments in an SQL statement within a C program. The example uses both simple and bracketed comments:

```
EXEC SQL
  CREATE VIEW PRJ_MAXPER         --projects with most support personnel
    /*
     * Returns number and name of the project
     */
   AS SELECT PROJNO, PROJNAME     -- number and name of project
        FROM DSN8910.PROJ
     /*
      * E21 is the systems support dept code
      */
   WHERE DEPTNO = 'E21'           -- systems support dept code
   AND PRSTAFF > 1;
```

For more information, see "SQL comments" on page 1087.

Uppercase and lowercase characters

A token in an SQL statement can include lowercase letters, but lowercase letters in an ordinary token are folded to uppercase. However, lowercase letters are folded to uppercase in a C or Java program only if the appropriate precompiler option is specified. Delimiter tokens are never folded to uppercase.

For example, the following two statements are equivalent after folder:

```
select * from DSN8C10.EMP where lastname = 'Smith';
```

```
SELECT * FROM DSN8C10.EMP WHERE LASTNAME = 'Smith';
```

Related concepts

Identifiers in SQL
An *identifier* is a token used to form a name. An identifier in an SQL statement is an SQL identifier or a host identifier. SQL identifiers can be ordinary identifiers or delimited identifiers.

Expressions
An *expression* specifies a value and can take a number of different forms, such as a simple value, consisting of only a constant or a column name, or it can be more complex with operators, other expressions, and more.

Identifiers in SQL

An *identifier* is a token used to form a name. An identifier in an SQL statement is an SQL identifier or a host identifier. SQL identifiers can be ordinary identifiers or delimited identifiers.

Ordinary identifiers

An *ordinary identifier* is an uppercase letter followed by zero or more characters, each of which is an uppercase letter, a digit, or the underscore character. If an identifier that is not delimited contains lowercase characters, but otherwise follows all the rules for an ordinary identifier, Db2 folds the lowercase letters to uppercase, and the identifier becomes an ordinary identifier. For more information about ordinary identifiers, see "Characters and tokens in SQL" on page 75.

An ordinary identifier should not be a reserved word. If a reserved word is used as an identifier in SQL, it must be specified in uppercase and must be a delimited identifier or specified in a host variable. For a list of reserved words, see Appendix B, "Reserved schema names and reserved words in Db2 for z/OS," on page 2247.

Identifiers that contain only DBCS characters can also be ordinary identifiers, unless otherwise specified.

The following list shows the rules for forming SQL ordinary identifiers:

- The UTF-8 representation of the name must not exceed 128 bytes.
- Continuation to the next line is not allowed.

If the SQL ordinary identifier contains DBCS characters, the following additional rules apply:

- The identifier, if encoded in EBCDIC, must start with a shift-out (X'0E') and end with a shift-in (X'0F'). There must be an even number of bytes between the shift-out and the shift-in. An odd-numbered byte between those shifts must not be a shift-out. DBCS blanks (X'4040' in EBCDIC) are not acceptable between the shift-out and the shift-in.
- The identifiers are not folded to uppercase or changed in any other way.

Delimited identifiers

A *delimited identifier* is a sequence of one or more characters enclosed within escape characters. For example, if the escape character is the quotation mark ("), the following example is a delimited identifier:

```
"VIEW"
```

The escape character is the quotation mark (")[2] except for:

- Dynamic SQL when the field SQL STRING DELIMITER on installation panel DSNTIPF is set to the quotation mark (") and either of these conditions is true:
  - DYNAMICRULES run behavior applies. For a list of the DYNAMICRULES option values that specify run, bind, define, or invoke behavior, see "Authorization IDs and dynamic SQL" on page 94.
  - DYNAMICRULES bind, define, or invoke behavior applies and installation panel field USE FOR DYNAMIC RULES is YES.

  In this case, the escape character is the apostrophe (').

  However, for COBOL application programs, if DYNAMICRULES run behavior does not apply and installation panel field USE FOR DYNAMICRULES is NO, a COBOL compiler option specifies whether the escape character is the quotation mark or apostrophe.
- Static SQL in COBOL application programs. A COBOL compiler option specifies whether the escape character is the quotation mark (") or the apostrophe (').

A delimited identifier can be used when the sequence of characters does not qualify as an ordinary identifier. Such a sequence, for example, could be an SQL reserved word, or it could begin with a digit. Two consecutive escape characters are used to represent one escape character within the delimited identifier. A delimited identifier that contains EBCDIC DBCS characters also must contain the necessary shift characters.

Leading and embedded blanks in the sequence are significant. Trailing blanks in the sequence are not significant. The length of a delimited identifier does not include the starting and ending escape characters. Embedded escape characters (that appear as two characters) are counted in the length as a single character.

[2] In CCSID 1026 and CCSID 1155, the code point for the quotation mark can be X'7F' or X'FC'. However, if the beginning delimiter is X'7F', the ending delimiter must also be X'7F'. If the beginning delimiter is X'FC', ending delimiter must also be X'FC'.

Limits for identifiers

See Appendix A, “Limits in Db2 for z/OS,” on page 2237 for length limits that Db2 imposes for identifiers.

Host identifiers

A *host identifier* is a name declared in the host program.

The rules for forming a host identifier are the rules of the host language. In non-Java programs, do not use names beginning with 'DB2', 'SQ'[3], 'SQL', 'sql', 'RDI', or 'DSN' because precompilers generate host variable names that begin with these characters. In Java, do not use names beginning with '__sJT_'.

Identifier restrictions for distributed data access

The Db2 internal processing of distributed access must sometimes convert the identifiers for *authorization-name*, *procedure-name*, and *schema-name* between CCSIDs. If there is any possibility that these identifiers will be used in distributed access, restrict the identifiers to characters whose representation in Unicode UTF-8 have code points in the range 0–127. You do not need to enter the identifiers in Unicode; this restriction refers to conversion that Db2 performs internally.

Related concepts

Characters and tokens in SQL
The most basic elements of SQL syntax are characters and tokens. Tokens are the basic syntactical units of the SQL language.

Naming conventions
The rules for forming a name depend on the type of the object designated by the name.

Related reference

Reserved schema names and reserved words in Db2 for z/OS
Restrictions exist on the use of certain words that are used by Db2 for z/OS. In some cases, these names are reserved and cannot be used by application programs. In other cases, certain names are not recommended for use by application programs though not prevented from being used by the database manager.

Naming conventions

The rules for forming a name depend on the type of the object designated by the name.

Many database objects have a schema qualified name. A schema qualified name may consist of a single SQL identifier (in which case the *schema-name* is implicit) or a *schema-name* followed by a period and an SQL identifier. For more information about the rules for SQL identifiers, see “Identifiers in SQL” on page 77.

The syntax diagrams use different terms for different types of names. The following list defines these terms.

accelerator-name
A name that identifies an accelerator-only table. An accelerator name is 1 to 8 uppercase characters or digits. The name must be unique within the Db2 subsystem or data sharing group.

alias-name
A qualified or unqualified name that designates an alias. A fully qualified alias name is a three-part name. The first part is a location name that designates the DBMS at which the alias is defined. The second part is a schema name. The third part is an SQL identifier. A period must separate each of the parts.

A two-part sequence is implicitly qualified by the location name of the current server. The first part is a schema name. The second part is an SQL identifier. A period must separate the two parts.

[3] 'SQ' is allowed in C, COBOL, and REXX.

A one-part or unqualified alias name is an SQL identifier with two implicit qualifiers. The first implicit qualifier is the location name of the current server. The second is a schema name, which is determined by the rules specified in “Unqualified alias, index, JAR file, mask, permission, sequence, table, trigger, and view names” on page 86.

For more information, see “Aliases” on page 88.

array-type-name
A qualified or unqualified name that designates an array type.

A qualified array type name is a two-part name. The first part is the schema name of the array type. The second part is an SQL identifier. A period must separate each of the parts.

An unqualified array type name is an SQL identifier with an implicit qualifier. The implicit qualifier is the schema name, which is determined by the context in which the array type appears, as described by the rules in “Unqualified object name resolution” on page 86.

authorization-name
An SQL identifier that designates a set of privileges. It can also designate a user, a group of users, or a role. For a user or a group of users, Db2 does not control this property. For a role, Db2 does control this property. See “Authorization IDs, roles, and authorization names” on page 92 for the distinction between an authorization name and an authorization ID.

aux-table-name
A qualified or unqualified name that designates an auxiliary table. The rules for the name are the same as the rules for *table-name*. See table-name.

bpname
A name that identifies a buffer pool. The following list shows the names of the different buffer pool sizes.

4KB
BP0, BP1, BP2, ..., BP49

8KB
BP8K0, BP8K1, BP8K2, ..., BP8K9

16KB
BP16K0, BP16K1, BP16K2, ..., BP16K9

32KB
BP32K, BP32K1, BP32K2, ..., BP32K9

built-in-type
A qualified or unqualified name that identifies an IBM-supplied data type. A qualified name is SYSIBM followed by a period and the name of the built-in data type. An unqualified name has an implicit qualifier, the schema name, which is determined by the rules in “Unqualified object name resolution” on page 86.

catalog-name
An SQL identifier that designates an integrated catalog facility (ICF) catalog. The identifier must start with a letter and must not include special characters, or the alphabetic extenders for national languages ($, #, and @ in the United States). These three code points (X'5B', X'7B', and X'7C') should be avoided because they represent different characters depending on the CCSID.

clone-table-name
A qualified or unqualified name that designates the name of a clone table. See the definition of *table-name* for more information about qualification of table names.

collection-id
An SQL identifier that identifies a collection of packages, such as a collection ID as a qualifier for a package ID.

column-name
A qualified or unqualified name that designates a column of a table or view.

A qualified column name is a qualifier followed by a period and an SQL identifier. The qualifier is a table name, a view name, a synonym, an alias, or a correlation name. The unqualified column name is an SQL identifier.

constraint-name
An SQL identifier that designates a primary key, check, referential, or unique constraint on a table.

context-name
An SQL identifier that designates a trusted context.

correlation-name
An SQL identifier that designates a table, a view, or individual rows of a table or view.

cursor-name
An SQL identifier that designates an SQL cursor. In SQLJ, *cursor-name* is a host variable (with no indicator variable) that identifies an instance of an iterator.

database-name
An SQL identifier that designates a database. The identifier must start with a letter and must not include special characters.

descriptor-name
A host identifier that designates an SQL descriptor area (SQLDA). See "Host variables" on page 227 for a description of a host identifier. A descriptor name never includes an indicator variable.

distinct-type-name
A qualified or unqualified name that designates a distinct type.

A qualified distinct type name is a two-part name. The first part is the schema name of the distinct type. The second part is an SQL identifier. A period must separate each of the parts.

An unqualified distinct type name is an SQL identifier with an implicit qualifier. The implicit qualifier is the schema name, which is determined by the context in which the distinct type appears as described by the rules in "Unqualified type, function, procedure, global variable, and specific names" on page 87.

external-program-name
A name that specifies the program that runs when the function is invoked or the procedure name is specified in a CALL statement.

function-name
A qualified or unqualified name that designates a user-defined function, a cast function that was generated when a distinct type was created, or a built-in function.

A qualified function name is a two-part name. The first part is the schema name of the function. The second part is an SQL identifier. A period must separate each of the parts.

An unqualified function name is an SQL identifier with an implicit qualifier. The implicit qualifier is the schema name, which is determined by the context in which the unqualified name appears as described by the rules in "Unqualified type, function, procedure, global variable, and specific names" on page 87.

global-variable-name
A qualified or unqualified name that designates a global variable.

A qualified global variable name is a two-part name. The first part is the schema name of the global variable. The second part is an SQL identifier. A period must separate each of the parts.

An unqualified global variable name is an SQL identifier with an implicit qualifier. The implicit qualifier is the schema name, which is determined by the context in which the unqualified name appears as described by the rules in "Unqualified type, function, procedure, global variable, and specific names" on page 87.

host-label
A token that designates a label in a host program.

host-variable

A sequence of tokens that designates a host variable. A host variable includes at least one host identifier, as explained in "Host variables" on page 227.

index-name

A qualified or unqualified name that designates an index.

A qualified index name is an authorization ID or schema name followed by a period and an SQL identifier.

An unqualified index name is an SQL identifier with an implicit qualifier. The implicit qualifier is an authorization ID, which is determined by the context in which the unqualified name appears as described by the rules in "Unqualified object name resolution" on page 86.

For an index on a declared temporary table, the qualifier must be SESSION.

FL 502 ***key-label-name***

An SQL identifier that corresponds to the value of the Integrated Cryptographic Service Facility (ICSF) key label. A keylabel-name can consist of up to 64 characters. The first character must be a letter or national character (#, $, @). It is recommended that the name not include national characters (@ (X'7C'), # (X'7B'), or $ (X'5B')).

location-name

An SQL identifier that designates the name of a location. A location name is 1 to 16 bytes, does not include alphabetic extenders (national characters), lowercase letters, or Katakana characters. The characters allowed in the delimited form are the same as those allowed in the ordinary form.

mask-name

A qualified or unqualified name that designates a mask.

A qualified mask name is a two-part name. The first part is the schema name. The second part is an SQL identifier. A period must separate each of the parts.

A one-part or unqualified mask name is an SQL identifier with an implicit qualifier. The implicit qualifier is an authorization ID, which is determined by the context in which the unqualified name appears as described by the rules in "Unqualified object name resolution" on page 86.

package-name

A qualified or unqualified name that designates a package. The unqualified form of a *package-name* is an SQL identifier. A *package-name* must not be a delimited identifier that includes lowercase letters or special characters. A *package-name* in an SQL statement must be qualified. In some contexts outside of SQL, a package name can be specified as an unqualified name.

parameter-name

An SQL identifier that designates a parameter in an SQL procedure or SQL function.

permission-name

A qualified or unqualified name that designates a permission.

A qualified permission name is a two-part name. The first part is the schema name. The second part is an SQL identifier. A period must separate each of the parts.

A one-part or unqualified permission name is an SQL identifier with an implicit qualifier. The implicit qualifier is an authorization ID, which is determined by the context in which the unqualified name appears as described by the rules in "Unqualified object name resolution" on page 86.

plan-name

An SQL identifier that designates an application plan. The identifier must not be a delimited identifier that includes lowercase letters or special characters.

procedure-name

A qualified or unqualified name that designates a stored procedure.

A fully qualified procedure name is a three-part name. The first part is a location name that identifies the DBMS at which the procedure is stored. The second part is the schema name of the stored procedure. The third part is an SQL identifier. A period must separate each of the parts in a qualified name.

A two-part procedure name is implicitly qualified with the location name of the current server. The first part is the schema name of the stored procedure. The second part is an SQL identifier. A period must separate the two parts.

A one part, or unqualified, procedure name is an SQL identifier with two implicit qualifiers. The first implicit qualifier is the location name of the current server. The second implicit qualifier is the schema name, which is determined by the context in which the unqualified name appears, as described by the rules in "Unqualified object name resolution" on page 86.

The SQL identifier in a qualified or unqualified name must not be an asterisk (*).

profile-name
An SQL identifier that corresponds to a RACF profile name.

program-name
An SQL identifier that designates an exit routine.

role-name
An SQL identifier that designates a role. The identifier cannot begin with the characters SYS and cannot be ACCESSCTRL, DATAACCESS, DBADM, DBCTRL, DBMAINT, NONE, NULL, PACKADM, PUBLIC, SECADM, or SQLADM.

routine-version-id
An SQL identifier of up to 64 EBCDIC bytes that designates a version of a routine. The UTF-8 representation of the identifier must not exceed 122 bytes.

savepoint-name
An SQL identifier that designates a savepoint.

schema-name
An SQL identifier that provides a logical grouping for SQL objects. A *schema-name* is used as a qualifier of the name of SQL objects.

seclabel-name
An SQL identifier that corresponds to the value of the RACF security label. It is recommended that the name not include national characters (@ (X'7C'), # (X'7B'), or $ (X'5B')). If the table is a Unicode table and the security label name does include national characters, an error might be issued if substitution occurs when Db2 converts the value from EBCDIC to Unicode.

sequence-name
A qualified or unqualified name that designates a sequence.

A qualified sequence name is a two-part name. The first part is the schema name. The second part is an SQL identifier. A period must separate each of the parts.

A one-part or unqualified sequence name is an SQL identifier with an implicit qualifier. The implicit qualifier is an authorization ID, which is determined by the context in which the unqualified name appears as described by the rules in "Unqualified alias, index, JAR file, mask, permission, sequence, table, trigger, and view names" on page 86.

server-name
An SQL identifier that designates an application server. The identifier must start with a letter and must not include lowercase letters or special characters.

specific-name
A qualified or unqualified name that designates a unique name for a user-defined function.

A qualified specific name is a two-part name. The first part is the schema name. The second part is an SQL identifier, and it must not be an asterisk (*). A period must separate each of the parts.

An unqualified specific name is an SQL identifier with an implicit qualifier. The implicit qualifier is the schema name, which is determined by the context in which the unqualified name appears as described by the rules in "Unqualified type, function, procedure, global variable, and specific names" on page 87.

A specific name can be used to identify a function to alter, comment on, drop, grant privileges on, revoke privileges from, or be the source function for another function. A specific name cannot be used to invoke a function. In addition to being used in certain SQL statements, a specific name must be used in Db2 commands to uniquely identify a function.

SQL-condition-name
An SQL identifier that designates a condition in an SQL routine or trigger.

SQL-label
An SQL identifier that designates a label in an SQL routine or trigger.

SQL-parameter-name
A qualified or unqualified name that designates a parameter in an SQL routine body. The unqualified form of an *SQL-parameter-name* is an SQL identifier. The qualified form is a *function-name* or *procedure-name* followed by a period and an SQL identifier.

SQL-variable-name
A qualified or unqualified name that designates a variable in an SQL routine or trigger body. The unqualified form of an *SQL-variable-name* is an SQL identifier. The qualified form is an *SQL-label* followed by a period (.) and an SQL identifier.

statement-name
An SQL identifier that designates a prepared SQL statement.

stogroup-name
An SQL identifier that designates a storage group.

synonym
An SQL identifier that designates a synonym, a table, or a view. The table or view must exist at the current server. A qualified name is never interpreted as a synonym.

table-name
A qualified or unqualified name that designates a table.

A fully qualified table name is a three-part name. The first part is a location name that designates the DBMS at which the table is stored. The second part is a schema name. The third part is an SQL identifier. A period must separate each of the parts.

A two-part table name is implicitly qualified by the location name of the current server. The first part is a schema name. The second part is an SQL identifier. A period must separate the two parts.

A one-part or unqualified table name is an SQL identifier with two implicit qualifiers. The first implicit qualifier is the location name of the current server. The second is a schema name, which is determined by the rules set forth in "Unqualified alias, index, JAR file, mask, permission, sequence, table, trigger, and view names" on page 86. For a declared temporary table, the qualifier (the second part in a three-part name and the first part in a two-part name) must be SESSION. For complete details on specifying a name when a declared temporary table is defined and then later referring to that declared temporary table in other SQL statements, see "DECLARE GLOBAL TEMPORARY TABLE" on page 1825.

table-space-name
An SQL identifier that designates a table space of an identified database. The identifier must start with a letter and must not include special characters. If a database is not identified, DSNDB04 is implicit.

trigger-name
A qualified or unqualified name that designates a trigger.

A qualified trigger name is a two-part name. The first part is the schema name of the trigger. The second part is an SQL identifier. A period must separate each of the parts.

An unqualified trigger name is an SQL identifier with an implicit qualifier. The implicit qualifier is the schema name, which is determined by the context in which the unqualified name appears as described by the rules in "Unqualified alias, index, JAR file, mask, permission, sequence, table, trigger, and view names" on page 86.

trigger-version-id
An SQL identifier of up to 64 EBCDIC bytes that designates a version of a trigger. The UTF-8 representation of the identifier must not exceed 122 bytes.

view-name

A qualified or unqualified name that designates a view.

A fully qualified view name is a three-part name. The first part is a location name that designates the DBMS where the view is defined. The second part is a schema name. The third part is an SQL identifier. A period must separate each of the parts.

A two-part view name is implicitly qualified by the location name of the current server. The first part is a schema name. The second part is an SQL identifier. A period must separate the two parts.

A one-part or unqualified view name is an SQL identifier with two implicit qualifiers. The first implicit qualifier is the location name of the current server. The second is a schema name, which is determined by the context in which the unqualified name appears as described by the rules in "Unqualified alias, index, JAR file, mask, permission, sequence, table, trigger, and view names" on page 86.

XML-attribute-name

An identifier that is used as an XML attribute name.

XML-element-name

An identifier that is used as an XML element name.

Related concepts

Identifiers in SQL

An *identifier* is a token used to form a name. An identifier in an SQL statement is an SQL identifier or a host identifier. SQL identifiers can be ordinary identifiers or delimited identifiers.

Related reference

Reserved schema names and reserved words in Db2 for z/OS

Restrictions exist on the use of certain words that are used by Db2 for z/OS. In some cases, these names are reserved and cannot be used by application programs. In other cases, certain names are not recommended for use by application programs though not prevented from being used by the database manager.

SQL path

The *SQL path* is an ordered list of schema names. Db2 uses the path to resolve the schema name for certain unqualified object names that appear in any context other than as the main object of an ALTER, CREATE, DROP, COMMENT, GRANT, RENAME, or REVOKE statement.

Db2 uses the path to resolve the schema name for the following object names:

- data types (both built-in types and distinct types)
- functions
- stored procedures
- global variables

Searching through the path from left to right, Db2 implicitly qualifies the object name with the first schema name in the SQL path that contains the same object with the same unqualified name for which the user has appropriate authorization. For functions, Db2 uses a process called function resolution in conjunction with the SQL path to determine which function to choose because several functions with the same name and number of parameters but different parameter data types might be defined in the same schema or other schemas in the SQL path. (For details, see "Function resolution" on page 239.) For procedures, Db2 selects a matching procedure name only if the number of parameters is also the same.

The SQL path does not apply to unqualified procedure names in ASSOCIATE LOCATOR and DESCRIBE PROCEDURE statements. For these statements, an implicit schema name is not generated.

For an example of how Db2 uses the SQL path to resolve the schema name, assume that the SQL path is SMITH, XGRAPHIC, SYSIBM, and that an unqualified distinct type name MYTYPE was specified. Db2 looks for MYTYPE first in schema SMITH, then XGRAPHIC, and then SYSIBM.

The PATH option establishes the SQL path that is used to resolve:

- Unqualified data type, global variable, and function names in static SQL statements
- Unqualified procedure names in SQL CALL statements that specify the procedure name as an identifier token (CALL *procedure-name*)

If the PATH option was not specified when the plan or package was created or last rebound or when native SQL procedure was defined or last changed, the default value of the SQL path is: SYSIBM, SYSFUN, SYSPROC, *plan or package qualifier*.

The CURRENT PATH special register determines the SQL path used to resolve:

- Unqualified data type, global variable, and function names in dynamic SQL statements
- Unqualified procedure names in SQL CALL statements that specify the procedure name in a host variable (CALL *host-variable*)

Generally, the initial value of the CURRENT PATH special register is one of the following:

- The value of the PATH option
- "SYSIBM", "SYSFUN", "SYSPROC", "SYSIBMADM", *value of CURRENT SQLID special register* if the PATH option was not specified.

If schema "SYSIBM", "SYSFUN", "SYSPROC", "SYSIBMADM" is not explicitly specified in the SQL path, the schema is implicitly assumed at the front of the path; if all are not specified, they are assumed in the order of "SYSIBM", "SYSFUN", "SYSPROC", "SYSIBMADM".

For example, assume that the SQL path is explicitly specified as SYSIBM, GEORGIA, SMITH. As implicitly assumed schemas, SYSFUN, SYSPROC, and SYSIBMADM are added to the beginning of the explicit path effectively making the path:

SYSFUN, SYSPROC, SYSIBMADM, SYSIBM, GEORGIA, SMITH

For more information about the SQL path for dynamic SQL, see "CURRENT PATH special register" on page 200 and "SET PATH" on page 2156.

Unqualified object name resolution

Most object names are implicitly or explicitly qualified with a schema name. Synonyms are an exception.

A synonym has a single part name. When Db2 encounters an unqualified name, Db2 must determine which object to process. This process is called *name resolution*.

When Db2 encounters a single part name in a context where an alias, table, view, or synonym can be specified, Db2 first checks to see if the name refers to a synonym that is defined by the current user.

Unqualified object names, other than synonyms, are implicitly qualified. The rules for qualifying a name differ depending on the type of object that the name identifies.

Unqualified alias, index, JAR file, mask, permission, sequence, table, trigger, and view names

The default schema is determined as follows:

- For static SQL statements, the default schema is the identifier specified in the QUALIFIER option of the BIND subcommand or the CREATE or ALTER statement for a SQL routine or trigger. If this option is not in effect for the plan, package, or native SQL procedure, the default schema is the authorization ID of the owner of the plan, package, or native SQL procedure.
- For dynamic SQL statements, the behavior as specified by the combination of the DYNAMICRULES option and the run time environment determines the default schema. (For a list of these behaviors and the DYNAMICRULES values that determine them, see Table 14 on page 94).
  - If DYNAMICRULES *run behavior* applies, the default schema is the schema in the CURRENT SCHEMA special register. Run behavior is the default.
  - If *bind behavior* applies, the default schema is the identifier that is implicitly or explicitly specified in the QUALIFIER option, as explained for static SQL statements.

  - If *define behavior* applies, the default schema is the owner of the function or stored procedure (the owner is the definer).
  - If *invoke behavior* applies, the default schema is the authorization ID of the invoker of the function or stored procedure.

  Exception: For bind, define, and invoke behavior, the default schema of PLAN_TABLE, DSN_STATEMNT_TABLE, and DSN_FUNCTION_TABLE (output from the EXPLAIN statement) is always the value in special register CURRENT SQLID.

Unqualified type, function, procedure, global variable, and specific names

The qualification of unqualified type (built-in type, distinct type, or array type), function, stored procedure, global variable, and specific names depends on the SQL statement in which the unqualified name appears.

- If an unqualified name is the main object of an ALTER, CREATE, COMMENT, DROP, GRANT, or REVOKE statement, the name is implicitly qualified with a schema name as follows:
  - In a static statement, the implicit schema name is the identifier specified in the QUALIFIER option of the BIND subcommand or the CREATE or ALTER statement for a SQL routine or trigger. If this option is not in effect for the package or procedure, the implicit qualifier is the authorization ID of the owner of the package or procedure.
  - In a dynamic statement, the implicit schema name is the schema in the CURRENT SCHEMA special register.
- Otherwise, the implicit schema name for the unqualified name is determined as follows:
  - For distinct type and array type names, Db2 searches the SQL path and selects the first schema in the path such that the data type exists in the schema and the user has authorization to use the type.
  - For global variable names, Db2 searches the SQL path and selects the first schema in the path such that the global variable exists in the schema and the user has authorization to use the global variable.
  - For function names, Db2 uses the SQL path in conjunction with function resolution, as described in "Function resolution" on page 239.
  - For stored procedure names in CALL statements, Db2 searches the SQL path and selects the first schema in the path such that the schema contains a procedure with the same name and number of parameters and the user has authorization to use the procedure.
  - For stored procedure names in ASSOCIATE LOCATORS and DESCRIBE PROCEDURE statements, Db2 does not use the SQL path because an implicit schema name is not generated for these statements.

  For information about the SQL path, see "SQL path" on page 85.

QUALIFIER bind option (Db2 Commands)

DYNAMICRULES bind option (Db2 Commands)

CREATE PROCEDURE (SQL - native)
The CREATE PROCEDURE statement defines an SQL procedure, or a version of a procedure, at the current server and specifies the source statements for the procedure.

ALTER PROCEDURE (SQL - native)
The ALTER PROCEDURE statement changes the definition of an SQL procedure at the current server. The procedure options, parameter names, and routine body can be changed and additional versions of the procedure can be defined and maintained using the ALTER PROCEDURE statement.

CREATE TRIGGER (advanced)

ALTER TRIGGER (advanced)

CREATE FUNCTION (compiled SQL scalar)

The CREATE FUNCTION (compiled SQL scalar) statement defines a compiled SQL scalar function at the current server and specifies the source statements for the function. The body of the function is written in the SQL procedural language. The function returns a single value each time it is invoked.

ALTER FUNCTION (compiled SQL scalar)
The ALTER FUNCTION (compiled SQL scalar) statement changes the description of a user-defined compiled SQL scalar function at the current server. The function options, parameter names, and routine body can be changed and additional versions of the procedure can be defined and maintained using the ALTER FUNCTION statement.

CURRENT SQLID special register
CURRENT SQLID specifies the SQL authorization ID of the process.

EXPLAIN

Aliases

An *alias* is an alternative name for an object such as a table, view, sequence, or another alias. It can be used to reference an object wherever that object can be referenced directly.

The option of referencing an object by an alias is not explicitly shown in the syntax diagrams or mentioned in the description of SQL statements.

Like tables, views, and sequences, an alias can be created, dropped, and associated with a comment. No authority is necessary to use an alias. However, access to the objects that are referred to by the alias still requires the appropriate authorization for the current statement.

An alias is created using the CREATE ALIAS statement.

An alias name designates an alias when it is preceded by the keyword ALIAS, as in CREATE ALIAS, DROP ALIAS, COMMENT ON ALIAS, and LABEL for an ALIAS. In all other contexts, an alias name designates a table, a view, or a sequence. For example, `COMMENT ON ALIAS A` specifies a comment about the alias A, whereas `COMMENT ON TABLE A` specifies a comment about the table or view designated by A.

An alias for a table or a view can be defined at a local server to refer to a table or a view that is at the current server or a remote server. An alias name for a table or view can be used wherever the table name or view name can be used to refer to the table or view in an SQL statement. The rules for forming an alias name for a table or view are the same as the rules for forming a table name or a view name. A fully qualified alias name (a three-part name) can refer to an alias at a remote server. However, the table or view identified by the alias at the remote server must exist at the remote server.

An alias for a sequence can be defined at the current server. An alias name for a sequence can be used wherever the sequence name can be used to refer to the sequence in an SQL statement. The rules for forming an alias name for a sequence are the same as the rules for forming a sequence name.

Statements that use three-part names and refer to distributed data result in DRDA access to the remote site. DRDA access for three-part names is used when the package that contains the query to distributed data is bound using the bind option DBPROTOCOL(DRDA), or the value of the DATABASE PROTOCOL field on installation panel DSNTIP5 is DRDA. When an application program uses three-part name aliases for remote table or view objects and DRDA access, the application program must be bound at each location that is specified in the three-part name. Also, each alias must be defined at the local site. An alias at a remote site can refer to another server if a referenced alias eventually refers to a table or view.

The effect of using an alias in an SQL statement is the same as text substitution. For example, if A is an alias for table Q.T, one of the steps involved in the preparation of `SELECT * FROM A` is the replacement of 'A' by 'Q.T'.

If an alias is defined as a public alias, it can be referenced by its unqualified name without any impact from the current default schema name. It can also be referenced using the schema qualifier SYSPUBLIC.

Related concepts

Synonyms (deprecated)

A synonym is an alternate name for a table or view. A synonym can be used to reference a table or view in cases where an existing table or view can be referenced. However, Db2 no longer supports the creation of new synonyms.

Related reference

CREATE ALIAS
The CREATE ALIAS statement defines an alias for a table, a view, or a sequence. The definition is recorded in the Db2 catalog at the current server.

Synonyms (deprecated)

A synonym is an alternate name for a table or view. A synonym can be used to reference a table or view in cases where an existing table or view can be referenced. However, Db2 no longer supports the creation of new synonyms.

Unsupported function: FL 504 Beginning in Db2 12, packages bound with APPLCOMPAT(V12R1M504) or higher cannot issue CREATE SYNONYM statements. Although there are some differences, you can use aliases instead. Unlike synonyms, aliases behave the same for all Db2 family products. For more information about aliases, see Aliases (Introduction to Db2 for z/OS) and "CREATE ALIAS" on page 1410. Existing synonyms remain supported, but support might be removed in the future.

Differences between synonyms and aliases

The following table summarizes the differences between aliases and synonyms, which are deprecated.

Table 13. Differences between synonyms and aliases

Characteristic	Synonyms (deprecated)	Aliases
FL 504 Can be created in application compatibility V12R1M504 and higher?	No	Yes
Requires authorization to create?	No	Yes
Can be defined on objects not at the current sever?	No	Yes
Can be defined on the name of an object that does not yet exist?	No	Yes, but the object must exist when the alias is used
Is dropped when referenced objects are dropped?	Yes	No
Uses a qualified object name for the object?	No, uses a one-part name	Yes
Can be referenced or used by users other than the object owner?	No	Yes

The option of referencing a table or view by a synonym is not explicitly shown in the syntax diagrams or mentioned in the description of SQL statements. But synonyms can be referred to in an SQL statement.

Like tables and views, a synonym can be dropped, and associated with a comment. No authority is necessary to use a synonym. However, access to the tables and views that are referenced by the synonym still requires the appropriate authorization for the current statement.

A synonym name designates a synonym when it is preceded by the keyword SYNONYM, as in DROP SYNONYM. In all other contexts, a synonym designates a table or a view. In all other contexts, a synonym designates a local table or view and can be used wherever the name of a table or view can be used in an SQL statement.

The effect of using a synonym in an SQL statement is the same as text substitution. For example, if S is a synonym for Q.T, one of the steps involved in the preparation of `SELECT * FROM S` is the replacement of 'S' by 'Q.T'.

CREATE ALIAS
The CREATE ALIAS statement defines an alias for a table, a view, or a sequence. The definition is recorded in the Db2 catalog at the current server.

Authorization, privileges, permissions, masks, and object ownership

Users (as identified by an authorization ID) can successfully execute SQL statements only if they have the authority to perform the specified operation. For example, to create a table, a user must be authorized to create tables.

The two forms of authorization are administrative authority and privileges.

Administrative authority

The holder of administrative authority is charged with the task of controlling Db2 and is responsible for the safety and integrity of the data.

Those with SYSADM authority implicitly have all privileges on all objects and control who will have access to Db2 and the extent of this access.

Those with SECADM authority manage security policies by enforcing row and column access control for tables that contain sensitive data. They define row permissions and column masks, which describe how tables that use row or column access controls should be accessed and which determine whether a trigger or a user-defined function is considered secure for those tables.

Privileges

Privileges are those activities that a user is allowed to perform. Authorized users can create objects, have access to objects that they own, and can pass on privileges on the objects that they own to other users by using the GRANT statement. Privileges can be granted to specific users or to PUBLIC. PUBLIC specifies that a privilege is granted to all users (including to future users).

The REVOKE statement can be used to revoke previously granted privileges.

Row permissions and column masks

A *row permission* is a database object that expresses an access control rule for a row of a specific table. A row permission is in the form of a search condition that describes to which rows users have access. Row permissions are applied after table privileges (like SELECT or INSERT) are checked.

A *column mask* is a database object that expresses an access control rule for a specific column in a table. A column mask is in the form of a CASE expression that describes to which column values users have access. Column masks are applied after table privileges (like SELECT or INSERT) are checked.

Row permissions and column masks can be created, changed, and dropped only by those with SECADM authority by using the CREATE MASK, CREATE PERMISSION, and DROP statements. The definition of a permission or a mask can reference other objects. Those with SECADM authority do not need additional privileges to reference those objects, such as SELECT privilege to retrieve from a table or EXECUTE privilege to invoke a user-defined function, in the definition of the row permission or column mask. Multiple row permissions and column masks can be created for a table. Only one column mask can be created for each column in a table. A row permission or a column mask can be created before row or column access control is enforced for a table. The definition of the row permission and the column mask is stored in the Db2 catalog. However, the permission and the mask do not take effect until the ALTER TABLE statement with the ACTIVATE ROW ACCESS CONTROL clause is used to enforce row access control or the ACTIVATE COLUMN ACCESS CONTROL clause is used to enforce column access control on the table.

When an ALTER TABLE statement is used to explicitly activate row access control for a table, a default row permission is implicitly created for the table which prevents all access to the table. After row access controls have been activated for a table, if the table is referenced explicitly in a data change statement and if multiple row permissions are defined for the table, a row access control search condition is derived by using the logical OR operator with the search condition of each defined row permission.

When an ALTER TABLE statement is used to explicitly activate column access control for a table, access to the table is not restricted. However, if the table is referenced in a data change statement, all column masks that have been created for the table are applied to mask the column values that are referenced in the output of the queries or to determine the column values that are used in the data change statements.

The authorization ID or role for the statement does not need authority to reference objects that are specified in the definition of the row permission or column mask.

Object ownership

When an object is created, one authorization ID is assigned ownership of the object. Ownership means that the user is authorized to reference the object in any applicable SQL statement. The privileges on the object can be granted by the owner, and cannot be revoked from the owner. Owners of views only receive the level of privileges that they have on the underlying table or view. The owner of the object that is being created is determined as follows:

- If the schema qualifier is not explicitly specified, the owner depends on how the CREATE statement is issued:
  - If the CREATE statement is embedded in a program, the owner of the object that is being created is the authorization ID that serves as the implicit qualifier for unqualified object names. This is the authorization ID that is in the QUALIFIER option when the plan, package, or native SQL procedure (that contains the CREATE statement) is created or last changed. If the QUALIFIER option is not used, the owner of the object is the authorization ID in the OWNER option when the plan, package, or native SQL procedure is created or last changed. If the OWNER option is not used, the owner is the owner of the plan, package, or native SQL procedure. If the plan or package was last bound in a trusted context that is defined with the ROLE AS OBJECT OWNER clause, a role is the owner.
  - If the CREATE statement is dynamically prepared, the owner of the object that is being created is the authorization ID of the process.
  - If the CREATE statement is execute in a trusted context that is defined with the ROLE AS OBJECT OWNER clause, the role of the primary authorization ID is the owner.
- If the schema qualifier is explicitly specified, the owner depends on the type of object that is being created unless the CREATE statement is executed in a trusted context that is defined with the ROLE AS OBJECT OWNER clause. When the CREATE statement is executed in a trusted context that is defined with the ROLE AS OBJECT OWNER clause, the owner of the object is determined as follows:
  - If the CREATE statement is embedded in a program, the role that owns the plan or package is the owner of the object.
  - If the CREATE statement is dynamically prepared, the primary authorization ID is the owner.

  If the schema qualifier is explicitly specified, and the CREATE statement is not executed in a trusted context that is defined with the ROLE AS OBJECT OWNER clause, the owner depends on the type of object that is being created: :

  - For an alias, auxiliary table, created global temporary table, table, or view, the owner of the object that is being created is the same as the explicit schema name.
  - For a user-defined distinct type, user-defined function, procedure, sequence, JAR files, or trigger, the owner of the object that is being created is the authorization ID of the process.

The rules that determine ownership of row permissions and column masks are the same as those that determine ownership of objects like user-defined distinct types, user-defined functions, procedures, sequences, JAR files, or trigger.

The owner of a row permission or a column mask does not have implicit owner privileges. Only users with SECADM authority can manage and maintain row permissions and column masks.

Authorization IDs, roles, and authorization names

Processes can successfully execute SQL statements only if they have the necessary authority. A process derives this authority from its authorization IDs. An authorization ID can also designate a user, a group of users, or a role.

An *authorization ID* is a character string that is associated with a process that is checked to determine the authority to perform a specified operation.

Db2 does not control the association of users to user groups. However, Db2 does control the association between users and roles when a trusted context is defined.

Db2 uses authorization IDs to provide authorization checking of SQL statements.

Whenever a connection is established between Db2 and a process, Db2 obtains an authorization ID and passes it to the authorization connection or sign-on exit routine. The list of one or more authorization IDs that is returned by the exit routine are used as the authorization IDs of the process. If the process is running in a trusted context with a role, the authorization IDs of the process includes this role.

Every process has exactly one primary authorization ID. Any other authorization IDs of a process are secondary authorization IDs. The use of these authorization IDs depends on the type of process (bind process, application process, or process involved in the creation of objects).

Primary authorization ID
An authorization ID that is used to established a connection between Db2 and an application process.

Secondary authorization ID
An authorization ID that is associated with a primary authorization ID.

Secondary authorization IDs includes all the authorization IDs that have been associated with a primary authorization ID by the connection or sign-on authorization exit routine, the CURRENT SQLID (when different from the primary authorization ID), and other authorization IDs like the stored procedure definer and call package owner for stored procedure package checking.

Authorization ID of the process
The user's primary and secondary authorization IDs. If the process is running in a trusted context with a role, the authorization IDs of the process includes this role.

A *role* is a database entity that groups together one or more privileges. A role is available only when the process is run in a trusted context. Users are associated with a role in the definition of a trusted context.

A trusted context can have a default role, specific roles for individual users, or no roles at all. A user in a trusted context can have only one active role. This is the role that is specifically defined for the user or the default role of the trusted context. The following restrictions apply to roles:

- A role cannot be a primary authorization ID.
- A role cannot be set by using a SET CURRENT SQLID statement.
- A role can be the schema qualifier of an object. However, when it is used as a schema qualifier, a role is considered to be a character string and does not add any implicit schema privileges (ALTERIN, CREATEIN, or DROPIN) to this role.
- A role must already exist for privileges to be granted to it.

The role that is in effect for a user is considered to be one of the secondary authorization IDs of the user.

Do not confuse an *authorization-name* that is specified in an SQL statement with an authorization ID of a process.

Example

Assume that SMITH is your TSO logon, DYNAMICRULES run behavior is in effect, and you execute the following statements interactively:

```
   CREATE TABLE TDEPT LIKE DSN8C10.DEPT;
   GRANT SELECT ON TDEPT TO KEENE;
```

Also assume that your site has not replaced the default exit routine for connection authorization and that you have not executed the SET CURRENT SQLID statement. Thus, when the GRANT statement is prepared and executed by SPUFI, the SQL authorization ID is SMITH. KEENE is an authorization name that is specified in the GRANT statement.

Authorization to execute the GRANT statement is checked against SMITH. The authorization rule is that the privilege set that is designated by SMITH must include the SELECT privilege with the GRANT option on SMITH.TDEPT. No check that involves KEENE is performed. If the GRANT statement specifies a role, the existence of the role is checked.

Authorization IDs and schema names

An authorization ID that has the same name as the name of a schema implicitly has certain privileges for that schema.

If an authorization ID is not a role and has the same name as the name of a schema, that authorization ID implicitly has the following privileges for that schema:

- CREATEIN privilege
- ALTERIN privilege
- DROPIN privilege

Authorization IDs and statement preparation

The authorization ID that is specified as the owner of the plan or package must be one of the authorization IDs of the bind process. The owner can be set to any value if one of the authorization IDs of the bind process has SYSADM or SYSCTRL authority.

A process that creates a plan or package is called a *bind process*. The connection with Db2 is the result of the execution of a BIND or REBIND subcommand. Both subcommands allow for the specification of the authorization ID of the owner of the plan or package.

BINDAGENT can specify an owner other than himself (or one of his representatives), but it has to be someone that granted him BINDAGENT. The default owner for BIND is the primary authorization ID. The default owner for REBIND is the previous owner of the plan or package (ownership is unchanged if an owner is not explicitly specified). If the BIND or REBIND is performed in a trusted context that is defined with the ROLE AS OBJECT OWNER clause, the owner of the plan or package is a role. If the OWNER bind option is specified, the role that is specified in it is the owner, otherwise the role that performs the bind or rebind becomes the owner.

The authorization ID that is used for the authorization checking of embedded SQL statements is that of the owner of the plan or package. If the application is bound in a trusted context using the ROLE AS OBJECT OWNER clause, the authorization ID that is used for authorization checking is the role that owns the plan or package, otherwise the authorization ID is the authorization ID of the owner of the plan or package. If an embedded SQL statement refers to tables or views at a Db2 subsystem other than the one at which the plan or package is bound, the authorization checking is deferred until run time. For more information on this, see “Authorization IDs and remote execution” on page 96.

If VALIDATE(BIND) is specified, the privileges required to use or manipulate objects at the Db2 subsystem at which the plan or package is bound must exist at bind time. If the privileges or the referenced objects do not exist and SQLERROR(NOPACKAGE) is in effect, the bind operation is unsuccessful. If SQLERROR(CONTINUE) is specified, then the bind is successful and any statements in error are flagged. If any statements in error are flagged, an error will occur when you attempt to execute them at run time.

If a plan or package is bound with VALIDATE(RUN), authorization checking is still performed at bind time, but the referenced objects and the privileges required to use these objects need not exist at this time. If any privilege required for a statement does not exist at bind time, an authorization check is performed whenever the statement is first executed within a unit of work, and all privileges required for the statement must exist at that time. If any privilege does not exist, execution of the statement is unsuccessful. When the authorization check is performed at run time, it is performed against the plan or package owner, not the SQL authorization ID. For the effect of this option on cursors, see "DECLARE CURSOR" on page 1814.

Authorization IDs and dynamic SQL

The bind option DYNAMICRULES determines the authorization ID that is used for checking authorization when dynamic SQL statements are processed. The set of values for the authorization ID and other dynamic SQL attributes is called the *dynamic SQL statement behavior*. The four possible behaviors are run, bind, define, and invoke.

This discussion applies to dynamic SQL statements that refer to objects at the current server. For those that refer to objects elsewhere, see "Authorization IDs and remote execution" on page 96.

In addition to determining the authorization ID, DYNAMICRULES also controls other dynamic SQL attributes such as the implicit qualifier that is used for unqualified alias, index, sequence, table, trigger, and view names; the source for application programming options; and whether certain SQL statements can be invoked dynamically.

As the following table shows, the combination of the value of the DYNAMICRULES option and the runtime environment determines which of the four dynamic SQl statement behaviors is used. DYNAMICRULES(RUN), which implies run behavior, is the default.

Table 14. How DYNAMICRULES and the runtime environment determine dynamic SQL statement behavior

	Behavior of dynamic SQL statements	
DYNAMICRULES value	**Stand-alone program environment**	**User-defined function or stored procedure environment**
RUN	Run	Run
BIND	Bind	Bind
DEFINERUN	Run	Define
DEFINEBIND	Bind	Define
INVOKERUN	Run	Invoke
INVOKEBIND	Bind	Invoke

Note: BIND and RUN values can be specified for packages, plans, and native SQL procedures. The other values can be specified for packages and native SQL procedures but not for plans.

In the following behavior descriptions, a package that *runs under* a user-defined function or stored procedure package is a package whose associated program meets one of the following conditions:

- The program is called by a user-defined function or stored procedure.

- The program is in a series of nested calls that start with a user-defined function or stored procedure.

Run behavior

Db2 uses the authorization IDs of the application process and the SQL authorization ID (the value of special register CURRENT SQLID) for authorization checking of dynamic SQL statements. If the process is running in a trusted context with a role associated with the primary authorization ID, the authorization IDs of the application process include this role.

A process that uses a plan and its associated packages is called an *application process*. At any time, the SQL authorization ID is the value of CURRENT SQLID. This SQL special register can be initialized by the connection or sign-on exit routine. If the exit routine does not set a value, the initial value of CURRENT SQLID is the primary authorization ID of the process. You can use the SQL statement SET CURRENT SQLID to change the value of CURRENT SQLID. Unless some authorization ID of the process has SYSADM authority, the new value must be one of the authorization IDs of the process. Thus, CURRENT SQLID usually contains either the primary authorization ID of the process or one of its secondary authorization IDs. The CURRENT SQLID cannot contain a role.

Privilege set

If the dynamically prepared statement is other than a CREATE, GRANT, or REVOKE statement, each privilege required for the statement can be a privilege designated by any authorization ID of the process. Therefore, the privilege set is the union of the set of privileges held by each authorization ID of the process. When the process is running in a trusted context with a role, the authorization IDs of the process include this role.

If the dynamic SQL statement is a CREATE, GRANT, or REVOKE statement, the only authorization ID that is used for authorization checking is the SQL authorization ID. Therefore, the privilege set is the privileges held by that single authorization ID of the process. If the process is running in a trusted context using the ROLE AS OBJECT OWNER clause for the a CREATE, GRANT, or REVOKE statement, the single authorization ID of the process that is checked is the role that is in effect.

Implicit qualification

When an SQL statement is dynamically prepared, the values of the CURRENT SCHEMA special register is used as the implicit qualifier. For example, it is used as the implicit qualifier for all unqualified tables, aliases, views, indexes, and sequences. For more information, see "Unqualified object name resolution" on page 86.

Bind behavior

The same rules that are used to determine the authorization ID for static (embedded) statements are used for dynamic statements. Db2 uses the authorization ID of the owner of the package or plan for authorization checking of dynamic SQL statements, as explained in "Authorization IDs and statement preparation" on page 93.

Privilege set

The privilege set is the privileges that are held by the owner of the package or plan.

Implicit qualification

The identifier specified in the QUALIFIER option of the bind command that is used to bind the SQL statements, or the CREATE PROCEDURE or ALTER PROCEDURE statement that is used to create a version of an SQL procedure is the implicit qualifier for all unqualified tables, views, aliases, indexes, and sequences. If the QUALIFIER option was not used when the plan, package, or native SQL procedure was created or last changed, the implicit qualifier is the owner of the plan, package, or native SQL procedure.

Define behavior

Define behavior applies only if the dynamic SQL statement is in a package that is run as a stored procedure or user-defined function (or *runs under* a stored procedure or user-defined function package), and the package was bound with DYNAMICRULES(DEFINEBIND) or DYNAMICRULES(DEFINERUN). Db2 uses the authorization ID of the stored procedure or user-defined function owner (the definer) for authorization checking of dynamic SQL statements in the application package.

Privilege set

The privilege set is the privileges that are held by the authorization ID of the owner.

Implicit qualification

The stored procedure or user-defined function owner is also the implicit qualifier. For example, the owner is the implicit qualifier for unqualified table, view, alias, index, and sequence names.

Invoke behavior

Invoke behavior applies only if the dynamic SQL statement is in a package that is run as a stored procedure or user-defined function (or *runs under* a stored procedure or user-defined function package), and the package was bound with DYNAMICRULES(INVOKEBIND) or DYNAMICRULES(INVOKERUN). Db2 uses the stored procedure or user-defined function invoker for authorization checking of dynamic SQL statements in the application package. The invoker can also be a role.

Privilege set

The privilege set is the privileges that are held by the invoker. However, if the invoker is the primary authorization ID of the process or the CURRENT SQLID value, secondary authorization IDs are also checked. This includes the role of the primary authorization ID, if running in a trusted context with a role. In that case, the privilege set is the union of the set of privileges held by each authorization ID of the process.

Implicit qualification

The stored procedure or user-defined function invoker is also the implicit qualifier. For example, it is the implicit qualifier for unqualified table, view, alias, index, and sequence names. The invoker can also be a role.

Restricted statements when run behavior does not apply

When bind, define, or invoke behavior is in effect, you cannot use the following dynamic SQL statements: ALTER, CREATE, COMMENT, DROP, GRANT, RENAME, and REVOKE.

Privileges required for using dynamic SQL statements (Managing Security)

Authorization IDs and remote execution

The authorization rules for remote execution depend on whether the distributed operation is DRDA access with a Db2 for z/OS server and requester. DRDA access with a server and requester other than Db2 can also effect the authorization rules for remote execution.

DRDA access with Db2 for z/OS only

To prepare and execute SQL statements using DRDA access, certain privileges are required by the package owner and additional privileges are required by the user who invokes the application.

Any static statement executed using DRDA access is in a package bound at a server other than the local Db2 subsystem. Before the package can be bound, its owner must have the BINDADD privilege and the CREATE IN privilege for the package's collection. Also required are enough privileges to execute the package's static SQL statements that refer to data on that server. All these privileges are recorded in the Db2 catalog of the server, not in the catalog of the local Db2 subsystem. Such privileges must be granted by GRANT statements executed at the server. This allows the server to control the creation and use of packages that are run from other DBMSs.

A user who invokes an application that has a plan at the local Db2 subsystem must have the EXECUTE privilege on the plan recorded in the Db2 catalog of the local subsystem. If that application uses a package that is bound at a Db2 server other than the local Db2 requester, the EXECUTE privilege on the package must also be recorded in the Db2 catalog of the server. The ID that must hold the authorization to run the package at the Db2 server depends on the value of the PRIVATE_PROTOCOL subsystem parameter at the Db2 server:

- If PRIVATE_PROTOCOL is set to NO, EXECUTE authority on the package must be explicitly granted to the primary user ID or an associated secondary ID at the Db2 server. If the local requester application invokes a stored procedure that resides at the Db2 server, EXECUTE authority on the stored procedure package must be explicitly granted at the Db2 server to the owner of the package that issues the CALL statement if either of the following is true:
  - The owner of the stored procedure does not have the authority to execute the remote stored procedure package.
  - The CALL statement is in the form of CALL: host-variable and neither the primary user ID nor an associated secondary ID has the authority to execute the remote stored procedure package.
- If PRIVATE_PROTOCOL is not set to NO, EXECUTE authority on the package must be explicitly granted to the local requester plan owner at the Db2 server. The plan owner needs no other privilege to execute the package. If the local requester application invokes a stored procedure that resides at the Db2 server, EXECUTE authority on the stored procedure package must be explicitly granted at the Db2 server to the Db2 requester plan owner of the application that issues the CALL statement if either of the following is true:
  - The owner of the stored procedure does not have the authority to execute the remote stored procedure package.
  - The CALL statement is in the form of CALL: host-variable and neither the primary user ID nor an associated secondary ID has the authority to execute the remote stored procedure package.

EXECUTE authority is also required to use a package for a user-defined function, trigger, or stored procedure that resides at the Db2 server. However, except as previously described for a specific stored procedure case, the PRIVATE_PROTOCOL subsystem parameter is not used to determine the ID that is required to hold the EXECUTE privilege on that package. The EXECUTE privilege on that package must be recorded in the Db2 catalog of the server.

Having the appropriate privileges recorded as described above allows the execution of the static SQL statements in the package, and the execution of dynamic SQL statements if DYNAMICRULES bind, define, or invoke behavior is in effect. If DYNAMICRULES run behavior is in effect, the authorization rules for dynamic SQL statements is different. Authorization for the execution of dynamic SQL statements must come from the set of authorization IDs that are derived during connection processing, and, if the process is running in a trusted connection, the role that is in effect. An application goes through connection processing when it first connects to a server or when it reuses a CICS or IMS thread that has a different primary authorization ID.

If an application uses Recoverable Resources Manager Services attachment facility (RRSAF) and has no plan, authority to execute the package is determined in the same way as when the requester is not Db2 for z/OS.

Managing connection requests from local applications (Managing Security)

DRDA access with a server or requester other than Db2
Specific privileges are required depending on whether Db2 is the server or the requester involved in DRDA access.

Related tasks

Checking authorization at a Db2 database server (Managing Security)

DRDA access with a server or requester other than Db2

Specific privileges are required depending on whether Db2 is the server or the requester involved in DRDA access.

Db2 for z/OS as the server: If the requester is not a Db2 for z/OS subsystem, there is no Db2 application plan involved. In this case, the privilege set of the authorization ID, which is determined by the DYNAMICRULES behavior, must have the EXECUTE privilege on the package. Dynamic SQL statements in the package are executed according to the DYNAMICRULES behavior, as described in "Authorization IDs and dynamic SQL" on page 94.

Db2 for z/OS as the requester: The authorization rules for remote execution are those of the server.

Authorization ID translations

When certain authorization IDs are sent to a remote DBMS, those authorization IDs might undergo translation before being used.

Translation can occur for a primary authorization ID, the authorization ID of the owner of an application plan, or the authorization ID of the owner of a package. For example, a user known as SMITH at the local DBMS could be known, after translation, as JONES at the server. Likewise, a package owner known as GRAY could be known as WINTERS at the server. If so, JONES or WINTERS would be used, instead of SMITH or GRAY, to determine the authorization ID for dynamic SQL statements in the package. If the DYNAMICRULES run behavior applies, JONES, who is executing the dynamic statement at the server, is used. If DYNAMICRULES bind behavior applies, WINTERS, the package owner at the server, is used.

Two sets of communications database (CDB) catalog tables control the translations. One set is at the local Db2, and the other set is at the remote Db2. Translation can take place at either or both sites.

Related concepts

Communications database for the requester (Managing Security)

Communications database for the server (Managing Security)

Other security measures

Even if Db2 authority requirements are satisfied, other security measures can be in effect when distributed data is accessed.

The fact that Db2 authority requirements are satisfied does not guarantee that a user has access to a given server. Other security measures can also come into play. For example, requests to execute remote SQL statements could be denied based on Resource Access Control Facility (RACF) considerations. Developing such security measures is discussed in Getting started with Db2 security (Managing Security) and Introduction to the RACF access control module (RACF Access Control Module Guide).

Data types

Db2 supports both IBM-supplied data types (built-in data types) and user-defined data types (distinct types).

The smallest unit of data that can be manipulated in SQL is called a *value.* How values are interpreted depends on the data type of their source. Values have the following sources:

- Columns
- Constants
- Expressions
- Functions
- Special registers
- Variables (such as host variables, SQL variables, global variables, parameter markers, and parameters of routines)

The following topics describes the built-in data types and distinct types.

Figure 22 on page 99 shows the built-in data types that Db2 supports.

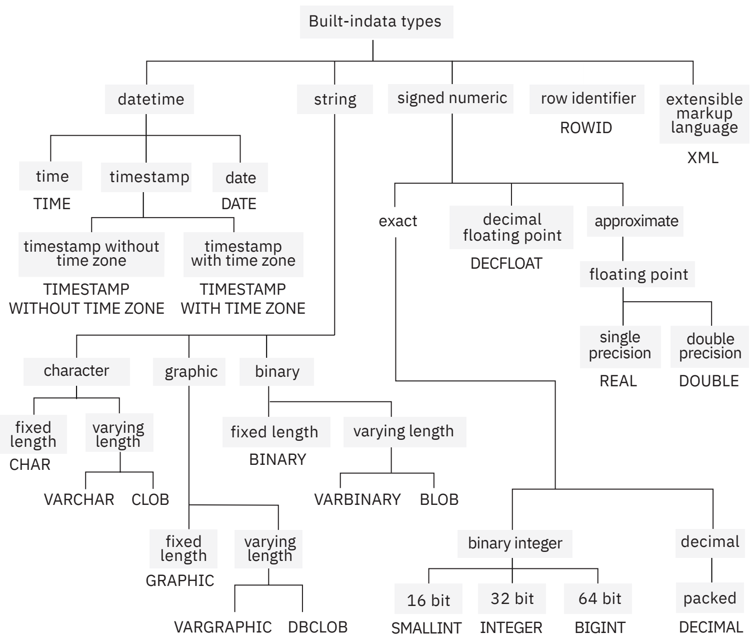

Figure 22. Built-in data types supported by Db2

NULLS

All data types include the null value. Distinct from all nonnull values, the null value is a special value that denotes the absence of a (nonnull) value.

Although all data types include the null value, some sources of values cannot provide the null value. For example, constants, columns that are defined as NOT NULL, and special registers cannot contain null values; the COUNT and COUNT_BIG functions cannot return a null value; and ROWID columns cannot store a null value although a null value can be returned for a ROWID column as the result of a query.

Related concepts

When to use null or default values (Introduction to Db2 for z/OS)

Related reference

CREATE TABLE

The CREATE TABLE statement defines a table. The definition must include its name and the names and attributes of its columns. The definition can include other attributes of the table, such as its primary key and its table space.

Numeric data types

The numeric data types are binary integer, decimal, decimal floating-point, and floating-point.

The numeric data types are categorized as follows:

- Exact numeric data types: binary integer and decimal
- Decimal floating-point
- Approximate numeric data types: floating-point

Binary integer includes small integer, large integer, and big integer. Binary numbers are exact representations of integers. Decimal numbers are exact representations of real numbers, with a fixed precision and scale. Binary and decimal numbers are considered exact numeric types.

Decimal floating-point includes DECFLOAT(16) and DECFLOAT(34), which are capable of representing either 16 or 34 significant digits. The decimal floating-point data type supports both exact representations of real numbers and approximations of real numbers, and is not considered to be either an exact numeric type or an approximate numeric type.

Floating-point includes single precision and double precision. Floating-point numbers are approximations of real numbers, and are considered to be approximate numeric types.

All numbers have a sign, a precision, and a scale. If a column value is zero, the sign is positive. Decimal floating point has distinct values for a number and the same number with various exponents (for example: 0.0, 0.00, 0.0E5, 1.0, 1.00, 1.0000). The precision is the total number of binary or decimal digits excluding the sign. The scale is the total number of binary or decimal digits to the right of the decimal point. If there is no decimal point, the scale is zero.

Small integer (SMALLINT)

A *small integer* is a binary integer with a precision of 15 bits.

The range of small integers is -32768 to +32767.

Large integer (INTEGER)

A *large integer* is a binary integer with a precision of 31 bits.

The range of large integers is -2147483648 to +2147483647.

Big integer (BIGINT)

A big integer is a binary integer with a precision of 63 bits.

The range of big integers is -9223372036854775808 to +9223372036854775807.

Single precision floating-point (REAL)

A *single precision floating-point* number is a short (32 bits) floating-point number.

The range of single precision floating-point numbers is about -7.2E+75 to 7.2E+75. In this range, the largest negative value is about -5.4E-79, and the smallest positive value is about 5.4E-079.

Double precision floating-point (DOUBLE or FLOAT)

A *double precision floating-point* number is a long (64 bits) floating-point number.

The range of double precision floating-point numbers is about -7.2E+75 to 7.2E+75. In this range, the largest negative value is about -5.4E-79, and the smallest positive value is about 5.4E-079.

Decimal (DECIMAL or NUMERIC)

A *decimal* number is a packed decimal number with an implicit decimal point.

The position of the decimal point is determined by the precision and the scale of the number. The scale, which is the number of digits in the fractional part of the number, cannot be negative or greater than the precision. The maximum precision is 31 digits.

All values of a decimal column have the same precision and scale. The range of a decimal variable or the numbers in a decimal column is -*n* to +*n*, where *n* is the largest positive number that can be represented with the applicable precision and scale. The maximum range is $1 - 10^{31}$ to $10^{31} - 1$.

Decimal floating-point (DECFLOAT)

The maximum precision of a decimal floating-point number is 34 digits.

The range of a decimal floating point number is either 16 or 34 digits of precision, and an exponent range of respectively 10^{-383} to 10^{+384} or 10^{-6143} to 10^{+6144}.

In addition to the finite numbers, decimal floating point numbers are able to represent one of the following named special values:

- Infinity - a value that represents a number whose magnitude is infinitely large.
- Quiet NaN - a value that represents undefined results which does not cause an invalid number condition.
- Signaling NaN - a value that represents undefined results which will cause an invalid number condition if used in any numerical operation.

When a number has one of these special values, its coefficient and exponent are undefined. The sign of an infinity is significant (that is, it is possible to have both positive and negative infinity). The sign of a NaN has no meaning for arithmetic operations. INF can be used in place of INFINITY.

Subnormal numbers and underflow

The decimal floating-point data type has a set of non-zero numbers that fall outside the range of normal decimal floating-point values. These numbers are called subnormal.

Non-zero numbers whose adjusted exponents are less than E_{min}[4] are called subnormal numbers. These subnormal numbers are accepted as operands for all operations and can result from any operation. If a result is subnormal before any rounding occurs, the subnormal condition is returned.

For a subnormal result, the minimum values of the exponent becomes $E_{\texttt{min}}$ `- (precision-1)`, called E_{tiny}, where precision is the working precision. If necessary, the result will be rounded to ensure that the exponent is no smaller than E_{tiny}. If the result becomes inexact during rounding, an underflow condition is returned. A subnormal result does not always return the underflow condition but will always return the subnormal condition.

When a number underflows to zero during a calculation, its exponent will be E_{tiny}. The maximum value of the exponent is unaffected.

The maximum value of the exponent for subnormal numbers is the same as the minimum value of the exponent which can arise during operations that do not result in subnormal numbers. This occurs where the length of the coefficient in decimal digits is equal to the precision.

Numeric host variables

Numeric host variables can be defined in all languages with a few exceptions.

Binary integer variables can be defined in all host languages.

Floating-point variables can be defined in all host languages. All languages, except Java, support System/390 floating-point format. Assembler, C, C++, PL/I, and Java also support IEEE floating-point format. In assembler, C, C++, and PL/I programs, the SQL processing option FLOAT tells Db2 whether floating-point variables contain data in System/390 floating-point format or IEEE floating-point format. The contents of floating-point host variables must match the format that is specified with the FLOAT SQL processing option.

Decimal variables can be defined in all host languages except Fortran.

In COBOL, decimal numbers can be represented in the following formats:

- Packed decimal format, denoted by USAGE PACKED-DECIMAL or COMP-3
- External decimal format, denoted by USAGE DISPLAY with SIGN LEADING SEPARATE
- NATIONAL decimal format denoted by USAGE NATIONAL and SIGN LEADING SEPARATE

Decimal floating-point variables can be defined in Assembler, C, C++, PL/I, and Java.

String representations of numeric values

String representations of numeric values can be used in some contexts. A valid string representation of a numeric value must conform to the rules for numeric constants.

The encoding scheme in use determines the types of strings can be used for string representation of numeric values. For ASCII and EBCDIC, a string representation of a numeric value must be a character string. For UNICODE, a string representation of a numeric value can be either a character string or a graphic string. Thus, the only time a graphic string can be used for a numeric value is when the encoding scheme is UNICODE.

When a decimal number is cast to a string (for example, using a CAST specification), the implicit decimal point is replaced by the default decimal separator character that is in effect when the statement is prepared.

When a string is cast to a decimal value (for example, using a CAST specification), the default decimal separator character in effect when the statement was prepared is used to interpret the string.

When a floating point or decimal floating-point number is cast to a string (for example, using a CAST specification), or a string is cast to a floating point or decimal floating-point number, the decimal separator character must be a period (.).

Related concepts

Constants
A *constant* (also called a *literal*) specifies a value. Constants are classified as null constants, string constants, numeric constants, or datetime constants. Numeric constants are further classified as integer, floating-point, decimal, or decimal floating-point. String constants are classified as character, graphic, or binary.

Numeric data types
The numeric data types are binary integer, decimal, decimal floating-point, and floating-point.

Arithmetic operators in expressions
If arithmetic operators are used, the result of the expression is a number derived from the application of the operators to the values of the operands.

Numeric host variables

Numeric host variables can be defined in all languages with a few exceptions.

Binary integer variables can be defined in all host languages.

Floating-point variables can be defined in all host languages. All languages, except Java, support System/390 floating-point format. Assembler, C, C++, PL/I, and Java also support IEEE floating-point format. In assembler, C, C++, and PL/I programs, the SQL processing option FLOAT tells Db2 whether floating-point variables contain data in System/390 floating-point format or IEEE floating-point format. The contents of floating-point host variables must match the format that is specified with the FLOAT SQL processing option.

Decimal variables can be defined in all host languages except Fortran.

In COBOL, decimal numbers can be represented in the following formats:

- Packed decimal format, denoted by USAGE PACKED-DECIMAL or COMP-3
- External decimal format, denoted by USAGE DISPLAY with SIGN LEADING SEPARATE
- NATIONAL decimal format denoted by USAGE NATIONAL and SIGN LEADING SEPARATE

Decimal floating-point variables can be defined in Assembler, C, C++, PL/I, and Java.

Character strings

A *character string* is a sequence of bytes. The length of the string is the number of bytes in the sequence. If the length is zero, the value is called the *empty string*. The empty string should not be confused with the null value.

Default CCSIDs for character strings

The value of the field MIXED DATA (on installation panel DSNTIPF) determines the default CCSIDs for a character string.

The following table shows how the value of the field MIXED DATA (on installation panel DSNTIPF) determines the default CCSIDs for a character string.

Table 15. Default CCSIDs for character strings

Encoding scheme	Value of MIXED DATA field	Default attribute
ASCII or EBCDIC	NO	Character: SBCS The value of the ASCII CCSID or EBCDIC CCSID field on installation panel determines the system CCSID for SBCS data.
ASCII or EBCDIC	YES	Character: MIXED The value of the ASCII CCSID or EBCDIC CCSID field on installation panel DSNTIPF determines the system CCSID for SBCS data, MIXED, and graphic data.
Unicode	Not applicable	Character: MIXED The CCSIDs are: • 367 for SBCS data • 1208 for MIXED data • 1200 for graphic data

The MIXED DATA field does not apply to Unicode columns in EBCDIC tables. Those columns follow the same rules that are shown for the Unicode encoding scheme in the previous table. For more information, see "Unicode columns in EBCDIC tables" on page 113.

Fixed-length character strings

When fixed-length character string distinct types, columns, and variables are defined, the length attribute is specified, and all values have the same length. For a fixed-length character string, the length attribute must be in the range 1–255 inclusive.

Varying-length character strings

The types of varying-length character strings are VARCHAR and character large object (CLOB). A CLOB is a type of LOB. A CLOB column is useful for storing large amounts of character data, such as documents written with a single character set.

When varying-length character strings, distinct types, columns, and variables are defined, the maximum length is specified and this length becomes the length attribute except for C NUL-terminated strings. Actual values might have a smaller value. For varying-length character strings, the length specifies the number of bytes.

For a VARCHAR string, the length attribute must be in the range 1 - 32704. For a VARCHAR column, the maximum for the length attribute is determined by the record size that is associated with the table, as described in Maximum record size the description of the CREATE TABLE statement. For a CLOB string, the length attribute must be in the range 1 - 2147483647 inclusive. For more information about CLOBs, see "Large objects (LOBs)" on page 116.

Character string variables

- Fixed-length character string variables can be used in all languages except REXX and Java. In C, CHAR string variables are limited to a length of 1.
- Varying-length character string variables can be used in all host languages with the following exceptions:
  - Fortran: varying-length non-LOB character strings cannot be used.
  - Assembler, C, and COBOL: varying-length non-LOB strings are simulated as described in *Db2 Application Programming and SQL Guide*. In C, NUL-terminated strings can also be used.
  - REXX: CLOBs and DBCLOBs cannot be used.

Character string encoding schemes

The method of representing DBCS and MBCS characters within a mixed string differs among the encoding schemes.

Each character string is further defined as one of the following subtypes:

Bit data

Data that is not associated with a coded character set and, therefore, is never converted. The CCSID for bit data is X'FFFF' (65535). The bytes do not represent characters.

Bit data is a form of character data. The pad character is a blank for assignments to bit data; the pad character is X'00' for assignments to binary data. It is recommended that binary data be used instead of character for bit data.

If both operands in a predicate are EBCDIC, both operands are padded with X'40'. Otherwise, both operands are padded with X'20'. For example, if both operands are ASCII, or if one operand is ASCII and the other operand is EBCDIC, both are padded with X'20'.

SBCS data

Data in which every character is represented by a single byte. Each SBCS string has an associated CCSID. If necessary, an SBCS string is converted before it is used in an operation with a character string that has a different CCSID.

Mixed data

Data that can contain a mixture of characters from a single-byte character set (SBCS) and a multiple-byte character set (MBCS). Each mixed string has an associated CCSID. If necessary, a mixed string is converted before an operation with a character string that has a different CCSID. If a mixed data string contains an MBCS character, it cannot be converted to SBCS data.

EBCDIC mixed data can contain shift characters, which are not MBCS data.

When the encoding scheme is Unicode or the Db2 installation is defined to support mixed data, Db2 recognizes MBCS sequences within mixed data string when performing character sensitive operations. These operations include parsing, character conversion, and the pattern matching specified by the LIKE predicate.

Character strings with a CLOB data type can only be SBCS or MIXED. BLOB should be used for binary strings.

The method of representing DBCS and MBCS characters within a mixed string differs among the encoding schemes.

- ASCII reserves a set of code points for SBCS characters and another set as the first half of DBCS characters. When it encounters the first half of a DBCS character, the system reads the next byte in order to obtain the complete character.
- EBCDIC makes use of two special code points:
  - A shift-out character (X'0E') to introduce a string of DBCS characters.

- A shift-in character (X'0F') to end a string of DBCS characters.

  DBCS sequences within mixed data strings are recognized as the string is read from left to right. At any time, the reading of the string is in SBCS mode or DBCS mode. In SBCS mode, which is the initial mode, any byte other than a shift-out is interpreted as an SBCS character. When a shift-out is read, the mode switches to DBCS mode. In DBCS mode, the next byte and every second byte after that byte is interpreted as the first byte of a DBCS character unless it is a shift character. If the byte is a shift-out, an error occurs. If the byte is a shift-in, the mode returns to SBCS mode. An error occurs if the mode is still DBCS mode after processing the last byte of the string. Because of the shift characters, EBCDIC mixed data requires more storage than ASCII mixed data.

- UTF-8 is a varying-length encoding of byte sequences. The high bits indicate the part of the sequence to which a byte belongs. The first byte indicates the number of bytes to follow in a byte sequence.

Examples of character encoding schemes

The same mixed date character string can be represented as character and hexadecimal data in different encoding schemes.

For the same mixed data character string, the following table shows character and hexadecimal representations of the character string in different encoding schemes. In EBCDIC, the shift-out and shift-in characters are needed to delineate the double-byte characters.

Table 16. Example of a character string in different encoding schemes

Data type and encoding scheme	Character representation	Hexadecimal representation (with spaces separating each character)
9 bytes in ASCII	元 gen 気 ki	8CB3 67 65 6E 8B43 6B 69
13 bytes in EBCDIC	$^{S}_{0}$元 $^{S}_{I}$ gen $^{S}_{0}$気 $^{S}_{I}$ ki	0E 4695 0F 87 85 95 0E 45B9 0F 92 89
11 bytes in Unicode UTF-8	元 gen 気 ki	E58583 67 65 6E E6B097 6B 69

Because of the differences of the representation of mixed data strings in ASCII, EBCDIC, and Unicode, mixed data is not transparently portable. To minimize the effects of these differences, use varying-length strings in applications that require mixed data and operate on ASCII, EBCDIC, and Unicode data.

String units specifications

The ability to specify string units for certain built-in functions and on the CAST specification allows you to process string data in a more "character-based manner" than a "byte-based manner". The string unit determines the length in which the operation is to occur. For more information, see "String unit specifications" on page 106.

Related concepts

String unit specifications
The ability to specify string units for certain built-in functions and on the CAST specification allows you to process string data in a more "character-based manner" than a "byte-based manner". The string unit determines the length in which the operation is to occur. You can specify CODEUNITS32, CODEUNITS16, or OCTETS as the units for the operation.

Numeric data types
The numeric data types are binary integer, decimal, decimal floating-point, and floating-point.

Characters and tokens in SQL

The most basic elements of SQL syntax are characters and tokens. Tokens are the basic syntactical units of the SQL language.

String unit specifications

The ability to specify string units for certain built-in functions and on the CAST specification allows you to process string data in a more "character-based manner" than a "byte-based manner". The string unit determines the length in which the operation is to occur. You can specify CODEUNITS32, CODEUNITS16, or OCTETS as the units for the operation.

CODEUNITS32
Specifies that Unicode UTF-32 is the units for the operation. CODEUNITS32 is useful when an application wants to process data in a simple fixed-length format and needs the same answer regardless of the storage format of the data (ASCII, EBCDIC, UTF-8, or UTF-16). Although the answers are in terms of CODEUNITS32, the data is not converted to UTF-32 to perform the function.

CODEUNITS16
Specifies that Unicode UTF-16 is the units for the operation. CODEUNITS16 is useful when an application wants to know how many double-byte characters are in a string.

OCTETS
Specifies that bytes are the units for the operation. OCTETS is often used when an application is interested in allocation buffer space or when operations need to use simple byte processing.

Determining the length of a string by counting in string units (CODEUNITS16 or CODEUNITS32) or bytes (OCTETS) can result in different answers. When OCTETS is specified, the length of a string is determined by simply counting the number of bytes in the string. Counting by CODEUNITS16 or CODEUNITS32 gives the same answer unless the data contains supplementary characters. For information about the difference between CODEUNITS16 and CODEUNITS32 when the data contains supplementary characters, see "Difference between CODEUNITS16 and CODEUNITS32" on page 107.

Example: Assume that NAME is a VARCHAR(128) column, encoded in Unicode UTF-8, that contains the value 'Jürgen'. The first two queries, which count the length of the string in CODEUNITS32 and CODEUNITS16, returns the same value, 6. The third query, which counts the length of the string in OCTETS, returns the value 7. These values are the length of the string as expressed in the string units that are specified.

```
SELECT CHARACTER_LENGTH(NAME,CODEUNITS32)
  FROM T1 WHERE NAME = 'Jürgen';
```

```
SELECT CHARACTER_LENGTH(NAME,CODEUNITS16)
  FROM T1 WHERE NAME = 'Jürgen';
```

```
SELECT CHARACTER_LENGTH(NAME,OCTETS)
  FROM T1 WHERE NAME = 'Jürgen';
```

The following table shows the UTF-8, UTF-16, and UTF-32 representations of 'Jürgen'.

Format	Representation of the name 'Jürgen'
UTF-8	x'4A**C3BC**7267656E'
UTF-16	x'004A**00FC**007200670065006E'
UTF-32	x'0000004A**000000FC**0000007200000067000000650000006E'

The bold highlighting in the table demonstrates how the representation of the character *ü* in 'Jürgen' differs between the three string units:

- The UTF-8 representation of the character ü is X'C3BC'. In UTF-8, characters that are not in the Latin-1 subset (essentially a through z, A through Z, and 0 through 9), such as accented characters or Japanese characters, are represented by multiple bytes.

- The UTF-16 representation of the character ü is X'00FC'. In UTF-16, each character is represented in 2 bytes. UTF-16 supplementary characters take two 2-byte code points.
- The UTF-32 representation of the character ü is X'000000FC'. In UTF-32, each character is represented in 4 bytes.

Specifying the string units on a built-in function does not affect the data type or the CCSID of the result of the function. If necessary, Db2 converts the data to Unicode for evaluation when CODEUNITS32 or CODEUNITS16 is specified. Db2 always evaluates the data in the encoding scheme of the output data when OCTETS is specified. For more information about the data types and CCSIDs of the results of functions, see the description of each function.

Differences between the way that characters are represented in ASCII, EBCDIC, and Unicode can affect the results of your queries.

Example: Assume that NAME is a VARCHAR(128) column, encoded in EBCDIC (CCSID 37), that contains the value 'Mit freundlichen Grüßen, Jürgen'. The following query returns the string 'Mit freundlichen Grüß':

```
SELECT SUBSTRING(C1,1,21,CODEUNITS16)
  FROM T1 WHERE C1 = 'Mit freundlichen Grüßen, Jürgen';
```

The following table shows the result data in more detail:

Format	Representation of 'Mit freundlichen Grüß'
EBCDIC	D489A340869985A4958493898388859540C799**DC59**
UTF-8	4D697420667265756E646C696368656E204772**C3BCC39F**
UTF-16	004D00690074002000660072006500750006E0064006C0069006300680 065006E002000470072**00FC00DF**

The bold highlighting in the table shows that the representation of the characters *ü* and *ß* in UTF-8 and UTF-16 each require two bytes. If OCTETS had been specified on the SUBSTRING function to have the string evaluated in UTF-8 bytes instead of EBCDIC OCTETS or CODEUNITS16, the result would have been 'Mit freundlichen Grü'. The character ß would have been lost.

Related concepts

Character strings
A *character string* is a sequence of bytes. The length of the string is the number of bytes in the sequence. If the length is zero, the value is called the *empty string*. The empty string should not be confused with the null value.

Difference between CODEUNITS16 and CODEUNITS32

CODEUNITS16 and CODEUNITS32 return the same answer unless the data contains supplementary characters.

A supplementary character is represented as two UTF-16 code units or one UTF-32 code unit. In UTF-8, a non-supplementary character is represented by 1 to 3 bytes and a supplementary character is represented by 4 bytes. In UTF-16, a non-supplementary character is represented by one CODEUNIT16 code unit or 2 bytes, and a supplementary character is represented by two CODEUNIT16 code units or 4 bytes. In UTF-32, a character is represented by one CODEUNIT32 code unit or 4 bytes. Thus, CODEUNITS16 and CODEUNITS32 return different answers when the data contains supplementary characters.

Example 1: The following table shows the hexadecimal values for the mathematical bold capital A and the Latin capital letter A. The mathematical bold capital A is a supplementary character that is represented by 4 bytes in UTF-8, UTF-16, and UTF-32.

Character	UTF-8 representation	UTF-16 representation	UTF-32 representation
Unicode value \u1D400 - 'A' MATHEMATICAL BOLD CAPITAL A	X'F09D9080'	X'D835DC00'	X'0001D400'
Unicode value \u0041 - 'A' LATIN CAPITAL LETTER A	X'41'	X'0041'	X'00000041'

Assume that C1 is a VARCHAR(128) column, encoded in Unicode UTF-8, and that table T1 contains one row with the value of the mathematical bold capital A (X'F09D9080'). The following similar queries return different answers:

```
-- Query:                                               -- Returns the value:
SELECT CHARACTER_LENGTH(C1,CODEUNITS32) FROM T1;        -- 1
SELECT CHARACTER_LENGTH(C1,CODEUNITS16) FROM T1;        -- 2
SELECT CHARACTER_LENGTH(C1,OCTETS) FROM T1;             -- 4
```

Example 2: Assume that C1 is a VARCHAR(128) column, encoded in Unicode UTF-8, and that table T1 contains one row with the value of the mathematical bold capital A (X'F09D9080'). The following similar queries return different answers.

```
-- Query:                                                -- Returns the value:
SELECT HEX(SUBSTRING(C1,1,1,CODEUNITS32)) FROM T1;      -- X'F09D9080'
SELECT HEX(SUBSTRING(C1,1,1,CODEUNITS16)) FROM T1;      -- X'20'
SELECT HEX(SUBSTRING(C1,1,2,CODEUNITS16)) FROM T1;      -- X'F09D9080'
SELECT HEX(SUBSTRING(C1,1,1,OCTETS)) FROM T1;           -- X'20'
SELECT HEX(SUBSTR(C1,1,1)) FROM T1;                     -- X'F0'
```

The value X'20' is the pad (blank) character.

Determining the length attribute of the final result

When CODEUNITS32, CODEUNITS16, or OCTETS is specified for a function or the CAST specification, the length attribute of the final result string is calculated by applying specific formulas depending on which function is specified.

To determine the final result of a function or the CAST specification, Db2 might need to use an intermediate result string if CODEUNITS32 or CODEUNITS16 is specified, depending on the encoding scheme of the data:

- ASCII and EBCDIC data require the use of a UTF-16 intermediate result string when either CODEUNITS32 or CODEUNITS16 is specified.
- UTF-8 data requires the use of a UTF-16 intermediate result string only when CODEUNITS16 is specified.

Regardless of whether an intermediate string is used, when CODEUNITS32, CODEUNITS16, or OCTETS is specified for a function or the CAST specification, the length attribute of the final result string is calculated by applying the formulas that are described in the following table. The length attributes that are calculated at each step in the formulas are measured in bytes, unless indicated otherwise.

Determining the length attribute of the string

The formulas for the length attribute of the final result string depend on the function.

The final value of the calculation for each length attribute (IML, rl, and the final result of the function) is limited by the maximum length of the function or by the maximum length of the corresponding data type of the result, whichever is applicable. Each length attribute is expressed in terms of bytes.

CAST specification, CHAR, CLOB, DBCLOB, GRAPHIC, VARCHAR, VARGRAPHIC

Follow these three steps to determine the length attribute of the final result:

1. Length of the intermediate string (IML)

When CODEUNITS32 or CODEUNITS16 is specified:

- If the source string is not in Unicode CCSID 1200, 1208, or 367, convert the source string to CCSID 1200, using the formulas in "Conversion rules for comparisons" on page 159 to determine the result length of the intermediate string (IML).
- If source string is in Unicode CCSID 1208 or 367, and CODEUNITS16 is specified, convert the source string to CCSID 1200, using the formulas in "Conversion rules for comparisons" on page 159 to determine the result length of the intermediate string (IML).
- Otherwise, the intermediate string is the same as the source string.

When OCTETS is specified:

- If the CCSID of the source string is different from the CCSID of the result of the function, convert the source string to the CCSID of the result of the function, using the formulas in "Conversion rules for comparisons" on page 159 to determine the result length of the intermediate string (IML).
- Otherwise, the intermediate string is the same as the source string.

Exception: For the GRAPHIC and VARGRAPHIC function, if the source string is EBCDIC, the source is widened with prefix X'42' before the source string is converted to CCSID 1200 and the length of the intermediate string is determined.

2. Result length attribute of the intermediate string (rl)

The result length (rl) of the intermediate string depends on whether a *length* argument was explicitly specified.

If *length* was not specified, the result length (rl) attribute is:

```
rl = IML
```

If *length* was specified, the result length (rl) attribute is:

```
IF (ol * n) < r_IML THEN
   rl = ol * n
ELSE
     IF intermediate string is in CCSID 1200
     (UTF-16) THEN
        rl = MIN( ol * n , IML + ( r  * 2 ))
     ELSE
        rl = MIN( ol * n , IML + r )
```

Where:

- ol = original *length* argument, expressed in the specified string units

  n =

  4 bytes for CODEUNITS32

  2 bytes for CODEUNITS16

- IML = length of the intermediate string
- r_IML = IML rounded up to next multiple of n
- r = ol - (r_IML/n), expressed in the specified string units

  The calculation for `r` is an estimate of the difference between the *length* argument and the estimated number of characters of the input argument, expressed in the specified string units.

3. Length of the final result string (the result of the function)

The result length attribute of the final string is determined by converting the result length (rl) of the intermediate string to the CCSID of the result of the function, using the formulas in "Conversion rules for comparisons" on page 159, if CCSID conversion is necessary. Otherwise, the result length attribute of the final string is rl.

CHARACTER_LENGTH, LOCATE, LOCATE_IN_STRING, POSITION

Follow these three steps to determine the length attribute of the final result:

1. Length of the intermediate string (IML)

The length of the intermediate string (IML) is determined the same way as for the CAST specification. (See Length of the intermediate string (IML).)

For the LOCATE, LOCATE_IN_STRING, and POSITION functions, this applies to both the *source-string* and *search-string*. If the CCSIDs of intermediate strings for the converted *source-string* and *search-string* differ, the intermediate string for the *search-string* is converted to the CCSID of intermediate string for the *source-string.*

2. Result length attribute of the intermediate string (rl)

The result length (rl) attribute is always 4 (the length of an integer):

```
rl = 4
```

3. Length of the final result string (the result the function)

The length of the final result of the function is always an integer.

INSERT, OVERLAY

Follow these three steps to determine the length attribute of the final result:

1. Length of the intermediate string (IML)

The length of the intermediate string (IML) for both the *source-string* and the *insert-string* is determined the same way as for the CAST specification. (See Length of the intermediate string (IML).)

If the CCSIDs of the intermediate strings for the converted *source-string* and *insert-string* differ, the intermediate string for the *insert-string* is converted to the CCSID of the intermediate string for the *source-string*.

2. Result length attribute of the intermediate string (rl)

The result length (rl) attribute of the intermediate string depends on whether the start and length arguments are constants.

If the *start* and *length* arguments are both constants, the result length attribute is:

```
rl = L1 - MIN ( MAX ( 0, L1 - (V2 - 1)
* n ), V3 * m) + L4
```

If at least one argument (the *start* or *length* argument) is not a constant, the result length attribute is:

```
rl = L1 + L4
```

Where:

- L1 and L4 are the length attributes of the intermediate strings of the *source-string* and *insert-string*, respectively.
- V2 and V3 are the *start* and *length* values, respectively, expressed in the specified string units.

m=

1 if the intermediate string of the *source-string* is not CCSID 1200 (UTF-16)

2 if the intermediate string of the *source-string* is CCSID 1200 (UTF-16)

n=

4 bytes for CODEUNITS32

2 bytes for CODEUNITS16

3. Length of the final result string (the result the function)

The length of the final result is the same as the length of the final result for the CAST specification. (See Length attribute of the final result string (the result of the function).)

LEFT, RIGHT

Follow these three steps to determine the length attribute of the final result:

1. **Length of the intermediate string (IML)**

   The length of the intermediate string (IML) is determined the same way as for the CAST specification. (See Length of the intermediate string (IML).)

2. **Result length attribute of the intermediate string (rl)**

   The result length (rl) attribute is the same as the length of the intermediate string:

   ```
   rl = IML
   ```

3. **Length of the final result string (the result of the function)**

   The result length attribute of the final string is determined by converting the result length (rl) of the intermediate string to the CCSID of the result of the function, using the formulas in "Conversion rules for comparisons" on page 159, if CCSID conversion is necessary. Otherwise, the result length attribute of the final string is rl.

   The result length attribute of the final string is:

   ```
   MIN(length of source string, length of CCSID
   converted string )
   ```

SUBSTRING

Follow these three steps to determine the length attribute of the final result:

1. **Length of the intermediate string (IML)**

   The length of the intermediate string (IML) is determined the same way as for the CAST specification. (See Length of the intermediate string (IML).)

2. **Result length attribute of the intermediate string (rl)**

   The result length (rl) of the intermediate string depends on whether a *length* argument was explicitly specified.

   If *length* was not specified, the result length (rl) attribute is:

   ```
   rl = IML
   ```

   If *length* was specified, the result length (rl) attribute is:

   ```
   rl = MIN(ol * n, IML)
   ```

   Where:

   - ol = original *length* argument, expressed in the specified string units

     n =

     4 bytes for CODEUNITS32

     2 bytes for CODEUNITS16

   - IML = length of the intermediate string

3. **Length of the final result string (the result of the function)**

   The length of the final result string is the same as for LEFT built-in function.

Examples

Example 1

Assume that T1 is a table encoded in EBCDIC and C1 is a CHAR(26) column (SBCS data with EBCDIC CCSID 37). The CHAR function is invoked in the following statement:

```
SELECT CHAR(C1,10,CODEUNITS32) as COL1 FROM T1;
```

Db2 uses an intermediate string to evaluate the function and determines the intermediate and final result string lengths using these steps:

1. C1, which is SBCS EBCDIC 37 data, is converted to Unicode 1200 (UTF-16). The result length of the conversion (using the formula from "Conversion rules for comparisons" on page 159, X * 2) is 26 * 2. Thus, the length of the intermediate string is 52 bytes (IML = 52).
2. The CHAR function is evaluated against the first 10 UTF-32 characters in this string. The result length attribute is 40 bytes (`rl = ol * n or 10 * 4`) because `ol * n < r_IML or 40 < 52`.
3. The 40 bytes of the string are converted back to SBCS EBCDIC 37. The result length of the conversion (using the formula from "Conversion rules for comparisons" on page 159, X * .5) is 40 * .5. Thus, the length of the final result of the functions is 20 bytes.

Example 2

This example is similar to the first example, except that the specified length for the function is 20 instead of 10. Assume that T1 is a table encoded in EBCDIC and C1 is a CHAR(26) column (SBCS data with EBCDIC CCSID 37). The CHAR function is invoked in the following statement:

```
SELECT CHAR(C1,20,CODEUNITS32) as COL1 FROM T1;
```

Db2 uses an intermediate string to evaluate the function and determines the intermediate and final result string lengths using these steps:

1. C1, which is SBCS EBCDIC 37 data, is converted to Unicode 1200 (UTF-16). The result length of the conversion (using the formula from "Conversion rules for comparisons" on page 159, X * 2) is 26 * 2. Thus, the length of the intermediate result string is 52 bytes (IML = 52).
2. The CHAR function is evaluated against the first 20 UTF-32 characters in this intermediate string. However, because the estimated number of characters in the intermediate string, as expressed in the specified string units, is only 13 characters (`r_IML/n or 52/4`), the intermediate string must be padded with 7 padding characters to satisfy the 20 characters that are requested (`r = ol - (r_IML/n) or 20 - 13`). In Unicode 1200 (UTF-16), each padding character takes 2 bytes.

   The result length attribute is then calculated to be 66 bytes (`rl = MIN(ol * n, IML + (r * 2)) or MIN(20 * 4, 52 + 14)`) because `ol * n < r_IML or 80 < 52` is not true.
3. The 66 bytes of the string are converted back to SBCS EBCDIC 37. The result length of the conversion (using the formula from "Conversion rules for comparisons" on page 159, X * .5) is 66 * .5. Thus, the length of the final result of the function is 33 bytes.

Graphic strings

A *graphic string* is a sequence of double-byte characters.

The length of the string is the number of characters in the sequence. Like character strings, graphic strings can be empty. An empty string should not be confused with the null value.

Fixed-length graphic strings

When fixed-length graphic string distinct types, columns, and variables are defined, the length attribute is specified and all values have the same length. For a fixed-length graphic string, the length attribute must be in the range 1–127 inclusive. A fixed-length graphic string column can also be called a GRAPHIC column.

Varying-length graphic strings

The types of varying-length graphic strings are VARGRAPHIC and *double-byte character large object (DBCLOB)*. DBCLOB is a type of LOB. A DBCLOB column is useful for storing large amounts of double-byte character data, such as documents written with a single double-byte character set.

When varying-length graphic strings, distinct types, columns, and variables are defined, the maximum length is specified and this length becomes the length attribute. Actual values might have a smaller value. For a varying-length graphic string, the length attribute must between 1 and 16352.

For a varying-length graphic string column, the maximum for the length attribute is determined by the record size associated with the table, as described Maximum record size in the description of the CREATE TABLE statement. For a DBCLOB string, the length attribute must be in the range 1–1 073 741 823 inclusive. In UTF-16, although supplementary characters use two 2-byte code points, supplementary characters are still considered double-byte characters. For more information about DBCLOBs, see "Large objects (LOBs)" on page 116.

Graphic string variables

Variables with a graphic string type cannot be defined in Fortran. Also, graphic string variables must follow these rules:

- Fixed-length graphic string host variables can be defined in all host languages, except REXX and Java. In C, fixed-length graphic-string variables are limited to a length of 1.
- Varying-length graphic string variables can be defined in all host languages, with the exception of DBCLOBs which cannot be used in REXX.

Graphic string encoding schemes

Each graphic string can be further defined as either double-byte data or Unicode data.

Double-byte data
Data in which every character is represented by a character from the double-byte character set (DBCS) that does not include shift-out or shift-in characters. Each double-byte graphic string has an associated ASCII or EBCDIC CCSID.

Unicode data
Data that contains characters represented by two bytes, except supplementary characters, which take two 2-byte code points per character. Each Unicode graphic string is encoded using UTF-16. The CCSID for UTF-16 is 1200.

String units in built-in functions

When working with graphic strings, you can specify the string unit in which the operation is to take place for certain built-in functions and the CAST specification. The string unit determines the length in which the operation is to occur.

For more information about string units, see "String unit specifications" on page 106.

Related concepts

"Unicode columns in EBCDIC tables" on page 113
A single encoding scheme is used for all character and character string data in a table. An exception is that an EBCDIC table can contain one or more Unicode columns in addition to EBCDIC string columns.

Unicode columns in EBCDIC tables

A single encoding scheme is used for all character and character string data in a table. An exception is that an EBCDIC table can contain one or more Unicode columns in addition to EBCDIC string columns.

An EBCDIC table can contain the following two types of Unicode columns:

Db2 12 or later Unicode columns
A Unicode column for character string data that was created in Db2 12 or later. The column is encoded in CCSID 1208 (UTF-8) or CCSID 1200 (UTF-16). Db2 12 or later Unicode columns are subject to fewer restrictions than Db2 11 Unicode columns.

Db2 11 Unicode columns

A Unicode column for character string data that was created in Db2 11. The column is encoded in CCSID 1208 (UTF-8).

Restrictions on Db2 11 Unicode columns in EBCDIC tables

Db2 11 Unicode columns in EBCDIC tables must satisfy the following criteria:

- The column must not be in the *column-name* list of a *unique-constraint* in a CREATE TABLE or ALTER TABLE statement.
- The column must not be in the *column-name* list of a *referential-constraint* in a CREATE TABLE or ALTER TABLE statement.
- The column must not be in the *column-name* list of a *references-clause* in a CREATE TABLE or ALTER TABLE statement.
- The column must not be in the *column-name* list of an ORGANIZE BY HASH clause in a CREATE TABLE or ALTER TABLE statement.
- The column must not be referenced in the CHECK(*check-condition*) clause in a CREATE TABLE or ALTER TABLE statement.
- The column must not be referenced in the CHECK(*check-condition*) clause in a CREATE TABLE or ALTER TABLE statement.
- The column can be the target of an ALTER COLUMN *column-alteration* clause in an ALTER TABLE statement only if the column is altered to the same data type, length, and CCSID. This change migrates a Db2 11 Unicode column to a Db2 12 Unicode column.
- In a *default-clause* in a CREATE TABLE or ALTER TABLE statement, a value cannot follow the DEFAULT keyword.
- The column cannot be used for *column-name* in a PARTITION BY RANGE clause in a CREATE TABLE or ALTER TABLE statement.
- The column cannot be altered.
- The column must not be referenced in a *join-condition* of a full outer join.
- In a CREATE TABLE or ALTER TABLE statement, the column definition must not contain a FIELDPROC clause.

Restrictions on EBCDIC tables with Db2 11 Unicode columns

An EBCDIC table that contains Db2 11 Unicode columns Unicode columns must satisfy the following criteria:

- The table name cannot be the *table-name* value in the LIKE clause of a CREATE TABLE statement.
- In an *as-result-table* clause in a CREATE TABLE statement, if the *from-clause* in the *fullselect* is an EBCDIC table that contains Db2 11 Unicode columns, the outermost SELECT list of the *fullselect* cannot contain a mixture of EBCDIC columns and Db2 11 Unicode columns.
- In a *materialized-query-definition* clause in a CREATE TABLE or ALTER TABLE statement, when ENABLE QUERY OPTIMIZATION is in effect, if the *from-clause* in the *fullselect* is an EBCDIC table that contains Db2 11 Unicode columns, the outermost SELECT list of the *fullselect* cannot contain a mixture of EBCDIC columns and Db2 11 Unicode columns.
- The EDITPROC clause must not be specified in the CREATE TABLE statement.
- The VALIDPROC clause must not be specified in the CREATE TABLE or ALTER TABLE statement.

Restriction on a created temporary table

When the LIKE clause is used to create a created temporary table, the table or view on which the created temporary table is based cannot be an EBCDIC table with a Db2 11 Unicode column.

Restriction on a declared temporary table

When the LIKE clause is used to create a declared temporary table, the table or view on which the declared temporary table is based cannot be an EBCDIC table with a Db2 11 Unicode column.

Restrictions on an index that has an index key with Db2 11 Unicode columns

- A CREATE INDEX statement must not specify DESC, PADDED, or RANDOM for a Db2 11 Unicode column in an EBCDIC table.
- An index that is defined on an EBCDIC table and is not an expression-based index must not include Db2 11 Unicode columns and Db2 12 Unicode columns. However, an expression-based index that is defined on an EBCDIC table can include Db2 11 Unicode columns and Db2 12 Unicode columns.

Restrictions on a table space that contains an EBCDIC table with Db2 11 Unicode columns

The CCSID of a table space that contains EBCDIC table with Db2 11 Unicode columns cannot be changed.

How the SQDA representnts Db2 11 Unicode columns are represented in EBCDIC tables

In an SQLVAR of an SQLDA after DESCRIBE or PREPARE INTO, Db2 11 Unicode columns in EBCDIC tables have these characteristics:

- For a column that is defined with CCSID 1208, the SQLTYPE field reflects VARCHAR and the SQLDATA field contains 1208, even though the column might be recorded in the catalog as VARBINARY with CCSID 1208.
- For a column that is defined with CCSID 1200, the SQLTYPE field reflects VARGRAPHIC and the SQLDATA field contains 1200, even though the column might be recorded in the catalog as VARBINARY with CCSID 1200.

Migrating Db2 11 Unicode columns in EBCDIC tables to Db2 12 or later Unicode columns in EBCDIC tables

Db2 11 Unicode columns in EBCDIC tables can be used with Db2 12, subject to the restrictions that exist in Db2. However, Db2 12 or later Unicode columns in EBCDIC tables have enhanced support, so you might want to convert Db2 11 Unicode columns to Db2 12 or later Unicode columns.

Procedure

To migrate Db2 11 Unicode columns in EBCDIC tables to Db2 12 or later Unicode columns columns, complete the following steps:

1. Run job DSNTIJPM. (You can run it before or after activating function level 500 in Db2 12. One of the reports that DSNTIJPM produces lists Db2 11 Unicode columns, the EBCDIC tables that contain them, and the indexes that are defined on the Db2 11 Unicode columns.
2. After Db2 12 function level 500 is activated, take one of the following actions:
   - Issue ALTER TABLE ALTER COLUMN to alter the Unicode column.
   - Issue ALTER TABLE DROP COLUMN and ALTER TABLE ADD COLUMN to drop and add the Unicode column.
   - Issue DROP TABLE AND CREATE TABLE to drop and recreate the table with the Unicode column.
3. Repopulate the column or table.

Related tasks

Run premigration queries (DSNTIJPM) (Db2 Installation and Migration)

Binary strings

A *binary string* is a sequence of bytes.

The length of a binary string is the number of bytes in the sequence. Binary strings are not associated with any CCSID. There are three binary string data types: BINARY, VARBINARY (BINARY VARYING) and BLOB (BINARY LARGE OBJECT).

Fixed-length binary strings

The type of fixed-length binary strings is BINARY. When fixed-length binary string distinct types, columns, and variables are defined, the length attribute is specified, and all values have the same length. For a fixed-length binary string, the length attribute must in the range 1–255 inclusive.

Varying-length binary strings

The types of varying-length binary strings are VARBINARY (BINARY VARYING) and BLOB (BINARY LARGE OBJECT)

When varying-length binary strings, distinct types, columns, and variables are defined, the maximum length is specified and this length becomes the length attribute. Actual length values might have a smaller value than the length attribute value. For varying-length binary strings, the actual length specifies the number of bytes in the string.

For a VARBINARY string, the length attribute must be between 1 and 32704. For a VARBINARY string column, the maximum for the length attribute is determined by the record size that is associated with the table, as described in "Maximum record size" on the description of the CREATE TABLE statement. Like a varying-length character string, varying-length binary string could be an empty string.

A binary string column is useful for storing non-character data, such as encoded or compressed data, pictures, voice, and mixed media. Another use is to hold structured data for exploitation by distinct types, user-defined functions, and stored procedures. Note, that although binary strings and FOR BIT DATA character strings might be used for similar purposes, the two data types are not compatible. The BINARY, BLOB, VARBINARY built-in functions and CAST specification can be used to change a FOR BIT DATA character string into a binary string.

Large objects (LOBs)

The term *large object (LOB)* refers to any of the following data types: CLOB, DBCLOB, or BLOB.

CLOB
A *character large object (CLOB)* is a varying-length string with a maximum length of 2,147,483,647 bytes (2 gigabytes minus 1 byte). A CLOB is designed to store large SBCS data or mixed data, such as lengthy documents. For example, you can store information such as an employee resume, the script of a play, or the text of novel in a CLOB. Alternatively, you can store such information in UTF-8 in a mixed CLOB. A CLOB is a varying-length character string.

DBCLOB
A *double-byte character large object (DBCLOB)* is a varying-length string with a maximum length of 1,073,741,823 double-byte characters. A DBCLOB is designed to store large DBCS data. For example, you could store the information mentioned for CLOB (an employee resume, the script for a play, or the text of a novel) in UTF-16 in a DBCLOB. A DBCLOB is a varying-length graphic string.

BLOB
A *binary large object (BLOB)* is a varying-length string with a maximum length of 2,147,483,647 bytes (2 gigabytes minus 1 byte). A BLOB is designed to store non-traditional data such as pictures, voice, and mixed media. BLOBs can also store structured data for use by distinct types and user-defined functions. A BLOB is a binary string.

Although BLOB strings and FOR BIT DATA character strings might be used for similar purposes, the two data types are not compatible. The BLOB function can be used to change a FOR BIT DATA character string into a BLOB string.

CREATE AUXILIARY TABLE
The CREATE AUXILIARY TABLE statement creates an auxiliary table at the current server for storing LOB data.

CREATE LOB TABLESPACE
The CREATE LOB TABLESPACE statement defines a large object (LOB) table space at the current server. If your data for a table does not fit entirely within a data page, you can define one or more columns as LOB columns. Each LOB column must have an associated auxiliary table in a LOB table space. If the table space for the base table is partitioned, an associated auxiliary table in a LOB table space is required for each LOB column, for each partition of the table space for the base table.

Restrictions using LOBs

With a few exceptions, you can use LOBs in the same contexts in which you can use other varying-length strings.

The following table shows the contexts in which LOBs cannot be used.

Table 17. Contexts in which LOBs cannot be used

Context of usage	**LOB (CLOB, DBCLOB, or BLOB)**
A GROUP BY clause	Not allowed
An ORDER BY clause	Not allowed
A CREATE INDEX statement that creates an index using an expression	Not allowed except when the index is created using an expression, in which case an inline LOB column can be referenced as the source data type for the SUBSTR and SUBSTRING built-in functions.
A SELECT DISTINCT statement	Not allowed
A MERGE statement	Cannot be used in the context of an INCLUDE *column-name* clause
A subselect of a set operation except UNION ALL	Not allowed
Predicates	Cannot be used in any predicate except EXISTS, LIKE, and NULL. This restriction includes a *simple-when-clause* in a CASE expression. `expression WHEN expression` in a *simple-when-clause* is equivalent to a predicate with `expression=expression`.
The definition of primary, unique, and foreign keys	Not allowed
Check constraints	Not allowed

Manipulating LOBs using locators

A LOB locator is a host variable with a value that represents a single LOB value in the database server. LOB locators provide a mechanism for you to easily manipulate very large objects in application programs without having to store the entire LOB value on the client machine where the application program might be running.

Because LOB values can be very large, the transfer of these values from the database server to host variables in client application programs can be time consuming. Also, application programs typically process LOB values a piece at a time, rather than as a whole. For these cases, the application can use a *large object locator* (LOB locator) to reference the LOB value.

For example, when selecting a LOB value, an application program could handle the value in either of these two ways:

- Select the entire LOB value and place it into an equally large host variable. This method is acceptable if the application program is going to process the entire LOB value at once.
- Select the LOB value into a LOB locator. Then, using the LOB locator, the application program can issue subsequent database operations on the LOB value (such as using it as a parameter to the scalar functions SUBSTR, CONCAT, COALESCE, LENGTH, doing an assignment, searching the LOB value with LIKE or POSSTR, or using it as a parameter to a user-defined function or procedure) by supplying the LOB locator value as input. The resulting output of the LOB locator operation, for example, the amount of data that is assigned to a client host variable, would then typically be a small subset of the input LOB value.

LOB locators can also represent more than just base values; they can also represent the value associated with a LOB expression. For example, a LOB locator might represent the value associated with:

```
   SUBSTR(lob_value_1 CONCAT lob_value_2 CONCAT lob_value_3 , 42, 6000000)
```

For non-locator-based host variables in an application program, when a null value is selected into that host variable, the indicator variable is set to -1, signifying that the value is null. For LOB locators, however, the meaning of indicator variables is slightly different. Because a LOB locator host variable itself can never be null, a negative indicator variable value indicates that the LOB value represented by the LOB locator is null. The null information is kept local to the client by virtue of the indicator variable value (the server does not track null values with valid LOB locators).

A LOB locator represents a value, not a row or location in the database. Therefore, after a value is selected into a LOB locator, no action that is subsequently performed on the original row or table will affect the value that is referenced by the LOB locator. The value associated with a LOB locator is valid until the transaction ends, or until the LOB locator is explicitly freed, whichever comes first.

A LOB locator is also not a database type, and it is never stored in the database. As a result, it cannot participate in views or check constraints. However, values for the SQLTYPE field of the SQLDA exist for LOB locators so that they can be described within an SQLDA structure that is used by FETCH, OPEN, CALL and EXECUTE statements.

For more information about manipulating LOBs with LOB locators, see Saving storage when manipulating LOBs by using LOB locators (Db2 Application programming and SQL).

Datetime values

Datetime values are neither strings nor numbers. Nevertheless, datetime values can be used in certain arithmetic and string operations and are compatible with certain strings.

Moreover, strings can represent datetime values, as discussed in “String representations of datetime values” on page 120.

Date

A *date* is a three-part value (year, month, and day) designating a point in time using the Gregorian calendar, which is assumed to have been in effect from the year 1 A.D.

[4] The range of the year part is 0001 to 9999. The range of the month part is 1 to 12. The range of the day part is 1 to 28, 29, 30, or 31, depending on the month and year.

The internal representation of a date is a string of 4 bytes. Each byte consists of two packed decimal digits. The first 2 bytes represent the year, the third byte the month, and the last byte the day.

The length of a DATE column as described in the catalog is the internal length, which is 4 bytes. The length of a DATE column as described in the SQLDA is the external length, which is 10 bytes unless a date exit routine was specified when your Db2 subsystem was installed. (Writing a date exit routine is described in Date and time routines (Db2 Administration Guide).) In that case, the string format of a date can be up to 255 bytes in length. Accordingly, DCLGEN[5] defines fixed-length string variables for DATE columns with a length equal to the value of the field LOCAL DATE LENGTH on installation panel DSNTIP4, or a length of 10 bytes if a value for the field was not specified.

A character-string representation must have an actual length that is not greater than 255 bytes and must not be a CLOB or DBCLOB.

Related reference

DATE FORMAT field (DATE DECP value) (Db2 Installation and Migration)
LOCAL DATE LENGTH field (DATELEN DECP value) (Db2 Installation and Migration)
DCLGEN (DECLARATIONS GENERATOR) (DSN) (Db2 Commands)

Time

A *time* is a three-part value (hour, minute, and second) designating a time of day using a 24-hour clock. The range of the hour part is 0 to 24. The range of the minute and second parts is 0 to 59. If the hour is 24, the minute and second parts are both zero.

The internal representation of a time is a string of 3 bytes. Each byte consists of two packed decimal digits. The first byte represents the hour, the second byte the minute, and the last byte the second.

The length of a TIME column as described in the catalog is the internal length which is 3 bytes. The length of a TIME column as described in the SQLDA is the external length which is 8 bytes unless a time exit routine was specified when the Db2 subsystem was installed. (Writing a time exit routine is described in Date and time routines (Db2 Administration Guide).) In that case, the string format of a time can be up to 255 bytes in length. Accordingly, DCLGEN "Date" on page 118 defines fixed-length string variables for TIME columns with a length equal to the value of the field LOCAL TIME LENGTH on installation panel DSNTIP4, or a length of 8 bytes if a value for the field was not specified.

A character-string representation must have an actual length that is not greater than 255 bytes and must not be a CLOB or DBCLOB.

Related reference

LOCAL TIME LENGTH field (TIMELEN DECP value) (Db2 Installation and Migration)
DCLGEN (DECLARATIONS GENERATOR) (DSN) (Db2 Commands)

Timestamp

A *timestamp* is a six-part or seven-part value (year, month, day, hour, minute, second, and optional fractional second) with an optional time zone specification, that represents a date and time.

The time portion of a timestamp value can includes a specification of fractional seconds. The number of digits in the fractional seconds portion is specified using an attribute in the range 0 - 12 with a default of 6. The time zone is the difference in hours and minutes between local time and UTC. The range of the hour offset is -12 to 14, and the minute offset is 00 to 59. The optional time zone is specified in the format ±th:tm, with values ranging from -12:59 to +14:00. A timestamp data type is TIMESTAMP WITHOUT TIME ZONE (generically referred to as TIMESTAMP) or TIMESTAMP WITH TIME ZONE.

[4] Historical dates do not always follow the Gregorian calendar. Dates between 1582-10-04 and 1582-10-15 are accepted as valid dates although they never existed in the Gregorian calendar.

[5] DCLGEN is a Db2 DSN subcommand for generating table declarations for designated tables or views. The declarations are stored in z/OS data sets, for later inclusion in Db2 source programs.

TIMESTAMP WITHOUT TIME ZONE

The internal representation of a timestamp is a string of 7 to 13 bytes, each of which consists of two packed decimal digits. The first 4 bytes represent the date, the next 3 bytes the time, and the remaining bytes the fractional seconds based on the precision of the timestamp.

The length of a TIMESTAMP WITHOUT TIME ZONE column as described in the catalog is the internal length, which is 7 to 13 bytes.

The length of a TIMESTAMP WITHOUT TIME ZONE column as described in the SQLDA is between 19 and 32 bytes, which corresponds to the length for the character-string representation of the value. For example, a 19 byte character-string representation has no fractional seconds; a 26 byte character-string representation has 6 digits of fractional seconds; and a 29 byte character-string representation has 9 digits of fractional seconds.

A character-string representation must have an actual length that is not greater than 255 bytes and must not be a CLOB or DBCLOB.

TIMESTAMP WITH TIME ZONE

The external representation of a TIMESTAMP WITH TIME ZONE value is the local timestamp followed by the time zone offset. For example, New York is 5 hours behind London during standard time, so New York time "8:15" on 2010-02-10 can be represented as '2010-02-10-08.15.00-5:00'. This timestamp with time zone value represents a UTC value '2010-02-10-13.15.00', which is derived by subtracting the time zone offset from local timestamp.

The internal representation of a timestamp is a string of 9 to 15 bytes that contains the UTC timestamp followed by the time zone. Each byte consists of 2 packed decimal digits. The first byte consists of two packed decimal digits representing time zone hour and the first bit is used to represent the sign of the time zone offset. The second byte of time zone, representing the time zone minute, also consists of two packed decimal digits. For example, time zone "-3:30" is represented as X'8330' and time zone "5:30" is represented as X'0530'.

The length of a TIMESTAMP WITH TIME ZONE column as described in the catalog is the internal length, which is between 9 to 15 bytes (a 7 to 13 bytes timestamp followed by 2 bytes time zone).

The length of a TIMESTAMP WITH TIME ZONE column as described in the SQLDA is the external length, which is between 147 and 160 bytes and corresponds to the length for the character-string representation of the value. For example, a 147 byte character representation has no fractional seconds, and a 160 byte character-string representation has 12 digits of fractional seconds, where the time zone component is 7 bytes.

A character-string representation must have an actual length that is not greater than 255 bytes and must not be a CLOB or DBCLOB. DCLGEN therefore defines 147 to 160 byte, varying-length string variables for TIMESTAMP WITH TIME ZONE columns.

Related concepts

Datetime constants
A *datetime constant* is a character string constant of a particular format.

Datetime host variables

Character-string host variables are normally used to contain date, time, and timestamp values. However, date, time, and timestamp host variables can also be specified in Java as java.sql.Date, java.sql.Time, and java.sql.Timestamp, respectively.

String representations of datetime values

Dates, times, and timestamp values can be represented by strings. For many host languages, there are no special SQL constants for datetime values and, except for Java, no host variables with a data type of date, time, or timestamp. Thus, to be retrieved, a datetime value must be assigned to a string variable.

Values whose data types are DATE, TIME, TIMESTAMP WITHOUT TIME ZONE, or TIMESTAMP WITH TIME ZONE are represented in a form that is transparent to the user of SQL. Dates, times, and timestamps (with or without time zones) can also be represented by strings. These representations directly concern the SQL user because, for many host languages there are no special SQL constants or host variables with a data type for DATE, TIME, TIMESTAMP WITHOUT TIME ZONE, or TIMESTAMP WITH TIME ZONE values (for variables with Java). Thus, to be retrieved, a datetime value must be assigned to a string variable. The format of the resulting string depends on the default date format and the default time format that is in effect when the statement is prepared.

Each datetime value is assigned an encoding scheme. This encoding scheme is used when the datetime value is converted from its internal form to the string representation in the form of the mixed CCSID if the field MIXED DATA is YES on installation panel DSNTIPF. Otherwise the SBCS CCSID of the assigned encoding scheme is used. For Unicode, the mixed CCSID is always used. The following table shows how the encoding scheme is determined:

Table 18. The encoding scheme of datetime values

Datetime expression	Result encoding scheme
Columns	The same encoding scheme as the table that contains the column
Host variables	If the statement references: • A single encoding scheme - The same encoding scheme • Multiple encoding schemes - The application encoding scheme
Special registers	If the statement references: • A single encoding scheme - The same encoding scheme • Multiple encoding schemes - The application encoding scheme
Expressions	If the statement references: • A single encoding scheme - The same encoding scheme • Multiple encoding schemes - The application encoding scheme

For ASCII and EBCDIC, a string representation of a datetime value must be a character string. For Unicode, a string representation of a datetime value can be either a character string or a graphic string. Thus, the only time a graphic string can be used for a datetime value is when the encoding scheme is Unicode.

In host languages other than Java, a datetime value must be assigned to a string variable. When a date or time is assigned to a string variable, the string format is determined by a precompiler option or subsystem parameter. When a string representation of a datetime value is used in other operations, it is converted to a datetime value. However, this can be done only if the string representation is recognized by Db2 or an exit provided by the installation and the other operand is a compatible datetime value. An input string representation of a date or time with LOCAL specified must have an actual length that is not greater than 255 bytes.

Datetime values that are represented by strings can appear in contexts that require values whose data types are DATE, TIME, TIMESTAMP WITHOUT TIME ZONE, or TIMESTAMP WITH TIME ZONE. A string representation of a date, time or timestamp (with or without time zone) can be passed as an argument to the DATE, TIME, TIMESTAMP, or TIMESTAMP_TZ function to obtain a datetime value. A CAST specification can also be used to turn a character representation of a date, time, or timestamp (with or without time zone) into a datetime value.

Date strings:

A string representation of a date is a string that starts with a digit and has a length of at least 8 characters. Trailing blanks can be included, leading blanks are not allowed, and leading zeros can be omitted in the month and day portions.

The following table shows the valid string formats for dates. Each format is identified by name and includes an associated abbreviation (for use by the CHAR function) and an example of its use. For an installation-defined date string format, the format and length must have been specified when Db2 was installed. They cannot be listed here.

Table 19. Formats for string representations of dates

Format name	Abbreviation	Date format	Example
International Standards Organization	ISO	yyyy-mm-dd	1987-10-12
IBM USA standard	USA	mm/dd/yyyy	10/12/1987
IBM European standard	EUR	dd.mm.yyyy	12.10.1987
Japanese industrial standard Christian era	JIS	yyyy-mm-dd	1987-10-12
Installation-defined	LOCAL	Any installation-defined form	—

Time strings:

A string representation of a time is a string that starts with a digit, and has a length of at least 4 characters. Trailing blanks can be included, leading blanks are not allowed, and leading zeros can be omitted in the hour part of the time; seconds can be omitted entirely. If you choose to omit seconds, an implicit specification of 0 seconds is assumed. Thus 13.30 is equivalent to 13.30.00.

The following table shows the valid string formats for times. Each format is identified by name and includes an associated abbreviation (for use by the CHAR function) and an example of its use. In the case of an installation-defined time string format, the format and length must have been specified when your Db2 subsystem was installed. They cannot be listed here.

Table 20. Formats for string representations of times

Format name	Abbreviation	Time format	Example
International Standards Organization [1]	ISO[1]	hh.mm.ss	13.30.05
IBM USA standard	USA	hh:mm AM or PM	1:30 PM
IBM European standard	EUR	hh.mm.ss	13.30.05
Japanese industrial standard Christian era	JIS	hh:mm:ss	13:30:05
Installation-defined	LOCAL	Any installation-defined form	—

Note: 1. This is an earlier version of the ISO format. JIS can be used to get the current ISO format.

In the USA format:

- The minutes can be omitted, thereby specifying 00 minutes. For example, 1 PM is equivalent to 1:00 PM.
- The letters A, M, and P can be lowercase.
- A single blank must precede the AM or PM.
- The hour must not be greater than 12 and cannot be 0 except for the special case of 00:00 AM.

Using the ISO format of the 24-hour clock, the correspondence between the USA format and the 24-hour clock is as follows:

- 12:01 AM through 12:59 AM correspond to 00.01.00 through 00.59.00
- 01:00 AM through 11:59 AM correspond to 01.00.00 through 11.59.00
- 12:00 PM (noon) through 11:59 PM correspond to 12.00.00 through 23.59.00
- 12:00 AM (midnight) corresponds to 24.00.00
- 00:00 AM (midnight) corresponds to 00.00.00

Timestamp strings:

A string representation of a timestamp is a character or graphic string that starts with a digit and has a length of at least 16 characters.

The character or graphic string must contain a value that conforms to one of the formats listed in "Datetime constants" on page 174, subject to the following rules:

- leading blanks are not allowed
- trailing blanks can be included
- leading zeros can be omitted from the month, day, hour, and time zone hour elements of the timestamp. An implicit specification of 0 is assumed for any digit that is omitted.
- the hour can be 24 if the minutes, seconds, and any fractional seconds are all zeroes.
- leading zeros must be included for the minute, second, and time zone minute elements of the timestamp.
- the number of digits of fractional seconds can vary from 0 to 12. An implicit specification of 0 is assumed if fractional seconds are omitted.
- the separator character that follows the seconds element can be omitted if fractional seconds are not included.
- an optional single blank can be included between the time and the time zone.
- an optional time zone can be included, in one of the following formats:
  - ±th:tm, with values ranging from -24:00 to +24:00. A value of -0:00 is treated the same as a value of +0:00.
  - ±th, with values ranging from -24 to +24, and an implicit specification of 00 is assumed for the time zone minute element.
  - uppercase Z to specify UTC

If a string representation of a timestamp is implicitly cast to a value with a timestamp data type, the timestamp precision is assumed to be 6, regardless of the number of digits of fractional seconds in the string. Beyond the sixth digit that represents fractional seconds, the digits are truncated and the missing digits are assumed to be zeros. For example, `1990-3-2-8.30.00.10` is equivalent to `1990-03-02-08.30.00.100000`. A string representation of a timestamp can be given a different timestamp precision by explicitly casting the value to a timestamp with a specified precision or, in the case of a constant, preceding the string with the TIMESTAMP keyword (for example, `TIMESTAMP 2007-03-28-14.50.35.123;` has the TIMESTAMP(3) data type).

If a string representation of a timestamp is implicitly cast to a TIMESTAMP WITHOUT TIME ZONE value, the string must not contain a time zone.

SQL statements also support the ODBC or JDBC string representation of a timestamp as an input value only. The ODBC and JDBC string representation of a timestamp has the form *yyyy-mm-dd hh:mm:ss.nnnnnn*.

LOCAL date and time exits: For LOCAL, the date exit for ASCII data is DSNXVDTA, the date exit for EBCDIC is DSNXVDTX, and the date exit for Unicode is DSNXVDTU. For LOCAL, the time exit for ASCII data is DSNXVTMA, the time exit for EBCDIC is DSNXVTMX, and the time exit for Unicode is DSNXVTMU.

Determination of the implicit time zone

Db2 uses the IMPLICIT_TIMEZONE parameter of DSNHDECP to implicitly determines the time zone to associate with a value that does not have a time zone on assignment to a TIMESTAMP WITH TIME ZONE column or variable.

The IMPLICIT_TIMEZONE parameter of DSNHDECP is used to support operations that combine TIMESTAMP WITHOUT TIME ZONE values and TIMESTAMP WITH TIME ZONE values and indicates the time zone to associate with TIMESTAMP WITHOUT TIME ZONE values. For example, on assignment of a value that does not have time zone information (the TIMESTAMP WITHOUT TIME ZONE data type, or a string representation of a timestamp without a time zone) to a TIMESTAMP WITH TIME ZONE target such as a column or variable, Db2 implicitly determines the time zone to associate with the value. The implicit time zone is determined as follows:

- If IMPLICIT_TIMEZONE is not specified or is specified as CURRENT, the implicit time zone is the value of the CURRENT TIME ZONE special register.
- If IMPLICIT_TIMEZONE is specified as SESSION, the implicit time zone is the value of the SESSION TIME ZONE special register.
- If IMPLICIT_TIMEZONE is specified as a character string in the format of '±th:tm' , the implicit time zone is the time zone value represented by the character string.

Restrictions on the use of local datetime formats

When you use a LOCAL format for date or time values, certain restrictions apply to the use of those values as input, as output, and for use in binding a package.

The following rules apply to the character-string representation of dates and times:

For input: In distributed operations, Db2 as a server uses its local date or time routine to evaluate host variables and constants. This means that character-string representation of dates and times can be:

- One of the standard formats
- A format recognized by the server's local date/time exit

For output: With DRDA access, Db2 as a server returns date and time host variables in the format defined at the server. To have date and time host variables returned in another format, use CHAR(*date-expression, XXXX*) where *XXXX* is JIS, EUR, USA, ISO, or LOCAL to explicitly specify the specific format.

For BIND PACKAGE COPY: When you use the COPY option to bind a copy of a local package at a remote site, Db2 uses the ISO format for output values in the remote package unless the SQL statement explicitly specifies a different format. Input values can be specified in the format described previously.

Row ID values

A *row ID* is a value that uniquely identifies a row in a table. A column or a host variable can have a row ID data type.

A ROWID column enables queries to be written that navigate directly to a row in the table because the column implicitly contains the location of the row. Each value in a ROWID column must be unique. Although the location of the row might change, for example across a table space reorganization, Db2 maintains the internal representation of the row ID value permanently. When a row is inserted into the table, Db2 generates a value for the ROWID column unless one is supplied. If a value is supplied, it must be a valid row ID value that was previously generated by Db2 and the column must be defined as GENERATED BY DEFAULT. Users cannot update the value of a ROWID column.

The internal representation of a row ID value is transparent to the user. The value is never subject to character conversion because it is considered to contain BIT data. The length of a ROWID column as described in the LENGTH column of catalog table SYSCOLUMNS is the internal length, which is 17 bytes. The length as described in the LENGTH2 column of catalog table SYSCOLUMNS is the length of a retrieved ROWID value, which is 40 bytes. The retrieved ROWID value is not permanent. If a commit operation and a REORG on the table space occur after the value is inserted, and before the value is retrieved, the physical location of the row might change.

A ROWID column can be either user-defined or implicitly generated by Db2. You can use the CREATE TABLE statement or the ALTER TABLE statement to define a ROWID column. If you define a LOB column in a table and the table does not have a ROWID column, Db2 implicitly generates a ROWID column. Db2 takes the following actions:

- Creates the column with a name of DB2_GENERATED_ROWID_FOR_LOBS*nn*.

  Db2 appends *nn* only if the column name already exists in the table, replacing *nn* with '00' and incrementing by '1' until the name is unique within the row.
- Defines the column as GENERATED ALWAYS and IMPLICITLY HIDDEN.
- Appends the column to the end of the row after all the other explicitly defined columns.

An implicitly hidden ROWID column can also be explicitly defined with the IMPLICITLY HIDDEN clause.

If you add a ROWID column to a table that already has an implicitly generated hidden ROWID column, Db2 ensures that the corresponding values in each column are identical. If the ROWID column that you add is defined as GENERATED BY DEFAULT, Db2 changes the attribute of the hidden ROWID column to GENERATED BY DEFAULT.

ROWID
The ROWID function returns a row ID representation of its argument.

XML values

An XML value represents well-formed XML in the form of an XML document, XML content, or a sequence of XML nodes.

An XML value that is stored in a table as the value of a column that is defined with the XML data type must be a well-formed XML document. XML values are processed in an internal representation that is not comparable to any string value. The only predicates that can be applied to the XML data type are the XMLEXISTS predicate and the NULL predicate.

An XML value can be transformed into a serialized string value that represents the XML document by using the XMLSERIALIZE function. Similarly, a string value that represents an XML document can be transformed to an XML value by using the XMLPARSE function.

The XML data type has a variable length and allows for a wide range of sizes. Although data of this type has no defined maximum length, it does have an effective maximum length limit when treated as a serialized string value that represents XML. The maximum effective length is the same as the Db2 limit for a LOB data value. Db2 treats XML string data in a similar manner as LOB data to accommodate very large XML values. Thus, XML values are constrained by the same maximum length limit as LOB data. Unlike the LOB data type which has a LOB locator type, there is no XML locator type.

Restrictions when using XML values: With a few exceptions, you can use XML values in the same contexts in which you can use other data type. XML values cannot be used in the following contexts:

- SELECT lists that are preceded by the DISTINCT clause
- GROUP BY clauses
- ORDER BY clauses
- A subselect of a fullselect with a set operator that is not UNION ALL

- Basic predicates, quantified predicates, BETWEEN predicates, DISTINCT predicates, IN predicates, or LIKE predicates
- Aggregate functions with the DISTINCT keyword
- Primary, unique, or foreign keys
- CREATE TYPE statements

No host languages have any built-in support for an XML data type.

User-defined data types

A *user-defined data type* is a data type that is defined using a CREATE TYPE statement.

The following types of user-defined data type are supported:

- Distinct type
- Array type

Distinct types

A *distinct type* is a user-defined data type that shares its internal representation with a built-in data type (its *source type*), but is considered to be a separate and incompatible data type for most operations.

For example, the semantics for a picture type, a text type, and an audio type that all use the built-in data type BLOB for their internal representation are quite different. A distinct type is created with the SQL statement CREATE TYPE.

For example, the following statement creates a distinct type named AUDIO:

```
CREATE TYPE AUDIO AS BLOB (1M);
```

Although AUDIO has the same representation as the built-in data type BLOB, it is a separate data type that is not comparable to a BLOB or to any other data type. This inability to compare AUDIO to other data types allows functions to be created specifically for AUDIO and assures that these functions cannot be applied to other data types.

The name of a distinct type is qualified with a schema name. The implicit schema name for an unqualified name depends on the context in which the distinct type appears. If an unqualified distinct type name is used:

- In a CREATE TYPE statement or the object of DROP, COMMENT, GRANT, or REVOKE statement, Db2 uses the normal process of qualification by authorization ID to determine the schema name.
- In any other context, Db2 uses the SQL path to determine the schema name. Db2 searches the schemas in the path, in sequence, and selects the first schema in the path such that the distinct type exists in the schema and the user has authorization to use the data type. For a description of the SQL path, see "SQL path" on page 85.

A distinct type does not automatically acquire the functions and operators of its source type because they might not be meaningful. (For example, it might make sense for a "length" function of the AUDIO type to return the length in seconds rather than in bytes.) Instead, distinct types support *strong typing*. Strong typing ensures that only the functions and operators that are explicitly defined on a distinct type can be applied to that distinct type. However, a function or operator of the source type can be applied to the distinct type by creating an appropriate user-defined function. The user-defined function must be sourced on the existing function that has the source type as a parameter. For example, the following series of SQL statements shows how to create a distinct type named MONEY based on data type DECIMAL(9,2), how to define the + operator for the distinct type, and how the operator might be applied to the distinct type:

```
CREATE TYPE MONEY AS DECIMAL(9,2);
CREATE FUNCTION "+"(MONEY,MONEY)
   RETURNS MONEY
   SOURCE SYSIBM."+"(DECIMAL(9,2),DECIMAL(9,2));
CREATE TABLE SALARY_TABLE
   (SALARY MONEY,
    COMMISSION MONEY);
SELECT SALARY + COMMISSION FROM SALARY_TABLE;
```

A distinct type is subject to the same restrictions as its source type. For example, if a CLOB value is not allowed as input to a function, you cannot specify a distinct type that is based on a CLOB as input.

The comparison operators are automatically generated for distinct types, except those that are based on a CLOB, DBCLOB, or BLOB. In addition, Db2 automatically generates functions for every distinct type that support casting from the source type to the distinct type and from the distinct type to the source type. For example, for the AUDIO type created above, these are generated cast functions:

```
FUNCTION schema-name.BLOB (schema-name.AUDIO) RETURNS SYSIBM.BLOB (1M)
FUNCTION schema-name.AUDIO (SYSIBM.BLOB (1M)) RETURNS schema-name.AUDIO
```

Array types

A user-defined *array type* is a data type that is defined as an array of elements. A user-defined array type can be either an *ordinary array* or *associative array*.

A user-defined ordinary array type has a maximum cardinality, which is specified on the CREATE TYPE (array) statement. A user-defined associative array has a maximum cardinality of 2 billion.

Array values

An *array value* is a structure that contains an ordered collection of elements.

All elements of an array value must have the same data type. The cardinality of the array is equal to the number of elements in the array.

An array value can be non-empty, empty (cardinality zero), or null. The individual elements in the array can be null or not null. An empty array, an array value of null, and an array for which all elements are the null value are different from each other. An uninitialized array is a null array.

The following example demonstrates the difference between an empty array, a null array, and an array for which individual elements are null.

```
SET PHONELIST = ARRAY[];
           /* Set an entire array to empty           */
SET PHONELIST = NULL;
           /* Set an entire array to the NULL value  */
SET PHONELIST = ARRAY[NULL];
           /* Set one element of an array to NULL    */
SET PHONELIST = ARRAY[NULL, NULL, NULL];
           /* Set three elements of an array to NULL */
```

An *ordinary array* has a defined upper bound on the number of elements, which is known as the maximum cardinality. Each element in the array is referenced by an associated index value that represents the position of that element in the array. The data type of the index values is INTEGER. If *n* is the number of elements in an ordinary array, the ordinal position that is associated with each element is an integer value greater than or equal to 1 and less than or equal to *n*.

Unlike the maximum cardinality of an array in programming languages such as C, the maximum cardinality of an ordinary array in SQL is not related to the physical representation of the array. The amount of memory that is required to represent the value of an ordinary array is usually proportional to the cardinality of the array, and not to the maximum cardinality of the array type. When an ordinary array is referenced, all of the values in the array are stored in main memory. Therefore, ordinary arrays that contain a large amount of data consume large amounts of main memory.

An *associative array* has no predefined upper bound on the number of elements. An associative array contains an ordered set of zero or more elements, where each element in the array is ordered by and can be referenced by an associated index value. The data type of the index values can be an integer or a character string other than a CLOB, but all index values for the array must have the same data type. The index values of an associative array are unique, and do not need to be contiguous.

A *user-defined array type* is a user-defined data type that is defined as an array. A global variable, an SQL variable or SQL parameter can be defined as a user-defined array type. Additionally, the result of an invocation of the built-in ARRAY_DELETE or TRIM_ARRAY functions, or the result of a CAST specification, can be a user-defined array type. An element of a user-defined array type can be referenced anywhere that an expression that returns the same data type as an element of that array can be used.

An *unnamed array type* is an array without an associated user-defined data type. The result of invocation of the aggregate built-in function ARRAY_AGG or of an array constructor is an array without an associated user-defined data type. An element of an array without an associated user-defined array type cannot be directly referenced.

The value of an array index can be specified by an expression. That expression can include a reference to a column. If a column is defined with a column mask, the column mask is applied using the normal rules for applying a column mask.

The value of an index for an array element is never null. If an expression specifies a value for an index, and the expression evaluates to the null value, the null value is returned for the array value.

An array value can be specified using one of the following methods:

- A simple reference to a global variable, an SQL variable, or SQL parameter that is a user-defined array type.
- Invocation of the ARRAY_AGG function.
- Invocation of the ARRAY_DELETE or TRIM_ARRAY built-in functions.
- Use of an array constructor.
- Invocation of a CAST specification that returns an array value.

An array value cannot be stored in a table or returned to an external application.

Datetime data in the elements of an array is considered to be CCSID UNICODE (1208).

Related reference

Array constructor
An array constructor returns an ordinary array. An array constructor is specified by a list of expressions or a fullselect.

ARRAY_AGG
The ARRAY_AGG function returns an array in which each value of the input set is assigned to an element of the array.

TRIM_ARRAY
The TRIM_ARRAY function deletes elements from the end of an ordinary array.

CREATE MASK
The CREATE MASK statement creates a column mask at the current server. A *column mask* is used for column access control and specifies the value that should be returned for a specified column.

CALL
The CALL statement invokes a stored procedure.

Promotion of data types

Data types can be classified into groups of related data types. Within such groups, an order of precedence exists in which one data type is considered to precede another data type. This precedence enables Db2 to support the *promotion* of one data type to another data type that appears later in the precedence order.

For example, Db2 can promote the data type CHAR to VARCHAR and the data type INTEGER to DOUBLE PRECISION; however, Db2 cannot promote a CLOB to a VARCHAR.

Db2 considers the promotion of data types when:

- Performing function resolution (see "Function resolution" on page 239)
- Casting distinct types (see "Casting between data types" on page 130)
- Assigning built-in data types to distinct types (see "User-defined type assignments" on page 153)

For each data type, the following table shows the precedence list (in order) that Db2 uses to determine the data types to which the data type can be promoted. The table indicates that the best choice is the same data type and not promotion to another data type. The table also shows data types that are considered equivalent during the promotion process. For example, CHARACTER and GRAPHIC are considered to be equivalent data types.

Table 21. Precedence of data types

Data type[1,2]	**Data type precedence list (in best-to-worst order)**
SMALLINT[3]	SMALLINT, INTEGER, BIGINT, decimal, real, double, DECFLOAT
INTEGER[3]	INTEGER, BIGINT, decimal, real, double, DECFLOAT
BIGINT[3]	BIGINT, decimal, real, double, DECFLOAT
decimal[3]	decimal, real, double, DECFLOAT
real	real, double, DECFLOAT
double	double, DECFLOAT
DECFLOAT	DECFLOAT
CHAR or GRAPHIC	CHAR or GRAPHIC, VARCHAR or VARGRAPHIC, CLOB or DBCLOB
VARCHAR or VARGRAPHIC	VARCHAR or VARGRAPHIC, CLOB or DBCLOB
CLOB or DBCLOB	CLOB or DBCLOB
BINARY	BINARY, VARBINARY, BLOB
VARBINARY	VARBINARY, BLOB
BLOB	BLOB
DATE	DATE
TIME	TIME
TIMESTAMP WITHOUT TIME ZONE	TIMESTAMP WITHOUT TIME ZONE or TIMESTAMP WITH TIME ZONE
TIMESTAMP WITH TIME ZONE	TIMESTAMP WITHOUT TIME ZONE or TIMESTAMP WITH TIME ZONE
ROWID	ROWID
XML	XML
A distinct type	The same distinct type

Table 21. Precedence of data types (continued)

Data type[1,2]	Data type precedence list (in best-to-worst order)

Notes:

1. The data types in lowercase letters represent the following data types:

   decimal
   DECIMAL(*p*,*s*) or NUMERIC(*p*,*s*)

   real
   REAL or FLOAT(*n*) where *n* is not greater than 21

   double
   DOUBLE, DOUBLE PRECISION, FLOAT or FLOAT(*n*) where *n* is greater than 21
2. Other synonyms for the listed data types are considered to be the same as the synonym listed.
3. Real and double are checked for function resolution purposes only. Additionally, the number of significant digits (even for DECFLOAT(16)), and the exponent range of DECFLOAT exceeds that of real and double (double has 16 significant digits). Therefore, DECFLOAT values will not be promoted to real or double.

Casting between data types

There are many occasions when a value with a given data type needs to be *cast* (changed) to a different data type or to the same data type with a different length, precision, or scale.

Data type promotion is one example where the promotion of one data type to another data type requires that the value be cast to the new data type. A data type that can be changed to another data type is *castable* from the base data type to the target data type.

The casting of one data type to another can occur implicitly or explicitly. The cast functions, CAST specification, or XMLCAST specification can be used to explicitly change a data type, depending on the data types involved. In addition, when a sourced user-defined function is created, the data types of the parameters of the source function must be castable to the data types of the function that is being created.

If truncation occurs when any data type is cast to a character or graphic data type, a warning occurs if any non-blank characters are truncated. The warning also occurs if any characters are truncated when a BLOB operand is cast, or if the time zone characters are truncated when a TIMESTAMP WITH TIME ZONE operand is cast to a string. This truncation behavior is similar to retrieval assignment of character or graphic strings. See "Retrieval assignment for character and graphic strings" in “String assignments” on page 149.

If truncation occurs when casting to a binary string, an error is returned.

For casts that involve a distinct type as either the data type to be cast to or from, Table 22 on page 131 shows the supported casts.

For casting a parameter marker or NULL value to the XML data type, the CAST specification can be used. XML input can also be specified for the CAST specification when the result data type is XML.

Casts that involve an array type as the target and a non-null source value must conform to the following rules:

- If the source value is an array with a user-defined array type:
  - The target array type must be the same user-defined array type.
  - If the target user-defined array type is an ordinary array, the cardinality of the source array value must be less than or equal to the maximum cardinality of the target array type.
- If the source value is an array without an associated user-defined array type:
  - The elements in the source array value must be castable to the data type of the elements of the target array type.

- The index values for the source array value must be castable to the data type of the index of the target array type.
- If the target user-defined array type is an ordinary array, the cardinality of the source array value must be less than or equal to the maximum cardinality of the target array type.

Table 22. Supported casts when a distinct type is involved

Data type ...	**Is castable to data type ...**
Distinct type *DT*	Base data type of distinct type *DT*
Source data type of distinct type *DT*	Distinct type *DT*
Distinct type *DT*	Distinct type *DT*
Data type *A*	Distinct type *DT* where *A* is promotable to the base data type of distinct type *DT* (see "Promotion of data types" on page 128)
INTEGER	Distinct type *DT* if *DT*'s base data type is SMALLINT
DOUBLE	Distinct type *DT* if *DT*'s base data type is REAL
VARCHAR	Distinct type *DT* if *DT*'s base data type is CHAR or GRAPHIC
VARGRAPHIC	Distinct type *DT* if *DT*'s base data type is GRAPHIC or CHAR
VARBINARY	Distinct type *DT* if *DT*'s base data type is BINARY

When a distinct type is involved in a cast, a cast function that was generated when the distinct type was created is used. How Db2 chooses the function depends on whether function notation or CAST specification syntax is used. (For details, see "Function resolution" on page 239 and "CAST specification" on page 266, respectively.) Function resolution is similar for both. However, in CAST specification, when an unqualified distinct type is specified as the target data type, Db2 first resolves the schema name of the distinct type and then uses that schema name to locate the cast function.

For casts between built-in data types, the following table shows the supported casts.

Table 23. Supported casts between built-in data types

Cast from data type –	To data type“1” on page 136																					
	SMALLINT	INTEGER	BIGINT	DECIMAL	DECFLOAT	REAL	DOUBLE	CHAR	VARCHAR	CLOB	GRAPHIC	VARGRAPHIC	DBCLOB	BINARY	VARBINARY	BLOB	DATE	TIME	TIMESTAMP WITHOUT TIME ZONE	TIMESTAMP WITH TIME ZONE	ROWID	XML

Table 23. Supported casts between built-in data types (continued)

Cast from data type –	To data type“1” on page 136																					
	SMALLINT	INTEGER	BIGINT	DECIMAL	DECFLOAT	REAL	DOUBLE	CHAR	VARCHAR	CLOB	GRAPHIC	VARGRAPHIC	DBCLOB	BINARY	VARBINARY	BLOB	DATE	TIME	TIMESTAMP WITHOUT TIME ZONE	TIMESTAMP WITH TIME ZONE	ROWID	XML
TIMESTAMP WITH TIME ZONE								Y	Y								Y	Y	Y	Y		
ROWID								Y	Y					Y	Y	Y					Y	
XML																						Y

Notes:

1. Other synonyms for the listed data types are considered to be the same as the synonym listed. Some exceptions exist when the cast involves character string data if the subtype is FOR BIT DATA.
2. The result length for these casts is `3 * LENGTH(graphic string)`.
3. These data types are castable between each other only if the data is Unicode.
4. FL 502 The conversion returns a Unicode graphic result. The result value must only be used in a context that supports Unicode data

Table 24 on page 136 shows where to find information about the rules that apply when casting to the identified target data types.

Table 24. Rules for casting to a data type

Target data type	Rules
SMALLINT	“SMALLINT” on page 570
INTEGER	“INTEGER or INT” on page 482

Table 24. Rules for casting to a data type (continued)

Target data type	Rules
BIGINT	"BIGINT" on page 396
DECIMAL	"DECIMAL or DEC" on page 441
NUMERIC	"DECIMAL or DEC" on page 441
REAL	"REAL" on page 537
DOUBLE	"DOUBLE_PRECISION or DOUBLE" on page 451
DECFLOAT	"DECFLOAT" on page 436
CHAR	"CHAR" on page 404
VARCHAR	"VARCHAR" on page 614
CLOB	"CLOB" on page 415
GRAPHIC	"GRAPHIC" on page 465
VARGRAPHIC	"VARGRAPHIC" on page 631
DBCLOB	"DBCLOB" on page 434
BINARY	"BINARY" on page 397
VARBINARY	"VARBINARY" on page 613
BLOB	"BLOB" on page 400
DATE	"DATE" on page 425
TIME	"TIME" on page 583
TIMESTAMP WITHOUT TIME ZONE	If the base data type is a character or graphic string, see "TIMESTAMP" on page 583, where one operand is specified. If the string contains a time zone, an error is returned. If the base data type is a DATE, the timestamp is composed of the specified date and a time of 00:00:00. If the source is a TIMESTAMP WITH TIME ZONE, the resulting timestamp is the timestamp without time zone element of the specified datetime value, which is the local timestamp in the corresponding time zone. For example: `cast('2008-04-12-07.30.00.0-6:00' as TIMESTAMP)` returns `2008-04-12-07.30.00.0`. If the source type is a TIMESTAMP WITHOUT TIME ZONE the timestamp is the specified value.
TIMESTAMP WITH TIME ZONE	If the base data type is a character or graphic string or TIMESTAMP WITHOUT TIME ZONE, see "TIMESTAMP_TZ" on page 595, where two arguments are specified. The first argument is the string or timestamp. The second argument is the precision of the first argument. If the value contains a time zone, an error is returned. If the source type is a TIMESTAMP WITH TIME ZONE, the timestamp is the specified value.
ROWID	"ROWID" on page 562

Table 25. The derived length of an argument when a built-in scalar function is invoked and implicit casting is required.

	Target data type								
Source data type	**CHAR**	**GRAPHIC**	**VARCHAR**	**VAR-GRAPHIC**	**CLOB**	**DBCLOB**	**BLOB**	**TIME STAMP (*precision*)**	**DECFLOAT**

Casting non-XML values to XML values

Table 26. Supported Casts from Non-XML Values to XML Values

Source Data Type	**Target Data Type**	
	XML	**Resulting XML Schema Type**
SMALLINT	Y	xs:short
INTEGER	Y	xs:int
BIGINT	Y	xs:long
DECIMAL	Y	xs:decimal
DECFLOAT	N	

Table 26. Supported Casts from Non-XML Values to XML Values (continued)

Source Data Type	Target Data Type	
	XML	**Resulting XML Schema Type**
REAL	N	
FLOAT	Y	xs:double
DOUBLE	Y	xs:double
CHAR	Y	xs:string
VARCHAR	Y	xs:string
CLOB	Y	xs:string
GRAPHIC	Y	xs:string
VARGRAPHIC	Y	xs:string
DBCLOB	Y	xs:string
BINARY	N	
VARBINARY	N	
BLOB	N	
character type FOR BIT DATA	N	
DATE	N	
TIME	N	
TIMESTAMP WITHOUT TIME ZONE	N	
TIMESTAMP WITH TIME ZONE	N	
ROWID	N	
distinct type	N	

When character string values are cast to XML values, the resulting xs:string atomic value cannot contain illegal XML characters. If the input character string is not in Unicode, the input characters are converted to Unicode.

Casting XML values to non-XML values

An XMLCAST from an XML value to a non-XML value can be described as two casts: an XQuery cast that converts the source XML value to a target XQuery data type that corresponds to the SQL target type, followed by a cast from the corresponding XQuery data type to the actual SQL type. The target XQuery data type is an XML schema data type like xs:decimal or xs:string, as shown in the follow table.

An XMLCAST is supported if the target type has a corresponding XQuery target type that is supported, and if there is a supported XQuery cast from the type of the source value to the corresponding XQuery target type. The target type that is used in the XQuery cast is based on the corresponding XQuery target type and might contain some additional restrictions.

The following table lists the XQuery types that result from such conversion.

Table 27. Supported Casts from XML Values to Non-XML Values

Target Data Type	**Source Data Type**	
	XML	**Corresponding XQuery Target Type**
SMALLINT	Y	xs:integer
INTEGER	Y	xs:integer
BIGINT	Y	xs:integer
DECIMAL	Y	xs:decimal
DECFLOAT	Y	xs:double
REAL	Y	xs:double
FLOAT	Y	xs:double
DOUBLE	Y	xs:double
CHAR	Y	xs:string
VARCHAR	Y	xs:string
CLOB	Y	xs:string
GRAPHIC	Y	xs:string
VARGRAPHIC	Y	xs:string
DBCLOB	Y	xs:string
BINARY	N	
VARBINARY	N	
BLOB	N	
character type FOR BIT DATA	N	
DATE	Y	xs:date
TIME	Y	xs:time
TIMESTAMP	Y	xs:dateTime
ROWID	N	
distinct type	N	

The following restrictions are in effect when a value is cast from an XQuery target data type to a target SQL data type:

- If the target type is one of the character or graphic string types, the resulting XML value is converted, if necessary, to the CCSID of the target data type using the rules described in "Conversion rules for string assignment" in “String assignments” on page 149, before it is converted to the target type with a limited length. Truncation occurs if the specified length limit is smaller than the length of the resulting string after CCSID conversion. A warning occurs if any non-blank characters are truncated. If the target type is a fixed-length string type (CHAR or GRAPHIC) and the specified length of the target type is greater than the length of the resulting string from CCSID conversion, blanks are padded at the end. This truncation and padding behavior is similar to retrieval assignment of character or graphic strings.
- If the target type is DOUBLE or REAL and the source XML value after the XQuery cast is an xs:double value of INF, -INF, or NaN, an error is returned. If the source value is an xs:double negative zero, the value is converted to positive zero. If the source value is beyond the range of the target data type, an overflow error is returned. If the source value contains more significant digits than the precision of the target data type, the source value is rounded to the precision of the target data type.

- If the target type is DECFLOAT and the source XML value is an xs:double value of INF, -INF, or NaN, the result will be the corresponding special DECFLOAT values INF, -INF, or NaN. If the source value is an xs:double negative zero, the result is negative zero. If the target type is DECFLOAT(16) and the source value is beyond the range of DECFLOAT(16), an overflow error is returned. If the source value has more than 16 significant digits, the value is rounded according to the ROUNDING mode that is in effect. This rounding behavior is the same as what is used during the cast of DECFLOAT(34) to DECFLOAT(16).
- If the target type is DECIMAL, the resulting xs:decimal value is converted, if necessary, to the precision and scale of the target data type. The necessary number of leading zeros is added or removed. In the fractional part of the number, the necessary number of trailing zeros is added or the necessary number of digits is eliminated. This truncation behavior is similar to the behavior of the cast from DECIMAL to DECIMAL.
- If the target type is DATE, TIME, or TIMESTAMP WITHOUT TIME ZONE, the resulting XML value is adjusted to UTC time and the time zone component is removed. If the source does not include a time zone and the target data type is TIMESTAMP WITH TIME ZONE, zeroes are used for the time zone component. If the target type is TIME and the resulting XML value contains a seconds component with non-zero digits after the decimal point, those digits are truncated. If the target type is DATE or timestamp, the year part of the resulting xs:date or xs:dateTime value must be in the range of 0001 to 9999. If the target type is timestamp and the precision of the target timestamp is less than 12, the fractional seconds part of the xs:dateTime value will be truncated to the target timestamp precision.

Implicit cast from numeric data to string data

When Db2 implicitly casts a numeric value to a string value, the target type is VARCHAR value which is then compatible with other character string or graphic string data types.

The length attribute and the CCSID attribute of the result of the cast are determined in the same way as the VARCHAR function. When GRAPHIC or VARGRAPHIC data types are involved, the encoding scheme must be UNICODE. The following table shows the target type and length:

Table 28. Target type and length attribute for implicit cast from numeric types to string types

Source data type	**Target data type**
SMALLINT	VARCHAR(6)
INTEGER	VARCHAR(11)
BIGINT	VARCHAR(20)
NUMERIC or DECIMAL	VARCHAR(*precision*+2)
REAL	VARCHAR(24)
FLOAT	VARCHAR(24)
DOUBLE	VARCHAR(24)
DECFLOAT	VARCHAR(42)

Implicit conversion from a numeric value to a string value can happen during:

- Assignment (where the source value is a number and the target operand is a character string or graphic string data type).

  Among assignment statements, implicit casting is not supported for the SET statements for special registers, the RETURNS clause and RETURN statement for functions, and the SQL control statements: RETURN, SIGNAL, and RESIGNAL.
- Application of concatenation operators (CONCAT and ||)
- Application of set operators.

Implicit conversion is not supported in the following cases:

- One operand of a set operator is a numeric value and the other operand is a string value

- A numeric value is compared to or assigned to a string value that is the result of a fullselect which included a set operator
- Assignment to a global variable that is the target of a SELECT INTO statement

Implicit cast from string data to numeric data

When Db2 implicitly casts a character string or graphic string value to a numeric value, the target type is DECFLOAT(34) which is compatible with other numeric data types.

When GRAPHIC or VARGRAPHIC data types are involved, the encoding scheme must be UNICODE. The following table shows the target type and length:

Table 29. Target type and length attribute for implicit cast from string types to numeric types

Source data type	Target data type
CHAR	DECFLOAT(34)
VARCHAR	DECFLOAT(34)
GRAPHIC	DECFLOAT(34)
VARGRAPHIC	DECFLOAT(34)
CHAR FOR BIT DATA or VARCHAR FOR BIT DATA	N/A
BINARY	N/A
VARBINARY	N/A
BLOB	N/A
CLOB	N/A
DBCLOB	N/A

Implicit conversion from a string value to a numeric value can happen during:

- Assignment (where the source value is a character string or graphic string and the target operand is a numeric data type).
- Comparisons

  When a character string or graphic string value is compared with a numeric value, Db2 implicitly converts the string value to DECFLOAT(34) and applies numeric comparison rule between the DECFLOAT(34) value and the other numeric value.

  - Basic predicates, quantified predicates, and DISTINCT predicates (one operand is numeric value and the other operand is character string or graphic string value)

    Numeric is the dominant data type. The character or graphic string value is cast to DECFLOAT(34) value.

  - BETWEEN predicates

    Numeric is the dominant data type. If any of the three operands is a numeric value, Db2 implicitly casts the character or graphic string operands to DECFLOAT data type.

  - IN predicates

    Numeric is the dominant data type. If any of the operands is a numeric value, Db2 implicitly casts the character or graphic string operands to DECFLOAT data type.

  - *Searched-when-clause* of CASE expression

Pair-wise comparison is performed. Implicit cast of each pair follows the same rule as for a basic predicate. Implicit string and numeric cast is supported on *searched-when-clause* of CASE expression.

  - Search conditions in SQL control statements (one operand is numeric value and the other operand is character string or graphic string value)

    The search condition can appear in SQL control statements like the CASE statement, the IF statement, the REPEAT statement, and the WHILE statement. For comparisons in the search condition, numeric is the dominant data type. The character string or graphic string value is cast to a DECFLOAT(34) value. Implicit string and numeric cast is supported on the *searched-when-clause* of the CASE statement.

- Arithmetic operators (unary arithmetic operators + and - and infix arithmetic operators +, -, *, and /)

  If the operand of unary arithmetic operators is of a character string or graphic string data type, that operand is implicitly cast to DECFLOAT(34). For infix arithmetic operators, if one operand is a numeric value or both operands are character or graphic string values, Db2 implicitly casts the character string or graphic string operand to the DECFLOAT data type.

Implicit conversion is not supported in the following cases:

- One operand of a set operator is a string value and the other operand is a numeric value
- A string value is compared to or assigned to a numeric value that is the result of a fullselect which included a set operator
- For FULL OUTER JOIN when the join condition is between string and numeric data types
- Assignment to a global variable that is the target of a SELECT INTO statement

Assignment and comparison

The basic operations of SQL are assignment and comparison.

Assignment operations are performed during the execution of statements such as CALL, INSERT, UPDATE, MERGE, FETCH, SELECT INTO, SET *host-variable* or SET *assignment-statement*, and VALUES INTO statements. In addition, when a function is invoked or a stored procedure is called, the arguments of the function or stored procedure are assigned. Comparison operations are performed during the execution of statements that include predicates and other language elements such as MAX, MIN, DISTINCT, GROUP BY, and ORDER BY.

The basic rule for both operations is that data types of the operands must be compatible. The compatibility rule also applies to other operations that are described under "Rules for result data types" on page 166.

The following table shows the compatibility of data types for assignments and comparisons.

Table 30. Data Type Compatibility for Assignments and Comparisons

Operand	Binary integer	Decimal number	Floating point	Decimal floating point	Character string	Graphic string	Binary string	Date	Time	Timestamp without time zone	Timestamp with time zone	Row ID	User-defined type	XML“8” on page 145
Binary integer	Yes	Yes	Yes	Yes	“1” on page 145	“1” on page 145	No	No	No	No	No	No	“2” on page 145	No
Decimal number	Yes	Yes	Yes	Yes	“1” on page 145	“1” on page 145	No	No	No	No	No	No	“2” on page 145	No
Floating point	Yes	Yes	Yes	Yes	“1” on page 145	“1” on page 145	No	No	No	No	No	No	“2” on page 145	No
Decimal floating point	Yes	Yes	Yes	Yes	“1” on page 145	“1” on page 145	No	No	No	No	No	No	“2” on page 145	No
Character string	“1” on page 145	“1” on page 145	“1” on page 145	“1” on page 145	Yes	Yes “3” on page 145, “4” on page 145	No “5” on page 145	Yes “7” on page 145	Yes “7” on page 145	Yes“7” on page 145	Yes “7” on page 145	No	“2” on page 145	No

XML“8” on page 145	No	No	No	No	No	No	No	No	No	No	No	No	No	Yes

Table 30. Data Type Compatibility for Assignments and Comparisons (continued)

Operand	Binary integer	Decimal number	Floating point	Decimal floating point	Character string	Graphic string	Binary string	Date	Time	Timestamp without time zone	Timestamp with time zone	Row ID	User-defined type	XML“8” on page 145

1. LOBs and bit data are not supported.
2. The compatibility rules for user-defined types are as follows:
   - A user-defined distinct type value is only comparable to a value that is defined with the same user-defined distinct type. In general, assignments are supported between a distinct type value and its source data type.
   - A user-defined array type value is only comparable to a value that is defined with the same user-defined array type.

     This means that in general, an ordinary array type is not compatible with an associative array type. The following exceptions apply only to a CALL statement for a remote stored procedure:

     – A source value that is an ordinary array with an integer index can be specified for a target that is defined as an associative array, if the definitions of the array elements of the two arrays are compatible. Db2 transforms the ordinary array into an associative array with an integer index, preserving the ordering of the elements in the original ordinary array. However, if the associative array is defined with a VARCHAR index, an SQL error code is returned.

     – A source value that is an associative array can be specified for a target defined as an ordinary array . Db2 transforms the associative array into an ordinary array, by assigning the values of the array elements in the associative array in the same order in the target ordinary array, and assigning appropriate index values.

   For additional information, see “User-defined type assignments” on page 153.
3. On assignment and comparison from Graphic to Character, the resulting length in bytes is 3 `* (LENGTH(`*`graphic-string`*`))`, depending on the CCSIDs.
4. Character strings with subtype FOR BIT DATA are not compatible with Graphic Data.
5. All character strings, even those with subtype FOR BIT DATA, are not compatible with binary strings.
6. LOBs are not supported.
7. The compatibility of datetime and string values is subject to the following considerations:
   - Datetime values can be assigned to string columns and to string variables that are not LOB values.
   - A valid string representation of a datetime value can be assigned to a datetime column or variable, or be compared to a datetime value, as explained in “Datetime assignments” on page 151.

   In some situations an assignment of a string value to a datetime variable might not be supported, such as in the following examples:
   - An assignment of a string representation of a datetime value to a datetime host variable.
   - An assignment in SQL PL when a datetime SQL variable or SQL parameter is the target of a SELECT INTO statement after a SET CURRENT PACKAGESET statement is issued.
8. Character and graphic strings, including LOBs, can be assigned to XML columns. For comparison, XML can only be compared using the XMLEXISTS and NULL predicates.

Compatibility with a column that has a field procedure is determined by the data type of the column, which applies to the decoded form of its values.

A basic rule for assignment operations is that a null value cannot be assigned to:

- A column that cannot contain null values
- A non-Java host variable that does not have an associated indicator variable

  For a host variable that does have an associated indicator variable, a null value is assigned by setting the indicator variable to a negative value. See “Host variables” on page 227 for a discussion of indicator variables.
- A Java host variable that is a primitive type

  For a Java host variable that is not a primitive type, the value of that variable is set to a Java null value.

Numeric assignments

The basic rule for numeric assignments is that the whole part of a decimal or integer number cannot be truncated. If necessary, the fractional part of a decimal number is truncated.

Decimal or integer to floating-point

Because floating-point numbers are only approximations of real numbers, the result of assigning a decimal or integer number to a floating-point column or variable might not be identical to the original number.

Floating-point or decimal to integer

When a single precision floating-point number is converted to integer, rounding occurs on the seventh significant digit, zeros are added to the end of the number, if necessary, starting from the seventh significant digit, and the fractional part of the number is eliminated. When a double precision floating-point or decimal number is converted to integer, the fractional part of the number is eliminated.

The following example shows single precision floating-point numbers converted to an integer:

```
Floating-point number:           Results when assigned to an integer column
                                  or host variable:
2.0000045E6                      2000000
2.00000555E8                     200001000
```

The following example shows a double precision floating-point number converted to an integer:

```
Floating-point number:           Results when assigned to an integer column
                                  or host variable:
2.0000045E6                      2000004
2.00000555E8                     200000555
```

The following example shows a decimal number converted to an integer:

```
Decimal number:                  Results when assigned to an integer column
                                  or host variable:
2000004.5                        2000004
200000555.0                      200000555
```

Decimal to decimal

When a decimal number is assigned to a decimal column or variable, the number is converted, if necessary, to the precision and the scale of the target.

The necessary number of leading zeros is added or eliminated, and, in the fractional part of the number, the necessary number of trailing zeros is added, or the necessary number of trailing digits is eliminated.

Decimal to DECFLOAT

When a decimal number is assigned to a DECFLOAT column or variable, the number is converted to the precision (16 or 34) of the target. Leading zeros are eliminated.

Depending on the precision and scale of the decimal number, and the precision of the target, the value might be rounded to fit.

For static SQL statements other than CREATE VIEW, the ROUNDING bind option or the native SQL procedure option determines the rounding mode.

For dynamic SQL statements (and static CREATE VIEW statements), the special register CURRENT DECFLOAT ROUNDING MODE determines the rounding mode.

Integer to decimal

When an integer is assigned to a decimal column or variable, the number is converted first to a temporary decimal number and then, if necessary, to the precision and scale of the target.

The precision and scale of the temporary decimal number is 5,0 for a small integer, 11,0 for a large integer, or 19,0 for a big integer.

Integer to DECFLOAT

When an integer is assigned to a DECFLOAT column or variable, the number is converted first to a temporary decimal number and then to DECFLOAT.

The precision and scale of the temporary decimal number is 5,0 for a small integer, 11,0 for a large integer, or 19,0 for a big integer. The decimal number is then converted to DECFLOAT using the rules for Decimal to DECFLOAT. See “Decimal to DECFLOAT” on page 146.

Floating-point to floating-point

When a single precision floating-point number is assigned to a double precision floating-point column or variable, the single precision data is padded with eight hex zeros. When a double precision floating-point number is assigned to a single precision floating-point column or variable, the double precision data is converted and rounded up on the seventh hex digit.

In assembler, C, or C++ applications that are prepared with the FLOAT(IEEE) SQL processing option, floating-point constants and values in host variables are assumed to have IEEE floating-point format. All floating-point data is stored in Db2 in System/390 floating-point format.

Therefore, when the FLOAT(IEEE) SQL processing option is in effect, Db2 performs the following conversions:

- When a number in short or long IEEE floating-point format is assigned to a single-precision or double-precision floating-point column, Db2 converts the number to System/390 floating-point format.
- When a single-precision or double-precision floating-point column value is assigned to a short or long floating-point host variable, Db2 converts the column value to IEEE floating-point format.

Floating-point to decimal

When a single precision floating-point number is assigned to a decimal column or variable, the number is first converted to a temporary decimal number.

When a single precision floating-point number is assigned to a decimal column or variable, the number is first converted to a temporary decimal number of precision 6 by rounding on the seventh decimal digit. Twenty five zeros are then appended to the number to bring the precision to 31. Because of rounding, a number less than $0.5×10^{-6}$ is reduced to 0.

When a double precision floating-point number is assigned to a decimal column or variable, the number is first converted to a temporary decimal number of precision 15, and then, if necessary, truncated to the precision and scale of the target. In this conversion, zeros are added to the end of the number, if necessary, to bring the precision to 16. The number is then rounded (using floating-point arithmetic) on the sixteenth decimal digit to produce a 15-digit number. Because of rounding, a number less in magnitude than $0.5×10^{-15}$ is reduced to 0. If the decimal number requires more than 15 digits to the left of the decimal point, an error is reported. Otherwise, the scale is given the largest possible value that allows the whole part of the number to be represented without loss of significance.

The following examples show the effect of converting a double precision floating-point number to decimal:

- The floating-point number, `.123456789098765E-05` in decimal notation is, `.00000123456789098765`. Rounding adds 5 in the 16th position, so the number becomes `.00000123456789148765` and truncates the result to `.000001234567891`. Zeros are then added to the end of a 31-digit result, and the number becomes `.0000012345678910000000000000000`.
- The floating-point number, `1.2339999999999E+01` in decimal notation is, `12.33999999999900`. Rounding adds 5 in the 16th position, so the number becomes `12.33999999999905` and truncates the result to `12.3399999999990`. Zeros are then added to the end of a 31-digit result and the number becomes `12.33999999999900000000000000000`.

Floating point to DECFLOAT

When a single or double precision floating-point number is assigned to a DECFLOAT column or variable, the number is first converted to a temporary string representation of the floating point number. The string representation of the number is then converted to DECFLOAT.

DECFLOAT to integer

When a DECFLOAT is assigned to a binary integer column or variable, the fractional part of the number is lost.

The following example shows decimal floating-point numbers converted to an integer:

```
Decimal floating-point number:          Results when assigned to an integer column
                                        or host variable:
```

```
2.0000045E6                         2000004
2.00000555E8                        200000555
```

DECFLOAT to decimal

When a DECFLOAT value is assigned to a decimal column or variable, the DECFLOAT value is converted, if necessary, to the precision and the scale of the target.

During the assignment, the necessary number of leading zeros is added and, in the fractional part of the number, the necessary number of trailing zeros is added, or rounding occurs.

For static SQL statements other than CREATE VIEW, the ROUNDING bind option or the native SQL procedure option determines the rounding mode.

For dynamic SQL statements (and static CREATE VIEW statements), the special register CURRENT DECFLOAT ROUNDING MODE determines the rounding mode.

The following example shows decimal floating-point numbers converted to a decimal value:

```
Decimal floating-point number:      Results when assigned to an decimal(15,0)
                                    column or host variable:
2.0000045E6                         2000005
Decimal floating-point number:      Results when assigned to an decimal(15,2)
                                    column or host variable:
2.0000045E6                         2000004.50
2.00000555E8                        200000555.00
```

DECFLOAT to floating-point

Because floating-point numbers are only approximations of real numbers, the result of assigning a DECFLOAT value to a floating-point column or variable might not be identical to the original number.

The DECFLOAT value is first converted to a string representation, and is then converted to floating-point number.

DECFLOAT(16) to DECFLOAT(34)

When a DECFLOAT(16) is assigned to a DECFLOAT(34) column or variable, the exponent of the source is converted to the corresponding exponent in the result format, and the coefficient is extended by appending zeros on the left.

DECFLOAT(34) to DECFLOAT(16)

When a DECFLOAT(34) is assigned to a DECFLOAT(16) column or variable, the exponent of the source is converted to the corresponding exponent in the result format.

The source coefficient is rounded to the precision of the target.

For static SQL statements, the `ROUNDING` bind option or the native SQL procedure option determines the rounding mode.

For static SQL statements other than CREATE VIEW, the ROUNDING bind option or the native SQL procedure option determines the rounding mode.

For dynamic SQL statements (and static CREATE VIEW statements), the special register CURRENT DECFLOAT ROUNDING MODE determines the rounding mode.

To COBOL integers

Assignment to COBOL integer variables uses the full size of the integer.

Thus, the value placed in the COBOL data item might be out of the range of values.

COBOL supports some data types with no SQL equivalent (BINARY decimal and DISPLAY decimal data items, for example). In most cases, you can use COBOL statements to convert between the unsupported COBOL data types and the data types that SQL supports.

For Db2 for z/OS, the only BINARY numeric variables allowed as HOST variable are integer binary variables. The only DECIMAL host variables supported by SQL are packed decimal host variables.

For example, if COL1 contains a value of 12345, the following statements cause the value 12345 to be placed in A, even though A has been defined with only 4 digits:

```
01  A  PIC  S9999  BINARY.
EXEC SQL SELECT COL1
         INTO :A
         FROM TABLEX
END-EXEC.
```

The following example COBOL statement results in 2345 being placed in A:

```
MOVE 12345 TO A.
```

String assignments

There are two types of string assignments; storage assignment and retrieval assignment.

- *Storage assignment* is when a value is assigned to a column or to a transition variable.
- *Retrieval assignment* is when a value is assigned to a variable, except for a transition variable.

The rules differ for storage and retrieval assignment.

Binary string assignment

Binary string assignment involves assignment at both the storage and the retrieval of binary strings.

Storage assignments

The length of a string that is assigned to a column or transition variable must not be greater than the length attribute of the column or parameter. If the string is longer than the length attribute of that column or transition variable, an error is returned.

When the string is assigned to a fixed-length binary string column or parameter of a function or procedure, and the length of the string is less than the length attribute of that column or parameter, the string is padded to the right with the necessary number of binary zeros.

Retrieval assignments

The length of a string that is assigned to a variable can be greater than the length attribute of the variable. When a string is assigned to a variable and the string is longer than the length attribute of the variable, the string is truncated on the right by the necessary number of bytes. When this occurs, a warning is returned.

Character and graphic string assignment

The rules for storage and retrieval assignment apply when both the source and the target are strings.

When a datetime data type is involved, see "Datetime assignments" on page 151. For the special considerations that apply when a distinct type is involved in an assignment, especially to a variable, see "Distinct type assignments" on page 153.

Storage assignment for character and graphic strings

The basic rule for character storage assignment is that the length of a string that is assigned to a column or transition variable must not be greater than the length attribute of the column or transition variable.

Trailing blanks are included in the length of the string. When the length of the string is greater than the length attribute of the column or the parameter, the following actions occur:

- If all of the trailing characters that must be truncated to make a string fit the target are blanks and the string is a character or graphic string, the string is truncated and assigned without warning.
- Otherwise, the string is not assigned and an error occurs to indicate that at least one of the excess characters is non-blank.

When a string is assigned to a fixed-length column or parameter and the length of the string is less than the length attribute of the target, the string is padded to the right with the necessary number of SBCS or DBCS blanks. The pad character is always a blank even for columns or parameters that are defined with the FOR BIT DATA attribute.

Retrieval assignment for character and graphic strings

The length of a string that is assigned to a variable can be greater than the length attribute of the variable. When the length of the string is greater than the length of the variable, the string is truncated on the right by the necessary number of SBCS or DBCS characters.

When truncation occurs, a warning is returned (SQLSTATE of '01004'). If the variable is a host variable, the value 'W' is assigned to the SQLWARN1 field of the SQLCA. Furthermore, if an indicator variable is provided and the source of the value is not a LOB, the indicator variable is set to the original length of the string. The truncation result of an improperly formed mixed string is unpredictable.

When a character string is assigned to a fixed-length variable and the length of the string is less than the length attribute of the target, the string is padded to the right with the necessary number of blanks. The pad character is always a blank even for strings defined with the FOR BIT DATA attribute.

When a string of length *n* is assigned to a varying-length string variable with a maximum length greater than *n*, the characters after the *n*th character of the variable are undefined.

Assignments involving mixed data strings

A mixed data string that contains MBCS characters cannot be assigned to an SBCS column, SBCS parameter, or SBCS variable.

The following rules apply when a mixed data string is assigned to a variable and the string is longer than the length attribute of the variable:

- If the string is not well-formed mixed data, it is truncated as if it were BIT or graphic data.
- If the string is well-formed mixed data, it is truncated on the right such that it is well-formed mixed data with a length that is the same as the length attribute of the variable and the number of characters lost is minimal.

Assignments involving C NUL-terminated strings

A C NUL-terminated string variable that is referenced in a CONNECT statement does not need to contain a NUL. Otherwise, Db2 enforces the convention that the value of a NUL-terminated string variable, either character or graphic, is NUL-terminated.

An input variable that does not contain a NUL will cause an error. A value that is assigned to an output variable will always be NUL-terminated even if a character must be truncated to make room for the NUL.

When a string of length *n* is assigned to a C NUL-terminated string variable with a length greater than *n*+1, the rules depend on whether the source string is a value of a fixed-length string or a varying-length string:

- If the source is a fixed-length string and the value of field PAD NUL-TERMINATED on installation panel DSNTIP4 is YES, the string is padded on the right with *x*-*n*-1 blanks, where *x* is the length of the variable. The padded string is then assigned to the variable and a NUL is appended at the end of the variable. If the value of field PAD NUL-TERMINATED is NO, the string is assigned to the first *n* bytes of the variable and a NUL is appended at the end of the variable.
- If the source is a varying-length string, the string is assigned to the first *n* bytes of the variable and a NUL is appended at the end of the variable.

Conversion rules for string assignment

A character or graphic string that is assigned to a column or variable is first converted, if necessary, to the coded character set of the target. Conversion is necessary only if certain conditions apply.

Conversion is necessary only if all the following conditions are true:

- The CCSIDs of string and target are different.
- Neither CCSID is X'FFFF' (neither the string nor the target is defined as BIT data).
- The string is neither null nor empty.

An error occurs if:

- The SYSSTRINGS table is used but contains no information about the pair of CCSIDs and Db2 cannot do the conversion through z/OS support for Unicode.
- A character of the string cannot be converted and the operation is assignment to a column or to a host variable that has no indicator variable. For example, a DBCS character cannot be converted to a variable with an SBCS CCSID.

A warning occurs if:

- A character of the string is converted to a substitution character. A *substitution character* is the character that is used when a character of the source character set is not part of the target character set. For example, assuming an EBCDIC target character set, if the source character set includes Katakana characters and the target character set does not, a Katakana character is converted to the EBCDIC SUB X'3F'.
- A character of the string cannot be converted and the operation is assignment to a variable that has an indicator variable. For example, a DBCS character cannot be converted if the variable has an SBCS CCSID. In this case, the string is not assigned to the variable and the indicator variable is set to -2.

Datetime assignments

A string value that is assigned to a date, time, or timestamp column, variable, or parameter must be a valid string representation of a date, a time, or a timestamp.

A value that is assigned to a date column, a date variable, or a date parameter must be a date, a valid string representation of a date, or a valid string representation of a timestamp without a time zone. When a string representation of a timestamp without a time zone is assigned to a date target, the Db2 database manager assigns the date portion of the timestamp to the date target, and does not use the time portion of the timestamp.

A date can be assigned only to the following items:

- a date column
- a character-string column
- a character-string variable
- a date variable

A value that is assigned to a time column, a time variable, or a time parameter must be a time, a valid string representation of a time, or a valid string representation of a timestamp without a time zone. When a string representation of a timestamp without a time zone is assigned to a time target, the Db2 database manager assigns the time portion of the timestamp to the time target, truncates any fractions of seconds, and does not use the date portion of the timestamp.

A time can be assigned only to the following items:

- a time column
- a character-string column
- a character-string variable
- a time variable

A value that is assigned to a timestamp column, a timestamp variable, or a timestamp parameter must be a timestamp, a timestamp constant, a valid string representation of a timestamp, or a valid string representation of a date. When a string representation of a date is assigned to a timestamp target, the Db2 database manager inserts zeroes for the time portion of the timestamp target.

A timestamp can be assigned only to the following items:

- a timestamp column
- a character-string or graphic-string column
- a timestamp variable
- a character-string or graphic-string variable

A valid string representation of a datetime value must not be a BLOB, CLOB, or DBCLOB. A datetime value cannot be assigned to a column that has a field procedure. If the timestamp precision of the target is less than the timestamp precision of the assigned value, the extra fractional seconds are truncated.

When a datetime value is assigned to a character-string variable or column, it is converted to its string representation. Leading zeros are not omitted from any part of the date, time, or timestamp. The required length of the target varies depending on the format of the string representation. If the length of the fixed length character-string target is greater than required, it is padded on the right with blanks. If the length of the target is less than required, the result depends on the type of datetime value involved, and the type of the target.

When a datetime value is assigned to a timestamp variable or column, it is converted to the target timestamp data type. If the source data type is not the same as the target data type, the source value is implicitly cast to the target data type. Db2 might implicitly cast data types during assignments that involve a distinct type.

- If the target is not a variable and has a character-string or graphic-string data type (except for BLOB, CLOB, or DBCLOB), truncation is not allowed. The length of the column must be at least the following values:
  - 10 for a **DATE**
  - 8 for a **TIME**
  - 19 for a **TIMESTAMP WITHOUT TIME ZONE** with a precision of `0, 20+`*p* with precision of *p*
  - Sufficient to include the time zone (truncation is not allowed), for a **TIMESTAMP WITH TIME ZONE**
- When the target is a character-string or graphic-string variable, the following rules apply:
  - **For a date:** The length of the variable must not be less than 10.
  - **For a time:** If the USA format is used, the length of the variable must not be less than 8. This format does not include seconds.

    If the ISO, EUR, or JIS format is used, the length of the variable must not be less than 5. If the length is 5, 6, or 7, the seconds part of the time is omitted from the result and SQLWARN1 is set to 'W'. In this case, the seconds part of the time is assigned to the indicator variable if one is provided, and, if the length is 6 or 7, the value is padded with blanks so that it is a valid string representation of a time.
  - **For a timestamp:** The length of the variable must not be less than 19. If the source is TIMESTAMP WITH TIME ZONE, the length of the variable must be sufficient to include the time zone, truncation is not allowed.
    - If the length is between 19 and 31, the timestamp is truncated like a string, which causes the omission of one or more digits of the fractional seconds part of a timestamp.
    - If the length is 20, the trailing decimal point is excluded so that the value is a valid string representation of a timestamp with precision 0.

Row ID assignments

A row ID value can be assigned only to a column, parameter, or host variable with a row ID data type.

For the value of the ROWID column, the column must be defined as GENERATED BY DEFAULT and the column must have a unique, single-column index. The value that is specified for the column must be a valid row ID value that was previously generated by Db2.

XML assignments

XML data can be assigned to a column, but when the target is not a column, the XML data type can only be assigned to another XML data type.

When the target is a column (for example, data change statements), the source can be the XML data type, or CHAR, VARCHAR, CLOB, GRAPHIC, VARGRAPHIC, DBCLOB, BINARY, VARBINARY, or BLOB data types. When the source is not XML data, the source is implicitly parsed as if the XMLPARSE function is invoked with the STRIP WHITESPACE option. If the source data is graphic data, the encoding scheme must be Unicode.

All other data types cannot be assigned to a target of the XML data type.

User-defined type assignments

User-defined type assignments include distinct type assignments and array assignments.

Distinct type assignments

The rules that apply to the assignments of distinct types to host variables are different than the rules for all other assignments that involve distinct types.

Assignments to host variables: The assignment of distinct type to a host variable is based on the source data type of the distinct type. Therefore, the value of a distinct type is assignable to a host variable only if the source data type of the distinct type is assignable to the host variable.

Example: Assume that distinct type AGE was created with the following SQL statement:

```
CREATE TYPE AGE AS SMALLINT;
```

When the statement was executed, Db2 also generated these cast functions:

```
AGE (SMALLINT) RETURNS AGE
AGE (INTEGER) RETURNS AGE
SMALLINT (AGE) RETURNS SMALLINT
```

Next, assume that column STU_AGE was defined in table STUDENTS with distinct type AGE. Now, consider this valid assignment of a student's age to host variable *HV_AGE*, which has an INTEGER data type:

```
SELECT STU_AGE INTO :HV_AGE FROM STUDENTS WHERE STU_NUMBER = 200;
```

The distinct type value is assignable to host variable *HV_AGE* because the source data type of the distinct type (SMALLINT) is assignable to the host variable (INTEGER). If distinct type AGE had been based on a character data type such as CHAR(5), the above assignment would be invalid because a character type cannot be assigned to an integer type.

Assignments other than to host variables: A distinct type can be the source or target of an assignment. Assignment is based on whether the data type of the value to be assigned is castable to the data type of the target. ("Casting between data types" on page 130 shows which casts are supported when a distinct type is involved). Therefore, a distinct type value can be assigned to any target other than a host variable when:

- The target of the assignment has the same distinct type, or
- The distinct type is castable to the data type of the target

Any value can be assigned to a distinct type when:

- The value to be assigned has the same distinct type as the target, or
- The data type of the assigned value is castable to the target distinct type

For examples, sssume that the source data type for distinct type AGE is SMALLINT:

```
   CREATE TYPE AGE AS SMALLINT;
```

Next, assume that two tables TABLE1 and TABLE2 were created with four identical column descriptions:

```
AGECOL   AGE
SMINTCOL SMALLINT
INTCOL   INTEGER
DECCOL   DEC(6,2)
```

Using the following SQL statement and substituting various values for X and Y to insert values into various columns of TABLE1 from TABLE2, the following table shows whether the assignments are valid. Db2 uses assignment rules in this INSERT statement to determine if X can be assigned to Y.

```
   INSERT INTO TABLE1 (Y)
        SELECT X FROM TABLE2;
```

Table 31. Assessment of various assignments for example INSERT statement

X (column in TABLE2)	Y (column in TABLE1)	Valid	Reason
AGECOL	AGECOL	Yes	Source and target are same distinct type
SMINTCOL	AGECOL	Yes	SMALLINT can be cast to AGE
INTCOL	AGECOL	Yes	INTEGER can be cast to AGE (because AGE's source type is SMALLINT)
DECCOL	AGECOL	No	DECIMAL cannot be cast to AGE
AGECOL	SMINTCOL	Yes	AGE can be cast to its source type of SMALLINT
AGECOL	INTCOL	No	AGE cannot be cast to INTEGER
AGECOL	DECCOL	No	AGE cannot be cast to DECIMAL

Array type assignments

An array value can only be assigned to a variable or parameter with a compatible user-defined array type.

The following values can be assigned to an array variable:

- The null value.
- The value of an array with a user-defined array type, where the source and target arrays have the same user-defined array type. The source value can be an array variable, an invocation of the TRIM_ARRAY function, an invocation of the ARRAY_DELETE function, or a CAST specification. The value of an ordinary array variable or parameter can only be assigned to an ordinary array target. The value of an associative array variable or parameter can only be assigned to an associative array target.
- The value of an array without a user-defined array type. The result of an invocation of aggregate built-in function ARRAY_AGG or of an array constructor is an array without an associated user-defined data type.

  For an assignment with a FETCH statement, the elements in the source array value must have the same data type as the elements of the user-defined array type of the target array. The index values of the source array value must have the same data type as the index of the user-defined array type of the target array.

For an assignment that is the result of a statement other than FETCH, the source array value is implicitly cast to the target array type.

Assignment of a value to an array element might affect the cardinality of the array, and might result in initializing other new array elements with the null value. Suppose that A is the target array variable, *c* is the cardinality of array A, *idx* is an expression that is used as the array index, and SV is the source value. Db2 assigns the values to the elements of the array as follows:

- If array A is the null value, A is set to an empty array.
- If A is an ordinary array:
  - If *idx* is less than or equal to *c*, the value in the element of A with array index *idx* is replaced by the value of SV.
  - If *idx* greater than *c*:
    - Each element of A with array index *i*, for every *i* that is greater than *c* and less than *idx*, is set to the null value.
    - The element of A with array index *idx* is set to the value of SV.
    - The cardinality of A is set to *idx*.
- If A is an associative array:
  - If *idx* matches an existing value of the array index for A, the value of the element with array index *idx* is replaced by the value of SV.
  - If *idx* does not match an existing value of the array index for A:
    - The element of A with array index *idx* is set to the value of SV.
    - The cardinality of A is incremented by 1.

The following values can be assigned to an element of an array variable:

- The null value
- The value of an expression, where the data type of the expression is assignable to the data type of the elements in the target array

Example: Assigning an array to another array

Suppose that arrays PHONELIST and HOMEPHONELIST are defined with the same user-defined array type named PLIST. PLIST is defined with VARCHAR(12) elements. The following statement assigns the values of the HOMEPHONELIST array to the PHONELIST array:

```
SET PHONELIST = HOMEPHONELIST;
```

Example: Assigning elements of an array to another array

Suppose that array V is defined with user-defined type MYARRAY. The following statement assigns the values 1, 2, and 3 to array V using an array constructor.

```
SET V = ARRAY[1,2,3];
```

This statement is equivalent to the following statement:

```
SET V = CAST(ARRAY[1,2,3] AS MYARRAY);
```

Example: Assigning values from a column to an array

Suppose that array V is defined with user-defined type MYARRAY. The following statement assigns the values from the column C1 in table T to array V using the ARRAY_AGG function.

```
SELECT ARRAY_AGG(C1) INTO V FROM T;
```

This statement is equivalent to the following statement:

```
SELECT CAST(ARRAY_AGG(C1) AS MYARRAY) INTO V FROM T;
```

Assignments to LOB locators

When a LOB locator is used, it can refer only to LOB data. If a LOB locator is used for the first fetch of a cursor, LOB locators must be used for all subsequent fetches.

Numeric comparisons

Numbers are compared algebraically, that is, with regard to sign. For example, -2 is less than +1. When numbers of different data types are compared, certain rules are in effect as to how the comparison is performed.

If one number is an integer and the other is decimal, the comparison is made with a temporary copy of the integer, which has been converted to decimal.

When decimal numbers with different scales are compared, the comparison is made with a temporary copy of one of the numbers that has been extended with trailing zeros so that its fractional part has the same number of digits as the other number.

If one number is double precision floating-point and the other is integer, decimal, or single precision floating-point, the comparison is made with a temporary copy of the other number which has been converted to double precision floating-point. However, if a single precision floating-point number is compared with a floating-point constant, the comparison is made with a single precision form of the constant.

Two floating-point numbers are equal only if the bit configurations of their normalized forms are identical.

If one number is DECFLOAT and the other number is integer, decimal, single precision floating-point, or double precision floating-point, the comparison is made with a temporary copy of the other number which has been converted to DECFLOAT.

If one number is DECFLOAT(16) and the other number is DECFLOAT(34), the DECFLOAT(16) value is converted to DECFLOAT(34) before the comparison.

Additionally, the DECFLOAT data type supports both positive and negative zero. Positive and negative zero have different binary representations, but the equal (=) predicate will return true for comparisons of positive and negative zero.

The functions, COMPARE_DECFLOAT and TOTALORDER can be used to perform comparisons at a binary level. For example, for a comparison of 2.0<>2.00.

The DECFLOAT data type also supports the specification of negative and positive NaN (quiet and signaling), and negative and positive infinity. From an SQL perspective, infinity = infinity, NaN = NaN, and sNaN = sNaN.

The following rules are the comparison rules for these special values:

- Infinity compares equal only to infinity of the same sign (positive or negative)
- NaN compares equal only to NaN of the same sign (positive or negative)
- sNaN compares equal only to sNaN of the same sign (positive or negative)

The ordering among the different special values is as follows: `-NAN < -SNAN < -INFINITY < 0 < INFINITY < SNAN <NAN`

String comparisons

String comparisons can occur with binary string, character strings, and graphic strings.

Binary string comparisons

Binary string comparisons are always performed according to the binary values.

Two binary strings are equal only if the lengths of the two strings are identical. If the strings are equal up to the length of the shorter string length, the shorter string is considered less than the longer string even when the remaining bytes in the longer string are hexadecimal zeros. This is illustrated in the following table:

Table 32. Binary string comparison where one operand is longer because of hexadecimal zeros

Hexadecimal value of the first operand	relationship	Hexadecimal value of the second operand
X'4100'	<	X'410000'
X'4100'	<	X'42'
X'4100'	=	X'4100'
X'4100'	>	X'41'
X'4100'	>	X'400000'

Binary strings cannot be compared to character strings (even FOR BIT DATA) unless the character string is cast to a binary string.

Character and graphic string comparisons

Two strings are compared by comparing the corresponding bytes of each string. If the strings do not have the same length, the comparison is made with a temporary copy of the shorter string that has been padded on the right with blanks so that it has the same length as the other string.

Two strings are equal if they are both empty or if all corresponding bytes are equal. An empty string is equal to a blank string. If two strings are not equal, their relationship (that is, which has the greater value) is determined by the comparison of the first pair of unequal bytes from the left end of the strings. This comparison is made according to the collating sequence associated with the encoding scheme of the data. For ASCII data, characters A through Z (both upper and lowercase) have a greater value than characters 0 through 9. For EBCDIC data, characters A through Z (both upper and lowercase) have a lesser value than characters 0 through 9.

Varying-length strings with different lengths are equal if they differ only in the number of trailing blanks. In operations that select one value from a collection of such values, the value selected is arbitrary. The operations that can involve such an arbitrary selection are DISTINCT, MAX, MIN, and references to a grouping column. See the description of GROUP BY for further information about the arbitrary selection involved in references to a grouping column.

For more information, see Objects with different CCSIDs in the same SQL statement (Db2 Internationalization Guide).

String comparisons with field procedures

The rules for string comparisons with field procedures depend on the values being compared. If a column with a field procedure is compared with the value of a variable or a constant, the variable or constant is encoded by the field procedure before the comparison is made. If the comparison operator is LIKE, the variable or constant is not encoded and the column value is decoded.

If a column with a field procedure is compared with another column, that column must have the same field procedure and both columns must have the same CCSID set. The comparison is performed on the encoded form of the values in the columns. If the encoded values are numeric, their data types must be identical; if they are strings, their data types must be compatible.

If two encoded strings of different lengths are compared, the shorter is temporarily padded with encoded blanks so that it has the same length as the other string.

In a CASE expression, if a column with a field procedure is used as the *result-expression* in a THEN or ELSE clause, all other columns that are used as *result-expressions* must have the same field procedure. Otherwise, no column used in a *result-expression* can name a field procedure.

Datetime comparisons

A date, time, or timestamp value can be compared with another value of the same data type, a datetime constant of the same data type, or with a string representation of a value of that data type. Additionally, a TIMESTAMP WITHOUT TIME ZONE value can be compared with a TIMESTAMP WITH TIME ZONE value.

All comparisons are chronological, which means the further a point in time is from January 1, 0001, the greater the value of that point in time. The time 24:00:00 compares greater than the time 00:00:00.

Comparisons that involve TIME values and string representations of time values always include seconds. If the string representation omits seconds, zero seconds are implied.

Comparisons that involve timestamp values are evaluated according to the following rules:

- When comparing timestamp values with different precisions, the higher precision is used for the comparison and any missing digits for fractional seconds are assumed to be zero.
- When comparing a TIMESTAMP WITH TIME ZONE value to a TIMESTAMP WITHOUT TIME ZONE value, the TIMESTAMP WITHOUT TIME ZONE value is cast to TIMESTAMP WITH TIME ZONE before the comparison is made.
- When comparing two TIMESTAMP WITH TIME ZONE values, the comparison is made using the UTC representations of the values. Two TIMESTAMP WITH TIME ZONE values are considered equal if they represent the same instance in UTC, regardless of the time zone offsets that are stored in the values. For example, '1999-04-15-08.00.00-08:00' (8:00 a.m. Pacific Standard Time) is the same as '1999-04-15-11.00.00-05:00' (11:00 a.m. Eastern Standard Time).
- When comparing a timestamp value with a string representation of a timestamp, the string representation is first converted to a the data type of the timestamp operand. With the except that the converted value has a precision of 12. If the timestamp operand is TIMESTAMP WITHOUT TIME ZONE, the string must not contain a specification of time zone.
- Timestamp comparisons are chronological without regard to representations that might be considered equivalent. For example, the following predicate is true:

  ```
  TIMESTAMP('1990-02-23-00.00.00') > '1990-02-22-24.00.00'
  ```

Example 1: Table TABLE1 has 2 columns: C1, which is defined as TIMESTAMP WITH TIME ZONE; and C2, which is defined as TIMESTAMP WITHOUT TIME ZONE:

```
CREATE TABLE TABLE1 (C1 TIMESTAMP WITH TIME ZONE, C2 TIMESTAMP);
```

A row is inserted into the table with the following INSERT statement. The input values are provided by character-string representations of a timestamp with a time zone.

```
INSERT INTO TABLE1 VALUES ( '2007-11-05-08.00.00-08:00', '2007-11-05-08.00.00');
```

Assuming that the implicit time zone is `-5:00`, the following SELECT statement will not return any rows. The string representation of the TIMESTAMP WITHOUT TIME ZONE value is cast to a TIMESTAMP WITH TIME ZONE value, which results in a timestamp with time zone value of

'2007-11-05-08.00.00-05:00' for column C2. The comparison predicate is false because the two values are not equal.

```
SELECT 1 FROM TABLE1 WHERE C1 = C2;
```

Example 2: When a TIMESTAMP WITHOUT TIME ZONE value is compared with a string representation of a TIMESTAMP WITHOUT TIME ZONE or a TIMESTAMP WITH TIME ZONE value, the string representation is cast to TIMESTAMP WITHOUT TIME ZONE (regardless of whether the string contains a time zone). The comparison is performed using the two TIMESTAMP WITHOUT TIME ZONE values. Assume that *string_hv* contains a timestamp with time zone value of '2007-11-05-08.00.00-08:00'. The string value is cast to a TIMESTAMP WITHOUT TIME ZONE value of '2007-11-05-08.00.00', which is compared with the value that is stored in column C2. The following SELECT statement returns a single row because a row exists in the table with a timestamp without time zone value of '2007-11-05-08.00.00'.

```
SELECT 1 FROM TABLE1 WHERE C2 = :string_hv;
```

Row ID comparisons

A value with a row ID type can only be compared to another row ID value.

The comparison of the row ID values is based on their internal representations. The maximum number of bytes that are compared is 17 bytes, which is the number of bytes in the internal representation. Therefore, row ID values that differ in bytes beyond the 17th byte are considered to be equal.

XML comparisons

The XML data type cannot be directly compared to any data type, including the XML data type. The method for doing comparison is through the use of the XMLEXISTS predicate.

Conversion rules for comparisons

When two strings are compared, one of the strings is first converted, if necessary, to the coded character set of the other string. Conversion is necessary only if certain rules apply.

Conversion is necessary only if all of the following are true:

- The CCSIDs of the two strings are different.
- Neither CCSID is X'FFFF' (neither string is defined as a binary string).
- The string selected for conversion is neither null nor empty.
- The following conversion tables (Table 34 on page 161 or Table 35 on page 162) indicate when conversion is necessary.

The string selected for conversion depends on the type of the operands. For the purpose of CCSID determination, string expressions in a statement are divided into 6 types, as described in the following table.

Table 33. Operand types

Type of operand	CCSID of the operand type
Columns	CCSID from the containing table
String constants	CCSID associated with the application encoding scheme. For dynamic statements, this is the CURRENT APPLICATION ENCODING SCHEME special register. For static statements, this is the ENCODING bind option or the APPLICATION ENCODING SCHEME option of the CREATE PROCEDURE or ALTER PROCEDURE statement for native SQL procedures..

Table 33. Operand types (continued)

Type of operand	CCSID of the operand type
Special registers	CCSID associated with the application encoding scheme. For dynamic statements, this is the CURRENT APPLICATION ENCODING SCHEME special register. For static statements, this is the ENCODING bind option or the APPLICATION ENCODING SCHEME option of the CREATE PROCEDURE or ALTER PROCEDURE statement for native SQL procedures.
Host variables	CCSID specified in the DECLARE VARIABLE statement, associated with the application encoding scheme, or specified in SQLDAID or SQLDA
Global variables	CCSID of UNICODE
Derived value based on a column	CCSID derived from the source of the derived value. A derived value based on a column is an expression whose source is directly or indirectly based on columns. The CCSID of such an expression is the CCSID derived from its source. For example: • The CCSID of `SUBSTR(column_1, 5, length(column_2))` is the CCSID of column_1. Note that the CCSID of column_2 has no influence on the CCSID of SUBSTR. • The CCSID of `column_1 || 'ABC'` is the CCSID of column_1, derived from the rules described in Table 34 on page 161. • The CCSID of `column_1 || GX'42C1'` is the DBCS CCSID from the CCSID set of column_1, derived from the rules described in Table 34 on page 161 and Table 35 on page 162. • The CCSID of `COALESCE(EBCDIC_column_1, ASCII_column_1)` is the UNICODE CCSID, derived from the rules described in Table 34 on page 161. • The CCSID of `CAST(string_column_1 AS GRAPHIC(10))` is the DBCS CCSID from the CCSID set of string_column_1. • The CCSID of `CAST(EBCDIC_string_column_1 AS VARCHAR(10) CCSID UNICODE)` is the UNICODE CCSID derived from the rules described in Table 34 on page 161. • The CCSID of `CASE WHEN(1=1) THEN '1' ELSE ASCII_column_1 END` is the CCSID of ASCII_column_1, derived from the rules described in Table 34 on page 161. • The CCSID of `CASE WHEN(1=1) THEN EBCDIC_column_1 ELSE ASCII_column_1 END` is the UNICODE CCSID derived from the rules described in Table 34 on page 161. • The CCSID of a scalar fullselect (`SELECT column_1 FROM table_1`) is the CCSID of column_1.

Table 33. Operand types (continued)

Type of operand	CCSID of the operand type
Derived value not based on a column	CCSID derived from the source of the derived value. A derived value not based on a column is an expression whose source is not directly or indirectly based on any column. The CCSID of such an expression is the CCSID derived from its source. • For example, the CCSID of `SUBSTR('ABDC', 1, length('AB"))` is the CCSID of the string constant 'ABCD'. Note that the CCSID of column_1 has no influence on the CCSID of SUBSTR. • the CCSID of `user_defined_function1(column1)` is the output CCSID defined by user_defined_function1. • the CCSID of the cast function of distinct type, shape, is the CCSID of distinct type, shape. • the CCSID of `CURRENT SQLID || UX'0041'` is the UNICODE DBCS CCSID, derived from the rules described in Table 34 on page 161 and Table 35 on page 162. • the CCSID of `CAST('abc' as CHAR(10) CCSID UNICODE)` is the UNICODE CCSID.

The following table shows which operand supplies the target CCSID set when the comparison is part of an SQL statement involving multiple tables with different CCSID sets.

Table 34. Operand that supplies the CCSID for character conversion

	Second operand					
First operand	**Column value**	**String constant**	**Special register**	**Host variable**	**Derived value based on a column**	**Derived value not based on a column**
Column value	“1” on page 162	first operand	first operand	first operand, “2” on page 162	“1” on page 162	first operand
String constant	second operand	“1” on page 162	“1” on page 162	“1” on page 162	second operand	“1” on page 162
Special register	second operand	“1” on page 162	“1” on page 162	“1” on page 162	second operand	“1” on page 162
Host variable	second operand	“1” on page 162	“1” on page 162	“1” on page 162	second operand, “2” on page 162	“1” on page 162
global variable	second operand					
Derived value based on a column	“1” on page 162	first operand	first operand	first operand, “2” on page 162	“1” on page 162	first operand
Derived value not based on a column	second operand	“1” on page 162	“1” on page 162	“1” on page 162	second operand	“1” on page 162

Table 34. Operand that supplies the CCSID for character conversion (continued)

	Second operand					
First operand	Column value	String constant	Special register	Host variable	Derived value based on a column	Derived value not based on a column

Note:

1. If the CCSID sets are different, both operands are converted, if necessary, to Unicode. SBCS and Mixed are converted to UTF-8. DBCS is converted to UTF-16. See the next table to determine which operand supplies the CCSID for character conversion.
2. If the encoding scheme that is in effect for the statement is EBCDIC or ASCII, the host variable is Unicode graphic, and the value of the field MIXED DATA on installation panel DSNTIPF is NO, the column or the derived value that is based on a column supplies the target CCSID set.

The following table shows which operand is selected for conversion when both operands are based on a column or are not based on a column as represented in the previous table.

Table 35. Operand that supplies the CCSID for character conversion when both operands are based or not based on a column

	Second operand		
First operand	SBCS data	Mixed data	DBCS data
SBCS data		second operand“1” on page 162	second operand
Mixed data	first operand“1” on page 162		second operand
DBCS data	first operand	first operand	

Note:

1. For ASCII and EBCDIC data, the conversion depends on the value of the field MIXED DATA on installation panel DSNTIPF at the Db2 that does the comparison. If MIXED DATA = YES, the SBCS operand is converted to MIXED. If MIXED DATA = NO, the MIXED operand is converted to SBCS

For example, assume a comparison of the form:

```
   string-constant-SBCS =derived-value-not-based-on-column-DBCS
```

Assume that the operands have different encoding schemes. First look at Table 34 on page 161. The relevant table entry is in the third row and second column. The value for this entry shows that if the CCSID sets are different, the operands are converted to Unicode. The first operand (string-constant-SBCS) is converted to UTF-8 (Mixed) if it is not already Unicode. In addition, the second operand (derived-value-not-based-on-column-DBCS) is converted to UTF-16 (Unicode DBCS) if necessary. After the operands have been converted to Unicode, Table 35 on page 162 is used to determine which operand supplies the specific CCSID for the conversion. The relevant table entry is in the second row and third column. It indicates that the second operand (derived-value-not-based-on-column-DBCS) determines the CCSID because DBCS data takes precedence over Mixed data.

An error occurs if a character of the string cannot be converted, the SYSSTRINGS table is used but contains no information about the pair of CCSIDs of the operands being compared, or Db2 cannot do the conversion through z/OS support for Unicode. A warning occurs if a character of the string is converted to a substitution character.

A derived value based on a column is an expression that includes columns that affects the result CCSID of the expression. For example, in the expression `COL1||'abc'`, COL1 determines the result CCSID. Therefore, the expression `COL1||'abc'` is considered to be a derived value based on a column that continues to give the column precedence in any further comparisons. The expression `CASE WHEN COL1 > 1 THEN 'abc' ELSE 'def' END` contains a column that does not affect the result CCSID of the expression and is therefore not considered to be a derived value based on a column.

The following table defines which expressions are considered to be a derived value based on a column.

Table 36. Derived values based on a column

Expression	**Condition**
expression1 || *expression2*	*expression1* or *expression2* is a column or a derived value based on a column
CASE *when-clause* THEN *result-expression* ELSE *result-expression* END	any *result-expression* is a *string-expression* that is a column or derived value based on a column
CAST(*expression* as *data-type*)	*expression* is a *string-expression* that is a column or a derived value based on a column and *data-type* is a string data type
Scalar-fullselect: (SELECT *expression* FROM *table*)	*expression* is a *string-expression* that is a column or a derived value based on a column and *data-type* is a string data type

When a statement contains multiple CCSID sets, if the length of one of the strings changes after CCSID conversion, the string becomes a varying-length string. That is, the data type becomes VARCHAR, CLOB, VARGRAPHIC, or DBCLOB. The following table shows the worse case resulting lengths of CCSID conversion, where X is length in bytes.

Table 37. Worst case result length of CCSID conversion, where X represents LENGTH(string in bytes)

		To CCSID								
		EBCDIC			**ASCII**			**Unicode**		
From CCSID		**SBCS**	**Mixed**	**DBCS**	**SBCS**	**Mixed**	**DBCS**	**SBCS**	**UTF-8**	**UTF-16**
EBCDIC	SBCS	X	X	X*2“1” on page 164	X	X	X*2“1” on page 164	X“1” on page 164	X*3	X*2
	Mixed	X	X	X*2“1” on page 164	X	X	X*2“1” on page 164	X“1” on page 164	X*3	X*2
	DBCS	X*0.5[1]	X+2	X	X*0.5[1]	X	X	X*0.5	X*1.5	X
ASCII	SBCS	X	X	X*2“1” on page 164	X	X	X*2“1” on page 164	X“1” on page 164	X*3	X*2
	Mixed	X	X*1.8	X*2“1” on page 164	X	X	X*2[1]	X“1” on page 164	X*3	X*2
	DBCS	X*0.5“1” on page 164	X+2	X	X*0.5“1” on page 164	X	X	X*0.5	X*1.5	X

Table 37. Worst case result length of CCSID conversion, where X represents LENGTH(string in bytes) (continued)

		To CCSID								
		EBCDIC			**ASCII**			**Unicode**		
From CCSID		**SBCS**	**Mixed**	**DBCS**	**SBCS**	**Mixed**	**DBCS**	**SBCS**	**UTF-8**	**UTF-16**
Unicode	SBCS	X	X	X*2	X	X	X*2	X	X	X*2
	UTF-8	X	X*1.25	X	X	X	X	X	X	X*2
	UTF-16	X*0.5	X+2	X	X*0.5	X	X	X*0.5	X*1.5	X

Note:

1. Because of the high probability of data loss, IBM does not provide conversion tables for this combination of two CCSIDs and data subtypes.

User-defined type comparisons

User-defined type comparisons include distinct type comparisons and array comparisons.

Distinct type comparisons

A value with a distinct type can only be compared to another value with exactly the same type because distinct types have strong typing, which means that a distinct type is compatible only with its own type.

To compare a distinct type to a value with a different data type, the distinct type value must be cast to the data type of the comparison value or the comparison value must be cast to the distinct type. For example, because constants are built-in data types, a constant can be compared to a distinct type value only if it is first cast to the distinct type or vice versa.

The following table shows examples of valid and invalid comparisons, assuming the following SQL statements were used to define two distinct types AGE_TYPE and CAMP_DATE and table CAMP_ROSTER table.

```
CREATE TYPE AGE_TYPE AS INTEGER;
CREATE TYPE CAMP_DATE AS DATE;
CREATE TABLE CAMP_ROSTER
   ( NAME                VARCHAR(20),
     ATTENDEE_NUMBER     INTEGER NOT NULL,
     AGE                 AGE_TYPE,
     FIRST_CAMP_DATE     CAMP_DATE,
     LAST_CAMP_DATE      CAMP_DATE,
     BIRTHDATE           DATE);
```

Table 38. Examples of valid and invalid comparisons involving distinct types

SQL statement	**Valid**	**Reason**
Distinct types with distinct types		

`SELECT * FROM CAMP_ROSTER`
`   WHERE FIRST_CAMP_DATE < LAST_CAMP_DATE;`
	Yes	Both values are the same distinct type.

Distinct types with columns of the same source data type		

`SELECT * FROM CAMP_ROSTER`
`   WHERE AGE > ATTENDEE_NUMBER;`
	No	A distinct type cannot be compared to integer.

Table 38. Examples of valid and invalid comparisons involving distinct types (continued)

SQL statement	Valid	Reason

`SELECT * FROM CAMP_ROSTER`
`   WHERE INTEGER(AGE) > ATTENDEE_NUMBER;`
`SELECT * FROM CAMP_ROSTER`
`   WHERE CAST(AGE AS INTEGER) > ATTENDEE_NUMBER;`
	Yes	The distinct type is cast to an integer, making the comparison of two integers.

`SELECT * FROM CAMP_ROSTER`
`   WHERE AGE > AGE_TYPE(ATTENDEE_NUMBER);`
`SELECT * FROM CAMP_ROSTER`
`   WHERE AGE > CAST(ATTENDEE_NUMBER as`
`AGE_TYPE);`
	Yes	Integer ATTENDEE_NUMBER is cast to the distinct type AGE_TYPE, making both values the same distinct type.

Distinct types with constants		

`SELECT * FROM CAMP_ROSTER`
`   WHERE AGE IN (15,16,17);`
	No	A distinct type cannot be compared to a constant.

`SELECT * FROM CAMP_ROSTER`
`   WHERE INTEGER(AGE) IN (15,16,17);`
	Yes	The distinct type is cast to the data type of constants, making all the values in the comparison integers.

`SELECT * FROM CAMP_ROSTER`
`   WHERE AGE IN`
`   (AGE_TYPE(15),AGE_TYPE(16),AGE_TYPE(17));`
	Yes	Constants are cast to distinct type AGE_TYPE, making all the values in the comparison the same distinct type.

`SELECT * FROM CAMP_ROSTER`
`   WHERE FIRST_CAMP_DATE > '06/12/99';`
	No	A distinct type cannot be compared to a constant.

`SELECT * FROM CAMP_ROSTER`
`   WHERE FIRST_CAMP_DATE >`
`   CAST('06/12/99' AS CAMP_DATE);`
	No	The string constant '06/12/99', a VARCHAR data type, cannot be cast directly to distinct type CAMP_DATE, which is based on a DATE data type. As illustrated in the next row, the constant must be cast to a DATE data type and then to the distinct type.

`SELECT * FROM CAMP_ROSTER`
`   WHERE FIRST_CAMP_DATE >`
`   CAST(DATE('06/12/1999') AS CAMP_DATE);`
	Yes	The string constant '06/12/99' is cast to the distinct type CAMP_DATE, making both values the same distinct type. To cast a string constant to a distinct type that is based on a DATE, TIME, or TIMESTAMP data type, the string constant must first be cast to a DATE, TIME, or TIMESTAMP data type.

Distinct types with host variables		

`SELECT * FROM CAMP_ROSTER`
`   WHERE AGE BETWEEN :HV_INTEGER`
`AND :HV_INTEGER2;`
	No	The host variables have integer data types. A distinct type cannot be compared to an integer.

`SELECT * FROM CAMP_ROSTER`
`   WHERE AGE`
`   BETWEEN CAST(:HV_INTEGER AS AGE_TYPE)`
`   AND AGE_TYPE(:HV_INTEGER2);`
	Yes	The host variables are cast to distinct type AGE_TYPE, making all the values the same distinct type.

Table 38. Examples of valid and invalid comparisons involving distinct types (continued)

SQL statement	Valid	Reason

`SELECT * FROM CAMP_ROSTER`
`   WHERE FIRST_CAMP_DATE > :HV_VARCHAR;`
	No	The host variable has a VARCHAR data type. A distinct type cannot be compared to a VARCHAR.

`SELECT * FROM CAMP_ROSTER`
`   WHERE FIRST_CAMP_DATE >`
`   CAST(DATE(:HV_VARCHAR) AS CAMP_DATE);`
	Yes	The host variable is cast to the distinct type CAMP_DATE, making both values the same distinct type. To cast a VARCHAR host variable to a distinct type that is based on a DATE, TIME, or TIMESTAMP data type, the host variable must first be cast to a DATE, TIME, or TIMESTAMP data type.

Array type comparisons

Comparisons of array values are not supported. Elements of arrays can be compared based on the comparison rules for the data types of the elements of the arrays.

Rules for result data types

Rules that are applied to the operands of an operation determine the data type of the result. Certain rules apply in certain situations and apply depending on the data type of operands.

The rules apply to:

- Corresponding columns in set operations (UNION, INTERSECT, or EXCEPT)
- Result expressions of a CASE expression
- Arguments of the scalar functions COALESCE, IFNULL, MAX, and MIN
- Expression values of the IN list of an IN predicate
- Expression values for the elements in an array constructor
- Expression values for the arguments for a collection-derived table (UNNEST specification)
- Arguments of a BETWEEN predicate, except if the data types of all operands are numeric
- Arguments for the aggregation group ranges in OLAP specifications

For the result data type of expressions that involve the operators '/', '*', '+' and '-', see "Arithmetic operators in expressions" on page 249.

For the result data type of expressions that involve the CONCAT operator, see "Concatenation operators in expressions" on page 246.

Evaluation of the operands of an operation determines the data type of the result. If an operation has more than one pair of operands, Db2 determines the result type of the first pair, uses this result type with the next operand to determine the next result type, and so on. The last intermediate result type and the last operand determine the result type of the operation.

With the exception of the COALESCE function, the result of an operation can be null unless the operands do not allow nulls.

If the data type and attributes of any operand column are not the same as those of the result, the operand column values are converted to conform to the data type and attributes of the result. The conversion operation is exactly the same as if the values were assigned to the result. For example:

- If one operand column is CHAR(10), and the other operand column is CHAR(5), the result is CHAR(10), and the values derived from the CHAR(5) column are padded on the right with five blanks.
- If the whole part of a number cannot be preserved then an error is returned.

Related concepts

Conversion rules for comparisons
When two strings are compared, one of the strings is first converted, if necessary, to the coded character set of the other string. Conversion is necessary only if certain rules apply.

Numeric operands

Numeric types are compatible only with other numeric types.

Table 39. Result data types with numeric operands

One operand	Other operand	Data type of the result
SMALLINT	SMALLINT	SMALLINT
INTEGER	INTEGER	INTEGER
INTEGER	SMALLINT	INTEGER
BIGINT	SMALLINT	BIGINT
BIGINT	INTEGER	BIGINT
BIGINT	BIGINT	BIGINT
DECIMAL(*w*,*x*)	SMALLINT	DECIMAL(*p*,*x*) where $p = x+\max(w-x,5)$[1]
DECIMAL(*w*,*x*)	INTEGER	DECIMAL(*p*,*x*) where $p = x+\max(w-x,11)$[1]
DECIMAL(*w*,*x*)	BIGINT	DECIMAL(*p*,*x*) where $p = x+\max(w-x,19)$[1]
DECIMAL(*w*,*x*)	DECIMAL(y,z)	DECIMAL(*p*,*s*) where $p = \max(x,z)+\max(w-x,y-z)$[1]$s = \max(x,z)$
REAL	REAL	REAL
REAL	DECIMAL, BIGINT, INTEGER, or SMALLINT	DOUBLE
REAL	BIGINT	DOUBLE
DOUBLE	DOUBLE, REAL, DECIMAL, BIGINT, INTEGER, or SMALLINT	DOUBLE
DECFLOAT(*n*)	SMALLINT	DECFLOAT(*n*)
DECFLOAT(*n*)	INTEGER	DECFLOAT(*n*)
DECFLOAT(*n*)	BIGINT	DECFLOAT(34)
DECFLOAT(*n*)	DECIMAL(<=16,*s*)	DECFLOAT(*n*)
DECFLOAT(*n*)	DECIMAL(>16,*s*)	DECFLOAT (34)
DECFLOAT(*n*)	REAL	DECFLOAT(*n*)
DECFLOAT(*n*)	DOUBLE	DECFLOAT(*n*)
DECFLOAT(*n*)	DECFLOAT(*m*)	DECFLOAT(max(*n*,*m*))

Table 39. Result data types with numeric operands (continued)

One operand	Other operand	Data type of the result

Notes:

1. Precision cannot exceed 31.

Character and graphic string operands

Character and graphic strings are compatible with other character and graphic strings as long as there is a conversion between their corresponding CCSIDs.

Table 40. Result data types with string operands

One operand	Other operand	Data type of the result
CHAR(*x*)	CHAR(*y*)	CHAR(*z*) where *z* = max (*x*, *y*)
GRAPHIC(*x*)	CHAR(*y*)	VARGRAPHIC(*y*) where *y* > maximum length of a graphic
GRAPHIC(*x*)	CHAR(*y*)	GRAPHIC(*z*) where *z* = max (*x*, *y*)
VARCHAR(*x*)	VARCHAR(*y*) or CHAR(*y*)	VARCHAR(*z*) where *z* = max (*x*, *y*)
VARCHAR(*x*)	GRAPHIC(*y*)	VARGRAPHIC(*z*) where *z* = max (*x*, *y*)
VARGRAPHIC(*x*)	VARGRAPHIC(*y*), GRAPHIC(*y*), VARCHAR(*y*), or CHAR(*y*)	VARGRAPHIC(*z*) where *z* = max (*x*, *y*)
CLOB(*x*)	CLOB(*y*), VARCHAR(*y*), or CHAR(*y*)	CLOB(*z*) where *z* = max (*x*, *y*)
CLOB(*x*)	GRAPHIC(*y*) or VARGRAPHIC(*y*)	DBCLOB(*z*) where *z* = max (*x*, *y*)
DBCLOB(*x*)	CHAR(*y*), VARCHAR(*y*), CLOB(y), GRAPHIC(*y*), VARGRAPHIC(*y*), or DBCLOB(*y*)	DBCLOB(*z*) where *z* = max (*x*, *y*)

Character string subtypes are determined as indicated in the following table:

Table 41. Result data types with character string operands

One operand	Other operand	Data type of the result
Bit data	Mixed, SBCS, or bit data	Bit data
Mixed data	Mixed or SBCS data	Mixed data
SBCS data	SBCS data	SBCS data

Binary string operands

Binary strings are compatible with other binary strings. Binary strings include BINARY, VARBINARY, and BLOB.

Table 42. Result data types with binary string operands

One operand	Other operand	Data type of the result
BINARY(*x*)	BINARY(*y*)	BINARY(*z*) where *z* = max(*x*,*y*)

Table 42. Result data types with binary string operands (continued)

One operand	Other operand	Data type of the result
VARBINARY(*x*)	BINARY(*y*) or VARBINARY(*y*)	VARBINARY(*z*) where *z* = max(*x*,*y*)
BLOB(*x*)	BINARY(*y*), VARBINARY(*y*), or BLOB(*y*)	BLOB(*z*) where *z* = max(*x*,*y*)

Datetime operands

A date, time, or timestamp value is compatible with another value of the same type or any string expression that contains a valid string representation of the same type.

A DATE type is compatible with another DATE type or any string expression that contains a valid string representation of a date. A string representation is a value that is a built-in character string data type or graphic string data type. A string representation must not be a CLOB or DBCLOB and must have an actual length that is not greater than 255 bytes. The data type of the result is DATE.

A TIME type is compatible with another TIME type or any string expression that contains a valid string representation of a time. A string representation is a value that is a built-in character string data type or graphic string data type. A string representation must not be a CLOB or DBCLOB and must have an actual length that is not greater than 255 bytes. The data type of the result is TIME.

A timestamp type is compatible with another timestamp type, a timestamp constant, or any string expression that contains a valid string representation of a timestamp. A string representation is a value that is a built-in character string data type or graphic string data type. A string representation must not be a CLOB or DBCLOB and must have an actual length that is not greater than 255 bytes. The data type of the result is a timestamp as determined in the following table.

Table 43. Result data types with datetime operands

One operand	Other operand	Data type of the result
TIMESTAMP(*x*) WITHOUT TIME ZONE	TIMESTAMP(*y*) WITHOUT TIME ZONE	TIMESTAMP(max(*x*,*y*)) WITHOUT TIME ZONE
TIMESTAMP(*x*) WITHOUT TIME ZONE	CHAR(*y*) or VARCHAR(*y*)	TIMESTAMP(*x*) WITHOUT TIME ZONE [1]
TIMESTAMP(*x*) WITH TIME ZONE	TIMESTAMP(*y*) WITH TIME ZONE	TIMESTAMP(max(*x*,y)) WITH TIME ZONE
TIMESTAMP(*x*) WITH TIME ZONE	CHAR(*y*) or VARCHAR(*y*)	TIMESTAMP(*x*) WITH TIME ZONE
TIMESTAMP(*x*) WITH TIME ZONE	TIMESTAMP(*y*) WITHOUT TIME ZONE	TIMESTAMP(max(*x*,*y*)) WITH TIME ZONE

Note: If one operand is TIMESTAMP(*x*) WITHOUT TIME ZONE and the other operand is CHAR(*y*) or VARCHAR(*y*), the result data type is TIMESTAMP(*x*) WITHOUT TIME ZONE even if the string representation contains a time zone.

If both operands are in the same encoding scheme, the result is in that encoding scheme. Otherwise the result is in the application encoding scheme.

Row ID operands

A row ID data type is compatible only with itself. The result has a row ID data type.

XML operands

XML data is compatible only with other XML data. The data type of the result is XML.

Other data types can be treated as an XML data type by using the CAST specification or XMLPARSE functions to cast character, graphic, or binary data to XML data.

Distinct type operands

A distinct type is compatible only with itself. The data type of the result is the distinct type.

Constants

A *constant* (also called a *literal*) specifies a value. Constants are classified as null constants, string constants, numeric constants, or datetime constants. Numeric constants are further classified as integer, floating-point, decimal, or decimal floating-point. String constants are classified as character, graphic, or binary.

All constants, except null constants, have the attribute NOT NULL. A negative sign in a numeric constant with a value of zero is ignored.

Constants, other than null constants, have a built-in data type. Therefore, an operation that involves a constant and a distinct type requires that the distinct type be cast to the built-in data type of the constant or the constant be cast to the distinct type. For example, see "User-defined type comparisons" on page 164, which contains an example of casting data types to compare a constant to a distinct type.

Null constants

A null constant indicates the null value.

The NULL constant has no data type. The data type of the NULL keyword is provided by the context in which it is used, or you can use CAST to assign a data type.

Integer constants

An *integer constant* specifies an integer as a signed or unsigned number with a maximum of 19 digits that does not include a decimal point.

The data type of an integer constant is large integer if its value is within the range of a large integer. The data type of an integer constant is big integer if its value is outside the range of a large integer, but within the range of a big integer. A constant that is defined outside the range of big integer values is considered a decimal constant.

For example, the following values are integer constants:

```
64      -15      +100      32767      720176
```

In syntax diagrams, the term *integer* is used for a large integer constant that must not include a sign.

Floating-point constants

A *floating-point constant* specifies a double-precision floating-point number as two numbers separated by an E.

The first number can include a sign and a decimal point. The second number can include a sign but not a decimal point. The value of the constant is the product of the first number and the power of 10 specified by the second number. It must be within the range of floating-point numbers. The number of characters in the constant must not exceed 30. Excluding leading zeros, the number of digits in the first number must not exceed 17 and the number of digits in the second must not exceed 2.

For examples, the following floating-point constants represent the numbers '150', '200000', -0.22, and '500':

```
  15E1     2.E5    -2.2E-1     +5.E+2
```

Decimal constants

A decimal constant is a signed or unsigned number of no more than 31 digits and either includes a decimal point or is not within the range of binary integers.

The precision is the total number of digits, including those, if any, to the right of the decimal point. The total includes all leading and trailing zeros. The scale is the number of digits to the right of the decimal point, including trailing zeros.

The precision is the total number of digits, including those, if any, to the right of the decimal point. The total includes all leading and trailing zeros. The scale is the number of digits to the right of the decimal point, including trailing zeros.

For example, the following decimal constants have, respectively, precisions and scales of 5 and 2; 4 and 0; 2 and 0; and 23 and 2:

```
  025.50   1000.   -15.   +375893333333333333333.33
```

Decimal floating-point constant

A *decimal floating-point* constant specifies a decimal floating-point number as two numbers separated by an E. The first number can include a sign and a decimal point. The second number can include a sign but not a decimal point.

The value of the constant is the product of the first number and the power of 10 specified by the second number. The value must be within the range of DECFLOAT(34). The number of characters in the constant must not exceed 42. Excluding leading zeros, the number of digits in the first number must not exceed 34 and the number of digits in the second number must not exceed 4.

A constant that is specified as two numbers separated by an E is a decimal-floating point constant only if the value is outside the range of a floating-point constant. A constant that is specified as a number that does not contain an E, and has more than 31 digits, is also a decimal-floating point constant.

In addition to numeric constants, the following special values can be used to specify decimal-floating point special values:

- INF or INFINITY - represents infinity
- NAN - represents quiet not-a-number
- SNAN - represents signaling not-a-number

The special values can be any combination of uppercase or lowercase letters and can be preceded by an operational sign (+ or -).

SNAN results in a warning or exception when it is used in a numerical operation; NAN does not. SNAN can be used in non-numerical operations without causing a warning or exception. For example, SNAN can be used in the VALUES list of an insert operation or as a constant used in a comparison in a predicate.

When the special values are used in a predicate, the following order of precedence applies:

```
-NAN < -SNAN < -INFINITY < -0 < 0 < INFINITY < SNAN < NAN
```

For example, The following decimal floating-point constants represent the numbers 123456789012345678, sNaN, and negative infinity:

```
  123456789012345678E0         SNAN       -INFINITY
```

When one of the special values is used in a context where it could be interpreted as an identifier, such as a column name, cast a string constant that represents the special value to decimal-floating point.

```
CAST ('snan' AS DECFLOAT)
CAST ('INF' AS DECFLOAT)
CAST ('Nan' AS DECFLOAT)
```

Character string constants

A *character string constant* specifies a varying-length character string. A character string constant has one of the two following forms:

- A sequence of characters that starts and ends with a string delimiter, which is either an apostrophe (') or a quotation mark ("). For the factors that determine which is applicable, see "Apostrophes and quotation marks as string delimiters" on page 323. This form of string constant specifies the character string contained between the string delimiters. The number of bytes between the delimiters must not be greater than 32704. The limit of 32704 refers to the length (in bytes) of the UTF-8 representation of the string. If you produced the string in a CCSID other than UTF-8 (for example, an EBCDIC CCSID), the length of the UTF-8 representation might differ from the length of the string's representation in the source CCSID. Two consecutive string delimiters are used to represent one string delimiter within the character string.
- An X followed by a sequence of characters that starts and ends with a string delimiter. This form of a character string constant is also called a *hexadecimal constant*. The characters between the string delimiters must be an even number of hexadecimal digits. The number of hexadecimal digits must not exceed 32704. A hexadecimal digit is a digit or any of the letters A through F. If the MIXED DATA subsystem parameter is set to YES, hexadecimal digits in a hexadecimal constant must be specified in upper case. Otherwise, an error might be returned when SQL statements are processed. Under the conventions of hexadecimal notation, each pair of hexadecimal digits represents a character. A hexadecimal constant allows you to specify characters that do not have a keyboard representation.

The following examples are character strings constants. The right most string in the example ('') represents an empty character string constant, which is a string of zero length.

```
'12/14/1985'    '32'    'DON''T CHANGE'    X'FFFF'    ''
```

A character string constant is classified as mixed data if it includes a DBCS substring. In all other cases, a character string constant is classified as SBCS data. For information about the CCSID that is assigned to the constant, see Determining the encoding scheme and CCSID of a string (Introduction to Db2 for z/OS). A mixed string constant can be continued from one line to the next only if the break occurs between single byte characters. A Unicode string is always considered mixed regardless of the content of the string.

For Unicode, character constants can be assigned to UTF-8 and UTF-16. The form of the constant does not matter. Typically, character string constants are used only with character strings, but they also can be used with graphic UTF-16 data. However, hexadecimal constants are just character data. Thus, hexadecimal constants being used to insert data into UTF-16 data strings should be in UTF-8 format, not UTF-16 format. For example, if you wanted to insert the number 1 into a UTF-16 column, you would use X'31', not X'0031'. Even though X'0031' is a UTF-16 value, Db2 treats it as two separate UTF-8 code points. Thus, X'0031' would become X'00000031'.

Binary string constants

A *binary-string constant* specifies a varying-length binary string.

A binary-string constant is formed by specifying a BX followed by a sequence of characters that starts and ends with a string delimiter. The characters between the string delimiters must be an even number of hexadecimal digits. The number of hexadecimal digits must not exceed 32704.

A hexadecimal digit is a digit or any of the letters A through F (upper case or lower case). Under the conventions of hexadecimal notation, each pair of hexadecimal digits represents one byte. Note that this representation is similar to the representation of the character-constant that uses the X'' form; however binary-string constant and character-string constant are not compatible and the X'' form can not be used to specify a binary-string constant, just as the BX'' form cannot be used to specify a character-string constant.

he following examples are binary-string constants:

```
BX'0000'    BX'C141C242'     BX'FF00FF01FF'
```

Graphic string constants

A *graphic string constant* specifies a varying-length graphic string. For more information, see “Graphic string constants” on page 173.

Datetime constants

A *datetime constant* is a character string constant of a particular format. For more information, see “Datetime constants” on page 174

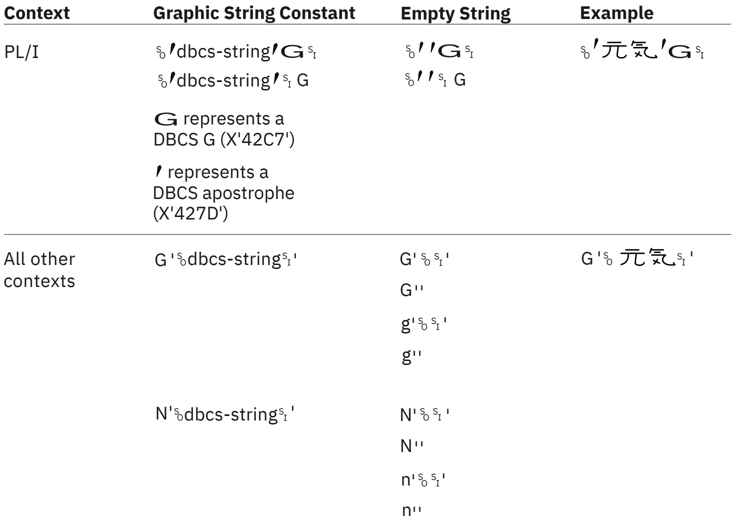
Related concepts

Data types
Db2 supports both IBM-supplied data types (built-in data types) and user-defined data types (distinct types).

Graphic string constants

A *graphic string constant* specifies a varying-length graphic string.

In EBCDIC environments, the forms of graphic string constants are shown in the following figure. (Shift-in and shift-out characters for EBCDIC data are discussed in “Character strings” on page 102.)[6]



Context	Graphic String Constant	Empty String	Example
PL/I	␎＇dbcs-string＇Ｇ␏ ␎＇dbcs-string＇␏ G Ｇ represents a DBCS G (X'42C7') ＇ represents a DBCS apostrophe (X'427D')	␎＇＇Ｇ␏ ␎＇＇␏ G	␎＇元気＇Ｇ␏
All other contexts	G'␎dbcs-string␏'	G'␎␏' G'' g'␎␏' g''	G'␎元気␏'
	N'␎dbcs-string␏'	N'␎␏' N'' n'␎␏' n''	

Lorem ipsum

Figure 23. Graphic string constants in EBCDIC

[6] The PL/I form of graphic string constants is supported only in static SQL statements.

In SQL statements and in host language statements in a source program, graphic string constants cannot be continued from one line to the next. A graphic string constant must be short enough so that its UTF-8 representation requires no more than 32704 bytes.

Db2 supports two types of hexadecimal graphic string constants.

- UX'xxxx' represents a string of graphic Unicode UTF-16 characters, where *x* is a hexadecimal digit. The number of digits must be a multiple of 4 and must not exceed 32704. Each group of 4 digits represents a single UTF-16 graphic character. For example, the UX constant for 'ABC' is UX'004100420043'.
- GX'xxxx' represents a string of graphic characters, where *x* is a hexadecimal digit. The number of digits must be a multiple of 4. Each group of 4 digits represents a single double-byte graphic character. The hexadecimal shift-in and shift-out ('OE'X and 'OF'X), which apply to EBCDIC only, are not included in the string.

  If the MIXED DATA installation option is set to NO, a GX constant cannot be used. Instead, a UX constant should be used. A GX constant cannot be used when the encoding scheme is UNICODE.

For information about the CCSID that is assigned to a graphic string constant, including UX'xxxx' and GX'xxxx' string constants, see Determining the encoding scheme and CCSID of a string (Introduction to Db2 for z/OS).

Datetime constants

A *datetime constant* is a character string constant of a particular format.

For more information about character-string constants, see "Constants" on page 170.

For information about the valid string formats, see "String representations of datetime values" on page 120.

Typically, character-string constants are used to represent constant datetime values in assignments and comparisons. However, the ANSI/ISO SQL standard form of a datetime constant can be used to specifically denote the constant as a datetime constant instead of a character-string constant. The format for the ANSI/ISO SQL standard datetime constants are as follows:

DATE *string-constant*

string-constant must contain a value that conforms to one of the valid formats for string representations of dates, subject to the following rules:

- leading blanks are not allowed.
- leading zeros can be omitted from the month and day elements of the date. An implicit specification of 0 is assumed for any digit that is omitted.
- leading zeros must be included for the year element of the date.
- trailing blanks can be included.

The data type of the value is DATE.

TIME *string-constant*

string-constant must contain a value that conforms to one of the valid formats for string representations of times, subject to the following rules:

- leading blanks are not allowed.
- leading zeros can be omitted from the hour elements of the time.
- the seconds element of the time can be omitted.
- trailing blanks can be included.
- if the USA format is not used and the minutes and seconds are all zeros, the hour can be 24.
- If the format is USA, the following additional rules apply:
  - the minutes element of the time can be omitted. For example, 1 PM is equivalent to 1:00 PM.
  - the letters A, M, and P can be specified in lowercase.
  - a single blank must precede the AM or PM.

- the hour must not be greater than 12 and cannot be 0 except when the time is specified as 00:00 AM.

An implicit specification of 0 is assumed for any digit that is omitted.

The correspondence between the USA format and the ISO format (24-hour clock) is as follows:

- 12:01 AM through 12:59 AM correspond to 00.01.00 through 00.59.00
- 01:00 AM through 11:59 AM correspond to 01.00.00 through 11.59.00
- 12:00 PM (noon) through 11:59 PM correspond to 12.00.00 through 23.59.00
- 12:00 AM (midnight) corresponds to 24.00.00
- 00:00 AM (midnight) corresponds to 00.00.00

The data type of the value is TIME.

TIMESTAMP *string-constant*

string-constant must contain a value that conforms to one of the formats listed in the following tables, subject to the following rules:

- leading blanks are not allowed.
- trailing blanks can be included.
- leading zeros can be omitted from the month, day, hour, and time zone hour elements of the timestamp. An implicit specification of 0 is assumed for any digit that is omitted.
- leading zeros must be included for the minute, second, and time zone minute elements of the timestamp
- the hour can be 24 if the minutes, seconds, and any fractional seconds are all zeroes.
- the separator character that follows the seconds element can be omitted if fractional seconds are not included.
- the number of digits of fractional seconds can vary from 0 to 12. An implicit specification of 0 is assumed if fractional seconds are omitted. The number of digits of fractional seconds determines the precision of the timestamp value.
- an optional single blank can be included between the time and the time zone elements.
- an optional time zone can be included, in one of the following formats:
  - ±th:tm, with values ranging from -24:00 to +24:00. A value of -0:00 is treated the same as +0:00.
  - ±th, with values ranging from -24 to +24 (an implicit specification of 00 is assumed for the time zone minute element)
  - uppercase Z to specify UTC

The data type of the value depends on the content of the string constant (where *p* is the number of digits of fractional seconds in the constant):

- **TIMESTAMP(*p*) WITHOUT TIME ZONE** if the content of the string constant conforms to the rules in the Table 44 on page 175 table.
- **TIMESTAMP(*p*) WITH TIME ZONE** if the content of the string constant conforms to the rules in the Table 45 on page 176 table.

Table 44. Formats used to specify a value for a data type of TIMESTAMP WITHOUT TIME ZONE

Description	**TIMESTAMP(0) WITHOUT TIME ZONE** [1, 3]	**TIMESTAMP(*p*) WITHOUT TIME ZONE** [2, 3]
Blank between date and time portions and colons in time portion.	• yyyy-mm-dd hh:mm:ss • yyyy-mm-dd hh:mm:ss.	yyyy-mm-dd hh:mm:ss.nnnnnnnnnnnn

Table 44. Formats used to specify a value for a data type of TIMESTAMP WITHOUT TIME ZONE (continued)

Description	TIMESTAMP(0) WITHOUT TIME ZONE [1, 3]	TIMESTAMP(*p*) WITHOUT TIME ZONE [2, 3]
Blank between date and time portions and periods in time portion.	• yyyy-mm-dd hh.mm.ss • yyyy-mm-dd hh.mm.ss.	yyyy-mm-dd hh.mm.ss.nnnnnnnnnnnn
Minus sign between date and time portions and colons in time portion.	• yyyy-mm-dd-hh:mm:ss • yyyy-mm-dd-hh:mm:ss.	yyyy-mm-dd-hh:mm:ss.nnnnnnnnnnnn
Minus sign between date and time portions and periods in time portion.	• yyyy-mm-dd-hh.mm.ss • yyyy-mm-dd-hh.mm.ss.	yyyy-mm-dd-hh.mm.ss.nnnnnnnnnnnn

Notes:

1. No fractional seconds; shown with and without optional trailing period after seconds
2. *p* is the number of digits of fractional seconds. *nnnnnnnnnnnn* can range 1 - 12 instances of *n*
3. As an additional format, the character T can be substituted as the separator between the date and time portions of the value.

Table 45. Formats used to specify a value for a data type of TIMESTAMP WITH TIME ZONE

Description	TIMESTAMP(0) WITH TIME ZONE[1, 3]	TIMESTAMP(*p*) WITH TIME ZONE [2, 3]
Blank between date and time portions and colons in time portion, no space between time and time zone.	• yyyy-mm-dd hh:mm:ss±th:tm • yyyy-mm-dd hh:mm:ss±th • yyyy-mm-dd hh:mm:ss.±th:tm • yyyy-mm-dd hh:mm:ss.±th	• yyyy-mm-dd hh:mm:ss.nnnnnnnnnnnn ±th:tm • yyyy-mm-dd hh:mm:ss.nnnnnnnnnnnn ±th
Minus sign between date and time portions and colons in time portion.	• yyyy-mm-dd-hh:mm:ss±th:tm • yyyy-mm-dd-hh:mm:ss±th • yyyy-mm-dd-hh:mm:ss.±th:tm • yyyy-mm-dd-hh:mm:ss.±th	• yyyy-mm-dd-hh:mm:ss.nnnnnnnnnnnn ±th:tm • yyyy-mm-dd-hh:mm:ss.nnnnnnnnnnnn ±th
Minus sign between date and time portions and periods in time portion.	• yyyy-mm-dd-hh.mm.ss±th:tm • yyyy-mm-dd-hh.mm.ss±th • yyyy-mm-dd-hh.mm.ss.±th:tm • yyyy-mm-dd-hh.mm.ss.±th	• yyyy-mm-dd-hh.mm.ss.nnnnnnnnnnnn ±th:tm • yyyy-mm-dd-hh.mm.ss.nnnnnnnnnnnn ±th
Blank between date and time portions, colons in time portion, blank between fractional seconds and sign for time zone.	• yyyy-mm-dd hh:mm:ss ±th:tm • yyyy-mm-dd hh:mm:ss ±th • yyyy-mm-dd hh:mm:ss. ±th:tm • yyyy-mm-dd hh:mm:ss. ±th	• yyyy-mm-dd hh:mm:ss.nnnnnnnnnnnn ±th:tm • yyyy-mm-dd hh:mm:ss.nnnnnnnnnnnn ±th

Table 45. Formats used to specify a value for a data type of TIMESTAMP WITH TIME ZONE (continued)

Description	TIMESTAMP(0) WITH TIME ZONE[1, 3]	TIMESTAMP(*p*) WITH TIME ZONE [2, 3]
Blank between date and time portions and periods in time portion.	• yyyy-mm-dd hh.mm.ss±th:tm • yyyy-mm-dd hh.mm.ss±th • yyyy-mm-dd hh.mm.ss.±th:tm • yyyy-mm-dd hh.mm.ss.±th	• yyyy-mm-dd hh.mm.ss.nnnnnnnnnnnn ±th:tm • yyyy-mm-dd hh.mm.ss.nnnnnnnnnnnn ±th

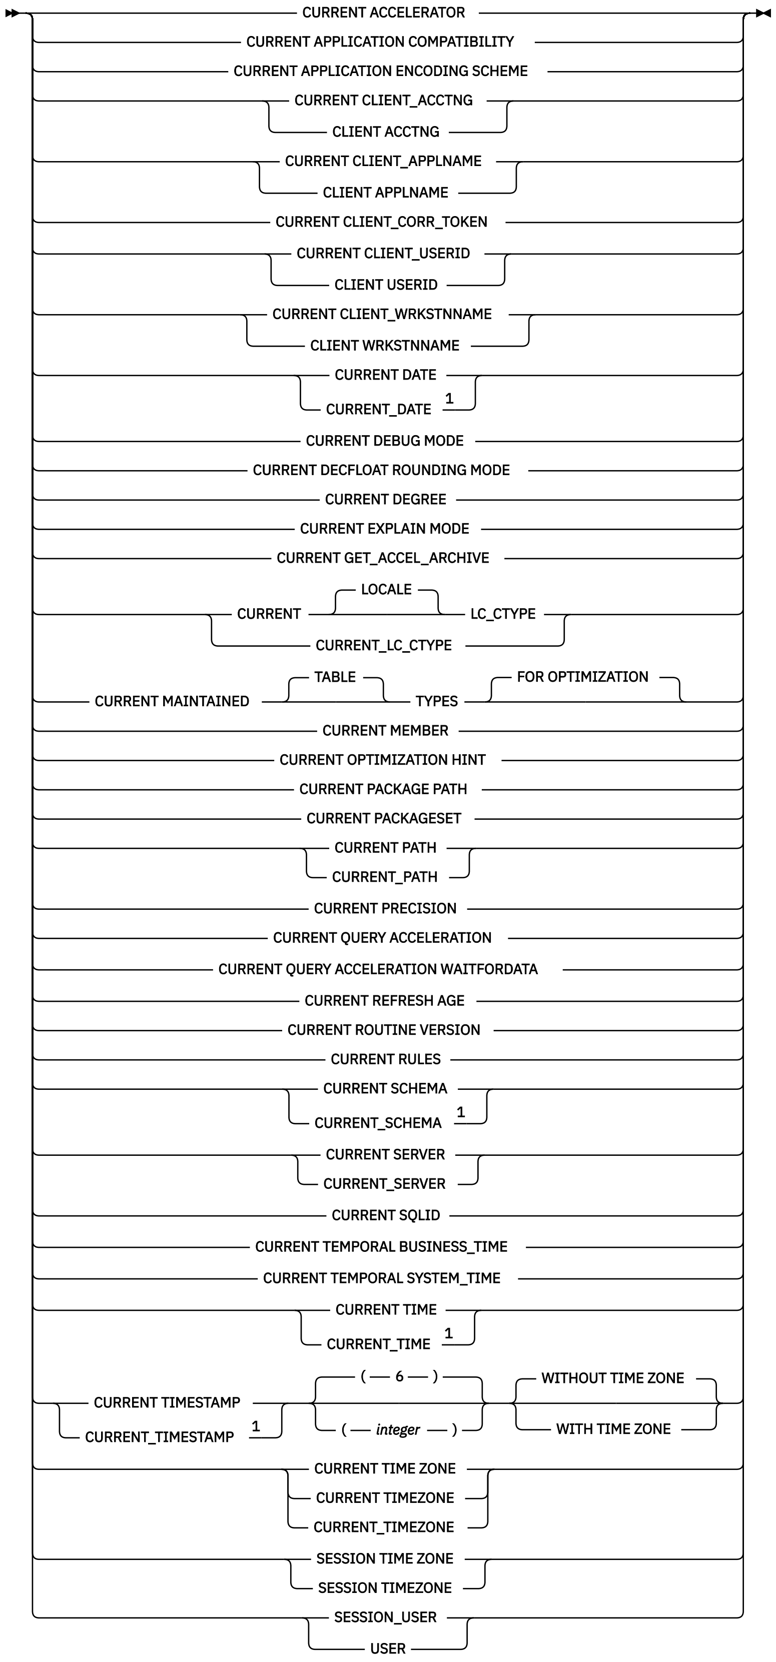
Notes:

1. No fractional seconds; shown with and without optional trailing period after seconds
2. *p* is the number of digits of fractional seconds. *nnnnnnnnnnnn* can range 1 - 12 instances of *n*
3. As an additional format, the character T can be substituted as the separator between the date and time portions of the value.

Special registers

A special register is a storage area that is defined for an application process by Db2 and is used to store information that can be referenced in SQL statements. A reference to a special register is a reference to a value provided by the current server. If the value is a string, its CCSID is a default CCSID of the current server.

The special registers can be referenced as follows:



Notes:

[1] The SQL standard uses the form with the underline.

General rules for special registers

Changing register values

A commit operation might cause special registers to be re-initialized. Whether a special register is affected by a commit depends on whether the special register has been explicitly set within the application process. For example, assume that the PATH special register has not been explicitly set with a SET PATH statement in the application process. After a commit, the value of PATH is re-initialized. For information on the initialization of PATH, which can take the current value of CURRENT SQLID into consideration, see "CURRENT SQLID special register" on page 207.

A rollback operation has no effect on the values of special registers. Nor does any SQL statement, with the following exceptions:

- SQL SET statements can change the values of the following special registers:
  - CURRENT ACCELERATOR
  - CURRENT APPLICATION COMPATIBILITY
  - CURRENT APPLICATION ENCODING SCHEME
  - CURRENT DEBUG MODE
  - CURRENT DECFLOAT ROUNDING MODE
  - CURRENT DEGREE
  - CURRENT EXPLAIN MODE
  - CURRENT GET_ACCEL_ARCHIVE
  - CURRENT LOCALE LC_CTYPE
  - CURRENT LOCK TIMEOUT
  - CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION
  - CURRENT OPTIMIZATION HINT
  - CURRENT PACKAGE PATH
  - CURRENT PACKAGESET
  - CURRENT PATH
  - CURRENT PRECISION
  - CURRENT QUERY ACCELERATION
  - CURRENT QUERY ACCELERATION WAITFORDATA
  - CURRENT REFRESH AGE
  - CURRENT ROUTINE VERSION
  - CURRENT RULES
  - CURRENT SCHEMA
  - CURRENT SQLID[7]
  - CURRENT TEMPORAL BUSINESS_TIME
  - CURRENT TEMPORAL SYSTEM_TIME
  - ENCRYPTION PASSWORD
  - SESSION TIME ZONE

[7] If the SET CURRENT SQLID statement is executed in a stored procedure or user-defined function package that has a dynamic SQL behavior other than run behavior, the SET CURRENT SQLID statement does not affect the authorization ID that is used for dynamic SQL statements in the package. The dynamic SQL behavior determines the authorization ID. For more information, see DYNAMICRULES bind option (Db2 Commands).

- SQL CONNECT statements can change the value of CURRENT SERVER.

Changing register values from IBM Data Server clients and drivers

In addition to using SQL SET statements, you can use the following IBM Data Server client and driver interfaces to change the values of most of the special registers that are listed under "Changing register values" on page 179:

- IBM Data Server Driver for JDBC and SQLJ method `DB2DataSource.setSpecialRegisters`
- For non-Java clients, the <specialregisters> subsection in the in db2dsdriver.cfg file

Use of these interfaces has the following restrictions:

- You cannot change the values of the following special registers:
  - CURRENT APPLICATION ENCODING SCHEME
  - CURRENT PACKAGESET
- The special register names are allowed to be in mixed case. Extraneous blanks between keywords are removed.
- The special register assigned value is stored as specified. The value must be valid for the special register.
- Special register values cannot be expressions, cannot reference other special registers, and cannot reference global variables.
- For CURRENT REFRESH AGE, the value 99999999999999 is not supported. Use the value ANY instead.
- Db2 treats all special register values that are passed through the client and driver interfaces as literal strings. For example, if a specified special register value is the same as the name of a special register, Db2 stores the special register name, and not the special register value.

Determining register values

You can use various statements to determine the value of a special register. For instance, a SELECT statement or a SET statement will provide the value of a special register. The following examples find the value of the CURRENT PRECISION special register:

```
SELECT CURRENT PRECISION FROM SYSIBM.SYSDUMMY1;

SET :hv = CURRENT PRECISION
```

CCSIDS for register values

Special registers that contain character strings have an associated CCSID. The particular CCSID depends on the context in which the special register is referenced. For more information, see Determining the encoding scheme and CCSID of a string (Introduction to Db2 for z/OS).

Datetime special registers

The datetime registers are named CURRENT DATE, CURRENT TIME, and CURRENT TIMESTAMP. Datetime special registers are stored in an internal format. When two or more of these registers are implicitly or explicitly specified in a single SQL statement, they represent the same point in time. A datetime special register is implicitly specified when it is used to provide the default value of a datetime column.

If the SQL statement in which a datetime special register is used is in a user-defined function or stored procedure that is within the scope of a trigger, Db2 uses the timestamp for the triggering SQL statement to determine the special register value.

The values of these special registers are based on:

- The time-of-day clock of the processor for the server executing the SQL statement
- The TIMEZONE parameter for this processor. The TIMEZONE parameter is in SYS1.PARMLIB(CLOCKXX).

To evaluate the references when the statement is being executed, a single reading from the time-of-day clock is incremented by the number of hours, minutes, and seconds specified by the TIMEZONE parameter. The values derived from this are assumed to be the local date, time, or timestamp, where local means local to the Db2 that executes the statement. This assumption is correct if the clock is set to local time and the TIMEZONE parameter is zero or the clock is set to UTC (Coordinated Universal Time) and the TIMEZONE parameter gives the difference from UTC.

Because the datetime special registers and the CURRENT TIMEZONE special register depend on the parameter PARMTZ(SYS1.PARMLIB(CLOCKXX)), their values are affected if the local time at the server is changed by the z/OS system command SET CLOCK. The values of the CURRENT DATE and CURRENT TIMESTAMP special registers might be affected if the local date at the server is changed by the system command SET DATE[8].

Where special registers are processed

In distributed applications, CURRENT APPLICATION ENCODING SCHEME, CURRENT SERVER, and CURRENT PACKAGESET are processed locally. All other special registers are processed at the server.

Rules for setting special registers by using profile tables

In remote applications, a special register can be referenced with a value from the profile attributes table. In addition to general rules, there are rules specific to using special registers set in profiles.

Changing register values

A rollback operation has no effect on the values of special registers.

SET statements for the following special registers can be specified in DSN_PROFILE_ATTRIBUTES table with the SPECIAL_REGISTER keyword. For detailed instructions, see Setting special registers by using profile tables (Db2 Administration Guide).

SET special register statement	Profile-specific considerations
“SET CURRENT ACCELERATOR” on page 2122	
“SET CURRENT APPLICATION COMPATIBILITY” on page 2123	
“SET CURRENT DEBUG MODE” on page 2126	
“SET CURRENT DECFLOAT ROUNDING MODE” on page 2127	
“SET CURRENT DEGREE” on page 2129	
“SET CURRENT EXPLAIN MODE” on page 2130	
“SET CURRENT GET_ACCEL_ARCHIVE” on page 2131	
“SET CURRENT LOCALE LC_CTYPE” on page 2132	The following syntax variations are not supported in profiles: • CURRENT LC_CTYPE • CURRENT_LC_CTYPE

[8] Whether the SET DATE command affects these special registers depends on the system level and the program temporary fix (PTF) level of the system.

SET special register statement	Profile-specific considerations
“SET CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION” on page 2134	The following syntax variations are not supported in profiles: • CURRENT MAINTAINED TYPES • CURRENT MAINTAINED TYPES FOR OPTIMIZATION
“SET CURRENT OPTIMIZATION HINT” on page 2135	
“SET CURRENT PACKAGE PATH” on page 2136	
“SET CURRENT PRECISION” on page 2141	
“SET CURRENT QUERY ACCELERATION” on page 2141	
“SET CURRENT QUERY ACCELERATION WAITFORDATA” on page 2143	
“SET CURRENT REFRESH AGE” on page 2146	The value 99999999999999 is not supported. Use the value ANY instead.
“SET CURRENT ROUTINE VERSION” on page 2147	
“SET CURRENT RULES” on page 2149	
“SET CURRENT SQLID” on page 2149	If the SET CURRENT SQLID statement is run in a stored procedure or user-defined function package that has a dynamic SQL behavior other than run behavior, the SET CURRENT SQLID statement does not affect the authorization ID that is used for dynamic SQL statements in the package. The dynamic SQL behavior determines the authorization ID. For more information, see DYNAMICRULES bind option (Db2 Commands).
“SET CURRENT TEMPORAL BUSINESS_TIME” on page 2151	
“SET CURRENT TEMPORAL SYSTEM_TIME” on page 2153	
“SET ENCRYPTION PASSWORD” on page 2154	
“SET PATH” on page 2156	
“SET SCHEMA” on page 2159	The following syntax variations are not supported in profiles: • CURRENT_SCHEMA (with underscore)
“SET SESSION TIME ZONE” on page 2161	The following syntax variations are not supported in profiles: • TIMEZONE • TIME ZONE • SESSION TIMEZONE

The following rules apply for the SET statements for special registers:

- An equal sign (=) must be specified between the special register name and the value that is assigned.
- The value that is specified for assignment must be valid for the special register.
- The value must not be an expression, or reference other special registers or variables, unless the statement is SET CURRENT PACKAGE PATH.
- The value that is specified for assignment is passed through this interface as a literal string, unless the statement is SET CURRENT PACKAGE PATH. For example, if a value to be assigned is the same as the name of a special register, Db2 stores the special register name, and not the special register value.
- The maximum length of a SET statement is 1024 bytes.
- The statement must be a Unicode string and encoded with the appropriate CCSID for the application.

Special register values that are set through the profile table take precedence over values that are set by the application before the first non-SET SQL statement. For example, values set by a profile override values that are set through a client connection or data source properties when the connection is first established. The special register values persist for the lifetime of the connection unless the application explicitly sets the special register. Special register values that are set explicitly by the application take precedence over values that are set by the profile table facility and values that are set by the client connection and data source properties. System directed connections, such as three-part name references, use the values of the special registers of the requesting Db2 site. For example, if a Java application establishes a connection to Db2 site 1, the special register values are established with the profile tables from site 1. Later, if the application runs an SQL statement with an implicit three-part name connection to Db2 site 2, then the special register values that are established on site 1 are referenced when the SQL statement runs on site 2.

Special register values that are set through the profile table facility observe the existing rules for inheritance within a routine as defined by INHERIT SPECIAL REGISTERS or DEFAULT SPECIAL REGISTERS routine options. After a user-defined function or a stored procedure completes, Db2 restores all special registers to the values they had before invocation.

As with other special register behavior, commits and rollbacks do not change special register values regardless of how they were established.

Special registers
A special register is a storage area that is defined for an application process by Db2 and is used to store information that can be referenced in SQL statements. A reference to a special register is a reference to a value provided by the current server. If the value is a string, its CCSID is a default CCSID of the current server.

Profile tables (Db2 Performance)

CURRENT ACCELERATOR special register

The CURRENT ACCELERATOR special register specifies a preferred target accelerator or accelerators to which Db2 sends dynamic SQL queries.

The CURRENT ACCELERATOR special register applies only to dynamic SQL queries. For static SQL queries, you can use the ACCELERATOR bind option to specify a particular accelerator.

If you have multiple accelerators on which the same set of Db2 tables are accelerated, by default the workload balancing algorithm (WLB) distributes the queries based on the queue length on each accelerator. When the CURRENT ACCELERATOR special register names a particular eligible accelerator server, Db2 considers sending eligible SQL to that server before it sends it to other accelerator servers. If the accelerator server that is named by the CURRENT ACCELERATOR isn't available, Db2 considers other available accelerator servers.

FL 509 For executing DML statements on an accelerator-only table that is defined in multiple accelerators, the CURRENT ACCELERATOR special register must specify one of the accelerators in which the table is defined.

Specifying a particular target accelerator is useful in the following situations:

- To direct queries to different accelerators based on the priorities of the workload. You can direct higher priority queries to the fastest, highest capacity accelerator, and you can direct lower priority queries to a slower accelerator.
- To avoid increased elapsed times that can occur when queries are sent to a remote accelerator. The WLB algorithm doesn't address the latency that occurs when a query is sent to a remote accelerator. If your environment includes both locally deployed accelerators and remote accelerators (for example, for disaster recovery), you can send higher priority queries to a local accelerator.

The data type is VARCHAR(8).

The initial value of CURRENT ACCELERATOR is determined by one of the following settings:

- If specified for the bind of a package, the ACCELERATOR bind option. This bind option does not have a default value.
- Otherwise, the default setting of CURRENT ACCELERATOR is blank (no preferred accelerator).

Example

The following statement sets the CURRENT ACCELERATOR special register so that ACCEL1 is the preferred accelerator.

```
SET CURRENT ACCELERATOR = ACCEL1;
```

“SET CURRENT ACCELERATOR” on page 2122
The SET CURRENT ACCELERATOR statement changes the value of the CURRENT ACCELERATOR special register.

ACCELERATOR bind option (Db2 Commands)

CURRENT APPLICATION COMPATIBILITY special register

CURRENT APPLICATION COMPATIBILITY specifies the application compatibility level support for dynamic SQL statements in packages.

The data type is VARCHAR(10).

Set the value with the SET CURRENT APPLICATION COMPATIBILITY statement.

For packages, the initial value is determined by the value of the APPLCOMPAT bind option. For a user-defined functions or stored procedures, the initial value is inherited according to the rules in “Special registers in a user-defined function or a stored procedure” on page 215. For advanced triggers, the initial value is V12R1.

The following CURRENT APPLICATION COMPATIBILITY values are supported to specify the application compatibility behavior of dynamic SQL statements:

V*vv*R*r*M*mmm*

Compatibility with the behavior of the identified Db2 function level. For example, V12R1M510 specifies compatibility with the highest available Db2 12 function level. The equivalent function level or higher must be activated.

For the new capabilities that become available in each application compatibility level, see:

- SQL changes in Db2 13 application compatibility levels
- SQL changes in Db2 12 application compatibility levels

Tip: Extra program preparation steps might be required to increase the application compatibility level for applications that use data server clients or drivers to access Db2 for z/OS. For more information, see Setting application compatibility levels for data server clients and drivers (Db2 Application programming and SQL).

V12R1
Compatibility with the behavior of Db2 12 function level 500. This value has the same result as specifying V12R1M500.

V11R1
Compatibility with the behavior of Db2 11 new-function mode. After migration to Db2 12, this value has the same result as specifying V12R1M100. For more information, see V11R1 application compatibility level (Db2 Application programming and SQL)

V10R1
Compatibility with the behavior of DB2 10 new-function mode. For more information, see V10R1 application compatibility level (Db2 Application programming and SQL).

Example

The following statement sets the host variable *CS* to the compatibility level.

```
EXEC SQL SET :CS = CURRENT APPLICATION COMPATIBILITY;
```

Related reference

BIND and REBIND options for packages, plans, and services (Db2 Commands)

SET CURRENT APPLICATION COMPATIBILITY
The SET CURRENT APPLICATION COMPATIBILITY statement assigns a value to the CURRENT APPLICATION COMPATIBILITY special register. This special register allows users to control the package compatibility level behavior for dynamic SQL.

APPL COMPAT LEVEL field (APPLCOMPAT subsystem parameter) (Db2 Installation and Migration)

-ACTIVATE (Db2) (Db2 Commands)

CURRENT APPLICATION ENCODING SCHEME special register

CURRENT APPLICATION ENCODING SCHEME specifies which encoding scheme is to be used for dynamic statements. It allows an application to indicate the encoding scheme that is used to process data. This register is not supported in REXX applications or in stored procedures written in REXX.

The value contained in the special register is a character representation of a CCSID. Although you can use the values ASCII, EBCDIC, or UNICODE to set the special register, what is stored in the special register is a character representation of the numeric CCSID that corresponds to the value used in the SET CURRENT APPLICATION ENCODING SCHEME statement. The value ASCII, EBCDIC, or UNICODE is not stored. The CCSID_ENCODING scalar function can be used to get a value of ASCII, EBCDIC, or UNICODE from a numeric CCSID value.

The data type is CHAR(8). If necessary, the value is padded on the right with blanks so that its length is 8 bytes.

For stored procedures and user-defined functions, the initial value of the CURRENT APPLICATION ENCODING SCHEME special register is determined by the value of the ENCODING bind option for the package that is associated with the procedure or function, or by the APPLICATION ENCODING SCHEME option of the CREATE FUNCTION, ALTER FUNCTION, CREATE PROCEDURE, or ALTER PROCEDURE statement for a compiled SQL function or a native SQL procedure. If the option was not specified, the initial value is the value of the field DEFAULT APPLICATION ENCODING SCHEME field on installation panel DSNTIPF.

For basic triggers, the initial value of the CURRENT APPLICATION ENCODING SCHEME special register is Unicode. For advanced triggers, the initial value of the CURRENT APPLICATION ENCODING SCHEME special register is the value of field DEFAULT APPLICATION ENCODING SCHEME on installation panel DSNTIPF.

Example

The CURRENT APPLICATION ENCODING SCHEME special register can be used like any other special register:

```
   EXEC SQL VALUES(CURRENT APPLICATION ENCODING SCHEME) INTO :HV1;
   EXEC SQL INSERT INTO T1 VALUES (CURRENT APPLICATION ENCODING SCHEME);
   EXEC SQL SET :HV1 = CURRENT APPLICATION ENCODING SCHEME;
   EXEC SQL SELECT C1 FROM T1 WHERE C1 = CURRENT APPLICATION ENCODING SCHEME;
```

Related reference

SET CURRENT APPLICATION ENCODING SCHEME
The SET CURRENT APPLICATION ENCODING SCHEME statement assigns a value to the CURRENT APPLICATION ENCODING SCHEME special register. This special register allows users to control which encoding scheme will be used for dynamic SQL statements after the SET statement has been executed.

CURRENT CLIENT_ACCTNG special register

CURRENT CLIENT_ACCTNG contains the value of the accounting string from the client information that is specified for the connection.

The data type is VARCHAR(255).

The value of the special register can be changed by using one of the following application programming interfaces (APIs):

- Set Client Information (sqleseti)
- SQLSetConnectAttr (ODBC)
- java.sql.Connection.setClientInfo (JDBC)
- The RRS DSNRLI SIGNON, AUTH SIGNON, CONTEXT SIGNON, or SET_CLIENT_ID function
- The WLM_SET_CLIENT_INFO stored procedure

The value for the accounting string will be obtained first from the accounting string that is set by the SET_CLIENT_ID function, AUTH SIGNON function, or the Set Client Information (sqleseti) API, or alternatively from the accounting token set by RRSAF if accounting string has not been set.

The application compatibility value of the package determines the length and blank padding of the CURRENT CLIENT_ACCTNG special register returned.

If one of these APIs is not used to set the value of the special register, an empty string is returned when the special register is referenced.

CICS attachment facility

For CICS tasks that access Db2, the CICS attachment facility normally does not pass an accounting string to Db2, unless the origin data for the CICS task contains adapter data that specifies the origin of the CICS task. If origin adapter data is present, the CICS attachment facility passes the data to Db2, preceded by an eye-catcher. For example:

```
CICS_ORIGIN_DATA:ADAPTER_DATA_1_2_3:adapter-data
```

adapter-data is the origin adapter data.

Example:

The following statement assigns the current value of the accounting string for a connection to host variable :ACCT_STRING.

```
SET :ACCT_STRING = CURRENT CLIENT_ACCTNG
```

Related reference

WLM_SET_CLIENT_INFO stored procedure

This procedure allows the caller to set client information that is associated with the current connection at the Db2 for z/OS server.

sqle_client_info data structure

CURRENT CLIENT_APPLNAME special register

CURRENT CLIENT_APPLNAME contains the value of the application name from the client information that is specified for the connection.

The data type is VARCHAR(255).

The default application name varies, depending on the connection:

- If the connection is from a remote application client driver, the default is the application name as supplied by the driver. Default values set by the IBM Data Server Driver for JDBC and SQLJ can be obtained from the DatabaseMetaData.getClientInfoProperties method.
- If the connection is from a remote Db2 12 for z/OS application, the default varies depending on which attachment facility is used:

  TSO attachment facility

  The default application name is one of the following cases:

  - The TSO logon user ID when the application runs in TSO foreground using TSO online applications like SPUFI.
  - The job name when the application runs in TSO background using TSO batch applications like DSNTEP2.

  RRS attachment facility interface

  The correlation ID that is provided at the call of the RRS DSNRLI SIGNON function.

  Call attachment facility

  The job name.

  CICS attachment facility

  If the origin data for the CICS task contains adapter data that indicates the origin of the CICS task, the CICS attachment facility passes the following items to Db2:

  - An eye-catcher string
  - The ID of the adapter that set the origin data

  That information is used as the default application name. For example:

  ```
  CICS_ORIGIN_DATA:ADAPTER_ID:name
  ```

  name is one of the following values:

  - IBM_zOS_Connect_CICS_SP for a CICS task that was initiated as a result of an inbound request from z/OS Connect
  - IBM WebSphere MQ for z/OS for a CICS task that was initiated by the CICS-MQ trigger monitor or CICS-MQ bridge

  If there is no adapter data in the CICS origin data, no data is passed from CICS to Db2. Db2 uses the first 8 bytes of the correlation ID. In particular, the correlation ID is a 12-byte string for a CICS transaction, where the first 8 bytes are used as the default application name.

  IMS Attachment facility

  An 8-byte string, the Program Specification Block (PSB) name, or the program name.

The value of the special register can be changed by using one of the following application programming interfaces (APIs):

- SQLE_CLIENT_INFO_APPLNAME (sqleseti)
- SQLSetConnectAttr (ODBC)
- java.sql.Connection.setClientInfo (JDBC)
- The RRS DSNRLI SIGNON, AUTH SIGNON, CONTEXT SIGNON, or SET_CLIENT_ID function
- The WLM_SET_CLIENT_INFO stored procedure

When the client application name is explicitly set, it overwrites the default application name described above and is used as the client application name.

The application compatibility value of the package determines the length and blank padding of the CURRENT CLIENT_APPLNAME special register returned.

If one of these APIs is not used to set the value of the special register, an empty string is returned when the special register is referenced.

Monitoring remote application statistics based on CURRENT CLIENT_APPLNAME (IFCID 411)

You can use start a trace that includes statistics class 10 (IFCID 411) to monitor statistics for remote DRDA applications based on the CURRENT CLIENT_APPLNAME special register. For more information, see Statistics trace (Db2 Performance).

Important: Monitoring of applications with IFCID 411 is limited to 6000 unique user ID values. If this limit is exceeded, Db2 issues DSNL030I with reason code 00D3105D and stops collecting the statistics for any new application names until DDF is restarted. For best results, use CLIENT_CORR_TOKEN special register to identify individual connections.

Example

Select the departments that are allowed to use the application that is being used in this connection.

```
SELECT DEPT
  FROM DEPT_APPL_MAP
  WHERE APPL_NAME = CURRENT CLIENT_APPLNAME
```

Related concepts

Related reference

WLM_SET_CLIENT_INFO stored procedure
This procedure allows the caller to set client information that is associated with the current connection at the Db2 for z/OS server.

sqle_client_info data structure

CURRENT CLIENT_CORR_TOKEN special register

CURRENT CLIENT_CORR_TOKEN contains the value of the client correlation token from the client information that is specified for the connection.

The data type is VARCHAR(255).

The value of the special register can be changed by using one of the following application programming interfaces (APIs):

- SQLE_CLIENT_INFO_PROGRAMID (sqleseti)
- java.sql.Connection.setClientInfo (JDBC)
- The RRS DSNRLI SIGNON, AUTH SIGNON, CONTEXT SIGNON, or SET_CLIENT_ID function

If one of these APIs is not used to set the value of the special register, the value defaults to the correlation identifier from the client driver such as an application identifier. If a correlation identifier is not provided by the client system, an LUWID (Logical Unit of Work ID) is generated which becomes the correlation token.

Example: Select the departments that are allowed to use the correlation token that is being used in this connection.

```
SELECT DEPT
  FROM DEPT_CORR_TOKEN_MAP
  WHERE CORR_TOKEN_NAME = CURRENT CLIENT_CORR_TOKEN
```

Related concepts

Related reference

WLM_SET_CLIENT_INFO stored procedure
This procedure allows the caller to set client information that is associated with the current connection at the Db2 for z/OS server.

sqle_client_info data structure

CURRENT CLIENT_USERID special register

CURRENT CLIENT_USERID contains the value of the client user ID from the client information that is specified for the connection.

The default client user ID is the primary authorization ID used to establish the connection.

The data type is VARCHAR(255).

The value of the special register can be changed by using one of the following application programming interfaces (APIs):

- SQLE_CLIENT_INFO_USERID (sqleseti)
- SQLSetConnectAttr (ODBC)
- java.sql.Connection.setClientInfo (JDBC)
- The RRS DSNRLI SIGNON, AUTH SIGNON, CONTEXT SIGNON, or SET_CLIENT_ID function
- The WLM_SET_CLIENT_INFO stored procedure

When the client user ID is explicitly set, it overwrites the primary authorization id described above and is used as the client user ID.

If the value set by the API exceeds 128 bytes, it is truncated to 128 bytes.

The application compatibility value of the package determines the length and blank padding of the CURRENT CLIENT_USERID special register returned.

Monitoring remote user statistics based on CURRENT CLIENT_USERID (IFCID 412)

You can start a trace that includes statistics class 11 (IFCID 412) to monitor statistics for remote DRDA users based on the CURRENT CLIENT_USERID special register. For more information, see Statistics trace (Db2 Performance).

Important: Monitoring of applications with IFCID 412 is limited to 6000 unique user ID values. If this limit is exceeded, Db2 issues DSNL030I with reason code 00D3105E and stops collecting the statistics for any new user IDs until DDF is restarted. For best results, use the CLIENT_CORR_TOKEN special register to identify individual connections.

Example

Find out in which department the current client user ID works.

```
SELECT DEPT
  FROM DEPT_USERID_MAP
  WHERE USER_ID = CURRENT CLIENT_USERID
```

CURRENT CLIENT_WRKSTNNAME special register

CURRENT CLIENT_WRKSTNNAME contains the value of the workstation name from the client information that is specified for the connection.

The data type is VARCHAR(255).

The default workstation name varies, depending on the connection:

- If the connection originates from a Db2 12 for z/OS requester, it is the client hostname.
- If the connection is from a remote application client driver, it is the client hostname where the request is submitted. Default values that are set by the IBM Data Server Driver for JDBC and SQLJ can be obtained from the DatabaseMetaData.getClientInfoProperties method.
- If the connection is from a remote Db2 12 for z/OS application, the default varies depending on which attachment facility is used:

  TSO attachment facility
  The default workstation name is one of the following cases:

  - The default workstation name is 'TSO' when the application runs in TSO foreground with TSO online applications like SPUFI.
  - The default workstation name is 'BATCH' when the application runs in TSO background with TSO batch applications like DSNTEP2.

  RRS attachment facility interface
  The default workstation name is 'RRSAF

  Call attachment facility
  The default workstation name is 'DB2CALL'.

  CICS attachment facility
  The default workstation name is the CICS region name.

IMS Attachment facility
The default workstation name is IMS region ID.

The value of the special register can be changed by using one of the following application programming interfaces (APIs):

- SQLE_CLIENT_INFO_WRKSTNNAME (`sqleseti`)
- SQLSetConnectAttr (ODBC)
- java.sql.Connection.setClientInfo (JDBC)
- The RRS DSNRLI SIGNON, AUTH SIGNON, CONTEXT SIGNON, or SET_CLIENT_ID function
- The WLM_SET_CLIENT_INFO stored procedure

When the client workstation name is explicitly set, it overwrites the default workstation name described above and is used as the client workstation name.

The application compatibility value of the package determines the length and blank padding of the CURRENT CLIENT_WRKSTNNAME special register returned.

If one of these APIs is not used to set the value of the special register, an empty string is returned when the special register is referenced.

Example: Get the name of the workstation that is being used in this connection.

```
SET :WS_NAME = CURRENT CLIENT_WRKSTNNAME
```

Client info properties support by the IBM Data Server Driver for JDBC and SQLJ (Db2 Application Programming for Java)

CURRENT DATE special register

The CURRENT DATE special register specifies a date that is based on a reading of the time-of-day clock when the SQL statement is executed at the current server.

If this special register is used more than one time within a single SQL statement, or used with CURRENT TIME or CURRENT TIMESTAMP within a single statement, all values are based on a single clock reading.[9]

The value of CURRENT DATE in a user-defined function or stored procedure is inherited according to the rules in Table 47 on page 215. For other applications, the date is derived by the Db2 that executes the SQL statement that refers to the special register. For a description of how the date is derived, see Datetime special registers.

Specifying CURRENT_DATE is equivalent to specifying CURRENT DATE.

Example

Display the average age of employees.

[9] Except for the case of a non-atomic multiple row INSERT or MERGE statement.

```
SELECT AVG(YEAR(CURRENT DATE - BIRTHDATE))
  FROM DSN8C10.EMP;
```

CURRENT DEBUG MODE special register

CURRENT DEBUG MODE specifies the default value for the DEBUG MODE option when advanced triggers and certain routines are created. The DEBUG MODE option specifies whether the trigger or routine should be built with the ability to run in debugging mode.

CURRENT DEBUG MODE specifies the default value for the DEBUG MODE option of the following statements:

- ALTER FUNCTION for a new version of an SQL scalar function
- ALTER PROCEDURE for a new version of a native SQL procedure
- ALTER TRIGGER (advanced) for a new version of a trigger
- CREATE FUNCTION for an SQL scalar function
- CREATE PROCEDURE for a Java procedure
- CREATE PROCEDURE for a native SQL procedure
- CREATE TRIGGER (advanced) for an advanced trigger

The data type is VARCHAR(8). The following values are valid:

- ALLOW — Specifies that the routine or trigger can be run in debugging mode.
- DISALLOW — Specifies that the routine or trigger cannot be run in debugging mode. A subsequent ALTER statement can change the DEBUG MODE option to allow the routine or trigger to run in debugging mode.
- DISABLE — Specifies that the routine or trigger can never be run in debugging mode. When DISABLE is in effect, the routine or trigger cannot be changed to run in debugging mode. A subsequent ALTER statement cannot change the DEBUG MODE option to allow or disallow the routine or trigger to run in debugging mode.

The value of CURRENT DEBUG MODE in a user-defined function, stored procedure, or trigger is determined according to the rules in Table 47 on page 215. In other contexts the initial value of CURRENT DEBUG MODE is DISALLOW.

You can change the value of the CURRENT DEBUG MODE special register by running the SET CURRENT DEBUG MODE statement.

Example

The following statement sets the host variable DEBUG_MODE_OPT to the value of the CURRENT DEBUG MODE special register.

```
VALUES CURRENT DEBUG MODE INTO :DEBUG_MODE_OPT;
```

Related reference

SET CURRENT DEBUG MODE
The SET CURRENT DEBUG MODE statement assigns a value to the CURRENT DEBUG MODE special register.

CURRENT DECFLOAT ROUNDING MODE special register

CURRENT DECFLOAT ROUNDING MODE specifies the default rounding mode that is used for DECFLOAT values.

The data type is VARCHAR(128). The following rounding modes are supported:

- ROUND_CEILING — rounds the value towards positive infinity. If all of the discarded digits are zero or if the sign is negative the result is unchanged other than the removal of the discarded digits. Otherwise, the result coefficient is incremented by 1.
- ROUND_DOWN — rounds the value towards 0 (truncation). The discarded digits are ignored.
- ROUND_FLOOR — rounds the value towards negative infinity. If all of the discarded digits are zero or if the sign is positive the result is unchanged other than the removal of discarded digits. Otherwise, the sign is negative and the result coefficient is incremented by 1.
- ROUND_HALF_DOWN — rounds the value to the nearest value; if the values are equidistant, rounds the value towards zero. If the discarded digits represent greater than half (0.5) of the value of a one in the next left position then the result coefficient is incremented by 1. Otherwise the discarded digits are ignored. This rounding mode is not recommended when creating a portable application because it is not supported by the IEEE draft standard for floating-point arithmetic.
- ROUND_HALF_EVEN — rounds the value to the nearest value; if the values are equidistant, rounds the value so that the final digit is even. If the discarded digits represents greater than half (0.5) of the value of one in the next left position then the result coefficient is incremented by 1. If they represent less than half, then the result coefficient is not adjusted (that is, the discarded digits are ignored). Otherwise the result coefficient is unaltered if its rightmost digit is even, or is incremented by 1 if its rightmost digit is odd (to make an even digit).
- ROUND_HALF_UP — rounds the value to the nearest value; if the values are equidistant, rounds the value away from zero. If the discarded digits represent greater than or equal to half (0.5) of the value of one in the next left position then the result coefficient is incremented by 1. Otherwise the discarded digits are ignored.
- ROUND_UP — rounds the value away from 0. If all of the discarded digits are zero the result is unchanged other than the removal of discarded digits. Otherwise, the result coefficient is incremented by 1. This rounding mode is not recommended when creating a portable application because it is not supported by the IEEE draft standard for floating-point arithmetic.

The initial value of CURRENT DECFLOAT ROUNDING MODE is the value of the ROUNDING bind option or the native SQL procedure option. If the ROUNDING option is not specified, the initial value is the value of the DEF DECFLOAT ROUND MODE field on installation panel DSNTIPF.

The value of CURRENT DECFLOAT ROUNDING MODE in a user-defined function or stored procedure is inherited according to the rules in Table 47 on page 215.

You can change the value of the CURRENT DECFLOAT ROUNDING MODE by executing the statement SET CURRENT DECFLOAT ROUNDING MODE.

Example: Set the DECFLOAT rounding mode to ROUND_CEILING:

```
SET CURRENT DECFLOAT ROUNDING MODE = 'ROUND_CEILING';
```

Related reference

SET CURRENT DECFLOAT ROUNDING MODE
The SET CURRENT DECFLOAT ROUNDING MODE statement assigns a value to the CURRENT DECFLOAT ROUNDING MODE special register. The special register sets the default rounding mode that is used with decimal floating point values (DECFLOAT).

CURRENT DEGREE special register

CURRENT DEGREE specifies the degree of parallelism for the execution of queries that are dynamically prepared by the application process.

The data type of the register is CHAR(3) and the only valid values are 1 (padded on the right with two blanks) and ANY.

If the value of CURRENT DEGREE is 1 when a query is dynamically prepared, the execution of that query will not use parallelism. If the value of CURRENT DEGREE is ANY when a query is dynamically prepared, the execution of that query can involve parallelism.

The initial value of CURRENT DEGREE is determined by the value of field CURRENT DEGREE on installation panel DSNTIP8. The default for the initial value of that field is 1 unless your installation has changed it to be ANY by modifying the value in that field. The initial value of CURRENT DEGREE in a user-defined function or stored procedure is inherited according to the rules in Table 47 on page 215.

You can change the value of the register by executing the statement SET CURRENT DEGREE.

CURRENT DEGREE is a register at the database server. Its value applies to queries that are dynamically prepared at that server and to queries that are dynamically prepared at another Db2 subsystem as a result of the use of a Db2 private connection between that server and that Db2 subsystem.

Example: The following statement inhibits parallelism:

```
SET CURRENT DEGREE = '1';
```

SET CURRENT DEGREE
The SET CURRENT DEGREE statement assigns a value to the CURRENT DEGREE special register.

CURRENT DEGREE field (CDSSRDEF subsystem parameter) (Db2 Installation and Migration)

CURRENT EXPLAIN MODE special register

The CURRENT EXPLAIN MODE special register contains the values that control the EXPLAIN behavior in regards to eligible dynamic SQL statements.

This facility generates and inserts EXPLAIN information into the EXPLAIN tables. Possible values for the CURRENT EXPLAIN MODE special register are YES, NO, and EXPLAIN. The data type is VARCHAR(128).

NO
Disable the ability to use EXPLAIN. No EXPLAIN information is kept. NO is the initial value of the EXPLAIN MODE special register.

YES
Enables the EXPLAIN facility and causes EXPLAIN information to be inserted into the EXPLAIN tables for eligible dynamic SQL statements after the statement is prepared and executed. All dynamic SQL statements are compiled and executed normally.

EXPLAIN
Enables the EXPLAIN facility and causes EXPLAIN information to be captured for any eligible dynamic SQL statement after the statement is prepared. This setting behaves similarly to YES, however, dynamic statements, except for SET statements, are not executed.

For values YES and EXPLAIN, prepared statements are not saved into the dynamic statement cache.

The initial value is NO. The initial value of CURRENT EXPLAIN MODE in a user-defined function or stored procedure is inherited according to the rules in “Special registers in a user-defined function or a stored procedure” on page 215.

The value can be changed using the SET CURRENT EXPLAIN MODE statement.

Prerequisites for using CURRENT EXPLAIN MODE:

- Both the PLAN_TABLE and DSN_STATEMENT_CACHE_TABLE exist on the Db2 server and the table names are qualified with the current SQLID that is used when running the application.
- The Dynamic statement cache is enabled.
- The client application contains some explainable statements.

Required authorization for using CURRENT EXPLAIN MODE:

If CURRENT EXPLAIN MODE is set to YES or EXPLAIN, the privilege set for the underlying statement must have the necessary authorization to use the EXPLAIN facility.

When the EXPLAIN privilege is in effect and CURRENT EXPLAIN MODE is set to EXPLAIN, any SQLCODE that is returned due to the EXPLAIN privilege override any SQLCODE that is returned due to CURRENT EXPLAIN MODE being set to EXPLAIN.

Considerations when using the CURRENT EXPLAIN MODE special register to explain the acceleration of rowset queries:

A rowset query cannot be passed to an accelerator server for processing in the following cases:

- If the rowset query is run remotely
- If the rowset query is declared WITH RETURN
- If the rowset query is run under an SQL PL routine

When a rowset query is run with the CURRENT EXPLAIN MODE special register set to YES or EXPLAIN, the EXPLAIN output indicates whether the local execution of a rowset cursor can be accelerated, depending on the content of the query. The EXPLAIN output will always indicate that remote rowset queries, rowset queries that are declared WITH RETURN, and rowset queries that run under an SQL PL routine cannot be accelerated.

Related reference

SET CURRENT EXPLAIN MODE
The SET CURRENT EXPLAIN MODE statement assigns a value to the CURRENT EXPLAIN MODE special register.

CURRENT GET_ACCEL_ARCHIVE special register

The CURRENT GET_ACCEL_ARCHIVE special register specifies whether a dynamic SQL query that references a table that is archived on an accelerator server uses the archived data. The special register does not apply to static SQL queries.

The data type is VARCHAR(255).

Valid values are:

NO

Specifies that if a table is archived on an accelerator server, and a query references that table, the query does not use the data that is archived.

YES

Specifies that if a table is archived on an accelerator server, and a query references that table, the query uses the data that is archived.

The initial value of CURRENT GET_ACCEL_ARCHIVE is determined by one of the following settings:

- The value of Db2 subsystem parameter GET_ACCEL_ARCHIVE. The default for the initial value of that subsystem parameter is NO unless your installation has changed the value.
- If specified for the bind of a package, the GETACCELARCHIVE bind option. This behavior enables the GETACCELARCHIVE bind option to be used to specify the acceleration archive behavior for dynamic SQL queries and not only static SQL queries. This bind option does not have a default value.

The initial value of CURRENT GET_ACCEL_ARCHIVE in a user-defined function or stored procedure is inherited according to the rules in “Special registers in a user-defined function or a stored procedure” on page 215.

You can change the value of the register by executing the SET CURRENT GET_ACCEL_ARCHIVE statement.

The precedence order (lowest to highest) for setting the value of the special register is as follows:

- The GET_ACCEL_ARCHIVE subsystem parameter
- The GETACCELARCHIVE bind option, if specified

- An explicit SET CURRENT GET_ACCEL_ARCHIVE statement

Example: The following statement sets the CURRENT GET_ACCEL_ARCHIVE special register so that when a table is archived on an accelerator server, the table reference does not include the archived data.

```
SET CURRENT GET_ACCEL_ARCHIVE=NO;
```

Related tasks

Enabling acceleration of SQL queries (Db2 Performance)

Related reference

SET CURRENT GET_ACCEL_ARCHIVE
The SET CURRENT GET_ACCEL_ARCHIVE statement changes the value of the CURRENT GET_ACCEL_ARCHIVE special register.

CURRENT LOCALE LC_CTYPE special register

CURRENT LOCALE LC_CTYPE specifies the LC_CTYPE locale that will be used to execute SQL statements that use a built-in function that references a locale. Functions LCASE, UCASE, and TRANSLATE (with a single argument) refer to the locale when they are executed.

The data type is CHAR(50). If necessary, the value is padded on the right with blanks so that its length is 50 bytes. The following values are supported:

blank

For a conversion to lowercase, SBCS uppercase characters A-Z are converted to SBCS lowercase characters a-z, and characters with diacritical marks are not converted. If the string contains MIXED or DBCS characters, full-width Latin uppercase characters A-Z are converted to full-width lowercase characters a-z.

For a conversion to uppercase, SBCS lowercase characters a-z are converted to SBCS uppercase characters A-Z, and characters with diacritical marks are not converted. If the string contains MIXED or DBCS characters, full-width Latin lowercase characters a-z are converted to full-width uppercase characters A-Z.

For optimal performance, specify a blank string unless your data must be processed by using rules that are defined by a specific locale.

UNI

Case conversions use both the NORMAL and SPECIAL casing capabilities as described in Select the conversions (z/OS: Unicode Services User’s Guide and Reference). UNI cannot be used with EBCDIC data.

UNI_60

The conversion uses Unicode Standard 6.0.0 and the NORMAL casing capability, as described in Select the conversions (z/OS: Unicode Services User’s Guide and Reference). You must not specify UNI_60 when *string-expression* is EBCDIC data.

UNI_90

The conversion uses Unicode Standard 9.0.0 and the NORMAL casing capability, as described in Select the conversions (z/OS: Unicode Services User’s Guide and Reference). You must not specify UNI_90 when *string-expression* is EBCDIC data.

UNI_SIMPLE

Case conversions use the NORMAL casing capabilities as described in Select the conversions (z/OS: Unicode Services User’s Guide and Reference). UNI_SIMPLE cannot be used with EBCDIC data.

locale name

The locale defines the rules for conversion to uppercase or lowercase characters. For information about locales and their naming conventions for EBCDIC data, see Locale naming conventions (XL C/C++ Programming Guide). For information about locales for Unicode and ASCII data, see z/OS Unicode Services User’s Guide and Reference.

The initial value of CURRENT LOCALE LC_CTYPE is determined by the value of field LOCALE LC_CTYPE on installation panel DSNTIPF. The default for the initial value of that field is blank unless your installation has changed the value of that field. The initial value of CURRENT LOCALE LC_CTYPE in a user-defined function or stored procedure is inherited according to the rules in Table 47 on page 215.

You can change the value of the register by executing the statement SET CURRENT LOCALE LC_CTYPE.

Some examples of locales for EBCDIC data include:

- Fr_BE
- Fr_FR@EURO
- En_US
- Ja_JP

Example

Save the value of current register CURRENT LOCALE LC_CTYPE in host variable *HV1*, which is defined as VARCHAR(50).

```
EXEC SQL VALUES(CURRENT LOCALE LC_CTYPE) INTO :HV1;
```

Related concepts

z/OS Unicode Services User’s Guide and Reference

Related reference

SET CURRENT LOCALE LC_CTYPE
The SET CURRENT LOCALE LC_CTYPE statement assigns a value to the CURRENT LOCALE LC_CTYPE special register. The special register allows control over the LC_CTYPE locale for statements that use a built-in function that refers to a locale, such as LCASE, UCASE, and TRANSLATE (with a single argument).

z/OS XL C/C++ Programming Guide

CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION special register

CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION specifies a value that identifies the types of objects that can be considered to optimize the processing of dynamic SQL queries. This register contains a keyword representing table types.

The data type is VARCHAR(255).

The initial value of CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION is determined by the value of field CURRENT MAINT TYPES on installation panel DSNTIP81. The default for the initial value of that field is SYSTEM unless your installation has changed the value of that field. The initial value of CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION in a user-defined function or stored procedure is inherited according to the rules in Table 47 on page 215.

You can change the value of the register by executing the SET CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION statement. The object types controlled by this special register are never considered by static embedded SQL queries.

Example: Set the CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION special register so that all materialized query tables are considered.

```
SET CURRENT MAINTAINED TABLE TYPES ALL;
```

Related reference

SET CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION

The SET CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION statement changes the value of the CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION special register.

CURRENT MEMBER special register

CURRENT MEMBER specifies the member name of a current Db2 data sharing member on which a statement is executing. The value of CURRENT MEMBER is a character string.

The data type is CHAR(8). If necessary, the member name is padded to the right with blanks so that its length is 8 bytes.

The value of a CURRENT MEMBER is a string of blanks when the application process is connected to a Db2 subsystem that is not a member of a data sharing group.

The SQL SET statement cannot change the value of CURRENT MEMBER.

Example: Use one of the following statements to set the host variable *MEM* to the name of the current Db2 member.

```
EXEC SQL SET :MEM = CURRENT MEMBER;
```

```
EXEC VALUES (CURRENT MEMBER) into :MEM;
```

CURRENT OPTIMIZATION HINT special register

CURRENT OPTIMIZATION HINT specifies the user-defined optimization hint that Db2 should use to generate the access path for dynamic statements.

The data type is VARCHAR(128).

The value of the register identifies the rows in *owner*.PLAN_TABLE that Db2 uses to generate the access path. Db2 uses information in the rows in *owner*.PLAN_TABLE for which the value of the OPTHINT column matches the value of the CURRENT OPTIMIZATION special register. If the value of the register is an empty string or all blanks, Db2 uses normal optimization and ignores optimization hints. If the value of the register includes any non-blank characters and Db2 was installed without optimization hints enabled (field OPTIMIZATION HINTS on installation panel DSNTIP8), a warning occurs.

The initial value of CURRENT OPTIMIZATION HINT is the value of the OPTHINT bind option or of the native SQL procedure option. The initial value of CURRENT OPTIMIZATION HINT in a user-defined function or stored procedure is inherited according to the rules in Table 47 on page 215. You can change the value of the special register by executing the statement SET CURRENT OPTIMIZATION HINT.

Example: Set the CURRENT OPTIMIZATION HINT special register so that Db2 uses the optimization plan hint that is identified by host variable *NOHYB* when generating the access path for dynamic statements.

```
SET CURRENT OPTIMIZATION HINT = :NOHYB
```

Related tasks

Specifying access paths in a PLAN_TABLE instance (Db2 Performance)

Preparing to influence access paths (Db2 Performance)

Related reference

SET CURRENT OPTIMIZATION HINT

The SET CURRENT OPTIMIZATION HINT statement assigns a value to the CURRENT OPTIMIZATION HINT special register.

CURRENT PACKAGE PATH special register

CURRENT PACKAGE PATH specifies a value that identifies the path used to resolve references to packages that are used to execute SQL statements. This special register applies to both static and dynamic statements.

The data type is VARCHAR(4096). The value can be an empty or blank string, or a list of one or more collection IDs, where the collection IDs are enclosed in double quotation marks and separated by commas. Any quotation marks within the string are repeated as they are in any delimited identifier. The delimiters and commas are included in the length of the special register.

The initial value of CURRENT PACKAGE PATH is an empty string. The value is a list of collections only if the application process has explicitly specified a list of collections by means of the SET CURRENT PACKAGE PATH statement.

The initial value of CURRENT PACKAGE PATH in a user-defined function or procedure is inherited according to the rules in Table 47 on page 215.

When CURRENT PACKAGE PATH or CURRENT PACKAGESET is set, Db2 uses the values in these registers to resolve the collection for a package. The value of CURRENT PACKAGE PATH takes priority over CURRENT PACKAGESET. In a distributed environment, the value of CURRENT PACKAGE PATH at the remote server takes precedence of the value of CURRENT PACKAGE PATH at the local server (the requester). For more information on package resolution, see Binding an application plan (Db2 Application programming and SQL).

Example: In an application that is using SQLJ packages (in collection SQLJ1 and SQLJ2) and a JDBC package in DB2JAVA, set the CURRENT PACKAGE PATH special register to check SQLJ1 first, followed by SQLJ2, and DB2JAVA:

```
SET CURRENT PACKAGE PATH = SQLJ1, SQLJ2, DB2JAVA;
```

The following statement sets the host variable to the value of the resulting list:

```
SET :HVPKLIST = CURRENT PACKAGE PATH;
```

The value of the host variable would be "SQLJ1", "SQLJ2", "DB2JAVA".

Related reference
SET CURRENT PACKAGE PATH
The SET CURRENT PACKAGE PATH statement assigns a value to the CURRENT PACKAGE PATH special register.

CURRENT PACKAGESET special register

CURRENT PACKAGESET specifies an empty string, a string of blanks, or the collection ID of the package that will be used to execute SQL statements.

The data type is VARCHAR(128).

The initial value of CURRENT PACKAGESET is an empty string. The value is a collection ID only if the application process has explicitly specified a collection ID by means of the SET CURRENT PACKAGESET statement.

The initial value of CURRENT PACKAGESET in a user-defined function or stored procedure is inherited according to the rules in Table 47 on page 215.

Example: Before passing control to another program, identify the collection ID for its package as ALPHA.

```
 EXEC SQL SET CURRENT PACKAGESET = 'ALPHA';
```

Related reference

SET CURRENT PACKAGESET
The SET CURRENT PACKAGESET statement assigns a value to the CURRENT PACKAGESET special register.

CURRENT PATH special register

CURRENT PATH specifies the SQL path used to resolve unqualified data type names and function names in dynamically prepared SQL statements. It is also used to resolve unqualified procedure names that are specified as host variables in SQL CALL statements (CALL *host-variable*).

The data type is VARCHAR(2048).

The CURRENT PATH special register contains a list of one or more schema names, where each schema name is enclosed in delimiters and separated from the following schema by a comma (any delimiters within the string are repeated as they are in any delimited identifier). The delimiters and commas are included in the 2048 character length.

For information on when the SQL path is used to resolve unqualified names in both dynamic and static SQL statements and the effect of its value, see "SQL path" on page 85.

The initial value of the CURRENT PATH special register is determined from the first of one of the following sets of conditions that is met:

- If the CURRENT PATH special register was assigned a value (by a SET PATH statement) in the scope of the invoking environment, the special register inherits the value from the invoking environment.
- If the connection is trusted, and both the role as object owner and qualifier options in effect, the special register is set to:"SYSIBM", "SYSFUN", "SYSPROC", "SYSIBMADM", "*role-name*" where *role-name* is the role that is associated with the user in the trusted context.
- Otherwise, the special register is set to: "SYSIBM", "SYSFUN", "SYSPROC", "SYSIBMADM", "*current-sqlid-value*".

The initial value of the CURRENT PATH special register in an SQL routine or trigger is determined from the first of one of the following sets of conditions that is met:

- In an SQL routine, the special register inherits the value from the invoking environment, if the special register was assigned a value (by a SET PATH statement) in the scope of the invoking environment.
- In a trigger, the special register inherits the value from the invoking environment, if the special register was assigned a value (by a SET PATH statement) in the scope of the invoking environment.
- In an SQL routine or trigger, the special register is set to the value specified for the SQL PATH routine or trigger option, if specified.
- In an SQL routine or trigger, the special register is set to the value specified for the SQL PATH routine or trigger option, if specified.
- If the connection is trusted, and both the role as object owner and qualifier options in effect, the special register is set to:"SYSIBM", "SYSFUN", "SYSPROC", "SYSIBMADM", "*role-name*" where *role-name* is the role that is associated with the user in the trusted context.
- Otherwise, the special register is set to: "SYSIBM", "SYSFUN", "SYSPROC", "SYSIBMADM", "*current-sqlid-value*".

If the value of the CURRENT SQLID special register changes after the initial value of PATH special register is established, the value of the PATH special register is unaffected when the CURRENT SQLID is updated. However, if a commit later occurs and a SET PATH statement has not been processed, the value of PATH special register is reinitialized taking into consideration the current value of the CURRENT SQLID special register.

You can change the value of the register by executing the statement SET PATH. For portability across the platforms, it is recommended that a SET PATH statement be issued at the beginning of an application.

Example: Set the special register so that schema SMITH is searched before the system schemas:

```
SET PATH = SMITH, SYSTEM PATH;
```

Related reference

SET PATH
The SET PATH statement assigns a value to the CURRENT PATH special register.

CURRENT PRECISION special register

CURRENT PRECISION specifies the rules to be used when both operands in a decimal operation have precisions of 15 or less.

The data type of the register is CHAR(5).

Valid values for the CURRENT PRECISION special register include 'DEC15', 'DEC31', or 'D*pp*.*s*' where '*pp*' is either 15 or 31 and '*s*' is a number between 1 and 9. DEC15 specifies the rules that do not allow a precision greater than 15 digits, and DEC31 specifies the rules that allow a precision of up to 31 digits. The rules for DEC31 are always used if either operand has a precision greater than 15. If the form 'D*pp*.*s*' is used, '*pp*' represents the precision that will be used as the rules where DEC15 and DEC31 rules are used, and '*s*' represents the minimum divide scale to use for division operations. The separator used in the form 'D*pp*.*s*' can be either the '.' or the ',' character, regardless of the setting of the default decimal point.

The initial value of CURRENT PRECISION is determined by the value of field DECIMAL ARITHMETIC on installation panel DSNTIP4. The default for the initial value is DEC15 unless your installation has changed it to be DEC31 by modifying the value in that field. The initial value of CURRENT PRECISION in a user-defined function or stored procedure is inherited according to the rules in Table 47 on page 215.

You can change the value of the register by executing the statement SET CURRENT PRECISION.

CURRENT PRECISION only affects dynamic SQL. When an SQL statement is dynamically prepared and the value of CURRENT PRECISION is DEC15 or D15.*s*, where 's' is a number between 1 and 9, DEC15 rules will apply. When an SQL statement is dynamically prepared and the value of CURRENT PRECISION is DEC31 or D31.*s*, where 's' is a number between 1 and 9, DEC31 rules will apply. Preparation of a statement with DEC31 instead of DEC15 is more likely to result in an error, especially for division operations. Specification of CURRENT PRECISION in the form 'D*pp*.*s*' where '*pp*' is either 15 or 31 and '*s*' represents the minimum divide scale, will in some cases make division errors less likely when '*pp*' is set to 31. For more information, see "Arithmetic with two decimal operands" on page 250.

Example 1: Set CURRENT PRECISION so that subsequent statements that are prepared use DEC31 rules for decimal arithmetic:

```
SET CURRENT PRECISION = 'DEC31';
```

Example 2: Set CURRENT PRECISION so that subsequent statements that are prepared use DEC31 rules for decimal arithmetic with a minimum divide scale of 3:

```
SET CURRENT PRECISION = 'D31.3';
```

Related reference

SET CURRENT PRECISION
The SET CURRENT PRECISION statement assigns a value to the CURRENT PRECISION special register.

CURRENT QUERY ACCELERATION special register

The CURRENT QUERY ACCELERATION special register specifies a value that identifies when Db2 sends dynamic SQL queries to an accelerator server and what Db2 does if the accelerator server fails. The special register does not apply to static SQL queries.

The data type is VARCHAR(255).

Valid values are:

NONE
Specifies that no queries are sent to an accelerator server.

ENABLE
Specifies that queries are accelerated only if Db2 determines that it is advantageous to do so. If an accelerator failure occurs while a query is running or if the accelerator returns an error, Db2 returns a negative SQLCODE to the application.

ENABLE WITH FAILBACK
Specifies that queries are accelerated only if Db2 determines that it is advantageous to do so. If the accelerator returns an error during the PREPARE or first OPEN for the query, Db2 executes the query without the accelerator. If the accelerator returns an error during a FETCH or a subsequent OPEN, Db2 returns the error to the user and does not execute the query.

Restriction: FL 504 If the query contains a passthrough-only expression, Db2 returns an error and does not accelerate the query, even if a matching user-defined function exists. For more information about passthrough-only expressions, see Accelerating queries with passthrough-only expressions.

ELIGIBLE
Specifies that queries are accelerated if they are eligible for acceleration. Db2 does not use cost information to determine whether to accelerate the queries. Queries that are not eligible for acceleration are executed by Db2. If an accelerator failure occurs while a query is running or if the accelerator returns an error, Db2 returns a negative SQLCODE to the application.

ALL
Specifies that queries are accelerated if they are eligible for acceleration. Db2 does not use cost information to determine whether to accelerate the queries. Queries that are not eligible for acceleration are not executed by Db2, and an SQL error is returned. If an accelerator failure occurs while a query is running or if the accelerator returns an error, Db2 returns a negative SQLCODE to the application.

The initial value of CURRENT QUERY ACCELERATION is determined by one of the following settings:

- The value of Db2 subsystem parameter QUERY_ACCELERATION. The default for the initial value of this subsystem parameter is NONE unless your installation has changed the value.
- If specified for the bind of a package, the QUERYACCELERATION bind option. This behavior enables the QUERYACCELERATION bind option to be used to specify the acceleration behavior for dynamic SQL queries and not only static SQL queries. This bind option does not have a default value.

The initial value of CURRENT QUERY ACCELERATION in a user-defined function or stored procedure is inherited according to the rules in "Special registers in a user-defined function or a stored procedure" on page 215.

You can change the value of the register by executing the SET CURRENT QUERY ACCELERATION statement.

The precedence order (lowest to highest) for setting the value of the special register is as follows:

- The QUERY_ACCELERATION subsystem parameter
- The QUERYACCELERATION bind option, if specified
- An explicit SET CURRENT QUERY ACCELERATION statement

Example: The following statement sets the CURRENT QUERY ACCELERATION special register so that no query acceleration occurs.

```
SET CURRENT QUERY ACCELERATION NONE;
```

Related concepts
How Db2 determines whether to accelerate eligible queries (Db2 Performance)

Related tasks
Enabling acceleration of SQL queries (Db2 Performance)

Related reference
SET CURRENT QUERY ACCELERATION

The SET CURRENT QUERY ACCELERATION statement changes the value of the CURRENT QUERY ACCELERATION special register.

CURRENT QUERY ACCELERATION WAITFORDATA special register

The CURRENT QUERY ACCELERATION WAITFORDATA special register specifies the maximum amount of time, if any, that the accelerator delays a dynamic SQL query while the accelerator waits for the replication of committed Db2 data changes that occurred prior to Db2 running the query. This special register does not apply to static SQL queries.

The data type is a DECIMAL(5,1) in the form of *nnnn.m*.

Valid values are a numeric constant in the range of 0.0 - 3600.0 seconds. For example, a value of 20.0 represents 20.0 seconds (or 20000 milliseconds), and a value of 30.5 represents 30.5 seconds (or 30500 milliseconds). The maximum value of 3600.0 means that the query is delayed for 60 minutes.

The default value is 0.0, which means that the query is not delayed and is run immediately on the accelerator. Other WAITFORDATA behavior is not applied to the query.

The wait time value can also be specified as an INTEGER numeric constant value ranging from 0 - 3600 seconds, which Db2 will convert to a DECIMAL (5,1) value.

You can change the value of the special register by executing the SET CURRENT QUERY ACCELERATION WAITFORDATA statement.

The initial value of CURRENT QUERY ACCELERATION WAITFORDATA is determined by one of the following settings:

- The value of Db2 QUERY_ACCEL_WAITFORDATA subsystem parameter. The default for the initial value of this subsystem parameter is 0.0 unless your installation has changed the value.
- If specified for the bind of a package, the ACCELERATIONWAITFORDATA bind option. This behavior enables the ACCELERATIONWAITFORDATA bind option to be used to specify the acceleration behavior for both dynamic SQL queries and static SQL queries. This bind option does not have a default value.

The initial value of CURRENT QUERY ACCELERATION WAITFORDATA in a user-defined function or stored procedure is inherited according to the rules in "Special registers in a user-defined function or a stored procedure" on page 215.

You can change the value of the register by executing the SET CURRENT QUERY ACCELERATION WAITFORDATA statement.

The precedence order (lowest to highest) for setting the value of the special register is as follows:

- The QUERY_ACCEL_WAITFORDATA subsystem parameter
- The ACCELERATIONWAITFORDATA bind option, if specified
- An explicit SET CURRENT QUERY ACCELERATION WAITFORDATA statement

For more information about the restrictions, requirements, and behaviors associated with CURRENT QUERY ACCELERATION WAITFORDATA, see "SET CURRENT QUERY ACCELERATION WAITFORDATA" on page 2143.

Example: The following statement sets the CURRENT QUERY ACCELERATION WAITFORDATA special register so that the accelerator delays queries for 180 seconds (three minutes) while it waits for committed Db2 data changes to be replicated to the accelerator.

```
SET CURRENT QUERY ACCELERATION WAITFORDATA 180;
```

Related reference

SET CURRENT QUERY ACCELERATION WAITFORDATA
The SET CURRENT QUERY ACCELERATION WAITFORDATA statement assigns a value to the CURRENT QUERY ACCELERATION WAITFORDATA special register.

WAIT FOR DATA field (QUERY_ACCEL_WAITFORDATA subsystem parameter) (Db2 Installation and Migration)

CURRENT QUERY ACCELERATION special register
The CURRENT QUERY ACCELERATION special register specifies a value that identifies when Db2 sends dynamic SQL queries to an accelerator server and what Db2 does if the accelerator server fails. The special register does not apply to static SQL queries.

CURRENT REFRESH AGE special register

CURRENT REFRESH AGE specifies a timestamp duration value. This duration is the maximum duration since a REFRESH TABLE statement has been processed on a system-maintained REFRESH DEFERRED materialized query table such that the materialized query table can be used to optimize the processing of a query. This special register affects dynamic statement cache matching.

The data type of the register is DECIMAL(20,6). For a description of durations, see "Datetime operands and durations" on page 256.

If CURRENT REFRESH AGE has a value of 99999999999999 (ANY), REFRESH DEFERRED materialized query tables are considered to optimize the processing of a dynamic SQL query. This value represents 9999 years, 99 months, 99 days, 99 hours, and 99 seconds.

The initial value of CURRENT REFRESH AGE is determined by the value of field CURRENT REFRESH AGE on installation panel DSNTIP81. The default for the initial value of that field is 0 unless your installation has changed it to ANY by modifying the value of that field. The initial value of CURRENT REFRESH AGE in a user-defined function or stored procedure is inherited according to the rules in Table 47 on page 215.

You can change the value of the register by executing the SET CURRENT REFRESH AGE statement.

Example : The following example retrieves the current value of the CURRENT REFRESH AGE special register into the host variable, *CURMAXAGE*:

```
   EXEC SQL VALUES (CURRENT REFRESH AGE) INTO :CURMAXAGE;
```

The value would be '99999999999999.000000'.

Related reference
SET CURRENT REFRESH AGE
The SET CURRENT REFRESH AGE statement changes the value of the CURRENT REFRESH AGE special register.

CURRENT ROUTINE VERSION special register

CURRENT ROUTINE VERSION specifies the version identifier that is to be used when invoking a native SQL procedure. CURRENT ROUTINE VERSION is used for CALL statements that use a host variable to specify the procedure name.

The data type of CURRENT ROUTINE VERSION is VARCHAR(64).

The initial value of CURRENT ROUTINE VERSION in a user-defined function or stored procedure is inherited according to the rules in Table 47 on page 215. In other contexts the initial value of CURRENT ROUTINE VERSION is an empty string. An empty string indicates that a version identifier is not in effect for the SQL routine. When an SQL routine that does not have a version identifier in effect is invoked, the currently active version (as indicated in the catalog) of that routine is used.

You can change the value of the CURRENT ROUTINE VERSION by executing the statement SET CURRENT ROUTINE VERSION.

Setting the CURRENT ROUTINE VERSION special register to a version identifier might affect native SQL procedures that are invoked until the value of CURRENT ROUTINE VERSION is changed. If a version of an SQL procedure has a version identifier that matches the version identifier in the special register, that version of the SQL procedure is used when the SQL procedure is invoked. If an SQL procedure does not have a version identifier that matches the version identifier in the special register, the currently active version of the SQL procedure (as defined in the catalog) is used when the SQL procedure is invoked.

Example: Set the host variable *ROUTINE_VER* to the value of the CURRENT ROUTINE VERSION special register:

```
VALUES CURRENT ROUTINE VERSION INTO :ROUTINE_VER;
```

Related reference

SET CURRENT ROUTINE VERSION

The SET CURRENT ROUTINE VERSION statement assigns a value to the CURRENT ROUTINE VERSION special register. The special register sets the override value for the version identifier of native SQL procedures when they are invoked.

CURRENT RULES special register

CURRENT RULES specifies whether certain SQL statements are executed in accordance with Db2 rules or the rules of the SQL standard.

The data type of the register is CHAR(3), and the only valid values are 'DB2' and 'STD'.

CURRENT RULES is a register at the database server. If the server is not the local Db2, the initial value of the register is 'DB2'. Otherwise, the initial value is the same as the value of the SQLRULES bind option. The initial value of CURRENT RULES in a user-defined function or stored procedure is inherited according to the rules in "Special registers in a user-defined function or a stored procedure" on page 215.

You can change the value of the register by executing the statement SET CURRENT RULES.

CURRENT RULES affects the statements listed in the following table. The table summarizes when the statements are affected and shows where to find detailed information. CURRENT RULES also affects whether Db2 issues an existence error (SQLCODE -204) or an authorization error (SQLCODE -551) when an object does not exist. For CURRENT RULES 'STD', Db2 issues an authorization error (SQLCODE -551) when an object does not exist instead of the existence error (SQLCODE -204).

Table 46. Summary of statements affected by CURRENT RULES

Statement	What is affected	Details in topic
ALTER TABLE	The following behaviors: • Enforcement of check constraints added. • Default value of the delete rule for referential constraints. • Whether Db2 creates LOB table spaces, auxiliary tables, and indexes on auxiliary tables for added LOB columns. See LOB table space implicit creation (Db2 Administration Guide). • Whether Db2 creates an index for an added ROWID column that is defined with GENERATED BY DEFAULT.	"ALTER TABLE" on page 1227
CREATE TABLE	The following behaviors: • Default value of the delete rule for referential constraints. • Whether Db2 creates LOB table spaces, auxiliary tables, and indexes on auxiliary tables for LOB columns if the table is explicitly created. See LOB table space implicit creation (Db2 Administration Guide). • Whether Db2 creates an index for a ROWID column that is defined with GENERATED BY DEFAULT if the table is explicitly created.	"CREATE TABLE" on page 1645

Table 46. Summary of statements affected by CURRENT RULES (continued)

Statement	What is affected	Details in topic
GRANT	Granting privileges to yourself.	"GRANT" on page 1958
REVOKE	Revoking privileges from authorization IDs	"REVOKE" on page 2065

Set CURRENT RULES so that a later ALTER TABLE statement is executed in accordance with the rules of the SQL standard:

```
SET CURRENT RULES = 'STD';
```

Related reference

SET CURRENT RULES
The SET CURRENT RULES statement assigns a value to the CURRENT RULES special register.

SQLRULES bind option (Db2 Commands)

CURRENT SCHEMA special register

The CURRENT SCHEMA special register specifies the schema name used to qualify unqualified database object references in dynamically prepared SQL statements.

The data type is VARCHAR(128).

For information on when the CURRENT SCHEMA is used to resolve unqualified names in dynamic SQL statements and the effect of its value, see "Unqualified object name resolution" on page 86.

The CURRENT SCHEMA special register contains a value that is a single identifier without delimiters.

The initial value of the special register is the value of CURRENT SQLID at the time the connection is established. If the connection is established as a trusted connection with a role as the object owner and qualifier, the initial value of the special register is the value of the role name that is associated with the user in the trusted context. The initial value of the special register in a user-defined function or procedure is inherited according to the rules in Table 47 on page 215.

The value of the special register can be changed by executing the SET SCHEMA statement. The value of CURRENT SCHEMA is the same as the value of CURRENT SQLID unless a SET SCHEMA statement has been issued specifying a different value. After a SET SCHEMA statement has been issued in an application, the values of CURRENT SCHEMA and CURRENT SQLID are separate. Therefore, if the value of CURRENT SCHEMA needs to be changed, a SET SCHEMA statement must be issued.

Specifying CURRENT_SCHEMA is equivalent to specifying CURRENT SCHEMA.

Example: Set the schema for object qualification to 'D123'.

```
SET SCHEMA = 'D123'
```

CURRENT SERVER special register

CURRENT SERVER specifies the location name of the current server.

The data type is CHAR(16). If necessary, the location name is padded on the right with blanks so that its length is 16 bytes.

The initial value of CURRENT SERVER depends on the CURRENTSERVER bind option. If CURRENTSERVER *X* is specified on the bind subcommand, the initial value is *X*. If the option is not specified, the initial value is the location name of the local Db2. The initial value of CURRENT SERVER in a user-defined function or stored procedure is inherited according to the rules in Table 47 on page 215. The value of CURRENT SERVER is changed by the successful execution of a CONNECT statement.

The value of CURRENT SERVER is a string of blanks when either of the following conditions apply:

- The application process is in the unconnected state
- The application process is connected to a local Db2 subsystem that does not have a location name.

Example

Set the host variable *CS* to the location name of the current server.

```
EXEC SQL SET :CS = CURRENT SERVER;
```

CURRENT SQLID special register

CURRENT SQLID specifies the SQL authorization ID of the process.

The data type is VARCHAR(128).

The SQL authorization ID is:

- The authorization ID used for authorization checking on dynamically prepared CREATE, GRANT, and REVOKE SQL statements.
- The owner of a table space, database, storage group, or synonym created by a dynamically issued CREATE statement.

The initial value of CURRENT SQLID can be provided by the connection or sign-on exit routine. If not, the initial value is the primary authorization ID of the process. The value remains in effect until one of the following events occurs:

- The SQL authorization ID is changed by the execution of a SET CURRENT SQLID statement.
- A SIGNON or re-SIGNON request is received from a CICS transaction subtask or an IMS independent region.
- The Db2 connection is ended.
- When running in a trusted connection, the user is switched.

The initial value of CURRENT SQLID in a user-defined function or stored procedure is inherited according to the rules in Table 47 on page 215.

CURRENT SQLID can only be referred to in an SQL statement that is executed by the current server.

CURRENT SQLID cannot be a role.

Examples for SET CURRENT SQLID

Example 1
Set the CURRENT SQLID to the primary authorization ID.

```
SET CURRENT SQLID = SESSION_USER;
```

Example 2
Set the SQL authorization ID to 'GROUP34' (one of the authorization IDs of the process).

```
  SET CURRENT SQLID = 'GROUP34';
```

CURRENT TEMPORAL BUSINESS_TIME special register

The CURRENT TEMPORAL BUSINESS_TIME special register specifies a TIMESTAMP(12) value that is used in the default BUSINESS_TIME period specification for references to application-period temporal tables.

When a query references an application-period temporal table and the value of the CURRENT TEMPORAL BUSINESS_TIME special register is not the null value, the query is affected as follows:

- If the columns of a BUSINESS_TIME period are defined as TIMESTAMP, the following period specification is implicit:

  ```
  FOR BUSINESS_TIME AS OF CURRENT TEMPORAL BUSINESS_TIME
  ```

- If the columns of a BUSINESS_TIME period are defined as DATE, the following period specification is implicit: :

  ```
  FOR BUSINESS_TIME AS OF CAST(CURRENT TEMPORAL BUSINESS_TIME AS DATE)
  ```

The initial value of the special register depends on the context as follows:

- If the special register is in a trigger, the initial value is inherited from the invoking application.
- If the special register is in a user-defined function or procedure that is defined with the INHERIT SPECIAL REGISTERS option, the initial value is inherited from the invoking application.
- If the special register is in a user-defined function or procedure that is defined with the DEFAULT SPECIAL REGISTERS option, the initial value is the null value.
- In other contexts, the initial value of the special register is the null value.

You can change the value of the special register by using the SET CURRENT TEMPORAL BUSINESS_TIME statement. If you change the value within a routine, that new value is not passed back to the invoking application.

Examples

Example of a query that references an application-period temporal table

Assume the following conditions:

- ATT is an application-period temporal table and POLICY_ID is a column in ATT.
- The value of the BUSTIMESENSITIVE bind option is YES.
- The value of CURRENT TEMPORAL BUSINESS_TIME is not null.

Then, suppose that you issue the following query:

```
SELECT * FROM ATT
WHERE POLICY_ID = 123;
```

Db2 generates an implicit BUSINESS_TIME period specification for the query as follows:

```
SELECT * FROM ATT
FOR BUSINESS_TIME AS OF CURRENT TEMPORAL BUSINESS_TIME
WHERE POLICY_ID = 123;
```

Example of a procedure that uses CURRENT TEMPORAL BUSINESS_TIME

Suppose that procedure MYPROC is defined as follows:

```
CREATE PROCEDURE MYPROC(OUT VAR1 VARCHAR(40), OUT VAR2 VARCHAR(40))
BEGIN
 SELECT CURRENT TEMPORAL BUSINESS_TIME INTO VAR1
 FROM SYSIBM.SYSDUMMY1;

 SET CURRENT TEMPORAL BUSINESS_TIME = TIMESTAMP('2011-01-01') + 5 DAYS ;

 SELECT CURRENT TEMPORAL BUSINESS_TIME INTO VAR2
 FROM SYSIBM.SYSDUMMY1;
END!
```

Suppose that the application defines string variables VAR1, VAR2, and VAR3 and contains the following SQL statements:

```
SET CURRENT TEMPORAL BUSINESS_TIME = TIMESTAMP('2008-01-01') + 5 DAYS ;

CALL MYPROC(VAR1, VAR2);
```

```
SELECT CURRENT TEMPORAL BUSINESS_TIME INTO VAR3
FROM SYSIBM.SYSDUMMY1;
```

After the execution of the SQL statements, the variables have the following values:

- VAR1 has value '2008-01-06-00.00.00.000000000000', which is the CURRENT TEMPORAL BUSINESS_TIME value that is set before the CALL statement invoked the procedure.
- VAR2 has value '2011-01-06-00.00.00.000000000000', which is the CURRENT TEMPORAL BUSINESS_TIME value that is set during the CALL statement.
- VAR3 has value '2008-01-06-00.00.00.000000000000', which is the CURRENT TEMPORAL BUSINESS_TIME value that is set before the CALL statement. The changes of the register value inside the procedure have no affect on the invoking application.

Example of a query that references CURRENT TEMPORAL BUSINESS_TIME

Assume that IN_TRAY is an application-period temporal table that contains users and subject lines for notes in the inbox. The following query returns the user ID and subject line for notes in the IN_TRAY table that were sent on the date that the CURRENT TEMPORAL BUSINESS_TIME special register is set to.

```
SELECT SOURCE, SUBJECT
FROM IN_TRAY
WHERE DATE (CURRENT TEMPORAL BUSINESS_TIME) = DATE (RECEIVED)
```

Related tasks

Related reference

table-reference
A *table-reference* specifies a result table as either a table or view, or an intermediate table.

BIND and REBIND options for packages, plans, and services (Db2 Commands)

SET CURRENT TEMPORAL BUSINESS_TIME
The SET CURRENT TEMPORAL BUSINESS_TIME statement changes the value of the CURRENT TEMPORAL BUSINESS_TIME special register.

Special registers in a user-defined function or a stored procedure
You can use all special registers in a user-defined function or a stored procedure. However, you can modify only some of those special registers.

CURRENT TEMPORAL SYSTEM_TIME special register

The CURRENT TEMPORAL SYSTEM_TIME special register specifies a TIMESTAMP(12) value that is used in the default SYSTEM_TIME period specification for references to system-period temporal tables.

When a query references a system-period temporal table and the value of the CURRENT TEMPORAL SYSTEM_TIME special register is not the null value, the following period specification is implicit:

```
FOR SYSTEM_TIME AS OF CURRENT TEMPORAL SYSTEM_TIME
```

The initial value of the special register depends on the context as follows:

- If the special register is in a trigger, the initial value is inherited from the invoking application.
- If the special register is in a user-defined function or procedure that is defined with the INHERIT SPECIAL REGISTERS option, the initial value is inherited from the invoking application.
- If the special register is in a user-defined function or procedure that is defined with the DEFAULT SPECIAL REGISTERS option, the initial value is the null value.
- In other contexts, the initial value of the special register is the null value.

You can change the value of the special register by using the SET CURRENT TEMPORAL SYSTEM_TIME statement. If you change the value within a routine, that new value is not passed back to the invoking application.

When the value of the CURRENT TEMPORAL SYSTEM_TIME special register is not null and the SYSTIMESENSITIVE bind option is set to YES, you cannot explicitly specify FOR SYSTEM_TIME in a *select-statement*.

Examples

Example of a query that references a system-period temporal table

Assume the following conditions:

- STT is a system-period temporal table, and POLICY_ID is a column of STT.
- The value of the SYSTIMESENSITIVE bind option is YES.
- The value of CURRENT TEMPORAL SYSTEM_TIME is not null.

Then, suppose that you issue the following query:

```
SELECT * FROM STT
WHERE POLICY_ID = 123;
```

Db2 generates an implicit SYSTEM_TIME period specification for the query as follows:

```
SELECT * FROM STT
FOR SYSTEM_TIME AS OF CURRENT TEMPORAL SYSTEM_TIME
WHERE POLICY_ID = 123;
```

Example of a procedure that uses CURRENT TEMPORAL SYSTEM_TIME

Suppose that procedure MYPROC is defined as follows:

```
CREATE PROCEDURE MYPROC(OUT VAR1 VARCHAR(40), OUT VAR2 VARCHAR(40))
BEGIN
 SELECT CURRENT TEMPORAL SYSTEM_TIME INTO VAR1
 FROM SYSIBM.SYSDUMMY1;

 SET CURRENT TEMPORAL SYSTEM_TIME = TIMESTAMP('2011-01-01') + 5 DAYS ;

 SELECT CURRENT TEMPORAL SYSTEM_TIME INTO VAR2
 FROM SYSIBM.SYSDUMMY1;
END!
```

Suppose that the application defines string variables VAR1, VAR2, and VAR3 and contains the following SQL statements:

```
SET CURRENT TEMPORAL SYSTEM_TIME = TIMESTAMP('2008-01-01') + 5 DAYS ;

CALL MYPROC(VAR1, VAR2);

SELECT CURRENT TEMPORAL SYSTEM_TIME INTO VAR3
FROM SYSIBM.SYSDUMMY1
```

After the execution of the SQL statements, the variables have the following values:

- VAR1 has value '2008-01-06-00.00.00.000000000000', which is the CURRENT TEMPORAL SYSTEM_TIME value that is set before the CALL statement invoked the procedure.
- VAR2 has value '2011-01-06-00.00.00.000000000000', which is the CURRENT TEMPORAL SYSTEM_TIME value that is set during the CALL statement.
- VAR3 has value '2008-01-06-00.00.00.000000000000', which is the CURRENT TEMPORAL SYSTEM_TIME value that is set before the CALL statement. The changes of the register value inside the procedure have no affect on the invoking application.

Example of a query that references a system-period temporal table

Assume that IN_TRAY is a system-period temporal table that contains users and subject lines for notes in the inbox. The following query returns the user IDs and subject lines based on the state of the messages in IN_TRAY as of the date that is specified by the CURRENT TEMPORAL SYSTEM_TIME special register.

```
SELECT SOURCE, SUBJECT
FROM IN_TRAY
```

If the special register is set to a non-null value, the previous statement is equivalent to the following statement:

```
SELECT SOURCE, SUBJECT
FROM IN_TRAY
FOR SYSTEM_TIME AS OF CURRENT TEMPORAL SYSTEM_TIME
```

BIND and REBIND options for packages, plans, and services (Db2 Commands)

SET CURRENT TEMPORAL SYSTEM_TIME
The SET CURRENT TEMPORAL SYSTEM_TIME statement changes the value of the CURRENT TEMPORAL SYSTEM_TIME special register.

Special registers in a user-defined function or a stored procedure
You can use all special registers in a user-defined function or a stored procedure. However, you can modify only some of those special registers.

CURRENT TIME special register

The CURRENT TIME special register specifies a time that is based on a reading of the time-of-day clock when the SQL statement is executed at the current server.

If this special register is used more than one time within a single SQL statement, or used with CURRENT DATE or CURRENT TIMESTAMP within a single statement, all values are based on a single clock reading.[10]

The value of CURRENT TIME in a user-defined function or stored procedure is inherited according to the rules in Table 47 on page 215. For other applications, the time is derived by the Db2 that executes the SQL statement that refers to the special register. For a description of how the date is derived, see Datetime special registers.

Specifying CURRENT_TIME is equivalent to specifying CURRENT TIME.

Example

Display information about all project activities and include the current date and time in each row of the result.

```
  SELECT DSN8C10.PROJACT.*, CURRENT DATE, CURRENT TIME
    FROM DSN8C10.PROJACT;
```

CURRENT TIMESTAMP special register

The CURRENT TIMESTAMP special register specifies a timestamp that is based on a reading of the time-of-day clock when the SQL statement is executed at the current server.

If this special register is used more than one time within a single SQL statement, or used with CURRENT DATE or CURRENT TIME within a single statement, all values are based on a single clock reading.[11]

The value of CURRENT TIMESTAMP in a user-defined function or stored procedure is inherited according to the rules in Table 47 on page 215.

Specifying CURRENT_TIMESTAMP is equivalent to specifying CURRENT TIMESTAMP.

[10] Except for the case of a non-atomic multiple row INSERT or MERGE statement.

[11] Except for the case of a non-atomic multiple row INSERT or MERGE statement.

If you want a timestamp with a specified precision, the special register can be referenced as CURRENT TIMESTAMP(*integer*), where *integer* can range 0 - 12. The default precision is 6. SYSDATE can also be specified as a synonym for CURRENT TIMESTAMP(0).

If you want a timestamp with a time zone, the special register can be referenced as CURRENT TIMESTAMP (*integer*) WITH TIME ZONE, or CURRENT TIMESTAMP WITH TIME ZONE. SYSTIMESTAMP can be specified as an alternative to CURRENT TIMESTAMP(12) WITH TIME ZONE. The time zone is determined from the CURRENT TIME ZONE special register.

Note: If the CURRENT TIMESTAMP special register is referenced in a timestamp with time zone context (for example, when compared with a timestamp with time zone column) the implicit time zone for the CURRENT TIMESTAMP special register will be based on the implicit time zone system parameter, which could be a different value from the CURRENT TIME ZONE special register. To avoid misinterpretation of the time zone in this case, CURRENT TIMESTAMP WITH TIME ZONE should be used.

Examples

Example 1

Display information about the full image copies that were taken in the last week.

```
  SELECT * FROM SYSIBM.SYSCOPY
    WHERE TIMESTAMP > CURRENT TIMESTAMP - 7 DAYS;
```

Example 2

Insert a row into the IN_TRAY table. The value of the RECEIVED column should be a timestamp that indicates when the row was inserted. The values for the other three columns come from the host variables *SRC* (CHAR(8)), *SUB* (CHAR(64)), and *TXT* (VARCHAR(200)).

```
INSERT INTO IN_TRAY
    VALUES (CURRENT TIMESTAMP, :SRC, :SUB, :TXT)
```

Example 3

Retrieve the value of the CURRENT TIMESTAMP special register with a precision of 8 and include the time zone:

```
SELECT CURRENT TIMESTAMP(8) WITH TIME ZONE
    FROM SYSIBM.SYSDUMMY1;
```

CURRENT TIME ZONE special register

The CURRENT TIME ZONE special register specifies a value that contains the difference between UTC and local time as defined by the current server, if the SESSION TIME ZONE special register has not been set.

The local time difference for the current server is set by z/OS, in the CLOCK*xx* PARMLIB member.

The data type is DECIMAL(6,0).

The difference between UTC and local time at the current server is represented by a time duration. A time duration is a decimal number in which the first two digits are the number of hours, the next two digits are the number of minutes, and the last two digits are the number of seconds. The number of hours is adjusted, if necessary, to fit in the range between -24 and 24 exclusive.

Subtracting CURRENT TIME ZONE from a local time converts that local time to UTC.

CURRENT TIMEZONE can be specified as an alternative to CURRENT TIME ZONE.

Example

The following statement selects all rows of the IN_TRAY table. Assume that the RECEIVED column is defined as TIMESTAMP WITHOUT TIME ZONE. Adjust the timestamp value in the RECEIVED column to UTC by subtracting the value of the CURRENT TIME ZONE special register.

```
  SELECT RECEIVED - CURRENT TIME ZONE, SOURCE, SUBJECT, NOTE_TEXT
        FROM IN_TRAY;
```

Related information

CLOCKxx (time of day parameters) (MVS Initialization and Tuning Reference)

ENCRYPTION PASSWORD special register

The ENCRYPTION PASSWORD special register specifies the encryption password and the password hint (if one exists) that are used by the ENCRYPT_TDES, DECRYPT_BIT, DECRYPT_CHAR, and DECRYPT_DB built-in functions.

DECRYPT_BIT, DECRYPT_CHAR, and DECRYPT_DB

This special register can only be set, by using the SET ENCRYPTION PASSWORD statement, and cannot be referenced directly. The ENCRYPTION PASSWORD special register contains the value of the password that is used by the ENCRYPT_TDES and DECRYPT_BIT, DECRYPT_CHAR, and DECRYPT_DB built-in functions to encrypt and decrypt data when a password is not explicitly specified as a function argument. The ENCRYPTION PASSWORD special register can also contain a password hint which is associated with the values that are encrypted using the encryption password. The password hint is a character string that is used to help in remembering the password. The GETHINT function is used to return the password hint for an encrypted value.

The initial value of the ENCRYPTION PASSWORD special register is the empty string (' ').

The initial value of the ENCRYPTION PASSWORD special register in a user-defined function or procedure is inherited from the invoking application. In other contexts, the initial value of the special register is the empty string.

The password is not related to Db2 authentication and is used only for data encryption.

Related reference

SET ENCRYPTION PASSWORD
The SET ENCRYPTION PASSWORD statement sets the value of the encryption password and, optionally, the password hint. The ENCRYPT_TDES, DECRYPT_BIT, DECRYPT_CHAR, and DECRYPT_DB built-in functions use this password and password hint for data encryption unless the functions are invoked with an explicitly specified password and hint. The password is not tied to Db2 authentication and is used only for data encryption.

SESSION TIME ZONE special register

The SESSION TIME ZONE special register specifies a value that identifies the time zone of the application process.

The data type is VARCHAR(128).

The time zone value is in the format of ±*th*:*tm*. *th* represents the time zone hour offset. *tm* represents the time zone minute offset. Valid values for *th* are between -12 and +14. Valid values for *tm* are between 0 and 59. SESSION TIMEZONE can be specified as an alternative to SESSION TIME ZONE.

The initial value of the special register in a user-defined function or stored procedure is inherited according to the rules in "Special registers in a user-defined function or a stored procedure" on page 215. In other contexts the initial value of the special register represents the same time zone as the CURRENT TIME ZONE special register.

The value of the special register can be changed by executing the SET SESSION TIME ZONE statement. After a SET SESSION TIME ZONE statement has been processed, the values of the SESSION TIME ZONE and CURRENT TIME ZONE special register might not reflect the same value.

Example

The following statement set the session time zone to '-8:00'.

```
SET SESSION TIME ZONE = '-8:00';
```

Related reference

SET SESSION TIME ZONE
The SET SESSION TIME ZONE statement assigns a value to the SESSION TIME ZONE special register.

SESSION_USER special register

SESSION_USER specifies the primary authorization ID of the process.

The data type is VARCHAR(128).

If SESSION_USER is referred to in an SQL statement that is executed at a remote Db2 and the primary authorization ID has been translated to a different authorization ID, SESSION_USER specifies the translated authorization ID. The value of SESSION_USER in a user-defined function or stored procedure is determined according to the rules in Table 47 on page 215.

USER can be specified as a synonym for SESSION_USER.

Example

Display information about tables, views, and aliases that are owned by the primary authorization ID of the process.

```
SELECT * FROM SYSIBM.SYSTABLES WHERE CREATOR = SESSION_USER;
```

Related concepts

Authorization ID translations
When certain authorization IDs are sent to a remote DBMS, those authorization IDs might undergo translation before being used.

Related tasks

Translating inbound IDs (Managing Security)

USER special register

USER specifies the primary authorization ID of the process. The data type is VARCHAR(128). SESSION_USER is the preferred spelling.

If USER is referred to in an SQL statement that is executed at a remote Db2 and the primary authorization ID has been translated to a different authorization ID, USER specifies the translated authorization ID. The value of USER in a user-defined function or stored procedure is determined according to the rules in Table 47 on page 215.

Example

Display information about tables, views, and aliases that are owned by the primary authorization ID of the process.

```
SELECT * FROM SYSIBM.SYSTABLES WHERE CREATOR = USER;
```

Related concepts

Authorization ID translations
When certain authorization IDs are sent to a remote DBMS, those authorization IDs might undergo translation before being used.

SESSION_USER specifies the primary authorization ID of the process.

Special registers in a user-defined function or a stored procedure

You can use all special registers in a user-defined function or a stored procedure. However, you can modify only some of those special registers.

After a user-defined function or a stored procedure completes, Db2 restores all special registers to the values they had before invocation.

The following table shows information that you need when you use special registers in a user-defined function or stored procedure.

Table 47. Characteristics of special registers in a user-defined function or a stored procedure

Special register	Initial value when INHERIT SPECIAL REGISTERS option is specified	Initial value when DEFAULT SPECIAL REGISTERS option is specified	Routine can use SET statement to modify?
CURRENT ACCELERATOR	Inherited from the invoking application[6]; otherwise, no preferred accelerator is used and Db2 will determine the target accelerator	The ACCELERATOR bind option value if specified for the user-defined function or stored procedure package; otherwise, no preferred accelerator is used and Db2 will determine the target accelerator	Yes
CURRENT APPLICATION COMPATIBILITY	The value of bind option APPLCOMPAT for the user-defined function or stored procedure package	The value of bind option APPLCOMPAT for the user-defined function or stored procedure package	Yes
CURRENT APPLICATION ENCODING SCHEME	The value of bind option ENCODING for the user-defined function or stored procedure package	The value of bind option ENCODING for the user-defined function or stored procedure package	Yes
CURRENT CLIENT_ACCTNG	Inherited from the invoking application	Inherited from the invoking application	Not applicable[5]
CURRENT CLIENT_APPLNAME	Inherited from the invoking application	Inherited from the invoking application	Not applicable[5]
CURRENT CLIENT_USERID	Inherited from the invoking application	Inherited from the invoking application	Not applicable[5]
CURRENT CLIENT_WRKSTNNAME	Inherited from the invoking application	Inherited from the invoking application	Not applicable[5]
CURRENT DATE	New value for each SQL statement in the user-defined function or stored procedure package[1]	New value for each SQL statement in the user-defined function or stored procedure package[1]	Not applicable[5]
CURRENT DEBUG MODE	Inherited from the invoking application	DISALLOW	Yes
CURRENT DECFLOAT ROUNDING MODE	Inherited from the invoking application	The value of bind option ROUNDING for the user-defined function or stored procedure package	Yes

Table 47. Characteristics of special registers in a user-defined function or a stored procedure (continued)

Special register	Initial value when INHERIT SPECIAL REGISTERS option is specified	Initial value when DEFAULT SPECIAL REGISTERS option is specified	Routine can use SET statement to modify?
CURRENT DEGREE	CURRENT DEGREE[2]	The value of field CURRENT DEGREE on installation panel DSNTIP8	Yes
CURRENT EXPLAIN MODE	Inherited from the invoking application	NO	Yes
CURRENT GET_ACCEL_ARCHIVE	Inherited from the invoking application[6]; otherwise, the subsystem parameter value will be used	The GETACCELARCHIVE bind option value if specified for the user-defined function or stored procedure package; otherwise, the subsystem parameter value will be used	Yes
CURRENT LOCALE LC_CTYPE	Inherited from the invoking application	The value of field CURRENT LC_CTYPE on installation panel DSNTIPF	Yes
CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION	Inherited from the invoking application	System default value	Yes
CURRENT MEMBER	New value for each SET *host-variable*=CURRENT MEMBER statement	New value for each SET *host-variable*=CURRENT MEMBER statement	Not applicable[5]
CURRENT OPTIMIZATION HINT	The value of bind option OPTHINT for the user-defined function or stored procedure package or inherited from the invoking application[6]	The value of bind option OPTHINT for the user-defined function or stored procedure package	Yes
CURRENT PACKAGE PATH	An empty string if the routine was defined with a COLLID value; otherwise, inherited from the invoking application[4]	An empty string, regardless of whether a COLLID value was specified for the routine[4]	Yes
CURRENT PACKAGESET	Inherited from the invoking application[3]	Inherited from the invoking application[3]	Yes
CURRENT PATH	The value of bind option PATH for the user-defined function or stored procedure package or inherited from the invoking application[6]	The value of bind option PATH for the user-defined function or stored procedure package	Yes
CURRENT PRECISION	Inherited from the invoking application	The value of field DECIMAL ARITHMETIC on installation panel DSNTIP4	Yes
CURRENT QUERY ACCELERATION	Inherited from the invoking application[6]; otherwise, the subsystem parameter value will be used	The QUERYACCELERATION bind option value if specified for the user-defined function or stored procedure package; otherwise, the subsystem parameter value will be used	Yes

Table 47. Characteristics of special registers in a user-defined function or a stored procedure (continued)

Special register	Initial value when INHERIT SPECIAL REGISTERS option is specified	Initial value when DEFAULT SPECIAL REGISTERS option is specified	Routine can use SET statement to modify?
CURRENT QUERY ACCELERATION WAITFORDATA	Inherited from the invoking application[6]; otherwise, the subsystem parameter value will be used	The ACCELERATIONWAITFORDATA bind option value if specified for the user-defined function or stored procedure package; otherwise, the subsystem parameter value will be used	Yes
CURRENT REFRESH AGE	Inherited from the invoking application	System default value	Yes
CURRENT ROUTINE VERSION	Inherited from the invoking application	The empty string	Yes
CURRENT RULES	Inherited from the invoking application	The value of bind option SQLRULES for the plan that invokes a user-defined function or stored procedure	Yes
CURRENT SCHEMA	Inherited from the invoking application	The value of CURRENT SCHEMA when the routine is entered	Yes
CURRENT SERVER	Inherited from the invoking application	Inherited from the invoking application	Yes
CURRENT SQLID	The primary authorization ID of the application process or inherited from the invoking application[7]	The primary authorization ID of the application process	Yes[8]
CURRENT TEMPORAL BUSINESS_TIME	Inherited from the invoking application	NULL	Yes
CURRENT TEMPORAL SYSTEM_TIME	Inherited from the invoking application	NULL	Yes
CURRENT TIME	New value for each SQL statement in the user-defined function or stored procedure package[1]	New value for each SQL statement in the user-defined function or stored procedure package[1]	Not applicable[5]
CURRENT TIMESTAMP	New value for each SQL statement in the user-defined function or stored procedure package[1]	New value for each SQL statement in the user-defined function or stored procedure package[1]	Not applicable[5]
CURRENT TIMESTAMP WITH TIME ZONE	New value for each SQL statement in the user-defined function or stored procedure package[1]	New value for each SQL statement in the user-defined function or stored procedure package[1]	Not applicable[5]
CURRENT TIME ZONE	Inherited from the invoking application	Inherited from the invoking application	Not applicable[5]

Table 47. Characteristics of special registers in a user-defined function or a stored procedure (continued)

Special register	Initial value when INHERIT SPECIAL REGISTERS option is specified	Initial value when DEFAULT SPECIAL REGISTERS option is specified	Routine can use SET statement to modify?
ENCRYPTION PASSWORD	Inherited from the invoking application	Inherited from the invoking application	Yes
SESSION TIME ZONE	Inherited from the invoking application	The value of CURRENT TIME ZONE when the routine is entered	Yes
SESSION_USER or USER	Primary authorization ID of the application process	Primary authorization ID of the application process	Not applicable[5]

Notes:

1. If the user-defined function or stored procedure is invoked within the scope of a trigger, Db2 uses the timestamp for the triggering SQL statement as the timestamp for all SQL statements in the package.
2. Db2 allows parallelism at only one level of a nested SQL statement. If you set the value of the CURRENT DEGREE special register to ANY, and parallelism is disabled, Db2 ignores the CURRENT DEGREE value.
3. If the routine definition includes a specification for COLLID, Db2 sets CURRENT PACKAGESET to the value of COLLID. If both CURRENT PACKAGE PATH and COLLID are specified, the CURRENT PACKAGE PATH value takes precedence and COLLID is ignored.
4. If the function definition includes a specification for PACKAGE PATH, Db2 sets CURRENT PACKAGE PATH to the value of PACKAGE PATH.
5. Not applicable because no SET statement exists for the special register.
6. If a program within the scope of the invoking program issues a SET statement for the special register before the user-defined function or stored procedure is invoked, the special register inherits the value from the SET statement. Otherwise, the special register contains the value that is set by the bind option for the user-defined function or stored procedure package.
7. If a program within the scope of the invoking program issues a SET CURRENT SQLID statement before the user-defined function or stored procedure is invoked, the special register inherits the value from the SET statement. Otherwise, CURRENT SQLID contains the authorization ID of the application process.
8. If the user-defined function or stored procedure package uses a value other than RUN for the DYNAMICRULES bind option, the SET CURRENT SQLID statement can be executed. However, it does not affect the authorization ID that is used for the dynamic SQL statements in the package. The DYNAMICRULES value determines the authorization ID that is used for dynamic SQL statements.

Special registers

A special register is a storage area that is defined for an application process by Db2 and is used to store information that can be referenced in SQL statements. A reference to a special register is a reference to a value provided by the current server. If the value is a string, its CCSID is a default CCSID of the current server.

Column names

The meaning of a column name depends on its context.

A column name can be used to:

- Declare the name of a column, as in a CREATE TABLE statement.
- Specify the name of a column, as in a CREATE FUNCTION statement to name a column of the result table of a table function.
- Identify a column, as in a CREATE INDEX statement.
- Specify values of the column, as in the following contexts:
  - In an *aggregate function*, a column name specifies all values of the column in the group or intermediate result table to which the function is applied. (Groups and intermediate result tables are explained in Chapter 6, "Queries," on page 1005.) For example, MAX(SALARY) applies the function MAX to all values of the column SALARY in a group.
  - In a *GROUP BY* or *ORDER BY* clause, a column name specifies all values in the intermediate result table to which the clause is applied. For example, ORDER BY DEPT orders an intermediate result table by the values of the column DEPT.
  - In an *expression,* a *search condition,* or a *scalar function,* a column name specifies a value for each row or group to which the construct is applied. For example, when the search condition CODE = 20 is applied to some row, the value specified by the column name CODE is the value of the column CODE in that row.
- Provide a column name for an expression to temporarily rename a column, as in the *correlation-clause* of a *table-reference* in a FROM clause or as in the AS clause in the *select-clause*.

Qualified column names

A qualifier for a column name can be a table name, a view name, an alias name, a synonym, or a correlation name. Whether a column name can be qualified depends, like its meaning, on its context.

- In some forms of the COMMENT and LABEL statements, a column name must be qualified. This is shown in the syntax diagrams.
- Where the column name specifies values of the column, a column name can be qualified at the user's option.
- In the column list of an INSERT statement, a column name can be qualified.
- In the *assignment-clause* of an UPDATE or a MERGE statement, a column name can be qualified.
- In all other contexts, a column name must not be qualified. This rule will be mentioned in the discussion of each statement to which it applies.

Where a qualifier is optional, it can serve two purposes. See "Column name qualifiers to avoid ambiguity" on page 220 for details.

Correlation names

A *correlation name* can be defined in the FROM clause of a query and after the name of the target table or view in an UPDATE, MERGE, or DELETE statement.

For example, the following clause establishes Z as a correlation name for X.MYTABLE:

```
FROM X.MYTABLE Z
```

With Z defined as a correlation name for table X.MYTABLE, only Z should be used to qualify a reference to a column of X.MYTABLE in that SELECT statement.

A correlation name is associated with a table, view, nested table expression or table function only within the context in which it is defined. Hence, the same correlation name can be defined for different purposes in different statements. In a nested table expression or table function, a correlation name is required.

As a qualifier, a correlation name can be used to avoid ambiguity or to establish a correlated reference. It can also be used merely as a shorter name for a table or view. In the example, Z might have been used merely to avoid having to enter X.MYTABLE more than once.

Names that are specified in a FROM clause are either *exposed* or *non-exposed*. A correlation name is always an exposed name. A table name or view name is said to be exposed in that FROM clause if a correlation name is not specified. For example, in the following FROM clause, a correlation name is specified for EMPLOYEE, but not for DEPARTMENT; therefore, DEPARTMENT is an exposed name, and EMPLOYEE is not an exposed name:

```
FROM EMPLOYEE E, DEPARTMENT
```

The use of a correlation name in the FROM clause also allows the option of specifying a list of column names to be associated with the columns of the result table. As with a correlation name, the listed column names should be the names that are used to reference the columns in that SELECT statement. For example, assume that the name of the first column in the DEPT table is DEPTNO. Given this FROM clause in a SELECT statement:

```
  FROM DEPT D (NUM,NAME,MGR,ANUM,LOC)
```

You should use D.NUM instead of D.DEPTNO to reference the first column of the table.

If a list of columns is specified, it must consist of as many names as there are columns in the *table-reference*. Each column must be unique and unqualified.

Column name qualifiers to avoid ambiguity

In the context of a function, a GROUP BY clause, an ORDER BY clause, an expression, or a search condition, a column name refers to values of a column in some table or view in a DELETE, MERGE, or UPDATE statement or *table-reference* in a FROM clause.

The tables, views, and *table-references*[12] that might contain the column are called the *object tables* of the context. Two or more object tables might contain columns with the same name. One reason for qualifying a column name is to designate the object from which the column comes. For information on avoiding ambiguity between SQL parameters and variables and column names, see "References to SQL parameters and SQL variables in external SQL procedures" on page 2268.

A nested table expression which is preceded by a TABLE keyword will consider *table-references* that precede it in the FROM clause as object tables. The *table-references* that follow it are not considered as object tables.

Table designators: A qualifier that designates a specific object table is called a *table designator*. The clause that identifies the object tables also establishes the table designators for them. For example, the object tables of an expression in a SELECT statement are named in the FROM clause that follows it, as in the following statement:

```
   SELECT DISTINCT Z.EMPNO, EMPTIME, PHONENO
     FROM DSN8C10.EMP Z, DSN8C10.EMPPROJACT
     WHERE WORKDEPT = 'D11'
       AND EMPTIME > 0.5
       AND Z.EMPNO = DSN8C10.EMPPROJACT.EMPNO;
```

Table designators in the FROM clause are established as follows:

- A name that follows a table or view name is both a correlation name and a table designator. Thus, Z is a table designator and qualifies the first column name in the select list.
- An exposed table or view name is a table designator. Thus, the qualified table name, DSN8C10.EMPPROJACT is a table designator and qualifies the second column name in the select list.

Two or more object tables can be instances of the same table. In this case, distinct correlation names must be used to unambiguously designate the particular instance of the table. In the following example,

[12] In the case of a *joined-table*, each *table-reference* within the *joined-table* is an object table.

the X and Y in the FROM clause are defined to refer, respectively, to the first and second instances of the DSN8C10.EMP table:

```
SELECT *
  FROM DSN8C10.EMP X, DSN8C10.EMP Y;
```

Avoiding undefined or ambiguous references in Db2 SQL: When a column name refers to values of a column, the following situations result in errors:

- No object table contains a column with the specified name. The reference is undefined.
- The column name is qualified by a table designator, but the table named does not include a column with the specified name. Again, the reference is undefined.
- The name is unqualified and more than one object table includes a column with that name. The reference is ambiguous.

Avoid ambiguous references by qualifying a column name with a uniquely defined table designator. If the column is contained in several object tables with different names, the table names can be used as designators. Ambiguous references can also be avoided without the use of the table designator by giving unique names to the columns of one of the object tables using the column name list following the correlation name.

Two or more object tables can be instances of the same table. A FROM clause that includes *n* references to the same table should include at least *n* - 1 unique correlation names.

For example, in the following FROM clause X and Y are defined to refer, respectively, to the first and second instances of the table EMP.

```
SELECT X.LASTNAME, Y.LASTNAME
  FROM DSN8C10.EMP X, DSN8C10.EMP Y
  WHERE Y.JOB = 'MANAGER'
    AND X.WORKDEPT = Y.WORKDEPT
    AND X.JOB <> 'MANAGER';
```

When qualifying a column with the exposed table name form of a table designator, either the qualified or unqualified form of the exposed table name can be used. However, the qualifier used and the table used must be the same after fully qualifying the table name or view name and the table designator.

Example 1: If the authorization ID of the statement is CORPDATA, the following statement is valid:

```
SELECT CORPDATA.EMPLOYEE.WORKDEPT
  FROM EMPLOYEE;
```

Example 2: If the authorization ID of the statement is REGION, the following statement is invalid because EMPLOYEE represents the table REGION.EMPLOYEE, but the qualifier for WORKDEPT represents a different table, CORPDATA.EMPLOYEE:

```
SELECT CORPDATA.EMPLOYEE.WORKDEPT               -- Incorrect
  FROM EMPLOYEE;
```

Example 3: If the authorization ID of the statement is REGION, the following statement is invalid because EMPLOYEE in the select list represents the table REGION.EMPLOYEE, but the explicitly qualified table name in the FROM clause represents a different table, CORPDATA.EMPLOYEE.

```
SELECT EMPLOYEE.WORKDEPT                       -- Incorrect
  FROM CORPDATA.EMPLOYEE;
```

Column name qualifiers in correlated references

A reference to a column of a table identified at a higher level is called a *correlated reference*. Because the same table or view can be identified at many levels, unique correlation names are recommended as table designators. It is good practice to use these unique correlation names to qualify column names.

A *subselect* is a form of a query that can be used as a component of various SQL statements. A *subquery* is a form of a fullselect that is enclosed within parenthesis. For example, a subquery can be used in a search condition. A fullselect that is used to retrieve a single value as an expression within a statement is called a *scalar fullselect* or a *scalar subquery*. A fullselect that is used in the FROM clause of a query is called a *nested table expression*.

A subquery can include search conditions of its own, and these search conditions can, in turn, include subqueries. Thus, an SQL statement can contain a hierarchy of subqueries. Those elements of the hierarchy that contain subqueries are said to be at a higher level than the subqueries they contain.

Every element of the hierarchy has a clause that establishes one or more table designators. This is the FROM clause, except in the highest level of a MERGE or UPDATE, where it is the table or view being updated. A search condition of a subquery can reference not only columns of the tables identified by the FROM clause of its own element of the hierarchy, but also columns of tables identified at any level along the path from its own element to the highest level of the hierarchy.

A correlated reference to column C of table T can be of the form C, T.C, or Q.C, if Q is a correlation name defined for T. However, **a correlated reference in the form of an unqualified column name is not good practice**. The following explanation is based on the assumption that a correlated reference is always in the form of a qualified column name and that the qualifier is a correlation name.

A qualified column name, Q.C, is a correlated reference only if these three conditions are met:

- Q.C is used in a search condition or in a select list of a subquery.
- Q does not name a table used in the FROM clause of that subquery.
- Q does name a table used at some higher level.

Q.C refers to column C of the table or view at the level where Q is used as the table designator of that table or view. Because the same table or view can be identified at many levels, unique correlation names are recommended as table designators. If Q is used to name a table at more than one level, Q.C refers to the lowest level that contains the subquery that includes Q.C.

If a correlation name is defined as the table designator of the table or view, but the table or view name is used as the column qualifier instead of the correlation name, an error is returned.

For example, in the following statement, the correlated reference X.WORKDEPT (in the last line) refers to the value of WORKDEPT in table DSN8C10.EMP at the level of the first FROM clause (which establishes X as a correlation name for DSN8C10.EMP.). The statement lists employees who make less than the average salary for their department.

```
SELECT EMPNO, LASTNAME, WORKDEPT
  FROM DSN8C10.EMP X
  WHERE SALARY < (SELECT AVG(SALARY)
                    FROM DSN8C10.EMP
                    WHERE WORKDEPT = X.WORKDEPT);
```

The following example shows a correlated reference in the select list of the subquery.

```
SELECT T1.KEY1
  FROM BP1TBL T1
  GROUP BY T1.KEY1
  HAVING MAX(T1.KEY1) = (SELECT MIN(T1.KEY1) + MIN(T2.KEY1)
                    FROM BP2TBL T2);
```

Related concepts

Queries

A *query* specifies a result table or an intermediate table. A query is a component of certain SQL statements.

Resolution of column name qualifiers and column names

The rules for resolving column name qualifiers apply to every SQL statement that includes a subselect and are applied before synonyms and aliases are resolved.

Names in a FROM clause are either *exposed* or *non-exposed*. A correlation name for a table name, view name, nested table expression, or reference to a table function is always exposed. A table name or a view name that is not followed by a correlation name is also exposed.

Although Db2 for z/OS does not enforce this rule strictly, in IBM SQL and ANSI/ISO SQL, the exposed names in a FROM clause must be unique, and the qualifier of a column name must be an exposed name. Therefore, for good programming practices, ensure that all exposed names are unique and that all qualified column names are qualified with the appropriate exposed name.

The rules for finding the referent of a column name qualifier are as follows:

1. Let Q be a one-, two-, or three-part name, and let Q.C denote a column name in subselect S. Q must designate a table or view identified in the statement that includes S and that table or view must have a column named C. An additional requirement differs for two cases:
   - If Q.C *is not* in a *search-condition* or S *is not* a subquery, Q must designate a table or view identified in the FROM clause of S. For example, if Q.C is in a SELECT clause, Q refers to a table or view in the following FROM clause.
   - If Q.C *is* in a *search-condition* and S *is* a subquery, Q must designate a table or view identified either in the FROM clause of S or in a FROM clause of a subselect that directly or indirectly includes S. For example, if Q.C is in a WHERE clause and S is the only subquery in the statement, the table or view that Q refers to is either in the FROM clause of S or the FROM clause of the subselect that includes S.
2. The same table or view can be identified more than once in the same statement. The particular occurrence of the table or view that Q refers to is determined by a procedure equivalent to the following steps:

   a. The one- and two-part names in every FROM clause and the one- and two-part qualifiers of column names are expanded into a fully-qualified form.

      For example, if a dynamic SQL statement uses FROM Q and DYNAMICRULES run behavior (RUN) is in effect, Q is expanded to S.A.Q, where S is the value of CURRENT SERVER and A is the value of CURRENT SCHEMA. (If DYNAMICRULES bind behavior is in effect instead, A is the plan or package qualifier as determined during the bind process or the qualifier for the native SQL procedure as determined when the procedure was defined.) This step is later referred to as "name completion". An error occurs if the first part of every name (the location) is not the same.

   b. Q, now a three-part name, is compared with every name in the FROM clause of S. If Q.C is in a *search-condition* and S is a subquery, Q is next compared with every name in the FROM clause of the subselect that contains S. If that subselect is a subquery, Q is then compared with every name in the FROM clause of the subselect containing that subquery, and so on. If a FROM clause includes multiple names, the comparisons in that clause are made in order from left to right.

   c. The referent of Q is selected by these rules:

      - If Q matches exactly one name, that name is selected.
      - If Q matches more than one name, but only one exposed name, that exposed name is selected.
      - If Q matches more than one exposed name, the first of those names is selected.
      - If Q matches more than one name, none of which are exposed names, the first of those names is selected.

      If Q does not match any name, or if the table or view designated by Q does not include a column named C, an error occurs.

   d. Otherwise, Q.C is resolved to column C of the occurrence of the table or view identified by the selected name.

3. A warning occurs for any of these cases:

   - The selected name is not an exposed name.
   - The selected name is an exposed name that has an unexposed duplicate that appears before the selected name in the ordered list of names to which Q is compared.
   - The selected name is an exposed name that has an exposed duplicate in the same FROM clause.
   - Another name would have been selected had the matching been performed before name completion.

   The rules for resolving column name qualifiers apply to every SQL statement that includes a subselect and are applied before synonyms and aliases are resolved. In the case of a searched UPDATE or DELETE statement, or a MERGE statement, the first clause of the statement identifies the table or view to be changed. That clause can include a correlation name and, with regard to name resolution, is equivalent to the first FROM clause of a SELECT statement. For example, a subquery in the search condition of an UPDATE statement can include a correlated reference to a column of the updated rows.

   The rules for column names in the ORDER BY clause are the same as other clauses.

Variables

A *variable* in an SQL statement specifies a value that can be changed when the SQL statement is executed. There are several types of variables used in SQL statements.

Global variables
Global variables are either built-in global variables or user-defined global variables. For more information about global variables, see "Global variables" on page 225.

Session variables
Session variables are either built-in session variables or user-defined session variables. For more information about session variables, see "Session variables" on page 226.

Host variables
Host variables are defined by statements of a host language. For more information about how to refer to host variables, see "Host variables" on page 227.

Transition variables
Transition variables are defined in a trigger and refer to either the old or new values of columns of the subject table or view of a trigger. For more information about how to refer to transition variables, see "CREATE TRIGGER (basic)" on page 1764.

SQL variables
SQL variables are defined by an SQL compound statement in an SQL function or SQL procedure. For more information about SQL variables, see "References to SQL parameters and variables in SQL PL" on page 2198.

SQL parameters
SQL parameters are defined in an CREATE FUNCTION (SQL Scalar), CREATE FUNCTION (SQL table), or CREATE PROCEDURE (SQL) statement. For more information about SQL parameters, see "References to SQL parameters and variables in SQL PL" on page 2198.

Parameter markers
Parameter markers are specified in an SQL statement that is dynamically prepared, instead of variables, other than global variables. For more information about parameter markers, see Parameter markers in the PREPARE statement.

Unless otherwise noted, the term *variable* in syntax diagrams is used to describe where a global variable, host variable, transition variable, SQL variable, SQL parameter, or parameter marker can be used.

Global variables

A global variable is a named memory variable that you access through SQL statements. Global variables let you share relational data between SQL statements without the need for application logic to support this data transfer.

The Db2 database management system supports the following types of global variables:

Built-in global variable

Built-in global variables are provided with the database manager and are used in SQL statements to retrieve scalar values associated with the variables. A built-in global variable is available to any SQL statement that runs on the database manager. Built-in global variables reside in the SYSIBM and SYSIBMADM schemas. As an example, the CLIENT_IPADDR built-in global variable can be referenced in an SQL statement to retrieve the IP address of the current client.

For a list of the built-in global variables and information on these variables, see "Built-in global variables" on page 329.

The READ privilege on a built-in global variable is required for any statement that retrieves the value of that variable. The READ privilege for the built-in global variables is implicitly granted to PUBLIC during installation.

The WRITE privilege on an updatable built-in global variable is required for any statement that assigns a value to that variable. You can control write access to an updatable built-in global variable through the GRANT (variable privileges) and REVOKE (variable privileges) statements.

Examples: Using built- in global variables

The value of a built-in global variable can be obtained by referencing the variable in the context in which the value is needed.

```
SELECT C1, C2
  FROM T1
  WHERE C3 = CLIENT_IPADDR
```

To access the global variable `CLIENT_HOST`, run the following query:

```
SELECT SYSIBM.CLIENT_IPADDR
  FROM SYSIBM.SYSDUMMY1
```

The query returns the IP address of the current client.

```
1111:2222:3333:4444:5555:6666:7777:8888
```

To change the value of an updatable built-in global variable, issue the "SET variable" statement:

```
SET SYSIBMADM.GET_ARCHIVE = 'Y'
```

User-defined global variable

A user-defined global variable is available to any active SQL statement that is running on the database manager on which the variable was defined. The value of a user-defined global variable is associated with a specific session, and contains a value that is unique to that session. User-defined global variables let users extend the functionality of the database management system by adding their own or third-party vendor variable definitions.

A user-defined global variable is created using the CREATE VARIABLE statement, and registered to the database manager in the catalog. A user-defined global variable resides in the schema in which it was created. For more information, see "CREATE VARIABLE" on page 1803.

You can control access to a user-defined global variable through the "GRANT (variable privileges)" on page 1987 and "REVOKE (variable privileges)" on page 2101 statements. The authorization that is required to use a global variable depends on where it is defined and how it is used.

- The authorization ID of an SQL statement that references a user-defined global variable and retrieves the value must have the READ privilege on the global variable.
- The authorization ID of an SQL statement that references a user-defined global variable and assigns a value to that variable must have the WRITE privilege on the global variable.

The value of a user-defined global variable can be obtained by referencing the variable in the context in which the value is needed. The value of a user-defined global variable can be changed with the following statements:

- EXECUTE
- FETCH
- SET
- SELECT INTO
- VALUES INTO
- CALL, if the variable is an argument to a procedure in which the corresponding parameter is defined as an OUT or INOUT parameter.

A reference, with an unqualified name, that is intended to resolve to a global variable could also resolve to an SQL variable, an SQL parameter, or even a column name, depending on the context of the reference and how the reference is qualified within that context. The implicit schema name for an unqualified variable name depends on the context in which the name appears:

- If an unqualified variable name is used in a CREATE VARIABLE, or the object of a DROP, COMMENT, GRANT, or REVOKE statement, the normal process of qualification by the authorization ID is used to determine the schema name.
- If an unqualified variable name is used in any other context, the SQL path is used to determine the schema name. The database manager searches the schemas in the SQL path in sequence. The schema that is selected is the first schema in the SQL path for which the global variable exists in the schema, and the user has authorization to use the variable. For a description of the SQL path, see "SQL path" on page 85.

Session variables

A session variable is a named memory variable that you access through SQL statements. Session variables let you share data between SQL statements without the need for application logic to support this data transfer.

The Db2 for z/OS supports the following types of session variables:

Built-in session variables

Built-in session variables are provided with the database manager. The value of a built-in session variable can be obtained by invoking the GETVARIABLE built-in function to retrieve the scalar value associated with the variable.

For more information about built-in session variables, see "Built-in session variables" on page 336.

User-defined session variables

User-defined session variables can be defined in connection and sign-on routines. A user-defined session variable is available to any active SQL statement that is running on the database manager on which the variable was defined. The value of a user-defined session variable is associated with a specific session and contains a value that is unique to that session. User-defined session variables let users extend the functionality of the database management system by adding their own or third-party vendor variable definitions.

Up to 10 user-defined session variables can be defined in the connection exit routine and the sign-on exit routine. For more information about defining user-defined session variables, see Session variables in connection and sign-on routines (Managing Security).

You can obtain the value of a user-defined or built-in session variable by invoking the GETVARIABLE function with the name of the session variable. For more information on retrieving the value of a session variable, see "GETVARIABLE" on page 464.

Host variables

Host variables are defined directly by statements of the host language or indirectly by SQL extensions. A *host-variable* in an SQL statement must identify a host variable that is described in the program according to the rules for declaring host variables. Host variables cannot be referenced in dynamic SQL statements; parameter markers must be used instead.

A *host variable* is either of these items that is referred to in an SQL statement:

- A variable in a host language such as a PL/I variable, C variable, Fortran variable, REXX variable, Java variable, COBOL data item, or Assembler language storage area
- A host language construct that was generated by an SQL precompiler from a variable declared using SQL extensions

Host variables are defined directly by statements in the host language or indirectly by SQL extensions as described in Db2 object relational extensions (Db2 Application programming and SQL). Host variables cannot be referenced in dynamic SQL statements; parameter markers must be used instead. For more information about parameter markers, see "Variables in dynamic SQL" on page 229.

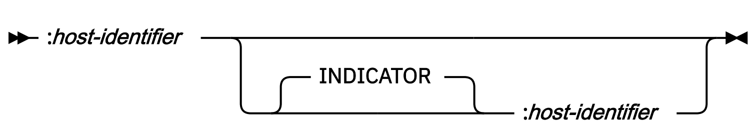
A host-variable in an SQL statement must identify a host variable that is described in the program according to the rules for declaring host variables.

In PL/I, C, and COBOL, host variables can be referred to in ways that do not apply to Fortran and Assembler language. This is explained in "Host structures in PL/I, C, and COBOL" on page 235. The following applies to all host languages.

The term *host-variable*, as used in the syntax diagrams, shows a reference to a host variable. In a SET *host variable* statement and the INTO clause of a FETCH, SELECT INTO, or VALUES INTO statement, a host variable is an output variable to which a value is assigned by Db2. In a CALL statement, a host variable can be an output argument that is assigned a value after execution of the procedure, an input argument that provides an input value for the procedure, or both an input and output argument. In all other contexts, a host variable is an input variable which provides a value to Db2.

Non-Java variable references

The general form of a host variable reference in all languages other than Java is:



Each host identifier must be declared in the source program, except in a program written in REXX. The first *host-identifier* designates the main variable, and the second *host-identifier* designates the associated *indicator variable*. An indicator variable must be a small integer. Depending on the operation, the main variable either provides a value to the database manager or is provided a value from the database manager. An input host variable provides a value in the runtime application code page. An output host variable is provided a value that, if necessary, is converted to the runtime application code page when the data is copied to the output application variable. A given host variable can serve as both an input and an output variable in the same program.

The purposes of an indicator variable are to:

- Specify a non-null value. A 0 (zero), or positive value of the indicator variable specifies that the associated, first *host-identifier* provides the value of this host variable reference.
- Specify the null value. A negative value of the indicator variable specifies the null value.

In addition, on output, the purposes of an indicator variable are to:

- Indicate that a numeric conversion error (such as a divide by 0 or overflow) has occurred. A value of -2 for the indicator variable indicates a null result because of either numeric truncation or arithmetic warnings.
- Indicate that a character could not be converted. A value of -2 for the indicator variable indicates a null result because of character string conversion warnings.
- Indicate that no value was returned. A value of -3 for the indicator variable indicates a null result because the current row of the cursor is on a hole that is detected during a multiple row FETCH.
- Report the original length of a truncated string, if the string is not a LOB.
- Report the seconds portion of a time if the time is truncated on assignment to a host variable.

If the second *host-identifier* is omitted, the host variable does not have an indicator variable. The value specified by the host variable V1 is always the value of V1, and null values cannot be assigned to the variable. Thus, do not use this form on output unless the corresponding result column cannot contain null values. If this form is used for an output host variable, and the returned value is null, Db2 returns an error at run time.

An indicator variable for an input host variable in an INSERT, MERGE, or UPDATE statement can also be set to some special values to indicate that a target column is to be set to the default value, or to indicate that a value should not be assigned to a target column. These special values are only allowed when extended indicators are enabled. Extended indicators are enabled when the EXTENDEDINDICATOR(YES) bind option is used, or when the WITH EXTENDED INDICATORS prepare attribute is specified for the statement.

When extended indicators are enabled, an input indicator variable for an assignment in an INSERT, MERGE, or UPDATE statement specifies that the target column for the associated host variable is assigned one of the following types of values:

- A non-null value: A 0 (zero), or positive value specifies that the associated *host-identifier* provides the value of this host variable reference.
- NULL: A -1, -2, -3, -4, or -6 value specifies the null value.
- DEFAULT: A -5 value specifies the default value of the target column.
- UNASSIGNED: A -7 value specifies that this host variable is treated as if a value was not specified for assignment to the target column in the statement.

These indicator values can also be used in indicator structures with host structures. When extended indicators are enabled, indicator values other than positive values, zero, and the negative values listed previously must not be used. The DEFAULT and UNASSIGNED extended indicator values must only be used in contexts where they are supported (INSERT, MERGE, and UPDATE statements). The DEFAULT and UNASSIGNED extended indicator values can only be used for an expression containing a single host parameter or a CAST of a single host parameter that is being assigned to a column. Output indicators are never set to extended indicator values.

When extended indicators are enabled, rules for data type validation in assignment and comparison are loosened for a host variable for which the associated indicator value is negative. Data type assignment and comparison validation rules are not enforced for a host variable for which the associated indicator value is NULL, DEFAULT, or ASSIGNED.

An SQL statement that references host variables must be within the scope of the declaration of those host variables. For host variables referenced in the SELECT statement of a cursor, that rule applies to the OPEN statement rather than to the DECLARE CURSOR statement.

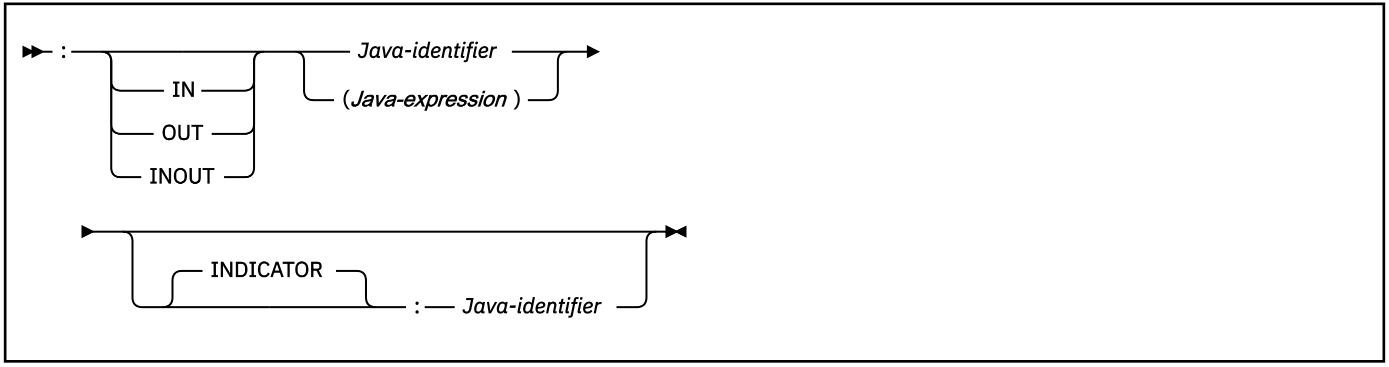
The CCSID of a string host variable is one of the following values:

- If a DECLARE VARIABLE statement with a CCSID clause for the host variable is specified, the CCSID of the host variable is the CCSID in the DECLARE VARIABLE statement.
- If a DECLARE VARIABLE statement with a CCSID clause is not specified for the host variable, the host variable CCSID is the default CCSID of the application requester at the time that the SQL statement that contains the host variable is executed, unless the CCSID is for a foreign encoding scheme. In that case, the host variable is converted to the default CCSID of the current server.

All references to host variables must be preceded by a colon. If an SQL statement references a host variable without a preceding colon, the precompiler issues an error for the missing colon or interprets the host variable as an unqualified column name, which might lead to unintended results. The interpretation of a host variable without a colon as a column name occurs when the host variable is referenced in a context in which a column name can also be referenced.

Java variable references

The general form of a host variable reference in Java is:



Each Java-identifier must be declared in the source program. The variable designated by the second Java-identifier is called an indicator variable and must be a short.

In Java, indicator variables are not always needed. Instead, instances of a Java class can be set to a null value. Variables defined as Java primitive types can not be set to a null value. When using an extended indicator variable, or when using a Java primitive type in assigning a null value or where the Java primitive type might be assigned null on output, indicator variables must be used.

If IN, OUT, or INOUT is not specified, the default depends on the context in which the variable is used. If the Java variable is used in an INTO clause, OUT is the default. Otherwise, IN is the default.

Variables in dynamic SQL

In dynamic SQL statements, parameter markers are used instead of variables other than global variables. Global variables are the only type of variable that can be specified in a dynamic SQL statement.

A *parameter marker* is a question mark (?) that represents a position in a dynamic SQL statement where the application will provide a value; that is, where a variable would be found if the statement string were a static SQL statement. The following examples show a static SQL statement that uses variables and a dynamic statement that uses parameter markers:

```
INSERT INTO DEPT VALUES (:HV_DEPTNO, :HV_DEPTNAME, :HV_MGRNO, :HV_ADMRDEPT)
INSERT INTO DEPT VALUES (?, ?, ?, ?)
```

For more information on parameter markers, see Parameter markers under the PREPARE statement.

LOB variables

Regular LOB variables (CLOB, DBCLOB, and BLOB), LOB locator variables and LOB file reference variables can be defined in all host languages with a few exceptions.

- Java supports file reference variables, but not locators for LOBs.

Where LOBs are allowed, the term meta-variable *variable* in a syntax diagram can refer to a regular variable, a locator variable, or a file reference variable. Because these variables are not native data types in host programming languages, SQL extensions are used, and the precompilers generate the host language constructs that are necessary to represent each variable.

When it is possible to define a variable that is large enough to hold an entire LOB value and the performance benefit of delaying the transfer of data from the server is not required, a LOB locator or LOB file reference is not needed. However, it is often not acceptable to store an entire LOB value in temporary storage due to host language restrictions, storage restrictions, or performance requirements.

When storing an entire LOB value at one time is not acceptable, you can use one of the following alternatives:

- Referencing the LOB value using a LOB locator, and accessing portions of the value
- Storing the entire LOB value in a file, and using a LOB file reference to access the data

LOB locator variables

A LOB locator variable is a host variable that contains the locator representing a LOB value on the database server.

See "Manipulating LOBs using locators" on page 117 for information about how locators can be used to manipulate LOB values.

A locator variable in an SQL statement must identify a LOB locator variable described in the program according to the rules for declaring locator variables. This is always indirectly through an SQL statement. For example, in C:

```
      static volatile SQL TYPE IS CLOB_LOCATOR *loc1;
```

The term *locator-variable*, as used in the syntax diagrams, shows a reference to a LOB locator variable. The meta-variable *locator-variable* can be expanded to include a *host-identifier* the same as that for *host-variable*.

Like all other host variables, a LOB locator variable can have an associated indicator variable. Indicator variables for LOB locator variables behave in the same way as indicator variables for other data types. When a null value is returned from the database, the indicator variable is set and the locator host variable is unchanged. This means a locator can never represent a null value. However, when the indicator variable associated with a LOB locator is null, the value of the referenced LOB value is null.

If a locator variable does not currently represent any value, an error occurs when the locator variable is referenced.

When a transaction commits, LOB locators that were acquired by the transaction are released unless a HOLD LOCATOR statement was issued for the LOB locator. When the transaction ends, all LOB locators are released.

It is the application programmer's responsibility to guarantee that any LOB locator is used only in SQL statements that are executed at the same server that originally generated the LOB locator. For example, assume that a LOB locator is returned from one server and assigned to a LOB locator variable. If that LOB locator variable is subsequently used in an SQL statement that is executed at a different server unpredictable results will occur.

XML variables

An XML variable can be defined as a string or file reference variable. Regular XML variables and XML file reference variables can be defined in all host languages with a few exceptions.

- REXX supports file reference variables for XML.
- Java supports XML and file reference variables for XML.

XML variables can be declared as the following variable types:

Where XML variables are allowed, the meta-variable *variable* in a syntax diagram can refer to a regular variable or a file reference variable. Because these variables are not native data types in host programming languages, SQL extensions are used, and the precompilers generate the host language constructs that are necessary to represent each variable.

When it is possible to define a variable that is large enough to hold an entire XML value and the performance benefit of delaying the transfer of data from the server is not required, an XML file reference is not needed. However, it is often not acceptable to store an entire XML value in temporary storage due to host language restrictions, storage restrictions, or performance requirements. When storing an entire XML value at one time is not acceptable, portions of the value can be accessed, or the entire value can be stored in a file. When the entire value is stored in a file, an XML file reference can be used to access the data.

XML host variables can be declared as the following variable types:

- XML AS CLOB(*n*)

  Declares a CLOB variable that contains XML data that is encoded in the CCSID for the variable.
- XML AS DBCLOB(*n*)

  Declares a DBCLOB variable that contains XML data that is encoded in the graphic CCSID for the variable.
- XML AS BLOB(*n*)

  Declares a BLOB variable that contains XML data that is encoded as specified within the data according to the XML 1.0 specification for determining encoding.
- XML AS CLOB_FILE

  Declares a CLOB file reference variable that contains XML data that is encoded in the CCSID for the file reference variable.
- XML AS DBCLOB_FILE

  Declares a DBCLOB file reference variable that contains XML data that is encoded in the CCSID for the file reference variable.
- XML AS BLOB_FILE

  Declares a BLOB file reference variable that contains XML data that is encoded in the CCSID for the file reference variable.

See "LOB or XML file reference variables " on page 232 for additional information about file reference variables.

Although the application XML variable declaration includes a LOB type specification, the variable declarations all are considered to be the XML data type, not the LOB type that is used in the application declaration. The application might also use non-XML variables in place of XML variables. For example, when a prepared statement is executed, the application might use a character variable to replace an XML parameter marker in the statement.

Although the XML data type is incompatible with all other data types, both XML and non-XML data types can be used for input to and output from XML data. Applications can use either XML variables, character variables, or binary string variables for input and output in SQL statements for XML data.

The following table summarizes the conversions built-in data types (including XML) to and from the supported variable data types within embedded applications. The built-in data types are specified in the rows. A Y indicates that the built-in data type can be assigned to or assigned from the variable type.

Table 48. Application variable compatibility with the built-in data types for applications that contain embedded SQL

	application variable data type					
built-in data type	**CHAR, VARCHAR, CLOB, CLOB_FILE**	**GRAPHIC, VARGRAPHIC, DBCLOB, DBCLOB_FILE**	**BINARY, VARBINARY, BLOB, BLOB_FILE**	**XML AS CLOB, XML AS CLOB_FILE**	**XML AS DBCLOB, XML AS DBCLOB_FILE**	**XML AS BLOB, XML AS BLOB_FILE**
CHAR	Y	Y				
VARCHAR	Y	Y				
CLOB	Y	Y				
GRAPHIC	Y	Y				
VARGRAPHIC	Y	Y				
DBCLOB	Y	Y				
BINARY			Y			

Table 48. Application variable compatibility with the built-in data types for applications that contain embedded SQL (continued)

	application variable data type					
built-in data type	CHAR, VARCHAR, CLOB, CLOB_FILE	GRAPHIC, VARGRAPHIC, DBCLOB, DBCLOB_FILE	BINARY, VARBINARY, BLOB, BLOB_FILE	XML AS CLOB, XML AS CLOB_FILE	XML AS DBCLOB, XML AS DBCLOB_FILE	XML AS BLOB, XML AS BLOB_FILE
VARBINARY			Y			
BLOB			Y			
XML	Y	Y	Y	Y	Y	Y

LOB or XML file reference variables

File reference variables are used for direct file input and output for LOB and XML values (when the XML value is declared using XML AS *variable-type*), and can be defined in all host languages.

Because these are not native data types, SQL extensions are used and the Db2 precompiler or coprocessor generates the host language constructs necessary to represent each variable. In the case of REXX, LOB values are mapped to strings. See "XML variables" on page 230 for more information about XML host variables.

A file reference variable represents (rather than contains) the file, just as a LOB locator represents, rather than contains, the LOB data. Database queries, updates, and inserts can use file reference variables to store or to retrieve single column values.

As with all other host variables, file reference variables can have an associated indicator variable. Indicator variables for file reference variables behave in the same way as indicator variables for other data types. When a null value is returned from the database manager, the indicator variable is set, and the variable is unchanged. When the indicator variable that is associated with a file reference variable is null, the value of the referenced LOB or XML object is null. This means that a file reference variable can never point to a null value.

The length attribute of a file reference variable is assumed to be the maximum length of a LOB or XML object.

A file reference variable has the following properties:

Data type
BLOB, CLOB, or DBCLOB. This property is specified when the variable is declared using BLOB_FILE, CLOB_FILE, or DBCLOB_FILE.

Direction
This must be specified by the application program at run time (it is implicitly specified as part of the File options value). The direction can be either of the following:

Input
Input is used as a source of data on an EXECUTE statement, an OPEN statement, an update operation, an insert operation, or a delete operation.

Output
Output is used as the target of data. For example, on a FETCH statement or a SELECT INTO statement.

File name
This must be specified by the application program at run time. It must be the complete path name of the file. Within an application, a file should only be referenced one time in a file reference variable.

File name length
This must be specified by the application program at run time. It is the length of the file name in bytes.

Data length
Sets the data length to the length of the new data that is written to the file. The length is in bytes. Data length is unused on input.

File options

Options are set by an INTEGER value in a field in the file reference variable structure. One of the following values must be specified in an application for each file reference variable before that file reference variable can be used in the application:

SQL_FILE_READ

This is a regular file that can be opened, read and closed. (The option is SQL-FILE-READ in COBOL, sql_file_read in FORTRAN, and READ in REXX.) SQL_FILE_READ is an input (from client to server) file option.

SQL_FILE_CREATE

Create a new file. If the file already exists, an error is returned. (The option is SQL-FILE-CREATE in COBOL, sql_file_create in FORTRAN, and CREATE in REXX.) SQL_FILE_CREATE is an output (from server to client) file option.

SQL_FILE_OVERWRITE

If an existing file with the specified name exists, it is overwritten; otherwise a new file is created. (The option is SQL-FILE-OVERWRITE in COBOL, sql_file_overwrite in FORTRAN, and OVERWRITE in REXX.). SQL_FILE_OVERWRITE is an output (from server to client) file option.

SQL_FILE_APPEND

If an existing file with the specified name exists, the output is appended to it; otherwise a new file is created. (The option is SQL-FILE-APPEND in COBOL, sql_file_append in FORTRAN, and APPEND in REXX.) SQL_FILE_APPEND is an output (from server to client) file option.

The encoding scheme CCSID of the file name is based on the encoding scheme of the application. The CCSID of the LOB or XML data (the contents of the file) can be set by the application by using a DECLARE *host-variable* CCSID statement if the CCSID of the LOB or XML data is different from the CCSID of the application. Db2 performs any character conversion that is required prior to insertion of the LOB or XML data into a table or writing of the LOB or XML data to a file.

Result set locator variables

A *result set locator variable* is a variable that contains the locator that identifies a stored procedure result set. A result set locator variable in an SQL statement must identify a result set locator variable described in the program according to the rules for declaring result set locator variables. This is always indirectly through an SQL statement.

For example, in C:

```
    static volatile SQL TYPE IS RESULT_SET_LOCATOR VARYING *loc1;
```

A result set locator variable in an SQL procedure is defined with the RESULT_SET_LOCATOR VARYING clause in a compound statement.

The meta-variable *rs-locator-variable*, as used in the syntax diagrams, shows a reference to a result set locator variable. A host variable that is a result set locator variable can have an association indicator variable. When the indicator variable that is associated with a result set locator is null, the referenced result set is not defined.

If a result set locator variable does not currently represent any stored procedure result set, an error occurs when the locator variable is referenced.

A commit operation destroys all open cursors that were declared in the stored procedure without the WITH HOLD option and the result set locators that are associated with those cursors. Otherwise, a cursor and its associated result set locator persist past the commit.

An application that is written in a programming language other than Java can access a result set that is returned from a stored procedure. A result set locator is used by the invoking application to access the result set. A result set locator value for a result set can be obtained from an ASSOCIATE LOCATOR statement or with the DESCRIBE PROCEDURE statement. For more information, see “ASSOCIATE LOCATORS” on page 1375 and “DESCRIBE PROCEDURE” on page 1874.

The result set locator value is specified on an ALLOCATE CURSOR statement to define a cursor in the invoking application and to associate it with a stored procedure result set. For more information, see "ALLOCATE CURSOR" on page 1088.

A DESCRIBE CURSOR statement can be used in the invoking application to obtain information on the characteristics of the columns of a stored procedure result set. For more information, see "DESCRIBE CURSOR" on page 1864.

The application can then access the rows of the result set using FETCH statements with the allocated cursor.

Related reference

compound-statement
A compound statement groups other statements together in an SQL routine or advanced trigger. A compound statement allows the declaration of SQL variables, cursors, and condition handlers.

Array variables

An array variable is a variable that is defined as a user-defined array type.

An array variable can be defined in one of the following ways:

- An array global variable that is defined using the CREATE VARIABLE statement.
- An SQL parameter that is defined using the CREATE FUNCTION (SQL scalar) or CREATE PROCEDURE (SQL native) statement.
- An SQL variable that is defined using the DECLARE clause of a compound statement.

An array variable (representing an entire array) can be referenced in the following contexts:

- An input argument to the NULL predicate.
- An input argument to the ARRAY_EXISTS predicate.
- An input argument to a built-in array scalar function (ARRAY_DELETE, ARRAY_FIRST, ARRAY_LAST, ARRAY_NEXT, ARRAY_PRIOR, or TRIM_ARRAY).
- An argument to UNNEST specification.
- The outer SELECT list of a fullselect that does not include a set operator, in the definition of a cursor that is not scrollable. In this case a FETCH statement for the cursor must specify an array variable as the target for the corresponding result column of the fullselect for the array variable.
- The outer select list of a SELECT INTO statement, when the target for the corresponding column of the result table of the fullselect is an array variable.
- The outer select list of a scalar fullselect, on the right side of a SET *assignment-statement* statement or an SQL PL *assignment-statement* statement, when the corresponding target of the assignment is an array variable.
- The source value for a VALUES INTO statement, when the target for value is an array variable.
- The target of an assignment from a FETCH statement, when the corresponding source data is an array value, and the FETCH statement is issued in an SQL PL context.
- The target of a SELECT INTO statement, when source data for the corresponding column of the result table is an array value.
- The target of an assignment for a SET *assignment-statement* statement or an SQL PL *assignment-statement* statement, when the corresponding source value is an array value.
- The target of a VALUES INTO statement, when the source data value is an array value.
- An argument to or from a routine (CALL statement or function invocation).
- The value that is returned in a RETURN statement of an SQL scalar function.
- An ORDER BY or GROUP BY clause of an outer fullselect.
- The source value in a USING clause for an EXECUTE statement or OPEN statement, in an SQL PL context.

An array variable can also be referenced in an array element specification. An element of a user-defined array type can be referenced anywhere that an expression that returns the same data type as an element of that array can be used.

Restriction: An array variable or an array element must not be referenced in an SQL statement, other than a CALL statement, after a connection at a remote server has been established. This restriction includes the case of an SQL statement that is executing at a remote server as a result of a three-part name or an alias that resolves to an object at a remote server.

Array element specification
The array element specification returns the element from an array specified by *array-index*.

Host structures in PL/I, C, and COBOL

A *host structure* is a PL/I structure, C structure, or COBOL group that is referred to in an SQL statement.

Host structures are defined by statements of the host language, as explained in Overview of programming applications that access Db2 for z/OS data (Db2 Application programming and SQL). As used here, the term *host structure* does not include an SQLCA or SQLDA.

In Java and REXX, there is no equivalent to a host structure.

The form of a host structure reference is identical to the form of a host variable reference. The reference :S1:S2 is a host structure reference if S1 names a host structure. If S1 designates a host structure, S2 must be a small integer variable or an array of small integer variables. S1 is the host structure and S2 is its indicator array.

A host structure can be referred to in any context where a list of host variables can be referenced. A host structure reference is equivalent to a reference to each of the host variables contained within the structure in the order which they are defined in the host language structure declaration. The *n*th variable of the indicator array is the indicator variable for the *n*th variable of the host structure.

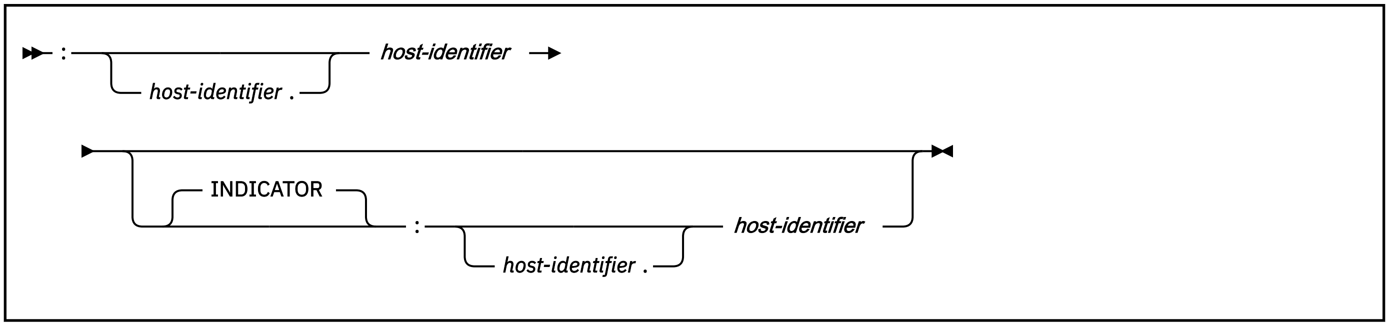
In PL/I, for example, if *V1*, *V2*, and *V3* are declared as the variables within the structure S1, the following two statements are equivalent:

```
   EXEC SQL FETCH CURSOR1 INTO :S1;
   EXEC SQL FETCH CURSOR1 INTO :V1, :V2, :V3;
```

If the host structure has *m* more variables than the indicator array, the last *m* variables of the host structure do not have indicator variables. If the host structure has *m* fewer variables than the indicator array, the last *m* variables of the indicator array are ignored. These rules also apply if a reference to a host structure includes an indicator variable or a reference to a host variable includes an indicator array. If an indicator array or variable is not specified, no variable of the host structure has an indicator variable.

In addition to structure references, individual host variables or indicator variables in PL/I, C, and COBOL can be referred to by qualified names. The qualified form is a host identifier followed by a period and another host identifier. The first host identifier must name a structure, and the second host identifier must name a host variable at the next level within that structure.

In PL/I, C, and COBOL, the syntax of *host-variable* is:



In general, a *host-variable* in an expression must identify a host variable (not a structure) described in the program according to the rules for declaring host variables. However, there are a few SQL statements that allow a host variable in an expression to identify a structure, as specifically noted in the descriptions of the statements.

The following examples show references to host variables and host structures:

```
  :V1   :S1.V1   :S1.V1:V2   :S1.V2:S2.V4
```

Host-variable arrays in PL/I, C, C++, and COBOL

A *host-variable array* is an array in which each element of the array contains a value for the same column. The first element in the array corresponds to the first value, the second element in the array corresponds to the second value, and so on.

Host-variable arrays can be referenced only as a simple reference in the following contexts. In syntax diagrams, *host-variable-array* designates a reference to a host-variable array.

- In a FETCH statement for a multiple-row fetch. See "FETCH" on page 1919.
- In the FOR *n* ROWS form of the INSERT statement with a host-variable array for the source data. See "INSERT" on page 1991.
- In a MERGE statement with multiple rows of source data. See "MERGE" on page 2014.
- In an EXECUTE statement to provide a value for a parameter marker in a dynamic FOR *n* ROWS form of the INSERT statement or a MERGE statement. See "EXECUTE" on page 1904.

Host-variable arrays are defined by statements of the host language, as explained in the following topics:

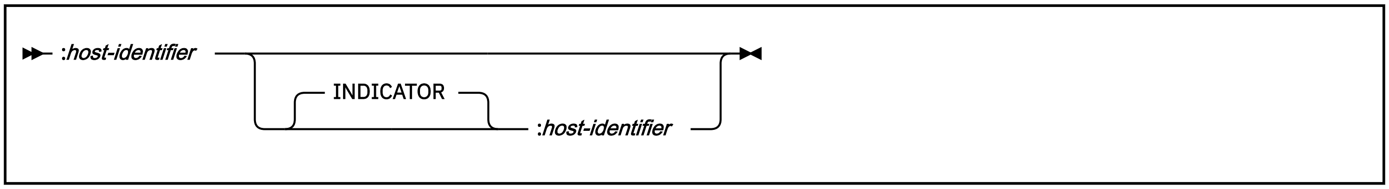
- Host-variable arrays in C and C++ (Db2 Application programming and SQL)
- Host-variable arrays in COBOL (Db2 Application programming and SQL)
- Host-variable arrays in PL/I (Db2 Application programming and SQL)

Tip: Host-variable arrays are not supported for assembler, FORTRAN, or REXX programs. However, you can use SQL descriptor areas (SQLDA) to achieve similar results in any host language. For more information see Defining SQL descriptor areas (SQLDA) (Db2 Application programming and SQL).

The form of a host-variable array reference is similar to the form of a host variable reference. The reference :COL1:COL1IND is a host-variable array reference if COL1 designates an array. If COL1 designates an array, COL1IND must be a one dimensional array of small integer host variables. The dimension of the host-variable array must be less than or equal to the dimension of the indicator array. If an indicator array is not specified, no variable of the main host-variable array has an indicator variable.

Syntax

In PL/I, C, C++, and COBOL, a *host-variable-array* reference has the following syntax:



Example

In the following example, *COL1* is the main host-variable array and *COL1IND* is its indicator array, If *COL1* has 10 elements for fetching a single column of data for multiple rows of data, *COL1IND* must also have 10 entries.

```
    EXEC SQL FETCH CURSOR FOR 5 ROWS  INTO :COL1 :COL1IND;
```

Using host-variable arrays in SQL statements (Db2 Application programming and SQL)

Functions

A *function* is an operation denoted by a function name followed by zero or more operands that are enclosed in parentheses. It represents a relationship between a set of input values and a set of result values.

The input values to a function are called *arguments*. For example, a function can be passed with two input arguments that have date and time data types and return a value with a timestamp data type as the result.

Types of functions

There are several ways to classify functions. One way to classify functions is as built-in functions, user-defined functions, or cast functions that are generated for distinct types.

Built-in functions

Built-in functions include operator functions such as "+", aggregate functions such as AVG, and scalar functions such as SUBSTR. For a list of the built-in aggregate and scalar functions and information on these functions, see Chapter 4, “Built-in functions,” on page 341.

The built-in functions are in schema SYSIBM.

The RANK, DENSE_RANK, and ROW_NUMBER specifications are sometimes referred to as built-in functions. Refer to “OLAP specifications” on page 279 for more information on these specifications.

User-defined functions

User-defined functions are functions that are created using the CREATE FUNCTION statement and registered to the Db2 in the catalog. These functions allow users to extend the function of Db2 by adding their own or third party vendor function definitions.

A user-defined function is an SQL, external, or sourced function. An SQL function is defined to the database using only SQL statements. An *external function* is defined to the database with a reference to an external program that is executed when the function is invoked. A *sourced function* is defined to the database with a reference to a built-in function or another user-defined function. Sourced functions can be used to override built-in aggregate and scalar functions for use on distinct types.

A user-defined function resides in the schema in which it was registered. The schema cannot be SYSIBM.

To help you define and implement user-defined functions, sample user-defined functions are supplied with Db2. You can also use these sample user-defined functions in your application program just as you would any other user-defined function if the appropriate installation job has been run.

For more information, see the following related topics:

- Appendix N, “Sample user-defined functions,” on page 2929
- Creating a user-defined function (Db2 Application programming and SQL)
- “CREATE FUNCTION” on page 1419

Generated user-defined functions for distinct types

Generated user-defined functions for distinct types (also called *cast functions*) are functions that Db2 automatically generates when a distinct type is created using the CREATE TYPE statement.

Cast functions support casting from the distinct type to the source type and from the source type to the distinct type. The ability to cast between the data types is important because a distinct type is compatible only with itself.

The generated cast functions reside in the same schema as the distinct type for which they were created. The schema cannot be SYSIBM.

For more information, see "CREATE TYPE" on page 1790

Other ways classify functions

Functions can also be classified as aggregate, scalar, or table functions, depending on the input data values and result values.

- An *aggregate function* receives a set of values for each argument (such as the values of a column) and returns a single-value result for the set of input values. Aggregate functions are sometimes called *column functions.* Built-in functions and user-defined sourced functions can be aggregate functions. Aggregate functions cannot be external user-defined function or SQL functions. For more information, see "Aggregate functions" on page 353.
- A *scalar function* receives a single value for each argument and returns a single-value result. Built-in functions and user-defined functions, external, sourced, and SQL, can be scalar functions. The functions that are created for distinct types are also scalar functions. For more information, see "Scalar functions" on page 382.
- A *table function* returns a table for the set of arguments it receives. Each argument is a single value. A table function can only be referenced in the FROM clause of a subselect. A table function can be defined as an external or SQL function, but a table function cannot be a sourced function.

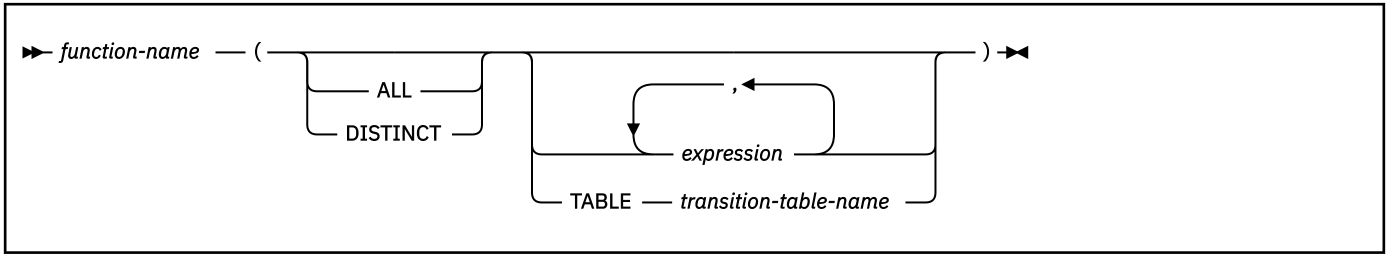
  Table functions can be used to apply SQL language processing power to data that is not stored in the database or to allow access to such data as if it were stored in a table. For example, a table function can read a file or get data from the web and return a result table.

  For more information, see .

For a list of the aggregate, scalar, and table functions and information on these functions, see Chapter 4, "Built-in functions," on page 341.

Function invocation

Each reference to a scalar or aggregate function (either built-in or user-defined) conforms to the following syntax:



In the above syntax, *expression* cannot include an aggregate function. See "Expressions" on page 244 for other rules for *expression*.

The ALL or DISTINCT keyword can only be specified for an aggregate function or a user-defined function that is sourced on an aggregate function.

When a function is invoked within a trigger body, the TABLE keyword can be specified to indicate that an argument is a trigger transition table. In this case, the corresponding parameter of the function must have been defined with the TABLE LIKE clause.

Table functions can be referenced only in the FROM clause of a subselect. For more information on referencing a table function, see the description of the "from-clause" on page 1015.

An array can only be specified as an argument to a function for a parameter that is defined with an array type. An array element specifies a scalar value, and can therefore be specified as an argument to a function when the data type of the array element is promotable to the data type of the corresponding parameter of the function definition.

When the function is invoked, the value of each of its parameters is assigned using storage assignment, to the corresponding parameter of the function. Control is passed to external functions according to the calling conventions of the host language. When execution of a user-defined aggregate or scalar function is complete, the result of the function is assigned, using storage assignment, to the result data type. For information about assignment rules, see "Assignment and comparison" on page 143.

Additionally, a character FOR BIT DATA argument cannot be passed as input for a parameter that is not defined as character FOR BIT DATA. Likewise, a character argument that is not FOR BIT DATA cannot be passed as input for a parameter defined as character FOR BIT DATA.

For compatibility with other SQL implementations, `UNIQUE` can be specified as a synonym for `DISTINCT` in aggregate functions.

Function resolution

After a function is invoked, Db2 must determine which function to execute. This process is called *function resolution* and it applies to both built-in and user-defined functions.

A function is invoked by its function name, which is implicitly or explicitly qualified with a schema name, followed by parentheses that enclose the arguments to the function. Within the database, each function is uniquely identified by its *function signature*, which is its schema name, function name, the number of parameters, and the data types of the parameters. A schema can contain several functions that have the same name but each of which have a different number of parameters or parameters with different data types. Also, a function with the same name, number of parameters, and types of parameters can exist in multiple schemas.

Overloading a function
A function name for which there are multiple function instances with the same number of parameters in the same schema is called an *overloaded function*.

Overriding a function
Functions can be *overridden* across the schemas of an SQL path, in which case there is more than one function with the same name and the same number of parameters in different schemas of the SQL path. These functions do not necessarily have different parameter data types.

Function resolution has two steps:

1. Db2 determines the set of candidate functions based on the qualification of the name of the invoked function, the unqualified name of the invoked function, and the number of arguments that are specified.
2. Db2 determines the best fit from the set of candidate functions based on the data types of the arguments of the invoked function as compared with the data types of the parameters of the functions in the set of candidate functions.

Function resolution is similar for functions that are invoked with a qualified or unqualified function name with the exception that for an unqualified name, Db2 needs to search more than one schema.

To improve performance of function resolution and to prevent potential issues as new functions are added, consider invoking user-defined functions by using a fully qualified name, including the schema name.

For a function invocation that passes a transition table, the data type, length, precision, and scale of each column in the transition table must exactly match the data type, length, precision, and scale of each column of the table that is named in the function definition.

The timestamp for the creation of a user-defined function must be older than the timestamp that results from an explicit bind for the plan or package that contains the function invocation. During automatic bind, built-in functions that are introduced in a Db2 release that is later than the Db2 release that is used to explicitly bind the package or plan are not considered for function resolution.

In a CREATE VIEW statement, function resolution occurs at the time the view is created. If another function with the same name is subsequently created, the view is not affected, even if the new function is a better fit than the one that was chosen at the time the view was created.

Qualified function resolution

When a function is invoked with a schema name and a function name, Db2 only searches the specified schema to resolve which function to execute.

Db2 selects candidate functions based on the following criteria:

- The name of the function instance must match the name in the function invocation.
- The number of input parameters in the function instance must match the number of arguments in the function invocation.
- The authorization ID of the statement must have the EXECUTE privilege to the function instance.

If no function meets these criteria, an error is returned. If one or more candidate functions are found in the schema, this set of candidate functions is processed for best fit.

For a function invocation that contains untyped parameter markers, the data types of those parameter markers are considered to match or be promotable to the data types of the parameters in the function instance.

Unqualified function resolution

When a function is invoked without a qualifier, Db2 searches the list of schemas in the SQL path to resolve which function instance to execute. For each schema in the SQL path, Db2 searches the schema for candidate functions based on the following criteria:

- The name of the function instance must match the name in the function invocation.
- The number of input parameters in the function instance must match the number of function arguments in the function invocation.
- The authorization ID of the statement must have the EXECUTE privilege on the function instance.

: If Db2 does not find any candidate functions, an error is returned.

If no function meets these criteria, an error is returned. If one or more candidate functions are found in the schema, this set of candidate functions is processed for best fit.

For a function invocation that contains untyped parameter markers, the data types of those parameter markers are considered to match or be promotable to the data types of the parameters in the function instance.

Determining the best fit

More than one function with the same name might exist that is a candidate for execution. In that case, Db2 determines which function is the best fit for the invocation by comparing the data types of the parameters of each function in the set of candidate functions to determine which function satisfies the best fit requirements.

Db2 determines the function, or set of functions, that meet the best fit requirements for the invocation by comparing the argument and parameter data types. The data type of the result of the function or the type of function (aggregate, scalar, or table) under consideration does not enter into the determination of best fit.

When determining whether the data types of the parameters are the same as the arguments:

- Synonyms of data types match. For example, DOUBLE and FLOAT are considered to be the same.
- Attributes of a data type (such as length, precision, scale, CCSID) are ignored. Therefore, CHAR(8) and CHAR(35) are considered to be the same, as are DECIMAL(11,2) and DECIMAL(4,3).
- The character and graphic types are considered to be the same. For example, the following data types are considered to be the same type: CHAR and GRAPHIC, VARCHAR and VARGRAPHIC, and CLOB and DBCLOB. CHAR(13) and GRAPHIC(8) are considered to be the same type.

- For this argument, if one function has a data type that fits the function invocation better than the data types in the other functions, that function is the best fit. The precedence list for the promotion of data types in shows the data types that fit each data type, in best-to-worst order.
- If the data types of the first parameter for all the candidate functions fit the function invocation equally well, Db2 repeats this process for the next argument of the function invocation. Db2 continues this process for each argument until a best fit is found.

A subset of the candidate functions is obtained by considering only those functions for which the data type of each input argument of the function invocation matches or is promotable to the data type of the corresponding parameter of the function instance. The precedence list for the promotion of data types in "Promotion of data types" on page 128 shows the data types that fit (considering promotion) for each data type in best-to-worst order. If this subset is not empty, the best fit is determined using the promotable process on this subset of candidate functions. If this subset is empty, and the original set of candidate functions consisted of a single function, the best fit is determined using the castable process on the original candidate function. Otherwise, an error is returned.

Promotable process

The *promotable process* determines the best fit for function resolution by considering only whether input arguments in the function invocation match or can be promoted to the data type of the corresponding parameter of the function definition.

For the subset of candidate functions, Db2 compares the parameter lists from left to right, using the following process:

- The data type of the argument in the function invocation is compared to the data type of the corresponding parameter in the definition of each candidate function. (synonyms of data types match and attributes of data type are ignored).
  - Attributes of a data type (such as length, precision, scale, CCSID) are ignored. Therefore, CHAR(8) and CHAR(35) are considered to be the same, as are DECIMAL(11,2) and DECIMAL(4,3).
  - The character and graphic types are considered to be the same. For example, the following data types are considered to be the same type: CHAR and GRAPHIC, VARCHAR and VARGRAPHIC, and CLOB and DBCLOB. CHAR(13) and GRAPHIC(8) are considered to be the same type.
- For this argument, if one candidate function has a data type that fits the function invocation better than the data types in the other candidate functions, that function is the best fit. The precedence list for the promotion of data types in "Promotion of data types" on page 128 shows the data types that fit each data type, in best-to-worst order.
- If the data types of the first parameter for more than one candidate functions fits the function invocation equally well, Db2 repeats this process for the next argument of the function invocation. Db2 continues this process for each argument until a best fit is found.

If only one candidate function remains after comparing all the arguments, that function is the best fit. If more than one candidate function remains, all the remaining candidate functions are considered to be equally the best fit. In this case, Db2 selects the function whose schema is first in the SQL path.

If a function is selected, its successful use depends on it being invoked in a context in which the returned result is allowed. For example, if the function returns a table where a table is not allowed, an error is returned.

Function resolution and input argument casting

In considering the best fit of a candidate function, Db2 determines if the input arguments can be implicitly cast to the data type of the corresponding parameter for function resolution.

The *castable process* determines the best fit of a function, first considering if the input arguments in the function invocation match or can be promoted to the data type of the corresponding parameter of the function definition, and then if the input arguments can be implicitly cast to the data type of the corresponding parameter for function resolution. For the set of candidate functions, Db2 compares the parameter lists from left to right, using the following process:

- The data type of the argument in the function invocation is compared to the data type of the corresponding parameter in the definition of the candidate function to ensure that each argument can be promoted or cast to the corresponding parameter. If not, an error is returned.

If a function is selected, its successful use depends on it being invoked in a context in which the returned result is allowed. For example, if the function returns a table where a table is not allowed, an error is returned.

Implicit casting for function resolution: Implicit casting for function resolution is not supported for arguments with a user-defined type, binary, ROWID, or XML data type. It is also not supported for built-in or user-defined cast functions. Implicit casting is supported for the following cases:

- A numeric data type can be cast to a value of another numeric data type that is not in the data type promotion list for the source data type. This includes casting a numeric value to a numeric data type that is lower in the promotion list.
- A numeric data type can be cast to a character or graphic string data type, except for a LOB.
- A character or graphic string data type, except for a LOB, can be cast to a numeric data type.
- A character or graphic string data type, except for a LOB, can be cast to a date, time, or timestamp data type.
- A varying length character string data type, except for a LOB, can be cast to a fixed length character data type.

Best-fit consideration

After determining the function that is the best fit, use of the function still might not be permitted. Each function is defined to return a result with a specific data type. If this result data type is not compatible with the context in which the function is invoked, an error occurs.

For example, assume functions named STEP are defined with different data types:

```
STEP(SMALLINT)returns CHAR(5)
STEP(DOUBLE)returns INTEGER
```

Assume also that the function is invoked with the following function reference (where S is a SMALLINT column):

```
SELECT ... 3+STEP(S) ...
```

Because there is an exact match on argument type, the first STEP is chosen. An error occurs on the statement because the result type is CHAR(5) instead of a numeric type as required for an argument of the addition operator.

In cases where the arguments of the function invocation are not an exact match to the data types of the parameters of the selected function, the arguments are converted to the data type of the parameter at execution using the same rules as assignment to columns. See "Assignment and comparison" on page 143. Problems with conversions can also occur when precision, scale, length, or the encoding scheme differs between the argument and the parameter. Conversion might occur for a character string argument when the corresponding parameter of the function has a different encoding scheme or CCSID. For example, an error occurs on function invocation when mixed data that actually contains DBCS characters is specified as an argument and the corresponding parameter of the function is declared with an SBCS subtype.

Additionally, a character FOR BIT DATA argument cannot be passed as input for a parameter that is not defined as character FOR BIT DATA. Likewise, a character argument that is not FOR BIT DATA cannot be passed as input for a parameter that is defined as character FOR BIT DATA.

An error also occurs in the following examples:

- The function is referenced in a FROM clause, but the function selected by the function resolution step is a scalar or aggregate function.
- The function calls for a scalar or aggregate function, but the function selected by the resolution step is a table function.

SQL path considerations for built-in functions

Function resolution applies to all functions, including built-in functions and other functions provided by Db2. If a function is invoked without its schema name, the SQL path is searched.

With the exception of the Db2 IBM MQ functions, the built-in functions are in schemas SYSIBM or SYSIBMADM.

Additional functions are available in other schemas, but are not considered as built-in functions because they are developed as user-defined functions that have no special processing considerations.

If SYSIBM is not first in the path, it is possible that Db2 will select another function instead of the intended built-in function. If schema "SYSIBM", "SYSFUN", "SYSPROC", "SYSIBMADM" is not explicitly specified in the SQL path, the schema is implicitly assumed at the front of the path. Db2 adds implicitly assumed schemas in the order of "SYSIBM", "SYSFUN", "SYSPROC", "SYSIBMADM".

Related concepts

SQL path
The *SQL path* is an ordered list of schema names. Db2 uses the path to resolve the schema name for certain unqualified object names that appear in any context other than as the main object of an ALTER, CREATE, DROP, COMMENT, GRANT, RENAME, or REVOKE statement.

Version resolution

Normally, the currently active version of an SQL function is used for invocation of the function.

However, if the invocation is a recursive invocation that occurs inside the body of the same function, and the currently active version has changed since the original invocation, the active version is not used. The version that is used in the original invocation is used for any recursive invocation until the entire function completes. This preserves the semantics of the version that is used by the original invocation.

The version used in the original invocation is also used when the recursive invocation is indirect. For example, assume that function FN1 invokes function FN2, which in turn invokes FN1 (indirect, recursive invocation). The invocation of function FN1 in function FN2 uses the version of FN1 that is active at the time of the original invocation of function FN1.

Since the currently active version is used at the next invocation (except in recursive invocations), it is possible that two or more versions of the same function can be run by a given thread. For example, an invocation of function FN1 in an application causes the currently active version of FN1 to load and execute. During or after execution of the original invocation of FN1, an ALTER FUNCTION statement that specifics ACTIVE VERSION FN1_V2 is run and changes the active version of the function FN1 to version FN1_V2. Subsequent invocations of function FN1 from the same thread will load and execute the currently active version of the function, FN1_V2.

Examples of function resolution

The following examples illustrate function resolution.

Example 1: Assume that MYSCHEMA contains two functions, both named FUNA, that were registered with these partial CREATE FUNCTION statements.

```
1.  CREATE FUNCTION MYSCHEMA.FUNA (VARCHAR(10), INT, DOUBLE) ...
2.  CREATE FUNCTION MYSCHEMA.FUNA (VARCHAR(10), REAL, DOUBLE) ...
```

Also assume that a function with three arguments of data types VARCHAR(10), SMALLINT, and DECIMAL is invoked with a qualified name:

```
   MYSCHEMA.FUNA(VARCHARCOL, SMALLINTCOL, DECIMALCOL)
```

Both MYSCHEMA.FUNA functions are candidates for this function invocation because they meet the criteria specified in "Function resolution" on page 239. The data types of the first parameter for the two function instances in the schema, which are both VARCHAR, fit the data type of the first argument of the function invocation, which is VARCHAR, equally well. However, for the second parameter, the data type of the first function (INT) fits the data type of the second argument (SMALLINT) better than the data type of second function (REAL). Therefore, Db2 selects the first MYSCHEMA.FUNA function as the function instance to execute.

Example 2: Assume that these functions were registered with these partial CREATE FUNCTION statements:

```
1.  CREATE FUNCTION SMITH.ADDIT (CHAR(5), INT, DOUBLE) ...
2.  CREATE FUNCTION SMITH.ADDIT (INT, INT, DOUBLE) ...
3.  CREATE FUNCTION SMITH.ADDIT (INT, INT, DOUBLE, INT) ...
4.  CREATE FUNCTION JOHNSON.ADDIT (INT, DOUBLE, DOUBLE) ...
5.  CREATE FUNCTION JOHNSON.ADDIT (INT, INT, DOUBLE) ...
6.  CREATE FUNCTION TODD.ADDIT (REAL) ...
7.  CREATE FUNCTION TAYLOR.SUBIT (INT, INT, DECIMAL) ...
```

Also assume that the SQL path at the time an application invokes a function is "TAYLOR" "JOHNSON", "SMITH". The function is invoked with three data types (INT, INT, DECIMAL) as follows:

```
   SELECT ... ADDIT(INTCOL1, INTCOL2, DECIMALCOL) ...
```

Function 5 is chosen as the function instance to execute based on the following evaluation:

- Function 6 is eliminated as a candidate because schema TODD is not in the SQL path.
- Function 7 in schema TAYLOR is eliminated as a candidate because it does not have the correct function name.
- Function 1 in schema SMITH is eliminated as a candidate because the INT data type is not promotable to the CHAR data type of the first parameter of Function 1.
- Function 3 in schema SMITH is eliminated as a candidate because it has the wrong number of parameters.
- Function 2 is a candidate because the data types of its parameters match or are promotable to the data types of the arguments.
- Both Function 4 and 5 in schema JOHNSON are candidates because the data types of their parameters match or are promotable to the data types of the arguments. However, Function 5 is chosen as the better candidate because although the data types of the first parameter of both functions (INT) match the first argument (INT), the data type of the second parameter of Function 5 (INT) is a better match of the second argument (INT) than Function 4 (DOUBLE).
- Of the remaining candidates, Function 2 and 5, Db2 selects Function 5 because schema JOHNSON comes before schema SMITH in the SQL path.

Expressions

An *expression* specifies a value and can take a number of different forms, such as a simple value, consisting of only a constant or a column name, or it can be more complex with operators, other expressions, and more.

Authorization

The use of some of the expressions, such as a *scalar-fullselect*, *sequence-reference*, *global-variable*, or *function-invocation*, requires having the appropriate authorization. For these objects, the privilege set that is defined below must include the following authorization:

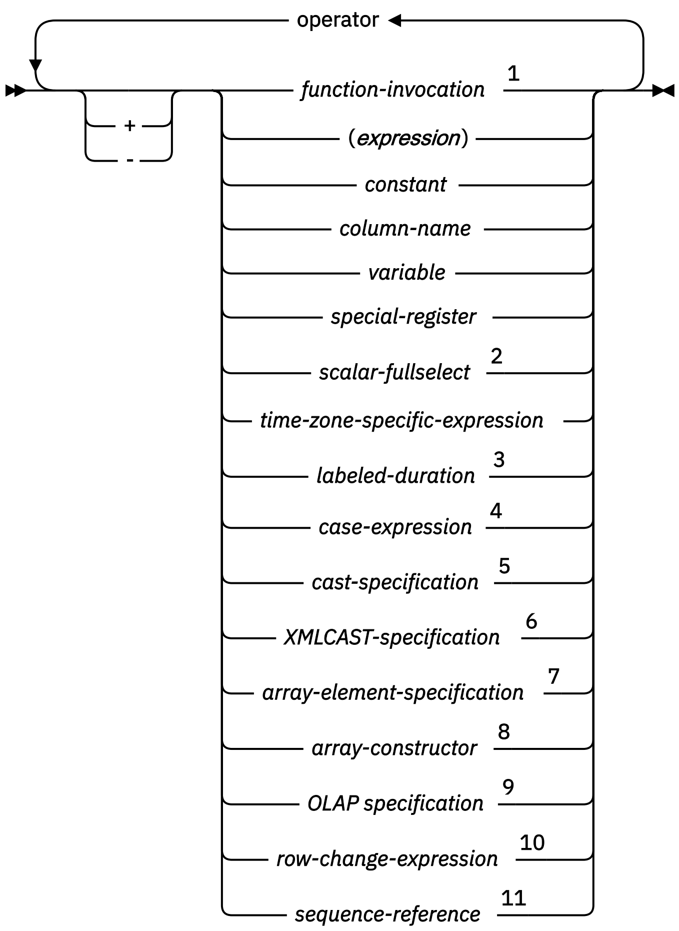
- *cast-specification*. The authorization to reference a user-defined type in a cast specification. For information about authorization considerations, see "CAST specification" on page 266.
- *function-invocation*. Authorization to execute the function. For information about how the particular function is chosen and authorization considerations, see "Function resolution" on page 239.
- *scalar-fullselect*. For information about authorization considerations, see "Authorization for queries" on page 1005.

- *sequence-reference*. The USAGE privilege on the specified sequence, ownership of the sequence, DATAACCESS authority, or SYSADM authority. For example, with a sequence reference, USAGE authorization on the sequence is required.
- *global-variable*. The READ privilege on the specified global variable, ownership of the global variable, DATAACCESS authority, or SYSADM authority.

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the statement is dynamically prepared, the privilege set is the union of the privilege sets that are held by each authorization ID of the process.

Syntax

The form of an expression is as follows:

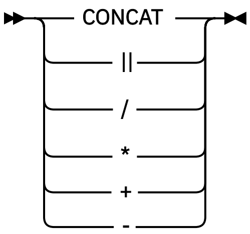


Notes:

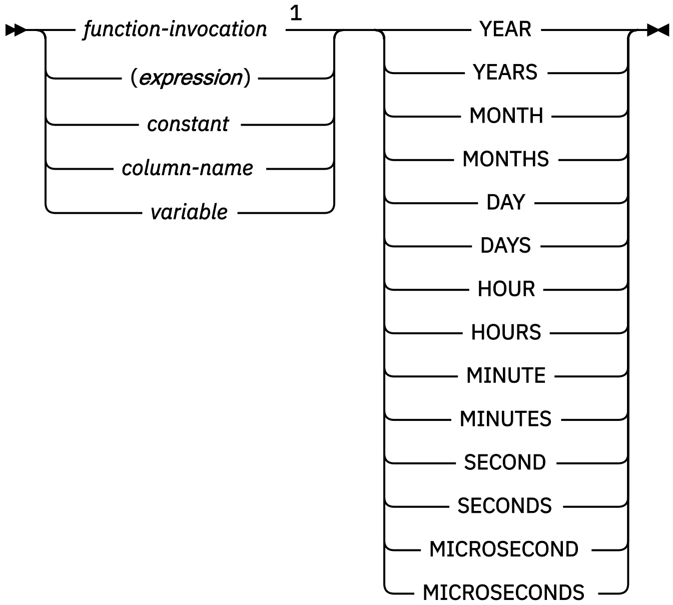
[1] Must be a scalar function. See "Functions" on page 237 for more information.
[2] See "Scalar-fullselect" on page 255 for more information.
[3] See Labeled durations for more information.
[4] See "CASE expressions" on page 263 for more information.
[5] See "CAST specification" on page 266 for more information.
[6] See "XMLCAST specification" on page 276 for more information.
[7] See "Array element specification" on page 277 for more information.
[8] See "Array constructor" on page 278 for more information.
[9] See "OLAP specifications" on page 279
[10] See "ROW CHANGE expression" on page 290

[11] See "Sequence reference" on page 291

operator:



labeled-duration:



Notes:

[1] Must be a scalar function.

Expressions without operators

If no operators are used, the result of the expression is the specified value. Each of the following examples is an expression that specifies a value based on a column named SALARY:

```
   SALARY     :SALARY     'SALARY'    MAX(SALARY)
```

Related concepts

Characters and tokens in SQL
The most basic elements of SQL syntax are characters and tokens. Tokens are the basic syntactical units of the SQL language.

Concatenation operators in expressions

When two strings operands are concatenated, the result of the expression is a string.

Introductory concepts

String data types (Introduction to Db2 for z/OS)
Concatenation of strings (Introduction to Db2 for z/OS)

The operands of concatenation must be compatible strings. A binary string cannot be concatenated with a character string, including character strings that are defined as FOR BIT DATA (for more information on the compatibility of data types, see the compatibility matrix in Table 30 on page 144). A distinct type that is based on a string type can be concatenated only if an appropriate user-defined function is created.

Both CONCAT and the vertical bars (||) represent the concatenation operator. Vertical bars (or the characters that must be used in place of vertical bars in some countries[13]) can cause parsing errors in statements passed from one DBMS to another. The problem occurs if the statement undergoes character conversion with certain combinations of source and target CCSIDs[13]. Thus, CONCAT is the preferable concatenation operator.

If either operand can be null, the result can be null, and if either is null, the result is the null value. Otherwise, the result consists of the first operand string followed by the second.

The following table shows how the string operands determine the data type and the length attribute of the result (the order in which the operands are concatenated has no effect on the result).

Table 49. Data type and length of concatenated operands

If one operand column is	And the other operand is	The data type of the result column is[1]
CHAR(*x*)	CHAR(*y*) with a combined length attribute that is less than 256	CHAR(*x*+*y*)[2]
	CHAR(*y*) with a combined length attribute that is greater than 255	VARCHAR(MIN(*x*'+*y*',32764))[3]
	VARCHAR(*y*)	
VARCHAR(*x*)	VARCHAR(*y*)	VARCHAR(MIN(*x*'+*y*',32764))[3]
CLOB(*x*)	CHAR(*y*)	CLOB(MIN(*x*'+*y*',2G))
	VARCHAR(*y*)	
	CLOB(*y*)	
	GRAPHIC(*y*)	DBCLOB(MIN(*x*+*y*,1G))
	VARGRAPHIC(*y*)	
	DBCLOB(*y*)	
GRAPHIC(*x*)	CHAR(*y*)	VARGRAPHIC(MIN(*x*+*y*,16382)) [4]
	VARCHAR(*y*)	
	VARGRAPHIC(*y*)	

[13] In various EBCDIC code pages, Db2 supports code point combinations X'4F4F', X'BBBB', and X'5A5A' to mean concatenation. X'BBBB' and X'5A5A' are interpreted to mean concatenation only on single byte character set Db2 subsystems. X'BBBB' is a pair of right brackets characters (']]') in some EBCDIC code pages and is not used as a concatenation operator when it appears in an array-index expression. Consider using CONCAT as a concatenation operator instead of X'BBBB' because X'BBBB' might be confused with right brackets in an array-index expression.

Table 49. Data type and length of concatenated operands (continued)

If one operand column is	**And the other operand is**	**The data type of the result column is**[1]
VARGRAPHIC(*x*)	CHAR(*y*)	VARGRAPHIC(MIN(*x*+*y*,16382)) [4]
	VARCHAR(*y*)	
	GRAPHIC(*y*)	
	GRAPHIC(*y*)	
DBCLOB(*x*)	CHAR(*y*)	DBCLOB(MIN(*x*+*y*,1G))
	VARCHAR(*y*)	
	CLOB(*y*)	
	GRAPHIC(*y*)	
	VARGRAPHIC(*y*)	
	DBCLOB(*y*)	
BINARY(*x*)	BINARY(*y*) with a combined length attribute that is less than 256	BINARY(*x*+*y*)
	BINARY(*y*) with a combined length attribute that is greater than 255	VARBINARY(MIN(*x*+*y*,32764))
VARBINARY(*x*)	VARBINARY(*y*)	VARBINARY(MIN(*x*+*y*,32764))
	BINARY(*y*)	
BLOB(*x*)	BLOB(*y*)	BLOB(MIN(*x*+*y*, 2G))

Notes:

1. - 2G represents 2,147,483,647 bytes
   - 1G represents 1,073,741,823 double-byte characters
2. Neither CHAR(*x*) nor CHAR(*y*) can contain mixed data. If either operand contains mixed data, the result is VARCHAR(MIN(*x*'+*y*',32764)).
3. If conversion of the first operand is required, *x*' = 3*x*; otherwise, it remains *x*. If conversion of the second operand is required, *y*'= 3*y*; otherwise, it remains *y*.
4. Both operands are converted to UTF-16, if necessary (that is, the operand is not already UTF-16), and the results are concatenated.

As the previous table shows, the length of the result is the sum of the lengths of the operands. However, the length of the result is two bytes less if redundant shift code characters are eliminated from the result. Redundant shift code characters exist when both character strings are EBCDIC mixed data, and the first string ends with a "shift-in" character (X'0F') and the second operand begins with a "shift-out" character (X'0E'). These two shift code characters are removed from the result.

The CCSID of the result is determined by the rules set forth in "Character conversion in set operations and concatenations" on page 1063. Some consequences of those rules are the following:

- If either operand is BIT data, the result is BIT data.
- The conversion that occurs when SBCS data is compared with mixed data depends on the encoding scheme. If the encoding scheme is Unicode, the SBCS operand is converted to MIXED. Otherwise, the

conversion depends on the field MIXED DATA on installation panel DSNTIPF for the Db2 that does the comparison:

- Mixed data if the MIXED DATA option at the server is YES. The result is not necessarily well-formed mixed data.
- SBCS data if the MIXED DATA option at the server is NO. If the mixed data cannot be converted to pure SBCS data, an error occurs.

If an operand is a string from a column with a field procedure, the operation applies to the decoded form of the value. The result does not inherit the field procedure.

One operand of concatenation can be a parameter marker. When one operand is a parameter marker, its data type and length attributes are considered to be the same as those for the operand that is not a parameter marker except for a string data type. Refer to Table 49 on page 247 for the formula used to calculate data type length for untyped parameter markers in the CONCAT operator when another operand is a string data type. The order of concatenation operations must be considered to determine these attributes in the case of nested concatenation.

No operand of concatenation can be a distinct type even if the distinct type is based on a character data type. To concatenate a distinct type, create a user-defined function that is sourced on the CONCAT operator. For example, if distinct types TITLE and TITLE_DESCRIPTION were both based on data type VARCHAR(25), the following user-defined function, named ATTACH, could be used to concatenate the two distinct types:

```
CREATE FUNCTION ATTACH (TITLE, TITLE_DESCRIPTION)
   RETURNS VARCHAR(50) SOURCE CONCAT (VARCHAR(), VARCHAR())
```

Alternatively, the concatenation operator could be overloaded by using a user-defined function to add the distinct types:

```
CREATE FUNCTION "||" (TITLE, TITLE_DESCRIPTION)
   RETURNS VARCHAR(50) SOURCE CONCAT (VARCHAR(), VARCHAR())
```

CONCAT
The CONCAT function combines two compatible string arguments.

Arithmetic operators in expressions

If arithmetic operators are used, the result of the expression is a number derived from the application of the operators to the values of the operands.

The result of the expression can be null. If any operand has the null value, the result of the expression is the null value. Arithmetic operators (except unary plus, which is meaningless) must not be applied to strings. For example, USER+2 is invalid. Multiplication and division operators must not be applied to datetime values, which can only be added and subtracted.

The prefix operator + (*unary plus*) does not change its operand. The prefix operator - (*unary minus*) reverses the sign of a nonzero, non-decimal floating-point operand. The prefix operator - (*unary minus*) reverses the sign of all decimal floating-point operands, including zero and special values; that is, signaling and non-signaling NaNs and plus and minus infinity. If the data type of *A* is *small integer*, the data type of -*A* is *large integer*. The first character of the token following a prefix operator must not be a plus or minus sign.

The *infix operators* specify addition (+), subtraction (-), multiplication (*), and division (/). The value of the second operand of division must not be zero.

Arithmetic with two integer operands

If both operands of an arithmetic operator are integers, the operation is performed in binary. The result is a large integer unless either (or both) operand is a big integer, in which case the result is a big integer.

The result of an integer arithmetic operation (including unary minus) must be within the range of the result type.

Arithmetic with an integer and a decimal operand

If one operand is an integer and the other operand is decimal, the operation is performed in decimal. The arithmetic operation uses a temporary copy of the integer that has been converted to a decimal number.

The temporary copy of the integer that has been converted to a decimal number has a precision *p* and scale 0. *p* is 19 for a big integer, 11 for a large integer, and 5 for a small integer. In the case of an integer constant, *p* depends on the number of digits in the integer constant. *p* is 5 for an integer constant consisting of 5 digits or fewer. Otherwise, *p* is the same as the number of digits in the integer constant.

Arithmetic with an integer and a decimal floating-point operand

If one operand is a small integer, large integer, or big integer and the other is a decimal floating-point number, the operation is performed in decimal floating point. The arithmetic operation uses a temporary copy of the integer that has been converted to a decimal floating-point number.

For small integer or large integer, the temporary copy of the integer is converted to DECFLOAT(16). For big integer, the temporary copy of the big integer is converted to DECFLOAT(34). The rules for two decimal floating point operands are then applied.

Arithmetic with two decimal operands

If both operands are decimal, the operation is performed in decimal.

The result of any decimal arithmetic operation is a decimal number with a precision and scale that depend on two factors:

The precision and scale of the operands

In the discussion of operations with two decimal operands, the precision and scale of the first operand are denoted by *p* and *s*, that of the second operand by *p'* and *s'*. Thus, for a division, the dividend has precision *p* and scale *s*, and the divisor has precision *p'* and scale *s'*.

Whether DEC31 or DEC15 is in effect for the operation

DEC31 and DEC15 specify the rules to be used when both operands in a decimal operation have precisions of 15 or less. DEC15 specifies the rules which do not allow a precision greater than 15 digits, and DEC31 specifies the rules which allow a precision of up to 31 digits. The rules for DEC31 are always used if either operand has a precision greater than 15.

For static SQL statements, the value of the field DECIMAL ARITHMETIC on installation panel DSNTIP4 or the SQL processing option DEC determines whether DEC15 or DEC31 is used.

For dynamic SQL statements, the value of the field DECIMAL ARITHMETIC on installation panel DSNTIP4, the SQL processing option DEC, or the special register CURRENT PRECISION determines whether DEC15 or DEC31 is used according to these rules:

- Field DECIMAL ARITHMETIC applies if either of these conditions is true:
  - DYNAMICRULES run behavior applies and the application has not set CURRENT PRECISION.

    For a list of the DYNAMICRULES option values that specify run, bind, define, or invoke behavior, see Table 14 on page 94.
  - DYNAMICRULES bind, define, or invoke behavior applies; the value of installation panel field USE FOR DYNAMICRULES is YES; and the application has not set CURRENT PRECISION.
- SQL processing option DEC applies if DYNAMICRULES bind, define, or invoke behavior is in effect, the value of installation panel field USE FOR DYNAMICRULES is NO, and the application has not set CURRENT PRECISION.
- Special register CURRENT PRECISION applies if the application sets the register.

The value of DECIMAL ARITHMETIC is the default value for the SQL processing option and the special register. SQL statements executed using SPUFI use the value in DECIMAL ARITHMETIC.

Decimal addition and subtraction

For decimal operations, the precision and scale of the result depends on the precision and scale of the operands.

If the operation is addition or subtraction and the operands do not have the same scale, the operation is performed with a temporary copy of one of the operands that has been extended with trailing zeros so that its fractional part has the same number of digits as the other operand.

The precision of the result is the minimum of *n* and the quantity `MAX(`*p*`-`*s*`,`*p*`'-`*s*`')+MAX(`*s*`,`*s*`')+1`. The scale is `MAX(`*s*`,`*s*`')`. *n* is 31 if DEC31 is in effect or if the precision of at least one operand is greater than 15. Otherwise, *n* is 15.

In COBOL, blanks must precede and follow a minus sign to avoid any ambiguity with COBOL host variable names (which allow the use of a dash).

Decimal multiplication

For decimal multiplication, the precision and scale of the result depends on the precision and scale of the operands.

For multiplication, the precision of the result is `MIN(`*n*`,`*p*`+`*p*`')`, and the scale is `MIN(`*n*`,`*s*`+`*s*`')`. *n* is 31 if DEC31 is in effect or if the precision of at least one operand is greater than 15. Otherwise, *n* is 15.

If both operands have a precision greater than 15, the operation is performed using a temporary copy of the operand with the smaller precision. If the operands have the same precision, the second operand is selected. If more than 15 significant digits are needed for the integral part of the copy, the statement's execution is ended and an error occurs. Otherwise, the copy is converted to a number with precision 15, by truncating the copy on the right. The truncated copy has a scale of `MAX(0,`*S*`-(`*P*`-15))`, where *P* and *S* are the original precision and scale. If, in the process of truncation, one or more nonzero digits are removed, SQLWARN7 in SQLCA is set to W, indicating loss of precision.

When both operands have a precision greater than 15, the foregoing formulas for the precision and scale of the result still apply, with one change: for the operand selected as the copy, use the precision and scale of the truncated copy; that is, use 15 as the precision and `MAX(0,`*S*`-(`*P*`-15))` for the scale.

Let *n* denote the value of the operand with the greater precision or the first operand in the case of operands with the same precision. The number of leading zeros in a 31-digit representation of *n* must be greater than the precision of the other operand. This is always the case if the precision of the operand is 15 or less. With greater precisions, overflow can occur even if the precision of the result is less than 31. For example, the expression:

```
   10000000000000000000000000. * 1
```

will cause overflow because the number of leading zeros in the 31-digit representation of the large number and the precision of the small number are both 5. See "Arithmetic with an integer and a decimal operand" on page 250.

Arithmetic with an integer and a decimal operand

If one operand is an integer and the other operand is decimal, the operation is performed in decimal. The arithmetic operation uses a temporary copy of the integer that has been converted to a decimal number.

The temporary copy of the integer that has been converted to a decimal number has a precision *p* and scale 0. *p* is 19 for a big integer, 11 for a large integer, and 5 for a small integer. In the case of an integer constant, *p* depends on the number of digits in the integer constant. *p* is 5 for an integer constant consisting of 5 digits or fewer. Otherwise, *p* is the same as the number of digits in the integer constant.

Decimal division

The rules for a specific decimal division depend on whether the DEC31 option is in effect for the operation, whether p is greater than 15, and whether p' is greater than 15.

The following table shows how the precision and scale of the result depend on these factors. In that table, the occurrence of "N/A" in a row implies that the indicated factor is not relevant to the case represented by the row.

Table 50. Precision (p) and scale (s) of the result of a decimal division

DEC31	*p*	*p'*	*P*	*S*
Not in effect	≤15	≤15	15	`15-(`*p*`-`*s*`+`*s*`')`
In effect	≤15	≤15	31	*N*`-(`*p*`-`*s*`+`*s*`')`, where *N* is 30-*p'* if *p'* is odd. *N* is 29-*p'* if *p'* is even.
N/A	>15	≤15	31	`N-(`*p*`-`*s*`+`*s*`')`, where *N* is 30-*p'* if *p'* is odd. *N* is 29-*p'* if *p'* is even.
N/A	N/A	>15	31	`15-(`*p*`-`*s*`+`*x*`)`, where *x* is `MAX(0,`*s*`'-(`*p*`'-15))` (See the following note)

If *p'* is greater than 15, the division is performed using a temporary copy of the divisor. If more than 15 significant digits are needed for the integral part of the divisor, the statement's execution is ended, and an error occurs. Otherwise, the copy is converted to a number with precision 15, by truncating the copy on the right. The truncated copy has a scale of `MAX(0,`*s*`'-(`*p*`'-15))`, which is the formula for *x*. If, in the process of truncation, one or more nonzero digits are removed, SQLWARN7 in SQLCA is set to W, indicating loss of precision.

Minimum divide result scale

If the calculated value of 's' is negative, an error occurs. If a minimum divide result scale is specified, this error does not occur.

The minimum scale is determined according to the following precedence:

Static SQL

1. The precompiler DEC option, if it is set with a non-zero scale.
2. The DECARTH subsystem parameter, if set with a non-zero scale.
3. The MINDVSCL subsystem parameter, if set to value other than NONE.
4. The DECDIV3 subsystem parameter, if set to YES.

Dynamic SQL

1. The CURRENT PRECISION special register, if it is set with a non-zero scale.
2. Either of the following cases:
   - For a package that was bound with DYNAMICRULES RUN or if the DYNRULS DECP value is set to YES: The DECARTH subsystem parameter, if it is set with a non-zero scale.
   - For all other cases: The precompiler DEC option, if it is set with a non-zero scale.
3. The MINDVSCL subsystem parameter, if set to value other than NONE.
4. The DECDIV3 subsystem parameter, if set to YES.

SQL statements that are executed using SPUFI

The DECARTH subsystem parameter value.

The default value for both the precompiler DEC option and the CURRENT PRECISION special register is DECIMAL ARITHMETIC.

A minimum divide result scale of 3 can be specified using the DECDIV3 subsystem parameter setting. A minimum divide scale result between 1 and 9 can be specified using the DECARTH subsystem parameter value of the form 'D*pp*.*s*' where '*pp*' is 15 or 31 and represents the precision and '*s*' represents the minimum divide scale, as a number between 1 and 9. Such a specification overrides the DECDIV3 subsystem parameter. When a minimum divide result scale is specified, the formula `MAX(s,s')`, where *s* represents the scale derived from the above table and *s'* represents the value specified by the minimum divide result scale, is applied and a new scale is derived. The newly derived scale is the scale of the result and overrides any scale derived using the table above.

For more information, see:

- DECIMAL ARITHMETIC field (DECARTH DECP value) (Db2 Installation and Migration)
- MINIMUM DIVIDE SCALE field (DECDIV3 subsystem parameter) (Db2 Installation and Migration)
- MINDVSCL subsystem parameter in DSN6SPRM (Db2 Installation and Migration)
- USE FOR DYNAMICRULES field (DYNRULS DECP value) (Db2 Installation and Migration)
- SQL processing options (see "DEC(15|31)")

Arithmetic with floating-point operands

If either operand of an arithmetic operator is floating-point, the operation is performed in floating-point. If necessary, the operands are first converted to double-precision floating-point numbers. Thus, if any element of an expression is a floating-point number, the result of the expression is a double-precision floating-point number.

An operation involving a floating-point number and an integer is performed with a temporary copy of the integer that has been converted to double-precision floating-point. An operation involving a floating-point number and a decimal number is performed with a temporary copy of the decimal number that has been converted to double-precision floating-point. The result of a floating-point operation must be within the range of floating-point numbers.

The order in which floating-point operands (or arguments to functions) are processed can affect the results slightly because floating-point operands are approximate representations of real numbers. Because the order in which operands are processed might be implicitly modified by Db2 (for example, Db2 might decide what degree of parallelism to use and what access plan to use), an application that uses floating-point operands should not depend on the results being precisely the same each time an SQL statement is executed.

Arithmetic with a floating-point and a decimal floating-point operand

If one operand is a floating-point number (real or double) and the other is a decimal floating-point number, the operation is performed in decimal floating-point. The arithmetic operation uses a temporary copy of the floating-point number that has been converted to a decimal floating-point number.

Arithmetic with two decimal floating-point operands

If both operands are decimal floating point, the operation is performed in decimal floating point. If one operand is DECFLOAT(*n*) and the other is DECFLOAT(*m*), the operation is performed in DECFLOAT(max(*n*,*m*)).

General arithmetic operation rules for DECFLOAT

The following general rules apply to all arithmetic operations on the DECFLOAT data type:

- Every operation on finite numbers is carried out as though an exact mathematical result is computed, using integer arithmetic on the coefficient where possible.

If the coefficient of the theoretical exact result has no more than the number of digits that reflect its precision (16 or 34), it is used for the result without change (unless there is an underflow or overflow condition). If the coefficient has more than the number of digits that reflect its precision, it is rounded to exactly the number of digits that reflect its precision (16 or 34), and the exponent is increased by the number of digits that are removed.

For static SQL statements other than CREATE VIEW, the ROUNDING bind option or the native SQL procedure option determines the rounding mode.

For dynamic SQL statements (and static CREATE VIEW statements), the special register CURRENT DECFLOAT ROUNDING MODE determines the rounding mode.

If the value of the adjusted exponent of the result is less than E_{min}, an exception condition is returned. In this case, the calculated coefficient and exponent form the result, unless the value of the exponent is less than E_{tiny}, in which case the exponent is set to E_{tiny}, the coefficient is rounded (possibly to zero) to match the adjustment of the exponent, and the sign is unchanged. If this rounding gives an inexact result, an underflow exception condition is returned.

If the value of the adjusted exponent of the result is larger than E_{max}, an overflow exception condition is returned. In this case, the result is as defined as an overflow exception condition and might be infinite. It will have the same sign as the theoretical result.

- Arithmetic that uses the special value infinity follows the usual rules, where negative infinity is less than every finite number and positive infinity is greater than every finite number.

  Under these rules, an infinite result is always exact. Certain uses of infinity return an invalid operation condition. The following list is a list of operations that can cause an invalid operation condition and the result of the operation is NaN when one of the operands is infinity but the other operand is not NaN nor sNaN.

  – Add +infinity to -infinity during an addition or subtraction operation
  – Multiply 0 by +infinity or -infinity
  – Divide either +infinity or -infinity by either +infinity or -infinity
  – The first argument to the MOD function is either +infinity or -infinity
  – Either argument of the QUANTIZE function is +infinity or -infinity
  – The second argument of the POWER® function is +infinity or -infinity
  – A NaN when used as an operand to an arithmetic operation

  The following arithmetic rules apply to arithmetic operations and the NaN value:

  – The result of any arithmetic operation that has an operand that is a NaN (a quiet NaN or signaling NaN) is NaN. The sign of the result is copied from the first operand that is a signaling NaN, or if neither operand is signaling, the sign is copied from the first operand that is a NaN. Whenever a result is a NaN, the sign of the result depends only on the copied operand.
  – The sign of the result of a multiplication or division will be negative only if the operands have different signs and neither is a NaN.
  – The sign of the result of an addition or subtraction will be negative only if the result is less than zero and neither operand is a NaN, except for the following cases where the result is a negative 0:
    - A result is rounded to zero, and the value, before rounding, had a negative sign
    - Subtract 0 from -0
    - Addition of operands with opposite signs (or subtraction of operands with the same sign), the result has a coefficient of 0, and the rounding mode is ROUND_FLOOR
    - Multiplication or division and the result has a coefficient of 0 and the signs of the operands are different
    - The first argument of the POWER function is -0, and the second argument is a positive odd number
    - The argument of the CEIL, FLOOR, or SQRT function is -0
    - The first argument of the ROUND or TRUNCATE function is -0

Examples involving special DECFLOAT values:

```
    INFINITY + 1              = INFINITY
    INFINITY + INFINITY       = INFINITY
    INFINITY + -INFINITY      = NAN        -- exception
    NAN + 1                   = NAN
    NAN + INFINITY            = NAN
    1 - INFINITY              = -INFINITY
    INFINITY - INFINITY       = NAN        -- exception
    -INFINITY - -INFINITY     = NAN        -- exception
    -0.0 - 0.0E1              = -0.0
    -1.0 * 0.0E1              = -0.0
    1.0E1 / 0                 = INFINITY
    -1.0E5 / 0.0              = -INFINITY
    1.0E5 / -0                = -INFINITY
    INFINITY / -INFINITY      = NAN        -- exception
    INFINITY / 0              = INFINITY
    -INFINITY / 0             = -INFINITY
    -INFINITY / -0            = INFINITY
```

Arithmetic with distinct type operands

A distinct type cannot be used with arithmetic operators even if its source data type is numeric. To perform an arithmetic operation, create a function with the arithmetic operator as its source. For example, if there were distinct types INCOME and EXPENSES, both of which had DECIMAL(8,2) data types, the following user-defined function, REVENUE, could be used to subtract one from the other.

```
   CREATE FUNCTION REVENUE ( INCOME, EXPENSES )
     RETURNS DECIMAL(8,2) SOURCE "-" ( DECIMAL, DECIMAL)
```

Alternately, the **-** (minus) operator could be overloaded using a function to subtract the new data types.

```
    CREATE FUNCTION "-" ( INCOME, EXPENSES )
      RETURNS DECIMAL(8,2) SOURCE "-" ( DECIMAL, DECIMAL)
```

Alternatively, the distinct type can be cast to a built-in data type and the result used as an operand of an arithmetic operator.

Scalar-fullselect

A *scalar-fullselect* as supported in an expression is a fullselect, enclosed in parentheses, that returns a single row consisting of a single column value. If the fullselect does not return a row, the result of the expression is the null value. If more than one row is to be returned for a scalar fullselect, an error occurs.

```
►►─ ( ── fullselect ── ) ─►◄
```

If a set operator is not specified in the outermost fullselect and the select list element is an expression that is simply a column name, the result column name is based on the name of the column. Otherwise, the result column is unnamed.

If a column mask is defined to mask the column values in the final result, and if a column mask is applied to the column in the select list of a *scalar-fullselect*, the result of the *scalar-fullselect* must not be derived using set operator EXCEPT or INTERSECT. See Chapter 6, “Queries,” on page 1005 for more information about how column access controls affect a fullselect.

A scalar fullselect cannot be used in the following instances:

- A CHECK constraint in CREATE TABLE and ALTER TABLE statements
- A CREATE VIEW statement where the view definition includes the WITH CHECK option
- A CREATE FUNCTION (SQL) statement (subselect already restricted from the expression in the RETURN clause)
- An argument in a CALL statement for an input parameter
- An argument to an aggregate function, other than the *XML-expression* argument of the XMLAGG function

- An ORDER BY clause
- A GROUP BY clause
- A join-condition of the ON clause for INNER and OUTER JOINs

If the scalar fullselect is a subselect, it is also referred to as a scalar subselect. See "subselect" on page 1007 for more information.

The following examples illustrate the use of *scalar-fullselect*. Assume that four tables (PARTS, PRODUCTS, PARTPRICE, and PARTINVENTORY) contain product data.

Example 1 - *scalar-fullselect* in a WHERE clause:
Find which products have the prices in the range of at least twice the lowest price of all the products and at most half the price of all the products.

```
SELECT PRODUCT, PRICE FROM PRODUCTS A
    WHERE
     PRICE BETWEEN 2 * (SELECT MIN(PRICE) FROM PRODUCTS)
           AND .5 * (SELECT MAX(PRICE) FROM PRODUCTS);
```

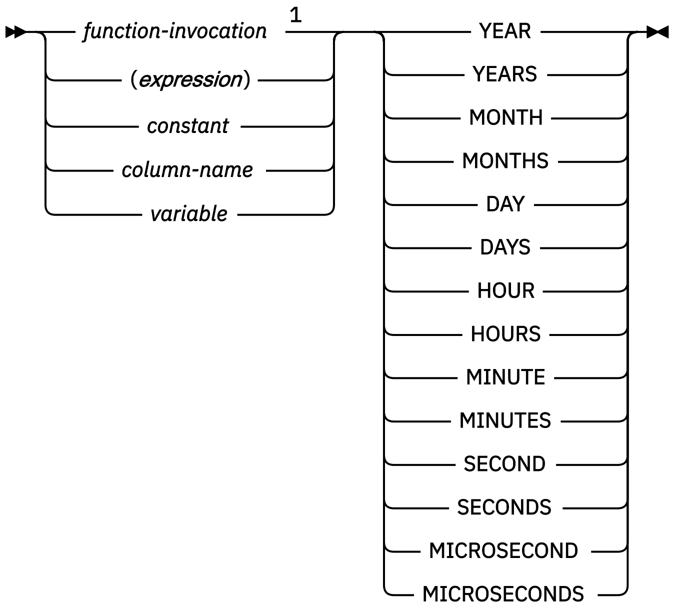
Example 2 - *scalar-fullselect* in a SELECT list:
For each part, find its price and its inventory.

```
SELECT PART,
      (SELECT PRICE FROM PARTPRICE WHERE PART=A.PART),
      (SELECT ONHAND# FROM INVENTORY WHERE PART=A.PART)
    FROM PARTS A;
```

Datetime operands and durations

Datetime values can be incremented, decremented, and subtracted. These operations can involve decimal numbers called durations. A *duration* is a positive or negative number representing an interval of time.

Labeled durations
The form a labeled duration is as follows:



Notes:

[1] Must be a scalar function.

A *labeled duration* represents a specific unit of time as expressed by a number (which can be the result of an expression) followed by one of the seven duration keywords.[14] The number specified is converted as if it were assigned to a DECIMAL(15,0) number, except for SECONDS, which uses DECIMAL(27,12) to allow 0 to 12 fractional second digits to be included.

A labeled duration can only be used as an operand of an arithmetic operator in which the other operand is a value of the data type of date, time, or timestamp. Thus, the expression HIREDATE + 2 MONTHS + 14 DAYS is valid, whereas the expression HIREDATE + (2 MONTHS + 14 DAYS) is not. In both of these expressions, the labeled durations are 2 MONTHS and 14 DAYS.

Date duration

A *date duration* represents a number of years, months, and days expressed as a DECIMAL(8,0) number. To be properly interpreted, the number must have the format *yyyymmdd*, where *yyyy* represents the number of years, *mm* the number of months, and *dd* the number of days. The result of subtracting one DATE value from another, as in the expression HIREDATE - BIRTHDATE, is a date duration.

Time duration

A *time duration* represents a number of hours, minutes, and seconds expressed as a DECIMAL(6,0) number. To be properly interpreted, the number must have the format *hhmmss*, where *hh* represents the number of hours, *mm* the number of minutes, and *ss* the number of seconds. The result of subtracting one TIME value from another is a time duration.

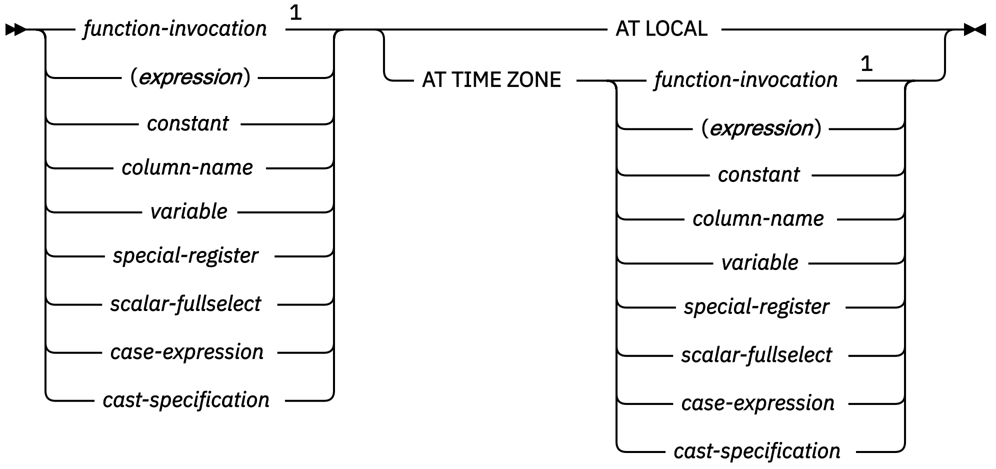
Timestamp duration

A *timestamp duration* represents a number of years, months, days, hours, minutes, seconds, and fractional seconds expressed as a DECIMAL(14+*s*,*s*) number, where s is the number of fractional seconds in the range from 0 to 12. To be interpreted properly, the number must have the format *yyyyxxddhhmmss.zzzzzzzzzzzz*, where *yyyy*, *xx*, *dd*, *hh*, *mm*, *ss*, and *zzzzzzzzzzzz* represent, respectively, the number of years, months, days, hours, minutes, seconds, and fractional seconds. The result of subtracting one timestamp value from another is a timestamp duration with a scale that matches the maximum timestamp precision of the timestamp operands.

Time zone specific expressions

Time zone specific expressions can be used to adjust timestamp values and character-string or graphic-string representations of timestamp values to specific time zones.

time-zone-specific-expressions



Notes:

[1] Must be a scalar function.

[14] The singular form of these keywords is also acceptable: YEAR, MONTH, DAY, HOUR, MINUTE, SECOND, and MICROSECOND.

The first operand for *time-zone-specific-expression* must be an expression that returns the value of either a built-in timestamp or a built-in character or graphic string data type. If the first operand is a character string or graphic string, it must not be a CLOB or DBCLOB value and its value must be a valid character-string or graphic-string representation of a timestamp. For the valid formats of string representations of datetime values, see "String representations of datetime values" on page 120.

If the first operand of *time-zone-specific-expression* returns a TIMESTAMP WITHOUT TIME ZONE value, the expression is implicitly cast to TIMESTAMP WITH TIME ZONE before being adjusted to the indicated time zone.

AT LOCAL
Specifies that the timestamp value is to be adjusted for the local time zone using the SESSION TIME ZONE special register.

AT TIME ZONE
Specifies that the timestamp is to be adjusted for the time zone that is represented by the expression.

expression is a character or graphic string. It must not be a CLOB or DBCLOB value, and its value must be left justified and be of the form '±*th*:*tm*', where *th* represents the time zone hour between -12 and +14, and *tm* represents the time zone minutes between 0 and 59, with values ranging from -12:59 to +14:00. The value must not be the null value.

The expression returns a TIMESTAMP WITH TIME ZONE value in the indicated time zone.

Syntax alternatives: TIMEZONE can be specified as an alternative to TIME ZONE.

Example 1

```
CAST('2010-04-12-10:30:00.0 -5:00' AT LOCAL AS TIMESTAMP)
```

Returns: `2010-04-12-07:30:00.000000`.

Example 2

Insert a timestamp value with a time zone into a table, tz, and retrieve it as a timestamp with the local time zone, with +08:00, and adjusted for UTC. Assume that table tz exists as follows:

```
CREATE TABLE tz(tstz TIMESTAMP WITH TIME ZONE);

INSERT INTO tz(tstz) VALUES(TIMESTAMP '2010-01-01-10.23.51-08:00');
```

1. Retrieve the value of the tstz column adjusted for the local time:

   ```
   SELECT tstz AT LOCAL
       FROM tz;
   ```

2. Retrieve the value of the tstz column adjusted for the time zone +08:00:

   ```
   SELECT tstz AT TIME ZONE '+08:00'
       FROM tz;
   ```

3. Retrieve the value of the tstz column adjusted for UTC:

   ```
   SELECT tstz AT TIME ZONE '+0:00'
       FROM tz;
   ```

Datetime arithmetic in SQL

The only arithmetic operations that can be performed on datetime values are addition and subtraction.

If a datetime value is the operand of addition, the other operand must be a duration. The specific rules governing the use of the addition operator with datetime values follow.

- If one operand is a date, the other operand must be a date duration or labeled duration of years, months, or days.

- If one operand is a time, the other operand must be a time duration or a labeled duration of hours, minutes, or seconds.
- If one operand is a timestamp, the other operand must be a duration. Any type of duration is valid.
- Neither operand of the addition operator can be a parameter marker. For a discussion of parameter markers, see Parameter markers in "PREPARE" on page 2037.

The rules for the use of the subtraction operator on datetime values are not the same as those for addition because a datetime value cannot be subtracted from a duration, and because the operation of subtracting two datetime values is not the same as the operation of subtracting a duration from a datetime value. The specific rules governing the use of the subtraction operator with datetime values follow.

- If the first operand is a date, the second operand must be a date, a date duration, a string representation of a date, or a labeled duration of years, months, or days.
- If the second operand is a date, the first operand must be a date, or a string representation of a date.
- If the first operand is a time, the second operand must be a time, a time duration, a string representation of a time, or a labeled duration of hours, minutes, or seconds.
- If the second operand is a time, the first operand must be a time, or string representation of a time.
- If the first operand is a timestamp, the second operand must be a timestamp, a string representation of a timestamp, or a duration. If the second operand is a string representation of a timestamp, it is implicitly converted to a timestamp with the same precision as the first operand.
- If the second operand is a timestamp, the first operand must be a timestamp or a string representation of a timestamp. If the first operand is a string representation of a timestamp, it is implicitly converted to a timestamp with the same precision as the second operand.
- Neither operand of the subtraction operator can be a parameter marker.

When an operand in a datetime expression is a string, it might undergo character conversion before it is interpreted and converted to a datetime value. When its CCSID is not that of the default for mixed strings, a mixed string is converted to the default mixed data representation. When its CCSID is not that of the default for SBCS strings, an SBCS string is converted to the default SBCS representation.

Date arithmetic

Date values can be subtracted, incremented, or decremented.

Subtracting dates: The result of subtracting one date (DATE2) from another (DATE1) is a date duration that specifies the number of years, months, and days between the two dates. The data type of the result is DECIMAL(8,0). If DATE1 is greater than or equal to DATE2, DATE2 is subtracted from DATE1. If DATE1 is less than DATE2, however, DATE1 is subtracted from DATE2, and the sign of the result is made negative. The following procedural description clarifies the steps involved in the operation RESULT = DATE1 - DATE2.

Date subtraction: result = date1 - date2

- If `DAY(DATE2) <= DAY(DATE1)` then `DAY(RESULT) = DAY(DATE1) - DAY(DATE2)`
- If `DAY(DATE2) > DAY(DATE1)` then `DAY(RESULT) = N + DAY(DATE1) - DAY(DATE2)` where *N* = the last day of `MONTH(DATE2)`. `MONTH(DATE2)` is then incremented by 1.
- If `MONTH(DATE2) <= MONTH(DATE1)` then `MONTH(RESULT) = MONTH(DATE1) - MONTH(DATE2)`
- If `MONTH(DATE2) > MONTH(DATE1)` then `MONTH(RESULT) = 12 + MONTH(DATE1) - MONTH(DATE2)` and `YEAR(DATE2)` is incremented by 1.
- `YEAR(RESULT) = YEAR(DATE1) - YEAR(DATE2)`

For example, the result of DATE('3/15/2005') - '12/31/2004' is 215 (or, a duration of 0 years, 2 months, and 15 days). In this example, notice that the second operand did not need to be converted to a date. According to one of the rules for subtraction, described under "Datetime arithmetic in SQL" on page 258, the second operand can be a string representation of a date if the first operand is a date.

Incrementing and decrementing dates: The result of adding a duration to a date, or of subtracting a duration from a date, is itself a date. (For the purposes of this operation, a month denotes the equivalent of a calendar page. Adding months to a date, then, is like turning the pages of a calendar, starting with the page on which the date appears.) The result must fall between the dates January 1, 0001 and December 31, 9999 inclusive. If a duration of years is added or subtracted, only the year portion of the date is affected. The month is unchanged, as is the day unless the result would be February 29 of a non-leap-year. Here the day portion of the result is set to 28, and the SQLWARN6 field of the SQLCA is set to W, indicating that an end-of-month adjustment was made to correct an invalid date. "Description of SQLCA fields" on page 2291 also describes how SQLWARN6 is set.

Similarly, if a duration of months is added or subtracted, only months and, if necessary, years are affected. The day portion of the date is unchanged unless the result would be invalid (September 31, for example). In this case the day is set to the last day of the month, and the SQLWARN6 field of the SQLCA is set to W to indicate the adjustment.

Adding or subtracting a duration of days will, of course, affect the day portion of the date, and potentially the month and year. Adding or subtracting a duration of days will not cause an end-of-the-month adjustment.

Date durations, whether positive or negative, can also be added to and subtracted from dates. As with labeled durations, the result is a valid date, and SQLWARN6 is set to W to indicate any necessary end-of-month adjustment.

When a positive date duration is added to a date, or a negative date duration is subtracted from a date, the date is incremented by the specified number of years, months, and days, in that order. Thus, DATE1+*X*, where *X* is a positive DECIMAL(8,0) number, is equivalent to the expression:

```
DATE1 + YEAR(X) YEARS + MONTH(X) MONTHS + DAY(X) DAYS
```

When a positive date duration is subtracted from a date, or a negative date duration is added to a date, the date is decremented by the specified number of days, months, and years, in that order. Thus, DATE1-*X*, where *X* is a positive DECIMAL(8,0) number, is equivalent to the expression:

```
DATE1 - DAY(X) DAYS - MONTH(X) MONTHS - YEAR(X) YEARS
```

Adding a month to a date gives the same day one month later unless that day does not exist in the later month. In that case, the day in the result is set to the last day of the later month. For example, January 28 plus one month gives February 28; one month added to January 29, 30, or 31 results in either February 28 or, for a leap year, February 29. If one or more months is added to a given date and then the same number of months is subtracted from the result, the final date is not necessarily the same as the original date.

If one or more months are added to a given date and then the same number of months is subtracted from the result, the final date is not necessarily the same as the original date. In addition, logically equivalent expressions might not produce the same result. For example, the following two expressions do not produce the same result:

```
 (DATE('2005 01 31') + 1 MONTH) + 1 MONTH    -- results in 2005-03-28
 DATE('2005 01 31') + 2 MONTHS               -- results in 2005-03-31
```

The order in which labeled date durations are added to and subtracted from dates can affect the results. When you add labeled date durations to a date, specify them in the order of YEARS + MONTHS + DAYS. When you subtract labeled date durations from a date, specify them in the order of DAYS - MONTHS - YEARS. For example, to add one year and one day to a date, specify:

```
DATE1 + 1 YEAR + 1 DAY
```

To subtract one year, one month, and one day from a date, specify:

```
DATE1 - 1 DAY - 1 MONTH - 1 YEAR
```

Time arithmetic

Times can be subtracted, incremented, or decremented.

Subtracting times: The result of subtracting one time (*TIME2*) from another (*TIME1*) is a time duration that specifies the number of hours, minutes, and seconds between the two times. The data type of the result is DECIMAL(6,0). If *TIME1* is greater than or equal to *TIME2*, *TIME2* is subtracted from *TIME1*. If *TIME1* is less than *TIME2*, however, *TIME1* is subtracted from *TIME2*, and the sign of the result is made negative. The following procedural description clarifies the steps involved in the operation `RESULT = TIME1 - TIME2`.

Time subtraction: *result = time1 - time2*

- If `SECOND(TIME2) <= SECOND(TIME1)` then `SECOND(RESULT) = SECOND(TIME1) - SECOND(TIME2)`.
- If `SECOND(TIME2) > SECOND(TIME1)` then `SECOND(RESULT) = 60 + SECOND(TIME1) - SECOND(TIME2)` and `MINUTE(TIME2)` is incremented by 1.
- If `MINUTE(TIME2) <= MINUTE(TIME1)` then `MINUTE(RESULT) = MINUTE(TIME1) - MINUTE(TIME2)`.
- If `MINUTE(TIME2) > MINUTE(TIME1)` then `MINUTE(RESULT) = 60 + MINUTE(TIME1) - MINUTE(TIME2)` and `HOUR(TIME2)` is incremented by 1.
- `HOUR(RESULT) = HOUR(TIME1) - HOUR(TIME2)`.

For example, the result of `TIME('11:02:26') - '00:32:56'` is '102930' (a duration of 10 hours, 29 minutes, and 30 seconds). In this example, notice that the second operand did not need to be converted to a time. According to one of the rules for subtraction, described under "Datetime arithmetic in SQL" on page 258, the second operand can be a string representation of a time if the first operand is a time.

Incrementing and decrementing times: The result of adding a duration to a time, or of subtracting a duration from a time, is itself a time. Any overflow or underflow of hours is discarded, thereby ensuring that the result is always a time. If a duration of hours is added or subtracted, only the hours portion of the time is affected. Adding 24 hours to the time '00:00:00' results in the time '24:00:00'. However, adding 24 hours to any other time results in the same time; for example, adding 24 hours to the time '00:00:59' results in the time '00:00:59'. The minutes and seconds are unchanged.

Similarly, if a duration of minutes is added or subtracted, only minutes and, if necessary, hours are affected. The seconds portion of the time is unchanged.

Adding or subtracting a duration of seconds affects the seconds portion of the time and might affect the minutes and hours.

Time durations, whether positive or negative, can also be added to and subtracted from times. The result is a time that has been incremented or decremented by the specified number of hours, minutes, and seconds, in that order. Thus, `TIME1 + X`, where *X* is a positive DECIMAL(6,0) number, is equivalent to the expression

```
TIME1 + HOUR(X) HOURS + MINUTE(X) MINUTES + SECOND(X) SECONDS
```

Timestamp arithmetic

Timestamps can be subtracted, incremented, or decremented.

If any of the operands are TIMESTAMP WITH TIME ZONE, any TIMESTAMP WITHOUT TIME ZONE values are implicitly cast to TIMESTAMP WITH TIME ZONE, and the datetime arithmetic operation is performed in UTC time (ignoring the time zone).

Subtracting timestamps: The result of subtracting one timestamp (*TS2*) from another (*TS1*) is a timestamp duration that specifies the number of years, months, days, hours, minutes, seconds, and fractional seconds between the two timestamps.

The data type of the result is DECIMAL(14+*s*,*s*), where *s* is the maximum timestamp precision of *TS1* and *TS2*. If *TS1* is greater than or equal to *TS2*, *TS2* is subtracted from *TS1*. If *TS1* is less than *TS2*. However, *TS1* is subtracted from *TS2* and the sign of the result is made negative. A subtraction that involves a timestamp with a time zone operand is based on the UTC value of the timestamp with the time zone. The time zone is ignored.

The following procedural description clarifies the steps involved in the operation *RESULT = TS1 - TS2*.

Timestamp subtraction: *result = ts1 - ts2*

- If MICROSECOND(*TS2*) <= MICROSECOND(*TS1*) then MICROSECOND(*RESULT*) = MICROSECOND(*TS1*) - MICROSECOND(*TS2*).
- If MICROSECOND(*TS2*) > MICROSECOND(*TS1*) then MICROSECOND(*RESULT*) = 1000000 + MICROSECOND(*TS1*)- MICROSECOND(*TS2*) and SECOND(*TS2*) is incremented by 1.
- If SECOND(*TS2*,*s*) <= SECOND(*TS1*,*s*) then SECOND(*RESULT*,*s*) = SECOND(*TS1*,*s*) - SECOND(*TS2*,*s*).
- If SECOND(*TS2*,*s*) > SECOND(*TS1*,*s*) then SECOND(*RESULT*,*s*) = 60 + SECOND(*TS1*,*s*) – SECOND(*TS2*,*s*).

  MINUTE(*TS2*) is incremented by 1.
- If HOUR(*TS2*) <= HOUR(*TS1*) then HOUR(*RESULT*) = HOUR(*TS1*) - HOUR(*TS2*).
- If HOUR(*TS2*) > HOUR(*TS1*) then HOUR(*RESULT*) = 24 + HOUR(*TS1*) - HOUR(*TS2*) and DAY(*TS2*) is incremented by 1.

The minutes part of the timestamps are subtracted as specified in the rules for subtracting times.

The date part of the timestamps is subtracted as specified in the rules for subtracting dates.

Incrementing and decrementing timestamps: The result of adding a duration to a timestamp, or of subtracting a duration from a timestamp, is itself a timestamp. The precision of the result timestamp matches the precision of the timestamp operand. The date and time arithmetic is performed as previously defined, except that an overflow or underflow of hours is carried into the date part of the result, which must be within the range of valid dates. The time arithmetic portion is similar to time arithmetic, except that it also considers the fractional seconds included in the duration. For example, subtracting a duration, *X*, from a timestamp, TIMESTAMP1, where *X* is a DECIMAL(14+s,s) number, is equivalent to the expression:

```
TIMESTAMP1 - YEAR(X)  YEARS - MONTH(X)  MONTHS - DAY(X)  DAYS
           - HOUR(X)  HOURS - MINUTE(X)  MINUTES - SECOND(X, s)  SECONDS
```

When subtracting a duration with a non-zero scale or a labeled duration of SECOND or SECONDS with a value that includes fractions of a second, the subtraction is performed as if the timestamp value has up to 12 fractional second digits. The resulting value is assigned to a timestamp value with the timestamp precision of the timestamp operand, which could result in truncation of fractional second digits.

When the result of an operation is midnight, the time portion of the result can be '24.00.00' or '00.00.00'. A comparison of those two values does not result in 'equal'. Microseconds overflow into seconds.

Precedence of operations

Expressions within parentheses are evaluated first. When the order of evaluation is not specified by parentheses, prefix operators are applied before multiplication and division, and multiplication, division, and concatenation are applied before addition and subtraction. Operators at the same precedence level are applied from left to right.

Example 1: In this example, the first operation is the addition in (SALARY + BONUS) because it is within parenthesis. The second operation is multiplication because it is a higher precedence level than the second addition operator and it is to the left of the division operator. The third operation is division because it is at a higher precedence level than the second addition operator. Finally, the remaining addition is performed.

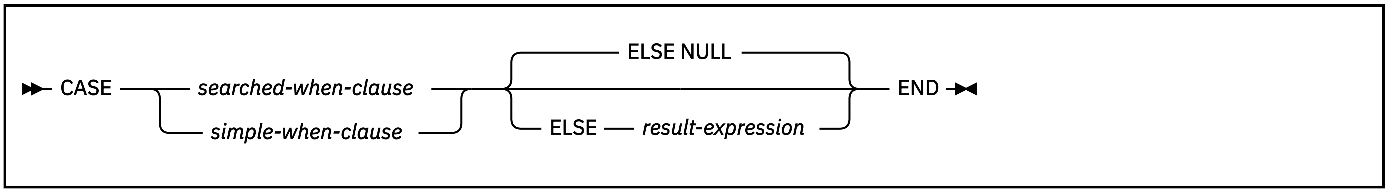
```
    1.10 * (SALARY + BONUS) + SALARY / :VAR3
        (2)       (1)      (4)      (3)
```

Example 2: In this example, the first operation (CONCAT) combines the character strings in the variables *YYYYMM* and *DD* into a string representing a date. The second operation (-) then subtracts that date from the date being processed in DATECOL. The result is a date duration that indicates the time elapsed between the two dates.

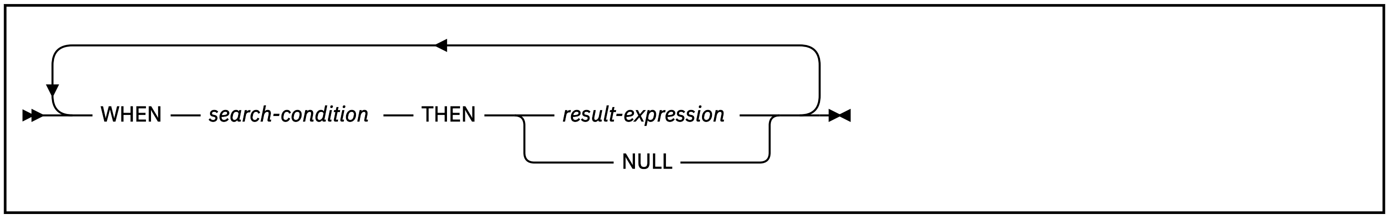
```
    DATECOL - :YYYYMM CONCAT :DD
           (2)         (1)
```

CASE expressions

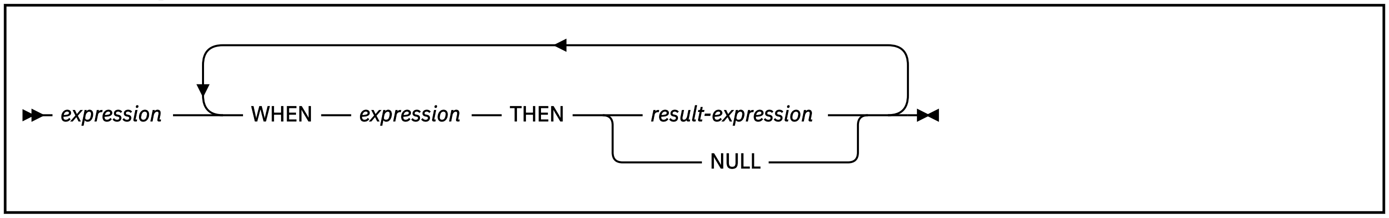
A CASE expression allows an expression to be selected based on the evaluation of one or more conditions.



searched-when-clause:



simple-when-clause:



In general, the value of the *case-expression* is the value of the *result-expression* following the first (leftmost) *when-clause* that evaluates to true. If no case evaluates to true and the ELSE keyword is present, the result is the value of the *result-expression* or NULL. If no case evaluates to true and the ELSE keyword is not present, the result is NULL. When a case evaluates to unknown (because of NULL values), the case is NOT true and hence is treated the same way as a case that evaluates to false.

searched-when-clause

Specifies a *search-condition* that is applied to each row or group of table data presented for evaluation, and the result when that condition is true.

Pair-wise comparison is performed. Implicit cast of each pair follows the same rule as for a basic predicate. The *searched-when-clause* performs implicit cast on string and numeric search conditions.

simple-when-clause

Specifies that the value of the *expression* prior to the first WHEN keyword is tested for equality with the value of each *expression* that follows the WHEN keyword. It also specifies the result for when that condition is true.

The data type of the *expression* prior to the first WHEN keyword must be compatible with the data types of the *expression* that follows each WHEN keyword. The data type of any of the expressions cannot be a CLOB, DBCLOB or BLOB. In addition, the *expression* prior to the first WHEN keyword cannot include a function that is not deterministic or has an external action.

***result-expression* or NULL**

Specifies the value that follows the THEN and ELSE keywords. It specifies the result of a *searched-when-clause* or a *simple-when-clause* that is true, or the result if no case is true. There must be at least one *result-expression* in the CASE expression with a defined data type. NULL cannot be specified for every case.

All *result-expression*s must have compatible data types. The attributes of the result are determined according to the rules that are described in "Rules for result data types" on page 166. When the result is a string, its attributes include a CCSID. For the rules on how the CCSID is determined, see Determining the encoding scheme and CCSID of a string (Introduction to Db2 for z/OS).

search-condition

Specifies a condition that is true, false, or unknown about a row or group of table data. The *search-condition* can be a predicate, including predicates that contain fullselects (scalar or non-scalar) or row-value expressions.

If *search-condition* in a *searched-when-clause* specifies a quantified predicate or an IN predicate that includes a fullselect, the CASE expression cannot be used in the following contexts:

- select lists
- a VALUES clause of an INSERT or MERGE statement
- a SET or assignment clause of an UPDATE, MERGE, or DELETE statement
- the right side of a SET or assignment statement
- the definition of a column mask or a row permission

If *search-condition* in a *searched-when-clause* specifies an EXISTS predicate, the CASE expression cannot be used in the following contexts:

- a VALUES clause of an INSERT or MERGE statement
- the right side of a SET or assignment statement
- The *diagnostic-string-expression* of a SIGNAL statement
- An ORDER BY clause or a GROUP BY clause

END

Ends a *case-expression*.

If a CASE expression is in a select list that derives the final result table, and if the *simple-when-clause* or the *searched-when-clause* references a basic predicate with a fullselect, column masks cannot be applied to the columns in the THEN clauses which derive the result of the CASE expression.

If a CASE expression is in a select list that derives the final result table, and if the *simple-when-clause* or *searched-when-clause* references a column for which column access control is activated, the column mask cannot be applied to the column and an error is returned.

If a CASE expression is in a SET clause of an UPDATE, MERGE, or DELETE statement, a VALUES clause of an INSERT or MERGE statement, or the fullselect of an INSERT from a fullselect, and if the *simple-when-clause* or the *searched-when-clause* references a column for which column access control is activated, the column access control is ignored for the column.

Two scalar functions, NULLIF and COALESCE, are specialized to handle a subset of the functionality provided by CASE. The following table shows the equivalent expressions using CASE or these functions.

Table 51. Equivalent case expressions

CASE expression	Equivalent expression
CASE WHEN e1=e2 THEN NULL ELSE e1 END	NULLIF(e1,e2)
CASE WHEN e1 IS NOT NULL THEN e1 ELSE e2 END	COALESCE(e1,e2)
CASE WHEN e1 IS NOT NULL THEN e1 ELSE COALESCE(e2,...,eN) END	COALESCE(e1,e2,...,eN)

Example 1 (simple-when-clause): Assume that in the EMPLOYEE table the first character of a department number represents the division in the organization. Use a CASE expression to list the full name of the division to which each employee belongs.

```
  SELECT EMPNO, LASTNAME,
      CASE SUBSTR(WORKDEPT,1,1)
      WHEN 'A' THEN 'Administration'
      WHEN 'B' THEN 'Human Resources'
      WHEN 'C' THEN 'Design'
      WHEN 'D' THEN 'Operations'
      END
  FROM EMPLOYEE;
```

Example 2 (searched-when-clause): You can also use a CASE expression to avoid "division by zero" errors. From the EMPLOYEE table, find all employees who earn more than 25 percent of their income from commission, but who are not fully paid on commission:

```
  SELECT EMPNO, WORKDEPT, SALARY+COMM FROM EMPLOYEE
  WHERE (CASE WHEN SALARY=0 THEN 0
              ELSE COMM/(SALARY+COMM)
              END) > 0.25;
```

Example 3 (searched-when-clause): You can use a CASE expression to avoid "division by zero" errors in another way. The following queries show an accumulation or summing operation. In the first query, Db2 performs the division before performing the CASE statement and an error occurs along with the results.

```
  SELECT REF_ID,PAYMT_PAST_DUE_CT,
      CASE
      WHEN PAYMT_PAST_DUE_CT=0 THEN 0
      WHEN PAYMT_PAST_DUE_CT>0 THEN
           SUM(BAL_AMT/PAYMT_PAST_DUE_CT)
          END
  FROM PAY_TABLE
 GROUP BY REF_ID,PAYMT_PAST_DUE_CT;
```

However, if the CASE expression is included in the SUM aggregate function, the CASE expression would prevent the errors. In the following query, the CASE expression screens out the unwanted division because the CASE operation is performed before the division.

```
  SELECT REF_ID,PAYMT_PAST_DUE_CT,
      SUM(CASE
      WHEN PAYMT_PAST_DUE_CT=0 THEN 0
      WHEN PAYMT_PAST_DUE_CT>0 THEN
        BAL_AMT/PAYMT_PAST_DUE_CT
          END)
  FROM PAY_TABLE
 GROUP BY REF_ID,PAYMT_PAST_DUE_CT;
```

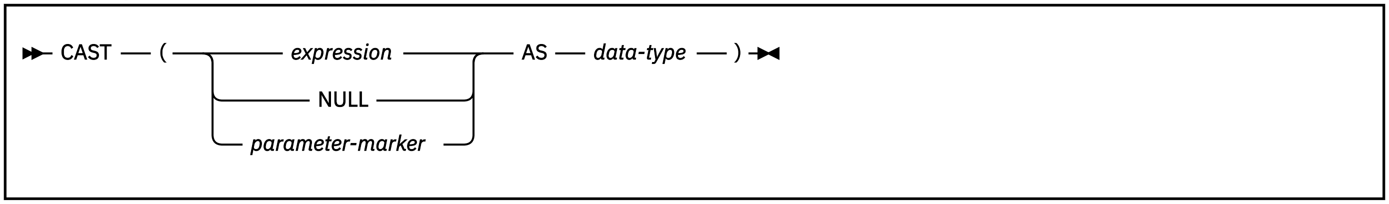
Example 4: This example shows how to group the results of a query by a CASE expression without having to re-type the expression. Using the sample employee table, find the maximum, minimum, and average salary. Instead of finding these values for each department, assume that you want to combine some departments into the same group.

```
SELECT CASE_DEPT,MAX(SALARY),MIN(SALARY),AVG(SALARY)
FROM (SELECT SALARY,CASE WHEN WORKDEPT = 'A00' OR WORKDEPT = 'E21'
                           THEN 'A00_E21'
                         WHEN WORKDEPT = 'D11' OR WORKDEPT = 'E11'
                           THEN 'D11_E11'
                         ELSE WORKDEPT
                     END AS CASE_DEPT
      FROM DSN8C10.EMP) X
      GROUP BY CASE_DEPT;
```

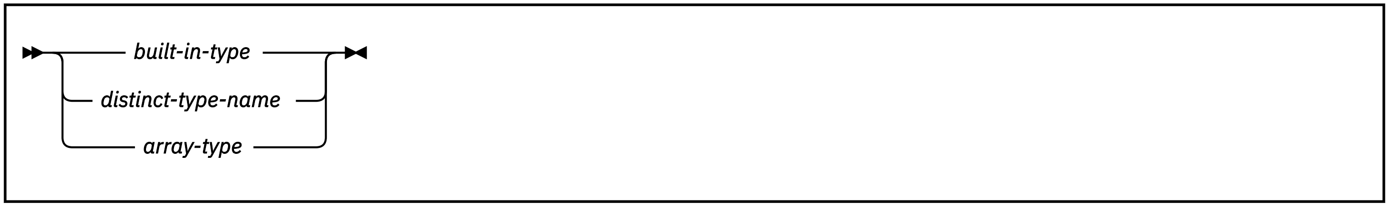
CAST specification

The CAST specification returns the first operand (the cast operand) converted to the data type that is specified by *data-type*.

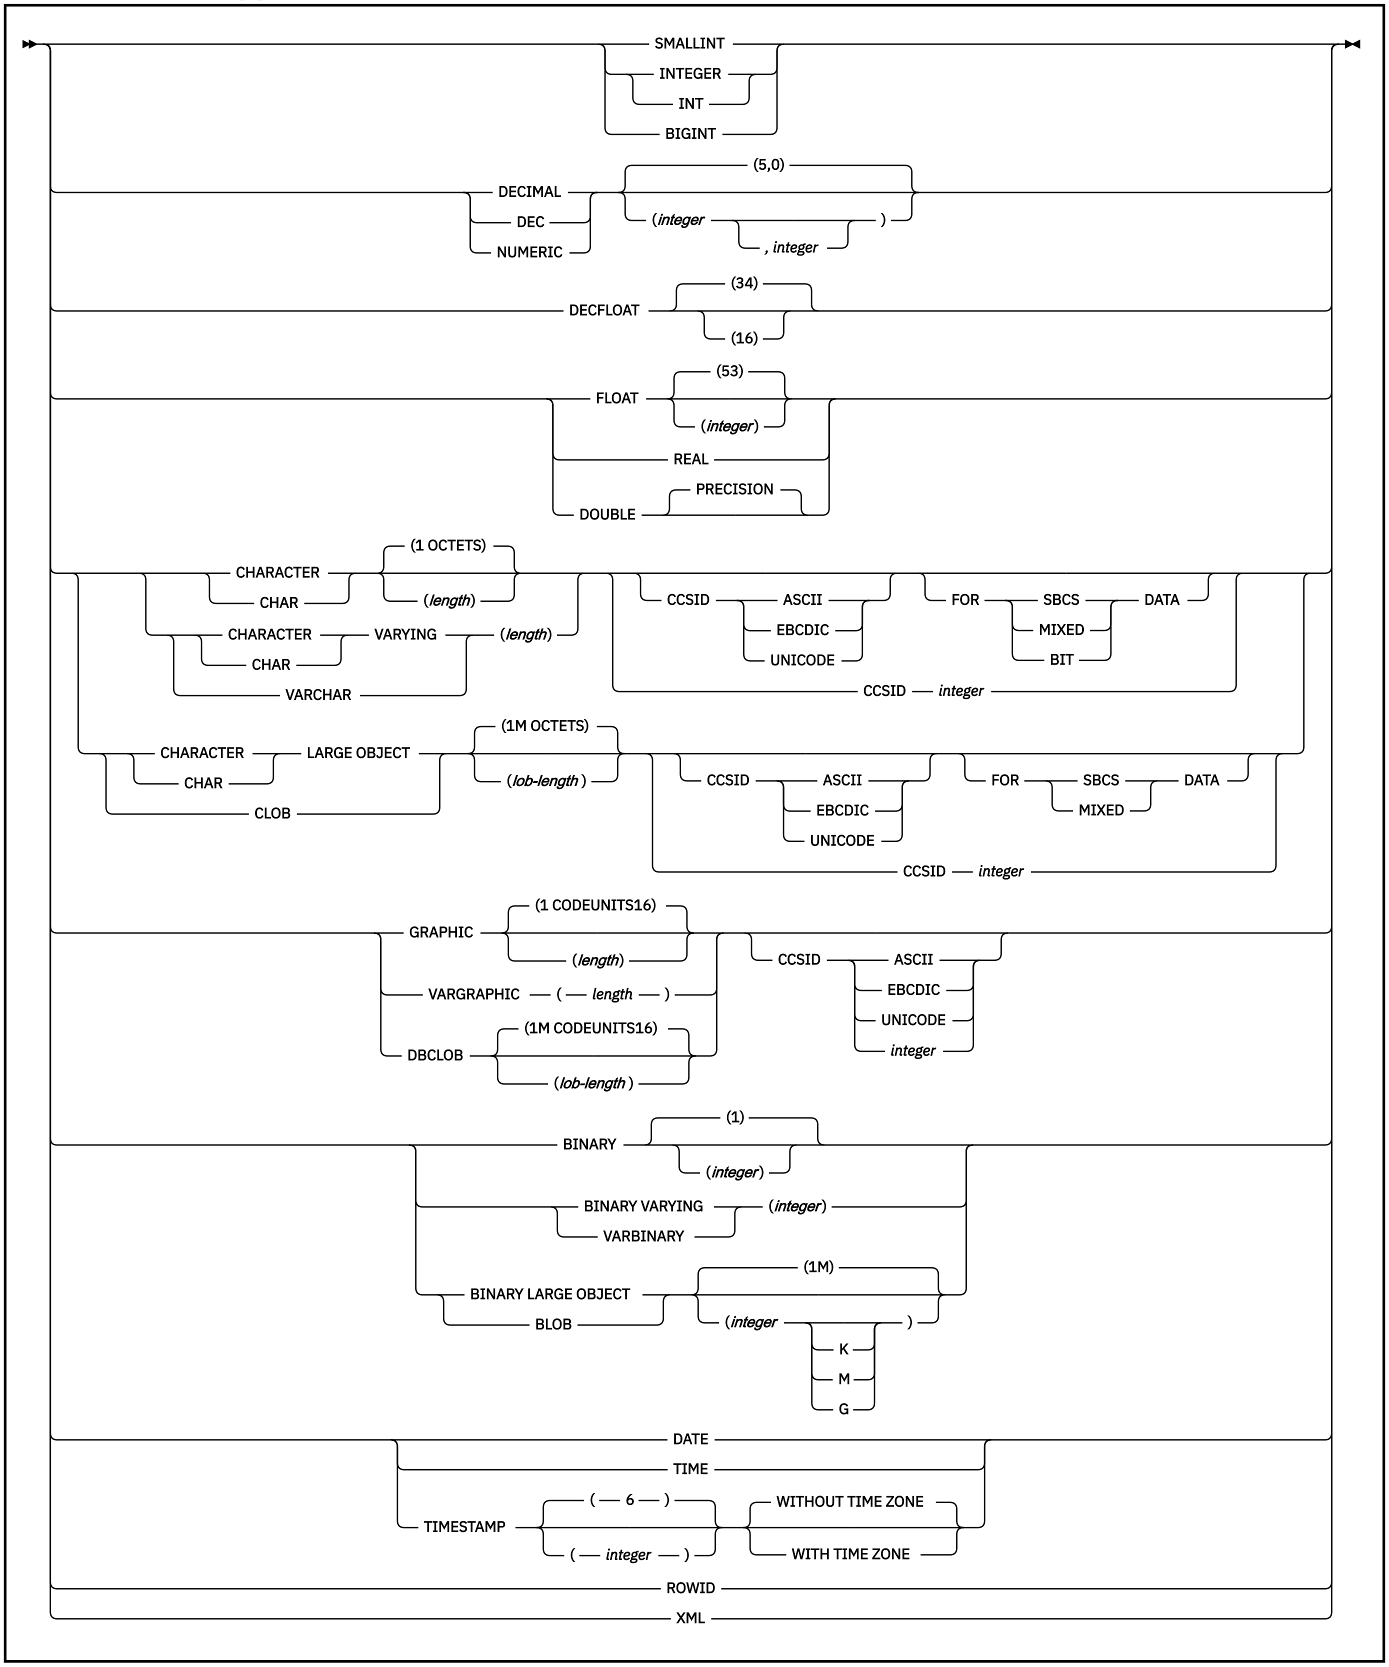
Syntax for CAST specification



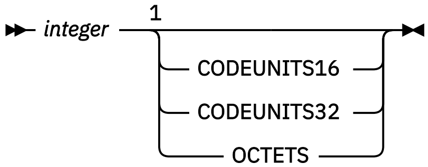
data-type:



built-in-type:



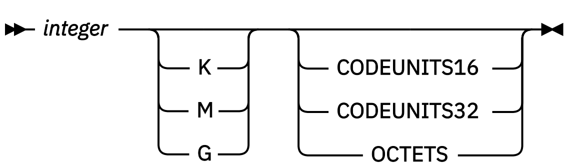
length:



Notes:

[1] FL 502 OCTETS and CODEUNITS32 must not be specified with GRAPHIC and VARGRAPHIC when the first argument is numeric data.

lob-length:



Description for CAST specification

If the data type of either operand is a distinct type, the privilege set must implicitly include EXECUTE authority on the generated cast functions for the distinct type. The CAST specification allows the second operand to be cast to a particular encoding scheme or CCSID if the second operand represents character data. The CCSID clause can be specified following CHAR, VARCHAR, CLOB, GRAPHIC, VARGRAPHIC, and DBCLOB data types.

expression

Specifies that the cast operand is an expression other than NULL or a parameter marker. The result is the value of the operand value converted to the specified target *data type*.

The supported casts are shown in "Casting between data types" on page 130. If the cast is not supported, an error is returned.

When any data type is cast to a character for graphic data type, a warning if any non-blank characters are truncated. The warning also occurs if any characters are truncated when a BLOB operand is cast, or if the time zone characters are truncated when a TIMESTAMP WITH TIME ZONE operand is cast to a string.

NULL

Specifies that the cast operand is null. The result is a null value with the specified target *data type*.

parameter-marker

A parameter marker, which is normally considered an expression, has a special meaning as a cast operand. When the cast operand is a *parameter-marker*, the *data type* that is specified represents the "promise" that the replacement value for the parameter marker will be assignable to the specified data type (using "store assignment" rules). Such a parameter marker is considered a *typed parameter marker*. Typed parameter markers are treated like any other typed value for the purpose of function resolution, a DESCRIBE of a select list, or column assignment.

data-type

Specifies the data type of the result. If the data type is not qualified, the SQL path is used to find the appropriate data type. For more information, see "SQL path" on page 85.

SMALLINT

For a small integer.

INTEGER or INT

For a large integer.

BIGINT

For a big integer.

DECIMAL(*integer,integer*) or DEC(*integer,integer*)
DECIMAL(*integer*) or DEC(*integer*)
DECIMAL or DEC

For a decimal number. The first integer is the precision of the number. That is, the total number of digits 1–31. The second integer is the scale of the number. That is, the number of digits to the right of the decimal point, which can range from 0 to the precision of the number.

You can use DECIMAL(*p*) for DECIMAL(*p*,0) and DECIMAL for DECIMAL(5,0).

You can also use the word NUMERIC instead of DECIMAL. For example, NUMERIC(8) is equivalent to DECIMAL(8). Unlike DECIMAL, NUMERIC has no allowable abbreviation.

DECFLOAT(*integer*)

For a decimal floating-point number. The value of *integer* must be either 16 or 34 and represents the number of significant digits that can be stored. If *integer* is omitted, the DECFLOAT value can represent 34 significant digits.

FLOAT(*integer*)
FLOAT

For a floating-point number. If *integer* is in the range 1– 21 inclusive, the format is single precision floating-point. If the integer is in the range 22–53 inclusive, the format is double precision floating-point.

You can use DOUBLE PRECISION or FLOAT for FLOAT(53).

For portability across operating systems, when specifying a floating-point data type, use REAL or DOUBLE instead of FLOAT.

REAL

For single precision floating-point.

DOUBLE or DOUBLE PRECISION

For double precision floating-point

CHARACTER(*integer*) or CHAR(*integer*)
CHARACTER or CHAR

For a fixed-length character string of length *integer*, which can range 1–255. If the length specification is omitted, a length of 1 character is assumed.

You can specify that the length of the result be evaluated in a specific number of string units: CODEUNITS16, CODEUNITS32, or OCTETS. If *expression* is a character string that is defined as bit data, CODEUNITS16, or CODEUNITS32 cannot be specified. For more information, see "String unit specifications" on page 106.

VARCHAR(*integer*), CHAR VARYING(*integer*), or CHARACTER VARYING(*integer*)

For a varying-length character string of maximum length *integer* in the range 1–32764.

You can specify that the length of the result be evaluated in a specific number of string units: CODEUNITS16, CODEUNITS32, or OCTETS. If *expression* is a character string that is defined as bit data, CODEUNITS16, or CODEUNITS32 cannot be specified. For more information, see "String unit specifications" on page 106.

CLOB(*integer* [K|M|G]), CHAR LARGE OBJECT(*integer* [K|M|G]), or CHARACTER LARGE OBJECT(*integer* [K|M|G])
CLOB, CHAR LARGE OBJECT, or CHARACTER LARGE OBJECT

For a character large object (CLOB) string of the specified maximum length in bytes. The maximum length must be in the range 1–2147483647.

When *integer* is not specified, the default length is `1 M`. The maximum value that can be specified for *integer* depends on whether a units indicator is also specified as shown in the following list.

integer
: The maximum value for *integer* is 2147483647. The maximum length of the string is *integer*.

***integer* K**
: The maximum value for *integer* is 2097152. The maximum length is 1024 times *integer*.

***integer* M**
: The maximum value for *integer* is 2048. The maximum length is 1,048,576 times *integer*.

***integer* G**
: The maximum value for *integer* is 2. The maximum length is 1,073,741,824 times *integer*.

integer can be separated from K, M, or G by 0 or more spaces.

If you specify a value that evaluates to 2 gigabytes (2,147,483,648), Db2 uses a value that is one byte less, or 2147483647.

You can specify that the length of the result be evaluated in a specific number of string units: CODEUNITS16, CODEUNITS32, or OCTETS. For more information, see "String unit specifications" on page 106.

GRAPHIC(*length*)
GRAPHIC

For a fixed-length graphic string of length *integer*, which can range 1–127. If the length specification is omitted, a length of 1 character is assumed.

You can specify that the length of the result be evaluated in a specific number of string units: CODEUNITS16 or CODEUNITS32. For more information, see "String unit specifications" on page 106.

VARGRAPHIC(*integer*)

For a varying-length graphic string of maximum length *integer* in the range 1–32764.

You can specify that the length of the result be evaluated in a specific number of string units: CODEUNITS16 or CODEUNITS32. For more information, see "String unit specifications" on page 106.

DBCLOB(*integer* [K|M|G])
DBCLOB

For a double-byte character large object (DBCLOB) string of the specified maximum length in double-byte characters. The maximum length must be in the range 1–1,073,741,823.

When *integer* is not specified, the default length is `1M`. The meaning of *integer* K|M|G is similar to CLOB. The difference is that the number specified is the number of double-byte characters.

integer can be separated from K, M, or G by 0 or more spaces.

You can specify that the length of the result be evaluated in a specific number of string units: CODEUNITS16, CODEUNITS32, or OCTETS. For more information, see "String unit specifications" on page 106.

BINARY(*integer*)
: A fixed-length binary string of length *integer*. The *integer* can range 1–255. If the length specification is omitted, a length of 1 byte is assumed.

BINARY VARYING(*integer*) or VARBINARY(*integer*)
: A varying-length binary string of maximum length *integer* in the range 1–32764.

BLOB (*integer* [K|M|G] or BINARY LARGE OBJECT(*integer* [K|M|G])
BLOB or BINARY LARGE OBJECT
: For a binary large object (BLOB) string of the specified maximum length in bytes. The maximum length must be in the range 1–2147483647.

When *integer* is not specified, the default length is 1M. The meaning of *integer* K|M|G is the same as for CLOB.

integer can be separated from K, M, or G by 0 or more spaces.

DATE
For a date.

TIME
For a time.

TIMESTAMP(*integer*) WITHOUT TIME ZONE
For a timestamp. *integer* specifies the optional timestamp precision attribute and must be in the range 0–12. The timestamp precision denotes the number of fractional second digits that are included in the timestamp. The default is 6.

TIMESTAMP(*integer*) WITH TIME ZONE
For a timestamp with time zone. *integer* specifies the optional timestamp precision attribute and must be in the range 0–12. The timestamp precision denotes the number of fractional second digits that are included in the timestamp. The default is 6.

- If the cast operand is *expression*, see "Casting between data types" on page 130 and use any of the target data types that are supported for the data type of the cast operand.
- If the cast operand is NULL, you can use any data type.
- If the cast operand is a *parameter-marker*:
  - If the target data type is a distinct type, the application that uses the parameter marker uses the base data type of the distinct type.
  - If the target data type is an array type:
    - The elements in the source array value must be castable to the data type of the elements of the target array type. The index values for the source array value must be castable to the data type of the index of the target array type.
    - If the target array type is an ordinary array, the cardinality of the source array value must be less than or equal to the maximum cardinality of the target array type.
  - Otherwise, any data type if valid.

CCSID *encoding-scheme*
Specifies the encoding scheme for the target data type. The specific CCSIDs for SBCS, BIT, and MIXED data are determined by the default CCSIDs for the server for the specified encoding scheme. The valid values are ASCII, EBCDIC, and UNICODE.

FOR *subtype* DATA
Specifies a subtype for a character string value, which has a data type of CHAR, VARCHAR, or CLOB. Do not use the FOR *subtype* DATA clause with values of any other data type (including any distinct type). *subtype* is one of the following keywords:

SBCS
The value contains single-byte data.

MIXED
The value contains mixed data. Do not specify MIXED if the value of MIXED DECP value is NO.

BIT
Column holds BIT data. Do not specify BIT for a CLOB value. Only character strings are valid when subtype is BIT.

CCSID *integer*
Specifies that the target data type be encoded using the CCSID *integer*. The value must be one of the CCSID values in DECP. If the second operand is CHAR, VARCHAR, or CLOB, the CCSID specified must be either a SBCS, or MIXED CCSID, or 65535 for bit data. If the second operand is GRAPHIC, VARGRAPHIC, or DBCLOB, the CCSID specified must be a DBCS CCSID. See Determining the CCSID of the result if neither CCSID *integer* nor CCSID *encoding-scheme* is specified. See Determining the CCSID of the result for special considerations regarding CCSID 367.

Notes for CAST specification

Interaction between length and CCSID clauses

If both the *length* and CCSID clauses are specified, the data is first cast to the specified CCSID, and then the *length* is applied. If either CODEUNITS16 or CODEUNITS32 is specified, the specification of length applies to the units specified. That is, the data is converted to an intermediate form (in Unicode), the length is applied, and the data is converted to the specified CCSID.

Resolution of cast functions

Db2 uses the implicit or explicit schema name and the data type name of *data-type*, and function resolution to determine the specific function to use to convert *expression* to *data-type*. See Qualified function resolution for more information.

Result of the CAST

When numeric data is cast to character data, the data type of the result is a fixed-length character string, which is similar to the result that the CHAR function would give. (For more information, see "CHAR" on page 404.) When character data is cast to numeric data, the data type of the result depends on the data type of the specified number. For example, character data that is cast to an integer becomes a large integer, which is similar to the result that the INTEGER function would give. (For more information see "INTEGER or INT" on page 482.)

If the data type of the result is character, and the FOR *subtype* DATA clause is not specified, the subtype of the result is determined by the following rules:

- If *expression* is graphic, the subtype of the result is mixed.
- If *expression* is a datetime data type, the subtype of the result is mixed. The exception is when the default encoding scheme is EBCDIC and there is no mixed or graphic data on the system for EBCDIC.
- If *expression* is a row ID and *data-type* is not CLOB, the result is bit data.
- If *expression* is character, the subtype of the result is the same as *expression*.
- Otherwise, the subtype depends on the encoding scheme of the result. If the encoding scheme of the result is not Unicode and the MIXED DECP value is NO, the subtype of the result is SBCS. Otherwise, the subtype of the result is mixed.

Casting constant values to DECFLOAT

To cast a constant value, where the value is negative zero, or a floating point constant to DECFLOAT, specify the value as a character string constant rather than a numeric constant. For example:

```
DECFLOAT('-0')              -- causes DB2 to retain the negative sign for a
                            --   value of negative zero
DECFLOAT('1.00E20')         -- causes DB2 to preserve the precision of the
                            --   floating point constant
```

Determining the CCSID and encoding scheme of the result

The CCSID of the result depends on whether the CCSID clause was specified and the context in which the CAST specification was specified.

If the CCSID clause was specified, the CCSID clause is used to determine the CCSID of the result as follows:

- If the CCSID clause was specified with EBCDIC, ASCII, or UNICODE, the clause determines the encoding scheme of the result. The CCSID of the result is the appropriate CCSID (from DECP) for that encoding scheme for the data type of the result.
- If the CCSID clause was specified with a numeric value representing bit data (65535), the CCSID of the result depends on the data type of the source. If the source data is not string data, the CCSID of the result is the appropriate CCSID for the application encoding scheme. See Note 1 in Determining the encoding scheme and CCSID of a string (Introduction to Db2 for z/OS). If the source is string data, the encoding scheme of the result is the same as the encoding scheme of expression, but the result is considered bit data.

- If the CCSID clause was specified with a numeric value, that number is the CCSID of the result. The encoding scheme of the result is determined from the numeric CCSID. In a CAST specification, CCSID 367 refers to ASCII data. For example, assume that MYDATA is string data to be cast to CHAR(10). The following CAST specification returns ASCII SBCS data:

  ```
  CAST(MYDATA AS CHAR(10) CCSID 367)
  ```

  To explicitly cast the data to Unicode SBCS, use the following syntax:

  ```
  CAST(MYDATA AS CHAR(10) CCSID UNICODE
        FOR SBCS DATA)
  ```

If the CCSID clause was not specified, the CCSID of the result is 65535 if the result is bit data. Otherwise, if the data type of the result is a character or graphic string data type, the encoding scheme and CCSID of the result are is determined as follows:

- If the *expression* and *data-type* are both character, the encoding scheme of the result is the same as *expression*. For example, assume CHAR_COL is a character column in the following sample:

  ```
  CAST(CHAR_COL AS VARCHAR(25))
  ```

  The result of the CAST is a varying length string with the same encoding scheme as the input. The CCSID of the result is the appropriate CCSID for the encoding scheme and subtype of the result.
- If the *expression* and *data-type* are both graphic, the encoding scheme and CCSID of the result is the same as *expression*.
- If the result is string and the *expression* is datetime, the result CCSID is the appropriate CCSID of the *expression* encoding scheme and the result subtype is the appropriate subtype of the CCSID.
- If the result is character, the encoding scheme and CCSID of the result depends on the context in which the CAST specification is specified:
  - If the statement follows the rules that are described for type 1 statements in Determining the encoding scheme and CCSID of a string (Introduction to Db2 for z/OS), the CCSID is determined as follows:
    - If the statement references a table or view, the encoding scheme of that table or view determines the encoding scheme for the result.
    - Otherwise, the encoding scheme is EBCDIC, the default EBCDIC CCSID is used, and the subtype depends on the MIXED DECP value.

    The CCSID of the result is the appropriate CCSID for the encoding scheme and subtype of the result.
  - Otherwise, the CCSID of the result is the appropriate CCSID for the application encoding scheme and subtype of the result.
- If the result is graphic, the encoding scheme and the CCSID of the result depends on the context in which the CAST specification is specified:
  - If the statement follows the rules that are described for type 1 statements in Determining the encoding scheme and CCSID of a string (Introduction to Db2 for z/OS), the CCSID is determined as follows:
    - If the statement references a table or view, the encoding scheme of that table or view determines the encoding scheme for the result.
    - Otherwise, the default EBCDIC encoding scheme is used for the result.

    The CCSID of the result is the appropriate CCSID for the encoding scheme and data type of the result.
  - Otherwise, the CCSID of the result is the appropriate CCSID for the application encoding scheme of the result.
- Otherwise, the CCSID of the result depends on the context in which the CAST specification was specified.

- If the statement follows the rules that are described for type 1 in statements in Determining the encoding scheme and CCSID of a string (Introduction to Db2 for z/OS), the CCSID is determined as follows:
    - If the statement references a table or view, the encoding scheme of that table or view determines the encoding scheme for the result.
    - Otherwise, the default EBCDIC encoding scheme is used for the result.

  The CCSID of the result is the appropriate CCSID for the encoding scheme and data type of the result.

Alternative syntax for casting distinct types

There is alternative syntax for casting a distinct type to its base data type and vice versa. Assume that a distinct type D_MONEY was defined with the following statement and column MONEY was defined with that data type.

```
CREATE TYPE D_MONEY AS DECIMAL(9,2);
```

DECIMAL(MONEY) is equivalent syntax to CAST(MONEY AS DECIMAL(9,2)). Both forms of the syntax use the cast function that Db2 generated when the distinct type D_MONEY was created to convert the distinct type to its source type of DECIMAL(9,2).

However, it is possible that different cast functions might be chosen for the equivalent syntax forms because of the difference in function resolution, particularly the treatment on unqualified names. Although the process of function resolution is similar for both, in the CAST specification as described above, Db2 uses the schema name of the target data type to locate the function. Therefore, if an unqualified data type name is specified as the target data type, Db2 uses the SQL path to resolve the schema name of the distinct type and then searches for the function in that schema. In function notation, when an unqualified function name is specified, Db2 searches the schemas in the SQL path to find an appropriate function match, as described under "Function resolution" on page 239. For example, assume that you defined the following distinct types, which implicitly gives you both USAGE authority on the distinct types and EXECUTE authority on the cast functions that are generated for them:

```
CREATE TYPE SCHEMA1.AGE AS DECIMAL(2,0);
   one of the generated cast functions is:
   FUNCTION SCHEMA1.AGE(SYSIBM.DECIMAL(2,0)) RETURNS SCHEMA1.AGE
CREATE TYPE SCHEMA2.AGE AS INTEGER;
   one of the generated cast functions is:
   FUNCTION SCHEMA2.AGE(SYSIBM.INTEGER) RETURNS SCHEMA2.AGE
```

If *STU_AGE*, an INTEGER host variable, is cast to the distinct type with either of the following statements and the SQL path is SYSIBM, SCHEMA1, SCHEMA2:

```
Syntax 1:  CAST(:STU_AGE AS AGE);
Syntax 2:  AGE(:STU_AGE);
```

different cast functions are chosen. For syntax 1, Db2 first resolves the schema name of distinct type AGE as SCHEMA1 (the first schema in the path that contains a distinct type named AGE for which you have EXECUTE authority for the appropriate generated cast function). Then it looks for a suitable function in that schema and chooses SCHEMA1.AGE because the data type of *STU_AGE*, which is INTEGER, is promotable to the data type of the function argument, which is DECIMAL(2,0). For syntax 2, Db2 searches all the schemas in the path for an appropriate function and chooses SCHEMA2.AGE. Db2 selects SCHEMA2.AGE over SCHEMA1.AGE because the data type of its argument (INTEGER) is an exact match for *STU_AGE* (INTEGER) and, therefore, a better match than the argument for SCHEMA1.AGE, which is DECIMAL(2,0).

Syntax alternatives for time zones

: TIMEZONE can be specified as an alternative to TIME ZONE.

Examples for CAST specification

Example 1

Assume that an application needs only the integer portion of the SALARY column, which is defined as DECIMAL(9,2) from the EMPLOYEE table. The following query for the employee number and the integer value of SALARY could be prepared.

```
SELECT EMPNO, CAST(SALARY AS INTEGER) FROM EMPLOYEE;
```

Example 2

Assume that two distinct types exist in schema SCHEMAX. Distinct type D_AGE was based on SMALLINT and is the data type for the AGE column in the PERSONNEL table. Distinct type D_YEAR was based on INTEGER and is the data type for the RETIRE_YEAR column in the same table. The following UPDATE statement could be prepared.

```
UPDATE PERSONNEL SET RETIRE_YEAR =?
                 WHERE AGE = CAST( ? AS SCHEMAX.D_AGE);
```

The first parameter is an untyped parameter marker that has a data type of RETIRE_YEAR. However, the application will use an integer for the parameter marker. The parameter marker does not need to be cast because the SET is an assignment.

The second parameter marker is a typed parameter marker that is cast to the distinct type D_AGE. Casting the parameter marker satisfies the requirement that comparisons must be performed with compatible data types. The application will use the base data type, SMALLINT, to process the parameter marker.

Example 3

A CAST specification can be used to explicitly specify the data type of a parameter in a context where a parameter marker must be typed. In the following example, the CAST specification is used to tell Db2 to assume that the value that will be provided as input to the TIME function will be CHAR(20). See "PREPARE" on page 2037 for a list of contexts when invoking functions where parameter markers can be untyped. For all other contexts when invoking a function, the CAST specification can be used to explicitly specify the type of a parameter marker.

```
INSERT INTO ADMF001.CASTSQLJ VALUES( TIME(CAST(? AS CHAR(20)) ) )
```

Example 4

Assume that an application wants to cast an EBCDIC string to Unicode UTF-8. The string contains the value 'Jürgen', which is 6 bytes in ASCII or EBCDIC and is 7 bytes in Unicode UTF-8. In the following query, the CAST specification is invoked with the *length* clause with CODEUNITS32 specified to ensure that the data is not truncated. (In this case, CODEUNITS16 could also be specified as the string unit.)

```
 SELECT CAST('Jürgen' AS VARCHAR(6 CODEUNITS32) CCSID UNICODE)
   FROM SYSIBM.SYSDUMMY1;
```

For this query, the data is converted from EBCDIC to Unicode UTF-16, the length clause is applied, and then the UTF-16 result is converted to UTF-8.

Example 5

When a keyword is used for a special value that is expressed as a constant in a context where the keyword could be interpreted as a name, the CAST specification can be used to explicitly cast the special value to decimal-floating point. Assume that MYTAB contains columns named C1 and INFINITY, and that you want to reference the decimal float-point value for infinity in the same SQL statement. Use the CAST specification to explicitly cast INFINITY as a decimal floating-point value to ensure that it is not interpreted as the name of a column, parameter or variable:

```
 SELECT INFINITY                              -- column named INFINITY
  FROM MYTAB
     WHERE C1 = CAST ('INFINITY' AS DECFLOAT) -- comparison is made with the
```

```
                                                  -- decimal floating-point
                                                  --  infinity value
```

Related concepts

Data types
Db2 supports both IBM-supplied data types (built-in data types) and user-defined data types (distinct types).

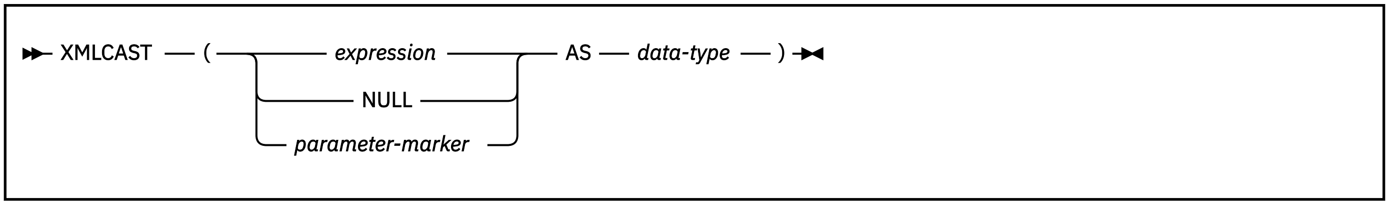
Casting between data types
There are many occasions when a value with a given data type needs to be *cast* (changed) to a different data type or to the same data type with a different length, precision, or scale.

Related reference

MIXED DATA field (MIXED DECP value) (Db2 Installation and Migration)

XMLCAST specification

The XMLCAST specification returns the first operand (the cast operand) converted to the type specified by *data-type*.



XMLCAST supports casts involving XML values, including conversions between non-XML data types and the XML data type. Either the type of the cast operand or the specified data type must be XML. If both the type of the cast operand and the target data type are XML, XMLCAST acts as a no-op.

expression
If the cast operand is an expression, the result is the argument value converted to the specified target data type. The expression or the target data type must be the XML data type. *expression* cannot be a host variable or parameter marker.

NULL
If the cast operand is the NULL keyword, the target data type must be the XML data type. The result is a null XML value.

parameter-marker
If the cast operand is a parameter marker, the target data type must be the XML data type.
A parameter marker (specified as a question mark character) is normally considered to be an expression, but in this case because it has special meaning. When the cast operand is a *parameter-marker*, the data type that is specified represents the "promise" that the replacement value for the parameter marker will be assignable to the specified data type (using assignment rules). Such a parameter marker is considered to be a typed parameter marker, which is treated like any other typed value for the purpose of function resolution, a describe operation on a select list, or column assignment.

data-type
The name of an SQL data type. If the name is not qualified, the SQL path is used to perform data type resolution. *data-type* must not specify a distinct type. If a data type has associated attributes, such as length or precision and scale, these attributes should be included when specifying a value for *data-type*. CHAR defaults to a length of 1, and DECIMAL defaults to a precision of 5 and a scale of 0 if not specified. CLOB and DBCLOB default to a length of 1M. When the target data type is XML and the source data type is TIMESTAMP, trailing zeroes in the fractional seconds part of the value are not included in the result. Restrictions on the supported data types are based on the specified cast operand. The default encoding scheme for string data types is Unicode. The encoding scheme can be changed by specifying the CCSID clause.

Table 52. Supported conversions from Non-XML values to XML values

Source data type	Target data type: XML	Resulting XML schema type
DATE	Y	xs:date
TIME	Y	xs:time
TIMESTAMP(*p*) WITH TIME ZONE	Y	xs:dateTime

Examples

Example 1: Create a null XML value.

```
XMLCAST(NULL AS XML)
```

Example 2: Convert a value extracted from an XMLQUERY expression into an INTEGER:

```
XMLCAST(XMLQUERY('/PRODUCT/QUANTITY'
  PASSING xmlcol) AS INTEGER)
```

Example 3: Convert a value extracted from an XMLQUERY expression into a varying-length character string:

```
XMLCAST(XMLQUERY('/PRODUCT/NAME'
  PASSING xmlcol) AS VARCHAR(20))
```

Note that in the above two examples, if the XMLQUERY returns a sequence of more than one node, the XMLCAST specification will return an error.

Example 4: Convert a value extracted from an SQL scalar subquery into an XML value:

```
XMLCAST((SELECT quantity FROM product AS p
  WHERE p.id = 1077) AS XML)
```

Array element specification

The array element specification returns the element from an array specified by *array-index*.

```
►►─ array-expression ── [array-index ]─►◄
```

array-expression
Specifies an SQL variable, SQL parameter, or global variable of an array type, or a CAST specification of a parameter marker to an array type.

[*array-index*]
An expression that specifies the array index of the element that is to be extracted from the array. An array index value for an ordinary array must be castable to INTEGER. The array index value must be between 1 and the cardinality of the array. An array index value for an associative array must be castable to the data type of the index for the array type. The array index value must represent an element that exists in the array. If the index value is a string that is longer than the index data type, the value is truncated, a warning is issued, and processing continues with the truncated value.

array-index must not be:

- An expression that references the CURRENT DATE, CURRENT TIME, or CURRENT TIMESTAMP special register
- A nondeterministic function
- A function that is defined with EXTERNAL ACTION
- A function that is defined with MODIFIES SQL DATA

- A sequence expression

In EBCDIC code pages, X'BBBB' is normally treated as a concatenation operator. Because this sequence of characters is a pair of right brackets characters (']]') in some EBCDIC code pages, it is not treated as a concatenation operator when used inside of an array-index expression.

The data type of the result is the data type that is specified for the array on the CREATE TYPE (array) statement. If *array-index* is null, or the array is null, the null value is returned.

If the array element is character or graphic data, the CCSID of the result is the CCSID of the array elements of the array type. If the array element is datetime data, the CCSID of the result is 1208.

Examples

Example 1: Suppose that PHONE_NUMBERS is an array variable that is defined as an array type. The array type is defined as an ordinary array of CHAR(10) elements. Also suppose that INT_VAR is an integer variable. The following assignment statements demonstrate how an index for an array element can be specified.

Set the first element of an array to NULL:

```
SET PHONE_NUMBERS[1] = NULL;
```

Set the third element to the value ‘4164789683’:

```
SET PHONE_NUMBERS[3] = '4164789683';
```

Set an array element to '4164788888’, and specify the array index with the variable INT_VAR:

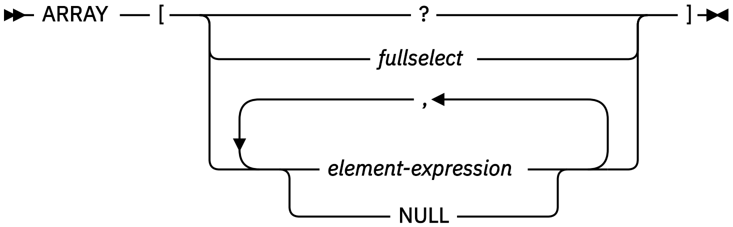
```
SET PHONE_NUMBERS[INT_VAR] = '4164788888';
```

Set an array element to ‘4164783322’, and specify the array index with the expression INT_VAR+5:

```
SET PHONE_NUMBERS[INT_VAR + 5] = ‘4164783322’;
```

Array constructor

An array constructor returns an ordinary array. An array constructor is specified by a list of expressions or a fullselect.



Authorization

No specific authorizations are required to reference an array constructor within an SQL statement. However, for the statement execution to be successful, all other authorization requirements for the statement must be satisfied.

fullselect
A fullselect that returns a single column. The data type of the column must be a data type that can be specified in a CREATE TYPE (array) statement as the data type of an array element. The values that are returned by the fullselect are the elements of the array. The cardinality of the array is equal to the number of rows that are returned by the fullselect. An ORDER BY clause in the fullselect can

be used to specify the order among the elements of the array. Otherwise, the order is undefined. The data type of the elements of the resulting array is the same as the data type of the result column of the fullselect.

element-expression

An expression that defines the value of an element in the array. The expression must return a value with a data type that can be specified in a CREATE TYPE (array) statement as the data type of an array element. The cardinality of the array is equal to the number of element expressions. The first element expression is assigned to the array element with array index 1. The second element expression is assigned to the array element with array index 2, and so on. All element expressions must have compatible data types. The data type of the elements of the resulting array are determined based on the rules that are described in "Rules for result data types" on page 166.

NULL

Specifies the null value.

If no value is specified within the brackets, the result is an empty array.

An array constructor cannot be specified in an inline SQL function, and can only be specified in the following specific contexts:

- As a source value for a SET *assignment-statement* statement or an SQL PL *assignment-statement* statement
- As the value that is to be returned in a RETURN statement of a user-defined scalar function

An array constructor cannot be used to construct an associative array. An associative array can be constructed only by assigning values to individual array elements.

Examples

Example 1: Suppose that the array variable RECENT_CALLS has the array type PHONENUMBERS. Assign an array of fixed numbers to RECENT_CALLS.

```
SET RECENT_CALLS = ARRAY[9055553907, 4165554213, 4085553678];
```

Example 2: Suppose that the array variable DEPT_PHONES has the array type PHONENUMBERS. Assign array phone numbers that are retrieved from the DEPARTMENT_INFO table to DEPT_PHONES.

```
SET DEPT_PHONES =
 ARRAY[SELECT DECIMAL(AREA_CODE CONCAT '555' CONCAT EXTENSION,16)
  FROM DEPARTMENT_INFO
  WHERE DEPTID = 624];
```

OLAP specifications

Online analytical processing (OLAP) specifications provide the ability to return ranking, row numbering, and aggregation information as a scalar value in the result of a query. An OLAP specification can be included in an expression, in a *select-list*, or in the ORDER BY clause of a *select-statement*. The query result to which the OLAP specifications is applied is the result table of the innermost subselect that includes the OLAP specification.

RANK, DENSE_RANK, and ROW_NUMBER are sometimes called window functions.

An OLAP specification is not valid in a `WHERE`, `VALUES`, `GROUP BY`, `HAVING`, or SET clause. An OLAP specification cannot be used as an argument of an aggregate function.

When invoking an OLAP specification, a window is specified that defines the rows over which the function is applied and in which order.

The result of a RANK, DENSE_RANK, or ROW_NUMBER specification is BIGINT. The result cannot be null.

CUME_DIST

FL 504 Returns a cumulative distribution of a row within an OLAP window, expressed as a value in the range of 0.0 - 1.0. The result is computed by dividing the number of rows preceding or equivalent to the current row in the OLAP window by the number of rows in the OLAP window.

The data type of the result is DECFLOAT(34). The result cannot be NULL.

Passthrough-only expression: This function is passthrough-only and cannot run on Db2 for z/OS without acceleration. For information about invoking this function, see Accelerating queries with passthrough-only expressions.

PERCENT_RANK

FL 504 Returns a relative percentile rank of a row within an OLAP window, expressed as a value between 0.0 - 1.0. When the number of rows in the OLAP window is greater than 1, the result is computed by dividing the RANK of the current row in the OLAP window minus 1 by the number of rows in the OLAP window minus 1. Otherwise, the result is 0.0.

Passthrough-only expression: This function is passthrough-only and cannot run on Db2 for z/OS without acceleration. For information about invoking this function, see Accelerating queries with passthrough-only expressions.

RANK or DENSE_RANK

Specifies that the ordinal rank of a row within the specified window is computed. Rows that are not distinct with respect to the ordering within the specified window are assigned the same rank. The results of the ranking can be defined with or without gaps in the numbers that result from duplicate values.

RANK

Specifies that the rank of a row is defined as 1 plus the number of rows that strictly precede the row. Thus, if two or more rows are not distinct with respect to the ordering, there will be one or more gaps in the sequential rank numbering.

DENSE_RANK

Specifies that the rank of a row is defined as 1 plus the number of preceding rows that are distinct with respect to the ordering. Therefore, there will be no gaps in the sequential rank numbering.

NTILE

FL 504 Returns the quantile rank of a row.

Passthrough-only expression: This function is passthrough-only and cannot run on Db2 for z/OS without acceleration. For information about invoking this function, see Accelerating queries with passthrough-only expressions.

num-tiles

An expression that specifies the number of quantiles. The expression must return a value that is a built-in numeric data type, CHAR, or VARCHAR data type. In a Unicode database, the expression can also be a GRAPHIC or VARGRAPHIC data type. CHAR, VARCHAR, GRAPHIC, and VARGRAPHIC are supported by using implicit casting. If the expression is not a SMALLINT, INTEGER, or BIGINT, it is cast to BIGINT before the function is evaluated. The value must be greater than 0. The expression must be a constant, a variable, or a cast of a constant or variable.

The data type of the result of NTILE is the same data type as the data type of *num-tiles* after any implicit casting. If the argument can be null, the result can be null. If the argument is null, the result is the null value.

The NTILE function computes the quantile rank of a row by dividing the ordered rows within the OLAP window into *num-tiles* quantiles and returns a value between 1 and MIN(*n*, *num-tiles*), where *n* is the number of rows within the OLAP window. If *n* is evenly divisible by *num-tiles*, the rows in the OLAP window are grouped into *num-tiles* quantiles, each containing (*n* / *num-tiles*) rows. Otherwise, each of the quantiles 1 through MOD(*n*, *num-tiles*) is assigned (*n* / *num-tiles* + 1) rows, and each of the quantiles (MOD(*n*, *num-tiles*) + 1) through *num-tiles* is assigned (*n* / *num-tiles*) rows. The result is the quantile rank which is associated with the current row.

Equivalent sort keys are not considered when rows are divided into quantiles. Rows with equivalent sort keys can be assigned to different quantiles based on the non-deterministic order of these sort keys. Therefore, NTILE is a non-deterministic function.

LAG

FL 504 Returns the expression value for the row at *offset* rows before the current row. The *offset* must be a positive integer constant. An *offset* value of 0 indicates the current row. If a window-partition-clause is specified, *offset* indicates *offset* rows before the current row and within the current partition. If *offset* is not specified, the value 1 is used. If *default-value* (which can be an expression) is specified, it will be returned if the *offset* goes beyond the scope of the current partition. Otherwise, the null value is returned. If 'IGNORE NULLS' is specified, all rows for which the expression value is the null value are not considered in the calculation. If 'IGNORE NULLS' is specified and all rows are null, default-value (or the null value if *default-value* was not specified) is returned.

Passthrough-only expression: This function is passthrough-only and cannot run on Db2 for z/OS without acceleration. For information about invoking this function, see Accelerating queries with passthrough-only expressions.

LEAD

FL 504 Returns the expression value for the row at *offset* rows after the current row. The *offset* must be a positive integer constant. An *offset* value of 0 indicates the current row. If a window-partition-clause is specified, *offset* indicates *offset* rows after the current row and within the current partition. If *offset* is not specified, the value 1 is used. If *default-value* (which can be an expression) is specified, it will be returned if the *offset* goes beyond the scope of the current partition. Otherwise, the null value is returned. If 'IGNORE NULLS' is specified, all rows for which the expression value is the null value are not considered in the calculation. If 'IGNORE NULLS' is specified and all rows are null, default-value (or the null value if *default-value* was not specified) is returned.

Passthrough-only expression: This function is passthrough-only and cannot run on Db2 for z/OS without acceleration. For information about invoking this function, see Accelerating queries with passthrough-only expressions.

ROW_NUMBER

Specifies that a sequential row number is computed for the row that is defined by the ordering, starting with 1 for the first row. If the ORDER BY clause is not specified in the window, the row numbers are assigned to the rows in an arbitrary order, as the rows are returned (not according to any ORDER BY clause in the *select-statement*).

PARTITION BY *partitioning-expression,...*

Defines the partition within which the OLAP operation is applied. A *partitioning-expression* is an expression that is used in defining the partitioning of the result table. Each column name that is referenced in a *partitioning-expression* must unambiguously reference a column of the result table of the subselect that contains the OLAP specification. A *partitioning-expression* cannot include a *scalar-fullselect* an XMLQUERY or XMLEXISTS expression or any function that is not deterministic or has an external action.

ORDER BY *sort-key-expression,...*

Defines the ordering of rows within a partition that is used to determine the value of the OLAP specification. It does not define the ordering of the result table.

sort-key-expression

Specifies an expression to use in defining the ordering of the rows within a window partition. Each column name that is referenced in a *sort-key-expression* must unambiguously reference a column of the result table of the subselect, including the OLAP specification. A *sort-key-expression* cannot include a scalar fullselect, an XMLQUERY or XMLEXISTS expression, or any function that is not deterministic or that has an external action.

ASC

Specifies that the values of *sort-key-expression* are used in ascending order.

DESC

Specifies that the values of *sort-key-expression* are used in descending order.

NULLS FIRST

Specifies that the window ordering considers null values before all non-null values in the sort order.

NULLS LAST

Specifies that the window ordering considers null values after all non-null values in the sort order.

FIRST_VALUE

FL 504 Returns the expression value for the first row in an OLAP window. If 'IGNORE NULLS' is specified, all rows for which the expression value is the null value are not considered in the calculation. If 'IGNORE NULLS' is specified and all values in the OLAP window are null, FIRST_VALUE returns the null value.

Passthrough-only expression: This function is passthrough-only and cannot run on Db2 for z/OS without acceleration. For information about invoking this function, see Accelerating queries with passthrough-only expressions.

LAST_VALUE

FL 504 Returns the expression value for the last row in an OLAP window. If 'IGNORE NULLS' is specified, all rows for which the expression value is the null value are not considered in the calculation. If 'IGNORE NULLS' is specified and all values in the OLAP window are null, LAST_VALUE returns the null value.

Passthrough-only expression: This function is passthrough-only and cannot run on Db2 for z/OS without acceleration. For information about invoking this function, see Accelerating queries with passthrough-only expressions.

NTH_VALUE

FL 504 Returns the expression value for the *nth-row* row in an OLAP window.

Passthrough-only expression: This function is passthrough-only and cannot run on Db2 for z/OS without acceleration. For information about invoking this function, see Accelerating queries with passthrough-only expressions.

expression

An expression that specifies the current row in an OLAP window. The expression must return a value that is a built-in data type.

nth-row

An expression that specifies which row of the OLAP window to return. The expression must return a value that is a built-in numeric data type, a CHAR, or a VARCHAR data type. In a Unicode database, the expression can also be a GRAPHIC or VARGRAPHIC data type. CHAR, VARCHAR, GRAPHIC, and VARGRAPHIC are supported using implicit casting. If the expression is not a SMALLINT, INTEGER, or BIGINT, it is cast to BIGINT before the function is evaluated. The value must be greater than 0. The expression must be a constant, a variable, or a cast of a constant or variable.

Db2 for z/OS does not support the FROM FIRST, FROM LAST, RESPECT NULLS, and IGNORE NULLS keywords for this function. Omitting these keywords in Db2 for Linux®, UNIX, and Windows results in the default behavior FROM FIRST RESPECT NULLS.

RATIO_TO_REPORT

FL 504 Returns the ratio of an argument to the sum of the arguments in an OLAP partition. The division is always performed using DECFLOAT(34). The result data type is DECFLOAT(34). If the argument can be null, the result can be null; if the argument is null, the result is the null value.

Passthrough-only expression: This function is passthrough-only and cannot run on Db2 for z/OS without acceleration. For information about invoking this function, see Accelerating queries with passthrough-only expressions.

window-aggregation-group-clause

The aggregation group of a given row is a set of rows that is defined in relation to the given row (in the ordering of the rows in the partition of the given row). *window-aggregation-group-clause* specifies the aggregation group. If this clause is not specified and a *window-order-clause* is also not specified, the aggregation group consists of all rows of the window partition. The aggregation group of all rows of the window partition can be explicitly specified using the RANGE or ROWS clauses.

If *window-order-clause* is specified, but *window-aggregation-group-clause* is not specified, the window aggregation group consists of all rows that precede a given row of the partition of the given row or all rows that are peers of the given row in the window ordering of the window partition that is defined by the *window-order-clause*

ROW

Specifies that the aggregation group is defined by counting rows.

RANGE

Specifies that the aggregation group is defined by an offset from a sort key.

group-start

Specifies the starting point for the aggregation group. The aggregation group end is the CURRENT ROW. Specifying *group-start* is equivalent to specifying *group-between* as BETWEEN *group-start* `AND CURRENT ROW`.

group-between
Specifies that the aggregation group start and end based on either ROWS or RANGE.

group-end
Specifies the ending point for the aggregation group. The aggregation group start is the CURRENT ROW. Specifying *group-end* is equivalent to specifying *group-between* as BETWEEN CURRENT ROW AND *group-end*.

UNBOUNDED PRECEDING
Specifies that the entire partition that precedes the current row is included in the aggregation group. This can be specified with either the ROWS or RANGE clauses. Including the entire partition that precedes the current row can also be specified with multiple *sort-key-expressions* in the *window-order-clause*.

UNBOUNDED FOLLOWING
Specifies that the entire partition that follows the current row is included in the aggregation group. This can be specified with either the ROWS or RANGE clauses. Including the entire partition that follows the current row can also be specified with multiple *sort-key-expressions* in the *window-order-clause*.

CURRENT ROW
Specifies that the aggregation group starts or ends based on the current row. IF ROWS is specified, the current row is the aggregation group boundary. If RANGE is specified, the aggregation group boundary includes the set of rows with the values specified for the *sort-key-expression* as the current row. This clause cannot be specified in *group-bound-2* if *group-bound-1* specifies *unsigned-constant* FOLLOWING.

***unsigned-constant* PRECEDING**
Specifies either the range or the number of rows that precede the current row. If ROWS is specified, *unsigned-constant* must be zero or a positive integer that indicates a number of rows. If RANGE is specified, the data type of *unsigned-constant* must be comparable to the data type of the *sort-key-expression* of the *window-order-clause*. Only one *sort-key-expression* is allowed, and the data type of *sort-key-expression* must allow subtraction. This clause cannot be specified in *group-bound-2* if *group-bound-1* is CURRENT ROW or *unsigned-constant* FOLLOWING.

***unsigned-constant* FOLLOWING**
Specifies either the range or the number of rows that follow the current row. If ROWS is specified, *unsigned-constant* must be zero or a positive integer that indicates a number of rows. If RANGE is specified, the data type of *unsigned-constant* must be comparable to the data type of the *sort-key-expression* of the *window-order-clause*. Only one *sort-key-expression* is allowed, and the data type of *sort-key-expression* must allow addition.

Notes for OLAP Specification

Using a column mask with an OLAP specification: If a column mask is used to mask the column values in the final result table and an OLAP specification is referenced in the select list that is used to derive the final result table, the column mask cannot be applied to the column that is specified in the *partitioning-expression* or the *sort-key-expression* in the OLAP specification.

Syntax alternatives and synonyms: For compatibility, the keywords DENSERANK and ROWNUMBER can be used as synonyms for DENSE_RANK and ROW_NUMBER respectively.

Examples for OLAP specification

Example 1: Display the ranking of employees that have a total salary of more than $30,000, in order by last name:

```
SELECT EMPNO, LASTNAME, FIRSTNME, SALARY+BONUS AS TOTAL_SALARY,
  RANK() OVER(ORDER BY SALARY+BONUS DESC) AS RANK_SALARY
  FROM EMP WHERE SALARY+BONUS > 30000
  ORDER BY LASTNAME;
```

If the result is to be ordered by rank, ORDER BY LASTNAME would be replaced with ORDER BY RANK_SALARY.

Example 2: Rank the departments according to their average total salary:

```
SELECT WORKDEPT, AVG(SALARY+BONUS) AS AVG_TOTAL_SALARY,
  RANK() OVER(ORDER BY AVG(SALARY+BONUS) DESC) AS RANK_AVG_SAL
  FROM EMP
  GROUP BY WORKDEPT
  ORDER BY RANK_AVG_SAL;
```

Example 3: Rank the departments according to their education level. Having multiple employees with the same rank in the department should not increase the next ranking value:

```
SELECT WORKDEPT, EMPNO, LASTNAME, FIRSTNME, EDLEVEL,
  DENSE_RANK() OVER
   (PARTITION BY WORKDEPT ORDER BY EDLEVEL DESC) AS RANK_EDLEVEL
  FROM EMP
  ORDER BY WORKDEPT, LASTNAME;
```

Example 4: Provide row numbers in the results of a query:

```
SELECT ROW_NUMBER() OVER(ORDER BY WORKDEPT, LASTNAME) AS NUMBER,
  LASTNAME, SALARY
  FROM EMP
  ORDER BY WORKDEPT, LASTNAME;
```

Example 5: List the top five wage earners:

```
SELECT EMPNO, LASTNAME, FIRSTNME, TOTAL_SALARY, RANK_SALARY
  FROM (SELECT EMPNO, LASTNAME, FIRSTNME, SALARY+BONUS AS TOTAL_SALARY,
        RANK() OVER (ORDER BY SALARY+BONUS DESC) AS RANK_SALARY
        FROM EMP) AS RANKED_EMPLOYEE
  WHERE RANK_SALARY < 6
  ORDER BY RANK_SALARY;
```

A nested table expression is used to first compute the result, including the ranking, before the rank can be used in the WHERE clause. A common table expression could also have been used.

Example 6: The following example is used to calculate the 30 day moving average for the stocks 'ABC' and 'XYX' during 2005:

```
CREATE VIEW V1 AS
    SELECT SYMBOL, TRADINGDATE,
                AVG(CLOSINGPRICE) OVER (PARTITION BY SYMBOL
                                                          ORDER BY TRADINGDATE
                                                          ROWS BETWEEN 29 PRECEDING AND CURRENT
ROW)
        FROM DAILYSTOCKDATA
        WHERE SYMBOL IN ('ABC', 'XYZ')
                  AND TRADINGDATE BETWEEN DATE('2005-01-01') - 2 MONTHS AND '2005-12-31';

SELECT SYMBOL, TRADINGDATE, MOVINGAVG30DAY
    FROM V1
  WHERE TRADINGDATE BETWEEN '2005-01-01' AND '2005-12-31'
    ORDER BY SYMBOL, TRADINGDATE;
```

Example 7: Calculate which quartile (4-quantiles) each employee's salary is in.

```
   SELECT EMPNO, SALARY, NTILE(4) OVER
         (ORDER BY SALARY) AS QUARTILE
      FROM EMPLOYEE
      ORDER BY SALARY
```

The result set is:

```
EMPNO  SALARY      QUARTILE
------ ----------- -----------
200340    31840.00           1
000290    35340.00           1
200330    35370.00           1
000310    35900.00           1
200310    35900.00           1
000280    36250.00           1
000270    37380.00           1
000300    37750.00           1
```

```
200240    37760.00           1
200120    39250.00           1
000320    39950.00           1
000230    42180.00           2
000340    43840.00           2
000170    44680.00           2
000330    45370.00           2
200280    46250.00           2
200010    46500.00           2
000260    47250.00           2
000240    48760.00           2
000250    49180.00           2
000120    49250.00           2
000220    49840.00           2
000190    50450.00           3
000180    51340.00           3
000150    55280.00           3
000200    57740.00           3
000160    62250.00           3
200170    64680.00           3
000110    66500.00           3
000210    68270.00           3
000140    68420.00           3
200140    68420.00           3
200220    69840.00           4
000060    72250.00           4
000130    73800.00           4
000050    80175.00           4
000100    86150.00           4
000090    89750.00           4
000020    94250.00           4
000070    96170.00           4
000030    98250.00           4
000010   152750.00           4

  42 record(s) selected.
```

Example 8: The query in the following example divides the rows into 3 buckets, grouping them by maximum salary. The maximum salary is included to show what values go into each bucket:

```
   SELECT NTILE(3) OVER (ORDER BY MAX_SALARY) AS Bucket,
MAX_SALARY FROM GOSALESDW.EMP_POSITION_DIM;
```

A portion of the output from the query is in the following table:

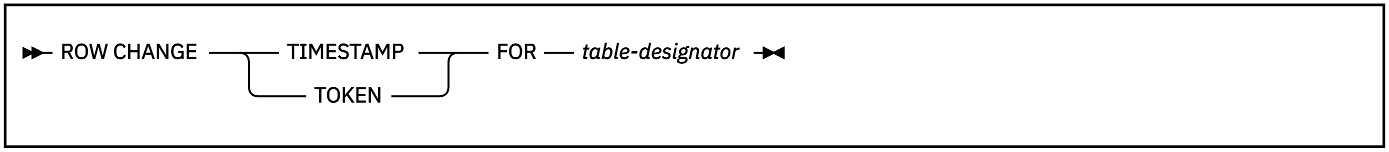
Table 53. Example output

BUCKET	MAX_SALARY
1	0.00
...	...
1	35000.00
2	5000.00
...	...
2	12000.00
3	13000.00
...	...
3	301500.00

ROW CHANGE expression

A ROW CHANGE expression returns a token or a timestamp that represents the last change to a row.

ROW CHANGE expression



TIMESTAMP

Specifies that a timestamp is returned that represents the last time when a row was changed. If the row has not been changed, the result is the time that the initial value was inserted.

TOKEN

Specifies that a token that is a BIGINT value is returned that represents a relative point in the modification sequence of a row. If the row has not been changed, the result is a token that represents when the initial value was inserted.

FOR *table-designator*

Identifies the table in which the expression is referenced. *table-designator* must be an exposed name that uniquely identifies a base table, a view, or a nested table expression of a subselect. If *table-designator* identifies a view or a nested table expression, the ROW CHANGE expression returns the TIMESTAMP or TOKEN of the base table of the view or the nested table expression. The view or nested table expression must contain only one base table in its outer subselect.

table-designator must not identify:

- An alias, a synonym, or a materialized view
- A nested table expression that is materialized
- A system-period temporal table, if the system time sensitive bind option is set to YES
- An archive-enabled table, if one of the following conditions is true:
  - For a static statement, the archive sensitive option in effect is YES.
  - For a dynamic statement, the archive sensitive option in effect is YES, and the GET_ARCHIVE built-in global variable is set to 'Y'.

The result can be null. The `ROW CHANGE TIMESTAMP` and `ROW CHANGE TOKEN` expressions are not deterministic.

Notes

Tables without a row change timestamp column:

For tables without a row change timestamp column, the ROW CHANGE TIMESTAMP expression returns a timestamp value that reflects changes made to the page instead of to the row. This timestamp value indicates that at least one row in the page has changed, but does not indicate which row, or even how many rows, have changed. The ROW CHANGE TIMESTAMP expression might indicate that a row has changed, however, the change might be for other rows in the same page.

In a data sharing environment, the returned timestamp value is based on the LRSN value of the page and reflects the most recent time the page was modified.

In a non-data sharing environment, the returned timestamp value is based on the RBA value of the page. In a non-data sharing environment, changes made to the same page within a half hour of each other might be indistinguishable. For example, issuing the following SELECT statements in a non-data sharing environment will possibly return the same value, even though the row was changed between the two SELECT statements:

```
CREATE TABLE T1 (C1 INTEGER NOT NULL);
INSERT INTO T1 VALUES (1);
SELECT ROW CHANGE TIMESTAMP FOR T1 FROM T1;
```

```
UPDATE T1 SET C1 = 2 WHERE C1 = 1;
SELECT ROW CHANGE TIMESTAMP FOR T1 FROM T1;
```

Example 1:

The following example returns all the rows that have been changed in the last day:

```
SELECT * FROM ORDERS
  WHERE ROW CHANGE TIMESTAMP FOR ORDERS >
    CURRENT TIMESTAMP - 24 HOURS;
```

Example 2:

The following example returns a timestamp value that corresponds to the most recent change to each row from the EMP table for those employees in department 20:

```
   SELECT ROW CHANGE TIMESTAMP FOR EMP
     FROM EMP WHERE DEPTNO = 20;
```

Example 3:

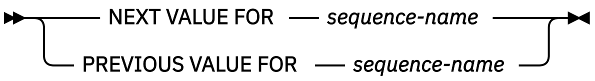
The following example returns a BIGINT value that corresponds to a relative point in the modification sequence of EMP with employee number '3500':

```
   SELECT ROW CHANGE TOKEN FOR EMP
     FROM EMP WHERE EMPNO = '3500';
```

Sequence reference

A sequence is referenced by using the NEXT VALUE and PREVIOUS VALUE expressions specifying the name of the sequence.

sequence-reference



NEXT VALUE FOR*sequence-name*

A NEXT VALUE expression generates and returns the next value for a specified sequence. A new value is generated for a sequence when a NEXT VALUE expression specifies the name of the sequence. However, if there are multiple instances of a NEXT VALUE expression specifying the same sequence name within a query, the sequence value is incremented only once for each row of the result, and all instances of NEXT VALUE return the same value for a row of the result. The NEXT VALUE expression is a not deterministic with external actions since it causes the sequence value to be incremented.

When the next value for the sequence is generated, if the maximum value for an ascending sequence or the minimum value for a descending sequence of the logical range of the sequence is exceeded and the NO CYCLE option is in effect, then an error occurs. To avoid this error, either alter the sequence attributes to extend the range of value or to enable cycles for the sequence or drop and re-create the sequence with a different data type that allows a larger range of values.

The data type and length attributes of the result of a NEXT VALUE expression are the same as for the specified sequence. The result cannot be null.

PREVIOUS VALUE FOR*sequence-name*

A PREVIOUS VALUE expression returns the most recently generated value for the specified sequence for a previous statement within the current application process. This value can be repeatedly referenced by using PREVIOUS VALUE expressions to specify the name of the sequence. There can be multiple instances of PREVIOUS VALUE expressions specifying the same sequence name within a single statement and they all return the same value.

A PREVIOUS VALUE expression can be used only if a NEXT VALUE expression specifying the same sequence name has already been referenced in the current application process.

The data type and length attributes of the result of a PREVIOUS VALUE expression are the same as for the specified sequence. The result cannot be null.

sequence-name

Identifies the sequence that is to be referenced. The combination of name and the implicit or explicit schema name must identify an existing sequence at the current server. *sequence-name* must not be the name of an internal sequence object that is generated by Db2 for an identity column. The contents of the SQL PATH are not used to determine the implicit qualifier of a sequence name.

Notes

Authorization:

If a sequence is referenced in a statement, the privileges that are held by the authorization ID of the statement must include at least one of the following:

- For the sequence identified in the statement:
  - The USAGE privilege on the sequence
  - Ownership of the sequence
- SYSADM or DATAACCESS authority

Generating values with NEXT VALUE:

When a value is generated for a sequence, that value is consumed, and the next time that a value is requested, a new value will be generated. This is true even when the statement containing the NEXT VALUE expression fails or is rolled back.

Scope of NEXT VALUE and PREVIOUS VALUE:

The value of PREVIOUS VALUE cannot be directly set and is a result of executing the NEXT VALUE expression for the sequence. The value of PREVIOUS VALUE persists until the next value is generated for the sequence in the current session, the sequence is dropped or altered, or the application session ends.

The value for the sequence cannot persist across a COMMIT or ROLLBACK for a local or remote application if, after the COMMIT or ROLLBACK, the Db2 application thread or server thread is assigned to another user or Db2 connection because of some form of thread reuse, re-signon, or connection pooling is in effect. For example, this can occur for CICS-Db2 applications and for client applications or middleware products that save the state of a session and then restore the state of a session for subsequent processing because they are not able to restore the NEXT or PREVIOUS VALUES for a sequence. In these situations, the availability of the value for a sequence should only be relied on until the end of the transaction. Examples of where this type of situation can occur include applications that do the following:

- issue an EXEC CICS SYNCPOINT command
- use XA protocols
- use connection pooling
- use the connection concentrator
- use Sysplex workload balancing
- connect to a z/OS server that uses DDF inactive threads

When there is a need to preserve the value that is associated with NEXT VALUE or PREVIOUS VALUE expressions across transaction boundaries for local or distributed applications that are subject to thread reuse, re-signon, or connection pooling, take one of the following actions to prevent the local or server thread from re-signon, being reused by a different user, or from being pooled:

- Define at least one cursor as WITH HOLD and leave it as OPEN.
- Specify the bind option KEEPDYNAMIC(YES).

Use as a unique key value:

The same sequence number can be used as a unique key value in two separate tables by referencing the sequence number with a NEXT VALUE expression for the first row (this generates the sequence value), and a PREVIOUS VALUE expression for the other rows (the instance of PREVIOUS VALUE refers to the sequence value most recently generated in the current session), as shown in the following example:

```
    INSERT INTO ORDER (ORDERNO, CUSTNO)
      VALUES (NEXT VALUE FOR ORDER_SEQ, 123456);
    INSERT INTO LINE_ITEM (ORDERNO, PARTNO, QUANTITY)
      VALUES (PREVIOUS VALUE FOR ORDER_SEQ, 987654, 1);
```

Allowed use of NEXT VALUE and PREVIOUS VALUE:

The NEXT VALUE and PREVIOUS VALUE expressions can be specified in the following places:

- Within the *select-clause* of a SELECT statement or SELECT statement that does not contain a DISTINCT keyword, a GROUP BY clause, an ORDER BY clause, or a set operator.
- Within a VALUES clause of an INSERT statement, including a multiple row INSERT statement with multiple VALUES clauses and the insert operation of a MERGE statement, which can include a NEXT VALUE expression for a particular sequence name for each VALUES clause.
- Within the *select-clause* of the fullselect of an INSERT statement.
- Within the SET clause of a searched or positioned UPDATE statement, including the update operation of the MERGE statement, though NEXT VALUE cannot be specified in the *select-clause* of the fullselect of an expression in the SET clause.

  A PREVIOUS VALUE expression can be specified anywhere with a SET clause of an update operation (the UPDATE or MERGE statement), but a NEXT VALUE expression can be specified only in a SET clause if it is not within the *select-clause* of the fullselect of an expression. For instance, the following uses of sequence references are supported:

  ```
  UPDATE T SET C1 = (SELECT PREVIOUS VALUE FOR S1 FROM T);
  UPDATE T SET C1 = PREVIOUS VALUE FOR S1;
  UPDATE T SET C1 = NEXT VALUE FOR S1;
  ```

  The following uses of sequence references are not supported:

  ```
  UPDATE T SET C1 = (SELECT NEXT VALUE FOR S1 FROM T);
  SET :C2 = (SELECT NEXT VALUE FOR S1 FROM T);
  ```

- In a SET *host-variable* or *assignment-statement*, except within the *select-clause* of the fullselect of an expression.

  The following uses of sequence references are supported:

  ```
  SET ORDERNUM = NEXT VALUE FOR INVOICE;
  SET ORDERNUM = PREVIOUS VALUE FOR INVOICE;
  ```

  The following uses of sequence references are not supported:

  ```
  SET X = (SELECT NEXT VALUE FOR S1 FROM T);
  SET X = (SELECT PREVIOUS VALUE FOR S1 FROM T);
  ```

- In a VALUES or VALUES INTO statement though not within the *select-clause* of the fullselect of an expression.
- Within the *SQL-routine-body* of a CREATE or ALTER PROCEDURE statement for a SQL procedure.
- Within the *RETURN-statement* of a CREATE FUNCTION statement for an SQL function.
- Within the *SQL-trigger-body* of a CREATE TRIGGER statement (PREVIOUS VALUE is not allowed).

Use of PREVIOUS VALUE in a nested application:

PREVIOUS VALUE is defined to have a linear scope within an application session. Therefore, in a nested application on entry to a nested function, procedure, or trigger, the nested application inherits the most recently generated value for a sequence. That is, an invocation of PREVIOUS VALUE in a nested application reflects sequence activity done in the invoking environment prior to entering the nested application. In addition, on return from a function, procedure, or trigger, the invoking application is affected by any sequence activity in the lower level applications. That is, an invocation of PREVIOUS VALUE in the invoking application after returning from the nested application reflects any sequence activity that occurred in the lower level applications.

Restrictions on the use of NEXT VALUE and PREVIOUS VALUE:

Some of the places where the NEXT VALUE and PREVIOUS VALUE expressions cannot be specified include the following:

- Join condition of a full outer join
- DEFAULT value for a column in a CREATE TABLE or ALTER TABLE statement
- Materialized query table definition in a CREATE TABLE or ALTER TABLE statement
- Condition of a CHECK constraint
- Input value specification for LOAD
- CREATE VIEW statement
- The SELECT list of a subselect that contains a NOT ATOMIC data change statement
- ORDER BY clause when used in an OLAP specification

In addition, the NEXT VALUE expression cannot be specified in the following places:

- A CASE expression
- The parameter list of an aggregate function
- A subquery in a context other than those explicitly allowed
- A SELECT statement for which the outer SELECT contains a DISTINCT operator or a GROUP BY clause
- A SELECT statement for which the outer SELECT is combined with another SELECT statement using a set operator
- A join condition of a join
- A nested table expression
- The parameter list of a table function
- A *select-clause* of the fullselect of an expression in the SET clause of an UPDATE, a DELETE, or a MERGE statement.
- A WHERE clause of the outer-most SELECT statement or a DELETE, an UPDATE, or a MERGE statement
- An ORDER BY clause of the outer-most SELECT statement
- The select list of a fullselect that contains an OFFSET clause
- An IF, WHILE, DO UNTIL, or CASE statement in an SQL routine

Using sequence expressions with a cursor:

Normally, a `SELECT NEXT VALUE FOR ORDER_SEQ FROM T1` would produce a result table containing as many generated values from the sequence ORDER_SEQ as the number of rows retrieved from T1. A reference to a NEXT VALUE expression in the SELECT statement of a cursor refers to a value that is generated for a row of the result table. A sequence value is generated for a NEXT VALUE expression each time a row is retrieved.

If blocking is done at a client in a DRDA environment, sequence values might get generated at the Db2 server before the processing of an application's FETCH statement. If the client application does not explicitly fetch all the rows that have been retrieved from the database, the application will never see all those values of the sequence that are generated but not fetched (as many values as the rows that are not fetched). These generated but not fetched values might constitute a gap in the sequence. If it is important to prevent such a gap in the sequence, do the following:

- Use NEXT VALUE only where it would function without being controlled by a cursor and where block-fetching by the client will have no effect on it.
- If you must use NEXT VALUE in the SELECT statement of a cursor-definition, weigh the importance of preventing the gap against performance and other implications of taking the following actions:

- Use FETCH FOR 1 ROW ONLY clause with the SELECT statement.
- Try preventing block-fetch by other means documented in Block fetch (Introduction to Db2 for z/OS).

Using the PREVIOUS VALUE expression with a cursor:

A reference to the PREVIOUS VALUE expression in a SELECT statement of a cursor is evaluated at OPEN time. In other words, a reference to the PREVIOUS VALUE expression in the SELECT statement of a cursor refers to the last value generated by this application process for the specified sequence prior to the opening of the cursor and, once evaluated at OPEN time, the value returned by PREVIOUS VALUE within the select statement of the cursor will not change from FETCH to FETCH, even if NEXT VALUE is invoked with the select statement of the cursor. After the cursor is closed, the value of PREVIOUS VALUE will be the last NEXT VALUE that is generated by the application process.

IF PREVIOUS VALUE is used in the SELECT statement of a cursor while the cursor is open, the value of PREVIOUS VALUE would be the last NEXT VALUE that was generated for the sequence before the cursor was opened. After the cursor is closed, the value of PREVIOUS VALUE would be the last NEXT VALUE generated by the application process.

Syntax alternatives and synonyms:

For compatibility, the keywords NEXTVAL and PREVVAL can be used as synonyms for NEXT VALUE and PREVIOUS VALUE respectively.

sequence-name.NEXTVAL can be specified in place of NEXT VALUE FOR *sequence-name*, and *sequence-name*.CURRVAL can be specified in place of PREVIOUS VALUE FOR *sequence-name*.

Example

Assume that there is a table called ORDER, and that a sequence called ORDER_SEQ is created as follows:

```
CREATE SEQUENCE ORDER_SEQ START WITH 1
                       INCREMENT BY 1
                       NO MAXVALUE
                       NO CYCLE
                       CACHE 24
```

The following examples illustrate how to generate an ORDER_SEQ sequence number with a NEXT VALUE expression:

```
INSERT INTO ORDER (ORDERNO, CUSTNO)
        VALUES (NEXT VALUE FOR ORDER_SEQ, 123456);
UPDATE ORDER SET ORDERNO = NEXT VALUE FOR ORDER_SEQ
    WHERE CUSTNO = 123456;
VALUES NEXT VALUE FOR ORDER_SEQ INTO :HV_SEQ;
```

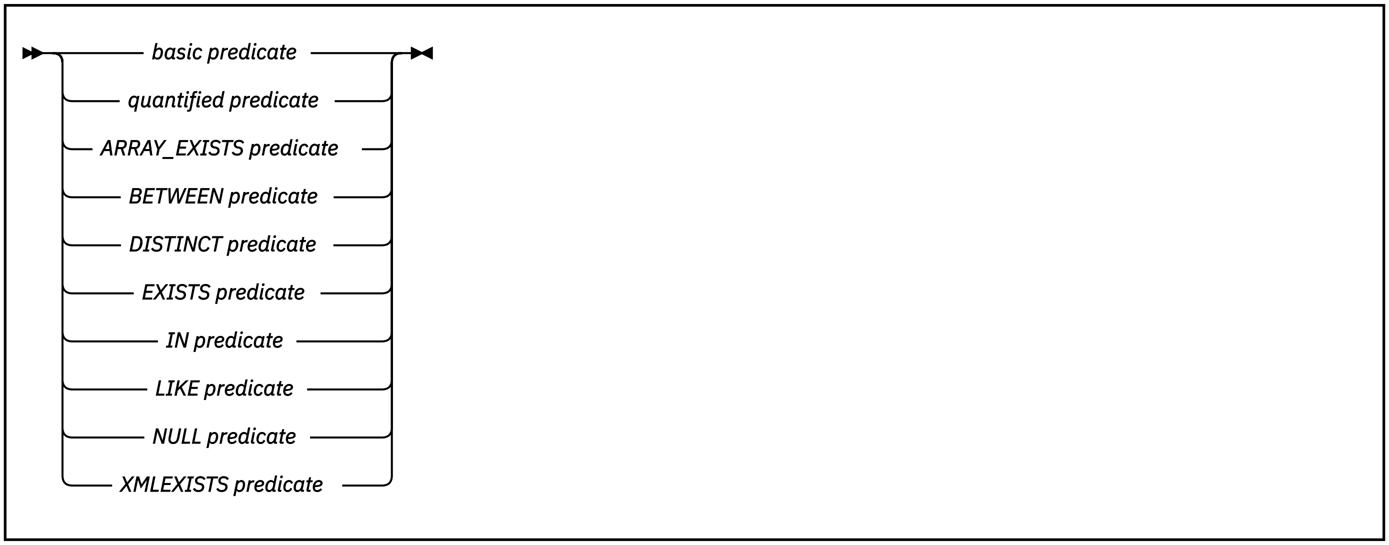
Predicates

A *predicate* specifies a condition that is true, false, or unknown about a given value, row, or group.

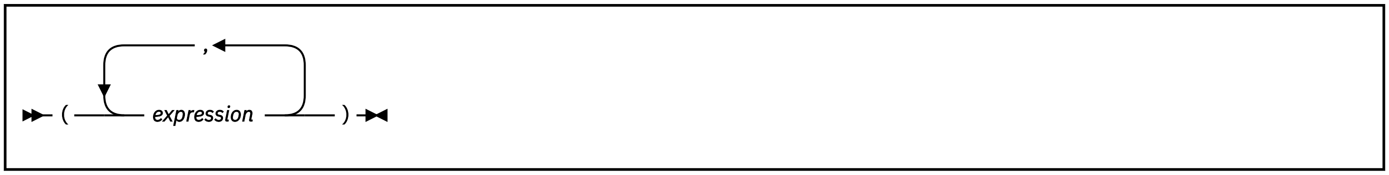
The following rules apply to predicates of any type:

- Predicates are evaluated after the expressions that are operands of the predicate.
- All values that are specified in the same predicate must be compatible.
- Except for the EXISTS predicate, a subquery in a predicate must specify a single column unless the operand on the other side of the comparison operator is a fullselect.
- The value of a host variable can be null (that is, the variable can have a negative indicator variable).
- The CCSID conversion of operands of predicates that involve two or more operands is done according to "Conversion rules for comparisons" on page 159.
- Use of an XML value is limited to the NULL or XMLEXISTS predicates.

The types of predicates are:



Row-value expression: The operand of several predicates (basic, quantified, DISTINCT, and IN) can be a *row-value-expression*:



A *row-value-expression* returns a single row that consists of one or more column values. The values can be specified as a list of expressions. The number of columns that are returned by the *row-value-expression* is equal to the number of expressions that are specified in the list.

For several examples of predicates that use distinct types , see "Assignment and comparison" on page 143. For examples of predicates that use distinct types, see "User-defined type comparisons" on page 164.

Related reference

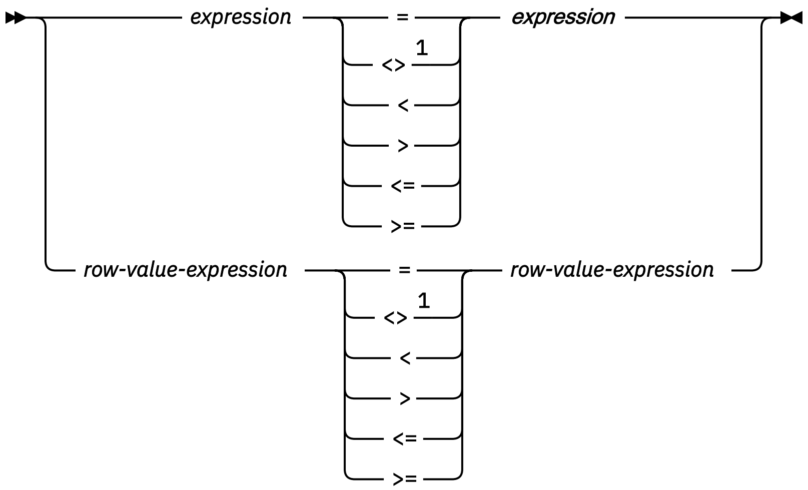
where-clause
The WHERE clause specifies a result table that consists of those rows of R for which the search condition is true. R is the result of the FROM clause of the subselect.

having-clause
The HAVING clause specifies a result table that consists of those groups of the intermediate result table for which the search-condition is true. The intermediate result table is the result of the previous clause. If this clause is not GROUP BY, the intermediate result table is considered a single group with no grouping columns of the previous clause of the subselect.

Basic predicate

A *basic predicate* compares two values or compares a set of values with another set of values.

[15] The following forms of the comparison operators are also supported in basic and quantified predicates in code pages where the exclamation point is X'5A': !=, !<, and !> . In addition, the forms ¬=, ¬<, and ¬> are supported as long as the code point used for the logical not symbol is the correct one for the specified code



Notes:

[1] Other comparison operators are also supported.[15]

When *expression* is a fullselect, the fullselect must return a single result column with a single value, whether null or not null. If the value of either operand is null or the result of the fullselect is empty, the result of the predicate is unknown. Otherwise, the result is either true or false.

When a *row-value-expression* is specified on the left side of the operator, another *row-value-expression*, with an identical number of value expressions, must be specified on the right side. The data types of the corresponding expressions or columns of the *row-value-expressions* must be compatible.

If the comparison operator is <, <=, >, or >=, a*row-value-expression* must not reference a non-deterministic expression, a function with external action, or a scalar fullselect.

The value of each expression on the left side is compared with the value of its corresponding expression on the right side. The result of the predicate depends on the operator, as in the following:

- If the operator is =, the result of the predicate is:
  - True - if all pairs of corresponding value expressions evaluate to true.
  - False - if any one pair of corresponding value expressions evaluates to false.
  - Unknown - if the comparisons is neither true nor false. That is, if at least one comparison of corresponding value expressions is unknown because of a null value and no pair of corresponding value expressions evaluates to false.
- If the operator is <>, the result of the predicate (Rx1,Rx2,...,R*xn*) <> (Ry1,Ry2,...,R*yn*) is:
  - True - if, and only if, R*xi*=R*yi* evaluates to false for some value of *i*. That is, there is at least one pair of non-null values, R*xi* and R*yi*, that are not equal to each other.
  - False - if, and only if, R*xi*=R*yi* evaluates to true for every value of *i*. That is, Rx1,Rx2,...,R*xn*)=(Ry1,Ry2,...,R*yn*) is true.
  - Unknown - if the comparison is neither true nor false. That is, R*xi* or R*yi* is a null value for some value of *i*, and there is no value of *j* such that R*xj*=R*yj* evaluates to false.
- If the operator is <, the result of the predicate is:

page. These forms of the operators are intended only to support existing SQL statements that use them and are not recommended for use when writing new SQL statements.

A logical not sign (¬) can cause parsing errors in statements passed from one DBMS to another. The problem occurs if the statement undergoes character conversion with certain combinations of source and target CCSIDs. To avoid this problem, substitute an equivalent operator for any operator that includes a not sign. For example, substitute '<>' for '¬=', '<=' for '¬>', and '>=' for '¬<'.

  - True - if, and only if, the first *N* pairs of the corresponding value expressions are equal and the next pair has the left value expression less than the right value expression for some value of *N*. That is, R*xi* = R*yi* is true for all values of *i* < *n* and R*xn* < R*yn* is true for some value of *n*.
  - False - if, and only if, all pairs of the corresponding value expressions are equal (R*x* = R*y* is true) or the first *N* pairs of the corresponding value expressions are equal and the next pair has the right value expression less than the left value expression for some value of *N*. That is, R*xi* = R*yi* is true for all values of *i* < *n* and R*xn* >= R*yn* is true for some value of *n*.
  - Unknown - if the comparison is neither true nor false.
- If the operator is <=, the result of the predicate is:
  - True - if, and only if, the first *N* pairs of the corresponding value expressions are equal and the next pair has the left value expression less than or equal to the right value expression for some value of *N*. That is, R*xi* = R*yi* is true for all values of *i* < *n* and R*xn* <= R*yn* is true for some value of *n*.
  - False - if, and only if, all pairs of the corresponding value expressions are equal (R*x* = R*y* is true) or the first *N* pairs of the corresponding value expressions are equal and the next pair has the right value expression less than the left value expression for some value of *N*. That is, R*xi* = R*yi* is true for all values of *i* < *n* and R*xn* > R*yn* is true for some value of *n*.
  - Unknown - if the comparison is neither true nor false.
- If the operator is >, the result of the predicate is:
  - True - if, and only if, the first *N* pairs of the corresponding value expressions are equal and the next pair has the left value expression greater than the right value expression for some value of *N*. That is, R*xi* = R*yi* is true for all values of *i* < *n* and R*xn* > R*yn* is true for some value of *n*.
  - False - if, and only if, all pairs of the corresponding value expressions are equal (R*x* = R*y* is true) or the first *N* pairs of the corresponding value expressions are equal and the next pair has the right value expression greater than the left value expression for some value of *N*. That is, R*xi* = R*yi* is true for all values of *i* < *n* and R*xn* <= R*yn* is true for some value of *n*.
  - Unknown - if the comparison is neither true nor false.
- If the operator is >=, the result of the predicate is:
  - True - if, and only if, the first *N* pairs of the corresponding value expressions are equal and the next pair has the left value expression greater than or equal to the right value expression for some value of *N*. That is, R*xi* = R*yi* is true for all values of *i* < *n* and R*xn* >= R*yn* is true for some value of *n*.
  - False - if, and only if, all pairs of the corresponding value expressions are equal (R*x* = R*y* is true) or the first *N* pairs of the corresponding value expressions are equal and the next pair has the right value expression greater than the left value expression for some value of *N*. That is, R*xi* = R*yi* is true for all values of *i* < *n* and R*xn* < R*yn* is true for some value of *n*.
  - Unknown - if the comparison is neither true nor false.

Table 54. For values x and y

Predicate	**Is true if and only if ...**
x = *y*	*x* is equal to *y*
x <> *y*	*x* is not equal to *y*
x < *y*	*x* is less than *y*
x > *y*	*x* is greater than *y*
x <= *y*	*x* is less than or equal to *y*
x >= *y*	*x* is greater than or equal to *y*

Examples for values x and y:

```
EMPNO = '528671'
SALARY < 20000
```

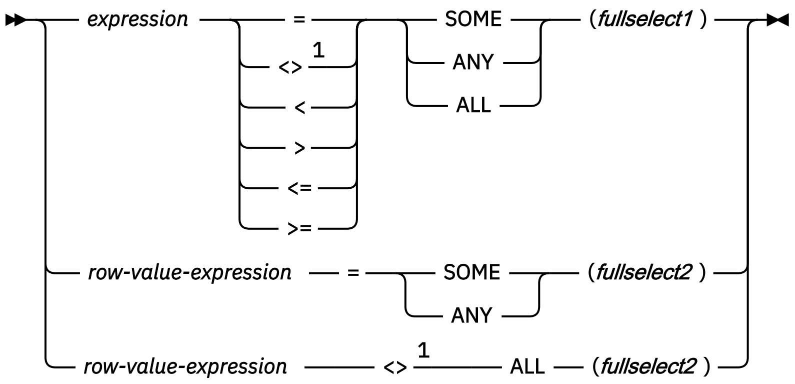
```
    PRSTAFF <> :VAR1
    SALARY >=  (SELECT AVG(SALARY) FROM DSN8C10.EMP)
```

Example: List the name, first name, and salary of the employee who is responsible for the 'SECRET' project. This employee might appear in either the PROJA1 or PROJA2 tables. A UNION is used in case the employee appears in both tables to eliminate duplicate RESPEMP values.

```
   SELECT LASTNAME, FIRSTNAME, SALARY
     FROM DSN8C10.EMP X
     WHERE EMPNO = (
   SELECT RESPEMP
     FROM PROJA1 Y
     WHERE MAJPROJ = 'SECRET'
   UNION
   SELECT RESPEMP
     FROM PROJA2 Z
     WHERE MAJPROJ = 'SECRET');
```

Quantified predicate

A *quantified predicate* compares a value or values with a collection of values.



Notes:

[1] Other comparison operators are also supported.[15]

When *expression* is specified, *fullselect1* must return a single result column, and can return any number of values, whether null or not null. The result depends on the operator that is specified:

- When the operator is ALL, the result of the predicate is:
  - True – if the result of the fullselect is empty or if the specified relationship is true for every value returned by the fullselect.
  - False – if the specified relationship is false for at least one value returned by the fullselect.
  - Unknown – if the specified relationship is not false for any values returned by the fullselect and at least one comparison is unknown because of a null value.
- When the operator is SOME or ANY, the result of the predicate is:
  - True – if the specified relationship is true for at least one value returned by the fullselect.
  - False – if the result of the fullselect is empty or if the specified relationship is false for every value returned by the fullselect.
  - Unknown – if the specified relationship is not true for any of the values returned by the fullselect and at least one comparison is unknown because of a null value.

When *row-value-expression* is specified, the number of result columns returned by *fullselect2* must be the same as the number of value expressions specified by *row-value-expression*, and *fullselect2* can return any number of rows of values. The data types of the corresponding expressions of the row value expressions must be compatible. The value of each expression from *row-value-expression* is compared with the value of the corresponding result column from *fullselect2*. The value of the predicate depends on the operator that is specified:

- When the operator is ALL, the result of the predicate is:
  - True – if the result of *fullselect2* is empty or if the specified relationship is true for every row returned by *fullselect2*.
  - False – if the specified relationship is false for at least one row returned by *fullselect2*.
  - Unknown – if the specified relationship is not false for any row returned by *fullselect2* and at least one comparison is unknown because of a null value.
- When the operator is SOME or ANY, the result of the predicate is:
  - True – if the specified relationship is true for at least one row returned by *fullselect2*
  - False – if the result of the fullselect is empty or if the specified relationship is false for every row returned by *fullselect2*.
  - Unknown – if the specified relationship is not true for any of the rows returned by *fullselect2* and at least one comparison is unknown because of a null value.

Quantified predicates are equivalent to IN predicates. See Table 60 on page 306 for some examples of equivalent quantified and IN predicates.

Examples: Use the following tables when referring to the following examples. In all examples, "row *n* of TBLA" refers to the row in TBLA for which COLA has the value *n*.

Table 55. TBLA

COLA
1
2
3
4

Table 56. TBLB

COLB	**COLC**
2	2
3	– –

Table 57. TBLC

COLB	**COLC**
2	2

Example 1: In the following predicate, the fullselect returns the values 2 and 3. The predicate is false for rows 1, 2, and 3 of TBLA, and is true for row 4.

```
COLA > ALL(SELECT COLB FROM TBLB
       UNION
       SELECT COLB FROM TBLC)
```

Example 2: In the following predicate, the fullselect returns the values 2 and 3. The predicate is false for rows 1 and 2 of TBLA, and is true for rows 3 and 4.

```
COLA > ANY(SELECT COLB FROM TBLB
       UNION
       SELECT COLB FROM TBLC)
```

Example 3: In the following predicate, the fullselect returns the values 2 and null. The predicate is false for rows 1 and 2 of TBLA, and is unknown for rows 3 and 4. The result is an empty table.

```
COLA > ALL(SELECT COLC FROM TBLB
       UNION
       SELECT COLC FROM TBLC)
```

Example 4: In the following predicate, the fullselect returns the values 2 and null. The predicate is unknown for rows 1 and 2 of TBLA, and is true for rows 3 and 4.

```
COLA > SOME(SELECT COLC FROM TBLB
       UNION
       SELECT COLC FROM TBLC)
```

Example 5: In the following predicate, the fullselect returns an empty result column. Hence, the predicate is true for all rows of TBLA.

```
COLA < ALL(SELECT COLB FROM TBLB WHERE COLB>3
       UNION
       SELECT COLB FROM TBLC WHERE COLB>3)
```

Example 6: In the following predicate, the fullselect returns an empty result column. Hence, the predicate is false for all rows of TBLA.

```
COLA < ANY(SELECT COLB FROM TBLB WHERE COLB>3
       UNION
       SELECT COLB FROM TBLC WHERE COLB>3)
```

If COLA were null in one or more rows of TBLA, the predicate would still be false for all rows of TBLA.

ARRAY_EXISTS predicate

The ARRAY_EXISTS predicate tests for the existence of an array element with the specified index in an array.

```
►►─ ARRAY_EXISTS (array-expression ,array-index ) ─►◄
```

array-expression

Specifies one of the following items:

- An SQL variable, SQL parameter, or global variable of an array type
- A CAST specification of an array or parameter marker to an array type.

array-index

Specifies the index for the array element that is to be tested. An array index value for an ordinary array must be castable to INTEGER. An array index value for an associative array must be castable to the data type of the array index.

array-index must *not* be an expression that references any of the following items:

- The CURRENT DATE, CURRENT TIME, or CURRENT TIMESTAMP special register
- A nondeterministic function
- A function that is defined with EXTERNAL ACTION
- A function that is defined with MODIFIES SQL DATA
- A sequence expression

The result of the ARRAY_EXISTS predicate is:

- True if *array-expression* includes an array index that is equal to the result of casting *array-index* to the data type of the array index of *array-expression*.
- False under either of the following conditions:

  - *array-expression* does not include an array index that is equal to the result of casting *array-index* to the data type of the array index of *array-expression*.
  - Either argument is null.
- Cannot be unknown.

Example: Suppose that array variable RECENT_CALLS is defined as an ordinary array of array type PHONENUMBERS. The following IF statement tests whether the recent calls list has reached the 40th saved call. If it has, the local integer variable EIGHTY_PERCENT is set to 1:

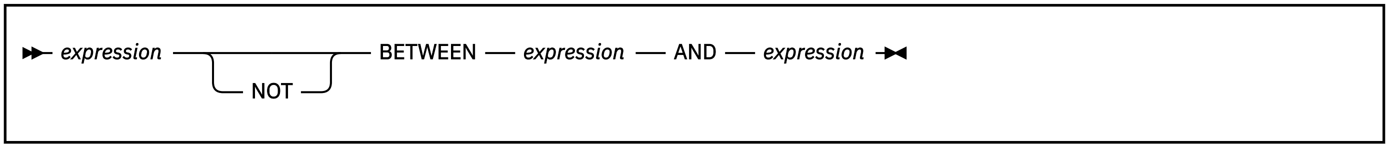
```
IF (ARRAY_EXISTS(RECENT_CALLS, 40))
 THEN SET EIGHTY_PERCENT = 1;
END IF
```

Related concepts

Array types
A user-defined *array type* is a data type that is defined as an array of elements. A user-defined array type can be either an *ordinary array* or *associative array*.

BETWEEN predicate

The BETWEEN predicate determines whether a given value lies between two other given values that are specified in ascending order.



Each of the predicate's two forms has an equivalent search condition, as shown in the following table:

Table 58. BETWEEN predicate and equivalent search conditions

BETWEEN predicate	Equivalent search condition
value1 BETWEEN *value2* AND *value3*	*value1* >= *value2* AND *value1* <= *value3*[1]
value1 NOT BETWEEN *value2* AND *value3* or, equivalently: NOT(*value1* BETWEEN *value2* AND *value3*)	*value1* < *value2* OR *value1* > *value3*[1]

Note: 1. Might not be equivalent if *value1*, *value2*, or *value3* are columns or derived values based on columns that are not the same CCSID set because the clause is evaluated in Unicode.

Search conditions are discussed in "Search conditions" on page 318.

If the operands include a mixture of datetime values and valid string representations of datetime values, all values are converted to the data type of the datetime operand.

Example: Consider the following predicate:

```
  A BETWEEN B AND C
```

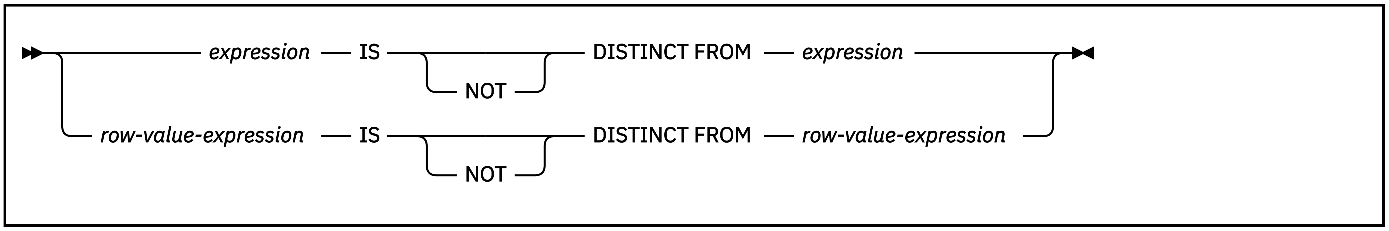
The following table shows the value of the predicate for various values of *A*, *B*, and *C*.

Value of *A*	Value of *B*	Value of *C*	Value of predicate
1,2, or 3	1	3	true
0 or 4	1	3	false

Value of *A*	Value of *B*	Value of *C*	Value of predicate
0	1	null	false
4	null	3	false
null	any value	any value	unknown
2	1	null	unknown
3	null	4	unknown

DISTINCT predicate

A distinct predicate compares a value with another value or a set of values with another set of values.



expression and *row-value-expression* cannot be array expressions.

The number of elements that are returned by the *row-value-expression* that specified after the distinct operator must match the number of elements that are returned by the *row-value-expression* that is specified prior to the distinct operator. The data types of the corresponding columns or expressions of the *row-value-expressions* must be compatible. When the predicate is evaluated, the value of each expression on the left side is compared with the value of its corresponding expression on the right side. The result of the predicate depends on the form of the predicate.

When the predicate is `IS DISTINCT`, the result of the predicate is true if at least one comparison of a pair of corresponding value expressions evaluates to false. Otherwise, the result of the predicate is false. The result cannot be unknown.

When the predicate `IS NOT DISTINCT FROM`, the result of the predicate is true if all pairs of corresponding value expressions evaluate to true (null values are considered equal to null values). Otherwise, the predicate is false. The result cannot be unknown.

The DISTINCT predicate cannot be used in the following contexts:

- The `ON` *join-condition* of a full outer join
- A check constraint
- A quantified predicate

The following DISTINCT predicates are logically equivalent to the corresponding search conditions:

Table 59. DISTINCT predicates and logically equivalent search conditions

DISTINCT predicate	Search condition

`value 1 IS NOT DISTINCT FROM value2`	`(value1 IS NOT NULL`
	` AND value2 IS NOT NULL`
	` AND value1 = value 2)`
	`OR`
	`(value1 IS NULL`
	` AND value2 IS NULL)`

`value 1 IS DISTINCT FROM value2`	`NOT (value1 IS NOT DISTINCT FROM value2)`

Example 1: Assume that T1 is a single-column table with three rows. Column C1 has the following values: 1, 2, and null. Consider the following query:

```
SELECT * FROM T1
   WHERE C1 IS DISTINCT FROM :HV;
```

The following table shows the value of the predicate for various values of C1 and the host variable.

Value of C1	Value of *HV*	Result of predicate
1	2	True
2	2	False
null	2	True
1	null	True
2	null	True
null	null	False

Example 2: Assume the same table as in the first example, but now consider the negative form of the predicate in the query:

```
SELECT * FROM T1
   WHERE C1 IS NOT DISTINCT FROM :HV;
```

The following table shows the value of the predicate for various values of C1 and the host variable.

Value of C1	Value of *HV*	Result of predicate
1	2	False
2	2	True
null	2	False
1	null	False
2	null	False
null	null	True

EXISTS predicate

The EXISTS predicate tests for the existence of certain rows. The fullselect can specify any number of columns, and can result in true or false.

►► EXISTS (*fullselect* [1]) ►◄

Notes:

[1] The outer SELECT list of *fullselect* must not contain an array value.

The result of the EXISTS predicate:

- Is true only if the number of rows that is specified by the fullselect is not zero.
- Is false only if the number of rows specified by the fullselect is zero.
- Cannot be unknown.

The SELECT clause in the fullselect can specify any number of columns because the values returned by the fullselect are ignored. For convenience, use:

```
SELECT *
```

Unlike the NULL, LIKE, and IN predicates, the EXISTS predicate has no form that contains the word NOT. To negate an EXISTS predicate, precede it with the logical operator NOT, as follows:

```
NOT EXISTS (fullselect)
```

The result is then false if the EXISTS predicate is true, and true if the predicate is false. Here, NOT is a logical operator and not a part of the predicate. Logical operators are discussed in "Search conditions" on page 318.

Example 1: The following query lists the employee number of everyone represented in DSN8C10.EMP who works in a department where at least one employee has a salary less than 20000. Like many EXISTS predicates, the one in this query involves a correlated variable.

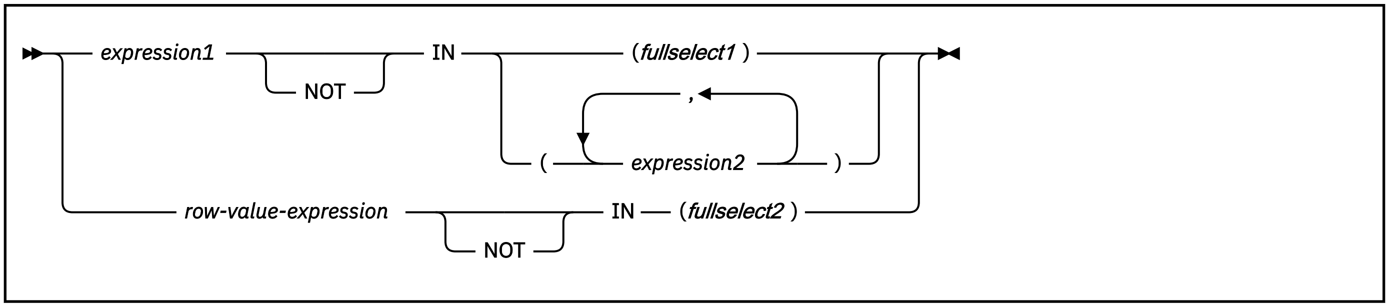
```
SELECT EMPNO
  FROM DSN8C10.EMP X
  WHERE EXISTS (SELECT * FROM DSN8C10.EMP
                WHERE X.WORKDEPT=WORKDEPT AND SALARY<20000);
```

Example 2: List the subscribers (SNO) in the state of California who made at least one call during the first quarter of 2009. Order the results according to SNO. Each MONTH*nn* table has columns for SNO, CHARGES, and DATE. The CUST table has columns for SNO and STATE.

```
SELECT C.SNO
  FROM CUST C
  WHERE C.STATE = 'CA'
  AND EXISTS (
  SELECT *
    FROM MONTH1
    WHERE DATE BETWEEN '01/01/2009 AND '01/31/2009'
    AND C.SNO = SNO
  UNION ALL
  SELECT *
    FROM MONTH2
    WHERE DATE BETWEEN '02/01/2009 AND '02/28/2009'
    AND C.SNO = SNO
  UNION ALL
  SELECT *
  FROM MONTH3
  WHERE DATE BETWEEN '03/01/2009 AND '03/31/2009'
  AND C.SNO = SNO
  )
  ORDER BY C.SNO;
```

IN predicate

The IN predicate compares a value or values with a set of values.



When *expression1* is specified, the IN predicate compares a value with a set of values. When *fullselect1* is specified, the fullselect must return a single result column, and can return any number of values, whether null or not null. The data type of *expression1* and the data type of the result column of *fullselect1* or *expression2* must be compatible. If *expression* is a single host variable, the host variable can identify a structure. Any host variable or structure that is specified must be described in the application program according to the rules for declaring host structures and variables.

When a *row-value-expression* is specified, the IN predicate compares values with a collection of values. The result table of the *fullselect2* must have the same number of columns as the *row-value-expression*. The data type of each expression in *row-value-expression* and the data type of its the corresponding result column of *fullselect2* must be compatible. The value of each expression in *row-value-expression* is compared with the value of its corresponding result column of *fullselect2*. The value of the predicate depends on the operator that is specified:

- When the operator is IN, the result of the predicate is:
  - True if at least one row returned from *fullselect2* is equal to the *row-value-expression*.
  - False if the result of *fullselect2* is empty or if no row returned from *fullselect2* is equal to the *row-value-expression*.
  - Otherwise, unknown (that is, if the comparison of *row-value-expression* to the row returned from *fullselect2* evaluates to unknown because of a null value for at least one row returned from *fullselect2* and no row returned from *fullselect2* is equal to the *row-value-expression*).
- When the operator is NOT IN, the result of the predicate is:

  True if the result of *fullselect2* is empty or if the *row-value-expression* is not equal to any of the rows returned by *fullselect2*.

  False if the *row-value-expression* is equal to at least one row returned by*fullselect2*.

  Otherwise, unknown (that is, if the comparison of *row-value-expression* to the row returned from *fullselect2* evaluates to unknown because of a null value for at least one row returned from *fullselect2* and the comparison of *row-value-expression* to the row returned from *fullselect2* is not true for any row returned by the *fullselect2*).

The IN predicate is equivalent to the quantified predicate as follows:

Table 60. IN predicate and equivalent quantified predicates

IN predicate	**Equivalent quantified predicate**
expression1 IN (*expression2*)	*expression1* = *expression2*
expression IN (*fullselect1*)	*expression* = ANY (*fullselect1*)
expression NOT IN (*fullselect1*)	*expression* <> ALL (*fullselect1*)
expression1 IN (*expressiona*, *expressionb*, ...)	*expression1* IN (SELECT * FROM R) When T is a table with a single row and R is a result table formed by the following fullselect: SELECT value1 FROM T UNION SELECT value2 FROM T UNION . . . UNION SELECT valuen FROM T
row-value-expression IN (*fullselect2*)	*row-value-expression* = SOME (*fullselect2*)
row-value-expression IN (*fullselect2*)	*row-value-expression* = ANY (*fullselect2*)
row-value-expression NOT IN (*fullselect2*)	*row-value-expression* <> ALL (*fullselect2*)

If the operands of the IN predicate have different data types or attributes, the rules that are used to determine the data type for evaluation of the IN predicate are those for UNION, EXCEPT, and INTERSECT. For a description, see "Rules for result data types" on page 166.

If the operands of the IN predicate are strings with different CCSIDs, the rules used to determine which operands are converted are those for operations that combine strings. See #unique_403.

Examples

Example 1
The following predicate is true for any row whose employee is in department D11, B01, or C01.

```
WORKDEPT IN ('D11', 'B01', 'C01')
```

Example 2
The following predicate is true for any row whose employee works in department E11.

```
EMPNO IN (SELECT EMPNO FROM DSN8C10.EMP
  WHERE WORKDEPT = 'E11')
```

Example 3
The following predicate is true if the date that a project is estimated to start (PRENDATE) is within the next two years.

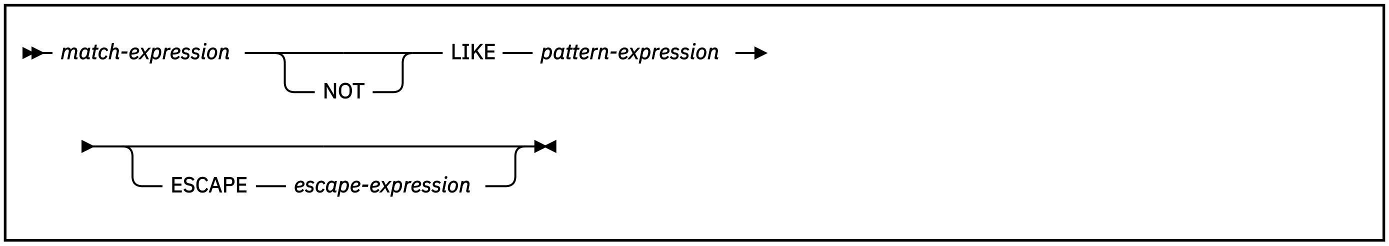
```
YEAR(PRENDATE)  IN (YEAR(CURRENT DATE),
                    YEAR(CURRENT DATE + 1 YEAR),
                    YEAR(CURRENT DATE + 2 YEARS))
```

Example 4
The following example obtains the phone number of an employee in DSN8C10.EMP where the employee number (EMPNO) is a value specified within the COBOL structure defined below.

```
77 PHNUM  PIC X(6).
01 EMPNO-STRUCTURE.
   05 CHAR-ELEMENT-1  PIC X(6) VALUE '000140'.
   05 CHAR-ELEMENT-2  PIC X(6) VALUE '000340'.
   05 CHAR-ELEMENT-3  PIC X(6) VALUE '000220'.
   .
   .
   .
EXEC SQL DECLARE PHCURS CURSOR FOR
     SELECT PHONENO FROM DSN8C10.EMP
       WHERE EMPNO IN
       (:EMPNO-STRUCTURE.CHAR-ELEMENT-1,
        :EMPNO-STRUCTURE.CHAR-ELEMENT-2,
        :EMPNO-STRUCTURE.CHAR-ELEMENT-3)
END-EXEC.
EXEC SQL OPEN PHCURS
END-EXEC.
EXEC SQL FETCH PHCURS INTO :PHNUM
END-EXEC.
```

LIKE predicate

The LIKE predicate searches for strings that have a certain pattern.



The *match-expression* is the string to be tested for conformity to the pattern specified in *pattern-expression*. Underscore and percent sign characters in the pattern have a special meaning instead of their literal meanings unless *escape-expression* is specified. For more information, see the description of *pattern-expression*.

The following rules summarize how a predicate in the form of `m LIKE p` is evaluated:

- If *m* or *p* is null, the result of the predicate is unknown.
- If *m* and *p* are both empty, the result of the predicate is true.
- If *m* is empty and *p* is not, the result of the predicate is unknown unless *p* consists of one or more percent signs.
- If *m* is not empty and *p* is empty, the result of the predicate is false.
- Otherwise, if *m* matches the pattern in *p*, the result of the predicate is true. The description of *pattern-expression* provides a detailed explanation on how the pattern is matched to evaluate the predicate to true or false.

  The way the pattern is matched to evaluate the predicate changes when *LIKE blank insignificant* behavior is enabled. For more information, see "LIKE blank insignificant behavior subsystem parameter" on page 313.

The values for *match-expression*, *pattern-expression*, and *escape-expression* must all be character or graphic strings or a mixture of both or they must all be binary strings (BLOBs). None of the expressions can yield a distinct type; however, an expression can be a function that casts a distinct type to its source type.

There are slight differences in what expressions are supported for each argument. The description of each argument lists the supported expressions.

match-expression
An expression that specifies the string to be tested for conformity to a certain pattern of characters.

LIKE *pattern-expression*
An expression that specifies the pattern of characters to be matched.

The expression can be specified by any one of the following:

- A constant
- A special register
- A variable
- A scalar function whose arguments are any of the above (though nested function invocations cannot be used)
- An array element specification
- A CAST specification whose arguments are any of the above
- An expression that concatenates (using CONCAT or ||) any of the above

The expression must also meet these restrictions:

- The maximum length of *pattern-expression* must not be larger than 4000 bytes.
- If a host variable is used in *pattern-expression*, the host variable must be defined in accordance with the rules for declaring string host variables and must not be a structure. For more information about the use of host variables with specific programming languages, see Host variables (Db2 Application programming and SQL).
- If *escape-expression* is specified, *pattern-expression* must not contain the escape character that is identified by *escape-expression*, except when immediately followed by the escape character, '%', or '_'. For example, if '+' is the escape character, any occurrences of '+' other than '++', '+_', or '+%' in the pattern is an error.

The pattern is used to specify the conformance criteria for values in the *match-expression* where:

- The underscore character (_) represents any single character.
- The percent sign (%) represents a string of zero or more characters.
- Any other character represents a single occurrence of itself.

If the *pattern-expression* must include either the underscore or the percent character, the *escape-expression* is used to specify a character to precede either the underscore or percent character in the pattern. For character strings, the terms *character*, *percent sign*, and *underscore* refer to SBCS characters. For graphic strings, the terms refer to double-byte or UTF-16 characters.

If the pattern is specified in a fixed-length string variable, any trailing blanks are interpreted as part of the pattern. Therefore, it is better to use a varying-length string variable with an actual length that is the same as the length of the pattern. If the host language does not allow varying-length string variables, place the pattern in a fixed-length string variable whose length is the length of the pattern.

A rigorous description of the pattern: This more rigorous description of the pattern ignores the use of the *escape-expression*.

Let *m* denote the value of *match-expression* and let *p* denote the value of *pattern-expression*. The string *p* is interpreted as a sequence of the minimum number of substring specifiers so each character of *p* is part of exactly one substring specifier. A substring specifier is an underscore, a percent sign, or any non-empty sequence of characters other than an underscore or a percent sign.

The result of the predicate is unknown if *m* or *p* is the null value. Otherwise, the result is either true or false. The result is true if *m* and *p* are both empty strings or there exists a partitioning of *m* into substrings such that:

- A substring of *m* is a sequence of zero or more contiguous characters and each character of *m* is part of exactly one substring.
- If the *n*th substring specifier is an underscore, the *n*th substring of *m* is any single character.
- If the *n*th substring specifier is a percent sign, the *n*th substring of *m* is any sequence of zero or more characters.
- If the *n*th substring specifier is neither an underscore nor a percent sign, the *n*th substring of *m* is equal to that substring specifier and has the same length as that substring specifier.
- The number of substrings of *m* is the same as the number of substring specifiers.

It follows that if *p* is an empty string and *m* is not an empty string, the result is false. Similarly, if *m* is an empty string and *p* is not an empty string consisting of a value other than percentage signs, the result is false.

The predicate `m NOT LIKE p` is equivalent to the search condition `NOT (m LIKE p)`.

Mixed data patterns: If *match-expression* represents mixed data, the pattern is assumed to be mixed data. For ASCII and EBCDIC, the special characters in the pattern are interpreted as follows:

- An SBCS underscore refers to one SBCS character.
- A DBCS underscore refers to one MBCS character.
- A percent sign (either SBCS or DBCS) refers to a string of zero or more SBCS or MBCS characters.

For EBCDIC, redundant shift bytes in *match-expression* or *pattern-expression* are ignored.

For Unicode, the special characters in the pattern are interpreted as follows:

- An SBCS or DBCS underscore refers to one character (either SBCS or MBCS).
- A percent sign (either SBCS or DBCS) refers to a string of zero or more SBCS or MBCS characters.

When the LIKE predicate is used with Unicode data, the Unicode percent sign and underscore use the code points indicated in the following table:

Character	UTF-8	UTF-16
Half-width %	X'25'	X'0025'
Full-width %	X'EFBC85'	X'FF05'
Half-width_	X'5F'	X'005F'

Character	UTF-8	UTF-16
Full-width_	X'EFBCBF'	X'FF3F'

The full-width or half-width % matches zero or more characters. The full-width or half-width_ character matches exactly one character. (For ASCII or EBCDIC data, a full-width _ character matches one DBCS character.)

Binary data patterns: For columns with binary data, the pattern contains bytes. The special bytes in the pattern are interpreted as follows:

- The code point for an SBCS underscore (X'6D') refers to 1 byte.
- The code point for an SBCS percent (X'6C') refers to any number of bytes.

Parameter marker:

When the pattern specified in a LIKE predicate is a parameter marker and a fixed-length character variable is used to replace the parameter marker, specify a value for the variable that is the correct length. If you do not specify the correct length, the select does not return the intended results.

For example, if the variable is defined as CHAR(10) and the value 'WYSE%' is assigned to that variable, the variable is padded with blanks on assignment. The pattern used is 'WYSE%   ', which requests Db2 to search for all values that start with 'WYSE' and end with five blank spaces unless *LIKE blank insignificant* behavior is in effect. If the search was intended to search only for the values that start with 'WYSE', then assign the value 'WYSE%%%%%%' to the variable.

ESCAPE *escape-expression*

An expression that specifies the escape character to be used to modify the special meaning of the underscore (_) and percent (%) characters in *pattern-expression*. Specifying an expression, which is optional, allows the LIKE predicate to explicitly test that the value contains a '%' or '_' in the character positions that you want. The escape character consists of a single SBCS (1 byte) or DBCS (2 bytes) character. An escape clause is allowed for Unicode mixed (UTF-8) data, but is restricted for ASCII and EBCDIC mixed data.

The expression can be specified by:

- A constant
- A variable
- A scalar function whose arguments are any of the above (though nested function invocations cannot be used)
- A CAST specification whose arguments are any of the above

The following rules also apply to the use of the ESCAPE clause and *escape-expression*:

- The result of *escape-expression* must be one SBCS or DBCS character or a binary string that contains exactly 1 byte.
- The ESCAPE clause cannot be used if *match-expression* is mixed data.
- If *escape-expression* is specified by a host variable, the host variable must be defined in accordance with the rules for declaring fixed-length string host variables.

  Note: If it is NUL-terminated, a C character string variable of length 2 can be specified.

  If the host variable has a negative indicator variable, the result of the predicate is unknown.
- The pattern must not contain the escape character except when followed by the escape character, '%' or '_'. For example, if '+' is the escape character, any occurrences of '+' other than '++', '+_', or '+%' in the pattern is an error.

The following table shows the effect of successive occurrences of the escape character, which in this case is the plus sign (+).

Table 61. Effect of successive occurrences of the escape character

When the pattern string is...	The actual pattern is...
+%	A percent sign
++%	A plus sign followed by zero or more arbitrary characters
+++%	A plus sign followed by a percent sign

Examples

Example 1

The following predicate is true when the string to be tested in NAME has the value SMITH, NESMITH, SMITHSON, or NESMITHY. It is not true when the string has the value SMYTHE:

```
NAME LIKE '%SMITH%'
```

Example 2

In the predicate below, a host variable named PATTERN holds the string for the pattern:

```
NAME LIKE :PATTERN ESCAPE '+'
```

Assume that the string in PATTERN has the following value:

```
AB+_C_%
```

Observe that in this string, the plus sign preceding the first underscore is an escape character. The predicate is true when the string being tested in NAME has the value AB_CD or AB_CDE. It is false when this string has the value AB, AB_, or AB_C.

Example 3

The following two predicates are equivalent; three of the four percent signs in the first predicate are redundant.

```
NAME LIKE 'AB%%%%CD'
NAME LIKE 'AB%CD'
```

Example 4

Assume that a distinct type named ZIP_TYPE with a source data type of CHAR(5) exists and an ADDRZIP column with data type ZIP_TYPE exists in some table TABLEY. The following statement selects the row if the zip code (ADDRZIP) begins with '9555'.

```
SELECT * FROM TABLEY
  WHERE CHAR(ADDRZIP) LIKE '9555%'
```

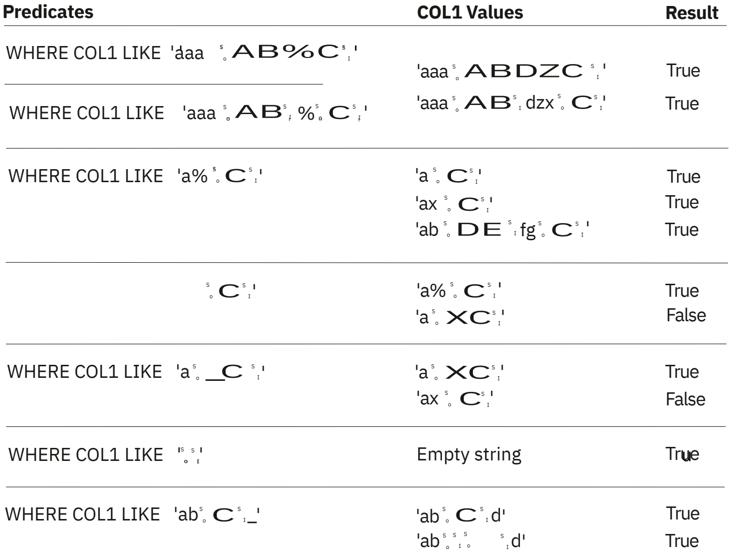
Example 5

The RESUME column in sample table DSN8C10.EMP_PHOTO_RESUME is defined as a CLOB. The following statement selects the RESUME column when the string JONES appears anywhere in the column.

```
SELECT RESUME FROM DSN8C10.EMP_PHOTO_RESUME
  WHERE RESUME LIKE '%JONES%'
```

Example 6

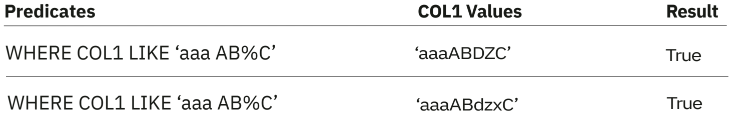
In the following table, assume COL1 is a column that contains mixed EBCDIC data. The table shows the results when the predicate in the first column is evaluated using the COL1 value in the second column:



Predicates	COL1 Values	Result
WHERE COL1 LIKE 'aaa $^{S}_{O}$ＡＢ％Ｃ$^{S}_{I}$'	'aaa$^{S}_{O}$ＡＢＤＺＣ$^{S}_{I}$'	True
WHERE COL1 LIKE 'aaa $^{S}_{O}$ＡＢ$^{S}_{I}$%$^{S}_{O}$Ｃ$^{S}_{I}$'	'aaa$^{S}_{O}$ＡＢ$^{S}_{I}$dzx$^{S}_{O}$Ｃ$^{S}_{I}$'	True
WHERE COL1 LIKE 'a%$^{S}_{O}$Ｃ$^{S}_{I}$'	'a$^{S}_{O}$Ｃ$^{S}_{I}$'	True
	'ax$^{S}_{O}$Ｃ$^{S}_{I}$'	True
	'ab$^{S}_{O}$ＤＥ$^{S}_{I}$fg$^{S}_{O}$Ｃ$^{S}_{I}$'	True
$^{S}_{O}$Ｃ$^{S}_{I}$'	'a%$^{S}_{O}$Ｃ$^{S}_{I}$'	True
	'a$^{S}_{O}$ＸＣ$^{S}_{I}$'	False
WHERE COL1 LIKE 'a$^{S}_{O}$_Ｃ$^{S}_{I}$'	'a$^{S}_{O}$ＸＣ$^{S}_{I}$'	True
	'ax$^{S}_{O}$Ｃ$^{S}_{I}$'	False
WHERE COL1 LIKE '$^{S}_{O}$$^{S}_{I}$'	Empty string	True
WHERE COL1 LIKE 'ab$^{S}_{O}$Ｃ$^{S}_{I}$_'	'ab$^{S}_{O}$Ｃ$^{S}_{I}$d'	True
	'ab$^{S}_{O}$$^{S}_{I}$$^{S}_{O}$ $^{S}_{I}$d'	True

Example 7

In the following table, assume COL1 is a column that contains mixed ASCII data. The table shows the results when the predicate in the first column is evaluated using the COL1 value in the second column:



Predicates	COL1 Values	Result
WHERE COL1 LIKE ‘aaa AB%C’	‘aaaABDZC’	True
WHERE COL1 LIKE ‘aaa AB%C’	‘aaaABdzxC’	True

Example 8

In the following table, assume COL1 is a column that contains Unicode data. The table shows the results when the predicate in the first column is evaluated using the COL1 value in the second column:

Table 62. COL1 contain Unicode data

Predicates	COL1 values	Result
WHERE COL1 LIKE 'aaaAB%C	'aaaABDZC'	True
	'aaaABdzxC'	True
	empty string	False
WHERE COL1 LIKE 'aaaAB %C'	'aaaABDZC'	True
	'aaaABdzxC'	True
	empty string	False
WHERE COL1 LIKE ''	'aaaABDZC'	False
	'aaaABdzxC'	False
	empty string	True
WHERE COL1 LIKE '%'	'aaaABDZC'	True
	'aaaABdzxC'	True
	empty string	True
WHERE COL1 LIKE ' %'	'aaaABDZC'	True
	'aaaABdzxC'	True
	empty string	False

Table 62. COL1 contain Unicode data (continued)

Predicates	COL1 values	Result
WHERE COL1 LIKE ' '	'aaaABDZC'	False
	'aaaABdzxC'	False
	empty string	False

LIKE blank insignificant behavior subsystem parameter

When the LIKE_BLANK_INSIGNIFICANT subsystem parameter is enabled, all of the blanks at the end of a fixed-length string are ignored. This behavior is called *LIKE blank insignificant* behavior. *LIKE blank significant* behavior, in which the blanks at the end of fixed-length strings are significant (not ignored), is the default behavior during installation or migration. For variable length strings, blanks are significant.

When you set the LIKE_BLANK_INSIGNIFICANT subsystem parameter, LIKE blank insignificant behavior takes effect the next time an SQL query statement with the LIKE predicate is executed after the statement is bound or prepared. If the statement is not prepared or bound, the LIKE behavior exhibits LIKE blank significant behavior regardless of the subsystem parameter setting.

For the following interfaces, enabling or disabling LIKE blank insignificant behavior takes effect immediately. This applies to both an explicit LIKE predicate (for example, UNLOAD) and an implicit LIKE predicate (for example, table check constraint).

- INSERT
- UPDATE
- MERGE
- UNLOAD
- REORG
- LOAD
- CHECK DATA

Before the LIKE predicate is applied, any trailing blanks in a CHARACTER or GRAPHIC column are stripped to the last non-blank character. If the column contains all blanks, the blank in character position 1 is not stripped. After stripping occurs, the LIKE predicate is applied against the stripped column data.

Tip: After you enable the LIKE_BLANK_INSIGNIFICANT subsystem parameter, existing rows might not conform to table check constraints that contain a LIKE predicate. Consider running the CHECK DATA utility on all affected tables to find the records that do not conform to the table check constraint.

The following examples, in which *b* represents a blank character, demonstrate how the LIKE predicate is evaluated when LIKE blank insignificant behavior is enabled.

```
SELECT C1
FROM T1
WHERE C1 LIKE '%xyz';
```

This LIKE predicate will match the following fixed-length strings:

- abcxyz
- abcxyz*b*
- abcxyz*bb*
- abcxyz*bb..b*'

While trailing blanks in the column data are insignificant, trailing blanks in the LIKE predicate are significant. The following example, in which*b* represents a blank character, applies to when the LIKE predicate contains one or more trailing blanks.

```
SELECT C1
FROM T1
WHERE C1 LIKE '%xyzbb';
```

This LIKE predicate will not match the following fixed-length strings:

- abcxyz
- abcxyz*b*
- abcxyz*bb*
- abcxyz*bbb*

The following example applies to when the LIKE predicate contains one or more single characters (_) in the last position.

```
SELECT C1
FROM T1
WHERE C1 LIKE '%xyz_';
```

This LIKE predicate will not match the following fixed-length strings, because they are all stripped to the 'abcxyz' string:

- abcxyz
- abcxyz*b*
- abcxyz*bb*
- abcxyz*bb..b*

The following example applies to when the LIKE predicate contains more than one single character (_) in the last position.

```
SELECT C1
FROM T1
WHERE C1 LIKE '%xyz__';
```

This LIKE predicate will not match the following fixed-length strings:

- abcxyz
- abcxyz*b*
- abcxyz*bb*
- abcxyz*bb..b*

The following example applies to when the LIKE predicate contains more than one single character (_) and a string of zero or more characters (%) are in the last positions.

```
SELECT C1
FROM T1
WHERE C1 LIKE '%xyz_%_';
This
```

This LIKE predicate will not match the following fixed-length strings:

- abcxyz
- abcxyz*b*
- abcxyz*bb*
- abcxyz*bb..b*

If the column data contains all blanks, every blank, except the blank in character position one, is stripped before the LIKE predicate is applied. For example, a CHAR(6) column contains the following values:

bbbbbb

The following LIKE predicates will match:

- LIKE '*b*'
- LIKE '_'
- LIKE '%'

The following LIKE predicates will not match:

- LIKE '*bbbbbbb*'
- LIKE '*bbbb*___'
- LIKE '_______'

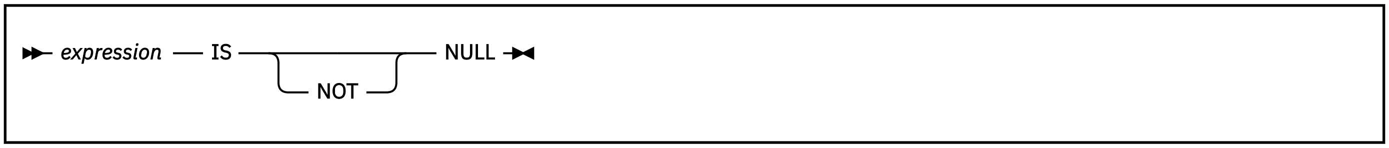
LIKE_BLANK_INSIGNIFICANT in macro DSN6SPRM (Db2 Installation and Migration)

NULL predicate

The NULL predicate tests for null values.



The result of a NULL predicate cannot be unknown. If the value of the expression is null, the result is true. If the value is not null, the result is false. If NOT is specified, the result is reversed.

A parameter marker must not be specified for or within the expression.

Notes

Syntax alternatives:
FL 504 For compatibility with other SQL dialects, you can use ISNULL as an alternative syntax for IS NULL and NOTNULL as alternative syntax for IS NOT NULL.

Example 1: The following predicate is true whenever PHONENO has the null value, and is false otherwise.

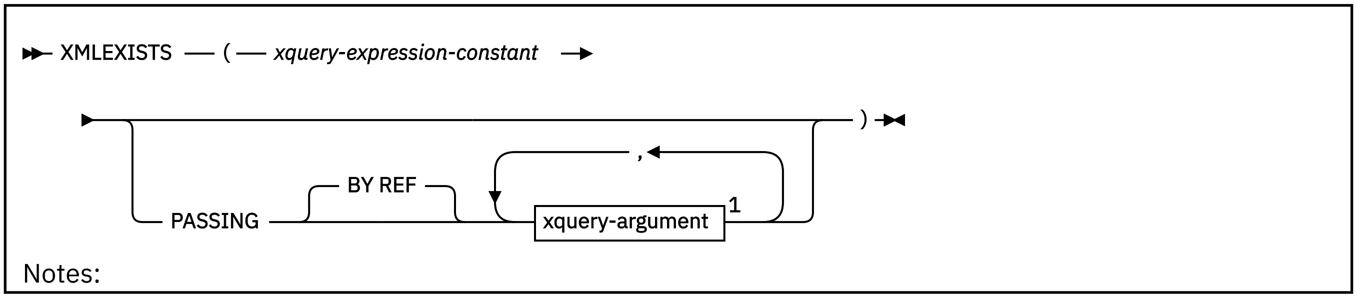
```
PHONENO IS NULL
```

Example 2: The following predicate is true whenever the array MYARRAY has the null value, and is false otherwise.

```
MYARRAY IS NULL
```

XMLEXISTS predicate

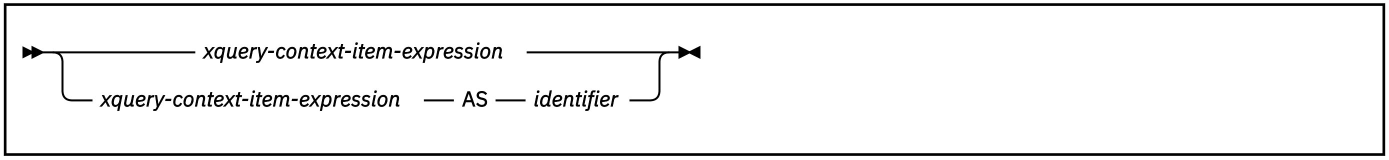
The XMLEXISTS predicate tests whether an XQuery expression returns a sequence of one or more items.



Notes:

[1] *xquery-context-item-expression* must not be specified more than one time.

xquery-argument



xquery-context-item-expression
xquery-context-item-expression
AS
identifier

xquery-expression-constant
Specifies a character string constant that is interpreted as an XQuery expression using supported XQuery language syntax. For information about the XQuery language syntax, see Overview of pureXML (Db2 Programming for XML). *xquery-expression-constant* cannot be an XQuery updating expression. The XQuery expression is evaluated with the arguments specified in *xquery-argument*. *xquery-expression-constant* must not be an empty string or a string of all blanks.

PASSING
Specifies input values and the manner in which these values are passed to the XQuery expression specified by *xquery-expression-constant*.

BY REF
Specifies that the XML input value arguments are to be passed by reference. When XML values are passed by reference, the XQuery evaluation uses the input node trees, preserving all properties including the original node identities and document order. If two arguments pass the same XML value, node identity comparisons and document ordering comparisons that involve some nodes that are contained between the two input arguments might refer to nodes within the same XML node tree.

This clause has no impact on how non-XML values are passed. The non-XML values create a new copy of the value during the cast to XML.

xquery-argument
Specifies an argument to use in the evaluation of the XQuery expression specified by *xquery-expression-constant*. A query argument is an expression that returns a value that is XML, integer, decimal, or a character or graphic string that is not a LOB. *xquery-argument* must not return ROWID, TIMESTAMP, binary string, REAL, DECFLOAT data types, or a character string data type that is bit data, and must not reference a sequence expression or a *OLAP-specification*.

An argument specifies a value and the manner in which that value is to be passed. How an argument in the PASSING clause is used in the XQuery expression depends on whether the argument is specified as the *xquery-context-item-expression* or an *xquery-variable-expression*. The argument includes an SQL expression that is evaluated before passing the result to the XQuery expression.

- If the resulting value is an XML value, it becomes an *input-xml-value*. It is passed by reference which means that the original values, not copies, are used in the evaluation of the XQuery expression.
- If the resulting value is not an XML value, the result of the expression must be able to be cast to an XML value. The cast value becomes an *input-xml-value*. An empty string is converted to an XML empty string.
- If the resulting value is a null value, it is converted to an XML empty sequence if the argument is *xquery-variable-expression*. If the argument is *xquery-context-expression*, the XMLEXISTS predicates returns unknown.

xquery-context-item-expression
xquery-context-item-expression specifies the *initial context item* in the XQuery expression specified by *xquery-expression-constant*. The value of the initial context item is the result of *xquery-context-item-expression* cast to XML. *xquery-context-item-expression* must not be specified more than one time.

xquery-context-item-expression must not be a sequence of more than one item. If the result of *xquery-context-item-expression* is an empty string, the XQuery expression is evaluated with the initial context item set to an XML empty string.

If the *xquery-context-item-expression* is not specified or is an empty string, the initial context item in the XQuery expression is undefined, and the XQuery expression must not reference the initial context item. An XQuery variable is not created for the context item expression.

If the *xquery-context-expression* is not specified or the *input-xml-value* that results from the *xquery-context-expression* is an XML empty sequence, the initial context item is undefined. If the XQuery expression refers to the initial context item, it must be specified with a value that is not an XML empty sequence.

xquery-variable-expression

xquery-variable-expression specifies an argument to the XQuery expression. An XQuery variable is created for each *xquery-variable-expression*, and the XQuery variable is set to the result of *xquery-argument-expression* cast to XML. If the result of *xquery-variable-expression* is an empty string, the XQuery variable is set to an XML empty string. If *xquery-variable-expression* is null, the XQuery variable is set to an XML empty sequence. For example, `PASSING T.A + T.B as "sum"` creates an XQuery variable named sum. The scope of the XQuery variables created from the PASSING clause is the XQuery expression that is specified by *xquery-expression-constant*.

AS *identifier*

Specifies that the value that is generated by *xquery-variable-expression* will be passed to *xquery-expression-constant* as an XQuery variable named *identifier*. The length of the name must not be longer than 128 bytes. The leading dollar sign ($) that precedes variable names in the XQuery language is not included in *identifier*. The name must be an XML NCName that is not the same as *identifier* for another *xquery-variable-expression* in the same PASSING clause.

The result of the predicate is determined as follows:

- The result is unknown if *xquery-context-item-expression* specified in the PASSING clause is a NULL value
- the result is false if the result of the XQuery expression is an empty sequence
- the result is true in all other cases

If the evaluation of the XQuery expression results in an error, XMLEXISTS returns an error. The XMLEXISTS predicate is not supported in ON clause of outer joins.

Example: Find all the purchase orders that buy a baby monitor. This example finds the product number for baby monitors from the product table and joins the result to the PurchaseOrders table. It then evaluates the XQuery expression //item[@partnum = *$n*] for each row and returns those rows that contain an item element node with a partNum attribute that is equal to the product number of ‘Baby Monitor'. The context item for the XQuery expression is PO.POrder. An XQuery variable, *$n*, is created and initialized to the value of S.prodno:

```
   SELECT S.prodno, count(*) as result
      FROM PurchaseOrders PO, Products S
      WHERE XMLEXISTS ('//item[@partNum = $n]'
                       PASSING PO.POrder,
                               S.prodno AS "n")
      AND S.prod_name = 'Baby Monitor';
```

The results might be similar to the following:

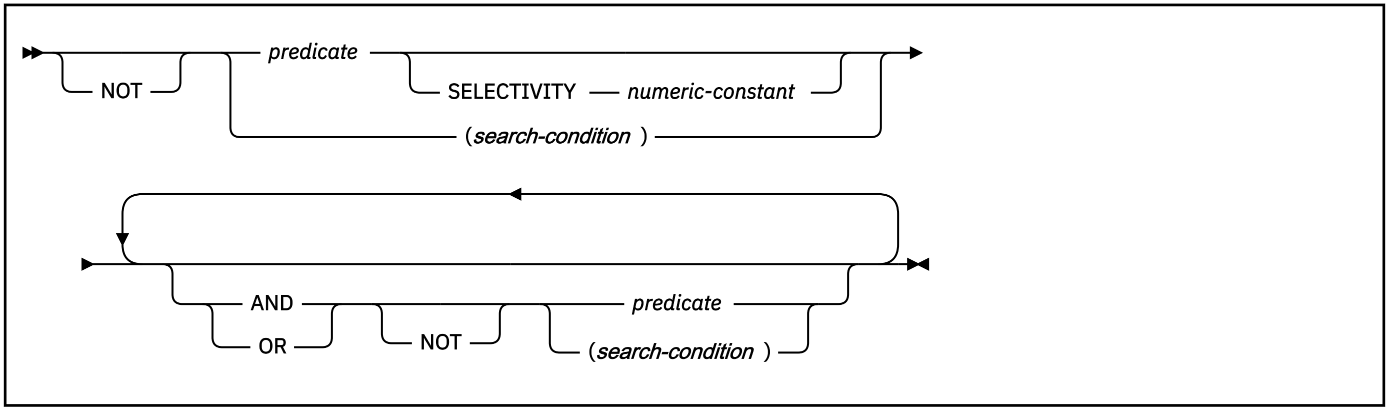
```
Prodno      result
-------------------------------

926-AA      1
```

Search conditions

A *search condition* specifies a condition that is true, false, or unknown about a given row or group. When the condition is true, the row or group qualifies for the results. When the condition is false or unknown, the row or group does not qualify.

Syntax



Description

SELECTIVITY *numeric-constant*
Specifies the expected selectivity percentage for the predicate. You can specify the SELECTIVITY clause only when the predicate contains one of the indexable spatial predicate functions and the predicate is in the form of `spatial-predicate-function operator expression`, where *operator* is either = or <. The selectivity value must be an integer or decimal constant value in the range from 0 to 1 (inclusive). For example, if you specify 0.01, the spatial predicate function is expected to filter out all but one percent of all the rows in the table. An error is returned if the SELECTIVITY clause is specified for a non-spatial predicate function.

The result of a search condition is derived by application of the specified *logical operators* (AND, OR, NOT) to the result of each specified predicate. If logical operators are not specified, the result of the search condition is the result of the specified predicate.

AND and OR are defined in the following table, in which *P* and *Q* are any predicates:

Table 63. Truth table for AND and OR

P	***Q***	***P* and *Q***	***P* or *Q***
True	True	True	True
True	False	False	True
True	Unknown	Unknown	True
False	True	False	True
False	False	False	False
False	Unknown	False	Unknown
Unknown	True	Unknown	True
Unknown	False	False	Unknown
Unknown	Unknown	Unknown	Unknown

NOT(true) is false and NOT(false) is true, but NOT(unknown) is still unknown. The NOT logical operator has no affect on an unknown condition. The result of NOT(unknown) is still unknown.

Search conditions within parentheses are evaluated first. If the order of evaluation is not specified by parentheses, NOT is applied before AND, and AND is applied before OR. The order in which operators at the same precedence level are evaluated is undefined to allow for optimization of search conditions.

Example 1: In the first of the search conditions below, AND is applied before OR. In the second, OR is applied before AND.

```
SALARY>:SS AND  COMM>:CC OR BONUS>:BB
SALARY>:SS AND (COMM>:CC OR BONUS>:BB)
```

Example 2: In the first of the search conditions below, NOT is applied before AND. In the second, AND is applied before NOT.

```
NOT SALARY>:SS  AND  COMM>:CC
NOT (SALARY>:SS AND  COMM>:CC)
```

Example 3: For the following search condition, AND is applied first. After the application of AND, the OR operators could be applied in either order without changing the result. Db2 can therefore select the order of applying the OR operators.

```
SALARY>:SS AND COMM>:CC OR BONUS>:BB OR SEX=:GG
```

Options affecting SQL

Certain Db2 precompiler or coprocessor options (referred to as SQL processing options), Db2 subsystem parameters (set through the installation panels), bind options, options for CREATE PROCEDURE and ALTER PROCEDURE statements for native SQL procedures, and special registers affect how SQL statements can be composed or determine how SQL statements are processed.

The following table summarizes the effect of these options and shows where to find more information. (Some of the items are described in detail following the table, while other items are described elsewhere.)

Table 64. Summary of items affecting composition and processing of SQL statements

SQL processing option	Other[1]	Affects
	DYNAMICRULES bind option or the native SQL procedures option	The rules that Db2 applies to dynamic SQL statements. For details about authorization, see "Authorization IDs and dynamic SQL" on page 94. The option can also affect decimal point representation, string delimiters, and decimal arithmetic. For details about how Db2 applies the options to dynamic SQL statements when DYNAMICRULES bind, define, or invoke behavior is in effect, see "SQL processing options for dynamic statements" on page 321.
	USE FOR DYNAMICRULES	Use of options for dynamic statements when DYNAMICRULES bind, define, or, invoke behavior is in effect. For details, see "SQL processing options for dynamic statements" on page 321.
COMMA PERIOD	DECIMAL POINT IS	Representation of decimal points in SQL statements. For details, see "Decimal point representation" on page 322.

Table 64. Summary of items affecting composition and processing of SQL statements (continued)

SQL processing option	Other[1]	Affects
APOSTSQL QUOTESQL	SQL STRING DELIMITER	Representation of string delimiters in SQL statements. For details, see "Apostrophes and quotation marks as string delimiters" on page 323.
	ASCII CCSID	A numeric value that determines the CCSID of ASCII string data. For details, see "Mixed data in character strings" on page 324.
	EBCDIC CCSID	A numeric value that determines the CCSID of EBCDIC string data and whether Katakana characters can be used in ordinary identifiers. For details, see "Katakana characters for EBCDIC" on page 324.
	UNICODE CCSID	A numeric value that determines the CCSID of Unicode string data. For details, see "Mixed data in character strings" on page 324.
CCSID	MIXED DATA	Use of ASCII or EBCDIC character strings with a mixture of SBCS and DBCS characters. For details, see "Mixed data in character strings" on page 324.
DATE TIME	DATE FORMAT TIME FORMAT LOCAL DATE LENGTH LOCAL TIME LENGTH	Formatting of datetime strings. For details, see "Formatting of datetime strings" on page 324.
STDSQL		Conformance with the SQL standard. For details, see "SQL standard language" on page 325.
NOFOR or STDSQL		Whether the FOR UPDATE clause must be specified (in the SELECT statement of the DECLARE CURSOR statement). For details, see "Positioned updates of columns" on page 325.
CONNECT		Whether the rules for the CONNECT(1) or CONNECT(2) SQL processing option apply. For details about the SQL processing option, see Descriptions of SQL processing options (Db2 Application programming and SQL).
	SQLRULES bind option	Whether a CONNECT statement is processed with Db2 rules or SQL standard rules.

Table 64. Summary of items affecting composition and processing of SQL statements (continued)

SQL processing option	Other[1]	Affects
	CURRENT RULES special register	Whether the statements ALTER TABLE, CREATE TABLE, GRANT, and REVOKE are processed with Db2 rules or SQL standard rules. For details, see "CURRENT RULES special register" on page 205. Whether Db2 automatically creates the LOB table space, auxiliary table, and index on the auxiliary table for a LOB column in a base table. For details, see Creating a table with LOB columns. Whether Db2 automatically creates an index on a ROWID column that is defined with GENERATED BY DEFAULT. For details, see the description of the clause for "CREATE TABLE" on page 1645. Whether an external stored procedure runs as a main or subprogram. For details, see "CREATE PROCEDURE (external)" on page 1575.
	SQLRULES bind option or CURRENT RULES special register	Whether SQLCODE +236 is issued when the SQLDA provided on DESCRIBE or PREPARE INTO is too small and the result columns do not involve LOBs or distinct types. For details, see "DESCRIBE" on page 1864 and Appendix F, "SQL descriptor area (SQLDA)," on page 2301.
DEC	DECIMAL ARITHMETIC or CURRENT PRECISION special register	Whether DEC15 or DEC31 rules are used when both operands in a decimal operation have 15 digits or less. For details, see "Arithmetic with two decimal operands" on page 250.

Note: [1] The entries in this column are fields on installation panels unless otherwise noted.

Related concepts
Options for SQL statement processing (Db2 Application programming and SQL)

SQL processing options for dynamic statements

Generally, dynamic statements use the application programming defaults specified on installation panel DSNTIPF. However, if the value of installation panel field USE FOR DYNAMICRULES is NO and DYNAMICRULES bind, define, or invoke behavior is in effect, certain SQL processing options are used instead of the application programming defaults.

The following SQL processing options are used instead of the application programming defaults:

- COMMA or PERIOD
- APOST or QUOTE
- APOSTSQL or QUOTESQL
- DEC(15) or DEC(31)

For some languages, the SQL processing option defaults to a value and no alternative is allowed. If the value of installation panel field USE FOR DYNAMICRULES is YES, dynamic statements use the application programming defaults regardless of the value of DYNAMICRULES option.

For additional information on the effect of SQL processing options and application programming defaults on:

- Decimal point representation, see "Decimal point representation" on page 322.
- String delimiters, see "Apostrophes and quotation marks as string delimiters" on page 323.
- Decimal arithmetic, see "Arithmetic with two decimal operands" on page 250.

For a list of the DYNAMICRULES option values that specify run, bind, define, or invoke behavior, see Table 14 on page 94.

DECFLOAT rounding mode

All views and SQL functions referenced in an SQL statement must either not have rounding mode information stored in the SYSENVIRONMENT catalog, or they must all have the same rounding mode information in the SYSENVIRONMENT catalog.

Decimal point representation

Decimal points in SQL statements are represented with either periods or commas.

Two values control the representation:

- The value of field DECIMAL POINT IS on installation panel DSNTIPF, which can be a comma (,) or period (.)
- COMMA or PERIOD, which are mutually exclusive SQL processing options for COBOL

These values apply to SQL statements as follows:

- For a distributed operation, the decimal point is the first of the following values that applies:
  - The decimal point value specified by the requester
  - The value of field DECIMAL POINT IS on panel DSNTIPF at the Db2 where the package is bound
- Otherwise:
  - For static SQL statements:
    - In a COBOL program, the SQL processing option COMMA or PERIOD determines the decimal point representation for every static SQL statement. If neither SQL processing option is specified, the value of DECIMAL POINT IS at precompilation time determines the representation.
    - In non-COBOL programs, the decimal representation for static SQL statements is always the period.
  - For dynamic SQL statements:
    - If DYNAMICRULES run behavior applies, the decimal point is the value of field DECIMAL POINT IS on installation panel DSNTIPF at the local Db2 when the statement is prepared.

      For a list of the DYNAMICRULES option values that specify run, bind, define, or invoke behavior, see Table 14 on page 94.
    - If DYNAMICRULES bind, define, or invoke behavior applies, and the value of installation panel field USE FOR DYNAMICRULES is YES, the decimal point is the value of field DECIMAL POINT IS.

      If bind, define, or invoke behavior applies, and field USE FOR DYNAMIC RULES is NO, the SQL processing option determines the decimal point representation. For COBOL programs, which supports SQL processing option COMMA or PERIOD, the decimal point representation is determined as described above for static SQL statements in COBOL programs. For programs written in other host languages, the default SQL processing option, which can only be PERIOD, is used.

If the comma is the decimal point, these rules apply:

- In any context, a comma intended as a separator must be followed by a space. Such commas could appear, for example, in a VALUES clause, an IN predicate, or an ORDER BY clause in which numbers are used to identify columns.
- In any context, a comma intended as a decimal point must not be followed by a space.

- If the DECIMAL POINT IS field (and not the SQL processing option) determines the comma as the decimal point, Db2 will recognize either a comma or a period as the decimal point in numbers in dynamic SQL.

DYNAMICRULES bind option (Db2 Commands)

Apostrophes and quotation marks as string delimiters

SQL processing options and Db2 installation panel fields control the representation of string delimiters in COBOL and SQL statements.

The following SQL processing options control the representation of string delimiters:

- APOST and QUOTE are mutually exclusive SQL processing options for COBOL. Their meanings are exactly what they are for the COBOL compilers:
  - APOST names the apostrophe (') as the string delimiter in COBOL statements.
  - QUOTE names the quotation mark (") as the string delimiter.

  Neither option applies to SQL syntax. Do not confuse them with the APOSTSQL and QUOTESQL options.
- APOSTSQL and QUOTESQL are mutually exclusive SQL processing options for COBOL. Their meanings are:
  - APOSTSQL names the apostrophe (') as the string delimiter and the quotation mark (") as the escape character in SQL statements.
  - QUOTESQL names the quotation mark (") as the string delimiter and the apostrophe (') as the escape character in SQL statements.

These values apply to SQL statements as follows:

- For a distributed operation, the string delimiter is the first of the following values that applies:
  - The SQL string delimiter value specified by the requester
  - The value of the field SQL STRING DELIMITER on installation panel DSNTIPF at the Db2 where the package is bound
- Otherwise:
  - For static SQL statements:

    In a COBOL program, the SQL processing option APOSTSQL or QUOTESQL determines the string delimiter and escape character. If neither SQL processing option is specified, the value of field SQL STRING DELIMITER on installation panel DSNTIPF determines the string delimiter and escape character.

    In a non-COBOL program, the string delimiter is the apostrophe, and the escape character is the quotation mark.
  - For dynamic SQL statements:
    - If DYNAMICRULES run behavior applies, the string delimiter and escape character is the value of field SQL STRING DELIMITER on installation panel DSNTIPF at the local Db2 when the statement is prepared.

      For a list of the DYNAMICRULES option values that specify run, bind, define, or invoke behavior, see Table 14 on page 94.
    - If DYNAMICRULES bind, define, or invoke behavior applies and the value of installation panel field USE FOR DYNAMICRULES is YES, the string delimiter and escape character is the value of field SQL STRING DELIMITER.

      If bind, define, or invoke behavior applies and USE FOR DYNAMICRULES is NO, the SQL processing option determines the string delimiter and escape character. For COBOL programs, SQL processing option APOSTSQL or QUOTESQL determines the string delimiter and escape character. If neither

SQL processing option is specified, the value of field SQL STRING DELIMITER determines them. For programs written in other host languages, the default SQL processing option, which can only be APOSTSQL, determines the string delimiter and escape character.

Katakana characters for EBCDIC

Ordinary identifiers with an EBCDIC encoding scheme can contain Katakana characters if the Db2 installation is set to allow it.

The field EBCDIC CCSID on installation panel DSNTIPF determines the system CCSIDs for EBCDIC-encoded data. Ordinary identifiers with an EBCDIC encoding scheme can contain Katakana characters if the field contains the value 5026 or 930. There are no corresponding SQL processing options. EBCDIC CCSID applies equally to static and dynamic statements. For dynamically prepared statements, the applicable value is always the one at the local Db2.

Mixed data in character strings

Mixed character data and graphic data are always allowed for Unicode, but for EBCDIC and ASCII, the specific installation of Db2 determines whether mixed data can be used.

The field MIXED DATA on installation panel DSNTIPF can have the value YES or NO for ASCII or EBCDIC character strings. The value YES indicates that character strings can contain a mixture of SBCS and DBCS characters. The value NO indicates that they cannot. Mixed character data and graphic data are always allowed for Unicode; that is the MIXED DATA field does not have an effect on Unicode data.

For static SQL statements, the value of the CCSID SQL processing option or the derived CCSID for the Db2 coprocessor determines whether ASCII or EBCDIC character strings can contain mixed data. If a mixed CCSID is used, mixed strings are allowed. If a single-byte CCSID is used, mixed strings are not allowed.

For dynamic SQL statements, the CCSID that is selected to convert the dynamic statement text to UTF-8 determines whether ASCII or EBCDIC character strings can contain mixed data. The CCSID for a dynamic statement is determined from the SQLDA override (if any) for the host variable on the PREPARE statement, the value of the CURRENT ENCODING SCHEME special register, and the ENCODING bind option.

The value of MIXED DATA affects the parsing of SQL character string constants, the execution of the LIKE predicate, and the assignment of character strings to host variables when truncation is needed. It can also affect concatenation, as explained in "Concatenation operators in expressions" on page 246. A value that applies to a statement executed at the local Db2 also applies to any statement executed at another server. An exception is the LIKE predicate, for which the applicable value of MIXED DATA is always the one at the statement's server.

The value of MIXED DATA also affects the choice of system CCSIDs for the local Db2 and the choice of data subtypes for character columns. When this value is YES, multiple CCSIDs are available for ASCII and EBCDIC data (SBCS, DBCS, and MIXED). The CCSID specified in the ASCII CCSID or EBCDIC CCSID field is the MIXED CCSID. In this case, Db2 derives the SBCS and MIXED CCSIDs from the DBCS CCSID specified installation panel DSNTIPF. Moreover, a character column can have any one of the allowable data subtypes—BIT, SBCS, or MIXED.

On the other hand, when MIXED DATA is NO, the only ASCII or EBCDIC system CCSIDs are those for SBCS data. Therefore, only BIT and SBCS can be data subtypes for character columns.

Formatting of datetime strings

The format for a datetime string that is in effect for a statement that is executed at the local Db2 is not necessarily in effect for a statement that is executed at a different server.

Fields on installation panel DSNTIP4 (DATE FORMAT, TIME FORMAT, LOCAL DATE LENGTH, and LOCAL TIME LENGTH) and SQL processing options affect the formatting of datetime strings.

The formatting of datetime strings is described in "String representations of datetime values" on page 120. Unlike the subsystem parameters and options previously described, a value in effect for a statement executed at the local Db2 is not necessarily in effect for a statement executed at a different server. See "Restrictions on the use of local datetime formats" on page 124 for more information.

SQL standard language

Db2 SQL and the SQL standard are not identical. The STDSQL SQL processing option addresses some of the differences.

- STDSQL(NO) indicates that conformance with the SQL standard is not intended. The default is the value of field STD SQL LANGUAGE on installation panel DSNTIP4 (which has a default of NO).
- STDSQL(YES)[16] indicates that conformance with the SQL standard is intended.

When a program is precompiled with the STDSQL(YES) option, the following rules apply:

Declaring host variables: All host variable declarations except in Java and REXX must lie between pairs of BEGIN DECLARE SECTION and END DECLARE SECTION statements:

```
BEGIN DECLARE SECTION
 -- one or more host variable declarations
END DECLARE SECTION
```

Separate pairs of these statements can bracket separate sets of host variable declarations.

Declarations for SQLCODE and SQLSTATE: The programmer must declare host variables for either SQLCODE or SQLSTATE, or both. SQLCODE should be defined as a fullword integer and SQLSTATE should be defined as a 5-byte character string. SQLCODE and SQLSTATE cannot be part of any structure. The variables must be declared in the DECLARE SECTION of a program; however, SQLCODE can be declared outside of the DECLARE SECTION when no host variable is defined for SQLSTATE. For PL/I, an acceptable declaration can look like this:

```
DECLARE SQLCODE BIN FIXED(31);
DECLARE SQLSTATE CHAR(5);
```

In Fortran programs, the variable SQLCOD should be used for SQLCODE, and either SQLSTATE or SQLSTA can be used for SQLSTATE.

Definitions for the SQLCA: An SQLCA must not be defined in your program, either by coding its definition manually or by using the INCLUDE SQLCA statement. When STDSQL(YES) is specified, the Db2 precompiler or coprocessor automatically generates an SQLCA that includes the variable name SQLCADE instead of SQLCODE and SQLSTAT instead of SQLSTATE. After each SQL statement executes, Db2 assigns status information to SQLCODE and SQLSTATE, whose declarations are described above, as follows:

- SQLCODE: Db2 assigns the value in SQLCADE to SQLCODE. In Fortran, SQLCAD and SQLCOD are used for SQLCADE and SQLCODE, respectively.
- SQLSTATE: Db2 assigns the value in SQLSTAT to SQLSTATE. (In Fortran, SQLSTT and SQLSTA are used for SQLSTAT and SQLSTATE, respectively.)
- No declaration for either SQLSTATE or SQLCODE: Db2 assigns the value in SQLCADE to SQLCODE.

If the precompiler or coprocessor encounters an INCLUDE SQLCA statement, it ignores the statement and issues a warning message. The precompiler or coprocessor also does not recognize hand-coded definitions, and a hand-coded definition creates a compile-time conflict with the generated definition. A similar conflict arises if definitions of SQLCADE or SQLSTAT, other than the ones generated by the Db2 precompiler or coprocessor, appear in the program.

Positioned updates of columns

Certain SQL processing options affect the use of the FOR UPDATE clause to achieve positioned column updates.

The NOFOR SQL processing option affects the use of the FOR UPDATE clause. The NOFOR option is in effect when either of the following are true:

[16] STDSQL(86) is a synonym, but STDSQL(YES) should be used.

- The NOFOR option is specified.
- The STDSQL(YES) option is in effect.

Otherwise, the NOFOR option is not in effect. The following table summarizes the differences when the option is in effect and when the option is not in effect:

Table 65. The NOFOR SQL processing option

When NOFOR is in effect	When NOFOR is not in effect
The use of the FOR UPDATE clause in the SELECT statement of the DECLARE CURSOR statement is optional. This clause restricts updates to the specified columns and causes the acquisition of update locks when the cursor is used to fetch a row. If no columns are specified, positioned updates can be made to any updatable columns in the table or view that is identified in the first FROM clause in the SELECT statement. If the FOR UPDATE clause is not specified, positioned updates can be made to any columns that the program has Db2 authority to update.	The FOR UPDATE clause must be specified.
DBRMs must be built entirely in virtual storage, which might possibly increase the virtual storage requirements of the Db2 precompiler or coprocessor. However, creating DBRMs entirely in virtual storage might cause concurrency problems with DBRM libraries.	DBRMs can be built incrementally using the Db2 precompiler or coprocessor.

SQL processing options do not affect ODBC behavior.

Mappings from SQL to XML

Db2 maps SQL to XML data according to industry standards and performs several different mappings.

To construct XML data from SQL data, the following mappings are performed:

- SQL character sets to XML character sets
- SQL identifiers to XML names
- SQL data values to XML data values

Db2 maps SQL to XML data according to industry standards. For complete information, see *Information technology - Database languages - SQL- Part 14: XML-Related Specifications (SQL/XML) ISO/IEC 9075-14:2003*.

Mapping SQL character sets to XML character sets

The character set used for XML data is Unicode UTF-8. SQL character data is converted into Unicode when it is used in XML built-in functions.

Mapping SQL identifiers to XML names

Many SQL identifiers that contain certain characters must be escaped when the SQL identifier is converted into an XML name.

Strings that start with 'XML', in any case combination, are reserved for standardization, and characters such as '#', '{', and '}' are not allowed in XML names. Many SQL identifiers containing these characters need to be escaped when the SQL identifiers are converted into XML names.

Db2 applies full escaping to SQL identifiers that are column names when it derives XML names. The mapping converts a colon (:) to _x003A_, _x to _x005F_x, and other restricted characters to a string of the form _x*uuuu*_ where *uuuu* is the Unicode value for the character. An identifier with an initial 'XML' (in any case combination) is escaped by mapping the initial x to _x0078_, or the initial X to _x0058_.

Mapping SQL data values to XML data values

SQL data values are mapped to XML values based on SQL data types.

The following data types are not supported and cannot be used as arguments to XML value constructors:

- ROWID
- Character strings that are defined with the FOR BIT DATA attribute
- Binary strings
- A string or a binary string distinct type that is based on a ROWID, FOR BIT DATA character string, or BLOB

For supported data types, the encoding scheme for XML values is Unicode.

Chapter 3. Built-in global variables and session variables

Db2 provides several built-in session variables and built-in global variables.

Built-in session variables contain information about the server and application process. Built-in global variables contain information about the database manager.

Built-in global variables

Built-in global variables are provided with the database manager and are used in SQL statements to retrieve scalar values associated with the variables.

As an example, the SYSIBM.PRODUCTID_EXT built-in global variable is referenced in an SQL statement to retrieve the extended product identifier of the database manager that invoked a function.

Authorization

The authorization ID of any statement that retrieves the value of the global variable is required to have one of the following:

- The READ privilege on that global variable
- DATAACCESS authority
- SYSADM authority

The READ privilege is granted to PUBLIC for built-in global variables, unless RACF external security is in use.

The authorization ID of any statement that assigns a value to a global variable is required to have one of the following:

- The WRITE privilege on that global variable
- DATAACCESS authority
- SYSADM authority

The WRITE privilege is not granted to PUBLIC for built-in global variables. The GRANT (variable privileges) statement can be used to grant the WRITE privilege to other users.

CATALOG_LEVEL

Contains the current catalog level.

This global variable has the following characteristics:

- It is read only, with values maintained by the system.
- The type is VARCHAR(30).
- The schema is SYSIBM.
- The scope of this global variable is session.

The format is V*vv*R*r*M*mmm*, where *vv* is the version, *r* is the release, and *mmm* is the modification level. For example, V12R1M510 identifies function level 510. For a list of all available function levels in Db2 12, see Db2 12 function levels (Db2 for z/OS What's New?).

Values V10R1 and V11R1 are also supported.

CLIENT_IPADDR

Contains the value of the client IP address for the connection.

For remote client connections, the value is the host IP address of the application that is used to establish the connection. For local host applications, the value is NULL. For remote host applications, the value is the IP address that is associated with the Db2 subsystem used to establish the connection as shown by issuing the -DISPLAY DDF command.

This global variable has the following characteristics:

- It is read only, with values maintained by the system.
- The type is CHAR(39).
- The schema is SYSIBM.
- The scope of this global variable is session.

The value is set by Db2 as obtained from the network. If the client did not connect by using the TCP/IP or SSL protocol, the value of the global variable is NULL.

```
1111:2222:3333:4444:5555:6666:7777:8888
```

Or IPv4-mapped IPv6 format:

```
::FFFF:9.30.115.135
```

Related information
DSNL085I (Db2 Messages)
DSNL089I (Db2 Messages)

DEFAULT_SQLLEVEL

Contains the value of the default value of the SQLLEVEL SQL processing option (DECPSQLL).

This global variable has the following characteristics:

- It is read only, with values maintained by the system.
- The type is VARCHAR(30)
- The schema is SYSIBM.
- The scope of this global variable is session.

The format is `V`*`vv`*`R`*`r`*`M`*`mmm`*, where *vv* is the version, *r* is the release, and *mmm* is the modification level. For example, `V12R1M510` identifies function level 510. For a list of all available function levels in Db2 12, see Db2 12 function levels (Db2 for z/OS What's New?).

GET_ARCHIVE

Contains a string value that indicates whether a reference to an archive-enabled table in a table-reference should include rows in the associated archive table.

This global variable has the following characteristics:

- It is updatable, with values maintained by the user.
- The type is CHAR(1).
- The schema is SYSIBMADM.
- The scope of this global variable is session.

The global variable can be set to the following:

Y

Specifies that when a table-reference is an archive-enabled table, the table reference includes rows in the associated archive table.

If the SYSIBMADM.GET_ARCHIVE global variable is set to 'Y' and the ARCHIVESENSITIVE bind option is set to 'Y', an archive-enabled table cannot be referenced in an SQL table function or in the definition of a row permission or column mask that is activated by a data change statement or query.

N

Specifies that when a table-reference is an archive-enabled table, the table reference does not include rows in the associated archive table. This is the default value.

Related concepts

Archive-enabled tables and archive tables (Introduction to Db2 for z/OS)

Related reference

table-reference
A *table-reference* specifies a result table as either a table or view, or an intermediate table.

MAX_LOCKS_PER_TABLESPACE

Contains a big integer value that specifies the default maximum number of page, row, or LOB locks that an application can simultaneously hold in a table space.

FL 507

If a single application exceeds the maximum number of locks in a single table space, lock escalation occurs.

The value that you specify for this field must be less than the value of the MAX_LOCKS_PER_USER built-in global variable (except when MAX_LOCKS_PER_USER is set to 0).

This global variable has the following characteristics:

- It is updatable, with values maintained by the user.
- The type is BIGINT.
- The schema is SYSIBMADM.
- The scope of this global variable is session.
- The default value is determined from the NUMLKTS subsystem parameter at the start of the application. Any subsequent changes to the NUMLKTS subsystem parameter do not affect the value of MAX_LOCKS_PER_TABLESPACE. You can use either of the following SET assignment statements to reinitialize MAX_LOCKS_PER_TABLESPACE using the current value of the NUMLKTS subsystem parameter:

```
SET SYSIBMADM.MAX_LOCKS_PER_TABLESPACE = DEFAULT;
```

```
SET SYSIBMADM.MAX_LOCKS_PER_TABLESPACE = NULL;
```

- The acceptable range of values is 0 - 104857600

Related reference

LOCKS PER TABLE(SPACE) field (NUMLKTS subsystem parameter) (Db2 Installation and Migration)
LOCKS PER USER field (NUMLKUS subsystem parameter) (Db2 Installation and Migration)

MAX_LOCKS_PER_USER

Contains a big integer value that specifies the maximum number of page, row, or LOB locks that a single application can concurrently hold for all table spaces.

FL 507

MAX_LOCKS_PER_USER has the following characteristics:

- It is updatable, with values maintained by the user.
- The type is BIGINT.
- The schema is SYSIBMADM.
- The scope of this global variable is session.
- The default value is determined from the NUMLKUS subsystem parameter at the start of the application. Any subsequent changes to the NUMLKUS subsystem parameter do not affect the value of MAX_LOCKS_PER_USER. You can use either of the following SET assignment statements to reinitialize MAX_LOCKS_PER_USER using the current value of the NUMLKUS subsystem parameter:

  ```
  SET SYSIBMADM.MAX_LOCKS_PER_USER = DEFAULT;
  ```

  ```
  SET SYSIBMADM.MAX_LOCKS_PER_USER = NULL;
  ```

- The acceptable range of values is 0 - 104857600

Related reference

LOCKS PER USER field (NUMLKUS subsystem parameter) (Db2 Installation and Migration)

MOVE_TO_ARCHIVE

Contains a string value that indicates whether the deletion of a row of an archive-enabled table should result in storing a copy of the deleted row in the associated archive table.

This global variable has the following characteristics:

- It is updatable, with values maintained by the user.
- The type is CHAR(1).
- The schema is SYSIBMADM.
- The scope of this global variable is session.

The global variable can be set to the following:

Y

Specifies that a delete of a row in an archive-enabled table will result in storing a copy of the deleted row in the associated archive table. Additionally, when the global variable is set to 'Y', an insert or update operation that specifies the archive-enabled table as the target of the statement will return an error.

E

Specifies that a delete of a row in an archive-enabled table will result in storing a copy of the deleted row in the associated archive table.

N

Specifies that a delete of a row in an archive-enabled table will not result in storing a copy of a deleted row in the associated archive table.

The default value is determined from the value of the MOVE_TO_ARCHIVE_DEFAULT subsystem parameter in macro DSN6SPRM.

Related concepts

Archive-enabled tables and archive tables (Introduction to Db2 for z/OS)

PRODUCTID_EXT

Contains the extended product identifier of the database manager that invoked the function.

This global variable has the following characteristics:

- It is read only, with values maintained by the system.
- The type is VARCHAR(30).
- The schema is SYSIBM

- The scope of this global variable is session.

The format of extended product identifier values is *pppvvrrmmm*, where *ppp* is a 3-letter product code (such as DSN for Db2 for z/OS), *vv* is the version, *rr* is the release, and *mmm* is the modification level. For example, DSN1201510 represents Db2 12 at the highest released function level.

REPLICATION_OVERRIDE

Indicates whether Db2 is to disable recording of temporal history for a system-period temporal table and allow an application to specify values for row-begin, row-end,transaction-start-ID, and generated expression columns.

PSPI

FL 503The global variable does not affect new values for row-begin, row-end, transaction-start-ID, and generated expression columns that are not explicitly specified as the target of an assignment clause for a data change statement. Db2 continues to generate values for these columns in other contexts.

This global variable has the following characteristics:

- It is updatable, with values maintained by the user.
- The type is CHAR(1).
- The schema is SYSIBMADM.
- The scope of this global variable is session.
- The default value is '**N**'

The global variable can be set to the following:

N

An application is not allowed to specify values for row-begin, row-end, transaction-start-ID, and generated expression columns. The recording of temporal history for a system-period temporal table is enabled.

N is the default.

Y

An application is allowed to specify values for row-begin, row-end, transaction-start-ID, and generated expression columns. The recording of temporal history for a system-period temporal table is disabled.

The REPLICATION_OVERRIDE built-in global variable is not intended for general use. It is intended for use by products that enable Db2 replication. The READ privilege on the variable is granted to PUBLIC. The WRITE privilege on the variable is not granted to PUBLIC.

Setting the SYSIBMADM.REPLICATION_OVERRIDE built-in global variable to 'Y' overrides the following default behaviors:

- Row-begin, row-end, transaction-start-ID, and generated expression columns are normally defined so that Db2 always generates the values. When the override is in effect, insert or update operations can specify values for row-begin, row-end, transaction-start-ID, or generated expression columns.
- Update and delete operations for system-period temporal tables normally generate historical rows. When the override is in effect, historical rows are not written to the associated history table for update and delete operations.

PSPI

SET_MAINT_MODE_RECORD_NO_TEMPORALHISTORY stored procedure

TEMPORAL_LOGICAL_TRANSACTION_TIME

Contains the value that is assigned to the row-begin column of a system-period temporal table, or to the end column in a history table during an insert, update, or delete operation.

This global variable has the following characteristics:

- It is updatable, with values maintained by the user or the system.
- The type is TIMESTAMP(12) WITHOUT TIME ZONE.
- The schema is SYSIBM.
- The scope of this global variable is session.

The global variable can be set to the following:

NULL

Specifies that temporal logical transactions are not in use. This is the default value. Db2 ensures the uniqueness of the generated values for row-begin columns in system-period temporal tables, and end columns in history tables across transactions, assuming that temporal logical transactions have not been used. If multiple rows are inserted or updated in system-period temporal tables within a single SQL unit of work, the values for the row-begin columns are the same for all of the rows and are unique from the values that are generated for the columns by another transaction. If a conflicting unit of work is updating the same row in the system-period temporal table, and the row to be inserted into the associated history table would have an end timestamp value greater than the begin timestamp value, an error is returned. If the begin timestamp value and end timestamp value for the row in the history table are the same, a row is not inserted into the history table.

Non-null value

Specifies a timestamp value to start a new temporal logical transaction. It is recommended that the value be later in time than the existing value of the global variable.

While the SYSIBM.TEMPORAL_LOGICAL_TRANSACTION_TIME built-in global variable is set to a non-null value, the application controls the scope of temporal logical transactions. Db2 does not ensure the uniqueness of the generated values for row-begin columns in system-period temporal tables, and end columns in history tables across transactions.

When the TEMPORAL_LOGICAL_TRANSACTIONS global variable is set to 0, within a unit of work, a single assignment of a non-null value can be made to the global variable.

The variable must not be assigned a value in the body of a before trigger.

The variable must not be assigned a non-null value if values have been assigned to row-begin columns or transaction-start-ID columns within the same unit of work.

During the execution of a data change operation, the value of the TEMPORAL_LOGICAL_TRANSACTION_TIME built-in global variable is the value established at the beginning of the data change statement.

TEMPORAL_LOGICAL_TRANSACTIONS

Specifies whether multiple temporal logical transactions are allowed within a single unit of work.

This global variable has the following characteristics:

- It is updatable, with values maintained by the user or the system.
- The type is SMALLINT.
- It is NOT NULL.
- The schema is SYSIBM.
- The scope of this global variable is session.

The global variable can be set to the following:

0

Disallows multiple temporal logical transactions in a single unit of work. This is the default value.

[1] Allows multiple temporal logical transactions in a single unit of work.

Rules for setting built-in global variables by using profile tables

In remote applications, some built-in global variables can be set with a value from the profile attributes table. When you set built-in global variables through the profile attributes table, be aware of the following rules and behavior.

You can set the following built-in global variables by specifying the GLOBAL_VARIABLE value for the KEYWORDS column in the DSN_PROFILE_ATRRIBUTES table. For detailed instructions, see Setting built-in global variables by using profile tables (Db2 Administration Guide).

Global variable	Examples
"GET_ARCHIVE" on page 330	`SET SYSIBMADM.GET_ARCHIVE = 'Y'`
FL 507 "MAX_LOCKS_PER_TABLESPACE" on page 331	`SET SYSIBMADM.MAX_LOCKS_PER_TABLESPACE = NULL`
FL 507 "MAX_LOCKS_PER_USER" on page 331	`SET SYSIBMADM.MAX_LOCKS_PER_USER = DEFAULT`
"MOVE_TO_ARCHIVE" on page 332	`SET SYSIBMADM.MOVE_TO_ARCHIVE = 'N'`

"TEMPORAL_LOGICAL_TRANSACTION_TIME" on page 334	`SET SYSIBM.TEMPORAL_LOGICAL_TRANSACTION_TIME =`
	`'2014-11-14-08.05.01.123456789'`

"TEMPORAL_LOGICAL_TRANSACTIONS" on page 334	`SET SYSIBM.TEMPORAL_LOGICAL_TRANSACTIONS = 0`

The following rules apply to SET statements for built-in global variables in the DSN_PROFILE_ATTRIBUTES table:

- The schema qualifier of the variable must be specified.
- The SET statement must have an equal sign (=) between the global variable name and the value that is assigned.
- Variable names can be specified in mixed case. Extraneous blanks between keywords are removed.
- The value that is specified for assignment must be valid for the variable and must not be an expression, or reference other special registers or variables.
- The value that is specified for assignment is passed through this interface as a string constant. For example, if a value to be assigned is the same as the name of a special register, Db2 stores the special register name, and not the special register value.
- The maximum length of the SET statement is 1024 bytes.
- The statement must be a Unicode string and encoded with the appropriate CCSID for the application.
- The variable is assigned the value and it is stored as specified.

Built-in global variable values persist for the lifetime of the connection unless the application explicitly sets the global variable. Built-in global variable values that are set explicitly by the application take precedence over values that are set in the profile tables. System directed connections, such as three-part name references, use the values of the global variables of the requesting Db2 site. For example, if a Java application establishes a connection to Db2 site 1, the global variable values are established with the profile tables from site 1. Later, if the application runs an SQL statement with an implicit three-part name connection to Db2 site 2, then the global variable values that are established on site 1 are referenced when the SQL statement runs on site 2.

Commit and rollback operations have no effect on the values of global variables, regardless of how they were established.

The authorization that is required to set built-in global variables is the same that is required to insert rows into the DSN_PROFILE_TABLE and DSN_PROFILE_ATTRIBUTES tables.

Built-in global variables
Built-in global variables are provided with the database manager and are used in SQL statements to retrieve scalar values associated with the variables.

Profile tables (Db2 Performance)

Built-in session variables

Db2 provides several built-in session variables that contain information about the server and application process. The value of a built-in session variable can be obtained by invoking the GETVARIABLE function with the name of the built-in session variable.

Db2 provides the following built-in session variables:

SYSIBM.APPLICATION_ENCODING_SCHEME
Contains a string that corresponds to the value that is specified for the APPLICATION ENCODING field on the DSNTIPF installation panel. The value will be EBCDIC, ASCII, UNICODE, or 1-65533, and this session variable can never be null.

SYSIBM.COBOL_STRING_DELIMITER
Contains a string that corresponds to the value that is specified for the STRING DELIMITER field on the DSNTIPF installation panel. The value will be DEFAULT, ", or ', and this session variable can never be null.

SYSIBM.DATA_SHARING_GROUP_NAME
Contains a string that corresponds to the name of the data sharing group for this Db2 subsystem. If the subsystem is not part of data sharing group, the null value is returned.

SYSIBM.DATE_FORMAT
Contains a string that corresponds to the value that is specified for the DATE FORMAT field on the DSNTIP4 installation panel. The value will be ISO, JIS, USA, EUR, or LOCAL, and this session variable can never be null.

SYSIBM.DATE_LENGTH
Contains a string that corresponds to the value that is specified for the LOCAL DATE LENGTH field on the DSNTIP4 installation panel. The value will be 10-254, or 0 for no exit, and this session variable can never be null.

SYSIBM.DECIMAL_ARITHMETIC
Contains a string that corresponds to the value that is specified for the DECIMAL ARITHMETIC field on the DSNTIP4 installation panel. The value will be DEC15, DEC31, 15, or 31, and this session variable can never be null.

SYSIBM.DECIMAL_POINT
Contains a string that corresponds to the value that is specified for the DECIMAL POINT IS field on the DSNTIPF installation panel. The value will be '.' or ',' and this session variable can never be null.

SYSIBM.DEFAULT_DECFLOAT_ROUND_MODE
Contains a string that corresponds to the value that is specified for the DECFLOAT ROUNDING MODE field on the DSNTIPF installation panel. This session variable can never be null.

SYSIBM.DEFAULT_SSID
Contains a string that corresponds to the value that is specified for the GROUP ATTACH field on the DSNTIPK installation panel or the SUBSYSTEM NAME field on the DSNTIPM installation panel. This session variable can never be null.

SYSIBM.DEFAULT_LANGUAGE
Contains a string that corresponds to the value that is specified for the LANGUAGE DEFAULT field on the DSNTIPF installation panel. The value will be ASM, C, CPP, IBMCOB, FORTRAN, or PL/I, and this session variable can never be null.

SYSIBM.DEFAULT_LOCALE_LC_CTYPE
Contains a string that corresponds to the value that is specified for the LOCALE LC_CTYPE field on the DSNTIPF installation panel. This session variable can never be null.

SYSIBM.DISTRIBUTED_SQL_STRING_DELIMITER
Contains a string that corresponds to the value that is specified for the DIST SQL STR DELIMTR field on the DSNTIPF installation panel. The value will be ", or ', and this session variable can never be null.

SYSIBM.DSNHDECP_NAME
Contains a string that corresponds to the fully qualified data set name of the data set from which the DSNHDECP or a user-specified application defaults module was loaded. For instance, 'DSN910.SDSNEXIT(DSNHDECP)'. This session variable can never be null.

SYSIBM.DYNAMIC_RULES
Contains a string that corresponds to the value that is specified for the USE FOR DYNAMICRULES field on the DSNTIP4 installation panel. The value will be YES or NO, and this session variable can never be null.

SYSIBM.ENCODING_SCHEME
Contains a string that corresponds to the value that is specified for the DEF ENCODING SCHEME field on the DSNTIPF installation panel. The value will be EBCDIC, ASCII, or UNICODE, and this session variable can never be null.

SYSIBM.MIXED_DATA
Contains a string that corresponds to the value that is specified for the MIXED DATA field on the DSNTIPF installation panel. The value will be YES or NO, and this session variable can never be null.

SYSIBM.NEWFUN
Contains a string that represents the default maximum level of the SQL function syntax that is accepted by the Db2 precompiler or the Db2 coprocessor, regardless of the Db2 function level. For more information about the NEWFUN option, see Descriptions of SQL processing options.

SYSIBM.PACKAGE_NAME
Contains a string that corresponds to the name of the package that is currently being executed. If a package is not currently being executed, the null value is returned. (This situation can occur when the plan that is being executed bound one or more DBRMs directly).

SYSIBM.PACKAGE_SCHEMA
Contains a string that corresponds to the collection ID of the package that is currently being executed. If a package is not currently being executed, the null value is returned.

SYSIBM.PACKAGE_VERSION
Contains a string that corresponds to the version of the package that is currently being executed. If a package is not currently being executed, the null value is returned.

SYSIBM.PAD_NUL_TERMINATED
Contains a string that corresponds to the value that is specified for the PAD NUL-TERMINATED field on the DSNTIP4 installation panel. The value will be YES or NO, and this session variable can never be null.

SYSIBM.PLAN_NAME
Contains a string that corresponds to the name to the plan that is currently being executed. This session variable can never be null.

SYSIBM.SECLABEL
Contains a string that corresponds to the RACF SECLABEL value, if any, that has been defined for the current userid. If a value has not been defined, the null value is returned.

SYSIBM.SQL_STRING_DELIMITER

Contains a string that corresponds to the value that is specified for the SQL STRING DELIMITER field on the DSNTIPF installation panel. The value will be DEFAULT, ", or ', and this session variable can never be null.

SYSIBM.SSID

Contains a string that corresponds to the actual Db2 subsystem identifier for this Db2 subsystem. This session variable can never be null.

SYSIBM.STANDARD_SQL

Contains a string that corresponds to the value that is specified for the STD SQL LANGUAGE field on the DSNTIP4 installation panel. The value will be YES or NO, and this session variable can never be null.

SYSIBM.SYSTEM_NAME

Contains a string that corresponds to the name of the Db2 for z/OS subsystem, as defined in field SUBSYSTEM NAME on installation panel DSNTIPM. This session variable can never be null.

SYSIBM.SYSTEM_ASCII_CCSID

Contains a value that represents the ASCII CCSIDs that are in use on this system. The information is returned as a comma-delimited string that corresponds to the ASCII CCSID that was specified on installation panel DSNTIPF. The three values that are returned correspond to the SBCS, MIXED, and graphic CCSID that are in use for ASCII data on this system. A value of 65534 for the MIXED or graphic CCSID indicates that this system does not support storing data in that CCSID. This session variable can never be null.

SYSIBM.SYSTEM_EBCDIC_CCSID

Contains a value that represents the EBCDIC CCSIDs that are in use on this system. The information is returned as a comma-delimited string that corresponds to the EBCDIC CCSID that was specified on installation panel DSNTIPF. The three values that are returned correspond to the SBCS, MIXED, and graphic CCSID that are in use for EBCDIC data on this system. A value of 65534 for the MIXED or graphic CCSID indicates that this system does not support storing data in that CCSID. This session variable can never be null.

SYSIBM.SYSTEM_UNICODE_CCSID

Contains a value that represents the Unicode CCSIDs that are in use on this system. The information is returned as a comma-delimited string that corresponds to the UNICODE CCSID that was specified on installation panel DSNTIPF. The three values that are returned correspond to the SBCS, MIXED, and graphic CCSID that are in use for Unicode data on this system. This session variable can never be null.

SYSIBM.TIME_FORMAT

Contains a string that corresponds to the value that is specified for the TIME FORMAT field on the DSNTIP4 installation panel. The value will be ISO, JIS, USA, EUR, or LOCAL, and this session variable can never be null.

SYSIBM.TIME_LENGTH

Contains a string that corresponds to the value that is specified for the LOCAL TIME LENGTH field on the DSNTIP4 installation panel. The value will be 8-254 or 0 for no exit, and this session variable can never be null.

SYSIBM.VERSION

Contains a string that represents the version of Db2.

The product identifier (PRDID) value is an 8-byte character value in *pppvvrrm* format, where: *ppp* is a 3-letter product code; *vv* is the version;*rr* is the release; and *m* is the modification level. In Db2 12 for z/OS, the modification level indicates a range of function levels:

DSN12015 for V12R1M500 or higher.
DSN12010 for V12R1M100.

For more information, see Product identifier (PRDID) values in Db2 for z/OS (Db2 Administration Guide).

This session variable can never be null.

For example, the following statement sets the value of host variable *hv1* to the name of the plan that is currently being executed:

```
   SET :hv1 = GETVARIABLE('SYSIBM.PLAN_NAME');
```

For more information about the GETVARIABLE function, see “GETVARIABLE” on page 464.

Chapter 4. Built-in functions

A *function* is an operation denoted by a function name followed by zero or more input values that are enclosed in parentheses. It represents a relationship between a set of input values and a set of result values. The input values to a function are called *arguments*.

The types of functions are aggregate, scalar, and table. A built-in function is classified as a aggregate function or a scalar function. A user-defined function can be a column, scalar, or table function.

If a column mask is used to mask the column values in the final result table and a column mask is applied to a column that is an argument for a function, the result of the function might be different because the column mask is applied to the column before the function operation can take place. For example, applying a column mask to column SSN can change the result of the aggregate function, COUNT(DISTINCT SSN).

The DISTINCT operation is performed on the unmasked column values. The keyword DISTINCT is not an argument of the function but rather a specification of an operation that is performed before the function is applied. If DISTINCT is specified, redundant duplicate values are eliminated before column mask is applied. If the column in aggregate function with DISTINCT keyword has column mask definition references columns that are non-grouping column and not the target column of the DISTINCT operation, the result of aggregate function can vary. Db2 does not guarantee the same row is returned from a group of duplicates in each execution, thus, the values in those non-DISTINCT/non-grouping columns in the returned row could be different each time.

OLAP specification and functions

The RANK, DENSE_RANK, and ROW_NUMBER specifications are sometimes referred to as built-in 'functions'. Refer to "OLAP specifications" on page 279 for more information on these specifications.

Db2 MQ functions

Db2 MQ functions integrate IBM MQ messaging operations within SQL statements. The functions help you integrate IBM MQ messaging with database applications. You can use the functions to access IBM MQ messaging from within SQL statements and to combine IBM MQ messaging with Db2 database access.

The functions can be scalar or table functions. For more information on using IBM MQ functions, see the information on enabling IBM MQ functions in Additional steps for enabling IBM MQ user-defined functions (Db2 Installation and Migration) and on programming techniques in IBM MQ with Db2 (Db2 Application programming and SQL).

Administrative task scheduler functions

The administrative task scheduler table functions provide information and status about the tasks that are scheduled to run using the administrative task scheduler. The administrative task scheduler provides the ability to run stored procedures, JCL jobs, and other administrative tasks according to a time or an event-based schedule. For more information, see Scheduling administrative tasks (Db2 Administration Guide).

List of supported built-in functions

This section contains an alphabetical list of the built-in functions that Db2 for z/OS supports.

Table 66. Supported built-in functions

Function name	Description
"ABS or ABSVAL" on page 382	Returns the absolute value of its argument
"ACOS" on page 383	Returns the arc cosine of an argument as an angle, expressed in radians
FL 507 "ADD_DAYS" on page 383"1" on page 353	Returns a datetime value that represents the first argument plus a specified number of days

Table 66. Supported built-in functions (continued)

Function name	Description
"ADD_MONTHS" on page 384	Returns a date that represents the date argument plus the number of months argument
"ADMIN_TASK_LIST" on page 668	Returns a table with one row for each of the tasks that are defined in the administrative task scheduler task list
"ADMIN_TASK_OUTPUT" on page 672	Returns the output parameter values and result sets, if available. If the task that was executed is not a stored procedure or the requested execution status is not available, the function returns an empty table.
"ADMIN_TASK_STATUS" on page 674	Returns a table with one row for each task in the administrative task scheduler task list that contains the status for the last time the task was run
"ARRAY_AGG" on page 354	Returns an array in which each value of the input set is assigned to an element of the array
"ARRAY_DELETE" on page 386	Returns an array with the requested elements deleted.
"ARRAY_FIRST" on page 387	Returns the minimum array index value of an array.
"ARRAY_LAST" on page 388	Returns the maximum array index value of an array.
"ARRAY_NEXT" on page 389	Returns the next larger array index value for an array, relative to a specified array index argument.
"ARRAY_PRIOR" on page 391	Returns the next smaller array index value for an array, relative to a specified array index argument.
"ARRAY_TRIM" on page 392	Returns an array after removing elements from the end of an ordinary array.
"ASCII" on page 392	Returns the ASCII code value of the most character of the argument as an integer
"ASCII_CHR" on page 393	Returns the character that corresponds to the ASCII code value that is specified by the argument
"ASCII_STR or ASCIISTR" on page 393	Returns an ASCII version of the character or graphic string argument
"ASIN" on page 394	Returns the arc sine of an argument as an angle, expressed in radians
"ATAN" on page 395	Returns the arc tangent of an argument as an angle, expressed in radians
"ATANH" on page 395	Returns the hyperbolic arc tangent of an argument as an angle, expressed in radians
"ATAN2" on page 395	Returns the arc tangent of *x* and *y* coordinates as an angle, expressed in radians
"AVG" on page 357	Returns the average of a set of numbers
"BLOB" on page 400	Returns a BLOB representation of its argument
"BLOCKING_THREADS" on page 677	Returns a table with one row for each lock or claim that threads hold against the databases that are specified in the input parameter
"BIGINT" on page 396	Returns a big integer representation of its argument

Table 66. Supported built-in functions (continued)

Function name	Description
“BITAND, BITANDNOT, BITOR, BITXOR, and BITNOT” on page 398	Return a corresponding base 10 integer value in a data type that is based on the data type of the input arguments
“BINARY” on page 397	Returns a fixed-length binary string representation of its argument
FL 507 “BTRIM” on page 401“1” on page 353	Removes the characters that are specified in a trim string from the beginning and end of a source string
“CARDINALITY” on page 402	Returns a value of that represents the number of elements of an array
“CCSID_ENCODING” on page 403	Returns the encoding scheme of a CCSID with a value of ASCII, EBCDIC, UNICODE, or UNKNOWN
“CEILING or CEIL” on page 404	Returns the smallest integer greater than or equal to the argument
“CHAR” on page 404	Returns a fixed-length character string representation of its argument
FL 506“CHARACTER_LENGTH or CHAR_LENGTH” on page 413	Returns the length of its argument in the number of string units that are specified
“CHR” on page 414	Returns the character that corresponds to the ASCII code value that is specified by the argument
“CLOB” on page 415	Returns a CLOB representation of the first argument
“COALESCE” on page 417	Returns the first argument in a set of arguments that is not null
“COLLATION_KEY” on page 418	Returns a string that represents the collation key of the argument in the specified collation
“COMPARE_DECFLOAT” on page 420	Returns a SMALLINT value that indicates whether two arguments are equal, or unordered, or whether one argument is greater than the other
“CONCAT” on page 421	Returns the concatenation of two strings
“CONTAINS” on page 422	Returns a result about whether or not a match was found during a search of a text search index
“CORR or CORRELATION” on page 357	Returns the coefficient of the correlation of a set of number pairs
“COS” on page 424	Returns the cosine of an argument that is expressed as an angle in radians
“COSH” on page 425	Returns the hyperbolic cosine of an argument that is expressed as an angle in radians
“COUNT” on page 358	Returns the number of rows or values in a set of rows or values
“COUNT_BIG” on page 359	Same as COUNT, except the result can be greater than the maximum value of an integer
FL 506 “COVAR_POP or COVARIANCE or COVAR” on page 360	Returns the population covariance of a set of number pairs
“COVAR_SAMP or COVARIANCE_SAMP” on page 361	Returns unbiased sample covariance (n-1) of a set of number pairs
FL 504 CUME_DIST“1” on page 353	Returns a cumulative distribution of a row in an OLAP window

Table 66. Supported built-in functions (continued)

Function name	Description
FL 504 "CUME_DIST (aggregate)" on page 361"1" on page 353	Returns the cumulative distribution of a row that is hypothetically inserted into a group of rows
"DATE" on page 425	Returns a date derived from its argument
"DAY" on page 426	Returns the day part of its argument
"DAYOFMONTH" on page 427	Similar to DAY
"DAYOFWEEK" on page 428	Returns an integer in the range 1 - 7, where 1 represents Sunday
"DAYOFWEEK_ISO" on page 429	Returns an integer in the range 1 - 7, where 1 represents Monday
"DAYOFYEAR" on page 431	Returns an integer in the range 1 - 366, where 1 represents January 1
"DAYS" on page 432	Returns an integer representation of a date
FL 507 "DAYS_BETWEEN" on page 432"1" on page 353	Returns the number of full days between the specified arguments
"DBCLOB" on page 434	Returns a DBCLOB representation of its argument
"DECIMAL or DEC" on page 441	Returns a decimal representation of its argument
"DECFLOAT" on page 436	Returns a DECFLOAT representation of its argument
"DECFLOAT_FORMAT" on page 438	Returns a DECFLOAT(34) value that is based on the interpretation of the input string using the specified format
"DECFLOAT_SORTKEY" on page 440	Returns a binary value that can be used when sorting DECFLOAT values
"DECODE" on page 442	Returns a specified *result-expression* based on a comparison of input expressions (similar to the CASE expression)
"DECRYPT_BINARY, DECRYPT_BIT, DECRYPT_CHAR, and DECRYPT_DB" on page 444	Returns the decrypted value of an encrypted argument that was encrypted using the ENCRYPT_TDES function
FL 505 "DECRYPT_DATAKEY_INTEGER, DECRYPT_DATAKEY_BIGINT, DECRYPT_DATAKEY_DECIMAL, DECRYPT_DATAKEY_VARCHAR, DECRYPT_DATAKEY_CLOB, DECRYPT_DATAKEY_VARGRAPHIC, DECRYPT_DATAKEY_DBCLOB, and DECRYPT_DATAKEY_BIT" on page 446	Returns the decrypted value of an encrypted argument that was encrypted using the algorithm that was specified when the data was encrypted
"DEGREES" on page 449	Returns the number of degrees for an argument that is expressed in radians
"DIFFERENCE" on page 449	Returns a value that represents the difference between the sounds of two strings based on applying the SOUNDEX function to the strings
"DIGITS" on page 450	Returns a character string representation of a number
"DOUBLE_PRECISION or DOUBLE" on page 451	Returns a double precision floating-point representation of its argument
"DSN_XMLVALIDATE" on page 452	Returns an XML value that is the result of applying XML schema validation to the first argument

Table 66. Supported built-in functions (continued)

Function name	Description
“EBCDIC_CHR” on page 453	Returns the character that corresponds to the EBCDIC code value that is specified by the argument
“EBCDIC_STR” on page 453	Returns an EBCDIC version of the string argument
FL 505 “ENCRYPT_DATAKEY” on page 454	Returns the argument as an encrypted value using the specified key label and algorithm
“ENCRYPT_TDES or ENCRYPT” on page 456	Returns the argument as an encrypted value using the Triple DES encryption algorithm
“EXP” on page 458	Returns the exponential function of an argument
“EXTRACT” on page 458	Returns a portion of a date or timestamp based on its arguments
FL 504 FIRST_VALUE“1” on page 353	Returns the expression value for the first row in an OLAP window
“FLOAT” on page 461	Same as DOUBLE
“FLOOR” on page 461	Returns the largest integer that is less than or equal to the argument
“GENERATE_UNIQUE and GENERATE_UNIQUE_BINARY” on page 462	Returns a character string of bit data that is unique compared to any other execution of the function
“GETHINT” on page 463	Returns the embedded password hint from encrypted data, if one exists
“GETVARIABLE” on page 464	Returns a varying-length character string representation of the value of a session variable
“GRAPHIC” on page 465	Returns a fixed-length graphic string representation of its argument
“GREATEST” on page 470	Returns the maximum value in a set of values
“GROUPING” on page 363	Returns a value that indicates if a row returned in a GROUP BY result is a row generated by a grouping set that excludes the column represented by its argument
FL 506 “HASH” on page 470	Returns a varying-length value that is the result of applying the specified algorithm to the first argument. It is intended for cryptographic purposes.
“HASH_CRC32, HASH_MD5, HASH_SHA1, and HASH_SHA256” on page 472	Return a fixed-length value that is the result of applying a hash algorithm to an input argument. They are intended for cryptographic purposes.
FL 506 “HEX” on page 474	Returns a hexadecimal representation of its argument
“HOUR” on page 474	Returns the hour part of its argument
“IDENTITY_VAL_LOCAL” on page 475	Returns the most recently assigned value for an identity column
“IFNULL” on page 479	Returns the first argument in a set of two arguments that is not null
“INSERT” on page 479	Returns a string that is composed of an argument inserted into another argument at the same position where some number of bytes have been deleted

Table 66. Supported built-in functions (continued)

Function name	Description
"INSTR" on page 482	Returns the starting position of the first occurrence of one string within another string
"INTEGER or INT" on page 482	Returns an integer representation of its argument
"JULIAN_DAY" on page 483	Returns an integer that represents the number of days from January 1, 4712 B.C.
FL 504 LAG"1" on page 353	Returns the expression value for the row at offset rows before the current row
"LAST_DAY" on page 484	Returns a date that represents the last day of the month of the date argument
FL 504 LAST_VALUE"1" on page 353	Returns the expression value for the last row in an OLAP window
"LCASE" on page 486	Returns a string with the characters converted to lowercase
FL 504 LEAD"1" on page 353	Returns the expression value for the row at offset rows after the current row
"LEAST" on page 486	Returns the minimum value in a set of values
"LEFT" on page 486	Returns a string that consists of the specified number of most bytes or the specified string units
"LENGTH" on page 488	Returns the length of its argument
"LN" on page 489	Returns the natural logarithm of an argument
"LOCATE" on page 490	Returns the starting position of one string within another string
"LOCATE_IN_STRING" on page 492	Returns the starting position of the first occurrence of one string within another string
"LOG10" on page 494	Returns the base 10 logarithm of an argument
"LOWER" on page 494	Returns a string with the characters converted to lowercase
"LPAD" on page 497	Returns a string that is padded on the with blanks or a specified string
"LTRIM" on page 499	Returns the characters of a string with the leading blanks or hexadecimal zeros removed
"MAX (aggregate)" on page 367	Returns the maximum value in a set of column values in a group
"MAX (scalar)" on page 501	Returns the maximum value in a set of values
"MAX_CARDINALITY" on page 501	Returns a value of type BIGINT that represents the maximum number of elements that an array can contain. This value is the cardinality that was specified in the CREATE TYPE statement for an ordinary array type.
"MICROSECOND" on page 502	Returns the microsecond part of its argument
"MIDNIGHT_SECONDS" on page 503	Returns an integer in the range 0 - 86400 that represents the number of seconds between midnight and the argument
"MIN (aggregate)" on page 369	Returns the minimum value in a set of values in a group
"MIN (scalar)" on page 504	Returns the minimum value in a set of values
"MINUTE" on page 505	Returns the minute part of its argument

Table 66. Supported built-in functions (continued)

Function name	Description
"MOD" on page 506	Returns the remainder of one argument divided by a second argument
"MONTH" on page 507	Returns the month part of its argument
"MONTHS_BETWEEN" on page 508	Returns an estimate of the number of months between two arguments
"MQREAD" on page 509	Returns a message from a specified IBM MQ location (return value of VARCHAR) without removing the message from the queue
"MQREADALL" on page 684	Returns a table containing the messages and message metadata from a specified IBM MQ location with a VARCHAR column and without removing the messages from the queue
"MQREADALLCLOB" on page 686	Returns a table containing the messages and message metadata from a specified IBM MQ location with a CLOB column and without removing the messages from the queue
"MQREADCLOB" on page 511	Returns a message from a specified IBM MQ location (return value of CLOB) without removing the message from the queue
"MQRECEIVE" on page 512	Returns a message from a specified IBM MQ location (return value of VARCHAR) with removal of message from the queue
"MQRECEIVEALL" on page 688	Returns a table containing the messages and message metadata from a specified IBM MQ location with a VARCHAR column and with removal of messages from the queue
"MQRECEIVEALLCLOB" on page 690	Returns a table containing the messages and message metadata from a specified IBM MQ location with a CLOB column and with removal of messages from the queue
"MQRECEIVECLOB" on page 513	Returns a message from a specified IBM MQ location (return value of CLOB) with removal of message from the queue
"MQSEND" on page 515	Sends data to a specified IBM MQ location, and returns a varying-length character string that indicates whether the function was successful or unsuccessful
"MULTIPLY_ALT" on page 517	Returns the product of the two arguments as a decimal value, used when the sum of the argument precisions exceeds 31
"NEXT_DAY" on page 518	Returns a timestamp that represents the first weekday, specified by the second argument, after the date argument
FL 507 "NEXT_MONTH" on page 519"1" on page 353	Returns the first day of the next month after the specified date
"NORMALIZE_DECFLOAT" on page 519	Returns a DECFLOAT value that is the result of normalizing the input argument
"NORMALIZE_STRING" on page 520	Returns a string value that is the result of normalizing the input Unicode value
FL 504 NTH_VALUE"1" on page 353	Returns the expression value for the nth-row row in an OLAP window
FL 504 NTILE"1" on page 353	Returns the quantile rank of a row
"NULLIF" on page 521	Returns NULL if the arguments are equal; else the first argument

Table 66. Supported built-in functions (continued)

Function name	Description
"NVL" on page 522	Returns the first argument that is not null
"OVERLAY" on page 522	Returns a string that is composed of an argument inserted into another argument at the same position where some number of bytes have been deleted
"PACK" on page 526	Returns a binary string value that contains a data type array and a packed representation of each non-null argument
"PERCENTILE_DISC" on page 371	Returns a percentile of a set of values
FL 504 PERCENT_RANK"1" on page 353	Returns a relative percentile rank of a row in an OLAP window
FL 504 "PERCENT_RANK (aggregate)" on page 372"1" on page 353	Returns the relative percentile rank of a row that is hypothetically inserted into a group of rows
"POSITION" on page 529	Returns the position of the first occurrence of an argument within another argument where the position is expressed in terms of the string units that are specified
"POSSTR" on page 531	Returns the position of the first occurrence of an argument within another argument
FL 506 "POWER or POW" on page 533	Returns the value of one argument raised to the power of a second argument
"QUANTIZE" on page 533	Returns a DECFLOAT value that is equal in value (except for any rounding) and sign to the first argument and which has an exponent set to be equal to the exponent of the second argument
"QUARTER" on page 535	Returns an integer in the range 1 - 4 that represents the quarter of the year for the date specified in the argument
"RADIANS" on page 535	Returns the number of radians for an argument that is expressed in degrees
"RAISE_ERROR" on page 536	Raises an error in the SQLCA with the specified SQLSTATE and error description
FL 506 "RANDOM or RAND" on page 537	Returns a double precision floating-point random number
FL 504 RATIO_TO_REPORT"1" on page 353	Returns the ratio of an argument to the sum of the arguments in an OLAP partition
"REAL" on page 537	Returns a single precision floating-point representation of its argument
FL 504 "REGEXP_COUNT" on page 538"1" on page 353	Returns a count of the number of times that a regular expression pattern is matched in a string
FL 504 "REGEXP_INSTR" on page 540"1" on page 353	Returns the starting or ending position of the matched substring, depending on the value of the **return_option** argument
FL 504 "REGEXP_LIKE" on page 543"1" on page 353	Returns an INTEGER value of 0 or 1 indicating if the regular expression pattern is found in a string
FL 504 "REGEXP_REPLACE" on page 545"1" on page 353	Returns a modified version of the source string where occurrences of the regular expression pattern found in the source string are replaced with the specified replacement string
FL 504 "REGEXP_SUBSTR" on page 548"1" on page 353	Returns one occurrence of a substring of a string that matches the regular expression pattern

Table 66. Supported built-in functions (continued)

Function name	Description
FL 507 REGR_AVGX, REGR_AVGY, REGR_SXX, REGR_SXY, and REGR_SYY"1" on page 353	Return quantities that can be used to compute various diagnostic statistics needed for the evaluation of the quality and statistical validity of a regression model
FL 507 REGR_COUNT"1" on page 353	Returns the number of non-null number pairs used to fit a regression line
FL 507 REGR_INTERCEPT or REGR_ICPT"1" on page 353	Returns the y-intercept of a regression line ("b" in the equation y = a * x + b)
FL 507 REGR_R2"1" on page 353	Returns the coefficient of determination ("R-squared" or "goodness-of-fit") for a regression
FL 507 REGR_SLOPE"1" on page 353	Returns the slope of a regression line ("a" in the equation y = a * x + b)
"REPEAT" on page 550	Returns a character string composed of an argument repeated a specified number of times
"REPLACE" on page 551	Returns a string in which all occurrences of an argument within a second argument are replaced with a third argument
"RID" on page 554	Returns the RID of a row
"RIGHT" on page 555	Returns a string that consists of the specified number of rightmost bytes or specified string units
"ROUND" on page 557	Returns a number rounded to the specified number of places to the right or of the decimal place
"ROUND_TIMESTAMP" on page 558	Returns a timestamp rounded to the unit specified by the timestamp format string
"ROWID" on page 562	Returns a row ID representation of its argument
"RPAD" on page 562	Returns a string that is padded on the right with blanks or a specified string
"RTRIM" on page 564	Returns the characters of an argument with the trailing blanks or hexadecimal zeros removed
"SCORE" on page 565	Returns a relevance score that measures how well a document matches the query used to search a text search index
"SECOND" on page 567	Returns the second part of its argument
"SIGN" on page 569	Returns the sign of an argument
"SIN" on page 569	Returns the sine of an argument that is expressed as an angle in radians
"SINH" on page 570	Returns the hyperbolic sine of an argument that is expressed as an angle in radians
"SMALLINT" on page 570	Returns a small integer representation of its argument
"SOAPHTTPC and SOAPHTTPV" on page 572	Returns a CLOB or VARCHAR representation of XML data from a request to a web service
"SOAPHTTPNC and SOAPHTTPNV" on page 573	Returns a complete CLOB or VARCHAR representation of XML data from a complete request to a web service

Table 66. Supported built-in functions (continued)

Function name	Description
"SOUNDEX" on page 571	Returns a value that represents the sound of the words in the argument
"SPACE" on page 574	Returns a string that consists of the number of blanks the argument specifies
"SQRT" on page 574	Returns the square root of its argument
"STDDEV_POP or STDDEV" on page 376	Returns the population standard deviation (division by *n*) of a set of numbers
"STDDEV_SAMP" on page 377	Returns the sample standard deviation (division by *n*-1) of a set of numbers
"STRIP" on page 575	Returns the characters of a string with the blanks (or specified character) at the beginning, end, or both beginning and end of the string removed
FL 506 "STRLEFT" on page 575	Returns a string that consists of the specified number of most bytes or the specified string units
FL 506 "STRPOS" on page 575	Returns the position of the first occurrence of an argument within another argument
FL 506 "STRRIGHT" on page 576	Returns a string that consists of the specified number of rightmost bytes or specified string units
"SUBSTR" on page 576	Returns a substring of a string
"SUBSTRING" on page 578	Returns a substring of a string using the specified string units
"SUM" on page 378	Returns the sum of a set of numbers
"TAN" on page 582	Returns the tangent of an argument that is expressed as an angle in radians
"TANH" on page 582	Returns the hyperbolic tangent of an argument that is expressed as an angle in radians
"TIME" on page 583	Returns a time derived from its argument
"TIMESTAMP" on page 583	Returns a timestamp derived from its arguments
"TIMESTAMPADD" on page 586	Returns a timestamp derived from adding the specified interval to a timestamp
"TIMESTAMP_FORMAT" on page 590	Returns a timestamp for a character string expression, using a specified format to interpret the string
"TIMESTAMP_ISO" on page 594	Returns a timestamp derived from its arguments
"TIMESTAMPDIFF" on page 587	Returns an estimated number of the specified intervals based on the difference between two timestamps
"TIMESTAMP_TZ" on page 595	Returns a timestamp with a time zone derived from its arguments
"TO_CHAR" on page 597	Returns a character string representation of a timestamp value that has been formatted using a specified character template
FL 506 "TO_CLOB" on page 597	Returns a CLOB representation of the first argument
"TO_DATE" on page 598	Returns a timestamp value that is based on the interpretation of the input string using the specified format

Table 66. Supported built-in functions (continued)

Function name	Description
“TO_NUMBER” on page 598	Returns a DECFLOAT(34) value that is based on the interpretation of the input string using the specified format
“TOTALORDER” on page 598	Returns a SMALLINT value that indicates the comparison order of two arguments
FL 506 “TO_TIMESTAMP” on page 599	Returns a timestamp for a character string expression, using a specified format to interpret the string
“TRANSLATE” on page 599	Returns a string with one or more characters translated
“TRIM” on page 602	Removes bytes from the beginning, from the end, or from both the beginning and end of a string expression
“TRIM_ARRAY” on page 604	Returns an array after removing elements from the end of an ordinary array.
“TRUNCATE or TRUNC” on page 605	Returns a number truncated to the specified number of places to the right or of the decimal point
“TRUNC_TIMESTAMP” on page 606	Returns a timestamp truncated to the unit specified by the timestamp format string
“UCASE” on page 609	Returns a string with the characters converted to uppercase
“UNICODE” on page 609	Returns the Unicode (UTF-16) code value of the most character of the argument as an integer
“UNICODE_STR or UNISTR” on page 610	Returns a string in Unicode (UTF-8 or UTF-16) that represents a Unicode encoding of the argument
“UNPACK” on page 695	Returns a row of values that are derived from unpacking the input binary string. It is used to unpack a string that was encoded according to the PACK function
“UPPER” on page 611	Returns a string with the characters converted to uppercase
“VALUE” on page 613	Same as COALESCE
“VARBINARY” on page 613	Returns a varying-length binary string representation of its argument
“VARCHAR” on page 614	Returns the varying-length character string representation of its argument
“VARCHAR9” on page 619	Returns the fixed-length character string representation of its argument
“VARCHAR_FORMAT” on page 622	Returns a varying-length character string representation of a timestamp, with the string in a specified format
“VARGRAPHIC” on page 631	Returns a varying-length graphic string representation of its argument
“VAR_POP or VARIANCE or VAR ” on page 378	Returns the biased variance (division by *n*) of a set of numbers
“VAR_SAMP or VARIANCE_SAMP” on page 379	Returns the sample variance (division by *n*-1) of a set of numbers

Table 66. Supported built-in functions (continued)

Function name	Description
“VERIFY_GROUP_FOR_USER” on page 636	Returns a value that indicates whether the primary authorization ID and the group authorization IDs that are associated with the first argument are included in the authorization names that are specified in the list of the second argument.
“VERIFY_ROLE_FOR_USER” on page 637	Returns a value that indicates whether the roles that are associated with the first argument are included in the role names that are specified in the list of the second argument
“VERIFY_TRUSTED_CONTEXT_ROLE_FOR_USER” on page 639	Returns a value that indicates whether the authorization ID that is associated with first argument has acquired a role in a trusted connection and whether that acquired role is included in the role names that are specified in the list of the second argument
“WEEK” on page 640	Returns an integer that represents the week of the year with Sunday as the first day of the week
“WEEK_ISO” on page 641	Returns an integer that represents the week of the year with Monday as first day of a week
“XMLAGG” on page 380	Returns an XML type that represents a concatenation of XML elements from a collection of XML elements
“XMLATTRIBUTES” on page 643	Returns an XML sequence that contains an XQuery attribute node for each non-null argument
“XMLCOMMENT” on page 644	Returns an XML value with a single comment node from a string expression
“XMLCONCAT” on page 644	Returns an XML value that represents a forest of XML elements generated by concatenating a variable number of arguments
“XMLDOCUMENT” on page 645	Returns an XML value with a single document node and zero or more nodes as its children
“XMLELEMENT” on page 646	Returns an XML value that represents an XML element
“XMLFOREST” on page 650	Returns an XML value that represents a forest of XML elements that all share a specific pattern
“XMLMODIFY” on page 652	Returns an XML value that might have been modified by the evaluation of an XQuery updating expression and XQuery variables that are specified as input arguments
“XMLNAMESPACES” on page 655	Returns the declaration of one or more XML namespaces
“XMLPARSE” on page 656	Returns an XML value from parsing the argument as an XML document
“XMLPI” on page 658	Returns an XML value with a single processing instruction node
“XMLQUERY” on page 658	Returns an XML value from the evaluation of an XPath expression against a set of arguments
“XMLSERIALIZE” on page 661	Returns an SQL character string or a BLOB value from an XML value
“XMLTABLE” on page 692	Returns a result table from the evaluation of XQuery expressions, possibly using specified input arguments as XQuery variables
“XMLTEXT” on page 664	Returns an XML value with a single text node that contains the value of the argument

Table 66. Supported built-in functions (continued)

Function name	Description
“XMLXSROBJECTID” on page 665	Returns the XSR object identifier of the XML schema that is used to validate the XML document specified in the argument
“XSLTRANSFORM” on page 666	The XSLTRANSFORM function transforms an XML document into a different data format. The output can be any form possible for the XSLT processor, including but not limited to XML, HTML, and plain text. **Note:** This is a Db2-supplied user-defined function.
“YEAR” on page 667	Returns the year part of its argument

Notes:

1. Supported in Db2 for z/OS as a passthrough-only expression, which is passed through to IBM Db2 Analytics Accelerator for z/OS. For more information, see Accelerating queries with passthrough-only expressions.

Aggregate functions

An aggregate function, which is also known as a *set function*, receives a set of values for each argument (such as the values of a column) and returns a single-value result for the set of input values. Certain rules apply to all aggregate functions.

The following information applies to all aggregate functions, except for the COUNT(*) and COUNT_BIG(*), variations of the COUNT and COUNT_BIG functions, and the XMLAGG function.

The argument of an aggregate function is a set of values derived from an expression. The expression must not include another aggregate function or a scalar fullselect. The scope of the set is a group or an intermediate result table, as explained in the information on the GROUP BY clause.

If a GROUP BY clause is specified in a query and the intermediate result from the FROM, WHERE, GROUP BY, and HAVING clauses is the empty set, then the aggregate functions are not applied and the result of the query is the empty set.

If the GROUP BY clause is not specified in a query and the intermediate result table of the FROM, WHERE, and HAVING clauses is the empty set, then the aggregate functions are applied to the empty set.

For example, the result of the following SELECT statement is the number of distinct values of JOB for employees in department D11:

```
SELECT COUNT(DISTINCT JOB)
  FROM DSN8C10.EMP
  WHERE WORKDEPT = 'D11';
```

The keyword DISTINCT is not an argument of the function but rather a specification of an operation that is performed before the function is applied. If DISTINCT is specified, redundant duplicate values are eliminated before column mask is applied. If the column in aggregate function with DISTINCT keyword has column mask definition references columns that are non-grouping column and not the target column of the DISTINCT operation, the result of aggregate function can vary. Db2 does not guarantee the same row is returned from a group of duplicates in each execution, thus, the values in those non-DISTINCT/non-grouping columns in the returned row could be different each time.

DISTINCT must not be specified preceding an XML value.

For compatibility with other SQL implementations, UNIQUE can be specified as a synonym for DISTINCT in aggregate functions.

When interpreting the DISTINCT clause for decimal floating-point values that are numerically equal, the number of significant digits in the value is not considered. For example, the decimal floating-point number

123.00 is not distinct from the decimal floating-point number 123. The representation of the number returned from the query will be any one of the representations encountered (for example, either 123.00 or 123).

An aggregate function can be used in a WHERE clause only if that clause is part of a subquery of a HAVING clause and the column name specified in the expression is a correlated reference to a group. If the expression includes more than one column name, each column name must be a correlated reference to the same group.

The result of the COUNT and COUNT_BIG functions cannot be the null value. As specified in the description of AVG, MAX, MIN, STDDEV, SUM, and VARIANCE, the result is the null value when the function is applied to an empty set. However, the result is also the null value when the function is specified in an outer select list, the argument is given by an arithmetic expression, and any evaluation of the expression causes an arithmetic exception (such as division by zero).

If the argument values of an aggregate function are strings from a column with a field procedure, the function is applied to the encoded form of the values and the result of the function inherits the field procedure.

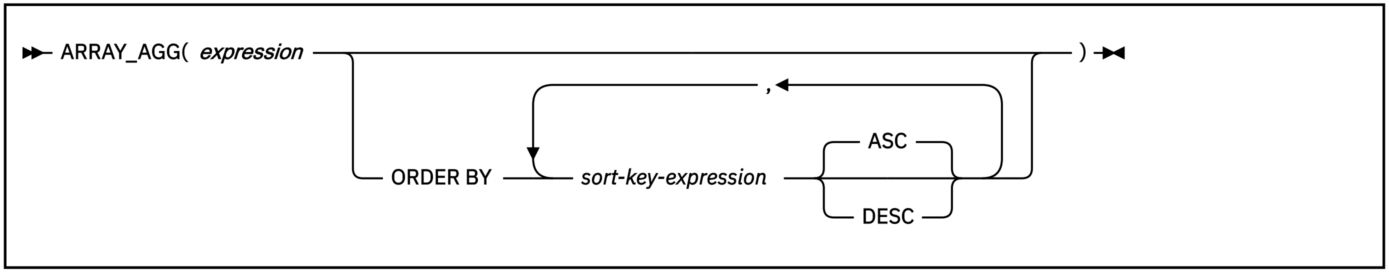
Related reference

group-by-clause
The GROUP BY clause specifies a result table that consists of a grouping of the rows of intermediate result table that is the result of the previous clause.

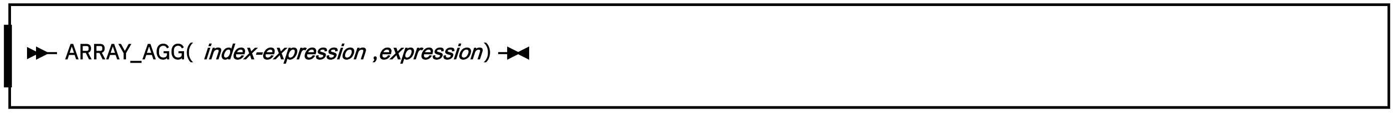
ARRAY_AGG

The ARRAY_AGG function returns an array in which each value of the input set is assigned to an element of the array.

Syntax for ordinary array aggregation



Syntax for associative array aggregation



The schema is SYSIBM.

Ordinary array aggregation

expression

Specifies an expression that returns a value with a data type that is valid for an array element. The data type of the expression must be a data type that can be specified in a CREATE TYPE (array) statement.

expression must not contain a scalar fullselect.

ORDER BY

Specifies the order of the rows from the same grouping set that are processed in the aggregation. If the ORDER BY clause is not specified, or if the ORDER BY clause cannot differentiate the order of the sort key value, the rows in the same grouping set are arbitrarily ordered.

If a SELECT clause includes multiple invocations of the ARRAY_AGG function, all invocations of ARRAY_AGG in the same SELECT clause that explicitly specify an ORDER BY clause must specify the same order, or not specify an order.

sort-key-expression

Specifies a sort key value that is either a column name or an expression. *sort-key-expression* must not reference a column for which a column mask is defined.

If the sort key value is a constant, the constant does not refer to the position of the output column, but is simply a constant, which implies that there is no sort key.

ASC

Processes the sort key in ascending order. This is the default option.

DESC

Processes the sort key in descending order.

Associative array aggregation

index-expression

Specifies an expression for the index of the associative array.

When the ARRAY_AGG function is invoked in a context in which there is a target user-defined array data type in the same statement, or the result of the ARRAY_AGG function is explicitly cast to a user-defined array data type, the data type of *index-expression* must be castable to the index data type of the target associative array data type. Otherwise, the expression must return a value with a data type that is valid for an array element. The data type of the expression must be a data type that can be specified in a CREATE TYPE (Array) statement.

Duplicate *index-expression* values must not exist in the grouping set that is used to produce the associative array.

expression

Specifies an expression that returns a value with a data type that is valid for an array element. The data type of the expression must be a data type that can be specified in a CREATE TYPE (array) statement.

The result data type of ARRAY_AGG is an array. The data type of an array element of the result array is the same as the type of *expression*.

The ARRAY_AGG function can be invoked only in the following contexts:

- The SELECT list of a SELECT INTO statement
- The SELECT list of the outermost fullselect in the definition of a cursor that is not scrollable, in an SQL PL context
- The SELECT list of a scalar subquery that provides a source value for a SET *assignment-statement* or SQL PL *assignment-statement*
- A RETURN statement in an SQL scalar function

The following restrictions apply to ARRAY_AGG:

- ARRAY_AGG cannot be used as part of an OLAP specification.
- A fullselect that contains an invocation of ARRAY_AGG cannot contain an ORDER BY clause.
- A fullselect that contains an invocation of ARRAY_AGG cannot contain a DISTINCT keyword in its SELECT list.
- The SELECT clause or HAVING clause of the fullselect that contains an invocation of ARRAY_AGG cannot contain a subquery.
- A SELECT clause that includes an invocation of the ARRAY_AGG function that returns an array of LOBs must not also include a GROUP BY clause.
- A SELECT clause that includes an invocation of the ARRAY_AGG function must not also include an invocation of the LISTAGG function or the XMLAGG function.

Examples for ARRAY_AGG

- Use ARRAY_AGG in an assignment statement to assign the values of the DECIMALARRAY ordinary array to the array INTARRAY.

```
SET INTARRAY = (SELECT ARRAY_AGG(VAL) FROM UNNEST(DECIMALARRAY) AS T(VAL));
```

- Use ARRAY_AGG in a SELECT INTO statement to assign the values of the ESALARIES ordinary array to the array ARRAY2.

```
SELECT ARRAY_AGG(T.VAL) INTO ARRAY2 FROM UNNEST(ESALARIES) AS T(VAL);
```

- Use ARRAY_AGG to aggregate a set of phone numbers into an ordinary array. The array elements are then assigned to ordinary array NUMBERS in order by priority, or in arbitrary order. Suppose that user-defined type PHONELIST and table EMPLOYEE have the following definitions:

```
CREATE TYPE PHONELIST AS DECIMAL(10,0) ARRAY[10];

CREATE TABLE EMPLOYEE ( ID INTEGER NOT NULL,
 PRIORITY INTEGER NOT NULL,
 PHONENUMBER DECIMAL(10,0),
 PRIMARY KEY(ID, PRIORITY)) ;
```

The following SQL PL procedure uses a SELECT INTO statement that returns a list of contact numbers under which an employee can be reached, ordered by priority.

```
CREATE PROCEDURE GETPHONENUMBERS
 (IN EMPID INTEGER,
 OUT NUMBERS PHONELIST)
 BEGIN
  SELECT ARRAY_AGG(PHONENUMBER ORDER BY PRIORITY)
   INTO NUMBERS
   FROM EMPLOYEE
  WHERE ID = EMPID;
 END
```

The following SQL PL procedure uses SET *assignment-statement* to return the list of contact numbers in an arbitrary order.

```
CREATE PROCEDURE GETPHONENUMBERS
 (IN EMPID INTEGER,
 OUT NUMBERS PHONELIST)
 BEGIN
  SET NUMBERS =
   (SELECT ARRAY_AGG(PHONENUMBER)
     FROM EMPLOYEE
     WHERE ID = EMPID);
 END
```

- Use ARRAY_AGG to aggregate a set of phone numbers into an associative array. The array elements are then assigned to associative array EMPLOYEES.

Suppose that user-defined type EMPPHONES and table EMPLOYEE have the following definitions:

```
CREATE TYPE EMPPHONES AS DECIMAL(10,0) ARRAY[INTEGER];

CREATE TABLE EMPLOYEE ( ID INTEGER NOT NULL,
 PRIORITY INTEGER NOT NULL,
 PHONENUMBER DECIMAL(10,0),
 PRIMARY KEY(ID, PRIORITY)) ;
```

Create a procedure that uses a SELECT INTO statement to aggregate priority 1 phone numbers into an associative array that is indexed by IDs from the EMPLOYEE table.

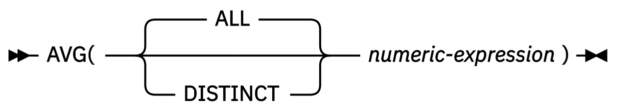
```

CREATE PROCEDURE GETPHONES
(OUT EMPLOYEES EMPPHONES)
BEGIN
SELECT ARRAY_AGG(ID, PHONENUMBER)
INTO EMPLOYEES
```

```
FROM EMPLOYEE WHERE PRIORITY=1;
END
```

AVG

The AVG function returns the average of a set of numbers.



The schema is SYSIBM.

The argument values can be of any built-in numeric data type, and their sum must be within the range of the data type of the result.

The arguments can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34).

The data type of the result is determined as follows:

- DECFLOAT(34) if the argument is DECFLOAT(*n*).
- Large integer if the argument is small integer.
- Double precision floating-point if the argument is single precision floating-point.
- Otherwise, the result is the same as the data type of the argument.

The result can be null.

If the data type of the argument values is decimal with precision *p* and scale *s*, the precision (P) and scale (S) of the result depend on *p* and the decimal precision option:

- If *p* is greater than 15 or the DEC31 option is in effect, P is 31 and S is `max(0,28-`*p*`+`*s*`)`.
- Otherwise, P is 15 and S is 15-*p*+*s*.

The function is applied to the set of values derived from the argument values by the elimination of null values. If DISTINCT is specified, redundant duplicate values are also eliminated.

If the function is applied to an empty set, the result is the null value. Otherwise, the result is the average value of the set. The order in which the summation part of the operation is performed is undefined but every intermediate result must be within the range of the result data type.

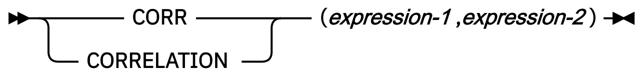
If the type of the result is integer, the fractional part of the average is lost.

Example: Assuming DEC15, set the DECIMAL(15,2) variable AVERAGE to the average salary in department D11 of the employees in the sample table DSN8C10.EMP.

```
EXEC SQL SELECT AVG(SALARY)
  INTO :AVERAGE
  FROM DSN8C10.EMP
  WHERE WORKDEPT = 'D11';
```

CORR or CORRELATION

The CORR function returns the coefficient of the correlation of a set of number pairs.



The schema is SYSIBM.

The argument values must each be the value of any built-in numeric data type.

If an argument is DECFLOAT(*n*), the result of the function is DECFLOAT(34). Otherwise, the result of the function is double precision floating-point. The result is between -1 and 1. The result can be null.

The function is applied to the set of (*expression-1*, *expression-2*) pairs derived from the argument values by the elimination of all pairs for which either *expression-1* or *expression-2* is null.

If the function is applied to an empty set, or if either STDDEV(*expression-1*) or STDDEV(*expression-2*) is equal to zero, the result is a null value. Otherwise, the result is the correlation coefficient for the value pairs in the set. The result is equivalent to the following expression:

```
COVARIANCE(expression-1,expression-2)/
  (STDDEV(expression-1)* STDDEV(expression-2))
```

The order in which the values are aggregated is undefined, but every intermediate result must be within the range of the result data type.

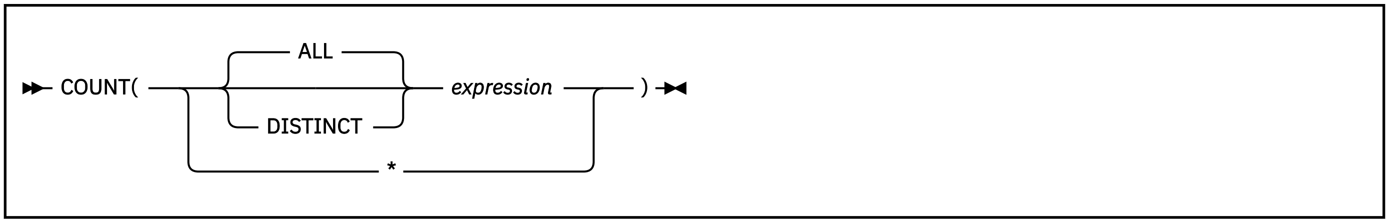
Using sample table DSN8C10.EMP, set the host variable :corrln (double-precision floating point) to the correlation between the salary and the bonus for those employees in department (WORKDEPT) 'A00'.

```
   SELECT CORRELATION(SALARY, BONUS) INTO :corrln
       FROM DSN8C10.EMP WHERE WORKDEPT = 'A00';
```

:corrln is set to approximately 9.99853953399538E-001.

COUNT

The COUNT function returns the number of rows or values in a set of rows or values.



The schema is SYSIBM.

The argument values can be of any built-in data type other than a BLOB, CLOB, DBCLOB, or XML.

The result is a large integer. The result cannot be null.

The argument of COUNT(*) is a set of rows. The result is the number of rows in the set. Any row that includes only null values is included in the count.

The argument of COUNT(*expression*) or COUNT(ALL *expression*) is a set of values. The function is applied to the set of values derived from the argument values by the elimination of null values. The result is the number of nonnull values in the set, including duplicates.

The argument of COUNT(DISTINCT *expression*) is a set of values. The function is applied to the set of values derived from the argument values by the elimination of null values and redundant duplicate values. The result is the number of different nonnull values in the set.

Example 1: Set the integer host variable FEMALE to the number of females represented in the sample table DSN8C10.EMP.

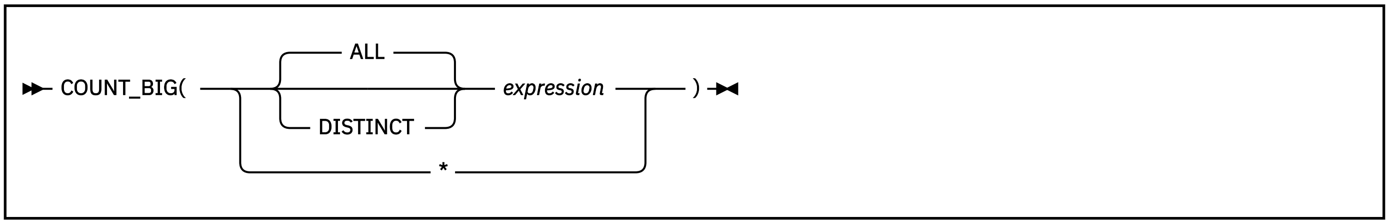
```
   EXEC SQL SELECT COUNT(*)
     INTO :FEMALE
     FROM DSN8C10.EMP
     WHERE SEX = 'F';
```

Example 2: Set the integer host variable FEMALE_IN_DEPT to the number of departments that have at least one female as a member.

```
EXEC SQL SELECT COUNT(DISTINCT WORKDEPT)
  INTO :FEMALE_IN_DEPT
  FROM DSN8C10.EMP
  WHERE SEX = 'F';
```

COUNT_BIG

The COUNT_BIG function returns the number of rows or values in a set of rows or values. It is similar to COUNT except that the result can be greater than the maximum value of an integer.



The schema is SYSIBM.

The argument values can be of any built-in data type other than a BLOB, CLOB, DBCLOB, or XML.

The result of the function is a decimal number with precision 31 and scale 0. The result cannot be null.

The argument of `COUNT_BIG(*)` is a set of rows. The result is the number of rows in the set. A row that includes only null values is included in the count.

The argument of `COUNT_BIG(`*`expression`*`)` or `COUNT_BIG(ALL` *`expression`* is a set of values. The function is applied to the set of values derived from the argument values by the elimination of null values. The result is the number of nonnull values in the set, including duplicates.

The argument of `COUNT_BIG(DISTINCT` *`expression`*`)` is a set of values. The function is applied to the set of values derived from the argument values by the elimination of null and redundant duplicate values. The result is the number of different nonnull values in the set.

Example 1: Set the integer host variable FEMALE to the number of females represented in the sample table DSN8C10.EMP.

```
EXEC SQL SELECT COUNT_BIG(*)
  INTO :FEMALE
  FROM DSN8C10.EMP
  WHERE SEX = 'F';
```

Example 2: Set the integer host variable FEMALE_IN_DEPT to the number of departments that have at least one female as a member.

```
EXEC SQL SELECT COUNT_BIG(DISTINCT WORKDEPT)
  INTO :FEMALE_IN_DEPT
  FROM DSN8C10.EMP
  WHERE SEX = 'F';
```

Example 3: To create a sourced function that is similar to the built-in COUNT_BIG function, the definition of the sourced function must include the type of the column that can be specified when the new function is invoked. In this example, the CREATE FUNCTION statement creates a sourced function that takes a CHAR column as input and uses COUNT_BIG to perform the counting. The result is returned as a double precision floating-point number. The query shown counts the number of unique departments in the sample employee table.

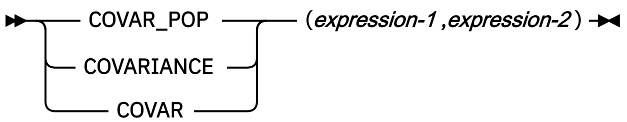
```
CREATE FUNCTION RICK.COUNT(CHAR()) RETURNS DOUBLE
       SOURCE SYSIBM.COUNT_BIG(CHAR());
SET CURRENT PATH RICK, SYSTEM PATH;
SELECT COUNT(DISTINCT WORKDEPT) FROM DSN8C10.EMP;
```

The empty parenthesis in the parameter list for the new function (RICK.COUNT) means that the input parameter for the new function is the same type as the input parameter for the function named in the SOURCE clause. The empty parenthesis in the parameter list in the SOURCE clause (SYSIBM.COUNT_BIG) means that the length attribute of the CHAR parameter of the COUNT_BIG function is ignored when Db2 locates the COUNT_BIG function.

COVAR_POP or COVARIANCE or COVAR

The COVAR_POP function returns the population covariance of a set of number pairs.

FL 506



The schema is SYSIBM.

The argument values must each be the value of any built-in numeric data type.

If an argument is DECFLOAT(*n*), the result of the function is DECFLOAT(34). Otherwise, the result of the function is double precision floating-point. The result can be null.

The function is applied to the set of (*expression-1*, *expression-2*) pairs that are derived from the argument values by the elimination of all pairs for which either *expression-1* or *expression-2* is null.

If the function is applied to an empty set, the result is a null value. Otherwise, the result is the population covariance of the value pairs in the set. The result is equivalent to the following output:

1. Let *avgexp1* be the result of AVG(*expression-1*) and let *avgexp2* be the result of AVG(*expression-2*).
2. The result of COVARIANCE(*expression-1*,*expression-2*) is AVG((*expression-1* - *avgexp1*) * (*expression-2* - *avgexp2*))

The order in which the values are aggregated is undefined, but every intermediate result must be within the range of the result data type.

Example

Using sample table DSN8C10.EMP, set the host variable COVARNCE (double-precision floating-point) to the population covariance between the salary and the bonus for those employees in department (WORKDEPT) 'A00'.

```
SELECT COVARIANCE(SALARY, BONUS)
 INTO :covarnce
  FROM DSN8C10.EMP
  WHERE WORKDEPT = 'A00'
```

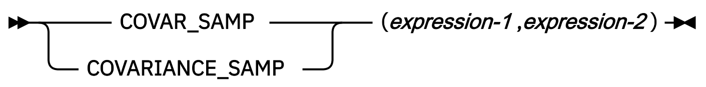
The value of COVARNCE is set to 1743000.

Notes

Syntax alternatives:
COVAR_POP should be used for conformance to the SQL standard.

COVAR_SAMP or COVARIANCE_SAMP

The COVAR_SAMP function returns unbiased sample covariance (n-1) of a set of number pairs.



The schema is SYSIBM.

The argument values must each be the value of any built-in numeric data type.

If an argument is DECFLOAT(*n*), the result of the function is DECFLOAT(34). Otherwise, the result of the function is double precision floating-point. The result can be null.

The function is applied to the set of (*expression-1*, *expression-2*) pairs that are derived from the argument values by the elimination of all pairs for which either *expression-1* or *expression-2* is null.

If the function is applied to an empty set, the result is a null value. Otherwise, the result is the sample covariance of the value pairs in the set. The result is equivalent to the following output:

1. Let *samp_avgexp1* be the result of `SUM(`*`expression-1`*`)/`*`n`*`-1` and let *samp_avgexp2* be the result of `SUM(`*`expression-2`*`)/`*`n`*`-1`.
2. The result of `COVAR_SAMP(`*`expression-1, expression-2`*`)` is `AVG((`*`expression-1 - samp_avgexp1`*`) * (`*`expression-2 - samp_avgexp2`*`))`

The order in which the values are aggregated is undefined, but every intermediate result must be within the range of the result data type.

The following restrictions apply to COVAR_SAMP:

- COVAR_SAMP cannot be used as part of an OLAP specification.

Notes

Syntax alternatives:
COVAR_SAMP should be used for conformance to the SQL standard.

Example

Using sample table DSN8C10.EMP, set the host variable COVARNCE (double-precision floating point) to the sample covariance between the salary and the bonus for those employees in department (WORKDEPT) 'A00'.

```
SELECT COVAR_SAMP(SALARY, BONUS)
  INTO :COVARNCE
  FROM DSN8C10.EMP
  WHERE WORKDEPT = 'A00';
```

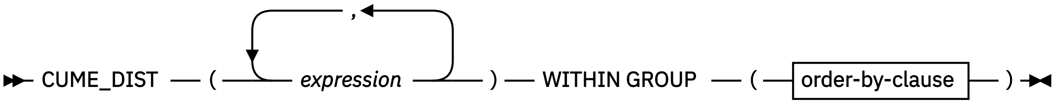
The value of COVARNCE is set to 2178750.

CUME_DIST (aggregate)

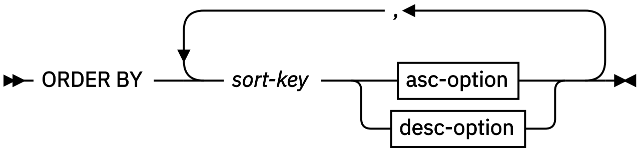
The CUME_DIST function returns the cumulative distribution of a row that is hypothetically inserted into a group of rows.

FL 504

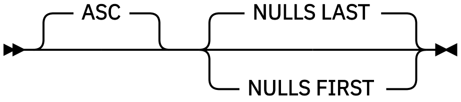
Passthrough-only expression: This function is passthrough-only and cannot run on Db2 for z/OS without acceleration. For information about invoking this function, see Accelerating queries with passthrough-only expressions.



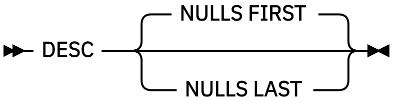
order-by-clause



asc-option



desc-option



The schema is SYSIBM.

expression
An expression that specifies a row that is hypothetically inserted into a group of rows. The expression must return a value that is a built-in data type. The expression must be a constant, a variable, or a cast of a constant or variable.

WITHIN GROUP
Indicates that the aggregation follows the specified ordering within the grouping set.

order-by-clause

ORDER BY
Specifies the order of the rows from the same grouping set that are processed in the aggregation.

sort-key
The sort key can be a column name or a sort-key-expression. If the sort key is a constant, it does not refer to the position of the output column (as in the ordinary ORDER BY clause), but it is a constant, which implies no sort key.

ASC
Uses the values of the *sort-key* in ascending order.

DESC
Uses the values of the *sort-key* in descending order.

NULLS FIRST
The ordering considers null values before all non-null values in the sort order.

NULLS LAST
The ordering considers null values after all non-null values in the sort order.

The number of expressions must be the same as the number of sort-key expressions. The data type of each expression and the data type of the corresponding sort-key expression must be compatible.

The data type of the result is DECFLOAT(34). The actual result is greater than 0.0 and less than or equal to 1.0.

Example

Set the host variable CD to the cumulative distribution of a hypothetical new employee's salary of 47000 within the salaries of the employees in department 'A00'.

```
SELECT CUME_DIST(47000) WITHIN GROUP (ORDER BY SALARY)
   INTO :CD FROM EMPLOYEE WHERE WORKDEPT = 'A00'
```

Related concepts

How Db2 determines whether to accelerate eligible queries (Db2 Performance)

GROUPING

When used in conjunction with *grouping-sets* and *super-groups*, the GROUPING function returns a value that indicates if a row returned in a GROUP BY result is a row generated by a grouping set that excludes the column represented by *expression*.

▶▶— GROUPING(*expression*) —▶◀

The schema is SYSIBM.

expression

An expression that matches a *grouping-expression* from the GROUP BY clause of the same subselect.

The result of the function is a small integer value. The result is one of the following values:

1

The value of *expression* in the returned row is a null value, and the row was generated by the *super-group*. This generated row can be used to provide *sub-total* values for the GROUP BY expression.

0

The value is other than the previously listed value.

Example

```
SELECT SALES_DATE, SALES_PERSON,
    SUM(SALES) AS UNITS_SOLD,
    GROUPING(SALES_DATE) AS DATE_GROUP,
    GROUPING(SALES_PERSON) AS SALES_GROUP
  FROM SALES
  GROUP BY CUBE (SALES_DATE, SALES_PERSON)
  ORDER BY SALES_DATE, SALES_PERSON;
```

The previous query returns results similar to the following:

```
SALES_DATE SALES_PERSON    UNITS_SOLD  DATE_GROUP  SALES_GROUP
---------- --------------- ----------- ----------- -----------
12/31/1995 GOUNOT                    1           0           0
12/31/1995 LEE                       6           0           0
12/31/1995 LUCCHESSI                 1           0           0
12/31/1995 -                         8           0           1
03/29/1996 GOUNOT                   11           0           0
03/29/1996 LEE                      12           0           0
03/29/1996 LUCCHESSI                 4           0           0
03/29/1996 -                        27           0           1
03/30/1996 GOUNOT                   21           0           0
03/30/1996 LEE                      21           0           0
03/30/1996 LUCCHESSI                 4           0           0
03/30/1996 -                        46           0           1
03/31/1996 GOUNOT                    3           0           0
03/31/1996 LEE                      27           0           0
03/31/1996 LUCCHESSI                 1           0           0
03/31/1996 -                        31           0           1
04/01/1996 GOUNOT                   14           0           0
04/01/1996 LEE                      25           0           0
04/01/1996 LUCCHESSI                 4           0           0
04/01/1996 -                        43           0           1
-          GOUNOT                   50           1           0
-          LEE                      91           1           0
-          LUCCHESSI                14           1           0
-          -                       155           1           1
```

An application can identify a SALES_DATE *sub-total* row because the value of DATE_GROUP is 0 and the value of SALES_GROUP is 1. A SALES_PERSON *sub-total* row can be identified because the value of DATE_GROUP is 1 and the value of SALES_GROUP is 0. A *grand total* row can be identified by the value 1 for both DATE_GROUP and SALES_GROUP.

Related reference

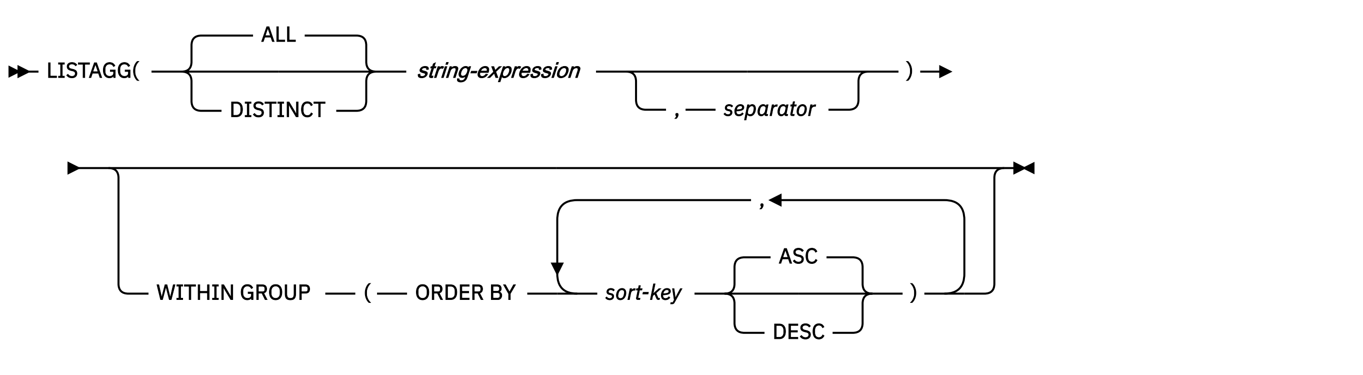
group-by-clause
The GROUP BY clause specifies a result table that consists of a grouping of the rows of intermediate result table that is the result of the previous clause.

Examples of grouping sets, rollup, and cube queries
You can use GROUPING SETS, ROLLUP, and CUBE clauses of the GROUP BY clause in subselect queries.

LISTAGG

The LISTAGG function aggregates a set of strings into one string by concatenating the strings. Optionally, a separator string can be provided which is inserted between contiguous input strings.

FL 501



The schema is SYSIBM.

The LISTAGG function aggregates a set of string values for a group into one string by appending the *string-expression* values based on the order that is specified in the WITHIN GROUP clause.

The function is applied to the set of values that are derived from the first argument by the elimination of null values. If a separator argument is specified that is not the null value, the separator value is inserted between each pair of non-null *string-expression* values.

string-expression
An expression that specifies the string values to aggregate. The expression must return a value that is a built-in character string, graphic string, or a binary string data type that is not a LOB. If the value is a CLOB, it is implicitly cast to VARCHAR before the function is evaluated up to a maximum length of 32704. If the value is a DBCLOB, it is implicitly cast to VARGRAPHIC before the function is evaluated up to a maximum length of 16352. If the value is a BLOB, it is implicitly cast to VARBINARY before the function is evaluated up to a maximum length of 32704.

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type.

If *string-expression* is a column encoded by a field procedure, the decoded value is used in the result.

separator
A constant expression that defines the string that is to be used between non-null *string-expression* values. The expression must return a value that is a built-in character string, graphic string, or a binary string data type.

LOBs are supported through implicit casting. If the value is a CLOB, it is implicitly cast to VARCHAR before the function is evaluated up to a maximum length of 32704. If the value is a DBCLOB, it is implicitly cast to VARGRAPHIC before the function is evaluated up to a maximum length of 16352.

If the value is a BLOB, it is implicitly cast to VARBINARY before the function is evaluated up to a maximum length of 32704.

The separator can be a literal, special register, variable, or an expression that is based on literals, special registers, or variables, provided that the expression does not include a non-deterministic function or a function that takes an external action.

WITHIN GROUP
Indicates that the aggregation follows the specified ordering within the grouping set.

If WITHIN GROUP is not specified, the ordering of strings within the result is not deterministic.

ORDER BY
Specifies the order of the rows from the same grouping set that are processed in the aggregation. If the ORDER BY clause cannot distinguish the order of the column data, the rows in the same grouping set are arbitrarily ordered.

sort-key
The sort key can be a column name or a *sort-key-expression*. If the sort key is a constant, it does not refer to the position of the output column (as in the ORDER BY clause of a query); It is a constant, which implies no sort key.

If the sort key value is a constant, the constant does not refer to the position of the output column, but is simply a constant, which implies that there is no sort key.

sort-key must not include a scalar fullselect, or any function that is non-deterministic or has an external action. *sort-key* must not reference a column for which a column mask is defined.

If *sort-key* is encoded by a field procedure, the encoded value determines the order.

ASC
Processes the *sort-key* in ascending order. This is the default option.

DESC
Processes the *sort-key* in descending order.

Result

The result data type of LISTAGG is based on the data type of *string-expression*, as shown in the following table:

Data type of string-expression	**Result data type and length**
CHAR(*n*) or VARCHAR(*n*)	VARCHAR(MIN(MAX(4000,*n*), 32704)
GRAPHIC(*n*) or VARGRAPHIC(*n*)	VARGRAPHIC(MIN(MAX(2000,*n*), 16352)
BINARY(*n*) or VARBINARY(*n*)	VARBINARY(MIN(MAX(4000,*n*), 32704)

The result data type can exceed VARCHAR(4000), VARBINARY(4000), or VARGRAPHIC(2000), if a derived size is used to determine the size of the result. The maximum possible value is the maximum for the result data type. The following example yields a return data type of VARCHAR(10000):

```
LISTAGG(CAST(NAME AS VARCHAR(10000)),',')
```

If the actual length of the aggregated result string exceeds the maximum for the result data type, an error is returned.

The result can be null. If the function is applied to an empty set, or all of the *string-expression* values in the set are null values, the result is a null value.

The following rules also apply:

- If the *string-expression* and *separator* are both bit data, the result is bit data. Otherwise, neither *string-expression* nor *separator* can be bit data.

- If *string-expression* and *separator* are both SBCS Unicode data, the CCSID of the result is the CCSID for SBCS Unicode data.
- If *string-expression* is SBCS Unicode data, and *separator* is not SBCS Unicode data, the CCSID of the result is the mixed CCSID for Unicode data.
- Otherwise, the CCSID of the result is the mixed CCSID that corresponds to the CCSID of *string-expression*. However, if the input is EBCDIC or ASCII and there is no corresponding system CCSID for mixed, the CCSID of the result is the CCSID of *string-expression*.

Results for accelerators: When multiple tables are joined, the result can differ when LISTAGG runs on an accelerator instead of Db2 for z/OS. To guarantee the same result from both environments, you can use an ORDER BY clause in a unique *sort-key* expression. This approach ensures that the result set is the always the same. However, the order of rows in the result can still differ, unless the statement also specifies a unique GROUP BY clause for the *sort-key* expression.

Rules

The following restrictions apply to LISTAGG:

- LISTAGG cannot be used as part of an OLAP specification.
- If DISTINCT is specified for LISTAGG, ORDER BY must be specified and the first *sort-key* of the ORDER BY specification must exactly match *string-expression*.
- A fullselect that contains an invocation of LISTAGG cannot contain an ORDER BY clause.
- A fullselect that contains an invocation of LISTAGG cannot contain a DISTINCT keyword in its SELECT list.
- A SELECT clause that includes an invocation of the LISTAGG function must not also include an invocation of the ARRAY_AGG function or the XMLAGG function.

Example

Produce an alphabetical list of comma-separated names, grouped by department, from the sample employee table.

```
SELECT WORKDEPT,
 LISTAGG(LASTNAME, ', ') WITHIN GROUP(ORDER BY LASTNAME)
 AS EMPLOYEES
 FROM EMP
 GROUP BY WORKDEPT;
```

The following result is returned.

```
---------+---------+---------+---------+---------+---------+---------+---------+---------+-------
WORKDEPT  EMPLOYEES
---------+---------+---------+---------+---------+---------+---------+---------+---------+-------
A00       HAAS, HEMMINGER, LUCCHESI, O'CONNELL, ORLANDO
B01       THOMPSON
C01       KWAN, NATZ, NICHOLLS, QUINTANA
D11       ADAMSON, BROWN, JOHN, JONES, LUTZ, PIANKA, SCOUTTEN, STERN, WALKER, YAMAMOTO, YOSHIMURA
D21       JEFFERSON, JOHNSON, MARINO, MONTEVERDE, PEREZ, PULASKI, SMITH
E01       GEYER
E11       HENDERSON, PARKER, SCHNEIDER, SCHWARTZ, SETRIGHT, SMITH, SPRINGER
E21       ALONZO, GOUNOT, LEE, MEHTA, SPENSER, WONG
```

Related reference

Employee table (DSN8C10.EMP) (Introduction to Db2 for z/OS)

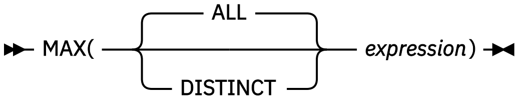
Function level 501 (activation enabled by APAR PI70535 - May 2017) (Db2 for z/OS What's New?)

Related information

Grouping values by using the LISTAGG function (Db2 Programming samples)

MAX (aggregate)

The MAX function returns the maximum value in a set of values of a group.



The schema is SYSIBM.

The arguments must be compatible. For more information on compatibility, refer to the compatibility matrix in Table 30 on page 144. All arguments except the first argument can be parameter markers.

expression

An expression that returns the value of a built-in data type. Each expression must return a value that is not a CLOB, DBCLOB, BLOB, ROWID, or XML. Character string arguments and binary string arguments cannot have a length attribute greater than 32704, and graphic string arguments cannot have a length attribute greater than 16352.

If there are any mixed character string or graphic string and numeric arguments, the string value is implicitly cast to a DECFLOAT(34) value.

The result of the function is the largest argument value. The data type of the result and its other attributes (for example, the length and CCSID of a string or a datetime value) are the same as the data type and attributes of the argument values. The result can be null.

The function is applied to the set of values derived from the argument values by the elimination of null values.

If the function is applied to an empty set, the result is the null value. Otherwise, the result is the maximum value in the set.

The specification of DISTINCT has no effect on the result and is not advised.

Examples

Example 1: Set the DECIMAL(8,2) variable MAX_SALARY to the maximum monthly salary of the employees represented in the sample table DSN8C10.EMP.

```
EXEC SQL SELECT MAX(SALARY) / 12
  INTO :MAX_SALARY
  FROM DSN8C10.EMP;
```

Example 2: Find the surname that comes last in the collating sequence for the employees represented in the sample table DSN8C10.EMP. Set the VARCHAR(15) variable *LAST_NAME* to that surname.

```
EXEC SQL SELECT MAX(LASTNAME)
  INTO :LAST_NAME
  FROM DSN8C10.EMP;
```

MEDIAN

The MEDIAN function returns the median of a set of numbers.

The schema is SYSIBM.

numeric-expression

An expression that returns a built-in numeric data type. *numeric-expression* must not include a scalar fullselect, or invoke a function that is non-deterministic or has an external action. *numeric-expression* must not reference a column for which a column mask is defined

If the argument is DECFLOAT(*n*), the result of the function is DECFLOAT(34). Otherwise, the result of the function is a double precision floating-point number.

The function is applied to the set of values that are derived from the argument values by the elimination of null values.

The result can be null. If *numeric-expression* is null or if the function is applied to the empty set, the result is the null value.

Specifying MEDIAN(*numeric-expression*) is equivalent to specifying PERCENTILE_CONT(0.5) WITHIN GROUP (ORDER BY numeric-expression).

Examples for MEDIAN

- The following statement calculates the median salary of the employees in department D11 from the EMPLOYEE table.

  ```
  SELECT MEDIAN(SALARY)
  FROM EMPLOYEE
  WHERE WORKDEPT = ‘D11’;
  ```

  The result is 24680.00. Department D11 has 11 employees. The middle row of a group of 11 values is the sixth row. The result of MEDIAN over that group is the value of the sixth row, which is 24680.00.

- The following statement calculates the median salary of the employees in department E21 from the EMPLOYEE table.

  ```
  SELECT MEDIAN(SALARY)
  FROM EMPLOYEE
  WHERE WORKDEPT = ‘E21’;
  ```

  The result is 24605.00. Department E21 has six employees. Because there are an even number of rows, the MEDIAN is computed by interpolating a value between the middle two rows. The middle two rows are the third row with the value 23840.00 and the fourth row with the value 25370.00. MEDIAN is computed by averaging those two values, which is 24605.00.

- The following statement calculates the median salary of the employees in department E21 from the EMPLOYEE table.

  ```
  SELECT MEDIAN(SALARY)
  FROM EMPLOYEE
  WHERE WORKDEPT = ‘E21’;
  ```

  The result is 24605.00. Department E21 has six employees. Because there are an even number of rows, the MEDIAN is computed by interpolating a value between the middle two rows. The middle two rows are the third row with the value 23840.00 and the fourth row with the value 25370.00. MEDIAN is computed by averaging those two values, which is 24605.00.

Notes for MEDIAN

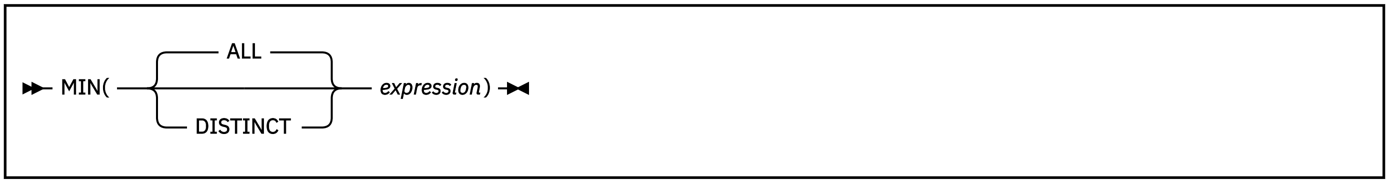
When EXPLAIN is issued against an SQL statement that references the MEDIAN function, but the statement cannot be run on the accelerator server for any reason, the following values are populated in the PLAN_TABLE table:

- For a SELECT statement, column QBLOCK_TYPE would have the value 'PRUNED', and column ACCESSTYPE would have the value ' ' (blank).
- For an INSERT statement with a subselect, the PLAN_TABLE rows for the subselect would have column QBLOCK_TYPE with the value 'NCOSUB', and column ACCESSTYPE with the value ' ' (blank).

Also, when a view is referenced in an SQL statement that uses the MEDIAN function, the tables referred to in the view must be enabled for acceleration. Those tables referred to in the view do not need to be enabled for acceleration when the view is created.

MIN (aggregate)

The MIN function returns the minimum value in a set of values of a group.



The schema is SYSIBM.

The arguments must be compatible. For more information on compatibility, refer to the compatibility matrix in Table 30 on page 144. All arguments except the first argument can be parameter markers.

expression

An expression that returns the value of a built-in data type. Each expression must return a value that is not a CLOB, DBCLOB, BLOB, ROWID, or XML. Character string arguments and binary string arguments cannot have a length attribute greater than 32704, and graphic string arguments cannot have a length attribute greater than 16352.

If there are any mixed character string or graphic string and numeric arguments, the string value is implicitly cast to a DECFLOAT(34) value.

The result of the function is the smallest argument value. The data type of the result and its other attributes (for example, the length and CCSID of a string or a datetime value) are the same as the data type and attributes of the argument values. The result can be null.

The function is applied to the set of values derived from the argument values by the elimination of null values.

If the function is applied to an empty set, the result is the null value. Otherwise, the result is the minimum value in the set.

The specification of DISTINCT has no effect on the result and is not advised.

Examples

Example 1: Set the DECIMAL(15,2) variable *MIN_SALARY* to the minimum monthly salary of the employees represented in the sample table DSN8C10.EMP.

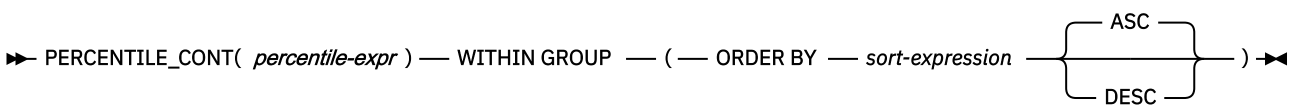
```
EXEC SQL SELECT MIN(SALARY) / 12
  INTO :MIN_SALARY
  FROM DSN8C10.EMP;
```

Example 2: Find the surname that comes first in the collating sequence for the employees represented in the sample table DSN8C10.EMP. Set the VARCHAR(15) variable *LAST_NAME* to that surname.

```
EXEC SQL SELECT MIN(LASTNAME)
  INTO :LAST_NAME
  FROM DSN8C10.EMP;
```

PERCENTILE_CONT

The PERCENTILE_CONT function returns a percentile of a set of values. The set of values is treated as a continuous distribution. The calculated percentile is an interpolated value that might not have appeared in the input set.



PERCENTILE_CONT(*percentile-expr*) WITHIN GROUP (ORDER BY *sort-expression*
ASC
DESC
)

The schema is SYSIBM.

percentile-expr
Specifies the percentile that is to be calculated by the function. *percentile-expr* must return a built-in numeric, character, or graphic string data type that is not a LOB. If the value is not a numeric data type is cast to DECFLOAT(34) before the function is evaluated. The value must be between 0 and 1.

WITHIN GROUP
Specifies that the percentile is to be calculated over the rows that are identified in the group.

sort-expression
Specifies the set of values over which to calculate the percentile and the order of the set. *sort-expression* must return a built-in numeric data type. A string value is implicitly cast to a numeric value. *sort-expression* must not include a scalar fullselect, or any function that is non-deterministic or has an external action. *sort-key-expression* must not reference a column for which a column mask is defined.

ASC
Specifies that the percentile is calculated using values from *sort-expression* in ascending order.

DESC
Specifies that the percentile is calculated using values from *sort-expression* in descending order.

The result is the value at the percentile that is specified by *percentile-expr* over the set of values identified by *sort-expression*.

For PERCENTILE_CONT, the set of values is treated as a continuous distribution. The calculated percentile is a interpolated value that might not have appeared in the input set. If the argument is DECFLOAT(*n*), the result of the function is DECFLOAT(34). Otherwise, the result of the function is a double-precision floating point number.

The function is applied to the set of values that are derived from *sort-expression* by the elimination of null values.

The result can be null. If *percentile-expr* is null, or if the function is applied to an empty set, the result is the null value.

The result of using `PERCENTILE_CONT(0.5) WITHIN GROUP (ORDER BY` *`sort-expression`*`)` is equivalent to `MEDIAN(`*`numeric-expression`*`)`.

Examples for PERCENTILE_CONT

- This example calculates the median salary of the employees in department D11 from the EMP table.

```
SELECT PERCENTILE_CONT(0.5) WITHIN GROUP (ORDER BY SALARY)
FROM DSN8C10.EMP
WHERE WORKDEPT = ‘D11’;
```

The result is 24,680.00. Department D11 has 11 employees. The middle row of a group of 11 values in the sixth row. Because there are an odd number of rows, the PERCENTILE_CONT function for the percentile 0.5 returns the value of the sixth row, which is 24,680.00.

- This example calculates the median commission of the employees in department E21 from the EMP table.

```
SELECT PERCENTILE_CONT(0.5) WITHIN GROUP (ORDER BY COMM)
FROM DSN8C10.EMP
WHERE WORKDEPT = ‘E21’;
```

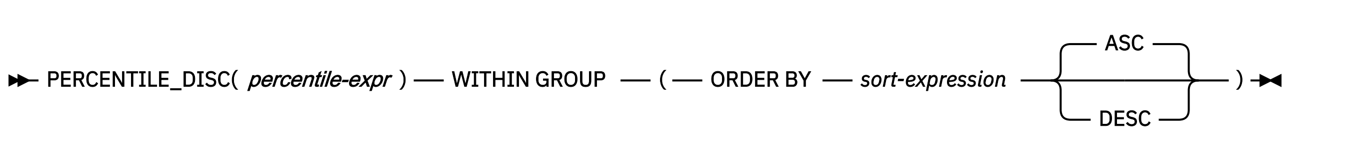
  The result is 1968.50. This example has an even number of rows, so the PERCENTILE_CONT function is computed by interpolating a value between the two middle rows. The two middle rows are row three with a value of 1907.00 and row four with a value of 2030.00. PERCENTILE_CONT is computed by averaging those two values, which is 1968.50.

- This example calculates the 95th percentile of total salary per department from the EMP table.

```
SELECT PERCENTILE_CONT(0.95) WITHIN GROUP (ORDER BY SALARY+BONUS)
FROM DSN8C10.EMP
GROUP BY WORKDEPT;
```

PERCENTILE_DISC

The PERCENTILE_DISC function returns a percentile of a set of values. Each value in the input set is treated as a discrete value. The calculated percentile is always a value that appeared in the input set.



The schema is SYSIBM.

percentile-expr
Specifies the percentile that is to be calculated by the function. *percentile-expr* must return a built-in numeric, character, or graphic string data type that is not a LOB. If the value is not a numeric data type is cast to DECFLOAT(34) before the function is evaluated. The value must be between 0 and 1.

WITHIN GROUP
Specifies that the percentile is to be calculated over the rows that are identified in the group.

sort-expression
Specifies the set of values over which to calculate the percentile and the order of the set. *sort-expression* must return a built-in numeric data type. *sort-expression* must not include a scalar fullselect, or any function that is non-deterministic or has an external action. *sort-key-expression* must not reference a column for which a column mask is defined.

ASC
Specifies that the percentile is calculated using values from *sort-expression* in ascending order.

DESC
Specifies that the percentile is calculated using values from *sort-expression* in descending order.

The result is the value at the percentile that is specified by *percentile-expr* over the set of values identified by *sort-expression*.

For PERCENTILE_DISC, each value in the input set is treated as a discrete value. The calculated percentile is always a value that appeared in the input set. The data type of the result is the same as the data type of the result of *sort-expression*.

The function is applied to the set of values that are derived from *sort-expression* by the elimination of null values.

The result can be null. If *percentile-expr* is null, or if the function is applied to an empty set, the result is the null value.

Examples for PERCENTILE_DISC

- This example calculates the median salary as a discrete value of the employees in department D11 from the EMP table.

  ```
  SELECT PERCENTILE_DISC(0.5) WITHIN GROUP (ORDER BY SALARY)
  FROM DSN8C10.EMP
  WHERE WORKDEPT = ‘D11’;
  ```

  The result is 24,680.00. Department D11 has 11 employees. The middle row of a group of 11 values in the sixth row. Because there are an odd number of rows, the PERCENTILE_DISC function for the percentile 0.5 returns the value of the sixth row, which is 24,680.00.

- This example calculates the median commission as a discrete value of the employees in department E21 from the EMP table.

  ```
  SELECT PERCENTILE_DISC(0.5) WITHIN GROUP (ORDER BY COMM)
  FROM DSN8C10.EMP
  WHERE WORKDEPT = ‘E21’;
  ```

  The result is 1907.00. This example has six rows, which is an even number of rows. The PERCENTILE_DISC function is computed by returning the value of the first of the two middle rows, which is row three with a value of 1907.00.

- This example calculates the 95th percentile of total salary per department from the EMP table.

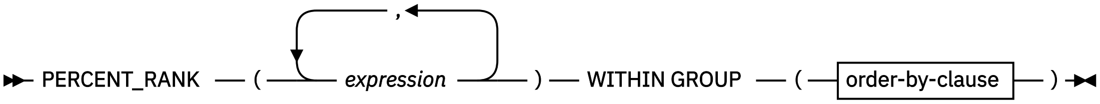
  ```
  SELECT PERCENTILE_DISC(0.95) WITHIN GROUP (ORDER BY SALARY+BONUS)
  FROM DSN8C10.EMP
  GROUP BY WORKDEPT;
  ```

PERCENT_RANK (aggregate)

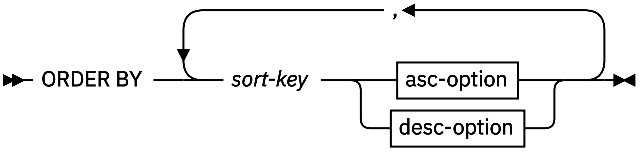
The PERCENT_RANK function returns the relative percentile rank of a row that is hypothetically inserted into a group of rows.

FL 504

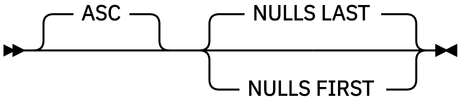
Passthrough-only expression: This function is passthrough-only and cannot run on Db2 for z/OS without acceleration. For information about invoking this function, see Accelerating queries with passthrough-only expressions.



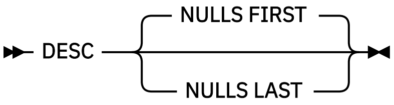
order-by-clause



asc-option



desc-option



The schema is SYSIBM.

expression

An expression that specifies a row that is hypothetically inserted into a group of rows. The expression must return a value that is a built-in data type. The expression must be a constant, a variable, or a cast of a constant or variable.

order-by-clause

ORDER BY

Specifies the order of the rows from the same grouping set that are processed in the aggregation.

sort-key

The sort key can be a column name or a *sort-key-expression*. If the sort key is a constant, it does not refer to the position of the output column. A constant implies no sort key, unlike a constant in the ordinary ORDER BY clause.

ASC

Uses the values of the *sort-key* in ascending order.

DESC

Uses the values of the *sort-key* in descending order.

NULLS FIRST

The ordering considers null values before all non-null values in the sort order.

NULLS LAST

The ordering considers null values after all non-null values in the sort order.

The number of expressions must be the same as the number of *sort-key* expressions. The data type of each expression and the data type of the corresponding *sort-key* expression must be compatible.

The data type of the result is DECFLOAT(34). The actual result is greater than 0.0 and less than or equal to 1.0.

Example

Set the host variable PR to the relative percentile rank of a hypothetical new employee's salary of 47000 within the salaries of the employees in department 'A00'.

```
   SELECT PERCENT_RANK(47000) WITHIN GROUP (ORDER BY SALARY)
      INTO :PR FROM EMPLOYEE WHERE WORKDEPT = 'A00'
```

PR is set to a value of 0.4.

The following result set is shown for reference.

```
   SELECT SALARY FROM EMPLOYEE WHERE WORKDEPT = 'A00' ORDER BY SALARY

SALARY
-----------
   39250.00
   46500.00
   49250.00
   66500.00
  152750.00

  5 record(s) selected.
```

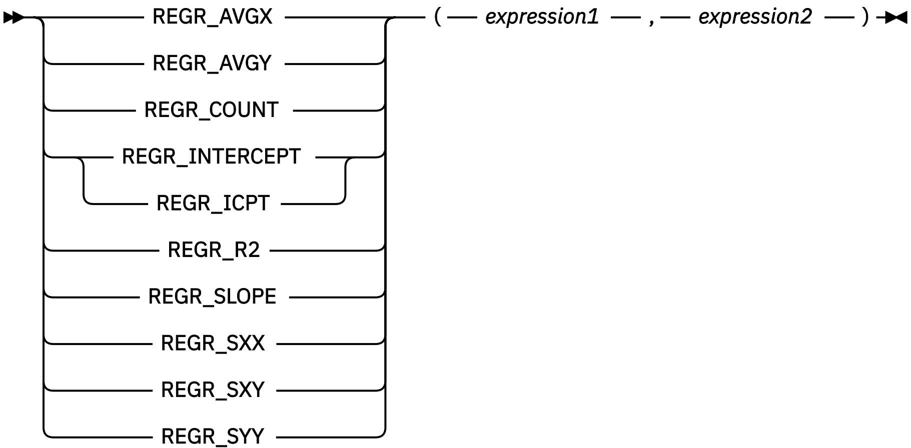
How Db2 determines whether to accelerate eligible queries (Db2 Performance)

Regression functions (REGR_AVGX, REGR_AVGY, REGR_COUNT, ...)

The regression functions support the fitting of an ordinary-least-squares regression line of the form y = a * x + b to a set of number pairs.

FL 507

Passthrough-only expression: This function is passthrough-only and cannot run on Db2 for z/OS without acceleration. For information about invoking this function, see Accelerating queries with passthrough-only expressions.



The schema is SYSIBM.

expression1
An expression that returns a value of any built-in numeric data type. It is interpreted as a value of the dependent variable (that is, a "y value").

expression2
An expression that returns a value of any built-in numeric data type. It is interpreted as a value of the independent variable (that is, an "x value").

The REGR_COUNT function returns the number of non-null number pairs used to fit the regression line.

The REGR_INTERCEPT (or REGR_ICPT) function returns the y-intercept of the regression line ("b" in the equation mentioned previously).

The REGR_R2 function returns the coefficient of determination ("R-squared" or "goodness-of-fit") for the regression.

The REGR_SLOPE function returns the slope of the line ("a" in the equation mentioned previously).

The REGR_AVGX, REGR_AVGY, REGR_SXX, REGR_SXY, and REGR_SYY functions return quantities that can be used to compute various diagnostic statistics needed for the evaluation of the quality and statistical validity of the regression model.

The data type of the result of REGR_COUNT is integer. For the remaining functions, if either argument is DECFLOAT(*n*), the data type of the result is DECFLOAT(34); otherwise, the data type of the result is double-precision floating-point. If either argument is a special decimal floating-point value, the rules for general arithmetic operations for decimal floating-point apply. For more information, see "General arithmetic operation rules for DECFLOAT" on page 253

The result can be null. When not null, the result of REGR_R2 is between 0 and 1, and the result of both REGR_SXX and REGR_SYY is non-negative.

Each function is applied to the set of (*expression1*, *expression2*) pairs derived from the argument values by the elimination of all pairs for which either *expression1* or *expression2* is null.

If the set is not empty and VARIANCE(*expression2*) is positive, REGR_COUNT returns the number of non-null pairs in the set, and the remaining functions return results that are defined as follows:

```
REGR_SLOPE(expression1,expression2) =
COVARIANCE(expression1,expression2)/VARIANCE(expression2)
```

```
REGR_INTERCEPT(expression1, expression2) =
AVG(expression1) - REGR_SLOPE(expression1, expression2) * AVG(expression2)
```

```
REGR_R2(expression1, expression2) =
POWER(CORRELATION(expression1, expression2), 2) if VARIANCE(expression1)>0
REGR_R2(expression1, expression2) = 1 if VARIANCE(expression1)=0
```

```
REGR_AVGX(expression1, expression2) = AVG(expression2)
```

```
REGR_AVGY(expression1, expression2) = AVG(expression1)
```

```
REGR_SXX(expression1, expression2) =
REGR_COUNT(expression1, expression2) * VARIANCE(expression2)
```

```
REGR_SYY(expression1, expression2) =
REGR_COUNT(expression1, expression2) * VARIANCE(expression1)
```

```
REGR_SXY(expression1, expression2) =
REGR_COUNT(expression1, expression2) * COVARIANCE(expression1, expression2)
```

If the set is not empty and VARIANCE(*expression2*) is equal to zero, then the regression line either has infinite slope or is undefined. In this case, the functions REGR_SLOPE, REGR_INTERCEPT, and REGR_R2 each return a null value, and the remaining functions return values as defined previously. If the set is empty, REGR_COUNT returns zero and the remaining functions return a null value.

The order in which the values are aggregated is undefined, but every intermediate result must be within the range of the result data type.

The regression functions are all computed simultaneously during a single pass through the data. In general, it is more efficient to use the regression functions to compute the statistics needed for a regression analysis than to perform the equivalent computations using ordinary column functions such as AVERAGE, VARIANCE, COVARIANCE, and so forth.

The usual diagnostic statistics that accompany a linear-regression analysis can be computed in terms of the functions listed previously. For example:

Adjusted R2
1 - ((1 - REGR_R2) * ((REGR_COUNT - 1) / (REGR_COUNT - 2)))

Standard error
SQRT((REGR_SYY-(POWER(REGR_SXY,2)/REGR_SXX))/(REGR_COUNT-2))

Total sum of squares
REGR_SYY

Regression sum of squares
POWER(REGR_SXY,2) / REGR_SXX

Residual sum of squares
(Total sum of squares)-(Regression sum of squares)

t statistic for slope
REGR_SLOPE * SQRT(REGR_SXX) / (Standard error)

t statistic for y-intercept
REGR_INTERCEPT/((Standard error) * SQRT((1/REGR_COUNT)+(POWER(REGR_AVGX,2)/REGR_SXX))

Examples

- Using the EMPLOYEE table, compute an ordinary-least-squares regression line that expresses the bonus of an employee in department (WORKDEPT) `'A00'` as a linear function of the employee's salary. Set the host variables SLOPE, ICPT, RSQR (double-precision floating point) to the slope, intercept, and coefficient of determination of the regression line, respectively. Also set the host variables AVGSAL and AVGBONUS to the average salary and average bonus, respectively, of the employees in department `'A00'`, and set the host variable CNT (integer) to the number of employees in department `'A00'` for whom both salary and bonus data are available. Store the remaining regression statistics in host variables SXX, SYY, and SXY.

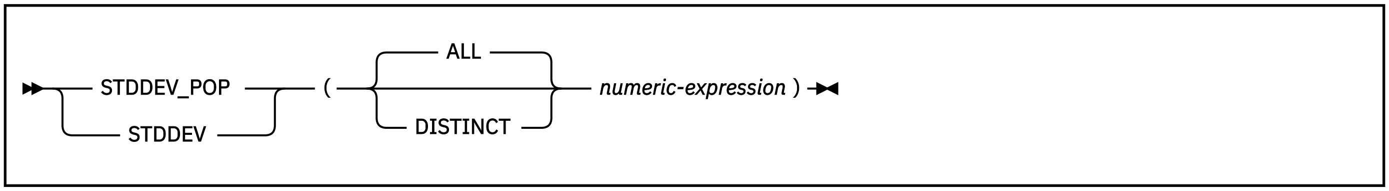
```
SELECT REGR_SLOPE(BONUS,SALARY), REGR_INTERCEPT(BONUS,SALARY),
REGR_R2(BONUS,SALARY), REGR_COUNT(BONUS,SALARY),
REGR_AVGX(BONUS,SALARY), REGR_AVGY(BONUS,SALARY),
REGR_SXX(BONUS,SALARY), REGR_SYY(BONUS,SALARY),
REGR_SXY(BONUS,SALARY)
INTO    :SLOPE, :ICPT,
:RSQR, :CNT,
:AVGSAL, :AVGBONUS,
:SXX, :SYY,
:SXY
FROM EMPLOYEE
WHERE WORKDEPT = 'A00'
```

When using the sample table, the host variables are set to the following approximate values:

```
SLOPE:  +1.71002671916749E-002
ICPT:  +1.00871888623260E+002
RSQR:  +9.99707928128685E-001
CNT:  3
AVGSAL:  +4.28333333333333E+004
AVGBONUS:  +8.33333333333333E+002
SXX:  +2.96291666666667E+008
SYY:  +8.66666666666667E+004
SXY:  +5.06666666666667E+006
```

STDDEV_POP or STDDEV

The STDDEV_POP function returns the population standard deviation (division by *n*) of a set of numbers.



The schema is SYSIBM.

The formula that is used to calculate the result is logically equivalent to:

```
STDDEV_POP = SQRT(VAR_POP)
```

The argument values must each be the value of any built-in numeric data type, and their sum must be within the range of the data type of the result.

The arguments can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34).

If the argument is DECFLOAT(*n*), the result of the function is DECFLOAT(34). Otherwise, the result of the function is double precision floating-point. The result can be null.

Before the function is applied to the set of values derived from the argument values, null values are eliminated. If DISTINCT is specified, redundant duplicate values are also eliminated.

If the function is applied to an empty set, the result is the null value. Otherwise, the result is the population standard deviation of the values in the set.

The order in which the values are aggregated is undefined, but every intermediate result must be within the range of the result data type.

Notes

Syntax alternatives:
STDDEV_POP should be used for conformance to the SQL standard.

Example

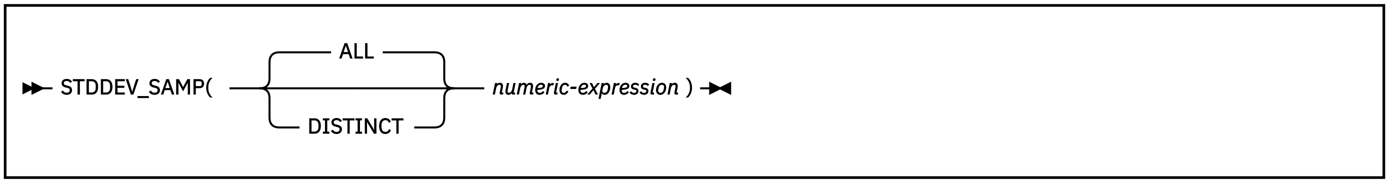
Using sample table DSN8C10.EMP, set the host variable DEV, which is defined as double precision floating-point, to the population standard deviation of the salaries for the employees in department 'A00' (WORKDEPT='A00').

```
    SELECT STDDEV_POP(SALARY)
      INTO :DEV
      FROM DSN8C10.EMP
      WHERE WORKDEPT = 'A00';
```

The value of DEV is set to an approximate value of 9742.43.

STDDEV_SAMP

The STDDEV_SAMP function returns the sample standard deviation (division by *n*-1) of a set of numbers.



The schema is SYSIBM.

The formula that is used to calculate the result is logically equivalent to:

```
STDDEV_SAMP = SQRT(VAR_SAMP)
```

The argument values must each be the value of any built-in numeric data type, and their sum must be within the range of the data type of the result.

The arguments can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34).

If the argument is DECFLOAT(*n*), the result of the function is DECFLOAT(34). Otherwise, the result of the function is double precision floating-point. The result can be null.

Before the function is applied to the set of values derived from the argument values, null values are eliminated. If DISTINCT is specified, redundant duplicate values are also eliminated.

If the function is applied to an empty set, the result is the null value. Otherwise, the result is the sample standard deviation of the values in the set.

The order in which the values are aggregated is undefined, but every intermediate result must be within the range of the result data type.

The following restrictions apply to STDDEV_SAMP:

- STDDEV_SAMP cannot be used as part of an OLAP specification.

Example

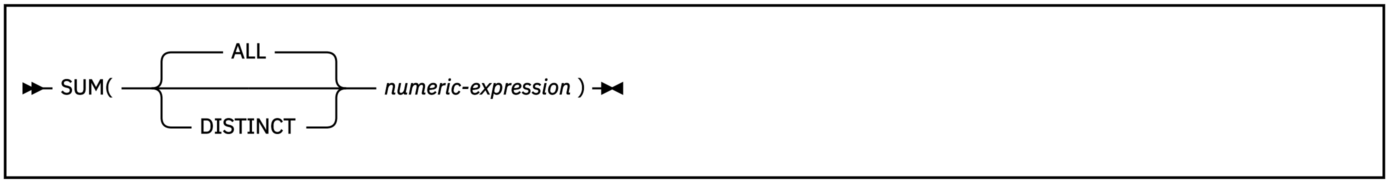
Using sample table DSN8C10.EMP, set the host variable DEV, which is defined as double precision floating-point, to the sample standard deviation of the salaries for the employees in department 'A00' (WORKDEPT='A00').

```
    SELECT STDDEV_SAMP(SALARY)
      INTO :DEV
      FROM DSN8C10.EMP
      WHERE WORKDEPT = 'A00';
```

The value of DEV is set to approximately 10892.37.

SUM

The SUM function returns the sum of a set of numbers.



The schema is SYSIBM.

The argument values can be of any built-in numeric data type, and their sum must be within the range of the data type of the result.

The arguments can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34).

The data type of the result is determined as follows:

- DECFLOAT(34) if the argument is DECFLOAT(*n*).
- Large integer if the argument is small integer.
- Double precision floating-point if the argument is single precision floating-point.
- Otherwise, the result is the same as the data type of the argument.

The result can be null.

If the data type of the argument values is decimal, the scale of the result is the same as the scale of the argument values, and the precision of the result depends on the precision of the argument values and the decimal precision option:

- If the precision of the argument values is greater than 15 or the DEC31 option is in effect, the precision of the result is min(31,*P*+10), where *P* is the precision of the argument values.
- Otherwise, the precision of the result is 15.

The function is applied to the set of values derived from the argument values by the elimination of null values. If DISTINCT is specified, redundant duplicate values are also eliminated.

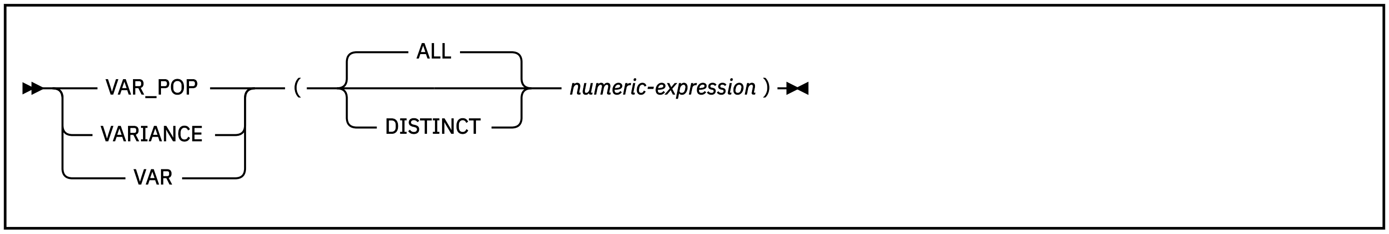
If the function is applied to an empty set, the result is the null value. Otherwise, the result is the sum of the values in the set. The order in which the summation is performed is undefined but every intermediate result must be within the range of the result data type.

Example: Set the large integer host variable *INCOME* to the total income from all sources (salaries, commissions, and bonuses) of the employees represented in the sample table DSN8C10.EMP. If DEC31 is not in effect, the resultant sum is DECIMAL(15,2) because all three columns are DECIMAL(9,2).

```
EXEC SQL SELECT SUM(SALARY+COMM+BONUS)
  INTO :INCOME
  FROM DSN8C10.EMP;
```

VAR_POP or VARIANCE or VAR

The VAR_POP or VARIANCE or VAR function returns the biased variance (division by *n*) of a set of numbers.



The schema is SYSIBM.

The formula that is used to calculate the result is logically equivalent to:

```
VAR_POP = SUM(X**2)/COUNT(X) - (SUM(X)/COUNT(X))**2
```

Two asterisks (**) represent exponentiation. The exponentiation operator is not supported by Db2 for z/OS.

The argument values can be of any built-in numeric type, and their sum must be within the range of the data type of the result. Before the function is applied to the set of values derived from the argument values, null values are eliminated. If DISTINCT is specified, redundant duplicate values are also eliminated.

The arguments can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34).

If the argument is DECFLOAT(*n*), the result of the function is DECFLOAT(34). Otherwise, the result of the function is double precision floating-point.

The result can be null; if any argument is null, the result is the null value.

Otherwise, the result is the population variance of the values in the set.

The order in which the values are added is undefined, but every intermediate result must be within the range of the result data type.

Notes

Syntax alternatives:
VAR_POP should be used for conformance to the SQL standard.

Example

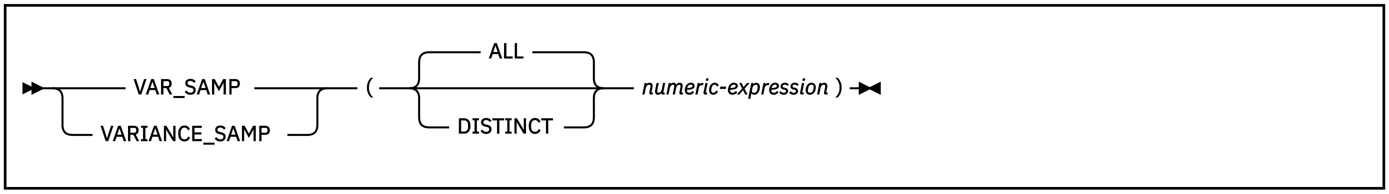
Using sample table DSN8C10.EMP, set host variable VARNCE, which is defined as double precision floating-point, to the population variance of the salaries (SALARY) for those employees in department (WORKDEPT) 'A00'.

```
    SELECT VAR_POP(SALARY)
      INTO :VARNCE
      FROM DSN8C10.EMP
      WHERE WORKDEPT = 'A00';
```

The value of VARNCE is set to 94915000.

VAR_SAMP or VARIANCE_SAMP

The VAR_SAMP or VARIANCE_SAMP function returns the sample variance (division by *n*-1) of a set of numbers.



The schema is SYSIBM.

The formula that is used to calculate the result is logically equivalent to:

```
VAR_SAMP = (SUM(X**2) - ((SUM(X)**2) / (COUNT(*)))) / (COUNT(*) - 1)
```

Two asterisks (**) represent exponentiation. The exponentiation operator is not supported by Db2 for z/OS.

The argument values can be of any built-in numeric type, and their sum must be within the range of the data type of the result. Before the function is applied to the set of values derived from the argument values, null values are eliminated. If DISTINCT is specified, redundant duplicate values are also eliminated.

The arguments can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34).

If the argument is DECFLOAT(*n*), the result of the function is DECFLOAT(34). Otherwise, the result of the function is double precision floating-point.

The result can be null; if any argument is null, the result is the null value.

Otherwise, the result is the sample variance of the values in the set.

The order in which the values are added is undefined, but every intermediate result must be within the range of the result data type.

The following restrictions apply to VAR_SAMP:

- VAR_SAMP cannot be used as part of an OLAP specification.

Notes

Syntax alternatives:
VAR_SAMP should be used for conformance to the SQL standard.

Example

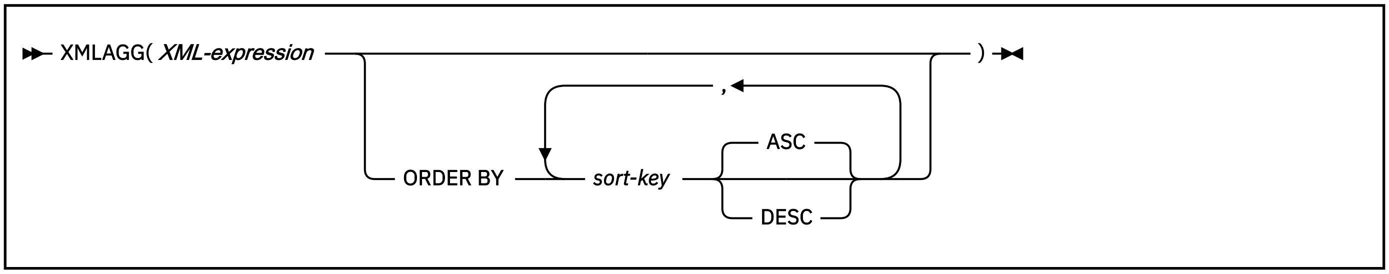
Using sample table DSN8C10.EMP, set host variable VARNCE, which is defined as double precision floating-point, to the sample variance of the salaries (SALARY) for those employees in department (WORKDEPT) 'A00'.

```
SELECT VAR_SAMP(SALARY)
  INTO :VARNCE_S
  FROM DSN8C10.EMP
  WHERE WORKDEPT = 'A00';
```

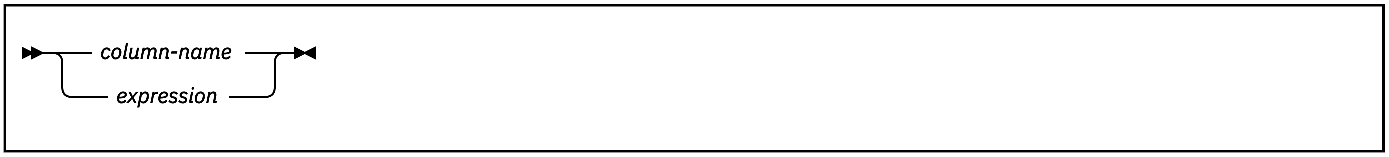
The value of VARNCE is set to 1186437500.

XMLAGG

The XMLAGG function returns an XML sequence that contains an item for each non-null value in a set of XML values.



sort-key



The schema is SYSIBM.

XML-expression
An expression that returns an XML value.

Unlike the arguments for other aggregate functions, a scalar fullselect is allowed in *XML-expression*.

ORDER BY
Specifies the order of the rows from the same grouping set that are processed in the aggregation. If the ORDER BY clause is not specified, or if the ORDER BY clause cannot differentiate the order of the sort key value, the rows in the same grouping set are arbitrarily ordered.

sort-key
Specifies a sort key value that is either a column name or an expression. The data type of the column or expression must not be a LOB or an XML value. A character string expression cannot have a length greater than 4000 bytes. If the sort key value is a constant, it does not refer to the position of the output column (as in the ordinary ORDER BY clause), but is simply a constant, which implies no sort key.

The ordering is based on the values of the sort keys, which might or might not be used in *XML-expression*.

If the sort key value is a character string that uses an encoding scheme other than Unicode, the ordering might be different. For example, a column PRODCODE uses EBCDIC. For two values, ('P001' and 'PA01'), relationship 'P001' > 'PA01' is true in EBCDIC, whereas 'P001' < 'PA01' is true in UTF-8. If the same sort key values are used in *XML-expression*, use the CAST specification to convert the sort key to Unicode to keep the ordering of XML values consistent with that of the sort key.

The function is applied to the set of values derived from the argument values by the elimination of null values.

The result can be null; if all *XML-expression* arguments are null. If the function is applied to an empty set, the result is the null value. Otherwise, the result is an XML sequence that contains an item for each value in the set.

The following restrictions apply to XMLAGG:

- XMLAGG cannot be used as part of an OLAP specification.
- A SELECT clause that includes an invocation of the XMLAGG function must not also include an invocation of the ARRAY_AGG function or the LISTAGG function.

Example: Group employees by their department, generate a 'Department' element for each department with its name as the attribute, nest all the 'emp' elements for employees in each department, and order the 'emp' elements by 'lname.'

```
  SELECT XMLSERIALIZE(XMLDOCUMENT
        ( XMLELEMENT
        ( NAME "Department",
          XMLATTRIBUTES ( e.dept AS "name" ),
          XMLAGG ( XMLELEMENT ( NAME "emp", e.lname)
                   ORDER BY e.lname)
                 ) ) AS "dept_list"
                     AS CLOB(1M))
    FROM employees e
    GROUP BY dept;
```

The result of the query would look similar to the following result:

```
   dept_list
 ---------------------------------------------
<Department name="Accounting">
  <emp>SMITH</emp>
  <emp>Yates</emp>
 </Department>
 <Department name="Shipping">
  <emp>Martin</emp>
  <emp>Oppenheimer</emp>
 </Department>
------------------------------------------------
```

Scalar functions

A scalar function can be used wherever an expression can be used. The restrictions on the use of aggregate functions do not apply to scalar functions, because a scalar function is applied to single set of parameter values rather than to sets of values. The argument of a scalar function can be a function. However, the restrictions that apply to the use of expressions and aggregate functions also apply when an expression or aggregate function is used within a scalar function. For example, the argument of a scalar function can be a aggregate function only if a aggregate function is allowed in the context in which the scalar function is used.

If the argument of a scalar function is a string from a column with a field procedure, the function applies to the decoded form of the value and the result of the function does not inherit the field procedure.

Example: The following SELECT statement calls for the employee number, last name, and age of each employee in department D11 in the sample table DSN8C10.EMP. To obtain the ages, the scalar function YEAR is applied to the expression:

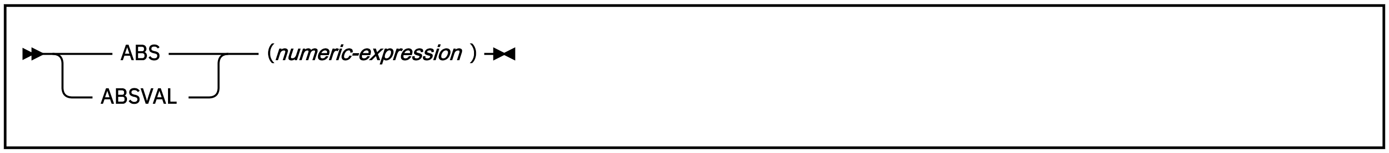
```
CURRENT DATE - BIRTHDATE
```

in each row of DSN8C10.EMP for which the employee represented is in department D11:

```
SELECT EMPNO, LASTNAME, YEAR(CURRENT DATE - BIRTHDATE)
  FROM DSN8C10.EMP
  WHERE WORKDEPT = 'D11';
```

ABS or ABSVAL

The ABS function returns the absolute value of a number.



The schema is SYSIBM.

The argument must be an expression that returns a value of any built-in numeric data type.

The arguments can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34).

The result of the function has the same data type and length attribute as the argument.

The result can be null; if the argument is null, the result is the null value.

Notes

Syntax alternatives:
ABS should be used for conformance to the SQL standard.

Example

Assume that host variable PROFIT is a large integer with a value of -50000. The following statement returns a large integer with a value of 50000.

```
SELECT ABS(:PROFIT)
  FROM SYSIBM.SYSDUMMY1;
```

ACOS

The ACOS function returns the arc cosine of the argument as an angle, expressed in radians. The ACOS and COS functions are inverse operations.

▶▶— ACOS(*numeric-expression*) —▶◀

The schema is SYSIBM.

The argument must be an expression that returns the value of any built-in numeric data type except for DECFLOAT. The value must be greater than or equal to -1 and less than or equal to 1. If the argument is not a double precision floating-point number, it is converted to one for processing by the function.

The result of the function is a double precision floating-point number.

The result can be null; if the argument is null, the result is the null value.

Example: Assume that host variable ACOSINE is DECIMAL(10,9) with a value of 0.070737202. The following statement:

```
   SELECT ACOS(:ACOSINE)
     FROM SYSIBM.SYSDUMMY1;
```

returns a double precision floating-point number with an approximate value of 1.49.

ADD_DAYS

The ADD_DAYS function returns a datetime value that represents the first argument plus a specified number of days.

FL 507

Passthrough-only expression: This function is passthrough-only and cannot run on Db2 for z/OS without acceleration. For information about invoking this function, see Accelerating queries with passthrough-only expressions.

▶▶— ADD_DAYS —(— *expression* — , — *numeric-expression* —) —▶◀

The schema is SYSIBM.

expression
An expression that specifies the starting date. The expression must return a value that is a DATE, TIMESTAMP WITHOUT TIME ZONE, CHAR, VARCHAR, GRAPHIC, or VARGRAPHIC data type. CHAR, VARCHAR, GRAPHIC, and VARGRAPHIC are supported by using implicit casting. If *expression* is a CHAR, VARCHAR, GRAPHIC, or VARGRAPHIC data type, it must be a valid string that is accepted by the TIMESTAMP scalar function and does not contain a time zone.

numeric-expression
An expression that specifies the number of days to add to the starting date specified by *expression*. The expression must return a value that is a built-in numeric, CHAR, VARCHAR, GRAPHIC, or VARGRAPHIC data type. CHAR, VARCHAR, GRAPHIC, and VARGRAPHIC are supported by using implicit casting. If the expression is not an INTEGER, it is cast to INTEGER before the function is evaluated. A negative numeric value can be used to subtract days.

The result of the function is a timestamp with the same precision as *expression* , if *expression* is a timestamp. Otherwise, the result of the function is a date. If any argument can be null, the result can be null; if any argument is null, the result is the null value.

Examples

- Assume that today is January 31, 2007. Set the host variable ADD_DAY with the current day plus 1 day.

```
SET :ADD_DAY = ADD_DAYS(CURRENT_DATE, 1)
```

The host variable ADD_DAY is set with the value representing 2007-02-01.

- Assume that DATE is a host variable with the value July 27, 1965. Set the host variable ADD_DAY with the value of that day plus 3 days.

```
SET :ADD_DAY = ADD_DAYS(:DATE,3)
```

The host variable ADD_DAY is set with the value representing the day plus 3 days, 1965-07-30.

- The ADD_DAYS function and datetime arithmetic can be used to achieve the same results. The following examples demonstrate this.

```
SET :DATEHV = DATE('2008-2-28') + 4 DAYS
SET :DATEHV = ADD_DAYS('2008-2-28', 4)
```

In both cases, the host variable DATEHV is set with the value '2008-03-03'.

Now consider the same examples but with the date '2008-2-29' as the argument.

```
SET :DATEHV = DATE('2008-2-29') + 4 DAYS
SET :DATEHV = ADD_DAYS('2008-2-29', 4)
```

In both cases, the host variable DATEHV is set with the value '2008-03-04'.

- Assume that DATE is a host variable with the value July 27, 1965. Set the host variable ADD_DAY with the value of that day minus 3 days.

```
SET :ADD_DAY = ADD_DAYS(:DATE,-3)
```

The host variable ADD_DAY is set to 1965-07-24; the value representing July 27, 1965 minus 3 days.

ADD_MONTHS

The ADD_MONTHS function returns a date that represents *expression* plus a specified number of months.

```
▶▶─ ADD_MONTHS( expression ,numeric-expression ) ─▶◀
```

The schema is SYSIBM.

expression

An expression that specifies the starting date. *expression* must return a value that is a date, timestamp, or a valid string representation of a date or timestamp. A string representation is a value that is a built-in character string data type or graphic string data type, that is not a LOB, and that has an actual length that is not greater than 255 bytes. A time zone in a string representation of a timestamp is ignored. For the valid formats of string representations of dates and timestamps, see "String representations of datetime values" on page 120.

If *expression* is a TIMESTAMP WITH TIME ZONE value, *expression* is first cast to a TIMESTAMP WITHOUT TIME ZONE value with the same precision as *expression*. If *expression* is a string, *expression* is first cast to DATE.

numeric-expression

An expression that returns a value of any built-in numeric data type. The integer portion of *numeric-expression* specifies the number of months to add to the starting date specified by *expression*.A negative numeric value is allowed.

numeric-expression can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34).

If *expression* is a timestamp with a time zone value, or a valid string representation of a timestamp with a time zone value, the result is determined from the UTC representation of the datetime value.

If *expression* is a timestamp value the result is a TIMESTAMP WITHOUT TIME ZONE with the same precision as *expression*. Otherwise, the result is a DATE value.

The result can be null; if any argument is null, the result is the null value.

If *expression* is the last day of the month or if the resulting month has fewer days than the day component of *expression*, the result is the last day of the resulting month. Otherwise, the result has the same day component as *expression*. Any hours, minutes, seconds, or fractional seconds information included in *expression* is not changed by the function.

The result CCSID is the appropriate CCSID of the argument encoding scheme and the result subtype is the appropriate subtype of the CCSID.

Example 1: Assume today is January 31, 2007. Set the host variable ADD_MONTH with the last day of January plus 1 month.

```
   SET :ADD_MONTH = ADD_MONTHS(LAST_DAY(CURRENT_DATE), 1);
```

The host variable ADD_MONTH is set with the value representing the end of February, 2007-02-28.

Example 2: Assume DATE is a host variable with the value July 27, 1965. Set the host variable ADD_MONTH with the value of that day plus 3 months.

```
   SET :ADD_MONTH = ADD_MONTHS(:DATE,3);
```

The host variable ADD_MONTH is set with the value representing the day plus 3 months, 1965-10-27.

Example 3: It is possible to achieve similar results with the ADD_MONTHS function and date arithmetic. The following examples demonstrate the similarities and contrasts.

```
   SET :DATEHV = DATE('2008-2-28') + 4 MONTHS;
```

```
   SET :DATEHV = ADD_MONTHS('2008-2-28', 4);
```

In both cases, the host variable DATEHV is set with the value '2008–06–29'.

Now consider the same examples but with the date '2008–2–29' as the argument.

```
   SET :DATEHV = DATE('2008-2-29') + 4 MONTHS;
```

The host variable DATEHV is set with the value '2008–06–29'.

```
   SET :DATEHV = ADD_MONTHS('2008-2-29', 4);
```

The host variable DATEHV is set with the value '2008–06–30'.

In this case, the ADD_MONTHS function returns the last day of the month, which is June 30, 2008, instead of June 29, 2008. The reason is that February 29 is the last day of the month. So, the ADD_MONTHS function returns the last day of June.

Example 4: Assume *TSZ* is an SQL variable with the timestamp with time zone value 2008-02-29.20.00.00.000000-08.00. Set *TIMESZ* to the value of that timestamp with time zone value plus 4 months.

```
SET TIMESZ: = ADD_MONTHS(TIMESTAMP_TZ(TSZ), 4);
```

The function returns a timestamp value that represents the timestamp plus 4 months: 2008-06-30-20.00.00.000000-8.00. The result of the ADD_MONTHS function does not contain a time zone.

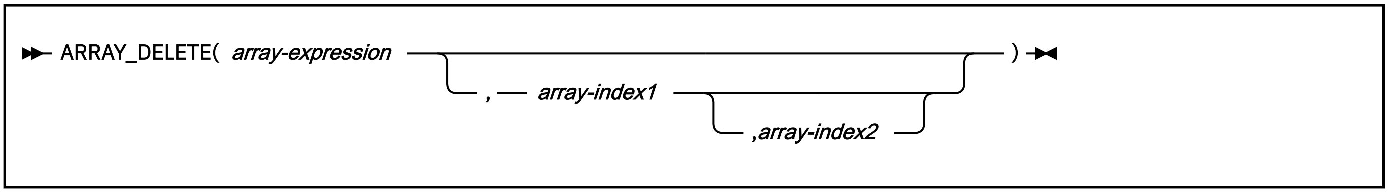
Example 5: Assume *TSZ* is a host variable with the value '2008-02-29-20.00.000000-08.00', which is a string representation of a timestamp with a time zone value. Set *TIMESZ* to the value of that timestamp with a time zone plus 4 months.

```
SET TIMESZ: = ADD_MONTHS(:TSZ, 4);
```

With the string representation of a timestamp as input, the ADD_MONTHS function returns a DATE value that represents the timestamp plus 4 months, 2008-06-30. The host variable *TIMESZ* is set with the value that represents the timestamp with time zone plus 4 months.

ARRAY_DELETE

The ARRAY_DELETE function deletes elements from an array.



The schema is SYSIBM.

array-expression
An SQL variable, SQL parameter, or global variable of an array type, or a CAST specification that specifies an SQL variable, SQL parameter, global variable, or parameter marker as the source value.

array-index1
An expression that results in a value that is castable to the data type of the array index. If *array-expression* is an ordinary array, *array-index1* must be the null value.

array-index2
An expression that results in a value that is castable to the data type of the array index. If *array-expression* is an ordinary array, *array-index2* must be the null value. If *array-index2* is specified and is a non-null value, *array-index1* must be a non-null value that is less than the value of *array-index2*. If *array-index2* is the null value, ARRAY_DELETE is evaluated as if *array-index2* was not specified.

The result of ARRAY_DELETE has the same data type as *array-expression*.

If *array-index1* and *array-index2* are not specified, or they are the null value, all of the elements of *array-expression* are deleted, and the cardinality of the result array value is 0. If only *array-index1* is specified with a non-null value, the array element at index value *array-index1* is deleted. If *array-index2* is specified with a non-null value, the elements ranging from index value *array-index1* to *array-index2*, inclusive, are deleted.

The result can be null; if the first argument is null, the result is the null value.

The ARRAY_DELETE function can be invoked only in the following contexts:

- A source value for SET *assignment-statement*, an SQL PL *assignment-statement*, or a VALUES INTO statement
- The value that is returned in a RETURN statement in an SQL scalar function

Notes

Syntax alternatives

CAST (*SQL-variable* AS *array-type*) can be specified as an alternative to *SQL-variable*. CAST (*SQL-parameter* AS *array-type*) can be specified as an alternative to *SQL-parameter*.

Examples

Example 1: Suppose that ordinary array variable RECENT_CALLS has the array type PHONENUMBERS. Use ARRAY_DELETE to delete all the elements from RECENT_CALLS. Assign the result to the RECENT_CALLS array.

```
SET RECENT_CALLS = ARRAY_DELETE(RECENT_CALLS);
```

After the SET statement is executed, RECENT_CALLS is an empty array, which has a cardinality of zero.

An equivalent way of setting RECENT_CALLS to an empty array is to use an array constructor:

```
SET RECENT_CALLS = ARRAY[ ];
```

Example 2: Suppose that PRODUCTS is defined as an associative array type with VARCHAR values for the array index, and that variables FLOOR_TILES and REMAINIING_TILES are defined as arrays of the PRODUCTS array type. Use ARRAY_DELETE to assign the elements from the FLOOR_TILES array variable that do not have an index value between 'PK5100' and 'PS2500', inclusive, to the REMAINING_TILES array variable.

```
SET REMAINING_TILES = ARRAY_DELETE(FLOOR_TILES,'PK5100','PS2500');
```

ARRAY_FIRST

The ARRAY_FIRST function returns the minimum array index value of an array.

▶▶ ARRAY_FIRST(*array-expression*) ▶◀

The schema is SYSIBM.

array-expression

An SQL variable, SQL parameter, or global variable of an array type, or a CAST specification that specifies an SQL variable, SQL parameter, global variable, or parameter marker as the source value.

The result of ARRAY_FIRST has the same data type as the array index. If *array-expression* is not null, and the array is not empty (the cardinality of the array is greater than 0), the value of the result is the minimum array index value, which is 1 for an ordinary array.

The result can be null; if the argument is null, the result is the null value.

If the array is empty (the cardinality of the array is 0), the result is the null value.

Notes

Syntax alternatives:

CAST (*SQL-variable* AS *array-type*) can be specified as an alternative to *SQL-variable*. CAST (*SQL-parameter* AS *array-type*) can be specified as an alternative to *SQL-parameter*.

Example 1: Suppose that SPECIALNUMBERS is an ordinary array variable, and the elements of the array are integers. Return the first index value in the array variable SPECIALNUMBERS to the SQL variable E_CONSTIDX.

```
SET E_CONSTIDX = ARRAY_FIRST(SPECIALNUMBERS);
```

The result is 1.

Example 2: Suppose that PHONELIST is an associative array variable with VARCHAR index values. Values have been assigned to the elements in the array with the following statements:

```
SET PHONELIST['Home'] = '4443051234';
SET PHONELIST['Work'] = '4443052345';
SET PHONELIST['Cell'] = '4447893456';
```

The order in which values are assigned to array elements in an associative array does not matter. The elements of an associative array are stored in the array variable in ascending order of the associated array index values. After the values have been assigned to the PHONELIST array variable using the SET *assignment-statement* statements, the elements in the array variable are ordered as follows:

Index value	Element value
Cell	4447893456
Home	4443051234
Work	4443052345

Assign the value of the first index in the array variable to the character string variable named X.

```
SET X = ARRAY_FIRST(PHONELIST);
```

The value of 'Cell' is assigned to X because 'Cell' is the index value of the first element in the array variable.

Assign the value of the array element with index X to the SQL variable NUMBER_TO_CALL.

```
SET NUMBER_TO_CALL = PHONELIST[X];
```

The assignment statement assigns the phone number '4447893456' to NUMBER_TO_CALL.

ARRAY_LAST

The ARRAY_LAST function returns the maximum array index value of an array.

```
▶▶─ ARRAY_LAST( array-expression ) ─▶◀
```

The schema is SYSIBM.

array-expression

An SQL variable, SQL parameter, or global variable of an array type, or a CAST specification that specifies an SQL variable, SQL parameter, global variable, or parameter marker as the source value.

The result of ARRAY_LAST has the same data type as the array index, which is INTEGER for an ordinary array. If *array-expression* is not null, and the array is not empty (the cardinality of the array is greater than 0), the value of the result is the maximum array index value, which is the current cardinality of the array for an ordinary array.

The result can be null; if the argument is null, the result is the null value.

If the array is empty (the cardinality of the array is 0), the result is the null value.

Notes

Syntax alternatives:

CAST (*SQL-variable* AS *array-type*) can be specified as an alternative to *SQL-variable*. CAST (*SQL-parameter* AS *array-type*) can be specified as an alternative to *SQL-parameter*.

Example 1: Suppose that SPECIALNUMBERS is an ordinary array variable, and the elements of the array are integers. The cardinality of the array is 10. Return the last index value in the array variable SPECIALNUMBERS to the SQL variable PI_CONSTIDX.

```
SET PI_CONSTIDX = ARRAY_LAST(SPECIALNUMBERS);
```

The result is 10.

Example 2: Suppose that PHONELIST is an associative array variable with VARCHAR index values. Values have been assigned to the elements in the array with the following statements:

```
SET PHONELIST['Home'] = '4443051234';
SET PHONELIST['Work'] = '4443052345';
SET PHONELIST['Cell'] = '4447893456';
```

The order in which values are assigned to array elements in an associative array does not matter. The elements of an associative array are stored in the array variable in ascending order of the associated array index values. After the values have been assigned to the PHONELIST array variable using the SET *assignment-statement* statements, the elements in the array variable are ordered as follows:

Index value	Element value
Cell	4447893456
Home	4443051234
Work	4443052345

Assign the value of the maximum index in the array variable to the character string variable named X.

```
SET X = ARRAY_LAST(PHONELIST);
```

The value of 'Work' is assigned to X because 'Work' is the index value of the last element in the array variable.

Assign the value of the array element with index X to the SQL variable NUMBER_TO_CALL.

```
SET NUMBER_TO_CALL = PHONELIST[X];
```

The assignment statement assigns the phone number '4443052345' to NUMBER_TO_CALL.

ARRAY_NEXT

The ARRAY_NEXT function returns the next larger array index value for an array, relative to a specified array index argument.

▸▸ ARRAY_NEXT(*array-expression* ,*array-index*) ▸◂

The schema is SYSIBM.

array-expression
An SQL variable, SQL parameter, or global variable of an array type, or a CAST specification that specifies an SQL variable, SQL parameter, global variable, or parameter marker as the source value.

array-index
An expression that results in a value that is castable to the data type of the array index. Valid values include any valid value for the data type.

array-index must *not* be an expression that references any of the following items:

- The CURRENT DATE, CURRENT TIME, or CURRENT TIMESTAMP special register
- A nondeterministic function
- A function that is defined with EXTERNAL ACTION
- A function that is defined with MODIFIES SQL DATA
- A sequence expression

The result of ARRAY_NEXT is the next larger array index value defined in the array, relative to the specified *array-index* value. If *array-index* is less than the minimum index array value in the array, the result is the first array index value that is defined in the array.

The data type of the result has the same data type as the array index.

The result is null under the following conditions:

- *array-expression* or *array-index* is null
- The array that is represented by *array-expression* is empty (the cardinality of the array is 0)
- The value of *array-index* is greater than or equal to the value of the last index in the array

Notes

Syntax alternatives:

> CAST (*SQL-variable* AS *array-type*) can be specified as an alternative to *SQL-variable*. CAST (*SQL-parameter* AS *array-type*) can be specified as an alternative to *SQL-parameter*.

Example 1: Suppose that SPECIALNUMBERS is an ordinary array variable, and the elements of the array are integers. The cardinality of SPECIALNUMBERS is 10. Set the NEXT_CONSTIDX variable to the value of the array index for the SPECIALNUMBERS array element that follows the array element that is associated with an array index value of 9.

```
SET NEXT_CONSTIDX = ARRAY_NEXT(SPECIALNUMBERS,9);
```

The result is 10.

Example 2: Suppose that PHONELIST is an associative array variable with VARCHAR index values. Values have been assigned to the elements in the array with the following statements:

```
SET PHONELIST['Home'] = '4443051234';
SET PHONELIST['Work'] = '4443052345';
SET PHONELIST['Cell'] = '4447893456';
```

The order in which values are assigned to array elements in an associative array does not matter. The elements of an associative array are stored in the array variable in ascending order of the associated array index values. After the values have been assigned to the PHONELIST array variable using the SET *assignment-statement* statements, the elements in the array variable are ordered as follows:

Index value	Element value
Cell	4447893456
Home	4443051234
Work	4443052345

Assign the array index value that follows an array index value named 'Fax' to the character string variable named X.

```
SET X = ARRAY_NEXT(PHONELIST,'Fax');
```

Array index value 'Fax' does not exist, but the string 'Home' follows the string 'Fax' in sorting order. Therefore, 'Home' is assigned to X.

Assign the value of the array element with index X to the SQL variable NUMBER_TO_CALL.

```
SET NUMBER_TO_CALL = PHONELIST[X];
```

Because the value of X is 'Home', the assignment statement assigns the phone number '4443051234' to NUMBER_TO_CALL.

ARRAY_PRIOR

The ARRAY_PRIOR function returns the next smaller array index value for an array, relative to a specified array index argument.

►► ARRAY_PRIOR(*array-expression* ,*array-index*) ►◄

The schema is SYSIBM.

array-expression
An SQL variable, SQL parameter, or global variable of an array type, or a CAST specification that specifies an SQL variable, SQL parameter, global variable, or parameter marker as the source value.

array-index
An expression that results in a value that is castable to the data type of the array index. Valid values include any valid value for the data type.

array-index must *not* be an expression that references any of the following items:

- The CURRENT DATE, CURRENT TIME, or CURRENT TIMESTAMP special register
- A nondeterministic function
- A function that is defined with EXTERNAL ACTION
- A function that is defined with MODIFIES SQL DATA
- A sequence expression

The result of ARRAY_PRIOR is the next smaller array index value that is defined in the array, relative to the specified *array-index* value. If *array-index* is greater than the maximum index array value in the array, the result is the last array index value that is defined in the array.

The data type of the result has the same data type as the array index.

The result is null under the following conditions:

- *array-expression* or *array-index* is null.
- The array that is represented by *array-expression* is empty (the cardinality of the array is 0).
- The value of *array-index* is less than or equal to the value of the first index in the array.

Notes

Syntax alternatives:

CAST (*SQL-variable* AS *array-type*) can be specified as an alternative to *SQL-variable*. CAST (*SQL-parameter* AS *array-type*) can be specified as an alternative to *SQL-parameter*.

Example 1: Suppose that SPECIALNUMBERS is an ordinary array variable, and the elements of the array are integers. The cardinality of SPECIALNUMBERS is 10. Set the PREV_CONSTIDX variable to the value of the array index for the SPECIALNUMBERS array element that precedes the array element that is associated with an array index value of 2.

```
SET PREV_CONSTIDX = ARRAY_PRIOR(SPECIALNUMBERS,2);
```

The result is 1.

Example 2: Suppose that PHONELIST is an associative array variable with VARCHAR index values. Values have been assigned to the elements in the array with the following statements:

```
SET PHONELIST['Home'] = '4443051234';
SET PHONELIST['Work'] = '4443052345';
SET PHONELIST['Cell'] = '4447893456';
```

The order in which values are assigned to array elements in an associative array does not matter. The elements of an associative array are stored in the array variable in ascending order of the associated array index values. After the values have been assigned to the PHONELIST array variable using the SET *assignment-statement* statements, the elements in the array variable are ordered as follows:

Index value	Element value
Cell	4447893456
Home	4443051234
Work	4443052345

Assign the array index value that precedes an array index value named 'Fax' to the character string variable named X.

```
SET X = ARRAY_PRIOR(PHONELIST,'Fax');
```

Array index value 'Fax' does not exist, but the string 'Cell' precedes the string 'Fax' in sorting order. Therefore, 'Cell' is assigned to X.

Assign the array index value that precedes array index value 'Cell' to the character string variable named X.

```
SET X = ARRAY_PRIOR(PHONELIST,'Cell');
```

The null value is assigned to X, because there is no array element before the array element with the index value 'Cell'.

ARRAY_TRIM

The ARRAY_TRIM function deletes elements from the end of an ordinary array.

►► ARRAY_TRIM — (*array-expression* , *numeric-expression*) ►◄

The ARRAY_TRIM function is identical to the TRIM_ARRAY function. For more information, see "TRIM_ARRAY" on page 604.

ASCII

The ASCII function returns the leftmost character of the argument as an integer.

►► ASCII(*string-expression*) ►◄

The schema is SYSIBM.

The argument can be any built-in character or graphic string data type, except for CLOB or DBCLOB. If the argument is an EBCDIC, Unicode, or graphic string, it is first converted to an SBCS ASCII character string (CCSID 367)[17] before the function is executed.

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type.

The result of the function is a large integer.

The result can be null; if the argument is null, the result is the null value.

[17] If the conversion does not exist, the ASCII function will return an error, or a substitution character might be returned.

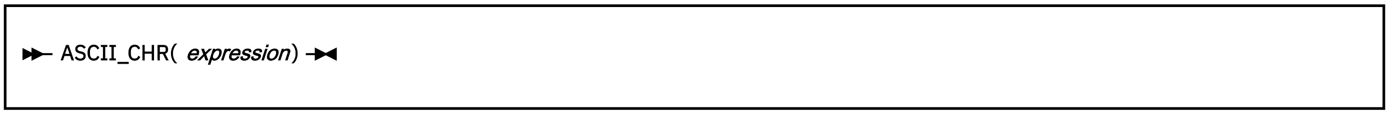
Example: The following statement returns the ASCII value for the character 'A':

```
SET :hv = ASCII('A');
```

The host variable, :hv, is set to an integer with the value 65.

ASCII_CHR

The ASCII_CHR function returns the character that has the ASCII code value that is specified by the argument.



The schema is SYSIBM.

expression
An expression that returns a built-in data type of BIGINT, INTEGER, or SMALLINT.

expression can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34) which is then assigned to a BIGINT value.

The result of the function is a fixed length character string encoded in the SBCS ASCII CCSID (regardless of the setting of the MIXED option in DSNHDECP). The length of the result is 1. If the value of *expression* is not in the range of 0 to 255, (0 to 127 if the SBCS ASCII CCSID for this system is CCSID 367) the null value is returned.

The result can be null; if the argument is null, the result is the null value.

Notes

Syntax alternatives:
CHR is a synonym for ASCII_CHR.

Examples

Example 1: Set :hv with the Euro symbol "€" in CCSID 923:

```
SET :hv = ASCII_CHR(164);  -- x'A4'
```

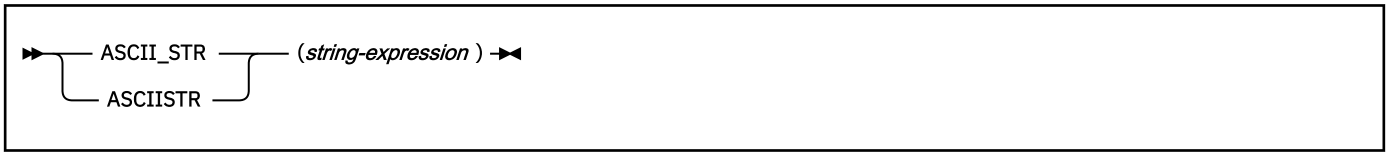
Set :hv with the Euro symbol "€" in CCSID 1252:

```
SET :hv = ASCII_CHR(128);  -- x'80'
```

In both cases, the "€" is assigned to :hv, but because the Euro symbol is located at different code points for the two CCSIDs, the input value is different.

ASCII_STR or ASCIISTR

The ASCII_STR function returns an ASCII version of the string in the system ASCII CCSID. The system ASCII CCSID is the SBCS ASCII CCSID on a MIXED=NO system or the MIXED ASCII CCSID on a MIXED=YES system.



The schema is SYSIBM.

string-expression

An expression that returns a value of a built-in character or graphic string. A character string must not be bit data. *string-expression* must be an ASCII, EBCDIC, or Unicode string.

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type.

ASCII_STR returns an ASCII version of the string. If the system ASCII CCSID does not support the backslash (\) character, *string-expression* must not contain Non-ASCII characters. Non-ASCII characters are converted to UTF-16 characters and appear in the result in the form \xxxx (or \xxxx\yyyy for surrogate characters), where *xxxx* and *yyyy* represent a UTF-16 code unit.

The length attribute of the result will be `MIN( ( 5*n),32704)`. Where *n* is the result of applying the formulas in Table 37 on page 163 based on input and output data types.

The result of the function is a varying-length character string in the system ASCII CCSID. If the actual length of the result string exceeds the maximum for the return type, an error occurs.

The result can be null; if the argument is null, the result is the null value.

Example

The following example returns the ASCII string equivalent of the Unicode (UTF-8) string, '4869206D616D6520697320D090D0BDD0B4D180D0B5D0B9202020F0908080':

```
SET :HV1 =
ASCII_STR(X'48692C206D79206E616D6520697320D090D0BDD0B4D180D0B5D0B920F0908080');
```

:HV1 is assigned the value 'Hi, my name is \0410\043D\0434\0440\0435\0439 \D800\DC00'. In this example, the UTF-8 characters D090, D0BD, D0B4, D180, D0B5, and D0B9 are converted to \0410\043D\0434\0440\0435\0439 and the non-ASCII character F0908080 is converted to \D800\DC00.

```
SET :HV1 = ASCII_STR('Hi, my name is Андрей (Andrei)');
```

:HV1 is assigned the value "Hi, my name is \0410\043D\0434\0440\0435\0439 (Andrei)"

ASIN

The ASIN function returns the arc sine of the argument as an angle, expressed in radians. The ASIN and SIN functions are inverse operations.

►► ASIN(*numeric-expression*) ►◄

The schema is SYSIBM.

The argument must be an expression that returns the value of any built-in numeric data type except for DECFLOAT. The value must be greater than or equal to -1 and less than or equal to 1. If the argument is not a double precision floating-point number, it is converted to one for processing by the function.

The result of the function is a double precision floating-point number.

The result can be null; if the argument is null, the result is the null value.

The result is greater than or equal to -π/2 and less than or equal to π/2.

Example: Assume that host variable ASINE is DECIMAL(10,9) with a value of 0.997494987. The following statement:

```
   SELECT ASIN(:ASINE)
     FROM SYSIBM.SYSDUMMY1;
```

returns a double precision floating-point number with an approximate value of 1.50.

ATAN

The ATAN function returns the arc tangent of the argument as an angle, expressed in radians. The ATAN and TAN functions are inverse operations.

▶▶— ATAN(*numeric-expression*) —▶◀

The schema is SYSIBM.

The argument must be an expression that returns the value of any built-in numeric data type that is not DECFLOAT. The value must be greater than or equal to -1 and less than or equal to 1. If the argument is not a double precision floating-point number, it is converted to one for processing by the function.

The result of the function is a double precision floating-point number.

The result can be null; if the argument is null, the result is the null value.

The result is greater than or equal to -π/2 and less than or equal to π/2.

Example: Assume that host variable ATANGENT is DECIMAL(10,9) with a value of 14.10141995. The following statement returns a double precision floating-point number with an approximate value of 1.50:

```
SELECT ATAN(:ATANGENT)
  FROM SYSIBM.SYSDUMMY1;
```

ATANH

The ATANH function returns the hyperbolic arc tangent of a number, expressed in radians. The ATANH and TANH functions are inverse operations.

▶▶— ATANH(*numeric-expression*) —▶◀

The schema is SYSIBM.

The argument must be an expression that returns the value of any built-in numeric data type that is not DECFLOAT. The value must be greater than -1 and less than 1. If the argument is not a double precision floating-point number, it is converted to one for processing by the function.

The result of the function is a double precision floating-point number.

The result can be null; if the argument is null, the result is the null value.

Example: Assume that host variable HATAN is DECIMAL(10,9) with a value of 0.905148254. The following statement returns a double precision floating-point number with an approximate value of 1.50:

```
SELECT ATANH(:HATAN)
  FROM SYSIBM.SYSDUMMY1;
```

ATAN2

The ATAN2 function returns the arc tangent of *x* and *y* coordinates as an angle, expressed in radians.

▶▶— ATAN2(*numeric-expression-1* ,*numeric-expression-2*) —▶◀

The schema is SYSIBM.

The first and second arguments specify the *x* and *y* coordinates, respectively.

Each argument must be an expression that returns the value of any built-in numeric data type that is not DECFLOAT. Both arguments must not be 0. Any argument that is not a double precision floating-point number is converted to one for processing by the function.

The result of the function is a double precision floating-point number.

The result can be null; if any argument is null, the result is the null value.

Example: Assume that host variables HATAN2A and HATAN2B are DOUBLE host variables with values of 1 and 2, respectively. The following statement returns a double precision floating-point number with an approximate value of 1.1071487:

```
SELECT ATAN2(:HATAN2A,:HATAN2B)
  FROM SYSIBM.SYSDUMMY1;
```

BIGINT

The BIGINT function returns a big integer representation of either a number or a character or graphic string representation of a number.

Numeric to Big Integer:

```
►► BIGINT( numeric-expression ) ►◄
```

String to Big Integer:

```
►► BIGINT( string-expression ) ►◄
```

The schema is SYSIBM.

Numeric to Big Integer

numeric-expression

An expression that returns a value of any built-in numeric data type.

The result is the same number that would occur if the argument were assigned to a big integer column or variable. If the whole part of the argument is not within the range of big integers, an error is returned. The fractional part of the argument is truncated.

String to Big Integer

string-expression

An expression that returns a value of a character or graphic string (except a CLOB and DBCLOB) with a length attribute that is not greater than 255 bytes. The string must contain a valid string representation of a number.

The result is the same number that would result from CAST(*string-expression* AS BIGINT). Leading and trailing blanks are eliminated and the resulting string must conform to the rules for forming an integer constant. If the whole part of the argument is not within the range of big integers, an error is returned.

The result of the function is a big integer.

The result can be null; if the argument is null, the result is the null value.

To increase the portability of applications, use the CAST specification.

Example 1: The following function returns the number 12345 (a BIGINT) for the number 12345.6:

```
SELECT BIGINT(12345.6)
   FROM SYSIBM.SYSDUMMY1;
```

Example 2: The following function returns a BIGINT value of 123456789012 for the number 00123456789012.

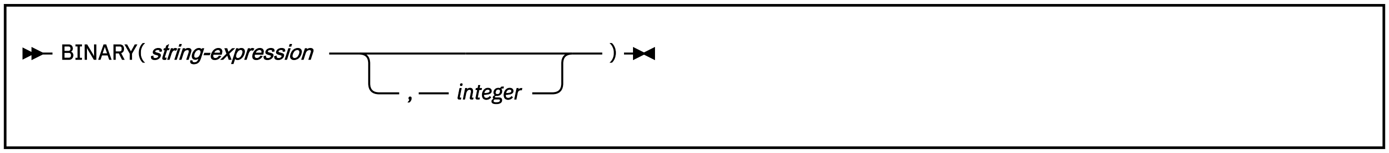
```
   SELECT BIGINT('00123456789012')
      FROM SYSIBM.SYSDUMMY1;
```

Related reference

CAST specification
The CAST specification returns the first operand (the cast operand) converted to the data type that is specified by *data-type*.

BINARY

The BINARY function returns a BINARY (fixed-length binary string) representation of a string of any type or of a row ID type.



The schema is SYSIBM.

string-expression
An expression that returns a value that is a built-in character string, graphic string, binary string, or a row ID type.

integer
An integer value that specifies the length attribute of the resulting binary string. The value must be an integer between 1 and 255 inclusive.

If *integer* is not specified:

- If the *string-expression* is the empty string constant, an error occurs
- Otherwise, the length attribute of the result is the same as the length attribute of *string-expression*, except when the input is graphic data. In this case, the length attribute of the result is twice the length of *string-expression*.

The result of the function is a fixed-length binary string.

The result can be null; if the first argument is null, the result is the null value.

The actual length is the same as the length attribute of the result. If the length of the *string-expression* is less than the length of the result, the result is padded with hexadecimal zeroes up to the length of the result. If the length of the *string-expression* is greater than the length attribute of the result, truncation is performed. A warning is returned unless the first input argument is a character string and all the truncated characters are blanks, or the first input argument is a graphic string and all the truncated characters are double-byte blanks, or the first input argument is a binary string and all the truncated bytes are hexadecimal zeroes.

Following examples assume EBCDIC encoding of the input string constants.

Example 1: The following function returns a fixed-length binary string with a length attribute 1 and a value BX'00'.

```
   SELECT BINARY('',1)
     FROM SYSIBM.SYSDUMMY1;
```

Example 2: The following function returns a fixed-length binary string with a length attribute 5 and a value BX'D2C2C80000'

```
   SELECT BINARY('KBH',5)
     FROM SYSIBM.SYSDUMMY1;
```

Example 3: The following function returns a fixed-length binary string with a length attribute 3 and a value BX'D2C2C8'

```
    SELECT BINARY('KBH')
      FROM SYSIBM.SYSDUMMY1;
```

Example 4: The following function returns a fixed-length binary string with a length attribute 3 and a value BX'D2C2C8'

```
    SELECT BINARY('KBH ',3)
      FROM SYSIBM.SYSDUMMY1;
```

Example 5: The following function returns a fixed-length binary string with a length attribute 3 and a value BX'D2C2C8', a warning is also returned.

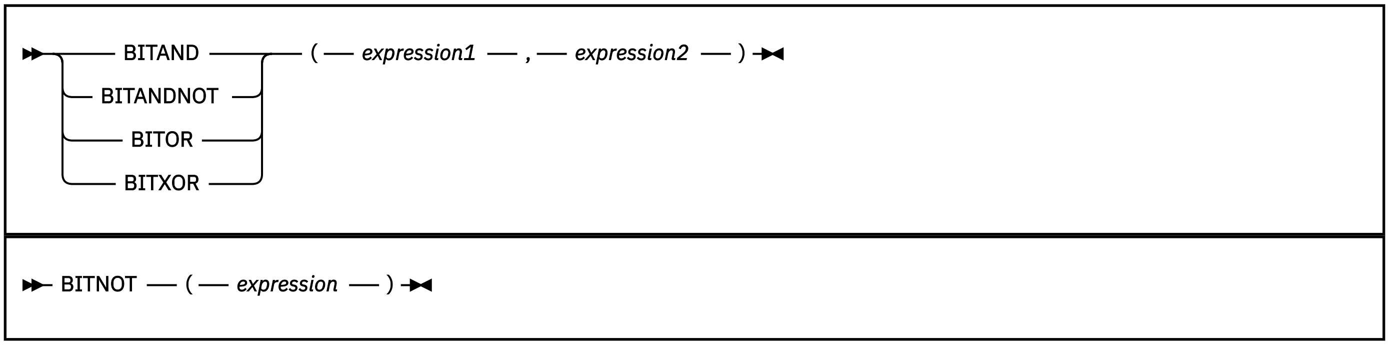
```
    SELECT BINARY('KBH 93',3)
      FROM SYSIBM.SYSDUMMY1;
```

Example 6: The following function returns a fixed-length binary string with a length attribute 3 and a value BX'C1C2C3', a warning is also returned.

```
    SELECT BINARY(BINARY('ABC',5),3)
      FROM SYSIBM.SYSDUMMY1;
```

BITAND, BITANDNOT, BITOR, BITXOR, and BITNOT

The bit manipulation functions operate on the *twos complement* representation of the integer value of the input arguments. The functions return the result as a corresponding base 10 integer value in a data type that is based on the data type of the input arguments.



The schema is SYSIBM.

Table 67. The bit manipulation funcitons

Function	Description	The bit in the *twos complement* representation of the result
BITAND	Performs a bitwise AND operation.	1 - only if the corresponding bits in both arguments are 1.
BITANDNOT	Clears any bit in the first argument that is in the second argument.	0 - if the corresponding bit in the second argument is 1. copied from the corresponding bit in the first argument - if the corresponding bit in the first argument is not 1.
BITOR	Performs a bitwise OR operation.	1 - unless the corresponding bits in both arguments are 0.

Table 67. The bit manipulation funcitons (continued)

Function	Description	The bit in the *twos complement* representation of the result
BITXOR	Performs a bitwise exclusive OR operation.	1 - unless the corresponding bits in both arguments are the same.
BITNOT	Performs a bitwise NOT operation.	Opposite of the corresponding bit in the argument.

expression*, *expression1*, or *expression2

expression, *expression1*, or *expression2* must be integer values represented by the data types SMALLINT, INTEGER, BIGINT, or DECFLOAT. Arguments that are of type DECIMAL, REAL, or DOUBLE are cast to DECFLOAT. The value is truncated to a whole number.

The bit manipulation functions can operate on up to 16 bits for SMALLINT, 32 bits for INTEGER, 64 bits for BIGINT, and 113 bits for DECFLOAT. The range of supported DECFLOAT values includes integers from -2_{122} to 2^{122} - 1. Special values such as NaN or INFINITY are not supported.

If the two arguments have different data types, the argument that supports fewer bits is cast to a value with the data type of the argument that supports more bits. This cast impacts the bits that are set for negative values. For example, -1 as a SMALLINT value has 16 bits set to 1. When -1 is cast to an INTEGER value, it has 32 bits set to 1.

The result of the functions with two arguments has the data type of the argument that is highest in the data type precedence list for promotion. If either argument is DECFLOAT, the data type of the result is DECFLOAT(34).

The result of the BITNOT function has the same data type as the input argument, except that DECIMAL, REAL, DOUBLE, or DECFLOAT(16) returns DECFLOAT(34).

The result can be null; if any argument is null, the result is the null value.

Due to differences in internal representation between data types and on different hardware platforms, using functions (such as HEX) or host language constructs to view or compare internal representations of BIT function results and arguments is data type-dependent and not portable. The data type- and platform-independent way to view or compare BIT function results and arguments is to use the actual integer values.

The BITXOR function is can be used to toggle bits in a value.

The BITANDNOT function can be used to clear bits.

BITANDNOT(*val*, *pattern*) operates more efficiently than BITAND(*val*, BITNOT(*pattern*)).

The following examples are based on an ITEM table with a PROPERTIES column of type INTEGER.

Return all items for which the third property bit is set.

```
SELECT ITEMID FROM ITEM
  WHERE BITAND(PROPERTIES, 4) = 4;
```

Return all items for which the fourth or the sixth property bit is set.

```
SELECT ITEMID FROM ITEM
  WHERE BITAND(PROPERTIES, 40) <> 0;
```

Clear the twelfth property of the item whose ID is 3412.

```
UPDATE ITEM
  SET PROPERTIES = BITANDNOT(PROPERTIES, 2048)
  WHERE ITEMID = 3412;
```

Set the fifth property of the item whose ID is 3412.

```
UPDATE ITEM
  SET PROPERTIES = BITOR(PROPERTIES, 16)
  WHERE ITEMID = 3412;
```

Toggle the eleventh property of the item whose ID is 3412.

```
UPDATE ITEM
  SET PROPERTIES = BITXOR(PROPERTIES, 1024)
  WHERE ITEMID = 3412;
```

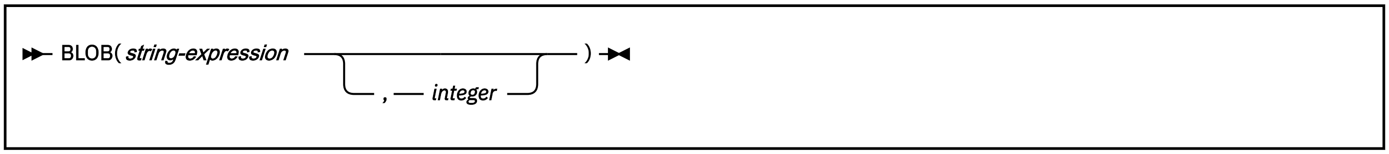
Switch all the bits in a 16-bit value that has only the second bit on.

```
SELECT  BITNOT(CAST(2 AS SMALLINT))
   FROM SYSIBM.SYSDUMMY1;
```

This example returns -3 (with a data type of SMALLINT).

BLOB

The BLOB function returns a BLOB representation of a string of any type or of a row ID type.



The schema is SYSIBM.

string-expression
An expression that returns a value that is a built-in character string, graphic string, binary string, or a row ID type.

integer
An integer value that specifies the length attribute of the resulting binary string. The value must be an integer between 1 and the maximum length of a BLOB.

Do not specify *integer* if *string-expression* is a row ID type.

If you do not specify *integer* and *string-expression* is an empty string constant, the length attribute of the result is 1, and the result is an empty string. Otherwise, the length attribute of the result is the same as the length attribute of *string-expression*, except when the input is graphic data. In this case, the length attribute of the result is twice the length of *expression*.

The result of the function is a BLOB.

The result can be null; if the first argument is null, the result is the null value.

The actual length of the result is the minimum of the length attribute of the result and the actual length of *string-expression* (or twice the length of *string-expression* when the input is graphic data). If the length of *string-expression* is greater than the length attribute of the result, truncation is performed. A warning is returned unless the first input argument is a character string and all the truncated characters are blanks, or the first input argument is a graphic string and all the truncated characters are double-byte blanks.

Example 1: The following function returns a BLOB for the string 'This is a BLOB'.

```
SELECT BLOB('This is a BLOB')
  FROM SYSIBM.SYSDUMMY1;
```

Example 2: The following function returns a BLOB for the large object that is identified by locator myclob_locator.

```
SELECT BLOB(:myclob_locator)
  FROM SYSIBM.SYSDUMMY1;
```

Example 3: Assume that a table has a BLOB column named TOPOGRAPHIC_MAP and a VARCHAR column named MAP_NAME. Locate any maps that contain the string 'Engles Island' and return a single binary string with the map name concatenated in front of the actual map.

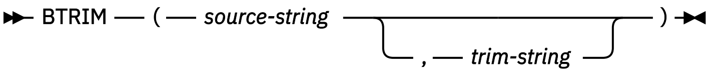
```
SELECT BLOB(MAP_NAME || ':  ') || TOPOGRAPHIC_MAP
  FROM ONTARIO_SERIES_4
  WHERE TOPOGRAPHIC_MAP LIKE BLOB('%Engles Island%')
```

BTRIM

The BTRIM function removes the characters that are specified in a trim string from the beginning and end of a source string.

FL 507

Passthrough-only expression: This function is passthrough-only and cannot run on Db2 for z/OS without acceleration. For information about invoking this function, see Accelerating queries with passthrough-only expressions.



The schema is SYSIBM.

This function compares the binary representation of each character (consisting of one or more bytes) in the trim string to the binary representation of each character (consisting of one or more bytes) at the beginning and end of the source string. The database collation does not affect the search. If *source-string* is defined as FOR BIT DATA, the search compares each byte in *trim-string* to the byte at the beginning and end of *source-string*.

source-string

An expression that specifies the string from which characters are to be removed. This expression must return a built-in character string, graphic string, numeric value, or datetime value. If the source string is:

- A numeric or datetime value, it is implicitly cast to VARCHAR before the function is evaluated
- A CLOB value, the length of the value is limited to the maximum size of a VARCHAR
- A DBCLOB value, the actual length of the value is limited to the maximum size of a VARGRAPHIC

trim-string

An expression that specifies the characters that are to be removed from the beginning and end of the source string. The expression must return a built-in character string, graphic string, numeric value, or datetime value. If the trim string is:

- Not a character string or graphic string, it is implicitly cast to VARCHAR before the function is evaluated
- A CLOB, the actual length of the value is limited to the maximum size of a VARCHAR
- A DBCLOB, the actual length of the value is limited to the maximum size of a VARGRAPHIC

The type of the source string determines the default trim string:

Type of source string	**Default trim string**
A graphic string	double-byte blank
A FOR BIT DATA string	X'20'
All other cases	single-byte blank

Restrictions:

- If the source string is not defined as FOR BIT DATA, then the trim string cannot be defined as FOR BIT DATA.
- If one parameter (source string or trim string) is character FOR BIT DATA, then the other parameter cannot be a graphic.

Result

The data type of the source string determines the data type of the result:

Data type of source string	Data type of result
VARCHAR or CHAR	VARCHAR
CLOB	CLOB
VARGRAPHIC or GRAPHIC	VARGRAPHIC
DBCLOB	DBCLOB

The length attribute of the data type of the result is the same as the length attribute of the data type of the source string. The length of the result is the length of the source string minus the number of string units that were removed. If all of the characters are removed, the result is an empty string with a length of zero.

If any argument can be null, the result can be null. If any argument is null, the result is the null value.

Examples

- The host variable BALANCE1 is of type CHAR(9) and has the value `'000345.50'`. The following statement returns the value `'345.5'`:

```
SELECT BTRIM(:BALANCE1, '0')
  FROM SYSIBM.SYSDUMMY1
```

- The host variable BALANCE2 is of type CHAR(9) and has the value `' 345.50'`. The following statement returns the value `'345.50'`.

```
SELECT BTRIM(:BALANCE2)
  FROM SYSIBM.SYSDUMMY1
```

CARDINALITY

The CARDINALITY function returns a value of type BIGINT that represents the number of elements of an array.

►► CARDINALITY(*array-expression*) ►◄

The schema is SYSIBM.

array-expression
An SQL variable, SQL parameter, or global variable of an array type, or a CAST specification that specifies an SQL variable, SQL parameter, global variable, or parameter marker as the source value.

The result of the CARDINALITY function is as follows:

- For an ordinary array, the result is the highest array index for which the array has an assigned element. Elements that have been assigned the null value are considered to be assigned elements.
- For an associative array, the result is the actual number of unique array index values that are defined in *array-expression*.
- For an empty array, the result is 0.

The data type of the result is BIGINT.

The result can be null; if *array-expression* is null, the result is the null value.

Example 1: Suppose that the array RECENT_CALLS is defined and contains a record of recent calls. RECENT_CALLS contains three elements. The following SET statement assigns the number of calls that have been stored in the array so far to SQL variable HOWMANYCALLS:

```
SET HOWMANYCALLS = CARDINALITY(RECENT_CALLS);
```

After the statement executes, HOWMANYCALLS contains 3.

Example 2: Suppose that the associative array variable CANADACAPITALS of array type CAPITALSARRAY contains all of the capitals for the 10 provinces and three territories in Canada, as well as the capital of the country, Ottawa. The following SET statement assigns the cardinality of CANADACAPTITALS to SQL variable NUMCAPITALS.

```
SET NUMCAPITALS = CARDINALITY(CANADACAPITALS) ;
```

After the statement executes, CANADACAPITALS contains 14.

CCSID_ENCODING

The CCSID_ENCODING function returns a string value that indicates the encoding scheme of a CCSID that is specified by the argument.

▶▶— CCSID_ENCODING(*expression*) —▶◀

The schema is SYSIBM.

expression

expression must be an expression that returns a value of a built-in numeric, character, or graphic string data type that is not a LOB. A character string must not have a length attribute greater than 255, and a graphic string must not have a length attribute greater than 127. If *expression* is a character or graphic string, the string must contain a valid string representation of a number. Leading and trailing blanks are eliminated and the resulting string must conform to the rules for forming a numeric constant.

The function returns a value of ASCII, EBCDIC, UNICODE, or UNKNOWN depending on the CCSID specified by expression.

The result of the function is a fixed-length character string of length 8, which is padded on the right if necessary.

The result can be null; if the argument is null, the result is the null value.

The CCSID of the result is determined from the context in which the function was invoked. For more information, refer to Determining the encoding scheme and CCSID of a string (Introduction to Db2 for z/OS).

Example 1: The following function returns a CCSID with a value for EBCDIC data.

```
    SELECT CCSID_ENCODING(37) AS CCSID
      FROM SYSIBM.SYSDUMMY1;
```

Example 2: The following function returns a CCSID with a value for ASCII data.

```
    SELECT CCSID_ENCODING(850) AS CCSID
      FROM SYSIBM.SYSDUMMY1;
```

Example 3: The following function returns a CCSID with a value for Unicode data.

```
SELECT CCSID_ENCODING(1208) AS CCSID
  FROM SYSIBM.SYSDUMMY1;
```

Example 4: The following function returns a CCSID with a value of UNKNOWN.

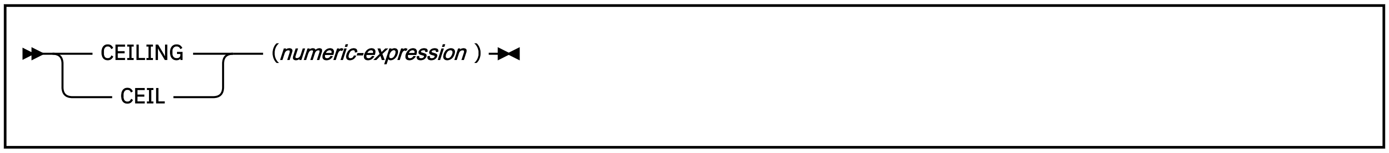
```
SELECT CCSID_ENCODING(1) AS CCSID
  FROM SYSIBM.SYSDUMMY1;
```

Example 5: The following function returns a CCSID with a value for EBCDIC data. The input data is a character string.

```
SELECT CCSID_ENCODING('37') AS CCSID
  FROM SYSIBM.SYSDUMMY1;
```

CEILING or CEIL

The CEILING function returns the smallest integer value that is greater than or equal to the argument.



The schema is SYSIBM.

The argument must be an expression that returns a value of any built-in numeric data type.

The argument can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34).

The result of the function has the same data type and length attribute as the argument except that the scale is 0 if the argument is DECIMAL. For example, an argument with a data type of DECIMAL(5,5) results in DECIMAL(5,0).

The result can be null; if the argument is null, the result is the null value.

Examples

Example 1

The following statement shows the use of CEILING on positive and negative values:

```
SELECT CEILING(3.5), CEILING(3.1), CEILING(-3.1), CEILING(-3.5)
  FROM SYSIBM.SYSDUMMY1;
```

This example returns: 04., 04., -03., -03.

Example 2

Using sample table DSN8C10.EMP, find the highest monthly salary for all the employees. Round the result up to the next integer. The SALARY column has a decimal data type.

```
SELECT CEILING(MAX(SALARY)/12)
  FROM DSN8C10.EMP;
```

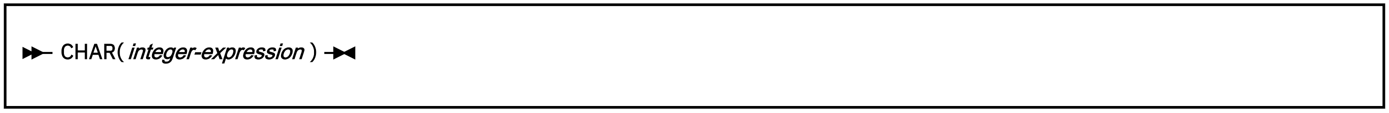
This example returns 04396. because the highest paid employee is Christine Haas who earns $52750.00 per year. Her average monthly salary before applying the CEILING function is 4395.83.

CHAR

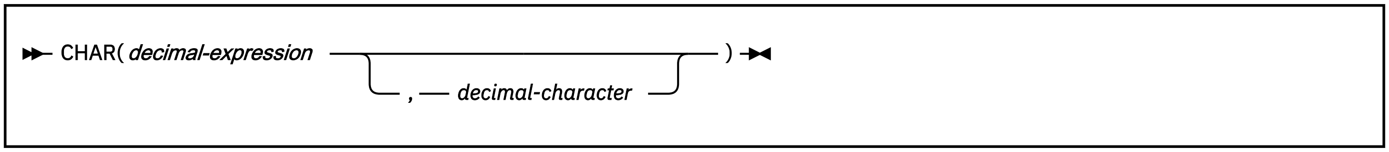
The CHAR function returns a fixed-length character string representation of the argument.

The syntax of the CHAR function depends on the data type of the input argument. The following types of input arguments are accepted.

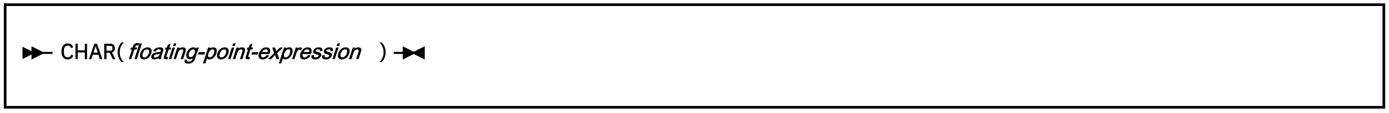
Integer to Character:



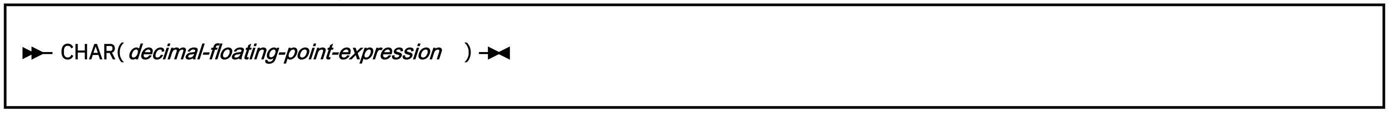
Decimal to Character:



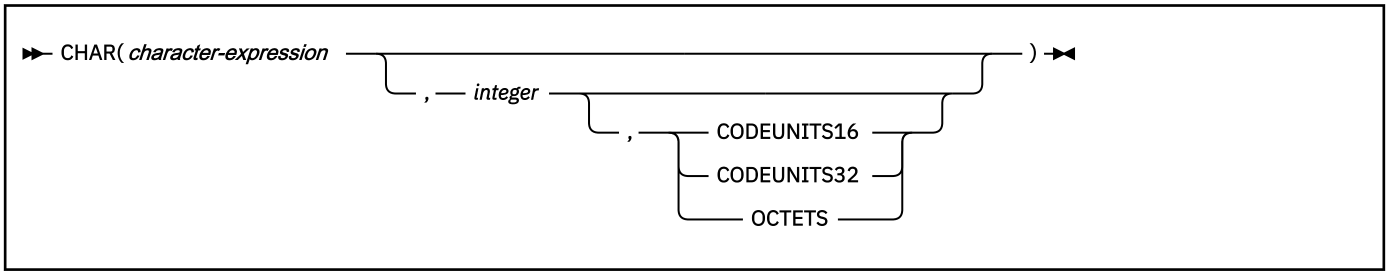
Floating-Point to Character:



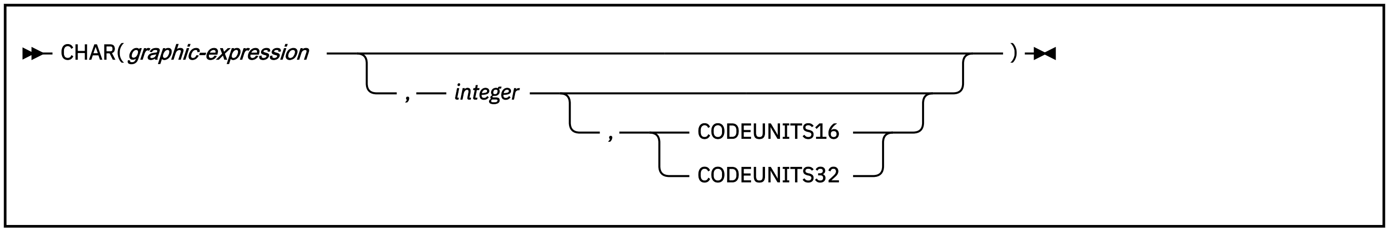
Decimal floating-point to Character:



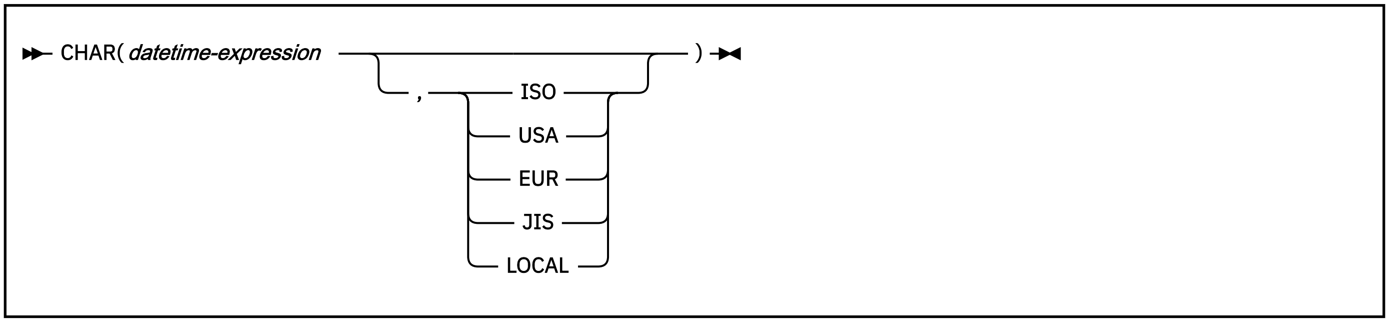
Character to Character:



Graphic to Character:



Datetime to Character:



Row ID to Character:

```
►► CHAR( row-ID-expression ) ►◄
```

The schema is SYSIBM.

The CHAR function returns a fixed-length character string representation of one of the following values:

- An integer number if the first argument is a SMALLINT, INTEGER, or BIGINT
- A decimal number if the first argument is a decimal number
- A double-precision floating-point number if the first argument is a DOUBLE or REAL
- A decimal floating-point number if the first argument is a DECFLOAT
- A character string value if the first argument is any type of character string
- A graphic string if the first argument is an EBCDIC or Unicode graphic string
- A datetime value if the first argument is a date, time, or timestamp
- A row ID value if the first argument is a row ID

The result of the function is a fixed-length character string (CHAR).

The result can be null; if the first argument is null, the result is the null value.

Integer to Character

integer-expression
An expression that returns a value that is a built-in integer data type (SMALLINT, INTEGER, or BIGINT).

The result is the fixed-length character string representation of the argument in the form of an SQL integer constant. The result is the smallest number of characters that can be used to represent the value of the argument, padded with blanks. The result consists of *n* characters that are the significant digits that represent the value of the argument with a preceding minus sign if the argument is negative. A positive value starts with a digit and always includes at least one trailing blank. Leading zeroes are not included. The result is left justified:

- If the argument is a small integer, the length of the result is 6. If the number of characters in the result is less than 6, the result is padded on the right with blanks.
- If the argument is a large integer, the length of the result is 11; if the number of characters in the result is less than 11, the result is padded on the right with blanks.
- If the argument is a big integer, the length of the result is 20. If the number of characters in the result is less than 20, the result is padded on the right with blanks.

A positive value always includes one trailing blank.

The CCSID of the result is determined from the application encoding scheme.

Decimal to Character

decimal-expression
An expression that returns a value that is a built-in decimal data type. To specify a different precision and scale for the value of the expression, apply the DECIMAL function before applying the CHAR function.

decimal-character
Specifies the single-byte character constant that is used to delimit the decimal digits in the result character string. The character must not be a digit, a plus sign (+), a minus sign (-), or a blank. The default is the period (.) or comma (,). For information on what factors govern the choice, see "Decimal point representation" on page 322.

The result is the fixed-length character string representation of the first argument. The result is the smallest number of characters that can be used to represent the value of the argument, except that trailing zeros are included.

The result includes a decimal character and up to *p* digits, where *p* is the precision of the *decimal-expression* with the preceding minus sign if the argument is negative. A positive value starts with a digit or the decimalcharacter, and always includes at least one trailing blank. Leading zeros are not returned. If the scale of *decimal-expression* is zero, the decimal character is not returned. If the number of bytes in the result is less than the defined length of the result, the result is padded on the right with blanks.[18]

The length of the result is 2 +*p*, where *p* is the precision of the *decimal-expression*.

The CCSID of the result is determined from the application encoding scheme.

Floating-Point to Character

floating-point-expression
An expression that returns a value that is a built-in floating-point data type (DOUBLE or REAL).

The result is the fixed-length character string representation of the argument in the form of an SQL floating-point constant. If the argument is negative, the first character of the result is a minus sign; otherwise, the first character is a digit. If the argument is zero, the result is 0E0.

The length of the result is 24. The result includes the smallest number of characters that can represent the value of the argument such that the mantissa consists of a single digit, other than zero, followed by a period and a sequence of digits.

If the number of characters in the result is less than 24, the result is padded on the right with blanks.

The CCSID of the result is determined from the application encoding scheme.

Decimal floating-point to Character

decimal-floating-point-expression
An expression that returns a value that is a built-in decimal floating-point data type (DECFLOAT).

The result is the fixed-length character string representation of the argument in the form of an SQL decimal floating-point constant.

If the result value is Infinity, sNaN, or NaN, the strings 'INFINITY', 'SNAN', and 'NAN', respectively, are returned. The DECFLOAT special value sNaN does not result in an exception when converted to a string.

The length of the result is 42. If the number of characters in the result is less than 42, the result is padded on the right with blanks. Trailing zeros are significant. If the argument is negative, the first character of the result is a minus sign. Otherwise, the first character is a digit, or a letter if the result value is Infinity, sNaN, or NaN.

The CCSID of the result is determined from the application encoding scheme.

Character to Character

character-expression
An expression that returns a value of a built-in character string.

integer
The length attribute for the resulting fixed-length character string. The value must be an integer constant between 1 and 255.

If the length is not specified, the length attribute of the result is the minimum of 255 and the length attribute of *character-expression*. If *character-expression* is an empty string constant, an error occurs.

If `CODEUNITS16` or `CODEUNITS32` is specified, see "Determining the length attribute of the final result" on page 108 for information about how to calculate the length attribute of the result string.

[18] If the function is invoked as CHAR and the BIF_COMPATIBILITY subsystem parameter is set to V9_DECIMAL_VARCHAR, or if the function is invoked as SYSCOMPAT_V9.CHAR, the result is formatted the same as the result of the CHAR9 function.

CODEUNITS16, CODEUNITS32, or OCTETS

Specifies the unit that is used to express *integer*. If *character-expression* is a character string that is defined as bit data, CODEUNITS16 and CODEUNITS32 cannot be specified.

CODEUNITS16

Specifies that *integer* is expressed in terms of 16-bit UTF-16 code units.

CODEUNITS32

Specifies that *integer* is expressed in terms of 32-bit UTF-32 code units.

OCTETS

Specifies that *integer* is expressed in terms of bytes.

For more information about CODEUNITS16, CODEUNITS32, and OCTETS, see "String unit specifications" on page 106.

The actual length is the same as the length attribute of the result. If the length of *character-expression* is less than the length attribute of the result, the result is padded with blanks to the length of the result. If the length of *character-expression* is greater than the length attribute of the result, the result is truncated. Unless all of the truncated characters are blanks, a warning is returned.

If *character-expression* is bit data, the result is bit data. Otherwise, the CCSID of the result is the same as the CCSID of *character-expression*.

Graphic to Character

graphic-expression

An expression that returns a value of a built-in graphic string.

integer

The length attribute for the resulting fixed-length character string. The value must be an integer constant between 1 and 255.

If the length is not specified, the length attribute of the result is the minimum of 255 and the length attribute of *graphic-expression*. The length attribute of *graphic-expression* is (3 * *length(graphic-expression)*). If *graphic-expression* is an empty string constant, an error occurs.

If CODEUNITS16 or CODEUNITS32 is specified, see "Determining the length attribute of the final result" on page 108 for information about how to calculate the length attribute of the result string.

CODEUNITS16 or CODEUNITS32

Specifies the unit that is used to express *integer*.

CODEUNITS16

Specifies that *integer* is expressed in terms of 16-bit UTF-16 code units.

CODEUNITS32

Specifies that *integer* is expressed in terms of 32-bit UTF-32 code units.

For more information about CODEUNITS16 and CODEUNITS32, see "String unit specifications" on page 106.

The actual length is the same as the length attribute of the result. If the length of *graphic-expression* is less than the length attribute of the result, the result is padded with blanks to the length of the result. If the length of *graphic-expression* is greater than the length attribute of the result, the result is truncated. Unless all of the truncated characters are blanks, a warning is returned.

The CCSID of the result is the character mixed CCSID that corresponds to the graphic CCSID of *graphic-expression*.

Datetime to Character

datetime-expression

An expression that is one of the following built-in data types:

date

The result is the character string representation of the date in the format that is specified by the second argument. If the second argument is omitted, the DATE precompiler option, if one is provided, otherwise field DATE FORMAT on installation panel DSNTIP4 specifies the format.

If the format is LOCAL, field LOCAL DATE LENGTH on installation panel DSNTIP4 specifies the length of the result. Otherwise, the length of the result is 10.

LOCAL denotes the local format at the Db2 subsystem that executes the SQL statement. If LOCAL is used for the format, a date exit routine must be installed at that Db2 subsystem.

An error occurs if the second argument is specified and is not a valid value.

time

The result is the character string representation of the time in the format that is specified by the second argument. If the second argument is omitted, the TIME precompiler option, if one is provided, otherwise field TIME FORMAT on installation panel DSNTIP4 specifies the format. If the format is LOCAL, the field LOCAL TIME LENGTH on installation panel DSNTIP4 specifies the length of the result. Otherwise, the length of the result is 8.

LOCAL denotes the local format at the Db2 subsystem that executes the SQL statement. If LOCAL is used for the format, a time exit routine must be installed at that Db2 subsystem.

An error occurs if the second argument is specified and is not a valid value.

timestamp without time zone

The result is the character string representation of the timestamp. If *datetime-expression* is a TIMESTAMP(0) value, the length of the result is 19. If *datetime-expression* is a TIMESTAMP(*integer*) value, the length of the result is 20+*integer*. Otherwise, the length of the result is 26. The second argument must not be specified.

timestamp with time zone

The result is the character string representation of the timestamp with time zone, formatted as *yyyy-mm-dd-hh.mm.ss.nnnnnn±th:tm* with the appropriate number of 'n' characters for the precision of the timestamp. If *datetime-expression* is a TIMESTAMP(0) WITH TIME ZONE, the length of the result is 147. If *datetime-expression* is a TIMESTAMP(*integer*) WITH TIME ZONE, the length of the result is 148+*integer*. The second argument must not be specified.

The CCSID of the result is determined from the context in which the function is invoked. For more information, see Determining the encoding scheme and CCSID of a string (Introduction to Db2 for z/OS).

ISO, EUR, USA, JIS, or LOCAL

Specifies the date or time format of the resulting character string. For more information, see "String representations of datetime values" on page 120.

Row ID to Character

row-ID-expression

An expression that returns a value that is a built-in row ID data type.

The result is the fixed-length character string representation of the argument. The result is bit data.

The length of the result is 40. If the length of *row-ID-expression* is less than 40, the result is padded on the right with hexadecimal zeros to a length of 40.

Recommendation: To increase the portability of applications, use the CAST specification when the first argument is numeric, or the first argument is a string and the length argument is specified. For more information, see "CAST specification" on page 266.

Notes

Syntax alternatives:

CHAR9 can be specified as an alternative to CHAR, except when the first argument is decimal data. See CHAR9.

Examples

Example 1:

HIREDATE is a DATE column in sample table DSN8C10.EMP. When it represents the date 15 December 1976 (as it does for employee 140), the following example returns the string value '12/15/1976' in character string variable *DATESTRING*:

```
  EXEC SQL SELECT CHAR(HIREDATE, USA)
    INTO :DATESTRING
    FROM DSN8C10.EMP
    WHERE EMPNO = '000140';
```

Example 2:

Host variable *HOUR* has a data type of DECIMAL(6,0) and contains a value of 50000. Interpreted as a time duration, this value is 5 hours. Assume that STARTING is a TIME column in some table. Then, when STARTING represents 17 hours, 30 minutes, and 12 seconds after midnight, the following example returns the value '10:30 PM':

```
  CHAR(STARTING+:HOURS, USA)
```

Example 3:

Assume that RECEIVED is defined as a TIMESTAMP column in table TABLEY. When the value of the date portion of RECEIVED represents the date 10 March 1997 and the time portion represents 6 hours and 15 seconds after midnight, the following example returns the string value '1997-03-10-06.00.15.000000':

```
  SELECT CHAR(RECEIVED)
    FROM TABLEY
    WHERE INTCOL = 1234;
```

Example 4:

For sample table DSN8C10.EMP, the following SQL statement sets the host variable *AVERAGE*, which is defined as CHAR(33), to the character string representation of the average employee salary.

```
  EXEC SQL SELECT CHAR(AVG(SALARY))
    INTO :AVERAGE
    FROM DSN8C10.EMP;
```

With DEC31, the result of AVG applied to a decimal number is a decimal number with a precision of 31 digits. The only host languages in which such a large decimal variable can be defined are Assembler and C. For host languages that do not support such large decimal numbers, use the method shown in this example.

Example 5:

For the rows in sample table DSN8C10.EMP, return the values in column LASTNAME, which is defined as VARCHAR(15), as a fixed-length character string and limit the length of the results to 10 characters.

```
  SELECT CHAR(LASTNAME,10)
    FROM DSN8C10.EMP;
```

For rows that have a LASTNAME with a length greater than 10 characters (excluding trailing blanks), a warning that the value is truncated is returned.

Example 6:

FIRSTNAME is a VARCHAR(12) column in a Unicode table T1. One of its values is the 6-character string 'Jürgen'. When FIRSTNAME has the values shown under 'Function', the results are shown under 'Returns':

```
Function ...                    Returns ...
-----------------------------------------------------------------------------------
CHAR(FIRSTNAME,3,CODEUNITS32)   'Jür         ' -- x'4AC3BC722020202020202020'
```

```
  CHAR(FIRSTNAME,3,CODEUNITS16)   'Jür      '    -- x'4AC3BC722020202020'
  CHAR(FIRSTNAME,3,OCTETS)        'Jü'           -- x'4AC3BC'
```

Example 7

For the rows in sample table DSN8C10.EMP, return the values in column EDLEVEL, which is defined as SMALLINT, as a fixed-length character string.

```
    SELECT CHAR(EDLEVEL)
      FROM DSN8C10.EMP;
```

An EDLEVEL of 18 is returned as CHAR(6) value '18   ' (18 followed by four blanks).

Example 8:

In sample table DSN8C10.EMP, the SALARY column is defined as DECIMAL(9,2). For those employees who have a salary of 52750.00, return the hire date and the salary, using a comma as the decimal character in the salary (52750,00).

```
    SELECT HIREDATE, CHAR(SALARY, ',')
      FROM DSN8C10.EMP
      WHERE SALARY = 52750.00;
```

The salary is returned as the string value '52750,00'.

Example 9:

Repeat the scenario in Example 8 except subtract the SALARY column from 60000.00 and return the salary with the default decimal character.

```
    SELECT HIREDATE, CHAR (60000.00 - SALARY)
      FROM DSN8C10.EMP
      WHERE SALARY = 52750.00;
```

The salary is returned as the string value '7250.00'.

Example 10:

Assume that host variable *SEASONS_TICKETS* is defined as INTEGER and has a value of 10000. Use the DECIMAL and CHAR functions to change the value into the character string ' 10000.00'.

```
    SELECT CHAR(DECIMAL(:SEASONS_TICKETS,7,2))
      FROM SYSIBM.SYSDUMMY1;
```

Example 11:

Assume that columns COL1 and COL2 in table T1 are both defined as REAL and that T1 contains a single row with the values 7.1E+1 and 7.2E+2 for the two columns. Add the two columns and represent the result as a character string.

```
    SELECT CHAR(COL1 + COL2)
      FROM T1;
```

The result is the character value '1.43E2   '.

Data types of columns (Introduction to Db2 for z/OS)

Related reference

“CHAR9” on page 412
The CHAR9 function returns a fixed-length character string representation of the argument. The CHAR9 function is intended for compatibility with previous releases of Db2 for z/OS that depend on the result format that is returned for decimal input values in Version 9 and earlier.

BIF COMPATIBILITY field (BIF_COMPATIBILITY subsystem parameter) (Db2 Installation and Migration)

CHAR9

The CHAR9 function returns a fixed-length character string representation of the argument. The CHAR9 function is intended for compatibility with previous releases of Db2 for z/OS that depend on the result format that is returned for decimal input values in Version 9 and earlier.

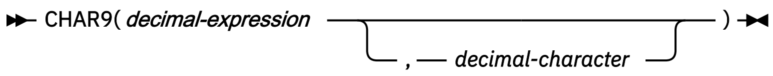
Important: For portable applications that might run on platforms other than Db2 for z/OS, use the CHAR function instead. Other Db2 family products do not support the CHAR9 function.

The first argument can be any one value of the following types:

- Integer number
- Decimal number
- Floating-point number
- Decimal floating-point number
- Character string
- Graphic string
- Datetime value
- Row ID value

If the first argument is a decimal number, the result is formatted as indicated in the following description. However, if the first argument is not a decimal number, the result is identical to the result of the CHAR function.

Decimal to Character:



Decimal to Character

decimal-expression

An expression that returns a value that is a built-in decimal data type. To specify a different precision and scale for the value of the expression, apply the DECIMAL function before applying the CHAR9 function.

decimal-character

Specifies the single-byte character constant (CHAR or VARCHAR) that delimits the decimal digits in the result character string. The character must not be a digit, a plus sign (+), a minus sign (-), or a blank. The default is the period (.) or comma (,). For information about the factors that govern the choice, see "Decimal point representation" on page 322

The result is the fixed-length character string representation of the argument. The result includes a decimal character and up to *p* digits, where *p* is the precision of the *decimal-expression* with the preceding minus sign if the argument is negative. Leading and trailing zeros are returned, and a leading blank is returned for a positive decimal value. The result includes a decimal character even if the scale of *decimal-expression* is zero. If the number of bytes in the result is less than the defined length of the result, the result is padded on the right with blanks.

The length of the result is 2 +*p*, where *p* is the precision of the *decimal-expression*.

The length attribute of the result is 2+p where p is the precision of *decimal-expression*.

The actual length of the result is the smallest number of characters that can be used to represent the result, except that trailing zeros are included. If the argument is negative, the result begins with a minus sign. Otherwise, the result begins with a digit. If the scale of *decimal-expression* is zero, the decimal character is not returned.

The CCSID of the result is determined from the context in which the function was invoked. For more information, see Determining the encoding scheme and CCSID of a string (Introduction to Db2 for z/OS).

Examples

The following table shows the difference between the results of the CHAR and CHAR9 functions for example decimal number arguments.

Table 68. Example results of CHAR and CHAR9 functions

Decimal argument	CHAR function result	CHAR9 function result
`(000.1)`	`'.1 '`	`' 000.1'`
`(1000)`	`'1000 '`	`' 1000.'`
`(1.1)`	`'1.1 '`	`' 1.1'`

Related concepts

Data types of columns (Introduction to Db2 for z/OS)

Related reference

CHAR

The CHAR function returns a fixed-length character string representation of the argument.

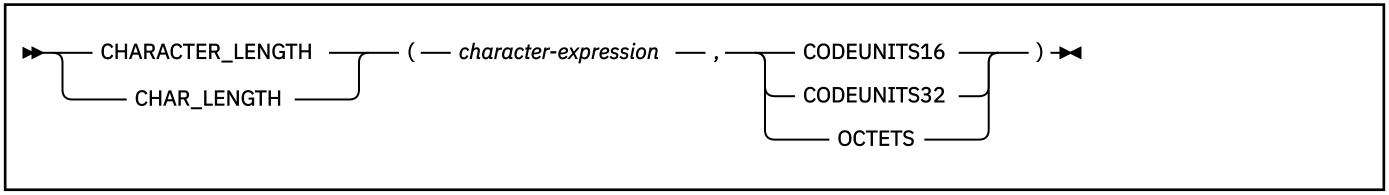
BIF COMPATIBILITY field (BIF_COMPATIBILITY subsystem parameter) (Db2 Installation and Migration)

CHARACTER_LENGTH or CHAR_LENGTH

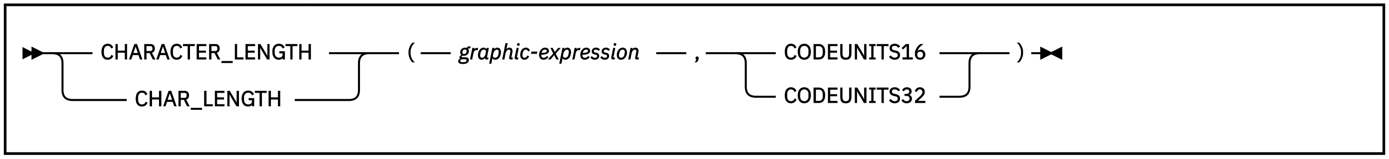
The CHARACTER_LENGTH function returns the length of the first argument in the specified string unit.

FL 506

Character string:



Graphic string:



The schema is SYSIBM.

Character string:

character-expression

An expression that returns a value of a built-in character string. *character-expression* cannot be bit data.

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type.

CODEUNITS16, CODEUNITS32, or OCTETS

Specifies the unit that is used to express the length of the result.

CODEUNITS16

Specifies that the result is expressed in terms of 16-bit UTF-16 code units.

CODEUNITS32

Specifies that the result is expressed in terms of 32-bit UTF-32 code units.

OCTETS
Specifies the result is expressed in terms of bytes.

For more information about CODEUNITS16, CODEUNITS32, and OCTETS, see "String unit specifications" on page 106.

The result of the function is a large integer.

The result can be null; if the argument is null, the result is the null value.

The result is the length of *character-expression* expressed in the number of string units that were specified. The length of fixed-length strings includes trailing blanks. The length of varying-length strings is the actual length and not the maximum length.

Graphic string:

graphic-expression
An expression that returns a value of a built-in graphic string.

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type.

CODEUNITS16 or CODEUNITS32
Specifies the unit that is used to express the length of the result.

CODEUNITS16
Specifies that the result is expressed in terms of 16-bit UTF-16 code units.

CODEUNITS32
Specifies that the result is expressed in terms of 32-bit UTF-32 code units.

For more information about CODEUNITS16 and CODEUNITS32 see "String unit specifications" on page 106.

The result of the function is a large integer.

The result can be null; if the argument is null, the result is the null value.

The result is the length of *graphic-expression* expressed in the number of string units that were specified. The length of fixed-length strings includes trailing blanks. The length of varying-length strings is the actual length and not the maximum length.

Example: Assume that NAME is a VARCHAR(128) column, encoded in Unicode UTF-8, that contains the value 'Jürgen'. The following two queries return the value 6:

```
SELECT CHARACTER_LENGTH(NAME,CODEUNITS32)
  FROM T1 WHERE NAME = 'Jürgen';
SELECT CHARACTER_LENGTH(NAME,CODEUNITS16)
  FROM T1 WHERE NAME = 'Jürgen';
```

The following two queries return the value 7:

```
SELECT CHARACTER_LENGTH(NAME,OCTETS)
  FROM T1 WHERE NAME = 'Jürgen';
SELECT LENGTH(NAME)
  FROM T1 WHERE NAME = 'Jürgen';
```

CHR

The CHR function returns the character that has the ASCII code value that is specified by the argument.

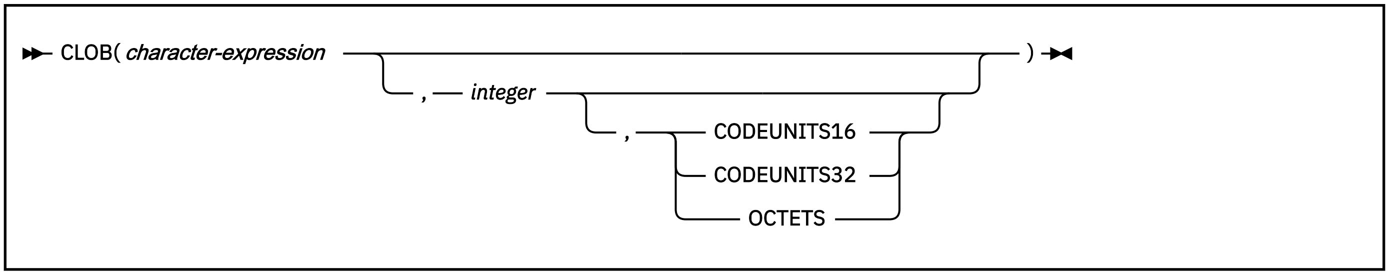
►► CHR(*expression*) ►◄

The CHR function is identical to the ASCII_CHR function. For more information, see "ASCII_CHR" on page 393.

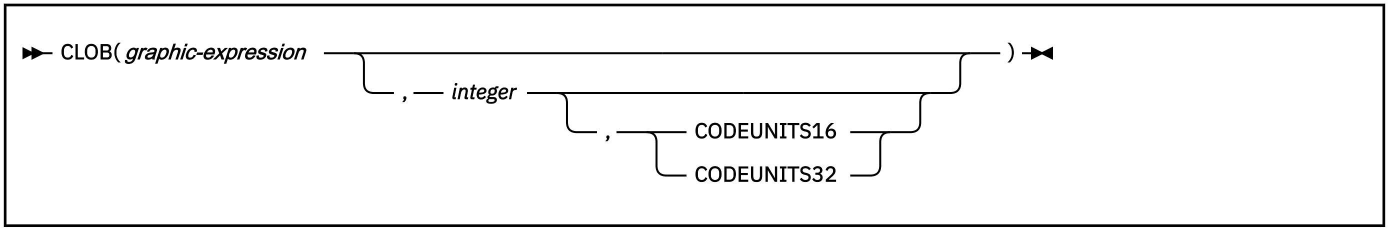
CLOB

The CLOB function returns a CLOB representation of a string.

Character to CLOB:



Graphic to CLOB:



The schema is SYSIBM.

Character to CLOB

character-expression
An expression that returns a value of a character string. If *character-expression* is bit data, an error occurs.

integer
An integer constant that specifies the length attribute of the resulting CLOB data type. The value must be between 1 and the maximum length of a CLOB, expressed in the units that are either implicitly or explicitly specified.

If you do not specify *integer* and *character-expression* is an empty string constant, the length attribute of the result is 1, and the result is an empty string. Otherwise, the length attribute of the result is the same as the length attribute of *character-expression*.

If CODEUNITS16 or CODEUNITS32 is specified, see "Determining the length attribute of the final result" on page 108 for information on how to calculate the length attribute of the result string.

CODEUNITS16, CODEUNITS32, or OCTETS
Specifies the unit that is used to express *integer*.

CODEUNITS16
Specifies that *integer* is expressed in terms of 16-bit UTF-16 code units.

CODEUNITS32
Specifies that *integer* is expressed in terms of 32-bit UTF-32 code units.

OCTETS
Specifies that *integer* is expressed in terms of bytes.

For more information about CODEUNITS16, CODEUNITS32, and OCTETS, see "String unit specifications" on page 106.

The result of the function is a CLOB.

The result can be null; if the first argument is null, the result is the null value.

The actual length of the result is the minimum of the length attribute of the result and the actual length of *character-expression*. If the length of *character-expression* is greater than the length specified, the result is truncated. Unless all of the truncated characters are blanks, a warning is returned.

The CCSID of the result is the same as the CCSID of *character-expression*.

Graphic to CLOB

graphic-expression
An expression that returns a value of a graphic string.

integer
An integer constant that specifies the length attribute of the resulting CLOB data type. The value must be between 1 and the maximum length of a CLOB, expressed in the units that are either implicitly or explicitly specified.

If you do not specify *integer* and *graphic-expression* is an empty string constant, the length attribute of the result is 1, and the result is an empty string. Otherwise, the length attribute of the result is (3 * *length*(*graphic-expression*)).

If CODEUNITS16 or CODEUNITS32 is specified, see "Determining the length attribute of the final result" on page 108 for information on how to calculate the length attribute of the result string.

CODEUNITS16 or CODEUNITS32
Specifies the unit that is used to express *integer*.

CODEUNITS16
Specifies that *integer* is expressed in terms of 16-bit UTF-16 code units.

CODEUNITS32
Specifies that *integer* is expressed in terms of 32-bit UTF-32 code units.

For more information about CODEUNITS16 and CODEUNITS32, see "String unit specifications" on page 106.

The result of the function is a CLOB.

The result can be null; if the first argument is null, the result is the null value.

The actual length of the result is the minimum of the length attribute of the result and the actual length of *graphic-expression*. If the length of *graphic-expression* is greater than the length specified, the result is truncated. Unless all of the truncated characters are blanks, a warning is returned.

The CCSID of the result is the character mixed CCSID that corresponds to the graphic CCSID of *graphic-expression*.

Notes

Syntax alternatives:
FL 506 TO_CLOB is a synonym for CLOB.

Examples

Example 1: The following function returns a CLOB for the string 'This is a CLOB'.

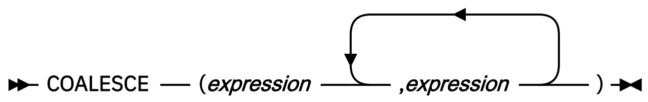
```
SELECT CLOB('This is a CLOB')
  FROM SYSIBM.SYSDUMMY1;
```

Example 2: FIRSTNME is a VARCHAR(12) column in table T1. One of its values is the 6-character string 'Jürgen'. When FIRSTNME has this value:

```
Function ...                         Returns ...
CLOB(FIRSTNME,3,CODEUNITS32)         'Jür'  -- x'4AC3BC72'
CLOB(FIRSTNME,3,CODEUNITS16)         'Jür'  -- x'4AC3BC72'
CLOB(FIRSTNME,3,OCTETS)              'Jü'   -- x'4AC3BC'
```

COALESCE

The COALESCE function returns the value of the first nonnull expression.



The schema is SYSIBM.

The arguments must be compatible. For more information on compatibility, refer to the compatibility matrix in Table 30 on page 144. The arguments can be of either a built-in or user-defined data type.

The arguments are evaluated in the order in which they are specified, and the result of the function is the first argument that is not null. The result can be null only if all arguments can be null. The result is null only if all arguments are null.

The selected argument is converted, if necessary, to the attributes of the result. The attributes of the result are determined using the "Rules for result data types" on page 166. If the COALESCE function has more than two arguments, the rules are applied to the first two arguments to determine a candidate result type. The rules are then applied to that candidate result type and the third argument to determine another candidate result type. This process continues until all arguments are analyzed and the final result type is determined.

If there are any mixed character string or graphic string and numeric arguments, the string value is implicitly cast to a DECFLOAT(34) value.

The COALESCE function can also handle a subset of the functions provided by CASE expressions. The result of using `COALESCE(e1,e2)` is the same as using the expression:

```
CASE WHEN e1 IS NOT NULL THEN e1 ELSE e2 END
```

VALUE can be specified as a synonym for COALESCE.

Example 1: Assume that SCORE1 and SCORE2 are SMALLINT columns in table GRADES, and that nulls are allowed in SCORE1 but not in SCORE2. Select all the rows in GRADES for which SCORE1 + SCORE2 > 100, assuming a value of 0 for SCORE1 when SCORE1 is null.

```
SELECT * FROM GRADES
  WHERE COALESCE(SCORE1,0) + SCORE2 > 100;
```

Example 2: Assume that a table named DSN8C10.EMP contains a DATE column named HIREDATE, and that nulls are allowed for this column. The following query selects all rows in DSN8C10.EMP for which the date in HIREDATE is either unknown (null) or earlier than 1 January 1960.

```
SELECT * FROM DSN8C10.EMP
  WHERE COALESCE(HIREDATE,DATE('1959-12-31')) < '1960-01-01';
```

The predicate could also be coded as `COALESCE(HIREDATE,'1959-12-31')` because, for comparison purposes, a string representation of a date can be compared to a date.

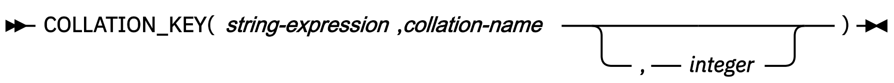
Example 3: Assume that for the years 1993 and 1994 there is a table that records the sales results of each department. Each table, S1993 and S1994, consists of a DEPTNO column and a SALES column, neither of which can be null. The following query provides the sales information for both years.

```
SELECT COALESCE(S1993.DEPTNO,S1994.DEPTNO) AS DEPT, S1993.SALES, S1994.SALES
  FROM S1993 FULL JOIN S1994 ON S1993.DEPTNO = S1994.DEPTNO
  ORDER BY DEPT;
```

The full outer join ensures that the results include all departments, regardless of whether they had sales or existed in both years. The COALESCE function allows the two join columns to be combined into a single column, which enables the results to be ordered.

COLLATION_KEY

The COLLATION_KEY function returns a varying-length binary string that represents the collation key of the argument in the specified collation.



The schema is SYSIBM.

The result of COLLATION_KEY on one string can be compared in binary form with the result of COLLATION_KEY on another string to determine their order within the specified *collation-name*. For the comparison to be meaningful, the results of the COLLATION_KEY must be from the same *collation-name*.

string-expression
An expression that returns a character or graphic string that is not a LOB for which the collation key is to be determined. If *string-expression* is a character string, it must not be FOR BIT DATA. If *string-expression* is not in Unicode UTF-16 (CCSID 1200), it is converted to Unicode UTF-16 before the corresponding collation key is obtained. The length of *string-expression* must not exceed 32704 bytes of the UTF-16 representation.

collation-name
A string constant or a string host variable that is not a binary string, CLOB, or DBCLOB. *collation-name* specifies the collation to use when determining the collation key. If *collation-name* is not an EBCDIC value, it is converted to EBCDIC. The length of *collation-name* must be between 1 and 255 bytes of the EBCDIC representation. The value of *collation-name* is not case sensitive and must be a left justified, valid "short path" collation setting for the parameter CUNBOPRM_Collation_Keyword in area CUN4BOPR. For detailed information about the "short path" setting in the parameter CUNBOPRM_Collation_Keyword, see Description of parameters in area CUNBOPRM (z/OS: Unicode Services User's Guide and Reference).

The value of the host variable must not be null. If the host variable has an associated indicator variable, the value of the indicator variable must not indicate a null value. *collation-name* must be left justified within the host variable. It must also be padded on the right with blanks if the length is less than that of the host variable and the host variable is a fixed length CHAR or GRAPHIC data type.

collation-name is in the form of CUN4BOPR_Collation_Keyword specification. You must specify a value that is acceptable for the z/OS CUNBOPR_Collation_Keyword parameter.

The following table lists some supported values:

Table 69. Collation Keywords Reference

Attribute name	**Key**	**Possible values**
Locale	L.R.V	<locale>
Strength	S	1, 2, 3, 4, I, D
Case_Level	K	X, O, D
Case_First	C	X, L, U, D
Alternate	A	N, S, D
Variable_Top	T	<hex digits>
Normalization	N	X, O, D
French	F	X, O, D
Hinayana	H	X, O, D

The following table describes the abbreviations for the collation keywords:

Abbreviation
Definition

D
default

O
on

X
off

1
primary

2
secondary

3
tertiary

4
quaternary

I
identical

S
shifted

N
non-ignorable

L
lower-first

U
upper-first

The following examples show keywords using the above specifications:

```
'UCA400R1_AS_LSV_S3_CU'
```

UCA version 4.0.1; ignore spaces, punctuation and symbols; use Swedish linguistic conventions; use case-first upper; compare case-sensitive.

```
'UCA400R1_AN_LSV_S3_CL_NO'
```

UCA version 4.0.1; do not ignore spaces, punctuation and symbols; use Swedish linguistic conventions; use case-first lower (or does not set it to mean the same, since lower is used in most locales as the default); normalization ON; compare case-sensitive.

integer
An integer value that specifies the length attribute of the result. If specified, the value must be an integer constant between 1 and 32704.

If the length is not specified, the length attribute of the result is determined as follows:

string-expression	**Result length attribute**
CHAR(*n*) or VARCHAR(*n*)	MIN (VARBINARY(12*n*), 32704)
GRAPHIC(*n*) or VARGRAPHIC(*n*)	MIN (VARBINARY(12*n*), 32704)

Regardless of whether the length is specified, the length of the collation key must be less than or equal to the length attribute of the result. The actual result length of the collation key is approximately six times of the length of *string-expression* where the length of *string-expression* is in Unicode byte representation. For certain *collation-name* such as UCA410_LKO_RKR (for Korean collation) the default length attribute of the result, 12*n*, might not be large enough and an error will be returned. To avoid such an error, the length attribute of the result must be explicitly specified to a larger constant. For the proper length attribute of the result, see Description of parameters in area CUNBOPRM (z/OS: Unicode Services User’s Guide and Reference) for information about target buffer length considerations for Collation Services.

The result can be null; if the first argument is null, the result is the null value.

The COLLATION_KEY function uses Unicode Collation Services in z/OS to return the collation key. See Locales supported for collation (z/OS: Unicode Services User’s Guide and Reference) for a list of supported collation versions.

If Unicode Collation Services are not available when the COLLATION_KEY function is run, an error is returned.

Example 1: The following query orders the employees by their surnames using the default Unicode Collation Algorithm V4.0.1(UCA), ignoring spaces, punctuation, and symbols, using Swedish linguistic conventions, and not comparing case:

```
SELECT FIRSTNAME, LASTNAME
  FROM DSN8C10.EMP
  ORDER BY COLLATION_KEY(LASTNAME, 'UCA400R1_AS_LSV_S2');
```

Example 2: The following query uses the COLLATION_KEY function on the LASTNAME column and the SALES_PERSON column to obtain the sort keys from the same collation name in order to do a culturally correct comparison. It finds the departments of employees in Quebec:

```
SELECT E.WORKDEPT
  FROM EMPLOYEE AS E INNER JOIN SALES AS S
  ON COLLATION_KEY(E.LASTNAME, 'UCA400R1_LFR_RCA') =
                 COLLATION_KEY(S.SALES_PERSON, 'UCA400R1_LFR_RCA')
  WHERE S.REGION = 'Quebec';
```

Example 3: Create an index EMPLOYEE_NAME_SORT_KEY for table EMPLOYEE based on built-in function COLLATION_KEY with collation name 'UCA410_LDE' tailored for German.

```
CREATE INDEX EMPLOYEE_NAME_SORT_KEY
  ON EMPLOYEE (COLLATION_KEY(LASTNAME, 'UCA410_LDE', 600),
             COLLATION_KEY(FIRSTNAME, 'UCA410_LDE', 600),
             ID);
```

Related reference

Description of parameters in area CUN4BOPR (z/OS: Unicode Services User’s Guide and Reference)

Locales supported for collation (z/OS: Unicode Services User’s Guide and Reference)

COMPARE_DECFLOAT

The COMPARE_DECFLOAT function returns a SMALLINT value that indicates whether the two arguments are equal or unordered, or whether one argument is greater than the other.

```
►► COMPARE_DECFLOAT( decfloat-expression1 ,decfloat-expression2 ) ►◄
```

The schema is SYSIBM.

decfloat-expression1
An expression that returns a DECFLOAT value.

decfloat-expression2
An expression that returns a DECFLOAT value.

decfloat-expression1 is compared with *decfloat-expression2* and the result is returned according to the following rules:

- If both arguments are finite, the comparison is algebraic and follows the procedure for DECFLOAT subtraction. If the different is exactly zero with either sign, the arguments are equal. If a nonzero difference is positive, the first argument is greater than the second argument. If a nonzero difference is negative, the first argument is less than the second.

- Positive zero and negative zero compare as equal.
- Positive infinity compares equal to positive infinity.
- Positive infinity compares greater than any finite number.
- Negative infinity compares equal to negative infinity.
- Negative infinity compares less than any finite number.
- Numeric comparison is exact and the result is determined for finite operands as if range and precision were unlimited. Overflow or underflow cannot occur.
- If either argument is NaN or sNaN (positive or negative), the result is unordered.

Numeric comparison is exact, and the result is determined for finite operands as if the range and precision were unlimited. An overflow or underflow condition cannot occur.

If one argument is DECFLOAT(16) and the other is DECFLOAT(34), the DECFLOAT(16) value is converted to DECFLOAT(34) before the comparison is made.

The arguments can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34).

One of the following values will be the result:

0
The arguments are exactly equal

1
decfloat-expression1 is less than *decfloat-expression2*

2
decfloat-expression1 is greater than *decfloat-expression2*

3
The arguments are unordered

The result of the function is a SMALLINT value.

The result can be null; if any argument is null, the result is the null value.

Examples: The following examples demonstrate the values that will be returned when the function is used:

```
    COMPARE_DECFLOAT(DECFLOAT(2.17), DECFLOAT(2.17))        = 0
    COMPARE_DECFLOAT(DECFLOAT(2.17), DECFLOAT(2.170))       = 2
    COMPARE_DECFLOAT(DECFLOAT(2.170), DECFLOAT(2.17))       = 1
    COMPARE_DECFLOAT(DECFLOAT(2.17), DECFLOAT(0.0))         = 2
    COMPARE_DECFLOAT(INFINITY,INFINITY)                     = 0
    COMPARE_DECFLOAT(INFINITY,-INFINITY)                    = 2
    COMPARE_DECFLOAT(DECFLOAT(-2),INFINITY)                 = 1
    COMPARE_DECFLOAT(NAN,NAN)                               = 3
    COMPARE_DECFLOAT(DECFLOAT(-0.1),SNAN)                   = 3
```

CONCAT

The CONCAT function combines two compatible string arguments.

▸▸— CONCAT(*string-expression-1* ,*string-expression-2*) —▸◂

The schema is SYSIBM.

The arguments must be compatible strings. For more information on compatibility, refer to the compatibility matrix in Table 30 on page 144.

Either argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type.

The result of the function is a string that consists of the first string followed by the second string.

The result can be null; if any argument is null, the result is the null value.

The CONCAT function is identical to the CONCAT operator. For more information, see "Concatenation operators in expressions" on page 246.

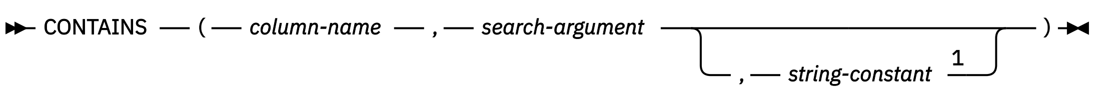
Example: Using sample table DSN8C10.EMP, concatenate column FIRSTNME with column LASTNAME. Both columns are defined as varying-length character strings.

```
SELECT CONCAT(FIRSTNME, LASTNAME)
  FROM DSN8C10.EMP;
```

CONTAINS

The CONTAINS function searches a text search index using criteria that are specified in a search argument and returns a result about whether or not a match was found.

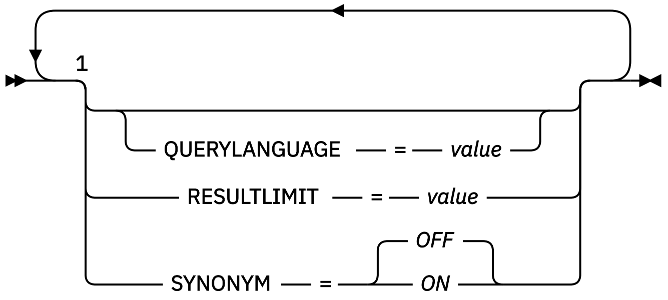
Requirement: To use the CONTAINS function, Text Search for Db2 for z/OS must be installed and configured. See IBM Text Search for Db2 for z/OS (IBM Text Search for Db2 for z/OS Installation, Administration, and Reference) for more information.



Notes:

[1] *string-constant* must conform to the rules for the *search-argument-options*.

search-argument-options



Notes:

[1] The same clause must not be specified more than once.

The schema is SYSIBM.

column-name
Specifies a qualified or unqualified name of a column that has a text search index that is to be searched. The column must exist in the table or view that is identified in the FROM clause in the statement and the column of the table, or the column of the underlying base table of the view must have an associated text search index. The underlying expression of the column of a view must be a simple column reference to the column of an underlying table, directly or through another nested view.

search-argument
Specifies an expression that returns a value that is a string value (except a LOB) that contains the terms to be searched for and must not be all blanks or the empty string. The actual length of the

string must not exceed 4096 Unicode characters. The value is converted to Unicode before it is used to search the text search index. The maximum number of terms per query must not exceed 1024.

string-constant

Identifies a string constant that specifies the search argument options that are in effect for the function.

The options that can be specified as part of the *search-argument-options* are as follows:

QUERYLANGUAGE = *value*

Specifies the query language. The value can be any of the supported language codes. If the QUERYLANGUAGE option is not specified, the default is the language value of the text search index that is used when this function is invoked. If the language value of the text search index is AUTO, the default value for QUERYLANGUAGE is en_US.

RESULTLIMIT = *value*

Specifies the maximum number of results to be returned from the underlying search engine. The *value* can be an integer value between 1 and 2 147 483 647. If the RESULTLIMIT option is not specified, no result limit is in effect for the query.

This scalar function cannot be called for each row of the result table, depending on the plan that the optimizer chooses. This function can be called once for the query to the underlying search engine, and a result set of all of the primary keys that match are returned from the search engine. This result set is then joined to the table containing the column to identify the result rows. In this case, the RESULTLIMIT value acts like a FETCH FIRST ?? ROWS from the underlying text search engine and can be used as an optimization. If the search engine is called for each row of the result because the optimizer determines that is the best plan, then the RESULTLIMIT option has no effect. Also, the RESULTLIMIT option has no effect when the CONTAINS function is used along with the comparison operators (<, >, <=, and >=) or the equality operator (=) and a value of 0 (zero).

SYNONYM = *OFF* or SYNONYM = *ON*

Specifies whether to use a synonym dictionary that is associated with the text search index. Use the Synonym Tool to add a synonym dictionary to the collection. The default is OFF.

OFF

Do not use a synonym dictionary.

ON

Use the synonym dictionary that is associated with the text search index.

The result of the function is a large integer. If the second argument can be null, the result can be null. If the second argument is null, the result is the null value. If the third argument is null, the result is as if the third argument was not specified.

The result is 1 if the document contains a match for the search criteria that are specified in the search argument. Otherwise, the result is 0.

CONTAINS is a non-deterministic function.

Examples

Example 1

Assume that information about employees' skills are stored in a table named EMP_RESUME. The following statement finds all of the employees who have "COBOL" in their resume. The text search argument is not case-sensitive.

```
SELECT EMPNO
    FROM EMP_RESUME
    WHERE RESUME_FORMAT = 'ascii'
        AND CONTAINS(RESUME, 'cobol') = 1
```

Example 2

The search argument does not need to be a string constant. The search argument can be any SQL string expression, including a string contained in a host variable.

The following statement searches for the exact term "ate" in the COMMENT column:

```
char search_arg[100]; /* input host variable */
...
EXEC SQL DECLARE C3 CURSOR FOR
   SELECT CUSTKEY
   FROM K55ADMIN.CUSTOMERS
   WHERE CONTAINS(COMMENT, :search_arg)= 1
   ORDER BY CUSTKEY;
strcpy(search_arg, "ate");
EXEC SQL OPEN C3;
...
```

Example 3

The following statement finds 10 students at random who wrote online essays that contain the phrase "fossil fuel" in Spanish, which is "combustible fósil." These students will be invited for a radio interview.

Use the synonym dictionary that was created for the associated text search index. Because only 10 students are needed, you can optimize the query by using the RESULTLIMIT option to limit the number of results from the underlying text search server.

```
SELECT FIRSTNME, LASTNAME
   FROM STUDENT_ESSAYS
   WHERE CONTAINS(TERM_PAPER, 'combustible fósil',
      'QUERYLANGUAGE= es_ES RESULTLIMIT  = 10 SYNONYM=ON') = 1
```

Example 4

The following example shows how the CAST specification can be used in a dynamically prepared statement to provide a typed parameter marker as an argument to the CONTAINS function. The CAST specification defines the data type for the parameter marker (?).

```
CONTAINS(C1,CAST(? AS CHAR(10)))
```

COS

The COS function returns the cosine of the argument, where the argument is an angle, expressed in radians. The COS and ACOS functions are inverse operations.

►► COS(*numeric-expression*) ►◄

The schema is SYSIBM.

The argument must be an expression that returns the value of any built-in numeric data type that is not DECFLOAT. If the argument is not a double precision floating-point number, it is converted to one for processing by the function.

The result of the function is a double precision floating-point number.

The result can be null; if the argument is null, the result is the null value.

Example: Assume that host variable COSINE is DECIMAL(2,1) with a value of 1.5. The following statement returns a double precision floating-point number with an approximate value of 0.07:

```
 SELECT COS(:COSINE)
   FROM SYSIBM.SYSDUMMY1;
```

COSH

The COSH function returns the hyperbolic cosine of the argument, where the argument is an angle, expressed in radians.

►►─ COSH(*numeric-expression*) ─►◄

The schema is SYSIBM.

The argument must be an expression that returns the value of any built-in numeric data type that is not DECFLOAT. If the argument is not a double precision floating-point number, it is converted to one for processing by the function.

The result of the function is a double precision floating-point number.

The result can be null; if the argument is null, the result is the null value.

Example: Assume that host variable HCOS is DECIMAL(2,1) with a value of 1.5. The following statement returns a double precision floating-point number with an approximate value of 2.35:

```
SELECT COSH(:HCOS)
  FROM SYSIBM.SYSDUMMY1;
```

DATE

The DATE function returns a date that is derived from a value.

►►─ DATE(*expression*) ─►◄

The schema is SYSIBM.

The argument must be an expression that returns one of the following built-in data types: a date, a timestamp, a character string, a graphic string, or any numeric data type.

- If *expression* is a character or graphic string, it must not be a CLOB or DBCLOB, and it must have one of the following values:
  - A valid string representation of a date or timestamp with an actual length that is not greater than 255 bytes. For the valid formats of string representations of dates and timestamps, see "String representations of datetime values" on page 120.
  - A character or graphic string with an actual length of 7 that represents a valid date in the form *yyyynnn*, where *yyyy* are digits denoting a year and *nnn* are digits between 001 and 366 denoting a day of that year.
- If *expression* is a number, it must be greater than or equal to one and less than or equal to 3652059.

If expression is not a DATE value, *expression* is cast as follows:

- If *expression* is a TIMESTAMP WITH TIME ZONE value, *expression* is cast to TIMESTAMP WITHOUT TIME ZONE, with the same precision as *expression*.
- If *expression* is a string, *expression* is cast to DATE.

The result of the function is a date.

The result can be null; if the argument is null, the result is the null value.

The other rules depend on the data type of the argument:

If the argument is a timestamp, the result is the date part of the timestamp.
If the argument is a date, the result is that date.
If the argument is a number, the result is the date that is *n*-1 days after January 1, 0001, where *n* is the integral part of the number.

If the argument is a string, the result is the date that is represented by the string. If the string contains a time zone, the time zone is ignored. If the CCSID of the string is not the same as the corresponding default CCSID at the server, the string is first converted to that CCSID.

The result CCSID is the appropriate CCSID of the argument encoding scheme and the result subtype is the appropriate subtype of the CCSID.

Example 1: Assume that RECEIVED is a TIMESTAMP column in some table, and that one of its values is equivalent to the timestamp '1988-12-25-17.12.30.000000'. For this value, the following statement returns the internal representation of 25 December 1988.

```
DATE(RECEIVED)
```

Example 2: Assume that DATCOL is a CHAR(7) column in some table, and that one of its values is the character string '1989061', which represents a date in the format *yyyynnn*, where *yyyy* is the year, and *nnn* is the day of the year. For this value, the following statement returns the internal representation of 2 March 1989.

```
DATE(DATCOL)
```

Example 3: Db2 recognizes '1989-03-02' as the ISO representation of 2 March 1989. So, the following statement returns the internal representation of 2 March 1989.

```
DATE('1989-03-02')
```

DAY

The DAY function returns the day part of a value.

```
►► DAY( expression ) ►◄
```

The schema is SYSIBM.

The argument must be an expression that returns one of the following built-in data types: a date, a timestamp, a character string, a graphic string, or any numeric data type.

- If *expression* is a character or graphic string, it must not be a CLOB or DBCLOB, and its value must be a valid string representation of a date or timestamp with an actual length that is not greater than 255 bytes. For the valid formats of string representations of dates and timestamps, see "String representations of datetime values" on page 120.
- If *expression* is a number, it must be a date duration or a timestamp duration. For the valid formats of datetime durations, see "Datetime operands" on page 169.

If *expression* is a timestamp with a time zone value, or a valid string representation of a timestamp with a time zone, the result is determined from the UTC representation of the datetime value.

The result of the function is a large integer.

The result can be null; if the argument is null, the result is the null value.

The other rules for the function depend on the data type of the argument:

If the argument is a date, timestamp, or string representation of either, the result is the day part of the value, which is an integer between 1 and 31.

If the argument is a date duration or timestamp duration, the result is the day part of the value, which is an integer between -99 and 99. A nonzero result has the same sign as the argument.

If the argument contains a time zone, the result is the day part of the value expressed in UTC.

Examples for DAY

Example 1

Set the INTEGER host variable DAYVAR to the day of the month on which employee 140 in the sample table DSN8C10.EMP was hired.

```
    EXEC SQL SELECT DAY(HIREDATE)
      INTO :DAYVAR
      FROM DSN8C10.EMP
      WHERE EMPNO = '000140';
```

Example 2

Assume that DATE1 and DATE2 are DATE columns in the same table. Assume also that for a given row in this table, DATE1 and DATE2 represent the dates 15 January 2000 and 31 December 1999, respectively. Then, for the given row, the following function invocation returns 15.

```
    DAY(DATE1 - DATE2)
```

Example 3

The following invocations of the DAY function all return the same result, which is 2. When the input argument contains a time zone, the result is determined from the UTC representation of the input value. The string representations of timestamps with a time zone in the example SELECT statement all have the same UTC representation: 2003-01-02-20.00.00. The day portion of the UTC representation is 2.

```
  SELECT DAY('2003-01-02-20.00.00'),
             DAY('2003-01-02-12.00.00-08:00'),
             DAY('2003-01-03-05.00.00+09:00')
     FROM SYSIBM.SYSDUMMY1;
```

Date, time, and timestamp data types (Introduction to Db2 for z/OS)

Datetime values

Datetime values are neither strings nor numbers. Nevertheless, datetime values can be used in certain arithmetic and string operations and are compatible with certain strings.

DAYOFMONTH

The DAYOFMONTH function returns the day part of a value. The function is similar to the DAY function, except DAYOFMONTH does not support a date or timestamp duration as an argument.

▶▶─ DAYOFMONTH(*expression*) ─▶◀

The schema is SYSIBM.

The argument must be an expression that returns a value of a date, a timestamp, a character string, or a graphic string built-in data type.

If *expression* is a character or graphic string, it must not be a CLOB or DBCLOB, and its value must be a valid string representation of a date or timestamp with an actual length that is not greater than 255 bytes. For the valid formats of string representations of dates and timestamps, see "String representations of datetime values" on page 120.

If *expression* is a timestamp with a time zone value, or a valid string representation of a timestamp with a time zone, the result is determined from the UTC representation of the datetime value.

The result of the function is a large integer between 1 and 31, which represents the day part of the value.

The result can be null; if the argument is null, the result is the null value.

Examples for DAYOFMONTH

Example 1

Set the INTEGER variable DAYVAR to the day of the month on which employee 140 in sample table DSN8C10.EMP was hired.

```
SELECT DAYOFMONTH(HIREDATE)
  INTO :DAYVAR
  FROM DSN8C10.EMP
  WHERE EMPNO = '000140';
```

Example 2

The following invocations of the DAYOFMONTH function return the same result, which is 2. When the input argument contains a time zone, the result is determined from the UTC representation of the input value. The string representations of timestamps with a time zone in the example SELECT statement all have the same UTC representation: 2003-01-02-20.00.00. The day portion of the UTC representation is 2.

```
SELECT DAYOFMONTH('2003-01-02-20.00.00'),
            DAYOFMONTH('2003-01-02-12.00.00-08:00'),
            DAYOFMONTH('2003-01-03-05.00.00+09:00')
        FROM SYSIBM.SYSDUMMY1;
```

Related concepts

Datetime values

Datetime values are neither strings nor numbers. Nevertheless, datetime values can be used in certain arithmetic and string operations and are compatible with certain strings.

DAYOFWEEK

The DAYOFWEEK function returns an integer, in the range 1–7 that represents the day of the week, where 1 is Sunday and 7 is Saturday. The DAYOFWEEK function is similar to the DAYOFWEEK_ISO function.

▶▶ DAYOFWEEK(*expression*) ▶◀

The schema is SYSIBM.

The argument must be an expression that returns a value of one of the following built-in data types: a date, a timestamp, a character string, or a graphic string.

If *expression* is a character or graphic string, it must not be a CLOB or DBCLOB, and its value must be a valid string representation of a date or timestamp with an actual length that is not greater than 255 bytes. For the valid formats of string representations of dates and timestamps, see "String representations of datetime values" on page 120.

If *expression* is a timestamp with a time zone, or a valid string representation of a timestamp with a time zone, the result is determined from the UTC representation of the datetime value.

The result of the function is a large integer.

Examples for DAYOFWEEK

The result can be null; if the argument is null, the result is the null value.

Example 1

The following statement uses sample table DSN8C10.EMP, set the integer host variable DAY_OF_WEEK to the day of the week that Christine Haas (EMPNO = '000010') was hired (HIREDATE). The result is that DAY_OF_WEEK is set to 6, which represents Friday.

```
SELECT DAYOFWEEK(HIREDATE)
  INTO :DAY_OF_WEEK
```

```
     FROM DSN8C10.EMP
     WHERE EMPNO = '000010';
```

Example 2

The following query returns four values: 1, 2, 1, and 2.

```
   SELECT DAYOFWEEK(CAST('10/11/1998' AS DATE)),
          DAYOFWEEK(TIMESTAMP('10/12/1998', '01.02')),
          DAYOFWEEK(CAST(CAST('10/11/1998' AS DATE) AS CHAR(20))),
          DAYOFWEEK(CAST(TIMESTAMP('10/12/1998', '01.02') AS CHAR(26)))
     FROM SYSIBM.SYSDUMMY1;
```

Example 3

The following invocations of the DAYOFWEEK function all return the value 5, which represents Thursday. (1 represents Sunday for DAYOFWEEK results.) When the input argument contains a time zone, the result is determined from the UTC representation of the input value. The string representations of the example timestamp with time zone values in the SELECT statement all have the same UTC representation: 2003-01-02-20.00.00.

```
SELECT DAYOFWEEK('2003-01-02-20.00.00'),
            DAYOFWEEK('2003-01-02-12.00.00-08:00'),
            DAYOFWEEK('2003-01-03-05.00.00+09:00')
        FROM SYSIBM.SYSDUMMY1;
```

DAYOFWEEK_ISO

The DAYOFWEEK_ISO function returns an integer in the range 1–7 that represents the day of the week, where 1 is Monday and 7 is Sunday. The DAYOFWEEK_ISO function is similar to the DAYOFWEEK function.

DAYOFWEEK_ISO

The DAYOFWEEK_ISO function returns an integer in the range 1–7 that represents the day of the week, where 1 is Monday and 7 is Sunday. The DAYOFWEEK_ISO function is similar to the DAYOFWEEK function.

▶▶— DAYOFWEEK_ISO(*expression*) —▶◀

The schema is SYSIBM.

The argument must be an expression that returns a value of one of the following built-in data types: a date, a timestamp, a character string, or graphic string.

If *expression* is a character or graphic string, it must not be a CLOB or DBCLOB, and its value must be a valid string representation of a date or timestamp with an actual length that is not greater than 255 bytes. For the valid formats of string representations of dates and timestamps, see “String representations of datetime values” on page 120.

If *expression* is a timestamp with a time zone, or a valid string representation of a timestamp with a time zone, the result is determined from the UTC representation of the datetime value.

The result of the function is a large integer.

The result can be null; if the argument is null, the result is the null value.

Examples for DAYOFWEEK_ISO

Example 1

Using sample table DSN8C10.EMP, set the integer host variable DAY_OF_WEEK to the day of the week that Christine Haas (EMPNO = '000010') was hired (HIREDATE). The result is that DAY_OF_WEEK is set to 5, which represents Friday.

```
    SELECT DAYOFWEEK_ISO(HIREDATE)
      INTO :DAY_OF_WEEK
      FROM DSN8C10.EMP
      WHERE EMPNO = '000010';
```

Example 2

The following query returns the following values: 7, 1, 7, and 1.

```
    SELECT DAYOFWEEK_ISO(CAST('10/11/1998' AS DATE)),
           DAYOFWEEK_ISO(TIMESTAMP('10/12/1998', '01.02')),
           DAYOFWEEK_ISO(CAST(CAST('10/11/1998' AS DATE) AS CHAR(20))),
           DAYOFWEEK_ISO(CAST(TIMESTAMP('10/12/1998', '01.02') AS CHAR(26)))
      FROM SYSIBM.SYSDUMMY1;
```

Example 3

The following table shows what is returned by the DAYOFWEEK_ISO function for various dates.

DATE	DAYOFWEEK_ISO returns:
2003-12-28	7
2003-12-31	3
2004-01-01	4
2004-01-10	6
2005-12-31	7
2006-01-01	7
2006-01-03	2

Example 4

The following invocations of the DAYOFWEEK_ISO function all return the same result, which is 4 for Thursday. (1 represents Monday in DAYOFWEEK_ISO results.) When the input argument contains a time zone, the result is determined from the UTC representation of the input value. The string representations of timestamps with a time zone in the example SELECT statement all have the same UTC representation: 2003-01-02-20.00.00.

```
 SELECT DAYOFWEEK_ISO('2003-01-02-20.00.00'),
             DAYOFWEEK_ISO('2003-01-02-12.00.00-08:00'),
             DAYOFWEEK_ISO('2003-01-03-05.00.00+09:00')
         FROM SYSIBM.SYSDUMMY1;
```

DAYOFWEEK

The DAYOFWEEK function returns an integer, in the range 1–7 that represents the day of the week, where 1 is Sunday and 7 is Saturday. The DAYOFWEEK function is similar to the DAYOFWEEK_ISO function.

DAYOFYEAR

The DAYOFYEAR function returns an integer, in the range 1–366 that represents the day of the year, where 1 is January 1.

►►— DAYOFYEAR(*expression*) —►◄

The schema is SYSIBM.

The argument must be an expression that returns a value of one of the following built-in data types: a date, a timestamp, a character string, or a graphic string.

If *expression* is a character or graphic string, it must not be a CLOB or DBCLOB, and its value must be a valid string representation of a date or timestamp with an actual length that is not greater than 255 bytes. For the valid formats of string representations of dates and timestamps, see “String representations of datetime values” on page 120.

If *expression* is a timestamp with a time zone value, or a valid string representation of a timestamp with a time zone, the result is determined from the UTC representation of the datetime value.

The result of the function is a large integer.

The result can be null; if the argument is null, the result is the null value.

Examples for DAYOFYEAR

Example 1

Using sample table DSN8C10.EMP, set the integer host variable AVG_DAY_OF_YEAR to the average of the day of the year on which employees were hired (HIREDATE). The result is that AVG_DAY_OF_YEAR is set to 202.

```
    SELECT AVG(DAYOFYEAR(HIREDATE))
      INTO :AVG_DAY_OF_YEAR
      FROM DSN8C10.EMP;
```

Example 2

The following invocations of the DAYOFYEAR function all return the same result, which is 2. When the input argument contains a time zone, the result is determined from the UTC representation of the input value. The string representations of timestamps with a time zone in the example SELECT statement all have the same UTC representation: 2003-01-02-20.00.00.

```
SELECT DAYOFYEAR('2003-01-02-20.00.00'),
            DAYOFYEAR('2003-01-02-12.00.00-08:00'),
            DAYOFYEAR('2003-01-03-05.00.00+09:00')
        FROM SYSIBM.SYSDUMMY1;
```

Date, time, and timestamp data types (Introduction to Db2 for z/OS)

Datetime values

Datetime values are neither strings nor numbers. Nevertheless, datetime values can be used in certain arithmetic and string operations and are compatible with certain strings.

DAYS

The DAYS function returns an integer representation of a date.

```
▶▶─ DAYS( expression) ─▶◀
```

The schema is SYSIBM.

The argument must be an expression that returns a value of one of the following built-in data types: a date, a timestamp, a character string, or a graphic string.

If *expression* is a character or graphic string, it must not be a CLOB or DBCLOB, and its value must be a valid string representation of a date or timestamp with an actual length that is not greater than 255 bytes. For the valid formats of string representations of dates and timestamps, see "String representations of datetime values" on page 120.

If *expression* is a timestamp with a time zone value, or a valid string representation of a timestamp with a time zone, the result is determined from the UTC representation of the datetime value.

The result of the function is a large integer.

The result can be null; if the argument is null, the result is the null value.

The result is 1 more than the number of days from January 1, 0001 to *D*, where *D* is the date that would occur if the DATE function were applied to the argument.

Examples for DAYS

Example 1

Set the INTEGER host variable DAYSVAR to the number of days that employee 140 had been with the company on the last day of 1997.

```
    EXEC SQL SELECT DAYS('1997-12-31') - DAYS(HIREDATE) + 1
      INTO :DAYSVAR
      FROM DSN8C10.EMP
      WHERE EMPNO = '000140';
```

Example 2

The following invocations of the DAYS function all return the same result, which is 731217. When the input argument contains a time zone, the result is determined from the UTC representation of the input value. The string representations of timestamps with a time zone in the example SELECT statement all have the same UTC representation: 2003-01-02-20.00.00.

```
SELECT DAYS('2003-01-02-20.00.00'),
            DAYS('2003-01-02-12.00.00-08:00'),
            DAYS('2003-01-03-05.00.00+09:00')
        FROM SYSIBM.SYSDUMMY1;
```

Related concepts

Date, time, and timestamp data types (Introduction to Db2 for z/OS)

Datetime values
Datetime values are neither strings nor numbers. Nevertheless, datetime values can be used in certain arithmetic and string operations and are compatible with certain strings.

DAYS_BETWEEN

The DAYS_BETWEEN function returns the number of full days between the specified arguments.

FL 507

Passthrough-only expression: This function is passthrough-only and cannot run on Db2 for z/OS without acceleration. For information about invoking this function, see Accelerating queries with passthrough-only expressions.

```
▶▶─ DAYS_BETWEEN ── ( ── expression1 ── , ── expression2 ── ) ─▶◀
```

The schema is SYSIBM.

expression1
An expression that specifies the first datetime value to compute the number of full days between two datetime values. The expression must return a value that is a DATE, TIMESTAMP WITHOUT TIME ZONE, CHAR, VARCHAR, GRAPHIC, or VARGRAPHIC data type. CHAR, VARCHAR, GRAPHIC, and VARGRAPHIC are supported by using implicit casting. If *expression1* is a CHAR, VARCHAR, GRAPHIC, or VARGRAPHIC data type, it must be a valid string that is accepted by the TIMESTAMP scalar function and does not contain a time zone.

expression2
An expression that specifies the second datetime value to compute the number of full days between two datetime values. The expression must return a value that is a DATE, TIMESTAMP WITHOUT TIME ZONE, CHAR, VARCHAR, GRAPHIC, or VARGRAPHIC data type. CHAR, VARCHAR, GRAPHIC, and VARGRAPHIC are supported by using implicit casting. If *expression2* is a CHAR, VARCHAR, GRAPHIC, or VARGRAPHIC data type, it must be a valid string that is accepted by the TIMESTAMP scalar function and does not contain a time zone.

If there is less than a full day between *expression1* and *expression2*, the result is zero. If *expression1* is later than *expression2*, the result is positive. If *expression1* is earlier than *expression2*, the result is negative. If *expression1* or *expression2* contains time information, this information is also used to determine the number of full days. If *expression1* or *expression2* does not contain time information, a time of midnight (00.00.00) is used for the argument that is missing time information.

The result of the function is an INTEGER. If either argument can be null, the result can be null. If either argument is null, the result is the null value.

Examples

- Set the host variable NUM_DAYS with the number of full days between 2012-03-03 and 2012-02-28.

  ```
  SET :NUM_DAYS = DAYS_BETWEEN(DATE '2012-03-03',
     DATE '2012-02-28')
  ```

  The host variable NUM_DAYS is set to 4 because an additional day is incurred for February 29, 2012.
- Set the host variable NUM_DAYS with the number of full days between 2013-09-11-23.59.59 and 2013-09-01-00.00.00.

  ```
  SET :NUM_DAYS = DAYS_BETWEEN(TIMESTAMP '2013-09-11-23.59.59',
     TIMESTAMP '2013-09-01-00.00.00')
  ```

  The host variable NUM_DAYS is set to 10 because there is 1 second less than a full 11 days between the arguments. It is positive because the first argument is later than the second argument.
- Set the host variable NUM_DAYS with the number of full days between 2013-09-01-00.00.00 and 2013-09-11-23.59.59.

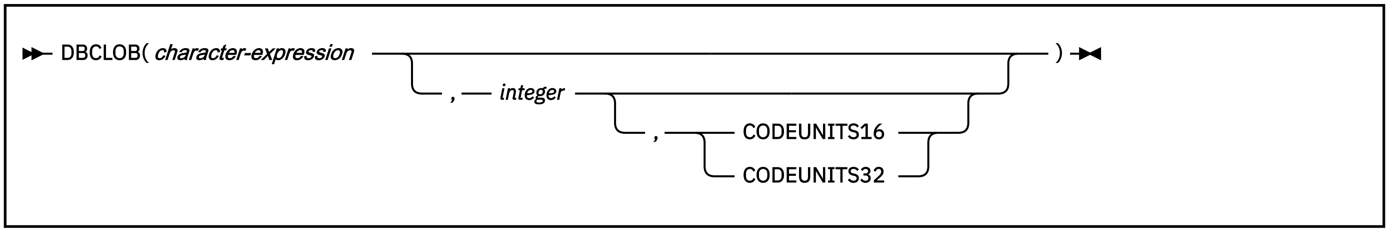
  ```
  SET :NUM_DAYS = DAYS_BETWEEN(TIMESTAMP '2013-09-01-00.00.00',
     TIMESTAMP '2013-09-11-23.59.59')
  ```

  The host variable NUM_DAYS is set to -10 because there is 1 second less than a full 11 days between the arguments. It is negative because the first argument is earlier than the second argument.

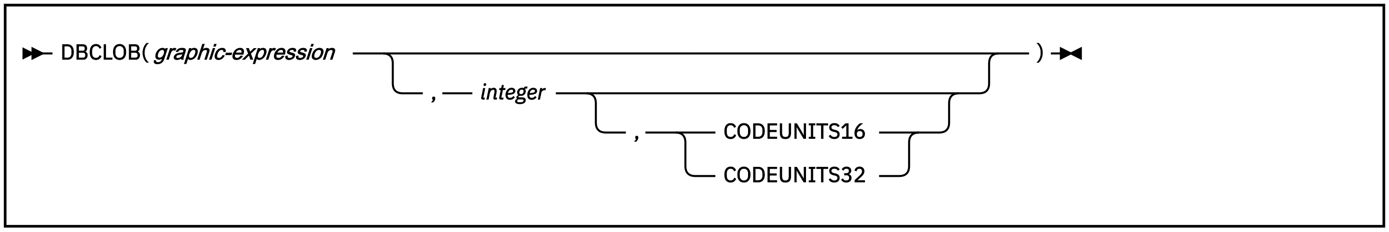
DBCLOB

The DBCLOB function returns a DBCLOB representation of a character string value (with the single-byte characters converted to double-byte characters) or a graphic string value.

Character to DBCLOB:



Graphic to DBCLOB:



The schema is SYSIBM.

Character to DBCLOB

character-expression
An expression that returns a value that is an EBCDIC-encoded or Unicode-encoded character string. It cannot be BIT data. The argument does not need to be mixed data, but any occurrences of X'0E' and X'0F' in the string must conform to the rules for EBCDIC mixed data. (See "Character strings" on page 102 for these rules.)

integer
The length attribute of the resulting DBCLOB. The value of *integer* must be between 1 and the maximum length of a DBCLOB, expressed in the units that are either implicitly or explicitly specified.

If CODEUNITS16 or CODEUNITS32 is specified, see "Determining the length attribute of the final result" on page 108 for information about how to calculate the length attribute of the result string. If CODEUNITS32 is specified, the value of *integer* must be between 1 and the maximum length of a DBCLOB divided by two (to allow for an intermediate result string that is long enough to evaluate the function).

If *integer* is not specified and *character-expression* is an empty string constant, the length attribute of the result is 1, and the result is an empty string. Otherwise, the length attribute of the result is the same as the length attribute of *character-expression*.

CODEUNITS16 or CODEUNITS32
Specifies the unit that is used to express *integer*. If CODEUNITS16 or CODEUNITS32 is specified, the input is EBCDIC, and there is no system CCSID for EBCDIC GRAPHIC data, an error occurs.

CODEUNITS16
Specifies that *integer* is expressed in terms of 16-bit UTF-16 code units.

CODEUNITS32
Specifies that *integer* is expressed in terms of 32-bit UTF-32 code units.

For more information about CODEUNITS16 and CODEUNITS32, see "String unit specifications" on page 106.

The actual length of the result is the minimum of the length attribute of the result and the actual length of *character-expression*. If the length of *character-expression*, as measured in single-byte characters, is greater than the specified length of the result, as measured in double-byte characters, the result is truncated. Unless all the truncated characters are blanks appropriate for *character-expression*, a warning is returned.

The CCSID of the result is the graphic CCSID that corresponds to the character CCSID of *character-expression*.

For EBCDIC input data, each character of *character-expression* determines a character of the result. The argument might need to be converted to the native form of mixed data before the result is derived. Let *M* denote the system CCSID for mixed data. The argument is not converted if any of the following conditions is true:

- The argument is mixed data and its CCSID is *M*.
- The argument is SBCS data and its CCSID is the same as the system CCSID for SBCS data. In this case, the operation proceeds as if the CCSID of the argument is *M*.

Otherwise, the argument is a new string *S* derived by converting the characters to the coded character set identified by *M*. If there is no system CCSID for mixed data, conversion is to the coded character set that the system CCSID for SBCS data identifies.

The result is derived from *S* using the following steps:

- Each shift character (X'0E' or X'0F') is removed.
- Each double-byte character remains as is.
- Each single-byte character is replaced by a double-byte character.

The replacement for a single-byte character is the equivalent DBCS character if an equivalent exists. Otherwise, the replacement is X'FEFE'. The existence of an equivalent character depends on *M*. If there is no system CCSID for mixed data, the DBCS equivalent of X'xx' for EBCDIC is X'42xx', except for X'40', whose DBCS equivalent is X'4040'.

For Unicode input data, each character of *character-expression* determines a character of the result. The argument might need to be converted to the native form of mixed data before the result is derived. Let *M* denote the system CCSID for mixed data. The argument is not converted if any of the following conditions is true:

- The argument is mixed data, and its CCSID is *M*.
- The argument is SBCS data, and its CCSID is the same as the system CCSID for SBCS data. In this case, the operation proceeds as if the CCSID of the argument is *M*.

Otherwise, the argument is a new string *S* derived by converting the characters to the coded character set identified by *M*.

The result is derived from *S* using the following steps:

- Each non-supplementary character is replaced by a Unicode double-byte character (a UTF-16 code point). A non-supplementary character in UTF-8 is between 1 and 3 bytes.
- Each supplementary character is replaced by a pair of Unicode double-byte characters (a pair of UTF-16 code points).

The replacement for a single-byte character is the Unicode equivalent character if an equivalent exists. Otherwise, the replacement is X'FFFD'.

Graphic to DBCLOB

graphic-expression
An expression that returns a value that is an EBCDIC-encoded or Unicode-encoded graphic string.

integer
The length attribute for the resulting varying-length graphic string. The value must be an integer between 1 and the maximum length of a DBCLOB, expressed in the units that are either implicitly or explicitly specified.

If CODEUNITS16 or CODEUNITS32 is specified, see “Determining the length attribute of the final result” on page 108 for information about how to calculate the length attribute of the result string.

If *integer* is not specified and *graphic-expression* is an empty string constant, the length attribute of the result is 1, and the result is an empty string. Otherwise, the length attribute of the result is the same as the length attribute of *graphic-expression*.

CODEUNITS16 or CODEUNITS32

Specifies the unit that is used to express *integer*. If CODEUNITS16 or CODEUNITS32 is specified, the input is EBCDIC, and there is no system CCSID for EBCDIC GRAPHIC data, an error occurs.

CODEUNITS16

Specifies that *integer* is expressed in terms of 16-bit UTF-16 code units.

CODEUNITS32

Specifies that *integer* is expressed in terms of 32-bit UTF-32 code units.

For more information about CODEUNITS16 and CODEUNITS32, see "String unit specifications" on page 106.

The actual length of the result is the minimum of the length attribute of the result and the actual length of *graphic-expression*. If the length of *graphic-expression* is greater than the length attribute of the result, truncation is performed. Unless all of the truncated characters are double-byte blanks, a warning is returned.

The CCSID of the result is the same as the CCSID of *graphic-expression*.

The result of the function is a DBCLOB.

The result can be null; if the first argument is null, the result is the null value.

The length attribute and actual length of the result are measured in double-byte characters because the result is a graphic string.

Example 1: Assume that the application encoding scheme is Unicode. The following statement returns a graphic (UTF-16) host variable.

```
VALUES DBCLOB('123')
  INTO :GHV1;
```

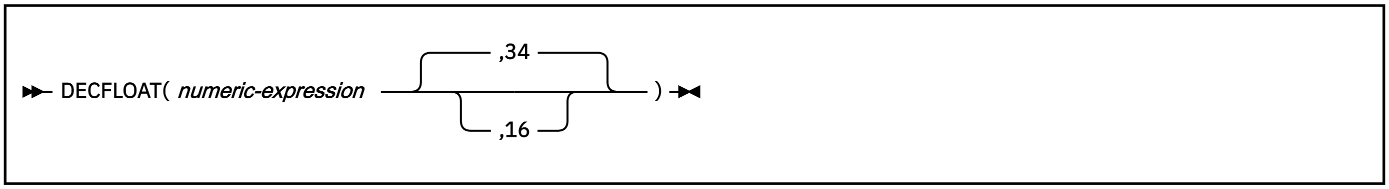
Example 2: FIRSTNAME is a VARCHAR(12) column (Unicode UTF-8 data) in table T1. One of its values is the 6-character string 'Jürgen'. When FIRSTNAME has this value:

```
Function ...                         Returns ...
DBCLOB(FIRSTNAME,3,CODEUNITS32)      'Jür'  -- x'004A00FC0072'
DBCLOB(FIRSTNAME,3,CODEUNITS16)      'Jür'  -- x'004A00FC0072'
```

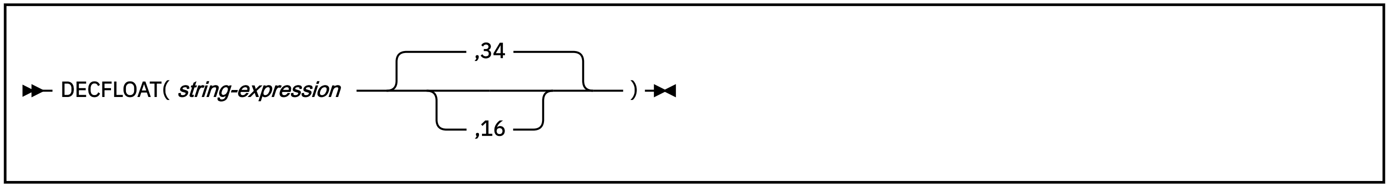
DECFLOAT

The DECFLOAT function returns a decimal floating-point representation of either a number or a character string representation of a number, a decimal number, an integer, a floating-point number, or a decimal floating-point number.

Numeric to DECFLOAT:



String to DECFLOAT:



The schema is SYSIBM.

Numeric to DECFLOAT

numeric-expression
An expression that returns a value of any built-in numeric data type.

34 or 16
Specifies the number of digits of precision for the result. The default is 34.

String to DECFLOAT

string-expression
An expression that returns a value of a character or graphic string (except a CLOB or DBCLOB) with a length attribute that is not greater than 255 bytes. Leading and trailing blanks are eliminated, and the resulting string is folded to uppercase. The expression must conform to the rules for forming a floating-point, decimal floating-point, integer, or decimal constant.

Use the *string-expression* syntax variation to specify a negative zero as a constant, or to preserve the precision of a floating point constant.

34 or 16
Specifies the number of digits of precision for the result. The default is 34.

The result is the same number that would result from CAST(`string-expression` AS DECFLOAT(n)) or CAST(`numeric-expression` AS DECFLOAT(n)). Leading and trailing blanks are removed from the string, and the resulting substring must conform to the rules for forming a string representation of an SQL decimal-floating point constant.

If necessary, the source is rounded to the precision of the target.

For static SQL statements other than CREATE VIEW, the ROUNDING bind option or the native SQL procedure option determines the rounding mode.

For dynamic SQL statements (and static CREATE VIEW statements), the special register CURRENT DECFLOAT ROUNDING MODE determines the rounding mode.

The result of the function is a DECFLOAT with the implicitly or explicitly specified number of digits of precision.

The result can be null; if the first argument is null, the result is the null value.

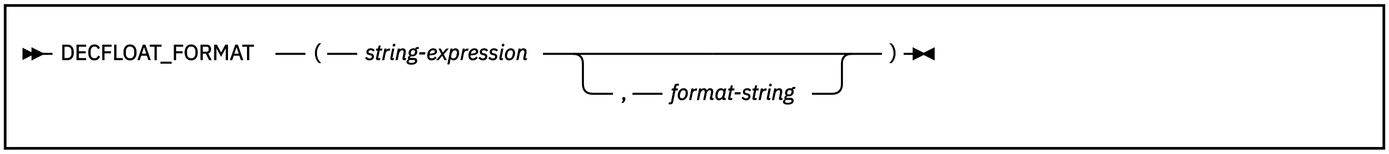
Note: To increase the portability of applications, use the CAST specification. For more information, see "CAST specification" on page 266.

Example: When a keyword is used for a special value that is expressed as a constant in a context where the keyword could be interpreted as a name, the DECFLOAT function can be used to explicitly cast the value to decimal-floating point. Assume that MYTAB contains columns C1 and SNAN, and that you want to reference the decimal floating-point value for infinity in the same SQL statement. Use the DECFLOAT function to explicitly cast SNAN as a decimal floating-point value to ensure that it is not interpreted as the name of a column, parameter or variable:

```
SELECT INFINITY                  -- column named SNAN
    FROM MYTAB
  WHERE C1 = DECFLOAT ('sNaN' ) -- comparison is made with the
                                -- decimal floating-point sNaN value
```

DECFLOAT_FORMAT

The DECFLOAT_FORMAT function returns a DECFLOAT(34) value that is based on the interpretation of the input string using the specified format.



The schema is SYSIBM.

string-expression
An expression that returns a value that is a CHAR and VARCHAR data type. If a supplied argument is a GRAPHIC or VARGRAPHIC data type, it is first converted to VARCHAR before evaluating the function. Leading and trailing blanks are removed from the string. If *format-string* is not specified, the resulting substring must conform to the rules for forming an SQL integer, decimal, floating-point, or decimal floating-point constant and not be greater than 42 bytes. Otherwise, the resulting substring must contain the components of a number that corresponds to the format specified by *format-string*.

format-string
An expression that returns a value that is a built-in character string data type. If a supplied argument is a graphic string (except DBCLOB), it is first converted to a character string before the function is evaluated. The actual length must not be greater than 254 bytes.

The value is a template for how *string-expression* is to be interpreted for conversion to a DECFLOAT value. *format-string* must contain a valid combination of the listed format elements according to the following rules:

- At least one '0' or '9' format element must be specified.
- A sign format element ('S', 'MI', 'PR') can be specified only one time.
- A decimal point format element can be specified only one time.
- Alphabetic format elements must be specified in upper case.
- A prefix format element can only be specified at the beginning of the format string, before any format elements that are not prefix format elements. When multiple prefix format elements are specified they can be specified in any order.
- A suffix format element can only be specified at the end of the format string, after any format elements that are not suffix format elements.
- A comma format element can be the first format element that is not a prefix format element. There can be any number of comma format elements.
- Blanks must not be specified between format elements. Leading and trailing blanks can be specified but are ignored.

Table 70. Format elements for the DECFLOAT_FORMAT function

Format element	**Description**
0 or 9	Each 0 or 9 represents a digit.
S	**Prefix** If *string-expression* represents a negative number, a leading minus sign (–) is expected at the specified location. If *string-expression* represents a positive number, a leading plus sign (+) or leading blank can be included at the specified location.

Table 70. Format elements for the DECFLOAT_FORMAT function (continued)

Format element	Description
$	**Prefix** A leading dollar sign ('$') is expected at the specified location.
MI	**Suffix** If *string-expression* represents a negative number, a trailing minus sign (–) is expected at the specified location. If *string-expression* represents a positive number, a trailing blank can be included at the specified location.
PR	**Suffix** If *string-expression* represents a negative number, a leading less than character (<) and a trailing greater than character (>) are expected. If *string-expression* represents a positive number, a leading blank and a trailing blank can be included.
,	Represents a group separator. A group separator is expected at the specified location if there is a character to the left of it that is not a prefix character.
.	A period represents a decimal point that is expected at the specified location.

If *format-string* is not specified, *string-expression* must conform to the rules for forming an SQL integer, decimal, floating-point, or decimal floating-point constant and have a length not greater than 42 bytes.

The result is a DECFLOAT(34).

The result can be null; if any argument is null, the result is the null value.

Notes

Syntax alternatives:
TO_NUMBER is a synonym for DECFLOAT_FORMAT.

Examples

Table 71. Examples of DECFLOAT_FORMAT

Example	Result
DECFLOAT_FORMAT('123.45')	123.45
DECFLOAT_FORMAT('–123456.78')	-123456.78
DECFLOAT_FORMAT('+123456.78')	123456.78
DECFLOAT_FORMAT('1.23E4')	12300
DECFLOAT_FORMAT('123.4', '9999.99')	123.40
DECFLOAT_FORMAT('001,234', '000,000')	1234
DECFLOAT_FORMAT('1234 ', '9999MI')	1234

Table 71. Examples of DECFLOAT_FORMAT (continued)

Example	Result
`DECFLOAT_FORMAT( '1234–', '9999MI' )`	-1234
`DECFLOAT_FORMAT( '+1234', 'S9999' )`	1234
`DECFLOAT_FORMAT( '–1234', 'S9999' )`	-1234
`DECFLOAT_FORMAT( ' 1234 ', '9999PR' )`	1234
`DECFLOAT_FORMAT( '<1234>', '9999PR' )`	-1234
`DECFLOAT_FORMAT( '$123,456.78', '$999,999.99' )`	123456.78

DECFLOAT_SORTKEY

The DECFLOAT_SORTKEY function returns a binary value that can be used when sorting DECFLOAT values. The sorting occurs in a manner that is consistent with the IEEE 754R specification on total ordering.

▶▶— DECFLOAT_SORTKEY(*decfloat-expression*) —▶◀

The schema is SYSIBM.

decfloat-expression

An expression that returns a DECFLOAT value.

decfloat-expression can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34).

The result is a fixed length binary string with a length attribute of 9 if *decfloat-expression* is a DECFLOAT(16) value or 17 if *decfloat-expression* is a DECFLOAT(34) value.

The result can be null; if the argument is null, the result is the null value.

Example: Assume that the following CREATE TABLE statement is used to create a table with a column that contains DECFLOAT values and the INSERT statements are used to populate the table:

```
CREATE TABLE T1(D1 DECFLOAT(16));
INSERT INTO T1 VALUES (2.100);
INSERT INTO T1 VALUES (2.10);
INSERT INTO T1 VALUES (2.1000);
INSERT INTO T1 VALUES (2.1);
```

Then the following SELECT statement is used to return the values from D1:

```
SELECT D1 FROM T1 ORDER BY D1;
```

The SELECT statement returns the following values, but because all numbers in the column have the same value, the ORDER BY clause has no effect and the values are returned in an arbitrary order:

```
D1
---------

2.1
2.1000
2.10
2.100
```

The following SELECT statement, which includes the DECFLOAT_SORTKEY function in the ORDER BY clause, returns the properly ordered values:

```
SELECT D1
   FROM T1
   ORDER BY (DECFLOAT_SORTKEY(D1));
```

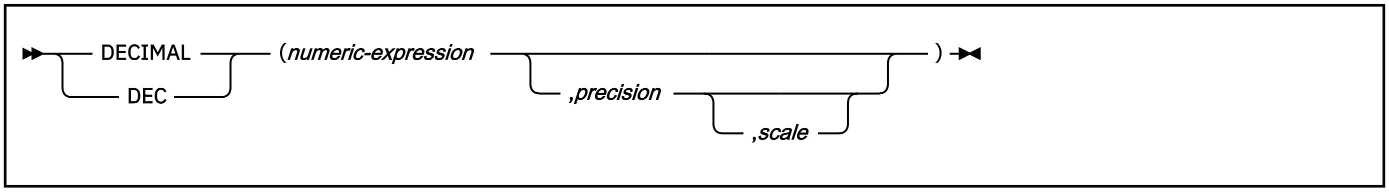
```
D1
--------

2.1000
2.100
2.10
2.1
```

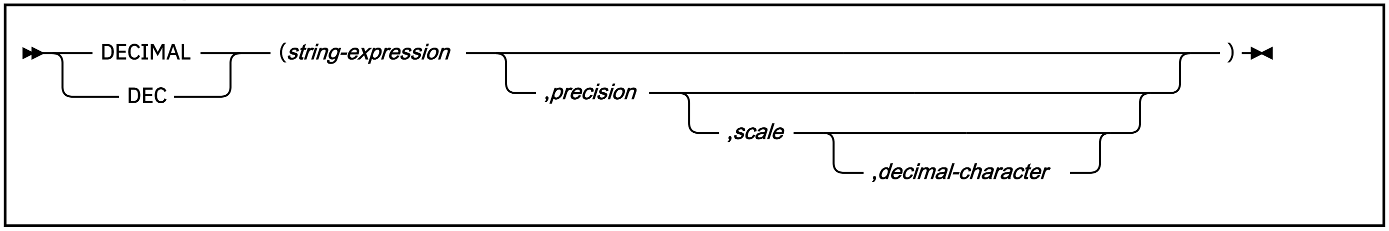
DECIMAL or DEC

The DECIMAL function returns a decimal representation of either a number or a character-string or graphic-string representation of a number, an integer, or a decimal number.

Numeric to Decimal:



String to Decimal:



The schema is SYSIBM.

Numeric to decimal

numeric-expression
An expression that returns a value of any built-in numeric data type.

precision
An integer constant with a value greater than or equal to 1 and less than or equal to 31.

The default for *precision* depends on the data type of the *numeric-expression*:

- 5 for small integer
- 11 for large integer
- 19 for big integer
- 15 for floating point or decimal
- 31 for decimal floating point

scale
An integer constant that is greater than or equal to zero and less than or equal to *precision*. The value specifies the scale of the result. The default value is 0.

The result of the function is the same number that would occur if the argument were assigned to a decimal column or variable with precision *p* and scale *s*, where *p* and *s* are specified by the second and third arguments. An error occurs if the number of significant digits required to represent the whole part of the number is greater than *p*-*s*.

String to decimal

string-expression
An expression that returns a value of a character or graphic string (except a CLOB or DBCLOB) with a length attribute that is not greater than 255 bytes. The string must contain a valid string representation of a number. Leading and trailing blanks are removed from the string, and the resulting substring must conform to the rules for forming a valid string representation of an SQL integer or decimal constant.

precision
An integer constant with a value in the range 1 to 31. The value of this second argument specifies the precision of the result. If not specified, the default is 15.

scale
An integer constant that is greater than or equal to zero and less than or equal to *precision*. The value specifies the scale of the result. The default value is 0.

decimal-character
A single-byte character constant used to delimit the decimal digits in *string-expression* from the whole part of the number. The character cannot be a digit, plus (+), minus (-), or blank. The default value is period (.) or comma (,); the default value cannot be used in *string-expression* if a different value for *decimal-character* is specified.

Digits are truncated from the end of the decimal number if the number of digits to the right of the decimal separator character is greater than the scale *s*. An error is returned if the number of significant digits to the left of the decimal character (the whole part of the number) in *string-expression* is greater than *p*-*s*.

The result of the function is a decimal number with precision of *p* and scale of *s*, where *p* and *s* are the second and third arguments. If the first argument can be null, the result can be null; if the first argument is null, the result is null.

Notes

Syntax alternatives:
To increase the portability of applications when the precision is specified, use the CAST specification. For more information, see "CAST specification" on page 266.

Examples

Example 1:

Represent the average salary of the employees in DSN8C10.EMP as an 8-digit decimal number with two of these digits to the right of the decimal point.

```
SELECT DECIMAL(AVG(SALARY),8,2)
  FROM DSN8C10.EMP;
```

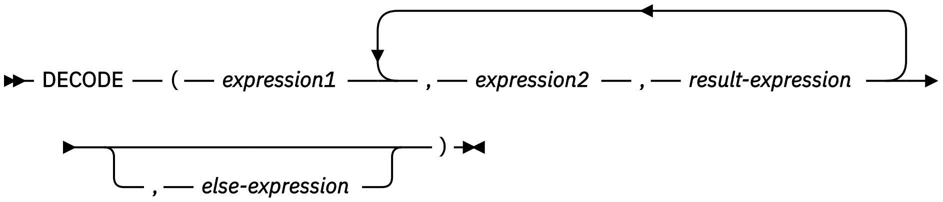
Example 2:

Assume that updates to the SALARY column are input as a character string that uses comma as the decimal character. For example, the user inputs 21400,50. The input value is assigned to the host variable NEWSALARY that is defined as CHAR(10), and the host variable is used in the following UPDATE statement:

```
UPDATE DSN8C10.EMP
  SET SALARY = DECIMAL (:NEWSALARY,9,2,',')
  WHERE EMPNO = :EMPID;
```

DECODE

The DECODE function compares each *expression2* to *expression1*. If *expression1* is equal to *expression2*, or both *expression1* and *expression2* are null, the value of the *result-expression* is returned. If no *expression2* matches *expression1*, the value of *else-expression* is returned. Otherwise a null value is returned.



The schema is SYSIBM.

The DECODE function is similar to the CASE expression, with the exception of how DECODE handles null values:

- A null value in *expression1* will match a corresponding null value in *expression2*.
- If the NULL keyword is used as an argument in the DECODE function, it must be cast to a data type that is appropriate for comparison.

An argument of DECODE must not represent an array value.

The rules for determining the result type of the result of the DECODE function are based on the corresponding CASE expression.

The following table shows equivalent DECODE functions and CASE expressions. Both the DECODE function and the corresponding CASE expression achieve the same result.

Table 72. Equivalent DECODE functions and CASE expressions (each returns the same results)

DECODE function	**CASE expression**	**Notes**

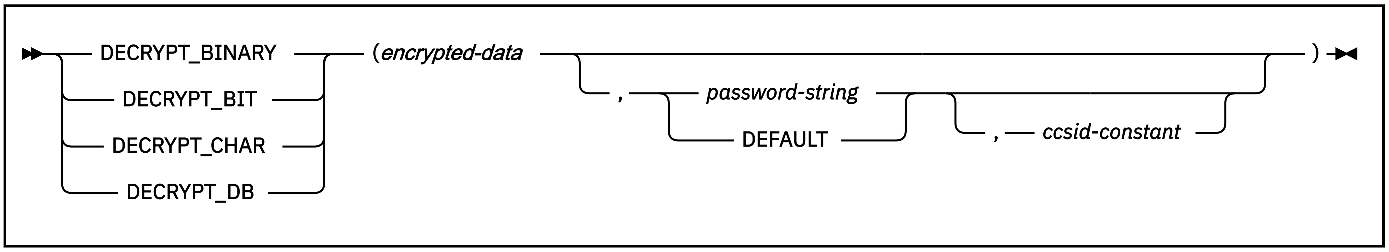
`DECODE(c1, 7, 'a',`
`  6, 'b', 'c')`
	`CASE c1`
	`  WHEN 7 THEN 'a'`
	`  WHEN 6 THEN 'b'`
	`  ELSE 'c'`
	`END`	

`DECODE(c1, var1, 'a',`
`  var2, 'b')`
	`CASE`
	`WHEN c1 = var1 OR`
	`    (c1 IS NULL AND`
	`    var1 IS NULL) THEN 'a'`
	`WHEN c1 = var2 OR`
	`    (c1 IS NULL AND`
	`    var2 IS NULL) THEN 'b'`
	`ELSE NULL`
	`END`
		The values of c1, var1, and var2 can be null values.

`SELECT ID, DECODE(STATUS,`
`     'A', 'Accepted',`
`      D', 'Denied',`
`CAST(NULL AS VARCHAR(1)),`
`   'Unknown', 'Other')`
`FROM CONTRACTS`
	`SELECT ID,`
	`CASE`
	`WHEN STATUS = 'A'`
	`  THEN 'Accepted'`
	`WHEN STATUS = 'D'`
	`  THEN 'Denied'`
	`WHEN STATUS IS NULL`
	`  THEN 'Unknown'`
	`ELSE 'Other'`
	`END`
	`FROM CONTRACTS`	

DECRYPT_BINARY, DECRYPT_BIT, DECRYPT_CHAR, and DECRYPT_DB

The decryption functions return a value that is the result of decrypting encrypted data. The decryption functions can decrypt only values that are encrypted by using the ENCRYPT_TDES function.



The schema is SYSIBM.

The password used for decryption is either the *password-string* value or the ENCRYPTION PASSWORD value, which is assigned by the SET ENCRYPTION PASSWORD statement.

encrypted-data
An expression that returns a complete, encrypted data value of a CHAR FOR BIT DATA, VARCHAR FOR BIT DATA, BINARY, or VARBINARY data type. The data string must have been encrypted using the ENCRYPT_TDES function. The length attribute must be greater than or equal to 0 (zero) and less than or equal to 32672.

password-string
An expression that returns a CHAR or VARCHAR value with at least 6 bytes and no more than 127 bytes. This expression must be the same password that was used to encrypt the data or decryption will result in a different value than was originally encrypted. For enhanced security, *password-string* should be specified using a host variable rather than a string constant. If the value of the password argument is null or not provided, the data will be decrypted using the ENCRYPTION PASSWORD value, which must have been assigned by the SET ENCRYPTION PASSWORD statement.

For a static SQL statement, it is recommended that the password be specified with a host variable rather than with a string constant.

DEFAULT
The data is decrypted using the ENCRYPTION PASSWORD value, which must have been assigned by the SET ENCRYPTION PASSWORD statement.

ccsid-constant
A integer constant that specifies the CCSID in which the data should be returned by the decryption function. If DECRYPT_BIT or DECRYPT_BINARY is specified, *ccsid-constant* must not be specified. The default is

- The ENCODING bind option of the plan or package or the APPLICATION ENCODING SCHEMA option of the CREATE PROCEDURE or ALTER PROCEDURE statement for native SQL procedures that contain the static SQL statements
- The value of the APPLICATION ENCODING special register for dynamic SQL statements

The data type of the result of the function is determined by the function that is specified and the data type of the first argument, as shown in the following table. If the cast from the actual type of the encrypted data to the result of the function is not supported, a warning or error is returned.

Table 73. Result of the decryption function

Function	Type of first argument	Actual type of encrypted data	Result
DECRYPT_BINARY	FOR BIT DATA “1” on page 445, BINARY, VARBINARY	Any string (except for LOBs)	VARBINARY

Table 73. Result of the decryption function (continued)

Function	Type of first argument	Actual type of encrypted data	Result
DECRYPT_BIT	FOR BIT DATA, BINARY, VARBINARY	CHAR, VARCHAR	VARCHAR FOR BIT DATA
DECRYPT_BIT	FOR BIT DATA, BINARY, VARBINARY	GRAPHIC, VARGRAPHIC (UTF16)	Warning or error If a warning is returned, the result is VARCHAR FOR BIT DATA
DECRYPT_BIT	FOR BIT DATA, BINARY, VARBINARY	GRAPHIC, VARGRAPHIC (not UTF16)	Warning or error If a warning is returned, the result is VARCHAR FOR BIT DATA
DECRYPT_BIT	FOR BIT DATA, BINARY, VARBINARY	BINARY, VARBINARY	Warning or error If a warning is returned, the result is VARCHAR FOR BIT DATA
DECRYPT_CHAR	FOR BIT DATA, BINARY, VARBINARY	CHAR, VARCHAR	VARCHAR(3)
DECRYPT_CHAR	FOR BIT DATA, BINARY, VARBINARY	GRAPHIC, VARGRAPHIC (UTF16)	VARCHAR(3)
DECRYPT_CHAR	FOR BIT DATA, BINARY, VARBINARY	GRAPHIC, VARGRAPHIC (not UTF16)	Warning or error If a warning is returned, the result is VARCHAR(3)
DECRYPT_CHAR	FOR BIT DATA, BINARY, VARBINARY	BINARY, VARBINARY	Warning or error If a warning is returned, the result is VARCHAR(3)
DECRYPT_DB	FOR BIT DATA, BINARY, VARBINARY	CHAR, VARCHAR, GRAPHIC, VARGRAPHIC	VARGRAPHIC
DECRYPT_DB	FOR BIT DATA, BINARY, VARBINARY	BINARY, VARBINARY	Warning or error If a warning is returned, the result is VARGRAPHIC

Notes:

1. FOR BIT DATA means CHAR or VARCHAR FOR BIT DATA

If *encrypted-data* included a hint, the hint is not returned by the function. The length attribute of the result is the length attribute of *encrypted-data* minus 8 bytes. The actual length of the value that is returned by the function will match the length of the original string that was encrypted. If *encrypted-data* includes bytes beyond the encrypted string, these bytes are not returned by the function.

Administration of encrypted data: The decryption functions can only decrypt data that was encrypted using the Triple DES encryption algorithm. Therefore, columns with encrypted data can only be used after replication if they were encrypted using the Triple DES encryption algorithm.

If the data is decrypted using a different CCSID than the originally encrypted value, it is possible that expansion might occur when converting the decrypted value to this CCSID. In such situations, the *encrypted-data* value must first be cast to a VARCHAR string with a larger number of bytes before performing the decryption functions.

The result can be null; if the first argument is null, the result is the null value.

For additional information about using the decryption functions, see “ENCRYPT_TDES or ENCRYPT” on page 456 and “GETHINT” on page 463.

Password protection: To prevent inadvertent access to the encryption password, do not specify *password-string* as a string constant in the source statement. Instead, use the ENCRYPTION PASSWORD special register or specify the password using a host variable.

Example 1: Set the ENCRYPTION PASSWORD value to 'Ben123' and use it as the password to insert a decrypted social security number into the table. Decrypt the value of the added social security number, using the ENCRYPTION PASSWORD value.

```
SET ENCRYPTION PASSWORD ='Ben123';
INSERT INTO EMP(SSN) VALUES ENCRYPT_TDES('289-46-8832');
SELECT DECRYPT_CHAR(SSN) FROM EMP;
```

This example returns the value '289-46-8832'.

Example 2: Decrypt the social security number that is inserted into the table. Instead of using the ENCRYPTION PASSWORD value, explicitly specify 'Ben123' as the encryption password.

```
SELECT DECRYPT_CHAR(SSN,'Ben123') FROM EMP;
```

This example returns the value '289-46-8832'.

Example 3: Insert a decrypted social security number into the table, explicitly specifying 'Ben123' as the password. Decrypt the data and have it converted to CCSID 1208.

```
SET ENCRYPTION PASSWORD ='Ben123';
INSERT INTO EMP(SSN) VALUES ENCRYPT_TDES('289-46-8832');
SELECT DECRYPT_CHAR(SSN) FROM EMP;
```

When a CCSID is specified, it might be necessary to explicitly cast the data to a longer value to ensure that there is room for expansion when the data is decrypted. The following example illustrates the technique:

```
SELECT DECRYPT_CHAR(CAST(SSN AS VARCHAR(57)),
                     'Ben123',1208)
               FROM EMP;
```

In the first case, where the data is not cast to a longer value, the result is a VARCHAR(11) value. In the second case, to allow for expansion, SSN is cast as VARCHAR`(57) (11 * 3 + 24)`. Casting the data to a longer value allows for three times expansion in the normal VARCHAR(11) result. Three times expansion is often associated with a worst case of ASCII or EBCDIC to Unicode UTF-8 conversion. In both cases in this example, the result is the VARCHAR(11) value '289-46-8832'.

DECRYPT_DATAKEY_INTEGER, DECRYPT_DATAKEY_BIGINT, DECRYPT_DATAKEY_DECIMAL, DECRYPT_DATAKEY_VARCHAR, DECRYPT_DATAKEY_CLOB, DECRYPT_DATAKEY_VARGRAPHIC, DECRYPT_DATAKEY_DBCLOB, and DECRYPT_DATAKEY_BIT

The data key decryption functions return a value that is the result of decrypting the first argument (previously encrypted using the ENCRYPT_DATAKEY function) using the algorithm that was specified when the data was encrypted. The name of the decryption function indicates the desired result data type. The name of the decryption function that is invoked must correspond to the original data type of the encrypted data.

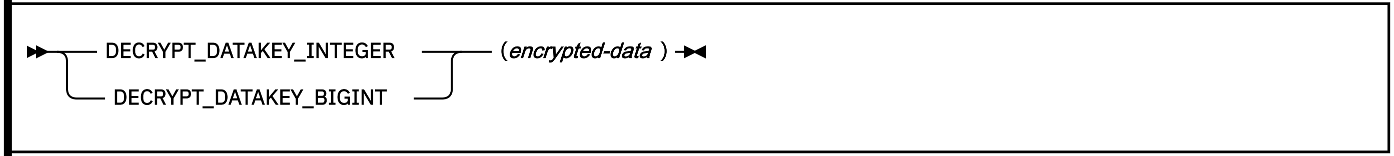
FL 505

Authorization

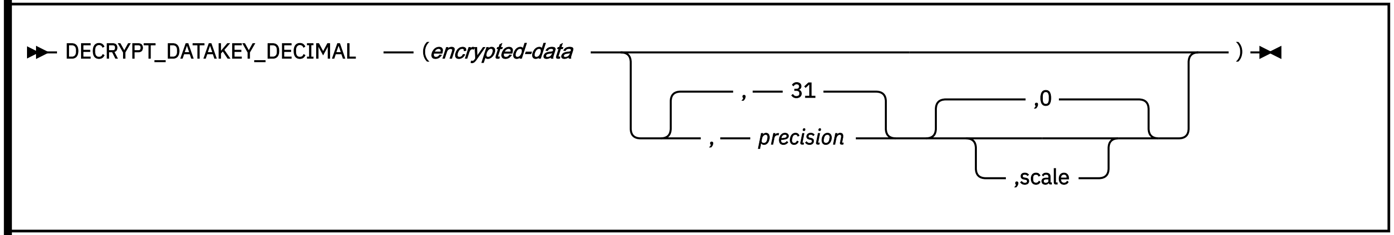
The primary authorization ID that is used to invoke the decrypt function must be authorized to use the key label that was used to encrypt the data. The key label is saved in the metadata stored with the encrypted value, so the key label does not need to be specified during decryption. When no ACEE is available for the primary authorization ID, Db2 creates one to check for the required authorization when the decrypt function executes. For more information, see When Db2 creates an ACEE (RACF Access Control Module Guide).

Syntax

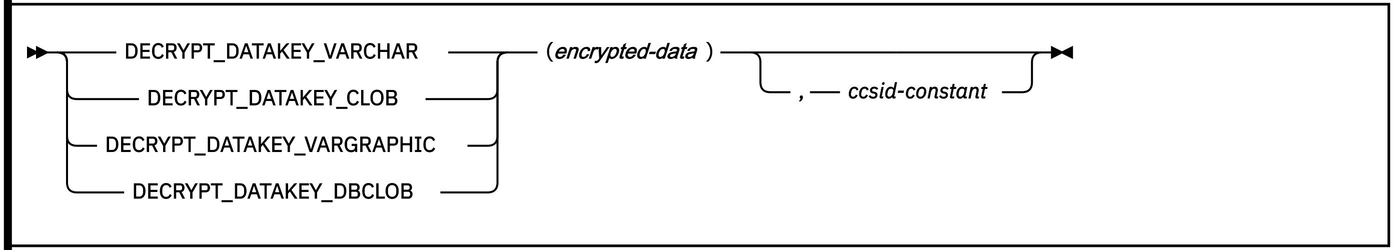
Integer:



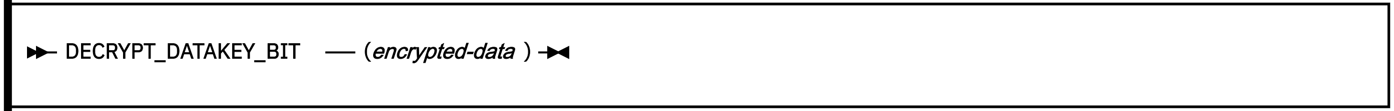
Decimal:



String:



Bit:



The schema is SYSIBM.

encrypted-data
An expression that returns a built-in VARBINARY or BLOB value. The value must be returned in the same format that the ENCRYPT_DATAKEY function returns.

ccsid-constant
An integer constant that specifies the CCSID in which the data should be returned by the decryption function. The value must be one of the CCSID values in DECP. If the result of the function is VARCHAR, the CCSID specified must be either an SBCS or MIXED CCSID. If the result of the function is CLOB, the CCSID specified must be a MIXED CCSID if the encoding scheme is Unicode; otherwise the CCSID specified must be an SBCS or MIXED CCSID. If the result of the function VARGRAPHIC or DBCLOB, the CCSID specified must be a DBCS CCSID. See Determining the encoding scheme and CCSID of a string (Introduction to Db2 for z/OS) for special considerations regarding CCSID 367.

If *ccsid* is not specified when *encrypted-data* is a character or graphic string, the default is determined from the encoding scheme and the data type of the result as follows:

- For static SQL statements, the ENCODING bind option of the plan or package or the APPLICATION ENCODING SCHEME option of the CREATE or ALTER statement for a compiled SQL scalar function, native SQL procedure, or advanced trigger.
- For dynamic SQL statements, the value of the APPLICATION ENCODING special register.

The default CCSID of the result is determined from the result data type:

- VARCHAR: the default result CCSID is the mixed data CCSID for the encoding scheme.
- CLOB: the default result CCSID is the mixed data CCSID for the encoding scheme.
- VARGRAPHIC or DBCLOB: the default result CCSID is the DBCS CCSID for the encoding scheme.

precision
An integer constant with a value greater than or equal to 1 and less than or equal to 31.

scale
An integer constant that is greater than or equal to zero and less than or equal to *precision*. The value specifies the scale of the result.

The data type of the result of the function is determined by the name of the decryption function that is invoked. The name of the decryption function must indicate the data type of the original value that was encrypted by the ENCRYPT_DATAKEY function.

Table 74. Data key decryption functions and the data type of the result

Function	Data type of the first argument	Original data type of the encrypted data	Data type of the result of the function
DECRYPT_DATAKEY_INTEGER	VARBINARY	INTEGER	INTEGER
DECRYPT_DATAKEY_BIGINT	VARBINARY	BIGINT	BIGINT
DECRYPT_DATAKEY_DECIMAL	VARBINARY	DECIMAL	DECIMAL (*precision*, *scale*)
DECRYPT_DATAKEY_BIT	VARBINARY	CHAR FOR BIT DATA, VARCHAR FOR BIT DATA	VARCHAR FOR BIT DATA
DECRYPT_DATAKEY_VARCHAR	VARBINARY	CHAR, VARCHAR	VARCHAR
DECRYPT_DATAKEY_CLOB	BLOB	CLOB	CLOB
DECRYPT_DATAKEY_VARGRAPHIC	VARBINARY	GRAPHIC, VARGRAPHIC	VARGRAPHIC
DECRYPT_DATAKEY_DBCLOB	BLOB	DBCLOB	DBCLOB

The length attribute of the result is the length attribute of the data type of *encrypted-data* minus 8 bytes. If a function returns a string data type, the length attribute of the result is the length attribute of the data type of *encryted-data* minus 16 bytes. The actual length of the result is the length of the original string that was encrypted. If the *encrypted-data* includes bytes beyond the encrypted string, these bytes are not returned by the function.

If the first argument is null, the result can be null; if the first argument is null, the result is the null value.

If the result data type is a string, the encrypted data is decrypted to the original CCSID, and then the intermediate result is cast to the specified CCSID for the result. If the result data type is VARCHAR FOR BIT DATA, the CCSID of the result is 65535. Otherwise, if the result data type is VARCHAR, CLOB, DBCLOB, or VARGRAPHIC, the CCSID of the result is *ccsid*. If the data is decrypted using a different CCSID than the originally encrypted value, it is possible that expansion might occur when converting the decrypted value to this CCSID. In such situations, the *encrypted-data* value must first be cast to a varying-length string with a larger number of bytes before performing the decryption.

Example

Decrypt the value in the PROTECTED_SSN VARBINARY column. The encrypted data was originally a character string.

```
SELECT DECRYPT_DATAKEY_VARCHAR(PROTECTED_SSN)
FROM CUSTOMER
WHERE CID = ?
```

The CCSID for the result was not specified, so it defaults as described for the *ccsid* parameter.

Related tasks

Defining columns for data encrypted using the ENCRYPT_DATAKEY built-in function. (Managing Security)

Related reference

ENCRYPT_DATAKEY
The ENCRYPT_DATAKEY function returns a value that is the result of encrypting the first argument using the specified key label and algorithm.

DEGREES

The DEGREES function returns the number of degrees of the argument, which is an angle, expressed in radians.

▶▶─ DEGREES(*numeric-expression*) ─▶◀

The schema is SYSIBM.

The argument must be an expression that returns the value of any built-in numeric data type that is not DECFLOAT. If the argument is not a double precision floating-point number, it is converted to one for processing by the function.

The result of the function is a double precision floating-point number.

The result can be null; if the argument is null, the result is the null value.

Example: Assume that host variable HRAD is a DOUBLE with a value of 3.1415926536. The following statement returns a double precision floating-point number with an approximate value of 180.0.

```
   SELECT DEGREES(:HRAD)
     FROM SYSIBM.SYSDUMMY1;
```

DIFFERENCE

The DIFFERENCE function returns a value, from 0 to 4, that represents the difference between the sounds of two strings, based on applying the SOUNDEX function to the strings. A value of 4 is the best possible sound match.

▶▶─ DIFFERENCE(*expression-1* ,*expression-2*) ─▶◀

The schema is SYSIBM.

expression-1* or *expression-2
Each expression must return a value that is a built-in numeric, character string, or graphic string data type that is not a LOB. A numeric argument is cast to a character string before the function is evaluated. For more information on converting a numeric string to a character string, see "VARCHAR" on page 614.

The data type of the result is INTEGER.

The result can be null; if any argument is null, the result is the null value.

Example 1: Find the DIFFERENCE and SOUNDEX values for 'CONSTRAINT' and 'CONSTANT':

```
SELECT DIFFERENCE('CONSTRAINT','CONSTANT'),
       SOUNDEX('CONSTRAINT'),
       SOUNDEX('CONSTANT')
   FROM SYSIBM.SYSDUMMY1;
```

This example returns the values 4, C523, and C523. Since the two strings return the same SOUNDEX value, the difference is 4 (the highest value possible).

Example 2: Find the DIFFERENCE and SOUNDEX values for 'CONSTRAINT' and 'CONTRITE':

```
SELECT DIFFERENCE('CONSTRAINT','CONTRITE'),
       SOUNDEX('CONSTRAINT'),
       SOUNDEX('CONTRITE')
   FROM SYSIBM.SYSDUMMY1;
```

This example returns the values 2, C523, and C536. In this case, the two strings return different SOUNDEX values, and hence, a lower difference value.

DIGITS

The DIGITS function returns a character string representation of the absolute value of a number.

```
►►─ DIGITS( numeric-expression ) ─►◄
```

The schema is SYSIBM.

The argument must be an expression that returns a value that is a SMALLINT, INTEGER, BIGINT, or DECIMAL built-in numeric data type.

The result of the function is a fixed-length character string representing the absolute value of the argument without regard to its scale. The result does not include a sign or a decimal point. Instead, it consists exclusively of digits, including, if necessary, leading zeros to fill out the string. The length of the string is:

- 5 if the argument is a small integer
- 10 if the argument is a large integer
- 19 if the argument is a big integer
- *p* if the argument is a decimal number with a precision of *p*

The result can be null; if the argument is null, the result is the null value.

The CCSID of the result is determined from the context in which the function was invoked. For more information, see Determining the encoding scheme and CCSID of a string (Introduction to Db2 for z/OS).

Example 1: Assume that an INTEGER column called INTCOL containing a 10-digit number is in a table called TABLEX. INTCOL has the data type INTEGER instead of CHAR(10) to save space. the following query lists all combinations of the first four digits in column INTCOL.

```
SELECT DISTINCT SUBSTR(DIGITS(INTCOL),1,4)
  FROM TABLEX;
```

Example 2: Assume that COLUMNX has the data type DECIMAL(6,2), and that one of its values is -6.28. For this value, the following statement returns the value '000628'.

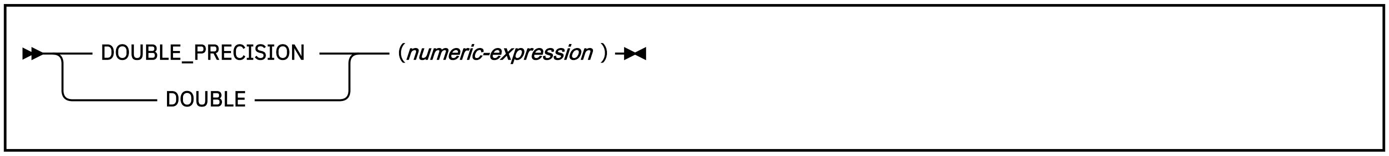
```
DIGITS(COLUMNX)
```

The result is a string of length six (the precision of the column) with leading zeros padding the string out to this length. Neither sign nor decimal point appear in the result.

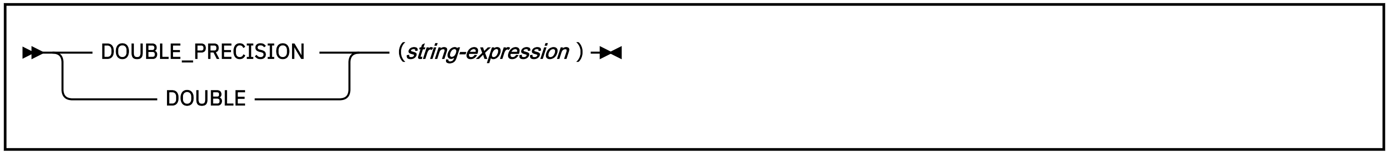
DOUBLE_PRECISION or DOUBLE

The DOUBLE_PRECISION and DOUBLE functions returns a floating-point representation of either a number or a character-string or graphic-string representation of a number, an integer, a decimal number, or a floating-point number.

Numeric to Double:



String to Double:



The schema is SYSIBM.

Numeric to Double

numeric-expression
An expression that returns a value of any built-in numeric data type.

The result is the same number that would occur if the expression were assigned to a double precision floating-point column or variable.

String to Double

string-expression
An expression that returns a value of a character or graphic string (except a CLOB or DBCLOB) with a length attribute that is not greater than 255 bytes. The string must contain a valid string representation of a number.

The result is the same number that would result from `CAST(`*`string-expression`*` AS DOUBLE PRECISION)`. Leading and trailing blanks are removed from the string, and the resulting substring must conform to the rules for forming a valid string representation of an SQL floating-point, integer, or decimal constant.

The result of the function is a double precision floating-point number.

The result can be null; if the argument is null, the result is the null value.

Notes

Syntax alternatives:
FLOAT is a synonym for DOUBLE or DOUBLE_PRECISION.

To increase the portability of applications, use the CAST specification. For more information, see "CAST specification" on page 266.

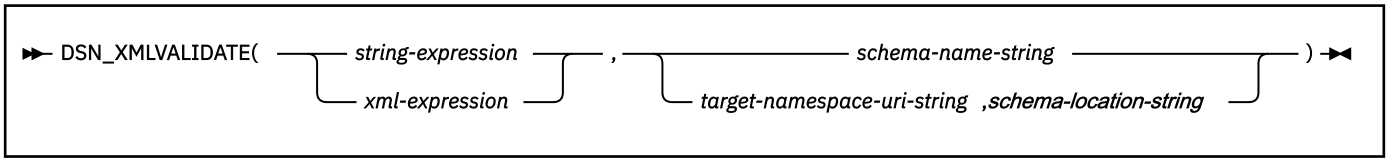
Example

Using sample table DSN8C10.EMP, find the ratio of salary to commission for employees whose commission is not zero. The columns involved in the calculation, SALARY and COMM, have decimal data types. To eliminate the possibility of out-of-range results, apply the DOUBLE function to SALARY so that the division is carried out in floating-point.

```
SELECT EMPNO, DOUBLE(SALARY)/COMM
  FROM DSN8C10.EMP
  WHERE COMM > 0;
```

DSN_XMLVALIDATE

The DSN_XMLVALIDATE function returns an XML value that is the result of applying XML schema validation to the first argument of the function. DSN_XMLVALIDATE can validate XML data that has a maximum length of 2 GB - 1 byte.



The schema is SYSIBM.

string-expression
An expression that returns a built-in character, graphic, or binary string. The value must be a well-formed XML document that conforms to the XML Version 1.0 standard.

xml-expression
An expression that returns an XML value in the XML data type. The value must be a well-formed XML document that conforms to XML Version 1.0 standard.

schema-name-string
An expression that returns a built-in varying length character string that is not a CLOB. The value specifies the name of the XML schema object that is used for validation. The value must not be an empty string or the null value, and the actual length must be less than or equal to 257. If the XML schema name is qualified, the qualifier must be SYSXSR (SYSXSR is the default qualifier). The value must identify a registered XML schema in the Db2 XML schema repository.

target-namespace-uri-string
An expression that returns a built-in varying length character string that is not a CLOB, with a length attribute that is not greater than 1000. The value specifies the target namespace name or universal resource identifier (URI) of the XML schema that is to be used for validation. If the value is an empty string of the null value, no namespace is used to locate the XML schema.

schema-location-string
An expression that returns a built-in varying length character string that is not a CLOB, with a length attribute that is not greater than 1000. The value specifies the XML schema location hint URI of the XML schema that is to be used for validation. If the value is an empty string of the null value, no schema location is used to locate the XML schema.

If *target-namespace-uri-string* and *schema-location-string* are specified, the combination must identify a registered XML schema in the Db2 XML schema repository, and there must be only one such registered XML schema.

A schema must be registered successfully in the Db2 XML schema repository before it can be used for DSN_XMLVALIDATE. If the validation fails, Db2 returns an error.

The result of the function is an XML value.

The result can be null; if the first argument is null, the result is the null value.

Example 1: The following example shows how the DSN_XMLVALIDATE function validates the XML data that is contained in the *value_host_var* host variable. The XML schema, SYSXSR.ORDERSCHEMA, was registered prior to this statement:

```
INSERT INTO T1(C1) VALUES(
    DSN_XMLVALIDATE(:value_host_var, 'SYSXSR.MYXMLSCHEMA'));
```

Example 2: The following example is similar to the previous example but references the namespace and schema location:

```
    INSERT INTO T1(C1) VALUES(
        DSN_XMLVALIDATE(:value_host_var,
                            'http://www.n1.com',
                            'http://www.n1.com/report.xsd'));
```

EBCDIC_CHR

The EBCDIC_CHR function returns the character that has the EBCDIC code value that is specified by the argument.

```
►► EBCDIC_CHR( expression) ►◄
```

The schema is SYSIBM.

expression
An expression that returns a BIGINT, INTEGER, or SMALLINT built-in data type value.

expression can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34) which is then assigned to a BIGINT value.

The result of the function is a CHAR(1) string encoded in the SBCS EBCDIC CCSID (regardless of the setting of the MIXED option in DSNHDECP). If the value of *expression* is not in the range 0 - 255, the null value is returned.

The result can be null; if the argument is null, the result is the null value.

Example: Set *hv* with the Euro symbol "€" in CCSID 1140:

```
    SET :hv = EBCDIC_CHR(159);  -- x'9F'
```

Set *hv* with the Euro symbol "€" in CCSID 1142:

```
    SET :hv = EBCDIC_CHR(90);  -- x'5A'
```

In both cases, the "€" is assigned to *hv*, but because the Euro symbol is located at different code points for the two CCSIDs, the input value is different.

EBCDIC_STR

The EBCDIC_STR function returns a string, in the system EBCDIC CCSID, that is an EBCDIC version of the string.

```
►► EBCDIC_STR( string-expression ) ►◄
```

The schema is SYSIBM.

The system EBCDIC CCSID is defined as the SBCS EBCDIC CCSID on a MIXED=NO system or the MIXED EBCDIC CCSID on a MIXED=YES system.

string-expression
An expression that returns a value of a built-in character or graphic string. If the string is a character string, it cannot be bit data. *string-expression* must be an ASCII, EBCDIC, or Unicode string. EBCDIC_STR returns an EBCDIC version of the string. Non-EBCDIC characters other than the Unicode replacement character (X'EFBFBD' in UTF-8 encoding or X'FFFD' in UTF-16 encoding), are converted to the form *xxxx*, where *xxxx* represents a UTF-16 code unit. The Unicode replacement character is converted to X'3F'.

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type.

The length attribute of the result is calculated using the formulas in Table 37 on page 163. The length attribute of the result will be `MIN( ( 5*n),32704)`. Where *n* is the result of applying the formulas in Table 37 on page 163 based on input and output data types.

The result of the function is an EBCDIC character string (in the system EBCDIC CCSID). If the actual length of the result string exceeds the maximum for the return type, an error occurs.

The result can be null; if the argument is null, the result is the null value.

Example: The following example returns the EBCDIC string equivalent of the text string "Hi my name is Андрей (Andrei)"

```
SET :HV1 = EBCDIC_STR('Hi, my name is Андрей (Andrei)');
```

HV1 is assigned the value "Hi, my name is \0410\043D\0434\0440\0435\0439 (Andrei)"

ENCRYPT_DATAKEY

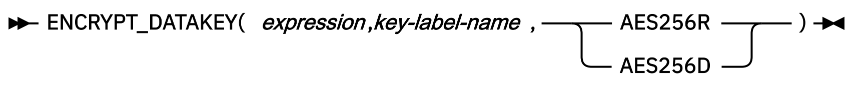
The ENCRYPT_DATAKEY function returns a value that is the result of encrypting the first argument using the specified key label and algorithm.

Authorization

The primary authorization ID used to invoke the ENCRYPT_DATAKEY function must be authorized to use the key label that is specified in *key-label-name*. Authorization for use of the key label is checked when the function is invoked. When no ACEE is available for the primary authorization ID, Db2 creates one to check for the required authorization when the ENCRYPT_DATAKEY function executes. For more information, see When Db2 creates an ACEE (RACF Access Control Module Guide).

FL 505

Syntax



The schema is SYSIBM.

expression
An expression that contains the data to be encrypted. The expression must return an INTEGER, BIGINT, DECIMAL, CHAR, VARCHAR, GRAPHIC, VARGRAPHIC, CLOB, or DBCLOB built-in data type.

key-label-name
An expression that contains the ICSF key label name.

A key label is the public name of a protected key and it must be defined in the ICSF key store. The primary authorization ID used to invoke the ENCRYPT_DATAKEY function must be authorized to use the key label.

AES256R
Specifies that the 256-bit AES CBC algorithm with a random initialization vector (IV) is used to encrypt the data. This algorithm results in a non-deterministic encrypted value and provides the highest level of protection.

A non-deterministic encrypted value is returned for every input value. The resulting text strings cannot be compared even when the encrypted values to be compared originated from the same unencrypted value. An encrypted value must be decrypted before using it in a comparison.

AES256D

Specifies that the 256-bit AES CBC algorithm with a fixed initialization vector (IV) will be used to encrypt the data. This algorithm results in a deterministic encrypted value. The resulting text value can be used in equal comparisons against the encrypted text strings. Identical input values encrypted using this mode all result in the same encrypted value. Equality comparisons can be performed on the encrypted values without decrypting the values.

The data type of the result is determined by the first argument as shown in the following table:

Table 75. Data type of the results of the ENCRYPT_DATAKEY function

Data type of the first argument	Data type of the result
BIGINT, INTEGER, DECIMAL, CHAR, VARCHAR, GRAPHIC, VARGRAPHIC	VARBINARY
CLOB, DBCLOB	BLOB

The length attribute and actual length of the result are determined as follows:

- Length attribute of result in bytes = (((length attribute of source data in bytes + 16 - 1) / 16) * 16) + 15-byte fixed header + 64 bytes for length attribute of key label.
- Actual length of result in bytes = (((actual length of source data in bytes + 16 - 1) / 16) * 16) + 15-byte fixed header + variable length key label in bytes. If *expression* is an empty string, the actual length of the result in bytes = 15-byte fixed header + variable length key label in bytes.

The actual length of the result can be longer than the length of *expression*. Therefore, when assigning a resulting encrypted value, ensure that the target is defined with a length attribute that can contain the entire encrypted value.

The result can be null; if *expression* is null, the result is the null value.

Notes

Administration of encrypted data

A replicated server must have access to the same security label and same decryption function for Db2 to be able to decrypt the data.

If AES256R is specified, the ENCRYPT_DATAKEY function is a non-deterministic function.

If AES256R and AES256D are mixed within the same column or a different key label is used for each row, the encrypted values must be decrypted before being used in any sort of comparison.

Example

Encrypt the values in the character column SSN and insert the resulting values into the PROTECTED_SSN column in the CUSTOMER table: The PROTECTED_SSN column is defined as VARBINARY. Use 'MYKEYLABEL' as the key label, and the AES256D encryption algorithm.

```
UPDATE CUSTOMER
  SET PROTECTED_SSN = ENCRYPT_DATAKEY(SSN,'MYKEYLABEL', AES256D);
```

Related tasks

Defining columns for data encrypted using the ENCRYPT_DATAKEY built-in function. (Managing Security)

Related reference

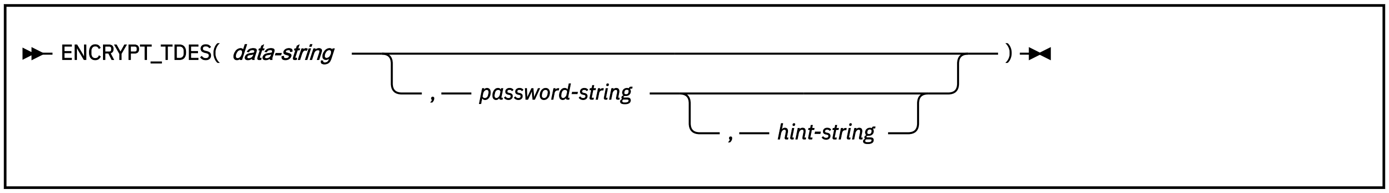
DECRYPT_DATAKEY_*type*

The data key decryption functions return a value that is the result of decrypting the first argument (previously encrypted using the ENCRYPT_DATAKEY function) using the algorithm that was specified when the data was encrypted. The name of the decryption function indicates the desired result data type. The name of the decryption function that is invoked must correspond to the original data type of the encrypted data.

ENCRYPT_TDES or ENCRYPT

The ENCRYPT_TDES function returns a value that is the result of encrypting the first argument by using the Triple DES encryption algorithm. The function can also set the password that is used for encryption.

The encryption password can also be set by using the ENCRYPTION PASSWORD value, which is assigned by using the SET ENCRYPTION PASSWORD statement.



The schema is SYSIBM.

data-string
An expression that returns the string value to be encrypted. The string expression must return a built-in string data type that is not a LOB. The length attribute must be greater than or equal to 0 (zero). The length attribute is limited to 32640 if *hint-string* is specified and 32672 if *hint-string* is not specified.

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type.

password-string
An expression that returns a CHAR or VARCHAR value with at least 6 bytes and no more than 127 bytes.

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type.

The value represents the password that is used to encrypt *data-string*. If the value of the password argument is null or not specified, the data is encrypted using the ENCRYPTION PASSWORD value, which must have been assigned by the SET ENCRYPTION PASSWORD statement.

hint-string
An expression that returns a CHAR or VARCHAR value up to 32 bytes that is to help data owners remember passwords (for example, 'Ocean' as a hint to remember 'Pacific').

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type.

If a hint value is specified, the hint is embedded into the result and can be retrieved using the GETHINT function. If this argument is null or not specified and no hint was specified when the ENCRYPTION PASSWORD was set, no hint is embedded in the result. If *password-string* is not specified, the hint can be specified using the SET ENCRYPTION PASSWORD statement.

The data type of the result is determined by the first argument as shown in the following table:

Table 76. Data type of the results of the ENCRYPT_TDES function

Data type of the first argument	Data type of the result
BINARY, VARBINARY	VARBINARY
CHAR, VARCHAR, GRAPHIC, VARGRAPHIC	VARCHAR FOR BIT DATA

The encoding scheme of the result is the same as the encoding scheme of *data-string*. If the result is character data, the result is bit data.

The length attribute of the result is different depending of whether *hint-string* is specified:

- If *hint-string* is specified, the length attribute of the result is the length attribute of the non-encrypted data + 24 bytes + number of bytes to the next 8 byte boundary + 32 bytes for the hint.

- If *hint-string* is not specified, the length attribute of the result is the length attribute of the non-encrypted data + 24 bytes + the number of bytes to the next 8 byte boundary.

The result can be null; if the first argument is null, the result is the null value.

The encrypted result is longer than the *data-string* value. Therefore, when assigning encrypted values, ensure that the target is declared with a length that can contain the entire encrypted value.

Notes

Data encryption considerations:

Password protection
To prevent inadvertent access to the encryption password, do not specify *password-string* as a string constant in the source for a program, procedure, or function. Instead, use the SET ENCRYPTION PASSWORD statement or a variable.

Encryption algorithm:
The internal encryption algorithm used is Triple DES cipher block chaining (CBC) with padding. The 128-bit secret key is derived from the password using an MD5 hash.

Encryption passwords and data
It is your responsibility to perform password management. After data is encrypted, only the password that is used to encrypt it can be used to decrypt it. If a different password is used to decrypt the data than was used to encrypt the data, the results of decryption will not match the original string. No error or warning is returned. CHAR variables might be padded with blanks if they are used to set password values. The encrypted result might contain null terminator and other non-printable characters.

Table column definitions
When defining columns and types to contain encrypted data, always calculate the length attribute as follows:

- For encrypted data with an embedded hint, the column length should be the length attribute of the non-encrypted data + 24 bytes + number of bytes to the next 8 byte boundary + 32 bytes for the hint.
- For encrypted data without an embedded hint, the column length should be the length attribute of the non-encrypted data + 24 bytes + number of bytes to the next 8 byte boundary.

Here are some sample column length calculations, which assume that a hint is not embedded:

```
Maximum length of non-encrypted data          6 bytes
24 bytes for encryption key                  24 bytes
Number of bytes to the next 8 byte boundary   2 bytes
                                            ---------

Encrypted data column length                 32 bytes
Maximum length of non-encrypted data         32 bytes
24 bytes for encryption key                  24 bytes
Number of bytes to the next 8 byte boundary   0 bytes
                                            ---------

Encrypted data column length                 56 bytes
```

Administration of encrypted data
Encrypted data can be decrypted only on servers that support the decryption of data that was encrypted using the Triple DES encryption algorithm. Hence, replication of columns with encrypted data should only be done to servers that support the decryption functions and the same encryption algorithms.

Syntax alternatives:
ENCRYPT is a synonym for ENCRYPT_TDES. Db2 supports this keyword to provide compatibility with other products in the Db2 family.

Examples

Example 1:

Encrypt the social security number that is inserted into the table. Set the ENCRYPTION PASSWORD value to 'Ben123' and use it as the password.

```
    SET ENCRYPTION PASSWORD ='Ben123';
    INSERT INTO EMP(SSN) VALUES ENCRYPT_TDES ('289-46-8832');
```

Example 2:

Encrypt the social security number that is inserted into the table. Explicitly specify 'Ben123' as the encryption password.

```
INSERT INTO EMP(SSN) VALUES ENCRYPT_TDES ('289-46-8832','Ben123');
```

Example 3

Encrypt the social security number that is inserted into the table. Specify 'Pacific' as the encryption password, and provide 'Ocean' as a hint to help the user remember the password of 'Pacific'.

```
INSERT INTO EMP(SSN) VALUES ENCRYPT_TDES ('289-46-8832','Pacific','Ocean');
```

The preceding statement returns a double precision floating-point number with an approximate value of 31.62.

EXP

The EXP function returns a value that is the base of the natural logarithm (e), raised to a power that is specified by the argument. The EXP and LN functions are inverse operations.

```
▶▶─ EXP( numeric-expression ) ─▶◀
```

The schema is SYSIBM.

The argument must be an expression that returns the value of any built-in numeric data type that is not DECFLOAT. If the argument is not a double precision floating-point number, it is converted to one for processing by the function.

The result of the function is a double precision floating-point number.

The result can be null; if the argument is null, the result is the null value.

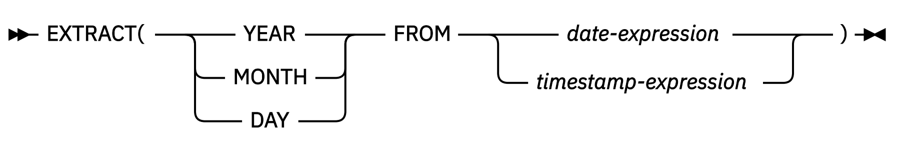
Example: Assume that host variable E is DECIMAL(10,9) with a value of 3.453789832. The following statement returns a double precision floating-point number with an approximate value of 31.62.

```
   SELECT EXP(:E)
     FROM SYSIBM.SYSDUMMY1;
```

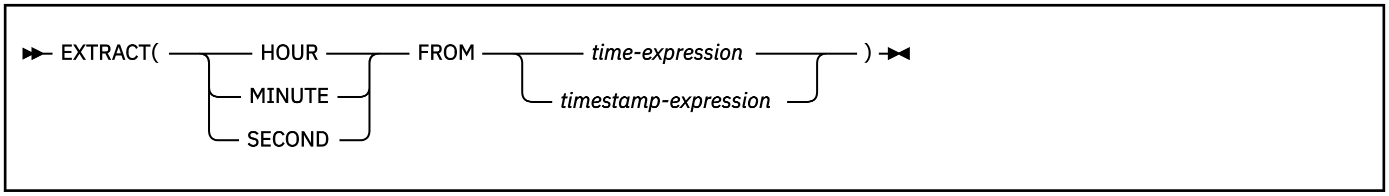
EXTRACT

The EXTRACT function returns a portion of a date or timestamp, based on its arguments.

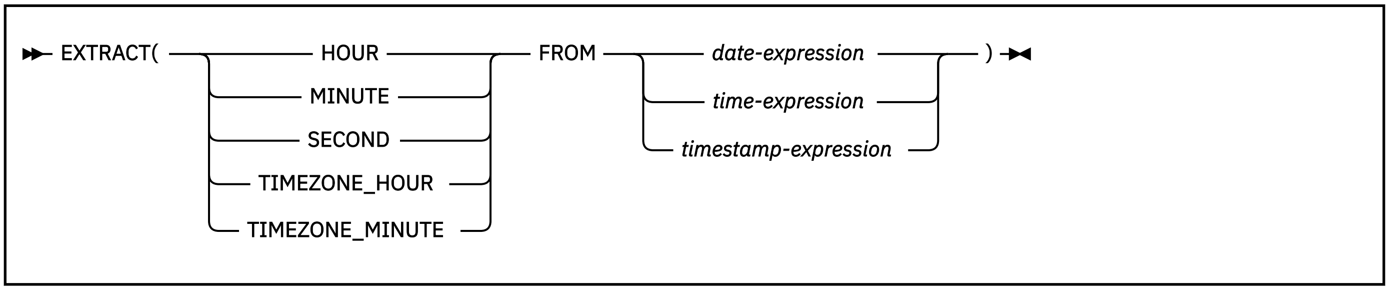
Extract date values:



Extract time values:



Extract time zone values:



The schema is SYSIBM.

The result can be null; if the argument is null, the result is the null value.

Extract date values

YEAR
Specifies that the year portion of *date-expression* or *timestamp-expression* is returned. The result is identical to the YEAR scalar function. For more information, see "YEAR" on page 667.

MONTH
Specifies that the month portion of *date-expression* or *timestamp-expression* is returned. The result is identical to the MONTH scalar function. For more information, see "MONTH" on page 507.

DAY
Specifies that the day portion of *date-expression* or *timestamp-expression* is returned. The result is identical to the DAY scalar function. For more information, see "DAY" on page 426.

date-expression
An expression that returns the value of either a built-in date or built-in character string data type.

If *date-expression* is a character or graphic string, it must not be a CLOB or DBCLOB and its value must be a valid character-string or graphic-string representation of a date. For the valid formats of string representations of dates, see "String representations of datetime values" on page 120.

timestamp-expression
An expression that returns the value of either a built-in timestamp or built-in character string data type.

If *timestamp-expression* is a character or graphic string, it must not be a CLOB or DBCLOB and its value must be a valid character-string or graphic-string representation of a timestamp. For the valid formats of string representations of timestamps, see "String representations of datetime values" on page 120.

Extract time values

HOUR
Specifies that the hour portion of *time-expression* or *timestamp-expression* is returned. The result is identical to the HOUR scalar function. For more information, see "HOUR" on page 474.

MINUTE
Specifies that the minute portion of *time-expression* or *timestamp-expression* is returned. The result is identical to the MINUTE scalar function. For more information, see "MINUTE" on page 505.

SECOND

Specifies that the second portion of *time-expression* or *timestamp-expression* is returned. The result is identical to the SECOND scalar function where the precision and scale of the result depend on the type of *time-expression* or *timestamp-expression*. For more information, see "SECOND" on page 567.

time-expression

An expression that returns the value of either a built-in time or built-in character string data type.

If *time-expression* is a character or graphic string, it must not be a CLOB or DBCLOB and its value must be a valid string representation of a time. For the valid formats of string representations of times, see "String representations of datetime values" on page 120.

timestamp-expression

An expression that returns the value of either a built-in timestamp or built-in character string data type.

If *timestamp-expression* is a character or graphic string, it must not be a CLOB or DBCLOB and its value must be a valid string representation of a timestamp. For the valid formats of string representations of timestamps, see "String representations of datetime values" on page 120.

Extract time zone values

TIMEZONE_HOUR

Specifies that the hour component of the time zone of the timestamp value is returned. TIMEZONE_HOUR can only be specified if the second argument is a *timestamp-expression* and the *timestamp-expression* contains a time zone.

TIMEZONE_MINUTE

Specifies that the minute component of the time zone of the timestamp value is returned. TIMEZONE_MINUTE can only be specified if the second argument is a *timestamp-expression* and the *timestamp-expression* contains a time zone.

The values of TIMEZONE_HOUR and TIMEZONE_MINUTE shall either both be non-negative or both be non-positive.

If the *timestamp-expression* argument includes a time zone, the result is determined from the UTC representation of the datetime value.

The data type of the result of the function depends on the part of the datetime value that is specified:

- The result is INTEGER, if one of the following is specified:
  - YEAR
  - MONTH
  - DAY
  - HOUR
  - MINUTE
  - TIMEZONE_HOUR
  - TIMEZONE_MINUTE
- The result is DECIMAL(2+*p*, *p*) where *p* is the fractional second precision, if SECOND is specified with a TIMESTAMP(*p*) value.
- The result is DECIMAL(8,6), if SECOND is specified with a TIME value or a string representation of a TIME or timestamp. The fractional digits contains fractional seconds.

Example 1:

Assume that the column PRSTDATE has an internal value that is equivalent to 2010-12-25. The following statement returns the value 12:

```
SELECT EXTRACT(MONTH FROM PRSTDATE)
  FROM PROJECT;
```

Example 2:

Assume that host variable *PRSTSZ* contains the value 2008-02-29-20.00.00.000000-08.30:

```
SELECT EXTRACT(HOUR FROM :PRSTSZ) FROM PROJECT;
```

The SELECT statement returns the value 4, which is the hour of the input datetime value expressed in UTC.

To return the same hour value as expressed in the input, cast the value to TIMESTAMP WITHOUT TIME ZONE before using the EXTRACT function:

```
SELECT EXTRACT(HOUR FROM CAST (:PRSTSZ AS TIMESTAMP ) ) FROM PROJECT;
```

The SELECT statement returns the value 20, which is the hour as it was originally expressed as a string in the host variable.

```
SELECT EXTRACT(TIMEZONE_HOUR FROM :PRSTSZ) FROM PROJECT;
```

This SELECT statement returns the value -8.

```
SELECT EXTRACT(TIMEZONE_MINUTE FROM :PRSTSZ) FROM PROJECT;
```

This SELECT statement returns the value -30.

FLOAT

The FLOAT function returns a floating-point representation of either a number or a string representation of a number.

```
▶▶─ FLOAT( numeric-expression ) ─▶◀
```

The schema is SYSIBM.

Notes

Syntax alternatives:

FLOAT is a synonym for DOUBLE_PRECISION or DOUBLE. For details, see "DOUBLE_PRECISION or DOUBLE" on page 451.

FLOOR

The FLOOR function returns the largest integer value that is less than or equal to the argument.

```
▶▶─ FLOOR( numeric-expression ) ─▶◀
```

The schema is SYSIBM.

The argument must be an expression that returns a value of any built-in numeric data type.

The argument can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34).

The result of the function has the same data type and length attribute as the argument. When the argument is DECIMAL, the scale of the result is 0 and not the scale of the input argument. For example, an argument with a date type of DECIMAL(5,5) results in DECIMAL(5,0).

The result can be null; if the argument is null, the result is the null value.

Example 1: Using sample table DSN8C10.EMP, find the highest monthly salary, rounding the result down to the next integer. The SALARY column has a decimal data type.

```
  SELECT FLOOR(MAX(SALARY)/12)
    FROM DSN8C10.EMP;
```

This example returns 04395 because the highest paid employee is Christine Haas who earns $52750.00 per year. Her average monthly salary before applying the FLOOR function is 4395.83.

Example 2: This example demonstrates using FLOOR with both positive and negative numbers.

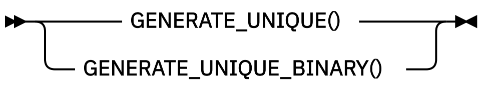
```
  SELECT FLOOR( 3.5),
         FLOOR( 3.1),
         FLOOR(-3.1),
         FLOOR(-3.5)
  FROM SYSIBM.SYSDUMMY1;
```

This example returns (leading zeros are shown to demonstrate the precision and scale of the result):

```
03. 03. -04. -04.
```

GENERATE_UNIQUE and GENERATE_UNIQUE_BINARY

The GENERATE_UNIQUE and GENERATE_UNIQUE_BINARY functions return a value that is unique, compared to any other execution of the same function.



The schema is SYSIBM.

The GENERATE_UNIQUE and GENERATE_UNIQUE_BINARY functions are defined as not deterministic. Although the functions have no arguments, the empty parentheses must be specified when the functions are invoked.

The result of either of the functions is a unique value that includes the internal form of the Universal Time, Coordinated (UTC) and, if in a sysplex environment, the sysplex member where the function was processed.

The data type of the result depends on which function was invoked. GENERATE_UNIQUE returns a bit data character string 13 bytes long (CHAR(13) FOR BIT DATA). GENERATE_UNIQUE_BINARY returns a BINARY(16) value.

The result cannot be null.

The results of these functions can be used to provide unique values in a table. The sequence is based on the time when the function was executed.

These functions differ from using the special register CURRENT TIMESTAMP in that a unique value is generated for each row of a multiple row insert statement, an insert statement with a fullselect, or an insert operation in a MERGE statement.

The timestamp value that is part of the result of either of these functions can be determined using the TIMESTAMP function with the result of GENERATE_UNIQUE or GENERATE_UNIQUE_BINARY as an argument.

Example: Create a table that includes a column that is unique for each row. Populate this column using the GENERATE_UNIQUE function. Notice that the UNIQUE_ID column is defined as FOR BIT DATA to identify the column as a bit data character string.

```
  CREATE TABLE EMP_UPDATE
   (UNIQUE_ID VARCHAR(13)FOR BIT DATA,
    EMPNO CHAR(6),
    TEXT VARCHAR(1000));
  INSERT INTO EMP_UPDATE VALUES (GENERATE_UNIQUE(),'000020','Update entry 1...');
  INSERT INTO EMP_UPDATE VALUES (GENERATE_UNIQUE(),'000050','Update entry 2...');
```

This table will have a unique identifier for each row if GENERATE_UNIQUE is always used to set the value the UNIQUE_ID column. You can create an insert trigger on the table to ensure that GENERATE_UNIQUE is used to set the value:

```
    CREATE TRIGGER EMP_UPDATE_UNIQUE
      NO CASCADE BEFORE INSERT ON EMP_UPDATE
      REFERENCING NEW AS NEW_UPD
      FOR EACH ROW MODE DB2SQL
      SET NEW_UPD.UNIQUE_ID = GENERATE_UNIQUE();
```

With this trigger, the previous INSERT statements that were used to populate the table could be issued without specifying a value for the UNIQUE_ID column:

```
    INSERT INTO EMP_UPDATE (EMPNO,TEXT) VALUES ('000020','Update entry 1...');
    INSERT INTO EMP_UPDATE (EMPNO,TEXT) VALUES ('000050','Update entry 2...');
```

The timestamp (in UTC) for when a row was added to EMP_UPDATE can be returned using:

```
    SELECT TIMESTAMP(UNIQUE_ID), EMPNO, TEXT FROM EMP_UPDATE;
```

Therefore, the table does not need a timestamp column to record when a row is inserted.

GETHINT

The GETHINT function returns a hint for the password if a hint was embedded in the encrypted data. A password hint is a phrase that helps you remember the password with which the data was encrypted. For example, 'Ocean' might be used as a hint to help remember the password 'Pacific'.

▶▶— GETHINT(*encrypted-data*) —▶◀

The schema is SYSIBM.

encrypted-data

An expression that returns a string that contains a complete, encrypted data string. *encrypted-data* must return a value that is a CHAR FOR BIT DATA, VARCHAR FOR BIT DATA, BINARY, or VARBINARY built-in data type. The string must have been encrypted using ENCRYPT_TDES function.

The result of the function is VARCHAR(32). The actual length of the result is the actual length of the hint that was provided when the data was encrypted.

The result can be null; if the argument is null, the result is the null value.

If no hint was specified when the ENCRYPT_TDES function was used to encrypt the data, the result is the null value.

The encoding scheme of the result is the same as the encoding scheme of *encrypted-data*. If *encrypted-data* is bit data, the CCSID of the result is the default character CCSID for that encoding scheme. Otherwise, the CCSID of the result is the same as the CCSID of *encrypted-data*.

For additional information about this function, see “DECRYPT_BINARY, DECRYPT_BIT, DECRYPT_CHAR, and DECRYPT_DB” on page 444 and “ENCRYPT_TDES or ENCRYPT” on page 456.

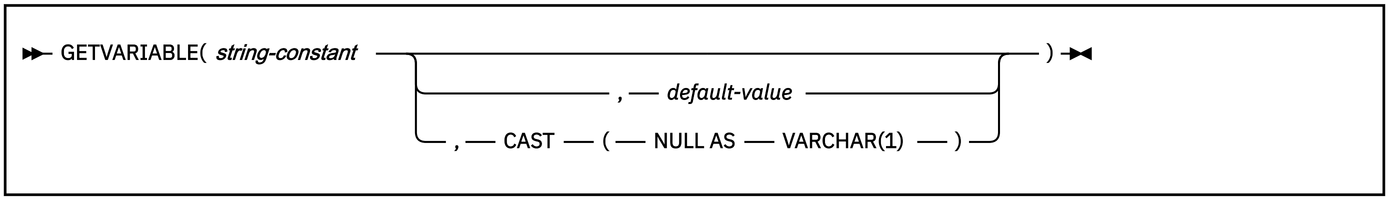
Example: This example shows how to embed a hint for the password when encrypting data and how to later use the GETHINT function to retrieve the embedded hint. In this example, the hint 'Ocean' is used to help remember the encryption password 'Pacific'.

```
    INSERT INTO EMP (SSN) VALUES ENCRYPT_TDES ('289-46-8832','Pacific','Ocean');
    SELECT GETHINT (SSN) FROM EMP;
```

The value that is returned is 'Ocean'.

GETVARIABLE

The GETVARIABLE function returns a varying-length character-string representation of the current value of the session variable that is identified by the argument.



The schema is SYSIBM.

string-constant
Specifies a string constant that contains the name of the session variable whose value is to be returned. The string constant:

- Must have a length that does not exceed 142 bytes.
- Must contain the fully qualified name of the variable, with no embedded blanks. Delimited identifiers must not be specified.
- Must not contain lowercase letters or characters that cannot be specified in an ordinary identifier.

The schema qualifier for the variable must be:

- SYSIBM for built-in session variables. For a list of the built-in session variables, see "Built-in session variables" on page 336.
- SESSION for user-defined session variables. User-defined session variables are established via the connection or signon exit routines. For more information, see Session variables in connection and sign-on routines (Managing Security).

default-value
Specifies a string constant that contains the value to be returned if the specified variable does not exist or is not supported by Db2. *default-value* must be a string constant that does not exceed 255 bytes.

If *default-value* is not specified and the specified user-defined session variable does not exist or the built-in session variable is not supported by Db2, an error is returned.

CAST(NULL AS VARCHAR(1))
Specifies that a null value is to be returned if the specified variable does not exist or is not supported by Db2.

The data type of the result is VARCHAR(255). The result can be null.

The CCSID of the result is the CCSID for Unicode mixed data.

Notes

The GETVARIABLE function cannot obtain the values of built-in global variables or user-defined global variables.

Examples

Example 1
Use the GETVARIABLE function to set the value of host variable :hv1 to the name of the plan that is currently being executed. The name of the built-in session variable that contains the name of the plan is SYSIBM.PLAN_NAME.

```
SET :hv1 = GETVARIABLE('SYSIBM.PLAN_NAME');
```

If Db2 does not support the name of the session variable, an error is returned. For example, the following statement returns an error because Db2 does not support a built-in session variable that is named SYSIBM.XYZ.

```
SET :hv1 = GETVARIABLE('SYSIBM.XYZ');
```

Example 2

Use the GETVARIABLE function to set the value of host variable :hv2 to the value for the user that is defined in user-defined session variable TEST. If the session variable has not been set or cannot be found, have the function return the value 'TEST FAILED'.

```
SET :hv2 = GETVARIABLE('SESSION.TEST','TEST FAILED');
```

Example 3

Use the GETVARIABLE function to set the value of host variable :hv3 to a string representation of the SYSTEM EBCDIC CCSIDs. The name of the built-in session variable that contains the system EBCDIC CCSIDs is SYSIBM.SYSTEM_EBCDIC_CCSID.

```
SET :hv3 = GETVARIABLE('SYSIBM.SYSTEM_EBCDIC_CCSID');
```

Regardless of the setting of the field MIXED DATA on the installation panel (YES or NO), the function returns three comma-delimited values that correspond to the SBCS, MIXED, and GRAPHIC CCSIDs for the encoding scheme.

For example, if the statement were issued on a system with the field MIXED DATA on the installation panel equal to NO and the default system CCSID of 37, this string would be returned:

'37,65534,65534'

If the statement were issued on a system with the field MIXED DATA on the installation panel equal to YES and a default system CCSID of 930 (the mixed CCSID for the system), this string would be returned:

'290,930,300'

GRAPHIC

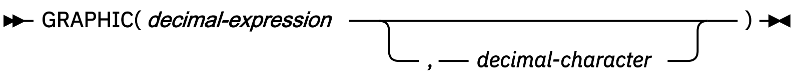
The GRAPHIC function returns a fixed-length graphic-string representation of the type of the first argument.

Syntax: Integer to Graphic

FL 502

Syntax: Decimal to Graphic

FL 502



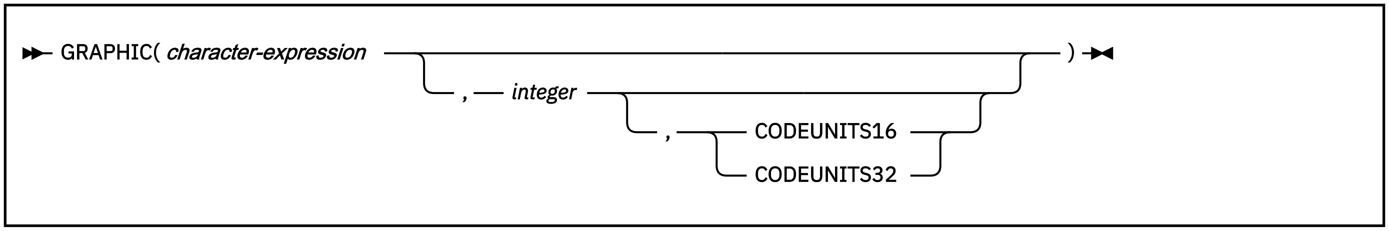
Syntax: Floating-point to Graphic

FL 502

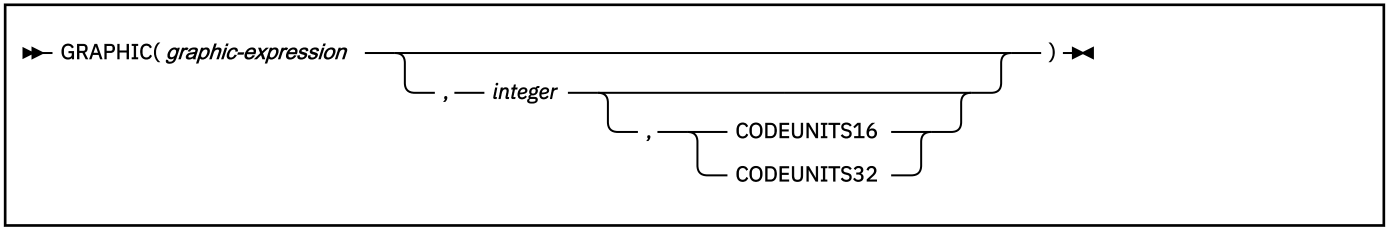
Syntax: Decimal floating-point to Graphic

FL 502

Syntax: Character to Graphic:



Syntax: Graphic to Graphic:



The schema is SYSIBM.

The GRAPHIC function returns a graphic-string representation of:

- FL 502 An integer number if the first argument is a SMALLINT, INTEGER, or BIGINT
- FL 502 A decimal number if the first argument is a decimal number
- FL 502 A double-precision floating-point number if the first argument is a DOUBLE or REAL
- FL 502 A decimal floating-point number if the first argument is DECFLOAT
- A character string if the first argument is any type of character string
- A graphic string if the first argument is an EBCDIC or Unicode graphic string

The result can be null; if the first argument is null, the result is the null value.

The length attribute of the result is measured in double-byte characters because it is a graphic string.

Integer to Graphic

FL 502

integer-expression
An expression that returns a value that is an integer data type (either SMALLINT, INTEGER, or BIGINT).

The result is a fixed-length graphic string of the argument in the form of an SQL integer constant. The result is the smallest number of characters that can be used to represent the value of the argument, padded with blanks. The result consists of n characters that are the significant digits that represent the value of the argument with a preceding minus sign if the argument is negative. A positive value starts with a digit and always includes at least one trailing blank. Leading zeroes are not included. The result is left justified.

- If the argument is a small integer, the length of the result is 6. If the number of characters in the result is less than 6, the result is padded on the right with blanks.
- If the argument is a large integer, the length of the result is 11. If the number of characters in the result is less than 11, the result is padded on the right with blanks.

- If the argument is a big integer, the length of the result is 20. If the number of characters in the result is less than 20, the result is padded on the right with blanks.

The CCSID of the result is 1200 (UTF-16).

Decimal to Graphic

FL 502

decimal-expression
An expression that returns a value that is a built-in decimal data type. If a different precision and scale is wanted, the DECIMAL scalar function can be used to make the change. To specify a different precision and scale for the value of the expression, apply the DECIMAL function before applying the GRAPHIC function.

decimal-character
Specifies the single-byte character constant that is used to delimit the decimal digits in the result graphic string. The character must not be a digit, a plus sign (+), a minus sign (-), or a blank. The default is the period (.) or comma (,). For information on what factors govern the choice, see Decimal point representation.

The result is a fixed-length graphic string representation of the first argument. The result is the smallest number of characters that can be used to represent the value of the argument, except that trailing zeros are included. The result includes a decimal character and up to *p* digits, where *p* is the precision of the *decimal-expression* with a preceding minus sign if the argument is negative. A positive value starts with a digit or the decimal-character, and always includes at least one trailing blank. Leading zeros are not returned. If the scale of *decimal-expression* is zero, the decimal character is not returned. If the number of bytes in the result is less than the defined length of the result, the result is padded on the right with blanks.

The length of the result is 2+*p* where *p* is the precision of the *decimal-expression*.

The CCSID of the result is 1200 (UTF-16).

Floating-point to Graphic

FL 502

floating-point-expression
An expression that returns a value that is a floating-point data type (DOUBLE or REAL).

The result is a fixed-length graphic string representation of the argument in the form of an SQL floating-point constant. If the argument is negative, the first character of the result is a minus sign; otherwise, the first character is a digit. If the argument is zero, the result is 0E0.

The length of the result is 24. The result includes the smallest number of characters that can represent the value of the argument such that the mantissa consists of a single digit, other than zero, followed by a period and a sequence of digits. If the number of characters in the result is less than 24, the result is padded on the right with blanks.

The CCSID of the result is 1200 (UTF-16).

Decimal floating-point to Graphic

FL 502

decimal-floating-point-expression
An expression that returns a value that is a built-in decimal floating-point data type (DECFLOAT).

The result is a fixed-length graphic string representation of the argument in the form of an SQL decimal floating-point constant.

If the result value is Infinity, sNaN, or NaN, the strings 'INFINITY', 'SNAN', and 'NAN', respectively, are returned. The DECFLOAT special value sNaN does not result in an exception when converted to a string.

The length of the result is 42. If the number of characters in the result is less than 42, the result is padded on the right with blanks. Trailing zeros are significant. If the argument is negative, the first character of the result is a minus sign. Otherwise, the first character is a digit, or a letter if the DECFLOAT value is Infinity, sNaN, or NaN.

The CCSID of the result is 1200 (UTF-16).

Character to Graphic

character-expression

An expression that returns a value that is an EBCDIC-encoded or Unicode-encoded character string. It cannot be BIT data. The argument does not need to be mixed data, but any occurrences of X'0E' and X'0F' in the string must conform to the rules for EBCDIC mixed data. (See "Character strings" on page 102 for these rules.)

The value of the expression must not be an empty string if *integer* is not specified or have the value X'0E0F' if the string is an EBCDIC string.

integer

The length of the resulting fixed-length graphic string in the units that are either implicitly or explicitly specified. The value must be an integer constant between 1 and 127. If the length of *character-expression* is less than the length specified, the result is padded with double-byte blanks to the length of the result.

If CODEUNITS16 or CODEUNITS32 is specified, see "Determining the length attribute of the final result" on page 108 for information about how to calculate the length attribute of the result string.

If *integer* is not specified, the length of the result for an EBCDIC string is the minimum of 127 and the length attribute of *character-expression*, excluding shift characters. For a Unicode (UTF-8) string, the length is data dependent, but does not exceed 127.

CODEUNITS16 or CODEUNITS32

Specifies the unit that is used to express *integer*. If CODEUNITS16 or CODEUNITS32 is specified, the input is EBCDIC, and there is no system CCSID for EBCDIC GRAPHIC data, an error occurs.

CODEUNITS16

Specifies that *integer* is expressed in terms of 16-bit UTF-16 code units.

CODEUNITS32

Specifies that *integer* is expressed in terms of 32-bit UTF-32 code units.

For more information about CODEUNITS16 and CODEUNITS32, see "String unit specifications" on page 106.

The CCSID of the result is the graphic CCSID that corresponds to the character CCSID of *character-expression*. If the input is EBCDIC and there is no system CCSID for EBCDIC GRAPHIC data, the CCSID of the result is X'FFFE'.

For EBCDIC data, each character of *character-expression* determines a character of the result. The argument might need to be converted to the native form of mixed data before the result is derived. Let *M* be the system CCSID for mixed data. The argument is not converted if any of the following conditions is true:

- The argument is mixed data and its CCSID is *M*.
- The argument is SBCS data and its CCSID is the same as the system CCSID for SBCS data. In this case, the operation proceeds as if the CCSID of the argument is *M*.

Otherwise, the argument is a new string *S* derived by converting the characters to the coded character set identified by *M*. If there is no system CCSID for EBCDIC mixed data, conversion is to the coded character set that the system CCSID for SBCS data identifies.

The result is derived from *S* using the following steps:

- Each shift character (X'0E' or X'0F') is removed.
- Each double-byte character remains as is.

- Each single-byte character is replaced by a double-byte character.

The replacement for an SBCS character is the equivalent DBCS character if an equivalent exists. Otherwise, the replacement is X'FEFE'. The existence of an equivalent character depends on *M*. If there is no system CCSID for mixed data, the DBCS equivalent of X'xxxx' for EBCDIC is X'42xx', except for X'40', whose DBCS equivalent is X'4040'.

For Unicode data:

Each character of *character-expression* determines a character of the result. The argument might need to be converted to the native form of mixed data before the result is derived. Let M be the system CCSID for mixed data. The argument is not converted if any of the following conditions is true:

- The argument is mixed data, and its CCSID is *M*.
- The argument is SBCS data, and its CCSID is the same as the system CCSID for SBCS data. In this case, the operation proceeds as if the CCSID of the argument is *M*.

Otherwise, the argument is a new string *S* derived by converting the characters to the coded character set identified by *M*.

The result is derived from *S* by using the following steps:

- Each non-supplementary character is replaced by a Unicode double-byte character (a UTF-16 code point). A non-supplementary character in UTF-8 is between 1 and 3 bytes.
- Each supplementary character is replaced by a pair of Unicode double-byte characters (a pair of UTF-16 code points).

The replacement for a single-byte character is the Unicode equivalent character if an equivalent exists. Otherwise, the replacement is X'FEFE'.

Graphic to Graphic

graphic-expression

An expression that returns a value that is a graphic string. The graphic string must not be an empty string if *integer* is not specified.

integer

The length of the resulting fixed-length graphic string in the units that are either implicitly or explicitly specified. The value must be an integer constant between 1 and 127. If the length of *graphic-expression* is less than the length specified, the result is padded with double-byte blanks to the length of the result.

If CODEUNITS16 or CODEUNITS32 is specified, see "Determining the length attribute of the final result" on page 108 for information about how to calculate the length attribute of the result string.

If *integer* is not specified, the length of the result is the minimum of 127 and the length attribute of *graphic-expression*.

CODEUNITS16 or CODEUNITS32

Specifies the unit that is used to express *integer*. If CODEUNITS16 or CODEUNITS32 is specified, the input is EBCDIC, and there is no system CCSID for EBCDIC GRAPHIC data, an error occurs.

CODEUNITS16

Specifies that *integer* is expressed in terms of 16-bit UTF-16 code units.

CODEUNITS32

Specifies that *integer* is expressed in terms of 32-bit UTF-32 code units.

For more information about CODEUNITS16 and CODEUNITS32, see "String unit specifications" on page 106.

If the length of the *graphic-expression* is greater than the specified length of the result, the result is truncated. Unless all the truncated characters are blanks, a warning is returned.

The CCSID of the result is the same as the CCSID of *graphic-expression*.

Notes

FL 502 Casting numeric data to Unicode:

The result of the GRAPHIC functions is Unicode (UTF-16) when the first argument is numeric data. The GRAPHIC function can only be invoked with numeric data for the first argument if the containing statement:

- references Unicode base tables or views only and the statement is qualified to be a single encoding scheme statement, or
- is considered a multiple encoding scheme statement and the application encoding scheme is Unicode.

Examples

Example 1:

Assume that MYCOL is a VARCHAR column in TABLEY. The following function returns the string in MYCOL as a fixed-length graphic string.

```
    SELECT GRAPHIC(MYCOL)
      FROM TABLEY;
```

Example 2:

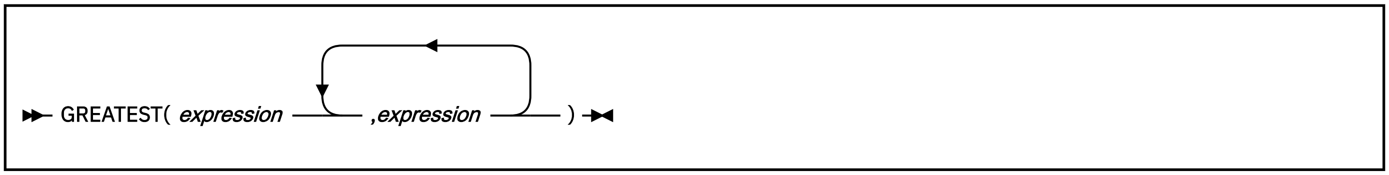
Assume that an EMPLOYEE_U table exists that is similar to the EMPLOYEE sample table except that it is a Unicode table. The SALARY and COMM columns are defined as DECIMAL with a precision of 9 and a scale of 2. Return the total income for employee Haas as a fixed-length graphic string using the comma decimal character.

```
 SELECT GRAPHIC(SALARY + COMM, ',')
 FROM EMPLOYEE_U
 WHERE LASTNAME = 'HAAS'
```

The result is the value `G'56970,00 '`.

GREATEST

The GREATEST function returns the maximum value in a set of values.

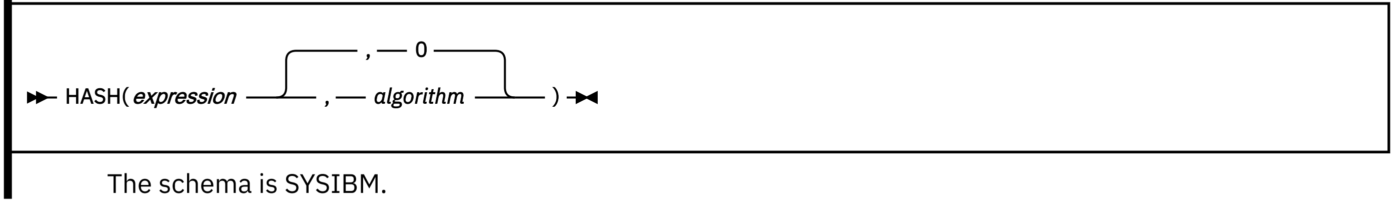


The GREATEST function is identical to the MAX scalar function. For more information, see "MAX (scalar)" on page 501.

HASH

The HASH function returns a varying-length value that is the result of applying the specified algorithm to the first argument. The function is intended for cryptographic purposes.

FL 506



The schema is SYSIBM.

expression
An expression that represents the string value that is to be hashed. The expression must return a built-in character string, graphic string, or binary string.

algorithm
An integer constant value of 0, 1, or 2 that indicates the hash algorithm to be used when the function name is HASH. If no algorithm is specified, the default value of 0 is used which indicates the MD5 algorithm.

The result is produced by applying the hash algorithm, *algorithm*, to *expression*.

The result of the function is VARBINARY, and the length attribute of the result depends on the hash algorithm used. The characteristics of the result are summarized in the following table:

Table 77. Characteristics of the result for each algorithm

Algorithm	**Value for algorithm parameter**	**Result size**	**Number of different values that can be returned**	**HASH function result data type**
MD5	0	128 bit	2^{128}	VARBINARY(16)
SHA1	1	160 bit	2^{160}	VARBINARY(20)
SHA256	2	256 bit	2^{256}	VARBINARY(32)

If the first argument can be null, the result can be null. If the first argument is null, the result is the null value.

Notes

Security considerations:
Security flaws have been identified in both the SHA1 and MD5 algorithms. You can find acceptable hash algorithms in applicable compliance documentation, such as National Institute of Standards and Technology (NIST) Special Publication 800-131A.

Syntax alternatives:
The HASH function is similar to the other hashing functions, where the hash algorithm is specified as part of the function name. For example:

```
HASH_MD5  (  expression  )
```

Invoking the HASH function for hashing is recommended to increase the portability of applications.

Examples

Example 1:
Invoke the HASH function to use the MD5 algorithm to generate a hashed value.

```
SELECT HEX(HASH('ABCDEFGHIJKLMNOPQRZTUVWXYZ' , 0 ))
FROM SYSIBM.SYSDUMMYU;
```

The following value is returned:

```
X'E433BC7BE26A152E54E2EA0C92778160'
```

Example 2:
Invoke the HASH_SHA1 function to use the SHA1 algorithm to generate a hashed value.

```
SELECT HEX(HASH('ABCDEFGHIJKLMNOPQRZTUVWXYZ', 1 ))
FROM SYSIBM.SYSDUMMYU;
```

The following value is returned:

```
X'8F34563A0FA4BA1A285C8035935D010629385474'
```

Example 3:

Invoke the HASH_SHA256 function to use the SHA256 algorithm to generate a hashed value.

```
SELECT HEX(HASH('ABCDEFGHIJKLMNOPQRZTUVWXYZ' , 2 ))
FROM SYSIBM.SYSDUMMYU;
```

The following value is returned:

```
X'403AC046B04F4A749E9810971083997B71F2B6FAF87CECCDE657E93FFCF700F0'
```

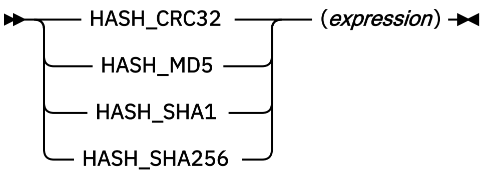
HASH_CRC32, HASH_MD5, HASH_SHA1, and HASH_SHA256
The hashing functions return a fixed-length value that is the result of applying a hash algorithm to an input argument. The functions are intended for cryptographic purposes.

HASH_CRC32, HASH_MD5, HASH_SHA1, and HASH_SHA256

The hashing functions return a fixed-length value that is the result of applying a hash algorithm to an input argument. The functions are intended for cryptographic purposes.



The schema is SYSIBM.

expression
An expression that represents the string value that is to be hashed. The expression must return a built-in character string, graphic string, or binary string.

The result is produced by applying the hash algorithm to *expression*. The hash algorithm is determined by the name of the function that is invoked.

The result of the function is BINARY, and the length attribute of the result depends on the hash algorithm specified. The characteristics of the result are summarized in the following table.

Table 78. Characteristics of the result for each algorithm

Function name	Algorithm	Result size	Number of different values that can be returned	Hash function result data type
HASH_CRC32	CRC32	32 bit	2^{32}	BINARY(4)
HASH_MD5	MD5	128 bit	2^{128}	BINARY(16)
HASH_SHA1	SHA1	160 bit	2^{160}	BINARY(20)
HASH_SHA256	SHA2-256	256 bit	2^{256}	BINARY(32)

If the first argument can be null, the result can be null. If the first argument is null, the result is the null value.

Note that security flaws have been identified in both the SHA1 and MD5 algorithms. You can find acceptable hash algorithms in applicable compliance documentation, such as National Institute of Standards and Technology (NIST) Special Publication 800-131A.

Notes

Syntax alternatives:
Hash functions HASH_MD5, HASH_SHA1, and HASH_SHA256 are similar to the following HASH function, where the hash algorithm is specified as an integer constant value of 0, 1, or 2:

```
HASH ( expression , integer-constant )
```

For these hash functions, invoking the HASH function for hashing is recommended to increase the portability of applications.

Examples

Example 1:
Invoke the HASH_CRC32 function to use the CRC32 algorithm to generate a hashed value.

```
SELECT HEX(HASH_CRC32('ABCDEFGHIJKLMNOPQRZTUVWXYZ'))
FROM SYSIBM.SYSDUMMYU;
```

The following value is returned:

```
X'B4B86309'
```

Example 2:

Invoke the HASH_MD5 function to use the MD5 algorithm to generate a hashed value.

```
SELECT HEX(HASH_MD5('ABCDEFGHIJKLMNOPQRZTUVWXYZ'))
FROM SYSIBM.SYSDUMMYU;
```

The following value is returned:

```
X'E433BC7BE26A152E54E2EA0C92778160'
```

Example 3:

Invoke the HASH_SHA1 function to use the SHA1 algorithm to generated a hashed value.

```
SELECT HEX(HASH_SHA1('ABCDEFGHIJKLMNOPQRZTUVWXYZ'))
FROM SYSIBM.SYSDUMMYU;
```

The following value is returned:

```
X'8F34563A0FA4BA1A285C8035935D010629385474'
```

Example 4:

Invoke the HASH_SHA256 function to use the SHA256 algorithm to generate hashed value.

```
SELECT HEX(HASH_SHA256('ABCDEFGHIJKLMNOPQRZTUVWXYZ'))
FROM SYSIBM.SYSDUMMYU;
```

The following value is returned:

```
X'403AC046B04F4A749E9810971083997B71F2B6FAF87CECCDE657E93FFCF700F0'
```

Related reference

HASH
The HASH function returns a varying-length value that is the result of applying the specified algorithm to the first argument. The function is intended for cryptographic purposes.

HEX

The HEX function returns a hexadecimal representation of a value.

▶▶— HEX(*expression*) —▶◀

The schema is SYSIBM.

The argument must an expression that returns a value of any built-in data type that is not XML. A character or binary string must not have a maximum length greater than 16352. A graphic string must not have a maximum length greater than 8176.

The result of the function is a character string.

The result can be null; if the argument is null, the result is the null value.

The result is a string of hexadecimal digits. The first two represent the first byte of the argument, the next two represent the second byte of the argument, and so forth. If the argument is a datetime value, the result is the hexadecimal representation of the internal form of the argument.

If the argument is a fixed-length string and the length of the result is less than 255, the result is a fixed-length string. Otherwise, the result is a varying-length string with a length attribute that depends on the following considerations:

If the argument is not a varying-length string, the length attribute of the result string is the same as the length of the result.

If the argument is a varying-length character or binary string, the length attribute of the result string is twice the length attribute of the argument.

If the argument is a varying-length graphic string, the length attribute of the result string is four times the length attribute of the argument.

If *expression* returns string data, the CCSID of the result is the SBCS CCSID that corresponds to the CCSID of *expression*. Otherwise, the CCSID of the result is determined from the context in which the function was invoked. For more information, see Determining the encoding scheme and CCSID of a string (Introduction to Db2 for z/OS).

If the argument is a graphic string, the length of the result is four times the maximum length of the argument. Otherwise, the length of the result is twice the (maximum) length of the argument.

Example: Return the hexadecimal representation of START_RBA in the SYSIBM.SYSCOPY catalog table.

```
   SELECT HEX(START_RBA) FROM SYSIBM.SYSCOPY;
```

HOUR

The HOUR function returns the hour part of a value.

▶▶— HOUR(*expression*) —▶◀

The schema is SYSIBM.

The argument must be an expression that returns a value of one of the following built-in data types: a time, a timestamp, a character string, a graphic string, or a numeric data type.

- If *expression* is a character or graphic string, it must not be a CLOB or DBCLOB, and its value must be a valid string representation of a time or timestamp with an actual length of not greater than 255 bytes. For the valid formats of string representations of times and timestamps, see "String representations of datetime values" on page 120.
- If *expression* is a number, it must be a time or timestamp duration. For the valid formats of time and timestamp durations, see "Datetime operands" on page 169.

If *expression* is a timestamp with a time zone, or a valid string representation of a timestamp with a time zone, the result is determined from the UTC representation of the datetime value.

The result of the function is a large integer.

The result can be null; if the argument is null, the result is the null value.

The other rules depend on the data type of the argument:

If the argument is a time, timestamp, or string representation of either, the result is the hour part of the value, which is an integer between 1 and 24.

If the argument is a time duration or timestamp duration, the result is the hour part of the value, which is an integer between -99 and +99. A nonzero result has the same sign as the argument.

If the argument contains a time zone, the result is the hour part of the value expressed in UTC.

Example 1: Assume that a table named CLASSES contains a row for each scheduled class. Also assume that the class starting times are in a TIME column named STARTTM. Select those rows in CLASSES that represent classes that start after the noon hour.

```
    SELECT *
      FROM CLASSES
      WHERE HOUR(STARTTM) > 12;
```

Example 2: The following invocations of the HOUR function returns the same result:

```
SELECT HOUR('2003-01-02-20.00.00'),
            HOUR('2003-01-02-12.00.00-08:00'),
            HOUR('2003-01-03-05.00.00+09:00')
        FROM SYSIBM.SYSDUMMY1;
```

For each invocation of the HOUR function in this SELECT statement, the result is 20.

When the input argument contains a time zone, the result is determined from the UTC representation of the input value. The string representations of a timestamp with a time zone in the SELECT statement all have the same UTC representation: 2003-01-02-20.00.00.

IDENTITY_VAL_LOCAL

The IDENTITY_VAL_LOCAL function returns the most recently assigned value for an identity column.

```
►►─ IDENTITY_VAL_LOCAL() ─►◄
```

The schema is SYSIBM.

The IDENTITY_VAL_LOCAL function is not deterministic.[19] Although the function has no input parameters, the empty parentheses must be specified when the function is invoked.

The result is DECIMAL(31,0), regardless of the actual data type of the identity column to which the result value corresponds.

[19] Being not deterministic affects what optimization (such as view processing and parallel processing) can be done when this function is used and in what contexts the function can be invoked. For example, the RAND function is another built-in scalar function that is not deterministic. Using functions that are not deterministic within a predicate can cause unpredictable results.

A *qualifying data change statement* refers to an insert operation (specified in either an INSERT statement or a MERGE statement).

The value that is returned is the value that was assigned to the identity column of the table identified in the most recent qualifying data change statement or LOAD utility operation for a table with an identity column. The insert operation has to be issued at the same level; that is, the value has to be available locally within the level at which it was assigned until replaced by the next assigned value. A new level is initiated when a trigger, function, or stored procedure is invoked. A trigger condition is at the same level as the associated triggered action.

The assigned value can be a value supplied by the user (if the identity column is defined as GENERATED BY DEFAULT) or an identity value that was generated by Db2.

The result can be null. The result is null in the following situations:

- When a qualifying data change statement has not been issued for a table containing an identity column at the current processing level
- When a COMMIT or ROLLBACK of a unit of work occurred since the most recent qualifying data change statement that assigned a value

The result of the function is not affected by a ROLLBACK TO SAVEPOINT statement.

Notes

Invoking the function within a qualifying data change statement:

Expressions in a qualifying data change statement are evaluated before values are assigned to the target columns of the qualifying data change statement. Thus, when you invoke IDENTITY_VAL_LOCAL in a qualifying data change statement, the value that is used is the most recently assigned value for an identity column from a previous qualifying data change statement. The function returns the null value if no such qualifying data change statement had been executed within the same level as the invocation of the IDENTITY_VAL_LOCAL function. Each qualifying data change statement that involves an IDENTITY column causes the identity value to be copied into connection-specific storage in Db2. Thus, the most recent identity value is used for a connection, regardless of what is happening with other concurrent user connections.

Invoking the function following a failed insert operation:

The function returns an unpredictable result when it is invoked after the unsuccessful execution of a qualifying data change statement for a table with an identity column. The value might be the value that would have been returned from the function had it been invoked before the failed qualifying data change statement or the value that would have been assigned had the qualifying data change statement succeeded. The actual value returned depends on the point of failure and is therefore unpredictable.

Invoking the function within the SELECT statement of a cursor:

Because the results of the IDENTITY_VAL_LOCAL function are not deterministic, the result of an invocation of the IDENTITY_VAL_LOCAL function from within the SELECT statement of a cursor can vary for each FETCH statement.

Invoking the function within the trigger condition of an insert trigger:

The result of invoking the IDENTITY_VAL_LOCAL function from within the condition of an insert trigger is the null value.

Invoking the function within a triggered action of an insert trigger:

Multiple before or after insert triggers can exist for a table. In such cases, each trigger is processed separately, and identity values generated by SQL statements issued within a triggered action are not available to other triggered actions using the IDENTITY_VAL_LOCAL function. This is the case even though the multiple triggered actions are conceptually defined at the same level.

Do not use the IDENTITY_VAL_LOCAL function in the triggered action of a before insert trigger. The result of invoking the IDENTITY_VAL_LOCAL function from within the triggered action of a before insert trigger is the null value.

The value for the identity column of the table for which the trigger is defined cannot be obtained by invoking the IDENTITY_VAL_LOCAL function within the triggered action of a before insert trigger. However, the value for the identity column can be obtained in the triggered action by referencing the trigger transition variable for the identity column.

The result of invoking the IDENTITY_VAL_LOCAL function in the triggered action of an after insert trigger is the value assigned to an identity column of the table identified in the most recent qualifying data change statement. That statement is the one invoked in the same triggered action that had a qualifying data change statement for a table containing an identity column. If a qualifying data change statement for a table containing an identity column was not executed within the same triggered action before invoking the IDENTITY_VAL_LOCAL function, then the function returns a null value.

Invoking the function following an insert operation with triggered actions:

The result of invoking the function after an insert that activates triggers is the value actually assigned to the identity column (that is, the value that would be returned on a subsequent SELECT statement). This value is not necessarily the value provided in the qualifying data change statement or a value generated by Db2. The assigned value could be a value that was specified in a SET transition variable statement within the triggered action of a before insert trigger for a trigger transition variable associated with the identity column.

Scope of IDENTITY_VAL_LOCAL:

The IDENTITY_VAL_LOCAL value persists until the next insert in the current session into a table that has an identity column defined on it, or the application session ends. The value is unaffected by COMMIT or ROLLBACK statements for local applications. The IDENTITY_VAL_LOCAL value cannot be directly set and is a result of inserting a row into a table. Client applications or middleware products that save the state of a session and then restore the state of a session for subsequent processing are not able to restore the IDENTITY_VAL_LOCAL value. In these situations, the availability of the IDENTITY_VAL_LOCAL value should only be relied on until the end of the transaction. Examples of where this type of situation can occur include applications that do the following actions:

- use XA protocols
- use connection pooling
- use the connection concentrator
- use sysplex workload balancing
- connect to a z/OS server that uses DDF inactive threads

When there is a need to preserve the value associated with IDENTITY_VAL_LOCAL across transaction boundaries for distributed applications, define the cursors as WITH HOLD, or specify the bind option KEEPDYNAMIC(YES) to prevent the server thread from being pooled.

Syntax alternatives:

Use a SELECT FROM data change statement to obtain the assigned value for an identity column. For more information, see data-change-table-reference.

Examples

Example 1:

Set the variable *IVAR* to the value assigned to the identity column in the EMPLOYEE table. The value returned from the function in the VALUES statement should be 1.

```
CREATE TABLE EMPLOYEE
(EMPNO         INTEGER GENERATED ALWAYS AS IDENTITY,
 NAME          CHAR(30),
 SALARY        DECIMAL(5,2),
 DEPTNO        SMALLINT);
INSERT INTO EMPLOYEE
(NAME, SALARY, DEPTNO)
VALUES ('Rupert', 989.99, 50);
VALUES IDENTITY_VAL_LOCAL() INTO :IVAR;
```

Example 2:

Assume two tables, T1 and T2, have an identity column named C1. Db2 generates values 1, 2, 3, . . . for the C1 column in table T1, and values 10, 11, 12, . . . for the C1 column in table T2.

```
CREATE TABLE T1 (C1 SMALLINT GENERATED ALWAYS AS IDENTITY,
                 C2 SMALLINT );
CREATE TABLE T2 (C1 DECIMAL(15,0) GENERATED BY DEFAULT AS IDENTITY
                                   (START WITH 10),
                 C2 SMALLINT );
INSERT INTO T1 (C2) VALUES (5);
INSERT INTO T1 (C2) VALUES (5);
SELECT * FROM T1;
    C1            C2
-----------   ----------

          1            5
          2            5
VALUES IDENTITY_VAL_LOCAL() INTO  :IVAR;
```

At this point, the IDENTITY_VAL_LOCAL function would return a value of 2 in IVAR. The following INSERT statement inserts a single row into T2 where column C2 gets a value of 2 from the IDENTITY_VAL_LOCAL function

```
INSERT INTO T2 (C2) VALUES (IDENTITY_VAL_LOCAL());
SELECT * FROM T2
 WHERE C1 = DECIMAL(IDENTITY_VAL_LOCAL(),15,0);
               C1                         C2
 ----------------------------------   ----------

                                10           2
```

Invoking the IDENTITY_VAL_LOCAL function after this insert would result in a value of 10, which is the value generated by Db2 for column C1 of T2. Assume another single row is inserted into T2. For the following INSERT statement, Db2 assigns a value of 13 to identity column C1 and gives C2 a value of 10 from IDENTITY_VAL_LOCAL. Thus, C2 is given the last identity value that was inserted into T2.

```
INSERT INTO T2 (C2, C1) VALUES (IDENTITY_VAL_LOCAL(), 13);
```

Example 3:

The IDENTITY_VAL_LOCAL function can also be invoked in an INSERT statement that both invokes the IDENTITY_VAL_LOCAL function and causes a new value for an identity column to be assigned. The next value to be returned is thus established when the IDENTITY_VAL_LOCAL function is invoked after the INSERT statement completes. For example, consider the following table definition:

```
 CREATE TABLE T1 (C1 SMALLINT GENERATED BY DEFAULT AS IDENTITY,
                  C2 SMALLINT);
```

For the following INSERT statement, specify a value of 25 for the C2 column, and Db2 generates a value of 1 for C1, the identity column. This establishes 1 as the value that will be returned on the next invocation of the IDENTITY_VAL_LOCAL function.

```
 INSERT INTO T1 (C2) VALUES (25);
```

In the following INSERT statement, the IDENTITY_VAL_LOCAL function is invoked to provide a value for the C2 column. A value of 1 (the identity value assigned to the C1 column of the first row) is assigned to the C2 column, and Db2 generates a value of 2 for C1, the identity column. This establishes 2 as the value that will be returned on the next invocation of the IDENTITY_VAL_LOCAL function.

```
 INSERT INTO T1 (C2) VALUES (IDENTITY_VAL_LOCAL());
```

In the following INSERT statement, the IDENTITY_VAL_LOCAL function is again invoked to provide a value for the C2 column, and the user provides a value of 11 for C1, the identity column. A value of 2 (the identity value assigned to the C1 column of the second row) is assigned to the C2 column. The assignment of 11 to C1 establishes 11 as the value that will be returned on the next invocation of the IDENTITY_VAL_LOCAL function.

Afte

```
INSERT INTO T1 (C2, C1) VALUES (IDENTITY_VAL_LOCAL(), 11);
```

r the 3 INSERT statements have been processed, table T1 contains the following actions:

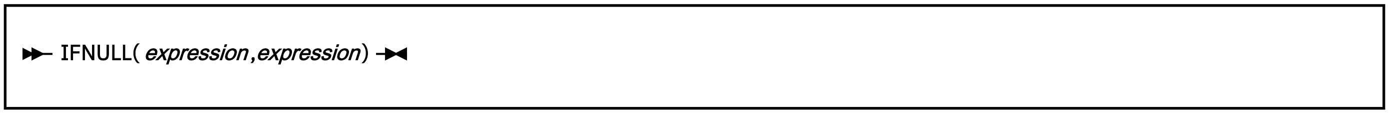
```
SELECT * FROM T1;
C1          C2
----------- -----------

          1          25
          2           1
         11           2
```

The contents of T1 illustrate that the expressions in the VALUES clause are evaluated before the assignments for the columns of the INSERT statement. Thus, an invocation of an IDENTITY_VAL_LOCAL function invoked from a VALUES clause of an INSERT statement uses the most recently assigned value for an identity column in a previous INSERT statement.

IFNULL

The IFNULL function returns the first nonnull expression.



The schema is SYSIBM.

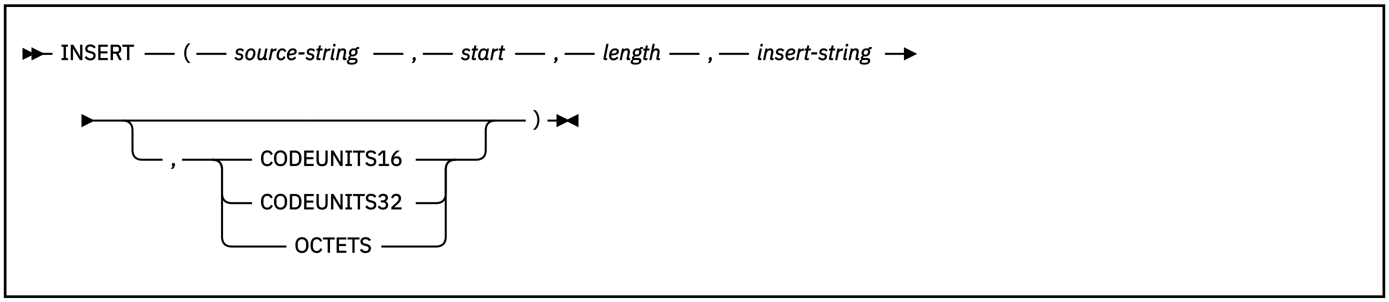
IFNULL is identical to the COALESCE scalar function except that IFNULL is limited to two arguments instead of multiple arguments. For a description, see "COALESCE" on page 417.

Example: For all the rows in sample table DSN8C10.EMP, select the employee number and salary. If the salary is missing (is null), have the value 0 returned.

```
SELECT EMPNO, IFNULL(SALARY,0)
  FROM DSN8C10.EMP;
```

INSERT

The INSERT function returns a string where, beginning at *start* in *source-string*, *length* characters have been deleted and *insert-string* has been inserted.



The schema is SYSIBM.

The INSERT function returns a string where *length* characters have been deleted from *source-string*, beginning at *start*, and where *insert-string* has been inserted into *source-string*, beginning at *start*.

source-string
An expression that specifies the source string. The expression must return a value that is a built-in character string, graphic string, or binary string data type that is not a LOB. The actual length of the string must be greater than or equal to 1 and less than or equal to 32704 bytes.

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type.

start

An expression that returns an integer. The integer specifies the starting point within the source string where the deletion of bytes and the insertion of another string is to begin. The value of the integer must be in the range of 1 to the length of *source-string* plus one. If OCTETS is specified and the result is graphic data, the value must be an odd value between 1 and twice the length of *source-string* plus one.

The argument can also be a character string or graphic string data type. The string argument is implicitly cast to a DECFLOAT(34) data type which is then assigned to an INTEGER.

length

An expression that specifies the length of the string to replace in *source-string* starting at *start*. *length* must be an expression that returns a value of the built-in INTEGER data type. *length* is expressed in the string unit specified, and the value must be in the range of 0 to the length of *source-string*. If OCTETS is specified and the result is graphic data, *length* must be even and be between 0 and twice the length of *source-string*. Not specifying *length* is equivalent to specifying a value of 1, except when OCTETS is specified and the result is graphic data, in which case, not specifying *length* is equivalent to specifying a value of 2.

The argument can also be a character string or graphic string data type. The string argument is implicitly cast to a DECFLOAT(34) data type which is then assigned to an INTEGER.

insert-string

An expression that specifies the string to be inserted into the source string, starting at the position identified by *start*. The expression must return a value that is a built-in character string, graphic string, or binary string data type that is not a LOB.

source-string and *insert-string* must have compatible data types.

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type.

CODEUNITS16, CODEUNITS32, or OCTETS

Specifies the units that are used to express *start* and *length*. If *source-string* is a character string that is defined as bit data, CODEUNITS16 and CODEUNITS32 cannot be specified. If *source-string* is a graphic string, OCTETS cannot be specified. If *source-string* is a binary string, CODEUNITS16, CODEUNITS32, and OCTETS cannot be specified.

If a string unit is not explicitly specified, the data type of the result determines the unit that is used:

- If the result is a graphic string, a string unit is two bytes. For ASCII and EBCDIC data, this corresponds to a double byte character. For Unicode, this corresponds to a UTF-16 code point.
- Otherwise, a string unit is a byte.

CODEUNITS16

Specifies that *start* and *length* are expressed in terms of 16-bit UTF-16 code units.

CODEUNITS32

Specifies that *start* and *length* are expressed in terms of 32-bit UTF-32 code units.

OCTETS

Specifies that *start* and *length* are expressed in terms of bytes.

For more information about CODEUNITS16, CODEUNITS32, and OCTETS, see "String unit specifications" on page 106.

If *source-string* and *insert-string* have different CCSID sets, *insert-string* (the string to be inserted) is converted to the CCSID of *source-string* (the source string).

The encoding scheme of the result is the same as *source-string*. The data type of the result of the function depends on the data type of *source-string* and *insert-string*:

- VARCHAR if *source-string* is a character string. The CCSID of the result depends on the arguments:

  - If either *source-string* or *insert-string* is character bit data, the result is bit data.
  - If *source-string* is SBCS Unicode data and *insert-string* is not SBCS Unicode data, the CCSID of the result is the mixed CCSID for Unicode data.
  - If both *source-string* and *insert-string* are SBCS Unicode data, the CCSID of the result is the CCSID for SBCS Unicode data.
  - Otherwise, the CCSID of the result is the mixed CCSID that corresponds to the CCSID of *source-string*. However, if the input is EBCDIC or ASCII and there is no corresponding system CCSID for mixed, the CCSID of the result is the CCSID of *source-string*.
- VARGRAPHIC if *source-string* is a graphic. The CCSID of the result is the same as the CCSID of *source-string*.
- VARBINARY if *source-string* and *insert-string* are both binary strings.

The length attribute of the result depends on the arguments:

- If *start* and *length* are constants, the length attribute of the result is:

  ```
  L1 - MIN((L1 - V2 + 1), V3) + L4
  ```

  where:

  L1 is the length attribute of *source-string*
  V2 is the value of *start*
  V3 is the value of *length*
  L4 is the length attribute of *insert-string*
- Otherwise, the length attribute of the result is the length attribute of *source-string* plus the length attribute of *insert-string*. In this case, the length attribute of *source-string* plus the length attribute of *insert-string* must not exceed 32704 for a VARCHAR result or 16352 for a VARGRAPHIC result.

If CODEUNITS16 or CODEUNITS32 is specified, the insert operation is performed on a Unicode version of the data. If needed, the data is converted to an intermediate form in order to evaluate the function. If an intermediate form is used, the actual length of the result depends on the original data (*source-string* and *insert-string*), and the representation of that data in Unicode. See "Determining the length attribute of the final result" on page 108 for more information on how to calculate the length attribute of the result string.

If CODEUNITS16 or CODEUNITS32 are not specified, the actual length of the result is:

```
A1 - MIN((A1 - V2 + 1), V3) + A4
```

where:

A1 is the actual length of *source-string*
V2 is the value of *start*
V3 is the value of *length*
A4 is the actual length of *insert-string*

If the actual length of the result string exceeds the maximum for the return data type, an error occurs.

The result can be null; if any argument is null, the result is the null value.

Example 1: The following example shows how the string 'INSERTING' can be changed into other strings. The use of the CHAR function limits the length of the resulting string to 10 bytes.

```
   SELECT CHAR(INSERT('INSERTING',4,2,'IS'),10),
          CHAR(INSERT('INSERTING',4,0,'IS'),10),
          CHAR(INSERT('INSERTING',4,2,''),10)
     FROM SYSIBM.SYSDUMMY1;
```

This example returns 'INSISTING ', 'INSISERTIN', and 'INSTING   '

Example 2: The previous example demonstrated how to insert text into the middle of some text. This example shows how to insert text before some text by using 1 as the starting point (*start*).

```
    SELECT CHAR(INSERT('INSERTING',1,0,'XX'),10),
           CHAR(INSERT('INSERTING',1,1,'XX'),10),
           CHAR(INSERT('INSERTING',1,2,'XX'),10),
           CHAR(INSERT('INSERTING',1,3,'XX'),10)
      FROM SYSIBM.SYSDUMMY1;
```

This example returns 'XXINSERTIN', 'XXNSERTING', 'XXSERTING ', and 'XXERTING '

Example 3: The following example shows how to insert text after some text. Add 'XX' at the end of string 'ABCABC'. Because the source string is 6 characters long, set the starting position to 7 (one plus the length of the source string).

```
    SELECT CHAR(INSERT('ABCABC',7,0,'XX'),10)
      FROM SYSIBM.SYSDUMMY1;
```

This example returns 'ABCABCXX '.

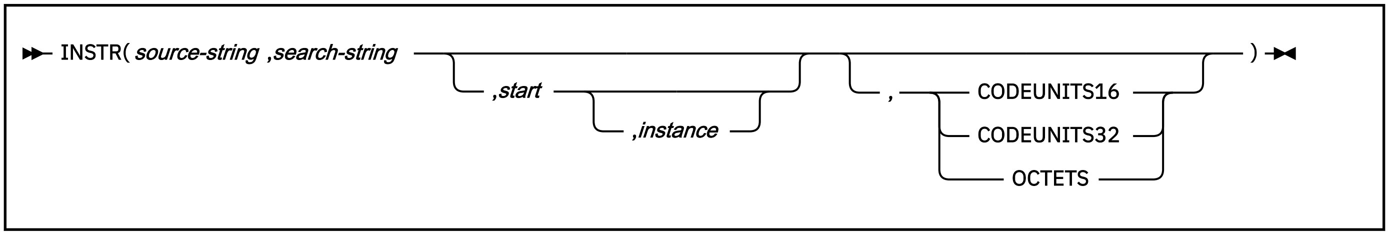
Example 4: The following example shows how the string 'Hegelstraße' can be changed to 'Hegelstrasse'.

```
    SELECT VARCHAR(INSERT('Hegelstraße',10,1,'ss'),15)
      FROM SYSIBM.SYSDUMMY1;
```

This example returns 'Hegelstrasse'.

INSTR

The INSTR function returns the position at which an argument starts within a specified string.



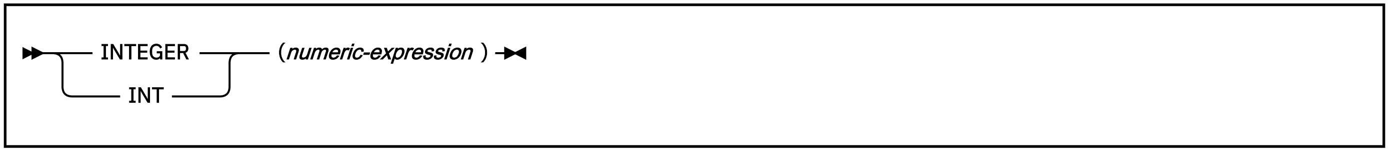
The schema is SYSIBM.

INSTR is identical to LOCATE_IN_STRING. For details, see "LOCATE_IN_STRING" on page 492.

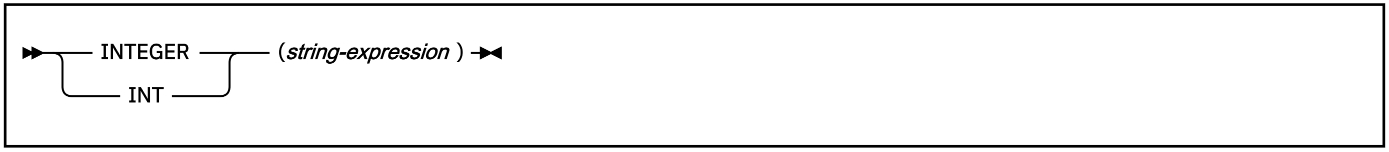
INTEGER or INT

The INTEGER function returns an integer representation of either a number or a character string or graphic string representation of an integer.

Numeric to Integer:



String to Integer:



The schema is SYSIBM.

Numeric to Integer

numeric-expression

An expression that returns a value of any built-in numeric data type.

The result is the same number that would occur if the argument were assigned to a large integer column or variable. If the whole part of the argument is not within the range of large integers, an error occurs. The fractional part of the argument is truncated.

String to Integer

string-expression

An expression that returns a value of a character or graphic string (except a CLOB or DBCLOB) with a length attribute that is not greater than 255 bytes. The string must contain a valid string representation of a number.

The result is the same number that would result from `CAST(`*`string-expression`*` AS INTEGER)`. Leading and trailing blanks are eliminated and the resulting string must conform to the rules for forming an integer constant. If the whole part of the argument is not within the range of large integers, an error is returned.

The result of the function is a large integer.

The result can be null; if the argument is null, the result is the null value.

Notes

Syntax alternatives:

To increase the portability of applications, use the CAST specification. For more information, see "CAST specification" on page 266.

Examples

Example 1:

Using sample table DSN8C10.EMP, find the average salary of the employees in department A00, rounding the result to the nearest dollar.

```
SELECT INTEGER(AVG(SALARY)+.5)
  FROM DSN8C10.EMP
  WHERE WORKDEPT = 'A00';
```

Example 2:

Using sample table DSN8C10.EMP, select the EMPNO column, which is defined as CHAR(6), in integer form.

```
SELECT INTEGER(EMPNO)
  FROM DSN8C10.EMP;
```

JULIAN_DAY

The JULIAN_DAY function returns an integer value that represents a number of days from January 1, 4713 B.C. (the start of the Julian date calendar) to the date that is specified in the argument.

▸▸ JULIAN_DAY(*expression*) ▸◂

The schema is SYSIBM.

The argument must be an expression that returns one of the following data types: a date, a timestamp, or a valid string representation of a date or timestamp. An argument with a character string data type must not be a CLOB. An argument with a graphic string data type must not be a DBCLOB. A string argument must have an actual length that is not greater than 255 bytes. For the valid formats of string representations of dates and timestamps, see "String representations of datetime values" on page 120.

If *expression* is a timestamp with a time zone, or a valid string representation of a timestamp with a time zone, the result is determined from the UTC representation of the datetime value.

The result of the function is a large integer.

The result can be null; if the argument is null, the result is the null value.

Examples for JULIAN_DAY

Example 1

Using sample table DSN8C10.EMP, set the integer host variable JDAY to the Julian day of the day that Christine Haas (EMPNO = '000010') was employed (HIREDATE = '1965-01-01'). The result is that JDAY is set to 2438762.

```
   SELECT JULIAN_DAY(HIREDATE)
     INTO :JDAY
     FROM DSN8C10.EMP
     WHERE EMPNO = '000010';
```

Example 2

Set integer host variable JDAY to the Julian day for January 1, 1998. The result is that JDAY is set to 2450815.

```
   SELECT JULIAN_DAY('1998-01-01')
     INTO :JDAY
     FROM SYSIBM.SYSDUMMY1;
```

Example 3

The following invocations of the JULIAN_DAY functions all return the same result, which is 2452642. When the input argument contains a time zone, the result is determined from the UTC representation of the input value. The string representations of timestamps with a time zone in the example SELECT statement all have the same UTC representation: 2003-01-02-20.00.00.

```
SELECT JULIAN_DAY('2003-01-02-20.00.00'),
            JULIAN_DAY('2003-01-02-12.00.00-08:00'),
            JULIAN_DAY('2003-01-03-05.00.00+09:00')
        FROM SYSIBM.SYSDUMMY1;
```

Related concepts

Date, time, and timestamp data types (Introduction to Db2 for z/OS)

Datetime values

Datetime values are neither strings nor numbers. Nevertheless, datetime values can be used in certain arithmetic and string operations and are compatible with certain strings.

Related reference

DAYOFWEEK

The DAYOFWEEK function returns an integer, in the range 1–7 that represents the day of the week, where 1 is Sunday and 7 is Saturday. The DAYOFWEEK function is similar to the DAYOFWEEK_ISO function.

LAST_DAY

The LAST_DAY scalar function returns a date that represents the last day of the month of the date argument.

▶▶— LAST_DAY(*expression*) —▶◀

The schema is SYSIBM.

expression

An expression that specifies the starting date. The expression must returns a value of one of the following data types:

- a date

- a timestamp
- a valid string representation of a date or timestamp

An argument with a character string data type must not be a CLOB. An argument with a graphic string data type must not be a DBCLOB. A string argument must have an actual length that is not greater than 255 bytes. A time zone in a string representation of a timestamp is ignored. For the valid formats of string representations of dates and timestamps, see "String representations of datetime values" on page 120.

If *expression* is a TIMESTAMP WITH TIME ZONE value, *expression* is first cast to a TIMESTAMP WITHOUT TIME ZONE value with the same precision as *expression*.

The result of the function has the same data type as *expression*, unless *expression* is a string, in which case the result data type is DATE.

The result CCSID is the appropriate CCSID of the argument encoding scheme and the result subtype is the appropriate subtype of the CCSID.

The result can be null; if the argument is null, the result is the null value.

Any hours, minutes, seconds, or fractional seconds information that is included in *expression* is not changed by the function.

Example 1: Set the host variable *END_OF_MONTH* with the last day of the current month.

```
    SET :END_OF_MONTH = LAST_DAY(CURRENT_DATE);
```

The host variable *END_OF_MONTH* is set with the value representing the end of the current month. If the current day is 2000-02-10, *END_OF_MONTH* is set to 2000-02-29.

Example 2: Set the host variable *END_OF_MONTH* with the last day of the month in EUR format for the given date.

```
    SET :END_OF_MONTH = CHAR(LAST_DAY('1965-07-07'), EUR);
```

The host variable *END_OF_MONTH* is set with the value '31.07.1965'.

Example 3: Assume that host variable *PRSTSZ* contains '2008-02-29.20.00.000000 -08.30'. The TIMESTAMP WITH TIME ZONE value is implicitly cast to TIMESTAMP WITHOUT TIME ZONE before the LAST_DAY function is evaluated.

```
SELECT LAST_DAY(:PRSTSZ)
        FROM PROJECT;
```

The LAST_DAY function returns the value '31' (month in UTC is March).

Example 4: Assume *PRSTSZ* is a host variable with the string value '2008-04-15.20.00.000000-08.30'. The string value, which is a string representation of a timestamp with a time zone, is implicitly cast to a DATE before the LAST_DAY function is evaluated. The LAST_DAY function returns the last day of the month as a DATE value.

```
SELECT LAST_DAY(:PRSTSZ)
    FROM PROJECT;
```

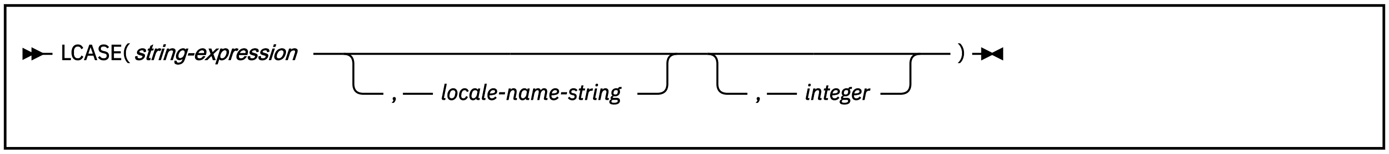
The LAST_DAY function returns the value ‘2008-04-30', the last day of the month of April, as a DATE value.

Example 5: Assuming that the default date format is ISO, the following select statement returns '2000–04–30', which is the last day of April in 2000:

```
SELECT LAST_DAY('2000-04-24')
    FROM SYSIBM.SYSDUMMY1;
```

LCASE

The LCASE function returns a string in which all the characters are converted to lowercase characters.

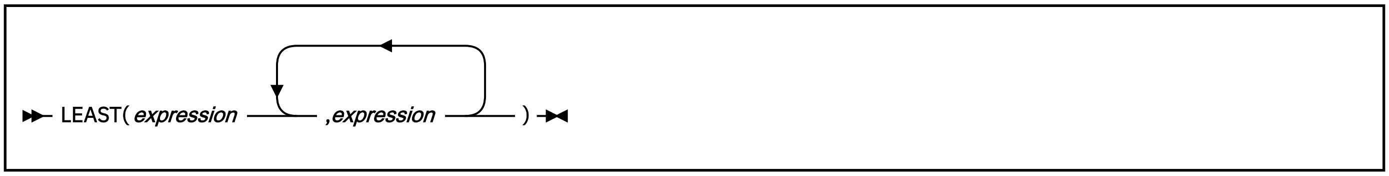


The schema is SYSIBM.

The LCASE function is identical to the LOWER function. For more information, see "LOWER" on page 494.

LEAST

The LEAST function returns the minimum value in a set of values.

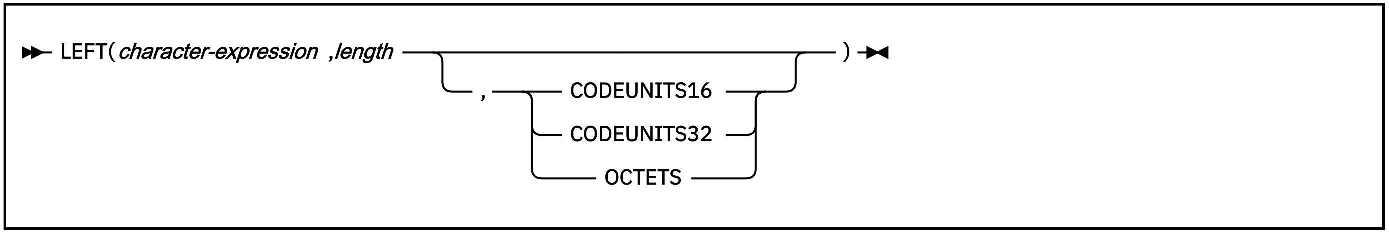


The LEAST function is identical to the MIN scalar function. For more information, see "MIN (scalar)" on page 504.

LEFT

The LEFT function returns a string that consists of the specified number of leftmost bytes of the specified string units.

Character string:



The schema is SYSIBM.

The LEFT function returns the leftmost string of *character-expression*, *graphic-expression*, or *binary-expression* consisting of length of the string units that are specified implicitly or explicitly.

character-expression
An expression that specifies the string from which the result is derived. The string must be a character string. A substring of *character-expression* is zero or more contiguous code points of *character-expression*.

The string can contain mixed data. Depending on the units that are specified to evaluate the function, the result is not necessarily a properly formed mixed data character string.

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type.

length
An expression that specifies the length of the result. The value must be an integer between 0 and *n*, where *n* is the length attribute of *character-expression*, expressed in the units that are either implicitly or explicitly specified.

The argument can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34) which is then assigned to an INTEGER value.

If CODEUNITS16 or CODEUNITS32 is specified, see "Determining the length attribute of the final result" on page 108 for information about how to calculate the length attribute of the result string.

CODEUNITS16, CODEUNITS32, or OCTETS

Specifies the unit that is used to express *integer*. If *string-expression* is a character string that is defined as bit data, CODEUNITS16 and CODEUNITS32 cannot be specified. If *string-expression* is a graphic string, OCTETS cannot be specified. If *string-expression* is a binary string, CODEUNITS16, CODEUNITS32, and OCTETS cannot be specified.

CODEUNITS16

Specifies that *integer* is expressed in terms of 16-bit UTF-16 code units.

CODEUNITS32

Specifies that *integer* is expressed in terms of 32-bit UTF-32 code units.

OCTETS

Specifies that *integer* is expressed in terms of bytes.

For more information about CODEUNITS16, CODEUNITS32, and OCTETS, see "String unit specifications" on page 106.

The *character-expression*, *graphic-expression*, or *binary-expression* is effectively padded on the right with the necessary number of padding characters so that the specified substring of the expression always exists. The encoding scheme of the data determines the padding character:

- For ASCII SBCS data or ASCII mixed data, the padding character is X'20'.
- For ASCII DBCS data, the padding character depends on the CCSID; for example, for Japanese (CCSID 301) the padding character is X'8140', while for simplified Chinese it is X'A1A1'.
- For EBCDIC SBCS data or EBCDIC mixed data, the padding character is X'40'.
- For EBCDIC DBCS data, the padding character is X'4040'.
- For Unicode SBCS data or UTF-8 (Unicode mixed data), the padding character is X'20'.
- For UTF-16 (Unicode DBCS) data, the padding character is X'0020'.
- For binary data, the padding character is X'00'.

The result of the function is a varying-length string with a length attribute that is the same as the length attribute of the first expression and a data type that depends on the data type of the expression:

- VARCHAR if *character-expression* is CHAR or VARCHAR
- CLOB if *character-expression* is CLOB
- VARGRAPHIC if *graphic-expression* is GRAPHIC or VARGRAPHIC
- DBCLOB if *graphic-expression* is DBCLOB
- VARBINARY if *binary-expression* is BINARY or VARBINARY
- BLOB if *binary-expression* is BLOB

The actual length of the result is determined from *length*.

The result can be null; if any argument is null, the result is the null value.

The CCSID of the result is the same as that of the first expression.

Notes

Syntax alternatives:

FL 506 STRLEFT is a synonym for LEFT.

Examples

Example 1: Assume that host variable *ALPHA* has a value of 'ABCDEF'. The following statement returns 'ABC', which are the three leftmost characters in *ALPHA*:

```
SELECT LEFT(:ALPHA,3)
  FROM SYSIBM.SYSDUMMY1;
```

Example 2: Assume that host variable *NAME*, which is defined as VARCHAR(50), has a value of 'KATIE AUSTIN' and the integer host variable FIRSTNAME_LEN has a value of 5. The following statement returns the value 'KATIE':

```
SELECT LEFT(:NAME, :FIRSTNAME_LEN)
  FROM SYSIBM.SYSDUMMY1;
```

Example 3: The following statement returns a zero length string.

```
SELECT LEFT('ABCABC',0)
  FROM SYSIBM.SYSDUMMY1;
```

Example 4: The FIRSTNME column in sample EMP table is defined as VARCHAR(12). Find the first name for an employee whose last name is 'BROWN' and return the first name in a 10-byte string.

```
SELECT LEFT(FIRSTNME,10)
  FROM DSN8C10.EMP
  WHERE LASTNAME='BROWN';
```

This function returns a VARCHAR(10) string that has the value of 'DAVID' followed by 5 blank characters.

Example 5: FIRSTNAME is a VARCHAR(12) column in table T1. One of its values is the 6-character string 'Jürgen'. When FIRSTNAME has this value:

```
Function ...                            Returns ...
LEFT(FIRSTNAME,2,CODEUNITS32)           'Jü'  -- x'4AC3BC'
LEFT(FIRSTNAME,2,CODEUNITS16)           'Jü'  -- x'4AC3BC'
LEFT(FIRSTNAME,2,OCTETS)                'J '  -- x'4A20'  A truncated string
```

Example 6: In the following example, the last invocation of the LEFT function returns a partial surrogate character:

```
Function ...                            Returns ...
LEFT('Jürgen',2,CODEUNITS32)            'Jü'    -- x'4AC3BC'
LEFT('Jürgen',2,CODEUNITS16)            'Jü'    -- x'4AC3BC'
LEFT('Jürgen',2,OCTETS)                 'J '    -- x'4A20'  A truncated string
HEX(LEFT('Jürgen',2))                   x'4AC3' -- The letter 'J' and a partial character
```

LENGTH

The LENGTH function returns the length of a value.

▸▸— LENGTH(*expression*) —▸◂

The schema is SYSIBM.

The argument must be an expression that returns a value of any built-in data type that is not XML.

The result of the function is a large integer.

The result can be null; if the argument is null, the result is the null value.

The result is the length of the argument. The length does not include the null indicator byte of column arguments that allow null values. The length of strings includes blanks. The length of a varying-length string is the actual length, not the maximum length.

The length of a graphic string is the number of double-byte characters. Unicode UTF-16 data is treated as graphic data; a UTF-16 supplementary character takes two DBCS characters to represent and as such is counted as two DBCS characters.

The length of all other values is the number of bytes used to represent the value:

- 2 for small integer
- 4 for large integer
- 8 for big integer
- The integer part of (*p*/2)+1 for decimal numbers with precision *p*
- 16 for DECFLOAT(34)
- 8 for DECFLOAT(16)
- 4 for single precision floating-point
- 8 for double precision floating-point
- The length of the string for strings
- 4 for DATE
- 3 for TIME
- 10 for TIMESTAMP
- 12 for TIMESTAMP WITH TIME ZONE
- 7+((*p*+1)/2) for TIMESTAMP(*p*)
- 9+((*p*+1)/2) for TIMESTAMP(*p*) WITH TIME ZONE
- The length of the row ID

Example 1: Assume that FIRSTNME is a VARCHAR(12) column that contains 'ETHEL' for employee 280. The following query returns the value 5:

```
SELECT LENGTH(FIRSTNME)
  FROM DSN8C10.EMP
  WHERE EMPNO = '000280';
```

Example 2: Assume that HIREDATE is a column of data type DATE. Then, regardless of value the following statement returns the value 4:

```
LENGTH(HIREDATE)
```

And the following function returns the value 10:

```
LENGTH(CHAR(HIREDATE, EUR))
```

LN

The LN function returns the natural logarithm of the argument. The LN and EXP functions are inverse operations.

►► LN(*numeric-expression*) ►◄

The schema is SYSIBM.

The argument must be an expression that returns the value of any built-in numeric data type that is not DECFLOAT. If the argument is not a double precision floating-point number, it is converted to one for processing by the function.

The result of the function is a double precision floating-point number.

The result can be null; if the argument is null, the result is the null value.

Notes

Syntax alternatives:

LOG is a synonym for LN. However, it is supported only for compatibility with previous Db2 releases. LN should be used instead of LOG because some database managers and applications implement LOG as the natural logarithm of a number instead of the common logarithm of a number.

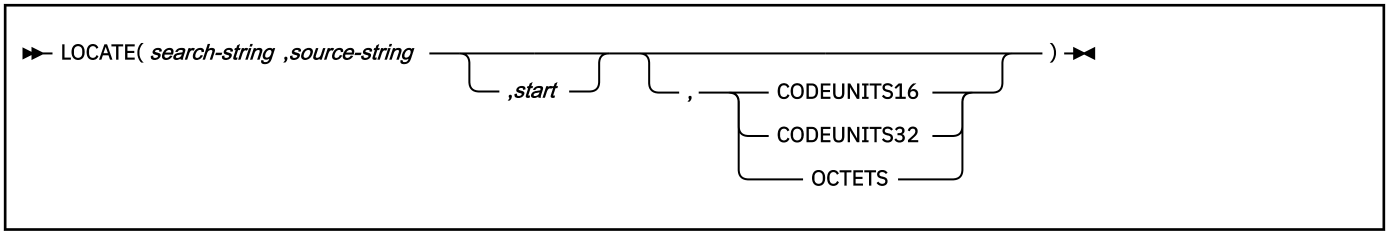
Examples

Example: Assume that host variable NATLOG is DECIMAL(4,2) with a value of 31.62. The following statement returns a double precision floating-point number with an approximate value of 3.45:

```
SELECT LN(:NATLOG)
  FROM SYSIBM.SYSDUMMY1;
```

LOCATE

The LOCATE function returns the position at which the first occurrence of an argument starts within another argument.



The schema is SYSIBM.

The LOCATE function returns the starting position of *search-string* within *source-string*. If *search-string* is not found and neither argument is null, the result is zero. If *search-string* is found, the result is a number from 1 to the actual length of *source-string*. If *search-string* has a length of zero, the result returned by the function is 1. If the optional *start* is specified, it indicates the character position in *source-string* at which the search is to begin. An optional string unit can be specified to indicate in what units the start and result of the function are expressed.

search-string

An expression that specifies the string that is to be searched for. *search-string* must return a value that is a built-in character string data type, graphic string data type, or binary string data type with an actual length that is no greater than 4000 bytes.

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type.

source-string

An expression that specifies the source string in which the search is to take place. *source-string* must return a value that is a built-in character string data type, graphic string data type, or binary string data type.

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type.

start

An expression that specifies the position within *search-string* where the search is to start.

start is expressed in the specified string unit and must return an integer value that is greater than or equal to zero.

The argument can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34) which is then assigned to an INTEGER value.

CODEUNITS16, CODEUNITS32, or OCTETS

Specifies the string unit that is used to express *start* and the result. If *source-string* is a character string that is defined as bit data, CODEUNITS16 and CODEUNITS32 cannot be specified. If *source-string* is a graphic string, OCTETS cannot be specified. If *source-string* is a binary string, CODEUNITS16, CODEUNITS32, and OCTETS cannot be specified.

CODEUNITS16

Specifies that *start* and the result are expressed in terms of 16-bit UTF-16 code units.

CODEUNITS32

Specifies that *start* and the result are expressed in terms of 32-bit UTF-32 code units.

OCTETS

Specifies that *start* and the result are expressed in terms of bytes.

If a string unit is not explicitly specified, the data type of the result determines the string unit that is used. If the result is graphic data, *start* and the returned position are expressed in two-byte units; otherwise, they are expressed in bytes.

For more information about CODEUNITS16, CODEUNITS32, and OCTETS, see "String unit specifications" on page 106.

The first and second arguments must have compatible string types. For more information on compatibility, see "Conversion rules for comparisons" on page 159.

The result of the function is a large integer.

The result can be null; if any argument is null, the result is the null value.

Notes

Similar functions:

If *start* is specified, the LOCATE function is similar to the following POSITION function, where *string-units* is CODEUNITS16, CODEUNITS32, or OCTETS:

```
POSITION(search-string,
              SUBSTRING(source-string, start, string-units)) + start - 1
```

If *start* is not specified, the search begins at the first position of *source-string* and the LOCATE function is similar to the following POSITION function, where *string-units* is CODEUNITS16, CODEUNITS32, or OCTETS:

```
POSITION(search-string, source-string, string-units)
```

For more information, see "POSITION" on page 529.

Examples

Example 1:

Find the location of the first occurrence of the character 'N' in the string 'DINING'.

```
SELECT LOCATE('N', 'DINING')
  FROM SYSIBM.SYSDUMMY1;
```

The result is the value 3.

Example 2:

For all the rows in the table named IN_TRAY, select the RECEIVED column, the SUBJECT column, and the starting position of the string 'GOOD' within the NOTE_TEXT column.

```
SELECT RECEIVED, SUBJECT, LOCATE('GOOD', NOTE_TEXT)
  FROM IN_TRAY
  WHERE LOCATE('GOOD', NOTE_TEXT) <> 0;
```

Example 3:

Locate the character 'ß' in the string 'Jürgen lives on Hegelstraße', and set the host variable LOCATION with the position, as measured in CODEUNITS32 units, within the string.

```
    SET :LOCATION = LOCATE('ß','Jürgen lives on Hegelstraße',1,CODEUNITS32);
```

The value of host variable LOCATION is set to 26.

Example 4:

Locate the character 'ß' in the string 'Jürgen lives on Hegelstraße', and set the host variable LOCATION with the position, as measured in CODEUNITS16 units, within the string.

```
    SET :LOCATION = LOCATE('ß','Jürgen lives on Hegelstraße',1,CODEUNITS16);
```

The value of host variable LOCATION is set to 26.

Example 5:

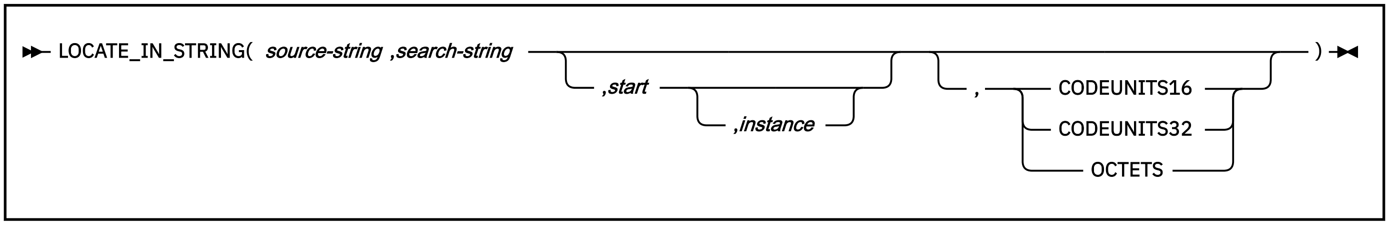
Locate the character 'ß' in the string 'Jürgen lives on Hegelstraße', and set the host variable LOCATION with the position, as measured in OCTETS, within the string.

```
    SET :LOCATION = LOCATE('ß','Jürgen lives on Hegelstraße',1,OCTETS);
```

The value of host variable LOCATION is set to 27.

LOCATE_IN_STRING

The LOCATE_IN_STRING function returns the position at which an argument starts within a specified string.



The schema is SYSIBM.

The LOCATE_IN_STRING function returns the starting position of a string (called the *search-string*) within another string (called the *source-string*). If the *search-string* is not found and neither argument is null, the result is zero. If the *search-string* is found, the result is a number from 1 to the actual length of the *source-string*.

If the optional *start* is specified, an optional instance number can also be specified. The instance argument is used to determine the specific occurrence of *search-string* within *source-string*. Each unique instance can include any of the characters in a previous instance, but not all characters in a previous instance. An optional string unit can be specified to indicate in what units the *start* and result of the function are expressed.

If the *search-string* has a length of zero, the result returned by the function is 1. If the *source-string* has a length of zero, the result returned by the function is 0. If neither condition exists, and if the value of *search-string* is equal to an identical length of a substring of contiguous positions within the value of *source-string*, the result returned by the function is the starting position of that substring within the *source-string* value; otherwise, the result returned by the function is 0.

source-string

An expression that specifies the source string in which the search is to take place. *source-string* must return a value that is a built-in character string data type, graphic string data type, or binary string data type.

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type.

search-string

An expression that specifies the string that is the object of the search. *search-string* must return a value that is a built-in character string data type, graphic string data type, or binary string data type with an actual length that is no greater than 4000 bytes.

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type.

start

An expression that specifies the position within *source-string* at which the search is to start. The expression must return a value that is a built-in INTEGER or SMALLINT data type.

The argument can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34) which is then assigned to an INTEGER value.

If the value of the integer is greater than zero, the search begins at *start* and continues for each position to the end of the string. If the value of the integer is less than zero, the search begins at the LENGTH(*source-string*) + *start* + 1 and continues for each position to the beginning of the string.

If *start* is not specified, the default is 1. If the value of the integer is zero, an error is returned.

instance

An expression that specifies which instance of *search-string* to search for within *source-string*. The expression must return a value that is a built-in INTEGER or SMALLINT data type. If *instance* is not specified, the default is 1. The value of the integer must be greater than or equal to one.

CODEUNITS16, CODEUNITS32, or OCTETS

Specifies the string unit that is used to express *start* and the result. If *source-string* is a character string that is defined as bit data, CODEUNITS16 and CODEUNITS32 cannot be specified. If *source-string* is a graphic string, OCTETS cannot be specified. If *source-string* is a binary string, CODEUNITS16, CODEUNITS32, and OCTETS cannot be specified.

CODEUNITS16

Specifies that *start* and the result are expressed in terms of 16-bit UTF-16 code units.

CODEUNITS32

Specifies that *start* and the result are expressed in terms of 32-bit UTF-32 code units.

OCTETS

Specifies that *start* and the result are expressed in terms of bytes.

If a string unit is not explicitly specified, the data type of the result determines the string unit that is used. If the result is graphic data, *start* and the returned position are expressed in two-byte units; otherwise, they are expressed in bytes.

For more information about CODEUNITS16, CODEUNITS32, and OCTETS, see "String unit specifications" on page 106.

The first and second arguments must have compatible string types. For more information on compatibility, see "Conversion rules for comparisons" on page 159.

At each search position, a match is found when the substring at that position and LENGTH(*search-string*) - 1 values to the right of the search position in *source-string*, is equal to *search-string*.

The result of the function is a large integer. The result is the starting position of the instance of *search-string* within *source-string*. The value is relative to the beginning of the string (regardless of the specification of *start*).

The result can be null; if any argument is null, the result is the null value.

Notes

Syntax alternatives:

INSTR is a synonym for LOCATE_IN_STRING.

Examples

Example 1:

Find the position of an occurrence of the character 'N' in the string 'WINNING' by searching from the start of the string as measured in bytes, within the string.

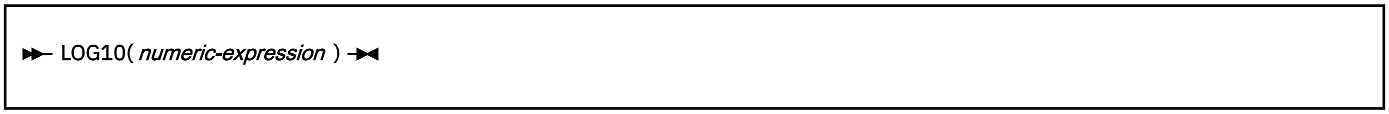
```
SELECT LOCATE_IN_STRING('WINNING','N',1,3,OCTETS),
  LOCATE_IN_STRING('WINNING','N',3,2,OCTETS),
  LOCATE_IN_STRING('WINNING','N',3,3,OCTETS),
  LOCATE_IN_STRING('WINNING','N',-1,3,OCTETS),
  LOCATE_IN_STRING('WINNING','N',-3,2,OCTETS),
  LOCATE_IN_STRING('WINNING','N',-3,3,OCTETS)
FROM SYSIBM.SYSDUMMY1;
```

Returns the values:

```
6    4    6    3    3    0
```

LOG10

The LOG10 function returns the common logarithm (base 10) of a number.



The schema is SYSIBM.

The argument is an expression that returns the value of any built-in numeric data type that is not DECFLOAT. If the argument is not a double precision floating-point number, it is converted to one for processing by the function.

The result of the function is a double precision floating-point number.

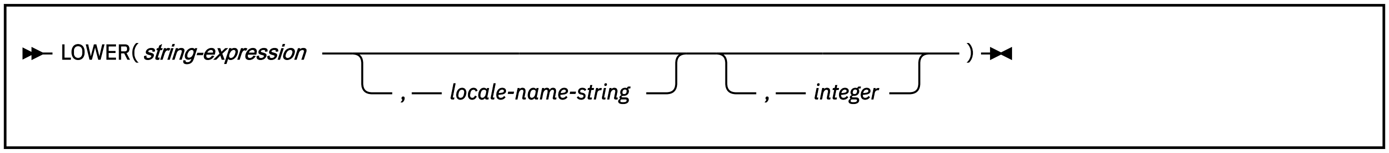
The result can be null; if the argument is null, the result is the null value.

Example: Assume that host variable HLOG is an INTEGER with a value of 100. The following statement returns a double precision floating-point number with an approximate value of 2:

```
SELECT LOG10(:HLOG)
  FROM SYSIBM.SYSDUMMY1;
```

LOWER

The LOWER function returns a string in which all the characters are converted to lowercase characters.



The schema is SYSIBM.

string-expression

An expression that specifies the string to be converted. *string-expression* must return a value that is a built-in character or graphic string. A character string argument must not be a CLOB, and a graphic string argument must not be a DBCLOB. If *string-expression* is an EBCDIC graphic string, a blank string must not be specified for *locale-name-string*. If *string-expression* is bit data, *locale-name-string* must not be specified.

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type.

locale-name-string

A string constant or a string host variable other than a CLOB or DBCLOB that specifies a valid locale name. If *locale-name-string* is not in EBCDIC, it is converted to EBCDIC. The length of *locale-name-string* must be between 1 and 255 bytes of the EBCDIC representation. The value of *locale-name-string* is not case sensitive and must be a valid locale. For information on locales and their naming conventions, see Building and using Dynamic Link Libraries (DLLs) (XL C/C++ Programming Guide). Some examples of locales include:

Fr_BE
Fr_FR@EURO
En_US
Ja_JP

The conversion process is determined by the value that is specified for the locale name, as follows:

blank

SBCS uppercase characters A-Z are converted to SBCS lowercase characters a-z, and characters with diacritical marks are not converted. If the string contains MIXED or DBCS characters, full-width Latin uppercase characters A-Z are converted to full-width lowercase characters a-z. For optimal performance, specify a blank string unless your data must be processed by using the rules that are defined by a specific locale.

UNI

The conversion uses both the NORMAL and SPECIAL casing capabilities as described in Select the conversions (z/OS: Unicode Services User’s Guide and Reference). You must not specify UNI when *string-expression* is EBCDIC data.

UNI_60

The conversion uses Unicode Standard 6.0.0 and the NORMAL casing capability, as described in Select the conversions (z/OS: Unicode Services User’s Guide and Reference). You must not specify UNI_60 when *string-expression* is EBCDIC data.

UNI_90

The conversion uses Unicode Standard 9.0.0 and the NORMAL casing capability, as described in Select the conversions (z/OS: Unicode Services User’s Guide and Reference). You must not specify UNI_90 when *string-expression* is EBCDIC data.

UNI_SIMPLE

Case conversions use the NORMAL casing capabilities as described in Select the conversions (z/OS: Unicode Services User’s Guide and Reference). UNI_SIMPLE cannot be used with EBCDIC data.

locale name

The locale defines the rules for conversion to lowercase characters.

The value of the host variable must not be null. If the host variable has an associated indicator variable, the value of the indicator variable must not indicate a null value. The locale name must be:

- left justified within the host variable
- padded on the right with blanks if its length is less than that of the host variable and the host variable is in fixed length character or graphic data type

If *locale-name-string* is not specified, the locale is determined by special register CURRENT LOCALE LC_CTYPE. For information about the special register, see “CURRENT LOCALE LC_CTYPE special register” on page 196. However, if an index references the LOWER function, the local is determined as follows (in order) to determine if the index can be used:

- At prepare time: using the value in the CURRENT LOCALE LC_CTYPE special register
- At bind time: using the value in the LOCALE LC_CTYPE field on installation panel DSNTIPF

If the index is chosen in the access path, the locale in the CURRENT LOCALE LC_CTYPE special register must remain the same at run time, and prepare or bind time. To avoid this dependency, do not omit *locale-name-string*.

If the LOWER function is referenced in an expression-based index, *locale-name-string* must be specified. See the examples section for an example of how the index can be used in a query.

integer

An integer value that specifies the length attribute of the result. If specified, *integer* must be an integer constant between 1 and 32704 bytes in the representation of the encoding scheme of *string-expression*.

If *integer* is not specified, the length attribute of the result is the same as the length of *string-expression*.

For Unicode data, usage of the LOWER function can result in expansion if certain characters are processed. For example, LOWER ('Ì') —UX'00CC'— will result in UX'006903070300' (if the LT_LT locale is in effect at the time). You should ensure that the result length is large enough to contain the result of the expression.

The result can be null; if the argument is null, the result is the null value.

Notes

Syntax alternatives:

LCASE is a synonym for LOWER. LOWER should be used for conformance to the SQL standard.

Examples

Example 1:

Return the characters in the value of host variable NAME in lowercase. NAME has a data type of VARCHAR(30) and a value of 'Christine Smith'. Assume that the locale in effect is blank.

```
  SELECT LCASE(:NAME)
    FROM SYSIBM.SYSDUMMY1;
```

The result is the value 'christine smith'.

Example 2:

Return the lowercase of 'Ì'. Assume that the locale in effect is LT_LT.

```
SELECT LOWER('Ì')
  FROM SYSIBM.SYSDUMMYU;
```

This would result in an error because of the expansion that occurs when certain Unicode characters are processed. To avoid the error, you would need to use the following statement instead:

```
SELECT LOWER(VARCHAR('Ì', 3))
  FROM SYSIBM.SYSDUMMYU;
```

The result of the preceding statement is the value UX'006903070300'.

Example 3:

Create an index EMPLOYEE_NAME_LOWER for table EMPLOYEE based on built-in function LOWER with locale name 'LT_LT'.

```
  CREATE INDEX EMPLOYEE_NAME_LOWER
    ON EMPLOYEE (LOWER(LASTNAME, 'LT_LT', 60),
                 LOWER(FIRSTNAME, 'LT_LT', 60),
                 ID);
```

Example 4:

Create an index LNAME for table T1 based on the LOWER function with the default local value, ' '. Then specify the same expression in a query.

```
   CREATE INDEX LNAME
     ON TI (LOWER(LASTNAME, ' '));

   SELECT LOWER(LASTNAME, ' ')
```

```
      FROM TI
      WHERE LOWER(LASTNAME, ' ') = 'smith';
```

Example 5:

Create an index LNAME that is based on the LOWER function with a locale name 'FR_CA' for the table T1. Then specify the same expression in a query except *locale-name-string* is omitted.

```
    CREATE INDEX LNAME
      ON TI (LOWER(LASTNAME, 'FR_CA'));
```

If the query is a dynamic statement and the CURRENT LOCALE LC_CTYPE special register contains 'FR_CA':

```
    SELECT LASTNAME
      FROM TI
      WHERE LOWER(LASTNAME)='smith';
```

At prepare time, locale 'FR_CA' in CURRENT LOCALE LC_CTYPE is used for LOWER(LASTNAME) in the predicate to determine whether index LNAME can be used for index access. If index LNAME is used in access path selection, at run time, the locale in CURRENT LOCALE LC_CTYPE must remain the same.

If the query is a static statement and locale 'FR_CA' has been set on the LOCALE LC_CTYPE field of installation panel DSNTIPF:

```
    SELECT LASTNAME
      FROM TI
      WHERE LOWER(LASTNAME)='smith';
```

At bind time, local 'FR_CA' in the LOCALE LC_CTYPE file of installation panel DSNTIPF is used for LOWER(LASTNAME) in the predicate to determine whether index LNAME is used for index access. If index LNAME is chosen in access path selection, the locale in the CURRENT LOCALE LC_CTYPE special register must contain 'FR_CA'.

Related concepts

z/OS Unicode Services User’s Guide and Reference

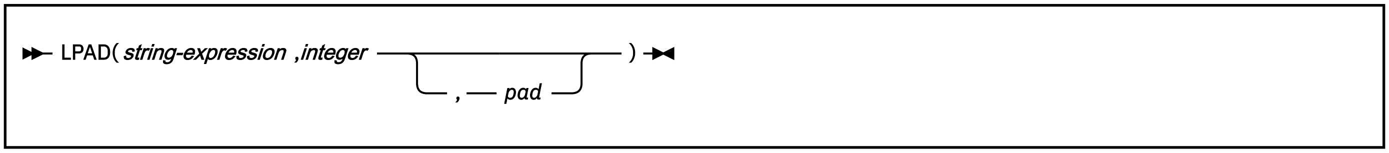
z/OS XL C/C++ Programming Guide

LPAD

The LPAD function returns a string that is composed of *string-expression* that is padded on the left, with *pad* or blanks. The LPAD function treats leading or trailing blanks in *string-expression* as significant.



Padding occurs only if the actual length of *string-expression* is less than *integer*, and if *pad* is not an empty string.

The schema is SYSIBM.

string-expression

An expression that specifies the source string. The expression must return a value that is a built-in string data type that is not a LOB.

integer

An integer constant that specifies the length of the result. The value must be zero or a positive integer that is less than or equal to *n*, where *n* is 32704 if *string-expression* is a character or binary string, or where *n* is 16352 if *string-expression* is a graphic string.

pad

An expression that specifies the string with which to pad. The expression must return a value that is a built-in string data type that is not a LOB. If *pad* is not specified, the pad character is determined as follows:

- SBCS blank character if *string-expression* is a character string.
- DBCS blank character if *string-expression* is a graphic string.
- Hexadecimal zero (X'00'), if *string-expression* is a binary string.

The result of the function is a varying length string that has the same CCSID of *string-expression*. *string-expression* and *pad* must have compatible data types. If the string expressions have different CCSID sets, then *pad* is converted to the CCSID set of *string-expression*. If either *string-expression* or *pad* is FOR BIT DATA, no character conversion occurs.

The length attribute of the result depends on *integer*. If *integer* is greater than 0, the length attribute of the result is *integer*. If *integer* is 0, the length attribute of the result is 1.

The actual length of the result is determined from *integer*. If *integer* is 0, the actual length is 0, and the result is the empty result string. If *integer* is less than the actual length of *string-expression*, the actual length is *integer* and the result is truncated.

The result can be null; if any argument is null, the result is the null value.

Example 1: Assume that NAME is a VARCHAR(15) column that contains the values 'Chris', 'Meg', and 'Jeff'. The following query will pad a value on the left with periods.

```
SELECT LPAD(NAME,15,'.' ) AS NAME
  FROM T1;
```

The results are similar to the following output:

```
NAME
---------------

..........Chris
............Meg
...........Jeff
```

Example 2: Similar to Example 1, the following query will only pad each value to a length of 5:

```
SELECT LPAD(NAME,5,'.' ) AS NAME
  FROM T1;
```

The results are similar to the following output:

```
NAME
---------------

Chris
..Meg
.Jeff
```

Example 3: Assume that NAME is a CHAR(15) column containing the values 'Chris', 'Meg', and 'Jeff. 'Note that the LPAD function does not pad because NAME is a fixed length character field and is blank padded already. However, since the length of the result is 5, the columns are truncated:

```
SELECT LPAD(NAME,5,'.' ) AS NAME
  FROM T1;
```

The results are similar to the following output:

```
NAME
---------------

Chris
Meg
Jeff
```

Example 4: Assume that NAME is a VARCHAR(15) column containing the values 'Chris', 'Meg', and 'Jeff'. Note that in some cases, a partial instance of the pad specification is returned.

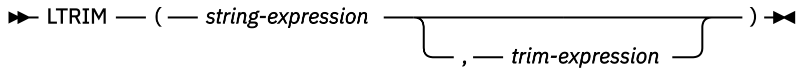
```
   SELECT LPAD(NAME,15,'123') AS NAME
     FROM T1
```

The results are similar to the following output:

```
NAME
---------------
1231231231Chris
123123123123Meg
12312312312Jeff
```

LTRIM

The LTRIM function removes bytes from the beginning of a string expression based on the content of a trim expression.



The schema is SYSIBM.

The LTRIM function removes all of the characters that are contained in *trim-expression* from the beginning of *string-expression*. The search is done by comparing the binary representation of each character (which consists of one or more bytes) in *trim-expression* to the bytes at the beginning of *string-expression*. If the *string-expression* is defined as FOR BIT DATA, the search is done by comparing each byte in *trim-expression* to the byte at the beginning of *string-expression*.

string-expression
An expression that specifies the source string. The argument must be an expression that returns a value that is a built-in string data type that is not a LOB, or a numeric data type. If the value is not a string data type, it is implicitly cast to VARCHAR before the function is evaluated. If *string-expression* is not FOR BIT DATA, *trim-expression* must not be FOR BIT DATA.

trim-expression
An expression that specifies the characters to remove from the beginning of *string-expression*. The expression must return a value that is a built-in string data type that is not a LOB, or a numeric data type. If the value is not a string data type, it is implicitly cast to VARCHAR before the function is evaluated.

The default for *trim-expression* depends on the data type of *string-expression*:

- A DBCS blank if *string-expression* is a DBCS graphic string. For ASCII, the CCSID determines the hex value that represents a DBCS blank. For example, for Japanese (CCSID 301), X'8140' represents a DBCS blank, while for Simplified Chinese, X'A1A1' represents a DBCS blank. For EBCDIC, X'4040' represents a DBCS blank.
- A UTF-16 or UCS-2 blank (X'0020') if *string-expression* is a Unicode graphic string.
- A value of X'00' if *string-expression* is a binary string.
- Otherwise, a single byte blank. For EBCDIC, X'40' represents a blank. If not EBCDIC, X'20' represents a blank.

string-expression and *trim-expression* must have compatible data types. If *string-expression* and *trim-expression* have different CCSID sets, *trim-expression* is converted to the CCSID of *string-expression*.

The result of the function depends on the data type of *string-expression*:

- VARCHAR if *string-expression* is a character string. If *string-expression* is defined as FOR BIT DATA the result is FOR BIT DATA.
- VARGRAPHIC if *string-expression* is a graphic string.

- VARBINARY if *string-expression* is a binary string.

The length attribute of the result is the same as the length attribute of *string-expression*.

The actual length of the result for a character or binary string is the length of *string-expression* minus the number of bytes that are removed. The actual length of the result for a graphic string is the length (in the number of double byte characters) of *string-expression* minus the number of double byte characters removed. If all of the characters bytes are removed, the result is an empty string (the length is zero).

The result can be null; if the argument is null, the result is the null value.

The CCSID of the result is the same as that of *string-expression*.

Notes

Valid content for EBCDIC mixed string input:
If *string-expression* is an EBCDIC mixed string, the string must contain valid EBCDIC mixed data.

Examples

***Example*: Use the LTRIM function to remove individual numbers in the second argument from the beginning of the first argument:**

```
SELECT LTRIM ('123DEFG123', '321'),
             LTRIM ('12DEFG123', '321'),
             LTRIM ('123123222XYZ22', '123'),
             LTRIM ('12321', '213'),
             LTRIM ('XYX123 ', '321')
   FROM SYSIBM.SYSDUMMY1
```

The result is 'DEFG123', 'DEFG123', 'XYZ22', '' (an empty string - all characters removed), and 'XYX123' (no characters removed).

The LTRIM function does not remove instances of '1', '2', and '3' on the right side of the string, following characters that are not '1', '2', or '3'.

***Example*: Use the LTRIM function to remove individual special characters in the second argument from the beginning of the first argument:**

```
SELECT LTRIM ('[[ -78]]', '- []')
   FROM SYSIBM.SYSDUMMY1
```

The result is '78]]'.

***Example*: Use the LTRIM function to remove dollar signs and periods in the second argument from the beginning of the first argument:**

```
SELECT LTRIM ('...$V..$AR', '$.')
   FROM SYSIBM.SYSDUMMY1
```

The result is 'V..$AR'.

***Example*: Use the LTRIM function to trim full multi-byte X'D090' characters:**
Assume that these strings are encoded in UTF-8.

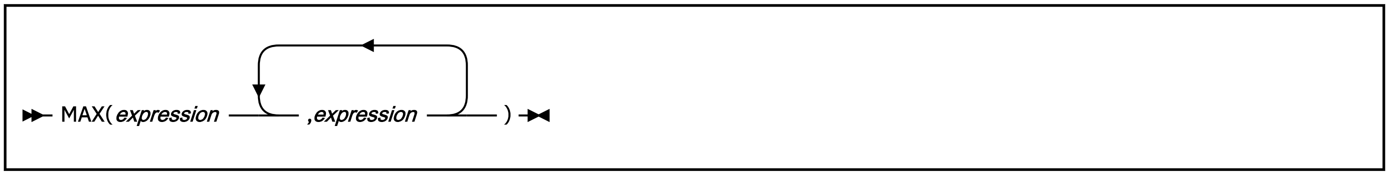
```
SELECT LTRIM (X'D090D091D092', X'D090')
   FROM SYSIBM.SYSDUMMY1
```

The result is X'D091D092'.

Note that the function does not remove individual bytes x'D0' and x'90'.

MAX (scalar)

The MAX scalar function returns the maximum value in a set of values.



The schema is SYSIBM.

The arguments must be compatible. For more information on compatibility, refer to the compatibility matrix in Table 30 on page 144. All but the first argument can be parameter markers. There must be two or more arguments.

Each argument must be an expression that returns a value of any built-in data type other than a CLOB, DBCLOB, BLOB, ROWID, or XML.

Character string arguments and binary string arguments cannot have a length attribute greater than 32704, and graphic string arguments cannot have a length attribute greater than 16352.

The arguments are evaluated in the order in which they are specified. The result of the function is the maximum argument value.

The result can be null; if any argument is null, the result is the null value.

The selected argument is converted, if necessary, to the attributes of the result. The attributes of the result are determined using the "Rules for result data types" on page 166. If the MAX function has more than two arguments, the rules are applied to the first two arguments to determine a candidate result type. The rules are then applied to that candidate result type and the third argument to determine another candidate result type. This process continues until all arguments are analyzed and the final result type and CCSID is determined.

Notes

Syntax alternatives:
GREATEST is a synonym for MAX.

Examples

Example 1: Assume the host variable *M1* is a DECIMAL(2,1) host variable with a value of 5.5, host variable *M2* is a DECIMAL(3,1) host variable with a value of 4.5, and host variable *M3* is a DECIMAL(3,2) host variable with a value of 6.25. The following function returns the value 6.25.

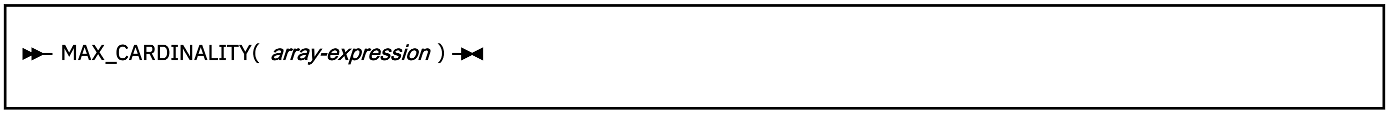
```
MAX(:M1,:M2,:M3)
```

Example 2: Assume the host variable *M1* is a CHAR(2) host variable with a value of 'AA', host variable *M2* is a CHAR(3) host variable with a value of 'AA ', and host variable *M3* is a CHAR(4) host variable with a value of 'AA A'. The following function returns the value 'AA A'.

```
MAX(:M1,:M2,:M3)
```

MAX_CARDINALITY

The MAX_CARDINALITY function returns a value of type BIGINT that represents the maximum number of elements that an array can contain. This value is the cardinality that was specified in the CREATE TYPE statement for an ordinary array type.



The schema is SYSIBM.

array-expression
An SQL variable, SQL parameter, or global variable of an array type, or a CAST specification that specifies an SQL variable, SQL parameter, global variable, or parameter marker as the source value.

The result of the MAX_CARDINALITY function is as follows:

- For an ordinary array, the result is the maximum number of elements that an array can contain.
- For an associative array, the result is the null value.

The data type of the result is BIGINT.

If the argument is an associative array, the result can be null and the result is the null value. Otherwise, the result cannot be null.

Examples

Example 1: Suppose that array type PHONENUMBERS and array variable RECENT_CALLS are defined as follows:

```
CREATE TYPE PHONENUMBERS AS DECIMAL(10,0) ARRAY[50];
CREATE VARIABLE RECENT_CALLS PHONENUMBERS;
```

The following statement sets LIST_SIZE to the maximum cardinality with which RECENT_CALLS was defined.

```
SET LIST_SIZE = MAX_CARDINALITY(RECENT_CALLS);
```

After the statement executes, LIST_SIZE contains 50.

MICROSECOND

The MICROSECOND function returns the microsecond part of a value.

►►— MICROSECOND(*expression*) —►◄

The schema is SYSIBM.

The argument must be an expression that returns a value of one of the following built-in data types: a timestamp, a character string, a graphic string, or a numeric data type.

- If *expression* is a character or graphic string, it must not be a CLOB or DBCLOB, and its value must be a valid string representation of a timestamp with an actual length of not greater than 255 bytes. For the valid formats of string representations of times and timestamps, see "String representations of datetime values" on page 120.
- If *expression* is a number, it must be a timestamp duration. For the valid formats of timestamp durations, see "Datetime operands" on page 169.

If *expression* is a timestamp with a time zone, or a valid string representation of a timestamp with a time zone, the result is determined from the UTC representation of the datetime value.

The result of the function is a large integer.

The result can be null; if the argument is null, the result is the null value.

The other rules depend on the data type of the argument:

If the argument is a timestamp or string representation of a timestamp, the result is the microsecond part of the value, which is an integer between 0 and 999999. If the precision of the timestamp exceeds 6, the value is truncated.

If the argument is a duration, the result is the microsecond part of the value, which is an integer between -999999 and 999999. A nonzero result has the same sign as the argument.

Example 1: Assume that table TABLEX contains a TIMESTAMP column named TSTMPCOL and a SMALLINT column named INTCOL. Select the microseconds part of the TSTMPCOL column of the rows where the INTCOL value is 1234:

```
   SELECT MICROSECOND(TSTMPCOL) FROM TABLEX
     WHERE INTCOL = 1234;
```

Example 2: The following invocations of the MICROSECOND function returns the same result:

```
SELECT MICROSECOND('2003-01-02-20.00.00.123456'),
            MICROSECOND('2003-01-02-12.00.00.123456-08:00'),
            MICROSECOND('2003-01-03-05.00.00.123456+09:00')
        FROM SYSIBM.SYSDUMMY1;
```

For each invocation of the MICROSECOND function in this SELECT statement, the result is 123456.

When the input argument contains a time zone, the result is determined from the UTC representation of the input value. The string representations of a timestamp with a time zone in the SELECT statement all have the same UTC representation: 2003-01-02-20.00.00.123456.

MIDNIGHT_SECONDS

The MIDNIGHT_SECONDS function returns an integer, in the range 0 - 86400, that represents the number of seconds between midnight and the time that is specified in the argument.

▸▸─ MIDNIGHT_SECONDS(*expression*) ─▸◂

The schema is SYSIBM.

The argument must be an expression that returns a value of one of the following built-in data types: a time, a timestamp, a character string, or a graphic string. If *expression* is a character or graphic string, it must not be a CLOB or DBCLOB, and its value must be a valid string representation of a time or timestamp with an actual length of not greater than 255 bytes. For the valid formats of string representations of times and timestamps, see "String representations of datetime values" on page 120.

If *expression* is a timestamp with a time zone, or a valid string representation of a timestamp with a time zone, the result is determined from the UTC representation of the datetime value.

The result of the function is a large integer.

The result can be null; if the argument is null, the result is the null value.

Example 1: Find the number of seconds between midnight and 00:01:00, and midnight and 13:10:10. Assume that host variable *XTIME1* has a value of '00:01:00', and that *XTIME2* has a value of '13:10:10'.

```
SELECT MIDNIGHT_SECONDS(:XTIME1), MIDNIGHT_SECONDS(:XTIME2)
     FROM SYSIBM.SYSDUMMY1;
```

This example returns 60 and 47410. Because there are 60 seconds in a minute and 3600 seconds in an hour, 00:01:00 is 60 seconds after midnight ((60 * 1) + 0), and 13:10:10 is 47410 seconds ((3600 * 13) + (60 * 10) + 10).

Example 2: Find the number of seconds between midnight and 24:00:00 of a specified day, and between midnight and 00:00:00 of the following day.

```
SELECT MIDNIGHT_SECONDS('2019-05-20-24:00:00'),
     MIDNIGHT_SECONDS('2019-05-21-00:00:00')
     FROM SYSIBM.SYSDUMMY1;
```

This example returns 86400 and 0. Although the two MIDNIGHT_SECONDS arguments represent the same point in time, different values are returned.

Example 3: The following invocations of the MIDNIGHT_SECONDS function return the same result:

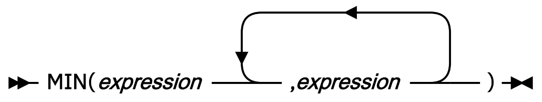
```
SELECT MIDNIGHT_SECONDS('2003-01-02-20.10.05.123456'),
             MIDNIGHT_SECONDS('2003-01-02-12.10.05.123456-08:00'),
        MIDNIGHT_SECONDS('2003-01-03-05.10.05.123456+09:00')
        FROM SYSIBM.SYSDUMMY1;
```

For each invocation of the MIDNIGHT_SECONDS function in this SELECT statement, the result is 72605.

When the input argument contains a time zone, the result is determined from the UTC representation of the input value. The string representations of a timestamp with a time zone in the SELECT statement all have the same UTC representation: 2003-01-02-20.10.05.123456.

MIN (scalar)

The MIN scalar function returns the minimum value in a set of values.



The schema is SYSIBM.

The arguments must be compatible. For more information on compatibility, refer to the compatibility matrix in Table 30 on page 144. All but the first argument can be parameter markers. There must be two or more arguments.

Each argument must be an expression that returns a value of any built-in data type other than a CLOB, DBCLOB, BLOB, ROWID, or XML.

Character string arguments and binary string arguments cannot have a length attribute greater than 32704, and graphic string arguments cannot have a length attribute greater than 16352.

The arguments are evaluated in the order in which they are specified. The result of the function is the minimum argument value.

The result can be null; if any argument is null, the result is the null value.

The selected argument is converted, if necessary, to the attributes of the result. The attributes of the result are determined using the "Rules for result data types" on page 166. If the MIN function has more than two arguments, the rules are applied to the first two arguments to determine a candidate result type. The rules are then applied to that candidate result type and the third argument to determine another candidate result type. This process continues until all arguments are analyzed and the final result type and CCSID is determined.

Notes

Syntax alternatives:
LEAST is a synonym for MIN.

Examples

Example 1: Assume the host variable *M1* is a DECIMAL(2,1) host variable with a value of 5.5, host variable *M2* is a DECIMAL(3,1) host variable with a value of 4.5, and host variable *M3* is a DECIMAL(3,2) host variable with a value of 6.25. The following function returns the value 4.5.

```
   MIN(:M1,:M2,:M3)
```

Example 2: Assume the host variable *M1* is a CHAR(2) host variable with a value of 'AA', host variable *M2* is a CHAR(3) host variable with a value of 'AAA', and host variable *M3* is a CHAR(4) host variable with a value of 'AAAA'. The following function returns the value 'AA'.

```
MIN(:M1,:M2,:M3)
```

MINUTE

The MINUTE function returns the minute part of a value.

▶▶─ MINUTE(*expression*) ─▶◀

The schema is SYSIBM.

The argument must be an expression that returns a value of one of the following built-in data types: a time, a timestamp, a character string, a graphic string, or a numeric data type.

- If *expression* is a character or graphic string, it must not be a CLOB or DBCLOB, and its value must be a valid string representation of a time or timestamp with an actual length of not greater than 255 bytes. For the valid formats of string representations of times and timestamps, see “String representations of datetime values” on page 120.
- If *expression* is a number, it must be a time or timestamp duration. For the valid formats of time and timestamp durations, see “Datetime operands” on page 169.

If *expression* is a timestamp with a time zone, or a valid string representation of a timestamp with a time zone, the result is determined from the UTC representation of the datetime value.

The result of the function is a large integer.

The result can be null; if the argument is null, the result is the null value.

The other rules depend on the data type of the argument:

If the argument is a time, timestamp, or string representation of either, the result is the minute part of the value, which is an integer between 0 and 59.

If the argument is a time duration or timestamp duration, the result is the minute part of the value, which is an integer between -99 and 99. A nonzero result has the same sign as the argument.

If the argument contains a time zone, the result is the minute part of the value expressed in UTC.

Examples

Example 1

Assume that a table named CLASSES contains one row for each scheduled class. Assume also that the class starting times are in the TIME column named STARTTM. Using these assumptions, select those rows in CLASSES that represent classes that start on the hour.

```
SELECT * FROM CLASSES
  WHERE MINUTE(STARTTM) = 0;
```

Example 2

Each invocation of the MINUTE function in the following SELECT statement returns the same result, which is 10.

```
SELECT MINUTE('2003-01-02-20.10.05.123456'),
            MINUTE('2003-01-02-12.10.05.123456-08:00'),
            MINUTE('2003-01-03-05.10.05.123456+09:00')
        FROM SYSIBM.SYSDUMMY1;
```

When the input argument contains a time zone, the result is determined from the UTC representation of the input value. The string representations of a timestamp with a time zone in the SELECT statement all have the same UTC representation: 2003-01-02-20.10.05.123456. The minute portion of the UTC representation is 10.

MOD

The MOD function divides the first argument by the second argument and returns the remainder.

```
►► MOD( numeric-expression-1 ,numeric-expression-2 ) ►◄
```

The schema is SYSIBM.

The formula used to calculate the remainder is:

```
MOD(x,y) = x - FLOOR(x/y) * y
```

Where `x/y` is the truncated integer result of the division. The result is negative only if the first argument is negative.

Each argument must be an expression that returns a value of any built-in numeric data type.

The arguments can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34).

The result can be null; if any argument is null, the result is the null value.

The attributes of the result are based on the arguments as follows:

- If both arguments are large or small integers, the data type of the result is large integer.
- If both arguments are integers and at least one argument is a big integer, the data type of the result is big integer.
- If one argument is an integer and the other is a decimal, the data type of the result is decimal with the same precision and scale as the decimal argument.
- If both arguments are decimal, the data type of the result is decimal. The precision of the result is `min(`*p*`-`*s*`,`*p*`'-`*s*`') + max(`*s*`,`*s*`')`, and the scale of the result is `max(`*s*`,`*s*`')`, where the symbols *p* and *s* denote the precision and scale of the first argument, and the symbols *p'* and *s'* denote the precision and scale of the second argument.
- If one argument is a floating-point number, and the other is not a DECFLOAT, or both argument is a floating-point number, the data type of the result is double precision floating-point.

  The operation is performed in floating-point. If necessary, the operands are first converted to double precision floating-point numbers. For example, an operation that involves a floating-point number and either an integer or a decimal number is performed with a temporary copy of the integer or decimal number that has been converted to double precision floating-point. The result of a floating-point operation must be within the range of floating-point numbers.
- If either argument is a DECFLOAT, the data type of the result is DECFLOAT(34).

  If either argument is a special decimal floating point value, the general rules for arithmetic operations apply. For more information, see "General arithmetic operation rules for DECFLOAT" on page 253.

  If one argument is a DECFLOAT and the second argument is zero, the result is NaN and an invalid operation condition is returned.

Example: Assume that *M1* and *M2* are two host variables. Find the remainder of dividing *M1* by *M2*.

```
SELECT MOD(:M1,:M2)
  FROM SYSIBM.SYSDUMMY1;
```

The following table shows the result for this function for various values of *M1* and *M2*.

***M1* data type**	***M1* value**	***M2* data type**	***M2* value**	**Result of `MOD(:M1,:M2)`**
INTEGER	5	INTEGER	2	1

M1 data type	*M1* value	*M2* data type	*M2* value	Result of `MOD(:M1,:M2)`
INTEGER	5	DECIMAL(3,1)	2.2	0.6
INTEGER	5	DECIMAL(3,2)	2.20	0.60
DECIMAL(4,2)	5.50	DECIMAL(4,1)	2.0	1.50
DECFLOAT	1	DECFLOAT	-INFINITY	1
DECFLOAT	-0	DECFLOAT	INFINITY	-0
DECFLOAT	-0	DECFLOAT	-INFINITY	-0

MONTH

The MONTH function returns the month part of a value.

▶▶─ MONTH(*expression*) ─▶◀

The schema is SYSIBM.

The argument must be an expression that returns one of the following built-in data types: a date, a timestamp, a character string, a graphic string, or a numeric data type.

- If *expression* is a character or graphic string, it must not be a CLOB or DBCLOB, and its value must be a valid string representation of a date or timestamp with an actual length of not greater than 255 bytes. For the valid formats of string representations of dates and timestamps, see "String representations of datetime values" on page 120.
- If *expression* is a number, it must be a date or timestamp duration. For the valid formats of date and timestamp durations, see "Datetime operands" on page 169.

If *expression* is a timestamp with a time zone, or a valid string representation of a timestamp with a time zone, the result is determined from the UTC representation of the datetime value.

The result of the function is a large integer.

The result can be null; if the argument is null, the result is the null value.

The other rules depend on the data type of the argument:

If the argument is a date, timestamp, or string representation of either, the result is the month part of the value, which is an integer between 1 and 12.

If the argument is a date duration or timestamp duration, the result is the month part of the value, which is an integer between -99 and 99. A nonzero result has the same sign as the argument.

If the argument contains a time zone, the result is the month part of the value expressed in UTC.

Example 1: Select all rows in the sample table DSN8C10.EMP for employees who were born in May:

```
    SELECT * FROM DSN8C10.EMP
      WHERE MONTH(BIRTHDATE) = 5;
```

Example 2: The following invocations of the MONTH function returns the same result:

```
SELECT MONTH('2003-01-02-20.10.05.123456'),
            MONTH('2003-01-02-12.10.05.123456-08:00'),
            MONTH('2003-01-03-05.10.05.123456+09:00')
        FROM SYSIBM.SYSDUMMY1;
```

For each invocation of the MONTH function in this SELECT statement, the result is 1.

When the input argument contains a time zone, the result is determined from the UTC representation of the input value. The string representations of a timestamp with a time zone in the SELECT statement all have the same UTC representation: 2003-01-02-20.10.05.123456. The month portion of the UTC representation is 1.

MONTHS_BETWEEN

The MONTHS_BETWEEN function returns an estimate of the number of months between two arguments.

▸▸─ MONTHS_BETWEEN(*expression1* ,*expression2*) ─▸◂

The schema is SYSIBM.

expression1* or *expression2

Expressions that return a value of any of the following built-in data types: a date, a timestamp, a character string, or a graphic string. If either expression is a character or graphic string, it must not be a CLOB or DBCLOB, and its value must be a valid string representation of a date or timestamp with an actual length that is not greater than 255 bytes. A time zone in a string representation of a timestamp is ignored. For the valid formats of string representations of dates and timestamps, see "String representations of datetime values" on page 120.

If *expression1* is a TIMESTAMP WITH TIME ZONE value, *expression1* is first cast to TIMESTAMP WITHOUT TIME ZONE with the same precision as *expression1*. If *expression2* is a TIMESTAMP WITH TIME ZONE value, *expression2* is first cast to TIMESTAMP WITHOUT TIME ZONE with the same precision as *expression2*.

If *expression1* represents a date that is later than *expression2*, the result is positive. If *expression1* represents a date that is earlier than *expression2*, the result is negative.

- If *expression1* and *expression2* represent dates or timestamps with the same day of the month, or both arguments represent the last day of their respective months, the result is a the whole number difference based on the year and month values, ignoring any time portions of timestamp arguments.
- Otherwise, the whole number part of the result is the difference based on the year and month values. The fractional part of the result is calculated from the remainder based on an assumption that every month has 31 days. If either argument represents a timestamp, the arguments are effectively processed as timestamps with maximum precision, and the time portions of these values are also considered when determining the result.

The result of the function is a DECIMAL(31,15).

The result can be null; if any argument is null, the result is the null value.

Examples 1: The following example calculates the months between two dates:

```
   SELECT MONTHS_BETWEEN ('2008-01-17','2008-02-17')
       AS MONTHS_BETWEEN
       FROM SYSIBM.SYSDUMMY1;
```

The results of this statement are similar to the following results:

```
MONTHS_BETWEEN
----------------------------

-1.00000000000000
```

Examples 2: The following example calculates the months between two dates:

```
   SELECT MONTHS_BETWEEN ('2008-02-20','2008-01-17')
       AS MONTHS_BETWEEN
       FROM SYSIBM.SYSDUMMY1;
```

The results of this statement are similar to the following results:

```
MONTHS_BETWEEN
----------------------------

1.096774193548387
```

Example 3: Calculate the number of months that project AD3100 will take. Assume that the start date is 1982-01-01 and the end date is 1983-02-01:

```
SELECT MONTHS_BETWEEN (PRENDATE, PRSDATE)
       FROM PROJECT
       WHERE PROJNO='AD3100';
```

The result is `13.000000000000000`.

Example 4: The following table illustrates the use of the MONTHS_BETWEEN function in certain situations:

Table 79. Additional examples using MONTHS_BETWEEN

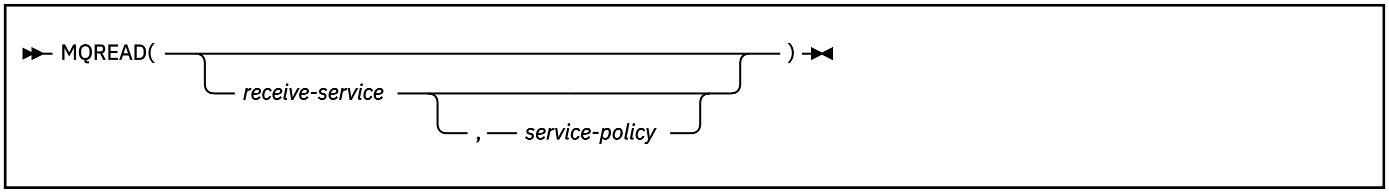
Value for *expression1*	**Value for *expression2***	**Value returned by MONTHS_BETWEEN (*expression1*,*expression2*)**	**Value returned by ROUND (MONTHS_BETWEEN (*expression1*,*expression2*)*31,2)**
2005-02-02	2005-01-01	1.032258064516129	32.00
2007-11-01-09.00.00.00000	2007-12-07-14.30.12.12345	-1.200945386592741	-37.23
2007-12-13-09.40.30.00000	2007-11-13-08.40.30.00000	1.000000000000000[1]	31.00[1]
2007–03–15	2007–02–20	0.838709677419354[2]	26.00[2]
2008-02-29	2008-02-28-12.00.00	0.016129032258064	0.50
2008-03-29	2008-02-29	1.000000000000000	31.00
2008-03-30	2008-02-29	1.032258064516129	32.00
2008-03-31	2008-02-29	1.000000000000000[3]	31.00[3]

Notes:

1. The time difference is ignored because the day of the month is the same for both values.
2. The result is not 23 because, even though February has 28 days, the assumption is that all months have 31 days.
3. The result is not 33 because both dates are the last day of their respective month, and so the result is only based on the year and month portions.

MQREAD

The MQREAD function returns a message from a specified IBM MQ location without removing the message from the queue.



The schema is DB2MQ.

The MQREAD function returns a message from the IBM MQ location that is specified by *receive-service*, using the quality-of-service policy that is defined in *service-policy*. Performing this operation does not remove the message from the queue that is associated with *receive-service*, but instead returns the message at the beginning of the queue.

receive-service

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be an empty string or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression must refer to a service point that is defined in the DB2MQ.MQSERVICE table. A service point is a logical end-point from which a message is sent or received. A service point definition includes the name of the IBM MQ queue manager and the name of the queue. See *IBM MQ Application Messaging Interface* for more details.

If *receive-service* is not specified or is the null value, `DB2.DEFAULT.POLICY` is used.

service-policy

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be an empty string or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression must refer to a service policy that is defined in the DB2MQ.MQPOLICY table. A service policy specifies a set of quality-of-service options that are to be applied to this messaging operation. These options include message priority and message persistence. See *IBM MQ Application Messaging Interface* for more details.

If *service-policy* is not specified or is the null value, `DB2.DEFAULT.POLICY` is used.

The result of the function is a varying-length string with a length attribute of 4000. The result can be null. If no messages are available to be returned, the result is the null value.

The CCSID of the result is the system CCSID that was in effect at the time that the IBM MQ function was installed into Db2.

Examples

Example 1: Retrieve the message at the beginning of the queue that is specified by the default service (Db2.DEFAULT.SERVICE), using the default policy (Db2.DEFAULT.POLICY)

```
SELECT MQREAD()
  FROM SYSIBM.SYSDUMMY1;
```

The message at the beginning of the queue specified by the default server and using the default policy is returned as VARCHAR(4000).

Example 2: Read the message from the beginning of the queue specified by the service MYSERVICE, using the default policy (Db2.DEFAULT.POLICY)

.

```
SELECT MQREAD('MYSERVICE')
  FROM SYSIBM.SYSDUMMY1;
```

The message at the beginning of the queue specified by MYSERVICE and using Db2.DEFAULT.POLICY is returned as VARCHAR(4000).

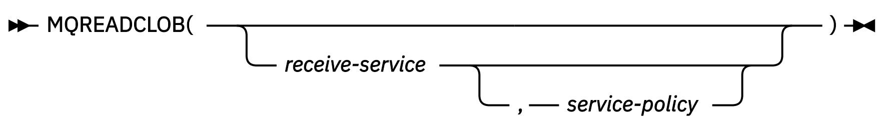
Example 3: Read the message from the beginning of the queue specified by the service MYSERVICE, using the policy MYPOLICY

```
SELECT MQREAD('MYSERVICE','MYPOLICY')
  FROM SYSIBM.SYSDUMMY1;
```

The message at the beginning of the queue specified by MYSERVICE and using the policy MYPOLICY is returned as VARCHAR(4000).

MQREADCLOB

The MQREADCLOB function returns a message from a specified IBM MQ location without removing the message from the queue.



The schema is DB2MQ.

The MQREADCLOB function returns a message from the IBM MQ location that is specified by *receive-service*, using the quality-of-service policy that is defined in *service-policy*. Performing this operation does not remove the message from the queue that is associated with *receive-service*, but instead returns the message at the beginning of the queue.

receive-service
An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be an empty string or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression must refer to a service point that is defined in the DB2MQ.MQSERVICE table. A service point is a logical end-point from which a message is sent or received. A service point definition includes the name of the IBM MQ queue manager and the name of the queue. See *IBM MQ Application Messaging Interface* for more details.

If *receive-service* is not specified or is the null value, DB2.DEFAULT.POLICY is used.

service-policy
An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be an empty string or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression must refer to a service policy that is defined in the DB2MQ.MQPOLICY table. A service policy specifies a set of quality-of-service options that are to be applied to this messaging operation. These options include message priority and message persistence. See *IBM MQ Application Messaging Interface* for more details.

If *service-policy* is not specified or is the null value, DB2.DEFAULT.POLICY is used.

The result of the function is a CLOB with a length attribute of 1 MB. The result can be null. If no messages are available to be returned, the result is the null value.

The CCSID of the result is the system CCSID that was in effect at the time that the IBM MQ function was installed into Db2.

Examples

Example 1: Read the message from the beginning of the queue specified by the default service (Db2.DEFAULT.SERVICE), using the default policy (Db2.DEFAULT.POLICY)

```
SELECT MQREADCLOB()
  FROM SYSIBM.SYSDUMMY1;
```

The message at the beginning of the queue specified by the default service and using the default policy is returned as a CLOB.

Example 2: Read the message from the beginning of the queue specified by the service MYSERVICE, using the default policy (Db2.DEFAULT.POLICY)

```
SELECT MQREADCLOB('MYSERVICE')
  FROM SYSIBM.SYSDUMMY1;
```

The message at the beginning of the queue specified by MYSERVICE and using the default policy is returned as a CLOB.

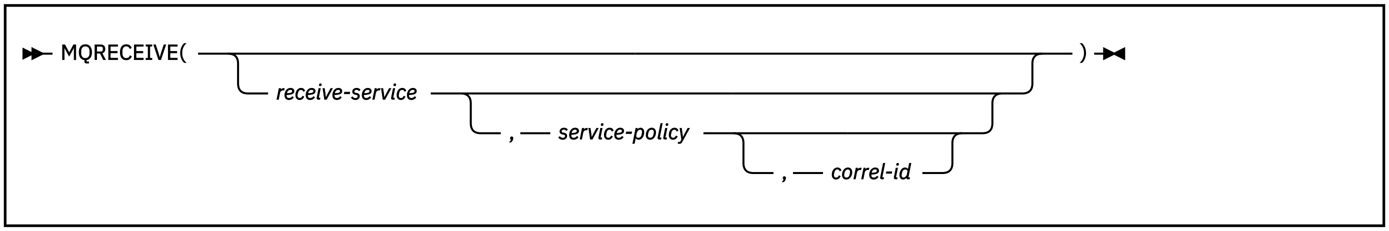
Example 3: Read the message from the beginning of the queue specified by the service MYSERVICE, using the policy MYPOLICY

```
    SELECT MQREADCLOB('MYSERVICE','MYPOLICY')
      FROM SYSIBM.SYSDUMMY1;
```

The message at the beginning of the queue specified by MYSERVICE and using the policy MYPOLICY is returned as a CLOB.

MQRECEIVE

The MQRECEIVE function returns a message from a specified IBM MQ location and removes the message from the queue.



The schema is DB2MQ.

The MQRECEIVE function returns a message from the IBM MQ location specified by *receive-service*, using the quality-of-service policy defined in *service-policy*. Performing this operation removes the message from the queue that is associated with *receive-service*.

receive-service
An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be an empty string or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression must refer to a service point that is defined in the DB2MQ.MQSERVICE table. A service point is a logical end-point from which a message is sent or received. A service point definition includes the name of the IBM MQ queue manager and the name of the queue. See *IBM MQ Application Messaging Interface* for more details.

If *receive-service* is not specified or is the null value, `DB2.DEFAULT.POLICY` is used.

service-policy
An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be an empty string or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression must refer to a service policy that is defined in the DB2MQ.MQPOLICY table. A service policy specifies a set of quality-of-service options that are to be applied to this messaging operation. These options include message priority and message persistence. See *IBM MQ Application Messaging Interface* for more details.

If *service-policy* is not specified or is the null value, `DB2.DEFAULT.POLICY` is used.

correl-id
An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The expression must have an actual length that is no greater than 24 bytes. The value of the expression specifies the correlation identifier that is associated with this message. A correlation identifier is often specified in request-and-reply scenarios to associate requests with replies. Only those messages with a matching correlation identifier are returned.

A fixed length string with trailing blanks is considered a valid value. However, when the *correl-id* is specified on another request such as MQSEND, the *correl-id* must be specified the same to be recognized as a match. For example, specifying a value of 'test' for *correl-id* for this function does not match a *correl-id* value of 'test   ' (with trailing blanks) specified earlier on an MQSEND request.

If *correl-id* is not specified, is an empty string, or is the null value, a correlation identifier is not used, and the message at the beginning of the queue is returned.

The result of the function is a varying-length string of length attribute of 4000. The result can be null. The result is null if no messages are available to return.

The CCSID of the result is the system CCSID that was in effect at the time that the IBM MQ function was installed into Db2.

Examples

Example 1: Retrieve the message from beginning of the queue specified by the default service (Db2.DEFAULT.SERVICE), using the default policy (Db2.DEFAULT.POLICY)

```
SELECT MQRECEIVE()
  FROM SYSIBM.SYSDUMMY1;
```

The message at the beginning of the queue is returned as VARCHAR(4000) and is deleted from the queue. The queue is specified by the default service and using the default policy.

Example 2: Retrieve the first message from the beginning of the queue specified by the service MYSERVICE, using the default policy, Db2.DEFAULT.POLICY

```
SELECT MQRECEIVE('MYSERVICE')
  FROM SYSIBM.SYSDUMMY1;
```

The message at the beginning of the queue is returned as VARCHAR(4000) and is deleted from the queue. The queue is specified by the service MYSERVICE using the default policy, Db2.DEFAULT.POLICY.

Example 3: Retrieve the message from the beginning of the queue specified by the service MYSERVICE, using the policy MYPOLICY

.

```
SELECT MQRECEIVE('MYSERVICE','MYPOLICY')
  FROM SYSIBM.SYSDUMMY1;
```

The message at the beginning of the queue is returned as VARCHAR(4000) and the message is deleted from the queue. The queue is specified by the service MYSERVICE using the policy MYPOLICY.

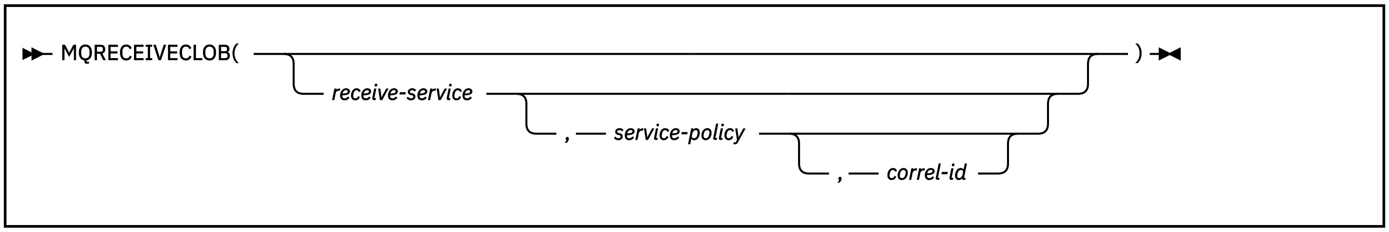
Example 4: Retrieve the first message with a correlation identifier that matches '1234' from the beginning of the queue specified by the service MYSERVICE, using the policy MYPOLICY.

```
SELECT MQRECEIVE('MYSERVICE','MYPOLICY','1234')
  FROM SYSIBM.SYSDUMMY1;
```

The first message with CORRELID of '1234' from the beginning of the queue is returned as VARCHAR(4000) and is deleted from the queue. The queue is specified by MYSERVICE and using MYPOLICY.

MQRECEIVECLOB

The MQRECEIVECLOB function returns a message from a specified IBM MQ location and removes the message from the queue.



The schema is DB2MQ.

The MQRECEIVECLOB function returns a message from the IBM MQ location that is specified by *receive-service*, using the quality-of-service policy that is defined in *service-policy*. Performing this operation removes the message from the queue that is associated with *receive-service*.

receive-service
An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be an empty string or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression must refer to a service point that is defined in the DB2MQ.MQSERVICE table. A service point is a logical end-point from which a message is sent or received. A service point definition includes the name of the IBM MQ queue manager and the name of the queue. See *IBM MQ Application Messaging Interface* for more details.

If *receive-service* is not specified or is the null value, `DB2.DEFAULT.POLICY` is used.

service-policy
An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be an empty string or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression must refer to a service policy that is defined in the DB2MQ.MQPOLICY table. A service policy specifies a set of quality-of-service options that are to be applied to this messaging operation. These options include message priority and message persistence. See *IBM MQ Application Messaging Interface* for more details.

If *service-policy* is not specified or is the null value, `DB2.DEFAULT.POLICY` is used.

correl-id
An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The expression must have an actual length that is no greater than 24 bytes. The value of the expression specifies the correlation identifier that is associated with this message. A correlation identifier is often specified in request-and-reply scenarios to associate requests with replies. Only those messages with a matching correlation identifier are returned.

A fixed length string with trailing blanks is considered a valid value. However, when the *correl-id* is specified on another request such as MQSEND, the *correl-id* must be specified the same to be recognized as a match. For example, specifying a value of 'test' for *correl-id* for this function does not match a *correl-id* value of 'test   ' (with trailing blanks) specified earlier on an MQSEND request.

If *correl-id* is not specified, is an empty string, or is the null value, a correlation identifier is not used, and the message at the beginning of the queue is returned.

The result of the function is a CLOB with a length attribute of 1 MB. The result can be null. If no messages are available to be returned, the result is the null value.

The CCSID of the result is the system CCSID that was in effect at the time that the IBM MQ function was installed into Db2.

Examples

Example 1: Retrieve the message from the beginning of the queue specified by the default service (Db2.DEFAULT.SERVICE), using the default policy (Db2.DEFAULT.POLICY)

```
SELECT MQRERECEIVECLOB()
  FROM SYSIBM.SYSDUMMY1;
```

The message at the beginning of the queue is returned as a CLOB and is deleted from the queue. The queue is specified by the default service and using the default policy.

Example 2: Retrieve the message from the beginning of the queue specified by the service MYSERVICE, using the policy (Db2.DEFAULT.POLICY)

```
SELECT MQRECEIVECLOB('MYSERVICE')
  FROM SYSIBM.SYSDUMMY1;
```

The message at the beginning of the queue is returned as a CLOB and is deleted from the queue. The queue is specified by MYSERVICE and using the default policy.

Example 3: Retrieve the message from the beginning of the queue specified by the service MYSERVICE, using the policy MYPOLICY

```
    SELECT MQRECEIVECLOB('MYSERVICE','MYPOLICY')
      FROM SYSIBM.SYSDUMMY1;
```

The message at the beginning of the queue is returned as a CLOB and is deleted from the queue. The queue is specified by MYSERVICE and using the policy MYPOLICY.

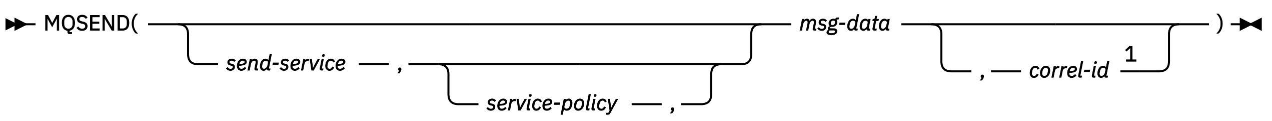
Example 4: Retrieve the first message from the beginning of the queue with a correlation identifier that matches '1234' from the queue specified by the service MYSERVICE, using the policy MYPOLICY

```
    SELECT MQRECEIVECLOB('MYSERVICE','MYPOLICY','1234')
      FROM SYSIBM.SYSDUMMY1;
```

The first message at the beginning of the queue with a correlation identifier with '1234' is returned as a CLOB and is deleted from the queue. The queue is specified by MYSERVICE and using the policy MYPOLICY.

MQSEND

The MQSEND function sends data to a specified IBM MQ location.



Notes:

[1] *correl-id* cannot be specified unless a send service and a service policy are also specified.

The schema is DB2MQ.

The MQSEND function sends the data that is contained in *msg-data* to the IBM MQ location that is specified by *send-service*, using the quality-of-service policy that is defined in *service-policy*.

send-service

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be an empty string or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression must refer to a service point that is defined in the DB2MQ.MQSERVICE table. A service point is a logical end-point from which a message is sent or received. A service point definition includes the name of the IBM MQ queue manager and the name of the queue.

If *send-service* is not specified or is the null value, Db2.DEFAULT.SERVICE is used.

service-policy

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be an empty string or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression must refer to a service policy that is defined in the DB2MQ.MQPOLICY table. A service policy specifies a set of quality-of-service options that are to be applied to this messaging operation. These options include message priority and message persistence. See *IBM MQ Application Messaging Interface* for more details.

If *service-policy* is not specified or is the null value, `DB2.DEFAULT.POLICY` is used.

msg-data

An expression that returns a value that is a built-in character string data type. If the expression is a CLOB, the value must not be longer than 1 MB. Otherwise, the value must not be longer than 4000 bytes. The value of the expression is the message data that is to be sent through IBM MQ. A null value, an empty string, and a fixed length string with trailing blanks are all considered valid values.

correl-id

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The expression must have an actual length that is no greater than 24 bytes. The value of the expression specifies the correlation identifier that is associated with this message. A correlation identifier is often specified in request-and-reply scenarios to associate requests with replies. *correl-id* must not be specified unless *send-service* and *service-policy* are also specified.

A fixed length string with trailing blanks is considered a valid value. However, when the *correl-id* is specified on another request such as MQRECEIVE, the *correl-id* must be specified the same to be recognized as a match. For example, specifying a value of 'test' for *correl-id* on MQSEND does not match a *correl-id* value of 'test   ' (with trailing blanks) specified subsequently on an MQRECEIVE request.

If *correl-id* is not specified, is an empty string, or is the null value, a correlation identifier is not sent.

The returned value is a varying-length character string with the value '1' if function execution was successful, or an error message if function execution was unsuccessful.

The CCSID of the result is the system CCSID that was in effect at the time that the IBM MQ function was installed into Db2.

Notes

The application needs to check the SQLCODE after issuing the MQSEND function. If the SQLCODE is not 0, the application needs to retrieve and handle the returned error message.

Examples

Example 1: Send the string "Testing msg" to the default service (Db2.DEFAULT.SERVICE), using the default policy (Db2.DEFAULT.POLICY) and no correlation identifier

```
SELECT MQSEND('Testing msg')
  FROM SYSIBM.SYSDUMMY1;
```

The message is sent to the default service, using the default policy.

Example 2: Send the message 'Testing 345' to the service MYSERVICE, using the policy MYPOLICY, with no correlation identifier

```
SELECT MQSEND('MYSERVICE','MYPOLICY','Testing 345')
  FROM SYSIBM.SYSDUMMY1;
```

The message 'Testing 345' is sent to the MYSERVICE service, using the policy MYPOLICY.

Example 3: Send the message 'Testing 123' to the service MYSERVICE, using the policy MYPOLICY and the correlation identifier 'TEST3'

```
SELECT MQSEND('MYSERVICE','MYPOLICY','Testing 123','TEST3')
  FROM SYSIBM.SYSDUMMY1;
```

The message 'Testing 123' is sent to the service MYSERVICE, using the policy MYPOLICY and the correlation identifier "TEST3".

Example 4: Send the message 'Testing 901' to the service "MYSERVICE", using the default policy (Db2.DEFAULT.POLICY), and no correlation identifier

```
SELECT MQSEND('MYSERVICE','Testing 901')
  FROM SYSIBM.SYSDUMMY1;
```

The message 'Testing 901' is sent to the service MYSERVICE, using the default policy (Db2.DEFAULT.POLICY).

MULTIPLY_ALT

The MULTIPLY_ALT scalar function returns the product of the two arguments. This function is an alternative to the multiplication operator and is especially useful when the sum of the precisions of the arguments exceeds 31.

▶▶─ MULTIPLY_ALT(*exact-numeric-expression-1* ,*exact-numeric-expression-2*) ─▶◀

The schema is SYSIBM.

Each argument must be an expression that returns the value of one of the following built-in numeric data types: DECIMAL, BIGINT, INTEGER, or SMALLINT.

The result of the function is a DECIMAL. The precision and scale of the result are determined as follows, using the symbols *p* and *s* to denote the precision and scale of the first argument, and the symbols *p'* and *s'* to denote the precision and scale of the second argument.

- The precision is MIN(31, *p*+*p'*)
- The scale is:
  - 0 if the scale of both arguments is 0
  - MIN(31, *s*+*s'*) if *p*+*p'* is less than or equal to 31
  - MAX(MIN(3, *s*+*s'*), 31-(*p*-*s*+*p'*-*s'*)) if *p*+*p'* is greater than 31.

The result can be null; if any argument is null, the result is the null value.

The MULTIPLY_ALT function is a better choice than the multiplication operator when performing decimal arithmetic where you want a scale of at least 3 and the sum of the precisions exceeds 31. In these cases, the internal computation is performed so that overflows are avoided and then assigned to the result type value using truncation for any loss of scale in the final result. Note that the possibility of overflow of the final result is still possible when the scale is 3.

The following table compares the result data types from the MULTIPLY_ALT function with the result data type of the multiplication operator when decimal data is used:

Type of Argument1	Type of Argument2	Result using MULTIPLY_ALT	Result using multiplication operator
DECIMAL(31,3)	DECIMAL(15,8)	DECIMAL(31,3)	DECIMAL(31,11)
DECIMAL(26,23)	DECIMAL(10,1)	DECIMAL(31,19)	DECIMAL(31,24)
DECIMAL(18,17)	DECIMAL(20,19)	DECIMAL(31,29)	DECIMAL(31,31)
DECIMAL(16,3)	DECIMAL(17,8)	DECIMAL(31,9)	DECIMAL(31,11)
DECIMAL(26,5)	DECIMAL(11,0)	DECIMAL(31,3)	DECIMAL(31,5)
DECIMAL(21,1)	DECIMAL(15,1)	DECIMAL(31,2)	DECIMAL(31,2)

Example

The following example multiplies two values where the data type of the first argument is DECIMAL(26,3) and the data type of the second argument is DECIMAL(9,8). The data type of the result is DECIMAL(31,7).

```
SELECT MULTIPLY_ALT(98765432109876543210987.654,5.43210987)
FROM SYSIBM.SYSDUMMY1
```

The result is 536504678578875294857887.5277415.

The complete product of these two numbers is 536504678578875294857887.52774154498, but the last 4 digits are truncated to match the scale of the result data type. Using the multiplication operator with the same values will cause an arithmetic overflow, since the result data type is DECIMAL(31,11) and the result value has 24 digits left of the decimal, but the result data type only supports 20 digits.

NEXT_DAY

The NEXT_DAY function returns a datetime value that represents the first weekday, named by *string-expression*, that is later than the date in *expression*.

```
►►─ NEXT_DAY( expression,string-expression ) ─►◄
```

The schema is SYSIBM.

If *expression* is a timestamp or valid string representation of a timestamp, the timestamp value has the same hours, minutes, seconds, and partial seconds as *expression*. If *expression* is a date, or a valid string representation of a date, then the hours, minutes, seconds, and partial seconds value of the result is 0.

expression

An expression that returns one of the following built-in data types: a date, a timestamp, a character string, or a graphic string. If *expression* is a character or graphic string, it must not be a CLOB or DBCLOB, and its value must be a valid string representation of a date or timestamp with an actual length of not greater than 255 bytes. A time zone in a string representation of a timestamp is ignored. For the valid formats of string representations of dates and timestamps, see "String representations of datetime values" on page 120.

If *expression* does not have data type TIMESTAMP WITHOUT TIME ZONE, *expression* is cast as follows:

- If *expression* is a TIMESTAMP WITH TIME ZONE value, *expression* is cast to TIMESTAMP WITHOUT TIME ZONE, with the same precision as *expression*.
- Otherwise, *expression* is cast to TIMESTAMP(6) WITHOUT TIME ZONE.

string-expression

An expression that returns a built-in character or graphic string data type that is not a LOB. For portability across the platforms, the value should compare equal to the full name of a day of the week or should compare equal to the abbreviation of a day of the week. For example:

Day of week	Abbreviation
MONDAY	MON
TUESDAY	TUE
WEDNESDAY	WED
THURSDAY	THU
FRIDAY	FRI
SATURDAY	SAT
SUNDAY	SUN

The minimum length of the input value is the length of the abbreviation. Leading blanks must not be specified in *string-expression*. Trailing blanks are trimmed from *string-expression*. The resulting value is folded to uppercase. Any characters other than blank that immediately follow a valid abbreviation are ignored.

If *expression* is a timestamp, the result is a TIMESTAMP WITHOUT TIME ZONE value with the same precision as *expression*. If *expression* is DATE, the result is a DATE value. Otherwise, the result is a TIMESTAMP(6) WITHOUT TIME ZONE value.

Any hours, minutes, seconds, or fractional seconds information that is included in *expression* is not changed by the function. If *expression* is a string that represents a date, the time information in the resulting timestamp value is all set to zero.

The result can be null; if any argument is null, the result is the null value.

The result CCSID is the appropriate CCSID of the argument encoding scheme and the result subtype is the appropriate subtype of the CCSID.

Example 1: Set the host variable NEXTDAY with a timestamp for the date of the Tuesday that follows April 24, 2007.

```
SET :NEXTDAY = NEXT_DAY(TIMESTAMP '2007-04-24-00.00.00.000000', 'TUESDAY');
```

The host variable NEXTDAY is set with the value of '2007-05-01-00.00.00.000000', since April, 24, 200 is itself a Tuesday'.

Example 2: Set the host variable vNEXTDAY with the date of the first Monday in May, 2007. Assume the host variable vDAYOFWEEK = 'MON':

```
SET :vNEXTDAY = NEXT_DAY(LAST_DAY(CURRENT_DATE),:vDAYOFWEEK);
```

The host variable vNEXTDAY is set with the value of '2007-05-07', assuming that the value of the CURRENT_DATE special register is '2007-04-24'.

NEXT_MONTH

The NEXT_MONTH function returns the first day of the next month after the specified date.

FL 507

Passthrough-only expression: This function is passthrough-only and cannot run on Db2 for z/OS without acceleration. For information about invoking this function, see Accelerating queries with passthrough-only expressions.

```
▶▶─ NEXT_MONTH ── ( ── datetime-expression ── ) ─▶◀
```

The schema is SYSIBM.

datetime-expression

An expression that specifies a date after which the first day of the next month is to be returned. The expression must return a value that is a DATE, TIMESTAMP WITHOUT TIME ZONE, CHAR, VARCHAR, GRAPHIC, or VARGRAPHIC data type. CHAR, VARCHAR, GRAPHIC, and VARGRAPHIC are supported using implicit casting. If *datetime-expression* is a CHAR, VARCHAR, GRAPHIC, or VARGRAPHIC data type, it must be a valid string accepted by the TIMESTAMP scalar function and does not contain a time zone.

The result of the function is DATE. If the argument can be null, the result can be null. If the argument is null, the result is the null value.

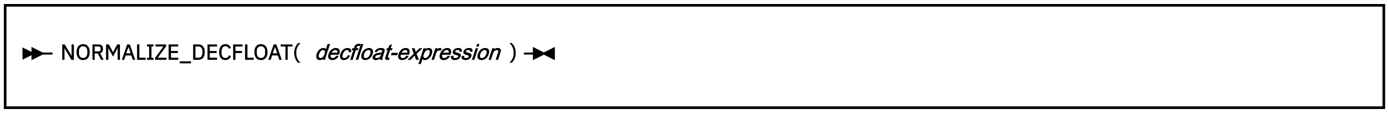
Examples

- The following example returns the date value of the first day of the next month after the date specified by the input:

```
values next_month('2007-02-18')
      Result: 2007-03-01
```

NORMALIZE_DECFLOAT

The NORMALIZE_DECFLOAT function returns a DECFLOAT value that is the result of the argument, set to its simplest form. That is, a non-zero number that has any trailing zeros in the coefficient has those zeros removed by dividing the coefficient by the appropriate power of ten and adjusting the exponent accordingly. A zero has its exponent set to 0.



The schema is SYSIBM.

decfloat-expression
The argument must be an expression that returns a DECFLOAT value.

decfloat-expression can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34).

If the argument is a special decimal floating point value then the general rules for arithmetic operations apply. For more information, see "General arithmetic operation rules for DECFLOAT" on page 253

The result of the function is a DECFLOAT(16) value if the data type of *decfloat-expression* is DECFLOAT(16). Otherwise, the result of the function is a DECFLOAT(34) value.

The result can be null; if the argument is null, the result is the null value.

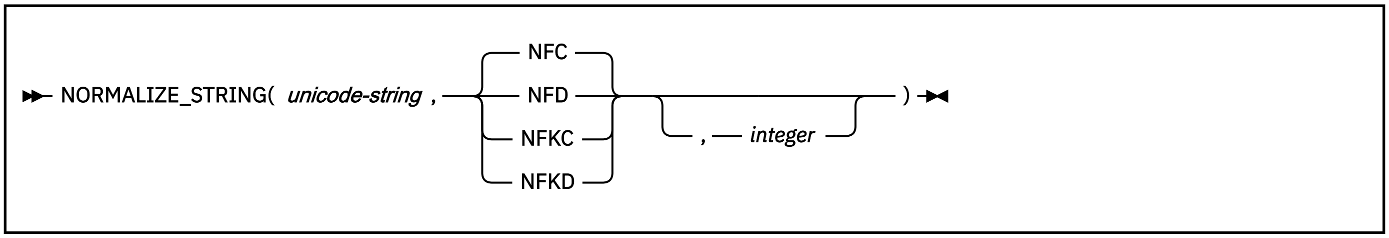
Examples: The following examples show the result of using the NORMALIZE_DECFLOAT function on various DECFLOAT values:

```
NORMALIZE_DECFLOAT(DECFLOAT(2.1))          = 2.1
NORMALIZE_DECFLOAT(DECFLOAT(-2.0))         = -2
NORMALIZE_DECFLOAT(DECFLOAT(1.200))        = 1.2
NORMALIZE_DECFLOAT(DECFLOAT(-120))         = -1.2E+2
NORMALIZE_DECFLOAT(DECFLOAT(120.00))       = 1.2E+2
NORMALIZE_DECFLOAT(DECFLOAT(0.00))         = 0
NORMALIZE_DECFLOAT(-NAN)                   = -NAN
NORMALIZE_DECFLOAT(-INFINITY)              = -INFINITY
```

NORMALIZE_STRING

The NORMALIZE_STRING function takes a Unicode string argument and returns a normalized string that can be used for comparison.

The NORMALIZE_STRING function can convert two strings that look the same (such as Å, which can be encoded in UTF-16 as X'00C5' and as X'0041030a') but might not be encoded using the same Unicode code point, to a normalized form that can be compared.



The schema is SYSIBM.

unicode_string
An expression that returns a value of a built-in character string or graphic string data type that is either Unicode UTF-8 or Unicode UTF-16, and is not a LOB. The CAST specification can be used to convert ASCII or EBCDIC data to Unicode for use with this function.

NFC, NFD, NFKC, or NFKD
Specifies the normalized form:

NFC
Canonical Decomposition followed by Canonical Composition

NFD
Canonical Decomposition

NFKC
Compatibility Decomposition followed by Canonical Composition

NFKD
Compatibility Decomposition

integer
The length attribute, in bytes if the string is a character string, or in double byte code points if the string is a graphic string, for the resulting variable length string. The value must be an integer between 1 and 32704 if the source string is character, or 16352 if the source string is graphic.

The result of the function is a varying length string with a data type that depends on the data type of *unicode-string*:

- VARCHAR if *unicode-string* is CHAR or VARCHAR
- VARGRAPHIC if *unicode-string* is GRAPHIC or VARGRAPHIC

The CCSID of the result is the same as the CCSID of *unicode-string*.

The length attribute of the result depends on whether *integer* is specified. If *integer* is specified, the length attribute of the result is *integer* bytes or double byte code points. If *integer* is not specified, the length attribute of the result is `MIN(3*n,32704)` for character strings, or `MIN(3*n,16352)` for graphic strings, where *n* is the length attribute of the source.

The result can be null; if the first argument is null, the result is the null value.

Example 1: In the following example, "ábc" is normalized to normalization form NFC:

```
    SET :hv1 = NORMALIZE_STRING('ábc',NFC) -- x'0061030100620063'
```

hv1 is set to 'ábc' -- X'00E100620063'. Using normalization form NFC, the two code-point sequence X'00610301', which represents the character 'á', is normalized to X'00E1' which is also the pre-composed equivalent of X'00610301'.

Example 2: In the following example, "ábc" is normalized to normalization form NFD.

```
    SET :hv1 = NORMALIZE_STRING('ábc',NFD) -- x'00E100620063'
```

hv1 is set to 'ábc' -- X'0061030100620063'. Using normalization form NFD, the code point X'00E1' is decomposed into the two code-point sequence X'00610301', which consists of the Latin lower case letter A and the combining acute accent character.

NULLIF

The NULLIF function returns the null value if the two arguments are equal; otherwise, it returns the value of the first argument.

▸▸— NULLIF(*expression*,*expression*) —▸◂

The schema is SYSIBM.

The two arguments must be compatible. The arguments can be of either a built-in or user-defined distinct type. Neither argument can be a BLOB, CLOB, DBCLOB, or XML. Character-string and graphic-string arguments are compatible with datetime values. For more information on compatibility, refer to the compatibility matrix in Table 30 on page 144.

If there are any mixed character string or graphic string and numeric arguments, the string value is implicitly cast to a DECFLOAT(34) value.

The attributes of the result are the attributes of the first argument.

Notes

Syntax alternatives:

The result of using `NULLIF(e1,e2)` is the same as using the CASE expression:

```
CASE WHEN e1=e2 THEN NULL ELSE e1 END
```

When e1=e2 evaluates to unknown because one or both arguments is null, CASE expressions consider the evaluation not true. In this case, NULLIF returns the value of the first argument.

Examples

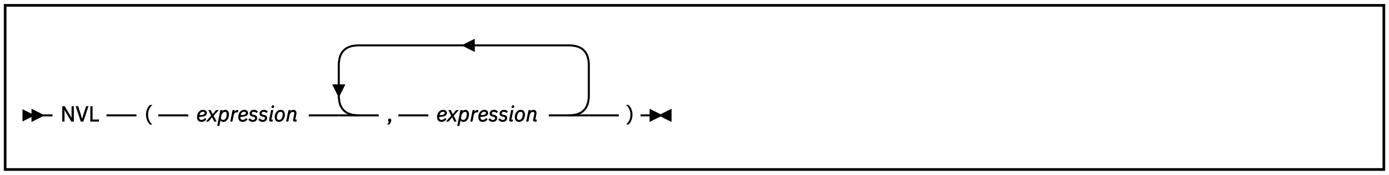
Example 1:

Assume that host variables *PROFIT*, *CASH*, and *LOSSES* have decimal data types with the values of 4500.00, 500.00, and 5000.00 respectively. The following function returns a null value:

```
NULLIF (:PROFIT + :CASH , :LOSSES)
```

NVL

The NVL function returns the first argument that is not null.

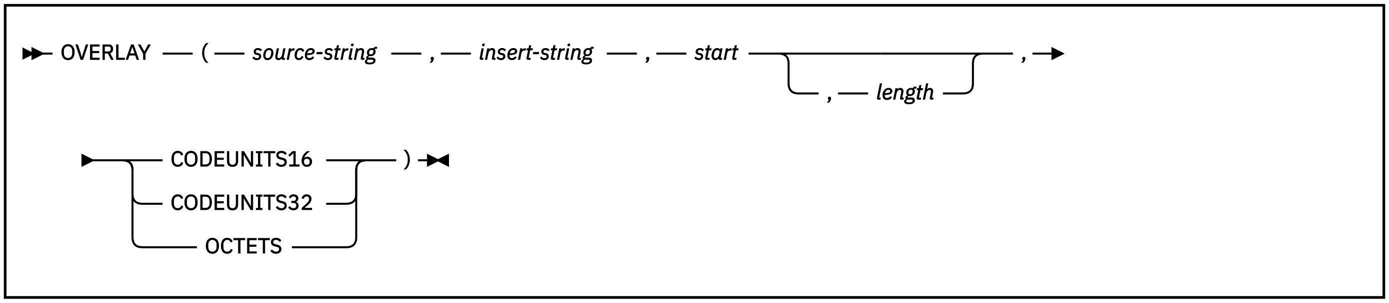


The schema is SYSIBM.

The NVL function is identical to the COALESCE function. For more information, see "COALESCE" on page 417.

OVERLAY

The OVERLAY function returns a string that is composed of one argument that is inserted into another argument at the same position where some number of bytes have been deleted.



The schema is SYSIBM.

The OVERLAY function returns a string where a substring of *length*, beginning at *start* has been deleted from *source-string*, and where *insert-string* has been inserted into *source-string* beginning at *start*. If the value of *start* plus *length* is greater than the length of *source-string*, the substring that is deleted is from *start* to the end of *source-string*.

If the length of the result string exceeds the maximum for the return type, an error is returned.

source-string

An expression that specifies the source string. The expression must return a value that is a built-in character string, graphic string, or binary string data type that is not a LOB.

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type.

The actual length of the string must be greater than or equal to 1 byte and less than or equal to 32704 bytes.

insert-string

An expression that specifies the string that is inserted into *source-string*, starting at the position that is identified by *start*. *insert-string* must return a value that is a built-in character string, graphic string, or binary string data type that is not a LOB. *source-string* and *insert-string* must have compatible data types.

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type.

start

An expression that returns an integer. The integer specifies the starting point within the source string where the deletion of bytes and the insertion of another string is to begin. The value of the integer must be in the range of 1 to the length of *source-string* plus one. If OCTETS is specified and the result is graphic data, the value must be an odd value between 1 and twice the length of *source-string* plus one.

The argument can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34) which is then assigned to an INTEGER value.

length

An expression that specifies the length of the string to replace in *source-string* starting at *start*. *length* must be an expression that returns a value of the built-in INTEGER data type. *length* is expressed in the string unit specified, and the value must be in the range of 0 to the length of *source-string*. If OCTETS is specified and the result is graphic data, *length* must be even and be between 0 and twice the length of *source-string*. Not specifying *length* is equivalent to specifying a value of 1, except when OCTETS is specified and the result is graphic data, in which case, not specifying *length* is equivalent to specifying a value of 2.

The argument can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34) which is then assigned to an INTEGER value.

CODEUNITS16, CODEUNITS32, or OCTETS

Specifies the units that are used to express *start* and *length* in the result. If *source-string* is a character string that is defined as bit data, CODEUNITS16 and CODEUNITS32 cannot be specified. If *source-string* is a graphic string, OCTETS cannot be specified. If *source-string* is a binary string, CODEUNITS16, CODEUNITS32, and OCTETS cannot be specified.

If a string unit is not explicitly specified, the data type of the result determines the unit that is used. If the result is a graphic string, a string unit is two bytes. For ASCII and EBCDIC data, this corresponds to a double byte character. For Unicode, this corresponds to a UTF-16 code point. Otherwise, a string unit is a byte.

CODEUNITS16

Specifies that *start* and *length* are expressed in terms of 16-bit UTF-16 code units.

CODEUNITS32

Specifies that *start* and *length* are expressed in terms of 32-bit UTF-32 code units.

OCTETS

Specifies that *start* and *length* are expressed in terms of bytes.

For more information about CODEUNITS16, CODEUNITS32, and OCTETS, see "String unit specifications" on page 106. *length* must be an even number if *source-string* is graphic data and OCTETS is specified

If *source-string* and *insert-string* have different CCSID sets, *insert-string* (the string to be inserted) is converted to the CCSID of *source-string* (the source string).

The encoding scheme of the result is the same as *source-string*. The data type of the result of the function depends on the data type of *source-string* and *insert-string*:

- VARCHAR if *source-string* is a character string. The CCSID of the result depends on the arguments:
  - If either *source-string* or *insert-string* is character bit data, the result is bit data.
  - If both *source-string* and *insert-string* are SBCS:
    - If both *source-string* and *insert-string* are SBCS Unicode data, the CCSID of the result is the CCSID for SBCS Unicode data.
    - If *source-string* is SBCS Unicode data and *insert-string* is not SBCS Unicode data, the CCSID of the result is the mixed CCSID for Unicode data.
    - Otherwise, the CCSID of the result is the same as the CCSID of *source-string*.
  - Otherwise, the CCSID of the result is the mixed CCSID that corresponds to the CCSID of *source-string*. However, if the input is EBCDIC or ASCII and there is no corresponding system CCSID for mixed, the CCSID of the result is the CCSID of *source-string*.
- VARGRAPHIC if *source-string* is a graphic. The CCSID of the result is the same as the CCSID of *source-string*.
- VARBINARY if *source-string* and *insert-string* are both binary strings.

The length attribute of the result depends on the arguments:

- If *start* and *length* are constants, the length attribute of the result is:

  ```
  L1 - MIN((L1 - V2 + 1), V3) + L4
  ```

  where:

  L1 is the length attribute of *source-string*
  V2 is the value of *start*
  V3 is the value of *length*
  L4 is the length attribute of *insert-string*
- Otherwise, the length attribute of the result is the length attribute of *source-string* plus the length attribute of *insert-string*. In this case, the length attribute of *source-string* plus the length attribute of *insert-string* must not exceed 32704 for a VARCHAR result or 16352 for a VARGRAPHIC result.

If CODEUNITS16 or CODEUNITS32 is specified, the insert operation is performed on a Unicode version of the data. If needed, the data is converted to an intermediate form in order to evaluate the function. If an intermediate form is used, the actual length of the result depends on the original data (*source-string* and *insert-string*), and the representation of that data in Unicode. See "Determining the length attribute of the final result" on page 108 for more information on how to calculate the length attribute of the result string.

If CODEUNITS16 or CODEUNITS32 are not specified, the actual length of the result is:

```
A1 - MIN((A1 - V2 + 1), V3) + A4
```

where:

A1 is the actual length of *source-string*
V2 is the value of *start*
V3 is the value of *length*
A4 is the actual length of *insert-string*

If the actual length of the result string exceeds the maximum for the return data type, an error occurs.

The result can be null; if any argument is null, the result is the null value.

Notes

Syntax alternatives:
The OVERLAY function is similar to the INSERT function, except that the length argument is optional. For more information, see "INSERT" on page 479.

Examples

Example 1:

The following example shows how the string 'INSERTING' can be changed into other strings. The use of the CHAR function limits the length of the resulting string to 10 bytes.

```
SELECT CHAR(OVERLAY('INSERTING','IS',4,2,OCTETS),10),
       CHAR(OVERLAY('INSERTING','IS',4,0,OCTETS),10),
       CHAR(OVERLAY('INSERTING','',4,2,OCTETS),10)
  FROM SYSIBM.SYSDUMMY1;
```

This example returns 'INSISTING ', 'INSISERTIN', and 'INSTING   '

Example 2:

Use the OVERLAY function to insert the character 'C' into the Unicode string '&N~AB', where '&' is the character for the musical symbol, G CLEF, and '~' is the character for combining tilde. The following table shows the Unicode string in different Unicode encoding forms:

Unicode format	&	N	~	A	B
UTF-8	X'F09D849E'	X'4E'	X'CC83'	X'41'	X'42'
UTF-16	X'D834DD1E'	X'004E'	X'0303'	X'0041'	X'0042'

Assume the host variable *UTF8_VAR* contains the UTF-8 representation of '&N~AB', and *UTF16_VAR* contains the UTF-16 representation of '&N~AB'. Then the following SELECT statement is run:

```
SELECT OVERLAY (:UTF8_VAR, 'C', 1, CODEUNITS16),
       OVERLAY (:UTF8_VAR, 'C', 1, CODEUNITS32),
       OVERLAY (:UTF8_VAR, 'C', 1, OCTETS)
   FROM SYSIBM.SYSDUMMY1
```

This statement returns the following values:

```
C N~AB
CN~AB
C?N~AB  -- ? is the invalid UTF-8 sequence X'9D849E'
```

Assume that the previous SELECT statement was not run, but the following SELECT statement is run:

```
SELECT OVERLAY (:UTF8_VAR, 'C', 5, CODEUNITS16),
       OVERLAY (:UTF8_VAR, 'C', 5, CODEUNITS32),
       OVERLAY (:UTF8_VAR, 'C', 5, OCTETS)
   FROM SYSIBM.SYSDUMMY1;
```

This statement returns the values:

```
&N~CB
&N~AC
&C~AB
```

Assume that the previous SELECT statement was not run, but the following SELECT statement is run:

```
 SELECT OVERLAY (:UTF16_VAR, 'C', 1, CODEUNITS16),
        OVERLAY (:UTF16_VAR, 'C', 1, CODEUNITS32)
    FROM SYSIBM.SYSDUMMY1;
```

This statement returns the values:

```
C?N~AB
CN~AB
```

Assume that the previous SELECT statement was not run, but the following SELECT statement is run:

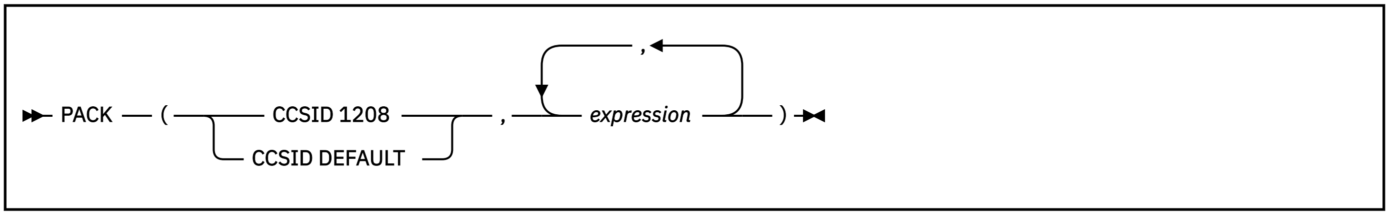
```
SELECT OVERLAY (:UTF16_VAR, 'C', 5, CODEUNITS16),
       OVERLAY (:UTF16_VAR, 'C', 5, CODEUNITS32),
   FROM SYSIBM.SYSDUMMY1;
```

This statement returns the values:

```
&N~CB
&N~AC
```

PACK

The PACK function returns a binary string value that contains a data type array and a packed representation of each non-null *expression* argument.



The schema is SYSIBM.

CCSID 1208
Specifies that CCSID 1208 is used to encode character string values.

CCSID DEFAULT
Specifies that character strings are to be packed in their original encoding, as-is, without CCSID conversion.

expression
An expression that returns a value to be encoded in the result string. The *expression* must be a built-in data type that is not DECFLOAT, GRAPHIC, VARGRAPHIC, ROWID, a LOB, XML, or a character string defined as FOR BIT DATA.

The result of the PACK function is a binary string that is constructed from the following items:

- A flag byte that is reserved for future use
- A 2-byte integer value that indicates the number of arguments encoded in the resulting string
- The data type array that contains an element with data type information for each of the encoded arguments
- The encoded values for the *expression* arguments in the order as specified in the function invocation.

The resulting binary string is formatted as follows:

2-byte length	Flag byte	Number of items	Data type array	Encoded data values
VARBINARY length	VARBINARY data			

The data type array includes an element for each *expression* argument in the same order as specified in the function invocation. Each array element contains a 2-byte SQLTYPE value that indicates the data type of the corresponding expression. When the SQLTYPE value is an odd number, the corresponding expression represents a null value and the value is not encoded in the resulting string. When the SQLTYPE value is an even number, the resulting string contains an encoded representation of the value depending on the data type. The following table describes the data types:

Table 80. Data types for the expression of the PACK function

Data type of expression	Description of the encoded representation of the value in the resulting string
SMALLINT, INTEGER, or BIGINT	The value of expression as a 16-bit signed binary integer, 32-bit signed binary integer, or 64-bit signed binary integer depending on the data type

Table 80. Data types for the expression of the PACK function (continued)

Data type of expression	**Description of the encoded representation of the value in the resulting string**
decimal(*p,s*)[1]	A sequence of 1-byte precision *p*, 1-byte scale *s*, and (*p*+2)/2 bytes of the signed packed-decimal number
real[2] or double[3]	The value of *expression* as a 64-bit IEEE floating-point format
CHAR or VARCHAR	A sequence of the 2-byte CCSID of the string encoding, followed by the 2-byte length of the string and then the argument data in the specified CCSID encoding
BINARY or VARBINARY	A sequence of: 2-byte length of the string, followed by the argument data
DATE	A 4-byte unsigned packed-decimal number representation of the date in the form of YYYYMMDD
TIME	A 3-byte unsigned packed-decimal number representation of the time in the form of HHMMSS
TIMESTAMP(*p*) WITHOUT TIME ZONE	A sequence of a 2-byte unsigned binary integer value of the precision *p*, followed by 7+ (*p*+1)/2 bytes of an unsigned packed-decimal number representation of the timestamp in the form of YYYYMMDDHHMMSSNN, where NN is zero to six bytes of the fractional seconds, depending on the precision *p*
TIMESTAMP(p) WITH TIME ZONE	A sequence of a 2-byte unsigned binary integer value of the precision *p*, followed by 7+ (*p*+1)/2 bytes of an unsigned packed-decimal number representation of the timestamp in the form of YYYYMMDDHHMMSSNN, where NN is zero to six bytes of the fractional seconds, depending on the precision *p*, and then followed by 2 bytes of an unsigned packed-decimal number representation of the time zone (with high order bit set for negative time zone value)

Note: The data types in lower case are defined as follows:

1. **decimal** = DECIMAL(*p,s*) or NUMERIC(*p,s*)
2. **real** = REAL or FLOAT(*n*) where *n* is the specification for a single precision floating point
3. **double** = DOUBLE, DOUBLE PRECISION, FLOAT or FLOAT(*n*) where *n* is the specification for a double precision floating point

The synonyms for the data types, in either long or short form, are considered the same as those that are listed.

All numeric data is represented in big endian format.

The result of the function is VARBINARY. The length attribute of the result is MIN (32704, the length of the header + length of data type array + SUM(maximum lengths of encoded expression values)). The result cannot be null.

Example 1: The following statement shows that the VARCHAR, DATE, and DOUBLE values are packed into a binary string, and the string is then returned to the application:

```
SELECT PACK(CCSID 1208, 'Alina', DATE'1977-08-01', DOUBLE(0.5))
  FROM SYSIBM.SYSDUMMYU;
```

The statement returns a VARBINARY string with the following content (The result is displayed in hexadecimal format and includes space separators for readability. The actual result is not in hexadecimal format and does not include any space separators):

```
00 0003 01C4 0180 01E0 04B80005416C696E61 19770801 3FE0000000000000
```

The character string 'Alina' is in UTF-8 (CCSID 1208) format regardless of the string's original encoding because of the CCSID 1208 specification in the PACK invocation.

The resulting string is VARBINARY(30). The length attribute of 30 is determined by the following elements:

1 (flag byte)
+2 (size of number of items)
+2*3 (2-byte data type times number of items)
+2 (CCSID) + 2 (length) + 5 (VARCHAR(5) data length)
+4 (DATE data length)
+8 (DOUBLE length)

The actual length of the result is also 30.

Example 2: The following statement shows that when NULL values are packed into a binary string, they do not occupy any space in the encoded values portion of the result:

```
SELECT PACK(CCSID DEFAULT, '', CAST(NULL AS TIME),
 CAST('Bridget' AS VARCHAR(20) CCSID EBCDIC))
 FROM SYSIBM.SYSDUMMYU;
```

The statement returns a VARBINARY string with the following content. (The result is displayed in hexadecimal format and includes space separators for readability. The actual result is not in hexadecimal format and does not include any space separators.)

```
00 0003 01C4 0185 01C4 04B80000 00250007C2D9C9C4C7C5E3
```

The character string '' (empty string) is packed in its original CCSID 1208 format, and 'Bridget' is packed in its original CCSID 37 format, because of the CCSID DEFAULT specification in the PACK invocation.

The resulting string is VARBINARY(40). The length attribute of 40 is determined by the following elements:

1 (flag byte)
+2 (size of number of items)
+2*3 (2-byte data type times number of items)
+2 (CCSID) + 2 (length) + 0 (empty string data length)
+3 (TIME data length)
+2 (CCSID) + 2 (length) + 20 (VARCHAR(20) max length)

The actual length of the resulting string is 24, which is determined by the following elements

1 (flag byte)
+2 (size of number of items)
+2*3 (2-byte data type times number of items)
+2 (CCSID) + 2 (length) + 0 (empty string data length)
+0 (NULL)
+2 (CCSID) + 2 (length) + 7 (VARCHAR(20) actual length)

Related reference

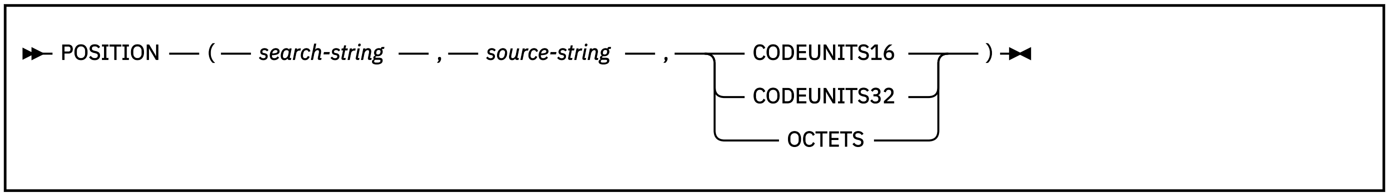
SQLTYPE and SQLLEN
The contents of the SQLTYPE and SQLLEN fields of the SQLDA depends on the SQL statement that is returning the value.

UNPACK

The UNPACK function returns a row of values that are derived from unpacking the input binary string. It is used to unpack a string that was encoded according to the PACK function.

POSITION

The POSITION function returns the position of the first occurrence of an argument within another argument, where the position is expressed in terms of the string units that are specified.



The schema is SYSIBM.

If *search-string* is not found and neither argument is null, the result is 0. If *search-string* is found, the result is a number from 1 to the actual length of *source-string*, expressed in the units that are explicitly specified.

search-string

An expression that specifies the string for which to search. *search-string* must return a value that is any built-in string data type with an actual length that is no greater than 4000 bytes.

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type.

The expression can be specified by any of the following items:

- A constant
- A special register
- A variable
- A scalar function whose arguments are any of the above (although nested function invocations cannot be used)
- An array element specification
- An expression that concatenates (using CONCAT or ||) any of the above
- A CAST specification whose arguments are any of the above
- A column name

These rules are similar to those that are described for *pattern-expression* for the LIKE predicate.

source-string

An expression that specifies the source string in which the search is to take place. *source-string* must return a value that is any built-in string data type.

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type.

The expression can be specified by any of the following items:

- A constant
- A special register
- A variable
- A scalar function whose arguments are any of the above (though nested function invocations cannot be used)
- A column name
- An array element specification
- A CAST specification whose arguments are any of the above

- An expression that concatenates (using CONCAT or ||) any of the above

CODEUNITS16, CODEUNITS32, or OCTETS

Specifies the string unit that is used to express the result. If *source-string* is a character string that is defined as bit data, CODEUNITS16, or CODEUNITS32 cannot be specified. If *source-string* is a graphic string, OCTETS cannot be specified.

CODEUNITS16

Specifies that the result is expressed in terms of 16-bit UTF-16 code units.

CODEUNITS32

Specifies that the result is expressed in terms of 32-bit UTF-32 code units.

OCTETS

Specifies that the result is expressed in terms of bytes.

For more information about CODEUNITS16, CODEUNITS32, and OCTETS, see “String unit specifications” on page 106.

The first and second arguments must have compatible string types. For more information on compatibility, see “Conversion rules for operations that combine strings”.

If the search string and source string have different CCSID sets, then the *search-string* is converted to the CCSID set of the source string. If either CODEUNITS16 or CODEUNITS32 is specified, the function might be evaluated on a temporary copy of the data in Unicode.

The strings can contain mixed data. If OCTETS is specified:

- For ASCII data, if the search string or source string contains mixed data, the search string is found only if the same combination of single-byte and double-byte characters are found in the source string in exactly the same positions.
- For EBCDIC data, if the search string or source string contains mixed data, the search string is found only if any shift-in or shift-out characters are found in the source string in exactly the same positions, ignoring any redundant shift characters.
- For UTF-8 data, if the search string or source string contains mixed data, the search string is found only if the same combination of single-byte and multi-byte characters are found in the source string in exactly the same position.

The result of the function is a large integer. The POSITION function accepts mixed data strings.

The result can be null; if any argument is null, the result is the null value.

When the POSITION function is invoked with OCTETS, the function operates on a strict byte-count basis without regard to single-byte or double-byte characters.

If the CCSID of the search string is different than the CCSID of the source string, it is converted to the CCSID of the source string.

The value of the result is determined by applying these rules in the order in which they appear:

- If *search-string* has a length of zero, the result is 1.
- If *source-string* has a length of zero, the result is 0.
- If the value of *search-string* is equal to an identical length of substring of contiguous positions within the value of *source-string*, the result is the starting position of the first such substring within the source string value.
- Otherwise, the result is 0. This includes the case where *search-string* is longer than *source-string*.

Examples

Example1:

Select the RECEIVED column, the SUBJECT column, and the starting position of the string 'GOOD BEER' within the NOTE_TEXT column for all rows in the IN_TRAY table that contain that string.

```
    SELECT RECEIVED, SUBJECT, POSITION('GOOD BEER', NOTE_TEXT, OCTETS)
      FROM IN_TRAY
      WHERE POSITION('GOOD BEER', NOTE_TEXT, OCTETS) <> 0;
```

Example 2:

Find the position of the character 'ß' in the string 'Jürgen lives on Hegelstraße', and set the host variable *LOCATION* with the position, as measured in CODEUNITS32 units, within the string.

```
SET :LOCATION = POSITION('ß','Jürgen lives on Hegelstraße',CODEUNITS32);
```

The value of host variable *LOCATION* is set to 27.

Example 3:

Find the position of the character 'ß' in the string 'Jürgen lives on Hegelstraße', and set the host variable *LOCATION* with the position, as measured in OCTETS, within the string.

```
SET :LOCATION = POSITION('ß','Jürgen lives on Hegelstraße',OCTETS);
```

The value of host variable *LOCATION* is set to 28.

Related reference

"LOCATE" on page 490
The LOCATE function returns the position at which the first occurrence of an argument starts within another argument.

POSSTR

The POSSTR function returns the position of the first occurrence of an argument within another argument.

```
►► POSSTR( source-string ,search-string ) ►◄
```

The schema is SYSIBM.

If *search-string* is not found and neither argument is null, the result is 0. If *search-string* is found, the result is a number from 1 to the actual length of *source-string*.

source-string
An expression that specifies the source string in which the search is to take place. *source-string* must return a value that is a built-in character string data type, graphic string data type, or binary string data type.

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type.

search-string
An expression that specifies the string for which to search. *search-string* must return a value that is a built-in character string data type, graphic string data type, or binary string data type with an actual length that is no greater than 4000 bytes.

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type.

The first and second arguments must have compatible string types. For more information on compatibility, see "Conversion rules for comparisons" on page 159.

If the *search-string* and *source-string* have different CCSID sets, then the *search-string* is converted to the CCSID set of the *source-string*.

Both *search-string* and *source-string* have zero or more contiguous positions. For character strings and binary strings, a position is a byte. For graphic strings, a position is a DBCS character. Graphic Unicode data is treated as UTF-16 data; a UTF-16 supplementary character takes two DBCS characters to represent and as such is counted as two DBCS characters.

The strings can contain mixed data.

- For ASCII data, if *search-string* or *source-string* contains mixed data, *search-string* is found only if the same combination of single-byte and double-byte characters are found in *source-string* in exactly the same positions.
- For EBCDIC data, if *search-string* or *source-string* contains mixed data, *search-string* is found only if any shift-in or shift-out characters are found in *source-string* in exactly the same positions, ignoring any redundant shift characters.
- For UTF-8 data, if *search-string* or *source-string* contains mixed data, *search-string* is found only if the same combination of single-byte and multi-byte characters are found in *source-string* in exactly the same position.

- If none of the above conditions are met, the result is 0.

The result of the function is a large integer. The value of the result is determined by applying these rules in the order in which they appear:

- If the length of *search-string*is zero, the result is 1.
- If the length of *source-string* is zero, the result is 0.
- If the value of *search-string* is equal to an identical length substring of contiguous positions from the value of *source-string*, the result is the starting position of the first such substring within the value of *source-string*.

The result can be null; if any argument is null, the result is the null value.

Notes

Syntax alternatives:

FL 506 STRPOS is a synonym for POSSTR.

POSSTR operates on a strict byte-count basis without regard to single-byte or double-byte characters. It is recommended that if either the *search-string* or *source-string* contains mixed data, POSITION should be used instead of POSSTR. The POSITION function operates on a character basis. In an EBCDIC encoding scheme, any shift-in and shift-out characters are not required to be in exactly the same position and their only significance is to indicate which characters are SBCS and which characters are DBCS.

Examples

Example: Select the RECEIVED column, the SUBJECT column, and the starting position of the string 'GOOD BEER' within the NOTE_TEXT column for all rows in the IN_TRAY table that contain that string.

```
SELECT RECEIVED, SUBJECT, POSSTR(NOTE_TEXT, 'GOOD BEER')
  FROM IN_TRAY
  WHERE POSSTR(NOTE_TEXT, 'GOOD BEER') <> 0;
```

Related reference

“LOCATE” on page 490
The LOCATE function returns the position at which the first occurrence of an argument starts within another argument.

“LOCATE_IN_STRING” on page 492
The LOCATE_IN_STRING function returns the position at which an argument starts within a specified string.

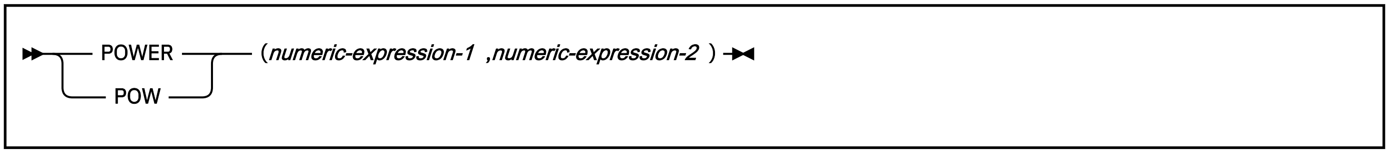
“POSITION” on page 529

The POSITION function returns the position of the first occurrence of an argument within another argument, where the position is expressed in terms of the string units that are specified.

POWER or POW

The POWER function returns the value of the first argument to the power of the second argument.

FL 506



The schema is SYSIBM.

Each argument must be an expression that returns the value of any built-in numeric data type. If either argument includes a DECIMAL or REAL data type, but not a DECFLOAT data type, the arguments are converted to a double precision floating-point number for processing by the function. If either argument includes a DECFLOAT data type, the arguments are converted to DECFLOAT for processing by the function.

The result of the function depends on the data type of the arguments:

- If both arguments are SMALLINT or INTEGER, the result is INTEGER.
- If either argument is a DECFLOAT, the data type of the result is DECFLOAT(34).

  If either argument is a DECFLOAT and one of the following statements is true, the result is NaN and an invalid operation condition:

  - both arguments are zero
  - the second argument has a non-zero fractional part
  - the second argument has more than 9 digits
  - the second argument is Infinite
- Otherwise, the result is DOUBLE.

The result can be null; if any argument is null, the result is the null value.

Examples

Example 1

Assume that host variable *HPOWER* is INTEGER with a value of 3. The following statement returns the value 8.

```
SELECT POWER(2,:HPOWER)
  FROM SYSIBM.SYSDUMMY1;
```

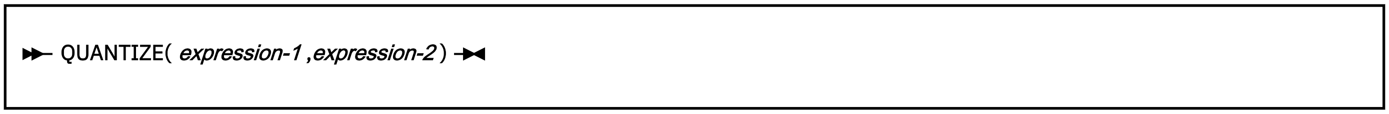
Example 2

The following statement returns the value 1.

```
SELECT POWER(0,0)
  FROM SYSIBM.SYSDUMMY1;
```

QUANTIZE

The QUANTIZE function returns a DECFLOAT value that is equal in value (except for any rounding) and sign to the first argument and that has an exponent that is set to equal the exponent of the second argument.



The schema is SYSIBM.

The number of digits that is returned (16 or 34) is the same as the number of digits in *expression-1*.

expression-1

The argument must be an expression that returns a value of any built-in numeric data type. If the argument is not a DECFLOAT value, it is converted to DECFLOAT(34) for processing.

The argument can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34).

expression-2

The argument must be an expression that returns a value of any built-in numeric data type. If the argument is not a DECFLOAT value, it is converted to DECFLOAT(34) for processing. *expression-2* is an expression that is used as an example pattern that will be used to rescale *expression-1*. The sign and coefficient of the second argument are ignored.

The argument can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34).

If one argument (after conversion) is DECFLOAT(16) and the other is DECFLOAT(34), the DECFLOAT(16) argument is converted to DECFLOAT(34) before the function is processed.

The coefficient of the result is derived from that of *expression-1*. It is rounded, if necessary (if the exponent is being increased), multiplied by a power of ten (if the exponent is being decreased), or remains unchanged (if the exponent is already equal to that of *expression-2*).

For static SQL statements other than CREATE VIEW, the ROUNDING bind option or the native SQL procedure option determines the rounding mode.

For dynamic SQL statements (and static CREATE VIEW statements), the special register CURRENT DECFLOAT ROUNDING MODE determines the rounding mode.

Unlike other arithmetic operations on the DECFLOAT data type, if the length of the coefficient after the quantize operation is greater than the precision specified by *expression-2*, a warning occurs. This ensures that, unless there is an error condition, the exponent of the result of QUANTIZE is always equal to that of *expression-2*. Furthermore:

- If either argument is NaN, NaN is returned
- If either argument is sNaN, NaN is returned and an exception occurs
- If both arguments are infinity (positive or negative), infinity (positive or negative) is returned.
- If one argument is infinity (positive or negative) and the other argument is not infinity (positive or negative), NaN is returned and an exception occurs

The result of the function is a DECFLOAT(16) value if both arguments are DECFLOAT(16). Otherwise, the result of the function is a DECFLOAT(34) value.

The result can be null; if any argument is null, the result is the null value.

Examples: The following examples illustrate the value that is returned for the QUANTIZE function given the input DECFLOAT values:

```
QUANTIZE(2.17, DECFLOAT(0.001))   = 2.170
QUANTIZE(2.17, DECFLOAT(0.01))    = 2.17
QUANTIZE(2.17, DECFLOAT(0.1))     = 2.2
QUANTIZE(2.17, DECFLOAT('1E+0'))  = 2
QUANTIZE(2.17, DECFLOAT('1E+1'))  = 0E+1
QUANTIZE(2, DECFLOAT(INFINITY))   = NAN   -- exception
QUANTIZE(-0.1, DECFLOAT(1) )      = 0
QUANTIZE(0, DECFLOAT('1E+5'))     = 0E+5
QUANTIZE(217, DECFLOAT('1E-1'))   = 217.0
QUANTIZE(217, DECFLOAT('1E+0'))   = 217
QUANTIZE(217, DECFLOAT('1E+1'))   = 2.2E+2
QUANTIZE(217, DECFLOAT('1E+2'))   = 2E+2
```

QUARTER

The QUARTER function returns an integer between 1 and 4 that represents the quarter of the year in which the date resides. For example, any dates in January, February, or March return the integer 1.

```
▶▶─ QUARTER( expression) ─▶◀
```

The schema is SYSIBM.

The argument must be an expression that returns one of the following built-in data types: a date, a timestamp, a character string, or a graphic string. If *expression* is a character or graphic string data type, it must not be a CLOB or DBCLOB, and its value must be a valid string representation of a date or timestamp with an actual length of not greater than 255 bytes. For the valid formats of string representations of dates and timestamps, see "String representations of datetime values" on page 120.

If *expression* is a timestamp with a time zone, or a valid string representation of a timestamp with a time zone, the result is determined from the UTC representation of the datetime value.

The result of the function is a large integer.

The result can be null; if the argument is null, the result is the null value.

Example 1: The following function returns 3 because August is in the third quarter of the year.

```
    SELECT QUARTER('2008-08-25')
      FROM SYSIBM.SYSDUMMY1
```

Example 2: Using sample table DSN8C10.PROJ, set the integer host variable *QUART* to the quarter of the year in which activity number 70 for project 'AD3111' occurred. Activity completion dates are recorded in column ACENDATE.

```
    SELECT QUARTER(ACENDATE)
      INTO :QUART
      FROM DSN8C10.PROJ
      WHERE PROJNO = 'AD3111' AND ACTNO = 70;
```

QUART is set to 4.

Example 3: The following invocations of the QUARTER function returns the same result:

```
SELECT QUARTER('2003-01-02-20.10.05.123456'),
            QUARTER('2003-01-02-12.10.05.123456-08:00'),
            QUARTER('2003-01-03-05.10.05.123456+09:00')
        FROM SYSIBM.SYSDUMMY1;
```

For each invocation of the QUARTER function in this SELECT statement, the result is 1.

When the input argument contains a time zone, the result is determined from the UTC representation of the input value. The string representations of a timestamp with a time zone in the SELECT statement all have the same UTC representation: 2003-01-02-20.10.05.123456. The month portion of the UTC representation is 1 for January, which is in the first quarter.

RADIANS

The RADIANS function returns the number of radians for an argument that is expressed in degrees.

```
▶▶─ RADIANS( numeric-expression ) ─▶◀
```

The schema is SYSIBM.

The argument must be an expression that returns the value of any built-in numeric data type that is not DECFLOAT. If the argument is not a double precision floating-point number, it is converted to one for processing by the function.

The result of the function is a double precision floating-point number.

The result can be null; if the argument is null, the result is the null value.

Example: Assume that host variable *HDEG* is an INTEGER with a value of 180. The following statement returns a double precision floating-point number with an approximate value of 3.1415926536.

```
SELECT RADIANS(:HDEG)
  FROM SYSIBM.SYSDUMMY1;
```

RAISE_ERROR

The RAISE_ERROR function causes the statement that invokes the function to return an error with the specified SQLSTATE (along with SQLCODE -438) and error condition. The RAISE_ERROR function always returns the null value with an undefined data type.

```
►►─ RAISE_ERROR( sqlstate ,diagnostic-string ) ─►◄
```

The schema is SYSIBM.

sqlstate

An expression that returns a character string (CHAR or VARCHAR) of exactly 5 characters.

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR(5) data type.

The *sqlstate* value must follow these rules for application-defined SQLSTATEs:

- Each character must be from the set of digits ('0' through '9') or non-accented upper case letters ('A' through 'Z').
- The SQLSTATE class (first two characters) cannot be '00', '01', or '02' because these are not error classes.
- If the SQLSTATE class (first two characters) starts with the character '0' through '6' or 'A' through 'H', the subclass (last three characters) must start with a letter in the range 'I' through 'Z'.
- If the SQLSTATE class (first two characters) starts with the character '7', '8', '9', or 'I' though 'Z', the subclass (last three characters) can be any of '0' through '9' or 'A through 'Z'.

diagnostic-string

An expression that returns a character string with a data type of CHAR or VARCHAR and a length of up to 70 bytes. The string contains EBCDIC data that describes the error condition. If the string is longer than 70 bytes, it is truncated.

Since the data type of the result of RAISE_ERROR is undefined, it can only be used in a SET *host-variable* or SQL procedure language*assignment-statement*. To use this function in another context, such as alone in a select list, you must use a cast specification to give a data type to the null value that is returned. The RAISE_ERROR function is most useful with CASE expressions.

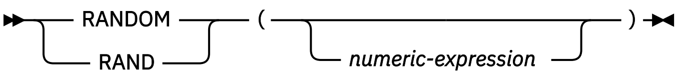
Example: For each employee in sample table DSN8C10.EMP, list the employee number and education level. List the education level as 'Post Graduate', 'Graduate' and 'Diploma' instead of the integer that it is stored as in the table. If an education level is greater than '20', raise an error ('70001') with a description.

```
SELECT EMPNO,
  CASE WHEN EDLEVEL < 16 THEN 'Diploma'
       WHEN EDLEVEL < 18 THEN 'Graduate'
       WHEN EDLEVEL < 21 THEN 'Post Graduate'
       ELSE RAISE_ERROR('70001',
                        'EDUCLVL has a value greater than 20')
  END
  FROM DSN8C10.EMP;
```

RANDOM or RAND

The RANDOM function returns a random floating-point value between 0 and 1. An argument can be specified as an optional seed value.

FL 506



The schema is SYSIBM.

numeric-expression

If *numeric-expression* is specified, it is used as the seed value. The argument must be an expression that returns a value of a built-in integer data type (SMALLINT or INTEGER). The value must be between 0 and 2,147,483,646.

The argument can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34) and then assigned to an INTEGER value.

The result of the function is a double precision floating-point number.

The result can be null; if the argument is null, the result is the null value.

A specific seed value, other than zero, will produce the same sequence of random numbers for a specific instance of a RANDOM function in a query each time the query is executed. The seed value is used only for the first invocation of an instance of the RANDOM function within a statement. `RANDOM(0)` is processed the same as `RANDOM()`.

Notes

Determinism:

RANDOM is a non-deterministic function.

Examples

Example 1

Assume that host variable *HRAND* is an INTEGER with a value of 100. The following statement returns a random floating-point number between 0 and 1, such as the approximate value .0121398:

```
SELECT RANDOM(:HRAND)
  FROM SYSIBM.SYSDUMMY1;
```

Example

To generate values in a numeric interval other than 0 to 1, multiply the RAND function by the size of the interval that you want. For example, to get a random number between 0 and 10, such as the approximate value 5.8731398, multiply the function by 10:

```
SELECT (RANDOM(:HRAND) * 10)
  FROM SYSIBM.SYSDUMMY1;
```

REAL

The REAL function returns a single-precision floating-point representation of either a number or a string representation of a number.

Numeric to Real:

String to Real:

```
►►— REAL( string-expression ) —►◄
```

The schema is SYSIBM.

Numeric to Real

numeric-expression

An expression that returns a value of any built-in numeric data type.

The result is the same number that would occur if the argument were assigned to a single precision floating-point column or variable. If the numeric value of the argument is not within the range of single precision floating-point, an error occurs.

String to Real

string-expression

An expression that returns a value of a character or graphic string (except a CLOB or DBCLOB) with a length attribute that is not greater than 255 bytes. The string must contain a valid string representation of a number.

The result is the same number that would result from CAST(`string-expression` AS REAL). Leading and trailing blanks are eliminated and the resulting string must conform to the rules for forming an SQL floating-point, integer, or decimal constant.

The result of the function is a single precision floating-point number.

The result can be null; if the argument is null, the result is the null value.

Notes

Syntax alternatives:

To increase the portability of applications, use the CAST specification. For more information, see "CAST specification" on page 266.

Examples

Example 1:

Using sample table DSN8C10.EMP, find the ratio of salary to commission for employees whose commission is not zero. The columns involved, SALARY and COMM, have decimal data types. To express the result in single precision floating-point, apply REAL to SALARY so that the division is carried out in floating-point (actually double precision) and then apply REAL to the complete expression so that the results are returned in single precision floating-point.

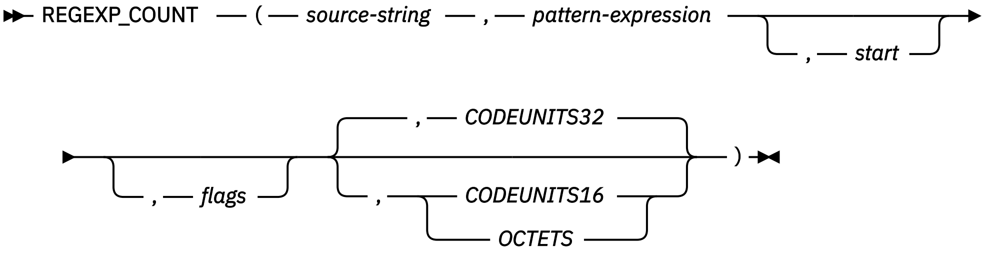
```
SELECT EMPNO, REAL(REAL(SALARY)/COMM)
  FROM DSN8C10.EMP
  WHERE COMM > 0;
```

REGEXP_COUNT

The REGEXP_COUNT scalar function returns a count of the number of times that a regular expression pattern is matched in a string.

FL 504

Passthrough-only expression: This function is passthrough-only and cannot run on Db2 for z/OS without acceleration. For information about invoking this function, see Accelerating queries with passthrough-only expressions.



The schema is SYSIBM.

source-string
An expression that specifies the string in which the search is to take place. This expression must return a built-in character string, graphic string, numeric value, Boolean value, or datetime value. A numeric, Boolean, or datetime value is implicitly cast to VARCHAR before the function is evaluated. A character string cannot specify the FOR BIT DATA attribute.

pattern-expression
An expression that specifies the regular expression string that is the pattern for the search. This expression must return a built-in character string, graphic string, numeric value, Boolean value, or datetime value. A numeric, Boolean, or datetime value is implicitly cast to VARCHAR before the function is evaluated. A character string cannot specify the FOR BIT DATA attribute.

start
An expression that specifies the position within *source-string* at which the search is to start. The expression must return a built-in character string, graphic string, Boolean, or numeric value. If the value is not of type INTEGER, it is implicitly cast to INTEGER before the function is evaluated. The value of the integer must be greater than or equal to 1. If OCTETS is specified and the source string is graphic data, the value of the integer must be odd. The default start value is 1. See parameter description for CODEUNITS16, CODEUNITS32, or OCTETS for the string unit that applies to the start position.

flags
An expression that specifies flags that controls aspects of the pattern matching. The expression must return a built-in character string that does not specify the FOR BIT DATA attribute. The string can include one or more valid flag values and the combination of flag values must be valid. An empty string is the same as the value 'c'. The default flag value is 'c'.

Table 81. Supported flag values

Flag value	Description
c	Specifies that matching is case-sensitive. This flag is the default value if 'c' or 'i' is not specified. This value must not be specified with a value of 'i'.
i	Specifies that matching is case insensitive. This value must not be specified with a value of 'c'.
m	Specifies that the input data can contain more than one line. By default, the '^' in a pattern matches only the start of the input string; the '$' in a pattern matches only the end of the input string. If this flag is set, "^" and "$" also matches at the start and end of each line within the input string.
n	Specifies that the '.' character in a pattern matches a line terminator in the input string. By default, the '.' character in a pattern does not match a line terminator. A carriage-return and line-feed pair in the input string behaves as a single-line terminator and matches a single "." in a pattern.
s	Specifies that the '.' character in a pattern matches a line terminator in the input string. This value is a synonym for the 'n' value.

Table 81. Supported flag values (continued)

Flag value	Description
x	Specifies that white space characters in a pattern are ignored, unless escaped.

CODEUNITS16, CODEUNITS32, or OCTETS

Specifies the string unit of the start value:

- CODEUNITS16 specifies that the start value is expressed in 16-bit UTF-16 code units.
- CODEUNITS32 specifies that the start value is expressed in 32-bit UTF-32 code units. This is the default.
- OCTETS specifies that the start value is expressed in bytes.

If the string unit is specified as CODEUNITS16 or OCTETS, and if the string unit of the source string is CODEUNITS32, an error is returned.

For more information, see "String unit specifications" on page 106.

The result of the function is an INTEGER that represents the number of occurrences of the pattern expression within the source string. If the pattern expression is not found and no argument is null, the result is 0.

If any argument of the REGEXP_COUNT function can be null, the result can be null. If any argument is null, the result is the null value.

Notes

- The regular expression processing is done by using the International Components for Unicode (ICU) regular expression interface.
- Considerations for non-Unicode databases:
  - A regular expression pattern supports only halfwidth control characters; use a character string data type for the pattern expression argument. A character string data type can be used for the pattern expression argument even when a graphic string data type is used for the source string argument.
  - The source string argument must be a graphic string data type if the pattern expression argument is a graphic string data type.

Example

Count the number of times "Steven" or "Stephen" occurs in the string "Steven Jones and Stephen Smith are the best players".

```
SELECT REGEXP_COUNT(
   'Steven Jones and Stephen Smith are the best players', 'Ste(v|ph)en')
      FROM sysibm.sysdummy1
```

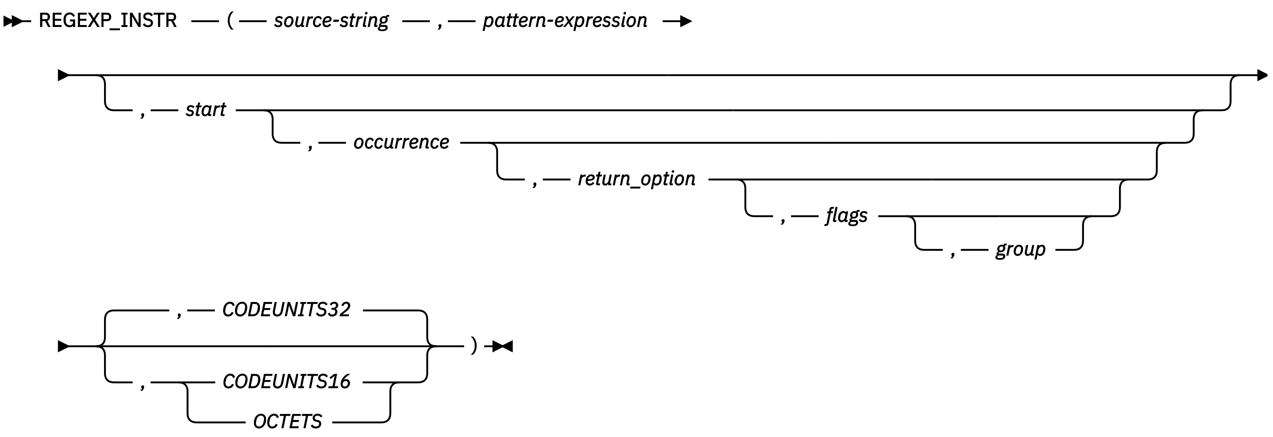
The result is 2.

REGEXP_INSTR

The REGEXP_INSTR scalar function returns the starting or ending position of the matched substring, depending on the value of the **return_option** argument.

FL 504

Passthrough-only expression: This function is passthrough-only and cannot run on Db2 for z/OS without acceleration. For information about invoking this function, see Accelerating queries with passthrough-only expressions.



The schema is SYSIBM.

source-string

An expression that specifies the string in which the search is to take place. This expression must return a built-in character string, graphic string, numeric value, Boolean value, or datetime value. A numeric, Boolean, or datetime value is implicitly cast to VARCHAR before the function is evaluated. A character string cannot specify the FOR BIT DATA attribute.

pattern-expression

An expression that specifies the regular expression string that is the pattern for the search. This expression must return a built-in character string, graphic string, numeric value, Boolean value, or datetime value. A numeric, Boolean, or datetime value is implicitly cast to VARCHAR before the function is evaluated. A character string cannot specify the FOR BIT DATA attribute.

start

An expression that specifies the position within *source-string* at which the search is to start. The expression must return a built-in character string, graphic string, Boolean, or numeric value. If the value is not of type INTEGER, it is implicitly cast to INTEGER before the function is evaluated. The value of the integer must be greater than or equal to 1. If OCTETS is specified and the source string is graphic data, the value of the integer must be odd. The default start value is 1. See parameter description for CODEUNITS16, CODEUNITS32, or OCTETS for the string unit that applies to the start position.

occurrence

An expression that specifies which occurrence of the pattern expression within the source string to search for. The expression must return a built-in character string, graphic string, Boolean, or numeric value. If the value is not of type INTEGER, it is implicitly cast to INTEGER before the function is evaluated. This value must be greater than or equal 1. The default occurrence value is 1, which indicates that only the first occurrence of the pattern expression is considered.

return-option

An expression that specifies what is returned relative to the occurrence. The expression must return a built-in character string, graphic string, Boolean, or numeric value. If the value is not of type INTEGER, it is implicitly cast to INTEGER before the function is evaluated. This value must be 0 or 1:

- A value of 0 returns the position of the first string unit of the occurrence.
- A value of 1 returns the position of the string unit that follows the occurrence.

The default return option value is 0.

flags

An expression that specifies flags that controls aspects of the pattern matching. The expression must return a built-in character string that does not specify the FOR BIT DATA attribute. The string can include one or more valid flag values and the combination of flag values must be valid. An empty string is the same as the value 'c'. The default flag value is 'c'.

Table 82. Supported flag values

Flag value	Description
c	Specifies that matching is case-sensitive. This flag is the default value if 'c' or 'i' is not specified. This value must not be specified with a value of 'i'.
i	Specifies that matching is case insensitive. This value must not be specified with a value of 'c'.
m	Specifies that the input data can contain more than one line. By default, the '^' in a pattern matches only the start of the input string; the '$' in a pattern matches only the end of the input string. If this flag is set, "^" and "$" also matches at the start and end of each line within the input string.
n	Specifies that the '.' character in a pattern matches a line terminator in the input string. By default, the '.' character in a pattern does not match a line terminator. A carriage-return and line-feed pair in the input string behaves as a single-line terminator and matches a single "." in a pattern.
s	Specifies that the '.' character in a pattern matches a line terminator in the input string. This value is a synonym for the 'n' value.
x	Specifies that white space characters in a pattern are ignored, unless escaped.

group

An expression that specifies which capture group of the pattern expression is used to determine the position within source string to return. The expression must return a built-in character string, graphic string, Boolean, or numeric value. If the value is not of type INTEGER, it is implicitly cast to INTEGER before the function is evaluated. This value must be greater than or equal to 0 and must not be greater than the number of capture groups in the pattern expression. The default group value is 0, which indicates that the position is based on the string that matches the entire pattern.

CODEUNITS16, CODEUNITS32, or OCTETS

Specifies the string unit of both the start value and the result:

- CODEUNITS16 specifies that the start value and result are expressed in 16-bit UTF-16 code units.
- CODEUNITS32 specifies that the start value and result are expressed in 32-bit UTF-32 code units. This is the default.
- OCTETS specifies that the start value and result are expressed in bytes.

If the string unit is specified as CODEUNITS16 or OCTETS, and the string unit of the source string is CODEUNITS32, an error is returned.

For more information, see "String unit specifications" on page 106.

The result of the function is a large integer. If the pattern expression is found, the result is a number from 1 to n, where n is the actual length of the source string plus 1. The result value represents the position expressed in the string units used to process the function. If the pattern expression is not found and no argument is null, the result is 0.

If any argument of the REGEXP_INSTR function can be null, the result can be null. If any argument is null, the result is the null value.

Notes

- The regular expression processing is done by using the International Components for Unicode (ICU) regular expression interface.
- Considerations for non-Unicode databases:

- A regular expression pattern supports only halfwidth control characters; use a character string data type for the pattern expression argument. A character string data type can be used for the pattern expression argument even when a graphic string data type is used for the source string argument.
- The source string argument must be a graphic string data type if the pattern expression argument is a graphic string data type.

Examples

Example 1:
Find the first occurrence of a 'o' that has a character that is preceding it.

```
SELECT REGEXP_INSTR('hello to you', '.o',1,1)
   FROM sysibm.sysdummy1
```

The result is 4, which is the position of the second 'l' character.

Example 2:
Find the second occurrence of a 'o' that has a character that is preceding it.

```
SELECT REGEXP_INSTR('hello to you', '.o',1,2)
   FROM sysibm.sysdummy1
```

The result is 7, which is the position of the character 't'.

Example 3:
Find the position after the third occurrence of the first capture group of the regular expression '(.o).' using case insensitive matching.

```
SELECT REGEXP_INSTR('hello TO you', '(.o).', 1,3,1,'i',1)
   FROM sysibm.sysdummy1
```

The result is 12, which is the position of the character 'u' at the end of the string.

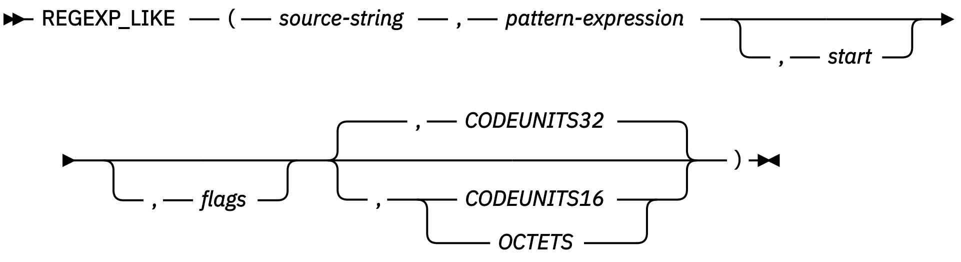
REGEXP_LIKE

The REGEXP_LIKE scalar function returns an INTEGER value of 0 or 1 indicating if the regular expression pattern is found in a string.

FL 504

Passthrough-only expression: This function is passthrough-only and cannot run on Db2 for z/OS without acceleration. For information about invoking this function, see Accelerating queries with passthrough-only expressions.

Db2 for z/OS casts the result of this function to an INTEGER (1 = 'true', 0 = 'false'). Db2 for z/OS currently does not support Boolean functions or data types.



The schema is SYSIBM.

source-string
An expression that specifies the string in which the search is to take place. This expression must return a built-in character string, graphic string, numeric value, Boolean value, or datetime value. A numeric, Boolean, or datetime value is implicitly cast to VARCHAR before the function is evaluated. A character string cannot specify the FOR BIT DATA attribute.

pattern-expression

An expression that specifies the regular expression string that is the pattern for the search. This expression must return a built-in character string, graphic string, numeric value, Boolean value, or datetime value. A numeric, Boolean, or datetime value is implicitly cast to VARCHAR before the function is evaluated. A character string cannot specify the FOR BIT DATA attribute.

start

An expression that specifies the position within *source-string* at which the search is to start. The expression must return a built-in character string, graphic string, Boolean, or numeric value. If the value is not of type INTEGER, it is implicitly cast to INTEGER before the function is evaluated. The value of the integer must be greater than or equal to 1. If OCTETS is specified and the source string is graphic data, the value of the integer must be odd. The default start value is 1. See parameter description for CODEUNITS16, CODEUNITS32, or OCTETS for the string unit that applies to the start position.

flags

An expression that specifies flags that controls aspects of the pattern matching. The expression must return a built-in character string that does not specify the FOR BIT DATA attribute. The string can include one or more valid flag values and the combination of flag values must be valid. An empty string is the same as the value 'c'. The default flag value is 'c'.

Table 83. Supported flag values

Flag value	Description
c	Specifies that matching is case-sensitive. This flag is the default value if 'c' or 'i' is not specified. This value must not be specified with a value of 'i'.
i	Specifies that matching is case insensitive. This value must not be specified with a value of 'c'.
m	Specifies that the input data can contain more than one line. By default, the '^' in a pattern matches only the start of the input string; the '$' in a pattern matches only the end of the input string. If this flag is set, "^" and "$" also matches at the start and end of each line within the input string.
n	Specifies that the '.' character in a pattern matches a line terminator in the input string. By default, the '.' character in a pattern does not match a line terminator. A carriage-return and line-feed pair in the input string behaves as a single-line terminator and matches a single "." in a pattern.
s	Specifies that the '.' character in a pattern matches a line terminator in the input string. This value is a synonym for the 'n' value.
x	Specifies that white space characters in a pattern are ignored, unless escaped.

CODEUNITS16, CODEUNITS32, or OCTETS

Specifies the string unit of the start value:

- CODEUNITS16 specifies that the start value is expressed in 16-bit UTF-16 code units.
- CODEUNITS32 specifies that the start value is expressed in 32-bit UTF-32 code units. This is the default.
- OCTETS specifies that the start value is expressed in bytes.

If the string unit is specified as CODEUNITS16 or OCTETS, and if the string unit of the source string is CODEUNITS32, an error is returned.

For more information, see "String unit specifications" on page 106.

The result of the function is an INTEGER value of 0 or 1. If the pattern expression is found, the result is true. If the pattern expression is not found, the result is false. If the value of any of the arguments is null, the result is unknown.

Examples

Example 1:

Select the employee number where the last name is spelled LUCCHESSI, LUCHESSI, or LUCHESI from the EMPLOYEE table without considering upper or lower case letters.

```
   SELECT EMPNO FROM EMPLOYEE
      WHERE REGEXP_LIKE(LASTNAME,'luc+?hes+?i','i') = 1
```

The result is 1 row with EMPNO value '000110'.

Exmaple 2:

Select any invalid product identifier values from the PRODUCT table. The expected format is 'nnn-nnn-nn' where 'n' is a digit 0 - 9.

```
SELECT PID FROM PRODUCT
   WHERE NOT REGEXP_LIKE(pid,'[0-9]{3}-[0-9]{3}-[0-9]{2}') = 1
```

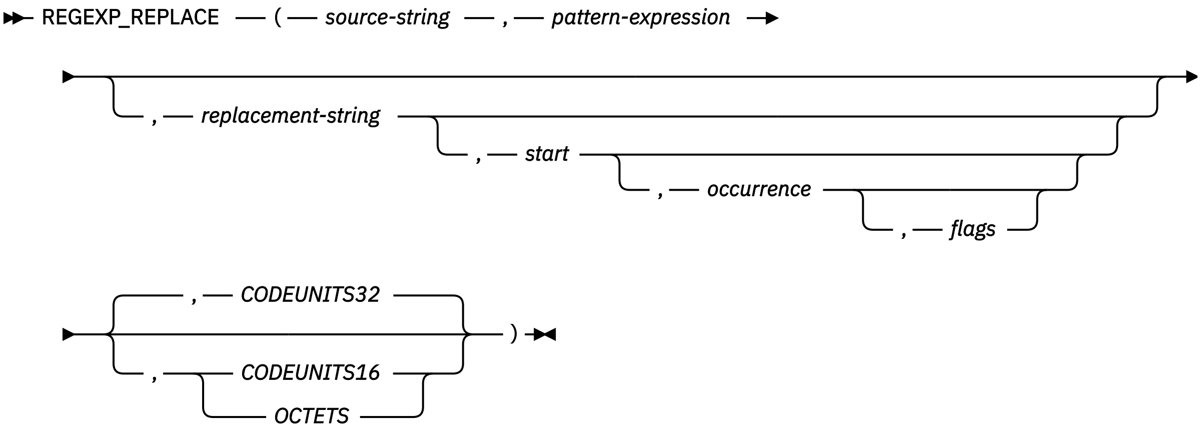
The result is 0 rows because all the product identifiers match the pattern.

REGEXP_REPLACE

The REGEXP_REPLACE scalar function returns a modified version of the source string where occurrences of the regular expression pattern found in the source string are replaced with the specified replacement string.

FL 504

Passthrough-only expression: This function is passthrough-only and cannot run on Db2 for z/OS without acceleration. For information about invoking this function, see Accelerating queries with passthrough-only expressions.



The schema is SYSIBM.

source-string

An expression that specifies the string in which the search is to take place. This expression must return a built-in character string, graphic string, numeric value, Boolean value, or datetime value. A numeric, Boolean, or datetime value is implicitly cast to VARCHAR before the function is evaluated. A character string cannot specify the FOR BIT DATA attribute.

pattern-expression

An expression that specifies the regular expression string that is the pattern for the search. This expression must return a built-in character string, graphic string, numeric value, Boolean value, or datetime value. A numeric, Boolean, or datetime value is implicitly cast to VARCHAR before the function is evaluated. A character string cannot specify the FOR BIT DATA attribute.

replacement-string

An expression that specifies the replacement string for matching substrings. The expression must return a value that is a built-in character string, graphic string, numeric value, Boolean value, or datetime value. A numeric, Boolean, or datetime value is implicitly cast to VARCHAR before the function is evaluated. A character string cannot specify the FOR BIT DATA attribute. The default replacement string is the empty string.

The content of the replacement string can include references to capture group text from the search to use in the replacement text. These references are of the form '$n' or '\n', where n is the number of the capture group and 0 represents the entire string that matches the pattern. The value for n must be in the range 0-9 and not greater than the number of capture groups in the pattern. For example, either '$2' or '\2' can be used to refer to the content found in the source string for the second capture group that is specified in the pattern expression. If the pattern expression must include a literal reference to a '$' or '\' character, that character must be preceded with an '/' character as an escape character ('\$' or '\\').

start

An expression that specifies the position within *source-string* at which the search is to start. The expression must return a built-in character string, graphic string, Boolean, or numeric value. If the value is not of type INTEGER, it is implicitly cast to INTEGER before the function is evaluated. The value of the integer must be greater than or equal to 1. If OCTETS is specified and the source string is graphic data, the value of the integer must be odd. The default start value is 1. See parameter description for CODEUNITS16, CODEUNITS32, or OCTETS for the string unit that applies to the start position.

occurrence

An expression that specifies which occurrence of the pattern expression within the source string is to be searched for and replaced. The expression must return a built-in character string, graphic string, Boolean, or numeric value. If the value is not of type INTEGER, it is implicitly cast to INTEGER before the function is evaluated. The occurrence value must be greater than or equal to 0. The default occurrence value is 0, which indicates that all occurrences of the pattern expression in the source string are replaced.

flags

An expression that specifies flags that controls aspects of the pattern matching. The expression must return a built-in character string that does not specify the FOR BIT DATA attribute. The string can include one or more valid flag values and the combination of flag values must be valid. An empty string is the same as the value 'c'. The default flag value is 'c'.

Table 84. Supported flag values

Flag value	Description
c	Specifies that matching is case-sensitive. This flag is the default value if 'c' or 'i' is not specified. This value must not be specified with a value of 'i'.
i	Specifies that matching is case insensitive. This value must not be specified with a value of 'c'.
m	Specifies that the input data can contain more than one line. By default, the '^' in a pattern matches only the start of the input string; the '$' in a pattern matches only the end of the input string. If this flag is set, "^" and "$" also matches at the start and end of each line within the input string.
n	Specifies that the '.' character in a pattern matches a line terminator in the input string. By default, the '.' character in a pattern does not match a line terminator. A carriage-return and line-feed pair in the input string behaves as a single-line terminator and matches a single "." in a pattern.
s	Specifies that the '.' character in a pattern matches a line terminator in the input string. This value is a synonym for the 'n' value.
x	Specifies that white space characters in a pattern are ignored, unless escaped.

CODEUNITS16, CODEUNITS32, or OCTETS

Specifies the string unit of the start value:

- CODEUNITS16 specifies that the start value is expressed in 16-bit UTF-16 code units.
- CODEUNITS32 specifies that the start value is expressed in 32-bit UTF-32 code units. This is the default.
- OCTETS specifies that the start value is expressed in bytes.

If the string unit is specified as CODEUNITS16 or OCTETS, and if the string unit of the source string is CODEUNITS32, an error is returned.

For more information, see "String unit specifications" on page 106.

The result of the function is a string. If there are no occurrences of the pattern to be replaced and no argument is null, the original string is returned. The data type of the string is the same data type as the source string, except for CHAR, which becomes VARCHAR, and VARGRAPHIC, which becomes GRAPHIC.

The length attribute of the result data type is determined based on the length attributes of the source string and the replacement string by using the following calculation:

```
MIN(MaxTypeLen, LAS+(LAS+1)*LAR)
```

where *MaxTypeLen* represents the maximum length attribute for the data type of the result, *LAS* represents the length attribute for the data type of the source string, and *LAR* represents the length attribute for the data type of the replacement string. If the replacement string is not specified, the value for *LAR* is 0. If the actual length of the result string exceeds the maximum for the return data type, an error is returned.

If the replacement string is specified, the result buffer length is 32672 bytes. If the replacement string is not specified, the result buffer length is the same as the length of the source string except for the following data types:

Table 85. Data types with different result buffer lengths

Data Type	Length (in bytes)
numerical	42
date	10
time	8
timestamp	32

If any argument of the REGEXP_REPLACE function can be null, the result can be null. If any argument is null, the result is the null value.

Notes

- The regular expression processing is done by using the International Components for Unicode (ICU) regular expression interface.
- Considerations for non-Unicode databases:
  - A regular expression pattern supports only halfwidth control characters; use a character string data type for the pattern expression argument. A character string data type can be used for the pattern expression argument even when a graphic string data type is used for the source string argument.
  - The source string argument must be a graphic string data type if the pattern expression argument is a graphic string data type.
  - The source string and replacement string arguments must both be character string data types or both be graphic string data types.

Example

Replace the second occurrence of the pattern 'R.d' with 'Orange' using a case sensitive search.

```
SELECT REGEXP_REPLACE(
   'Red Yellow RED Blue Red Green Blue', 'R.d','Orange',1,2,'c')
      FROM sysibm.sysdummy1
```

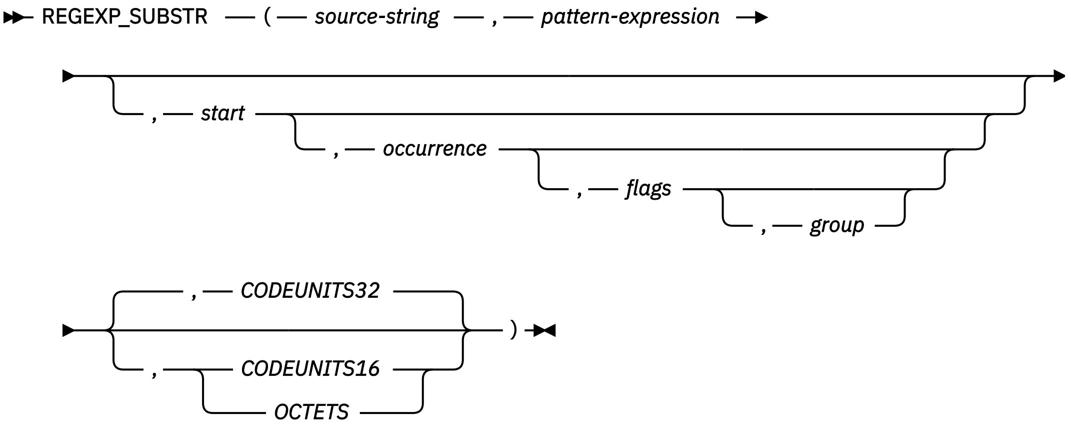
The result is 'Red Yellow RED Blue Orange Green Blue'.

REGEXP_SUBSTR

The REGEXP_SUBSTR scalar function returns one occurrence of a substring of a string that matches the regular expression pattern.

FL 504

Passthrough-only expression: This function is passthrough-only and cannot run on Db2 for z/OS without acceleration. For information about invoking this function, see Accelerating queries with passthrough-only expressions.



The schema is SYSIBM.

source-string
An expression that specifies the string in which the search is to take place. This expression must return a built-in character string, graphic string, numeric value, Boolean value, or datetime value. A numeric, Boolean, or datetime value is implicitly cast to VARCHAR before the function is evaluated. A character string cannot specify the FOR BIT DATA attribute.

pattern-expression
An expression that specifies the regular expression string that is the pattern for the search. This expression must return a built-in character string, graphic string, numeric value, Boolean value, or datetime value. A numeric, Boolean, or datetime value is implicitly cast to VARCHAR before the function is evaluated. A character string cannot specify the FOR BIT DATA attribute.

start
An expression that specifies the position within *source-string* at which the search is to start. The expression must return a built-in character string, graphic string, Boolean, or numeric value. If the value is not of type INTEGER, it is implicitly cast to INTEGER before the function is evaluated. The value of the integer must be greater than or equal to 1. If OCTETS is specified and the source string is graphic data, the value of the integer must be odd. The default start value is 1. See parameter description for CODEUNITS16, CODEUNITS32, or OCTETS for the string unit that applies to the start position.

occurrence
An expression that specifies which occurrence of the pattern expression within *source-string* to search for. The expression must return a built-in character string, graphic string, Boolean, or numeric value. If the value is not of type INTEGER, it is implicitly cast to INTEGER before the function is evaluated. The

occurrence value must be greater than or equal 1. The default occurrence value is 1, which indicates that only the first occurrence of the pattern expression is considered.

flags

An expression that specifies flags that controls aspects of the pattern matching. The expression must return a built-in character string that does not specify the FOR BIT DATA attribute. The string can include one or more valid flag values and the combination of flag values must be valid. An empty string is the same as the value 'c'. The default flag value is 'c'.

Table 86. Supported flag values

Flag value	Description
c	Specifies that matching is case-sensitive. This flag is the default value if 'c' or 'i' is not specified. This value must not be specified with a value of 'i'.
i	Specifies that matching is case insensitive. This value must not be specified with a value of 'c'.
m	Specifies that the input data can contain more than one line. By default, the '^' in a pattern matches only the start of the input string; the '$' in a pattern matches only the end of the input string. If this flag is set, "^" and "$" also matches at the start and end of each line within the input string.
n	Specifies that the '.' character in a pattern matches a line terminator in the input string. By default, the '.' character in a pattern does not match a line terminator. A carriage-return and line-feed pair in the input string behaves as a single-line terminator and matches a single "." in a pattern.
s	Specifies that the '.' character in a pattern matches a line terminator in the input string. This value is a synonym for the 'n' value.
x	Specifies that white space characters in a pattern are ignored, unless escaped.

group

An expression that specifies which capture group of the pattern expression within source string to return. The expression must return a built-in character, binary, or graphic string, or a Boolean value. If the value is not of type INTEGER, it is implicitly cast to INTEGER before the function is evaluated. The group value must be greater than or equal to 0 and must not be greater than the number of capture groups in the pattern expression. The default group value is 0, which indicates that the string that matches the entire pattern is to be returned.

CODEUNITS16, CODEUNITS32, or OCTETS

Specifies the string unit of the start value:

- CODEUNITS16 specifies that the start value is expressed in 16-bit UTF-16 code units.
- CODEUNITS32 specifies that the start value is expressed in 32-bit UTF-32 code units. This is the default.
- OCTETS specifies that the start value is expressed in bytes.

If the string unit is specified as CODEUNITS16 or OCTETS, and if the string unit of the source string is CODEUNITS32, an error is returned.

For more information, see "String unit specifications" on page 106.

The result of the function is a string. The data type of the string is the same data type as the source string, except for CHAR, which becomes VARCHAR; and GRAPHIC, which becomes and VARGRAPHIC. The length attribute of the result data type is same as the length attribute of the source string. The actual length of the result is the length of the occurrence in the string that matches the pattern expression. If the pattern expression is not found, the result is the null value.

The result buffer length is the same as the length of the source string except for the following data types:

Table 87. Data types with different result buffer lengths

Data Type	Length (in bytes)
numerical	42
date	10
time	8
timestamp	32

The result of the REGEXP_SUBSTR function can be null. If any argument is null, the result is the null value.

Notes

- The regular expression processing is done by using the International Components for Unicode (ICU) regular expression interface.
- Considerations for non-Unicode databases:
  - A regular expression pattern supports only halfwidth control characters; use a character string data type for the pattern expression argument. A character string data type can be used for the pattern expression argument even when a graphic string data type is used for the source string argument.
  - The source string argument must be a graphic string data type if the pattern expression argument is a graphic string data type.

Examples

Example 1:

Return the string which matches any character preceding a 'o'.

```
SELECT REGEXP_SUBSTR('hello to you', '.o',1,1)
   FROM sysibm.sysdummy1
```

The result is 'lo'.

Example 2:

Return the third string occurrence which matches any character preceding a 'o'.

```
SELECT REGEXP_SUBSTR('hello to you', '.o',1,3)
   FROM sysibm.sysdummy1
```

The result is 'yo'.

REPEAT

The REPEAT function returns a character string that is composed of an argument that is repeated a specified number of times.

►►─ REPEAT(*expression* , *integer*) ─►◄

The schema is SYSIBM.

expression

An expression that specifies the string to be repeated. The expression must return a value that is a built-in character string, graphic string, or binary string data type that is not a LOB.

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type.

The actual length of the string must be greater or equal to 1 and less than or equal to 32704 bytes.

integer

integer must be a positive large integer value that specifies the number of times to repeat the string.

The argument can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34) which is then assigned to an INTEGER value.

The result can be null; if any argument is null, the result is the null value.

The encoding scheme of the result is the same as *expression*. The data type of the result of the function depends on the data type of *expression*:

- VARBINARY if *expression* is a binary string
- VARCHAR if *expression* is a character string
- VARGRAPHIC if *expression* is graphic string

The CCSID of the result is the same as the CCSID of *expression*.

If *integer* is a constant, the length attribute of the result is the length attribute of *expression* times *integer*. Otherwise, the length attribute depends on the data type of the result:

- 4000 for VARBINARY and VARCHAR
- 2000 for VARGRAPHIC

The actual length of the result is the actual length of *expression* times *integer*. If the actual length of the result string exceeds the maximum for the return type, an error occurs.

Example 1: Repeat 'abc' two times to create 'abcabc'.

```
SELECT REPEAT('abc',2)
  FROM SYSIBM.SYSDUMMY1;
```

Example 2: List the phrase 'REPEAT THIS' five times. Use the CHAR function to limit the output to 60 bytes.

```
SELECT CHAR(REPEAT('REPEAT THIS',5), 60)
  FROM SYSIBM.SYSDUMMY1;
```

This example results in 'REPEAT THISREPEAT THISREPEAT THISREPEAT THISREPEAT THIS   '.

Example 3: For the following query, the LENGTH function returns a value of 0 because the result of repeating a string zero times is an empty string, which is a zero-length string.

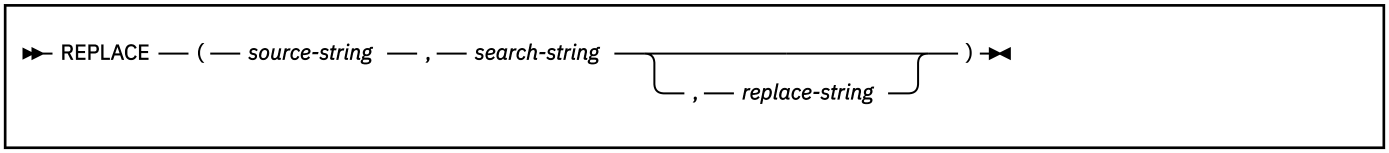
```
SELECT LENGTH(REPEAT('REPEAT THIS',0))
  FROM SYSIBM.SYSDUMMY1;
```

Example 4: For the following query, the LENGTH function returns a value of 0 because the result of repeating an empty string any number of times is an empty string, which is a zero-length string.

```
SELECT LENGTH(REPEAT('', 5))
  FROM SYSIBM.SYSDUMMY1;
```

REPLACE

The REPLACE function replaces all occurrences of *search-string* in *source-string* with *replace-string*. If *search-string* is not found in *source-string*, *source-string* is returned unchanged.



The schema is SYSIBM.

source-string

An expression that specifies the source string. The expression must return a value that is a built-in character string, graphic string, or binary string data type that is not a LOB and it cannot be an empty string.

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type.

The actual length of *source-string* must be 32764 bytes or less for character and binary strings or 16382 or less for graphic strings.

search-string

An expression that specifies the string to be removed from the source string. The expression must return a value that is a built-in character string, graphic string, or binary string data type that is not a LOB; the value cannot be an empty string.

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type.

The actual length of *search-string* must be 4000 bytes or less for character and binary strings or 2000 or less for graphic strings, unless the CCISD of *search-string* is Unicode DBCS. If the CCSID is Unicode DBCS, the actual length must be 16382 or less.

replace-string

An expression that specifies the replacement string. The expression must return a value that is a built-in character string, graphic string, or binary string data type that is not a LOB.

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type.

The actual length of *replace-string* must be 32764 bytes or less for character and binary strings or 16382 or less for graphic strings.

If *replace-string* is not specified or is an empty string, nothing replaces the string that is removed from the source string.

All three arguments must have compatible data types. If the expressions have different CCSID sets, then the expressions are converted to the CCSID set of *source-string*.

The data type of the result of the function depends on the data type of *source-string*, *search-string*, and *replace-string*:

- VARCHAR if *source-string* is a character string. The encoding scheme of the result is the same as *source-string*. The CCSID of the result depends on the arguments:
  - If *source-string*, *search-string*, or *replace-string* is bit data, the result is bit data.
  - If *source-string*, *search-string*, and *replace-string* are all SBCS Unicode data, the CCSID of the result is the CCSID for SBCS Unicode data.
  - If *source-string* is SBCS Unicode data, and *search-string* or *replace-string* is not SBCS Unicode data, the CCSID of the result is the mixed CCSID for Unicode data.
  - Otherwise, the CCSID of the result is the mixed CCSID that corresponds to the CCSID of *source-string*. However, if the input is EBCDIC or ASCII and there is no corresponding system CCSID for mixed, the CCSID of the result is the CCSID of *source-string*.
- VARGRAPHIC if *source-string* is a graphic. The encoding scheme of the result is the same as *source-string*. The CCSID of the result is the same as the CCSID of *source-string*.
- VARBINARY if *source-string*, *search-string*, and *replace-string* are binary strings.

The length attribute of the result depends on the arguments:

- If the length attribute of *replace-string* is less than or equal to the length attribute of *search-string*, the length attribute of the result is the length attribute of *source-string*.
- If the length attribute of *replace-string* is greater than the length attribute of *search-string*, the length attribute of the result is determined as follows depending on the data type of the result:

- For VARCHAR or VARBINARY:
  - If `L1 < = 4000`, the length attribute of the result is `MIN(4000, (L3*(L1/L2)) + MOD(L1,L2))`
  - Otherwise, the length attribute of the result is `MIN(32764, (L3*(L1/L2)) + MOD(L1,L2))`
- For VARGRAPHIC:
  - If `L1 < = 2000`, the length attribute of the result is `MIN(2000, (L3*(L1/L2)) + MOD(L1,L2))`
  - Otherwise, the length attribute of the result is `MIN(16382, (L3*(L1/L2)) + MOD(L1,L2))`

where:

L1 is the length attribute of *source-string*
L2 is the length attribute of *search-string* if the search string is a string constant. Otherwise, L2 is 1.
L3 is the length attribute of *replace-string*

If the result is a character string or binary string, the length attribute of the result must not exceed 32764. If the result is a graphic string, the length attribute of the result must not exceed 16382.

The actual length of the result is the actual length of *source-string* plus the number of occurrences of *search-string* that exist in *source-string* multiplied by the actual length of *replace-string* minus the actual length of *search-string*. If the actual length of the result string exceeds the maximum for the return data type, an error occurs.

The result can be null; if any argument is null, the result is the null value.

Examples

Example 1

Replace all occurrences of the character 'N' in the string 'DINING' with 'VID'. Use the CHAR function to limit the output to 10 bytes.

```
SELECT CHAR(REPLACE('DINING','N','VID'),10)
  FROM SYSIBM.SYSDUMMY1;
```

The result is the string 'DIVIDIVIDG'.

Example 2

Replace string 'ABC' in the string 'ABCXYZ' with nothing, which is the same as removing 'ABC' from the string.

```
SELECT REPLACE('ABCXYZ','ABC','')
  FROM SYSIBM.SYSDUMMY1;
```

The result is the string 'XYZ'.

Example 3

Replace string 'ABC' in the string 'ABCCABCC' with 'AB'. This example illustrates that the result can still contain the string that is to be replaced (in this case, 'ABC') because all occurrences of the string to be replaced are identified prior to any replacement.

```
SELECT REPLACE('ABCCABCC','ABC','AB')
  FROM SYSIBM.SYSDUMMY1;
```

The result is the string 'ABCABC'.

Related concepts

Character strings
A *character string* is a sequence of bytes. The length of the string is the number of bytes in the sequence. If the length is zero, the value is called the *empty string*. The empty string should not be confused with the null value.

Binary strings

A *binary string* is a sequence of bytes.

Graphic strings
A *graphic string* is a sequence of double-byte characters.

RID

The RID function returns the record ID (RID) of a row. The RID is used to uniquely identify a row.

```
▶▶─ RID( table-designator ) ─▶◀
```

The schema is SYSIBM.

The function might return a different value when it is invoked multiple times for a row. For example, after the REORG utility is run, the RID function might return a different value for a row than would have been returned prior to the REORG utility being run. The RID function is not deterministic.

table-designator

table-designator must be an exposed name that uniquely identifies a base table, a view, or a nested table expression of a subselect in which the function is referenced.

If *table-designator* specifies a view or a nested table expression, the RID function returns the RID of the base table of the view or nested table expression. The specified view or nested table expression must contain only one base table in its outer subselect.

table-designator must not identify:

- A table function
- A collection-derived table
- An alias, a synonym, or a materialized view
- A nested table expression that is materialized
- A system-period temporal table, if the system time sensitive bind option is YES
- An archive-enabled table, if one of the following conditions is true:
  - For a static statement, the archive sensitive option in effect is YES.
  - For a dynamic statement, the archive sensitive option in effect is YES, and the GET_ARCHIVE built-in global variable is set to 'Y'.

The result of the function is BIGINT. The result can be null.

Notes

Considerations for RID values:

Db2 might reuse RID numbers when a REORG operation is performed. If the RID function is used to obtain a value for a row and an application depends on that value remaining the same as long as the row exists, consider the following alternatives:

- Add a ROWID column to the table to provide a value that can be associated with each row, rather than invoking the RID function to generate a value for a row.
- Define a primary key for the table, using the columns of the primary key to ensure uniqueness, rather than invoking the RID function to generate a value for a row.

Examples

Example 1:

Return the RID and last name of employees who are in department '20':

```
SELECT RID(EMP), LASTNAME
 FROM EMP
 WHERE DEPTNO = '20';
```

Example 2:

Return the RID and last name of employees who are in department '20', in a query that specifies a correlation name of A for table EMP. A is the exposed name for table EMP, so it is used as the argument to the RID function.

```
SELECT RID(A), LASTNAME
 FROM EMP AS A
 WHERE DEPTNO = '20';
```

If EMP is specified as the argument to the RID function instead of the exposed name, A, an error is returned.

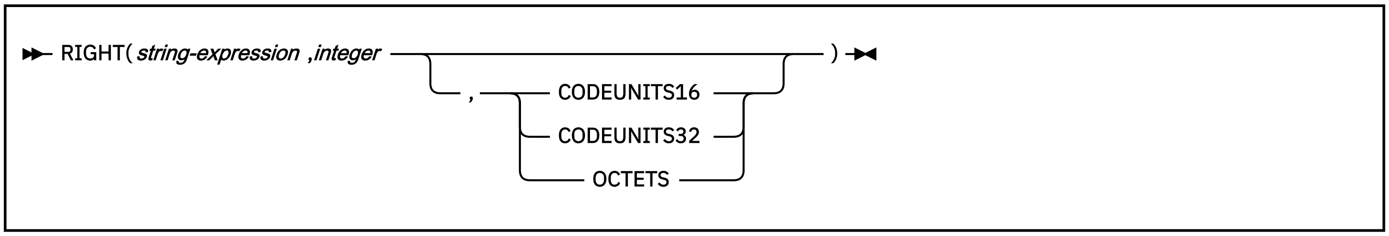
Example 3:

Set the host variable *HV_EMP_RID* as the value of the RID for the employee with the employee number of '3500':

```
SELECT RID(EMP) INTO :HV_EMP_RID
 FROM EMP
 WHERE EMPNO = '3500';
```

RIGHT

The RIGHT function returns a string that consists of the specified number of rightmost bytes or specified string unit from a string.



The schema is SYSIBM.

string-expression

An expression that specifies the string from which the result is derived. The string must be any built-in string data type. A substring of *string-expression* is zero or more contiguous code points of *string-expression*. A partial surrogate character in the expression is replaced with a blank.

The string can contain mixed data. Depending on the units that are specified to evaluate the function, the result is not necessarily a properly formed mixed data character string.

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type.

integer

An expression that specifies the length of the result. The value must be an integer between 0 and *n*, where *n* is the length attribute of *string-expression*, expressed in the units that are either implicitly or explicitly specified.

The argument can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34) which is then assigned to an INTEGER value.

If CODEUNITS16 or CODEUNITS32 is specified, see "Determining the length attribute of the final result" on page 108 for information about how to calculate the length attribute of the result string.

CODEUNITS16, CODEUNITS32, or OCTETS

Specifies the unit that is used to express *integer*. If *string-expression* is a character string that is defined as bit data, CODEUNITS16 and CODEUNITS32 cannot be specified. If *string-expression* is a graphic string, OCTETS cannot be specified. If *string-expression* is a binary string, CODEUNITS16, CODEUNITS32, and OCTETS cannot be specified.

CODEUNITS16

Specifies that *integer* is expressed in terms of 16-bit UTF-16 code units.

CODEUNITS32
Specifies that *integer* is expressed in terms of 32-bit UTF-32 code units.

OCTETS
Specifies that *integer* is expressed in terms of bytes.

For more information about CODEUNITS16, CODEUNITS32, and OCTETS, see “String unit specifications” on page 106.

The *string-expression* is effectively padded on the right with the necessary number of padding characters so that the specified substring of *string-expression* always exists. The encoding scheme of the data determines the padding character:

- For ASCII SBCS data or ASCII mixed data, the padding character is X'20'.
- For ASCII DBCS data, the padding character depends on the CCSID; for example, for Japanese (CCSID 301) the padding character is X'8140', while for simplified Chinese it is X'A1A1'.
- For EBCDIC SBCS data or EBCDIC mixed data, the padding character is X'40'.
- For EBCDIC DBCS data, the padding character is X'4040'.
- For Unicode SBCS data or UTF-8 data (Unicode mixed data), the padding character is X'20'.
- For UTF-16 data (Unicode DBCS data), the padding character is X'0020'.
- For binary data, the padding character is X'00'.

The result of the function is a varying-length string with a length attribute that is the same as the length attribute of *string-expression* and a data type that depends on the data type of *string-expression*:

- VARBINARY if *string-expression* is BINARY or VARBINARY
- VARCHAR if *string-expression* is CHAR or VARCHAR
- CLOB if *string-expression* is CLOB
- VARGRAPHIC if *string-expression* is GRAPHIC or VARGRAPHIC
- DBCLOB if *string-expression* is DBCLOB
- BLOB if *string-expression* is BLOB

The actual length of the result is determined from *integer*.

The result can be null; if any argument is null, the result is the null value.

The CCSID of the result is the same as that of *string-expression*.

Notes

Syntax alternatives:
FL 506 STRRIGHT is a synonym for RIGHT.

Examples

Example 1: Assume that host variable *ALPHA* has a value of 'ABCDEF'. The following statement returns the value 'DEF', which are the three rightmost characters in *ALPHA*.

```
SELECT RIGHT(ALPHA,3)
  FROM SYSIBM.SYSDUMMY1;
```

Example 2: The following statement returns a zero length string.

```
SELECT RIGHT('ABCABC',0)
  FROM SYSIBM.SYSDUMMY1;
```

Example 3: FIRSTNME is a VARCHAR(12) column in table T1. When FIRSTNME has the 6-character string 'Jürgen' as a value:

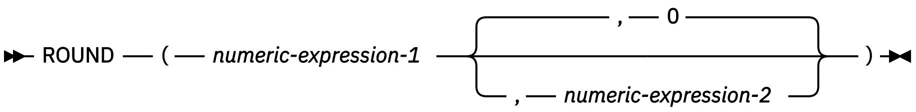
```
Function ...                    Returns ...
RIGHT(FIRSTNME,5,CODEUNITS32)   'ürgen'  -- x'C3BC7267656E'
RIGHT(FIRSTNME,5,CODEUNITS16)        'ürgen'  -- x'C3BC7267656E'
RIGHT(FIRSTNME,5,OCTETS)             ' rgen'  -- x'207267656E'   A truncated string
```

Example 4: In the following example, the last invocation of the RIGHT function returns a partial surrogate character:

```
Function ...                         Returns ...
RIGHT('Jürgen',5,CODEUNITS32)        'ürgen'       -- x'C3BC7267656E'
RIGHT('Jürgen',5,CODEUNITS16)        'ürgen'       -- x'C3BC7267656E'
RIGHT('Jürgen',5,OCTETS)             ' rgen'       -- x'207267656E'   A truncated string
HEX(RIGHT('Jürgen',5))               x'BC7267656E' -- A partial character followed by 'rgen'
```

ROUND

The ROUND function returns a number that is rounded to the specified number of places to the right or left of the decimal place.



The schema is SYSIBM.

numeric-expression-1

An expression that returns a value of any built-in numeric data type.

If *expression-1* is a decimal floating-point data type, the DECFLOAT ROUNDING MODE will not be used. The rounding behavior of ROUND corresponds to a value of ROUND_HALF_UP. If you want a different rounding behavior, use the QUANTIZE function.

The argument can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34).

numeric-expression-2

An expression that returns a value that is a built-in numeric, character string or graphic string data type. If the value is not of type INTEGER, it is implicitly cast to INTEGER before evaluating the function.

The absolute value of integer specifies the number of places to the right of the decimal point for the result if *numeric-expression-2* is not negative. If *numeric-expression-2* is negative, *numeric-expression-1* is rounded to the sum of the absolute value of *numeric-expression-2*+1 number of places to the left of the decimal point.

If the absolute value of *numeric-expression-2* is larger than the number of digits to the left of the decimal point, the result is 0. (For example, `ROUND(748.58,-4)` returns 0.)

If *numeric-expression-1* is positive, a digit value of 5 is rounded to the next higher positive number. If *numeric-expression-1* is negative, a digit value of 5 is rounded to the next lower negative number.

The result of the function has the same data type and length attribute as the first argument except that the precision is increased by one if the argument is DECIMAL and the precision is less than 31. For example, an argument with a data type of DECIMAL(5,2) results in DECIMAL(6,2). An argument with a data type of DECIMAL(31,2) results in DECIMAL(31,2).

The result can be null; if any argument is null, the result is the null value.

Example 1: Calculate the number '873.726' rounded to '2', '1', '0', '-1', and '-2' decimal places respectively.

```
SELECT ROUND(873.726,2),
       ROUND(873.726,1),
       ROUND(873.726,0),
       ROUND(873.726,-1),
       ROUND(873.726,-2),
       ROUND(873.726,-3),
       ROUND(873.726,-4)
  FROM SYSIBM.SYSDUMMY1;
```

This example returns the values '0873.730', '0873.700', '0874.000', '0870.000', '0900.000', '1000.000', and '0000.000'.

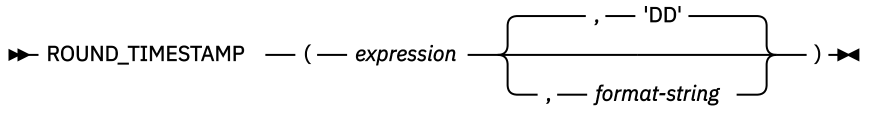
Example 2: To demonstrate how numbers are rounded in positive and negative values, calculate the numbers '3.5', '3.1', '-3.1', '-3.5' rounded to '0' decimal places.

```
    SELECT ROUND(3.5,0),
           ROUND(3.1,0),
           ROUND(-3.1,0),
           ROUND(-3.5,0)
      FROM SYSIBM.SYSDUMMY1;
```

This example returns the values '04.0', '03.0', '-03.0', and '-04.0'. (Notice that in the positive value '3.5' is rounded up to the next higher number while in the negative value '-3.5' is rounded down to the next lower negative number.)

ROUND_TIMESTAMP

The ROUND_TIMESTAMP scalar function returns a timestamp that is rounded to the unit that is specified by the timestamp format string. If *format-string* is not specified, *expression* is rounded to the nearest day, as if 'DD' was specified for format-string.



The schema is SYSIBM.

expression

FL 507 An expression that returns a value of any of the following built-in data types: a date, a timestamp, a character string, or a graphic string. If *expression* is a character or graphic string, it must not be a CLOB or DBCLOB, and its value must be a valid string representation of a timestamp with an actual length that is not greater than 255 bytes. A time zone in a string representation of a timestamp is ignored. For the valid formats of string representations of dates and timestamps, see “String representations of datetime values” on page 120.

Passthrough-only support: FL 507 If *expression* is a date, Db2 passes the function through to IBM Db2 Analytics Accelerator as a passthrough-only expression. For more information, see Accelerating queries with passthrough-only expressions.

format-string

An expression that returns a built-in character string or graphic string data type, with a length that is not greater than 255 bytes. *format-string* contains a template of how the timestamp represented by expression should be rounded. For example, if *format-string* is 'DD', the timestamp that is represented by *expression* is rounded to the nearest day. *format-string* must be a valid template for a timestamp, and not include leading or trailing blanks.

Allowable values for *format-string* are listed in the following table.

Table 88. ROUND_TIMESTAMP and TRUNC_TIMESTAMP format models

Format model	Description of rounding or truncating for the format model	ROUND_TIMESTAMP example	TRUNC_TIMESTAMP example
CC SCC	Century. One greater than the first two digits of a four digit year. For ROUND_TIMESTAMP, rounds up on the 50th year of the century.	Input Value: 1897-12-04-12.22.22.000000 Result: 1901-01-01-00.00.00.000000	Input Value: 1897-12-04-12.22.22.000000 Result: 1801-01-01-00.00.00.000000
SYYYY YYYY YEAR SYEAR YYY YY Y	Year. For ROUND_TIMESTAMP, rounds up on July 1 to January 1st of the next year.	Input Value: 1897-12-04-12.22.22.000000 Result: 1898-01-01-00.00.00.000000	Input Value: 1897-12-04-12.22.22.000000 Result: 1897-01-01-00.00.00.000000
IYYY IYY IY I	ISO year. For ROUND_TIMESTAMP, rounds up on July 1 to the first day of the next ISO year. The first day of the ISO year is defined as the Monday of the first ISO week.	Input Value: 1897-12-04-12.22.22.000000 Result: 1898-01-03-00.00.00.000000	Input Value: 1897-12-04-12.22.22.000000 Result: 1897-01-04-00.00.00.000000
Q	Quarter. For ROUND_TIMESTAMP, rounds up on the 16th day of the second month of the quarter.	Input Value: 1999-06-04-12.12.30.000000 Result: 1999-07-01-00.00.00.000000	Input Value: 1999-06-04-12.12.30.000000 Result: 1999-04-01-00.00.00.000000
MONTH MON MM RM	Month. For ROUND_TIMESTAMP, rounds up on the 16th day of the month.	Input Value: 1999-06-18-12.12.30.000000 Result: 1999-07-01-00.00.00.000000	Input Value: 1999-06-18-12.12.30.000000 Result: 1999-06-01-00.00.00.000000

Table 88. ROUND_TIMESTAMP and TRUNC_TIMESTAMP format models (continued)

Format model	Description of rounding or truncating for the format model	ROUND_TIMESTAMP example	TRUNC_TIMESTAMP example
WW	Same day of the week as the first day of the year. For ROUND_TIMESTAMP, rounds up on the 12th hour of the 4th day of the week, with respect to the first day of the year.	Input Value: 2000-05-05-12.12.30.000000 Result: 2000-05-06-00.00.00.000000	Input Value: 2000-05-05-12.12.30.000000 Result: 2000-04-29-00.00.00.000000
IW	Same day of the week as the first day of the ISO year. For ROUND_TIMESTAMP, rounds up on the 12th hour of the 4th day of the week, with respect to the first day of the ISO year.	Input Value: 2000-05-05-12.12.30.000000 Result: 2000-05-08-00.00.00.000000	Input Value: 2000-05-05-12.12.30.000000 Result: 2000-05-01-00.00.00.000000
W	Same day of the week as the first day of the month. For ROUND_TIMESTAMP, rounds up on the 12th hour of the 4th day of the week, with respect to the first day of the month.	Input Value: 2000-06-21-12.12.30.000000 Result: 2000-06-22-00.00.00.000000	Input Value: 2000-06-21-12.12.30.000000 Result: 2000-06-15-00.00.00.000000
DDD DD J	Day. For ROUND_TIMESTAMP, rounds up on the 12th hour of the day.	Input Value: 2000-05-17-12.59.59.000000 Result: 2000-05-18-00.00.00.000000	Input Value: 2000-05-17-12.59.59.000000 Result: 2000-05-17-00.00.00.000000
DAY DY D	Starting day of the week. For ROUND_TIMESTAMP, rounds up with respect to the 12th hour of the 4th day of the week. The first day of the week is always Sunday.	Input Value: 2000-05-17-12.59.59.000000 Result: 2000-05-21-00.00.00.000000	Input Value: 2000-05-17-12.59.59.000000 Result: 2000-05-14-00.00.00.000000

Table 88. ROUND_TIMESTAMP and TRUNC_TIMESTAMP format models (continued)

Format model	Description of rounding or truncating for the format model	ROUND_TIMESTAMP example	TRUNC_TIMESTAMP example
HH HH12 HH24	Hour. For ROUND_TIMESTAMP, rounds up at 30 minutes.	Input Value: 2000-05-17-23.59.59.000000 Result: 2000-05-18-00.00.00.000000	Input Value: 2000-05-17-23.59.59.000000 Result: 2000-05-17-23.00.00.000000
MI	Minute. For ROUND_TIMESTAMP, rounds up at 30 seconds.	Input Value: 2000-05-17-23.58.45.000000 Result: 2000-05-17-23.59.00.000000	Input Value: 2000-05-17-23.58.45.000000 Result: 2000-05-17-23.58.00.000000
SS	Second. For ROUND_TIMESTAMP, rounds up at 500000 microseconds.	Input Value: 2000-05-17-23.58.45.500000 Result: 2000-05-17-23.58.46.000000	Input Value: 2000-05-17-23.58.45.500000 Result: 2000-05-17-23.58.45.000000

If *expression* does not have data type TIMESTAMP WITHOUT TIME ZONE, *expression* is cast as follows:

- If *expression* is a TIMESTAMP WITH TIME ZONE value, *expression* is cast to TIMESTAMP WITHOUT TIME ZONE, with the same precision as *expression*.
- Otherwise, *expression* is cast to TIMESTAMP(6) WITHOUT TIME ZONE.

The result of the function has the same data type as the data type to which *expression* is cast.

The result can be null; if any argument is null, the result is the null value.

The result CCSID is the appropriate CCSID of the argument encoding scheme and the result subtype is the appropriate subtype of the CCSID.

Examples

- Set the host variable *RND_TMSTMP* with the input timestamp rounded to the nearest year value.

```
   SET :RND_TMSTMP = ROUND_TIMESTAMP(TIMESTAMP_FORMAT('2000-08-14 17:30:00',
                                        'YYYY-MM-DD HH24:MI:SS'), 'YEAR');
```

  The value set is '2001-01-01-00.00.00.000000'.

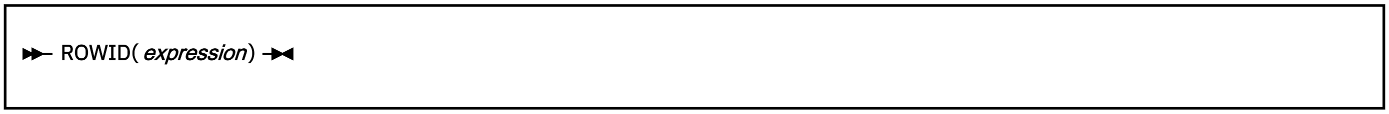
- Assume *PRSTSZ* is an SQL variable with the TIMESTAMP WITH TIME ZONE value '2008-04-15.20.00.000000-08:30'. The input value is first cast to TIMESTAMP WITHOUT TIME ZONE (as '2008-04-15.20.00.000000') for the ROUND_TIMESTAMP function.

```
SELECT ROUND_TIMESTAMP(PRSTSZ)
    FROM PROJECT;
```

  The ROUND_TIMESTAMP function returns a TIMESTAMP WITHOUT TIME ZONE value of '2008-04-16.00.00.000000'.

ROWID

The ROWID function returns a row ID representation of its argument.



The schema is SYSIBM.

The argument must be an expression that returns a value of a built-in character string data type, other than a CLOB, with a maximum length that is no greater than 255 bytes. Although the character string can contain any value, it is recommended that the character string contain a ROWID value that was previously generated by Db2 to ensure a valid ROWID value is returned. For example, the function can be used to convert a ROWID value that was cast to a CHAR value back to a ROWID value.

If the actual length of *expression* is less than 40, the result is not padded. If the actual length of *expression* is greater than 40, the result is truncated. If non-blank characters are truncated, a warning is returned.

The result of the function is a ROWID value.

The length attribute of the result is 40. The actual length of the result is the length of *expression*.

The result can be null; if the argument is null, the result is the null value.

A null ROWID value cannot be used as the value for a row ID column in the database.

Examples

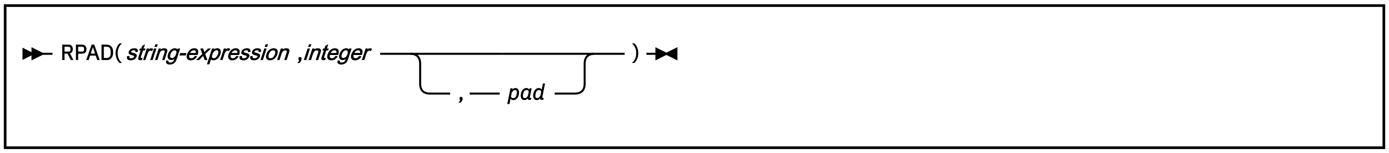
Example 1:

Assume that table EMPLOYEE contains a row ID column, 'EMP_ROWID'. Also assume that the table contains a row that is identified by a ROWID value that is equivalent to X'F0DFD230E3C0D80D81C201AA0A280100000000000203'. Using direct row access, select the employee number for that row.

```
SELECT EMPNO
  FROM EMPLOYEE
  WHERE EMP_ROWID=ROWID(X'F0DFD230E3C0D80D81C201AA0A280100000000000203');
```

RPAD

The RPAD function returns a string that is padded on the right with blanks or a specified string.



The schema is SYSIBM.

The RPAD function returns a string composed of *string-expression* padded on the right, with *pad* or blanks. The RPAD function treats leading or trailing blanks in *string-expression* as significant. Padding will only occur if the actual length of *string-expression* is less than *integer*, and *pad* is not an empty string.

string-expression

An expression that specifies the source string. The expression must return a value that is a built-in string data type that is not a LOB.

integer

An integer constant that specifies the length of the result. The value must be zero or a positive integer that is less than or equal to *n*, where *n* is 32704 if *string-expression* is a character or binary string, or where *n* is 16352 if *string-expression* is a graphic string.

pad

An expression that specifies the string with which to pad. The expression must return a value that is a built-in string data type that is not a LOB. If *pad* is not specified, the pad character is determined as follows:

- SBCS blank character if *string-expression* is a character string.
- DBCS blank character if *string-expression* is a graphic string.
- Hexadecimal zero (X'00'), if *string-expression* is a binary string.

The result of the function is a varying length string that has the same CCSID of *string-expression*. *string-expression* and *pad* must have compatible data types. If the string expressions have different CCSID sets, then *pad* is converted to the CCSID set of *string-expression*. If either *string-expression* or *pad* is FOR BIT DATA, no character conversion occurs. The actual length of the result is determined from *integer*.

The length attribute of the result depends on *integer*. If *integer* is greater than 0, the length attribute of the result is *integer*. If *integer* is 0, the length attribute of the result is 1.

The actual length of the result is determined from *integer*. If *integer* is 0, the actual length is 0, and the result is the empty string. If *integer* is less than the actual length of *string-expression*, the actual length is *integer* and the result is truncated.

The result can be null; if any argument is null, the result is the null value.

Example 1: Assume that NAME is a VARCHAR(15) column that contains the values 'Chris', 'Meg', and 'Jeff'. The following query will completely pad out a value on the right with periods.

```
SELECT RPAD(NAME,15,'.' ) AS NAME
  FROM T1;
```

The results are similar to the following output:

```
NAME
---------------

Chris..........
Meg............
Jeff...........
```

Example 2: Similar to Example 1, the following query will completely pad out a value on the right with *pad* (note that in some cases there is a partial instance of the padding specification):

```
SELECT RPAD(NAME,15,'123' ) AS NAME
  FROM T1;
```

The results are similar to the following output:

```
NAME
---------------

Chris1231231231
Meg123123123123
Jeff12312312312
```

Example 3: Similarly, the following query will only pad each value to a length of 5:

```
SELECT RPAD(NAME,5,'.') AS NAME
  FROM T1;
```

The results are similar to the following output:

```
NAME
---------------

Chris
Meg..
Jeff.
```

Example 4: Assume that NAME is a CHAR(15) column that contains the values 'Chris', 'Meg', and 'Jeff'. Note that the result of RTRIM in the following example is a varying length string with the blanks removed:

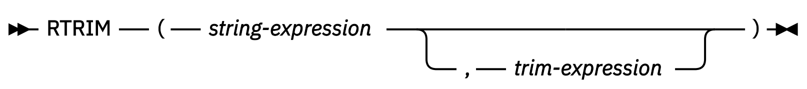
```
SELECT RPAD(RTRIM(NAME),15,'.') AS NAME
  FROM T1;
```

The results are similar to the following output:

```
NAME
---------------
Chris..........
Meg............
Jeff...........
```

RTRIM

The RTRIM function removes bytes from the end of a string expression based on the content of a trim expression.



The schema is SYSIBM.

The RTRIM function removes all of the characters contained in *trim-expression* from the end of *string-expression*. The search is done by comparing the binary representation of each character (which consists of one or more bytes) in *trim-expression* to the bytes at the end of *string-expression*. If *string-expression* is defined as FOR BIT DATA, the search is done by comparing each byte in *trim-expression* to the byte at the end of *string-expression*.

string-expression
An expression that specifies the source string. The argument must be an expression that returns a value that is a built-in string data type that is not a LOB, or a numeric data type. If the value is not a string data type, it is implicitly cast to VARCHAR before the function is evaluated. If *string-expression* is not FOR BIT DATA, *trim-expression* must not be FOR BIT DATA.

trim-expression
An expression that specifies the characters to remove from the end of *string-expression*. The expression must return a value that is a built-in string data type that is not a LOB, or a numeric data type. If the value is not a string data type, it is implicitly cast to VARCHAR before the function is evaluated.

The default for *trim-expression* depends on the data type of *string-expression*:

- A DBCS blank if *string-expression* is a DBCS graphic string. For ASCII, the CCSID determines the hex value that represents a DBCS blank. For example, for Japanese (CCSID 301), X'8140' represents a DBCS blank, while for Simplified Chinese, X'A1A1' represents a DBCS blank. For EBCDIC, X'4040' represents a DBCS blank.
- A UTF-16 or UCS-2 blank (X'0020') if *string-expression* is a Unicode graphic string.
- A value of X'00' if *string-expression* is a binary string.
- Otherwise, a single byte blank. For EBCDIC, X'40' represents a blank. When not EBCDIC, X'20' represents a blank.

string-expression and *trim-expression* must have compatible data types. If *string-expression* and *trim-expression* have different CCSID sets, *trim-expression* is converted to the CCSID of *string-expression*.

The result of the function depends on the data type of *string-expression*.

- VARCHAR if *string-expression* is a character string. If *string-expression* is defined as FOR BIT DATA, the result is FOR BIT DATA.
- VARGRAPHIC if *string-expression* is a graphic string.

- VARBINARY if *string-expression* is a binary string.

The length attribute of the result is the same as the length attribute of *string-expression*.

The actual length of the result for a character or binary string is the length of *string-expression* minus the number of bytes removed. The actual length of the result for a graphic string is the length (in number of double byte characters) of *string-expression* minus the number of double byte characters removed. If all of the characters are removed, the result is an empty string (the length is zero).

The result can be null; if the argument is null, the result is the null value.

The CCSID of the result is the same as that of *string-expression*.

Notes

Valid content for EBCDIC mixed string input:
If *string-expression* is an EBCDIC mixed string, the string must contain valid EBCDIC mixed data.

Examples

***Example:* Use the RTRIM function to remove individual numbers in the second argument from the end (right side) of the first argument:**

```
SELECT RTRIM ('123DEFG123', '321'),
             RTRIM ('12322XYZ12322222', '123'),
             RTRIM ('12321', '213'),
             RTRIM ('123XYX', '321')
        FROM SYSIBM.SYSDUMMY1
```

The result is '123DEFG', '12322XYZ', '' (empty string - all characters removed), and '123XYX' (no characters removed).

The RTRIM function does not remove instances of '1', '2', and '3' at the beginning of the string, before characters that are not '1', '2', or '3'.

***Example:* Use the RTRIM function to remove individual characters in the second argument from the end (right side) of the first argument:**

```
SELECT RTRIM ('((-78.0))' , '-0.()')
   FROM SYSIBM.SYSDUMMY1
```

The result is '((-78'.

***Example:* Use the RTRIM function to remove dollar signs and periods in the second argument from the end (right side) of the first argument:**

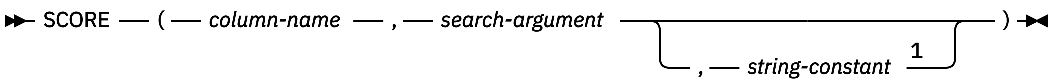
```
SELECT RTRIM ('...$VAR$...', '$.')
   FROM SYSIBM.SYSDUMMY1
```

The result is '...$VAR'.

SCORE

The SCORE function searches a text search index using criteria that are specified in a search argument and returns a relevance score that measures how well a document matches the query.

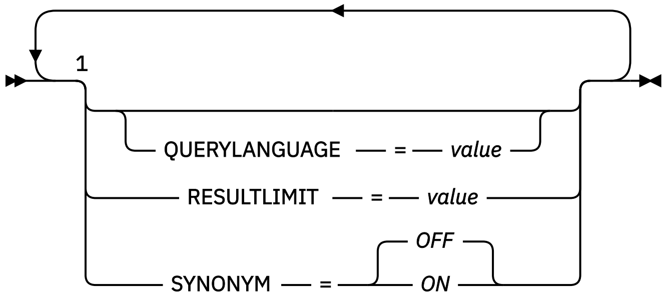
Requirement: To use the SCORE function, Text Search for Db2 for z/OS must be installed and configured. See IBM Text Search for Db2 for z/OS (IBM Text Search for Db2 for z/OS Installation, Administration, and Reference) for more information.



Notes:

[1] *string-constant* must conform to the rules for the *search-argument-options*.

search-argument-options



Notes:

[1] The same clause must not be specified more than once.

The schema is SYSIBM.

column-name
Specifies a qualified or unqualified name of a column that has a text search index that is to be searched. The column must exist in the table or view that is identified in the FROM clause in the statement and the column of the table, or the column of the underlying base table of the view must have an associated text search index. The underlying expression of the column of a view must be a simple column reference to the column of an underlying table, either directly or through another nested view.

search-argument
Specifies an expression that returns a value that is a string value (except a LOB) that contains the terms to be searched for and must not be all blanks or the empty string. The actual length of the string must not exceed 4096 Unicode characters. The value is converted to Unicode before it is used to search the text search index. The maximum number of terms per query must not exceed 1024.

string-constant
Identifies a string constant that specifies the search argument options that are in effect for the function.

The options that can be specified as part of the *search-argument-options* are as follows:

QUERYLANGUAGE = *value*
Specifies the query language. The value can be any of the supported language codes. If the QUERYLANGUAGE option is not specified, the default is the language value of the text search index that is used when this function is invoked. If the language value of the text search index is AUTO, the default value for QUERYLANGUAGE is en_US.

RESULTLIMIT = *value*
Specifies the maximum number of results that are to be returned from the underlying search engine. The *value* can be an integer value between 1 and 2 147 483 647. If the RESULTLIMIT option is not specified, no result limit is in effect for the query.

This scalar function cannot be called for each row of the result table, depending on the plan that the optimizer chooses. This function can be called once for the query to the underlying search engine, and a result set of all of the primary keys that match are returned from the search engine. This result set is then joined to the table containing the column to identify the result rows. In this case, the RESULTLIMIT value acts like a FETCH FIRST ?? ROWS from the underlying text search engine and can be used as an optimization. If the search engine is called for each row of the result because the optimizer determines that is the best plan, then the RESULTLIMIT option has no effect.

SYNONYM = *OFF* or SYNONYM = *ON*

Specifies whether to use a synonym dictionary that is associated with the text search index. Use the Synonym Tool to add a synonym dictionary to the collection. The default is OFF.

OFF

Do not use a synonym dictionary.

ON

Use the synonym dictionary that is associated with the text search index.

The result of the function is a double-precision floating-point number. If the second argument can be null, the result can be null. If the second argument is null, the result is the null value. If the third argument is null, the result is as if the third argument was not specified.

The result is greater than 0 but less than 1 if the column contains a match for the search criteria that the search argument specifies. The better a document matches the query, the more relevant the score and the larger the result value. If the column does not contain a match, the result is 0.

Notes

Determinism:

SCORE is a non-deterministic function.

Examples

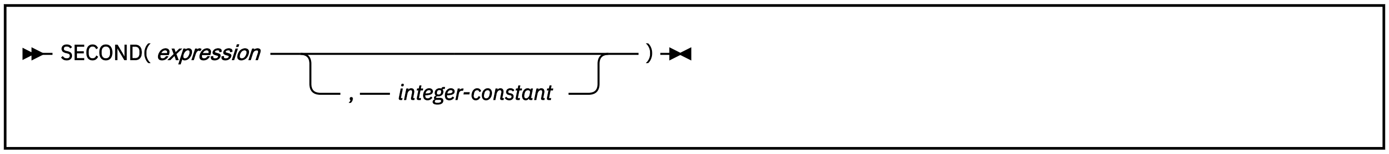
Assume that information about employees' skills are stored in a table named EMP_RESUME. The following statement generates a list of employees in the order of how well their resumes matches the query "programmer AND (java OR cobol)", along with a relevance value that is normalized between 0 (zero) and 100.

```
SELECT EMPNO, INTEGER(SCORE(RESUME, 'programmer AND
    (java OR cobol)') * 100) AS RELEVANCE
    FROM EMP_RESUME
    WHERE RESUME_FORMAT = 'ascii'
    AND CONTAINS(RESUME, 'programmer AND (java OR cobol)') = 1
    ORDER BY RELEVANCE DESC
```

Db2 first evaluates the CONTAINS predicate in the WHERE clause, and therefore, does not evaluate the SCORE function in the SELECT list for every row of the table. In this case, the arguments for SCORE and CONTAINS must be identical.

SECOND

The SECOND function returns the seconds part of a value with optional fractional seconds.



The schema is SYSIBM.

expression

expression must be an expression that returns a value of one of the following built-in data types: a time, a timestamp, a character string, a graphic string, or a numeric data type.

- If *expression* is a character or graphic string, it must not be a CLOB or DBCLOB, and its value must be a valid string representation of a time or timestamp with an actual length that is not greater than 255 bytes. For the valid formats of string representations of times and timestamps, see "String representations of datetime values" on page 120.
- If *expression* is a number, it must be a time or timestamp duration. For the valid formats of time and timestamp durations, see "Datetime operands" on page 169.

integer-constant

integer-constant must be an integer constant that represents the scale for the fractional seconds portion of *expression*. The value must be in the range 0 through 12. If *integer-constant* is not specified, the result does not include fractional seconds.

If *expression* is a timestamp with a time zone, or a valid string representation of a timestamp with a time zone, the result is determined from the UTC representation of the datetime value.

The result of the function with a single argument is a large integer. The result of the function with two arguments is DECIMAL(2+*s*,*s*) where *s* is the value of *integer-constant*.

The result can be null; if the first argument is null, the result is the null value.

The other rules depend on the data type of the argument:

If the argument is a time, timestamp, or string representation of a time or a timestamp:

The result is the seconds part of the value (0 to 59) and any fractional seconds that are included in the value. If the second argument is specified, the result includes *integer-constant* digits of the fractional seconds part of the value where applicable. If there are no fractional seconds in the value, zeros are returned.

If the argument is a time duration or timestamp duration:

The result is the seconds part of the value (-99 to 99) and any fractional seconds that are included in the value. If the second argument is specified, the result includes *integer-constant* digits of the fractional seconds part of the value where applicable. If there are no fractional seconds in the value, zeros are returned. A nonzero result has the same sign as the *expression*.

Example 1: Assume that the variable *TIME_DUR* is declared in a PL/I program as DECIMAL(6,0) and can therefore be interpreted as a time duration. When *TIME_DUR* has the value 153045, the following function returns the value 45.

```
   SECOND(:TIME_DUR)
```

Example 2: Assume that RECEIVED is a TIMESTAMP column and that one of its values is the internal equivalent of '1988-12-25-17.12.30.000000'. The following function returns the value 30.

```
   SECOND(RECEIVED)
```

Example 3: The following invocations of the SECOND function returns the same result:

```
SELECT SECOND('2003-01-02-20.10.05.123456'),
            SECOND('2003-01-02-12.10.05.123456-08:00'),
            SECOND('2003-01-03-05.10.05.123456+09:00')
        FROM SYSIBM.SYSDUMMY1;
```

For each invocation of the SECOND function in this SELECT statement, the result is 5.

When the input argument contains a time zone, the result is determined from the UTC representation of the input value. The string representations of a timestamp with a time zone in the SELECT statement all have the same UTC representation: 2003-01-02-20.10.05.123456. The second portion of the UTC representation is 5.

Example 4: Return the seconds with fractional seconds from a current timestamp with milliseconds.

```
SELECT SECOND(CURRENT_TIMESTAMP(3),3)
  FROM SYSIBM.SYSDUMMY1;
```

The SELECT statement returns a DECIMAL(5,3) value that is based on the current timestamp and could be something like `54.321`.

SIGN

The SIGN function returns an indicator of the sign of the argument.

►► SIGN(*numeric-expression*) ►◄

The schema is SYSIBM.

The returned value is one of the following values:

-1
if the argument is less than zero

- 0
if the argument is DECFLOAT negative zero

0
if the argument is zero

1
if the argument is greater than zero

The argument must be an expression that returns a value of any built-in numeric data type, except DECIMAL(31,31).

The argument can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34).

The result has the same data type and length attribute as the argument, except that precision is increased by one if the argument is DECIMAL and the scale of the argument is equal to its precision. For example, an argument with a data type of DECIMAL(5,5) will result in DECIMAL(6,5).

The result can be null; if the argument is null, the result is the null value.

Example: Assume that host variable *PROFIT* is a large integer with a value of 50000.

```
SELECT SIGN(:PROFIT)
  FROM SYSIBM.SYSDUMMY1;
```

This example returns the value 1.

SIN

The SIN function returns the sine of the argument, where the argument is an angle, expressed in radians.

►► SIN(*numeric-expression*) ►◄

The schema is SYSIBM.

The SIN and ASIN functions are inverse operations.

The argument must be an expression that returns the value of any built-in numeric data type that is not DECFLOAT. If the argument is not a double precision floating-point number, it is converted to one for processing by the function.

The result of the function is a double precision floating-point number.

The result can be null; if the argument is null, the result is the null value.

Example: Assume that host variable *SINE* is DECIMAL(2,1) with a value of 1.5. The following statement returns a double precision floating-point number with an approximate value of 0.99.

```
SELECT SIN(:SINE)
  FROM SYSIBM.SYSDUMMY1;
```

SINH

The SINH function returns the hyperbolic sine of the argument, where the argument is an angle, expressed in radians.

►►─ SINH(*numeric-expression*) ─►◄

The schema is SYSIBM.

The argument must be an expression that returns the value of any built-in numeric data type that is not DECFLOAT. If the argument is not a double precision floating-point number, it is converted to one for processing by the function.

The result of the function is a double precision floating-point number.

The result can be null; if the argument is null, the result is the null value.

Examples

Example 1:

Assume that host variable *HSINE* is DECIMAL(2,1) with a value of 1.5. The following statement returns a double precision floating-point number with an approximate value of 2.12.

```
   SELECT SINH(:HSINE)
     FROM SYSIBM.SYSDUMMY1;
```

SMALLINT

The SMALLINT function returns a small integer representation either of a number or of a string representation of a number.

Numeric to Smallint:

►►─ SMALLINT(*numeric-expression*) ─►◄

String to Smallint:

►►─ SMALLINT(*string-expression*) ─►◄

The schema is SYSIBM.

Numeric to Smallint

numeric-expression

An expression that returns a value of any built-in numeric data type.

The result is the same number that would occur if the argument were assigned to a small integer column or variable. If the whole part of the argument is not within the range of small integers, an error occurs. If present, the decimal part of the argument is truncated.

String to Smallint

string-expression

An expression that returns a value of character or graphic string (except a CLOB or DBCLOB) with a length attribute that is not greater than 255 bytes for a character string or 127 for a graphic string. The string must contain a valid string representation of a number.

The result is the same number that would result from CAST(*string-expression* AS SMALLINT). Leading and trailing blanks are eliminated and the resulting string must conform to the rules for forming an SQL integer constant.

The result of the function is a small integer.

The result can be null; if the argument is null, the result is the null value.

Notes

Syntax alternatives:
To increase the portability of applications, use the CAST specification. For more information, see "CAST specification" on page 266.

Examples

Example 1:
Using sample table DSN8C10.EMP, find the average education level (EDLEVEL) of the employees in department 'A00'. Round the result to the nearest full education level.

```
SELECT SMALLINT(AVG(EDLEVEL)+.5)
  FROM DSN8C10.EMP
  WHERE DEPT = 'A00';
```

Assuming that the five employees in the department have education levels of '19', '18', '14', '18', and '14', the result is '17'.

SOUNDEX

The SOUNDEX function returns a 4-character code that represents the sound of the words in the argument. The result can be compared to the results of the SOUNDEX function of other strings.

▶▶ SOUNDEX(*expression*) ▶◀

The schema is SYSIBM.

expression
An *expression* that must return a value of any built-in numeric, character, or graphic string data type that is not a LOB. A numeric, mixed character, or graphic string value is cast to a Unicode SBCS character string before the function is evaluated. For more information about converting numeric data to a character string, see "VARCHAR" on page 614. For more information about converting mixed or graphic strings to Unicode SBCS, see "CAST specification" on page 266.

The data type of the result is CHAR(4).

The result can be null; if the argument is null, the result is the null value.

The CCSID of the result is the Unicode SBCS CCSID.

The SOUNDEX function is useful for finding strings for which the sound is known but the precise spelling is not. It makes assumptions about the way that letters and combinations of letters sound that can help to search for words with similar sounds. The comparison of words can be done directly or by passing the strings as arguments to the DIFFERENCE function. For more information, see "DIFFERENCE" on page 449.

Example 1: Use the SOUNDEX function to find a row where the sound of the LASTNAME value closely matches the phonetic spelling of 'Loucesy':

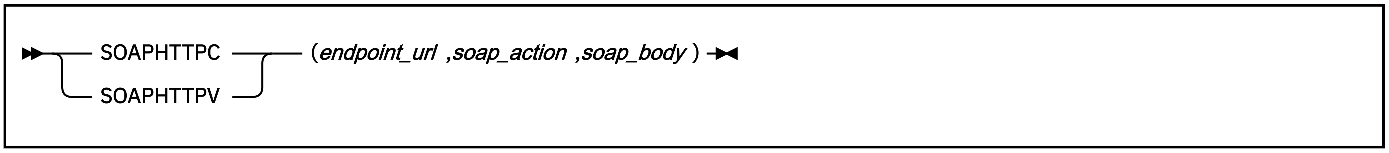
```
SELECT EMPNO, LASTNAME
   FROM DSN910.EMPLOYEE
   WHERE SOUNDEX(LASTNAME) = SOUNDEX('Loucesy');
```

This example returns the following row:

```
000110 LUCCHESSI;
```

SOAPHTTPC and SOAPHTTPV

The SOAPHTTPC function returns a CLOB representation of XML data that results from a SOAP request to the web service that is specified by the first argument. The SOAPHTTPV function returns a VARCHAR representation of XML data that results from a SOAP request to the web service that is specified by the first argument.



The schema is DB2XML.

These functions are deprecated and might not be available in future releases of Db2.

endpoint_url
An expression that returns a value of a built-in character string or graphic string data type that is not a LOB. The value specifies the URL of the web service endpoint for which Db2 is acting as a client.

soap_action
An expression that returns a value of a built-in character string or graphic string data type that is not a LOB. The value specifies a SOAP action URI reference. If it is required for the web service that is specified in *endpoint_url*, the required value is defined in the WSDL of that web service.

soap_body
An expression that returns a value of a built-in character string data type that is defined as VARCHAR(3072) or CLOB(1M). The value specifies the name of an operation with the requested namespace URI, an encoding style, and input arguments. *soap_body* can include well-formed XML content for the SOAP body. The specific operations and arguments for a web service are defined in the WSDL of the specified web service.

If the arguments can be null, the result can be null; if all of the arguments are null, the result is the null value.

The result can be null; if all of the arguments are null, the result is the null value.

Example 1: The following SQL statement retrieves information (as VARCHAR data) about a web service:

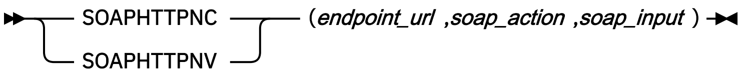
```
SELECT DB2XML.SOAPHTTPV(
     'http://www.myserver.com/services/db2sample/ivt.dadx/SOAP',
     'http://tempuri.org/db2sample/ivt.dadx',
     '<testInstallation xmlns="http://tempuri.org/db2sample/ivt.dadx" />')
   FROM SYSIBM.SYSDUMMY1
```

Example 2: The following SQL statement inserts the results (as CLOB data) from a request to a web service into a table:

```
INSERT INTO EMPLOYEE(XMLCOL)
  VALUES (DB2XML.SOAPHTTPC(
     'http://www.myserver.com/services/db2sample/list.dadx/SOAP',
     'http://tempuri.org/db2sample/list.dadx',
     '<listDepartments xmlns="http://tempuri.org/db2sample/list.dadx">
         <deptNo>A00</deptNo>
      </listDepartments>'))
```

SOAPHTTPNC and SOAPHTTPNV

The SOAPHTTPNC and SOAPHTTPNV functions allow you to specify a complete SOAP message as input and to return complete SOAP messages from the specified web service. The returned SOAP messages are CLOB or VARCHAR representations of the returned XML data.



The schema is DB2XML.

endpoint_url

Specifies the URL of the web service for which Db2 is acting as a client. *endpoint_url* is defined as a VARCHAR(4096) value. The URL is in the following format:

```
proto://[user[:password]@]hostname[:port]/[path]
```

Where *proto* can be http or https.

soap_action

Specifies a SOAP action URI reference. *soap_action* is defined as a VARCHAR(4096) value. Depending on the web server, *soap_action* might be required. If it is required for the web service that is specified in *endpoint_url*, the required value is defined in the WSDL of that web service.

soap_input

Specifies an XML document that contains the complete SOAP message. *soap_input* can contain optional SOAP headers and must contain a SOAP body that specifies the operation name and parameters to the web service. *soap_input* should be well-formed XML that is defined as VARCHAR(32672) or CLOB(1M).

Example 1: The following SQL statement retrieves information (as VARCHAR data) about a web service:

```
SELECT DB2XML.SOAPHTTPNV(
       'http://rpc.geocoder.us/service/soap/',
       '"http://rpc.geocoder.us/Geo/Coder/US#geocode_address"',
       '<?xml version="1.0" encoding="UTF-8" ?>' ||
       '<SOAP-ENV:Envelope ' ||
       'xmlns:SOAP-ENV="http://schemas.xmlsoap.org/soap/envelope/" ' ||
       'xmlns:xsd="http://www.w3.org/2001/XMLSchema" ' ||
       'xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">' ||
       '<SOAP-ENV:Body>' ||
       '<ns0:geocode_address ' ||
       'xmlns:ns0="http://rpc.geocoder.us/Geo/Coder/US/" ' ||
       'SOAP-ENV:encodingStyle="http://schemas.xmlsoap.org/soap/encoding/">' ||
       '<address xsi:type="xsd:string">555 Bailey Avenue, San Jose,' ||
       'CA,95141</address>' ||
       '</ns0:geocode_address>' ||
       '</SOAP-ENV:Body>' ||
       '</SOAP-ENV:Envelope>')
   FROM SYSIBM.SYSDUMMY1;
```

Example 2: The following SQL statement inserts the results (as CLOB data) from a request to a web service into a table:

```
INSERT INTO EMPLOYEE(XMLCOL)
  VALUES (DB2XML.SOAPHTTPNC(
     'http://www.myserver.com/services/db2sample/list.dadx/SOAP',
     'http://tempuri.org/db2sample/list.dadx',
     '<?xml version="1.0" encoding="UTF-8" ?>' ||
     '<SOAP-ENV:Envelope ' ||
     'xmlns:SOAP-ENV="http://schemas.xmlsoap.org/soap/envelope/" ' ||
     'xmlns:xsd="http://www.w3.org/2001/XMLSchema" ' ||
     'xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">' ||
     '<SOAP-ENV:Body>' ||
     '<listDepartments xmlns="http://tempuri.org/db2sample/list.dadx">
         <deptNo>A00</deptNo>
      </listDepartments>' ||
     '</SOAP-ENV:Body>' ||
     '</SOAP-ENV:Envelope>'))
```

SPACE

The SPACE function returns a character string that consists of the number of SBCS blanks that the argument specifies.

▶▶─ SPACE(*numeric-expression*) ─▶◀

The schema is SYSIBM.

numeric-expression

An expression that returns the value of any built-in integer data type. The expression specifies the number of SBCS blanks for the result, and it must be between 0 and 32764.

The argument can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34) which is then assigned to a BIGINT value.

The result of the function is a varying-length character string (VARCHAR) that contains SBCS data.

If *numeric-expression* is a constant, the length attribute of the result is the constant. Otherwise, the length attribute of the result is 4000. The actual length of the result is the value of *numeric-expression*. The actual length of the result must not be greater than the length attribute of the result.

The result can be null; if the argument is null, the result is the null value.

Example: The following statement returns a character string that consists of 5 blanks followed by a zero-length string.

```
    SELECT SPACE(5), SPACE(0)
      FROM SYSIBM.SYSDUMMY1;
```

Related concepts

Character strings
A *character string* is a sequence of bytes. The length of the string is the number of bytes in the sequence. If the length is zero, the value is called the *empty string*. The empty string should not be confused with the null value.

SQRT

The SQRT function returns the square root of the argument.

▶▶─ SQRT(*numeric-expression*) ─▶◀

The schema is SYSIBM.

The argument must be an expression that returns the value of any built-in numeric data type. If the argument is DECFLOAT, the operation is performed in DECFLOAT. Otherwise, the argument is converted to a double precision floating-point number for processing by the functions.

The argument can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34).

If the argument is DECFLOAT(*n*), the result is DECFLOAT(*n*). Otherwise, the result of the function is a double precision floating-point number. If the argument is a special decimal floating point value, the general rules for arithmetic operations apply. For more information, see "General arithmetic operation rules for DECFLOAT" on page 253

The result can be null; if the argument is null, the result is the null value.

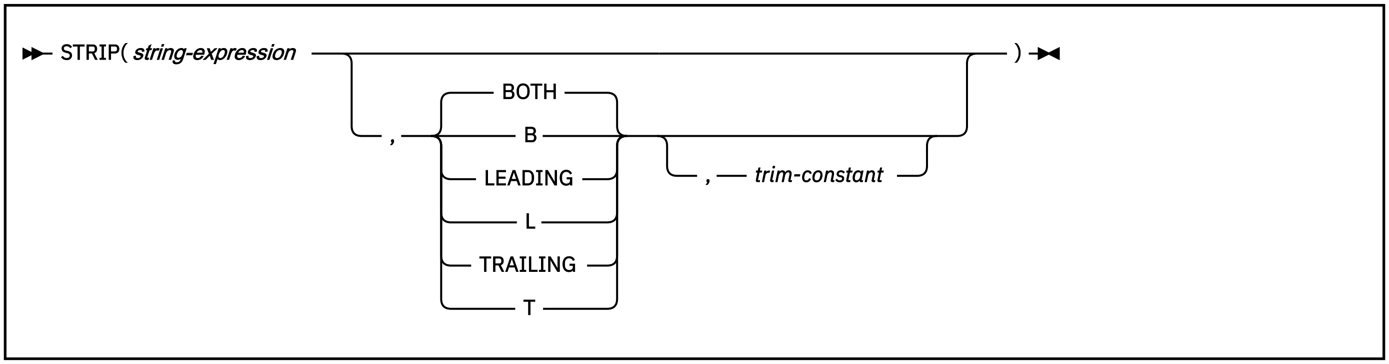
Example: Assume that host variable *SQUARE* is defined as DECIMAL(2,1) and has a value of 9.0. Find the square root of *SQUARE*.

```
   SELECT SQRT(:SQUARE)
     FROM SYSIBM.SYSDUMMY1;
```

This example returns a double precision floating-point number with an approximate value of 3.

STRIP

The STRIP function removes blanks or another specified character from the end, the beginning, or both ends of a string expression.



The schema is SYSIBM.

The STRIP function is similar to the TRIM scalar function.

Notes

Valid content for EBCDIC mixed string input:
If *string-expression* is an EBCDIC mixed string, the string must contain valid EBCDIC mixed data.

Related reference

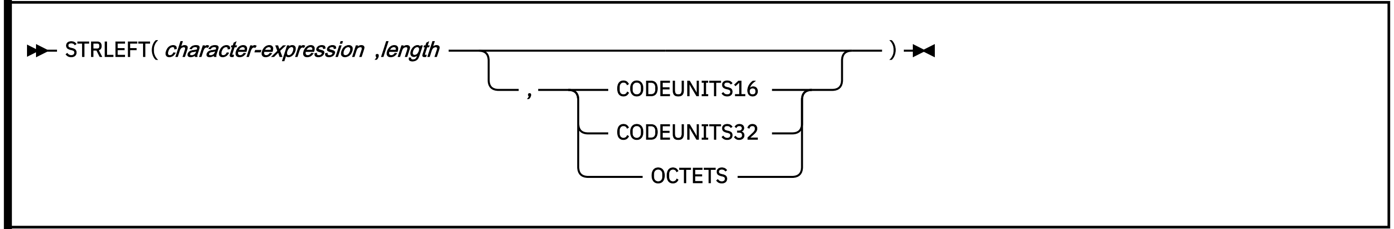
TRIM
The TRIM function removes bytes from the beginning, from the end, or from both the beginning and end of a string expression.

STRLEFT

The STRLEFT function returns a string that consists of the specified number of leftmost bytes of the specified string units.

FL 506

Character string:

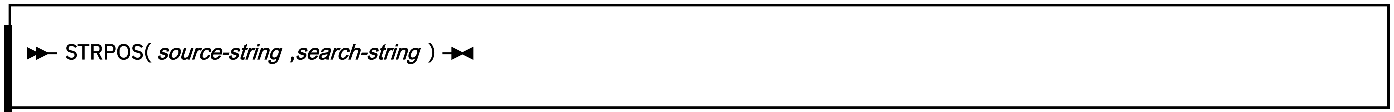


The STRLEFT function is identical to the LEFT function. For more information, see "LEFT" on page 486.

STRPOS

The STRPOS function returns the position of the first occurrence of an argument within another argument.

FL 506

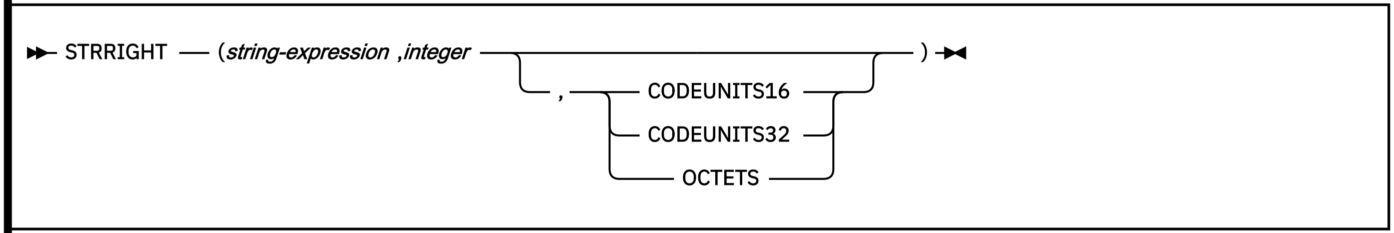


The STRPOS function is identical to the POSSTR function. For more information, see "POSSTR" on page 531.

STRRIGHT

The STRRIGHT function returns a string that consists of the specified number of rightmost bytes or specified string unit from a string.

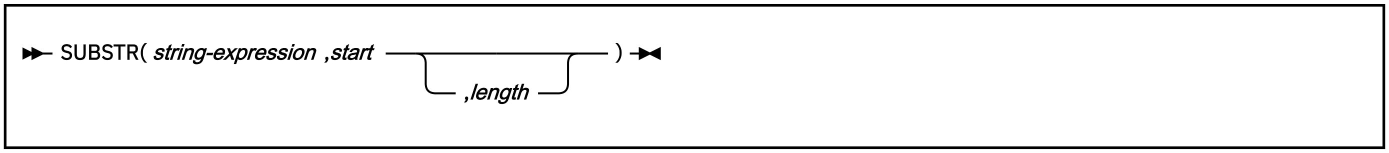
FL 506



The STRRIGHT function is identical to the RIGHT function. For more information, see "RIGHT" on page 555.

SUBSTR

The SUBSTR function returns a substring of a string.



The schema is SYSIBM.

string-expression

An expression that specifies the string from which the result is derived. The string must be a character, graphic, or binary string. If *string-expression* is a character string, the result of the function is a character string. If it is a graphic string, the result of the function is a graphic string. If it is a binary string, the result of the function is a binary string.

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type.

A substring of *string-expression* is zero or more contiguous characters of *string-expression*. If *string-expression* is a graphic string, a character is a DBCS character. If *string-expression* is a character string or a binary string, a character is a byte. The SUBSTR function accepts mixed data strings. However, because SUBSTR operates on a strict byte-count basis, the result will not necessarily be a properly formed mixed data string.

start

An expression that specifies the position within *string-expression* to be the first character of the result. The value of the large integer must be between 1 and the length attribute of *string-expression*. (The length attribute of a varying-length string is its maximum length.) A value of 1 indicates that the first character of the substring is the first character of *string-expression*.

The argument can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34) which is then assigned to an INTEGER value.

length

An expression that specifies the length of the resulting substring. If specified, *length* must be an expression that returns a value that is a built-in large integer data type.

The argument can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34) which is then assigned to an INTEGER value.

The value must be greater than or equal to 0 and less than or equal to *n*, where *n* is the length attribute of *string-expression* - *start* + 1. The specified length must not, however, be the large integer constant 0.

If *length* is explicitly specified, *string-expression* is effectively padded on the right with the necessary number of characters so that the specified substring of *string-expression* always exists. Hexadecimal zeros are used as the padding character when *string-expression* is binary data. Otherwise, a blank is used as the padding character.

If *string-expression* is a fixed-length string, omission of *length* is an implicit specification of LENGTH(*string-expression*) - *start* + 1, which is the number of characters (or bytes) from the character (or byte) specified by start to the last character (or byte) of *string-expression*. If *string-expression* is a varying-length string, omission of length is an implicit specification of the greater of zero or LENGTH(*string-expression*) - *start* + 1. If the resulting length is zero, the result is an empty string.

If *length* is explicitly specified by a large integer constant that is 255 or less, and *string-expression* is not a LOB, the result is a fixed-length string with a length attribute of *length*. If *length* is not explicitly specified, but *string-expression* is a fixed-length string and *start* is an integer constant, the result is a fixed-length string with a length attribute equal to LENGTH(*string-expression*) - *start* + 1. In all other cases, the result is a varying-length string. If *length* is explicitly specified by a large integer constant, the length attribute of the result is *length*; otherwise, the length attribute of the result is the same as the length attribute of *string-expression*.

The result can be null; if any argument is null, the result is the null value.

The CCSID of the result is the CCSID of *string-expression*.

Example 1: FIRSTNME is a VARCHAR(12) column in sample table DSN8C10.EMP. When FIRSTNME has the value 'MAUDE':

```
Function:                 Returns:
-----------------------------------
SUBSTR(FIRSTNME,2,3)      -- 'AUD'
SUBSTR(FIRSTNME,2)        -- 'AUDE'
SUBSTR(FIRSTNME,2,6)      -- 'AUDE' followed by two blanks
SUBSTR(FIRSTNME,6)        -- a zero-length string
SUBSTR(FIRSTNME,6,4)      -- four blanks
```

Example 2: Sample table DSN8C10.PROJ contains column PROJNAME, which is defined as VARCHAR(24). Select all rows from that table for which the string in PROJNAME begins with 'W L PROGRAM'.

```
SELECT * FROM DSN8C10.PROJ
  WHERE SUBSTR(PROJNAME,1,12) = 'W L PROGRAM ';
```

Assume that the table has only the rows that were supplied by Db2. Then the predicate is true for just one row, for which PROJNAME has the value 'W L PROGRAM DESIGN'. The predicate is not true for the row in which PROJNAME has the value 'W L PROGRAMMING' because, in the predicate's string constant, 'PROGRAM' is followed by a blank.

Example 3: Assume that a LOB locator named *my_loc* represents a LOB value that has a length of 1 gigabyte. Assign the first 50 bytes of the LOB value to host variable *PORTION*.

```
SET :PORTION = SUBSTR(:my_loc,1,50);
```

Example 4: Assume that host variable *RESUME* has a CLOB data type and holds an employee's resume. This example shows some of the statements that find the section of department information in the resume and assign it to host variable *DeptBuf*. First, the POSSTR function is used to find the beginning and ending location of the department information. Within the resume, the department information starts with the string 'Department Information Section' and ends immediately before the string 'Education Section'.

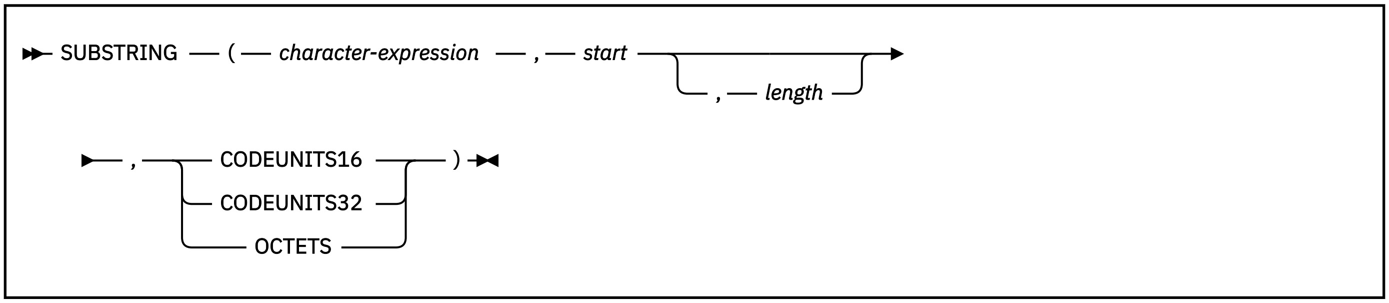
Then, using these beginning and ending positions, the SUBSTR function assigns the information to the host variable.

```
SET :DInfoBegPos = POSSTR(:RESUME, 'Department Information Section');
SET :DInfoEnPos = POSSTR(:RESUME, 'Education Section');
SET :DeptBuf = SUBSTR(:RESUME, :DInfoBegPos, :DInfoEnPos - :DInfoBegPos);
```

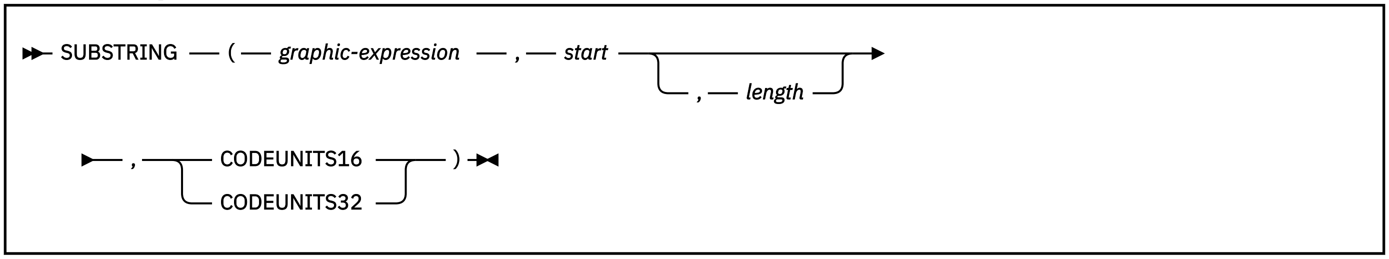
SUBSTRING

The SUBSTRING function returns a substring of a string.

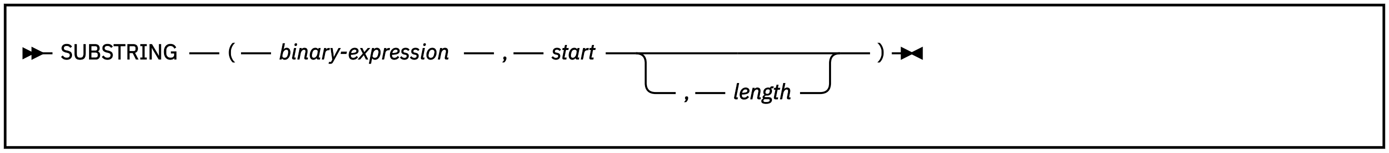
Character:



Graphic:



Binary:



The schema is SYSIBM.

Character

character-expression
An expression that specifies the string from which the result is derived. The string must be a built-in character string.

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type.

The result of the function is a character string.

A substring of *character-expression* is zero or more contiguous units of *character-expression*. If CODEUNITS32 is specified, a unit is a Unicode UTF-32 character. If CODEUNITS16 is specified, a unit is a Unicode UTF-16 character. If OCTETS is specified, a unit is a byte.

start
An expression that specifies the position within the *character-expression* that is to be the first string unit of the result. *start* is expressed in the specified string unit, and must return an integer value.

The argument can also be another numeric value, a character string, or a graphic string data type. The input is implicitly cast to a numeric value of DECFLOAT(34) which is then assigned to an INTEGER value.

The value of *start* can be positive, negative, or zero. A value of 1 indicates that the first string unit of the result is the first string unit of *character-expression*.

length

An expression that specifies the maximum length of the resulting substring.

If *character-expression* is a fixed-length string, omission of *length* is an implicit specification of `CHARACTER_LENGTH(`*`character-expression`*`) - `*`start`*` + 1`, which is the number of string units (CODEUNITS16, CODEUNITS32, or OCTETS) from *start* to the last position of *character-expression*.

If *character-expression* is a varying length string, omission of *length* is an implicit specification of zero or `CHARACTER_LENGTH(`*`character-expression`*`) - `*`start`*` + 1`, whichever is greater. If the resulting length is zero, the result is an empty string.

If specified, *length* must be an expression that returns a value of an integer data type.

The argument can also be another numeric value, a character string, or a graphic string data type. The input is implicitly cast to a numeric value of DECFLOAT(34) which is then assigned to an INTEGER value.

The value must be greater than or equal to 0. If a value greater than *n* is specified, where *n* is the length attribute of *`character-expression - start`*`+ 1`, then *n* is used as the length of the resulting substring. The value is expressed in the units that are explicitly specified.

For more information, see Rigorous description of the actual length and result.

CODEUNITS16, CODEUNITS32, or OCTETS

Specifies the string unit that is used to express *start* and *length*. If *character-expression* is a character string that is defined as bit data, CODEUNITS16 and CODEUNITS32 cannot be specified.

CODEUNITS16

Specifies that *start* and *length* are expressed in terms of 16-bit UTF-16 code units.

CODEUNITS32

Specifies that *start* and *length* are expressed in terms of 32-bit UTF-32 code units.

OCTETS

Specifies that *start* and *length* are expressed in terms of bytes.

For more information about CODEUNITS16, CODEUNITS32, and OCTETS, see “String unit specifications” on page 106.

Graphic

graphic-expression

An expression that specifies the string from which the result is derived. The string must be a built-in graphic string. The result of the function is a graphic string. A partial surrogate character in the expression is replaced with a blank.

A substring of *graphic-expression* is zero or more contiguous units of *graphic-expression*. If CODEUNITS32 is specified, a unit is a Unicode UTF-32 character. If CODEUNITS16 is specified, a unit is a Unicode UTF-16 character.

start

An expression that specifies the position within the *graphic-expression* that is to be the first string unit of the result. *start* is expressed in the specified string unit, and must return an integer value. The value of *start* can be positive, negative, or zero. A value of 1 indicates that the first string unit of the result is the first string unit of *graphic-expression*.

The argument can also be another numeric value, a character string, or a graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34) which is then assigned to an INTEGER value.

length

An expression that specifies the maximum length of the resulting substring.

If *graphic-expression* is a fixed-length string, omission of *length* is an implicit specification of `CHARACTER_LENGTH(`*`graphic-expression`*`) - `*`start`*` +1`, which is the number of units (CODEUNITS16, CODEUNITS32) either explicitly or implicitly specified, from the start position to the last position of *graphic-expression*. If *graphic-expression* is a varying length string, omission of *length* is an implicit specification of zero or `CHARACTER_LENGTH(`*`graphic-expression`*`) -`*`start`*` +1`, which is the number of units (CODEUNITS16, CODEUNITS32) either explicitly or implicitly specified, whichever is greater. If the resulting length is zero, the result is an empty string.

If specified, *length* must be an expression that returns a value of an integer data type.

The argument can also be another numeric value, a character string, or a graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34) which is then assigned to an INTEGER value.

The value must be greater than or equal to 0. If a value greater than *n* is specified, where *n* is the length attribute of *`graphic-expression - start`*`+ 1`, then *n* is used as the length of the resulting substring. The value is expressed in the units that are explicitly specified.

For more information, see Rigorous description of the actual length and result.

CODEUNITS16 or CODEUNITS32

Specifies the string unit that is used to express *start* and *length*.

CODEUNITS16

Specifies that *start* and *length* are expressed in terms of 16-bit UTF-16 code units.

CODEUNITS32

Specifies that *start* and *length* are expressed in terms of 32-bit UTF-32 code units.

For more information about CODEUNITS16 and CODEUNITS32, see "String unit specifications" on page 106.

Binary

binary-expression

An expression that specifies the string from which the result is derived. The string must be a built-in binary string. The result of the function is a binary string.

A substring of *binary-expression* is zero or more contiguous units of *binary-expression*.

start

An expression that specifies the position within *binary-expression* to be the first byte of the result. It must be an integer value. *start* can be negative or zero. (The length attribute of a varying-length string is its maximum length.) A value of 1 indicates that the first byte of the substring is the byte unit of *binary-expression*.

length

An expression that specifies the length of the resulting substring.

If *binary-expression* is a fixed-length string, omission of *length* is an implicit specification of `LENGTH(`*`binary-expression`*`) - `*`start`*` +1` from the start position to the last position of *binary-expression*. If *binary-expression* is a varying length string, omission of *length* is an implicit specification of zero or `CHARACTER_LENGTH(`*`binary-expression`*`) -`*`start`*` +1`, whichever is greater. If the resulting length is zero, the result is an empty string.

If specified, *length* must be a value of an integer data type. The value must be greater than or equal to 0 If a value greater than *n* is specified, where *n* is the length attribute of binary-expression - start+ 1, then *n* is used as the length of the resulting substring.

For more information, see Rigorous description of the actual length and result.

Rigorous description of the actual length and result

In this description, the term *character* means the “unit specified by string units” or "bytes" if the input is binary.

Let *C* be the value of the first argument, let *LC* be the length in characters of *C*, and let *S* be the value of the *start*.

- If *length* is specified, let *L* be the value of *length* and let *E* be *S*+*L*. Otherwise, let *E* be the larger of *LC* + 1 and *S*.
- If either *C*, *S*, or *L* is the null value, the result of the function is the null value.
- If *E* is less than *S*, an exception condition is raised: data exception — substring error.
- Otherwise:
  - If *S* is greater than *LC* or if *E* is less than 1 (one), the result of the function is a zero-length string.
  - Otherwise:
    - Let *S1* be the larger of *S* and 1 (one). Let *E1* be the smaller of *E* and *LC*+1. Let *L1* be *E1*–*S1*.
    - The result of the function is a character string that contains the *L1* characters of *C* starting at character number *S1* in the same order that the characters appear in *C*.

The data type of the result depends on the data type of the first argument, as shown in the following table.

Table 89. Data type of the result of SUBSTRING

Data type of the first argument	Data type of the result
CHAR or VARCHAR	VARCHAR
CLOB	CLOB If *character-expression* is mixed data, the result is mixed data. Otherwise, the result is SBCS data.
GRAPHIC or VARGRAPHIC	VARGRAPHIC
DBCLOB	DBCLOB
BINARY or VARBINARY	VARBINARY
BLOB	BLOB

The length attribute of the result is equal to the length attribute of the first argument. If CODEUNITS16 or CODEUNITS32 is specified, see “Determining the length attribute of the final result” on page 108 for information about how to calculate the length attribute of the result string.

The result can be null; if any argument is null, the result is the null value.

If the first argument is character or graphic data, the CCSID of the result is the same as that of the first argument.

Example 1: C1 is a VARCHAR(12) column in table T1. One of its values is the string 'ABCDEFG'. When C1 has the value 'ABCDEFG':

```
Function:                        Returns:
--------------------------------------------------------
SUBSTRING(C1,-2,2,OCTETS)                 -- a zero-length string
SUBSTRING(C1,-2,4,OCTETS)        'A'
SUBSTRING(C1,-2,OCTETS)          'ABCDEFG'
SUBSTRING(C1,0,1,OCTETS)                  -- a zero-length string
```

Example 2: FIRSTNAME is a VARCHAR(12) column in table T1. One of its values is the 6-character string 'Jürgen'. When FIRSTNAME has the value 'Jürgen':

```
Function:                                   Returns:
--------------------------------------------------------------
SUBSTRING(FIRSTNAME,1,2,CODEUNITS32)       'Jü'  -- x'4AC3BC'
SUBSTRING(FIRSTNAME,1,2,CODEUNITS16)       'Jü'  -- x'4AC3BC'
SUBSTRING(FIRSTNAME,1,2,OCTETS)            'J '  -- x'4A20' (a truncated string)
SUBSTRING(FIRSTNAME,8,CODEUNITS16)               -- a zero-length string
SUBSTRING(FIRSTNAME,8,4,OCTETS)                  -- a zero-length string
```

TAN

The TAN function returns the tangent of the argument, where the argument is an angle, expressed in radians.

▶▶— TAN(*numeric-expression*) —▶◀

The schema is SYSIBM.

The TAN and ATAN functions are inverse operations.

The argument must be an expression that returns the value of any built-in numeric data type that is not DECFLOAT. If the argument is not a double precision floating-point number, it is converted to one for processing by the function.

The result of the function is a double precision floating-point number.

The result can be null; if the argument is null, the result is the null value.

Example: Assume that host variable *TANGENT* is DECIMAL(2,1) with a value of 1.5. The following statement returns a double precision floating-point number with an approximate value of 14.10 .

```
SELECT TAN(:TANGENT)
  FROM SYSIBM.SYSDUMMY1;
```

TANH

The TANH function returns the hyperbolic tangent of the argument, where the argument is an angle, expressed in radians.

▶▶— TANH(*numeric-expression*) —▶◀

The schema is SYSIBM.

The TANH and ATANH functions are inverse operations.

The argument must be an expression that returns the value of any built-in numeric data type that is not DECFLOAT. If the argument is not a double precision floating-point number, it is converted to one for processing by the function.

The result of the function is a double precision floating-point number.

The result can be null; if the argument is null, the result is the null value.

Example: Assume that host variable *HTANGENT* is DECIMAL(2,1) with a value of 1.5. The following statement returns a double precision floating-point number with an approximate value of 0.90.

```
SELECT TANH(:HTANGENT)
  FROM SYSIBM.SYSDUMMY1;
```

TIME

The TIME function returns a time that is derived from a value.

The schema is SYSIBM.

The argument must be an expression that returns a value of one of the following built-in data types: a time, a timestamp, a character string, or a graphic string. If *expression* is a character or graphic string, it must not be a CLOB or DBCLOB, and its value must be a valid string representation of a time or timestamp with an actual length of not greater than 255 bytes. A time zone in a string representation of a timestamp is ignored. For the valid formats of string representations of times and timestamps, see "String representations of datetime values" on page 120.

If *expression* is a TIMESTAMP WITH TIME ZONE value, *expression* is first cast to TIMESTAMP WITHOUT TIME ZONE, with the same precision as *expression*.

If expression is not a TIME value, *expression* is cast as follows:

- If *expression* is a TIMESTAMP WITH TIME ZONE value, *expression* is cast to TIMESTAMP WITHOUT TIME ZONE, with the same precision as *expression*.
- If *expression* is a string, *expression* is cast to TIME.

The result of the function is a time.

The result can be null; if the argument is null, the result is the null value.

The other rules depend on the data type of the argument:

If the argument is a time
the result is that time.

If the argument is a timestamp
the result is the time part of the timestamp.

If the argument is a string
the result is the time or time part of the timestamp represented by the string. If the CCSID of the string is not the same as the corresponding default CCSID at the server, the string is first converted to that CCSID.

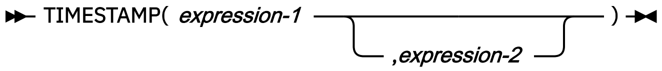
The result CCSID is the appropriate CCSID of the argument encoding scheme and the result subtype is the appropriate subtype of the CCSID.

Example: Assume that a table named CLASSES contains one row for each scheduled class. Assume also that the class starting times are in the TIME column named STARTTM. Using these assumptions, select those rows in CLASSES that represent classes that start at 1:30 P.M.

```
SELECT *
  FROM CLASSES
  WHERE TIME(STARTTM) = '13:30:00';
```

TIMESTAMP

The TIMESTAMP function returns a TIMESTAMP WITHOUT TIME ZONE value from its argument or arguments.



The schema is SYSIBM.

The rules for the arguments depend on whether the second argument is specified.

- **If only one argument is specified:**

  The argument must be an expression that returns a value of one of the following built-in data types: a date, a timestamp, a character string, a graphic string, or a binary string. If *expression-1* is a character or graphic string, it must not be a CLOB or DBCLOB and it must have one of the following values:

  - A valid string representation of a date or timestamp with an actual length that is not greater than 255 bytes. A time zone in a string representation of a timestamp is ignored. For the valid formats of string representations of timestamps, see "String representations of datetime values" on page 120.
  - A character string or graphic string with an actual length of 8 that is assumed to be a IBM zSystems Store Clock value.
  - A character string with an actual length of 13 that is assumed to be a result from the GENERATE_UNIQUE function.
  - A character string or graphic string with an actual length of 14 that represents a valid date and time in the form *yyyyxxddhhmmss*, where *yyyy* is the year, *xx* is the month, *dd* is the day, *hh* is the hour, *mm* is the minute, and *ss* is the seconds.[20]

  If *expression-1* is a binary string, it must not be a BLOB and its value must be one of the following:

  - A binary string with an actual length of 8 bytes that is assumed to be a IBM zSystems Store Clock value.
  - A binary string with an actual length of 16 bytes that is assumed to be a IBM zSystems Store Clock extended value.
  - A binary string with an actual length of 13 bytes that is assumed to be a result from the GENERATE_UNIQUE function.

- **If both arguments are specified:**

  - If the data type of the second argument is not an integer:

    The first argument must be an expression that returns a value of one of the following built-in data types: a date, a character string, or a graphic string. The second argument must be an expression that returns a value of one of the following built-in data types: a time, a character string, or a graphic string. A character string or graphic string must be a valid string representation of a time.

    If *expression-1* is a character string or graphic string, it must not be a CLOB or DBCLOB, and its value must be a valid string representation of a date with an actual length that is not greater than 255 bytes. If *expression-2* is a character string or graphic string, it must not be a CLOB or DBCLOB, and its value must be a valid string representation of a time with an actual length that is not greater than 255 bytes. For the valid formats of string representations of dates and times, see "String representations of datetime values" on page 120.

  - If the data type of the second argument is integer:

    The first argument must be an expression that returns a value of one of the following built-in data types: a timestamp, a date, a character string, or a graphic string. The second argument must be an integer constant in the range 0 to 12 that represents the timestamp precision.

    If *expression-1* is a character string or graphic string, it must not be a CLOB or DBCLOB, and its value must be a valid string representation of a timestamp or a date with an actual length that is not greater than 255 bytes.

    If *expression-1* is a binary string, it must not be a BLOB, and its value must conform to the rules for when only one argument is specified. The second argument must be an integer constant in the range 0 to 12 that represents the timestamp precision.

The result of the function is a TIMESTAMP WITHOUT TIME ZONE value.

[20] A character or graphic string with an actual length of 14 that represents a valid date and time (as allowed for the TIMESTAMP function) is also allowed as input to other scalar functions that accept a timestamp as an input argument.

The timestamp precision and other rules depend on whether the second argument is specified:

If both arguments are specified and the second argument is not an integer:
The result is a TIMESTAMP(6) WITHOUT TIME ZONE value with the date that is specified by the first argument and the time that is specified by the second argument. The fractional seconds part of the timestamp is zero.

If both arguments are specified and the second argument is an integer:
The result is a TIMESTAMP WITHOUT TIME ZONE value with the precision that is specified in the second argument.

If only one argument is specified and it is a TIMESTAMP (*p*) WITHOUT TIME ZONE:
The result is that TIMESTAMP (*p*) WITHOUT TIME ZONE value.

If only one argument is specified and it is a TIMESTAMP(*p*) WITH TIME ZONE:
The result is the argument value, cast to TIMESTAMP(*p*) WITHOUT TIME ZONE. The value is the local timestamp, not UTC.

If only one argument is specified and it is a date:
The result is that date with an assumed time of midnight that is cast to TIMESTAMP(0) WITHOUT TIME ZONE.

If only one argument is specified and it is a character or graphic string:
The result is the TIMESTAMP(6) WITHOUT TIME ZONE value that is represented by that string extended with any missing time information. If the argument is a string of length 14, the TIMESTAMP has a fractional seconds part of zero. The string value must not contain a specification of time zone.

If only one argument is specified and it is a binary string:
The result is the TIMESTAMP(6) WITHOUT TIME ZONE value that is represented by that string. If the year value in the resulting timestamp is greater than 9999 an error is returned.

If the arguments include only date information, the time information in the result value is all zeros.

The result can be null; if any argument is null, the result is the null value.

If an argument is a string with a CCSID that is not the same as the corresponding default CCSID at the server, the string is first converted to that CCSID.

The result CCSID is the appropriate CCSID of the argument encoding scheme and the result subtype is the appropriate subtype of the CCSID. If both arguments are specified and their encoding schemes are different, the result CCSID is the appropriate CCSID of the application encoding scheme.

Notes

Specifying an LRSN as an argument:
When a 6-byte LRSN is used as the argument to the TIMESTAMP function, it must be left justified and padded on the right to a total length of 8 bytes. When a 10-byte LRSN is used, it must be left justified and padded on the right to a total length of 16 bytes.

Effect of leap seconds or the system time zone on the result of the TIMESTAMP function with a binary value as the first argument:
Db2 does not adjust for leap seconds or the system time zone when it converts an IBM zSystems Store Clock value or an IBM zSystems Store Clock extended value to a timestamp value.

Syntax alternatives:
If only one argument is specified, the CAST specification should be used for maximal portability. For more information, see "CAST specification" on page 266.

TIMESTAMP_TZ is a similar function. For more information, see "TIMESTAMP_TZ" on page 595.

Examples

Example: TIMESTAMP with a DATE column and a TIME column as arguments
Assume that table TABLEX contains a DATE column named DATECOL and a TIME column named TIMECOL. For some row in the table, assume that DATECOL represents 25 December 2008 and

TIMECOL represents 17 hours, 12 minutes, and 30 seconds after midnight. The following function returns the value '2008-12-25-17.12.30.000000'.

```
    TIMESTAMP(DATECOL, TIMECOL)
```

Example: TIMESTAMP with a timestamp with time zone argument

Assume that host variable *PRSTSZ* contains '2008-02-29.20.00.000000 -08.30. The following statement returns the value '2008-02-29.20.00.000000':

```
SELECT TIMESTAMP(:PRSTSZ)
    FROM PROJECT;
```

Example: TIMESTAMP with a timestamp and an integer as arguments

The following invocation of the TIMESTAMP function converts a timestamp string with 7 digits of fractional seconds to a TIMESTAMP(9) WITHOUT TIME ZONE value and returns a value of '2007-09-24-15.53.37.216247400':

```
     TIMESTAMP('2007-09-24-15.53.37.2162474',9);
```

TIMESTAMPADD

The TIMESTAMPADD function returns the result of adding the specified number of the designated interval to the timestamp value.

▶▶— TIMESTAMPADD(*interval* ,*number* ,*expression*) —▶◀

The schema is SYSIBM.

interval

An expression that returns a value of a built-in SMALLINT or INTEGER data type. The following values are valid values for *interval*:

Table 90. Valid values for intervals

Valid values for *interval*	equivalent intervals
1	Microseconds
2	Seconds
4	Minutes
8	Hours
16	Days
32	Weeks
64	Months
128	Quarters
256	Years

number

An expression that returns a value of a built-in SMALLINT or INTEGER data type.

expression

An expression that returns a value of a built-in TIMESTAMP WITHOUT TIME ZONE data type.

The result of the function is timestamp without time zone, with the same timestamp precision as *expression*.

The result can be null; if any argument is null, the result is the null value.

The result is determined using the normal rules for datetime arithmetic. See “Datetime arithmetic in SQL” on page 258. When the interval to add is expressed as weeks, the result is calculated as if `number x 7 days` had been specified. When the interval to add is expressed as quarters, the result is calculated as if `number x 3 months` had been specified.

Example 1: The following example will add 40 years to the specified timestamp. An interval of 256 designates years, while 40 specifies the number of intervals to add. The following statement returns the value '2005-07-27-15.30.00.000000'.

```
SELECT TIMESTAMPADD(256,40,TIMESTAMP('1965-07-27-15.30.00'))
  FROM SYSIBM.SYSDUMMY1;
```

Example 2: The following example will add 18 months to the specified timestamp. An interval of 64 designates months, while 18 specifies the number of intervals to add. The following statement returns the value '2008-07-20-08.08.00.000000'.

```
SELECT TIMESTAMPADD(64,18,TIMESTAMP('2007-01-20-08.08.00'))
  FROM SYSIBM.SYSDUMMY1;
```

Example 3: The following example will subtract 16 quarters (4 years) from the specified timestamp. An interval of 128 designates quarters, while -16 specifies the number of intervals to add (the '-' adds a negative amount). The following statement returns the value '2003-09-28-05.30.00.000000'.

```
SELECT TIMESTAMPADD(128,-16,TIMESTAMP('2007-09-28-05.30.00'))
   FROM SYSIBM.SYSDUMMY1;
```

Example 4: The following example will add 18 weeks to the specified timestamp. An interval of 32 designates weeks, while 18 specifies the number of intervals to add. The following statement returns the value '2007-05-27-08.08.00.000000'.

```
SELECT TIMESTAMPADD(32,18,TIMESTAMP('2007-01-20-08.08.00'))
    FROM SYSIBM.SYSDUMMY1;
```

TIMESTAMPDIFF

The TIMESTAMPDIFF function returns an estimated number of intervals of the type that is defined by the first argument, based on the difference between two timestamps.

```
▶▶─ TIMESTAMPDIFF( numeric-expression ,string-expression ) ─▶◀
```

The schema is SYSIBM.

numeric-expression

An expression that returns a value that is a built-in SMALLINT or INTEGER data type. The value specifies the interval that is used to determine the difference between two timestamps. The following table lists the valid values for *numeric-expression*:

Table 91. Valid values for numeric-expression and equivalent intervals that are used to determine the difference between two timestamps

Valid values for *numeric-expression*	**equivalent intervals**
1	Microseconds
2	Seconds
4	Minutes
8	Hours
16	Days
32	Weeks

Table 91. Valid values for numeric-expression and equivalent intervals that are used to determine the difference between two timestamps (continued)

Valid values for *numeric-expression*	equivalent intervals
64	Months
128	Quarters
256	Years

string-expression

An expression that returns a value of a built-in character string or a graphic string data type that is not a LOB. The value is expected to be the result of subtracting two timestamps and converting the result to a character string of length 22. The string value must not have more than 6 digits to the right of a decimal point.

If the supplied argument is a graphic string, it is first converted to a character string before the function is executed.

The following table describes the elements of *string-expression*:

Table 92. TIMESTAMPDIFF String Elements

String elements	Valid values	Character position from the decimal point (negative is left)
Years	1-9998 or blank	-14 to -11
Months	0-11 or blank	-10 to -9
Days	0-30 or blank	-8 to -7
Hours	0-24 or blank	-6 to -5
Minutes	0-59 or blank	-4 to -3
Seconds	0-59	-2 to -1
Decimal separator	period	0
Microsecond	000000-999999	1 to 6

The result of the function is an integer with the same sign as the second argument.

The result can be null; if any argument is null, the result is the null value.

The returned value is determined for each interval as indicated by the following table:

Table 93. TIMESTAMPDIFF Computations

Result interval	Computation using duration elements
Years	years
Quarters	integer value of (months+(years*12))/3
Months	months + (years*12)
Weeks	integer value of ((days+(months*30))/7)+(years*52)
Days	days + (months*30)+(years*365)
Hours	hours+ ((days + (months*30)+(years*365))*24)
Minutes (the absolute value of the duration must not exceed 40850913020759.999999)	minutes + (hours+((days+(months*30)+(years*365))*24))*60
Seconds (the absolute value of the duration must be less than 680105031408.000000)	seconds + (minutes+(hours+((days+(months*30) +(years*365))*24))*60)*60

Table 93. TIMESTAMPDIFF Computations (continued)

Result interval	Computation using duration elements
Microseconds (the absolute value of the duration must be less than 3547.483648)	microseconds + (seconds+(minutes*60))*1000000

The following assumptions are used in estimating a difference:

- One year has 365 days
- One year has 52 weeks
- One year has 12 months
- One month has 30 days
- One day has 24 hours
- One hour has 60 minutes
- One minute has 60 seconds

The use of these assumptions imply that some result values are an estimate of the interval. Consider the following examples:

- Difference of 1 month where the month has less than 30 days.

  ```
  TIMESTAMPDIFF(16, CHAR(TIMESTAMP('1997-03-01-00.00.00')
          - TIMESTAMP('1997-02-01-00.00.00')))
  ```

  The result of the timestamp arithmetic is a duration of 00000100000000.000000, or 1 month. When the TIMESTAMPDIFF function is invoked with 16 for the interval argument (days), the assumption of 30 days in a month is applied and the result is 30.
- Difference of 1 day less than 1 month where the month has less than 30 days.

  ```
  TIMESTAMPDIFF(16, CHAR(TIMESTAMP('1997-03-01-00.00.00')
          - TIMESTAMP('1997-02-02-00.00.00')))
  ```

  The result of the timestamp arithmetic is a duration of 00000027000000.000000, or 27 days. When the TIMESTAMPDIFF function is invoked with 16 for the interval argument (days), the result is 27.
- Difference of 1 day less than 1 month where the month has 31 days.

  ```
  TIMESTAMPDIFF(64, CHAR(TIMESTAMP('1997-09-01-00.00.00')
          - TIMESTAMP('1997-08-02-00.00.00')))
  ```

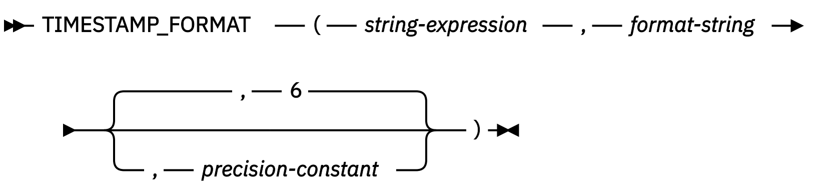
  The result of the timestamp arithmetic is a duration of 00000030000000.000000, or 30 days. When the TIMESTAMPDIFF function is invoked with 64 for the interval argument (months), the result is 0. The days portion of the duration is 30, but it is ignored because the interval specified months.

Example: The following statement estimates the age of employees in months and returns that value as AGE_IN_MONTHS:

```
SELECT
  TIMESTAMPDIFF(64, CAST(CURRENT_TIMESTAMP-CAST(BIRTHDATE AS TIMESTAMP)
                AS CHAR(22)))
    AS AGE_IN_MONTHS
  FROM EMPLOYEE;
```

TIMESTAMP_FORMAT

The TIMESTAMP_FORMAT function returns a TIMESTAMP WITHOUT TIME ZONE value that is based on the interpretation of the input string using the specified format.



The schema is SYSIBM.

string-expression
An expression that returns a value of any built-in character or graphic string data type, other than a CLOB or DBCLOB, with an actual length that is not greater than 255 bytes. The *string-expression* must contain the components of a timestamp that correspond to the format that is specified in *format-string*, except for hour, minute, second, or fractional seconds.

format-string
An expression that returns a value that is a built-in character or graphic string data type, other than a CLOB or DBCLOB. The actual length must not be greater than 255 bytes. The value is a template for how *string-expression* is interpreted and then converted to a timestamp value.

A valid *format-string* must contain at least one format element, must not contain multiple specifications for any component of a timestamp, and can contain any combination of the format elements, unless otherwise noted in the following table. For example, *format-string* cannot contain both YY and YYYY, because both are used to interpret the year component of a *string-expression*. Two format elements can be separated by one or more of the following separator characters:

- minus sign (-)
- period (.)
- forward slash (/)
- comma (,)
- apostrophe (')
- semicolon (;)
- colon (:)
- blank ( )

Separator characters can also be specified at the start or end of *format-sting*. These separator characters can be used in any combination in the format string, for example 'YYYY/MM-DD HH:MM.SS'. Separator character that is specified in a *string-expression* are used to separate components and are not required to match the separator character that is specified in the *format-string*.

Table 94. Format elements for the TIMESTAMP_FORMAT function

Format element	Related timestamp component	Description
AM or PM [1]	hour	Meridian indicator (morning or evening) without periods. This format element uses the exact strings "AM" or "PM".
A.M. or P.M. [1]	hour	Meridian indicator (morning or evening) with periods. This format element uses the exact strings "A.M." or "P.M."
D [1]	none	Day of the week (1-7).

Table 94. Format elements for the TIMESTAMP_FORMAT function (continued)

Format element	Related timestamp component	Description
DD	day	Day of the month (0-31).
DDD	month, day	Day of the year (001-366).
FF or FF*n*	fractional seconds	Fractional seconds (0-999999999999). The number *n* is used to specify the number of digits that is expected in the *string-expression*. Valid values for *n* are 1-12 with no leading zeros. Specifying FF is equivalent to specifying FF6. When the component in *string-expression* that corresponds to the FF format element is followed by a separator character or is the last component, the number of digits for the fractional seconds can be less than what is specified by the format element. In this case, zero digits are padded onto the right of the number of specified digits.
HH	hour	HH behaves the same as HH12.
HH12	hour	Hour of the day (01-12) in 12-hour format. AM is the default meridian indicator.
HH24	hour	Hour of the day (00-24) in 24-hour format.
J	year, month, and day	Julian day, the number of days since January 1, 4713 BC. (0000000-9999999)
MI	minute	Minute (00-59).
MM	month	Month (01-12).
MONTH, Month, or month [1, 2]	month	Name of the month in English.
MON, Mon, or mon [1, 2]	month	Abbreviated name of the month in English.
NNNNNN	microseconds	Microseconds, in the same format as FF6. (000000-999999).
RR	year	Last two digits of the adjusted year (00-99).
RRRR	year	RRRR behaves the same as YYYY.
SS	seconds	Seconds (00-59).
SSSSS	hours, minutes, and seconds	Seconds since the previous midnight (00000 - 86400).
Y	year	Last digit of the year (0-9). First three digits of the current year are used to determine the full 4-digit year.
YY	year	Last two digits of the year (00-99). First two digits of the current year are used to determine the full 4-digit year.
YYY	year	Last three digits of the year (000-999). First digit of the current year is used to determine the full 4-digit year.
YYYY	year	4-digit year (0000-9999).

Table 94. Format elements for the TIMESTAMP_FORMAT function (continued)

Format element	Related timestamp component	Description

Notes:

1. This format element is case sensitive.
2. Only these exact spellings and case combinations can be used. If this format element is specified in an invalid case combination an error is returned.
3. The D format element does not contribute to any components of the resulting timestamp. However, a specified value for this format element must be correct for the combination of the day component of the resulting timestamp. For example, a value of '5' for *string-expression* is valid for a format string value of 'D'. However, value of '9' for *string-expression* would result in an error for the same *format-string*.

The RR format element can be used to change how a specification for a year is to be interpreted by adjusting the value to produce a 4-digit value depending on the last two digits of the current year according to the following table:

Table 95. Correspondence of adjusted year value and timestamp component

Digits of the current year	Two-digit year in *string-expression*	First two digits of the year component of timestamp
00-50	00-49	First two digits of the current year
51-99	00-49	First two digits of the current year + 1
00-50	50-99	First two digits of the current year -1
51-99	50-99	First two digits of the current year

For example, if the current year is 2007, '86' with format 'RR' means 1986, but if the current year is 2052, it means 2086.

The following defaults are used when a *format-string* does not include a format element for one of the following components of a timestamp:

Timestamp component	Default
year	current year, as 4 digits
month	current month. as 2 digits
day	01 (first day of the month)
hour	00
minute	00
second	00
fractional seconds	a number of zeros to match the timestamp precision of the result

If *string-expression* does not include a value that corresponds to an hour, minute, second, or fractional seconds format element that is specified in the *format-string*, the same defaults are used.

Leading zeros can be specified for any component of the timestamp value (that is, month, day, hour, minutes, seconds) that does not have the maximum number of significant digits for the corresponding format element in the *format-string*.

A substring of the *string-expression* that represents a component of a timestamp (such as year, month, day, hour, minutes, seconds) can include fewer than the maximum number of digits for that component of the timestamp that is indicated by the corresponding format element. Any missing digits default to zero. For example, with a format-string of 'YYYY-MM-DD HH24:MI:SS', an input value of '999-3-9 5:7:2' produces the same result as '0999-03-09 05:07:02'.

precision-constant

An integer constant that specifies the timestamp precision of the result. The value must be in the range 0 to 12. If *precision-constant* is not specified, the timestamp precision defaults to 6.

The result of the function is a TIMESTAMP with a precision that is based on *precision-constant*.

If either of the first two arguments can be null, the result can be null; if either of the first two arguments is null, the result is the null value.

The result CCSID is the appropriate CCSID of the encoding scheme of the first argument and the result subtype is the appropriate subtype of the CCSID.

Notes

Julian and Gregorian calendar:

The transition from the Julian calendar to the Gregorian calendar on 15 October 1582 is taken into account by this function.

Determinism:

TIMESTAMP_FORMAT is a deterministic function. However, the following invocations of the function depend on the value of the special register CURRENT TIMESTAMP.

- *format-string* is not a constant
- *format-string* is a constant and includes format elements that are locale sensitive
- *format-string* is a constant and does not include a format element that fully defines the year (that is, J or YYYY). In this case the current year is used.
- *format-string* is a constant and does not include a format element that fully defines the month (for example, J, MM, MONTH, or MON). In this case the current month is used.

These invocations, which depend on the value of a special register, cannot be used wherever special registers cannot be used.

Using the 'D', 'Y', and 'y' format elements:

Db2 for z/OS does not support the 'DY', 'dy', and 'Dy' format elements that are supported by other platforms. If 'DY' or 'Dy' is specified in the format string, it is interpreted as the 'D' format element followed by the 'Y' or 'y' format element. This behavior might change in a future release. To ensure that a 'D' followed by 'Y' or 'y' is interpreted as two separate format elements, include a separator character after the 'D' format element.

Syntax alternatives:

FL 506 TO_TIMESTAMP is a synonym for TIMESTAMP_FORMAT.

TO_DATE is a synonym for TIMESTAMP_FORMAT.

Examples

Example 1:

Insert a row into the IN_TRAY table with a receiving timestamp that is equal to one second before the beginning of the year 2000 (December 31, 1999 at 23:59:59).

```
INSERT INTO IN_TRAY (RECEIVED)
    VALUES (TIMESTAMP_FORMAT('1999-12-31 23:59:59', 'YYYY-MM-DD HH24:MI:SS'))
```

Example 2:

An application receives strings of date information into a variable called *INDATEVAR*. This value is not strictly formatted and might include two or four digits for years, and one or two digits for months and days. Date components might be separated with minus sign (-) or forward-slash (/) characters and are expected to be in day, month, and year order. Time information consists of hours (in 24-hour format) and minutes, and is usually separated by a colon. Sample values include '15/12/98 13:48' and '9-3-2004 8:02'. Insert such values into the IN_TRAY table.

```
INSERT INTO IN_TRAY (RECEIVED)
    VALUES (TIMESTAMP_FORMAT(:INDATEVAR, 'DD/MM/RRRR HH24:MI'))
```

The use of 'RRRR' in the format allows for 2-digit and 4-digit year values and assigns the missing first two digits based on the current year. If 'YYYY' is used, input values with a 2-digit year will have leading zeros. The forward-slash separator also allows the minus sign character. Assuming a current year of 2007, resulting timestamp values from the sample values are as follows:

```
'15/12/98 13:48' --> 1998-12-15-13.48.00.000000
'9-3-2004 8:02' --> 2004-03-09-08.02.00.000000
```

TIMESTAMP_ISO

The TIMESTAMP_ISO function returns a timestamp value that is based on a date, a time, or a timestamp argument.

```
▶▶─ TIMESTAMP_ISO(  expression) ─▶◀
```

The schema is SYSIBM.

If the argument is a date, TIMESTAMP_ISO inserts a value of zero for the time and the partial seconds parts of the timestamp. If the argument is a time, TIMESTAMP_ISO inserts the value of CURRENT DATE for the date part of the timestamp and a value of zero for the partial seconds part of the timestamp.

expression

An expression that returns a value of one of the following built-in data types:

- a TIMESTAMP WITHOUT TIME ZONE
- a date
- a time
- a character string
- or a graphic string

If *expression* is a character or graphic string, it must not be a CLOB or DBCLOB and its value must be a valid string representation of a date, a time, or a timestamp. For the valid formats of string representations of dates, times, and timestamps, see "String representations of datetime values" on page 120.

If *expression* is a timestamp, the result of the function is timestamp without time zone, with the same precision as *expression*. Otherwise, the result of the function is a TIMESTAMP (6) WITHOUT TIME ZONE.

The result can be null; if the argument is null, the result is the null value.

Notes

Syntax alternatives:

Use the CAST specification for maximum portability. For more information, see "CAST specification" on page 266.

Examples

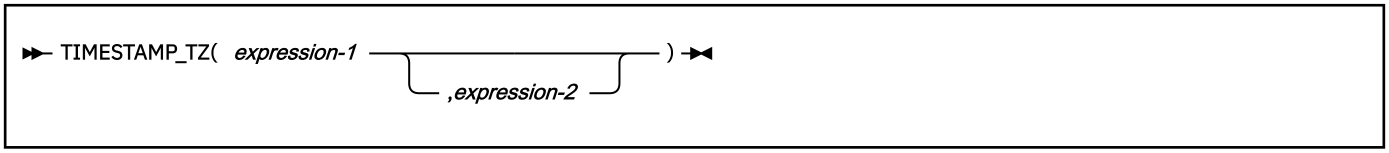
Example 1:

Assume the following date value '1965-07-27'. The following statement returns the value '1965-07-27-00.00.00.000000'.

```
    SELECT TIMESTAMP_ISO( DATE( '1965-07-27' ) )
      FROM SYSIBM.SYSDUMMY1
```

TIMESTAMP_TZ

The TIMESTAMP_TZ function returns a TIMESTAMP WITH TIME ZONE value from the input arguments.



The schema is SYSIBM.

expression-1

An expression that returns a value of one of the following built-in data types:

- a timestamp without time zone
- a timestamp with time zone
- a character string
- a graphic string

If *expression-1* is a character string or a graphic string, it must conform to the following rules:

- It must not be a CLOB or DBCLOB
- Its value must be a valid string representation of a timestamp without a time zone or a timestamp with a time zone value
- It must have an actual length that is not greater than 255 bytes

For the valid formats of string representations of datetime values, see "String representations of datetime values" on page 120.

If *expression-2* is specified, *expression-1* must be a timestamp without a time zone, or a string representation of a timestamp without a time zone.

expression-2

An expression that returns a character string or a graphic string.

If *expression-2* is a character string or graphic string, it must not be a CLOB or DBCLOB, and its value must be a valid string representation of a time zone in the format of '±*th*:*tm*' with values ranging from -24:00 to +24:00, where *th* represents time zone hour and *tm* represents time zone minute.

The result of the function is equivalent to invoking the CAST specification, as indicated in the following table:

Table 96. TIMESTAMP_TZ function and equivalent CAST specification

TIMESTAMP_TZ function syntax	Equivalent CAST specification syntax
TIMESTAMP_TZ(*timestamp_wo_tz*)	CAST(*timestamp_wo_tz* AS TIMESTAMP WITH TIME ZONE)
TIMESTAMP_TZ(*timestamp_wo_tz*, *n*)	CAST(*timestamp_wo_tz* AS TIMESTAMP(*n*) WITH TIME ZONE)
TIMESTAMP_TZ(*timestamp_wo_tz*, *timezone*)	CAST(CONCAT(VARCHAR(*timestamp_wo_tz*, *timezone*) AS TIMESTAMP WITH TIME ZONE)

Table 96. TIMESTAMP_TZ function and equivalent CAST specification (continued)

TIMESTAMP_TZ function syntax	Equivalent CAST specification syntax
TIMESTAMP_TZ(*timestamp_wo_tz*, *timezone*, *n*)	CAST(CONCAT(VARCHAR(*timestamp_wo_tz*, *timezone*) AS TIMESTAMP(*n*) WITH TIME ZONE)
TIMESTAMP_TZ(*timestamp_w_tz*)	CAST(*timestamp_w_tz* AS TIMESTAMP WITH TIME ZONE)
TIMESTAMP_TZ(*timestamp_w_tz*, *n*)	CAST(*timestamp_w_tz* AS TIMESTAMP(*n*) WITH TIME ZONE)
TIMESTAMP_TZ(*timestamp_w_tz*, *timezone*)	N/A
TIMESTAMP_TZ(*timestamp_w_tz*, *timezone*, *n*)	N/A

timestamp_wo_tz
A timestamp without time zone value.

timestamp_w_tz
A timestamp with time zone value.

timezone
A time zone value.

n
The precision value.

When a string representation of a timestamp is a single-byte character set (SBCS) with a CCSID that is not the same as the default CCSID for SBCS data, that value is converted to the default CCSID for SBCS data before it is interpreted and converted to a timestamp value.

Notes

Syntax alternatives:

If only one argument is specified, the CAST specification should be used to ensure maximal portability. For more information, see "CAST specification" on page 266

FROM_TZ can be specified as a synonym for TIMESTAMP_TZ when TIMESTAMP_TZ specifies both *expression-1* and *expression-2*.

Examples

Example 1:

Assume that *TIMES* is a host variable with the value 2008-02-29-20.00.00.000000 and that *TZ* is a host variable with the value -3:00. Convert the value of *TIMES* and *TZ* to a timestamp with time zone.

```
SET :TIMESZ = TIMESTAMP_TZ(:TIMES, :TZ);
```

The host variable *TIMESZ* is set with the value that represents the timestamp with time zone as 2008-02-29-20.00.00.000000 -03:00.

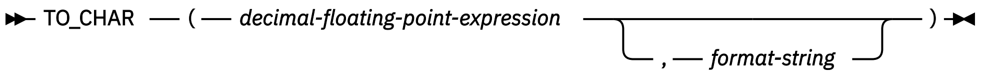
TO_CHAR

The TO_CHAR function returns a character string representation of a timestamp value that has been formatted using a specified character template.

Character to VARCHAR

Timestamp to VARCHAR

Decimal floating-point to VARCHAR



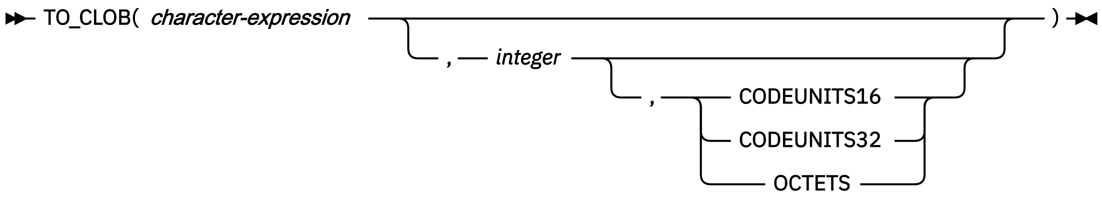
The TO_CHAR scalar function is identical to the VARCHAR FORMAT scalar function. For more information, see “VARCHAR_FORMAT” on page 622.

TO_CLOB

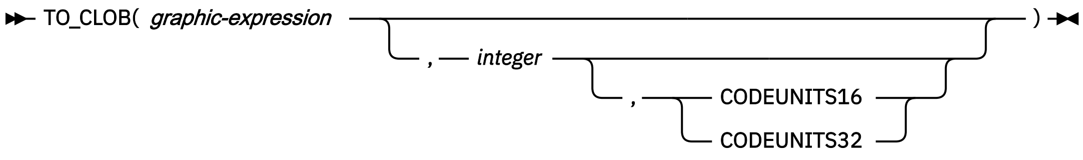
The TO_CLOB function returns a CLOB representation of a string.

FL 506

Character to CLOB:



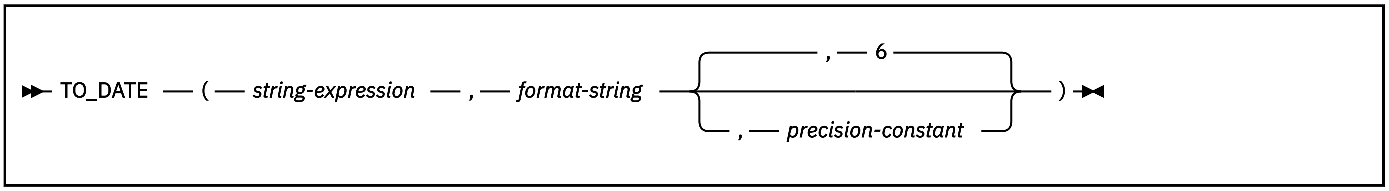
Graphic to CLOB:



The TO_CLOB function is identical to the CLOB function. For more information, see “CLOB” on page 415.

TO_DATE

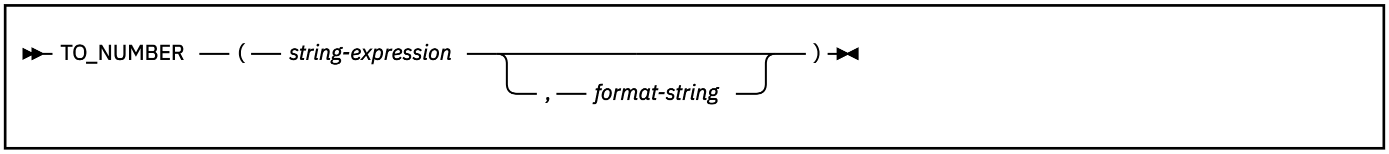
The TO_DATE function returns a timestamp value that is based on the interpretation of the input string using the specified format.



The TO_DATE scalar function is identical to the TIMESTAMP_FORMAT scalar function. For more information, see TIMESTAMP_FORMAT.

TO_NUMBER

The TO_NUMBER function returns a DECFLOAT(34) value that is based on the interpretation of the input string using the specified format.

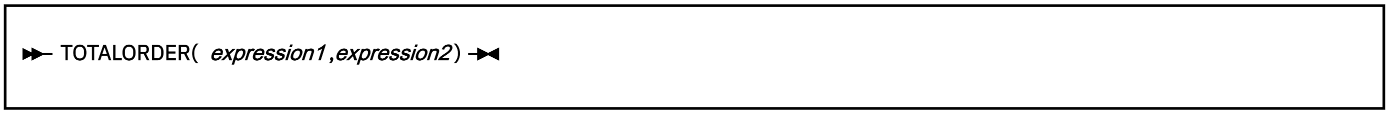


The schema is SYSIBM.

The TO_NUMBER scalar function is identical to the DECFLOAT_FORMAT scalar function. For more information, see "DECFLOAT_FORMAT" on page 438.

TOTALORDER

The TOTALORDER function returns an ordering for DECFLOAT values. The TOTALORDER function returns a small integer value that indicates how *expression1* compares with *expression2*.



The schema is SYSIBM.

expression1

An expression that returns a built-in DECFLOAT value.

The argument can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34).

expression2

An expression that returns a built-in DECFLOAT value.

The argument can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34).

Numeric comparison is exact, and the result is determined for finite operands as if range and precision are unlimited. An overflow or underflow conditions cannot occur.

If one value is DECFLOAT(16) and the other is DECFLOAT(34), the DECFLOAT(16) value is converted to DECFLOAT(34) before the comparison is made.

TOTALORDER determines ordering based on the total order predicate rules of IEEE 754R, with the following result:

- -1 if the first argument is lower in order compared to the second.
- 0 if both arguments have the same order.

- 1 if the first argument is higher in order compared to the second.

The ordering of the special values and finite numbers is as follows:

```
-NAN<-SNAN<-INFINITY<-0.10<-0.100<-0<0<0.100<0.10<INFINITY<SNAN<NAN
```

The result of the function is a SMALLINT value.

The result can be null; if any argument is null, the result is the null value.

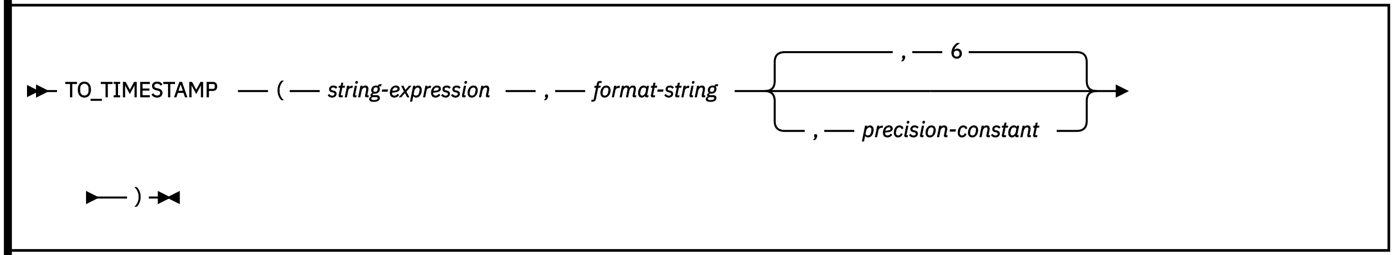
Examples: The following examples show the use of the TOTALORDER function to compare decimal floating point values:

```
TOTALORDER(-INFINITY, -INFINITY)                  = 0
TOTALORDER(DECFLOAT(-1.0), DECFLOAT(-1.0))     = 0
TOTALORDER(DECFLOAT(-1.0), DECFLOAT(-1.00))    = -1
TOTALORDER(DECFLOAT(-1.0), DECFLOAT(-0.5))     = -1
TOTALORDER(DECFLOAT(-1.0), DECFLOAT(0.5))      = -1
TOTALORDER(DECFLOAT(-1.0), INFINITY)           = -1
TOTALORDER(DECFLOAT(-1.0), SNAN)               = -1
TOTALORDER(DECFLOAT(-1.0), NAN)                = -1
TOTALORDER(NAN, DECFLOAT(-1.0))                = 1
TOTALORDER(-NAN, -NAN)                         = 0
TOTALORDER(-SNAN, -SNAN)                       = 0
TOTALORDER(NAN, NAN)                           = 0
TOTALORDER(SNAN, SNAN)                         = 0
```

TO_TIMESTAMP

The TO_TIMESTAMP function returns a TIMESTAMP WITHOUT TIME ZONE value that is based on the interpretation of the input string using the specified format.

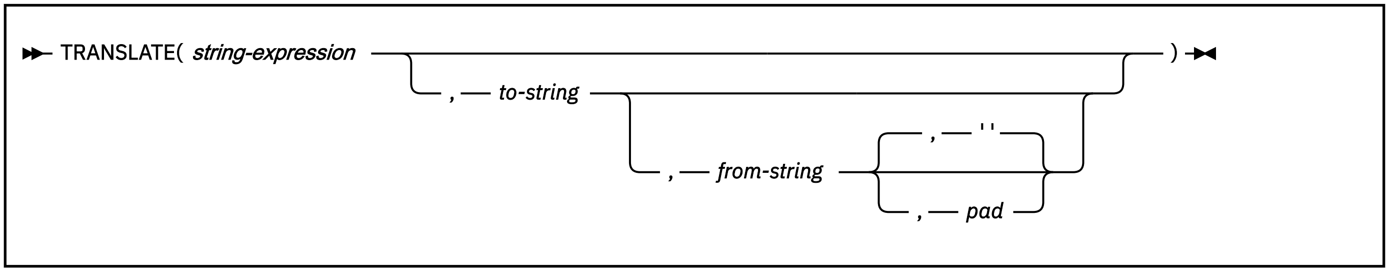
FL 506



The TO_TIMESTAMP function is identical to the TIMESTAMP_FORMAT function. For more information, see "TIMESTAMP_FORMAT" on page 590.

TRANSLATE

The TRANSLATE function returns a value in which one or more characters of the first argument might have been converted to other characters.



The schema is SYSIBM.

string-expression
An expression that specifies the string to be converted. *string-expression* must return a value that is a built-in character or graphic string data type that is not a LOB. If *string-expression* is an EBCDIC or

ASCII graphic string and *string-expression* is the only argument that is specified, the locale name that is specified by the CURRENT LOCALE LC_CTYPE special register must be a non-blank string.

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type.

to-string

An expression that specifies the characters to which certain characters in *string-expression* are to be converted. This string is sometimes called the *output translation table*. *to-string* must return a value that is a built-in character or graphic string data type that is not a LOB.

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type.

If the length of *to-string* is less than the length of *from-string*, *to-string* is padded to the length of *from-string* with the *pad* or a blank. If the length of *to-string* is greater than *from-string*, the extra characters in *to-string* are ignored without warning.

from-string

An expression that specifies the characters that if found in *string-expression* are to be converted. This string is sometimes called the *input translation table*. When a character in *from-string* is found, the character in *string-expression* is converted to the character in *to-string* that is in the corresponding position of the character in *from-string*.

from-string must return a value that is a built-in character or graphic string data type that is not a LOB.

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type.

If *from-string* contains duplicate characters, the first occurrence of the character is used, and no warning is issued. The default value for *from-string* is a string that starts with the character X'00' and ends with the character X'FF' (decimal 255).

pad

An expression that specifies the character with which to pad *to-string* if its length is less than *from-string*. *pad* is an expression that must return a value that is a built-in character or graphic string data type that is not a LOB and has a length of 1. A length of 1 is one single byte for character strings and one double byte string for graphic strings. The default is a blank that is appropriate for *string-expression*.

If *string-expression* is the only argument that is specified, the string is converted to uppercase based on the locale name that is specified by the CURRENT LOCALE LC_CTYPE special register, as follows:

blank

SBCS lowercase characters a-z are converted to SBCS uppercase characters A-Z, and characters with diacritical marks are not converted. If the string contains MIXED or DBCS characters, full-width lowercase characters a-z are converted to full-width Latin uppercase characters A-Z. For optimal performance, specify a blank string unless your data must be processed by using rules that are defined by a specific locale.

UNI

The conversion uses both the NORMAL and SPECIAL casing capabilities as described in Select the conversions (z/OS: Unicode Services User’s Guide and Reference). You must not specify UNI when *string-expression* is EBCDIC data.

UNI_90

The conversion uses Unicode Standard 9.0.0 and the NORMAL casing capability, as described in Select the conversions (z/OS: Unicode Services User’s Guide and Reference). You must not specify UNI_60 when *string-expression* is EBCDIC data.

UNI_90

The conversion uses Unicode Standard 6.0.0 and the NORMAL casing capability, as described in Select the conversions (z/OS: Unicode Services User’s Guide and Reference). You must not specify UNI_90 when *string-expression* is EBCDIC data.

UNI_SIMPLE

Case conversions use the NORMAL casing capabilities as described in Select the conversions (z/OS: Unicode Services User’s Guide and Reference). UNI_SIMPLE cannot be used with EBCDIC data.

locale name

The locale defines the rules for conversion to uppercase characters.

For Unicode data, usage of the TRANSLATE function (the TRANSLATE function with one argument is equivalent to the UPPER function) can result in expansion if certain characters are processed. You should ensure that the result string is large enough to contain the result of the expression.

If more than one argument is specified, the result string is built one piece at a time from *string-expression*. If *string-expression* is CHAR or VARCHAR, a piece is one byte long. If *string-expression* is GRAPHIC or VARGRAPHIC, a piece is two bytes long.

For each piece in *string-expression*, the *from-string* is searched for that same piece.

- If the piece in *string-expression* matches a piece in *from-string,* and there is a corresponding piece in *to-string,* that piece in *to-string* is moved to the result string. If the piece in *string-expression* matches a piece in *from-string,* but there is no corresponding piece in *to-string*, the *pad* is moved to the result string.
- If the piece in *string-expression* does not match any piece in *from-string*, the piece in string-expression is moved to the result string.

The string can contain mixed data. If only one argument is specified, the UPPER function is performed on the argument, and the rules for operating on mixed data in the UPPER function are observed. Full-width Latin lowercase a-z are converted to full-width Latin uppercase letters A-Z. If more than one argument is specified, the function operates as previously described for CHAR and VARCHAR data. The result is not necessarily a properly formed mixed data character string.

The encoding scheme of the result is the same as *string-expression*. The data type of the result of the function depends on the data type of *string-expression*, *to-string*, *from-string*, and *pad*:

- VARCHAR if *string-expression* is a character string. The CCSID of the result depends on the arguments:
  - If *string-expression*, *to-string*, *from-string*, or *pad* is bit data, the result is bit data.
  - If *string-expression*, *to-string*, *from-string*, and *pad* are all SBCS:
    - If *string-expression*, *to-string*, *from-string*, and *pad* are all SBCS Unicode data, the CCSID of the result is the CCSID for SBCS Unicode data.
    - If *string-expression* is SBCS Unicode data, and *to-string*, *from-string*, or *pad* are not SBCS Unicode data, the CCSID of the result is the mixed CCSID for Unicode data.
    - Otherwise, the CCSID of the result is the same as the CCSID of *string-expression*.
  - Otherwise, the CCSID of the result is the mixed CCSID that corresponds to the CCSID of *string-expression*. However, if the input is EBCDIC or ASCII and there is no corresponding system CCSID for mixed, the CCSID of the result is the CCSID of *string-expression*.
- VARGRAPHIC if *string-expression* is a graphic. The CCSID of the result is the same as the CCSID of *source-string.*

The result can be null; if the first argument is null, the result is the null value.

Examples

Example 1

Return the string 'abcdef' in uppercase characters. Assume that the locale in effect is blank.

```
SELECT TRANSLATE ('abcdef')
  FROM SYSIBM.SYSDUMMY1
```

The result is the value 'ABCDEF'.

Example 2

Assume that host variable *SITE* has a data type of VARCHAR(30) and contains 'Hanauma Bay'.

```
    SELECT TRANSLATE (:SITE)
      FROM SYSIBM.SYSDUMMY1
```

Returns the value 'HANAUMA BAY'. The result is all uppercase characters because only one argument is specified.

```
    SELECT TRANSLATE (:SITE, 'j', 'B')
      FROM SYSIBM.SYSDUMMY1
```

Returns the value 'Hanauma jay'.

```
    SELECT TRANSLATE (:SITE, 'ei', 'aa')
      FROM SYSIBM.SYSDUMMY1
```

Returns the value 'Heneume Bey'.

```
    SELECT TRANSLATE (:SITE, 'bA', 'Bay', '%')
      FROM SYSIBM.SYSDUMMY1
```

Returns the value 'HAnAumA bA%'.

```
    SELECT TRANSLATE (:SITE, 'r', 'Bu')
      FROM SYSIBM.SYSDUMMY1
```

Returns the value 'Hana ma ray'.

Example 3

Assume that host variable *SITE* has a data type of VARCHAR(30) and contains 'Pivabiska Lake Place'.

```
    SELECT TRANSLATE (:SITE, '$$', 'Ll')
      FROM SYSIBM.SYSDUMMY1
```

Returns the value 'Pivabiska $ake P$ace'.

```
    SELECT TRANSLATE (:SITE, 'pLA', 'Place', '.')
      FROM SYSIBM.SYSDUMMY1
```

Returns the value 'pivAbiskA LAk. pLA..'.

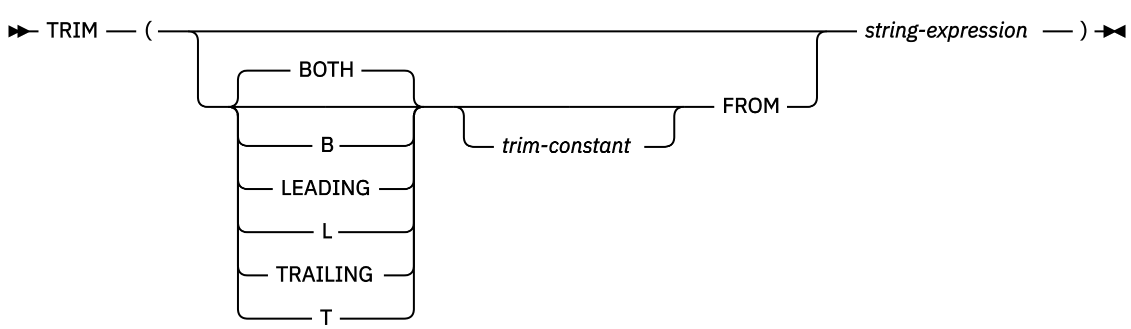
z/OS Unicode Services User’s Guide and Reference

TRIM

The TRIM function removes bytes from the beginning, from the end, or from both the beginning and end of a string expression.



The schema is SYSIBM.

The first argument, if specified, indicates whether characters are removed from the end or the beginning of the string. If the first argument is not specified, the characters are removed from both the end and the beginning of the string.

trim-constant

Specifies a constant that indicates the binary, SBCS, or DBCS character that is to be removed. If *string-expression* is a character string, *trim-constant* must be an SBCS or DBCS single-character (2 bytes) constant. If *string-expression* is a binary string, *trim-constant* must be a single-byte binary string constant. If *string-expression* is a DBCS graphic or DBCS-only string, *trim-constant* must be a graphic constant that consists of a single DBCS character.

The default for t*rim-constant* depends on the data type of *string-expression*:

- A DBCS blank if *string-expression* is a DBCS graphic string. For ASCII, the CCSID determines the hex value that represents a DBCS blank. For example, for Japanese (CCSID 301), X'8140' represents a DBCS blank, while for Simplified Chinese, X'A1A1' represents a DBCS blank. For EBCDIC, X'4040' represents a DBCS blank.
- A UTF-16 or UCS-2 blank (X'0020') if *string-expression* is a Unicode graphic string.
- A value of X'00' if *string-expression* is a binary string.
- Otherwise, a single byte blank. For EBCDIC, X'40' represents a blank. When not EBCDIC, X'20' represents a blank.

string-expression

An expression that returns a value that is a built-in character string data type, graphic data type, binary string data type, or numeric data type. *string-expression* must not be a LOB. If *string-expression* is numeric, it is cast to a character string before the function is evaluated. For more information about converting numeric to a character string, see "VARCHAR" on page 614.

string-expression and *trim-expression* must have compatible data types.

The data type of the result depends on the data type of *string-expression*:

- If *string-expression* is a character string data type, the result is VARCHAR. If *string-expression* is defined as FOR BIT DATA the result is FOR BIT DATA.
- If *string-expression* is a graphic string data type, the result is VARGRAPHIC.
- If *string-expression* is a binary string data type, the result is VARBINARY.

The length attribute of the result is the same as the length attribute of *string-expression*. The actual length of the result is the length of *string-expression* minus the number of characters removed. If all of the characters are removed, the result is an empty string.

If *string-expression* can be null, the result can be null; if *string-expression* is null, the result is the null value.

The CCSID of the result is the same as that of *string-expression*.

Notes

Valid content for EBCDIC mixed string input:

If *string-expression* is an EBCDIC mixed string, the string must contain valid EBCDIC mixed data.

Examples

Example: **Assume the host variable *HELLO* of type CHAR(9) has a value of ' Hello '.**

```
SELECT TRIM(:HELLO), TRIM(TRAILING FROM :HELLO)
       FROM SYSIBM.SYSDUMMY1
```

Results in '`Hello`' and ' `Hello`' respectively.

***Example:* Assume the host variable *BALANCE* of type CHAR(9) has a value of '000345.50'.**

```
SELECT TRIM(L '0' FROM :BALANCE)
        FROM SYSIBM.SYSDUMMY1
```

Results in '`345.50`'

Related reference

STRIP

The STRIP function removes blanks or another specified character from the end, the beginning, or both ends of a string expression.

TRIM_ARRAY

The TRIM_ARRAY function deletes elements from the end of an ordinary array.

```
▶▶─ TRIM_ARRAY ── (array-expression ,numeric-expression ) ─▶◀
```

The schema is SYSIBM.

array-expression

An SQL variable, SQL parameter, or global variable of an ordinary array type, or a CAST specification of a parameter marker to an array type. An associative array type cannot be specified.

numeric-expression

Specifies the number of elements that are trimmed from the end of the array. *numeric-expression* can be any numeric data type with a value that can be cast to INTEGER. The value of *numeric-expression* must be greater than or equal to 0 and less than or equal to the cardinality of *array-expression*.

TRIM_ARRAY returns a value with the same array type as *array-expression*, with the cardinality reduced by the value of INTEGER(*numeric-expression*).

The result can be null; if any argument is null, the result is the null value.

The TRIM_ARRAY function can be invoked only in the following contexts:

- A source value for SET *assignment-statement* or SQL PL *assignment-statement*, or a VALUES INTO statement
- The value that is returned in a RETURN statement in an SQL scalar function

Notes

Syntax alternatives:

CAST (*SQL-variable* AS *array-type*) can be specified as an alternative to *SQL-variable*. CAST (*SQL-parameter* AS *array-type*) can be specified as an alternative to *SQL-parameter*.

ARRAY_TRIM is a synonym for the TRIM_ARRAY built in function.

Examples

Example 1:

Suppose that PHONENUMBERS is a user-defined array type that is defined as an ordinary array. RECENT_CALLS is an array variable of the PHONENUMBERS type. The following statement removes the last element from the array variable RECENT_CALLS.

```
SET RECENT_CALLS = TRIM_ARRAY(RECENT_CALLS,1);
```

Example 2:

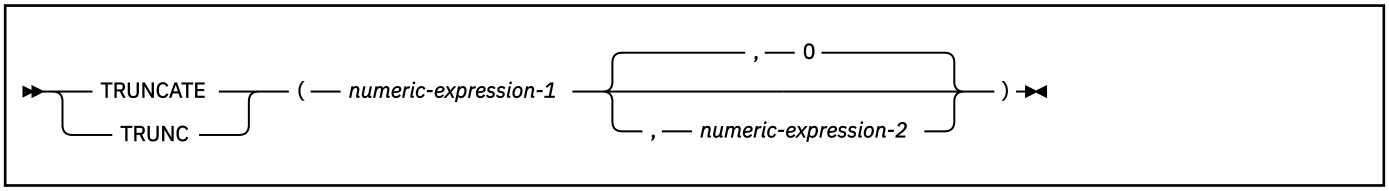
Suppose that INTARRAY is a user-defined array type that is defined as an ordinary array with integer elements. SPECIALNUMBERS and LOWPRIMES are array variables of the INTARRAY type. The

SPECIALNUMBERS array contains the values of all the prime numbers less than 1000, which is 168 values. The following statement assigns the 10 smallest prime numbers in the SPECIALNUMBERS array to the first 10 elements of the LOWPRIMES array.

```
SET LOWPRIMES = TRIM_ARRAY(SPECIALNUMBERS,CARDINALITY(SPECIALNUMBERS)-10);
```

TRUNCATE or TRUNC

The TRUNCATE function returns the first argument, truncated as specified. Truncation is to the number of places to the right or left of the decimal point this is specified by the second argument.



The schema is SYSIBM.

numeric-expression-1

An expression that returns a value of any built-in numeric data type.

If *expression-1* is a decimal floating-point data type, the DECFLOAT ROUNDING MODE will not be used. The rounding behavior of TRUNCATE corresponds to a value of ROUND_DOWN. If you want a different rounding behavior, use the QUANTIZE function.

The argument can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34).

numeric-expression-2

An expression that returns a value that is a built-in SMALLINT or INTEGER data type. The absolute value of the integer specifies the number of places to truncate. The value of *numeric-expression-2* determines whether truncation is to the right or left of the decimal point.

If *numeric-expression-2* is not negative, *numeric-expression-1* is truncated to the absolute value of *numeric-expression-2* places to the right of the decimal point.

If *numeric-expression-2* is negative, *numeric-expression-1* is truncated to 1 + (the absolute value of *numeric-expression-2*) places to the left of the decimal point. If 1 + (the absolute value of *numeric-expression-2*) is greater than or equal to the number of digits to the left of the decimal point, the result is 0. For example, `TRUNCATE(748.58,-4)` returns 0.

The argument can also be a character string or graphic string data type. The string input is implicitly cast to a numeric value of DECFLOAT(34), which is then assigned to an INTEGER value.

The result of the function has the same data type and length attribute as the first argument.

The result can be null; if any argument is null, the result is the null value.

Example 1: Using sample employee table DSN8C10.EMP, calculate the average monthly salary for the highest paid employee. Truncate the result to two places to the right of the decimal point.

```
   SELECT TRUNCATE(MAX(SALARY/12),2)
     FROM DSN8C10.EMP;
```

Because the highest paid employee in the sample employee table earns $52750.00 per year, the example returns the value 4395.83.

Example 2: Return the number 873.726 truncated to 2, 1, 0, -1, -2, -3, and -4 decimal places respectively.

```
   SELECT TRUNC(873.726,2),
          TRUNC(873.726,1),
          TRUNC(873.726,0),
          TRUNC(873.726,-1),
          TRUNC(873.726,-2),
          TRUNC(873.726,-3),
          TRUNC(873.726,-4)
     FROM TABLEX
     WHERE INTCOL = 1234;
```

This example returns the values 873.720, 873.700, 873.000, 870.000, 800.000, 0000.000, and 0000.000.

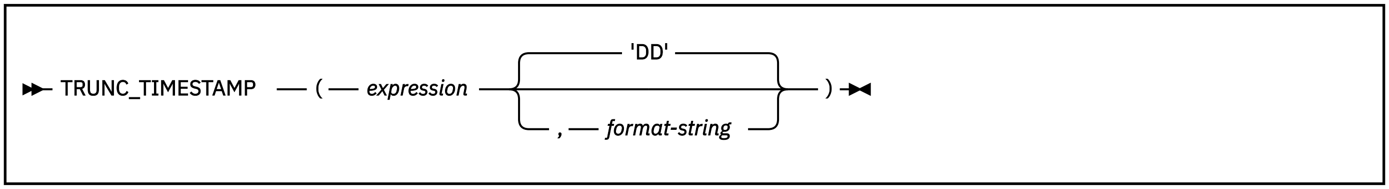
Example 3: Calculate both positive and negative numbers.

```
SELECT TRUNCATE( 3.5, 0),
    TRUNCATE( 3.1, 0),
    TRUNCATE(-3.1, 0),
    TRUNCATE(-3.5, 0)
    FROM TABLEX;
```

This example returns: the values 3.0, 3.0, -3.0, -3.0.

TRUNC_TIMESTAMP

The TRUNC_TIMESTAMP function returns a TIMESTAMP WITHOUT TIME ZONE value that is the *expression*, truncated to the unit that is specified by the *format-string*. If *format-string* is not specified, *expression* is truncated to the nearest day, as if 'DD' was specified for *format-string*.



The schema is SYSIBM.

expression
An expression that returns a value of any of the following built-in data types: a timestamp, a character string, or a graphic string. If expression is a character or graphic string, it must not be a CLOB or DBCLOB, and its value must be a valid string representation of a timestamp with an actual length that is not greater than 255 bytes. A time zone in a string representation of a timestamp is ignored. For the valid formats of string representations of dates and timestamps, see "String representations of datetime values" on page 120.

format-string
An expression that returns a built-in character string or graphic string data type, with a length that is not greater than 255 bytes. *format-string* contains a template of how the timestamp represented by expression should be truncated. For example, if *format-string* is 'DD', the timestamp that is represented by *expression* is truncated to the nearest day. *format-string* must be a valid template for a timestamp, and not include leading or trailing blanks. Allowable values for *format-string* are listed in the following table.

Table 97. ROUND_TIMESTAMP and TRUNC_TIMESTAMP format models

Format model	Description of rounding or truncating for the format model	ROUND_TIMESTAMP example	TRUNC_TIMESTAMP example
CC SCC	Century. One greater than the first two digits of a four digit year. For ROUND_TIMESTAMP, rounds up on the 50th year of the century.	Input Value: 1897-12-04-12.22.22.000000 Result: 1901-01-01-00.00.00.000000	Input Value: 1897-12-04-12.22.22.000000 Result: 1801-01-01-00.00.00.000000

Table 97. ROUND_TIMESTAMP and TRUNC_TIMESTAMP format models (continued)

Format model	Description of rounding or truncating for the format model	ROUND_TIMESTAMP example	TRUNC_TIMESTAMP example
SYYYY YYYY YEAR SYEAR YYY YY Y	Year. For ROUND_TIMESTAMP, rounds up on July 1 to January 1st of the next year.	Input Value: 1897-12-04-12.22.22.000000 Result: 1898-01-01-00.00.00.000000	Input Value: 1897-12-04-12.22.22.000000 Result: 1897-01-01-00.00.00.000000
IYYY IYY IY I	ISO year. For ROUND_TIMESTAMP, rounds up on July 1 to the first day of the next ISO year. The first day of the ISO year is defined as the Monday of the first ISO week.	Input Value: 1897-12-04-12.22.22.000000 Result: 1898-01-03-00.00.00.000000	Input Value: 1897-12-04-12.22.22.000000 Result: 1897-01-04-00.00.00.000000
Q	Quarter. For ROUND_TIMESTAMP, rounds up on the 16th day of the second month of the quarter.	Input Value: 1999-06-04-12.12.30.000000 Result: 1999-07-01-00.00.00.000000	Input Value: 1999-06-04-12.12.30.000000 Result: 1999-04-01-00.00.00.000000
MONTH MON MM RM	Month. For ROUND_TIMESTAMP, rounds up on the 16th day of the month.	Input Value: 1999-06-18-12.12.30.000000 Result: 1999-07-01-00.00.00.000000	Input Value: 1999-06-18-12.12.30.000000 Result: 1999-06-01-00.00.00.000000
WW	Same day of the week as the first day of the year. For ROUND_TIMESTAMP, rounds up on the 12th hour of the 4th day of the week, with respect to the first day of the year.	Input Value: 2000-05-05-12.12.30.000000 Result: 2000-05-06-00.00.00.000000	Input Value: 2000-05-05-12.12.30.000000 Result: 2000-04-29-00.00.00.000000

Table 97. ROUND_TIMESTAMP and TRUNC_TIMESTAMP format models (continued)

Format model	Description of rounding or truncating for the format model	ROUND_TIMESTAMP example	TRUNC_TIMESTAMP example
IW	Same day of the week as the first day of the ISO year. For ROUND_TIMESTAMP, rounds up on the 12th hour of the 4th day of the week, with respect to the first day of the ISO year.	Input Value: 2000-05-05-12.12.30.000000 Result: 2000-05-08-00.00.00.000000	Input Value: 2000-05-05-12.12.30.000000 Result: 2000-05-01-00.00.00.000000
W	Same day of the week as the first day of the month. For ROUND_TIMESTAMP, rounds up on the 12th hour of the 4th day of the week, with respect to the first day of the month.	Input Value: 2000-06-21-12.12.30.000000 Result: 2000-06-22-00.00.00.000000	Input Value: 2000-06-21-12.12.30.000000 Result: 2000-06-15-00.00.00.000000
DDD DD J	Day. For ROUND_TIMESTAMP, rounds up on the 12th hour of the day.	Input Value: 2000-05-17-12.59.59.000000 Result: 2000-05-18-00.00.00.000000	Input Value: 2000-05-17-12.59.59.000000 Result: 2000-05-17-00.00.00.000000
DAY DY D	Starting day of the week. For ROUND_TIMESTAMP, rounds up with respect to the 12th hour of the 4th day of the week. The first day of the week is always Sunday.	Input Value: 2000-05-17-12.59.59.000000 Result: 2000-05-21-00.00.00.000000	Input Value: 2000-05-17-12.59.59.000000 Result: 2000-05-14-00.00.00.000000
HH HH12 HH24	Hour. For ROUND_TIMESTAMP, rounds up at 30 minutes.	Input Value: 2000-05-17-23.59.59.000000 Result: 2000-05-18-00.00.00.000000	Input Value: 2000-05-17-23.59.59.000000 Result: 2000-05-17-23.00.00.000000
MI	Minute. For ROUND_TIMESTAMP, rounds up at 30 seconds.	Input Value: 2000-05-17-23.58.45.000000 Result: 2000-05-17-23.59.00.000000	Input Value: 2000-05-17-23.58.45.000000 Result: 2000-05-17-23.58.00.000000

Table 97. ROUND_TIMESTAMP and TRUNC_TIMESTAMP format models (continued)

Format model	Description of rounding or truncating for the format model	ROUND_TIMESTAMP example	TRUNC_TIMESTAMP example
SS	Second. For ROUND_TIMESTAMP, rounds up at 500000 microseconds.	Input Value: 2000-05-17-23.58.45.500000 Result: 2000-05-17-23.58.46.000000	Input Value: 2000-05-17-23.58.45.500000 Result: 2000-05-17-23.58.45.000000

expression is cast as follows:

- If *expression* is a timestamp with time zone value, *expression* is cast to a timestamp without time zone value, with the same precision as *expression*.
- Otherwise, *expression* is cast to TIMESTAMP(6) WITHOUT TIME ZONE.

The result of the function is a timestamp with time zone.

The result can be null; if any argument is null, the result is the null value.

The result CCSID is the appropriate CCSID of the argument encoding scheme and the result subtype is the appropriate subtype of the CCSID.

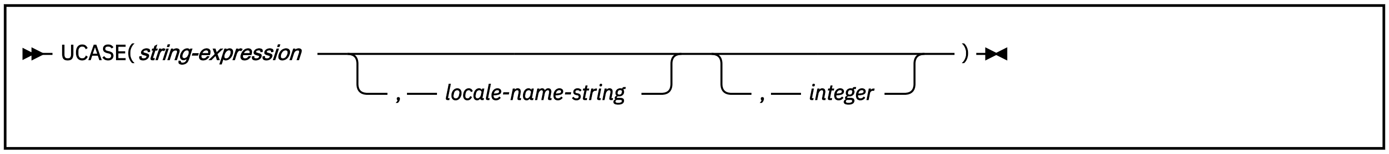
Example: Set the host variable *TRNK_TMSTMP* with the specified date rounded to the nearest year value.

```
SET :TRNK_TMSTMP = TRUNC_TIMESTAMP('2008-03-14-17.30.00', 'YEAR');
```

The host variable *TRNK_TMSTMP* is set with the value '2008-01-01-00.00.00.000000'.

UCASE

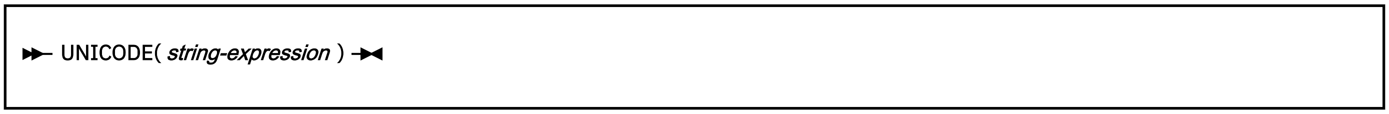
The UCASE function returns a string in which all the characters have been converted to uppercase characters, based on the CCSID of the argument.



The UCASE function is identical to the UPPER function. For more information, see “UPPER” on page 611.

UNICODE

The UNICODE function returns the Unicode UTF-16 code value of the leftmost character of the argument as an integer.



The schema is SYSIBM.

string-expression can be of any built-in string data type that is not a LOB.

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type.

If the argument is ASCII, EBCDIC, or Unicode UTF-8, it is first converted to a Unicode UTF-16 string (CCSID 1200) before the function is executed.

The result of the function is an INTEGER.

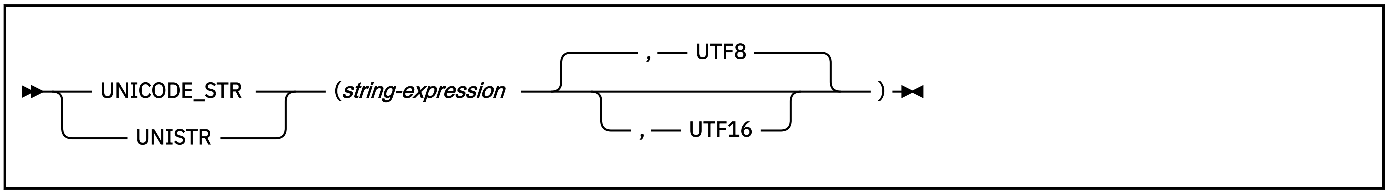
The result can be null; if the argument is null, the result is the null value.

Example: The following example returns the Unicode value of 峰 as an integer and assigns the value to the host variable *hv*:

`Set :hv = UNICODE('峰');` *hv* is set to an integer with a value '23792'.

UNICODE_STR or UNISTR

The UNICODE_STR function returns a string in Unicode UTF-8 or UTF-16, depending on the specified option. The string represents a Unicode encoding of the input string.



The schema is SYSIBM.

string-expression
An expression that returns a value of a built-in character or graphic string. A character string must not be bit data. Values that are preceded by a backslash ('\') are treated as Unicode UTF-16 characters (for example '\0041' is the Unicode UTF-16 representation for 'A'). A double backslash '\\' indicates a backslash in the string. A partial surrogate character in the expression is replaced with a blank.

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type.

UTF8 or UTF16
Specifies the Unicode encoding of the result. If UTF8 is specified, the result is returned as a Unicode UTF-8 character string. If UTF16 is specified, the result is returned as a Unicode UTF-16 graphic string. UTF8 is the default.

The result of the function depends on the second argument:

- VARCHAR if UTF8 is specified
- VARGRAPHIC if UTF16 is specified

The length attribute of the result depends on the second argument (UTF8 or UTF16). The length attribute of the result is calculated using the formulas in Table 37 on page 163. If the result is a character string, the length attribute of the result is `MIN(`*n*`,32704)`. If the result is a graphic string, the length attribute of the result is `MIN(`*n*`,16352)`. Where *n* is the result of applying the formulas in Table 37 on page 163 based on input and output data types.

If the actual length of the result string exceeds the maximum for the return type, an error occurs.

The result can be null; if the argument is null, the result is the null value.

Examples

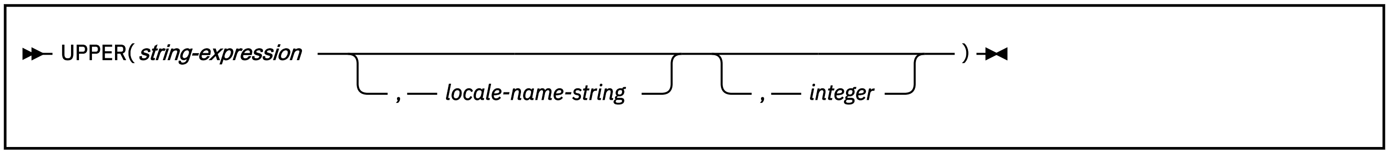
Example 1:
The following example sets the host variable *HV1* to a VARCHAR value that represents the Unicode UTF-8 string that corresponds to the argument:

```
SET :HV1 = UNICODE_STR('Hi, my name is \5CF0');
```

HV1 is assigned a Unicode UTF-8 string with the following value 'Hi, my name is 峰'

UPPER

The UPPER function returns a string in which all the characters have been converted to uppercase characters.



The schema is SYSIBM.

string-expression

An expression that specifies the string to be converted. *string-expression* must return a value that is a built-in character or graphic string. A character string argument must not be a CLOB, and a graphic string argument must not be a DBCLOB. If *string-expression* is an EBCDIC graphic string, a blank string must not be specified for *locale-name-string*. If *string-expression* is bit data, *locale-name-string* must not be specified.

locale-name-string

A string constant or a string host variable other than a CLOB or DBCLOB that specifies a valid locale name. If *locale-name-string* is not in EBCDIC, it is converted to EBCDIC. The length of *locale-name-string* must be between 1 and 255 bytes of the EBCDIC representation. The value of *locale-name-string* is not case sensitive and must be a valid locale. For information about locales and their naming conventions, see Locale naming conventions (XL C/C++ Programming Guide). Some examples of locales include:

Fr_BE
Fr_FR@EURO
En_US
Ja_JP

The conversion process is determined by the value that is specified for the locale name, as follows:

blank

SBCS lowercase characters a-z are converted to SBCS uppercase characters A-Z, and characters with diacritical marks are not converted. If the string contains MIXED or DBCS characters, full-width lowercase characters a-z are converted to full-width Latin uppercase characters A-Z. For optimal performance, specify a blank string unless your data must be processed by using the rules that are defined by a specific locale.

UNI

The conversion uses both the NORMAL and SPECIAL casing capabilities as described in Select the conversions (z/OS: Unicode Services User's Guide and Reference). You must not specify UNI when *string-expression* is EBCDIC data.

UNI_60

The conversion uses Unicode Standard 6.0.0 and the NORMAL casing capability, as described in Select the conversions (z/OS: Unicode Services User's Guide and Reference). You must not specify UNI_60 when *string-expression* is EBCDIC data.

UNI_90

The conversion uses Unicode Standard 9.0.0 and the NORMAL casing capability, as described in Select the conversions (z/OS: Unicode Services User's Guide and Reference). You must not specify UNI_90 when *string-expression* is EBCDIC data.

UNI_SIMPLE

Case conversions use the NORMAL casing capabilities as described in Select the conversions (z/OS: Unicode Services User's Guide and Reference). UNI_SIMPLE cannot be used with EBCDIC data.

locale name

The locale defines the rules for conversion to uppercase characters.

The value of the host variable must not be null. If the host variable has an associated indicator variable, the value of the indicator variable must not indicate a null value. The locale name must be:

- left justified within the host variable
- padded on the right with blanks if its length is less than that of the host variable and the host variable is in fixed length CHAR or GRAPHIC data type

If *locale-name-string* is not specified, the locale is determined by special register CURRENT LOCALE LC_CTYPE. For information about the special register, see "CURRENT LOCALE LC_CTYPE special register" on page 196.

If the UPPER function is referenced in an expression-based index, *locale-name-string* must be specified

integer
An integer value that specifies the length attribute of the result. If specified, *integer* must be an integer constant between 1 and 32704 bytes in the representation of the encoding scheme of *string-expression*.

If *integer* is not specified, the length attribute of the result is the same as the length of *string-expression*.

For Unicode data, usage of the UPPER function can result in expansion if certain characters are processed. For example, `UPPER(UX'FB03')` will result in UX'004600460049'. You should ensure that the result string is large enough to contain the result of the expression.

The result can be null; if the argument is null, the result is the null value.

Notes

Syntax alternatives:
UCASE is a synonym for UPPER. UPPER should be used for conformance to the SQL standard.

Examples

Example 1:
Return the string 'abcdef' in uppercase characters. Assume that the locale in effect is blank.

```
   SELECT UPPER('abcdef')
     FROM SYSIBM.SYSDUMMY1
```

The result is the value 'ABCDEF'.

Example 2:
Return the string 'ﬃ' in the uppercase characters ('FFI'). Assume that the locale in effect is "UNI".

```
SELECT UPPER(UX'FB03')
  FROM SYSIBM.SYSDUMMYU;
```

This would result in an error because of the expansion that occurs when certain Unicode characters are processed. To avoid the error, you would need to use the following statement instead:

```
SELECT UPPER(CAST(UX'FB03' AS VARCHAR(3))
  FROM SYSIBM.SYSDUMMYU;
```

The result of the preceding statement is the value 'FFI'.

Example 3:
Create an index EMPLOYEE_NAME_UPPER for table EMPLOYEE based on built-in function UPPER with locale name 'Fr_FR@EURO'.

```
   CREATE INDEX EMPLOYEE_NAME_UPPER
      ON EMPLOYEE (UPPER(LASTNAME, 'Fr_FR@EURO', 60),
                   UPPER(FIRSTNAME, 'Fr_FR@EURO', 60),
                   ID);
```

The result is the value 'ABCDEF'.

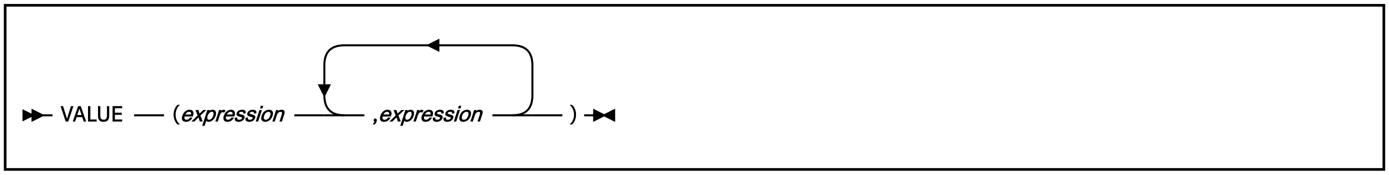
z/OS Unicode Services User’s Guide and Reference

Related reference

z/OS XL C/C++ Programming Guide

VALUE

The VALUE function returns the value of the first non-null expression.

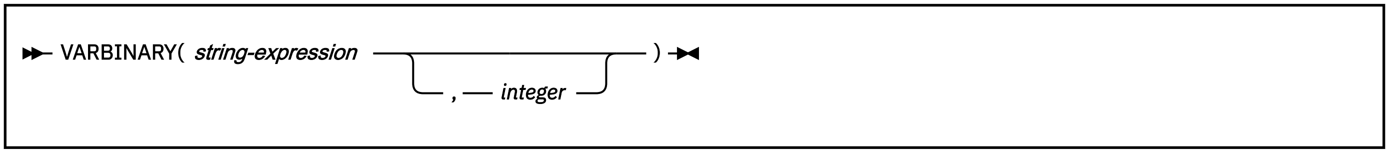


The schema is SYSIBM.

The VALUE function is identical to the COALESCE function. COALESCE should be used for conformance to SQL standard. For more information, see “COALESCE” on page 417.

VARBINARY

The VARBINARY function returns a VARBINARY (varying-length binary string) representation of a string of any type.



The schema is SYSIBM.

string-expression
An expression that returns a value that is a built-in character string, graphic string, binary string, or a row ID type.

integer
An integer value that specifies the length attribute of the resulting binary string. The value must be an integer between 1 and 32704 inclusive. If integer is not specified:

- If the *string-expression* is the empty string constant, the length attribute of the result is 1.
- Otherwise, the length attribute of the result is the same as the length attribute of the *string-expression*, unless the *string-expression* is a graphic string. In this case, the length attribute of the result is twice the length attribute of the *string-expression*.

The result of the function is a varying-length binary string.

The result can be null; if the first argument is null, the result is the null value.

The actual length of the result is the minimum of the length attribute of the result and the actual length of the *string-expression* (or twice the length of the *string-expression* if *string-expression* returns a graphic string). If the length of the *string-expression* is greater than the length attribute of the result, truncation is performed, and a warning is returned unless the *string-expression* is a character string and all the truncated characters are blanks, or the *string-expression* is a graphic string and all the truncated characters are double-byte blanks.

Example 1: The following function returns a varying-length binary string with a length attribute 1, actual length 0, and a value of empty string:

```
SELECT VARBINARY('')
  FROM SYSIBM.SYSDUMMY1;
```

Example 2: The following function returns a varying-length binary string with a length attribute 5, actual length 3, and a value BX'D2C2C8':

```
SELECT VARBINARY('KBH',5)
  FROM SYSIBM.SYSDUMMY1;
```

Example 3: The following function returns a varying-length binary string with a length attribute 3, actual length 3, and a value BX'D2C2C8'

```
SELECT VARBINARY('KBH ',3)
  FROM SYSIBM.SYSDUMMY1;
```

Example 4: The following function returns a varying-length binary string with a length attribute 3, actual length 3, and a value BX'D2C2C8', a warning is also returned.

```
SELECT VARBINARY('KBH-93',3)
  FROM SYSIBM.SYSDUMMY1;
```

Example 5: The following function returns a varying-length binary string with a length attribute 3, actual length 3, and a value BX'C1C2C3', a warning is also returned.

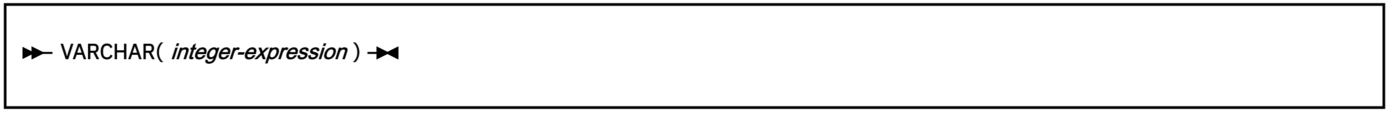
```
SELECT VARBINARY(BINARY('ABC',5),3)
  FROM SYSIBM.SYSDUMMY1;
```

VARCHAR

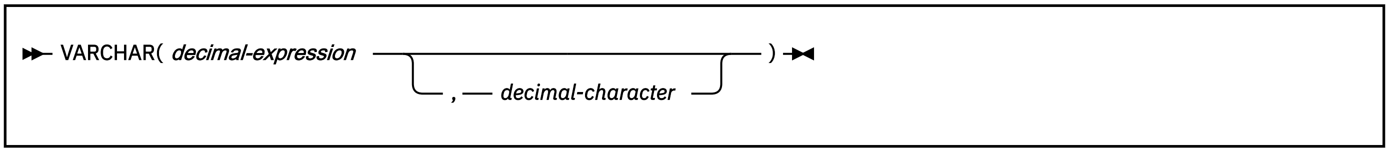
The VARCHAR function returns a varying-length character string representation of the value specified by the first argument.

The syntax of the VARCHAR function depends on the data type of the input argument. The following types of input arguments are accepted.

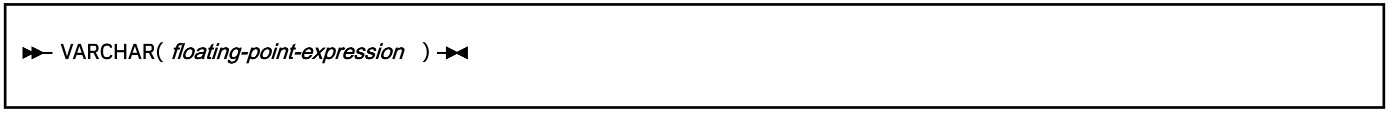
Integer to Varchar:



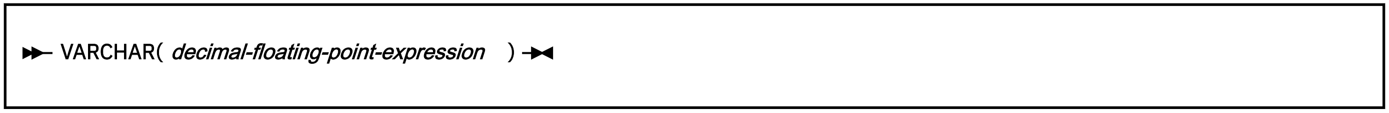
Decimal to Varchar:



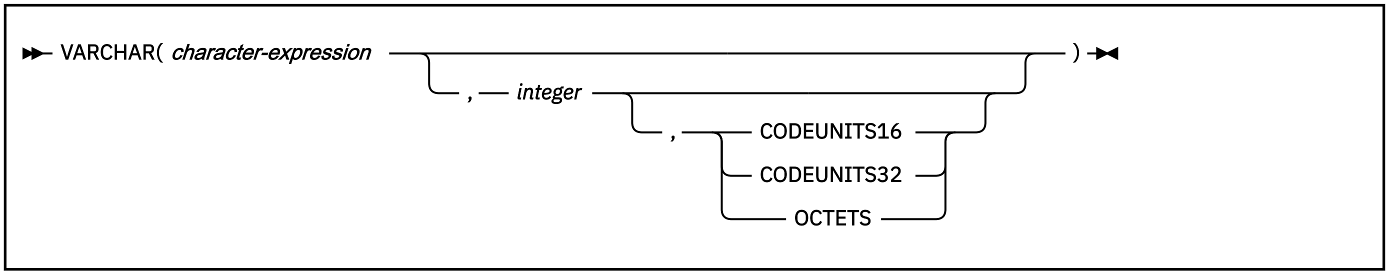
Floating-point to Varchar:



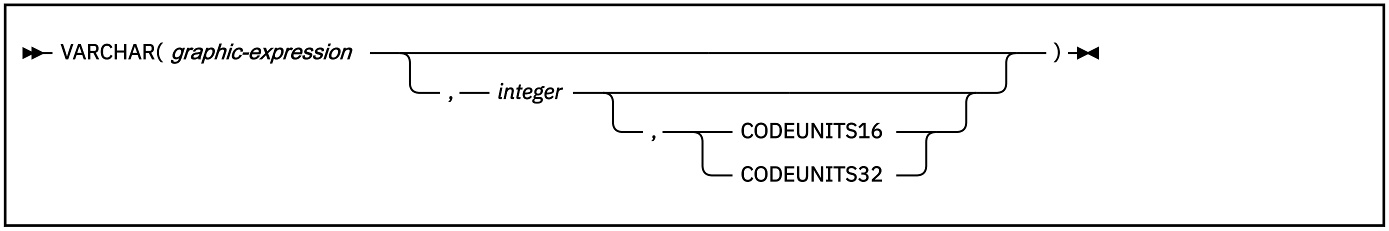
Decimal floating point to Varchar:



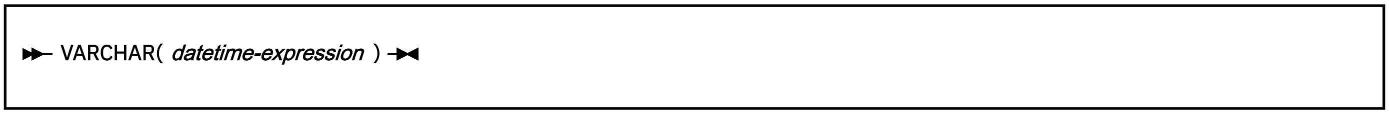
Character to Varchar:



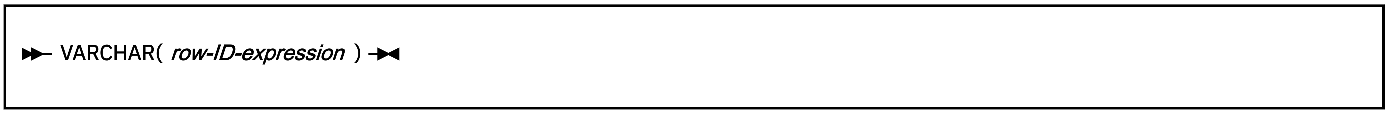
Graphic to Varchar:



Datetime to Varchar:



Row ID to Varchar:



The schema is SYSIBM.

The VARCHAR function returns a varying-length character string representation of one of the following values:

- An integer number if the first argument is a SMALLINT, INTEGER, or BIGINT
- A decimal number if the first argument is a decimal number
- A double-precision floating-point number if the first argument is a DOUBLE or REAL
- A decimal floating-point number if the first argument is a DECFLOAT
- A character string value if the first argument is any type of character string
- A graphic string if the first argument is an EBCDIC or Unicode graphic string
- A datetime value if the first argument is a date, time, or timestamp
- A row ID value if the first argument is a row ID

The result of the function is a varying-length character string (VARCHAR).

The result can be null; if the first argument is null, the result is the null value.

Integer to Varchar

integer-expression
An expression that returns a value that is a built-in integer data type (SMALLINT, INTEGER, BIGINT).

The result is a varying-length character string representation of the argument in the form of an SQL integer constant. The actual length of the result is the smallest number of characters that can be used to represent the value of the argument. The result consists of n characters that are the significant digits that represent the value of the argument with a preceding minus sign if the argument is negative. A positive value starts with a digit. Leading zeroes are not included.

- If the argument is a small integer, the length attribute of the result is 6.
- If the argument is a large integer, the length attribute of the result is 11.
- If the argument is a big integer, the length attribute of the result is 20.

The CCSID of the result is determined from the application encoding scheme.

Decimal to Varchar

decimal-expression
An expression that returns a value that is a built-in decimal data type. To specify a different precision and scale for the expression's value, apply the DECIMAL function to the expression before applying the VARCHAR function.

decimal-character
Specifies the single-byte character constant that is used to delimit the decimal digits in the result character string. The character must not be a digit, a plus sign (+), a minus sign (-), or a blank. The default is the period (.) or comma (,). For information on what factors govern the choice, see “Decimal point representation” on page 322.

The result is a varying-length character string representation of the first argument. The actual length of the result is the smallest number of characters that can be used to represent the result, except that trailing zeros are included. The result includes a decimal character and up to *p* digits where *p* is the precision of *decimal-expression* with a preceding minus sign if the argument is negative. A positive value starts with a digit or the *decimal-character*. Leading zeros are not returned. If the scale of decimal expression is zero, the decimal character is not returned.

The length attribute of the result is 2+*p* where *p* is the precision of *decimal-expression*.

[21]

The CCSID of the result is determined from the application encoding scheme.

Floating-point to Varchar

floating-point-expression
An expression that returns a value that is a built-in floating-point data type.

The result is a varying-length character string representation of the argument in the form of an SQL floating-point constant. If the argument is negative, the first character of the result is a minus sign; otherwise, the first character is a digit. If the argument is zero, the result is 0E0.

The length attribute of the result is 24. The actual length of the result is the smallest number of characters that can represent the value of the argument such that the mantissa consists of a single digit other than zero followed by a period and a sequence of digits.

The CCSID of the result is determined from the application encoding scheme.

Decimal floating-point to Varchar

decimal-floating-point-expression
An expression that returns a value that is the built-in DECFLOAT data type.

The result is the varying-length character string representation of the argument in the form of an SQL decimal floating-point constant.

If the result value is one of the special values Infinity, sNaN, or NaN, the strings ’INFINITY’, ’SNAN’, or ’NAN’, respectively, are returned. The DECFLOAT special value sNaN does not result in an exception when it is converted to a string.

[21] If the BIF_COMPATIBILITY system parameter is set to V9_DECIMAL_VARCHAR, or if the SYSCOMPAT_V9.VARCHAR function is used, the format of the result matches the result of the VARCHAR9 function with decimal input.

The length attribute of the result is 42. The actual length of the result is the smallest number of characters that represents the value of the argument, including the sign, digits, and period. Trailing zeros are significant. If the argument is negative, the first character of the result is a minus sign. Otherwise, the first character is a digit, or a letter if the result value is Infinity, sNaN, or NaN.

The CCSID of the result is determined from the application encoding scheme.

Character to Varchar

character-expression
An expression that returns a value that is a built-in character data type.

integer
Specifies the length attribute for the resulting varying-length character string. The value must be between 1 and 32764, expressed in the units that are either implicitly or explicitly specified. If the length is not specified, the length of the result is the same as the length of *character-expression*.

If CODEUNITS16, CODEUNITS32, or OCTETS is specified, see "Determining the length attribute of the final result" on page 108 for information about how to calculate the length attribute of the result string.

If a length attribute is not specified and if the *character-expression* is an empty string constant, the length attribute of the result is 1 and the result is an empty string. Otherwise, the length attribute of the result is the same as the length attribute of the first argument.

CODEUNITS16, CODEUNITS32, or OCTETS
Specifies the unit that is used to express *integer*. If *character-expression* is a character string that is defined as bit data, CODEUNITS16 and CODEUNITS32 cannot be specified.

CODEUNITS16
Specifies that *integer* is expressed in terms of 16-bit UTF-16 code units.

CODEUNITS32
Specifies that *integer* is expressed in terms of 32-bit UTF-32 code units.

OCTETS
Specifies that *integer* is expressed in terms of bytes.

For more information about CODEUNITS16, CODEUNITS32, and OCTETS, see "String unit specifications" on page 106.

The actual length of the result is the minimum of the length attribute of the result and the actual length of *character-expression*. If the length of *character-expression* is greater than the length attribute of the result, the result is truncated. Unless all the truncated characters are blanks appropriate for *character-expression*, a warning is returned.

If *character-expression* is bit data, the result is bit data. Otherwise, the CCSID of the result is the same as the CCSID of *character-expression*.

Graphic to Varchar

graphic-expression
An expression that returns a value that is a built-in graphic data type.

integer
The length attribute for the resulting varying-length graphic string. The value must be between 1 and 32704, expressed in the units that are either implicitly or explicitly specified.

If CODEUNITS16 or CODEUNITS32 is specified, see "Determining the length attribute of the final result" on page 108 for information about how to calculate the length attribute of the result string.

If a length attribute is not specified, the length attribute of the result is determined as follows (where *n* is the length attribute of the first argument):

- If the *graphic-expression* is the empty graphic string constant, the length attribute of the result is 1.
- If the result is SBCS data, the result length is *n*.

- If the result is mixed data, the result length is `3*(length(graphic-expression)`.

CODEUNITS16 or CODEUNITS32
Specifies the unit that is used to express *integer*.

CODEUNITS16
Specifies that *integer* is expressed in terms of 16-bit UTF-16 code units.

CODEUNITS32
Specifies that *integer* is expressed in terms of 32-bit UTF-32 code units.

For more information about CODEUNITS16 or CODEUNITS32, see "String unit specifications" on page 106.

The actual length of the result is the minimum of the length attribute of the result and the actual length of *graphic-expression*. If the length of the graphic expression is greater than the length attribute of the result, the result is truncated. Unless all the truncated characters were blanks appropriate for *graphic-expression*, a warning is returned.

The CCSID of the result is the character mixed CCSID that corresponds to the graphic CCSID of *graphic-expression*.

Datetime to Varchar

datetime-expression
An expression whose value has one of the following three built-in data types:

date
The result is a varying-length character string representation of the date in the format that is specified by the DATE precompiler option, if one is provided, or else field DATE FORMAT on installation panel DSNTIP4 specifies the format. If the format is to be LOCAL, field LOCAL DATE LENGTH on installation panel DSNTIP4 specifies the length of the result. Otherwise, the length attribute and actual length of the result is 10.

LOCAL denotes the local format at the Db2 that executes the SQL statement. If LOCAL is used for the format, a time exit routine must be installed at that Db2.

An error occurs if the second argument is specified and is not a valid value.

time
The result is a varying-length character string representation of the time in the format specified by the TIME precompiler option, if one is provided, or else field TIME FORMAT on installation panel DSNTIP4 specifies the format. If the format is to be LOCAL, the field LOCAL TIME LENGTH on installation panel DSNTIP4 specifies the length of the result. Otherwise, the length attribute and actual length of the result is 8.

LOCAL denotes the local format at the Db2 that executes the SQL statement. If LOCAL is used for the format, a time exit routine must be installed at that Db2.

An error occurs if the second argument is specified and is not a valid value.

timestamp
The result is the character string representation of the timestamp with time zone. The second argument must not be specified.

- If *datetime-expression* is a TIMESTAMP (0) WITHOUT TIME ZONE, the length of the result is 19.
- If *datetime-expression* is a TIMESTAMP (*p*) WITHOUT TIME ZONE, the length of the result is 20+*p* where p is the timestamp precision. The second argument must not be specified.
- If *datetime-expression* is a TIMESTAMP (0) WITH TIME ZONE, the length of the result is 25.
- If *datetime-expression* is a TIMESTAMP (*p*) WITH TIME ZONE, the length of the result is 26 +*p* where *p* is the timestamp precision. The second argument must not be specified

The CCSID of the result is determined from the context in which the function was invoked. For more information, see Determining the encoding scheme and CCSID of a string (Introduction to Db2 for z/OS).

Row ID to Varchar

row-ID-expression

An expression that returns a value that is a built-in row ID data type.

The result is a varying-length character string representation (VARCHAR) of the argument. It is bit data.

The length attribute of the result is 40. The actual length of the result is the length of *row-ID-expression*.

Notes

Syntax alternatives: VARCHAR9 can be specified as an alternative to VARCHAR. The result of the function is the same, except when the first argument is decimal data.

Examples

Example 1: Assume that host variable *JOB_DESC* is defined as VARCHAR(8). Using sample table DSN8C10.EMP, set *JOB_DESC* to the varying-length string equivalent of the job description (column JOB defined as CHAR(8)) for the employee with the last name of 'QUINTANA'.

```
SELECT VARCHAR(JOB)
  INTO :JOB_DESC
  FROM DSN8C10.EMP
  WHERE LASTNAME = 'QUINTANA';
```

Example 2: FIRSTNME is a VARGRAPHIC(6) column in a Unicode table T1. One of its values is the string 'Jürgen' (X'004A00FC007200670055006E'). When FIRSTNME has this value:

```
Function ...                           Returns ...
-------------------------------------------------------
VARCHAR(FIRSTNME,3,CODEUNITS32)        'Jür'  -- x'4AC3BC72'
VARCHAR(FIRSTNME,3,CODEUNITS16)        'Jür'  -- x'4AC3BC72'
VARCHAR(FIRSTNME,3,OCTETS)             'Jü'   -- x'4AC3BC'
```

Related concepts

Data types of columns (Introduction to Db2 for z/OS)

Related reference

“VARCHAR9” on page 619
The VARCHAR9 function returns a fixed-length character string representation of the argument. The VARCHAR9 function is intended for compatibility with previous releases of Db2 for z/OS that depend on the result format that is returned for decimal input values in Version 9 and earlier.

BIF COMPATIBILITY field (BIF_COMPATIBILITY subsystem parameter) (Db2 Installation and Migration)

VARCHAR9

The VARCHAR9 function returns a fixed-length character string representation of the argument. The VARCHAR9 function is intended for compatibility with previous releases of Db2 for z/OS that depend on the result format that is returned for decimal input values in Version 9 and earlier.

Important: For portable applications that might run on platforms other than Db2 for z/OS, use the VARCHAR function instead. Other Db2 family products do not support the VARCHAR9 function.

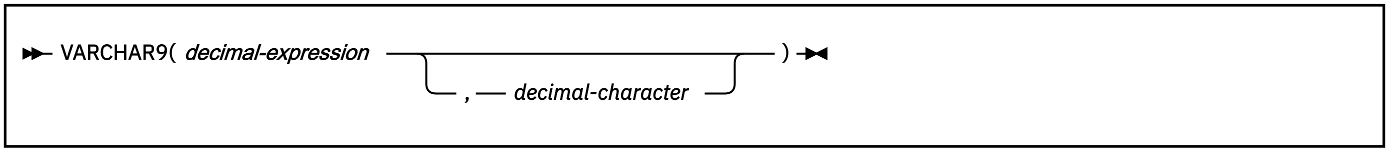
The first argument can be any value of the of the following types:

- Integer number
- Decimal number
- Floating-point number

- Character string
- Graphic string
- Datetime value
- Row ID value

If the first argument is a decimal number, the result is formatted as indicated in the following description. However, if the first argument is not a decimal number, the result is identical to the result of the VARCHAR function.

Decimal to Varchar:



Decimal to Varchar

decimal-expression
An expression that returns a value that is a built-in decimal data type. To specify a different precision and scale for the expression's value, apply the DECIMAL function to the expression before applying the VARCHAR9 function.

decimal-character
Specifies the single-byte character constant (CHAR or VARCHAR) that is used to delimit the decimal digits in the result character string. The character must not be a digit, a plus sign (+), a minus sign (-), or a blank. The default is the period (.) or comma (,). For information about the factors that govern the choice, see "Decimal point representation" on page 322

The result is a varying-length character string representation of the argument. The result includes a decimal character and up to *p* digits where *p* is the precision of *decimal-expression* with a preceding minus sign if the argument is negative. Leading and trailing zeros are returned. The result includes a decimal character even if the scale of *decimal-expression* is zero.

The CCSID of the result is determined from the context in which the function was invoked. For more information, see Determining the encoding scheme and CCSID of a string (Introduction to Db2 for z/OS).

Examples

The following table shows the difference between the results of the VARCHAR and VARCHAR9 functions for example decimal number arguments.

Table 98. Example results of VARCHAR and VARCHAR9 functions

Decimal Argument	VARCHAR Function Result	VARCHAR9 Function Result
`(000.1)`	`'.1'`	`'0.1'`
`(1000.)`	`'1000'`	`'1000. '`
`(1.1)`	`'1.1'`	`'1.1'`

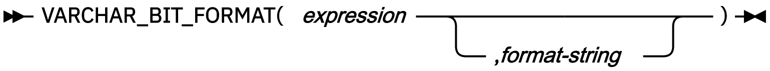
Related concepts
Data types of columns (Introduction to Db2 for z/OS)

Related reference
VARCHAR
The VARCHAR function returns a varying-length character string representation of the value specified by the first argument.

BIF COMPATIBILITY field (BIF_COMPATIBILITY subsystem parameter) (Db2 Installation and Migration)

VARCHAR_BIT_FORMAT

The VARCHAR_BIT_FORMAT function returns a bit data string representation of a character string that has been formatted using a format-string.



expression

An expression that returns a value of any built-in numeric, character-string, or graphic-string data type that is not a LOB. A numeric or graphic argument is cast to a VARCHAR data type before evaluating the function. *expression* must not return bit data..

All leading and trailing blanks are removed from *expression* before evaluating the function.

If a format-string is specified, the length of *expression* must be equal to the length of the *format-string* and the value of *expression* must conform to the template specified by the *format-string*. If a*format-string* is not specified, the value of *expression* (after removing leading and trailing blanks) should be an even number of characters from the ranges '0' to '9', 'a' to 'f', and 'A' to 'F'. If the length is an odd number of characters, the string is padded on the right with one '0' character.

format-string

An expression that returns a built-in character string or graphic string data type. format-string contains a template for how the value for expression is to be interpreted. format-string must not return bit data.

The valid format strings are: '*xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx*' and '*XXXXXXXX-XXXX-XXXX-XXXX-XXXXXXXXXXXX*', where each '*x*' or '*X*' corresponds to one hexadecimal digit in the result. If '*X*' is specified, the corresponding hexadecimal digit must not be a lower case character. If '*x*' is specified, the corresponding hexadecimal digit must not be an upper case character.

The result is a varying-length bit data string. The length attribute of the result is half the length attribute of *expression*. If a format-string is not specified, the actual length is half the actual length of *expression* (after leading and trailing blanks have been removed and padding to an even number of characters). If a *format-string* is specified, the actual length is half the actual length of the *format-string* (after removing the non-digit separator characters). If any of the arguments can be null, the result can be null; if any of the arguments is null, the result is the null value.

Examples

Represent a Universal Unique Identifier in its binary form

```
SELECT VARCHAR_BIT_FORMAT (’d83d6360-1818-11db-9804-b622a1ef5492’,
’xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx’)
FROM SYSIBM.SYSDUMMY1
```

Result returned: `X’D83D6360181811DB9804B622A1EF5492’`

Represent a Universal Unique Identifier in its binary form:

```
SELECT VARCHAR_BIT_FORMAT (’D83D6360-1818-11DB-9804-B622A1EF5492’,
’XXXXXXXX-XXXX-XXXX-XXXX-XXXXXXXXXXXX’)
FROM SYSIBM.SYSDUMMY1
```

Result returned: `X’D83D6360181811DB9804B622A1EF5492’`

Represent a string of hexadecimal characters in binary form:

```
SELECT VARCHAR_BIT_FORMAT (’ef01abC9’) FROM SYSIBM.SYSDUMMY1
```

Result returned: `X’EF01ABC9’`

VARCHAR_FORMAT

The VARCHAR_FORMAT function returns a character string representation of the first argument, in the format indicated by *format-string* if it is specified.

Character to VARCHAR

```
►► VARCHAR_FORMAT( character-expression ) ►◄
```

Timestamp to VARCHAR

```
►► VARCHAR_FORMAT( timestamp-expression ,format-string ) ►◄
```

Numeric to VARCHAR

```
►► VARCHAR_FORMAT( numeric-expression ─┬─────────────────────┬─ ) ►◄
                                        └─ , ── format-string ─┘
```

The schema is SYSIBM.

Character to VARCHAR

character-expression

An expression that returns a value that must be a built-in CHAR or VARCHAR data type. If a supplied argument is a GRAPHIC or VARGRAPHIC data type, it is first converted to VARCHAR before evaluating the function.

The length attribute of the result and the actual length are determined as follows:

- If *string-expression* is an empty string constant, the length attribute of the result is 1.
- Otherwise, the length attribute of the result is that same as the length attribute of *string-expression*.
- The actual length of the result is the minimum of the length attribute of the result and the actual length of *string-expression*.

The value of the result is the same as the value of *character-expression*.

If *character-expression* returns graphic data, the CCSID of the result is the character mixed CCSID that corresponds to the graphic argument. If *character-expression* returns bit data, the result is bit data. Otherwise, the CCSID of the result is the same as the CCSID of *character-expression*.

Timestamp to VARCHAR

timestamp-expression

An expression that returns a value that must be a DATE or TIMESTAMP, or a valid character string or graphic string representation of a date or timestamp that is not a CLOB or DBCLOB. If the argument is a graphic string representation of a data or timestamp, it is first converted to a character string before evaluating the function.

If *timestamp-expression* is a DATE or a valid string representation of a date, it is first converted to a TIMESTAMP(0) value, assuming a time of exactly midnight (00.00.00). If the HH12 format element is specified and the time component of the first argument is 24:00:00, the input timestamp value is adjusted to 00:00:00 and the date is incremented by one day.

For the valid formats of string representations of datetime values, see "String representations of datetime values" on page 120.

format-string

An expression that returns a built-in character string or graphic string data type that is not a LOB and has a length attribute that is not greater than 255 bytes. If the value is not a CHAR or VARCHAR data type, it is implicitly cast to VARCHAR before the function is evaluated. If the *expression* returns timestamp data type, the resulting substring must conform to the rules for formatting a timestamp. If the *expression* returns timestamp with a time zone, the resulting substring must conform to the rules for formatting a timestamp with time zone.

The value is a template for how *timestamp-expression* is to be formatted.

A valid *format-string* can contain a combination of the format elements listed below. Two format elements can be separated by one or more of the following separator characters.

- minus sign (-)
- period (.)
- forward slash (/)
- comma (,)
- apostrophe (')
- semicolon (;)
- colon (:)
- blank ( )

Separator characters can also be specified at the start or end of *format-string*. *format-string* can also be an empty string, a string of blanks, or a string of separator characters.

The following table lists the valid format elements that *format-string* can contain.

Table 99. Valid format elements of format-string

Format element	Description (assuming the default is to return leading zeros)
AM or PM [1]	Meridian indicator (morning or evening) without periods. This format element uses the exact strings “AM” or “PM”.
A.M. or P.M. [1]	Meridian indicator (morning or evening) with periods. This format element uses the exact strings “A.M.” or “P.M.”.
CC	Century (00-99). If the last two digits of the four digit year are zero, the result is the first two digits of the year. Otherwise, the result is the first two digits of the year plus one.
D [1]	Day of the week (1-7). 1 is Sunday and 7 is Saturday.
DD	Day of the month (01-31).
DDD	Day of the year (001-366).

Table 99. Valid format elements of format-string (continued)

Format element	Description (assuming the default is to return leading zeros)
FF or FF*n*	Fractional seconds (0-999999). The number *n* is used to specify the number of digits to include in the returned value. Valid values for *n* are 1-12 (FF1-FF12) with no leading zeros. Specifying FF is equivalent to specifying FF6. If the timestamp precision of *timestamp-expression* is less than what is specified by the format, zero digits are padded onto the right of the specified digits.
HH	Hour of the day (01-12).
HH12	Hour of the day (01-12).
HH24	Hour of the day (00-24).
ID	ISO day of the week (1-7). 1 is Monday and 7 is Sunday.
IW	ISO week of the year (01-53). The week starts on Monday and includes 7 days. Week 1 is the first week of the year to contain a Thursday, which is equivalent to the first week of the year to contain January 4.
I	ISO year (0-9). The last digit of the year based on the ISO week that is returned.
IY	ISO year (00-99). The last two digits of the year based on the ISO week that is returned.
IYY	ISO year (000-999). The last three digits of the year based on the ISO week that is returned.
IYYY	ISO year (0000-9999). The last four digits of the year based on the ISO week that is returned.
J	Julian date (0000000-9999999).
MI	Minute (00-59).
MM	Month (01-12). January is 01.
MONTH, Month, or month [1, 2]	Name of the month in uppercase, sentence case, or lowercase format in English.
MON, Mon, or mon [1, 2]	Three-character abbreviated name of the month in uppercase, sentence case, or lowercase format in English.

Table 99. Valid format elements of format-string (continued)

Format element	Description (assuming the default is to return leading zeros)
NNNNNN	Microseconds (000000-999999). This format is equivalent to specifying FF6.
Q	Quarter (1-4). January through March is 1.
RR	Last two digits of the year (00-99). RR behaves the same as YY.
RRRR	Year (0000-9999). RRRR behaves the same as YYYY.
SS	Seconds (00-59).
SSSSS	Seconds since the previous midnight (00000-86400).
TZH	Time zone hour. (-24 to +24, This range accommodates daylight saving time changes.)
TZM	Time zone minute (00–59).
W	Week of the month (1-5). Week 1 starts on the first day of the month and ends on the seventh day.
WW	Week of the year (01-53). Week 1 begins on January 1 and ends on January 7.
Y	Last digit of the year (0-9).
YY	Last two digits of the year (00-99).
YYY	Last three digits of the year (000-999).
YYYY	Year (0000-9999).

Notes:

1. This format element is case sensitive. In cases where the format elements are ambiguous, the case insensitive format elements will be considered first.
2. Only these exact spellings and case combinations can be used. If this format element is specified in an invalid case combination an error is returned.

If *timestamp-expression* is a TIMESTAMP WITHOUT TIME ZONE value, *format-string* must not contain TZH or TZM.

The result is a representation of *timestamp-expression* in the format specified by *format-string*. *format-string* is interpreted as a series of format elements that can be separated by one or more separator characters. A string of characters in *format-string* is interpreted as the longest matching format element in the previous table. If two format elements that contain the same characters are not separated by a separator character, the specification is interpreted, starting from the left, as the longest matching element in the table, and continues until matches are found for the remainder of the format string. For example, 'YYYYYYDD' is interpreted as the format elements, 'YYYY', 'YY', and 'DD'.

If the first argument is timestamp with time zone, or the second argument is a constant that contains a format element for a time zone, the resulting string contains a timestamp with time zone. Otherwise, the resulting string does not contain a time zone.

The result is the varying-length character string that contains *timestamp-expression* in the format that is specified by *format-string*. If *format-string* is a constant, The length attribute of the result is the maximum of 255 and the length attribute of *format-string*. Otherwise, the length attribute is 255. The *format-string* determines the actual length of the result. The actual length must not be greater than the length attribute of the result.

The result can be null; if any argument is null, the result is the null value.

The CCSID of the result is determined from the context in which the function is invoked. For more information, see Determining the encoding scheme and CCSID of a string (Introduction to Db2 for z/OS).

Decimal floating-point to VARCHAR

numeric-expression

An expression that returns a value of any built-in numeric data type. If the argument is not a decimal floating-point value, it is converted to DECFLOAT(34) for processing.

format-string

An expression that must return a value that is a built-in CHAR, VARCHAR, or numeric data type. If the value is not a CHAR or VARCHAR data type, it is implicitly cast to VARCHAR before evaluating the function. If the supplied argument is a GRAPHIC or VARGRAPHIC data type, it is first converted to VARCHAR before evaluating the function. The actual length must not be greater than 254 bytes.

The value is a template for how *numeric-expression* is to be formatted. A *format-string* must contain a valid combination of the listed format elements according to the following rules:

- A sign format element ('S', 'MI', 'PR') can be specified only one time.
- A decimal point format element can be specified only one time.
- Alphabetic format elements must be specified in upper case.
- A prefix format element can only be specified at the beginning of the format string, before any format elements that are not prefix format elements. When multiple prefix format elements are specified they can be specified in any order.
- A suffix format element can only be specified at the end of the format string, after any format elements that are not suffix format elements. When multiple suffix format elements are specified they can be specified in any order.
- A comma format element must not be the first format element that is not a prefix format element. There can be any number of comma format elements.
- Blanks must not be specified between format elements. Leading and trailing blanks can be specified but are ignored when formatting the result.

Table 100. Format elements for the VARCHAR_FORMAT (numeric to VARCHAR) function

Format element	Description
0	Each 0 represents a significant digit. Leading zeros in a number are formatted as zeros.
9	Each 9 represents a significant digit that can be included at the specified location. Leading zeros in a number are formatted as blanks. Only group separators that have at least one digit to the left of the separator are generated.

Table 100. Format elements for the VARCHAR_FORMAT (numeric to VARCHAR) function (continued)

Format element	Description
S	**Prefix** If *numeric-expression* is a negative number, a leading minus sign (–) is included. If *numeric-expression* is a positive number, a leading plus sign (+) is included in the result.
$	**Prefix** A leading dollar sign ($) is included the result.
MI	**Suffix** If *numeric-expression* is a negative number, a trailing minus sign (–) is included in the result. If *numeric-expression* is a positive number, a trailing blank is included in the result.
PR	**Suffix** If *numeric-expression* is a negative number, a leading less than character (<) and a trailing greater than character (>) are included in the result. If *numeric-expression* is a positive number, a leading blank and a trailing blank are included in the result.
, (comma)	Each comma represents a group separator that is included at the specified location in the result provided there would be a character to the left of it that is not a prefix character. This comma is used a group separator.
. (period/decimal point)	A period represents the decimal point that is included at the specified location in the result. This period is used as a decimal point.

If *format-string* is not specified, the function is equivalent to VARCHAR(*numeric-expression*).

The result is a representation of the *numeric-expression* value (which might be rounded) in the format that is specified by *format-string*. Prior to being formatted, the value of *numeric-expression* is rounded by using the ROUND function, if the number of digits to the right of the decimal point is greater than the number of digit format elements ('0' or '9') to the right of the decimal point in *format-string*. *format-string* is applied according to the following rules:

- The result does not include any digit characters to the left of the decimal point if all of the following conditions are true:
  - -1 < *rounded-input-value* < 1
  - *format-string* does not include a '0' format element to the left of the decimal point
  - *format-string* includes at least one digit format element ('0' or '9') to the right of the decimal point
- The result includes a single 0 character immediately before the implicit or explicit decimal point if all of the following conditions are true:
  - The value of *rounded-input-value* is 0 or -0
  - *format-string* includes only the '9' digit format elements to the left of the implicit or explicit decimal point
  - *format-string* does not include any digit format elements to the right of the decimal point

- If *format-string* includes both '0' and '9' format elements to the left of the decimal point, the position of the first digit format element from the beginning of the format string determines the presence of leading blanks or zeroes. All '9' format elements specified after the leftmost '0' format element to the left of the implicit or explicit decimal point are treated the same as if a '0' format element had been specified. For example, the *format-string* value '99099' is the same as the value '99000'.
- If the number of digits to the right of the decimal point in *rounded-input-value* is less than the number of digit format elements to the right of the decimal point in *format-string*, the result includes the number of digit characters to the right of the decimal point that corresponds to the number of digit format elements to the right of the decimal point in *format-string*, padded to the right with zeros.
- If the number of digits to the left of the decimal point in *rounded-input-value* is greater than the number of digit format elements to the left of the decimal point in *format-string*, the result is a string of number sign (#) characters that matches the length that *format-string* produces in the result for valid values.
- If the value of *rounded-input-value* represents any of the positive or negative special values, Infinity, sNaN, or NaN, the string 'INFINITY', 'SNAN', 'NAN', '-INFINITY', '-SNAN', or '-NAN' is returned without using the format that is specified by *format-string*. The decimal floating-point special value sNaN does not result in an exception when converted to a string.
- If format-string does not include any of the sign format elements 'S', ''MI', or 'PR', and the value of *rounded-input-value* is negative, a minus sign (–) is included in the result. Otherwise, a blank is included in the resulting string. The minus sign or blank immediately precedes the first digit of the result to the left of the decimal point, or the decimal point if there are no digits to the left of the decimal point.

The result is a varying-length character string representation of *rounded-input-value*. If a single argument is specified the length attribute is 42. Otherwise the length attribute is 254. The actual length of the result is determined by *format-string*, if specified. Otherwise, the actual length of the result is the smallest number of characters that can represent the value of *rounded-input-value*. If the resulting string exceeds the length attribute of the result, the result will be truncated.

The CCSID of the result is determined from the context in which the function is invoked. For more information, see Determining the encoding scheme and CCSID of a string (Introduction to Db2 for z/OS)

Notes

Julian and Gregorian calendar:
For timestamp to a varying length character string, the transition from the Julian calendar to the Gregorian calendar on 15 October 1582 is taken into account by this function.

Determinism:
VARCHAR_FORMAT is a deterministic function.

Using the 'D', 'Y', and 'y' format elements:
Db2 for z/OS does not support the 'DY', 'dy', and 'Dy' format elements that are supported by other platforms. If 'DY' or 'Dy' is specified in the format string, it is interpreted as the 'D' format element followed by the 'Y' or 'y' format element. This behavior might change in a future release. To ensure that a 'D' followed by 'Y' or 'y' is interpreted as two separate format elements, include a separator character after the 'D' format element.

Syntax alternatives:
TO_CHAR is a synonym for VARCHAR_FORMAT.

Examples

Example 1: Timestamp to VARCHAR
Set the character variable *TVAR* to a string representation of the timestamp value of RECEIVED from CORPDATA.IN_TRAY, formatted as 'YYYY-MM-DD HH24:MI:SS.

```
SELECT VARCHAR_FORMAT(RECEIVED,'YYYY-MM-DD HH24:MI:SS')
  INTO :TVAR
  FROM CORPDATA.IN_TRAY;
```

Assuming that the value in the RECEIVED column is 'January 1, 2000 at 10am', the following string is returned:

```
'2000-01-01 10:00:00'
```

Assuming that the value in the RECEIVED column is now one second before the beginning of the year 2000 ('December 31, 1999 at 23:59:59pm', the following string is returned:

```
'1999-12-31 23:59:59'
```

The result would be different if HH12 had been specified instead of HH24 in the format string:

```
'1999-12-31 11:59:59'
```

Example 2: Timestamp to VARCHAR

Assume that the variable *TMSTAMP* is defined as a TIMESTAMP and has the following value: 2007-03-09-14.07.38.123456. The following examples show several invocations of the function and the resulting string values. The result data type in each case is VARCHAR(255).

```
Function invocation                          Result
-------------------                          ------
VARCHAR_FORMAT(TMSTAMP,'YYYYMMDDHHMISSFF3')  20070309020738123
VARCHAR_FORMAT(TMSTAMP,'YYYYMMDDHH24MISS')   20070309140738
VARCHAR_FORMAT(TMSTAMP,'YYYYMMDDHHMI')       200703090207
VARCHAR_FORMAT(TMSTAMP,'DD/MM/YY')           09/03/07
VARCHAR_FORMAT(TMSTAMP,'MM-DD-YYYY')         03-09-2007
VARCHAR_FORMAT(TMSTAMP,'J')                  2454169
VARCHAR_FORMAT(TMSTAMP,'Q')                  1
VARCHAR_FORMAT(TMSTAMP,'W')                  2
VARCHAR_FORMAT(TMSTAMP,'IW')                 10
VARCHAR_FORMAT(TMSTAMP,'WW')                 10
VARCHAR_FORMAT(TMSTAMP,'Month')              March
VARCHAR_FORMAT(TMSTAMP,'MONTH')              MARCH
VARCHAR_FORMAT(TMSTAMP,'MON')                MAR
```

Example 3: Timestamp to VARCHAR

Assume that the variable *DTE* is defined as a DATE and has the value of '2007-03-09'. The following examples show several invocations of the function and the resulting string values. The result data type in each case is VARCHAR(255):

```
 Function invocation                       Result
-------------------                        ------
VARCHAR_FORMAT(DTE,'YYYYMMDD')             20070309
VARCHAR_FORMAT(DTE,'YYYYMMDDHH24MISS')     20070309000000
```

Assuming that today is May 26, 2008, the function returns:

```
26-MAY-2007
```

If the format string is 'YYYY-MON-YYYY', the result would be:

```
2007-MAY-2007
```

Example 4: Timestamp to VARCHAR

Format the hour of the specified string representation of a timestamp using a 12 hour clock and a 24 hour clock:

```
   SELECT
      VARCHAR_FORMAT(TIMESTAMP('1979-04-07-14.00.00.000000'), 'HH'),
      VARCHAR_FORMAT(TIMESTAMP('1979-04-07-14.00.00.000000'), 'HH12'),
      VARCHAR_FORMAT(TIMESTAMP('1979-04-07-14.00.00.000000'), 'HH24'),
      VARCHAR_FORMAT(TIMESTAMP('2000-01-01-00.00.00.000000'), 'HH'),
      VARCHAR_FORMAT(TIMESTAMP('2000-01-01-12.00.00.000000'), 'HH'),
      VARCHAR_FORMAT(TIMESTAMP('2000-01-01-24.00.00.000000'), 'HH'),
      VARCHAR_FORMAT(TIMESTAMP('2000-01-01-00.00.00.000000'), 'HH12'),
      VARCHAR_FORMAT(TIMESTAMP('2000-01-01-12.00.00.000000'), 'HH12'),
      VARCHAR_FORMAT(TIMESTAMP('2000-01-01-24.00.00.000000'), 'HH12'),
      VARCHAR_FORMAT(TIMESTAMP('2000-01-01-00.00.00.000000'), 'HH24'),
      VARCHAR_FORMAT(TIMESTAMP('2000-01-01-12.00.00.000000'), 'HH24'),
      VARCHAR_FORMAT(TIMESTAMP('2000-01-01-24.00.00.000000'), 'HH24')
    FROM SYSIBM.SYSDUMMY1;
```

The previous SELECT statement returns the following values:

```
'02'  '02'  '14'  '12'  '12'  '12'  '12'  '12'  '12'  '00'  '12'  '24'
```

Note that the values '00' and '24' on a 24 hour scale both map to a value of '12' on a 12 hour scale.

Example 5: Timestamp with time zone to VARCHAR

Assume that column PRSTSZ contains a timestamp with time zone value of '2008-02-29.20.00.000000 -08:00'. The following statement returns the value '2008-02-29 20:00:00.000000 -08:00'.

```
SELECT VARCHAR_FORMAT(PRSTSZ, 'YYYY-MM-DD HH24:MI:SS.NNNNNN TZH:TZM'))
    FROM PROJECT;
```

Example 6: decimal floating-point to VARCHAR

Assume that the variables *POSNUM* and *NEGNUM* are defined as DECFLOAT(34) and have the following values: '1234.56' and '-1234.56', respectively. The following examples show several invocations of the function and the resulting string values. The result data type in each case is VARCHAR(254).

Function invocation	Result
`VARCHAR_FORMAT(POSNUM)`	`'1234.56'`
`VARCHAR_FORMAT(NEGNUM)`	`'-1234.56'`
`VARCHAR_FORMAT(POSNUM,'9999.99')`	`' 1234.56'`
`VARCHAR_FORMAT(NEGNUM,'9999.99')`	`'-1234.56'`
`VARCHAR_FORMAT(POSNUM,'99999.99')`	`'  1234.56'`
`VARCHAR_FORMAT(NEGNUM,'99999.99')`	`' -1234.56'`
`VARCHAR_FORMAT(POSNUM,'00000.00')`	`' 01234.56'`
`VARCHAR_FORMAT(NEGNUM,'00000.00')`	`'-01234.56'`
`VARCHAR_FORMAT(POSNUM,'9999.99MI')`	`'1234.56 '`
`VARCHAR_FORMAT(NEGNUM,'9999.99MI')`	`'1234.56-'`
`VARCHAR_FORMAT(POSNUM,'S9999.99')`	`'+1234.56'`
`VARCHAR_FORMAT(NEGNUM,'S9999.99')`	`'-1234.56'`
`VARCHAR_FORMAT(POSNUM,'9999.99PR')`	`' 1234.56 '`
`VARCHAR_FORMAT(NEGNUM,'9999.99PR')`	`'<1234.56>'`

Function invocation	Result
`VARCHAR_FORMAT(POSNUM,'S$9,999.99')`	`'+$1,234.56'`
`VARCHAR_FORMAT(NEGNUM,'S$9,999.99')`	`'-$1,234.56'`

VARGRAPHIC

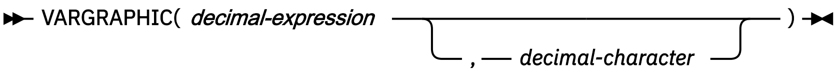
The VARGRAPHIC function returns a varying-length graphic string representation of the first argument.

Syntax for integer to vargraphic

FL 502

Syntax for decimal to vargraphic

FL 502



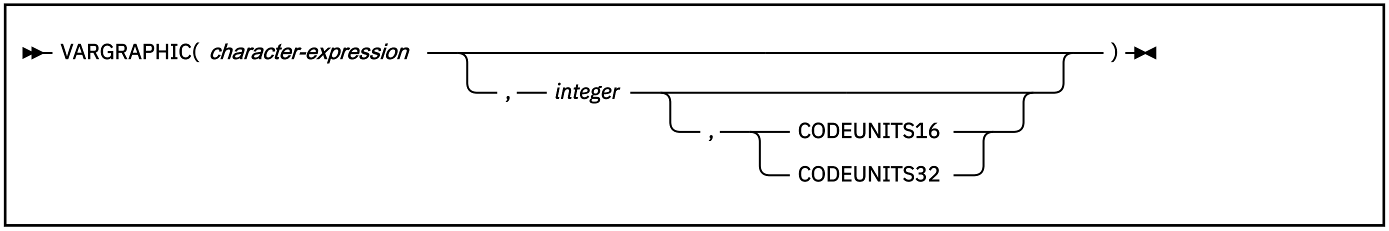
Syntax for floating-point to vargraphic

FL 502

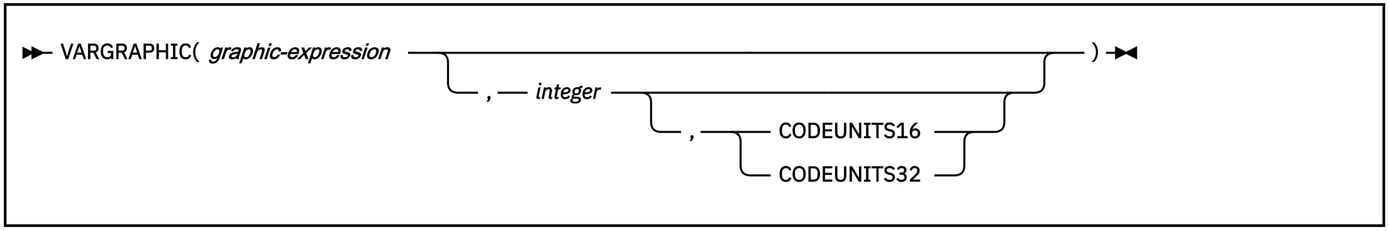
Syntax for decimal floating-point to vargraphic

FL 502

Syntax for character to vargraphic:



Syntax for graphic to vargraphic:



The schema is SYSIBM.

The GRAPHIC function returns a varying length-graphic-string representation of:

- FL 502 An integer number if the first argument is a SMALLINT, INTEGER, or BIGINT
- FL 502 A decimal number if the first argument is a decimal number
- FL 502 A double-precision floating-point number if the first argument is a DOUBLE or REAL
- FL 502 A decimal floating-point number if the first argument is DECFLOAT
- A character string if the first argument is any type of character string
- A graphic string if the first argument is an EBCDIC or Unicode graphic string

The result can be null; if the first argument is null, the result is the null value.

The length attribute and actual length of the result are measured in double-byte characters because the result is a graphic string.

Integer to vargraphic

FL 502

integer-expression

An expression that returns a value that is an integer data type (either SMALLINT, INTEGER, or BIGINT).

The result is a varying-length graphic string of the argument in the form of an SQL integer constant. The actual length of the result is the smallest number of characters that can be used to represent the value of the argument. The result consists of n characters that are the significant digits that represent the value of the argument with a preceding minus sign if the argument is negative. A positive value starts with a digit. Leading zeroes are not included.

- If the argument is a small integer, the length attribute of the result is 6.
- If the argument is a large integer, the length attribute of the result is 11.
- If the argument is a big integer, the length attribute of the result is 20.

The CCSID of the result is 1200 (UTF-16).

Decimal to vargraphic

FL 502

decimal-expression

An expression that returns a value that is a built-in decimal data type. If a different precision and scale is wanted, the DECIMAL scalar function can be used to make the change. To specify a different precision and scale for the value of the expression, apply the DECIMAL function before applying the VARGRAPHIC function.

decimal-character

Specifies the single-byte character constant that is used to delimit the decimal digits in the result graphic string. The character must not be a digit, a plus sign (+), a minus sign (-), or a blank. The default is the period (.) or comma (,). For information on what factors govern the choice, see Decimal point representation.

The result is a varying-length graphic string representation of the first argument. The actual length of the result is the smallest number of characters that can be used to represent the result, except that trailing zeros are included. The result includes a decimal character and up to *p* digits, where *p* is the precision of the *decimal-expression* with a preceding minus sign if the argument is negative. A positive value starts with a digit or the decimal-character, and always includes at least one trailing blank. Leading zeros are not returned. If the scale of *decimal-expression* is zero, the decimal character is not returned. If the number of bytes in the result is less than the defined length of the result, the result is padded on the right with blanks.

The length of the result is 2+*p* where *p* is the precision of the *decimal-expression*.

The CCSID of the result is 1200 (UTF-16).

Floating-point to vargraphic

FL 502

floating-point-expression
An expression that returns a value that is a floating-point data type (DOUBLE or REAL).

The result is a varying-length graphic string representation of the argument in the form of an SQL floating-point constant. If the argument is negative, the first character of the result is a minus sign; otherwise, the first character is a digit. If the argument is zero, the result is 0E0.

The length of the result is 24. The actual length of the result includes the smallest number of characters that can represent the value of the argument such that the mantissa consists of a single digit, other than zero, followed by a period and a sequence of digits. If the number of characters in the result is less than 24, the result is padded on the right with blanks.

The CCSID of the result is 1200 (UTF-16).

Decimal floating-point to vargraphic

FL 502

decimal-floating-point expression
An expression that returns a value that is a built-in decimal floating-point data type (DECFLOAT).

The result is a varying-length graphic string representation of the argument in the form of an SQL decimal floating-point constant.

If the result value is Infinity, sNaN, or NaN, the strings 'INFINITY', 'SNAN', and 'NAN', respectively, are returned. The DECFLOAT special value sNaN does not result in an exception when converted to a string.

The length of the result is 42. The actual length of the result is the smallest number of characters that represents the value of the argument, including the sign, digits, and the period. Trailing zeros are significant. If the argument is negative, the first character of the result is a minus sign. Otherwise, the first character is a digit, or a letter if the DECFLOAT value is Infinity, sNaN, or NaN.

The CCSID of the result is 1200 (UTF-16).

Character to vargraphic

character-expression
An expression that returns a value of a built-in character string data type that contains an EBCDIC-encoded or Unicode-encoded character string value. It cannot be BIT data. The argument does not need to be mixed data, but any occurrences of X'0E' and X'0F' in the string must conform to the rules for EBCDIC mixed data. (See "Character strings" on page 102 for these rules.)

integer
The length attribute of the resulting varying-length graphic string. The value must be an integer constant between 1 and 16352.

If CODEUNITS16 or CODEUNITS32 is specified, see "Determining the length attribute of the final result" on page 108 for information about how to calculate the length attribute of the result string.

If *integer* is not specified and if the *character-expression* is an empty string constant or has a value X'0E0F', the length attribute of the result is 1 and the result is an empty string. Otherwise, the length attribute of the result is the same as the length attribute of the first argument.

CODEUNITS16 or CODEUNITS32
Specifies the unit that is used to express *integer*. If CODEUNITS16 or CODEUNITS32 is specified, the input is EBCDIC, and there is no corresponding CCSID for EBCDIC GRAPHIC data, an error occurs.

CODEUNITS16
Specifies that *integer* is expressed in terms of 16-bit UTF-16 code units.

CODEUNITS32
Specifies that *integer* is expressed in terms of 32-bit UTF-32 code units.

For more information about CODEUNITS16 and CODEUNITS32, see "String unit specifications" on page 106.

The actual length of the result is the minimum of the length attribute of the result and the actual length of *character-expression*. If the length of *character-expression*, as measured in single-byte characters, is greater than the specified length of the result, as measured in double-byte characters, the result is truncated. Unless all the truncated characters are blanks appropriate for *character-expression*, a warning is returned.

The CCSID of the result is the graphic CCSID that corresponds to the character CCSID of *character-expression*. If the input is EBCDIC and there is no system CCSID for EBCDIC GRAPHIC data, the CCSID of the result is X'FFFE'.

For EBCDIC input data:

Each character of *character-expression* determines a character of the result. The argument might need to be converted to the native form of mixed data before the result is derived. Let *M* denote the system CCSID for mixed data. The argument is not converted if any of the following conditions is true:

- The argument is mixed data and its CCSID is *M*.
- The argument is SBCS data and its CCSID is the same as the system CCSID for SBCS data. In this case, the operation proceeds as if the CCSID of the argument is *M*.

Otherwise, the argument is a new string *S* derived by converting the characters to the coded character set identified by *M*. If there is no system CCSID for mixed data, conversion is to the coded character set that the system CCSID for SBCS data identifies.

The result is derived from *S* using the following steps:

- Each shift character (X'0E' or X'0F') is removed.
- Each double-byte character remains as is.
- Each single-byte character is replaced by a double-byte character.

The replacement for a single-byte character is the equivalent DBCS character if an equivalent exists. Otherwise, the replacement is X'FEFE'. The existence of an equivalent character depends on *M*. If there is no system CCSID for mixed data, the DBCS equivalent of X'*xx*' for EBCDIC is X'42*xx*', except for X'40', whose DBCS equivalent is X'4040'.

For Unicode input data:

Each character of *character-expression* determines a character of the result. The argument might need to be converted to the native form of mixed data before the result is derived. Let *M* denote the system CCSID for mixed data. The argument is not converted if any of the following conditions is true:

- The argument is mixed data, and its CCSID is *M*.
- The argument is SBCS data, and its CCSID is the same as the system CCSID for SBCS data. In this case, the operation proceeds as if the CCSID of the argument is *M*.

Otherwise, the argument is a new string *S* derived by converting the characters to the coded character set identified by *M*.

The result is derived from *S* using the following steps:

- Each non-supplementary character is replaced by a Unicode double-byte character (a UTF-16 code point). A non-supplementary character in UTF-8 is between 1 and 3 bytes.
- Each supplementary character is replaced by a pair of Unicode double-byte characters (a pair of UTF-16 code points).

The replacement for a single-byte character is the Unicode equivalent character if an equivalent exists. Otherwise, the replacement is X'FFFD'.

Graphic to vargraphic

graphic-expression

An expression that returns a value of a built-in graphic string data type that contains an EBCDIC-encoded or Unicode-encoded graphic string value.

integer

The length attribute for the resulting varying-length graphic string. The value must be an integer constant between 1 and 16352.

If CODEUNITS16 or CODEUNITS32 is specified, see "Determining the length attribute of the final result" on page 108 for information about how to calculate the length attribute of the result string.

If *integer* is not specified and if the *graphic-expression* is an empty string constant, the length attribute of the result is 1 and the result is an empty string. Otherwise, the length attribute of the result is the same as the length attribute of the first argument.

CODEUNITS16 or CODEUNITS32

Specifies the unit that is used to express *integer*. If CODEUNITS16 or CODEUNITS32 is specified, the input is EBCDIC, and there is no corresponding CCSID for EBCDIC GRAPHIC data, an error occurs.

CODEUNITS16

Specifies that *integer* is expressed in terms of 16-bit UTF-16 code units.

CODEUNITS32

Specifies that *integer* is expressed in terms of 32-bit UTF-32 code units.

For more information about CODEUNITS16 and CODEUNITS32, see "String unit specifications" on page 106.

The actual length of the result depends on the number of characters in *graphic-expression*. If the length of *graphic-expression* is greater than the length specified, the result is truncated. Unless all of the truncated characters are double-byte blanks, a warning is returned.

The CCSID of the result is the same as the CCSID of *graphic-expression*.

Notes

FL 502 **Casting numeric data to Unicode**: The result of the VARGRAPHIC functions is Unicode (UTF-16) when the first argument is numeric data. The VARGRAPHIC function can only be invoked with numeric data for the first argument if the containing statement:

- references Unicode base tables or views only and the statement is qualified to be a single encoding scheme statement, or
- is considered a multiple encoding scheme statement and the application encoding scheme is Unicode.

Examples

Example 1:

FL 502 Assume that an EMPLOYEE_U table exists that is similar to the EMPLOYEE sample table except that it is a Unicode table. The EDLEVEL column is defined as SMALLINT. Assume that employee Christine Haas was in school for 18 years. The following statement returns the EDLEVEL column value as a varying-length graphic string.

```
SELECT VARGRAPHIC(EDLEVEL)
 FROM EMPLOYEE_U
 WHERE LASTNAME = 'HAAS'
```

The result value is G'18'.

Example 2:

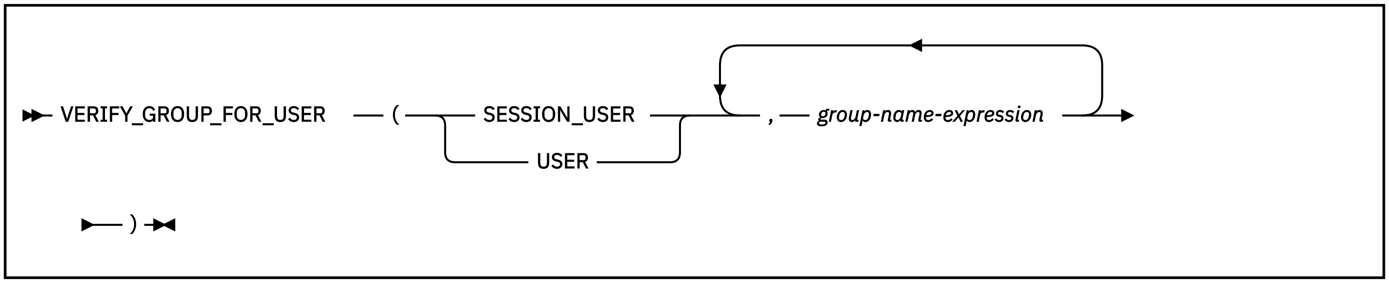
FL 502 Assume that an EMPLOYEE_U table exists that is similar to the EMPLOYEE sample table except that it is a Unicode table. The SALARY and COMM columns are defined as DECIMAL with a precision of 9 and a scale of 2. Assume that employee Christine Haas has a salary of $52750.00 and a commission of $4220.00. Return the total of the salary and commission for employee Christine Haas as a varying-length graphic string using the comma decimal character.

```
SELECT VARGRAPHIC(SALARY + COMM, ',')
 FROM EMPLOYEE_U
 WHERE LASTNAME = 'HAAS'
```

The result value is G'56970,00'.

VERIFY_GROUP_FOR_USER

The VERIFY_GROUP_FOR_USER function returns a value that indicates whether the primary authorization ID and the secondary authorization IDs that are associated with the first argument are in the authorization names that are specified in the list of the second argument.



The schema is SYSIBM.

SESSION_USER or USER
Specifies the value of the SESSION_USER (or USER) special register.

group-name-expression
An expression that specifies an authorization name. The existence of the authorization name at the current server is not verified. *group-name-expression* must return a built-in character string data type or graphic string data type that is not a LOB. The string must have a length that does not exceed the maximum length of an SQL identifier. The content of the string is not folded to uppercase and is not left justified.

The result of the function is a large integer. The result cannot be null.

The result is 1 if the primary or secondary authorization IDs that are associated with the user that is identified by the SESSION_USER (or USER) special register is in the list that is specified by *group-name-expression*. Otherwise, the result is 0.

Notes

Syntax alternatives:
The VERIFY_GROUP_FOR_USER function is deterministic within a connection. It is not deterministic across connections. The function can be referenced in a CREATE MASK or a CREATE PERMISSION statement and is considered for table expressions or the merging of views.

Examples

Example 1:

In the following example, the EMPLOYEE table has column access control enabled. If the connection is established outside a trusted context and Mary, who has a secondary authorization ID of "MGR", queries the social security number of Tom from the EMPLOYEE table, the social security number is returned. When Mary is no longer a manager, the same query displays the last four digits of Tom's social security number.

Assume that a user who has SECADM authority has created the following column mask:

```
CREATE MASK SSN_MASK ON EMPLOYEE
    FOR COLUMN SSN
    RETURN
    CASE WHEN VERIFY_GROUP_FOR_USER(SESSION_USER, 'MGR') = 1
        THEN SSN
        ELSE 'XXX-XX-' || SUBSTR(SSN, 8, 4)
    END
    ENABLE;

COMMIT;
```

An ALTER TABLE statement is then issued to activate the column mask on the EMPLOYEE table:

```
ALTER TABLE EMPLOYEE
    ACTIVATE COLUMN ACCESS CONTROL;

COMMIT;
```

Mary connects to Db2, issues the following query, then disconnects from Db2:

```
SELECT SSN
    FROM EMPLOYEE
    WHERE NAME = 'Tom';
```

Mary receives Tom's social security number.

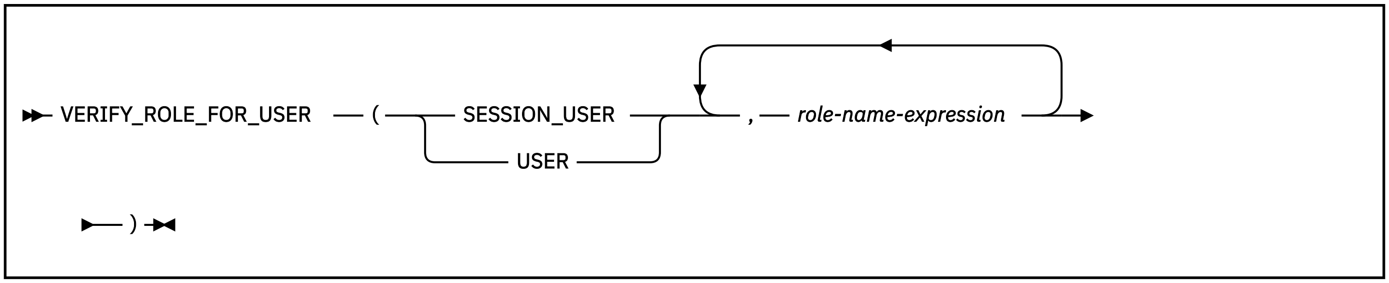
When Mary is no longer a manager, the secondary authorization ID, MGR is removed for her authorization ID. The next time Mary connects to Db2 and issues the following command, only the last four digits of Tom's social security number are displayed because of the column mask SSN_MASK:

```
SELECT SSN
    FROM EMPLOYEE
    WHERE NAME = 'Tom';
```

VERIFY_ROLE_FOR_USER

The VERIFY_ROLE_FOR_USER function returns a value that indicates whether the roles that are associated with the authorization ID that is specified in the first argument are included in the role names that are specified in the list of the second argument.

If the only way to acquire a role is under a trusted connection that is associated with a trusted context, the VERIFY_ROLE_FOR_USER function is equivalent to the VERIFY_TRUSTED_CONTEXT_ROLE_FOR_USER function.



The schema is SYSIBM.

SESSION_USER or USER
Specifies the value of the SESSION_USER (or USER) special register.

role-name-expression
An expression that specifies a role name. The existence of the role name at the current server is not verified. *role-name-expression* must return a built-in character string data type or graphic string data type that is not a LOB. The string must have a length that does not exceed the maximum length of an SQL identifier. The content of the string is not folded to uppercase and is not left justified.

The result of the function is a large integer. The result cannot be null.

The result is 1 if any of the roles that are associated with the user that is identified by the SESSION_USER (or USER) special register is in the list of roles specified by *role-name-expression*. Otherwise, the result is 0.

Notes

Determinism:

The VERIFY_ROLE_FOR_USER function is deterministic within a trusted connection. It is not deterministic across trusted connections. The function can be referenced in a CREATE MASK or a CREATE PERMISSION statement and is considered for table expressions or the merging of views.

Examples

Example 1:

Assume that the following statements have been issued to create specific roles and the trusted context CTX1:

```
CREATE ROLE EMPLOYEE;
COMMIT;

CREATE ROLE MGR;
COMMIT;

CREATE ROLE PAYROLL;
COMMIT;

CREATE TRUSTED CONTEXT CTX1
    BASED UPON CONNECTION USING SYSTEM AUTHID ADMF001
    ATTRIBUTES (ADDRESS '9.30.131.203', ENCRYPTION 'LOW')
    DEFAULT ROLE EMPLOYEE
    ENABLE
    WITH USE FOR SAM, JOE ROLE MGR WITH AUTHENTICATION;

COMMIT;
```

Joe, who is a manager, issues the following dynamic query through the trusted connection CTX1 to view the salaries of the employees in the DSN8910.EMP table that are in his department:

```
SELECT SALARY FROM DSN8910.EMP
    WHERE VERIFY_ROLE_FOR_USER(SESSION_USER,'MGR','PAYROLL')= 1
    AND WORKDEPT = ?;
```

Example 2:

For the following example, suppose that a user with SECADM authority needs to control access for specific users who execute a statement that is accessing a table:

Is the current user, B, using role X to run a statement owned by user C

```
SESSION_USER = B AND
VERIFY_ROLE_FOR_USER(SESSION_USER, 'X')
```

Is the current user, B, using role X to run a statement owned by role D

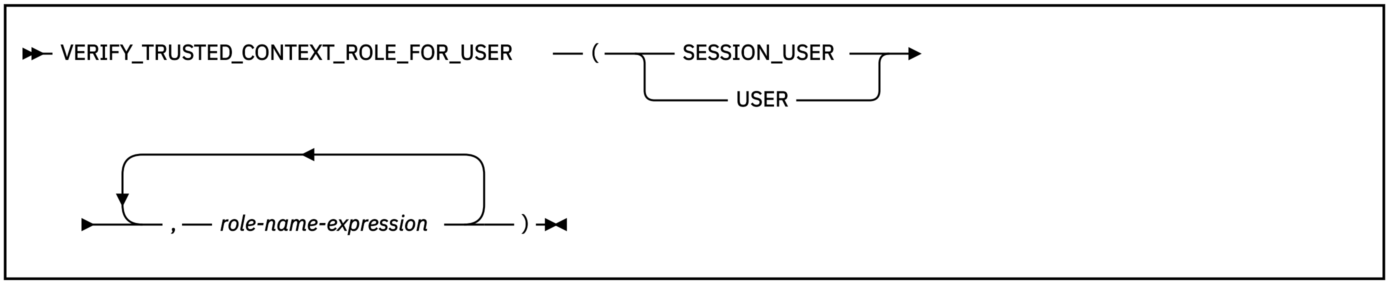
```
SESSION_USER = B AND
VERIFY_ROLE_FOR_USER(SESSION_USER, 'X')
```

Is the current user, B, using role B to execute a dynamic statement

```
SESSION_USER = B AND
VERIFY_ROLE_FOR_USER(SESSION_USER, 'B')
```

VERIFY_TRUSTED_CONTEXT_ROLE_FOR_USER

The VERIFY_TRUSTED_CONTEXT_FOR_USER function returns a value that indicates whether the authorization ID that is associated with first argument has acquired a role in a trusted connection and whether that acquired role is included in the role names that are specified in the list of the second argument.



The schema is SYSIBM.

SESSION_USER or USER
Specifies the value of the SESSION_USER (or USER) special register.

role-name-expression
An expression that specifies a role name. The existence of the role name at the current server is not verified. *role-name-expression* must return a built-in character string data type or graphic string data type that is not a LOB. The string must have a length that does not exceed the maximum length of an SQL identifier. The content of the string is not folded to uppercase and is not left justified.

The result of the function is a large integer. The result cannot be null.

The result is 1 if the user that is identified by the SESSION_USER (or USER) special register has acquired a role under a trusted connection that is associated with a trusted context and that role is in the list of *role-name-expression*. Otherwise, the result is 0.

Notes

Determinism:
The VERIFY_TRUSTED_CONTEXT_ROLE_FOR_USER function is deterministic within a trusted connection. It is not deterministic across trusted connections. The function can be referenced in a CREATE MASK or a CREATE PERMISSION statement and is considered for table expressions or the merging of views.

Examples

Example 1:
Assume that the following statements have been issued to create specific roles and the trusted context CTX1:

```
CREATE ROLE EMPLOYEE;
COMMIT;

CREATE ROLE MGR;
COMMIT;

CREATE ROLE PAYROLL;
COMMIT;

CREATE TRUSTED CONTEXT CTX1
    BASED UPON CONNECTION USING SYSTEM AUTHID ADMF001
    ATTRIBUTES (ADDRESS '9.30.131.203', ENCRYPTION 'LOW')
    DEFAULT ROLE EMPLOYEE
    ENABLE
    WITH USE FOR SAM, JOE ROLE MGR WITH AUTHENTICATION;

COMMIT;
```

Joe, who is a manager, issues the following dynamic query through the trusted connection CTX1 to view the salaries of the employees in the DSN8910.EMP table that are in his department:

```
SELECT SALARY FROM DSN8910.EMP
    WHERE VERIFY_TRUSTED_CONTEXT_ROLE_FOR_USER(SESSION_USER,'MGR','PAYROLL')= 1
    AND WORKDEPT = ?;
```

Example 2:

For the following example, suppose that a user with SECADM authority needs to control access for specific users who execute a statement that is accessing a table:

Is the current user, B, using role X to run a statement owned by user C?

```
SESSION_USER = B AND
VERIFY_TRUSTED_CONTEXT_ROLE_FOR_USER(SESSION_USER, 'X')
```

Is the current user, B, using role X to run a statement owned by role D?

```
SESSION_USER = B AND
VERIFY_TRUSTED_CONTEXT_ROLE_FOR_USER(SESSION_USER, 'X')
```

Is the current user, B, using role B to execute a dynamic statement?

```
SESSION_USER = B AND
VERIFY_TRUSTED_CONTEXT_ROLE_FOR_USER(SESSION_USER, 'B')
```

WEEK

The WEEK function returns an integer in the range of 1 to 54 that represents the week of the year. The week starts with Sunday, and January 1 is always in the first week.

▶▶— WEEK(*expression*) —▶◀

The schema is SYSIBM.

The argument must be an expression that returns a value of one of the following built-in data types: a date, a timestamp, a character string, or a graphic string. If *expression* is a character or graphic string, it must not be a CLOB or DBCLOB, and its value must be a valid string representation of a date or timestamp with an actual length that is not greater than 255 bytes. For the valid formats of string representations of dates and timestamps, see "String representations of datetime values" on page 120.

If *expression* is a timestamp with a time zone, or a valid string representation of a timestamp with a time zone, the result is determined from the UTC representation of the datetime value.

The result of the function is a large integer.

The result can be null; if the argument is null, the result is the null value.

Example 1: Using sample table DSN8C10.PROJ, set the integer host variable *WEEK* to the week of the year that project 'AD2100' ended.

```
   SELECT WEEK(PRENDATE)
     INTO :WEEK
     FROM DSN8C10.PROJ
     WHERE PROJNO = 'AD2100';
```

The result is that *WEEK* is set 6.

Example 2: The following invocations of the WEEK function returns the same result:

```
SELECT WEEK('1993-08-10-20.00.00'),
            WEEK('1993-08-10-20.00.00-08:00'),
            WEEK('1993-08-10-20.00.00+09:00')
        FROM SYSIBM.SYSDUMMY1;
```

For each invocation of the WEEK function in this SELECT statement, the result is 33.

When the input argument contains a time zone, the result is determined from the UTC representation of the input value. The string representations of a timestamp with a time zone in the SELECT statement all have the same UTC representation: '1993-08-10-20.00.00'.

WEEK_ISO

The WEEK_ISO function returns an integer in the range of 1 to 53 that represents the week of the year. The week starts with Monday and includes seven days. Week 1 is the first week of the year that contains a Thursday, which is equivalent to the first week that contains January 4.

▶▶─ WEEK_ISO(*expression*) ─▶◀

With the WEEK_ISO function, the first one, two, or three days in January might be included in the last week of the previous year. Likewise, the last one, two, or three days in December might be included in the first week of the next year.

The schema is SYSIBM.

The argument must be a date, a timestamp, or a valid string representation of a date or timestamp. A string representation must not be a CLOB or DBCLOB value and must have an actual length that is not greater than 255 bytes. For the valid formats of string representations of dates and timestamps, see "String representations of datetime values" on page 120.

If *expression* is a timestamp with a time zone, or a valid string representation of a timestamp with a time zone, the result is determined from the UTC representation of the datetime value.

The result of the function is a large integer.

The result can be null; if the argument is null, the result is the null value.

Example 1: Using sample table DSN8C10.PROJ, set the integer host variable *WEEKISO* to the week of the year that project 'AD2100' ended.

```
    SELECT WEEK_ISO(PRENDATE)
      INTO :WEEKISO
      FROM DSN8C10.PROJ
      WHERE PROJNO = 'AD2100';
```

Example 2: The following list shows what is returned by the WEEK_ISO function for various dates.

```
    DATE:           WEEK_ISO returns:
    ---------------------------------
    2003-12-28      52
    2003-12-31       1
    2004-01-01       1
    2005-01-01      53
    2005-01-04       1
    2005-12-31      52
    2006-01-01      52
    2006-01-03       1
```

Example 3: The following invocations of the WEEK_ISO function returns the same result:

```
SELECT WEEK_ISO('1993-08-10-20.00.00'),
            WEEK_ISO('1993-08-10-20.00.00-08:00'),
            WEEK_ISO('1993-08-10-20.00.00+09:00')
        FROM SYSIBM.SYSDUMMY1;
```

For each invocation of the WEEK_ISO function in this SELECT statement, the result is 32.

When the input argument contains a time zone, the result is determined from the UTC representation of the input value. The string representations of a timestamp with a time zone in the SELECT statement all have the same UTC representation: '1993-08-10-20.00.00' .

WRAP

The WRAP built-in function encodes a readable data definition statement into an obfuscated data definition statement. The procedural logic and embedded SQL statements in an *obfuscated data definition statement* are scrambled in such a way that any intellectual property in the logic cannot be easily extracted.

```
►►─ WRAP ── ( ── object-definition-string ── ) ─►◄
```

The schemas is SYSIBM.

The WRAP function is not deterministic.

object-defintion-string

A string of any built-in character type that contains any of the following data definition statements:

- CREATE FUNCTION (compiled SQL scalar)
- CREATE FUNCTION (inlined SQL scalar)
- CREATE FUNCTION (SQL table)
- CREATE PROCEDURE (SQL - native)
- CREATE TRIGGER (basic)
- CREATE TRIGGER (advanced)

object-defintion-string must not be bit data, and it cannot contain the VERSION keyword.

The result is a string of type CLOB(2M) that contains an encoded version of the input statement. The result cannot be null. The encoded statement consists of the following parts:

- The original statement up to and including the routine signature or trigger name.
- The WRAPPED keyword.
- The product identifier of the database manager that invoked the function.

  The product identifier (PRDID) value is an 8-byte character value in *pppvvrrm* format, where: *ppp* is a 3-letter product code; *vv* is the version;*rr* is the release; and *m* is the modification level. In Db2 12 for z/OS, the modification level indicates a range of function levels:

  `DSN12015` for `V12R1M500` or higher.
  `DSN12010` for `V12R1M100`.

  For more information, see Product identifier (PRDID) values in Db2 for z/OS (Db2 Administration Guide).
- The encoded remainder of the data definition statement, in the form of a string of letters (a-z and A-Z), digits (0-9), underscores, and colons. It is converted to Unicode UTF-8 before it is encoded. An error is issued if *object-definition-string* cannot be converted or if the intermediate string exceeds the maximum length for SQL statements. A warning occurs if a character is converted to the substitution character.

  The encoded data definition statement can be up to one-third longer than the plain text form of the statement. If the result exceeds the maximum length for SQL statements, an error is issued.

Important: The encoding of the statement is meant to obfuscate the content and is not considered a form of strong encryption.

Examples

Example 1

The following example, produces an obfuscated version of a function that computes a yearly salary from an hourly wage given a 40 hour work week.

```
SELECT WRAP('CREATE FUNCTION salary(wage DECFLOAT)
RETURNS DECFLOAT
RETURN wage * 40 * 52')
FROM SYSIBM.SYSDUMMY1
```

The result is similar to the following form:

```
CREATE FUNCTION salary(wage DECFLOAT) WRAPPED DSN12015
ablGWmdiWmtyTmduTmJqTmtaUmtCUmZqUmdiXodK3idaWmdaWmdaWmZG1mIaG
icaGy31TyStm_qGbe3sDxdxjtC8ymVGLpMXnuL8lkmNuRhhZ6qYJ2YYdXGaa
```

Example 2

The following statement produced an obfuscated version of a trigger that sets a complex default value.

```
SELECT WRAP('CREATE OR REPLACE TRIGGER trig1
BEFORE INSERT ON emp
REFERENCING NEW AS n FOR EACH ROW
WHEN (n.bonus IS NULL)
SET n.bonus = n.salary * .04')
FROM SYSIBM.SYSDUMMY1
```

The result is similar to the following form:

```
CREATE TRIGGER trig1 WRAPPED DSN12015
ablGWmdiWmtyTmduTmJqTmtaUmtGUnteUmZKWmtqWidaWmdaWmdaXmdyWncaGica
GK6ot_81NzyodncdrRIJFp_tBjpJeIwg_dTKNHcdtHPSaNCpmqBKH2pMwExkRTJW
Zr:dJd0_gSbehW:4Xx1UGPGnDxvmJfa5ZAGOr_1sfFiyaPrkOXzt5UMTmsASfyJR
ksbPfM2dlATbq:0RW
```

Related tasks

Obfuscating source code of SQL procedures, SQL functions, and triggers (Db2 Administration Guide)

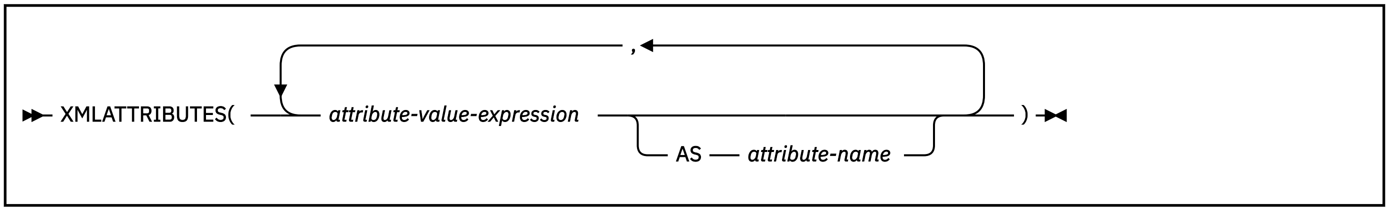
Related reference

CREATE_WRAPPED stored procedure

The CREATE_WRAPPED procedure encodes a readable data definition statement into an obfuscated data definition statement and then deploys the object in the database. The procedural logic and embedded SQL statements in an *obfuscated data definition statement* are scrambled in such a way that any intellectual property in the logic cannot be easily extracted.

XMLATTRIBUTES

The XMLATTRIBUTES function constructs XML attributes from the arguments. This function can be used as an argument only for the XMLELEMENT function.



The schema is SYSIBM.

The result is an XML sequence that contains an XQuery attribute node for each non-null *attribute-value-expression* argument.

attribute-value-expression

An expression that returns a value for the attribute. The data type of *attribute-value-expression* must not be ROWID, a LOB, a distinct type that is based on a ROWID or a LOB, or XML.

The result of *attribute-value-expression* is mapped to an XML value according to the rules for mapping an SQL value to an XML value. If the expression is not a simple column reference, an attribute name must be specified.

AS *attribute-name*

Specifies an attribute name. The name is an SQL identifier that must be in the form of an XML qualified name, or QName. If *attribute-name* is a qualified name, the namespace prefix must be declared within the scope of the qualified name.

attribute-name cannot be 'xmlns' or prefixed with 'xmlns:'. A namespace is declared using the function XMLNAMESPACES. The attribute names for an element must be unique for the XML element to be well-formed.

If *attribute-name* is not specified, the expression for *attribute-value* must be a column name. The attribute name will be created from the column name using the fully escaped mapping from a column name to an XML attribute name.

The result of the function is an XML value. The result can be null; if all *attribute-value-expression* arguments are null, the result is the null value.

XMLCOMMENT

The XMLCOMMENT function returns an XML value with a single comment node from a string expression. The content of the comment node is the value of the input string expression, mapped to Unicode (UTF-8).

►► XMLCOMMENT(*string-expression*) ►◄

The schema is SYSIBM.

string-expression
An expression that returns a value of a built-in character or graphic string that is not a LOB and is not bit data. The result of *string-expression* is converted to UTF-8 and then parsed to check for conformance to the content of XML comment as specified by the following rules:

- '--' (double-hyphen) must not occur in the string expression
- The string expression must not end with a hyphen ('-')
- Each character of the string can be any Unicode character, excluding the surrogate blocks, X'FFFE', and X'FFFF'

If *string-expression* does not conform to the previous rules, an error is returned.

The result of the function is an XML value that is an XML sequence that contains one XML comment node.

The result can be null; if the argument is null, the result is the null value.

Example: Generate an XML comment:

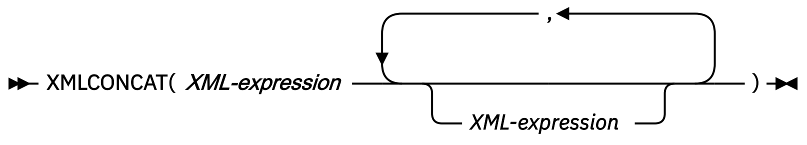
```
   SELECT XMLCOMMENT('This is an XML comment')
     FROM SYSIBM.SYSDUMMY1;
```

The result of the query would look similar to the following result:

```
<!--This is an XML comment-->
```

XMLCONCAT

The XMLCONCAT function returns an XML sequence that contains the concatenation of a variable number of XML input arguments.



The schema is SYSIBM.

XML-expression
An expression that returns an XML value.

The data type of the result is XML. The result of the function is an XML sequence that contains the concatenation of the non-null input XML values. Null values in the input are ignored. The result can be null; if the result of every input value is null, the result is the null value.

Example: Concatenate first name and last name elements by using 'first' and 'last' element names for each employee.

```
   SELECT XMLSERIALIZE( XMLCONCAT
                   ( XMLELEMENT ( NAME "first", e.fname),
                     XMLELEMENT ( NAME "last", e.lname)
                            ) ) AS "result"
   FROM employees e;
```

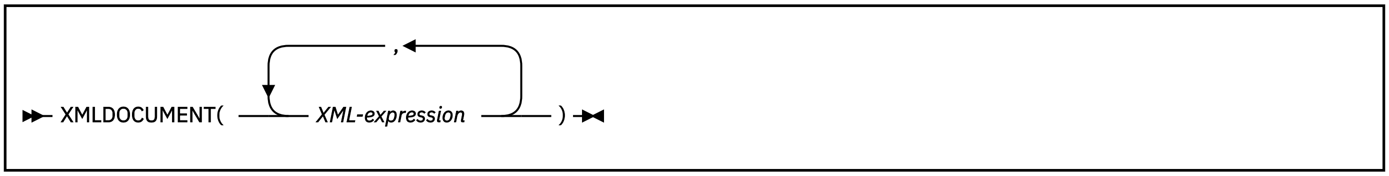
The result of the query would look similar to the following result:

```
result
 ---------------------------------------------

 <first>John</first><last>Smith</last>
 <first>Mary</first><last>Smith</last>
```

XMLDOCUMENT

The XMLDOCUMENT function returns an XML value with a single document node and zero or more nodes as its children. The content of the generated XML document node is specified by a list of expressions.



The schema is SYSIBM.

XML-expression
An expression that returns an XML value. A sequence item in the XML value must not be an attribute node. If *XML-expression* returns a null value, it is ignored for further processing. However, if all *XML-expression* values are null, the result of the function is the null value.

The result of the function is an XML value.

The result can be null; if all of the arguments are null, the result is the null value.

The resulting XML value is built from the list of *XML-expression* arguments. The children of the resulting document node are constructed as follows:

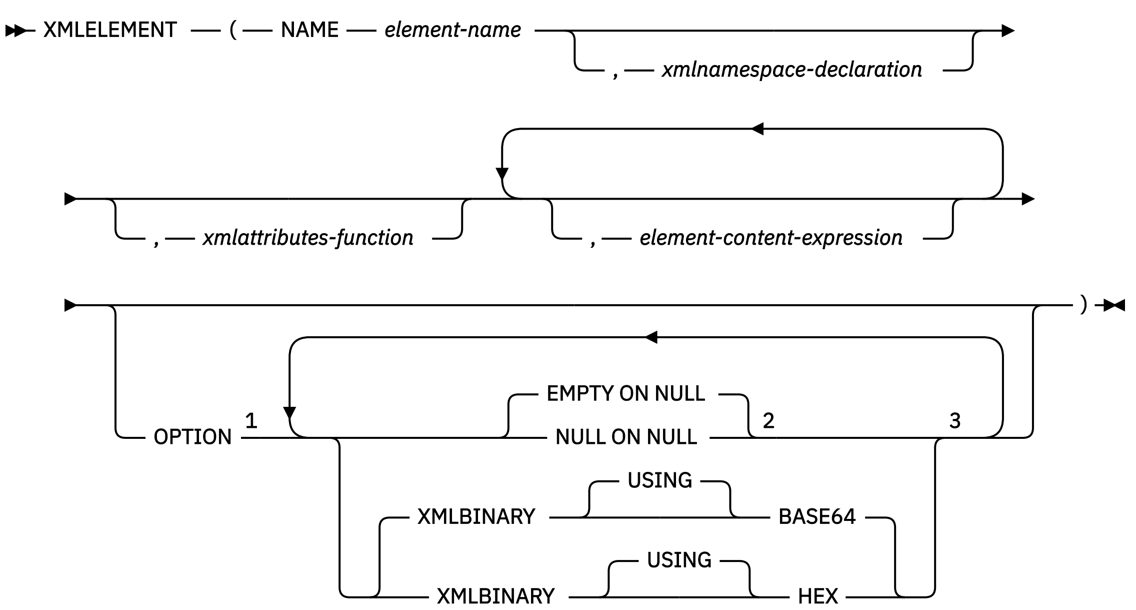
1. All of the non-null XML values that are returned by *XML-expression* are concatenated together. The result is a sequence of nodes or atomic values, which is referred to in the following steps as the *input sequence*. Any document node in the input sequence is replaced by copies of its children.
2. For each node in the input sequence, a new deep copy of the node is constructed. A *deep copy* of a node is a copy of the whole subtree that is rooted at that node, including the node itself and its descendants and attributes. Each copied node has a new node identity. Copied element nodes are given the type annotation 'xdt:untyped', and copied attribute nodes are given the type annotation 'xdt:untypedAtomic'. For each adjacent sequence of one or more atomic values that is returned in the input sequence, a new text node is constructed that contains the result of casting each atomic value to a string, with a single blank character inserted between adjacent values. The resulting sequence of nodes is called the *content sequence*. Adjacent text nodes in the content sequence are merged into a single text node by concatenating the contents of the text nodes with no intervening blanks. After concatenation, any text node that contains a zero-length string is deleted from the content sequence.
3. The nodes in the content sequence become the children of the new document node.

Example 1: Insert a constructed document into an XML column:

```
   INSERT INTO T1 VALUES(123,
     (SELECT XMLDOCUMENT(XMLELEMENT(NAME "Emp",
             e.fname || ' ' || e.lname),
             XMLCOMMENT('This is just a simple example'))
       FROM EMPLOYEE e
       WHERE e.empid = 123));
```

XMLELEMENT

The XMLELEMENT function returns an XML value that is an XML element node.



Notes:

[1] The OPTION clause can only be specified if at least one *xmlattributes-function* or *element-content-expression* is specified

[2] If *element-content-expression* is not specified, EMPTY ON NULL and NULL ON NULL must not be specified.

[3] The same clause must not be specified more than one time.

The schema is SYSIBM.

NAME *element-name*
Specifies the name of an XML element. *element-name* is an SQL identifier that must be in the form of an XML qualified name, or QName. If the name is qualified, the namespace prefix must be declared within the scope.

xmlnamespaces-declaration
Specifies the XML namespace declarations that are the result of the XMLNAMESPACES function. The namespaces that are declared are in the scope of the XMLELEMENT function. The namespaces apply to any nested XML functions within the XMLELEMENT function, regardless of whether or not they appear inside another subselect. See "XMLNAMESPACES" on page 655 for more information on declaring XML namespaces.

If *xmlnamespaces-declaration* is not specified, namespace declarations are not associated with the constructed XML element node.

xmlattributes-function
Specifies the attributes for the XML element. The attributes are the result of the XMLATTRIBUTES function. See "XMLATTRIBUTES" on page 643 for more information on constructing attributes.

If *xmlattributes-function* is not specified, attributes are not explicitly part of the constructed XML element node.

element-content-expression

The content of the generated XML element node is specified by an expression or a list of expressions. Each *element-content-expression* must return a value of any built-in data type or distinct type. The expression is used to construct the namespace declarations, attributes, and content of the constructed element node.

If *element-content-expression* is not specified, an empty string is used as the content for the element and NULL ON NULL or EMPTY ON NULL must not be specified.

OPTION

Specifies additional options for constructing the XML element. This clause has no impact on nested invocations of the XMLELEMENT function invocations that are specified in *element-content-expression*.

EMPTY ON NULL or NULL ON NULL

Specifies if a null value or an empty element is returned when the values of each *element-content-expression* is a null value. This option only affects null handling of element contents, not attribute values. The option is not inherited by a nested invocation of XMLELEMENT function within an *element-content-expression*.

EMPTY ON NULL

If the value of each *element-content-expression* is null, an empty element is returned.

EMPTY ON NULL is the default.

NULL ON NULL

If the value of each *element-content-expression* is null, a null value is returned.

XMLBINARY USING BASE64 or XMLBINARY USING HEX

Specifies the assumed encoding of binary input data, character string data with the FOR BIT DATA attribute, ROWID, or a distinct type that is based on one of these types. The encoding applies to element content or attribute values.

XMLBINARY USING BASE64

Specifies that the assumed encoding is base64 characters, as defined for XML schema type xs:base64Binary. The base64 encoding uses a 64-character subset of US-ASCII (10 digits, 26 lowercase characters, 26 uppercase characters, '+' and '/') to represent every 6 bits of the binary or bit data by one printable character in the subset. These characters are selected so that they are universally representable. In addition, the '=' character represents a line pad character. Using this method, the size of the encoded data is 33 percent larger than the original binary or bit data.

XMLBINARY USING BASE64 is the default.

XMLBINARY USING HEX

Specifies that the assumed encoding is hexadecimal characters as defined for XML schema type xs:hexBinary encoding. The hex encoding represents each byte (8 bits) with two hexadecimal characters. Using this method, the encoded data is twice the size of the original binary or bit data.

This function takes an element name, an optional collection of namespace declarations, an optional collection of attributes, and zero or more optional arguments that make up the content of the XML element. The result is an XML sequence that contains an XML element node or the null value. If the results of all *element-content-expression* arguments are empty strings, the result is an XML sequence that contains an empty element.

The result of the function is an XML value. The result can be null; if all *element-content-expression* arguments are null and the NULL ON NULL option is in effect, the result is the null value.

Notes

Constructing an element node:

The resulting element node is constructed as follows:

1. *xmlnamespace-declaration* adds a set of in-scope namespaces for the constructed element. Each in-scope namespace associates a namespace prefix (or the default namespace) with a namespace URI. The in-scope namespaces define the set of namespace prefixes that are available for interpreting QNames within the scope of the element.
2. If the *xmlattributes-function* is specified, it is evaluated and the result is a sequence of attribute nodes.
3. Each *element-content-expression* is evaluated and the result is converted into a sequence of nodes as follows:
   - If the result type is not XML, it is converted to an XML text node that contains the result of the *element-content-expression* this is mapped to XML.
   - If the result type is XML, the result is a sequence of items. Some of the items in that sequence might be document nodes. Each document node in the sequence is replaced by the sequence of its top-level children. Then for each node in the resulting sequence, a new deep copy of the node is constructed, including its children and attributes. Each copied node has a new node identity. Copied element nodes are given the type annotation xdt:untyped, and copied attribute nodes are given the type annotation xdt:untypedAtomic. For each adjacent sequence of one or more atomic values that are returned in the sequence, a new text node is constructed that contains the result of casting each atomic value to a string, with a single blank character inserted between adjacent values. If any of these atomic values cannot be cast into a string, an error is returned.
4. The result sequence of *xmlattributes-function* and the resulting sequences of all *element-content-expression* clauses are concatenated into one sequence which is called the *content sequence*. Any sequence of adjacent text nodes in the content sequence is merged into a single text node by concatenating their contents, with no intervening blanks. After concatenation, any text node that is a zero-length string is deleted from the content sequence.
5. If the content sequence contains an attribute node that follows a node that is not an attribute node, an error is returned. Attribute nodes that occur in the content sequence become attributes of the new element node. If two or more of these attribute nodes have the same name, an error is returned. A namespace declaration is created that corresponds to any namespace that is used in the names of the attribute nodes if the namespace URI is not in the in-scope namespaces of the constructed element.
6. Element, text, comment, and processing instruction nodes in the content sequence become the children of the constructed element node.
7. The constructed element node is given a type annotation of xdt:untyped, and each of its attributes is given a type annotation of xdt:untypedAtomic. The node name of the constructed element node is the XML element name that is specified after the NAME keyword.

Rules for using namespaces within XMLELEMENT:

The following rules describe scoping of namespaces:

- The namespaces that are declared in the XMLNAMESPACES function are the in-scope namespaces of the element node that are constructed by the XMLELEMENT function. If the element node is serialized, each of its in-scope namespaces will be serialized as a namespace attribute unless it is an in-scope namespace of the parent of the element node and the parent element is also serialized.
- The scope of these namespaces is the lexical scope of the XMLELEMENT function, including the element name, the attribute names that are specified in the XMLATTRIBUTES function, and all *element-content-expressions*. These are used to resolve the QNames in the scope.
- If an XMLQUERY or XMLEXISTS function is in an *element-content-expression*, the namespaces become the *statically known namespaces* of the XQuery expression of the XMLQUERY or XMLEXISTS function. Statically known namespaces are used to resolve the QNames that are in the XQuery expression. If the XQuery prolog declares a namespace that has the same prefix within the scope of the XQuery expression, the namespace that is declared in the prolog will override the namespaces that are declared in the XMLNAMESPACES function.
- If an attribute of the constructed element comes from *element-content-expression*, its namespace might not already be declared as an in-scope namespace of the constructed element. In this case, a new namespace is created for it. If the prefix of the attribute name is already bound to a different

URI by a in-scope namespace, Db2 generates a different prefix to be used in the attribute name. A namespace is created for this generated prefix. The name of the generated prefix follows the following pattern: db2ns-*xx*, where *xx* is a pair of characters chosen from the set [A-Z,a-z,0-9].

Examples

Example 1:

The following statement uses the XMLELEMENT function to create an XML element that contains an employees name. The statement also stores the employee number as an attribute named serial. If there is a null value in the referenced column, the function returns the null value:

```
    SELECT e.empno, e.firstnme, e.lastname,
           XMLELEMENT ( NAME "foo:Emp",
             XMLNAMESPACES('http://www.foo.com' AS "foo"),
             XMLATTRIBUTES(e.empno as "serial"),
                           e.firstnme,
                           e.lastname
                           OPTION NULL ON NULL ) AS "Result"
        FROM EMP e
        WHERE e.edlevel = 12;
```

The result of the query would look similar to the following result:

```
 EMPNO  FIRSTNME  LASTNAME  Result
-----  --------  --------  ------------------------------------

A0001  John      Parker    <foo:Emp xmlns:foo="http://www.foo.com"
                                serial="A0001">JohnParker</foo:Emp>
B0001  (null)    Smith     <foo:Emp xmlns:foo="http://www.foo.com"
                                serial="B0001">Smith</foo:Emp>
B0002  (null)    (null)    (null)
(null) (null)    (null)    (null)
```

Example 2:

The following example is similar to Example 1, however, when a null value is in one of the referenced columns, an empty element is returned:

```
    SELECT e.empno, e.firstnme, e.lastname,
      XMLELEMENT (NAME "foo:Emp",
                  XMLNAMESPACES('http://www.foo.com' AS "foo"),
                  XMLATTRIBUTES(e.empno as "serial"),
                                e.firstnme,
                                e.lastname
                             OPTION EMPTY ON NULL) AS "Result"
     FROM EMP e
     WHERE e.edlevel = 12;
```

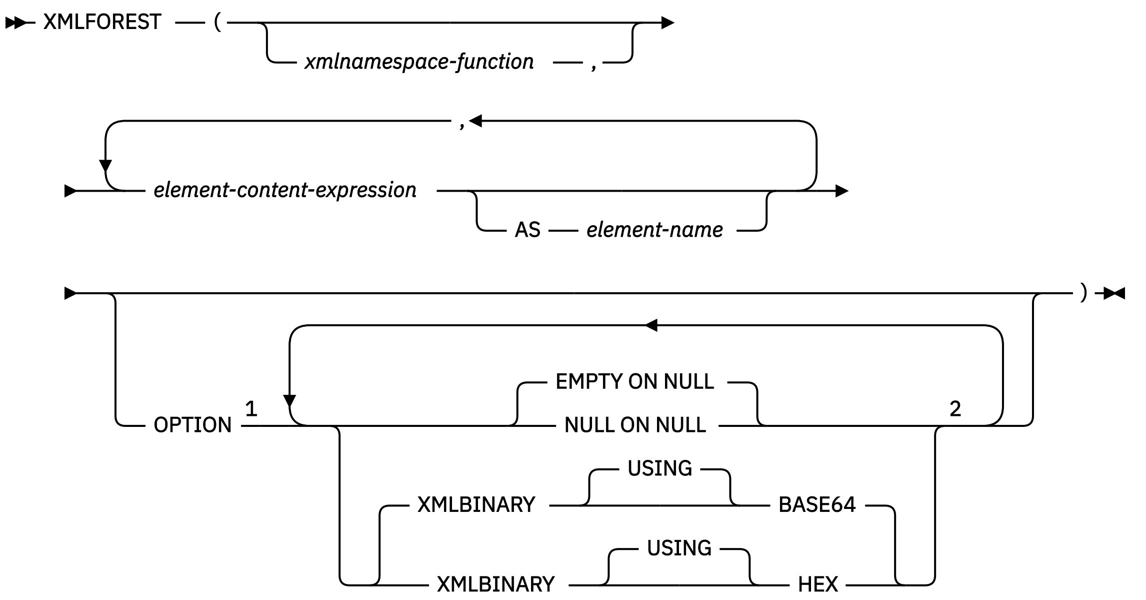
The result of the query would look similar to the following result:

```
EMPNO    FIRSTNME    LASTNAME    Result
-----    --------    --------    ------------------------------------

A0001    John        Parker      <foo:Emp xmlns:foo="http://www.foo.com"
                                  serial="A0001">JohnParker</foo:Emp>
B0001    (null)      Smith       <foo:Emp xmlns:foo="http://www.foo.com"
                                  serial="B0001">Smith</foo:Emp>
B0002    (null)      (null)      <foo:Emp xmlns:foo="http://www.foo.com"
                                  serial="B0002"/>
(null)   (null)      (null)      <foo:Emp xmlns:foo="http://www.foo.com"/>
```

XMLFOREST

The XMLFOREST function returns an XML value that is a sequence of XML element nodes.



Notes:

[1] The OPTION clause can only be specified if at least one *xmlattributes-function* or *element-content-expression* is specified.

[2] The same clause must not be specified more than one time.

The schema is SYSIBM.

xmlnamespace-function
Specifies the XML namespace declarations that are the result of the XMLNAMESPACES function. The namespaces that are declared are in the scope of the XMLFOREST function. The namespaces apply to any nested XML functions within the XMLFOREST function, regardless of whether or not those functions appear inside another subselect. See "XMLNAMESPACES" on page 655 for more information on declaring XML namespaces.

If *xmlnamespace-function* is not specified, namespace declarations are not associated with the constructed sequence of XML element nodes.

element-content-expression
Specifies an expression that returns a value that is used for the content of a generated XML element. The result of the expression is mapped to an XML value according to the mapping rules from an SQL value to an XML value. If the expression is not a simple column reference, *element-name* must be specified.

AS *element-name*
Specifies an identifier that is used for the XML element name.

An XML element name must be an XML QName. If the name is qualified, the namespace prefix must be declared within the scope.

If *element-name* is not specified, *element-content-expression* must be a column name. The element name is created from the column name using the fully escaped mapping from a column name to a QName.

OPTION
Specifies options for the result for NULL values, binary data, and bit data. The options will not be inherited by the XMLELEMENT or XMLFOREST functions that appear in *element-content-expression*.

EMPTY ON NULL or NULL ON NULL

Specifies if a null value or an empty element is returned when the values of each *element-content-expression* is a null value. EMPTY ON NULL and NULL on NULL only affect null handling of the *element-content-expression* arguments, not the handling of values from an *xmlattributes-function* argument.

EMPTY ON NULL

If the value of each *element-content-expression* is null, an empty element is returned.

EMPTY ON NULL is the default.

NULL ON NULL

If the value of each *element-content-expression* is null, a null value is returned.

XMLBINARY USING BASE64 or XMLBINARY USING HEX

Specifies the assumed encoding of binary input data, character string data with the FOR BIT DATA attribute, ROWID, or a distinct type that is based on one of these types. The encoding applies to element content or attribute values.

XMLBINARY USING BASE64

Specifies that the assumed encoding is base64 characters, as defined for XML schema type xs:base64Binary encoding. The base64 encoding uses a 64-character subset of US-ASCII (10 digits, 26 lowercase characters, 26 uppercase characters, '+' and '/') to represent every 6 bits of the binary or bit data by one printable character in the subset. These characters are selected so that they are universally representable. In addition, the '=' character represents a line pad character. Using this method, the size of the encoded data is 33 percent larger than the original binary or bit data.

XMLBINARY USING BASE64 is the default.

XMLBINARY USING HEX

Specifies that the assumed encoding is hexadecimal characters, as defined for XML schema type xs:hexBinary encoding. The hex encoding represents each byte (8 bits) with two hexadecimal characters. Using this method, the encoded data is twice the size of the original binary or bit data.

The XMLFOREST function can be expressed using the XMLCONCAT and XMLELEMENT functions.

This function takes an optional set of namespace declarations and one or more arguments that make up the name and element content for one or more element nodes. The result is an XML sequence containing a sequence of element nodes or the null value.

The result of the function is an XML value. The result can be null; if all the *element-content-expression* arguments are null and the NULL ON NULL option is in effect, the result is the null value.

Example: Generate an Emp element for each employee in the sample EMP table who was hired in 1980 or later. Concatenate the values of columns FIRSTNME and LASTNAME to form the Name attribute of the Emp element. Use XMLFOREST to create two nested elements of the Emp element: The Hiredate element and the Department element. The Hiredate element value is the HIREDATE column value. The Department element value is the WORKDEPT column value.

```
SELECT e.EMPNO AS "ID",
 XMLSERIALIZE(
   XMLELEMENT(
    NAME "Emp",
    XMLATTRIBUTES(e.FIRSTNME || ' ' || e.LASTNAME AS "Name"),
    XMLFOREST(e.HIREDATE AS "Hiredate",e.WORKDEPT AS "Department"))
  AS CLOB(100))
 AS "Result"
 FROM EMP e
 WHERE YEAR(HIREDATE)>='1980';
```

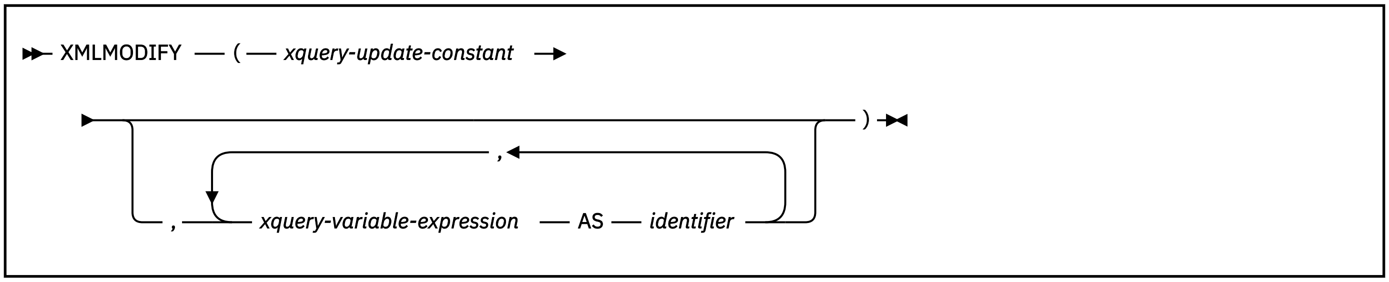
The query returns results similar to these:

```
ID      Result
------------------------------------------
000070  <Emp Name="EVA PULASKI">
         <Hiredate>1980-09-30</Hiredate>
```

```
          <Department>D21</Department>
        </Emp>
000100  <Emp Name="THEODORE SPENSER">
          <Hiredate>1980-06-19</Hiredate>
          <Department>E21</Department>
        </Emp>
000270  <Emp Name="MARIA PEREZ">
          <Hiredate>1980-09-30</Hiredate>
          <Department>D21</Department>
        </Emp>
000290  <Emp Name="JOHN PARKER">
          <Hiredate>1980-05-30</Hiredate>
          <Department>E11</Department>
        </Emp>
```

XMLMODIFY

The XMLMODIFY function returns an XML value that might have been modified by the evaluation of an XQuery updating expression and XQuery variables that are specified as input arguments.



The schema is SYSIBM.

xquery-update-constant

Specifies an SQL character string constant that is interpreted as an XQuery updating expression that uses supported XQuery language syntax. *xquery-update-constant* must be one of the following items:

- An insert expression.
- A delete expression.
- A replace expression.
- A FLWOR expression that contains an updating expression in its return clause.
- A conditional expression that contains an updating expression in its then or else clause.
- A sequence expression that contains two or more updating expressions, separate by commas. All operands are either updating expressions or an empty sequence.

xquery-update-constant must not be an empty string or a string of all blanks.

xquery-variable expression

xquery-variable-expression specifies an SQL expression whose value is available to the XQuery expression that is specified by *xquery-update-constant* during execution.

The data type of *xquery-variable-expression* can be XML, integer, decimal, or a character or graphic string that is not a LOB. *xquery-variable-expression* must not return a ROWID, TIMESTAMP, binary string, REAL, DECFLOAT data types, or a character string that is bit data, and *xquery-variable-expression* must not reference a sequence expression. If the result value is of type XML, it is passed by reference, which means that the original values, not copies, are used in the evaluation of the XQuery expression. A null XML value is converted to an XML empty sequence. If the resulting value is not of type XML, the result of the expression must be castable to an XML value. A null value is converted to an XML empty sequence. The non-XML values creates a new copy of the value during the cast to XML.

An XQuery variable is created for each *xquery-variable-expression* this is specified, and the XQuery variable is set to a value that is equal to the *input-xml-value*.

AS *identifier*

Specifies that the value that is generated by *xquery-variable-expression* is passed to *xquery-update-constant* as an XQuery variable named *identifier*. The length of the name must not be longer than 128 bytes. If the length of the name is longer than 128 bytes, an error is returned. The leading dollar sign ($) that precedes variable names in the XQuery language is not included in *identifier*. The name must be an XML 1.0 NCName that is not the same as the identifier for another *xquery-variable-expression* in the same PASSING clause. If the identifier is not an XML 1.0 NCName an error is returned. If more than one *xquery-variable expression* have the same name, an error is returned. If the result of an *xquery-variable expression* is null, an empty sequence is assigned to the corresponding XQuery variable.

The XMLMODIFY function can only be used in an SQL UPDATE statement or within the update clause of an SQL MERGE statement. The XMLMODIFY function must be the topmost expression on the right hand side of the SET assignment clause of the update.

In an XMLMODIFY invocation, updating expressions cannot modify new nodes that are added by other updating expressions. For example, if an updating expression adds a new element node, another updating expression cannot change the newly created node.

For an XMLMODIFY invocation, the Db2 database manager applies updating expressions in the following order:

1. The following operations, in a non-deterministic order:
   - Insert operations that do not use ordering keywords, such as before, after, as first, or as last
   - Replace operations in which the keyword value of is specified, and the target node is an attribute node, text node, comment node, or processing instruction node
2. Insert operations that use ordering keywords such as before, after, as first, or as last
3. Replace operations in which the keyword value of is not specified
4. Replace operations in which the keyword value of is specified, and the target node is an element node
5. All delete operations

The *target-xml-column* is the XML column in the SET assignment clause that is to be updated by the value that is returned by the XMLMODIFY function. The initial context item in the XQuery updating expression is the value of the *target-xml-column* that is passed by reference. Only the value of the *target-xml-column* can be modified by the XQuery updating expression. In other words, the target expression nodes in the XQuery updating expression must be a node in the value of *target-xml-column*. The *target-xml-column* must be an XML column that is defined in the XML versioning format.

The value of *target-xml-column* that is modified by the XQuery updating expression is returned by the function. If the value of *target-xml-column* is null, the function returns null. Otherwise, the result of the XMLMODIFY function must be a well-formed XML document. If the XQuery updating expressions makes no modifications to the value of *target-xml-column*, the unmodified XML value is returned by the function. The XMLMODIFY function preserves the original node identities and the document order of *target-xml-column*. Although XMLMODIFY modifies *target-xml-column* by reference, for each row that is updated by the SQL UPDATE statement, any reference to *target-xml-column* in the SQL UPDATE statement is the value of the *target-xml-column* before the row is updated.

Example 1: The following is an example of an XMLMODIFY function with an XQuery insert expression. Assume that a table contains a column named PO that contains an XML document, 'purchaseOrders':

```
UPDATE purchaseOrders
   SET PO = XMLMODIFY('declare namespace ipo="http://www.example.com/IPO";
                       declare namespace pyd="http://www.examplepayment.com";
                       insert node $payment/@pyd:paidDate
                         as first into /ipo:purchaseOrder/billTo',
                       XMLPARSE(DOCUMENT
                                                '<payment xmlns:pyd="http://
www.examplepayment.com"
                                    pyd:paidDate="2000-01-07">278.94
                                                 </payment>') AS "payment")
```

The result of the purchaseOrders XML document in the PO column is as follows:

```
<ipo:purchaseOrder
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xmlns:ipo="http://www.example.com/IPO"
  xmlns:pyd="http://www.examplepayment.com"
  orderDate="1999-12-01" pyd:paidDate="2000-01-07">

<shipTo exportCode="1" xsi:type="ipo:UKAddress">
<name>Helen Zoe</name>
      <street>47 Eden Street</street>
      <city>Cambridge</city>
      <postcode>CB1 1JR</postcode>
  </shipTo>
  .
  .
  .
 </ipo:purchaseOrder>
```

Example 2: Assume that table PURCHASEORDER contains a column named PORDER that contains the following XML document:

```
<ipo:purchaseOrder
 xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
 xmlns:ipo="http://www.example.com/IPO"
 xmlns:pyd="http://www.examplepayment.com"
 orderDate="1999-12-01" pyd:paidDate="2000-01-07">
 <shipTo exportCode="1" xsi:type="ipo:UKAddress">
  <name>Helen Zoe</name>
  <street>47 Eden Street</street>
  <city>Cambridge</city>
  <postcode>CB1 1JR</postcode>
 </shipTo>
 <items>
  <item partNum="872-AA">
   <productName>Lawnmower</productName>
   <quantity>1</quantity>
   <USPrice>149.99</USPrice>
   <shipDate>2011-05-20</shipDate>
  </item>
  <item partNum="945-ZG">
   <productName>Sapphire Bracelet</productName>
   <quantity>2</quantity>
   <USPrice>178.99</USPrice>
   <comment>Not shipped</comment>
  </item>
 </items>
</ipo:purchaseOrder>
```

The following is an example of an XMLMODIFY function with an XQuery replace expression and an XQuery delete expression.

```
UPDATE PURCHASEORDER
 SET PORDER = XMLMODIFY(
 'declare namespace ipo="http://www.example.com/IPO";
  replace value of node /ipo:purchaseOrder/items/item[@partNum="872-AA"]/quantity
  with xs:integer(2),
  delete node /ipo:purchaseOrder/items/item[@partNum="945-ZG"]’);
```

After the UPDATE statement executes, the result is as follows:

```
<ipo:purchaseOrder
 xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
 xmlns:ipo="http://www.example.com/IPO"
 xmlns:pyd="http://www.examplepayment.com"
 orderDate="1999-12-01" pyd:paidDate="2000-01-07">
 <shipTo exportCode="1" xsi:type="ipo:UKAddress">
  <name>Helen Zoe</name>
  <street>47 Eden Street</street>
  <city>Cambridge</city>
  <postcode>CB1 1JR</postcode>
 </shipTo>
 <items>
  <item partNum="872-AA">
   <productName>Lawnmower</productName>
   <quantity>2</quantity>
   <USPrice>149.99</USPrice>
```

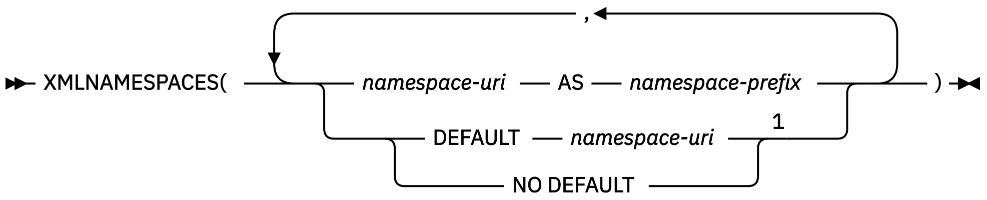
```
    <shipDate>2011-05-20</shipDate>
  </item>
</items>
</ipo:purchaseOrder>
```

Related concepts

Basic updating expressions (Db2 Programming for XML)

XMLNAMESPACES

The XMLNAMESPACES function constructs namespace declarations from the arguments. This function can be used as an argument only for specific functions, such as the XMLELEMENT function and the XMLFOREST function.



Notes:

[1] The DEFAULT or NO DEFAULT clause can only be specified one time.

The schema is SYSIBM.

The result is one or more XML namespace declarations containing in-scope namespaces for each non-null input value.

namespace-uri

Specifies an SQL character string constant that contains the namespace name or a universal resource identifier (URI). The character string constant must not be an empty string if it is used with *namespace-prefix*. *namespace-uri* cannot be `http://www.w3.org/XML/1998/namespace` or `http://www.w3.org/2000/xmlns/`.

AS *namespace-prefix*

Specifies a namespace prefix. The prefix is an SQL identifier that must be in the form of an XML NCName. The prefix must not be "xml" or "xmlns". The prefix must be unique within the list of namespace declarations.

The following namespace prefixes are pre-defined in SQL/XML: "xml", "xs", "xsd", "xsi", and "sqlxml". Their bindings are:

- xmlns:xml = "http://www.w3.org/XML/1998/namespace"
- xmlns:xs = "http://www.w3.org/2001/XMLSchema"
- xmlns:xsd = "http://www.w3.org/2001/XMLSchema"
- xmlns:xsi = "http://www.w3.org/2001/XMLSchema-instance"
- xmlns:sqlxml= "http://standards.iso.org/iso/9075/2003/sqlxml"

DEFAULT *namespace-uri* or NO DEFAULT

Specifies whether a default namespace is to be used within the scope of this namespace declaration.

The scope of this namespace declaration is the specified XML element and all XML expressions that are contained in the specified XML element.

DEFAULT *namespace-uri*

Specifies the default namespace to use within the scope of this namespace declaration. The *namespace-uri* applies for unqualified names in the scope unless it is overridden in a nested scope by another DEFAULT declaration or by a NO DEFAULT declaration.

namespace-uri specifies an SQL character string constant that contains a namespace name or universal resource identifier (URI). The character string constant can be an empty string in the context of the DEFAULT clause.

NO DEFAULT

Specifies that no default namespace is to be used within the scope of this namespace declaration. There is no default namespace in the scope unless the NO DEFAULT clause is overridden in a nested scope by a DEFAULT declaration.

The result of the function is an XML value that is an XML sequence that contains an XML namespace declaration for each specified namespace. The result cannot be null.

Example 1: Generate an "employee" element for each employee. The employee element is associated with XML namespace "urn:bo', which is bound to prefix "bo". The element contains attributes for names and a hiredate subelement.

```
SELECT e.empno, XMLSERIALIZE(XMLELEMENT(NAME "bo:employee",
                   XMLNAMESPACES('urn:bo' as "bo"),
                   XMLATTRIBUTES(e.lastname, e.firstnme),
                   XMLELEMENT(NAME "bo:hiredate", e.hiredate)) AS CLOB(50))
   FROM employee e where e.edlevel = 12;
```

The result of the query would be similar to the following result:

```
00029 <bo:employee xmlns:bo="urn:bo" LASTNAME="PARKER" FIRSTNME="JOHN">
      <bo:hiredate>198-5-3</bo:hiredate>
      </bo:employee>
00031 <bo:employee xmlns:bo="urn:bo" LASTNAME="SETRIGHT"
      FIRSTNME="MAUDE">
      <bo:hiredate>1964-9-12</bo:hiredate>
      </bo:employee>
```

Example 2: Generate two elements for each employee using XMLFOREST. The first "lastname" element is associated with the default namespace "http://hr.org", and the second "job" element is associated with XML namespace "http://fed.gov", which is bound to prefix "d".

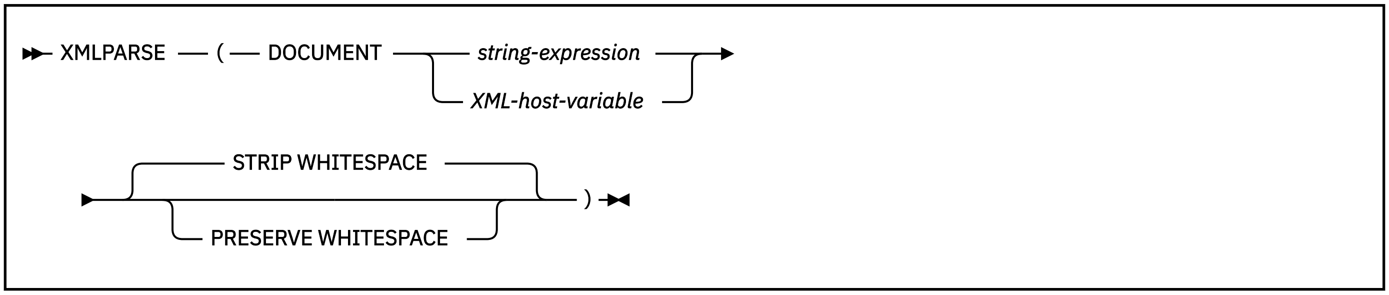
```
SELECT empno, XMLSERIALIZE(XMLFOREST(
          XMLNAMESPACES(DEFAULT 'http://hr.org', 'http://fed.gov' AS "d"),
         lastname, job AS "d:job") AS CLOB(50))
FROM employee where edlevel = 12;
```

The result of the query would be similar to the following result:

```
00029 <LASTNAME xmlns="http://hr.org" xmlns:d="http://fed.gov">PARKER
      </LASTNAME>
      <d:job xmlns="http://hr.org" xmlns:d="http://fed.gov">
      OPERATOR</d:job>
00031 <LASTNAME xmlns="http://hr.org" xmlns:d="http://fed.gov">
      SETRIGHT</LASTNAME>
      <d:job xmlns="http://hr.org" xmlns:d="http://fed.gov">
      OPERATOR</d:job>
```

XMLPARSE

The XMLPARSE function parses the argument as an XML document and returns an XML value.



The schema is SYSIBM.

DOCUMENT

Specifies that the character string expression to be parsed must evaluate to a well-formed XML document that conforms to XML 1.0.

string-expression

An expression that returns a character, graphic, or binary string.

string-expression must evaluate to a character string that conforms to the definition of a well-formed XML document as defined in XML 1.0.

XML-host-variable

An XML host variable that contains a well-formed XML document as defined in XML 1.0. *XML-host-variable* must not be binary XML data.

STRIP WHITESPACE or PRESERVE WHITESPACE

Specifies whether whitespace is to be removed or preserved. Any DTD attributes for xml:space have no impact on whitespace handling.

STRIP WHITESPACE

Specifies that whitespace (space that is between element nodes without any non-whitespace text nodes) will be stripped unless the nearest containing element has a value of 'preserve' for the xml:space attribute.

STRIP WHITESPACE is the default.

PRESERVE WHITESPACE

Specifies that all whitespace is preserved, even when the nearest containing element has a value of 'default' for the xml:space attribute.

The result of the function is XML. If *string-expression* can be null, the result can be null; if *string-expression* is null, the result is the null value.

Notes

Direct use of XMLPARSE with character string input:

Applications should avoid direct use of the XMLPARSE function with character string input and should send strings that contain XML documents directly by using host variables to maintain the match between the external encoding and the encoding in the XML declaration. If XMLPARSE must be used in this situation, a BLOB type should be specified as the argument to avoid code page conversion.

Examples

Example 1:

The following example inserts an XML document into the EMP table and preserves the whitespace in the original XML document. Assume that *hv* contains the value, '`<a xml:space='preserve'> <b> <c>c</c>b </b> </a>`':

```
    INSERT INTO EMP (id, xvalue) VALUES(1001,
                      XMLPARSE(DOCUMENT :hv
                               PRESERVE WHITESPACE));
```

XMLPARSE will treat the value in *hv* for the insert statement as equivalent to the following value:

```
<a xml:space='preserve'> <b> <c>c</c>b </b>
</a>
```

Example 2:

The following example inserts an XML document into the EMP table and strips the whitespace in the original XML document. Assume that *hv* contains the value, '`<a xml:space='preserve'> <b xml:space='default'> <c>c</c>b </b> </a>`':

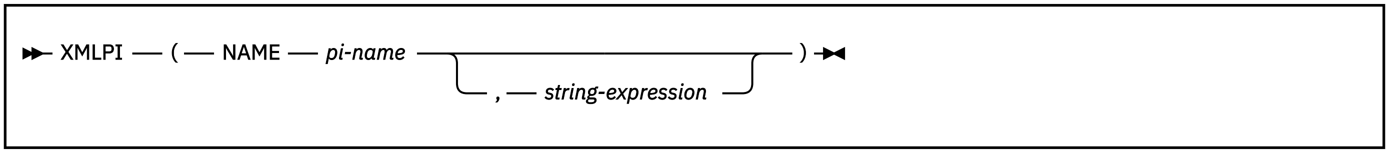
```
    INSERT INTO EMP (id, xvalue) VALUES(1001,
                     XMLPARSE(DOCUMENT :hv
                              STRIP WHITESPACE));
```

XMLPARSE will treat the value in *hv* for the insert statement as equivalent to the following value:

```
    <a xml:space='preserve'>
    <b xml:space='default'><c>c</c>b </b>
    </a>
```

XMLPI

The XMLPI function returns an XML value with a single processing instruction node.



The schema is SYSIBM.

NAME *pi-name*
Specifies the name of a processing instruction. The name is an SQL identifier that must be in the form of an XML NCName. The name must not contain "xml" in any case combination.

string-expression
An expression that returns a value of a built-in character or graphic string that is not a LOB and is not bit data The resulting string will be converted to UTF-8 and parsed to check for conformance to the content of XML processing instruction as specified by the following rules:

- The string must not contain the substring '?>' as this terminates a processing instruction.
- Each character can be any Unicode character, excluding the surrogate blocks, X'FFFE', and X'FFFF'.

If the resulting string does not conform to the preceding rules, an error is returned. The resulting string becomes the contents of the constructed processing instruction node. If *string-expression* is not specified or is an empty string, the contents of the procession instruction node are empty.

The result of the function is an XML value. The result can be null; if the *string-expression* argument is null, the result is the null value.

Example: Generate an XML processing instruction node:

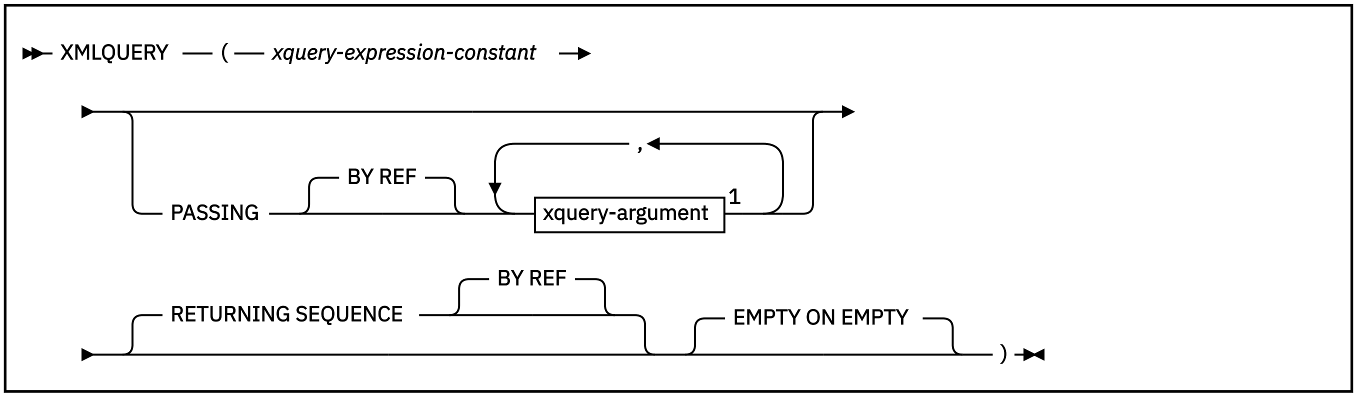
```
    SELECT XMLPI(NAME "Instruction", 'Push the red button')
      FROM SYSIBM.SYSDUMMY1;
```

The result looks similar to the following results:

```
    <?Instruction Push the red button?>
```

XMLQUERY

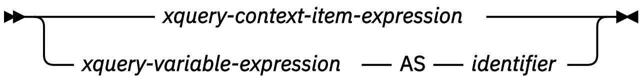
The XMLQUERY function returns an XML value from the evaluation of an XQuery expression, by using specified input arguments, a context item, and XQuery variables.



Notes:

[1] *xquery-context-item-expression* must not be specified more than one time.

xquery-argument:



The schema is SYSIBM.

xquery-expression-constant
Specifies an SQL character string constant that is interpreted as an XQuery expression using supported XQuery language syntax. For information about the supported XQuery expressions, see XQuery prologs and expressions (Db2 Programming for XML). *xquery-expression-constant* cannot be an XQuery updating expression. The XQuery expression is evaluated with the arguments specified in *xquery-argument*, and returns an output sequence that is also returned as the result of the XMLQUERY function. *xquery-expression-constant* must not be an empty string or a string of all blanks.

PASSING
Specifies input values and the manner in which these values are passed to the XQuery expression that is specified by *xquery-expression-constant*.

BY REF
Specifies that the XML input value arguments are to be passed by reference. When XML values are passed by reference, the XQuery evaluation uses the input node trees which preserves all properties, including the original node identities and document order. If two arguments pass the same XML value, node identity comparisons and document ordering comparisons involving some nodes that are contained between the two input arguments might refer to nodes that are within the same XML node tree.

BY REF has no impact on how non-XML values are passed. The non-XML values create a new copy of the value during the cast to XML.

xquery-argument
Specifies an argument that is passed to the XQuery expression that is specified by *xquery-expression-constant*. A query argument is an expression that returns a value that is XML, integer, decimal, or a character or graphic string that is not a LOB. *xquery-argument* must not return ROWID, TIMESTAMP, binary string, REAL, DECFLOAT data types, or a character string data type that is bit data, and must not reference a sequence expression.

xquery-argument specifies both a value and the manner in which that value is to be passed. How an argument in the PASSING clause is used in the XQuery expression depends on whether the argument is specified as *xquery-context-item-expression* or *xquery-variable-expression*. *xquery-argument* includes an SQL expression that is evaluated before passing the result to the XQuery expression.

- If the resulting value is of type XML, it becomes an *input-xml-value*. It is passed by reference, which means that the original values, not copies, are used in the evaluation of the XQuery expression. A null XML value is converted to an XML empty sequence.
- If the resulting value is not of type XML, the result of the expression must be able to be cast to an XML value. A null value is converted to an XML empty sequence. The converted value becomes an *input-xml-value*.

When *xquery-expression-constant* is evaluated, an XQuery variable receives a value that is equal to *input-xml-value* and a name as specified by the AS clause.

xquery-context-item-expression
xquery-context-item-expression specifies the initial context item in the XQuery expression specified by *xquery-expression-constant*. The value of the initial context item is the result of

xquery-context-item-expression cast to XML. *xquery-context-item-expression* must not be specified more than one time.

xquery-context-item-expression must not be a sequence of more than one item. If *input-xml-value* is an empty XML string, the XQuery expression is evaluated with the initial context item set to an empty XML string. If the value of *input-xml-value* is null, the function returns a null value.

If the *xquery-context-item-expression* is not specified or is an empty sequence, the initial context item in the XQuery expression is undefined and the XQuery expression must not reference the initial context item.

An XQuery variable is not created for the context item expression.

xquery-variable-expression

xquery-variable-expression specifies an SQL expression whose value is available to the XQuery expression that is specified by *xquery-expression-constant* during execution. The sequence cannot contain a sequence reference.

An XQuery variable is created for each *xquery-variable-expression*, and the XQuery variable is set to a value equal to *input-xml-value*. For example, `PASSING T.A + T.B AS "sum"` creates an XQuery variable named sum. The scope of the XQuery variables that are created from the PASSING clause is the XQuery expression that is specified by *xquery-expression-constant*.

AS *identifier*

Specifies that the value that is generated by *xquery-variable-expression* is passed to *xquery-expression-constant* as an XQuery variable named *identifier*. The length of the name must not be longer than 128 bytes. The leading dollar sign ($) that precedes variable names in the XQuery language is not included in *identifier*. The name must be an XML 1.0 NCName that is not the same as the identifier for another *xquery-variable-expression* in the same PASSING clause.

RETURNING SEQUENCE

Specifies that the XQuery expression returns a sequence.

BY REF

Specifies that the result of the XQuery expression is returned by reference. If this value contains nodes, any expression that is using the return value of the XQuery expression will receive node references directly, preserving all node properties including the original node identities and document order.

EMPTY ON EMPTY

Specifies that an empty sequence that results from processing the XQuery expression is returned as an empty sequence.

The result of the function is an XML value, and the result can be null. For example, if *xquery-context-item-expression* is specified and if its value is null, the result of the function is the null value.

If the evaluation of the XQuery expression results in an error, the XMLQUERY function returns the XQuery error.

Notes

Implicit casting of a non XML value to an XML value:

If the result of *xquery-argument* is not an XML type, the value is cast to XML as follows. The SQL data type of the expression is mapped to a corresponding XML Schema data type according to the following table:

Table 101. SQL data types and corresponding XML schema data types

SQL data type	XML schema data type
CHAR, VARCHAR	xs:string
GRAPHIC, VARGRAPHIC	xs:string
SMALLINT	xs:integer

Table 101. SQL data types and corresponding XML schema data types (continued)

SQL data type	XML schema data type
INTEGER	xs:integer
BIGINT	xs:integer
DECIMAL	xs:decimal
DOUBLE	xs:double
FLOAT	xs:double

Let *V* be the value of the expression. An atomic value of the corresponding XML schema data type is constructed such that the result of `cast (V as varchar)` is a lexical representation of the constructed atomic value. For example, an SQL VARCHAR value '123' is converted to an atomic value '123' of xs:string type. An SQL integer '12' is converted to an atomic value '12' of xs:integer. An SQL decimal value '1.20' is converted to an atomic value '1.2' of xs:decimal.

Examples

Example 1:

The following example returns an XML value from evaluation of the specified XQuery expression:

```
  SELECT XMLQUERY('//item[productName=$n]'
                  PASSING PO.POrder,
                  :hv AS "n") AS "Result"
     FROM PurchaseOrders PO;
```

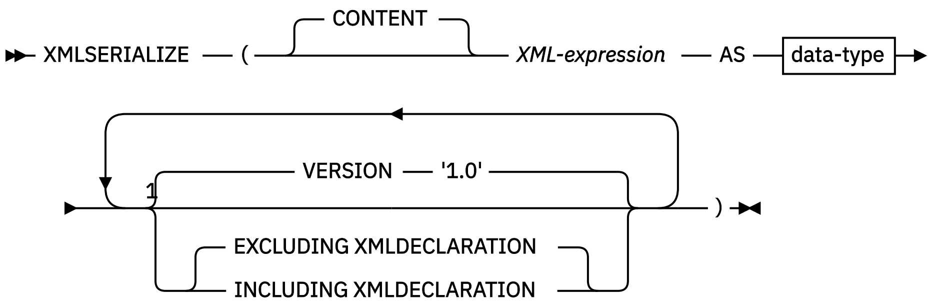
Assume that the value of the host variable *hv* is 'Baby Monitor', the result is similar to the following results:

```
Result
-----------------------------------------------------------------------

<item partNum="926-AA"><productName>Baby Monitor</productName><quantity>1
</quantity><USPrice>39.98</USPrice><shipDate>1999-05-21</shipDate></item>
```

XMLSERIALIZE

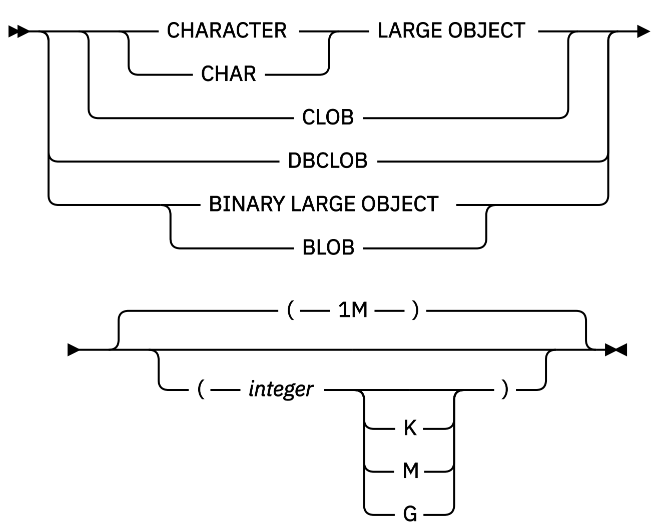
The XMLSERIALIZE function returns a serialized XML value of the specified data type that is generated from the first argument.



Notes:

[1] The same clause must not be specified more than one time.

data-type



The schema is SYSIBM.

CONTENT
Specifies that any XML value can be specified and the result of the serialization is based on this input value.

XML-expression
An expression that returns an XML value that is not an attribute node. The atomic values in the input sequence must be able to be cast to xs:string. *XML-expression* is the input to the serialization process.

AS *data type*
Specifies the data type of the result. The implicit or explicit length attribute for the specified result data type must be sufficient to contain the serialized output.

The CCSID of a resulting character or graphic string is determined by the data type of the result:

- If the result is a CLOB, the CCSID for mixed Unicode data (1208).
- If the result is a DBCLOB, the CCSID for graphic Unicode data (1200).

VERSION '1.0'
Specifies the XML version of the serialized value. The only version that is supported is '1.0', which must be specified as a string constant.

EXCLUDING XMLDECLARATION or INCLUDING XMLDECLARATION
Specifies whether an XML declaration is included in the result.

EXCLUDING XMLDECLARATION
Specifies that an XML declaration is not included in the result.

EXCLUDING XMLDECLARATION is the default.

INCLUDING XMLDECLARATION
Specifies that an XML declaration is included in the result. The XML declaration contains values for XML serialization version 1.0 and an encoding specification of UTF-8. An XML sequence is effectively converted to have a single document node by applying the XMLDOCUMENT function to *XML-expression* prior to serializing the resulting XML nodes.

The data type and length attribute of the result are determined from the specified *data-type*. The result can be null; if the *XML-expression* argument is null, the result is the null value.

Notes

Serializing a sequence:

The value of the input argument to XMLSERIALIZE is a sequence. Before a sequence is serialized, it is normalized. The purpose of sequence normalization is to create a sequence that can be serialized as a well-formed XML document or external general parsed entity, that also reflects the content of the input sequence to the extent possible. If the input sequence is an XML empty string, the result of serialization is an empty string. Otherwise, the result is constructed as follows:

- For each item in the sequence, if the item is atomic, the lexical representation of the item is obtained by casting it to an xs:string
- Each subsequence of adjacent strings in the sequence is merged into a single string with the values of the adjacent strings separated by a single space.
- For each item in the sequence, if the item is a string, a text node is created with a value that is equal to the string.
- For each node in the sequence, if the node is a document node, it is replaced it by its children.
- Each node must not be an attribute node.
- Each subsequence of adjacent text nodes in the sequence are merged into a single text node that with the values of the adjacent text nodes concatenated in order without a space between each node. Any text nodes of zero length are dropped.
- A document node is created and the sequence of nodes that was generated is copied as the children of the new document node.

Let *S* be any sequence, the normalization described in the preceding list is equivalent to `XMLDOCUMENT(S)`. Therefore, the following two expressions produce the same result:

- `XMLSERIALIZE(S AS CLOB)`
- `XMLSERIALIZE(XMLDOCUMENT(S) AS CLOB)`

Each instance of the following characters that appear in the content of a text node or in the value of an attribute node is mapped as following during serialization:

Character in content of text node	during serialization, the character is mapped to
'&' (X'26')	'&amp;'
'<'(X'3C')	'&lt;'
'>'(X'3E')	'&gt;'
carriage return (X'0D')	'&#x0d;'
quote (X'22')[1]	'&quot;'

Note: The quote character is only mapped if it is inside of an attribute value.

Syntax alternatives:

`XML2CLOB(`*`XML-expression`*`)` can be specified as an alternative to `XMLSERIALIZE(`*`XML-expression`*` AS CLOB(2G))`. XML2CLOB is supported only for compatibility with previous releases of Db2.

Examples

Example 1:

Serialize XML values into CLOB(100) values. The XMLELEMENT function generates the XML values from the concatenation of the FIRSTNME and LASTNAME column values of the sample EMP table.

```
SELECT e.EMPNO as "ID",
 XMLSERIALIZE(
  XMLELEMENT(
   NAME "Emp",
   e.FIRSTNME || ' ' || e.LASTNAME)
  AS CLOB(100))
 AS "Result"
 FROM EMP e
 WHERE LASTNAME LIKE 'P%';
```

The query returns results similar to these:

```
ID      Result
-----------------------------------
000070  <Emp>EVA PULASKI</Emp>
000160  <Emp>ELIZABETH PIANKA</Emp>
000270  <Emp>MARIA PEREZ</Emp>
000290  <Emp>JOHN PARKER</Emp>
```

Example 2:

Serialize XML values into BLOB(1K) values. The XMLELEMENT function generates the XML values from the concatenation of the FIRSTNME and LASTNAME column values of the sample EMP table.

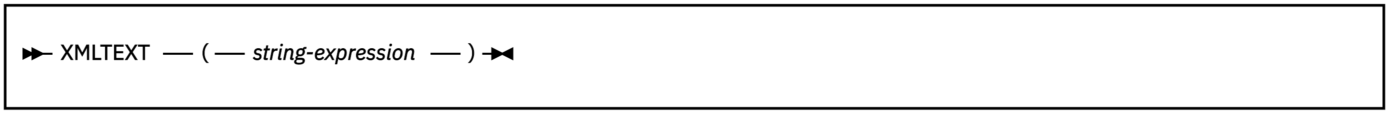
```
SELECT e.EMPNO as "ID",
 XMLSERIALIZE(
  XMLELEMENT(
   NAME "Emp",
   e.FIRSTNME || ' ' || e.LASTNAME)
  AS BLOB(1K))
 AS "Result"
 FROM EMP e
 WHERE LASTNAME LIKE 'P%';
```

The query returns results similar to these:

```
ID      Result
--------------------------------------------------------------
000070  3C456D703E4556412050554C41534B493C2F456D703E
000160  3C456D703E454C495A414245544820504941E4B413C2F456D703E
000270  3C456D703E4D415249412050455245A3C2F456D703E
000290  3C456D703E4A4F484E205041524B45523C2F456D703E
```

XMLTEXT

The XMLTEXT function returns an XML value with a single text node that contains the value of the argument.



The schema is SYSIBM.

string-expression

An expression that returns a value of a built-in character or graphic string that is not bit data. Any character in the resulting string must be a valid XML 1.0 character when it is converted to UTF-8.

If *string-expression* is an empty string, an empty text node is returned.

The result of the function is an XML value.

The result can be null; if the argument is null, the result is the null value.

Example 1: The following example returns an XML value with a single text node that contains the specified value:

```
  SELECT XMLTEXT('The stock symbol for Johnson&Johnson is JNJ.') AS "Result"
     FROM SYSIBM.SYSDUMMY1;
```

The result looks similar to the following results:

```
Result
---------------------------------------------------
```

```
The stock symbol for Johnson&amp;Johnson is JNJ.
```

Example 2: The XMLTEXT function enables the XMLAGG function to construct mixed content, as in the following example:

```
 SELECT XMLELEMENT(NAME "para",
         XMLAGG(XMLCONCAT( XMLTEXT( plaintext),
                           XMLELEMENT( NAME "emphasis",
                           emphtext ))
                  ORDER BY seqno ), '.' ) as "result"
    FROM T;
```

Suppose that the content of the table T is as the following example:

```
seqno    plaintext                                          emphtext
-----    ------------------------------------------------   ----------------
1        This query shows how to construct                  mixed content
2        using XMLAGG and XMLTEXT. Without                  XMLTEXT
3        XMLAGG cannot group text nodes with other nodes,   mixed content
         therefore, cannot generate
```

The result looks like the following result:

```
result
---------------------------------------------------------------------------
<para>This query shows how to construct <emphasis>mixed content</emphasis>
using XMLAGG and XMLTEXT. Without <emphasis>XMLTEXT</emphasis>, XMLAGG
cannot group text nodes with other nodes, therefore, cannot generate
<emphasis>mixed content</emphasis>.</para>
```

XMLXSROBJECTID

The XMLXSROBJECTID function returns the XSR object identifier of the XML schema that is used to validate the XML document specified in the argument.

```
▶▶─ XMLXSROBJECTID( xml-value-expression ) ─▶◀
```

The schema is SYSIBM.

xml-value-expression

An expression that results in a value with a data type of XML. The resulting XML value must be an XML sequence with a single item that is an XML document or the null value.

The XSR object identifier is returned as a BIGINT value and provides the key to a single row in the SYSIBM.XSROBJECTS table.

The result can be null; if the argument is null, the result is the null value.

If *xml-value-expression* does not specify a validated XML document, the function returns 0.

Notes

The XML schema that corresponds to an XSR object ID returned by the function might no longer exist, because an XML schema can be dropped without affecting XML values that were validated using that XML schema. Therefore, queries that use the XSR object ID to fetch further XML schema information from the SYSIBM.XSROBJECTS table might return an empty result set.

Examples

Example 1:

Use the XMLXSROBJECTID function in conjunction with the DSN_XMLVALIDATE function to find all XML documents that are not validated in a table and validate them:

```
UPDATE orders
        SET content = dsn_xmlvalidate(content, 'SYSXSR.PO1')
    WHERE XMLXSROBJECTID(content) = 0;
```

Example 2:

Use the XMLXSROBJECTID function to find the names and target namespaces of the XML schemas that are used to validate the XML documents in a table:

```
SELECT DISTINCT s.XSROBJECTNAME, s.targetNamespace
    FROM orders o, XSROBJECTS s
    WHERE XMLXSROBJECTID(content) = s.XSROBJECTID;
```

XSLTRANSFORM

The XSLTRANSFORM function transforms an XML document into a different data format. The output can be any form possible for the XSLT processor, including but not limited to XML, HTML, and plain text.

▶▶─ XSLTRANSFORM(*xml-document* ,*xsl-stylesheet* ,*xsl-parameters*) ─▶◀

The schema is SYSFUN.

xml-document

An expression that returns a well-formed XML document with a data type of CHAR, VARCHAR, or CLOB(2 MB). The input expression can contain XMLSERIALIZE to serialize an XML data type into a CLOB. The *xml-document* is transformed with the XSL style sheet that is specified in *xsl-stylesheet*. The XML document must at minimum be single-rooted and well-formed.

xsl-stylesheet

An expression that returns a well-formed XML document with a data type of CHAR, VARCHAR, or CLOB(256 KB). The input expression can contain XMLSERIALIZE to serialize an XML data type into a CLOB. The document is an XSL style sheet that conforms to the W3C XSLT Version 1.0 Recommendation. This style sheet is applied to transform the value that is specified in *xml-document*.

xsl-parameters

An expression that returns a well-formed XML document or empty string with a data type of CHAR, VARCHAR, or CLOB(64 KB). The input expression can contain XMLSERIALIZE to serialize an XML data type into a CLOB. The *xsl-parameters* provides parameter values to the XSL style sheet specified in *xsl-stylesheet*. The value of the parameter can be specified as an attribute, or as a text node. If both are specified, the value in the attribute is used. The *xsl-stylesheet* document must have matching `param` name attribute values. The syntax of the parameter document is as follows:

```
<params xmlns="http://www.ibm.com/XSLTransformParameters">
 <param name="..." value="..."/>
 <param name="...">enter value here</param>
...
</params>
```

Important: If *xsl-parameters* are not needed, you still must supply an empty string or the function result is null.

The result of the function is of type CLOB(2 MB).

This user-defined function requires IBM SDK for z/OS, Java Technology Edition Version 6.

This user-defined function uses the XSLT support that is provided by the W3C XSL Transformations V1.0 Recommendation.

Tip: To create your own variation of XSLTRANSFORM, start with the CREATE FUNCTION shown in sample member DSNTESR. Change the function name and size of the definition of the input parameters for your environment.

Example 1: This example illustrates how to use XSLT as a formatting engine in a C program.

```
EXEC SQL BEGIN DECLARE SECTION;
SQL TYPE IS CLOB(2M)    xmldoc;
SQL TYPE IS CLOB(256K)   stylesheet;
SQL TYPE IS CLOB(64K)   xslparms;
SQL TYPE IS CLOB(2M)    result;
EXEC SQL END DECLARE SECTION;

EXEC SQL
SET :xmldoc = CLOB('<?xml version="1.0"?><hi>Hello</hi>');

EXEC SQL SET :stylesheet = CLOB( '<?xml version="1.0"?>
    <xsl:stylesheet xmlns:xsl="http://www.w3.org/1999/XSL/Transform" version="1.0">
    <xsl:output indent="yes"/>
    <xsl:param name="parm" select="'World'"/>
    <xsl:template match="hi">
      <out>
        <xsl:value-of select="."/>
        <xsl:text>, </xsl:text>
        <xsl:value-of select="$parm"/>
        <xsl:text>!!!</xsl:text>
      </out>
    </xsl:template>
  </xsl:stylesheet>');

EXEC SQL SET :xslparms = CLOB(
  '<params xmlns="http://www.ibm.com/XSLTransformParameters">
      <param name="parm">Silicon Valley</param>
   </params>');

EXEC SQL
    SELECT SYSFUN.XSLTRANSFORM(:xmldoc, :stylesheet, :xslparms)
       INTO :result FROM SYSIBM.SYSDUMMY1;
```

The XML document is transformed by the XSL style sheet. The result of the transformation is:

```
<?xml version="1.0" encoding="UTF-8"?>
<out>Hello, Silicon Valley!!!</out>
```

XSL Transformations (XSLT)

YEAR

The YEAR function returns the year part of a value that is a character or graphic string. The value must be a valid string representation of a date or timestamp.

▶▶— YEAR(*expression*) —▶◀

The schema is SYSIBM.

The argument must be an expression that returns one of the following built-in data types: a date, a timestamp, a character string, a graphic string, or a numeric data type.

- If *expression* is a character or graphic string, it must not be a CLOB or DBCLOB, and its value must be a valid string representation of a date or timestamp with an actual length of not greater than 255 bytes.

For the valid formats of string representations of dates and timestamps, see “String representations of datetime values” on page 120.

- If *expression* is a number, it must be a date or timestamp duration. For the valid formats of date and timestamp durations, see “Datetime operands” on page 169.

If *expression* is a timestamp with a time zone, or a valid string representation of a timestamp with a time zone, the result is determined from the UTC representation of the datetime value.

The result of the function is a large integer.

The result can be null; if the argument is null, the result is the null value.

The other rules depend on the data type of the argument specified:

If the argument is a date, a timestamp, or a string representation of either, the result is the year part of the value, which is an integer between 1 and 9999.
If the argument is a date duration or a timestamp duration, the result is the year part of the value, which is an integer between -9999 and 9999. A nonzero result has the same sign as the argument.
If the argument contains a time zone, the result is the year part of the value expressed in UTC.

Example 1: From the table DSN8C10.EMP, select all rows for employees who were born in 1941.

```
   SELECT *
     FROM DSN8C10.EMP
     WHERE YEAR(BIRTHDATE) = 1941;
```

Example 2: The following invocations of the YEAR function returns the same result:

```
SELECT YEAR('1993-08-10-20.00.00'),
            YEAR('1993-08-10-20.00.00-08:00'),
            YEAR('1993-08-10-20.00.00+09:00')
        FROM SYSIBM.SYSDUMMY1;
```

For each invocation of the YEAR function in this SELECT statement, the result is 1993.

When the input argument contains a time zone, the result is determined from the UTC representation of the input value. The string representations of a timestamp with a time zone in the SELECT statement all have the same UTC representation: '1993-08-10-20.00.00'.

Table functions

A table function can be used only in the FROM clause of a statement. Table functions return columns of a table and resemble a table created using a CREATE TABLE statement. Table functions can be qualified with a schema name.

ADMIN_TASK_LIST

The ADMIN_TASK_LIST function returns a table with one row for each of the tasks that are defined in the administrative task scheduler task list.

Authorization

The user who calls this function must have MONITOR1 privilege.

```
▶▶─ ADMIN_TASK_LIST() ─▶◀
```

The schema is DSNADM.

The result of the function is a table with the format shown in the following table. All the columns are nullable except TASK_NAME.

Table 102. Format of the resulting table for ADMIN_TASK_LIST

Column name	Data type	Contains
BEGIN_ TIMESTAMP	TIMESTAMP	Contains the timestamp of when the task can first run. When the task begins to run depends on what values this and other columns contain: • If BEGIN_TIMESTAMP contains a non-null value: – If POINT_IN_TIME and TRIGGER_TASK_NAME contain null values, the task begins to run at the timestamp in BEGIN_TIMESTAMP – If POINT_IN_TIME contains a non-null value, the task begins to run at the next point in time that is defined at or after the timestamp in BEGIN_TIMESTAMP – If TRIGGER_TASK_NAME is a non-null value, the task begins to run at the next time that the task identified in TRIGGER_TASK_NAME completes or after the timestamp in BEGIN_ TIMESTAMP • If BEGIN_TIMESTAMP contains a null value: – If POINT_IN_TIME and TRIGGER_TASK_NAME contain null values, the task begins to run immediately – If POINT_IN_TIME contains a non-null value, the task begins to run at the next point in time that is defined – If TRIGGER_TASK_NAME is a non-null value, the task begins to run at the next time that the task identified in TRIGGER_TASK_NAME completes
END_ TIMESTAMP	TIMESTAMP	Contains the timestamp of when the task is last able to run. If this column is NULL, there are no restrictions as to when the task must not run.
MAX_ INVOCATIONS	INTEGER	Contains the maximum number of times the task can run. The maximum number applies to all types of schedules: triggered by events, scheduled by time interval, or by point in time. If this column is null, the task has no limit on the number of times it can be run. If both END_TIMESTAMP and MAX_INVOCATIONS contain values, the value in END_TIMESTAMP takes precedence over the value for MAX_INVOCATIONS. That is, if the value in END_TIMESTAMP is reached, even though the number of times the task has run has not reached the value for MAX_INVOCATIONS, the task will not run again
INTERVAL	INTEGER	Contains an integer that indicates the duration between the start of one instance of a task and the start of the next instance of the same task. If the value of this column is NULL, the task is not scheduled to run at a regular interval.
POINT_IN_ TIME	VARCHAR(400)	Contains one or more points in time (in UNIX cron format) for which the task is scheduled to run. If the value of this column is NULL, the task is not scheduled to run at a specific point in time. The format contains the following pieces of information separated by blanks: given hour, given minute, given day of the week, given day of the month, given month of the year.

Table 102. Format of the resulting table for ADMIN_TASK_LIST (continued)

Column name	Data type	Contains
TRIGGER_ TASK_NAME	VARCHAR(128)	Contains the task name of the task that, when its execution is complete, will trigger the running of the task that is described in the row. Task name DB2STOP is reserved for Db2 stop events and task name DB2START is reserved for Db2 start events. Those events are handled by the administrative task scheduler that is associated with the Db2 subsystem that is starting or stopping. If the value of this column is NULL, the task that is described in this row will not be triggered to run by another task.
TRIGGER_ TASK_COND	CHAR(2)	Contains the type of comparison that is to be made to the return code after the running of task that is indicated in TRIGGER_TASK_NAME. The following values are possible: **GT** Greater than **GE** Greater than or equal to **EQ** Equal to **LT** Less than **LE** Less tan or equal to **NE** Not equal to If this column contains NULL, the task is triggered to run without consideration of the return code of the task that is indicated in TRIGGER_TASK_NAME.
TRIGGER_ TASK_CODE	INTEGER	Contains the return code from running the task indicated in TRIGGER_TASK_NAME. If the running of this task is triggered by a stored procedure, TRIGGER_TASK_CODE contains the SQLCODE that must be returned by the stored procedure in order for this task to run. If the running of this task is triggered by a JCL job, TRIGGER_TASK_CODE contains the MAXRC that must be returned by the job in order for this task to run. "ADMIN_TASK_STATUS" on page 674 returns the SQLCODE or MAXRC value in the SQLCODE or MAXRC column. If TRIGGER_TASK_COND is NULL, this column will also be NULL.

Table 102. Format of the resulting table for ADMIN_TASK_LIST (continued)

Column name	Data type	Contains
DB2_SSID	VARCHAR(4)	Contains the Db2 subsystem ID of the Db2 subsystem that is associated with the administrative task scheduler that should run this task. The value in this column is used in a data sharing environment where, for example different Db2 members have different configurations and running the task relies on a certain environment. A value in DB2_SSID will prevent an administrative scheduler of other members to run this task, so that the task can only be run as long as the administrative task scheduler of the subsystem indicated in DB2_SSID is running. For a task that is being triggered by a Db2 start or Db2 stop event as indicated in the TRIGGER_TASK_NAME column, a value in DB2_SSID will allow the task to be run only when the indicated subsystem is starting or stopping. If no value is indicated in DB2_SSID, each subsystem that starts or stops will trigger a the task to be run locally, provided that the triggered task is run serially. If this column is NULL, any administrative scheduler can run this task.
PROCEDURE_ SCHEMA	VARCHAR(128)	Contains the schema of the Db2 stored procedure that this task will run. If the value of this column is null, Db2 uses a default schema.
PROCEDURE_ NAME	VARCHAR(128)	Contains the name of the Db2 stored procedure that this task will run. If the value of this column is NULL, no stored procedure will be called when this task is run.
PROCEDURE_ INPUT	VARCHAR(4096)	Contains a statement that returns one row of data. The returned value will be used as the input parameter of the stored procedure that this task will run. If this column contains the null value, no parameters are passed to the stored procedure when this task is run.
JCL_LIBRARY	VARCHAR(44)	Contains the name of the data set that contains the JCL job that is run when this task is run. If the value of this column is the null value, no JCL job will be run when this task is run.
JCL_MEMBER	VARCHAR(8)	Contains the name of the library member that contains the JCL job that is run when this task is run. If the value of this column is the null value, the data set that is specified in JCL_LIBRARY is sequential and contains the JCL job that is run when this task is run.

Table 102. Format of the resulting table for ADMIN_TASK_LIST (continued)

Column name	Data type	Contains
JOB_WAIT	VARCHAR(8)	Contains one of the following values, which indicates whether the JCL job can be run synchronously. If the value in the column is not null, this column contains one of the following values: **NO** Runs asynchronously **YES** Runs synchronously **PURGE** Runs synchronously and then the job status in z/OS is purged
TASK_NAME	VARCHAR(128)	Contains the unique name that is assigned to this task.
DESCRIPTION	VARCHAR(128)	Contains a description of the task if one exists.
USERID	VARCHAR(128)	Contains the authorization ID of the user under which the task will be invoked. If this column is NULL, the task is invoked by the default authorization ID that is associated with the administrative task scheduler.
CREATOR	VARCHAR(128)	Contains the authorization ID that added the task to the administrative task scheduler task list.
LAST_MODIFIED	TIMESTAMP	Timestamp of when the task was added or last modified.

Example 1: Retrieve information about all of the tasks that are defined in the administrative task scheduler task list:

```
SELECT *
  FROM TABLE (DSNADM.ADMIN_TASK_LIST()) AS T;
```

ADMIN_TASK_OUTPUT

For an execution of a stored procedure, the ADMIN_TASK_OUTPUT function returns the output parameter values and result sets, if available. If the task that was executed is not a stored procedure or the requested execution status is not available, the function returns an empty table.

Authorization

The user who calls this function must have MONITOR1 privilege.

```
►► ADMIN_TASK_OUTPUT( task-name ,num-invocations ) ►◄
```

The schema is DSNADM.

Important: The ADMIN_TASK_OUTPUT function returns as many output parameter values and result sets as possible. However, this information is not always available. The administrative task scheduler cannot store output that exceeds 32,180 bytes in length. Therefore, some output parameters and result set values might be null if the values are too long to be stored by the administrative task scheduler. Also, if the result sets are too large to be stored, only some of the most recent rows of each result set might be available (for example, the first rows missing).

task-name

Specifies the unique name of the task whose execution output you want returned. This is an input parameter of type VARCHAR(128).

num-invocations

Specifies the execution number of the task whose output you want returned. This value must be a valid value in the NUM_INVOCATIONS column of the returned table of DSNADM.ADMIN_TASK_STATUS(NULL) for the specified task. This is an input parameter of type INTEGER.

The result of the function is a table with the format shown in the following table. This function might return an empty table for the output of a stored procedure for the following reasons:

- The stored procedure does not have output parameters or result sets.
- The output of the stored procedure was not stored at execution time, because the SYSIBM.ADMIN_TASKS_HIST table was not available.
- The *num-invocations* parameter is not valid.
- The output for the task that is specified by the *num-invocations* parameter is no longer stored, because the task is older than the value that is specified for the MAXHIST parameter of the administrative task scheduler. (The MAXHIST parameter specifies the maximum number of execution statuses to keep for each task.)

Table 103. Format of the resulting table for ADMIN_TASK_OUTPUT

Column name	Data type	Contains
RESULT_SET	SMALLINT	Contains the stored procedure result set number with a value beginning at 1, or NULL if this value is for an output parameter of the stored procedure.
ROW	SMALLINT	Contains the result set row number with a value beginning at 1, or NULL if this value is for an output parameter of the stored procedure.
COLUMN	SMALLINT	Contains the result set column number, or the index of an output parameter of the stored procedure parameters, with a value beginning at 1. Only the values of output parameters are returned, and the results include the index in all parameters of the stored procedure.
TYPE	CHAR(8)	Contains the type of the returned string. Possible types are: • DATE • TIME • TIMESTMP • CHAR • VARCHAR • FLOAT • BIGINT • INTEGER • SMALLINT • OTHER The value OTHER includes all other data types that are not supported in this stored procedure.
VALUE	VARCHAR(32180)	Contains the string representation of the output parameter value or the result set column value. This column is null if the TYPE column contains OTHER.

Related tasks

Displaying the results of a stored procedure task (Db2 Administration Guide)

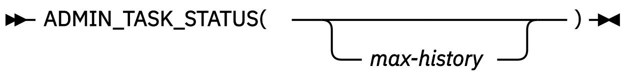
ADMIN_TASK_STATUS

The ADMIN_TASK_STATUS function returns a table with one row for each task that is defined in the administrative task scheduler task list. Each row indicates the status of the task for the last time it was run.

Optionally, if you specify the *max-history* parameter, the function returns a row of data for each execution of a task (up to the *max-history* value). For tasks that have not been executed, this function returns a row of data with a NULL status.

Authorization

The user who calls this function must have MONITOR1 privilege.



The schema is DSNADM.

max-history

Specifies the maximum number of execution statuses per task to be returned. The most recent execution statuses are returned.

If the parameter is set to NULL, all available task execution statuses are returned. If the parameter is set to 1, only the status for the last time the task was run is returned, which is the same result as not specifying this option. This is an input parameter of type INTEGER.

The result of the function is a table with the format shown in the following table.

Table 104. Format of the resulting table for ADMIN_TASK_STATUS

Column name	Data type	Contains
TASK_NAME	VARCHAR(128)	Contains the name of the task that has run, is running, or has been bypassed.
STATUS	VARCHAR(10)	Contains one of the following values that indicates task status: **RUNNING** The task is currently running **COMPLETED** The task has finished running. For asynchronous tasks (JCL jobs), this column contains COMPLETED whenever the job is submitted to be run. Otherwise, this column contains COMPLETED only after the task has finished running. **NOTRUN** The task was not run at the scheduled invocation time. The MSG column contains the error or warning message that indicates why the task was not run. **UNKNOWN** The scheduler shut down while the task was running. The scheduler is started again but cannot know the execution status of this interrupted task.

Table 104. Format of the resulting table for ADMIN_TASK_STATUS (continued)

Column name	Data type	Contains
NUM_ INVOCATIONS	INTEGER	Contains the number of times the administrative task scheduler attempted to run the task, including the current time if the task is currently running. The values in this column does not indicate if the task was successfully run.
START_ TIMESTAMP	TIMESTAMP	Contains the time when the task started running if the STATUS column contains COMPLETED, RUNNING, or UNKNOWN. Otherwise, this column contains the time that the task should have started to run but could not.
END_ TIMESTAMP	TIMESTAMP	Contains the time when the task finished running.
JOB_ID	CHAR(8)	Contains the job ID that is assigned to the JCL job submitted by the administrative task scheduler. This column contains NULL if the task is a stored procedure or if the STATUS column does not contain COMPLETED.
MAXRC	INTEGER	Contains the highest return code from submitting a JCL job. If the task is synchronous, the value in this column is changed to the return code that is returned when the job finishes running. This column is set to NULL if the task is a stored procedure, if the STATUS column does not contain COMPLETED, or if a synchronous task is finished and has run with JES3 in a z/OS 1.7 or earlier system.

Table 104. Format of the resulting table for ADMIN_TASK_STATUS (continued)

Column name	Data type	Contains
COMPLETION_ TYPE	INTEGER	Contains one of the following values that indicates the completion type of the JCL job submitted by the administrative task scheduler: **0** No completion information **1** Job ended normally **2** Job ended by completion code **3** Job had a JCL error **4** Job was canceled **5** Job abended **6** Converter abended while processing the job **7** Job failed security checks **8** Job failed in end-of-memory This column contains NULL if the task is a stored procedure, if the STATUS column does not contain COMPLETED, or if the JCL job is run with JES3 in a z/OS 1.7 or earlier system.
SYSTEM_ ABENDCD	INTEGER	Contains the system abend code returned by a failed JCL job that was submitted by the administrative task scheduler. This column contains NULL if the task is a stored procedure, if the STATUS column does not contain COMPLETED, or if the JCL job is run with JES3 in a z/OS 1.7 or earlier system.
USER_ABENDCD	INTEGER	Contains the user abend code returned by a failed JCL job that was submitted by the administrative task scheduler. This column contains NULL if the task is a stored procedure, if the STATUS column does not contain COMPLETED, or if the JCL job is run with JES3 in a z/OS 1.7 or earlier system.
MSG	VARCHAR(128)	Contains the error or warning message from the last time the task was run.
SQLCODE	INTEGER	Contains the SQLCODE set by Db2 when a stored procedure was called by the administrative task scheduler. This column contains NULL if the task is a JCL job or if the STATUS column does not contain COMPLETED.
SQLSTATE	CHAR(5)	Contains the SQLSTATE set by Db2 when a stored procedure was called by the administrative task scheduler. This column contains NULL if the task is a JCL job or if the STATUS column does not contain COMPLETED.

Table 104. Format of the resulting table for ADMIN_TASK_STATUS (continued)

Column name	Data type	Contains
SQLERRP	VARCHAR(8)	Contains the SQLERRP set by Db2 when a stored procedure was called by the administrative task scheduler. This column contains NULL if the task is a JCL job or if the STATUS column does not contain COMPLETED.
SQLERRMC	VARCHAR(70)	Contains the SQLERRMC set by Db2 when a stored procedure was called by the administrative task scheduler. This column contains NULL if the task is a JCL job or if the STATUS column does not contain COMPLETED.
DB2_SSID	VARCHAR(4)	Contains the Db2 subsystem ID that is associated with the administrative task scheduler that ran the task or should have run the task.
USERID	VARCHAR(128)	Contain the user ID that the task ran under.

Example 1: Retrieve status information about all of the tasks that have run in the administrative task scheduler task list:

```
SELECT *
  FROM TABLE (DSNADM.ADMIN_TASK_STATUS()) AS T;
```

BLOCKING_THREADS

The BLOCKING_THREADS function returns a table that contains one row for each lock or claim that threads hold against the databases that are specified in the input parameter.

Authorization

The set of privileges for each specified database must include one of the following privileges or authorities:

- DISPLAYDB privilege
- DISPLAY privilege
- DBMAINT authority
- DBCTRL authority
- DBADM authority
- System DBADM authority
- SYSOPR authority
- SYSCTRL authority
- SYSADM authority

For implicitly created databases, the database privilege or authority can be held on the implicitly created database or on DSNDB04.

Syntax

```
▶▶─ BLOCKING_THREADS( dbname ) ─▶◀
```

The schema is SYSIBMADM.

dbname

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The expression must have an actual length that is no greater than 128 bytes. The value of the expression must refer to a database for which information is to be displayed. Multiple databases can be specified in the following forms:

Table 105. Forms of dbname and dbstring

Form	**Displays the information of...**
dbname1:dbname2	All databases with names, in UNICODE order, that are between *dbname1* and *dbname2* inclusive
*dbname**	All databases with names that begin with the string *dbname*
**dbname*	All databases with names that end with the string *dbname*
dbname	All databases with names that contain the string *dbname*
dbstring1*dbstring2	All databases with names that contain the strings *dbstring1* and *dbstring2*

The result of the function is a table with the format shown in the following table. All of the columns are nullable.

Table 106. Format of the resulting table for BLOCKING_THREADS

Column name	**Data type**	**Contains...**
ACQUIRED_TS	TIMESTAMP (12)	The time when the lock or claim was acquired
AGE	VARCHAR (128)	The elapsed time between when the lock or claim was acquired and when the function was invoked, with the following abbreviated keywords: **D** Days **H** Hours **M** Minutes **S** Seconds. Microseconds are represented by up to six decimal digits.
CORRID	VARCHAR (255)	The correlation identifier of the thread. If the STATE value indicates a physical lock (P-lock), CORRID has a null value or empty string.

Table 106. Format of the resulting table for BLOCKING_THREADS (continued)

Column name	Data type	Contains...
CONNID	VARCHAR (255)	The connection identifier of the thread. If the STATE value indicates a P-lock, CONNID has a null value or empty string.
USERID	VARCHAR (255)	The user ID of the thread. If the STATE value indicates a P-lock, USERID has a null value or empty string.
LUWID	VARCHAR (255)	The logical-unit-of-work identifier of the thread. If the STATE value indicates a P-lock, LUWID has a null value or empty string.
SSID	CHAR (4)	In data sharing, the Db2 data sharing member where the thread is running. Otherwise, this column is unused.
TYPE	CHAR (1)	The type of blocker held by the thread. TYPE can have one of the following values: **L** Lock **C** Claim **I** Indicates that the row is for informational purposes. The INFO column contains the information. **E** Indicates that an error occurred. The INFO column explains the error. **D** Indicates that the row is for serviceability purposes. The INFO column contains the serviceability information.

Table 106. Format of the resulting table for BLOCKING_THREADS (continued)

Column name	**Data type**	**Contains...**
SUBTYPE	CHAR (2)	The type of lock or claim that blocking threads hold. Locks for blocking threads can have one of the following values: **00** Page lock **01** Database lock **02** Page set lock **03** Data set lock (partition) **05** Index compression lock **06** Lock-specific partition **07** Page set or data set open **08** Utility I/O damage assessment **09** Page set piece locks Continues in next row.

Table 106. Format of the resulting table for BLOCKING_THREADS (continued)

Column name	Data type	Contains...
SUBTYPE (cont.)		**0A** Database exception table (DBET) entry locks **0D** Buffer manager (BM) SYSLGRNG recording lock or group buffer pool (GBP) conversion dependent lock **0E** Utility serialization lock **0F** Mass delete lock for table **10** Table lock for segmented table space **12** Package lock **18** Row lock **1F** Distributed data facility (DDF) communications database (CDB) P-lock **22** Resource limit facility (RLF) P-lock **27** DBET logical page list (LPL) or group buffer pool recovery pending (GRECP) locks **30** LOB lock **32** LPL recovery lock **36** Serialization lock for adding partitions **39** Load database definition (DBD) lock **3A** Compression dictionary build lock **3B** Compression dictionary load lock **41** Utility catalog access lock

Table 106. Format of the resulting table for BLOCKING_THREADS (continued)

Column name	Data type	Contains...
SUBTYPE (cont.)		Claims for blocking threads can have one of the following values: **20** WR claim **40** RR claim **60** RR, WR claim **80** CS claim **A0** CS, WR claim
DURATION	CHAR (2)	The duration of the lock or claim. Locks can have one of the following values: **20** Manual **21** Manual+1 **40** Commit **41** Commit+1 **60** Allocation **80** Plan **81** Utility **FE** Interest Claims can have one of the following values: **CM** Commit **CH** Cursor hold **AL** Allocation

Table 106. Format of the resulting table for BLOCKING_THREADS (continued)

Column name	Data type	Contains...
STATE	CHAR (2)	The state in which the lock is held. Locks can have one of the following values: **01** Unprotected share **02** Intent shared **03** Intent exclusive **04** Shared **05** Update **06** Shared intent exclusive **07** Non-shared update **08** Exclusive **09** Intent exclusive P-lock **0A** Intent shared P-lock **0B** Shared intent exclusive P-lock
DBID	SMALLINT	The database identifier
OBID	SMALLINT	The object identifier
DBNAME	VARCHAR (24)	The database name
OBJECT_QUALIFIER	VARCHAR (128)	The schema of a table or index
OBJECT NAME	VARCHAR (128)	The name of a table, index, or table space
PAGENUM_OR_RID	VARCHAR (10)	Indicates one of the following values in hexadecimal format: • The page number if the lock is a page lock • The record ID if the lock is a row lock • The dataset number if the lock is a dataset lock • The partition number if the lock is a partition lock

Table 106. Format of the resulting table for BLOCKING_THREADS (continued)

Column name	**Data type**	**Contains...**
PACKAGE	VARCHAR (512)	The qualified package name (COLLECTION_ID.NAME.CONTOKEN) if the lock is a package lock
CATALOG_LEVEL	VARCHAR (10)	The catalog level. This column is currently not used and reserved for future use.
INFO	VARCHAR (1024)	Informational text if TYPE is I, D, or E

The function returns an informational message (TYPE=I) for any specified databases that do not hold any locks or claims.

Examples

Retrieve information about the threads that hold locks and claims against the Db2 catalog and directory databases:

```
SELECT *
  FROM TABLE (SYSIBMADM.BLOCKING_THREADS('DSNDB06,DSNDB01'));
```

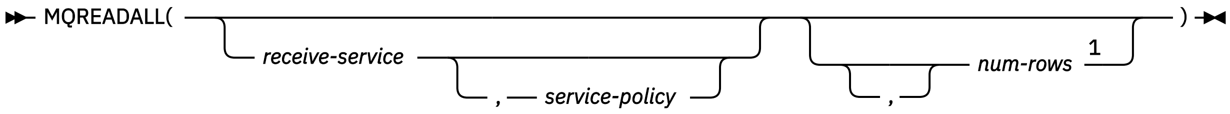
MQREADALL

The MQREADALL function returns a table that contains the messages and message metadata from a specified IBM MQ location without removing the messages from the queue.



Notes:

[1] The comma is required before *num-rows* when any of the preceding arguments to the function are specified.

The schema is DB2MQ.

The MQREADALL function returns a table containing the messages and message meta-data from the IBM MQ location that is specified by *receive-service*, using the quality-of-service policy that is defined in *service-policy*. Performing this operation does not remove the messages from the queue that is associated with *receive-service*.

receive-service

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be an empty string or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression must refer to a service point that is defined in the DB2MQ.MQSERVICE table. A service point is a logical end-point from which a message is sent or received. A service point definition includes the name of the IBM MQ queue manager and the name of the queue. See *IBM MQ Application Messaging Interface* for more details.

If *receive-service* is not specified or is the null value, `DB2.DEFAULT.POLICY` is used.

service-policy

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be an empty string or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression must refer to a service policy that is defined in the DB2MQ.MQPOLICY table. A service policy specifies a set of quality-of-service options that are to be applied to this messaging operation. These options include message priority and message persistence. See *IBM MQ Application Messaging Interface* for more details.

If *service-policy* is not specified or is the null value, `DB2.DEFAULT.POLICY` is used.

num-rows

An expression that returns a value that is a SMALLINT or INTEGER data type whose value is a positive integer or zero. The value of the expression specifies the maximum number of messages to return.

If *num-rows* is not specified or if the value of the expression is zero, all available messages are returned.

The result of the function is a table with the format shown in the following table. All the columns are nullable.

Table 107. Format of the resulting table for MQREADALL

Column name	Data type	Contains
MSG	VARCHAR(4000)	The contents of the IBM MQ message
CORRELID	VARCHAR(24)	The correlation ID that is used to relate messages
TOPIC	VARCHAR(40)	The topic that the message was published with, if available
QNAME	VARCHAR(48)	The name of the queue from which the message was received
MSGID	CHAR(24)	The unique message identifier assigned by IBM MQ
MSGFORMAT	VARCHAR(8)	The format of the message, as defined by IBM MQ

Examples

Example 1

Read all the messages from the queue specified by the default service (Db2.DEFAULT.SERVICE), using the default policy (Db2.DEFAULT.POLICY).

```
SELECT * FROM TABLE (MQREADALL()) AS T;
```

The messages and all the metadata are returned as a table.

Example 2

Read all the messages from the beginning of the queue specified by the service MYSERVICE, using the default policy (Db2.DEFAULT.POLICY).

```
SELECT T.MSG, T.CORRELID
     FROM TABLE (MQREADALL ('MYSERVICE')) AS T;
```

Only the MSG and CORRELID columns are returned.

Example 3

Read all the messages from the queue specified by the default service (Db2.DEFAULT.SERVICE), using the default policy (Db2.DEFAULT.POLICY). Only messages with a CORRELID of '1234' are returned.

```
SELECT *
  FROM TABLE (MQREADALL(10)) AS T
      WHERE T.CORRELID = '1234';
```

All columns are returned.

Example 4

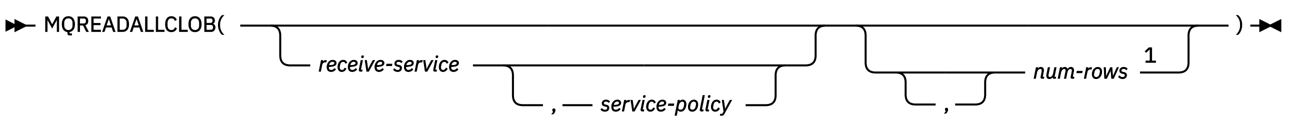
Retrieve the first 10 messages from the beginning of the queue specified by the default service (Db2.DEFAULT.SERVICE), using the default policy (Db2.DEFAULT.POLICY).

```
SELECT *
  FROM TABLE (MQREADALL(10)) AS T;
```

The first 10 messages and all the columns are returned as a table.

MQREADALLCLOB

The MQREADALLCLOB function returns a table that contains the messages and message metadata from a specified IBM MQ location without removing the messages from the queue.



Notes:

[1] The comma is required before *num-rows* when any of the preceding arguments to the function are specified.

The schema is DB2MQ.

The MQREADALLCLOB function returns a table containing the messages and message meta-data from the IBM MQ location that is specified by *receive-service*, using the quality-of-service policy that is defined in *service-policy*. Performing this operation does not remove the messages from the queue that is associated with *receive-service*.

receive-service

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be an empty string or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression must refer to a service point that is defined in the DB2MQ.MQSERVICE table. A service point is a logical end-point from which a message is sent or received. A service point definition includes the name of the IBM MQ queue manager and the name of the queue. See *IBM MQ Application Messaging Interface* for more details.

If *receive-service* is not specified or is the null value, `DB2.DEFAULT.POLICY` is used.

service-policy

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be an empty string or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression must refer to a service policy that is defined in the DB2MQ.MQPOLICY table. A service policy specifies a set of quality-of-service options that are to be applied to this messaging operation. These options include message priority and message persistence. See *IBM MQ Application Messaging Interface* for more details.

If *service-policy* is not specified or is the null value, `DB2.DEFAULT.POLICY` is used.

num-rows

An expression that returns a value that is a SMALLINT or INTEGER data type whose value is a positive integer or zero. The value of the expression specifies the maximum number of messages to return.

If *num-rows* is not specified or if the value of the expression is zero, all available messages are returned.

The result of the function is a table with the format shown in the following table. All the columns in the table are nullable.

Table 108. Format of the resulting table for MQREADALLCLOB

Column name	Data type	Contains
MSG	CLOB(1M)	The contents of the IBM MQ message
CORRELID	VARCHAR(24)	The correlation ID that is used to relate messages
TOPIC	VARCHAR(40)	The topic that the message was published with, if available
QNAME	VARCHAR(48)	The name of the queue from which the message was received
MSGID	CHAR(24)	The unique message identifier assigned by IBM MQ
MSGFORMAT	VARCHAR(8)	The format of the message, as defined by IBM MQ

The CCSID of the result is the system CCSID that was in effect at the time that the IBM MQ function was installed into Db2.

Examples

Example 1

Read all the messages from the queue specified by the default service (Db2.DEFAULT.SERVICE), using the default policy (Db2.DEFAULT.POLICY).

```
SELECT * FROM TABLE (MQREADALLCLOB()) AS T;
```

The messages and all the metadata are returned as a table.

Example 2

Read all the messages from the queue specified by the service MYSERVICE, using the default policy (Db2.DEFAULT.POLICY).

```
SELECT T.MSG, T.CORRELID
  FROM TABLE (MQREADALLCLOB('MYSERVICE')) AS T;
```

Only the MSG and CORRELID columns are returned as a table.

Example 3

Read all the messages from the queue specified by the service MYSERVICE, using the default policy (Db2.DEFAULT.POLICY), with a correlation identifier of '1234'.

```
SELECT * FROM TABLE (MQREADALLCLOB('MYSERVICE')) AS T
      WHERE T.CORRELID = '1234';
```

All columns are returned.

Example 4

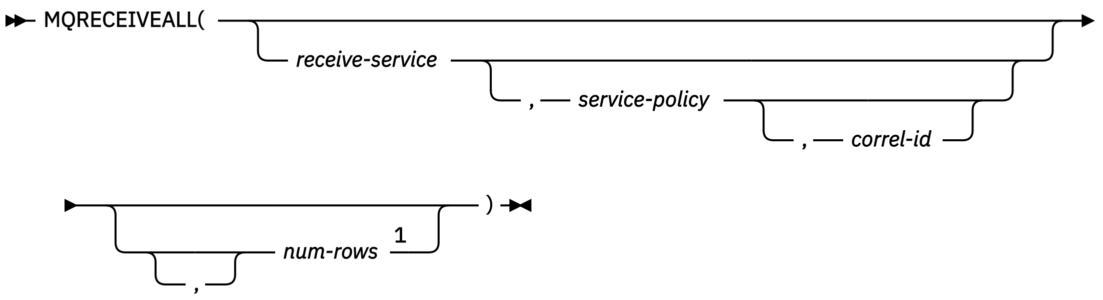
Read the first 10 messages from the queue specified by the default service (Db2.DEFAULT.SERVICE), using the default policy (Db2.DEFAULT.POLICY).

```
SELECT * FROM TABLE (MQREADALLCLOB('10')) AS T;
```

All columns are returned.

MQRECEIVEALL

The MQRECEIVEALL function returns a table that contains the messages and message metadata from a specified IBM MQ location and removes the messages from the queue.



Notes:

[1] The comma is required before *num-rows* when any of the preceding arguments to the function are specified.

The schema is DB2MQ.

The MQRECEIVEALL function returns a table containing the messages and message meta-data from the IBM MQ location that is specified by *receive-service*, using the quality-of-service policy that is defined in *service-policy*. Performing this operation removes the messages from the queue that is associated with *receive-service*.

receive-service

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be an empty string or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression must refer to a service point that is defined in the DB2MQ.MQSERVICE table. A service point is a logical end-point from which a message is sent or received. A service point definition includes the name of the IBM MQ queue manager and the name of the queue. See *IBM MQ Application Messaging Interface* for more details.

If *receive-service* is not specified or is the null value, `DB2.DEFAULT.POLICY` is used.

service-policy

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be an empty string or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression must refer to a service policy that is defined in the DB2MQ.MQPOLICY table. A service policy specifies a set of quality-of-service options that are to be applied to this messaging operation. These options include message priority and message persistence. See *IBM MQ Application Messaging Interface* for more details.

If *service-policy* is not specified or is the null value, `DB2.DEFAULT.POLICY` is used.

correl-id

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The expression must have an actual length that is no greater than 24 bytes. The value of the expression specifies the correlation identifier that is associated with this message. A correlation identifier is often specified in request-and-reply scenarios to associate requests with replies. Only those messages with a matching correlation identifier are returned.

A fixed length string with trailing blanks is considered a valid value. However, when the *correl-id* is specified on another request such as MQSEND, the *correl-id* must be specified the same to be recognized as a match. For example, specifying a value of 'test' for *correl-id* for this function does not match a *correl-id* value of 'test   ' (with trailing blanks) specified earlier on an MQSEND request.

If *correl-id* is not specified, is an empty string, or is the null value, a correlation identifier is not used, and the message at the beginning of the queue is returned.

num-rows

An expression that returns a value that is a SMALLINT or INTEGER data type whose value is a positive integer or zero. The value of the expression specifies the maximum number of messages to return.

If *num-rows* is not specified or if the value of the expression is zero, all available messages are returned.

The result of the function is a table with the format shown in the following table. All of the columns are nullable.

Table 109. Format of resulting table for MQRECEIVEALL

Column name	Data type	Contains
MSG	VARCHAR(4000)	The contents of the IBM MQ message
CORRELID	VARCHAR(24)	The correlation ID that is used to relate messages
TOPIC	VARCHAR(40)	The topic that the message was published with, if available
QNAME	VARCHAR(48)	The name of the queue from which the message was received
MSGID	CHAR(24)	The unique message identifier assigned by IBM MQ
MSGFORMAT	VARCHAR(8)	The format of the message, as defined by IBM MQ

The CCSID of the result is the system CCSID that was in effect at the time that the IBM MQ function was installed into Db2.

Examples

Example 1

Retrieve all the messages from the queue specified by the default service (Db2.DEFAULT.SERVICE), using the default policy (Db2.DEFAULT.POLICY).

```
SELECT * FROM TABLE (MQRECEIVEALL()) AS T;
```

The messages and all the metadata are returned as a table and the messages are removed from the queue.

Example 2

Retrieve all the messages from the queue specified by the service MYSERVICE, using the default policy (Db2.DEFAULT.POLICY).

```
SELECT T.MSG, T.CORRELID
  FROM TABLE  (MQRECEIVEALL('MYSERVICE')) AS T;
```

Only the MSG and CORRELID columns are returned. The messages are removed from the queue.

Example 3

Retrieve all the messages from the beginning of the queue specified by the service MYSERVICE, using the policy MYPOLICY, with a correlation identifier of '1234'.

```
SELECT T.MSG, T.CORRELID
  FROM TABLE  (MQRECEIVEALL('MYSERVICE','MYPOLICY','1234')) AS T;
```

Only the MSG and CORRELID columns are returned. The messages are removed from the queue.

Example 4

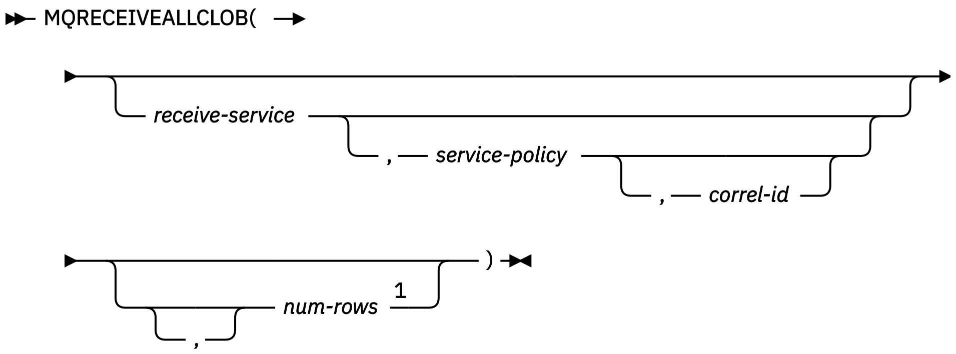
Retrieve the first 10 messages from the beginning of the queue specified by the default service (Db2.DEFAULT.SERVICE), using the default policy (Db2.DEFAULT.POLICY).

```
    SELECT * FROM TABLE (MQRECEIVEALL(10)) AS T;
```

All columns are returned. The messages are removed from the queue.

MQRECEIVEALLCLOB

The MQRECEIVEALLCLOB function returns a table that contains the messages and message metadata from a specified IBM MQ location and removes the messages from the queue.



Notes:

[1] The comma is required before *num-rows* when any of the preceding arguments to the function are specified.

The schema is DB2MQ.

The MQRECEIVEALLCLOB function returns a table containing the messages and message metadata from the IBM MQ location that is specified by *receive-service*, using the quality-of-service policy that is defined in *service-policy*. Performing this operation removes the messages from the queue that is associated with *receive-service*.

receive-service
An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be an empty string or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression must refer to a service point that is defined in the DB2MQ.MQSERVICE table. A service point is a logical end-point from which a message is sent or received. A service point definition includes the name of the IBM MQ queue manager and the name of the queue. See *IBM MQ Application Messaging Interface* for more details.

If *receive-service* is not specified or is the null value, `DB2.DEFAULT.POLICY` is used.

service-policy
An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be an empty string or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression must refer to a service policy that is defined in the DB2MQ.MQPOLICY table. A service policy specifies a set of quality-of-service options that are to be applied to this messaging operation. These options include message priority and message persistence. See *IBM MQ Application Messaging Interface* for more details.

If *service-policy* is not specified or is the null value, `DB2.DEFAULT.POLICY` is used.

correl-id

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The expression must have an actual length that is no greater than 24 bytes. The value of the expression specifies the correlation identifier that is associated with this message. A correlation identifier is often specified in request-and-reply scenarios to associate requests with replies. Only those messages with a matching correlation identifier are returned.

A fixed length string with trailing blanks is considered a valid value. However, when the *correl-id* is specified on another request such as MQSEND, the *correl-id* must be specified the same to be recognized as a match. For example, specifying a value of 'test' for *correl-id* for this function does not match a *correl-id* value of 'test   ' (with trailing blanks) specified earlier on an MQSEND request.

If *correl-id* is not specified, is an empty string, or is the null value, a correlation identifier is not used, and the message at the beginning of the queue is returned.

num-rows

An expression that returns a value that is a SMALLINT or INTEGER data type whose value is a positive integer or zero. The value of the expression specifies the maximum number of messages to return.

If *num-rows* is not specified or if the value of the expression is zero, all available messages are returned.

The result of the function is a table with the format shown in the following table. All of the columns are nullable.

Table 110. Format of resulting table for MQRECEIVEALLCLOB

Column name	Data type	Contains
MSG	CLOB(1M)	The contents of the IBM MQ message
CORRELID	VARCHAR(24)	The correlation ID that is used to relate messages
TOPIC	VARCHAR(40)	The topic that the message was published with, if available
QNAME	VARCHAR(48)	The name of the queue from which the message was received
MSGID	CHAR(24)	The unique message identifier assigned by IBM MQ
MSGFORMAT	VARCHAR(8)	The format of the message, as defined by IBM MQ

The CCSID of the result is the system CCSID that was in effect at the time that the IBM MQ function was installed into Db2.

Examples

Example 1

Retrieve all the messages from the queue specified by the default service (Db2.DEFAULT.SERVICE), using the default policy (Db2.DEFAULT.POLICY)

```
SELECT * FROM TABLE (MQRECEIVEALLCLOB()) AS T;
```

The messages and all the metadata are returned as a table, and the messages are removed.

Example 2

Retrieve all the messages from the beginning of the queue specified by the service MYSERVICE, using the policy (Db2.DEFAULT.POLICY)

```
SELECT T.MSG, T.CORRELID
  FROM TABLE (MQRECEIVEALLCLOB('MYSERVICE')) AS T;
```

Only the MSG and CORRELID columns are returned as a table, and the messages removed from the queue.

Example 3

Retrieve all the messages from the queue specified by the service MYSERVICE, using the policy "MYPOLICY", with a correlation identifier of '1234'

```
    SELECT *
      FROM TABLE (MQRECEIVEALLCLOB('MYSERVICE','MYPOLICY','1234')) AS T;
```

All columns are returned, and the messages removed from the queue.

Example 4

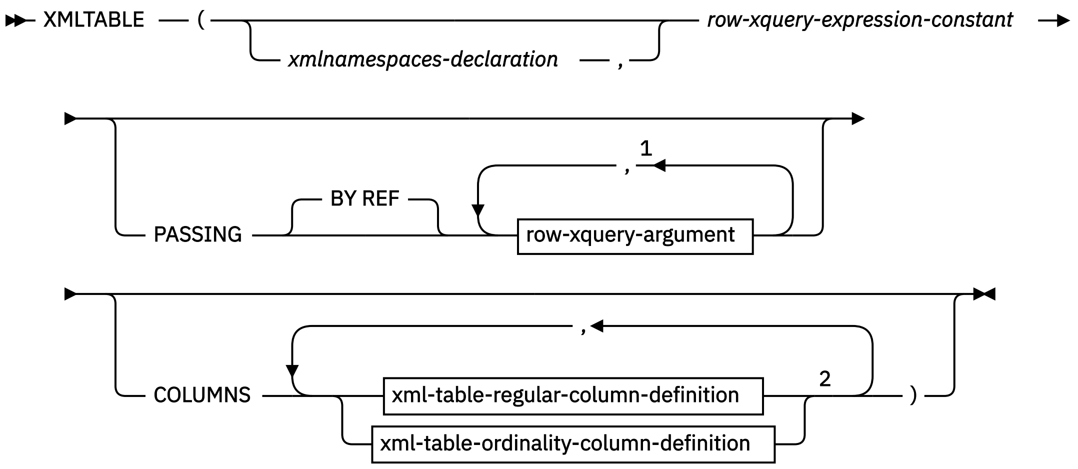
Retrieve the first 10 messages from the beginning of the queue specified by the default service (Db2.DEFAULT.SERVICE), using the default policy (Db2.DEFAULT.POLICY)

```
    SELECT *
      FROM TABLE (MQRECEIVEALLCLOB(10)) AS T;
```

All columns are returned, and the messages removed from the queue.

XMLTABLE

The XMLTABLE function returns a result table from the evaluation of XQuery expressions, possibly by using specified input arguments as XQuery variables. Each item in the result sequence of the row XQuery expression represents one row of the result table.



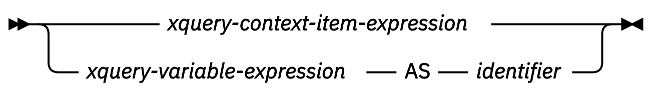
XMLTABLE
(
xmlnamespaces-declaration
,
row-xquery-expression-constant
PASSING
BY REF
,
1
row-xquery-argument
COLUMNS
,
xml-table-regular-column-definition
2
xml-table-ordinality-column-definition
)

Notes:

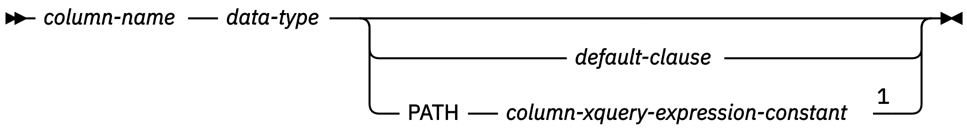
[1] *xquery-context-item-expression* must not be specified more than one time.

[2] The xml-table-ordinality-column-definition clause must not be specified more than one time.

row-xquery-argument



xml-table-regular-column-definition



Notes:

[1] Neither the *default-clause* or the PATH clause can be specified more than one time.

xml-table-ordinality-column-definition

```
►►— column-name —— FOR ORDINALITY —►◄
```

The schema is SYSIBM.

The function name cannot be specified as a qualified name.

xmlnamespaces-declaration

Specifies one or more XML namespace declarations, using the XMLNAMESPACES function, that become part of the static context of the *row-xquery-expression-constant* and the *column-xquery-expression-constant*. The set of statically known namespaces for XQuery expressions which are arguments of XMLTABLE is the combination of the pre-established set of statically known namespaces and the namespace declarations specified in this clause. The XQuery prolog within an XQuery expression can override these namespaces.

If *xmlnamespaces-declaration* is not specified, only the pre-established set of statically known namespaces apply to the XQuery expressions.

row-xquery-expression-constant

Specifies an SQL character string constant that is interpreted as an XQuery expression using supported XQuery language syntax. *row-xquery-expression-constant* cannot be an XQuery updating expression. This expression determines the number of rows in the result table. The expression is evaluated using the optional set of input XML values that is specified in *row-xquery-argument*, and returns an output XQuery sequence where one row is generated for each item in the sequence. If the sequence is empty, the result of XMLTABLE is an empty table. *row-xquery-expression-constant* must not contain an empty string or a string of all blanks.

PASSING

Specifies input values and the manner in which these values are passed to *row-xquery-expression-constant*.

BY REF

Specifies that any XML input arguments are, by default, passed by reference. When XML values are passed by reference, the XQuery evaluation uses the input node trees, if any exist, directly from the specified input expressions and preserves all properties, including the original node identities and document order.

This clause has no impact on how non-XML values are passed. The non-XML values create a new copy of the value during the cast to XML.

row-xquery-argument

Specifies an argument that is to be passed to the XQuery expression specified by *row-xquery-expression-constant*. *row-xquery-argument* is an SQL expression that returns a value that is not a ROWID, LOB, DATE, TIME, TIMESTAMP, BINARY, VARBINARY, REAL, DECFLOAT, or character string with FOR BIT DATA attribute.

How *row-xquery-argument* is used in the XQuery expression depends on whether the argument is specified as an *xquery-context-item-expression* or an *xquery-variable-expression*.

If the data type of *row-xquery-argument* is not XML, the result of the expression for the argument is implicitly cast to XML. A null value is converted to an XML empty sequence if the argument is *xquery-variable-expression*.

row-xquery-argument must not contain NEXT VALUE or PREVIOUS VALUE expressions or OLAP specifications.

xquery-context-item-expression

An expression that returns a value that is XML, integer, decimal, or a character or graphic string that is not a LOB. *xquery-context-item-expression* must not be a character string that is bit data.

xquery-context-item-expression specifies the initial context item for the *row-xquery-expression*. The value of the initial context item is the result of *xquery-context-item-expression* cast to XML. *xquery-context-item-expression* must not be specified more than one time.

xquery-variable-expression

Specifies an SQL expression whose value is available to the XQuery expression specified by *row-xquery-expression-constant* during execution. The expression must returns a value that is XML, integer, decimal, or a character or graphic string that is not a LOB.

xquery-variable-expression specifies an argument that will be passed to *row-xquery-expression-constant* as an XQuery variable. If *xquery-variable-expression* is a null value, the XQuery variable is set to an XML empty sequence. The scope of the XQuery variables that are created from the PASSING clause is the XQuery expression specified by *row-xquery-expression-constant*.

AS *identifier*

Specifies that the value generated by *xquery-variable-expression* will be passed to *row-xquery-expression-constant* as an XQuery variable. The variable name will be *identifier*. The leading dollar sign ($) that precedes variable names in the XQuery language is not included in *identifier*. The identifier must not be greater than 128 bytes in length. Two arguments within the same PASSING clause cannot use the same identifier.

COLUMNS

Specifies the output columns of the result table including the column name, data type, and how the column value is computed for each row. If this clause is not specified, a single unnamed column of data type XML is returned, with the value based on the sequence item from evaluating the XQuery expression in the *row-xquery-expression-constant* (equivalent to specifying PATH '.'). To reference the result column, a *column-name* must be specified in the *correlation-clause* following the function.

xml-table-regular-column-definition

Specifies one output column of the result table including the column name, data type, and an XQuery expression to extract the value from the sequence item for the row.

column-name

Specifies the name of the column in the result table. The name cannot be qualified and the same name cannot be used for more than one column of the table.

data-type

Specifies the data type of the column. See CREATE TABLE for the syntax and a description of types available. A *data-type* can be used in XMLTABLE if there is a supported XMLCAST from the XML data type to the specified *data-type*.

default-clause

Specifies a default value for the column. See CREATE TABLE for the syntax and a description of the *default-clause*. For XMLTABLE result columns, the default is applied when the processing of the XQuery expression contained in *column-xquery-expression-constant* returns an empty sequence. This default value will not be inherited by declared global temporary tables even when the INCLUDING COLUMN DEFAULTS clause is specified in the definition of the declared global temporary table.

PATH *column-xquery-expression-constant*

Specifies an SQL character string constant that is interpreted as an XQuery expression using supported XQuery language syntax. The *column-xquery-expression-constant* specifies an XQuery expression that determines the column value with respect to an item that is the result of evaluating the XQuery expression in *row-xquery-expression-constant*. Given an item from the result of processing the *row-xquery-expression-constant* as the externally provided context item, the *column-xquery-expression-constant* is evaluated and returns an output sequence. The column value is determined based on this output sequence as follows.

- If the output sequence contains zero items, the *default-clause* provides the value of the column.
- If an empty sequence is returned and no *default-clause* was specified, a null value is assigned to the column.
- If a non-empty sequence is returned, the value is cast to the *data-type* specified for the column using the XMLCAST expression. An error could be returned from processing this XMLCAST.

The value for *column-xquery-expression-constant* must not be an empty string or a string of all blanks. If this clause is not specified, the default XQuery expression is simply the *column-name*.

xml-table-ordinality-column-definition

Specifies the ordinality column of the result table.

column-name

Specifies the name of the column in the result table. The name cannot be qualified and the same name cannot be used for more than one column of the table.

FOR ORDINALITY

Specifies that *column-name* is the ordinality column of the result table. The data type of this column is BIGINT. The value of this column in the result table is the sequential number of the item for the row in the resulting sequence from evaluating the XQuery expression in *row-xquery-expression-constant*.

The result of the function is a table. The encoding scheme of the table is Unicode. If the evaluation of any of the XQuery expressions results in an error, the XMLTABLE function returns the XQuery error.

Example: List as a table result the purchase order items for orders with a status of 'NEW':

```
SELECT U."PO ID", U."Part #", U."Product Name",
     U."Quantity", U."Price", U."Order Date"
  FROM PURCHASEORDER P,
     XMLTABLE(XMLNAMESPACES('http://podemo.org' AS "pod"),
              '$po/PurchaseOrder/itemlist/item' PASSING P.PORDER as "po"
              COLUMNS "PO ID"         INTEGER       PATH '../../@POid',
                      "Part #"        CHAR(6)       PATH 'product/@pid',
                      "Product Name"  CHAR(50)      PATH 'product/pod:name',
                      "Quantity"      INTEGER       PATH 'quantity',
                      "Price"         DECIMAL(9,2)  PATH 'product/pod:price',
                      "Order Date"    TIMESTAMP     PATH '../../dateTime'
              ) AS U
   WHERE P.STATUS = 'NEW'
```

Row functions

A row function can be used only in contexts that are specifically described for the function.

UNPACK

The UNPACK function returns a row of values that are derived from unpacking the input binary string. It is used to unpack a string that was encoded according to the PACK function.

```
▶▶─ UNPACK ── ( ── expression ── ) ─▶◀
```

The schema is SYSIBM.

expression

An expression that returns the string value to be unpacked. The *expression* must be a binary string that is not a BLOB and that is not null. The format of the binary string must match the one that is produced by the PACK function.

The UNPACK function can only be specified in the SELECT list and the SET clause of the UPDATE statement.

The result of the function is a row of fields corresponding to the data elements that were encoded in the input packed string. The result is not null.

Example 1: Assume that a user-defined function named myUDF returns a VARBINARY result. The body of the function includes the following invocation of the PACK function to pack some data into a binary string:

```
  SET :udf_result = PACK(CCSID 1208, 'Alina', DATE('1977-08-01'),
                      DOUBLE(0.5));
```

The following SELECT statement unpacks the result of the myUDF function and returns a row of individual column values:

```
  SELECT UNPACK(myUDF(C1)).* AS(Name VARCHAR(40) CCSID UNICODE,
                             DOB DATE,
                             Score DOUBLE)
    FROM T1;
```

The use of ".*" indicates that the result of the UNPACK function should be flattened into a list of result column values. When the UNPACK function is used in a select clause, an AS clause is specified to provide the names and data types for the resulting values.

Example 2: Assume that a user-defined function UDF_SCORE returns a VARBINARY result. The PACK function is invoked to return a binary string in which the column values of table T1 are encoded and packed. The UNPACK function returns the individual data values for a row with column names ID, SCORE, and CONF:

```
  SELECT T1.C1, T1.C2, T1.C3, T1.C4,
         UNPACK( UDF_SCORE( PACK(CCSID 1208, T1.C1, T1.C2, T1.C3)) ).*
                AS (ID INT, SCORE DOUBLE, CONF DOUBLE)
    FROM T1;
```

Example 3: Assume that a user-defined function named myUDF returns a VARBINARY result. The body of the function includes the following invocation of the PACK function to pack some data into a binary string. The character data that is packed includes EBCDIC and Unicode data. The CCSID DEFAULT clause causes the data to be packed with its original encoding.

```
SET :udf_result = PACK(CCSID DEFAULT,
 CAST('Privet' AS VARCHAR(10) CCSID UNICODE),
 CAST(NULL AS TIME),CAST('Bridget' AS VARCHAR(20) CCSID EBCDIC));
```

The following SELECT statement unpacks the result of the myUDF function and returns a row of individual column values. The CCSID clauses ensure that the data is unpacked in the same encoding scheme as it was before it was packed.

```
SELECT UNPACK(myUDF(C1)).* AS(MSG VARCHAR(10) CCSID UNICODE,
 DOB DATE,
 NAME VARCHAR(20) CCSID EBCDIC)
 FROM T1;
```

Related reference

PACK
The PACK function returns a binary string value that contains a data type array and a packed representation of each non-null *expression* argument.

select-clause
The SELECT clause specifies the columns of the final result table. The column values are produced by the application of the *select list* to R. The select list is a list of names and expressions specified in the SELECT clause, and R is the result of the previous operation of the subselect. For example, if SELECT, FROM, and WHERE are the only clauses specified, then R is the result of that WHERE clause.

unpacked-row
An *unpacked-row* specifies a row that is the result of an invocation of the UNPACK built-in function.

Chapter 5. Procedures that are supplied with Db2

A *procedure* is an application program that can be started through the SQL CALL statement. The procedure is specified by a procedure name, which may be followed by arguments that are enclosed within parentheses. This information contains syntax diagrams, semantic descriptions, rules, and examples of the use of the system supplied procedures.

Important: Do not create additional versions of Db2-supplied procedures by specifying the VERSION keyword. Only versions that are supplied with Db2 are supported. Additional versions of such routines cause the installation and configuration of Db2-supplied routines to fail.

CALL statement
The CALL statement invokes a stored procedure.

Installation information for procedures and functions that are supplied with Db2 (Db2 Installation and Migration)

ADMIN_COMMAND_DB2 stored procedure

The SYSPROC.ADMIN_COMMAND_DB2 stored procedure executes one or more Db2 commands on a connected Db2 subsystem, or on a Db2 data sharing group member. This stored procedure also returns the command output messages.

GUPI

Environment

ADMIN_COMMAND_DB2 must run in a WLM-established stored procedure address space.

Authorization

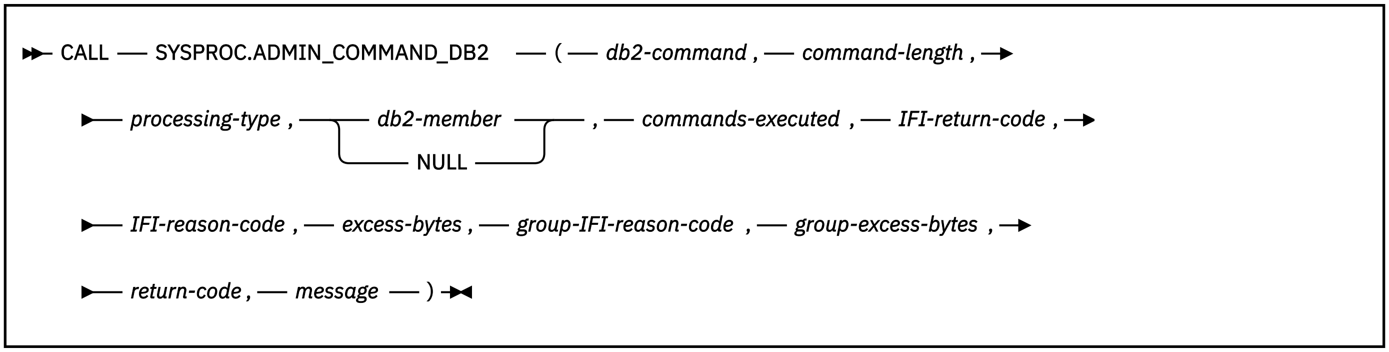
To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges on each package that the stored procedure uses:

- The EXECUTE privilege on the package for DSNADMCD
- Ownership of the package
- PACKADM authority for the package collection
- SYSADM authority

To execute the Db2 command, you must use a privilege set that includes the authorization to execute the Db2 command. For more information, see "Privileges and authorization IDs for commands" in Commands in Db2 (Db2 Commands).

Syntax

The following syntax diagram shows the SQL CALL statement for invoking this stored procedure:



```
►► CALL ── SYSPROC.ADMIN_COMMAND_DB2 ── ( ── db2-command , ── command-length , ──►

►── processing-type , ──┬── db2-member ──┬── , ── commands-executed , ── IFI-return-code , ──►
                        └── NULL ────────┘

►── IFI-reason-code , ── excess-bytes , ── group-IFI-reason-code , ── group-excess-bytes , ──►

►── return-code , ── message ── ) ►◄
```

Option descriptions

db2-command

Specifies any Db2 command, such as -DISPLAY THREAD(*), or multiple Db2 commands. With multiple Db2 commands, use a null value (CHAR string of '\0') to delimit the commands. The Db2 command is executed using the authorization ID of the user who invoked the stored procedure.

If you specify *processing-type*, you must specify the command name in full, such as "-DISPLAY THREAD". You cannot abbreviate Db2 commands, such as "-DIS THD".

This is an input parameter of type VARCHAR(32704) and cannot be null.

command-length

Specifies the length of the Db2 command or commands. When multiple Db2 commands are specified in *db2-command*, *command-length* is the sum of all of those commands, including the '\0' command delimiters.

This is an input parameter of type INTEGER and cannot be null.

processing-type

Identifies the action that you want ADMIN_COMMAND_DB2 to complete. You can request ADMIN_COMMAND_DB2 to parse the output messages of a command and provide the formatted result in a global temporary table, or you can request for a command to run synchronously.

If you specify *processing-type*, you must specify *db2-command* as a full command name, such as "-DISPLAY THREAD". You cannot abbreviate Db2 commands, such as "-DIS THD".

To request output message parsing, specify one of the following values:

Note: If you specify any of the following values, ADMIN_COMMAND_DB2 returns the parsed output message in a second result, as described in the Output section. Otherwise, if you specify any value that does not appear in the list below, ADMIN_COMMAND_DB2 returns the complete unparsed command output message, and only one result set is returned.

BP

Parse "-DISPLAY BUFFERPOOL" command output messages.

DB

Parse "-DISPLAY DATABASE" command output messages and return database information.

TS

Parse "-DISPLAY DATABASE(...) SPACENAM(...)" command output messages and return table spaces information.

IX

Parse "-DISPLAY DATABASE(...) SPACENAM(...)" command output messages and return index spaces information.

THD

Parse "-DISPLAY THREAD" command output messages.

If the -DISPLAY THREAD command includes the SCOPE(GROUP) option, ADMIN_COMMAND_DB2 returns parsed output in the second result set (in created temporary table SYSIBM.DB2_THREAD_STATUS) only for the data sharing member that appears first in the output.

ADMIN_COMMAND_DB2 returns unparsed output in the first result set (in created temporary table SYSIBM.DB2_CMD_OUTPUT) for the other data sharing members.

UT
Parse "-DISPLAY UTILITY" command output messages.

GRP
Parse "-DISPLAY GROUP" command output messages.

DDF
Parse "-DISPLAY DDF" command output messages.

LS
Parse "-DISPLAY DATABASE(...) SPACENAM(...)" command output messages and return information for LOB table spaces.

XS
Parse "-DISPLAY DATABASE(...) SPACENAM(...)" command output messages and return information for XML table spaces.

UN
Parse "-DISPLAY DATABASE(...) SPACENAM(...)" command output messages and return information for table spaces when the type is unknown.

To request for a command to run synchronously, specify:

SYC
Issue the command synchronously.

Only the following commands can be processed synchronously. For all other commands, SYC is ignored.

- -ALTER BUFFERPOOL
- -SET LOG
- -SET SYSPARM
- -STOP DATABASE

This is an input parameter of type VARCHAR(3).

db2-member
Specifies the name of a single data sharing group member on which an IFI request is to be executed

This is an input parameter of type VARCHAR(8).

commands-executed
Provides the number of commands that were executed

This is an output parameter of type INTEGER.

IFI-return-code
Provides the IFI return code

This is an output parameter of type INTEGER.

IFI-reason-code
Provides the IFI reason code

This is an output parameter of type INTEGER.

excess-bytes
Indicates the number of bytes that did not fit in the return area

This is an output parameter of type INTEGER.

group-IFI-reason-code
Provides the reason code for the situation in which an IFI call requests data from members of a data sharing group, and not all the data is returned from group members.

This is an output parameter of type INTEGER.

group-excess-bytes

Indicates the total length of data that was returned from other data sharing group members and did not fit in the return area

This is an output parameter of type INTEGER.

return-code

Provides the return code from the stored procedure. Possible values are:

0

The stored procedure did not encounter an SQL error during processing. Check the *IFI-return-code* value to determine whether the Db2 command issued using the instrumentation facility interface (IFI) was successful or not.

12

The stored procedure encountered an SQL error during processing. The *message* output parameter contains messages describing the SQL error.

This is an output parameter of type INTEGER.

message

Contains messages describing the SQL error encountered by the stored procedure. If no SQL error occurred, then no message is returned.

The first messages in this area are generated by the stored procedure. Messages that are generated by Db2 might follow the first messages.

This is an output parameter of type VARCHAR(1331).

Example

The following C language sample shows how to invoke ADMIN_COMMAND_DB2:

```
#include    <stdio.h>
#include    <stdlib.h>
#include    <string.h>

/******************** DB2 SQL Communication Area ********************/
EXEC SQL INCLUDE SQLCA;

int main( int argc, char *argv[] )    /* Argument count and list    */
{
  /****************** DB2 Host Variables ****************************/
  EXEC SQL BEGIN DECLARE SECTION;

  /* SYSPROC.ADMIN_COMMAND_DB2 parameters                           */
  char        command[32705];         /* DB2 command                */
  short int   ind_command;            /* Indicator variable         */
  long int    lencommand;             /* DB2 command length         */
  short int   ind_lencommand;         /* Indicator variable         */
  char        parsetype[4];           /* Parse type required        */
  short int   ind_parsetype;          /* Indicator variable         */
  char        mbrname[9];             /* DB2 data sharing group     */
                                      /* member name                */
  short int   ind_mbrname;            /* Indicator variable         */
  long int    excommands;             /* Number of commands exec.   */
  short int   ind_excommands;         /* Indicator variable         */
  long int    retifca;                /* IFI return code            */
  short int   ind_retifca;            /* Indicator variable         */
  long int    resifca;                /* IFI reason code            */
  short int   ind_resifca;            /* Indicator variable         */
  long int    xsbytes;                /* Excessive bytes            */
  short int   ind_xsbytes;            /* Indicator variable         */
  long int    gresifca;               /* IFI group reason code      */
  short int   ind_gresifca;           /* Indicator variable         */
  long int    gxsbytes;               /* Group excessive bytes      */
  short int   ind_gxsbytes;           /* Indicator variable         */
  long int    retcd;                  /* Return code                */
  short int   ind_retcd;              /* Indicator variable         */
  char        errmsg[1332];           /* Error message              */
  short int   ind_errmsg;             /* Indicator variable         */

  /* Result Set Locators                                            */
  volatile SQL TYPE IS RESULT_SET_LOCATOR * rs_loc1,
                                            rs_loc2;

  /* First result set row                                           */
  long int    rownum;                 /* Sequence number of the     */
                                      /* table row                  */

```

Output

This stored procedure returns the following output parameters, which are described in "Option descriptions" on page 698:

- *commands-executed*
- *IFI-return-code*
- *IFI-reason-code*
- *excess-bytes*
- *group-IFI-reason-code*
- *group-excess-bytes*
- *return-code*
- *message*

In addition to the preceding output, the stored procedure returns two result sets.

The first result set is returned in the created global temporary table SYSIBM.DB2_CMD_OUTPUT and contains the Db2 command output messages that were not parsed.

The following table shows the format of the first result set:

Table 111. Result set row for first ADMIN_COMMAND_DB2 result set

Column name	Data type	Contents
ROWNUM	INTEGER	Sequence number of the table row, from 1 to *n*
TEXT	CHAR(80)	Db2 command output message line

The format of the second result set varies, depending on the Db2 command issued and the *processing-type* value.

- Result set row for second ADMIN_COMMAND_DB2 result set (*processing-type* = "BP")
- Result set row for second ADMIN_COMMAND_DB2 result set (*processing-type* = "THD")
- Result set row for second ADMIN_COMMAND_DB2 result set (*processing-type* = "UT")
- Result set row for second ADMIN_COMMAND_DB2 result set (*processing-type* = "DB" or "TS" or "IX")
- Result set row for second ADMIN_COMMAND_DB2 result set (*processing-type* = "GRP")
- Result set row for second ADMIN_COMMAND_DB2 result set (*processing-type* = "DDF")

The following table shows the format of the result set returned in the created global temporary table SYSIBM.BUFFERPOOL_STATUS when *processing-type* = "BP":

Table 112. Result set row for second ADMIN_COMMAND_DB2 result set (processing-type = "BP")

Column name	Data type	Contents
ROWNUM	INTEGER	Sequence number of the table row, from 1 to *n*
BPNAME	CHAR(6)	Buffer pool name
VPSIZE	INTEGER	Buffer pool size
VPSEQT	INTEGER	Sequential steal threshold for the buffer pool
VPPSEQT	INTEGER	Parallel sequential threshold for the buffer pool
VPXPSEQT	INTEGER	Assisting parallel sequential threshold for the buffer pool
DWQT	INTEGER	Deferred write threshold for the buffer pool
PCT_VDWQT	INTEGER	Vertical deferred write threshold for the buffer pool (as a percentage of virtual buffer pool size)
ABS_VDWQT	INTEGER	Vertical deferred write threshold for the buffer pool (as absolute number of buffers)
PGSTEAL	CHAR(4)	Page-stealing algorithm that Db2 uses for the buffer pool
ID	INTEGER	Buffer pool internal identifier
USE_COUNT	INTEGER	The number of open table spaces or index spaces that reference this buffer pool
PGFIX	CHAR(3)	Specifies whether the buffer pool should be fixed in real storage when it is used
AUTOSIZE	VARCHAR(3)	Specifies whether automatic buffer pool adjustment is on or off
FRAMESIZE	VARCHAR(4)	The frame size that the buffer pool uses
ALLOC_FRAME4K	INTEGER	The number of buffers that are allocated with a 4K frame size
ALLOC_FRAME1M	INTEGER	The number of buffers that are allocated with a 1M frame size
VPSIZEMIN	INTEGER	The minimum buffer pool size
VPSIZEMAX	INTEGER	The maximum buffer pool size

The following table shows the format of the result set returned in the created global temporary table SYSIBM.DB2_THREAD_STATUS when *processing-type* = "THD":

Table 113. Result set row for second ADMIN_COMMAND_DB2 result set (processing-type = "THD")

Column name	Data type	Contents
ROWNUM	INTEGER	Sequence number of the table row, from 1 to *n*
TYPE	INTEGER	Thread type: **0** Unknown **1** Active **2** Inactive **3** Indoubt **4** Postponed
NAME	CHAR(8)	Connection name used to establish the thread
STATUS	CHAR(11)	Status of the conversation or socket
ACTIVE	CHAR(1)	Indicates whether a thread is active or not. An asterisk means that the thread is active within Db2.
REQ	CHAR(5)	Current number of Db2 requests on the thread
ID	CHAR(12)	Recovery correlation ID associated with the thread
AUTHID	CHAR(8)	Authorization ID associated with the thread
PLAN	CHAR(8)	Plan name associated with the thread
ASID	CHAR(4)	Address space identifier
TOKEN	CHAR(6)	Unique thread identifier
COORDINATOR	CHAR(46)	Name of the two-phase commit coordinator
RESET	CHAR(5)	Indicates whether or not the thread needs to be reset to purge info from the indoubt thread report
URID	CHAR(20)	Unit of recovery identifier
LUWID	CHAR(35)	Logical unit of work ID of the thread
WORKSTATION	VARCHAR(255)	Client workstation name
USERID	VARCHAR(128)	Client user ID

Table 113. Result set row for second ADMIN_COMMAND_DB2 result set (processing-type = "THD") (continued)

Column name	Data type	Contents
APPLICATION	VARCHAR(255)	Client application name
ACCOUNTING	VARCHAR(255)	Client accounting information.
LOCATION	VARCHAR(4050)	Location name of the remote system
DETAIL	VARCHAR(4050)	Additional thread information

The following table shows the format of the result set returned in the created global temporary table SYSIBM.UTILITY_JOB_STATUS when *processing-type* = "UT":

Table 114. Result set row for second ADMIN_COMMAND_DB2 result set (processing-type = "UT")

Column name	Data type	Contents
ROWNUM	INTEGER	Sequence number of the table row, from 1 to *n*
CSECT	CHAR(8)	Name of the command program CSECT that issued the message
USER	CHAR(8)	User ID of the person running the utility
MEMBER	CHAR(8)	Utility job is running on this member
UTILID	CHAR(16)	Utility job identifier
STATEMENT	INTEGER	Utility statement number
UTILITY	CHAR(20)	Utility name
PHASE	CHAR(20)	Utility restart from the beginning of this phase
COUNT	INTEGER	Number of pages or records processed in a utility phase
STATUS	CHAR(18)	Utility status
DETAIL	VARCHAR(4050)	Additional utility information
NUM_OBJ	INTEGER	Total number of objects in the list of objects the utility is processing
LAST_OBJ	INTEGER	Last object that started

The following table shows the format of the result set returned in the created global temporary table SYSIBM.DB_STATUS when *processing-type* = "DB" or "TS" or "IX":

Table 115. Result set row for second ADMIN_COMMAND_DB2 result set (processing-type = "DB" or "TS" or "IX")

Column name	Data type	Contents
ROWNUM	INTEGER	Sequence number of the table row, from 1 to *n*
DBNAME	CHAR(8)	Name of the database

Table 115. Result set row for second ADMIN_COMMAND_DB2 result set (processing-type = "DB" or "TS" or "IX") (continued)

Column name	Data type	Contents
SPACENAM	CHAR(8)	Name of the table space or index
TYPE	CHAR(2)	Status type: **DB** Database **TS** Table space **IX** Index
PART	SMALLINT	Individual partition or range of partition
STATUS	CHAR(18)	Status of the database, table space or index

The following table shows the format of the result set returned in the created global temporary table SYSIBM.DATA_SHARING_GROUP when *processing-type* = "GRP":

Table 116. Result set row for second ADMIN_COMMAND_DB2 result set (processing-type = "GRP")

Column name	Data type	Contents
ROWNUM	INTEGER	Sequence number of the table row, from 1 to *n*
DB2_MEMBER	CHAR(8)	Name of the Db2 group member
ID	INTEGER	ID of the Db2 group member
SUBSYS	CHAR(4)	Subsystem name of the Db2 group member
CMDPREF	CHAR(8)	Command prefix for the Db2 group member
STATUS	CHAR(8)	Status of the Db2 group member
DB2_LVL	CHAR(6)	Db2 version, release and modification level
SYSTEM_NAME	CHAR(8)	Name of the z/OS system where the member is running, or was last running in cases when the member status is QUIESCED or FAILED
IRLM_SUBSYS	CHAR(4)	Name of the IRLM subsystem to which the Db2 member is connected
IRLMPROC	CHAR(8)	Procedure name of the connected IRLM

The following table shows the format of the result set returned in the created global temporary table SYSIBM.DDF_CONFIG when *processing-type* = "DDF":

Table 117. Result set row for second ADMIN_COMMAND_DB2 result set (processing-type = "DDF")

Column name	Data type	Contents
ROWNUM	INTEGER NOT NULL	Sequence number of the table row, from 1 to *n*
STATUS	CHAR(6) NOT NULL	Operational status of DDF
LOCATION	CHAR(18) NOT NULL	Location name of DDF
LUNAME	CHAR(17) NOT NULL	Fully qualified LUNAME of DDF
GENERICLU	CHAR(17) NOT NULL	Fully qualified generic LUNAME of DDF
IPV4ADDR	CHAR(17) NOT NULL	IPV4 address of DDF
IPV6ADDR	CHAR(39)	IPV6 address of DDF
TCPPORT	INTEGER NOT NULL	SQL listener port used by DDF
RESPORT	INTEGER NOT NULL	Resync listener port used by DDF
SQL_DOMAIN	CHAR(45) NOT NULL	Domain name associated with the IP address in IPV4ADDR or IPV6ADDR
RSYNC_DOMAIN	CHAR(45)	Domain name associated with a specific member IP address
SECPORT	INTEGER	Secure SQL listener TCP/IP port number
IPNAME	CHAR(8)	IPNAME used by DDF
ALIASNAME1	CHAR(18)	An alias name value specified in the BSDS DDF record.
ALIASPORT1	INTEGER	TCP/IP port associated with ALIASNAME1
ALIASSECPORT1	INTEGER	Secure TCP/IP port associated with ALIASNAME1
ALIASNAME2	CHAR(18)	An alias name value specified in the BSDS DDF record
ALIASPORT2	INTEGER	TCP/IP port associated with ALIASNAME2

Table 117. Result set row for second ADMIN_COMMAND_DB2 result set (processing-type = "DDF") (continued)

Column name	Data type	Contents
ALIASSECPORT2	INTEGER	Secure TCP/IP port associated with ALIASNAME2
ALIASNAME3	CHAR(18)	An alias name value specified in the BSDS DDF record
ALIASPORT3	INTEGER	TCP/IP port associated with ALIASNAME3
ALIASSECPORT3	INTEGER	Secure TCP/IP port associated with ALIASNAME3
ALIASNAME4	CHAR(18)	An alias name value specified in the BSDS DDF record
ALIASPORT4	INTEGER	TCP/IP port associated with ALIASNAME4
ALIASSECPORT4	INTEGER	Secure TCP/IP port associated with ALIASNAME4
ALIASNAME5	CHAR(18)	An alias name value specified in the BSDS DDF record
ALIASPORT5	INTEGER	TCP/IP port associated with ALIASNAME5
ALIASSECPORT5	INTEGER	Secure TCP/IP port associated with ALIASNAME5
ALIASNAME6	CHAR(18)	An alias name value specified in the BSDS DDF record
ALIASPORT6	INTEGER	TCP/IP port associated with ALIASNAME6
ALIASSECPORT6	INTEGER	Secure TCP/IP port associated with ALIASNAME6
ALIASNAME7	CHAR(18)	An alias name value specified in the BSDS DDF record
ALIASPORT7	INTEGER	TCP/IP port associated with ALIASNAME7
ALIASSECPORT7	INTEGER	Secure TCP/IP port associated with ALIASNAME7
ALIASNAME8	CHAR(18)	An alias name value specified in the BSDS DDF record
ALIASPORT8	INTEGER	TCP/IP port associated with ALIASNAME8
ALIASSECPORT8	INTEGER	Secure TCP/IP port associated with ALIASNAME8
MEMBER_IPV4ADDR	CHAR(17)	IPV4 address associated with the specific member of a data sharing group

Table 117. Result set row for second ADMIN_COMMAND_DB2 result set (processing-type = "DDF") (continued)

Column name	Data type	Contents
MEMBER_IPV6ADDR	CHAR(39)	IPV6 address associated with the specific member of a data sharing group

GUPI

ADMIN_COMMAND_DSN stored procedure

The SYSPROC.ADMIN_COMMAND_DSN stored procedure executes a BIND, REBIND, FREE, or DCLGEN DSN subcommand and returns the output from the DSN subcommand execution.

Environment

GUPI

ADMIN_COMMAND_DSN runs in a WLM-established stored procedures address space. TCB=1 is also required.

Authorization

To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges:

- The EXECUTE privilege on the ADMIN_COMMAND_DSN stored procedure
- Ownership of the stored procedure
- SYSADM authority

To execute the DSN subcommand, you must use a privilege set that includes the authorization to execute the DSN subcommand.

Syntax

The following syntax diagram shows the SQL CALL statement for invoking this stored procedure:

```
►► CALL ── SYSPROC.ADMIN_COMMAND_DSN ── ( ── DSN-subcommand , ── message ── ) ►◄
```

Option descriptions

DSN-subcommand

Specifies the DSN subcommand to be executed. If the DSN subcommand passed to the stored procedure is not BIND, REBIND, FREE, or DCLGEN, an error message is returned. The DSN subcommand is performed using the authorization ID of the user who invoked the stored procedure.

ADMIN_COMMAND_DSN does not support three-part names if a wildcard character is specified in the package name.

This parameter is case sensitive. You must specify *DSN-subcommand* in uppercase characters.

This is an input parameter of type VARCHAR(32704) and cannot be null.

message

Contains messages if an error occurs during stored procedure execution.

The stored procedure might not return a result set if *message* is not blank. Even if *message* is not blank, the stored procedure might return a result set if the error described in *message* occurred after the stored procedure executed at least one DSN subcommand, and the stored procedure can successfully insert the DSN subcommand output message in the result set and open the result set cursor.

A blank *message* does not mean that the DSN subcommand completed successfully. The calling application must read the result set to determine if the DSN subcommand was successful or not.

This is an output parameter of type VARCHAR(1331).

Example

The following C language sample shows how to invoke ADMIN_COMMAND_DSN:

```
 #include    <stdio.h>
 #include    <stdlib.h>
 #include    <string.h>

/******************** DB2 SQL Communication Area ********************/
 EXEC SQL INCLUDE SQLCA;

 int main( int argc, char *argv[] )    /* Argument count and list    */
 {
   /****************** DB2 Host Variables ****************************/
   EXEC SQL BEGIN DECLARE SECTION;

   /* SYSPROC.ADMIN_COMMAND_DSN parameters                          */

   char        subcmd[32705];          /* BIND, REBIND, FREE, or     */
                                       /* DCLGEN DSN subcommand      */
   char        errmsg[1332];           /* Error message              */

   /* Result set locators                                           */
   volatile SQL TYPE IS RESULT_SET_LOCATOR *rs_loc1;

   /* Result set row                                                */
   long int    rownum;                 /* Sequence number of the     */
                                       /* table row                  */
   char        text[256];              /* DSN subcommand output row  */
   EXEC SQL END DECLARE SECTION;

   /******************************************************************/
   /* Set input parameter to execute a REBIND PLAN DSN subcommand    */
   /******************************************************************/
   strcpy(subcmd, "REBIND PLAN (DSNACCOB) FLAG(W)");

   /******************************************************************/
   /* Call stored procedure SYSPROC.ADMIN_COMMAND_DSN                */
   /******************************************************************/
   EXEC SQL CALL SYSPROC.ADMIN_COMMAND_DSN (:subcmd, :errmsg);

   /******************************************************************/
   /* Retrieve result set when the SQLCODE from the call is +446,    */
   /* which indicates that result sets were returned                 */
   /******************************************************************/
   if (SQLCODE == +466)               /* Result sets were returned   */
   {
     /* Establish a link between the result set and its locator      */
     EXEC SQL ASSOCIATE LOCATORS (:rs_loc1)
              WITH PROCEDURE SYSPROC.ADMIN_COMMAND_DSN;

     /* Associate a cursor with the result set                       */
     EXEC SQL ALLOCATE C1 CURSOR FOR RESULT SET :rs_loc1;

     /* Perform fetches using C1 to retrieve all rows from the       */
     /* result set                                                   */
     EXEC SQL FETCH C1 INTO :rownum, :text;
     while(SQLCODE==0)
     {
       EXEC SQL FETCH C1 INTO :rownum, :text;
     }

     EXEC SQL CLOSE C1;
   }
```

```
    return;
  }
```

Output

This stored procedure returns an error message, *message*, if an error occurs.

The stored procedure returns one result set that contains the DSN subcommand output messages.

The following table shows the format of the result set returned in the created global temporary table SYSIBM.DSN_SUBCMD_OUTPUT:

Table 118. Result set row for ADMIN_COMMAND_DSN result set

Column name	Data type	Contents
ROWNUM	INTEGER	Sequence number of the table row, from 1 to *n*
TEXT	VARCHAR(255)	DSN subcommand output message line

About Db2 and related commands (Db2 Commands)

ADMIN_COMMAND_MVS stored procedure

The SYSPROC.ADMIN_COMMAND_MVS stored procedure issues the QUERY COPYPOOL, LIST COPYPOOL, Db2 START, Db2 STOP, DUMP, or DISPLAY WLM command.

Environment

GUPI

The load module for the ADMIN_COMMAND_MVS stored procedure, DSNADMCM, must reside in an APF-authorized library. The ADMIN_COMMAND_MVS stored procedure runs in a WLM-established stored procedures address space, and all of the libraries that are specified in the STEPLIB DD statement must be APF-authorized.

Authorization

To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges:

- The EXECUTE privilege on the stored procedure
- Ownership of the stored procedure
- SYSADM authority

ADMIN_COMMAND_MVS uses an extended MCS console to issue the requested command.

The caller of ADMIN_COMMAND_MVS must have READ access to the MVS.MCSOPER.* or MVS.MCSOPER.*xxxxxxxx* (where *xxxxxxxx* is the name of the extended console) resource profile of the RACF OPERCMDS class. By default, unless overwritten by CONSNAME which is specified in the *subparameters* input parameter of ADMIN_COMMAND_MVS, the name of the extended MCS console is DSNADMCM. If MVS.MCSOPER.*xxxxxxxx* exists, the ADMIN_COMMAND_MVS caller must have READ access to this profile. Otherwise, the caller must have READ access to MVS.MCSOPER.*.

In the OPERPARM segment of the extended MCS console's user profile (defined in a security product, such as RACF), specify the following console attributes:

- STORAGE= 512 or higher
- AUTH= ALL
- UD= NO
- HC= NO
- INTIDS= NO
- UNKNIDS= NO

You must also set the ROUTCODE, LEVEL, and MSCOPE console attributes. The attributes that you specify depend on the type of command:

START DB2, STOP DB2, DISPLAY WLM, LIST COPYPOOL, or QUERY COPYPOOL commands
Specify:

- ROUTCODE=NONE
- LEVEL=NB
- MSCOPE=*

DUMP command
Specify:

- ROUTCODE=ALL
- LEVEL=NB ALL
- MSCOPE=*

STOP DB2 command when Db2 is already stopping
Specify:

- ROUTCODE=ALL
- LEVEL=NB ALL
- MSCOPE=*ALL

Important: Specify ROUTCODE=ALL and MSCOPE=*ALL only when you anticipate that Db2 is already stopping when the STOP DB2 command is issued by ADMIN_COMMAND_MVS, and plan to increase the STORAGE value in these cases.

If the OPERPARM segment of the extended MCS console's user profile is not defined, default values are applied for all console attributes, except for the following attributes:

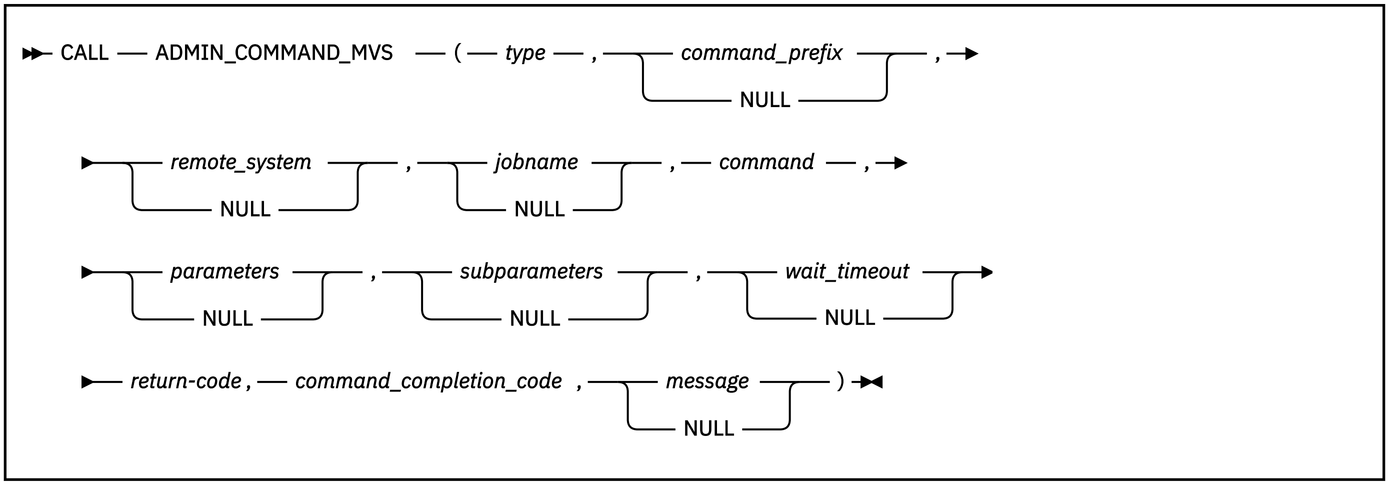
- STORAGE=512
- AUTH=ALL
- LEVEL=NB
- MSCOPE=*

For more information about controlling attributes for users of extended MCS consoles, see Defining console attributes for extended MCS consoles (z/OS MVS Planning: Operations).

The extended MCS console must be authorized to execute the requested command.

Syntax

The following syntax diagram shows the SQL CALL statement for invoking this stored procedure:



Option descriptions

type

Specifies the type of command to be issued.

Valid values are:

- HSM
- DB2
- DUMP
- WLM

This parameter is an input parameter of type VARCHAR(24) and cannot be null.

command_prefix

Specifies the command prefix that identifies which Db2 subsystem to direct the command to.

This parameter is an input parameter of type VARCHAR(8).

You cannot specify null for this parameter if the *type* parameter is set to Db2.

remote_system

Specifies the z/OS system to which the Db2 command is to be routed.

This parameter is an input parameter of type VARCHAR(8).

You cannot specify null for this parameter if both of the following conditions apply:

- Db2 is the *type* parameter
- The Db2 command will be routed to a z/OS system that is different from the system where the stored procedure is executing

jobname

Specifies the name of the batch job or started task to be modified.

This parameter is an input parameter of type VARCHAR(8).

You cannot specify null for this parameter if HSM is the *type* parameter.

command

Specifies the command to be executed.

Valid values depend on the value of the *type* parameter.

- When the *type* parameter is set to Db2, valid values are:
  - START

  - STOP
- When the *type* parameter is set to DUMP, the valid value is DUMP.
- When the *type* parameter is set to HSM, valid values are:
  - QUERY COPYPOOL
  - LIST COPYPOOL
- When the *type* parameter is set to WLM, the valid value is DISPLAY.

This parameter is an input parameter of type VARCHAR(126) and cannot be null.

parameters

Specifies the parameters of the command, or the program parameters that will be passed to the started task.

Valid values depend on the value of the *command* parameter.

This parameter is an input parameter of type VARCHAR(124).

You cannot specify null for this parameter if the *type* parameter is set to HSM, DUMP, or WLM.

subparameters

Specifies the sub-parameters of the command. The following keyword-value pairs are supported:

CONSNAME=*console-name*

The name of the console that the stored procedure activates. If not specified, the default is DSNADMCM. The specified console must not already be active.

IRLMPROC=*procedure-name*

The procedure name of the connected IRLM. The stored procedure performs the following actions if IRLMPPROC is specified:

- If Db2 is already stopping when the stored procedure issues the STOP DB2 command, it starts monitoring IRLM termination after the DSN9022I message is received.
- If Db2 is not stopped or is not already stopping when the stored procedure issues the STOP DB2 command, it starts monitoring IRLM termination after message DSN3100I is received.

Monitoring occurs within the specified *wait-timeout period* and ends when the IRLM address space terminates or the wait timeout period expires. The stored procedure reports Db2 normal termination only after it determines that IRLM address space is terminated.

The IRLM procedure name is 1 - 8 characters. The first character must be a letter A - Z, #, $, or @; the remaining characters can be A through Z, 0 - 9, or #, $, or @.

This keyword-value pair can only be specified when the *type* parameter is Db2, the *command* parameter is STOP, and the SSNM keyword is not specified.

SSNM=*subsystem-name*

The Db2 subsystem name. The stored procedure performs the following actions:

- If Db2 is already stopping when the stored procedure issues the STOP DB2 command, it starts monitoring *ssnm*MSTR termination after the DSN9022I message is received.
- If Db2 is not stopped or is not already stopping when the stored procedure issues the STOP DB2 command, the keyword is ignored and no monitoring of *ssnm*MSTR termination occurs.

Monitoring occurs within the specified *wait-timeout period* and ends when the system services address space (*ssnm*MSTR) terminates or the wait timeout period expires. The stored procedure reports Db2 normal termination only after it determines that the *ssnm*MSTR address space is terminated.

The subsystem name is 1 - 4 characters. The first character must be a letter A - Z, #, $, or @; the remaining characters can be A through Z, 0 - 9, or #, $, or @.

This keyword-value pair can be specified only when the the *type* parameter is Db2, the *command* parameter is STOP, and the IRLMPROC keyword is not specified.

LIST_CP_KEYWORDS=DUMPVOLS

This keyword-value pair can be specified only when the *type* parameter is HSM and the *command* parameter is LIST COPYPOOL.

QUERY_CP_BACKUP=*number-of-versions*

The number of copy pool backup versions. This key-value pair can be specified only when the *command* parameter is set to QUERY COPYPOOL.

Alternatively, if no key-value pairs specified for *subparameters*, the following values are supported:

- DUMPVOLS, when the *command* parameter is LIST COPYPOOL.
- The number of copy pool backup versions, when *command* parameter is QUERY COPYPOOL.

This parameter is an input parameter of type VARCHAR(124).

You cannot specify null for this parameter if both of the following conditions apply:

- The *type* parameter is set to HSM
- The *command* parameter is set to QUERY COPYPOOL

wait_timeout

Specifies the amount of time (in seconds) that this procedure waits for the command to complete and for the message to be routed to the console. If the console is already active, the wait time includes the time that the procedure waits for the console to become available. If stopping Db2 and the IRLM or *ssnm*MSTR address space termination is being monitored, the wait time includes the time the procedure monitors the status of these address spaces.

For Db2 START and Db2 STOP, valid values are 1-900, and the default wait time is 180 seconds. Otherwise, valid values are 1-120, and the default wait time is 5 seconds.

This parameter is an input parameter of type INTEGER.

return_code

Provides the return code from the stored procedure.

Possible values are:

0

The stored procedure did not encounter any errors during processing. However, this return code does not indicate that the command executed successfully. The *command_completion_code* output parameter indicates whether the command executed successfully or not.

4

The stored procedure issued the command but was unable to determine the command execution status based on the command messages that were retrieved within the prescribed wait time. For example, the wait time might have expired.

When *return_code* is 4, the *command_completion_code* parameter is set to 8 or 16.

All command messages that were retrieved within the prescribed wait time are returned in the result set.

8

The stored procedure issued the command but was unable to determine the command execution status because it was unable to retrieve all the command messages that were queued to the extended MCS console. When *return_code* is 8, the *command_completion_code* parameter is set to 8 or 16. All the command messages that were retrieved so far are returned in the result set. For STOP DB2, the latest IRLM address space (*irlmproc*) or system services address space (*ssnm*MSTR) status information (from the 'D A' output) is also returned in the result set if IRLM address space (*irlmproc*)or system services address space (*ssnm*MSTR) termination monitoring was performed successfully. For STOP DB2, the latest IRLM address space (*irlmproc*) or Db2 system services address space (*ssnm*MSTR) status information (from the 'D A' output) is also returned in the result set if IRLM or MSTR termination monitoring was performed successfully.

12
The stored procedure encountered an error during processing. The *message* output parameter contains messages that describe the error.

This parameter is an output parameter of type INTEGER.

command_completion_code

Indicates the completion status of the command.

Possible values are:

0

One of the following conditions applies:

- The command completed successfully.
- If the *command* parameter is QUERY COPYPOOL, there is no FlashCopy® process that is active in the background.

For details about *command_completion_code* 0, see Table 119 on page 717.

4

One of the following conditions applies:

- The command was not processed. For example, Db2 was already stopped when STOP DB2 was requested.
- If the *command* parameter is QUERY COPYPOOL, one or more FlashCopy processes are active in the background.

For details about *command_completion_code* 4, see Table 120 on page 718.

8
The command started but the completion status is unknown. For details about *command_completion_code* 8, see Table 121 on page 719.

12
The command completed abnormally. For details about *command_completion_code* 12, see Table 122 on page 721.

16
The command output does not satisfy the conditions that are listed for *command_completion_code* 0, 4, 8, or 12.

This parameter is an output parameter of type INTEGER.

The following tables describe the messages that ADMIN_COMMAND_MVS looks for when assigning a specific value to *command_completion_code*.

Table 119. Description of command_completion_code 0

Command	Command completion code description	Messages received
DISPLAY WLM	DISPLAY WLM completed successfully.	Message IWM029I was received.
DUMP	DUMP completed successfully.	Both of the following messages were received: • IEA794I • IEA911E or IEA611I

Table 119. Description of command_completion_code 0 (continued)

Command	Command completion code description	Messages received
LIST COPYPOOL	The list of copy pools that was output by LIST COPYPOOL is complete.	Both of the following messages were received: • COPYPOOL=*xx...xx*, where *xx...xx* is the name of the copy pool that is specified in the *parameters* input parameter • ARC0140I
QUERY COPYPOOL	No FlashCopy processes are active in the background.	Message ARC1821I was received. The number of copy pool backup versions (as specified in the *subparameters* input parameter) and the number of copy pool versions that are not in active FlashCopy relationships is the same. Message ARC1820I was not received.
START DB2	START DB2 completed successfully.	Message DSN9022I *cmd_prefix* was received, which indicates that Db2 START completed normally.
STOP DB2	STOP DB2 completed successfully.	• DSN3100I *cmd_prefix* • Message '*irlm_procname* NOT FOUND' was found in the 'D A, *irlm_procname*' command output when the stored procedure checked the IRLM address space status.

Table 120. Description of command_completion_code 4

Command	Command completion code description	Messages received
QUERY COPYPOOL	One or more FlashCopy processes are active in the background.	One or more ARC1820I messages and zero or more ARC1821I messages were received. The number of copy pool backup versions (as specified in the *subparameters* input parameter) and the number of copy pool versions that are in active and not in active FlashCopy relationships is the same.
START DB2	Db2 is already active when the command was issued.	Message DSNY003I *cmd_prefix* was received.
STOP DB2	One of the following scenarios applies: • Db2 was already stopped when the command was issued. • Db2 was in the process of stopping when the command was issued, and it stopped successfully.	Db2 was already stopped: • DSN3106I *cmd_prefix* Db2 was in the process of stopping: • DSNY004I *cmd_prefix*and DSN9022I *cmd_prefix*, where DSN9022I *cmd_prefix* indicates that Db2 STOP completed normally, and either message '*ssnm*MSTR NOT FOUND' was found in the 'D A, *ssnm*MSTR' command output when the stored procedure checked the *ssnm*MSTR address space status, or message '*irlm_procname* NOT FOUND' was found in the 'D A, *irlm_procname*' command output when the stored procedure checked the IRLM address space status.

Table 121. Description of command_completion_code 8

Command	Command completion code description	Messages received	Expected completion messages not received
DUMP	The dump was captured but not written.	Message IEA794I was received.	One of the following messages was not received: • IEA911E • IEA611I
LIST COPYPOOL	The listing from LIST COPYPOOL is truncated.	Message COPYPOOL=*xx...xxx* was received, where *xx...xx* is the name of the copy pool that is specified in the *parameters* input parameter.	Message ARC0140I was not received.
QUERY COPYPOOL	One or more FlashCopy processes are active or not active in the background.	One or more ARC1820I or ARC1821I messages was received.	The total number of ARC1820I and ARC1821I messages is not equal to the total number of copy pool backup versions that is specified in the *subparameters* input parameter.
START DB2	Db2 is in the process of starting, but the completion status of START DB2 is unknown.	Message DSNY024I *cmd_prefix* was received.	One of the following messages was not received: • DSN9023I *cmd_prefix* • DSNV086E *cmd_prefix* • DSN3104I *cmd_prefix* • DSN9022I *cmd_prefix*, which indicates that Db2 START completed normally • DSN3100I *cmd_prefix*

Table 121. Description of command_completion_code 8 (continued)

Command	Command completion code description	Messages received	Expected completion messages not received
STOP DB2	Db2 is in the process of stopping, but the completion status of STOP DB2 is unknown.	One of the following messages was received: • DSNY002I *cmd_prefix* • DSNY004I *cmd_prefix*	DSNY002I *cmd_prefix* received: • None of the following messages were received: – DSN3100I *cmd_prefix* – DSN3107I *cmd_prefix* – DSN9023I *cmd_prefix* – Or, message DSN3100I *cmd_prefix* was received but message '*irlm_procname* NOT FOUND' was not found in the 'D A, *irlm_procname*' command output when the stored procedure checked the IRLM address soace status. DSNY004I *cmd_prefix* received: • None of the following messages were received: – DSN9022I *cmd_prefix*, which indicates that Db2 STOP completed normally – DSN9023I *cmd_prefix* • Or, message DSN9022I *cmd_prefix* was received but either message '*irlm_procname* NOT FOUND' was not found in the 'D A, *irlm_procname*' command output when the stored procedure checked the IRLM address space status, or message '*ssnm*MSTR NOT FOUND' was not found in the 'D A, *ssnm*MSTR' command output when the stored procedure checked the *ssnm*MSTR address space status.

Table 122. Description of command_completion_code 12

Command	Command completion code description	Messages received
DISPLAY WLM	DISPLAY WLM completed abnormally.	One of the following messages was received: • IWM002I • IWM003I • IWM030I
LIST COPYPOOL	No output was generated from LIST COPYPOOL.	Message ARC0140I was received, but message COPYPOOL=*xx...xxx* was not received, where *xx...xxx* is the name of the copy pool that is specified in the *parameters* input parameter.
START DB2	START DB2 completed abnormally.	One of the following messages was received: • DSN9023I *cmd_prefix* • DSNV086E *cmd_prefix* • DSN3106I *cmd_prefix* • DSN3107I *cmd_prefix* • DSN3104I *cmd_prefix* • DSN3100I *cmd_prefix*
STOP DB2	STOP DB2 completed abnormally.	One of the following messages was received: • DSN3107I *cmd_prefix* • DSN9023I *cmd_prefix*

message

Contains messages that describe the error that was encountered by the stored procedure.

This parameter is an output parameter of type VARCHAR(1331).

Example

The following C language example shows how to invoke ADMIN_COMMAND_MVS.

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>
 /******************* DB2 SQL Communication Area *********************/
EXEC SQL INCLUDE SQLCA;
int main( int argc, char *argv[] )    /* Argument count and list    */
{
 /****************** DB2 Host Variables ****************************/
 EXEC SQL BEGIN DECLARE SECTION;
 /* SYSPROC.ADMIN_COMMAND_MVS parameters                           */
 EXEC SQL BEGIN DECLARE SECTION;
 /* SYSPROC.ADMIN_COMMAND_MVS parameters                           */
 char       ptype[25];           /* Command type                   */
 char       pcprefix[9];         /* DB2 subsystem command prefix   */
 char       prmtsys[9];          /* Remote system                  */
 char       pjobnm[9];           /* Started task job name          */
 char       pcmd[127];           /* Command to be executed         */

             :pparms:ind_pparms,
             :psubparms:ind_psubparms,
             :pwait:ind_pwait,
             :prc:ind_prc,
             :pccc:ind_pccc,
             :pmsg:ind_pmsg);
 /******************************************************************/
 /* Retrieve result set when the SQLCODE from the call is +446,    */
 /* which indicates that result sets were returned                 */
  /******************************************************************/
 if (SQLCODE == +466)               /* Result sets were returned   */
 {
 /* Establish a link between the result set and its locator      */
 EXEC SQL ASSOCIATE LOCATORS (:rs_loc1)
         WITH PROCEDURE SYSPROC.ADMIN_COMMAND_MVS;
 /* Associate a cursor with the result set                       */
 EXEC SQL ALLOCATE C1 CURSOR FOR RESULT SET :rs_loc1;
 /* Perform fetches using C1 to retrieve all rows from the       */
 /* result set                                                   */
 EXEC SQL FETCH C1 INTO :rownum, :text;
  while(SQLCODE==0)
  {
   EXEC SQL FETCH C1 INTO :rownum, :text;
  }
 }
 return;
}
```

Output

This stored procedure returns the following output parameters, which are described in "Option descriptions" on page 714:

- *return-code*

- *command_completion_code*
- *message*

In addition to the preceding output, the stored procedure returns one result set that contains the command messages. For STOP DB2, the latest IRLM or Db2 *ssnm*MSTR address space status information (from the 'D A' output) is also returned in the result set if IRLM or MSTR termination monitoring was performed successfully.

For Db2 START, Db2 STOP, and DUMP commands, both solicited messages (which are command responses) and unsolicited messages (which are other system messages) are retrieved and returned. Otherwise, only solicited messages are returned.

The following table shows the format of the result set that is returned in the created global temporary table SYSIBM.MVS_CMD_OUTPUT:

Table 123. Result set row for ADMIN_COMMAND_MVS result set

Column name	Data type	Contents
ROWNUM	INTEGER NOT NULL	Sequence number of the table row (1...*n*)
TEXT	VARCHAR(2000) NOT NULL	A command message line

GUPI

ADMIN_COMMAND_UNIX stored procedure

The SYSPROC.ADMIN_COMMAND_UNIX stored procedure executes a z/OS UNIX System Services command and returns the output.

Environment

GUPI

ADMIN_COMMAND_UNIX runs in a WLM-established stored procedure address space.

The load module for ADMIN_COMMAND_UNIX, DSNADMCU, must be program controlled if the BPX.DAEMON.HFSCTL FACILITY class profile has not been set up. For information on how to define DSNADMCU to program control, see installation job DSNTIJRA.

Authorization

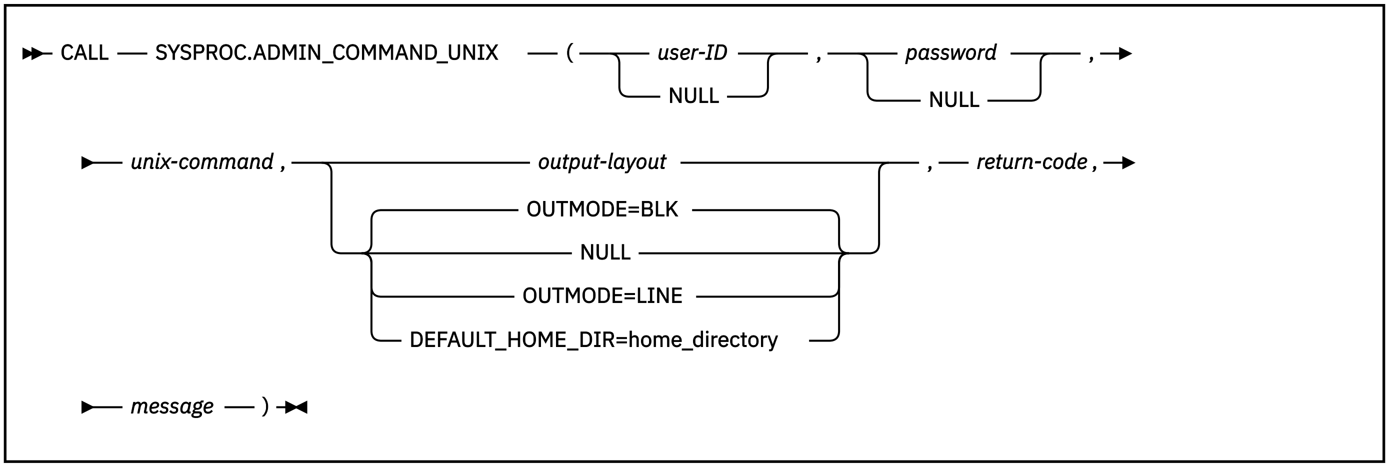
To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges on each package that the stored procedure uses:

- The EXECUTE privilege on the package for DSNADMCU
- Ownership of the package
- PACKADM authority for the package collection
- SYSADM authority

The user specified in the *user-ID* input parameter of the SQL CALL statement must have the appropriate authority to execute the z/OS UNIX System Services command.

Syntax

The following syntax diagram shows the SQL CALL statement for invoking this stored procedure:



Option descriptions

user-ID

Specifies the user ID under which the z/OS UNIX System Services command is issued.

If *user-ID* is NULL, *password* must also be NULL. If the *user-ID* and *password* values are NULL, the login process uses the primary authorization ID of the process.

You can specify NULL for this parameter in the following circumstances:

- The authorization ID that is associated with the stored procedure address space has daemon authority.
- The authorization ID that is associated with the stored procedure address space does not have daemon authority but is authorized to the BPX.SRV.*userid* SURROGAT class profile, where *userid* is the authorization ID of the stored procedure. For more information about how the RACF security administrator can authorize the authorization ID that is associated with the stored procedure address space to a SURROGAT class profile, see Defining servers to process users without passwords or password phrases.

  Daemon authority is given to any superuser that is permitted to the BPX.DAEMON FACILITY class profile. If the BPX.DAEMON FACILITY class profile is not defined, all superusers have daemon authority.

This is an input parameter of type VARCHAR(128).

password

Specifies the password associated with the input parameter *user-ID*.

The value of *password* is passed to the stored procedure as part of payload, and is not encrypted. It is not stored in dynamic cache when parameter markers are used.

If *password* is NULL, *user-ID* must also be NULL. If the *user-ID* and *password* values are NULL, the login process uses the primary authorization ID of the process.

You can specify NULL for this parameter in the following circumstances:

- The authorization ID that is associated with the stored procedure address space has daemon authority.
- The authorization ID that is associated with the stored procedure address space does not have daemon authority but is authorized to the BPX.SRV.*userid* SURROGAT class profile, where *userid* is the authorization ID of the stored procedure.

This is an input parameter of type VARCHAR(100).

unix-command

Specifies the z/OS UNIX System Services command to be executed.

This is an input parameter of type VARCHAR(32704) and cannot be null.

output-layout

Specifies how the output from the z/OS UNIX System Services command is returned and the default home directory of the specified *user-ID*.

The output from the z/OS UNIX System Services command is a multi-line message. Possible values are:

OUTMODE=LINE

Each line is returned as a row in the result set.

OUTMODE=BLK

The lines are blocked into 32677 blocks and each block is returned as a row in the result set.

You specify the default home directory for *user-ID* as follows:

DEFAULT_HOME_DIR=home_directory

If the home directory of the specified *user-ID* does not exist, or *user-ID* does not have a home directory, the SYSPROC.ADMIN_COMMAND_UNIX stored procedure runs the command under the default home directory that you specify.

The maximum length of home_directory is 1007.

If you need to specify both OUTMODE and DEFAULT_HOME_DIR, consider the following examples:

```
OUTMODE=LINE,DEFAULT_HOME_DIR=/tmp
```

```
DEFAULT_HOME_DIR=/tmp,OUTMODE=LINE
```

If a null or empty string is provided, the default option OUTMODE=BLK is used.

This is an input parameter of type VARCHAR(1024).

return-code

Provides the return code from the stored procedure. Possible values are:

0

The call completed successfully.

4

The stored procedure used the default home directory.

12

The call did not complete successfully. The *message* output parameter contains messages describing the error.

This is an output parameter of type INTEGER.

message

Contains messages describing the error encountered by the stored procedure. If no error occurred, then no message is returned.

The first messages in this area are generated by the stored procedure. Messages that are generated by Db2 might follow the first messages.

This is an output parameter of type VARCHAR(1331).

Example

The following C language sample shows how to invoke ADMIN_COMMAND_UNIX:

```
#include    <stdio.h>
#include    <stdlib.h>
#include    <string.h>

 /******************** DB2 SQL Communication Area ********************/
 EXEC SQL INCLUDE SQLCA;

 int main( int argc, char *argv[] )    /* Argument count and list    */
 {
   /****************** DB2 Host Variables ****************************/
   EXEC SQL BEGIN DECLARE SECTION;

   /* SYSPROC.ADMIN_COMMAND_UNIX parameters                          */
   char        userid[129];            /* User ID                    */
   short int   ind_userid;             /* Indicator variable         */
   char        password[101];           /* Password                   */
   short int   ind_password;           /* Indicator variable         */
   char        command[32705];         /* USS command                */
   short int   ind_command;            /* Indicator variable         */
   char        layout[1025];           /* Command output layout      */
   short int   ind_layout;             /* Indicator variable         */
   long int    retcd;                  /* Return code                */
   short int   ind_retcd;              /* Indicator variable         */
   char        errmsg[1332];           /* Error message              */
   short int   ind_errmsg;             /* Indicator variable         */

   /* Result set locators                                            */
   volatile SQL TYPE IS RESULT_SET_LOCATOR *rs_loc1;

   /* Result set row                                                 */
   long int    rownum;                 /* Sequence number of the     */
                                       /* table row                  */
   char        text[32678];            /* A row in USS command output*/
   EXEC SQL END DECLARE SECTION;

   /******************************************************************/
   /* Assign values to input parameters to execute a USS command     */
   /* Set the indicator variables to 0 for non-null input parameters */
   /* Set the indicator variables to -1 for null input parameters    */
   /******************************************************************/
   strcpy(userid, "USRT001");
   ind_userid = 0;
   strcpy(password, "N1CETEST");
   ind_password = 0;
   strcpy(command, "ls");
   ind_command = 0;
   ind_layout = -1;

   /******************************************************************/
   /* Call stored procedure SYSPROC.ADMIN_COMMAND_UNIX               */
   /******************************************************************/
   EXEC SQL CALL SYSPROC.ADMIN_COMMAND_UNIX
                        (:userid    :ind_userid,
                         :password  :ind_password,
                         :command   :ind_command,
                         :layout    :ind_layout,
                         :retcd     :ind_retcd,
                         :errmsg    :ind_errmsg);

   /******************************************************************/
   /* Retrieve result set when the SQLCODE from the call is +446,    */
   /* which indicates that result sets were returned                 */
   /******************************************************************/
   if (SQLCODE == +466)               /* Result sets were returned   */
   {
     /* Establish a link between the result set and its locator      */
     EXEC SQL ASSOCIATE LOCATORS (:rs_loc1)
              WITH PROCEDURE SYSPROC.ADMIN_COMMAND_UNIX;

     /* Associate a cursor with the result set                       */
     EXEC SQL ALLOCATE C1 CURSOR FOR RESULT SET :rs_loc1;

     /* Perform fetches using C1 to retrieve all rows from the       */
     /* result set                                                   */
     EXEC SQL FETCH C1 INTO :rownum, :text;
     while(SQLCODE==0)
     {
       EXEC SQL FETCH C1 INTO :rownum, :text;
     }

     EXEC SQL CLOSE C1;
   }

   return(retcd);
 }
```

Output

This stored procedure returns the following output parameters, which are described in "Option descriptions" on page 724:

- *return-code*
- *message*

In addition to the preceding output, the stored procedure returns one result set that contains the z/OS UNIX System Services command output messages.

The following table shows the format of the result set returned in the created global temporary table SYSIBM.USS_CMD_OUTPUT:

Table 124. Result set row for ADMIN_COMMAND_UNIX result set

Column name	Data type	Contents
ROWNUM	INTEGER	Sequence number of the table row, from 1 to *n*
TEXT	VARCHAR(32677)	A block of text or a line from the output messages of a z/OS UNIX System Services command

GUPI

ADMIN_DS_BROWSE stored procedure

The SYSPROC.ADMIN_DS_BROWSE stored procedure returns either text or binary records from certain data sets or their members. You can browse a physical sequential (PS) data set, a generation data set, a partitioned data set (PDS) member, or a partitioned data set extended (PDSE) member. This stored procedure supports only data sets with LRECL=80 and RECFM=FB.

Environment

GUPI

The load module for ADMIN_DS_BROWSE, DSNADMDB, must reside in an APF-authorized library. ADMIN_DS_BROWSE runs in a WLM-established stored procedures address space, and all libraries in this WLM procedure STEPLIB DD concatenation must be APF-authorized.

Authorization

To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges on each package that the stored procedure uses:

- The EXECUTE privilege on the package for DSNADMDB
- Ownership of the package
- PACKADM authority for the package collection
- SYSADM authority

The ADMIN_DS_BROWSE caller also needs authorization from an external security system, such as RACF, in order to browse or view an z/OS data set resource.

Syntax

The following syntax diagram shows the SQL CALL statement for invoking this stored procedure:

```
▶▶─ CALL ── SYSPROC.ADMIN_DS_BROWSE ── ( ── data-type , ── data-set-name , ── member-name , ─▶

▶── dump-option , ── return-code , ── message ── ) ─▶◀
```

Option descriptions

data-type

Specifies the type of data to be browsed and how the data set will be allocated. Possible values are:

1
Text data with exclusive access

2
Binary data with exclusive access

3
Text data with shared access. This value is valid only if browsing a library member.

4
Binary data with shared access. This value is valid only if browsing a library member.

This is an input parameter of type INTEGER and cannot be null.

data-set-name

Specifies the name of the data set, or of the library that contains the member to be browsed. Possible values are:

PS data set name
If reading from a PS data set, the *data-set-name* contains the name of the PS data set.

PDS or PDSE name
If reading from a member that belongs to this PDS or PDSE, the *data-set-name* contains the name of the PDS or PDSE.

GDS name
If reading from a generation data set, the *data-set-name* contains the name of the generation data set, such as USERGDG.FILE.G0001V00.

This is an input parameter of type CHAR(44) and cannot be null.

member-name

Specifies the name of the PDS or PDSE member, if reading from a PDS or PDSE member. Otherwise, a blank character.

This is an input parameter of type CHAR(8) and cannot be null.

dump-option

Specifies whether to use the Db2 standard dump facility to dump the information necessary for problem diagnosis when an SQL error occurred or when a call to the IBM routine IEFDB476 to get messages about an unsuccessful SVC 99 call failed.

Possible values are:

Y
Generate a dump.

N
Do not generate a dump.

This is an input parameter of type CHAR(1) and cannot be null.

return-code

Provides the return code from the stored procedure. Possible values are:

0
The call completed successfully.

12

The call did not complete successfully. The *message* output parameter contains messages describing the error.

This is an output parameter of type INTEGER.

message

Contains messages describing the error encountered by the stored procedure. If no error occurred, then no message is returned.

The first messages in this area are generated by the stored procedure. Messages that are generated by Db2 or by z/OS might follow the first messages.

This is an output parameter of type VARCHAR(1331).

Example

The following C language sample shows how to invoke ADMIN_DS_BROWSE:

```
#include    <stdio.h>
#include    <stdlib.h>
#include    <string>

/******************** DB2 SQL Communication Area ********************/
 EXEC SQL INCLUDE SQLCA;

 int main( int argc, char *argv[] )    /* Argument count and list    */
 {
   /****************** DB2 Host Variables ****************************/
   EXEC SQL BEGIN DECLARE SECTION;

   /* SYSPROC.ADMIN_DS_BROWSE parameters                             */
   long int    datatype;               /* Data type                  */
   char        dsname[45];             /* Data set name              */
   char        mbrname[9];             /* Library member name        */
   char        dumpopt[2];             /* Dump option                */
   long int    retcd;                  /* Return code                */
   char        errmsg[1332];           /* Error message              */

   /* Result set locators                                            */
   volatile SQL TYPE IS RESULT_SET_LOCATOR *rs_loc1;

   /* Result set row                                                 */
   long int    rownum;                 /* Sequence number of the     */
                                       /*   table row                */
   char        text_rec[81];           /* A data set record          */
   EXEC SQL END DECLARE SECTION;

   /******************************************************************/
   /* Assign values to input parameters to browse a library member   */
   /******************************************************************/
   datatype = 1;
   strcpy(dsname, "USER.DATASET.PDS");
   strcpy(mbrname, "MEMBER0A");
   strcpy(dumpopt, "N");

   /******************************************************************/
   /* Call stored procedure SYSPROC.ADMIN_DS_BROWSE                  */
   /******************************************************************/
   EXEC SQL CALL SYSPROC.ADMIN_DS_BROWSE
                        (:datatype, :dsname, :mbrname, :dumpopt,
                         :retcd,    :errmsg);

   /******************************************************************/
   /* Retrieve result set when the SQLCODE from the call is +446,    */
   /* which indicates that result sets were returned                 */
   /******************************************************************/
   if (SQLCODE == +466)               /* Result sets were returned   */
   {
     /* Establish a link between the result set and its locator      */
     EXEC SQL ASSOCIATE LOCATORS (:rs_loc1)
              WITH PROCEDURE SYSPROC.ADMIN_DS_BROWSE;

     /* Associate a cursor with the result set                       */
     EXEC SQL ALLOCATE C1 CURSOR FOR RESULT SET :rs_loc1;

     /* Perform fetches using C1 to retrieve all rows from the      */
```

```
      /* result set                                                   */
      EXEC SQL FETCH C1 INTO :rownum, :text_rec;
      while(SQLCODE==0)
      {
        EXEC SQL FETCH C1 INTO :rownum, :text_rec;
      }

      EXEC SQL CLOSE C1;
    }

    return(retcd);
  }
```

Output

This stored procedure returns the following output parameters, which are described in "Option descriptions" on page 728:

- *return-code*
- *message*

In addition to the preceding output, the stored procedure returns one result set that contains the text or binary records read.

The following table shows the format of the result set returned in the created global temporary table SYSIBM.TEXT_REC_OUTPUT containing text records read:

Table 125. Result set row for ADMIN_DS_BROWSE result set (text records)

Column name	**Data type**	**Contents**
ROWNUM	INTEGER	Sequence number of the table row, from 1 to *n*.
TEXT_REC	VARCHAR(80)	Record read (text format).

The following table shows the format of the result set returned in the created global temporary table SYSIBM.BIN_REC_OUTPUT containing binary records read:

Table 126. Result set row for ADMIN_DS_BROWSE result set (binary records)

Column name	**Data type**	**Contents**
ROWNUM	INTEGER	Sequence number of the table row, from 1 to *n*.
BINARY_REC	VARCHAR(80) FOR BIT DATA	Record read (binary format).

GUPI

ADMIN_DS_DELETE stored procedure

The SYSPROC.ADMIN_DS_DELETE stored procedure deletes certain data sets or their members. You can delete a physical sequential (PS) data set, a partitioned data set (PDS), a partitioned data set extended (PDSE), a generation data set (GDS), or a member of a PDS or PDSE.

Environment

GUPI

The load module for ADMIN_DS_DELETE, DSNADMDD, must reside in an APF-authorized library. ADMIN_DS_DELETE runs in a WLM-established stored procedures address space, and all libraries in this WLM procedure STEPLIB DD concatenation must be APF-authorized.

Authorization

To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges:

- The EXECUTE privilege on the ADMIN_DS_DELETE stored procedure
- Ownership of the stored procedure
- SYSADM authority

The ADMIN_DS_DELETE caller also needs authorization from an external security system, such as RACF, in order to delete an z/OS data set resource.

Syntax

The following syntax diagram shows the SQL CALL statement for invoking this stored procedure:

```
►► CALL ── SYSPROC.ADMIN_DS_DELETE ── ( ── data-set-type , ── data-set-name , ─►

►── parent-data-set-name , ── dump-option , ── return-code , ── message ── ) ─►◄
```

Option descriptions

data-set-type
Specifies the type of data set to delete. Possible values are:

1
Partitioned data set (PDS)

2
Partitioned data set extended (PDSE)

3
Member of a PDS or PDSE

4
Physical sequential data set (PS)

6
Generation data set (GDS)

This is an input parameter of type INTEGER and cannot be null.

data-set-name
Specifies the name of the data set, library member, or GDS absolute generation number to be deleted. Possible values are:

PS, PDS, or PDSE name
If *data-set-type* is 1, 2, or 4, the *data-set-name* contains the name of the PS, PDS, or PDSE to be deleted.

PDS or PDSE member name
If *data-set-type* is 3, the *data-set-name* contains the name of the PDS or PDSE member to be deleted.

absolute generation number
If *data-set-type* is 6, the *data-set-name* contains the absolute generation number of the GDS to be deleted, such as G0001V00.

This is an input parameter of type CHAR(44) and cannot be null.

parent-data-set-name
Specifies the name of the library that contains the member to be deleted, or of the GDG that contains the GDS to be delete. Otherwise blank. Possible values are:

blank
If *data-set-type* is 1, 2, or 4, the *parent-data-set-name* is left blank.

PDS or PDSE name
If *data-set-type* is 3, the *parent-data-set-name* contains the name of the PDS or PDSE whose member is to be deleted.

GDG name
If *data-set-type* is 6, the *parent-data-set-name* contains the name of the GDG that the GDS to be deleted belongs to.

This is an input parameter of type CHAR(44) and cannot be null.

dump-option
Specifies whether to use the Db2 standard dump facility to dump the information necessary for problem diagnosis when a call to the IBM routine IEFDB476 to get messages about an unsuccessful SVC 99 call failed.

Possible values are:

Y
Generate a dump.

N
Do not generate a dump.

This is an input parameter of type CHAR(1) and cannot be null.

return-code
Provides the return code from the stored procedure. Possible values are:

0
Data set, PDS member, PDSE member, or GDS was deleted successfully.

12
The call did not complete successfully. The *message* output parameter contains messages describing the error.

This is an output parameter of type INTEGER.

message
Contains messages describing the error encountered by the stored procedure. If no error occurred, then no message is returned.

The first messages in this area are generated by the stored procedure. Messages that are generated by z/OS might follow the first messages.

This is an output parameter of type VARCHAR(1331).

Example

The following C language sample shows how to invoke ADMIN_DS_DELETE:

```
#include    <stdio.h>
#include    <stdlib.h>
#include         <string.h>

/******************** DB2 SQL Communication Area ********************/
 EXEC SQL INCLUDE SQLCA;

 int main( int argc, char *argv[] )    /* Argument count and list    */
 {
   /****************** DB2 Host Variables ****************************/
   EXEC SQL BEGIN DECLARE SECTION;

   /* SYSPROC.ADMIN_DS_DELETE parameters                             */
   long int    dstype;                 /* Data set type              */
   char        dsname[45];             /* Data set name ,            */
                                       /* member name, or            */
                                       /* generation # (G0001V00)    */
   char        parentds[45];           /* PDS, PDSE, GDG or blank    */
   char        dumpopt[2];             /* Dump option                */
```

```
    long int    retcd;                  /* Return code                 */
    char        errmsg[1332];           /* Error message               */
    EXEC SQL END DECLARE SECTION;

    /******************************************************************/
    /* Assign values to input parameters to delete a data set         */
    /******************************************************************/
    dstype = 4;
    strcpy(dsname, "USER.DATASET.PDS");
    strcpy(parentds, " ");
    strcpy(dumpopt, "N");

    /******************************************************************/
    /* Call stored procedure SYSPROC.ADMIN_DS_DELETE                  */
    /******************************************************************/
    EXEC SQL CALL SYSPROC.ADMIN_DS_DELETE
                         (:dstype, :dsname, :parentds, :dumpopt,
                          :retcd,  :errmsg);

    return(retcd);
  }
```

Output

This stored procedure returns the following output parameters, which are described in "Option descriptions" on page 731:

- *return-code*
- *message*

GUPI

ADMIN_DS_LIST stored procedure

The SYSPROC.ADMIN_DS_LIST stored procedure returns a list of data set names, a generation data group (GDG), a partitioned data set (PDS) member, a partitioned data set extended (PDSE) member, or generation data sets of a GDG.

Environment

GUPI

The load module for ADMIN_DS_LIST, DSNADMDL, must reside in an APF-authorized library. ADMIN_DS_LIST runs in a WLM-established stored procedures address space, and all libraries in this WLM procedure STEPLIB DD concatenation must be APF-authorized.

Authorization

To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges on each package that the stored procedure uses:

- The EXECUTE privilege on the package for DSNADMDL
- Ownership of the package
- PACKADM authority for the package collection
- SYSADM authority

The ADMIN_DS_ LIST caller also needs authorization from an external security system, such as RACF, in order to perform the requested operation on an z/OS data set resource.

Syntax

The following syntax diagram shows the SQL CALL statement for invoking this stored procedure:

```
►► CALL ── SYSPROC.ADMIN_DS_LIST ── ( ── data-set-name , ── list-members , ── list-generations , ──►

►── max-results , ── dump-option , ── return-code , ── message ── ) ─►◄
```

Option descriptions

data-set-name

Specifies the data set name. You can use masking characters, except for when you list members of a PDS/PDSE (*list-members* = 'Y') or the generation data sets of a GDG (*list-generations* = 'Y'). For example: `USER.*` or `USER.A*CD`. In addition, the specified data set name cannot start with a masking character.

If no masking characters are used, only one data set will be listed.

This is an input parameter of type CHAR(44) and cannot be null.

list-members

Specifies whether to list PDS or PDSE members. Possible values are:

Y

List members. Only set to Y when *data-set-name* is a fully qualified PDS or PDSE.

N

Do not list members.

This is an input parameter of type CHAR(1) and cannot be null.

list-generations

Specifies whether to list generation data sets. Possible values are:

Y

List generation data sets. Only set to Y when *data-set-name* is a fully qualified GDG.

N

Do not list generation data sets.

This is an input parameter of type CHAR(1) and cannot be null.

max-results

Specifies the maximum number of result set rows. This option is applicable only when both list-members and list-generations are 'N'.

This is an input parameter of type INTEGER and cannot be null.

dump-option

Specifies whether to use the Db2 standard dump facility to dump the information necessary for problem diagnosis when any of the following errors occur:

- SQL error.
- A call to the IBM routine IEFDB476 to get messages about an unsuccessful SVC 99 call failed.
- Load Catalog Search Interface module error.

Possible values are:

Y

Generate a dump.

N

Do not generate a dump.

This is an input parameter of type CHAR(1) and cannot be null.

return-code

Provides the return code from the stored procedure. Possible values are:

0
: The call completed successfully.

4
: Processing completed, but some data sets received catalog management errors. Data set information is returned for the data sets that did not receive catalog management errors. Error information is returned for the data sets that received catalog management errors.

12
: The call did not complete successfully. The *message* output parameter contains messages describing the error.

This is an output parameter of type INTEGER.

message

Contains messages describing the error encountered by the stored procedure. If no error occurred, then no message is returned.

The first messages in this area are generated by the stored procedure. Messages that are generated by Db2 or by z/OS might follow the first messages.

This is an output parameter of type VARCHAR(1331).

Example

The following C language sample shows how to invoke ADMIN_DS_LIST:

```
 #pragma csect(CODE,"SAMDLPGM")
 #pragma csect(STATIC,"PGMDLSAM")
 #pragma runopts(plist(os))

 #include    <stdio.h>
 #include    <stdlib.h>
 #include    <string.h>

/******************** DB2 SQL Communication Area ********************/
 EXEC SQL INCLUDE SQLCA;

 int main( int argc, char *argv[] )    /* Argument count and list    */
 {
   /****************** DB2 Host Variables ****************************/
   EXEC SQL BEGIN DECLARE SECTION;

   /* SYSPROC.ADMIN_DS_LIST parameters                               */
   char        dsname[45];            /* Data set name or filter    */
   char        listmbr[2];            /* List library members       */
   char        listgds[2];            /* List GDS                   */
   long int    maxresult;             /* Maximum result set rows    */
   char        dumpopt[2];            /* Dump option                */
   long int    retcd;                 /* Return code                */
   char        errmsg[1332];          /* Error message              */

   /* Result set locators                                            */
   volatile SQL TYPE IS RESULT_SET_LOCATOR *rs_loc1;

   /* Result set row                                                 */
   char        dsnamer[45];           /* Data set name,             */
                                      /* library member name, or    */
                                      /* absolute generation number */
   long int    createyr;              /* Create year                */
   long int    createday;             /* Create day                 */
   long int    type;                  /* Data set type              */
