Version 5 Release 4
Note
Before using this information and the product it supports, read the information in “Notices,” on page 19.

Sixth Edition (February 2006)
This edition applies to version 5, release 4, modification 0 of i5/OS (5722-SS1) and to all subsequent releases and modifications until otherwise indicated in new editions. This version does not run on all reduced instruction set computer (RISC) models nor does it run on CISC models.

iv  System i: Security Secure Sockets Layer (SSL)
Secure Sockets Layer (SSL)

This topic describes how to use SSL on your server.

Secure Sockets Layer (SSL) has become an industry standard for enabling applications for secure communication sessions over an unprotected network, such as the Internet.

What’s new for V5R4

This topic describes what is new to the Secure Sockets Layer (SSL) this release.

Product withdrawn: IBM® Cryptographic Access Provider product, 5722-AC3 (128-bit)

The IBM Cryptographic Access Provider product, 5722-AC3 (128-bit) is no longer required. This is a new development for the V5R4 release of i5/OS®. All V5R4 systems are capable of the function that was previously provided in the 5722-AC3 product.

How to see what’s new or changed

To help you see where technical changes have been made, this information uses:

- The image to mark where new or changed information begins.
- The image to mark where new or changed information ends.

Use this to view and print a PDF of this information.

To view or download the PDF version of this document, select Secure Sockets Layer (SSL).

Saving PDF files

To save a PDF on your workstation for viewing or printing:

1. Right-click the PDF in your browser (right-click the link above).
2. Click the option that saves the PDF locally.
3. Navigate to the directory in which you want to save the PDF.
4. Click Save.

Downloading Adobe Reader

You need Adobe Reader installed on your system to view or print these PDFs. You can download a free copy from the Adobe Web site (www.adobe.com/products/acrobat/readstep.html).

Scenarios

The SSL scenarios are designed to help you maximize the benefits of enabling SSL on your System i™ platform.

Read the SSL scenarios to increase your understanding of SSL on the iSeries™ server by providing possible examples of how SSL can work for you.
Related information

Scenario: Secure Telnet with SSL
Scenario: Enhance iSeries SSL performance
Scenario: Protect private keys with cryptographic hardware

Scenario: Securing a client connection to your Management Central server with SSL

This scenario explains how to use SSL to secure the connection between a remote client and an System i model that is acting as a central system by using the iSeries Navigator Management Central server.

Situation:

A company has a local area network (LAN) that includes several iSeries servers in their office. This company’s system administrator, Bob, has specified one of the iSeries servers as the central system (hereafter referred to as System A) for the LAN. Bob uses the Management Central server on System A to manage all of the other endpoints on his LAN.

Bob is concerned about connecting to the Management Central server on System A from a network connection that is external to his company’s LAN. Bob travels for work a lot, and requires a secure connection to the Management Central server while he is away. He wants to ensure the connection between his PC and the Management Central server is secure when he is not in the company office. Bob decides to enable SSL on his PC and on the System A’s Management Central server. With SSL enabled in this way, Bob can be certain that his connection to the Management Central server is secure when he is traveling.

Objectives:

Bob wants to secure the connection between his PC and the Management Central server. Bob does not require additional security for the connection between the Management Central server on System A and the endpoints that are on the LAN. Other employees that work from the company office do not need additional security for their connections to the Management Central server, either. Bob’s plan is to configure his PC and the Management Central server on System A, so that his connection uses server authentication. Connections to the Management Central server from other PCs or iSeries servers on the LAN are not secured with SSL.

Details:

The following table illustrates the types of authentication used, based on the enabling or disabling of SSL on a PC client:

<table>
<thead>
<tr>
<th>SSL status on Bob’s PC</th>
<th>Specified authentication level for the Management Central server on System A</th>
<th>SSL connection enabled?</th>
</tr>
</thead>
<tbody>
<tr>
<td>SSL off</td>
<td>Any</td>
<td>No</td>
</tr>
<tr>
<td>SSL on</td>
<td>Any</td>
<td>Yes (server authentication)</td>
</tr>
</tbody>
</table>

Server authentication means that Bob’s PC authenticates the Management Central server’s certificate. Bob’s PC acts as an SSL client when connecting to the Management Central server. The Management Central server acts as an SSL server and must prove its identity. The Management Central server does this by providing a certificate issued by a Certificate Authority (CA) that Bob’s PC trusts.
Prerequisites and assumptions

Bob must perform these administration and configuration tasks in order to secure the connection between his PC and the Management Central server on System A:

1. System A meets the prerequisites for SSL.
2. OS/400\textsuperscript{®} V5R3 or a later version of i5/OS is installed on System A.
3. The iSeries Navigator PC client runs V5R3 or later of iSeries Access for Windows\textsuperscript{®}.
4. Get a Certificate Authority (CA) for iSeries servers.
5. Create a certificate that is signed by the CA, for System A.
6. Send the CA and a certificate to System A, and import them into the key database.
7. Assign the certificate with the Management Central server identification, and the application identifications for all of the iSeries Access servers. The TCP central server, database server, data queue server, file server, network print server, remote command server and signon server are all iSeries Access servers.
   a. On System A, Start IBM Digital Certificate Manager. Bob obtains or create certificates, or otherwise sets up or changes his certificate system now.
   b. Click Select a Certificate Store.
   c. Select *SYSTEM and click Continue.
   d. Enter the *SYSTEM Certificate Store password, and click Continue. When the menu reloads, expand Manage Applications.
   e. Click Update certificate assignment.
   f. Select Server and click Continue.
   g. Select the Management Central Server, and click Update certificate assignment. This assigns a certificate to the Management Central server to use.
   h. Click Assign New Certificate. DCM reloads to the Update certificate assignment page with a confirmation message.
   i. Click Done.
   j. Assign the certificate to all of the client access servers.
8. Download the CA to the PC client.

Before Bob can enable SSL on the Management Central server, he must install the SSL Prerequisites and set up digital certificates on the system. Once he has met the prerequisites, he can complete the following procedures to enable SSL for the Management Central server.

Configuration steps

Bob needs to complete the following steps in order to secure his PC client connection to the Management Central server on System A, with SSL:

1. "Step 1: Deactivate SSL for the iSeries Navigator client” on page 4
2. "Step 2: Set the authentication level for the Management Central server” on page 4
3. "Step 3: Restart the Management Central server on the central system” on page 4
4. "Step 4: Activate SSL for the iSeries Navigator client” on page 4
5. "Optional step: Deactivate SSL for the iSeries Navigator client” on page 5

**Configuration details: Secure a client connection to your Management Central server with SSL**

This topic shows the expanded configurations steps for using SSL to secure a client connection to your Management Central server.

The following information assumes you have read through the Scenario: Secure a client connection to your Management Central server with SSL.

In this scenario, an System i model is specified as the central system in a company’s local area network (LAN). Bob uses the Management Central server on the central system (referred to here as System A) to manage the endpoints on the company network. The following information explains how to perform the steps required to secure an external client connection to the Management Central server. Follow along as Bob completes the scenario configuration steps.

**Related concepts**

- "SSL prerequisites" on page 16
- "Scenario: Securing all connections to your Management Central server with SSL" on page 5

This scenario explains how to use SSL to secure all connections with an System i model that is acting as a central system by using the iSeries Navigator Management Central server.

**Related information**

- Set up certificates for the first time

**Step 1: Deactivate SSL for the iSeries Navigator client:**

This step is only necessary if you have already enabled SSL for the iSeries Navigator client.

1. In iSeries Navigator, expand My Connections.
2. Right-click System A and select Properties.
3. Click the Secure Sockets tab and deselect Use Secure Sockets Layer (SSL) for connection.
4. Exit iSeries Navigator and restart it.

The padlock disappears from the Management Central container in iSeries Navigator, indicating an unsecured connection. This indicates to Bob that he no longer has an SSL-secured connection between his client and the central system of his company.

**Step 2: Set the authentication level for the Management Central server:**

1. In iSeries Navigator, right-click Management Central, and select Properties.
2. Click the Security tab, and select Use Secure Sockets Layer (SSL).
3. Select Any for the authentication level (available on V5R3 or later of iSeries Access for Windows).
4. Click OK to set this value on the central system.

**Step 3: Restart the Management Central server on the central system:**

1. In iSeries Navigator, expand My Connections.
2. On System A, expand Network-->Servers and select TCP/IP.
3. Right-click Management Central and select Stop. The central system view collapses, and a message displays, explaining you are not connected to the server.
4. After the Management Central server has stopped, click Start to restart it.

**Step 4: Activate SSL for the iSeries Navigator client:**

1. In iSeries Navigator, expand My Connections.
2. Right-click System A and select Properties.
3. Click the Secure Sockets tab and select Use Secure Sockets Layer (SSL) for connection.
4. Exit iSeries Navigator and restart it.
A padlock appears next to the Management Central server in iSeries Navigator, indicating an SSL-secured connection. This indicates to Bob that he has successfully activated an SSL-secured connection between his client and the central system of his company.

**Note:** This procedure only secures the connection between one PC and the Management Central server. Other client connections with the Management Central server, as well as connections from endpoints to the Management Central server, will not be secure. To secure other clients, ensure they meet the prerequisites and repeat “Step 4: Activate SSL for the iSeries Navigator client” on page 4. To secure other connections with the Management Central server, see Scenario: Secure all connections to your Management Central server with SSL.

**Optional step: Deactivate SSL for the iSeries Navigator client:**
If Bob wants to work from the company office and does not want an SSL connection affecting the performance of his PC, he can easily deactivate it by performing the following steps:
1. In iSeries Navigator, expand My Connections.
2. Right-click System A and select Properties.
3. Click the Secure Sockets tab and deselect Use Secure Sockets Layer (SSL) for connection.
4. Exit iSeries Navigator and restart it.

**Scenario: Securing all connections to your Management Central server with SSL**
This scenario explains how to use SSL to secure all connections with an System i model that is acting as a central system by using the iSeries Navigator Management Central server.

**Situation:**
A company has just set up a wide area network (WAN) that includes several System i models in remote locations (endpoints). The endpoints are centrally managed by one system (the central system), located at the main office. Tom is the company’s security specialist. Tom wants to use Secure Sockets Layer (SSL) to secure all of the connections between the Management Central server on the company’s central system and all iSeries Access servers and clients.

**Details:**
Tom can manage all connections to the Management Central server securely, with SSL. To use SSL with the Management Central server, Tom needs to secure iSeries Navigator on the PC that he uses to access the central system.

Tom chooses from two authentication levels for the Management Central server:

**Server authentication**
Provides authentication of the server certificate. The client must validate the server, whether the client is iSeries Navigator on a PC, or the Management Central server on the central system. When iSeries Navigator connects to the central system, the PC is the SSL client and the Management Central server running on the central system is the SSL server. The central system acts as an SSL client when connecting to an endpoint system. The endpoint system acts as an SSL server. The server must prove its identity to the client by providing a certificate that was issued by a Certificate Authority that the client trusts. There must be a valid certificate issued by a trusted CA for every SSL server.

**Client and server authentication**
Provides authentication of both the central system and the endpoint system certificates. This is a stronger security level than the server authentication level. In other applications, this is known as client authentication, where the client must supply a valid trusted certificate. When the central...
system (SSL client) attempts to establish a connection with an endpoint system (SSL server), the central system and the endpoint system authenticate each other’s certificates for certificate authority authenticity.

**Note:** Client and server authentication only happens between two System i models. Client authentication is not performed by the server when the client is a PC.

Unlike other applications, Management Central also provides authentication through a validation list, called Trusted Group validation list. Generally the validation list stores information that identifies the user, such as a user identification, and authentication information, such as password, personal identification number, or digital certificate. This authentication information is encrypted.

Most applications typically do not specify that you enable both server and client authentication, because server authentication almost always occurs during SSL session enablement. Many applications have client authentication configuration options. Management Central uses the term "server and client authentication" instead of client authentication because of the dual role that the central system plays in the network. When PC users connect to the central system, the central system acts as a server. However, when the central system is connecting to an endpoint system, it acts as a client. The following illustration shows how the central system operates as both a server and client in a network.

**Note:** In this illustration, the certificate associated with the Certificate Authority must be stored in the key database on the central system and on all of the endpoint systems. The Certificate Authority must on the central system, all the endpoints, as well as the PC.
Prerequisites and assumptions:

Tom must perform the following administration and configuration tasks, in order to secure all of the connections to the Management Central server:

- [Diagram of network connections and certificate authority]
1. System A meets the prerequisites for SSL.
2. The central system and all endpoint systems run V5R2 or later versions of OS/400 or i5/OS. V5R4 i5/OS connections to V5R1 OS/400 systems are not allowed.
3. The iSeries Navigator PC client runs V5R2 or later of iSeries Access for Windows.
4. Get a Certificate Authority (CA) for System i models.
5. Create a certificate that is signed by the CA, for System A.
6. Send the CA and a certificate to System A, and import them into the key database.
7. Assign the certificates with the Management Central application identification, and the application identifications for all of the iSeries Access servers. The TCP central server, database server, data queue server, file server, network print server, remote command server and signon server are all iSeries Access servers.
   a. Start IBM Digital Certificate Manager on the Management Central server. If Tom needs to obtain or create certificates, or otherwise set up or change his certificate system, he does so now.
   b. Click Select a Certificate Store.
   c. Select *SYSTEM and click Continue.
   d. Enter the SYSTEM Certificate Store password, and click Continue. When the menu reloads, expand Manage Applications.
   e. Click Update certificate assignment.
   f. Select Server and click Continue.
   g. Select the Management Central server, and click Update certificate assignment. This assigns a certificate to the Management Central server to use.
   h. Choose the certificate you want to assign to the application, and click Assign New Certificate.
      DCM reloads to the Update certificate assignment page with a confirmation message.
   i. Click Cancel to return to the list of applications.
   j. Repeat this procedure for all iSeries Access servers.
8. Download the CA to the iSeries Navigator PC client.

**Configuration steps:**

Before Tom can enable SSL on the Management Central server, he must install the prerequisite programs and set up digital certificates on the central system. See the Prerequisites and assumptions for this scenario before continuing. Once he has met the prerequisites, he can complete the following procedures to secure all connections to the Management Central server:

Note: If SSL has been enabled for iSeries Navigator, Tom must disable it before he can enable SSL on the Management Central server. If SSL has been enabled for iSeries Navigator and not the Management Central server, attempts by iSeries Navigator to connect with the central system will fail.

1. “Step 1: Configure the central system for server authentication” on page 9
2. “Step 2: Configure endpoint systems for server authentication” on page 10
3. “Step 3: Restart the Management Central server on the central system” on page 10
4. “Step 4: Restart the Management Central server on all endpoint systems” on page 10
5. “Step 5: Activate SSL for the iSeries Navigator client” on page 11
6. “Step 6: Configure the central system for client authentication” on page 11
7. “Step 7: Configure endpoint systems for client authentication” on page 11
8. “Step 8: Copy the validation list to the endpoint systems” on page 12
9. “Step 9: Restart the Management Central server on the central system” on page 12
10. “Step 10: Restart the Management Central server on all endpoint systems” on page 12

Related concepts
Review the following list to see the applications that you can use to secure with SSL on the System i platform.

**Related tasks**

- **Configuration details: Secure a client connection to your Management Central server with SSL** on page 4
  
  This topic shows the expanded configurations steps for using SSL to secure a client connection to your Management Central server.

**Configuration details: Secure all connections to your Management Central server with SSL**

This topic shows the details for using SSL to secure all connections to your Management Central server.

The following information assumes that you have read through the following information:

**Scenario: Secure all connections to your Management Central server with SSL**

You now want to understand how to perform the steps required to secure all connections to the Management Central server. Follow along as Tom completes the scenario.

Before Tom can enable SSL on the Management Central server, he must install the prerequisite programs and set up digital certificates on the System i model. Once he has met the prerequisites, he can complete the following procedures to secure all connections to the Management Central server.

**Note:** If SSL has been enabled for iSeries Navigator, Tom must disable it before he can enable SSL on the Management Central server. If SSL has been enabled for iSeries Navigator, and not the Management Central server, attempts by iSeries Navigator to connect with the central system will fail.

SSL allows Tom to secure transmissions between a central system and an endpoint system, as well as between the iSeries Navigator client and the central system. SSL provides transport and authentication of certificates and encryption of data. An SSL-connection can only occur between an SSL-enabled central system and an SSL-enabled endpoint system. Tom needs to configure server authentication before he can configure client authentication:

**Related concepts**

- "SSL prerequisites" on page 16
- "Scenario: Securing all connections to your Management Central server with SSL" on page 5

This scenario explains how to use SSL to secure all connections with an System i model that is acting as a central system by using the iSeries Navigator Management Central server.

**Related information**

- Set up certificates for the first time

**Step 1: Configure the central system for server authentication:**

1. In iSeries Navigator, right-click **Management Central** and select **Properties**.
2. Click the Security tab and select Use Secure Sockets Layer (SSL).
3. Select Server as the authentication level.
4. Click OK to set this value on the central system.

**Note:** Do NOT restart the Management Central server until told to do so, later. If you restart the server now, you will not be able to contact your endpoint servers. You must complete more configuration tasks before the server can be restarted, activating SSL. You must propagate the SSL configuration to the endpoint systems first, with the compare and update task.

**Step 2: Configure endpoint systems for server authentication:**
After Tom configures the central system for server authentication, he needs to configure the endpoint systems for server authentication. He completes the following tasks:
1. Expand Management Central.
2. Compare and update system values for the endpoint systems:
   a. Under Endpoint Systems, right-click the central system and select Inventory → Collect.
   b. Check the System Values option on the collect dialog box, in order to collect the system values inventory for the central system. Deselect any other options. Click OK and wait for the inventory task to complete.
   d. Define a new system group that includes all the endpoint systems to connect to, using SSL. Name this new system group ‘Trusted Group.’
   e. To display the new group, ‘Trusted Group,’ expand the list of system groups.
   f. After the collection is complete, right-click the new system group and select System Values → Compare and Update.
   g. Verify that the central system displays in the Model System field.
   h. In the Category field, select Management Central.
   i. Verify that Use Secure Sockets Layer is set to Yes and select Update to propagate this value to the ‘Trusted Group’.
   j. Verify that SSL Authentication Level is set to Server and select Update to propagate this value to the ‘Trusted Group’.

**Note:** If these values are not set, complete Step 1: Configure the central system for server authentication.

k. Click OK. Wait until the Compare and Update completes processing before continuing to the next step.

**Step 3: Restart the Management Central server on the central system:**
1. In iSeries Navigator, expand My Connections.
2. Expand the central system.
3. Expand Network → Servers and select TCP/IP.
4. Right-click Management Central and select Stop. The central system view collapses, and a message displays, explaining that you are not connected to the server.
5. Once the Management Central server has stopped, click Start to restart it.

**Step 4: Restart the Management Central server on all endpoint systems:**
1. In iSeries Navigator, expand My Connections.
2. Expand the endpoint system that you are restarting.
3. Expand Network → Servers and select TCP/IP.
4. Right-click Management Central and select Stop.
5. Once the Management Central server has stopped, click Start to restart it.
6. Repeat this procedure for each endpoint system.

Step 5: Activate SSL for the iSeries Navigator client:
1. In iSeries Navigator, expand My Connections.
2. Right-click the central system, and select Properties.
3. Click the Secure Sockets tab and select Use Secure Sockets Layer (SSL) for connection.
4. Exit iSeries Navigator and restart it.

Note: After you have completed these steps, server authentication is configured for your central and endpoint systems. You can optionally configure your central and endpoint systems for client authentication as well. Steps 6 through 10 should be completed if you want to enable client authentication on your central and endpoint systems.

Step 6: Configure the central system for client authentication:

Now that Tom has completed the configuration for server authentication, he can opt to perform the following optional client authentication procedures. Client authentication provides validation of Certificate Authority and trusted group for both the endpoint systems and the central system. When the central system (SSL client) tries to use SSL to connect to an endpoint system (SSL server), the central system and the endpoint system authenticate each other’s certificates through both server authentication and client authentication. This is also referred to as Certificate Authority and Trusted Group authentication.

Note: You cannot complete client authentication configuration until you have configured server authentication. If you have not configured server authentication, go back and do so, now.
1. In iSeries Navigator, right-click Management Central and select Properties.
2. Click the Security tab and select Use Secure Sockets Layer (SSL).
3. Select Client and server for the authentication level.
4. Click OK to set this value on the central system.

Note: Do NOT restart the Management Central server until told to do so, later. If you restart the server now, you will not be able to contact your endpoint servers. You must complete more configuration tasks before the server can be restarted, activating SSL. You must propagate the SSL configuration to the endpoint systems first, with the compare and update task.

Step 7: Configure endpoint systems for client authentication:
Compare and update system values for the endpoint systems:

1. Expand Management Central.
2. Compare and update system values for the endpoint systems:
   a. Under Endpoint Systems, right-click the central system and select Inventory → Collect.
   b. Check the System Values option on the collect dialog box, in order to collect the system values inventory for the central system. Deselect any other options. Click OK and wait for the inventory task to complete.
   c. After the collection is complete, right-click the ‘Trusted Group’ and select System Values → Compare and Update.
   d. Verify that the central system displays in the Model System field.
   e. In the Category field, select Management Central.
   f. Verify that Use Secure Sockets Layer is set to Yes and select Update to propagate this value to the ‘Trusted Group’.
   g. Verify that SSL Authentication Level is set to Client and Server and select Update to propagate this value to the ‘Trusted Group’.
Step 6: Configure the central system for client authentication.

h. Click OK. Wait until the Compare and Update completes processing before continuing to the next step.

Step 8: Copy the validation list to the endpoint systems:
This task assumes that your central system is V5R3 or greater. On pre-V5R3 systems, QYPSVLDL.VLDL was located in QUSRJOSY.SLIB, not QMGTC2.SLIB. Therefore, if you have pre-V5R3 systems, you will need to send the validation list to these systems and place it in QUSRJOSY.SLIB, instead of QMGTC2.SLIB. For V5R3 and greater systems, continue with the following steps:

1. In iSeries Navigator, expand Management Central → Definitions.
2. Right-click Package, and select New Definition.
3. In the New Definition window, work with the following:
   a. Name: Type the name of the definition.
   b. Source system: Select the name of the central system.
   c. Selected files and folders: Click in the field, and type /QSYS.LIB/QMGTC2.SLIB/QYPSVLDL.VLDL.
4. Click the Options tab, and select Replace existing file with the file being sent.
5. Click Advanced.
6. In the Advanced Options window, specify Yes to allow object differences on restore, and change the Target release to be the earliest release of your endpoints.
7. Click OK to refresh the list of definitions and display the new package.
8. Right-click the new package, and select Send.
9. In the Send dialog box, expand System Groups→Trusted Group, located in the Available Systems and Groups list. This group is the one you defined in “Step 2: Configure endpoint systems for server authentication” on page 10.

   Note: The Send task will always fail on the central system, because it is always the source system. The Send task should complete successfully on all endpoint systems.
10. If you have any pre-V5R3 systems in Trusted Group, you must manually go to those systems and move the QYPSVLDL.VLDL object from QMGTC2.SLIB to QUSRJOSY.SLIB. If there is already a version of QYPSVLDL.VLDL in QUSRJOSY.SLIB, delete it and replace it with the newer one from QMGTC2.SLIB

Step 9: Restart the Management Central server on the central system:

1. In iSeries Navigator, expand My Connections.
2. Expand the central system.
3. Expand Network → Servers and select TCP/IP.
4. Right-click Management Central and select Stop. The central system view collapses, and a message displays, explaining that you are not connected to the server.
5. Once the Management Central server has stopped, click Start to restart it.

Step 10: Restart the Management Central server on all endpoint systems:

Note: Repeat this procedure for each endpoint system.

1. In iSeries Navigator, expand My Connections.
2. Expand the endpoint system that you are restarting.
3. Expand Network → Servers and select TCP/IP.
4. Right-click Management Central and select Stop.
5. Once the Management Central server has stopped, click Start to restart it.
SSL concepts
SSL concepts includes supplemental information, providing some basic building blocks for the Secure Sockets Layer (SSL) protocols.

With the SSL protocol, you can establish secure connections between clients and server applications which provide authentication of one or both endpoints of the communication session. SSL also provides privacy and integrity of the data that client and server applications exchange.

History of SSL
Netscape developed The Secure Sockets Layer Protocol (SSL) in 1994, as a response to the growing concern over security on the Internet.

SSL was originally developed for securing web browser and server communications. The specification was designed in such a way so you can enable other applications, such as TELNET and FTP, to use SSL.

Related concepts
- Supported SSL and Transport Layer Security (TLS) protocols
  This topic describes which versions of the SSL and TLS protocols the i5/OS implementation supports.

How SSL works
SSL is actually two protocols. The protocols are the record protocol and the handshake protocol. The record protocol controls the flow of the data between the two endpoints of an SSL session.

The handshake protocol authenticates one or both endpoints of the SSL session and establishes a unique symmetric key used to generate keys to encrypt and decrypt data for that SSL session. SSL uses asymmetric cryptography, digital certificates, and SSL handshake flows, to authenticate one or both endpoints of an SSL session. Typically, SSL authenticates the server. Optionally, SSL authenticates the client. A digital certificate, issued by a Certificate Authority, can be assigned to each of the endpoints or to the applications using SSL on each endpoint of the connection.

The digital certificate is comprised of a public key and some identifying information that a trusted Certificate Authority (CA) has digitally signed. Each public key has an associated private key. The private key is not stored with or as part of the certificate. In both server and client authentication, the endpoint which is being authenticated must prove that it has access to the private key associated with the public key contained within the digital certificate.

SSL handshakes are performance intensive operations because of the cryptographic operations using the public and private keys. After an initial SSL session has been established between two endpoints, the SSL session information for these two endpoints and applications can be cached in secure memory to speed up subsequent SSL session enablements. When an SSL session is resumed, the two endpoints use an abbreviated handshake flow to authenticate that each has access to unique information without using the public or private keys. If both can prove that they have access to this unique information, then new symmetric keys are established and the SSL session resumes. For TLS Version 1.0 and SSL Version 3.0 sessions, cached information will not remain in the secure memory for greater than 24 hours. In OS/400 V5R2 and subsequent releases or i5/OS, you can minimize SSL handshake performance impacts on the main CPU by using cryptographic hardware.

Supported SSL and Transport Layer Security (TLS) protocols
This topic describes which versions of the SSL and TLS protocols the i5/OS implementation supports.
There are several versions of the SSL protocol defined. The latest version, the Transport Layer Security Protocol (TLS), is based on SSL 3.0 and is a product of the Internet Engineering Task Force (IETF). The i5/OS implementation supports the following versions of the SSL and TLS protocols:

- TLS Version 1.0
- TLS Version 1.0 with SSL Version 3.0 compatibility

**Note:**

1. Specifying TLS Version 1.0 with SSL Version 3.0 compatibility means that TLS will be negotiated if possible and if that is not possible then SSL Version 3.0 will be negotiated. If SSL Version 3.0 cannot be negotiated, the SSL handshake will fail.

2. The System i also supports TLS Version 1.0 with SSL Version 3.0 and SSL Version 2.0 compatibility. This is specified with the protocol value of **ALL**, which means that TLS will be negotiated if possible and if that is not possible then SSL Version 3.0 will be negotiated. If SSL Version 3.0 cannot be negotiated, SSL Version 2.0 will be negotiated. If SSL Version 2.0 cannot be negotiated, the SSL handshake will fail.

- SSL Version 3.0
- SSL Version 2.0
- SSL Version 3.0 with SSL Version 2.0 compatibility

**SSL Version 3.0 versus SSL Version 2.0**

SSL version 3.0 is an almost totally different protocol compared to SSL Version 2.0. Some of the major differences between the two protocols include:

- SSL Version 3.0 handshake protocol flows are different than SSL Version 2.0 handshake flows.
- SSL Version 3.0 uses the BSAFE 3.0 implementation from RSA Data Security, Incorporated. BSAFE 3.0 includes a number of timing attack fixes and the SHA-1 hashing algorithm. The SHA-1 hashing algorithm is considered to be more secure than the MD5 hashing algorithm. SHA-1 allows SSL Version 3.0 to support additional cipher suites which use SHA-1 instead of MD5.
- SSL Version 3.0 protocol reduces man-in-the-middle (MITM) type of attacks from occurring during SSL handshake processing. In SSL Version 2.0, it was possible, though unlikely, that a MITM attack might accomplish cipher specification weakening. Weakening the cipher can allow an unauthorized person to break the SSL session key.

**TLS Version 1.0 versus SSL Version 3.0**

The latest industry standard SSL protocol based on SSL version 3.0 is Transport Layer Security (TLS) Version 1.0. Its specifications are defined by the Internet Engineering Task Force (IETF) in RFC 2246, *The TLS Protocol*.

The major goal of TLS is to make SSL more secure and to make the specification of the protocol more precise and complete. TLS provides these enhancements over SSL Version 3.0:

- A more secure MAC algorithm
- More granular alerts
- Clearer definitions of “gray area” specifications

Any System i applications that are enabled for SSL will automatically obtain TLS support unless the application has specifically requested to use only SSL Version 3.0 or SSL Version 2.0.

TLS provides the following security improvements:

- **Key-Hashing for Message Authentication** TLS uses Key-Hashing for Message Authentication Code (HMAC), which ensures that a record cannot be altered while travelling over an open network such as
the Internet. SSL Version 3.0 also provides keyed message authentication, but HMAC is more secure than the (Message Authentication Code) MAC function that SSL Version 3.0 uses.

- **Enhanced Pseudorandom Function (PRF)** PRF generates key data. In TLS, the HMAC defines the PRF. The PRF uses two hash algorithms in a way which guarantees its security. If either algorithm is exposed, the data will remain secure as long as the second algorithm is not exposed.

- **Improved finished message verification** Both TLS Version 1.0 and SSL Version 3.0 provide a finished message to both endpoints that authenticates that the exchanged messages were not altered. However, TLS bases this finished message on the PRF and HMAC values, which again is more secure than SSL Version 3.0.

- **Consistent certificate handling** Unlike SSL Version 3.0, TLS attempts to specify the type of certificate which must be exchanged between TLS implementations.

- **Specific alert messages** TLS provides more specific and additional alerts to indicate problems that either session endpoint detects. TLS also documents when certain alerts should be sent.

  [The TLS Protocol]

**Server authentication**

With server authentication, the client will ensure that the server certificate is valid and that it is signed by a certificate authority (CA) which the client trusts.

SSL will use asymmetric cryptography and handshake protocol flows to generate a symmetric key which will be used only for this unique SSL session. This key is used to generate a set of keys which are used for encrypting and decrypting data which will flow over the SSL session. Subsequently, when an SSL handshake has completed, one or both ends of the communication link will have been authenticated. Additionally, a unique key will have been generated to encrypt and decrypt the data. Once the handshake is completed then application layer data will flow encrypted across that SSL session.

**Client authentication**

Many applications allow the option to enable client authentication. With client authentication, the server will ensure that the client certificate is valid and that it is signed by a Certificate Authority which the server trusts.

The following System i applications support client authentication:

- IBM HTTP Server (powered by Apache)
- FTP server
- Telnet server
- Management Central endpoint system
- Directory Server (LDAP)

Troubleshooting SSL on page 17

This very basic troubleshooting information is intended to help you thin out the list of possible problems that the System i platform can encounter with SSL.

SSL prerequisites

- IBM Digital Certificate Manager (DCM), option 34 of i5/OS (5722-SS1)
- TCP/IP Connectivity Utilities for iSeries (5722-TC1)
- IBM HTTP Server for iSeries (5722-DG1)
- If you are trying to use the HTTP server to use the DCM, ensure that you have the IBM Developer Kit for Java™ (5722-JV1) installed. Otherwise, the HTTP admin server will not start.
- You may also want to install cryptographic hardware to use with SSL to speed up the SSL handshake processing. If you want to install cryptographic hardware, you must also install Option 35, the Cryptographic Service Provider.

Application security with SSL

Review the following list to see the applications that you can use to secure with SSL on the System i platform.

You can secure the following System i applications with SSL:

- Enterprise Identity Mapping (EIM)
- FTP server
- HTTP server (powered by Apache)
- iSeries Access for Windows
- Directory Server (LDAP)
- Distributed relational database architecture (DRDA®) and distributed data management (DDM) server
- Management Central server
- Telnet server
- Websphere Application Server — Express
- Applications that are written to the iSeries Access for Windows set of APIs (application programming interfaces)
- Applications developed using the secure sockets Application Programmable Interfaces (APIs) supported on the System i platform. The supported APIs are Global Secure Toolkit (GSKit) and the SSL_System i APIs.

Troubleshooting SSL

This very basic troubleshooting information is intended to help you thin out the list of possible problems that the System i platform can encounter with SSL.

It is important to understand that this is not a comprehensive source for troubleshooting information, but rather a guide to aid in common problem resolution.

Verify that the following statements are true:

- You have met the prerequisites for SSL on the System i platform.
- Your certificate authority and certificates are valid and have not expired.

If you have verified that the previous statements are true for your system and you still have an SSL-related problem, try the following options:

- The SSL error code in the server job log can be cross referenced in an error table to find more information about the error. For example, this table maps the -93 that might be seen in a server job log to the constant SSL_ERROR_SSL_NOT_AVAILABLE.
  - A negative return code (indicated by the dash before the code number) indicates that you are using an SSL_ API.
  - A positive return code indicates that you are using a GSKit API. Programmers can code the gsk_strerror() or SSL_strerror() API in their programs to obtain a brief description of an error return code. Some applications make use of this API and print out a message to the job log containing this sentence.

If more detailed information is required, the message id provided in the table can be displayed on an System i model to show potential cause and recovery for this error. Additional documentation explaining these error codes may be located in the individual secure socket API that has returned the error.

- The following two header files contain the same constant names for System SSL return codes as the table, but without the message ID cross reference:
  - QSYSINC/H.GSKSSL
  - QSYSINC/H.QS0SSL

Remember that although the names of the System SSL return codes remain constant in these two files, more than one unique error can be associated with each return code.
