# Cryptography

IBM offers several IBM® i cryptography solutions. A comprehensive cryptography solution is an important part of a successful security strategy. IBM offers both software cryptography and a family of cryptographic hardware options for protecting data and for securing transaction processing.

You can make cryptography an integral part of your security solution. To ensure that you understand how cryptography works and how you can implement it in your system, review these topics:

**Note:** This information includes programming examples. Read the <u>"Code license and disclaimer information"</u> on page 234 for important legal information.

# What's new for IBM i 7.3

This topic provides the new and changed information for the Cryptography topic collection.

Miscellaneous updates have been made to this topic collection.

# How to see what's new or changed

To help you see where technical changes have been made, this information uses:

- The >> image to mark where new or changed information begins.
- The «image to mark where new or changed information ends.

In PDF files, you might see revision bars () in the left margin of new and changed information.

To find other information about what's new or changed this release, see the Memo to users.

# **PDF file for Cryptography**

To view and print a PDF file of the Cryptography topic collection.

You can view or download the PDF version of this information, select Cryptography PDF.

# Saving PDF files

To save a PDF on your workstation for viewing or printing:

- 1. Right-click the PDF link in your browser.
- 2. Click the option that saves the PDF locally.
- 3. Navigate to the directory in which you want to save the PDF.
- 4. Click Save.

# **Downloading Adobe Reader**

You need Adobe Reader installed on your system to view or print these PDFs. You can download a free copy from the Adobe Web site (www.adobe.com/products/acrobat/readstep.html) .

#### **Related concepts**

Related information for Cryptography

This topic provides information about product manuals and Web sites that relate to the IBM i Cryptography topic collection. You can view or print any of the PDFs.

# **Cryptography concepts**

This topic provides a basic understanding of cryptographic function and an overview of the cryptographic services for the systems running the IBM i operating system.

# Cryptography

Cryptography is the study and implementation of processes, which manipulate data for the purpose of hiding and authenticating information.

The IBM i cryptographic services help ensure data privacy, maintain data integrity, authenticate communicating parties, and prevent repudiation when a party refutes having sent a message.

# **Cryptographic algorithms**

A cryptographic *algorithm* is a mathematical procedure that is used in the transformation of data for the purpose of securing data.

### Cipher algorithms

A cipher algorithm transforms understandable information (plaintext) into an unintelligible piece of data (ciphertext), and can transform that unintelligible data back into understandable information.

There are two types of cipher algorithms:

#### Symmetric

With a *symmetric or secret* key algorithm, the key is a shared secret between two communicating parties. Encryption and decryption both use the same key. The Advanced Encryption Standard (AES) is an example of a symmetric key algorithm.

There are two types of symmetric key algorithms:

#### - Block cipher

In a *block cipher*, the cipher algorithm works on a fixed-size block of data. For example, if the block size is eight, eight bytes of plaintext are encrypted at a time. Normally, the user's interface to the encrypt/decrypt operation handles data longer than the block size by repeatedly calling the low-level cipher function.

#### - Stream cipher

Stream ciphers do not work on a block basis, but convert 1 bit (or 1 byte) of data at a time. Basically, a stream cipher generates a keystream based on the provided key. The generated keystream is then XORed with the plaintext data.

#### Asymmetric

With an *asymmetric* or *public key* algorithm (PKA), a pair of keys is used. One of the keys, the private key, is kept secret and not shared with anyone. The other key, the public key, is not secret and can be shared with anyone. When data is encrypted by one of the keys, it can only be decrypted and recovered by using the other key. The two keys are mathematically related, but it is virtually impossible to derive the private key from the public key. The RSA algorithm is an example of a public key algorithm.

Public key algorithms are slower than symmetric key algorithms. Applications typically use public key algorithms to encrypt symmetric keys (for key distribution) and to encrypt hashes (in digital signature generation).

Together, the key and the cryptographic algorithm transform data. All of the supported algorithms are in the public domain. Therefore, it is the key that controls access to data. You must safeguard the keys to protect data.

#### One-way hash algorithms

A cryptographic hash algorithm produces a fixed-length output string (often called a digest) from a variable-length input string. For all practical purposes, the following statements are true of a good hash function:

- Collision resistant: If any portion of the data is modified, a different hash will be generated.
- One-way: The function is irreversible. That is, given a digest, it is not possible to find the data that produces it.

#### Key distribution algorithms

When encrypted data must be decrypted at another location, distributing the key in a secure manner can be a challenge. There are many methods of key distribution. Some employ a cryptographic algorithm.

- **RSA:** An RSA public key is used to encrypt a symmetric key which is then distributed. The corresponding private key is used to decrypt it.
- **Diffie-Hellman:** The communicating parties generate and exchange D-H parameters which are then used to generate PKA key pairs. The public keys are exchanged and each party is then able to compute the symmetric key independently.

#### Random number generation algorithms

Many security-related functions rely on random number generation. Random number generation is performed both in IBM i using Cryptographic Services and on the cryptographic coprocessors using CCA. Both use a FIPS approved pseudorandom number generator (PRNG).

On the cryptographic coprocessor, an electronic noise source provides unpredictable input to a random bit-value accumulator. Periodically the hardware outputs seed to a FIPS 140-1 approved pseudorandom number generator.

The IBM i pseudorandom number generator resides in the IBM i LIC (Licensed Internal Code). It uses a PRNG algorithm from Appendix 3 of FIPS 186-2, Digital Signature Standard (DSS).

Cryptographically strong pseudorandom numbers rely on good seed. The FIPS 186-1 algorithm is seeded from a system seed digest. The system automatically generates seed using data collected from system information or by using the random number generator function on a cryptographic coprocessor if one is available. System-generated seed can never be truly unpredictable. If a cryptographic coprocessor is not available, you should add your own random seed (via the Add Seed for Pseudorandom Number Generator API) to the system seed digest. This should be done as soon as possible any time the Licensed Internal Code is installed.

# **Cryptographic operations**

Different cryptographic *operations* may use one or more *algorithms*. You choose the cryptographic operation and algorithm(s) depending on your purpose. For example, for the purpose of ensuring data integrity, you might want to use a MAC (message authentication code) operation with the AES algorithm.

The system provides several API sets that support cryptographic operations. See the **System cryptography overview** information at the bottom of this topic for more information.

# **Data privacy**

Cryptographic operations for the purpose of data privacy (confidentiality) prevent an unauthorized person from reading a message. The following operations are included in data privacy:

#### **Encrypt and Decrypt**

The encrypt operation changes plaintext data into ciphertext through the use of a cipher algorithm and key. To restore the plaintext data, the decrypt operation must employ the same algorithm and key.

Encryption and decryption may be employed at any level of the operating system. There are three levels:

#### Field level encryption

With field level encryption, the user application explicitly requests cryptographic services. The user application completely controls key generation, selection, distribution, and what data to encrypt.

#### **Session level encryption**

With encryption at the session layer, the system requests cryptographic services instead of an application. The application may or may not be aware that encryption is happening.

#### Link level encryption

Link level encryption is performed at the lowest level of the protocol stack, usually by specialized hardware.

The Cryptographic Coprocessors may be used for both field level encryption and Secure Sockets Layer (SSL) session establishment encryption. While VPN is supported in IBM i, it does not use the coprocessor. Furthermore, the system does not support SNA session level encryption at all.

#### **Translate**

The translate operation decrypts data from encryption under one key and encrypts the data under another key. This is done in one step to avoid exposing the plaintext data within the application program.

# Data integrity, authenticity, and non-repudiation

Encrypted data does not mean the data can not be manipulated (for example, repeated, deleted, or even altered). To rely on data, you need to know that it comes from an authorized source and is unchanged. Additional cryptographic operations are required for these purposes.

#### Hash (Message Digest)

Hash operations are useful for authentication purposes. For example, you can keep a copy of a digest for the purpose of comparing it with a newly generated digest at a later date. If the digests are identical, the data has not been altered.

#### MAC (Message Authentication Code)

A MAC operation uses a secret key and cipher algorithm to produce a value (the MAC) which later can be used to ensure the data has not been modified. Typically, a MAC is appended to the end of a transmitted message. The receiver of the message uses the same MAC key, and algorithm as the sender to reproduce the MAC. If the receiver's MAC matches the MAC sent with the message, the data has not been altered.

The MAC operation helps authenticate messages, but does not prevent unauthorized reading because the transmitted data remains as plaintext. You must use the MAC operation and then encrypt the entire message to ensure both data privacy and integrity.

#### HMAC (Hash MAC)

An HMAC operation uses a cryptographic hash function and a secret shared key to produce an authentication value. It is used in the same way a MAC is used.

#### Sign/Verify

A sign operation produces an authentication value called a digital signature. A sign operation works as follows:

- 1. The data to be signed is hashed, to produce a digest.
- 2. The digest is encrypted using a PKA algorithm and a private key, to produce the signature.

The verify operation works as follows:

- 1. The signature is decrypted using the sender's PKA public key, to produce digest 1.
- 2. The data that was signed is hashed, to produce digest 2.
- 3. If the two digests are equal, the signature is valid.

Theoretically, this also verifies the sender because only the sender should posses the private key. However, how can the receiver verify that the public key actually belongs to the sender? Certificates are used to help solve this problem.

# Key and random number generation

Many security-related functions rely on random number generation, for example, salting a password or generating an initialization vector. An important use of random numbers is in the generation of cryptographic key material. Key generation has been described as the most sensitive of all computer security functions. If the random numbers are not cryptographically strong, the function will be subject to attack.

#### **Financial PINs**

Personal identification number (PIN) generation and handling are also considered cryptographic operations.

A PIN is a unique number assigned to an individual by an organization. PINs are commonly assigned to customers by financial institutions. The PIN is typed in at a keypad and compared with other customer associated data to provide proof of identity.

To generate a PIN, customer validation data is encrypted by a PIN key. Other processing is done on the PIN as well, such as putting it in a particular format.

# **Key management**

Key management is the secure handling and storage of cryptographic keys. This includes key storage and retrieval, key encryption and conversions, and key distribution.

#### **Key storage**

Key storage on the system includes the following:

- · Cryptographic Services keystore
  - In addition, keys can also be stored on the Cryptographic Coprocessors themselves.
- · Digital certificate manager certificate store
- CCA keystore (used with the Cryptographic Coprocessors)
- JCE keystore

### **Key Encryption and Conversions**

Keys must be encrypted prior to sending or storing them outside the secured system environment. In addition, keys should be handled in encrypted form within the system as much as possible to reduce the risk of exposure. The management of encrypted keys is often done via a hierarchical key system.

- At the top is a master key (or keys). The master key is the only clear key value and must be stored in a secure fashion.
- Key-encrypting keys (KEKs) are used to encrypt other keys. Typically, a KEK is used to encrypt a stored key, or a key that is sent to another system. KEKs are normally encrypted under a master key.
- Data keys are keys used directly on user data (such as to encrypt or MAC). A data key may be encrypted under a KEK or under a master key.

Various uses of a key will require the key to be in different forms. For example, keys received from other sources will normally be converted to an internal format. Likewise, keys sent out of the system are converted to a standard external format before sending. Certain key forms are standard, such as an ASN.1 BER-encoded form, and others are peculiar to a cryptographic service provider, such as the Cryptographic Coprocessors.

#### **Key Distribution**

Typically, data encryption is performed using symmetric key algorithms. The symmetric keys are distributed using asymmetric key algorithms as described above. Keys are made ready to send by using an Export operation. Keys are received into the system using an Import operation.

# System cryptography overview

#### **Cryptographic Service Providers**

A cryptographic service provider (CSP) is the software or hardware that implements a set of cryptographic operations. The system supports several CSPs:

- 4769 Cryptographic Coprocessor
- 4767 Cryptographic Coprocessor (no longer available, but still supported)
- IBM i LIC
- Java<sup>™</sup> Cryptography Extensions

## **Cryptographic API sets**

User applications can utilize cryptographic services indirectly via IBM i functions such as SSL, VPN IPSec, and LDAP. User applications can also access cryptographic services directly using the following APIs:

• CCA

The Common Cryptographic Architecture (CCA) API set is provided for running cryptographic operations on a Cryptographic Coprocessor.

• IBM i Cryptographic Services

The IBM i Cryptographic Services API set is provided for running cryptographic operations within the Licensed Internal Code.

Java Cryptography

Java Cryptography Extension (JCE) is a standard extension to the Java Software Development Kit.

Network Authentication Service

GSS (Generic Security Services), Java GSS, and Kerberos APIs are part of the Network Authentication Service which provides authentication and security services. These services include session level encryption capability.

• IBM i SSL and JSSE

IBM i SSL and JSSE support the Secure Sockets Layer Protocol. APIs provide session level encryption capability.

SQL

Structured Query Language is used to access or modify information in a database. SQL supports encryption/decryption of database fields.

This table indicates what CSPs are used under each user interface.

CSP APIs	IBM i LIC	JCE	4769, 4767
CCA			Х
IBM i Cryptographic Services	Х		
Java Cryptography		Х	Х
Network Authentication Service	Х	Х	
IBM i SSL and JSSE	Х	Χ	Х
SQL	Х		

#### **Related concepts**

Initializing a keystore file

A keystore file is a database file that stores operational keys, that is keys encrypted under the master key. This topic provides information on how to keep records of your DES and PKA keys on systems running the IBM i operating system.

#### 4769 Cryptographic Coprocessor

IBM offers Cryptographic Coprocessors, which are available on a variety of system models. Cryptographic Coprocessors contain hardware engines, which perform cryptographic operations used by IBM i application programs and IBM i SSL transactions.

#### Cryptographic services key management

Cryptographic services key management for the IBM i operating system allows you to store and manage master keys and keystores. Since you are exchanging sensitive data to manage master keys and keystores, it is recommended that you use a secure session.

# Cryptographic services key management

Cryptographic services key management for the IBM i operating system allows you to store and manage master keys and keystores. Since you are exchanging sensitive data to manage master keys and keystores, it is recommended that you use a secure session.

Cryptographic Services supports a hierarchical key system. At the top of the hierarchy is a set of master keys. These keys are the only key values stored in the clear (unencrypted). Cryptographic services securely stores the master keys within the IBM i Licensed Internal Code (LIC).

Eight general-purpose master keys are used to encrypt other keys which can be stored in keystore files. Keystore files are database files. Any type of key supported by cryptographic services can be stored in a keystore file, for example AES, RC2, RSA, SHA1-HMAC.

In addition to the eight general-purpose master keys, cryptographic services supports two special-purpose master keys. The ASP master key is used for protecting data in the Independent Auxiliary Storage Pool (in the Disk Management GUI is known as an Independent Disk Pool). The save/restore master key is used to encrypt the other master keys when they are saved to media using a Save System (SAVSYS) operation.

You can work with Cryptographic services key management using the IBM Navigator for i interface. You can access IBM Navigator for i by visiting the following URL from a Web browser where *hostA* is your IBM i name:

# http://hostA:2001

After you connect to IBM Navigator for i, click **Security > Cryptographic Services Key Management**. You can, thereafter, work with managing master keys and cryptographic keystore files.

You can also use the cryptographic services APIs or the control language (CL) commands to work with the master keys and keystore files.

**Note:** You should use Secure Sockets Layer (SSL) to reduce the risk of exposing key values while performing key management functions.

Cryptographic Services API set IBM Navigator for i

# **Managing master keys**

Master keys are used to encrypt other keys. You can load, set, and test master keys. You can clear a master key only after you have set it.

Cryptographic Services allows you to set up eight general-purpose master keys and two-special purpose master keys that cannot be directly modified or accessed by the user (including the security officer). The two special purpose master keys are the Save/Restore master key used for encrypting the master keys while on SAVSYS media and the auxiliary storage pool (ASP) master key used for ASP encryption. Cryptographic Services master keys are 256-bit AES keys that are securely stored within the IBM i Licensed Internal Code (LIC).

Master keys are used to encrypt other keys. If a master key is lost, all keys encrypted under that master key, and consequently all data encrypted under those keys, are lost. It is important you backup the master keys both by saving the passphrases, and by using a SAVSYS operation. To protect the master keys while on the save media, they are encrypted with the save/restore master key.

**Note:** You should use Secure Sockets Layer (SSL) to reduce the risk of exposing key values while performing key management functions.

Each master key is composed of four 32-byte values, called versions. The versions are new, current, old, and pending.

- The new master key version contains the value of the master key while it is being loaded.
- The *current* master key version contains the active master key value. This is the value that will be used when a master key is specified on a cryptographic operation (unless specifically stated otherwise).
- The *old* master key version contains the previous current master key version. It is used to prevent the loss of data and keys when the master key is changed.
- The *pending* master key version holds a master key value that has been restored to the system but cannot be correctly decrypted.

Each version of a master key has a key verification value (KVV). The KVV is a 20-byte hash of the key value. It is used to determine if a master key has changed, or what version of a master key was used in an encryption operation.

The following describes master key operations. All master key operations will create a CY (Cryptographic Configuration) audit record.

# Loading and setting master keys

To use a master key, you must first load its key parts, and then set it.

**Note:** If a master key is lost, all keys encrypted under that master key, and consequently all data encrypted under those keys, are lost. Therefore, it is important to backup your master keys. Whenever a master key is changed, you should make a backup by performing a SAVSYS operation. Even when backed up using the SAVSYS operation, you should write down the passphrases for the master keys and store them securely; this is in case the Licensed Internal Code install from the SAVSYS operation fails.

The load master key operation takes a passphrase as input. It is hashed and then loaded into the new version. You can load as many passphrases as desired. Each passphrase is XORed into the new version of the master key. To ensure that no single individual has the ability to reproduce a master key, you should assign passphrases to several people. Loading a master key part does not affect the current master key version.

To load a master key from the IBM Navigator for i interface, follow these steps:

- 1. Select **Security** from your IBM Navigator for i window.
- 2. Select Cryptographic Services Key Management.
- 3. Select Manage Master Keys.

- 4. Select the Master key.
- 5. Select Load Part from the Select Actions menu.
- 6. Specify the **Passphrase** and click **OK**.

You can also use the Add Master Key Part (ADDMSTPART) CL command to load a key part for the specified master key.

Or, if you prefer to write your own application to load a master key part, you can do so by using the Load Master Key Part (QC3LDMKP; Qc3LoadMasterKeyPart) API.

To activate the new master key value, which consists of the passphrases previously loaded, you set it. The following steps are performed when a master key is set:

- 1. The current version master key value and Key Verification Value (KVV) are moved to the old version wiping out what was in the old version.
- 2. The new version master key value is finalized. Then, new version master key value and its KVV are moved to the current version.
- 3. The new version is erased.

To set the master key, select the Master key and then from the Select Actions menu, select Set.

You can also use the Set Master Key (SETMSTKEY) command to set the specified master key that has parts already added.

Or, if you prefer to write your own application to set the master key, you can do so by using the Set Master Key (OPM, QC3SETMK; ILE, Qc3SetMasterKey) API.

**Note:** The Set Master Key operation returns the master key's Key Verification Value (KVV). You can use this value at a later date to determine whether the master key has been changed.

#### **Related tasks**

Saving and restoring master keys

If a master key is lost, all keys encrypted under that master key, and consequently all data encrypted under those keys, are lost. Therefore, it is important to backup your master keys.

#### **Related information**

Key Management APIs IBM Navigator for i Control language

# Loading and setting auxiliary storage pool master key

You can set the auxiliary storage pool (ASP) master key as you would any other master key, by first loading key parts and then setting the ASP master key. The ASP master key is used for protecting data in the independent auxiliary storage pool (known as an independent disk pool in the graphical interface).

When you set up an encrypted independent auxiliary storage pool (IASP), the system generates a data key which encrypts data written to that IASP, and decrypt data read from that IASP. The IASP data key is kept with the IASP and is protected with the ASP master key.

**Important:** To encrypt an independent disk pool from the disk management folder of the graphical interface, it must be a V6R1 or later version system and it must have Encrypted ASP Enablement feature of IBM i installed. This feature can be ordered separately for a fee.

To set the ASP master key, you must first load master key parts and then set the ASP master key. You can load as many master key parts as you want for the ASP master key. By setting the save/restore master key, the new ASP master key version moves to the current ASP master key version.

To load the ASP master key from the IBM Navigator for i interface, follow these steps:

- 1. Select **Security** from your IBM Navigator for i window.
- 2. Select Cryptographic Services Key Management.
- 3. Select Manage Master Keys.

- 4. Select the ASP master key.
- 5. Select Load Part from the Select Actions menu.
- 6. Use the Load Part dialog to specify the passphrase.

You can also use the Add Master Key Part (ADDMSTPART) CL command to load a key part for the ASP master key.

Or, if you prefer to write your own application to load the ASP master key, you can do so by using the Load Master Key Part (OPM, QC3LDMKP; ILE, Qc3LoadMasterKeyPart) API.

To set the ASP master key, select the **ASP master key** and then from the **Select Actions** menu, select **Set**.

You can also use the Set Master Key (SETMSTKEY) CL command to set the ASP master key that has parts already added.

Or, if you prefer to write your own application to set the ASP master key, you can do so by using the Set Master Key (QC3SETMK; Qc3SetMasterKey) API.

#### **Related information**

Independent auxiliary storage pool (ASP)

# Loading and setting save/restore master key

The save/restore master key is a special purpose master key used to encrypt all the other master keys when you save them in a Save System (SAVSYS) operation. The save/restore master key itself is not saved. The save/restore master key has a default value. So, for optimum security, the save/restore master key should be set to another value.

The save/restore master key has only two versions. The versions are new and current.

**Note:** Since the save/restore master key is not included in the Save System operation, it is recommended that you write the passphrases for the save/restore master key and store them securely.

You should set the save/restore master key before performing the SAVSYS operation. To set the save/restore master key, you must first load master key parts and then set the save/restore master key.

You can load as many master key parts as you want for the save/restore master key. Setting the save/restore master key causes the new save/restore master key version to move to the current save/restore master key version. After the save/restore master key has been set, you should perform the SAVSYS operation to save the master keys on the save media.

To load a save/restore master key from the IBM Navigator for i interface, follow these steps:

- 1. Select **Security** from your IBM Navigator for i window.
- 2. Select Cryptographic Services Key Management.
- 3. Select Manage Master Keys.
- 4. Select the Save/Restore master key.
- 5. Select **Load Part** from the **Select Actions** menu.
- 6. Specify the **Passphrase** and click **OK**.

If you prefer to write your own application to load the save/restore master key, you can do so by using the Load Master Key Part (QC3LDMKP; Qc3LoadMasterKeyPart) API.

You can also use the Add Master Key Part (ADDMSTPART) CL command to load a master key part for the save/restore master key.

To set the save/restore master key, select the **Save/Restore master key** and then from the **Select Actions** menu, select **Set**.

If you prefer to write your own application to set the save/restore master key, you can do so by using the Set Master Key (QC3SETMK; Qc3SetMasterKey) API.

You can also use the Set Master Key (SETMSTKEY) CL command to set the save/restore master key that has parts already added.

You cannot use **Option 5, Save Licensed Internal Code** from the **IPL or Install the System** menu to save the master key. You must use the SAVSYS operation. You should also perform a SAVSYS operation whenever you load and set any of the master keys.

#### **Related information**

Key Management APIs

IBM Navigator for i

Control language

# **Testing master keys**

You can check the Key Verification Value (KVV) for any version of any master key. The KVV is a 20-byte hash of the key value. By checking its KVV, you can test if the master key value is what you believe it to be. For example, if you save the KVV returned on the set master key operation, you can use it to compare against the value returned on the check KVV operation at a later date to determine if the master key has changed.

To check a master key KVV using IBM Navigator for i, follow these steps:

- 1. Select **Security** from your IBM Navigator for i window.
- 2. Select Cryptographic Services Key Management.
- 3. Select Manage Master Keys.
- 4. Select the master key that you want to test.
- 5. Select **Properties** from the **Select Actions** menu.

You can also use the Check Master KVV (CHKMSTKVV) CL command to test a specified master key and version.

If you prefer to write your own application, you can use the Test Master Key (QC3TSTMK, QcTestMasterKey) API.

#### Note:

- 1. The ASP Master Key and the Save/Restore Master Keys do not have pending versions. Also, the Save/Restore Master Key does not have an old version.
- 2. If the KVV for the Save/Restore Master Key is hexadecimal 16C1D3E3C073E77DB28F33E81EC165313318CE54, it is set to the default value. For optimum security, you should load and set the Save/Restore Master Key.

### **Related information**

Key Management APIs

IBM Navigator for i

Control language

# **Clearing master keys**

You can clear any version of any master key. Before clearing an old master key version, care should be taken to ensure no keys or data are still encrypted under it. You can clear a master key version only if it is set.

**Note:** The ASP master key and the save/restore master keys do not have pending versions. Also, the save/restore master key does not have an old version.

To clear a master key using IBM Navigator for i, follow these steps:

- 1. Select **Security** from your IBM Navigator for i window.
- 2. Select Cryptographic Services Key Management.
- 3. Select Manage Master Keys.

- 4. Select the master key.
- 5. Select Clear from the Select Actions menu.

You can also use the Clear Master Key (CLRMSTKEY) command to clear the specified master key version.

Or, if you prefer to write your own application to clear a master key, you can do so by using the Clear Master Key (QC3CLRMK; Qc3ClearMasterKey) API.

**Note:** By clearing the save/restore master key, it will be set to its default value. For optimum security, you should load and set the save/restore master key.

#### **Related information**

Key Management APIs IBM Navigator for i Control language

# **Saving and restoring master keys**

If a master key is lost, all keys encrypted under that master key, and consequently all data encrypted under those keys, are lost. Therefore, it is important to backup your master keys.

There are two methods of backing up your master keys:

#### Save the individual passphrases

Master key passphrases should not be stored on the system in plaintext. Also, do not encrypt them under any master key or any key encrypted under a master key. If the master keys are lost (for example, when the Licensed Internal Code is installed) or damaged, you will be unable to recover the passphrases and therefore the master keys. Store the passphrases securely outside the system, such as in separate safes.

#### Save the master keys by performing a SAVSYS operation

Master keys are saved as part of a SAVSYS operation. To protect the master keys while on save media, they are encrypted with the save/restore master key. The save/restore master key is the only master key that is not saved as part of the SAVSYS operation.

To back up the master keys, follow these steps:

- 1. Set the save/restore master key.
- 2. Perform a SAVSYS operation.

To recover the master keys on the target system, the save/restore master key on the target system must match the save/restore master key on the source system at the time of the SAVSYS operation. If they match, the master keys are automatically decrypted and made ready for use. If they do not match, the restored master keys are put in pending versions. When you attempt to use a master key that has a pending version (for example, you encrypt using a key from a keystore file that is encrypted under a master key with a pending version), you get an error message indicating there is an unrecovered master key. You must either recover the pending master key version by setting the correct value for the save/restore master key on the target system, or you must clear the pending master key version.

The save/restore master key has a default value. Therefore, if it is not changed on either the source or target systems, the master keys will restore without any intervention. However, using the default save/restore master key is not recommended as this provides little protection. You should load and set the save/restore master key for optimum security of the master keys while on SAVSYS media.

When master keys are restored and decrypted successfully with the save/restore master key, they are moved into the current versions. If a master key already has a current version, it is moved to the old version. Therefore, it is important that there are no keys on the system encrypted under the old version, because that will be lost. After restoring the master keys, you must translate all keystore files and any other keys encrypted under a master key.

There might be instances when you do not want your master keys, or some of your master keys, to be distributed to another system through the SAVSYS media. When you do not want any of your master

**12** IBM i: Cryptography

keys to successfully restore and decrypt on another system, ensure you have loaded and set the save/restore master key prior to the SAVSYS operation, and do not share it with the target system. On the target system, the pending versions are needed to be cleared.

If you want to distribute only some of your master keys, you can do the same. Then, share the passphrases for the master keys you want to share. Otherwise, you will need to temporarily clear the master keys you do not want distributed.

Even when the master keys are backed up using the SAVSYS operation, you should write down the passphrases for the master keys and store them securely; this is in case the Licensed Internal Code install from the SAVSYS operation fails.

You cannot use **Option 5, Save Licensed Internal Code** from the **IPL or Install the System** menu to save the master key. You must use the SAVSYS operation.

**Note:** Any time you change a master key, you must back it up.

# Managing cryptographic keystore files

You can create keystore files, and add, generate, delete, import, export, and retrieve attributes for key records.

A *keystore* is a set of database files that are used for storing cryptographic keys. Any type of key that is supported by cryptographic services can be stored in a keystore file. Some examples of the types of keys supported by cryptographic services are AES, RC2, RSA, and MD5-HMAC. You can create as many keystore files as you want, and add as many key records as you want into a keystore file. Since each keystore file is a separate system object, you can authorize different users to each file. You can save and restore each keystore file at different times. This depends on how often key records are added to the keystore file and how often the master key for the keystore file is changed.

You can manage keystore files from the IBM Navigator for i interface, or use the Cryptographic Services APIs or control language (CL) commands.

**Note:** You should use Secure Sockets Layer (SSL) to reduce the risk of exposing key values while performing key management functions.

# Creating a new keystore file

You can create as many keystore files as desired. When you create a keystore file using the IBM Navigator for i interface it is automatically added to your list of managed keystore files.

To create a new keystore file using the IBM Navigator for i interface, follow these steps:

- 1. Select **Security** from your IBM Navigator for i window.
- 2. Select Cryptographic Services Key Management.
- 3. Select Manage Cryptographic Keystore Files.
- 4. Click Create New Keystore.
- 5. Enter the **Keystore name** for the new keystore you want to create and specify the **Library** in which you want to create the new keystore.
- 6. Enter the **Description** of the new keystore that you want to create.
- 7. Enter the **Master key** that you want to be associated with the new keystore file.
- 8. Select the **Public authority** that you want to assign to the new keystore file.
- 9. Click OK.

You can also use the Create Keystore File (CRTCKMKSF) command to create a database file for storing cryptographic key records.

Or, if you prefer to write your own application to create a new keystore file, you can do so by using the Create Keystore (QC3CRTKS; Qc3CreateKeyStore) API.

To add an existing keystore file to your list of managed keystore files using the IBM Navigator for i interface, see Adding an existing keystore file

#### **Related information**

Key Management APIs

IBM Navigator for i

Control language

# Adding an existing keystore file

From the IBM Navigator for i interface, you can add an existing keystore file to your list of managed keystore files.

To add an existing keystore file to your list of managed keystore files, follow these steps:

- 1. Select **Security** from your IBM Navigator for i window.
- 2. Select Cryptographic Services Key Management.
- 3. Select Manage Cryptographic Keystore Files.
- 4. Click Add Keystore.
- 5. Specify the **File name** and the **Library**.
- 6. Click OK.

#### **Related information**

Cryptographic Services API set IBM Navigator for i Control language

# **Translating keystore files**

When the master key for a keystore file is changed, all keys in that keystore file must be translated (re-encrypted). You can translate a keystore to another master key, or if the same master key is specified, to the current version of the master key.

To translate a keystore using the IBM Navigator for i, follow these steps:

- 1. Select **Security** from your IBM Navigator for i window.
- 2. Select Cryptographic Services Key Management.
- 3. Select Manage Cryptographic Keystore Files.
- 4. Select the **Keystore** you want to translate.
- 5. Select Translate from the Select Actions menu.
- 6. Select the **Master key** to which you want to translate the keystore file.

**Note:** In order to avoid losing keys, a keystore file should be translated soon after the master key for that keystore file has changed. If the master key is changed again before you have translated the keystore file, all the keys in the keystore file will be lost.

You can also use the Translate Keystore File (TRNCKMKSF) command to translate key records stored in the specified keystore files to another master key, or if the same master key is specified, to the current version of the master key.

Or, if you prefer to write your own application, use the Translate Key Store (QC3TRNKS; Qc3TranslateKeyStore) API.

To learn about how you can determine the translation status of keystore files, see <u>Viewing translation</u> status of keystore files

## **Related tasks**

Distributing keys

You can move a keystore file and single keys from one system to another without exposing clear key values.

Cryptographic Services API set
IBM Navigator for i
Control language

# Viewing translation status of keystore files

You can view the translation status of each keystore file to determine whether a keystore file requires translation.

For example, you used master key 5 to encrypt all keys in a single keystore file. However, all keys might not be encrypted under the same version of the master key because after you created a keystore file and assigned master key 5 to that keystore file, you added several key records. Later, you changed master key 5 using the load and set master key operations. After that, you added several key records to the keystore file. The keystore file now has some keys encrypted under the current version of the master key and some keys encrypted under the old version of the master key. If you change master key 5 again and add more key records, there will be some keys encrypted under the current version, some keys encrypted under the old version, and some keys lost.

To view the translation status of each keystore file from the IBM Navigator for i interface, follow these steps:

- 1. Select **Security** from your IBM Navigator for i window.
- 2. Select Cryptographic Services Key Management.
- 3. Select Manage Cryptographic Keystore Files.
- 4. Select the **Keystore** you want to translate.
- 5. Select **Properties** from the **Select Actions** menu.

The translation statuses explain if the keystore file requires translation:

#### Current

Indicates that all keys are encrypted under the current version of the keystore file's master key. No translation is needed.

#### **Old (Translation needed)**

Indicates that the keystore file contains at least one key that is encrypted under the old version of the keystore file's master key. You should translate the keystore file so that all keys will be encrypted under the current version of the master key.

#### Lost (Recovery needed)

Indicates that the keystore file contains at least one key that is not encrypted under the old or current version of the keystore file's master key. To recover lost keys, first translate the keystore file. This will ensure that any keys with a translation status of old become current. Then, set a master key to the master key value that no longer exists and translate the keystore file to that master key. All keys in the keystore file should now have a translation status of current.

**Note:** To view the translation status of each key record using the IBM Navigator for i interface, open the keystore file. The Keystore Contents page displays the translation status of each key record.

You can also determine the translation status of key records programmatically. Use the Retrieve Key Record Attributes (QC3RTVKA; Qc3RetrieveKeyRecordAtr) API or the Retrieve Keystore Records (QC3RTVKS, Qc3RetrieveKeystoreRecords) API to obtain the Key Verification Value (KVV) of the master key at the time the key record was added. Then, compare it with the KVV returned on the Test Master Key (QC3TSTMK; Qc3TestMasterKey) API, to determine the translation status of the key record.

Similarly, you can use the Display Keystore File Entry (DSPCKMKSFE) and Check Master KVV (CHKMSTKVV) CL commands to determine the translation status of a key record.

#### **Related tasks**

Translating keystore files

When the master key for a keystore file is changed, all keys in that keystore file must be translated (re-encrypted). You can translate a keystore to another master key, or if the same master key is specified, to the current version of the master key.

#### **Related information**

IBM Navigator for i

Control language

# **Distributing keys**

You can move a keystore file and single keys from one system to another without exposing clear key values.

#### Moving a keystore file

In general, you should not share master keys with another system. Each system should have unique master keys. However, to move an entire keystore file from one system to another without exposing clear key values, you need to set up identical master key values on both systems. To avoid exposing your master key values, perform the following steps.

- 1. Set up a temporary master key on both systems by loading and setting an unused master key with identical passphrases.
- 2. On the source system, create a duplicate of the keystore file (for example, using the CRTDUPOBJ CL command).
- 3. Translate the duplicated keystore file to the temporary master key.
- 4. Move the keystore file to the target system.
- 5. Delete the translated keystore file from the source system. (You still have the original keystore file.)
- 6. On the target system, translate the keystore file to another master key.
- 7. Clear the temporary master key on both systems.

#### Note:

- If the target system already has a file by the same name, you will need to rename one of the files. You could also export individual keys from the source system keystore file and write them into the target system keystore file as described below.
- To merge two keystore files together, you will need to export the keys out of one of the keystore files, and write them into the other keystore file using the Write Key Record API or the New Key Record wizard from the IBM Navigator for i interface as described below. If there are duplicate label names, you will have to provide a new name on the Write Key Record API or the New Key Record wizard from the IBM Navigator for i interface.

#### Moving single keys

To move a single key that is encrypted under a master key (in or outside of keystore) to another system, use the Export Key API or the Export Key wizard from the IBM Navigator for i interface. The export operation translates the key from encryption under the master key to encryption under a key-encrypting key (KEK). On the target system, you can then use the Write Key Record API or the New Key Record wizard from the IBM Navigator for i interface to move the migrated key into the keystore. Both systems must agree on the KEK ahead of time.

**Note:** The Export Key API is shipped with public authority \*EXCLUDE. Be careful about the access you give to the Export Key API. Anyone with access to master key-encrypted keys and the Export Key API can obtain the clear key values.

# **Related tasks**

Translating keystore files

When the master key for a keystore file is changed, all keys in that keystore file must be translated (re-encrypted). You can translate a keystore to another master key, or if the same master key is specified, to the current version of the master key.

### Exporting a key record

An export operation is used to translate (re-encrypt) a key encrypted under a master key to encryption under a key-encrypting key (KEK).

# Managing key records

You can create a new key record by generating or importing a key into it. You can also export a key out of a key record, extract a public key from a key record, view a key record's attributes, and delete a key record.

You can store any type of key that is supported by cryptographic services in a keystore file. You can add as many key records as you want in a keystore file and manage them from the IBM Navigator for i interface, or you can choose to use the Cryptographic Services APIs and control language (CL) commands.

Each record in a keystore file holds a key or a key pair. Besides the encrypted key value, the record contains the key type (for example, TDES, AES, RSA), the key size, the Key Verification Value (KVV) of the master key at the time the key value was encrypted, and a label. All fields in the keystore record are stored as CCSID 65535 except for the record label. At the time the record label was assigned, it was converted from the job CCSID or the job default CCSID to Unicode UTF-16 (CCSID 1200).

# Adding a new key record

You can add a new key record into a keystore file. You can either have the system generate a random key value for you, or you can supply a key value. The supplied key value can be specified in the clear or encrypted.

You can add a new key record to a keystore using the New Key Record wizard from the IBM Navigator for i interface. You can either have the key automatically generated or you can specify the key value. If the specified key value is encrypted, the wizard prompts you for the location of the key for use in decrypting the key value.

To add a key record using the New Key Record wizard, follow these steps:

- 1. Select **Security** from your IBM Navigator for i window.
- 2. Select Cryptographic Services Key Management.
- 3. Select Manage Cryptographic Keystore Files.
- 4. Right-click the **Keystore** to which you want to add the key record, select **OpenKeyStore** to display the keystore contents.
- 5. Click the **New Key Record** button.
- 6. Follow the steps in the New Key Record wizard.

You can also use the Add Keystore File Entry (ADDCKMKSFE) CL command to add a key record with the specified clear key value or key pair. Or you can use the Generate Keystore File Entry (GENCKMKSFE) CL command to generate a random key or key pair for a key record.

Or, if you prefer to write your own application, you can use the Generate Key Record (QC3GENKR; Qc3GenKeyRecord) or Write Key Record (QC3WRTKR; Qc3WriteKeyRecord) APIs.

#### **Related information**

Cryptographic Services API set
IBM Navigator for i
Control language

#### Exporting a key record

An export operation is used to translate (re-encrypt) a key encrypted under a master key to encryption under a key-encrypting key (KEK).

Usually you encrypt a key under a KEK for one of the reasons below:

- You plan to send the key to another system. Normally you should not share master keys with other systems. Instead you exchange a KEK. For example, Alice generates an RSA key pair and sends the public key to Bob. Bob encrypts the key he wishes to send Alice with Alice's public key and sends it to Alice. Only Alice will be able to decrypt the key.
- The key will be stored with the data it encrypts. You should not store the key encrypted under the master key, because if the master key changes you might not remember to translate the key. By encrypting it under a KEK, you reduce that risk.

You can export key records using the Export key wizard from the IBM Navigator for i interface. The wizard will take you through the steps required to export a key from a key record in a keystore file to a stream file. The wizard requires that you first choose another key record that will be used as the KEK. The KEK must already exist in a keystore file.

To export key records to another system, follow these steps:

- 1. Select **Security** from your IBM Navigator for i window.
- 2. Select Cryptographic Services Key Management.
- 3. Select Manage Cryptographic Keystore Files.
- 4. Select the **Keystore** that contains the key record that you want to export.
- 5. Select the **Key record** you want to export.
- 6. Select **Export** from the **Select Actions** menu.
- 7. Follow the steps in the Export Key wizard.

If you prefer to write your own application, use the Export Key (QC3EXPKY; Qc3ExportKey) API.

**Note:** Anyone with authority to a keystore file and the Export key wizard can obtain the clear key values for all keys in the file. Because the Export key wizard uses the Export Key API, you can control access to this function by the access you give to the Export Key API. The Export Key API is shipped with public authority \*EXCLUDE.

#### **Related tasks**

Distributing keys

You can move a keystore file and single keys from one system to another without exposing clear key values.

### Extracting a public key

You can extract a public key if you want to send the public key to another individual. A public key can be extracted from a BER encoded PKCS #8 string or from a key record that contains a public or private PKA key. The public key is extracted in X.509 SubjectPublicKeyInfo format.

To extract a public key from a key record using IBM Navigator for i follow these steps:

- 1. Select **Security** from your IBM Navigator for i window.
- 2. Select Cryptographic Services Key Management.
- 3. Select Manage Cryptographic Keystore Files.
- 4. Select the **Keystore** that contains the public key record that you want to extract.
- 5. Select the **Key record** that you want to extract.
- 6. Select Extract Public Key from the Select Actions menu.
- 7. Specify the extract location.

If you prefer to write your own application, use the Extract Public Key (QC3EXTPB; Qc3ExtractPublicKey) API which can extract a public key from a keystore file record or from a BER encoded PKCS #8 string.

#### **Related information**

Cryptographic Services API set
IBM Navigator for i
Control language

# Viewing a key record's attributes

Even though you cannot view the value of the key, you can view the attributes of a key stored in a keystore file. These include the key record label, the key type, the key size, the disallowed functions, the id of the master key that encrypts the key value and the Key Verification Value (KVV) of the master key.

To view a key record's attributes using IBM Navigator for i, follow these steps:

- 1. Select **Security** from your IBM Navigator for i window.
- 2. Select Cryptographic Services Key Management.
- 3. Select Manage Cryptographic Keystore Files.
- 4. Select the **Keystore** that contains the key record that you want to view the attributes for.
- 5. Select the **Key record** that you want to view.
- 6. Select **Properties** from the **Select Actions** menu.

You can also use the Display Keystore File Entry (DSPCKMKSFE) CL command to display the attributes of a keystore file record.

Or, if you prefer to write your own application, you can use the Retrieve Key Record Attributes (QC3RTVKA; Qc3RetrieveKeyRecordAtr) or Retrieve Keystore Records (QC3RTVKS, Qc3RetrieveKeystoreRecords) API.

## Deleting a key record

By deleting a key record, you also delete the key associated with the key record. The data encrypted under the key will be lost.

To delete a key record from the IBM Navigator for i interface, follow these steps:

- 1. Select **Security** from your IBM Navigator for i window.
- 2. Select Cryptographic Services Key Management.
- 3. Select Manage Cryptographic Keystore Files.
- 4. Select the **keystore** that contains the key record that you want to delete.
- 5. Select the **key record** that you want to delete.
- 6. Select **Delete** from the **Select Actions** menu.

**Note:** Make sure you have no data or keys encrypted under the key in the key record (that you want to delete) before you delete it.

You can also use the Remove Keystore File Entry (RMVCKMKSFE) CL command to delete a key record from a keystore file.

Or, if you prefer to write your own application, use the Delete Key Record (QC3DLTKR; Qc3DeleteKeyRecord) API.

# 4769 Cryptographic Coprocessor

IBM offers Cryptographic Coprocessors, which are available on a variety of system models. Cryptographic Coprocessors contain hardware engines, which perform cryptographic operations used by IBM i application programs and IBM i SSL transactions.

Note: The IBM 4767 Cryptographic Coprocessor is no longer available but it is still supported.

The 4769 Cryptographic Coprocessor is available on the Power 9 model as hardware feature EJ35 or EJ37.

Cryptographic Coprocessors can be used to augment your system in the following ways:

You can use a Cryptographic Coprocessor to implement a broad range of IBM i based applications. Examples are applications for performing financial PIN transactions, bank-to-clearing-house transactions, EMV transactions for integrated circuit (chip) based credit cards, and basic SET block processing. To do this, you or an applications provider must write an application program, using a security programming interface (SAPI) to access the security services of your Cryptographic Coprocessor. The SAPI for the Cryptographic Coprocessor conforms to IBM's Common Cryptographic Architecture (CCA). The SAPI is contained in the CCA Cryptographic Service Provider (CCA CSP) which is delivered as IBM i Option 35.

To meet capacity and availability requirements, an application can control up to eight Coprocessors. The application must control access to individual Coprocessor by using the Cryptographic\_Resource\_Allocate (CSUACRA) and Cryptographic\_Resource\_Deallocate (CSUACRD) CCA APIs.

- You can use a Cryptographic Coprocessor along with DCM to generate and store private keys associated with SSL digital certificates. A Cryptographic Coprocessor provides a performance assist enhancement by handling SSL private key processing during SSL session establishment.
- When using multiple Coprocessors, DCM configuration gives you the following options for using hardware to generate and store the private key associated with a digital certificate.
  - The private key is generated in hardware and stored (that is retained) in hardware. With this option
    the private key never leaves the Coprocessor, and thus the private key cannot be used or shared with
    another Coprocessor. This means that you and your application have to manage multiple private keys
    and certificates.
  - The private key is generated in hardware and stored in software (that is stored in a keystore file). This option allows a single private key to be shared among multiple Coprocessors. A requirement is that each Coprocessor must share the same master key. You can use the Clone master keys page to set up your Coprocessors to have the same master key. The private key is generated in one of the Coprocessors and is then saved in the keystore file, encrypted under the master key of that Coprocessor. Any Coprocessor with an identical master key can use that private key.
- The IBMJCECCAI5OS implementation extends Java Cryptography Extension (JCE) and Java Cryptography Architecture (JCA) to add the capability to use hardware cryptography by using the IBM Common Cryptographic Architecture (CCA) interfaces. This new provider takes advantage of hardware cryptography within the existing JCE architecture and gives Java 2 programmers the significant security and performance advantages of hardware cryptography with minimal changes to existing Java applications. As the complexities of hardware cryptography are taken care of within the normal JCE, advanced security and performance using hardware cryptographic devices are made easily available. The IBMJCECCAI5OS provider plugs into the JCE framework in the same manner as the current providers. For hardware requests, the CCA APIs are called by the new native methods. The IBMJCECCAI5OS stores CCA RSA key labels in a new Java keystore type of JCECCAI5OSKS.
- Features: Cryptographic Coprocessors contain hardware engines, which perform cryptographic
  operations used by IBM i application programs and SSL transactions. Each IBM Cryptographic
  Coprocessor contains a tamper-resistant hardware security module (HSM) which provides secure
  storage for store master keys. The HSM is designed to meet FIPS 140 security requirements. To meet
  your capacity and high availability needs, multiple Cryptographic Coprocessors are supported. The
  features information describes in greater detail what the Cryptographic Coprocessors and CCA CSP have
  to offer.

**20** IBM i: Cryptography

- Requirements: Your system must meet some requirements before you can install and use a Cryptographic Coprocessor. Use the requirements page to determine whether you are ready to install and use a Cryptographic Coprocessor on your system.
- Cryptography hardware concepts: Depending on your familiarity with cryptography, you may need more information about a term or concept. This page explains some basic concepts regarding the cryptographic hardware available for your system, enabling you to better understand how to maximize your usage of cryptography and cryptographic hardware options with your system.
- Related information: See Related information for additional sources of cryptography information recommended by IBM.

Using hardware cryptography

#### **Related tasks**

#### Cloning master keys

Master key cloning is a method for securely copying a master key from one Cryptographic Coprocessor to another without exposing the value of the master key. If you are using multiple coprocessors with SSL on your system running the IBM i operating system, use the Cryptographic Coprocessor configuration Web-based utility to clone master keys.

# **Cryptographic hardware concepts**

To better understand how to maximize your use of cryptography and cryptographic hardware options with your system running the IBM i operating system, this topic provides basic concepts regarding cryptographic hardware.

# Key types associated with the Cryptographic Coprocessor

Your Coprocessor uses various key types. Not all DES or Triple DES keys can be used for all symmetric key operations. Likewise, not all public key algorithm (PKA) keys can be used for all asymmetric key operations. This is a list of the various key types which the Coprocessor uses:

#### Master key

This is a clear key, which means that no other key encrypted it. The Coprocessor uses the master key to encrypt all operational keys. The Coprocessor stores the master key in a tamper-responding module. You cannot retrieve the master key from the Coprocessor. The Coprocessor responds to tamper attempts by destroying the master key and destroying its factory certification. The 4769 coprocessors have four master keys: one for encrypting DES keys, one for encrypting PKA keys, one for encrypting AES keys, and one for encrypting APKA keys.

#### **Double-length key-encrypting keys**

Your Coprocessor uses this type of Triple-DES key to encrypt or decrypt other DES or Triple DES keys. Key-encrypting-keys are generally used to transport keys between systems. However, they can also be used for storing keys offline for backup. If key-encrypting-keys are used to transport keys, the clear value of the key-encrypting-key itself must be shared between the two systems. Exporter key-encrypting keys are used for export operations where a key encrypted under the master key is decrypted and then encrypted under the key-encrypting keys. Importer key-encrypting keys are used for import operations where a key encrypted under the key-encrypting key is decrypted and then encrypted under the master key.

#### **Double-length PIN keys**

Your Coprocessor uses this type of key to generate, verify, encrypt, and decrypt PINs used in financial operations. These are Triple DES keys.

#### MAC keys

Your Coprocessor uses this type of key to generate Message Authentication Codes (MAC). These can be either DES or Triple DES keys.

#### Cipher keys

Your Coprocessor uses this type of key to encrypt or decrypt data. These can be AES, DES, or Triple DES keys.

#### Single-length compatibility keys

Your Coprocessor uses this type of key to encrypt or decrypt data and generate MACs. These are DES keys and are often used when encrypted data or MACs are exchanged with systems that do not implement the Common Cryptographic Architecture.

#### **Private keys**

Your Coprocessor uses private keys for generating digital signatures and for decrypting DES or Triple DES keys encrypted by the public key.

#### **Public keys**

Your Coprocessor uses public keys for verifying digital signatures, for encrypting DES or Triple DES keys, and for decrypting data encrypted by the private key.

#### **Key forms**

The Coprocessor works with keys in one of four different forms. The key form, along with the key type, determines how a cryptographic process uses that key. The four forms are:

#### Clear form

The clear value of the key is not protected by any cryptographic means. Clear keys are not usable by the Coprocessor. The clear keys must first be imported into the secure module and encrypted under the master key and then stored outside the secure module.

# **Operational form**

Keys encrypted under the master key are in operational form. They are directly usable for cryptographic operations by the Coprocessor. Operational keys are also called internal keys. All keys that are stored in the system keystore file are operational keys. However, you do not need to store all operational keys in the keystore file.

#### **Export form**

Keys encrypted under an exporter key-encrypting key as the result of an export operation are in export form. These keys are also called external keys. A key in export form can also be described as being in import form if an importer key-encrypting key with the same clear key value as the exporter key-encrypting key is present. You may store keys in export form in any manner you choose except in keystore files.

#### **Import form**

Keys encrypted under an importer key-encrypting key are in import form. Only keys in import form can be used as the source for an import operation. These keys are also called external keys. A key in import form can also be described as being in export form if an exporter key-encrypting key with the same clear key value as the importer key-encrypting key is present. You may store keys in import form in any manner you choose except in keystore files.

#### **Function control vector**

IBM provides a digitally signed value known as a function control vector. This value enables the cryptographic application within the Coprocessor to yield a level of cryptographic service consistent with applicable import regulations and export regulations. The function control vector provides your Coprocessor with the key length information necessary to create keys.

#### **Control vectors**

A control vector, different from a function control vector, is a known value associated with a key that governs the following:

- · Key type
- What other keys this key can encrypt
- · Whether your Coprocessor can export this key
- Other allowed uses for this key

The control vector is cryptographically linked to a key and can not be changed without changing the value of the key at the same time.

#### **Key store file**

An IBM i database file that is used to store keys which you encrypted under the master key of the Coprocessor.

#### Key token

A data structure that can contain a cryptographic key, a control vector, and other information related to the key. Key tokens are used as parameters on most of the CCA API verbs that either act on or use keys.

#### **Features**

Cryptographic Coprocessors provide cryptographic processing capability and a means to securely store cryptographic keys. You can use the Coprocessors with IBM i SSL or with IBM i application programs written by you or an application provider. Cryptographic functions supported include encryption for keeping data confidential, message digests and message authentication codes for ensuring that data has not been changed, and digital signature generation and verification. In addition, the Coprocessors provide basic services for financial PIN, EMV, and SET applications.

**Note:** The IBM 4767 Cryptographic Coprocessor is no longer available but it is still supported.

# IBM 4769 Cryptographic Coprocessors

The primary benefit of the IBM Cryptographic Coprocessors is their provision of a secure environment for executing cryptographic functions and managing cryptographic keys. Master keys are stored in a battery backed-up, tamper-resistant hardware security module (HSM). The HSM is designed to meet Federal Information Processing Standard (FIPS) PUB 140 security requirements.

You can use the Coprocessors with IBM i SSL or with IBM i application programs written by you or an application provider. The 4769 Cryptographic Coprocessor offers improved performance over the 4767.

## **SSL** application features

Establishment of secure sockets layer (SSL) or transport layer security (TLS) sessions requires computationally intensive cryptographic processing. When the Cryptographic Coprocessors are used with IBM i, SSL can offload this intensive cryptographic processing, and free the system CPU for application processing. The Cryptographic Coprocessors also provide hardware-based protection for the private key that is associated with the system's SSL digital certificate.

The 4769 Cryptographic Coprocessor can be used with SSL in several different ways. First, through Digital Certificate Manager the Cryptographic Coprocessors can be used to create and store a private key in the FIPS 140 certified HSM for use by SSL. Secondly, the Cryptographic Coprocessors can be used to create a private key, encrypt it with the master key (all performed within the HSM), and then store the encrypted private key by using the system software in a keystore file. This enables a given private key

to be used by multiple Cryptographic Coprocessor cards. Master keys are always stored in the FIPS 140 certified hardware module. Lastly, if private keys created via Digital Certificate Manager are not created using the Cryptographic Coprocessors, SSL can still use the Cryptographic Coprocessors for offload by simply varying the device description on. This accelerator mode of operation does not provide secure key storage, but it does process cryptographic operations at a much higher rate than in the other two modes.

# **IBM i CCA application features**

You can use your Cryptographic Coprocessor to provide a high-level of cryptographic security for your applications. To implement IBM i applications using the facilities of a Cryptographic Coprocessor you or an applications provider must write an application program using a security application programming interface (SAPI) to access the security services of your Cryptographic Coprocessor. The SAPI for the Cryptographic Coprocessor conforms to the IBM Common Cryptographic Architecture (CCA) and is supplied by IBM i Option 35 CCA Cryptographic Service Provider (CCA CSP).

With IBM i the Cryptographic Coprocessor SAPI supports application software that is written in ILE C, RPG, and Cobol. Application software via the SAPI can call on CCA services to perform a wide range of cryptographic functions, including Tripe-Data Encryption Standard (T-DES), RSA, ECC, MD5, SHA, and RIPEMD-160 algorithms. Basic services supporting financial PIN, EMV2000 (Europay, MasterCard, Visa) standard, and SET (Secure Electronic Transaction) block processing are also available. In support of an optional layer of security the Cryptographic Coprocessor provides a role-based access control facility, which allows you to enable and control access to individual cryptographic operations that are supported by the Coprocessor. The role-based access controls define the level of access that you give to your users.

The SAPI is also used to access the key management functions of the Coprocessor. Key-encrypting keys and data encryption keys can be defined. These keys are generated in the Cryptographic Coprocessor and encrypted under the master key so that you can store these encrypted keys outside of your Coprocessor. You store these encrypted keys in a keystore file, which is an IBM i database file. Additional key management functions include the following:

- Create keys using cryptographically secure random-number generator.
- Import and export encrypted T-DES, RSA, ECC, and AES keys securely.
- · Clone a master key securely.

Multiple Cryptographic Coprocessor cards can be used to meet your performance capacity and/or high-availability requirements. See Manage multiple Cryptographic Coprocessors for more information.

Security APIs for the 4769 Cryptographic Coprocessor are documented in the IBM PCIe Cryptographic Coprocessor CCA Basic Services Reference and Guide, Release 5.6x and 7.x. You can find these and other publications in the IBM PCIe Cryptographic Coprocessor documentation library.

Security APIs for the 4767 Cryptographic Coprocessor are documented in the IBM PCIe Cryptographic Coprocessor CCA Basic Services Reference and Guide, Release 5.6x You can find these and other publications in the IBM PCIe Cryptographic Coprocessor documentation library.

# **Related concepts**

4764 Cryptographic Coprocessor

# **Scenarios: Cryptographic Coprocessor**

To give you some ideas of how you can use this cryptographic hardware with your system running the IBM i operating system, read these usage scenarios.

# Scenario: Protecting private keys with cryptographic hardware

This scenario might be useful for a company that needs to increase the security of the system digital certificate private keys that are associated with the IBM i SSL-secured business transactions.

#### Situation:

A company has a system dedicated to handling business-to-business (B2B) transactions. This company's system specialist, Sam, has been informed by management of a security requirement from its B2B customers. The requirement is to increase the security of the system's digital certificate private keys that are associated with the SSL-secured business transactions that Sam's company performs. Sam has heard that there is a cryptographic hardware option available for systems that both encrypts and stores private keys associated with SSL transactions in tamper-responding hardware: a Cryptographic Coprocessor card.

Sam researches the Cryptographic Coprocessor, and learns that he can use it with the IBM i Digital Certificate Manager (DCM) to provide secure SSL private key storage, as well as increase system performance by off-loading from the system those cryptographic operations which are completed during SSL-session establishment.

**Note:** To support load balancing and performance scaling, Sam can use multiple Cryptographic Coprocessors with SSL on the system.

Sam decides that the Cryptographic Coprocessor meets his company's requirement to increase the security of his company's system.

#### **Details:**

- 1. The company's system has a Cryptographic Coprocessor installed and configured to store and protect private keys.
- 2. Private keys are generated by the Cryptographic Coprocessor.
- 3. Private keys are then stored on the Cryptographic Coprocessor.
- 4. The Cryptographic Coprocessor resists both physical and electronic hacking attempts.

# **Prerequisites and assumptions:**

1. The system has a Cryptographic Coprocessor installed and configured properly. Planning for the Cryptographic Coprocessor includes getting SSL running on the system.

**Note:** To use multiple Cryptographic Coprocessor cards for application SSL handshake processing, and securing private keys, Sam will need to ensure that his application can manage multiple private keys and certificates.

- 2. Sam's company has Digital Certificate Manager (DCM) installed and configured, and uses it to manage public Internet certificates for SSL communications sessions.
- 3. Sam's company obtain certificates from a public Certificate Authority (CA).
- 4. The Cryptographic Coprocessor is varied on prior to using DCM. Otherwise, DCM will not provide a page for selecting a storage option as part of the certificate creation process.

## **Configuration steps:**

Sam needs to perform the following steps to secure private keys with cryptographic hardware on his company's system:

1. Ensure that the prerequisites and assumptions for this scenario have been met.

- 2. Use the IBM Digital Certificate Manager (DCM) to create a new digital certificate, or renew a current digital certificate:
  - a. Select the type of certificate authority (CA) that is signing the current certificate.
  - b. Select the **Hardware** as your storage option for certificate's private key.
  - c. Select which cryptographic hardware device you want to store the certificate's private key on.
  - d. Select a public CA to use.

The private key associated with the new digital certificate is now stored on the Cryptographic Coprocessor specified in Step 2.c. Sam can now go into the configuration for his company's web server and specify that the newly created certificate be used. Once he restarts the web server, it will be using the new certificate.

### **Related concepts**

#### Managing multiple Cryptographic Coprocessors

You can have up to eight Cryptographic Coprocessors per partition. The maximum number of Cryptographic Coprocessors supported per system is dependent on the system mode. This topic provides information on using multiple coprocessors with SSL in systems running the IBM i operating system.

#### Planning for the Cryptographic Coprocessor

This information is pertinent to those planning to install an IBM Cryptographic Coprocessor in their system running the IBM i operating system.

# Configuring the Cryptographic Coprocessor

Configuring your Cryptographic Coprocessor allows you to begin to use all of its cryptographic operations. To configure the Cryptographic Coprocessor on your system running the IBM i operating system, you can either use the Cryptographic Coprocessor configuration Web-based utility or write your own application.

### Configuring the Cryptographic Coprocessor for use with IBM i applications

This topic lists the steps needed to make Cryptographic Coprocessors ready for use with an IBM i application.

#### **Related information**

Managing public Internet certificates for SSL communications sessions

# Scenario: Writing an IBM i application to use the Cryptographic Coprocessor

This scenario could help an IBM i programmer reason through the process of writing a program that calls the Cryptographic Coprocessor to verify user data such as financial personal identification numbers (PINs), which are entered at automatic teller machines (ATMs).

#### **Situation:**

Suppose you are a system programmer for a large financial Credit Union. You have been assigned the task of getting a Cryptographic Coprocessor PCIe card that is installed in the Credit Union system to verify members' financial personal identification numbers (PINs) when they are entered at automatic teller machines (ATMs).

You decide to write an IBM i application program using the CCA CSP (cryptographic service provider) APIs that are a part of Option 35 to access the cryptographic services in the Cryptographic Coprocessors to verify members' PINs. IBM i application programs written for the Cryptographic Coprocessor utilize the coprocessor to perform security-sensitive tasks and cryptographic operations.

**Note:** Multiple Cryptographic Coprocessors can be used via the CCA CSP. The application must control access to individual Coprocessor by using the Cryptographic\_Resource\_Allocate (CSUACRA) and Cryptographic\_Resource\_Deallocate (CSUACRD) CCA APIs.

#### **Details:**

- 1. A Credit Union member enters his or her PIN at an ATM.
- 2. The PIN is encrypted at the ATM, and then sent along the network to the Credit Union's system.
- 3. The system recognizes the transaction request, and calls a program to verify the member's PIN.

- 4. The program sends a request containing the encrypted PIN, member's account number, PIN-generating key, and PIN encrypting key to the Cryptographic Coprocessor.
- 5. The Cryptographic Coprocessor confirms or denies the validity of the PIN.
- 6. The program sends the Cryptographic Coprocessor's results to the ATM.
  - a. If the PIN is confirmed, the member can successfully complete a transaction with the Credit Union.
  - b. If the PIN is denied, the member is unable to complete a transaction with the Credit Union.

# Prerequisites and assumptions:

- 1. Your company has a system with a properly installed and configured Cryptographic Coprocessor. Refer to the following information:
  - a. Plan for the Cryptographic Coprocessor
  - b. Configure the Cryptographic Coprocessor
  - c. Configure the Cryptographic Coprocessor for use with IBM i applications
- 2. You are familiar with Option 35: The Common Cryptographic Architecture Cryptographic Service Provider (CCA CSP). It is packaged as IBM i Option 35, and provides a security application programming interface (SAPI) to which you can write applications that allow you to access the cryptographic services of the Cryptographic Coprocessor.
- 3. You have access to the <u>CCA Basic Services Guide</u> , where you can find Financial Services Support verbs to use in your application.

# **Configuration steps:**

One way to accomplish your objective of using the Cryptographic Coprocessor to validate PINs is to write two IBM i applications:

- 1. Write a program that loads the both the PIN verification keys, and PIN encrypting keys, and stores them in a keystore file. Assuming that clear key parts are used, you need to use the following APIs:
  - Logon Control (CSUALCT)
  - Key\_Part\_Import (CSNBKPI)
  - Key\_Token\_Build (CSNBKTB)
  - Key Record Create (CSNBKRC)
  - Key\_Record\_Write (CSNBKRW)
  - Optional API: KeyStore\_Designate (CSUAKSD)
- 2. Write a second program that calls the Encrypted\_PIN\_Verify (CSNBPVR) API to verify encrypted PINs, and then reports their valid or invalid status back to the ATM.

#### **Related concepts**

#### Secure access

Access control restricts the availability of system resources to only those users you have authorized to interact with the resources. The system allows you to control authorization of users to system resources.

Configuring the Cryptographic Coprocessor

Configuring your Cryptographic Coprocessor allows you to begin to use all of its cryptographic operations. To configure the Cryptographic Coprocessor on your system running the IBM i operating system, you can either use the Cryptographic Coprocessor configuration Web-based utility or write your own application.

# Scenario: Enhancing system SSL performance by using the 4769 Cryptographic Coprocessor

In this scenario, a company orders and installs the 4769 Cryptographic Coprocessor. The scenario specifies the steps this company takes to get the card configured to enhance the SSL performance of its system running the IBM i operating system.

#### **Situation:**

A company's system handles thousands of secured Internet transactions per day. The company's transactions use the Secure Sockets Layer and Transport Layer Security protocols (SSL and TLS), a common method for securing Internet transactions. This company's system administrator, Sue, wants to free system resources for additional application processing, including the ability to support even more SSL transactions. Sue is looking for a solution that fits these objectives:

- A sizeable increase in the available system resources for application processing, including additional SSL transactions
- · Minimal installation and configuration effort
- Minimal resource management requirements

Based on these objectives, Sue orders and installs an IBM 4769 PCIe Cryptographic Coprocessor. The 4769 Cryptographic Coprocessor is specially designed to accelerate the very compute-intensive processing that is required when establishing an SSL and TLS session. You can obtain the IBM 4767 Cryptographic Coprocessor by ordering hardware feature code EJ32 or EJ33. You can obtain the IBM 4769 Cryptographic Coprocessor by ordering hardware feature code EJ35 or EJ37.

#### **Details:**

- 1. The system has a 4769 Cryptographic Coprocessor installed and configured.
- 2. The system receives a high number of SSL transaction requests from the network.
- 3. The 4769 Cryptographic Coprocessor performs the cryptographic processing in the initiation of SSL transactions.

## **Prerequisites and assumptions:**

This scenario assumes that Sue has planned for the installation of the 4769 Cryptographic Coprocessor, and then configured the card properly. This scenario also assumes that Sue has already set up a digital certificate for SSL.

# **Configuration steps:**

Sue completes the following steps to enhance the SSL performance of her company's system:

- 1. Order Hardware Feature code EJ35 or EJ37, which provides the 4769 Cryptographic Coprocessor.
  - 2. Install and configure the 4769 Cryptographic Coprocessor.
  - 3. Ensure that the device is varied on and that the function control vector is loaded.

#### **Related concepts**

Loading a function control vector

The function control vector tells the Cryptographic Coprocessor for the system running the IBM i operating system what key length to use to create keys. You cannot perform any cryptographic functions without loading a function control vector.

# **Planning for the Cryptographic Coprocessor**

This information is pertinent to those planning to install an IBM Cryptographic Coprocessor in their system running the IBM i operating system.

# Before you install

It is important that you take ensure your system meets the requirements necessary for the Cryptographic Coprocessor, prior to installing it. These requirements include hardware and software prerequisites. Additionally, you need to ensure the secure access of your system's resources prior to installing a Cryptographic Coprocessor. Lastly, familiarize yourself with the object authorities that are required for the security APIs (SAPI). [link to related topics here]

- · Requirements
- · Secure access
- · Object authorities required for SAPI

#### **Related concepts**

Scenario: Protecting private keys with cryptographic hardware

This scenario might be useful for a company that needs to increase the security of the system digital certificate private keys that are associated with the IBM i SSL-secured business transactions.

# Requirements

Your system must run the IBM i operating system and must meet these requirements before you install and use the Cryptographic Coprocessors.

**Note:** The IBM 4767 Cryptographic Coprocessor is no longer available, but it is still supported.

## Requirements for the 4769 Cryptographic Coprocessor

The 4769 Cryptographic Coprocessor can be ordered by specifying Hardware Feature Code EJ35 or EJ37, depending on the system model. Refer to the IBM Power Systems Hardware Information Center to determine which system models support the Cryptographic Coprocessors.

Your Cryptographic Coprocessor is a PCIe card and requires the following software:

- IBM i: The 4769 Cryptographic Coprocessor requires IBM i 7.3 or later.
- IBM i Option 35 Common Cryptographic Architecture Cryptographic Service Provider (CCA CSP) provides the SAPI.
- IBM i 5733-CY3 Cryptographic Device Manager provides the CCA firmware for the 4764, 4765, 4767, and 4769 Cryptographic Coprocessors.
- IBM i Option 34 Digital Certificate Manager (if you are planning on using the Cryptographic Coprocessor configuration web-based utility).
- IBM i 5770—TC1 TCP/IP Connectivity Utilities (if you are planning on using the Cryptographic Coprocessor configuration web-based utility).
- IBM i 5770–DG1 IBM HTTP Server (if you are planning on using the Cryptographic Coprocessor configuration web-based utility).

**Hardware note:** The Cryptographic Coprocessors destroy their factory certification if allowed to cool below -15 degrees C (5 degrees F). If your Coprocessor destroys its factory certification, you can no longer use the card, and you must contact your hardware service provider to order a new Cryptographic Coprocessor.

#### **Related concepts**

4769 Cryptographic Coprocessor

IBM offers Cryptographic Coprocessors, which are available on a variety of system models. Cryptographic Coprocessors contain hardware engines, which perform cryptographic operations used by IBM i application programs and IBM i SSL transactions.

4764 Cryptographic Coprocessor

#### **Related information**

IBM Power Systems Hardware Information Center

#### **Secure access**

Access control restricts the availability of system resources to only those users you have authorized to interact with the resources. The system allows you to control authorization of users to system resources.

Your organization should identify each system resource in the organization's security hierarchy. The hierarchy should clearly delineate the levels of access authorization users have to resources.

All of the service programs in IBM i Option 35 are shipped with \*EXCLUDE authority for \*PUBLIC. You must give users \*USE authority for the service program that they need to use. In addition, you must also give users \*USE authority to the QC6SRV service program in library QCCA.

Users who take part in setting up a Cryptographic Coprocessor must have \*IOSYSCFG special authority to use the Master\_Key\_Process (CSNBMKP), Access\_Control\_Initialize (CSUAACI), or Cryptographic\_Facility\_Control (CSUACFC) security application programming interfaces (SAPIs). These three SAPIs are used to perform all configuration steps for the Cryptographic Coprocessors. For all SAPIs, users may require additional object authorities.

For the most secure environments, consider assigning the role of Coprocessor Administrators to a set of users who do not have \*ALLOBJ special authority. This way, users with \*ALLOBJ special authority cannot alter the configuration of the Coprocessor because they will not be able to log on to an administrative role on the Coprocessor. They can, however, control object authority to the SAPI service programs, preventing misuse by the administrators.

In order to use the Cryptographic Coprocessor configuration web utility, users must have \*SECADM special authority.

Cryptographic Coprocessors have separate access controls which are unrelated to the access controls of the system. The Cryptographic Coprocessor access controls allow you to control access to the Cryptographic Coprocessor hardware commands.

For even more security, limit the capabilities of the default role within your Cryptographic Coprocessor. Assign capabilities among other roles to require two or more people to perform security-sensitive functions, like changing the master key. You can do this when you work with roles and profiles.

**Note:** You should consider some standard physical security measures as well, such as keeping your system behind a locked door.

### **Related concepts**

Creating and defining roles and profiles

Cryptographic Coprocessors on systems running the IBM i operating system use role-based access control. In a role-based system, you define a set of roles, which correspond to the classes of Coprocessor users. You can enroll each user by defining an associated user profile to map the user to one of the available roles.

<sup>&</sup>lt;sup>1</sup>Use of AES or Data Encryption Standard (DES) or public key algorithm (PKA) keystore for this API is optional.

<sup>5\*</sup>USE authority for the PKA keystore library is required if \*USE or \*CHANGE authority is required for the PKA keystore.

<sup>6\*</sup>USE authority for the AES keystore library is required if \*USE or \*CHANGE authority is required for the AES keystore.

#### **Related concepts**

Secure access

Access control restricts the availability of system resources to only those users you have authorized to interact with the resources. The system allows you to control authorization of users to system resources.

# Configuring the Cryptographic Coprocessor

Configuring your Cryptographic Coprocessor allows you to begin to use all of its cryptographic operations. To configure the Cryptographic Coprocessor on your system running the IBM i operating system, you can either use the Cryptographic Coprocessor configuration Web-based utility or write your own application.

The easiest and fastest way to configure your Cryptographic Coprocessor is to use the Cryptographic Coprocessor configuration web-based utility found by clicking on the IBM i Tasks Page link on the IBM Navigator for i welcome page at http://server-name:2001. The utility includes the Basic configuration wizard that is used for configuring (and initializing) a Coprocessor that has not been previously configured. If HTTP and SSL have not been previously configured, you will need to do the following before using the Configuration Wizard.

- Start the HTTP Administrative server.
- Configure the HTTP Administrative server to use SSL.
- Use DCM to create a certificate, specifying that the private key be generated and stored in software.
- Use DCM to receive the signed certificate.
- Associate the certificate with the HTTP Administrative server application ID.
- Restart the HTTP Administrative server to enable it for SSL processing.

<sup>&</sup>lt;sup>2</sup>More than one parameter may optionally use keystore. The authority requirements differ on each of those parameters.

<sup>&</sup>lt;sup>3</sup>The Key\_Store\_Initialize SAPI does not require authority to all three files simultaneously.

<sup>&</sup>lt;sup>4\*</sup>USE authority for the DES keystore library is required if \*USE or \*CHANGE authority is required for the DES keystore.

If the Cryptographic Coprocessor has already been configured, then click on the **Manage configuration** option to change the configuration for specific portions of the Coprocessor.

If you would prefer to write your own application to configure the Coprocessor, you can do so by using the Cryptographic\_Facility\_Control (CSUACFC), Access\_Control\_Initialize (CSUAACI), Master\_Key\_Process (CSNBMKP), and Key\_Store\_Initialize (CSNBKSI) API verbs. Many of the pages in this section include one or more program examples that show how to configure the Coprocessor via an application. Change these programs to suit your specific needs.

Whether you choose to use the Cryptographic Coprocessor configuration utility or write your own applications, the following outlines the steps you must take to properly configure your Cryptographic Coprocessor:

### **Related concepts**

Scenario: Protecting private keys with cryptographic hardware

This scenario might be useful for a company that needs to increase the security of the system digital certificate private keys that are associated with the IBM i SSL-secured business transactions.

Configuring the Cryptographic Coprocessor for use with DCM and SSL

This topic provides information on how to make the Cryptographic Coprocessor ready for use with SSL in IBM i.

Scenario: Writing an IBM i application to use the Cryptographic Coprocessor

This scenario could help an IBM i programmer reason through the process of writing a program that calls the Cryptographic Coprocessor to verify user data such as financial personal identification numbers (PINs), which are entered at automatic teller machines (ATMs).

# **Creating a device description**

The device description specifies a default location for key storage. You can create a device description with or without naming any keystore files for the Cryptographic Coprocessor on your system running the IBM i operating system.

You must create a device description for your Cryptographic Coprocessor on your system. The device description is used by CCA CSP to help direct cryptographic requests to the Coprocessor. Additionally, the device description gives your Coprocessor a default location for keystore file storage. The Basic configuration wizard in the Cryptographic Coprocessor configuration utility, found by clicking on the IBM i Tasks page link on the IBM Navigator for i welcome page at http://server-name:2001, can create a device description for you, or you can create a device description yourself by using the **Create Device Crypto CL** command.

To create a device description using the Basic configuration wizard, follow these steps:

- 1. Point your web browser to the IBM i Tasks page by clicking on the IBM i Tasks page link on the IBM Navigator for i welcome page at http://server-name:2001
- 2. Click on Cryptographic Coprocessor configuration.
- 3. Click on the button labeled Start secure session.
- 4. Click **Basic configuration** wizard.
- 5. Click **continue** on the **Welcome** page.
- 6. Click on the list entry with the device name set to \*CREATE for the resource you want to use.
- 7. Continue as instructed by the Basic configuration wizard.

#### Creating a device description using CL

To create a device description using the CL command, follow these steps:

- 1. Type CRTDEVCRP at the CL command line
- 2. Specify a name for the device as prompted. If you want to set up a default device, name the device CRP01. Otherwise, each application you create must use the Cryptographic Resource Allocate (CSUACRA) API in order to access your device description.

- 3. Specify the name of a default PKA keystore file or let the parameter default to \*NONE.
- 4. Specify the name of a default DES keystore file or let the parameter default to \*NONE.
- 5. Specify a description as prompted.
- 6. Use either the Vary Configuration (VRYCFG) or the Work with Configuration Status (WRKCFGSTS) CL commands to vary on the device once you have created the device description. This typically takes one minute, but it may take ten minutes to complete.

**Note:** The APPTYPE defaults to \*CCA, so you do not need to specify it on the **Create** command. However, if you have changed it to another value, you need to change it back to \*CCA before the device can vary on.

You have now completed creation of the device description.

# Naming files to keystore file

Before you can perform any operation in IBM i using a keystore file or key stored in a keystore file, you must name the keystore file.

You can name three types of keystore files. One type stores Data Encryption Standard (DES) keys and Triple-DES keys. The second type stores Advanced Encryption Standard (AES) keys. AES, DES, and Triple DES are symmetric cryptographic algorithms; the Cryptographic Coprocessor uses the same key to encrypt and decrypt. The third type stores public key algorithm (PKA) keys. Public key algorithms are asymmetric; keys are created in pairs. Cryptographic Coprocessors use one key to encrypt and the other to decrypt. Cryptographic Coprocessors support the RSA public key algorithm and the Elliptic Curve public key algorithm.

You can name a keystore file using three methods:

- Use a program to name the keystore file explicitly
- Configure the keystore file on the device description
- Name the keystore file in an environment variable

To name a keystore file from a program, use the Key\_Store\_Designate (CSUKSD) security application programming interface (SAPI). If you name keystore files that use a program, your Cryptographic Coprocessor only uses the names for the job that ran the program. However, by naming keystore files explicitly in your program, you can use separate keystore files from other users.

If you name keystore files on the device description, you do not have to name them in your program. This option is only available for DES and PKA keystores.

To name a keystore file in an environment variable, use the Add Environment Variable (ADDENVVAR) CL command to add the QIBM\_CCA\_AES\_KEYSTORE variable for AES keystores, or the QIBM\_CCA\_DES\_KEYSTORE variable for DES keystores, or the QIBM\_CCA\_PKA\_KEYSTORE variable for PKA keystores.

Using the device description or environment variables may help if you are trying to maintain the same program source across multiple IBM platforms. It is also useful if you are porting a program from another implementation of Common Cryptographic Architecture.

You need to store your cryptographic keys in a secure form so that you can use them over time and exchange them with other users and systems, as appropriate. You can store your cryptographic keys by using your own methods, or you can store them in a keystore file. You can have as many keystore files as you want, and you can create multiple keystore files for each type of key. You can place as many cryptographic keys in your keystore files as you want.

Since each keystore file is a separate system object, you can authorize different users to each file. You can save and restore each keystore file at different times. This depends on how often the file's data changes or which data it is protecting.

# Creating and defining roles and profiles

Cryptographic Coprocessors on systems running the IBM i operating system use role-based access control. In a role-based system, you define a set of roles, which correspond to the classes of Coprocessor

**36** IBM i: Cryptography

users. You can enroll each user by defining an associated user profile to map the user to one of the available roles.

The capabilities of a role are dependent on the access control points or cryptographic hardware commands that are enabled for that role. You can then use your Cryptographic Coprocessor to create profiles that are based on the role you choose.

A role-based system is more efficient than one in which the authority is assigned individually for each user. In general, you can separate the users into just a few different categories of access rights. The use of roles allows you to define each of these categories just once, in the form of a role.

The role-based access control system and the grouping of permissible commands that you can use are designed to support a variety of security policies. In particular, you can set up Cryptographic Coprocessors to enforce a dual-control, split-knowledge policy. Under this policy no one person should be able to cause detrimental actions other than a denial-of-service attack, once the Cryptographic Coprocessor is fully activated. To implement this policy, and many other approaches, you need to limit your use of certain commands. As you design your application, consider the commands you must enable or restrict in the access-control system and the implications to your security policy.

Every Cryptographic Coprocessor must have a role called the default role. Any user that has not logged on to the Cryptographic Coprocessor will operate with the capabilities defined in the default role. Users who only need the capabilities defined in the default role do not need a profile. In most applications, the majority of the users will operate under the default role, and will not have user profiles. Typically, only security officers and other special users need profiles.

When Cryptographic Coprocessors are in an un-initialized state, the default role has the following access control points enabled:

- PKA96 One Way Hash
- · Set Clock
- · Re-initialize Device
- Initialize access control system roles and profiles
- · Change the expiration data in a user profile
- Reset the logon failure count in a user profile
- · Read public access control information
- Delete a user profile
- Delete a role

The default role is initially defined such that the functions permitted are those functions that are related to access control initialization. This guarantees that the Cryptographic Coprocessor will be initialized before you do any useful cryptographic work. The requirement prevents security "accidents" in which someone might accidentally leave authority intact when you put the Coprocessor into service.

**Note:** The default role for previous adapters (4764, 4765, and 4767) is an ASCII encoded string named "DEFAULT". The default role for the 4769 adapter is an ASCII encoded string of the form "DFLTXXXX", such that XXXX refers to the domain of the adapter. The 4769 currently only operates in stand alone mode such that the default role will run under the authorities granted to "DFLT0000". The 4769 also includes a pre-defined role "INITADM" and established roles for possible other (future) domains numbered up to 255. These roles and variations of them should be considered reserved and not used when creating other role authorities for managing a 4769 cryptographic coprocessor environment.

Note: Read the "Code license and disclaimer information" on page 234 for important legal information.

## **Defining roles**

The easiest and fastest way to define new roles (and redefine the default role) is to use the Cryptographic Coprocessor configuration web-based utility found by clicking on the IBM i Tasks page link on the IBM Navigator for i welcome page at http://server-name:2001. The utility includes the Basic configuration wizard that is used when the Coprocessor is in an un-initialized state. The Basic configuration wizard can

define either 1 or 3 administrative roles along with redefining the default role. If the Coprocessor already has been initialized, then click on **Manage configuration** and then click on **Roles** to define new roles or change or delete existing ones.

If you would prefer to write your own application to manage roles, you can do so by using the Access\_Control\_Initialization (CSUAACI) and Access\_Control\_Maintenance (CSUAACM) API verbs. To change the default role in your Coprocessor, specify "DEFAULT" (4767) or "DFLT0000" (4769) encoded in ASCII into the proper parameter. "DEFAULT" must be padded with one ASCII space character for a total of eight characters. Otherwise, there are no restrictions on the characters that you may use for role IDs or profile IDs.

# **Defining profiles**

After you create and define a role for your Coprocessor, you can create a profile to use under this role. A profile allows users to access specific functions for your Coprocessor that may not be enabled for the default role.

The easiest and fastest way to define new profiles is to use the Cryptographic Coprocessor configuration web-based utility found by clicking on the IBM i Tasks page link on the IBM Navigator for i welcome page at http://server-name:2001. The utility includes the Basic configuration wizard that is used when the Coprocessor is in an un-initialized state. The Basic configuration wizard can define either one or three administrative profiles. If the Coprocessor has already been initialized, click **Manage configuration** > **Profiles** to define new profiles or change or delete existing ones.

If you want to write your own application to manage profiles, you can use the Access\_Control\_Initialization (CSUAACI) and Access\_Control\_Maintenance (CSUAACM) API verbs.

# **Coprocessor for SSL**

If you will be using the Coprocessor for SSL, the default role must at least be authorized to the following access control points:

- Digital Signature Generate
- · Digital Signature Verify
- PKA Key Generate
- PKA Clone Key Generate
- RSA Encipher Clear Data
- RSA Decipher Clear Data
- Delete Retained Key
- · List Retain Keys

The Basic configuration wizard in the Cryptographic Coprocessor configuration utility automatically redefines the default role such that it can be used for SSL without any changes.

To avoid security hazards, consider denying the following access control points (also called cryptographic hardware commands) for the default role, after you have set up all of the roles and profiles:

**Note:** You should enable only those access control points that are necessary for normal operations. At a maximum, you should only enable specifically required functions. To determine which access control points are required, refer to the CCA Basic Services Guide. Each API lists the access control points that are required for that API. If you do not need to use a particular API, consider disabling the access control points that are required for it.

- Load first part of Master Key
- · Combine Master Key Parts
- · Set Master Kev
- Generate Random Master Key
- · Clear New Master Key Register

**38** IBM i: Cryptography

- Clear Old Master Key Register
- Translate CV
- · Set Clock

**Attention:** If you intend to disable the Set Clock access control point from the default role, ensure that the clock is set before you disable access. The clock is used by the Coprocessor when users try to log on. If the clock is set incorrectly, users can not log on.

- · Re-initialize device
- · Initialize access control system
- Change authentication data (for example, pass phrase)
- Reset password failure count
- Read Public Access Control Information
- Delete user profile
- Delete role
- · Load Function Control Vector
- Clear Function Control Vector
- Force User Logoff
- Set EID
- Initialize Master Key Cloning Control
- Register Public Key Hash
- · Register Public Key, with Cloning
- Register Public Key
- PKA Clone Key Generate (Access control point required for SSL)
- Clone-Information Obtain Parts 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15
- Clone-Information Install Parts 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15
- Delete retained key (Access control point required for SSL)
- List retained keys (Access control point required for SSL)
- Encipher Under Master Key
- · Data Key Export
- · Data Key Import
- · Re-encipher to Master Key
- Re-encipher from Master Key
- · Load First Key Part
- · Combine Key Parts
- Add Key Part
- · Complete Key part
- Clear AES New Master Key
- Clear APKA New Master Key
- Clear New Asymmetric Master Key
- Clear AES Old Master Key
- · Clear APKA Old Master Key
- Clear Old Asymmetric Master Key
- · Load First AES Master Key Part
- · Load First APKA Master Key Part

- · Load First Asymmetric Master Key Part
- · Combine AES Master Key Parts
- · Combine APKA Master Key Parts
- Combine Asymmetric Master Key Parts
- · Activate New AES Master Key
- Activate New APKA Master Key
- · Set Asymmetric Master Key

For the most secure environment, consider locking the access-control system after initializing it. You can render the access-control system unchangeable by deleting any profile that would allow use of the Access Control Initialization or the Delete Role access control point. Without these access control points, further changes to any role are not possible. With authority to use either the Initialize Access Control or Delete Role access control points, one can delete the DEFAULT role.

Deleting the DEFAULT role will cause the automatic recreation of the initial DEFAULT role. The initial DEFAULT role permits setting up any capabilities. Users with access to these access control points have unlimited authority through manipulation of the access-control system. Before the Coprocessor is put into normal operation, the access-control setup can be audited through the use of the Access\_Control\_Maintenance (CSUAACM) and Cryptographic\_Facility\_Query (CSUACFQ) API verbs.

If for any reason the status response is not as anticipated, the Coprocessor should not be used for application purposes until it has been configured again to match your security policy. If a role contains permission to change a pass phrase, the pass phrase of any profile can be changed. You should consider if passphrase changing should be permitted and, if so, which role(s) should have this authority.

If any user reports an inability to log on, this should be reported to someone other than (or certainly in addition to) an individual with pass phrase changing permission. Consider defining roles so that dual-control is required for every security sensitive operation to protect against a malicious insider acting on his/her own. For example, consider splitting the following groups of access control points between two or more roles. It is recommended that one person should not be able to use all of the commands in the Master key group, because this could represent a security risk.

The Master key group consists of these access control points:

- Load 1st part of Master Key
- · Combine Master Key Parts
- · Set Master Key
- Generate Random Master Key
- · Clear New Master Key Register
- · Clear Old Master Key Register

By the same token, one person should not be authorized to all of the commands in the Cloning key group.

The Cloning key group consists of these access control points:

- Initialize Master Key Cloning Control
- Register Public Key Hash
- · Register Public Key, with Cloning
- Register Public Key
- PKA Clone Key Generate
- Clone-Information Obtain Parts 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15
- Clone-Information Install Parts 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15

After you create and define a profile for your Coprocessor, you must load a function control vector for your Coprocessor. Without the function control vector, your Coprocessor cannot perform any cryptographic functions.

**40** IBM i: Cryptography

# **Coprocessor for IBMJCECCAI50S JCE provider**

If you will be using the Coprocessor for the IBMJCECCAI5OS JCE provider, the default role must at least be authorized to the following access control points:

- Digital Signature Generate
- Digital Signature Verify
- · PKA Key Generate
- PKA Key Import
- PKA Encipher Clear Key
- PKA Decipher Clear Key
- · Delete Retained Key
- · List Retained Key Names
- · Generate Key

The Basic configuration wizard in the Cryptographic Coprocessor configuration utility automatically redefines the default role such that it can be used with the IBMJCECCAI5OS JCE provider without any changes.

# **Related concepts**

#### Secure access

Access control restricts the availability of system resources to only those users you have authorized to interact with the resources. The system allows you to control authorization of users to system resources.

#### Loading a function control vector

The function control vector tells the Cryptographic Coprocessor for the system running the IBM i operating system what key length to use to create keys. You cannot perform any cryptographic functions without loading a function control vector.

#### Creating and defining roles and profiles

Cryptographic Coprocessors on systems running the IBM i operating system use role-based access control. In a role-based system, you define a set of roles, which correspond to the classes of Coprocessor users. You can enroll each user by defining an associated user profile to map the user to one of the available roles.

# Example: ILE C program for enabling all access control points in the default role for your Coprocessor

Change this IBM i ILE C program example to suit your needs for enabling all access control points in the default role for your Coprocessor.

**Note:** Read the "Code license and disclaimer information" on page 234 for important legal information.

```
SETDEFAULT
    Sample program to authorize the default role to all access
                                                                                       */
    control points in the cryptographic coprocessor.

Creating and defining roles and profiles

Cryptographic Coprocessors on systems running the IBM i operating system use role-based access control. In a role-based system, you define a set of roles, which correspond to the classes of Coprocessor users. You can enroll each user by defining an associated user profile to map the user to one of the available roles.

# Example: ILE RPG program for creating roles or profiles for your Coprocessor

Change this IBM i ILE RPG program example to suit your needs for creating roles and profiles for your Coprocessor.

Note: Read the "Code license and disclaimer information" on page 234 for important legal information.

CSUAACI failed with return/reason codes 9999/9999.
SECOFR1, SECOFR2, and SECOFR3 profiles were successfully created. The Default role was successfully changed.
```

Creating and defining roles and profiles

Cryptographic Coprocessors on systems running the IBM i operating system use role-based access control. In a role-based system, you define a set of roles, which correspond to the classes of Coprocessor users. You can enroll each user by defining an associated user profile to map the user to one of the available roles.

# Example: ILE RPG program for enabling all access control points in the default role for your Coprocessor

Change this IBM i ILE RPG program example to suit your needs for enabling all access control points in the default role for your Coprocessor.

Note: Read the "Code license and disclaimer information" on page 234 for important legal information.

Creating and defining roles and profiles

Cryptographic Coprocessors on systems running the IBM i operating system use role-based access control. In a role-based system, you define a set of roles, which correspond to the classes of Coprocessor users. You can enroll each user by defining an associated user profile to map the user to one of the available roles.

# Example: ILE C program for changing an existing profile for your Coprocessor

Change this IBM i ILE C program example to suit your needs for changing an existing profile for your Coprocessor.

Note: Read the "Code license and disclaimer information" on page 234 for important legal information.

```
/* Change certain fields in a user profile on the
/* card. This program changes the expiration date using a new
/* date in the form YYYYMMDD.
/* COPYRIGHT 5769-SS1 (C) IBM CORP. 1999, 2007
/* This material contains programming source code for your
/* This material contains programming source code for your
/* consideration. These examples have not been thoroughly
/* tested under all conditions. IBM, therefore, cannot
/* guarantee or imply reliability, serviceability, or function
/* of these program. All programs contained herein are

Creating and defining roles and profiles

Cryptographic Coprocessors on systems running the IBM i operating system use role-based access control. In a role-based system, you define a set of roles, which correspond to the classes of Coprocessor users. You can enroll each user by defining an associated user profile to map the user to one of the available roles.

# Setting the environment ID and clock

The Cryptographic Coprocessor on your system running the IBM i operating system uses the EID to verify which Coprocessor created a key token. It uses the clock for time and date stamping and to control whether a profile can log on.

Note: Read the "Code license and disclaimer information" on page 234 for important legal information.

## The Environment ID (EID)

Your Coprocessor stores the EID as an identifier. The easiest and fastest way to set the EID is to use the Cryptographic Coprocessor configuration web-based utility found by clicking on the IBM i Tasks page link on the IBM Navigator for i welcome page at http://server-name:2001. The utility includes the Basic configuration wizard that is used when the Coprocessor is in an un-initialized state. If the Coprocessor already has been initialized, then click on **Manage configuration** and then click on **Attributes** to set the EID.

If you would prefer to write your own application to set the EID, you can do so by using the Cryptographic\_Facility\_Control (CSUACFC) API verb. Two example programs are provided for your consideration. One of them is written in ILE C, while the other is written in ILE RPG. Both perform the same function.

Your Cryptographic Coprocessor copies the EID into every PKA key token that your Coprocessor creates. The EID helps the Coprocessor identify keys that it created as opposed to keys that another Coprocessor created.

#### The clock

The Coprocessor uses its clock-calendar to record time and date and to determine whether a profile can log on. The default time is Greenwich Mean Time (GMT). Because of its function, you should set the clock inside your Coprocessor before removing the default role's capability of setting it.

The easiest and fastest way to set the clock is to use the Cryptographic Coprocessor configuration web-based utility found by clicking on the IBM i Tasks page link on the IBM Navigator for i welcome page at http://server-name:2001. The utility includes the Basic configuration wizard that is used when the Coprocessor is in an un-initialized state. If the Coprocessor already has been initialized, then use click on **Manage configuration** and then click on **Attributes** to set the clock.

If you would prefer to write your own application to set the clock, you can do so by using the Cryptographic Facility Control (CSUACFC) API verb.

Setting the environment ID and clock

The Cryptographic Coprocessor on your system running the IBM i operating system uses the EID to verify which Coprocessor created a key token. It uses the clock for time and date stamping and to control whether a profile can log on.

## Example: ILE C program for setting the clock on your Coprocessor

Change this IBM i ILE C program example to suit your needs for setting the clock on your Coprocessor.

```
/* Set the clock on the card, based on a string from
/* the command line. The command line string must be of
/* form YYYYMMDDHHMMSSWW, where WW is the day of week (01
/* means Sunday and 07 means Saturday).
/* COPYRIGHT 5769-SS1 (C) IBM CORP. 1999, 2007
/* This material contains programming source code for your
/* consideration. These examples have not been thoroughly
/* tested under all conditions. IBM, therefore, cannot
/* guarantee or imply reliability, serviceability, or function
/* of these program. All programs contained herein are
/* provided to you "AS IS". THE IMPLIED WARRANTIES OF
/* MERCHANTABILITY AND FITNESS FOR A PARTICULAR PURPOSE ARE
     ARE EXPRESSLY DISCLAIMED. IBM provides no program services for
    these programs and files.
/*
/* Note: Input format is more fully described in Chapter 2 of
           IBM CCA Basic Services Reference and Guide
/*
           (SC31-8609) publication.
   Parameters:
/*
      char * new time 16 characters
      CALL PGM(SETCLOCK) PARM('1999021011375204')
/* Note: This program assumes the device to use is
           already identified either by defaulting to the CRP01 device or by being explicitly named using the
,
/*
           Cryptographic_Resource_Allocate verb. Also this
/*
/*
           device must be varied on and you must be authorized
           to use this device description.
/\star Use these commands to compile this program on the system:
/* ADDLIBLE LIB(QCCA)
/* CRTCMOD MODULE(SETCLOCK) SRCFILE(SAMPLE)
/* CRTPGM PGM(SETCLOCK) MODULE(SETCLOCK)
/*
             BNDSRVPGM(QCCA/CSUACFC)
/*
/* Note: Authority to the CSUACFC service program in the
           QCCA library is assumed.
```

```
/* The Common Cryptographic Architecture (CCA) verb used is
/* Cryptographic_Facilities_Control (CSUACFC).
#include "csucincl.h"

CSUACFC failed with return/reason codes 9999/9999.
The request completed successfully.
This program loads the time and date into the card.
It requires a single command line parameter containing the new date and time in the form YYYYMMDDHHMMSSWW, where WW is the
day of the week, 01 meaning Sunday and 07 meaning Saturday.
```

Setting the environment ID and clock

The Cryptographic Coprocessor on your system running the IBM i operating system uses the EID to verify which Coprocessor created a key token. It uses the clock for time and date stamping and to control whether a profile can log on.

## Loading a function control vector

The function control vector tells the Cryptographic Coprocessor for the system running the IBM i operating system what key length to use to create keys. You cannot perform any cryptographic functions without loading a function control vector.

After you create and define role and profile, you must load a function control vector (FCV) for your Cryptographic Coprocessor. Without it, your Coprocessor will be unable to perform any cryptographic operations.

A function control vector is a digitally signed value stored in a file provided by IBM. When you install IBM i Option 35, two stream files are copied to the /QIBM/ProdData/CAP directory:

#### **FCV.CRT**

Contains the FCV for the 4764

#### FCV4765.CRT

Contains the FCV for the 4765

When you install 5733-CY3 a stream file is placed in the /QIBM/ProdData/CryptoDevMgr directory:

#### FCVECC4765.CRT

Contains the FCV for the 4765 that enables ECC

#### **FCV4767.CRT**

Contains the FCV for the 4767

#### **FCV4769.CRT**

Contains the FCV for the 4769

These values enable the cryptographic application within the Coprocessor to yield a level of cryptographic service consistent with applicable import and export regulations.

The easiest and fastest way to load the FCV is to use the Cryptographic Coprocessor configuration web-based utility found by clicking on the IBM i Tasks page link on the IBM Navigator for i welcome page at http://server-name:2001. The utility includes the Basic configuration wizard that is used when the Coprocessor is in an un-initialized state. If the Coprocessor has already been initialized, then click on **Manage configuration** and then click on **Attributes** to load the FCV.

If you would prefer to write your own application to load the FCV, you can do so by using the Cryptographic\_Facility\_Control (CSUACFC) API verb.

Two other example programs are provided that show how to clear the function control vector. One of them is written in ILE C, while the other is written in ILE RPG.

After you load a function control vector for your Coprocessor, you can load and set a master key using master key to use to encrypt keys.

**Note:** Read the "Code license and disclaimer information" on page 234 for important legal information.

#### **Related concepts**

### Creating and defining roles and profiles

Cryptographic Coprocessors on systems running the IBM i operating system use role-based access control. In a role-based system, you define a set of roles, which correspond to the classes of Coprocessor users. You can enroll each user by defining an associated user profile to map the user to one of the available roles.

### Loading and setting a master key

After you load a function control vector, load and set the master key. The master key is used to encrypt other keys. It is a special key-encrypting key stored within the Coprocessor secure module on systems running the IBM i operating system.

Scenario: Enhancing system SSL performance by using the 4769 Cryptographic Coprocessor

In this scenario, a company orders and installs the 4769 Cryptographic Coprocessor. The scenario specifies the steps this company takes to get the card configured to enhance the SSL performance of its system running the IBM i operating system.

# Example: ILE C program for loading a function control vector for your Cryptographic Coprocessor

Change this IBM i ILE C program example to suit your needs for loading a function control vector for your Cryptographic Coprocessor.

```
/* Load the Function Control Vector into the 4765 card.
/★ The Function Control Vector enables the cryptographic
/* functions of the 4765.
                                                                                             */

## Loading and setting a master key

After you load a function control vector, load and set the master key. The master key is used to encrypt other keys. It is a special key-encrypting key stored within the Coprocessor secure module on systems running the IBM i operating system.

After you load a function control vector, you can load and set a master key. The Coprocessor uses the master key to encrypt all operational keys. The master key is a special key-encrypting key stored in the clear (not encrypted) within the Coprocessor secure module. Your Coprocessor uses the master key to encrypt other keys so that you can store those keys outside of your Coprocessor. The master key is a 168-bit key formed from at least two 168-bit parts exclusive ORed together.

Note: Read the "Code license and disclaimer information" on page 234 for important legal information.

## Loading a master key

There are three registers for your master keys: New, Current, and Old. The new master key register is used to hold a pending master key while it is being built. It is not used to encrypt any keys. The Current master key register holds the master key that is currently being used to encrypt newly generated/imported/re-enciphered keys. The old master key register holds the previous master key. It is used to recover keys after a master key change has occurred. When you load a master key, the Coprocessor places it into the New master key register. It remains there until you set the master key.

Choose one of these three ways to create and load a master key, based on your security needs:

- Load the first key parts and the subsequent key parts separately to maintain split knowledge of the key as a whole. This is the least secure method, but you can increase security by giving each key part to a separate individual.
- Use random key generation, which will remove any human knowledge of the key. This is the most secure method for loading a master key, but you will need to clone this randomly generated master key into a second Cryptographic Coprocessor in order to have a copy of it.
- Use a pre-existing master key by cloning it from another Coprocessor.

## Setting a master key

Setting the master key causes the key in the Current master key register to move to the Old master key register. Then, the master key in the New master key register moves to the Current master key register.

**Note:** It is vital for retrieval of data encrypted by the master key that you have a backup copy of the master key at all times. For example write it on a piece of paper, and make sure that you store the backup copy with appropriate security precautions. Or, clone the master key to another Coprocessor.

The easiest and fastest way to load and set master keys is to use the Cryptographic Coprocessor configuration web-based utility found by clicking on the IBM i Tasks page link on the IBM Navigator for i welcome page at http://server-name:2001. The utility includes the Basic configuration wizard that is used when the Coprocessor is in an un-initialized state. If the Cryptographic Coprocessor already has been initialized, then click on **Manage configuration** and then click on **Master keys** to load and set master keys.

If you would prefer to write your own application to load and set master keys, you can do so by using the Master\_Key\_Process (CSNBMKP) API verb.

## **Re-encrypting keys**

When you set a master key, you should re-encrypt all keys that were encrypted under the former master key to avoid losing access to them. You must do this before you change and set the master key.

You can re-encrypt keys in keystore by using the Cryptographic Coprocessor configuration web-based utility found by clicking on the IBM i Tasks page link on the IBM Navigator for i welcome page at http://server-name:2001. The Cryptographic Coprocessor must have already been initialized. Click on "Manage configuration" and then click on either "DES keys" to re-encrypt DES keys, or "PKA keys" to re-encrypt PKA keys.

If you have keys that are not in keystore or if you would prefer to write your own application to re-encrypt keys, you can do so by using the Key\_Token\_Change (CSNBKTC) or PKA\_Key\_Token\_Change (CSNDKTC) API verbs.

An example program is provided for your consideration.

#### **Related concepts**

Loading a function control vector

The function control vector tells the Cryptographic Coprocessor for the system running the IBM i operating system what key length to use to create keys. You cannot perform any cryptographic functions without loading a function control vector.

D* these programs and files.
D*
D* Note: Input format is more fully described in Chapter 2 of
            IBM CCA Basic Services Reference and Guide
D*
            (SC31-8609) publication.
D*
D* Parameters:
                      (FIRST, MIDDLE, LAST, CLEAR, SET)
(24 bytes entered in hex -> X'01F7C4....')
      OPTION
D*
       KEYPART
                        Required for FIRST, MIDDLE, and LAST
D*
D*
D* The master key is loaded in 3 or more parts. Specify FIRST
D* when loading the first part, MIDDLE when loading all parts
D* between the first and the last, and LAST when loading the final
D* part of the master key.
D* As the master key parts are entered, they are Exclusively OR'ed
D* with the current contents of the master key register. After the D* last master key, if the contents do not have odd parity in every
D* byte, a non-zero return/reason code will be returned. In order
D* to ensure that the final result has odd parity, each key part
D* should have odd parity in every byte. This is assuming that there
D* is an odd number of key parts. (If there is an even number of
D* key parts, then one of the key parts should have even parity).
D*
D* A byte has odd parity if is contains:
D* an odd parity nibble: 1, 2, 4, 7, 8, B, D, or E
D* an even parity nibble: 0, 3, 5, 6, 9, A, C, or F.
D*
D*
     For example 32, A4, 1F, and 75 are odd parity bytes because
D*
                        they contain both an odd parity and an even parity
                        nibble.
D*
D*
                        05, 12, 6C, and E7 are even parity bytes because
D*
D*
                        they contain either two even parity nibbles or
D*
                        two odd parity nibbles.
D\star The New master key register must be empty before the first part D\star of a master key can be entered. Use CLEAR to ensure that the
D* New master key register is empty before loading the master key
D* parts.
D\star After loading the master key, use SET to move the master key from D\star the New-master-key register to the Current-master-key register.

D* the Current-master-key register.
D* Example:
      CALL PGM(LOAD_KM) (CLEAR)
D*
D*
       CALL PGM(LOAD_KM)
D*
          (FIRST X'0123456789ABCDEFFEDCBA98765432100123456789ABCDEF')
D*
D*
D*
       CALL PGM(LOAD_KM)
D*
          (MIDDLE X'1032A873458010F7EF3438373132F1F2F4F8B3CDCDCDCEF1')
D*
       CALL PGM(LOAD_KM)
D*
          (LAST X'2040806789ABCDEFFEDC3434346432100123456789FEDCBA')
D*
D*
D*
       CALL PGM(LOAD_KM) (SET)
D*
D*
D*
D* Use these commands to compile this program on the system:
D* CRTRPGMOD MODULE(LOAD_KM) SRCFILE(SAMPLE)
D* CRTPGM PGM(LOAD_KM) MODULE(LOAD_KM)
               BNDSRVPGM(QCCA/CSNBMKP)
D*
D* Note: Authority to the CSNBMKP service program in the
```

```
D*
       QCCA library is assumed.

Loading and setting a master key

After you load a function control vector, load and set the master key. The master key is used to encrypt other keys. It is a special key-encrypting key stored within the Coprocessor secure module on systems running the IBM i operating system.

# Configuring the Cryptographic Coprocessor for use with DCM and SSL

This topic provides information on how to make the Cryptographic Coprocessor ready for use with SSL in IBM i.

The following section lists the steps needed to make the Cryptographic Coprocessor ready for use with SSL.

## **Using your Coprocessor with DCM and SSL**

To install the Cryptographic Coprocessor and prerequisite software, you must do the following:

• Install the Coprocessor in your system.

For feature EJ35 or EJ37, install your Cryptographic Coprocessor, as instructed in the instructions that are shipped with your Cryptographic Coprocessor.

- Install IBM i Option 35 CCA CSP and 5733-CY3 Cryptographic Device Manager.
- Set IBM i object authorities for secure access.
- Use your web browser to go to the IBM i Tasks page found by clicking on the IBM i Tasks page link on the IBM Navigator for i welcome page at http://server-name:2001.
- Configure the Coprocessor.

The Cryptographic Coprocessor is now ready to be used to create private keys for SSL certificates.

- Use DCM to create a certificate, specifying that the private key be generated by the hardware.
- Use DCM to receive the signed certificate.

**Note:** If you plan to use multiple cards for SSL, see "Managing multiple Cryptographic Coprocessors" on page 149 and "Cloning master keys" on page 158.

Managing multiple Cryptographic Coprocessors

You can have up to eight Cryptographic Coprocessors per partition. The maximum number of Cryptographic Coprocessors supported per system is dependent on the system mode. This topic provides information on using multiple coprocessors with SSL in systems running the IBM i operating system.

#### Secure access

Access control restricts the availability of system resources to only those users you have authorized to interact with the resources. The system allows you to control authorization of users to system resources.

#### Configuring the Cryptographic Coprocessor

Configuring your Cryptographic Coprocessor allows you to begin to use all of its cryptographic operations. To configure the Cryptographic Coprocessor on your system running the IBM i operating system, you can either use the Cryptographic Coprocessor configuration Web-based utility or write your own application.

## Configuring the Cryptographic Coprocessor for use with IBM i applications

This topic lists the steps needed to make Cryptographic Coprocessors ready for use with an IBM i application.

# Using the Cryptographic Coprocessor for IBM i applications

To install the Cryptographic Coprocessor and prerequisite software, you must do the following:

- Install the Coprocessor in your system.
  - Install your Cryptographic Coprocessor, as instructed in the instructions that are shipped with your Cryptographic Coprocessor.
- Install IBM i Option 35 CCA CSP and install 5733-CY3 Cryptographic Device Manager.
- Set IBM i object authorities for secure access.
- Use your web browser to go to the IBM i Tasks page found by clicking on the IBM i Tasks page link on the IBM Navigator for i welcome page at http://server-name:2001.
- · Configure the Coprocessor.
- Write your application to use the Cryptographic Coprocessor.

**Note:** If you plan to use multiple cards for your IBM i applications, see <u>"Managing multiple Cryptographic Coprocessors"</u> on page 149.

#### **Related concepts**

Scenario: Protecting private keys with cryptographic hardware

This scenario might be useful for a company that needs to increase the security of the system digital certificate private keys that are associated with the IBM i SSL-secured business transactions.

# Migrating to the Cryptographic Coprocessor

- If you have worked with cryptography before, you might have a requirement to migrate from a previous cryptography product to the 4769 Cryptographic Coprocessor.
- The IBM 4767 Cryptographic Coprocessor is no longer available, but it is still supported.
- Migrating from the 4767 to the 4769:

If you are replacing your 4767 Cryptographic Coprocessor with the 4769 Cryptographic Coprocessor, then ensure that the roles and profiles for the 4769 Coprocessor are set up similarly to those used with the 4767 Coprocessor. This includes configuring your "DFLT0000" role (4769) to be equivalent to your "DEFAULT" role (4767). The 4764, 4765, 4767, and 4769 Cryptographic Coprocessors can all use the same CCA APIs and keystore files.

# **Managing the Cryptographic Coprocessor**

After you set up your Cryptographic Coprocessor, you can begin writing programs to make use of your Cryptographic Coprocessor's cryptographic functions. This section is mainly for IBM i application use of the Cryptographic Coprocessor.

**Note:** Many of the pages in this section include one or more program examples. Change these programs to suit your specific needs. Some require that you change only one or two parameters while others require more extensive changes. For security reasons, IBM recommends that you individualize these program examples rather than using the default values provided.

## Logging on or off of the Cryptographic Coprocessor

You can log on or off the Cryptographic Coprocessor by working with role-restricted IBM i APIs.

## Logging on

You need to log on only if you wish to use an API that uses an access control point that is not enabled in the default role. Log on with a profile that uses a role that has the access control point you want to use enabled.

After you log on to your Cryptographic Coprocessor, you can run programs to utilize the cryptographic functions for your Cryptographic Coprocessor. You can log on by writing an application that uses the Logon\_Control (CSUALCT) API verb.

## Logging off

When you have finished with your Cryptographic Coprocessor, you should log off of your Cryptographic Coprocessor. You can log off by writing an application that uses the Logon\_Control (CSUALCT) API verb.

#### Note:

Read the "Code license and disclaimer information" on page 234 for important legal information **Related concepts** 

Creating AES, DES, and PKA keys

You can create Advanced Encryption Standard (AES), Data Encryption Standard (DES), and Public key algorithm (PKA) keys. You can create AES keys and store them in an AES keystore. You can create DES keys and store them in a DES keystore. You can create PKA keys and store them in a PKA keystore. The AES, DES, and PKA keys can be created by writing IBM i programs.

## Example: ILE C program for logging on to your Cryptographic Coprocessor

Change this IBM i ILE C program example to suit your needs for logging on to your Cryptographic Coprocessor.

Note: Read the "Code license and disclaimer information" on page 234 for important legal information.

```
/★ Note: This verb is more fully described in Chapter 2 of

## **Query status or request information**

You can query the Cryptographic Coprocessor on your system running the IBM i operating system to determine characteristics such as which algorithms are enabled, the key lengths it supports, the status of the master key, the status of cloning, and the clock setting.

The easiest and fastest way to query the Cryptographic Coprocessor is to use the Cryptographic Coprocessor configuration web-based utility. Click on **Display configuration** and then select a device, then select items you want to display.

If you would prefer to write your own application to query the Coprocessor, you can do so by using the Cryptographic\_Facility\_Query (CSUACFQ) API verb. The IBM PCI Cryptographic Coprocessor CCA

Basic Services Reference and Guide describes the Cryptographic\_Facility\_Query (CSUACFQ) security application programming interface, the types of information that you can request, and the format of the information that is returned.

## Example: Querying the status of your Cryptographic Coprocessor

Change this IBM i program example to suit your needs for querying the status of your Cryptographic Coprocessor. This program uses the STATEID and TIMEDATE keywords.

**Note:** Read the "Code license and disclaimer information" on page 234 for important legal information.

```
/* Ouery the card for status or other information.
/* This sample program uses the STATEID and TIMEDATE keywords.

## Initializing a keystore file

A keystore file is a database file that stores operational keys, that is keys encrypted under the master key. This topic provides information on how to keep records of your DES and PKA keys on systems running the IBM i operating system.

You can initialize two different types of keystores for your Cryptographic Coprocessor. The Cryptographic Coprocessor uses one type to store PKA keys and the other to store DES keys. You need to initialize a keystore file if you plan to store keys in it. Even though retain keys are not stored in a keystore file, one is still required because CCA searches for labels in key store files before it searches for labels in the coprocessor.

The CCA CSP creates a DB2® keystore file, if one does not already exist. If a keystore file already exists, the CCA CSP deletes the file and recreates a new one.

To initialize a keystore, you can use the Cryptographic Coprocessor configuration utility. Click on **Manage configuration** and then click on **AES keys**, **DES keys**, or **PKA keys** depending upon what keystore file you wish to initialize. With the utility, you can only initialize a file if it does not already exist.

If you would rather write your own application to initialize a keystore file, you can do so by using the KeyStore\_Initialize (CSNBKSI) API verb.

After you create a keystore for your Cryptographic Coprocessor, you can generate DES and PKA keys to store in your keystore files.

#### **Related concepts**

#### Cryptography concepts

This topic provides a basic understanding of cryptographic function and an overview of the cryptographic services for the systems running the IBM i operating system.

#### Creating AES, DES, and PKA keys

You can create Advanced Encryption Standard (AES), Data Encryption Standard (DES), and Public key algorithm (PKA) keys. You can create AES keys and store them in an AES keystore. You can create DES keys and store them in a DES keystore. You can create PKA keys and store them in a PKA keystore. The AES, DES, and PKA keys can be created by writing IBM i programs.

# **Example: ILE C program for initializing a keystore for your Cryptographic Coprocessor**Change this IBM i ILE C program example to suit your needs for initializing a keystore for your Cryptographic Coprocessor.

Note: Read the "Code license and disclaimer information" on page 234 for important legal information.

The file was succesully initialized.
```

## Creating AES, DES, and PKA keys

You can create Advanced Encryption Standard (AES), Data Encryption Standard (DES), and Public key algorithm (PKA) keys. You can create AES keys and store them in an AES keystore. You can create DES keys and store them in a DES keystore. You can create PKA keys and store them in a PKA keystore. The AES, DES, and PKA keys can be created by writing IBM i programs.

You can use your Cryptographic Coprocessor to create three types of cryptographic keys.

• AES keys base their content on a symmetric algorithm. This means that cryptography uses the same key value to encrypt and decrypt data. Use AES keys to encrypt or decrypt files.

To create AES keys with your Cryptographic Coprocessor, write a program.

• DES keys base their content on a symmetric algorithm. This means that cryptography uses the same key value to encrypt and decrypt data. Use DES keys to encrypt or decrypt files, working with PINS, and managing keys.

To create DES keys with your Cryptographic Coprocessor, write a program.

PKA keys base their content on an asymmetric algorithm, meaning that cryptography uses different keys
for encryption and decryption. Use PKA keys for signing files with digital signatures and for managing
keys.

To create PKA keys with your Cryptographic Coprocessor, write a program.

**Note:** If you choose to use the program examples provided, change them to suit your specific needs. For security reasons, IBM recommends that you individualize these program examples rather than using the default values provided.

Store your AES, DES, and PKA keys in the keystore file you created for them using a keystore file. You can also store PKA keys in your Cryptographic Coprocessor. See the information at <a href="http://www.ibm.com/security/cryptocards/pciecc/library.shtml">http://www.ibm.com/security/cryptocards/pciecc/library.shtml</a> for more information on storing your keys in the hardware.

**Note:** Read the "Code license and disclaimer information" on page 234 for important legal information.

#### **Related concepts**

Logging on or off of the Cryptographic Coprocessor

You can log on or off the Cryptographic Coprocessor by working with role-restricted IBM i APIs.

#### Encrypting or decrypting a file

One of the more practical uses for the Cryptographic Coprocessor on your system running the IBM i operating system is encrypting and decrypting data files.

#### Generating and verifying a digital signature

You can protect data from undetected changes by including a proof of identity value called a digital signature. You can write programs to generate and verify a digital signature for the Cryptographic Coprocessor on your system running the IBM i operating system.

Initializing a keystore file

A keystore file is a database file that stores operational keys, that is keys encrypted under the master key. This topic provides information on how to keep records of your DES and PKA keys on systems running the IBM i operating system.

#### **Related tasks**

#### Working with PINs

A financial institution uses personal identification numbers (PINs) to authorize personal financial transactions for its customers. A PIN is similar to a password except that a PIN consists of decimal digits and is normally a cryptographic function of an associated account number. You can use the Cryptographic Coprocessor of your system running the IBM i operating system to work with PINs.

## Example: Creating a DES key with your Cryptographic Coprocessor

Change this IBM i program example to suit your needs for creating a DES key with your Cryptographic Coprocessor.

Note: Read the "Code license and disclaimer information" on page 234 for important legal information.

## **Encrypting or decrypting a file**

One of the more practical uses for the Cryptographic Coprocessor on your system running the IBM i operating system is encrypting and decrypting data files.

You can use one of these cryptographic methods to protect a file:

- Treat the whole file as a string of bytes (which is the method the program example uses).
- Encrypt each record or part of each record.

Write your own program protect data in many different formats, not just data files.

#### Related concepts

#### Creating AES, DES, and PKA keys

You can create Advanced Encryption Standard (AES), Data Encryption Standard (DES), and Public key algorithm (PKA) keys. You can create AES keys and store them in an AES keystore. You can create DES keys and store them in a DES keystore. You can create PKA keys and store them in a PKA keystore. The AES, DES, and PKA keys can be created by writing IBM i programs.

## Example: Encrypting data with your Cryptographic Coprocessor

Change this IBM i program example to suit your needs for encrypting data with your Cryptographic Coprocessor.

**Note:** Read the "Code license and disclaimer information" on page 234 for important legal information.

/* Parameters:
/* char * key label, 1 to 64 characters
/* char * input file name, 1 to 21 characters (lib/file)
/* char * output file name, 1 to 21 characters (lib/file)
      CALL PGM(ENCFILE) PARM( 'MY.KEY.LABEL' 'QGPL/MYDATA' + 'QGPL/CRYPTDATA' )
/* Note: This program assumes the device you want to use is
/* already identified either by defaulting to the CRP01
            device or has been explicitly named using the
/*
/*
            Cryptographic_Resource_Allocate verb. Also this
            device must be varied on and you must be authorized
           to use this device description.
          This program assumes the keystore file you will use is already identifed either by being specified on the
/*
        cryptographic device or has been previously named using the Key_Store_Designate verb. Also you must be authorized to add and update records in this file.
/*
           The output file should NOT have key fields since all
            data in the file will be encrypted and therefore trying
            to sort the data will be meaningless.
           (This is NOT checked by the program)

## **Working with PINs**

A financial institution uses personal identification numbers (PINs) to authorize personal financial transactions for its customers. A PIN is similar to a password except that a PIN consists of decimal digits

and is normally a cryptographic function of an associated account number. You can use the Cryptographic Coprocessor of your system running the IBM i operating system to work with PINs.

To work with PINs, write a program.

#### **Related concepts**

## Creating AES, DES, and PKA keys

You can create Advanced Encryption Standard (AES), Data Encryption Standard (DES), and Public key algorithm (PKA) keys. You can create AES keys and store them in an AES keystore. You can create DES keys and store them in a DES keystore. You can create PKA keys and store them in a PKA keystore. The AES, DES, and PKA keys can be created by writing IBM i programs.

#### Example: Working with PINs on your Cryptographic Coprocessor

Change this IBM i program example to suit your needs for working with PINs on your Cryptographic Coprocessor.

Note: Read the "Code license and disclaimer information" on page 234 for important legal information.

```
F* PINSAMPLE
     F*
           Sample program that shows the use of the appropriate
           CCA Security API (SAPI) verbs for generating and verifying
     F* PINS
     F* The keys are created by first building a key token
     F* and then importing key parts using Key_Part_Import.
F* Four keys are created each with a different
F* key type - PINGEN, PINVER, IPINENC, and OPINENC. T
     F* PINGEN key will be used to generate a Clear PIN with the
     F* Clear_PIN_Generate verb. The OPINENC key will be used
F* to encrypt the PIN with the Clear_PIN_Encrypt verb.
F* The Encrypted_PIN_Verify with verify that the PIN is good
F* using the IPINENC key (to decrypt) and the PINVER key
     F* to verify the PIN.

                  IBM CCA Basic Services Reference and Guide
                   (SC31-8609) publication.
     F*
     F* Parameters:
            none.
     F*
     F* Example:
     F* CALL PGM(PINSAMPLE)
     F \star Use these commands to compile this program on the system:
     F* CRTPGMOD MODULE(PINSAMPLE) SRCFILE(SAMPLE)
F* CRTPGM PGM(PINSAMPLE) MODULE(PINSAMPLE)
                     BNDSRVPGM(QCCÁ/CSNBKPÌ QCCA/CSNBPGN + QCCA/CSNBCPE QCCA/CSNBPVR)
     F* Note: Authority to the CSNBKPI, CSNBPGN, CSNBCPE, and F* CSNBPVR service programs in the QCCA library is assumed.
     F* The Common Cryptographic Architecture (CCA) verbs used are
     F* Key_Part_Import (CSNBKPI), Clear_PIN_Generate (CSNBPGN),
F* Clear_PIN_Encrypt (CSNBCPE), and Encrypted_PIN_Verify (CSNBPVR).
```

```
F* Note: This program assumes the card you want to load is
      already identifed either by defaulting to the CRP01 device or has been explicitly named using the
F*
F*
F*
      Cryptographic_Resource_Allocate verb. Also this
F*
      device must be varied on and you must be authorized
      to use this device descrption.
F*
F* Declare parameters that are common to all of the CCA verbs

C*
C* Clear key value for PINGEN/PINVER form will be:
C*
      01234567 01765432 01234567 01765432
C*
C*
C* The key will be imported into two parts that get exclusived
C* OR'ed together. This program uses as key parts:
C*
C*
      00224466 00775533 00224466 00775533 and
C*
C*
      01010101 01010101 01010101 01010101
C*
C* Converting these to decimal results in
C*
      2245734 7820595
                       2245734 7820595 and
C*
C*
      16843009 16843009 16843009 16843009
C*
C*
    In this example, the left half of the key is the same as the right half. PIN keys in CCA are double length keys.
C*
C*
C*
    However, some implementation of DES (including Cryptographic
```

```
Support/400) use single length keys for PINs. If both
  halves of a double are the same, then they produce the
  same output as a single length key, thereby allowing you to exchange data with non-CCA systems.
C* Import the PINGEN key

# Generating and verifying a digital signature

You can protect data from undetected changes by including a proof of identity value called a digital signature. You can write programs to generate and verify a digital signature for the Cryptographic Coprocessor on your system running the IBM i operating system.

# Generating a digital signature

A digital signature relies on hashing and public key cryptography. When you sign data, you hash the data and encrypt the results with your private key. The encrypted hash value is called a digital signature.

If you change the original data, a different digital signature will be generated.

To use a PKA key to sign a file, write a program.

# Verifying a digital signature

Verifying a digital signature is the opposite of signing data. Verifying a signature will tell you if the signed data has changed or not. When a digital signature is verified, the signature is decrypted using the public key to produce the original hash value. The data that was signed is hashed. If the two hash values match, then the signature has been verified. To do this, write a program.

Read the "Code license and disclaimer information" on page 234 for important legal information.

#### **Related concepts**

Creating AES, DES, and PKA keys

You can create Advanced Encryption Standard (AES), Data Encryption Standard (DES), and Public key algorithm (PKA) keys. You can create AES keys and store them in an AES keystore. You can create DES keys and store them in a DES keystore. You can create PKA keys and store them in a PKA keystore. The AES, DES, and PKA keys can be created by writing IBM i programs.

## Example: Signing a file with your Cryptographic Coprocessor

Change this IBM i program example to suit your needs for signing a file with your Cryptographic Coprocessor.

Note: Read the "Code license and disclaimer information" on page 234 for important legal information.

If you choose to use this program example, change it to suit your specific needs. For security reasons, IBM recommends that you individualize these program examples rather than using the default values provided.

```

# **Managing multiple Cryptographic Coprocessors**

You can have up to eight Cryptographic Coprocessors per partition. The maximum number of Cryptographic Coprocessors supported per system is dependent on the system mode. This topic provides information on using multiple coprocessors with SSL in systems running the IBM i operating system.

Spreading the work across multiple Cryptographic Coprocessors and multiple jobs gives you better performance provided that they are all configured the same. Only one Coprocessor (cryptographic device description) may be allocated to a job at one time. However, the job can switch between Coprocessors by deallocating the current Coprocessor and allocating a new one. For the IBM i SSL user, the allocation and deallocation of the Coprocessors is managed by the system if the SSL configuration in DCM indicates that more than one Coprocessor is to be used for SSL session establishment.

If you configure all of the Coprocessors the same, then all operational keys will work identically on all of the Coprocessors. Any data encrypted on one Coprocessor can be decrypted on a different Coprocessor. All keystore files will work interchangeably with any of the Coprocessors. The most important part of configuring the Coprocessors identically is the master keys. If you entered the master key in parts for one Coprocessor, you must enter the same master key parts for all of the other Coprocessors if you want them to work interchangeably. If a random master key was generated inside of the Coprocessor, then you must clone the master key to the other Coprocessors if you want all of the Coprocessors to work interchangeably.

There may be certain situations where you do not want all of the Coprocessors to be configured the same. They could all have different configurations or they could be set up in groups where the configuration within a group is the same but between groups is different. For these cases, all operational keys may not work identically on all of the Coprocessors. Data encrypted on one Coprocessor may not be able to be recovered on a different Coprocessor. Also, the keystore files may not work interchangeably among Coprocessors. For these situations, you must keep track of which keystore files and operational keys will work for a given Coprocessor. While configuring the Coprocessors differently may limit the scalability of cryptographic applications, it can provide more granularity in terms of security. For example, you can grant different object authorities to different cryptographic device descriptions.

If you use retained PKA keys then the Coprocessors are also not interchangeable. Retained keys can not be exported in any manner outside of the Coprocessor. Therefore, any cryptographic request that uses that retained key must be sent to the Coprocessor that stores the retained key.

The following material is only applicable if you are using IBM i:

# Allocating a device

The Cryptographic\_Resource\_Allocate (CSUACRA) API verb is used to explicitly allocate a cryptographic device to your job so that the system can determine how to route all subsequent cryptographic requests. If you use any of the CCA API verbs without first explicitly using the Cryptographic\_Resource\_Allocate (CSUACRA) API verb, the system will attempt to allocate the default cryptographic device. The default device is the cryptographic device named CRP01. It must be created by either using the Basic Configuration wizard or the Create Device Crypto (CRTDEVCRP) CL command. You only need to use CSUACRA when you wish to use a device other than the default cryptographic device. A device allocated to a job, either explicitly or implicitly, remains allocated until either the job ends or the device is deallocated using the Cryptographic\_Resource\_Deallocate (CSUACRD) API verb.

# **Deallocating a device**

When you have finished using a Cryptographic Coprocessor, you should deallocate the Cryptographic Coprocessor by using the Cryptographic\_Resource\_Deallocate (CSUACRD) API verb. A cryptographic device description can not be varied off until all jobs using the device have deallocated it.

#### **Related concepts**

4769 Cryptographic Coprocessor

IBM offers Cryptographic Coprocessors, which are available on a variety of system models. Cryptographic Coprocessors contain hardware engines, which perform cryptographic operations used by IBM i application programs and IBM i SSL transactions.

#### Scenario: Protecting private keys with cryptographic hardware

This scenario might be useful for a company that needs to increase the security of the system digital certificate private keys that are associated with the IBM i SSL-secured business transactions.

#### Configuring the Cryptographic Coprocessor for use with DCM and SSL

This topic provides information on how to make the Cryptographic Coprocessor ready for use with SSL in IBM i.

Managing multiple Cryptographic Coprocessors

You can have up to eight Cryptographic Coprocessors per partition. The maximum number of Cryptographic Coprocessors supported per system is dependent on the system mode. This topic provides information on using multiple coprocessors with SSL in systems running the IBM i operating system.

# **Cloning master keys**

Master key cloning is a method for securely copying a master key from one Cryptographic Coprocessor to another without exposing the value of the master key. If you are using multiple coprocessors with SSL on your system running the IBM i operating system, use the Cryptographic Coprocessor configuration Web-based utility to clone master keys.

This is performed by a process of splitting the master key into n shares, where n is a number from 1 to 15. m shares are required to rebuild the master key in another Coprocessor, where m is a number from 1 to 15 and less than or equal to n.

The term "cloning" is used to differentiate the process from "copying" because no one share, or any combination of fewer than *m* shares, provide sufficient information needed to rebuild the master key.

The Coprocessor containing the master key to be cloned is referred to as either the master-key-share source node or the Sender. The Sender must generate a retained RSA key pair. This private key must also have been marked as suitable for use with cloning when it was generated. The key is known as either the Coprocessor Share Signing key or the Sender key. The Coprocessor that will receive the master key is referred to as either the master-key-share target node or the Receiver. The Receiver must also generate a retained RSA key pair and must also have been marked as suitable for use with cloning. This key is known as either the Coprocessor Share Receiving key or simply the Receiver key.

Both the Sender and Receiver public keys must be digitally signed or certified by a retained private key in a Coprocessor, referred to as the public key certifying node or the Certifier. This retained private key is the Certifier key. It is also referred to as the Share Administration key. The associated public key must be registered in both the Sender and the Receiver before shares can be generated and received. A Cryptographic Coprocessor can take on the role of Certifier only, or can it be both Certifier and Sender, or it can be both Certifier and Receiver.

As each share is generated it is signed by the Coprocessor using the Sender private key and encrypted by a newly generated triple DES key. The triple DES key is then wrapped or encrypted by the Receiver public key.

As each share is received, the signature on the share is verified using the Sender public key, the triple DES key is unwrapped or decrypted using the Receiver private key, and the share decrypted using the triple DES key. When m number of shares have been received, the cloned master key will be complete within the new master key register of the Receiver.

The easiest and fastest way to clone master keys is to use the Cryptographic Coprocessor configuration web-based utility. The utility includes the Master key cloning advisor. To start the master key cloning advisor, follow these steps:

- 1. Click on **Manage configuration** on the Cryptographic Coprocessor configuration page.
- 2. Click on Master keys.
- 3. Select a device.
- 4. Enter a valid Coprocessor profile and password.
- 5. Click on the **Clone** button.

If you would prefer to write your own application to clone master keys, you can do so by using the following API verbs:

- Cryptographic Facility Control (CSUACFC)
- PKA Key Token Build (CSNDPKB) (may not be needed depending upon how you write your application)
- PKA Key Generate (CSNDPKG)
- PKA\_Public\_Key\_Register (CSNDPKR)
- One\_Way\_Hash (CSNBOWH)

**158** IBM i: Cryptography

- Digital\_Signature\_Generate (CSNDDSG)
- Master\_Key\_Distribution (CSUAMKD)

#### **Example programs**

Nine pairs of example programs are provided for your consideration. Each pair contains a program written in ILE C and a program written in ILE RPG. Both perform the same function.

**Note:** Read the "Code license and disclaimer information" on page 234 for important legal information.

#### **Related concepts**

4769 Cryptographic Coprocessor

IBM offers Cryptographic Coprocessors, which are available on a variety of system models. Cryptographic Coprocessors contain hardware engines, which perform cryptographic operations used by IBM i application programs and IBM i SSL transactions.

```

#### Example: ILE RPG program for obtaining a master key share

Change this IBM i ILE RPG program example to suit your needs for obtaining a master key share.

```
D* GETSHARE
D*
D* Sample program to obtain a master key share as part of the
D* master key cloning process.
D*
D* COPYRIGHT 5769-SS1 (C) IBM CORP. 2000, 2007
D*
D* This material contains programming source code for your
D\star consideration. These example has not been thoroughly D\star tested under all conditions. IBM, therefore, cannot
D* guarantee or imply reliability, serviceability, or function
D* of these programs. All programs contained herein are
D* provided to you "AS IS". THE IMPLIED WARRANTIES OF

D* these programs and files.
D*
D\star Note: Input format is more fully described in Chapter 2 of D\star IBM CCA Basic Services Reference and Guide
D*
            (SC31-8609) publication.
D*
D* Parameters: Share number
                   Name of share sender private key
D*
D*
                   Name of certifying key
D*
                   Path name of stream file containing receiver certificate
D*
D* Example:
      CALL PGM(GETSHARE) PARM(2 SENDR SAKEY RECVR.PUB)
```

```
D*
D* Use these commands to compile this program on the system:
D* CRTRPGMOD MODULE(GETSHARE) SRCFILE(SAMPLE)
D* CRTPGM PGM(GETSHARE) MODULE(GETSHARE)
D*
            BNDDIR(QCCA/QC6BNDDIR)
D*
D* Note: Authority to the CSUAMKD service program
          in the QCCA library is assumed.
D*
D*
D* The Common Cryptographic Architecture (CCA) verbs used is
D* Master_Key_Distribution (CSUAMKD).

D* Note: Input format is more fully described in Chapter 2 of
         IBM CCA Basic Services Reference and Guide
D*
D*
         (SC31-8609) publication.
D* Parameters: Share number
D*
                Name of share receiver private key
D*
                Name of certifying key
D*
                Path name of stream file containing sender certificate
D* Example:
     CALL PGM(PUTSHARE) PARM(2 RECVR SAKEY SENDER.PUB)
D*
D* Use these commands to compile this program on the system:
D* CRTRPGMOD MODULE(PUTSHARE) SRCFILE(SAMPLE)
D* CRTPGM PGM(PUTSHARE) MODULE(PUTSHARE)
           BNDDIR(QCCA/QC6BNDDIR)
D*

# **Troubleshooting the Cryptographic Coprocessor**

Use these troubleshooting methods to tackle some of the basic problems that might occur with the Cryptographic Coprocessor on your system running the IBM i operating system. If the troubleshooting information does not address your problem, contact your service representative.

Always assure that you have applied all current PTFs for the relevant products and programs.

#### Using return codes

The primary method for detecting and troubleshooting problems is by monitoring return codes and reason codes.

- A return code of 0 indicates successful completion. To provide some additional information, the Cryptographic Coprocessor associates some non-zero reason codes with this return code.
- A return code of 4 indicates that the application programming interface (API) has completed
  processing, but an unusual event occurred. It could be related to a problem created by the application
  program, or it could be a normal occurrence based on data that is supplied to the API.
- A return code of 8 indicates that the API did not complete successfully. An application programming error most likely caused this.
- A return code of 12 normally indicates some type of problem in the setup or configuration of your Coprocessor. This code means that the processing of the API did not complete successfully.
- A return code of 16 normally indicates a severe error in Common Cryptographic Architecture Cryptographic Service Provider (CCA CSP), system licensed internal code, or the Cryptographic Coprocessor licensed internal code. For these types of errors, you should contact your service representative.

You can also troubleshoot problems by analyzing the messages that appear in the job log or in the system operator (QSYSOPR) queue. Generally, any event that sends a message to the job log also returns an associated return code and a reason code to the calling programming. Messages sent to the system operator message, if reporting a severe problem, will normally point to a source of additional information

about the problem. Such information is intended for IBM service, and therefore you may not necessarily find them useful for problem determination.

#### **Common errors**

You should watch out for these common errors:

- **Did you vary on the device?** You cannot send any requests to your Cryptographic Coprocessor until you vary on the device.
- Is the CCA finding a device? If you do not explicitly use the Cryptographic\_Resource\_Allocate API, you must name the cryptographic device CRP01. If you do not name it that, the CCA cannot select any device. Either name the device CRP01 or change your program to use the Cryptographic\_Resource\_Allocate CCA API to select the device.
- Are you selecting the correct device? If you have a default device (for example, a device named CRP01) and an additional device, the Cryptographic Coprocessor will select the default device, unless you use Cryptographic\_Resource\_Allocate.
- Is the Cryptographic Coprocessor finding a keystore file? If you do not explicitly use the Key\_Store\_Designate SAPI, the CCA CSP support will attempt to use the files named on the device description. If you have named no files on the device description, the Cryptographic Coprocessor will not find any files.
- Have you loaded and set a master key? The Cryptographic Coprocessor will not complete any
  cryptographic requests other than those for configuring your Cryptographic Coprocessor, unless you
  load a master key.
- Does the Old master key register contain a key? The Cryptographic Coprocessor cannot re-encrypt keys under the Current master key unless the Old master key register contains a value.
- Does your default role have authority to use a given hardware command? If not, you will need to log on by using a profile that uses a role that has the correct authority.
- Does any role have authority to use a given hardware command? If your Cryptographic
  Coprocessor requires the hardware command and you have not authorized a role to use that
  command, you must reinitialize your Cryptographic Coprocessor. Do this by using either the
  Cryptographic\_Facility\_Control API or the Hardware Service Manager that is found in System Service
  Tools. Using the Cryptographic\_Facilty\_Control API requires that you authorize a role to the hardware
  command that reinitializes the Cryptographic Coprocessor. If no such role exists, you must use the
  Hardware Service Manager.
- Is a function control vector loaded? Your Cryptographic Coprocessor cannot run any cryptographic operations other than configuration until you load a function control vector.
- If you are loading a master key, did you begin by clearing out the new master key register? If your Cryptographic Coprocessor has a partially loaded new master key register, you cannot load the first part of a master key.
- Did you remember to set the clock in your Coprocessor before removing the authority to do so
  from the DEFAULT role? If not, you must reinitialize your Cryptographic Coprocessor by using either
  the Cryptographic\_Facility\_Control API or the Hardware Service Manager found in System Service
  Tools. Using the Cryptographic\_Facilty\_Control API requires that you authorize a role to the hardware
  command that reinitializes the Cryptographic Coprocessor. If no such role exists, you must use the
  Hardware Service Manager.
- Did you set the EID before trying to generate public-private key pairs? You must set the EID before you can generate RSA keys.

- Did you correctly initialize the first byte of a null key token to binary 0? If not, the CCA support may try to use it as a key label. CCA Support will either report it as a bad label format or report that it could find the key record.
- Do you use the same name for a label in a PKA keystore file and a retained PKA key? If so, your Cryptographic Coprocessor will never find the retained key because the Cryptographic Coprocessor always searches the keystore file first.
- Do you have EBCDIC data in any fields in a skeleton PKA key token? The Cryptographic Coprocessor specifically checks for ASCII data in a number of the fields and will return an error if it finds EBCDIC data.

## **Reinitializing the Cryptographic Coprocessor**

If you set up your Cryptographic Coprocessor incorrectly, you can end up with an unusable configuration with which you cannot perform any cryptographic functions and cannot use any of the APIs to recover. For example, you can configure it such that you have no role authorized to set the master key and no role authorized to change or create new roles or profiles. You can call the hardware command for reinitializing the card by using the Cryptographic\_Facility\_Control (CSUACFC) SAPI.

However, in some cases, there may not be a role that is authorized to any hardware command. In this case, you must reload the Licensed Internal Code by using the function that is provided in Hardware Service Manager in System Service Tools.

## **Updating the Licensed Internal Code in the Cryptographic Coprocessor**

Loading the Licensed Internal Code in your Cryptographic Coprocessor erases the master key, all private keys, and all roles and profiles that are stored in your Cryptographic Coprocessor. Because of this, the system does not automatically load PTFs for the Licensed Internal Code in the Cryptographic Coprocessor, and the PTFs always require action on your part to enable them. Before you load the Licensed Internal Code, take appropriate actions to ensure that you can recover, such as ensuring that you have a hard copy of your master key.

**Note:** If you randomly generated your master key, you will need to clone that key into a second Cryptographic Coprocessor. If you do not, you will lose all your encrypted keys when you reinitialize your Cryptographic Coprocessor.

#### **Related tasks**

#### Using the Hardware Service Manager

Hardware service manager is a tool for displaying and working with the IBM i system hardware from both a logical and a packaging viewpoint, an aid for debugging input/output (I/O) processors and devices, and is also used to reinitialize the Cryptographic Coprocessor (set it back to an un-initialized state).

# Example: ILE C program for reinitializing the Cryptographic Coprocessor

Change this IBM i ILE C program example to suit your needs for reinitializing your Cryptographic Coprocessor.

**Note:** Read the "Code license and disclaimer information" on page 234 for important legal information.

If you choose to use the program example that is provided, change it to suit your specific needs. For security reasons, IBM recommends that you individualize these program examples rather than using the default values provided.

```

## **Using the Hardware Service Manager**

Hardware service manager is a tool for displaying and working with the IBM i system hardware from both a logical and a packaging viewpoint, an aid for debugging input/output (I/O) processors and devices, and is also used to reinitialize the Cryptographic Coprocessor (set it back to an un-initialized state).

When the Cryptographic Coprocessor is re-initialized, the Cryptographic Coprocessor Licensed Internal Code is reloaded into the Coprocessor. Some but not all program temporary fixes (PTFs) for the Coprocessor licensed internal code may require the use of hardware service manager to activate them. This extra step is included to allow you to prepare for recovery because reloading certain segments of the licensed internal code will cause any configuration data including master keys, retained RSA private keys, roles, and profiles to be lost.

There may be situations where the Cryptographic Coprocessor must be reset back to an unintialized state. For example, if the Coprocessor is not configured correctly, there could be a scenario where the Coprocessor cannot perform any useful function and cannot be corrected using the Cryptographic Coprocessor configuration utility or a user-written application. Another example is if the passwords for the administrative profiles are forgotten and no other profile uses a role that is authorized to change passwords.

Hardware service manager is found in System Service Tools. To use the Hardware service manager, proceed as follows:

1. Use the Start System Service Tools (STRSST) CL command by typing STRSST at the CL command line and pressing enter.

The System Service Tools Signon display should be shown.

2. Enter the service tools user profile name and password.

The System Service Tools display should appear.

```
System Service Tools (SST)

Select one of the following:

1. Start a service tool
2. Work with active service tools
3. Work with disk units
4. Work with diskette data recovery
5. Work with system partitions
6. Work with system capacity

Selection
1

F3=Exit F10=Command entry F12=Cancel
```

3. Select 1 to start a service tool and press Enter.

The Start a Service Tool display will be shown.

```
Start a Service Tool

Warning: Incorrect use of this service tool can cause damage to data in this system. Contact your service representative for assistance.

Select one of the following:

1. Product activity log
2. Trace Licensed Internal Code
3. Work with communications trace
4. Display/Alter/Dump
5. Licensed Internal Code log
6. Main storage dump manager
7. Hardware service manager

Selection
7

F3=Exit F12=Cancel F16=SST menu
```

4. Select **7** to start Hardware Service Manager.

The Hardware Service Manager screen display shows the menu of available options.

```
Hardware Service Manager

8. Type 6 next to the cryptography device that you want to reinitialize, and then press Enter.

#### Select Cryptography Debug Function

Select one of the following:

- 1. Reinitialize Flash Memory
- 2. Select IOP Debug Function

Selection

F3=Exit F12=Cancel

9. Select **1** to reinitialize flash memory (reload the Cryptographic Coprocessor Licensed Internal Code). A confirmation screen will be displayed. If you are applying a PTF ensure that you have taken the necessary precautions regarding your encrypted data and keys, and have a backup of the master key. Press Enter to continue.

#### Reinitialize Flash Memory Function

#### DANGER:

Performing this initialization of the flash memory on the cryptography device will cause ALL key information stored on the device to be DESTROYED. This will cause all data encrypted using this device to be rendered unusable.

#### WARNING:

Performing this initialization of the flash memory on the cryptography device will take an estimated 10 minutes.

Press Enter to proceed.

F3=Exit F12=Cancel

The following display shows the status of the reinitialization and is updated until the reinitialization is completed.

# Reinitialize Flash Memory Status Flash memory reinitialization in progress... Estimated time: 10.0 minutes Elapsed time: 2.5 minutes

When reinitialization is complete, a message will be displayed.

Reinitialization of cryptography device was successful.

```
Select one of the following:

1. Reinitialize Flash Memory
2. Select IOP Debug Function

Selection
```

After reinitialization is complete, exit all the way out of system service tools by pressing function key F3 on each screen as necessary.

#### **Related concepts**

F3=Fxit

Reinitializing the Cryptographic Coprocessor

F12=Cancel

If you set up your Cryptographic Coprocessor incorrectly, you can end up with an unusable configuration with which you cannot perform any cryptographic functions and cannot use any of the APIs to recover. For example, you can configure it such that you have no role authorized to set the master key and no role authorized to change or create new roles or profiles. You can call the hardware command for reinitializing the card by using the Cryptographic\_Facility\_Control (CSUACFC) SAPI.

The following resources provide additional information relating to cryptographic concepts or hardware:

#### **Manuals**

- IBM PCIe Cryptographic Coprocessor documentation library (http://www.ibm.com/security/cryptocards/pciecc4/library) contains the CCA 7.3x Basic Services Manual and other related documentation for the 4769 Cryptographic Coprocessor. IBM PCIe Cryptographic Coprocessor documentation library (http://www.ibm.com/security/cryptocards/pciecc2/library) contains the CCA 5.6x Basic Services Manual for the 4767 Cryptographic Coprocessor. These downloadable PDF documents are intended for systems and applications analysts and application programmers who will evaluate or create CCA programs.
- The CCA Basic Services Manual is intended for systems and applications analysts and application
  programmers who will evaluate or create programs for the IBM Common Cryptographic Architecture
  (CCA) support. Go to the IBM Cryptographic Coprocessor Library for a downloadable PDF of this
  manual.

#### Web site

• The IBM Cryptographic hardware (http://www.ibm.com/security/cryptocards) contains information about the 4769 PCIe Cryptographic Coprocessor hardware solution.

#### Other information

• Protecting IBM i data with encryption

#### **Related concepts**

4769 Cryptographic Coprocessor

IBM offers Cryptographic Coprocessors, which are available on a variety of system models. Cryptographic Coprocessors contain hardware engines, which perform cryptographic operations used by IBM i application programs and IBM i SSL transactions.

# **Code license and disclaimer information**

IBM grants you a nonexclusive copyright license to use all programming code examples from which you can generate similar function tailored to your own specific needs.

SUBJECT TO ANY STATUTORY WARRANTIES WHICH CANNOT BE EXCLUDED, IBM, ITS PROGRAM DEVELOPERS AND SUPPLIERS MAKE NO WARRANTIES OR CONDITIONS EITHER EXPRESS OR IMPLIED, INCLUDING BUT NOT LIMITED TO, THE IMPLIED WARRANTIES OR CONDITIONS OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE, AND NON-INFRINGEMENT, REGARDING THE PROGRAM OR TECHNICAL SUPPORT. IF ANY.

UNDER NO CIRCUMSTANCES IS IBM, ITS PROGRAM DEVELOPERS OR SUPPLIERS LIABLE FOR ANY OF THE FOLLOWING, EVEN IF INFORMED OF THEIR POSSIBILITY:

- 1. LOSS OF, OR DAMAGE TO, DATA;
- 2. DIRECT, SPECIAL, INCIDENTAL, OR INDIRECT DAMAGES, OR FOR ANY ECONOMIC CONSEQUENTIAL DAMAGES; OR
- 3. LOST PROFITS, BUSINESS, REVENUE, GOODWILL, OR ANTICIPATED SAVINGS.

SOME JURISDICTIONS DO NOT ALLOW THE EXCLUSION OR LIMITATION OF DIRECT, INCIDENTAL, OR CONSEQUENTIAL DAMAGES, SO SOME OR ALL OF THE ABOVE LIMITATIONS OR EXCLUSIONS MAY NOT APPLY TO YOU.

# **Notices**

This information was developed for products and services offered in the U.S.A.

IBM may not offer the products, services, or features discussed in this document in other countries. Consult your local IBM representative for information on the products and services currently available in your area. Any reference to an IBM product, program, or service is not intended to state or imply that only that IBM product, program, or service may be used. Any functionally equivalent product, program, or service that does not infringe any IBM intellectual property right may be used instead. However, it is the user's responsibility to evaluate and verify the operation of any non-IBM product, program, or service.

IBM may have patents or pending patent applications covering subject matter described in this document. The furnishing of this document does not grant you any license to these patents. You can send license inquiries, in writing, to:

IBM Director of Licensing IBM Corporation North Castle Drive Armonk, NY 10504-1785 U.S.A.

For license inquiries regarding double-byte (DBCS) information, contact the IBM Intellectual Property Department in your country or send inquiries, in writing, to:

Intellectual Property Licensing Legal and Intellectual Property Law IBM Japan Ltd. 1623-14, Shimotsuruma, Yamato-shi Kanagawa 242-8502 Japan

The following paragraph does not apply to the United Kingdom or any other country where such provisions are inconsistent with local law: INTERNATIONAL BUSINESS MACHINES CORPORATION PROVIDES THIS PUBLICATION "AS IS" WITHOUT WARRANTY OF ANY KIND, EITHER EXPRESS OR IMPLIED, INCLUDING, BUT NOT LIMITED TO, THE IMPLIED WARRANTIES OF NON-INFRINGEMENT, MERCHANTABILITY OR FITNESS FOR A PARTICULAR PURPOSE. Some states do not allow disclaimer of express or implied warranties in certain transactions, therefore, this statement may not apply to you.

This information could include technical inaccuracies or typographical errors. Changes are periodically made to the information herein; these changes will be incorporated in new editions of the publication. IBM may make improvements and/or changes in the product(s) and/or the program(s) described in this publication at any time without notice.

Any references in this information to non-IBM Web sites are provided for convenience only and do not in any manner serve as an endorsement of those Web sites. The materials at those Web sites are not part of the materials for this IBM product and use of those Web sites is at your own risk.

IBM may use or distribute any of the information you supply in any way it believes appropriate without incurring any obligation to you.

Licensees of this program who wish to have information about it for the purpose of enabling: (i) the exchange of information between independently created programs and other programs (including this one) and (ii) the mutual use of the information which has been exchanged, should contact:

IBM Corporation Software Interoperability Coordinator, Department YBWA 3605 Highway 52 N Rochester, MN 55901 U.S.A. Such information may be available, subject to appropriate terms and conditions, including in some cases, payment of a fee.

The licensed program described in this document and all licensed material available for it are provided by IBM under terms of the IBM Customer Agreement, IBM International Program License Agreement or any equivalent agreement between us.

Any performance data contained herein was determined in a controlled environment. Therefore, the results obtained in other operating environments may vary significantly. Some measurements may have been made on development-level systems and there is no guarantee that these measurements will be the same on generally available systems. Furthermore, some measurements may have been estimated through extrapolation. Actual results may vary. Users of this document should verify the applicable data for their specific environment.

Information concerning non-IBM products was obtained from the suppliers of those products, their published announcements or other publicly available sources. IBM has not tested those products and cannot confirm the accuracy of performance, compatibility or any other claims related to non-IBM products. Questions on the capabilities of non-IBM products should be addressed to the suppliers of those products.

All statements regarding IBM's future direction or intent are subject to change or withdrawal without notice, and represent goals and objectives only.

All IBM prices shown are IBM's suggested retail prices, are current and are subject to change without notice. Dealer prices may vary.

This information is for planning purposes only. The information herein is subject to change before the products described become available.

This information contains examples of data and reports used in daily business operations. To illustrate them as completely as possible, the examples include the names of individuals, companies, brands, and products. All of these names are fictitious and any similarity to the names and addresses used by an actual business enterprise is entirely coincidental.

#### COPYRIGHT LICENSE:

This information contains sample application programs in source language, which illustrate programming techniques on various operating platforms. You may copy, modify, and distribute these sample programs in any form without payment to IBM, for the purposes of developing, using, marketing or distributing application programs conforming to the application programming interface for the operating platform for which the sample programs are written. These examples have not been thoroughly tested under all conditions. IBM, therefore, cannot guarantee or imply reliability, serviceability, or function of these programs. The sample programs are provided "AS IS", without warranty of any kind. IBM shall not be liable for any damages arising out of your use of the sample programs.

Each copy or any portion of these sample programs or any derivative work, must include a copyright notice as follows:

- (your company name) (year). Portions of this code are derived from IBM Corp. Sample Programs.
- © Copyright IBM Corp. \_enter the year or years\_.

If you are viewing this information softcopy, the photographs and color illustrations may not appear.

# **Programming interface information**

This Cryptography publication documents intended Programming Interfaces that allow the customer to write programs to obtain the services of IBM i.

## **Trademarks**
